ETIENNE, ROBERT. This young man worked at firft under Simon de Colines, who had married his mother, and then fet up in bufinefs for himfelf at Paris. He had received a very liberal education, and was well acquainted with the ancient languages, and was deeply fkilled in principles of found criticifm. He carried the art of typography to a very high pitch of excellence, as a number of his books well known at prefent will teftify. His office is faid to have refembled a learned feminary, in which the Latin language was the only one allowed to be fpoken by all the perfons employed by him. He eftablifhed an early reputation by the editions of the bible in different languages. He was the firft perfon who introduced the divifion of the whole into verfes; of which, we are informed, he made the neceffary preparations, as he was on a journey on horfeback from Paris to Lyons. Thefe divifions have been ufeful as marks for reference, but in other refpects they have been injurious to the work, on account of the faultinefs of the divifions which not unfrequently give a wrong fenfe to important paffages of the facred writings. In the year 1532 he publifhed his excellent "Thefaurus Linguæ Latinæ" in two volumes folio. This work obtained a very high reputation, and has paffed through many editions: the beft are faid to be that printed in London in 1734, and the one printed at Bafil in 1740. Both editions confift of four volumes folio. In the year 1539 the reputation of Robert attracted the attention of Francis I. who reimburfed him fome of his expences in procuring manufcripts and founding new types, and gave him the honour of king's printer for Greek and Latin books. At the reformation this worthy printer, in common with many biblical critics, fell under the fufpicion of herefy, and endured a long perfecution excited by the doctors of the Sorbonne, who, in the year 1548 unanimoufly decreed that

that his bible with a verfion by Leo Judæ, and notes, ought to be fuppreffed, and placed in the lift of prohibited books. By many liberal and refpectable perfons Etienne was fupported againft the fanaticifm of bigots and priefts, but, at length, he thought it advifeable to withdraw to Geneva, where he more openly avowed himfelf a friend to the reformed religion. He felt himfelf called on to vindicate his conduct, and publifhed an apology, in which he retaliated upon his perfecutors, and the church, by whom he had been driven into a kind of exile. At Geneva he continued to follow his profeffion, and publifhed many books in favour of the Proteftant caufe. He was elected burgher of Geneva, and lived in habits of friendfhip with Beza and Calvin. He died in the year 1559, at the age of fifty-fix. He has been, fince his death, to the prefent day, the theme of admiration with the learned, and by the illuftrious De Thou he was confidered as better entitled to the gratitude of his country, by the perfection which he gave to the art of printing, than thofe warriors who had extended the boundaries of the French empire. Moreri.

Etienne, Charles, a phyfician of the faculty of Paris, who is confidered by his biographers as an honour to the age in which he lived, in confequence of the extent and variety of his attainments. He was born about the year 1503. His father, Henry Etienne, and his brothers, Francis and Robert, were all celebrated for the ingenuity with which they cultivated the art of printing. But this family was not lefs unfortunate than ingenious; for, being attached to the caufe of the Proteftant reformation, fome of them were banifhed from France, and others died in prifon. Charles, however, during thefe troubles, lived and flourifhed at Paris, where he had for many years practifed his profeffion, when his brother Robert became the object of perfecution, and fled to Geneva. He immediately undertook the fuperintendence of his printing-office, which he continued to manage for feveral years, in the hope of effecting the reftoration of his brother, practifing medicine at the fame time with his former diftinction and fuccefs. Robert died at Geneva, however, in 1559; and Charles terminated his life unfortunately, a few years afterwards, having died in a dungeon in 1564, at the age of about fixty.

Dr. Etienne, the fubject of this article, made feveral difcoveries of minor importance in anatomy, which had efcaped his predeceffors, efpecially Galen, of whom he was a great admirer; he publifhed fome anatomical figures, the execution of which, however, was claimed by a furgeon of the name of Riviere, and generally allowed to be his; but the explanations were admitted to be Etienne's. He publifhed a great number of works, fome of which have no connection with his profeffion, efpecially the hiftories of Lorraine, of Flanders, and of the dukes of Milan. The works relative to medicine, befides the anatomical book juft mentioned, were principally on botanical fubjects. He alfo wrote a volume, confifting of three books, "De Nutrimentis," Paris, 1550. Eloy.

Etienne, Henry, the fon of Robert, was born at Paris in 1528, and became diftinguifhed as one of the moft learned men of his time. His father fpared neither pains nor expence in his education, and the youth had a great facility in acquiring the Greek language. At the age of eighteen he affifted his father in collating the MSS. of Dionyfius Halicarnenfis. After he had performed this bufinefs he fet out on his travels; ftaid fome time in Italy, where he became well acquainted with the learned men of that country, and obtained much valuable information from the Italian libraries. From Italy he came to England, and from thence he paffed through the Low Countries in his way to Paris, whither he returned at the moment his father was driven from that city. Here he followed the united profeffions of printer and editor. In 1554 he publifhed the Odes of Anacreon from the MSS. which he found in Italy. He accompanied his edition with fragments of Sappho and other lyric poets, and with an elegant metrical verfion. To him the learned are likewife indebted for various other Greek authors, publifhed from MSS. which he had collected in his travels, all of which he corrected and enriched with valuable annotations. In 1572 he publifhed his "Thefaurus Linguæ Græcæ," in four volumes folio, a capital companion to the Latin Thefaurus by his father. Scapula made an abridgement of this vaft work, which greatly hindered the fale of the original, and thus defrauded the learned author of the recompence to which he had the moft folid claim. This valuable man was protected by Henry IV. of France, who was fo far attached to him, that he employed him in a work entitled "Sur la precellence de la Langue Francoife." He was, however, too deeply imbued with the liberal principles which real literature almoft always infufes in the minds of her votaries, to efcape the malice of the monks. They brought a profecution againft him for his "Preparation á l'Apologie pour Herodote." Apprifed of his great danger, and well knowing the rancour of his enemies, he fled from the city and took refuge in the mountains of Auvergne. Scarcely had he left the city, when finding that he had efcaped their cruel fangs, they burnt the excellent man in effigy, regretting, no doubt, that they had not his perfon on which to wreak their vengeance. After this Etienne refided chiefly at Geneva, though he made occafional vifits to his literary friends in Germany and France. He was fubject to many difficulties, and doomed to other and fevere perfecutions, which at length fo far broke his fpirits as to caufe derangement, and in this ftate, as well as in poverty, he died at an alms-houfe at Lyons in 1598. Befides editing the Poetæ Græci Principes; Maximus Tyrius; Diodorus Siculus; Medicæ artis Principes poft Hippoc. and Galen; and the Nov. Teft. Græc., to which he prefixed an admirable preface; he was author of fome excellent pieces, befides what have been already mentioned; *viz.* Dialogues "De bene inftituendis linguæ Græcæ ftudiis;" "De criticis veteribus Græcis et Latinis," and other pieces in the French language, as well in verfe as in profe. He was a man of many fingularities, but truly refpectable, and highly refpected. He left feveral children, of whom his fon Paul fucceeded him in his Genevan printing-office, and inherited a fhare of his reputation. Moreri.

Etienne, *Saint*, in Latin *Fanum Sancti Stephani*, or *Furania*, in *Geography*, a confiderable town of France, in the department of the Loire, chief place of a diftrict of the fame name, with a population of 16,259 individuals. It is fituated on the river Furan, 36 miles S.W. of Lyons, and 348 miles S. by E. of Paris. N. lat. 45° 22'. The town is divided into two cantons, Eaft and Weft, the former with three communes and 12,735 inhabitants, the latter with three communes and 14,669 inhabitants; the whole canton has a territorial extent of 92½ kiliometres. There are at Saint Etienne and in the neighbourhood feveral manufactures of fwords and fire arms, cutlery, and hardware of all forts, ribbands, filks, and good bleaching grounds. The diftrict abounds with coal-mines, and the proximity of two large rivers, the Rhône and Loire, affords great facility for the tranfport of the produce of the manufactures.

As chief place of a diftrict, Saint Etienne has a fub-prefect, two courts of juftice, and a regifter office. The diftrict contains 9 cantons, 76 communes, and 99,261 inhabitants,

ants, on a territorial extent of $1142\frac{1}{2}$ kiliometres.—Alſo, a ſmall town of France, in the department of the Maritime Alps, chief place of a canton in the diſtrict of Puget-Theniers, with a population of 1689 individuals; its canton has a territorial extent of $212\frac{1}{2}$ kiliometres, and three communes, with 3089 inhabitants.

Etienne *de Baigorry*, *Saint*, a town of France, in the department of the Lower Pyrenées, chief place of a canton in the diſtrict of Mauléon, with a population of 6187 individuals. The canton contains 10 communes and 10,939 inhabitants, on a territorial extent of 210 kiliometres.

Etienne *de Cuines*, *Saint*, a ſmall town of France, in the department of Montblanc, chief place of a canton in the diſtrict of St. Jean de Maurienne, with a population of 830 individuals. The canton has a territorial extent of $117\frac{1}{2}$ kiliometres and 6 communes, with 6496 inhabitants.

Etienne *de Lugdarès*, *Saint*, a ſmall town of France, in the department of the Ardèche, chief place of a canton in the diſtrict of l'Argentiere, with a population of 1509 individuals. The canton has ſeven communes and 3439 inhabitants, on a territorial extent of 185 kiliometres.

Etienne *de Montluc*, *Saint*, a town of France, in the department of the Lower Loire, chief place of a canton in the diſtrict of Savenay, with a population of 4118 individuals. The number of the inhabitants of the canton amounts to 12,453; they are diſperſed in five communes, on a territorial extent of $272\frac{1}{2}$ kiliometres.

Etienne *de Saint Geoire*, *Saint*, a ſmall town of France, in the department of the Iſère, chief place of a canton in the diſtrict of St. Marcellin. It has 1546 inhabitants, and its canton compriſes, on a territorial extent of $162\frac{1}{2}$ kiliometres, 13 communes, with a population of 9381 individuals.

Etienne *en Dévoluy*, *Saint*, a ſmall town of France, in the department of the Upper Alps, chief place of a canton in the diſtrict of Cap, with only 766 inhabitants: but the canton has four communes, and a population of 2184 individuals, on a territorial extent of $262\frac{1}{2}$ kiliometres.

Etienne *les Orgues*, *Saint*, a ſmall town of France, in the department of the Lower Alps, chief place of a canton in the diſtrict of Forcalquier, with a population of 984 individuals. The canton has a territorial extent of $272\frac{1}{2}$ kiliometres, 12 communes, and 4260 inhabitants.

ETIOLATION *of Plants*, in *Gardening*, the rendering them white, criſp, and tender, by excluding the action of light from them. See Blanching.

ETIQUETTE, a French term, primarily denoting a ticket or title affixed to a bag or bundle of papers, expreſſing its contents. It is alſo uſed when applied to the Spaniſh and ſome other courts, to ſignify a particular account of what is to be done daily in the king's houſhold, and in the chief ceremonies relating to it. It likewiſe denotes thoſe forms that regulate the decorum of conduct towards perſons of various ranks and ſtations.

ETIVAZ in *Geography*, a ſmall town of Switzerland, in that part of the canton of Berne which is called the Ober Land, or Upper Country, being at the foot of the higheſt Alps, and extending to the glaciers, or ice mountains. It is ſituated in the diſtrict of Geſſenay, and is remarkable for its mineral ſprings, the water of which has a ſulphureous taſte.

ETLINGEN, or Ettlingen, a ſmall town of Germany, in the grand duchy of Baden, ſituated on the river Alb, between Pfortzheim and Raſtadt, at the diſtance of 12 miles from each. N. lat. 48° 55′.

ETMARSHAUSEN, or Etmershausen, a ſmall town of Germany, in the duchy of Saxe Coburg, in the diſtrict of Saltzungen, remarkable only for the following inſcription, which is engraved on an old garden gate of ſtone, in Latin characters: "wer weiſz obs wahr iſt," (who knows whether it be true.) It is become a proverbial ſaying in that part of Saxony, and frequently uſed as a polite inſinuation that a perſon is ſuſpected of having rather deviated from or embelliſhed the truth; people then obſerve that what has been related is engraven at the garden gate at Etmarſhauſen. The origin, occaſion, or motive of the inſcription itſelf, has never yet been explained, and has puzzled ſeveral antiquaries of the neighbourhood.

ETMASER, a town of Arabia, in the province of Yemen; 36 miles N. of Chamir.

ETMULLER, Michael, in *Biography*, an eminent phyſician, was born at Leipſic on the 26th of May, 1644. Poſſeſſing a taſte for the ſciences which his native city afforded him the moſt ample means of cultivating, he diligently ſtudied under the celebrated profeſſors of that period. He afterwards ſpent a conſiderable time in travelling through France, England, Holland, Italy, and Germany, with a view to the farther acquiſition of knowledge; and on his return took the degree of doctor of medicine at Leipſic in Auguſt 1668. In the year 1676, he was appointed profeſſor of botany in that univerſity, and extraordinary profeſſor of ſurgery and anatomy. He fulfilled thoſe offices with great applauſe; and his death, which happened on the 9th of March, 1683, when he was but 39 years of age, was generally regretted by the faculty of Leipſic. The diſorder, which occaſioned it, was contracted while he was employed in ſome chemical experiments. He was a very voluminous writer, and his works were deemed ſufficiently intereſting at the time of their publication to be tranſlated into moſt of the European languages. His medical practice and opinions were built upon the theory of Sylvius de la Boë, and the chemical ſect.

Etmuller, Michael Ernest, ſon of the preceding, was born at Leipſic on the 26th of Auguſt, 1673; and, after having ſtudied at Zittau, Altemberg, and other ſchools of Germany, he took the degree of doctor of medicine at his native place, in 1697. He afterwards travelled to the moſt eminent univerſities of Europe, and became ſucceſſively profeſſor of anatomy, of philoſophy, and of pathology at Leipſic. He had likewiſe been two years director of the Academia Naturæ Curioſorum, when his death occurred, on the 25th of September, 1732. He has left ſome diſſertations of his own, but is chiefly known as the editor of the works of his father.

ETNA. See Ætna.

ETOBESA, or Etobema, in *Ancient Geography*, a town of Spain, in Edetania, mentioned by Livy under the name of Etoviſſa, and ſituated at ſome diſtance W. of Valencia.

ETOCETUM, a place in the iſle of Albion, according to the Itinerary of Antonine, which Gale fixes at Wall, near Litchfield.

ETOILE, in *Geography*, a town of France, in the department of Drôme, and diſtrict of Valence; 3 leagues N.W. of Creſt.

ETOLIA. See Ætolia.

ETON, in *Geography*, a large village in the hundred of Stoke, and county of Buckingham, England, is noted for its great public ſeminary, or college, in which many eminent ſtateſmen, authors, military heroes, &c. have received their ſcholaſtic education. This college was originally founded by king Henry the Sixth, in the year 1440, for a provoſt, ten prieſts, four clerks, ſix choriſters, twenty-five poor grammar-ſcholars, and twenty-five poor men. The firſt provoſt was Henry Sever, who was ſucceeded by William Waynfleet, founder of Magdalen college, Oxford. This foundation was particularly excepted in the act for the diffolution of colleges and chantries, in the time of Edward VI. Its eftablifhment, however, has been in fome degree altered, and now confifts of a provoft, feven fellows, two fchoolmafters, two conducts, feven clerks, feventy fcholars, and ten chorifters, befides inferior officers and fervants. The annual election of fcholars to King's college, Cambridge, founded alfo by Henry VI. takes place about the end of July, or the beginning of Auguft, when twelve of the fenior boys are put on the roll to fucceed in this college as vacancies occur. The average number of vacancies are about nine in two years: at nineteen years of age the fcholars are fuperannuated. Eton college alfo fends two fcholars to Merton college, Oxford, where they are denominated poftmafters. It has a few exhibitions, of twenty-one guineas each, fo its fuperannuated fcholars, towards whofe affiftance Mr. Chamberlayne, a late fellow, has bequeathed an eftate of 80*l. per annum*, after the death of his widow. The fcholars elected to King's college fucceed to fellowfhips at three years' ftanding. The independent fcholars at Eton, commonly called Oppidans, are very numerous; the average number having been for feveral years paft from 300 to 350: when Dr. Bernard was mafter, under whom the fchool particularly flourifhed, the number at one time exceeded 520. Among the many diftinguifhed perfons who received their education here we find the names of bifhop Fleetwood, bifhop Pearfon, John Hales, Dr. Stanhope, fir Robert Walpole, Horace Walpole, Oughtred the mathematician, Boyle the philofopher, Waller, Gray, Weft, the late earls Camden and Chatham, and the late learned Jacob Bryant; with many other eminent literary and public characters of the prefent day.

An ancient cuftom, appertaining to this college, called the "Montem," or "Ad montem," muft not be paffed unnoticed. This is a proceffion of all the fcholars, &c., made every third year on Whit-Tuefday, to a tumulus, which has acquired the name of *Salt-hill*, by which alfo the neighbouring inns have been long known. The chief object of this ceremony is to collect money for *falt*, as the phrafe is, from all perfons prefent, even from paffengers travelling the road. The collecting fcholars are called falt-bearers, and are dreffed in rich filk habits. This ceremony has been frequently honoured with the prefence of the king and royal family, whofe liberal contributions, added to thofe of the nobility and gentry educated at Eton, who purpofely attend this meeting, have fo far augmented the collection, that it has been known to exceed 800*l.* The fum fo collected is given to the fenior fcholar who is going to Cambridge for his fupport at the univerfity. It would perhaps be a vain endeavour to trace the origin of all the circumftances of this fingular cuftom, particularly that of collecting money for *falt*, which has been in ufe for time immemorial. The proceffion itfelf feems to have been coeval with the foundation of the college, and it has been conjectured, with much probability, that it was that of the bairn or boy bifhop. It is fo afferted in a note among the MS. collections bequeathed to the Britifh Mufeum by Mr. Cole, who was of Eton and King's college: but whence he procured this information, which, if correct, might be decifive, does not appear. The cuftom of hunting a ram by the Eton fcholars on Saturday in the election week, fuppofed to have been an ancient tenure, was abolifhed by the late provoft Dr. Cooke.

Eton college confifts of two quadrangles: in the firft are the fchool, the chapel, and lodgings for the mafters and fcholars. The other is occupied by the library, the provoft's lodgings, and the apartments of the fellows. The chapel, as far as relates to its external appearance, is a very handfome ftructure; the infide has none of that ornamental architecture fo much admired in King's college chapel at Cambridge, to which this has fometimes been compared, but is quite plain, and has been much disfigured by fome injudicious alterations, made in the beginning of the laft century, when feveral of the monuments were removed, and others concealed behind the wainfcot then placed at the eaft end. The whole length of the chapel is 175 feet, including the ante-chapel, which is 62 feet long. Among the eminent perfons who are buried in this chapel, are Richard, lord Grey of Wilton, henchman to king Henry VIII.; John Longland, bifhop of Lincoln, confeffor to that monarch; fir Henry Saville, the learned warden of Merton, and provoft of this college, who founded the Savilian profefforfhips of aftronomy and geometry at Oxford; fir Henry Wotton, an eminent ambaffador and ftatefman, who was alfo provoft of Eton; Francis Rowfe, a diftinguifhed writer among the puritans, and one of the lords of Cromwell's upper-houfe, who died while provoft of Eton in 1658; Dr. Alleftree, alfo provoft, an eminent royalift, who built the new or upper fchool, with the cloifters beneath, at the expence of 1500*l.*, and died in 1680; and Nathaniel Ingelo, who died in 1683. The monuments of fome of the above-mentioned perfons are not now to feen. Sir Henry Wotton's tomb has the following fingular infcription:

> "Hic jacet hujus fententiæ primus auctor—
> Difputandi pruritus fit ecclefiarum fcabies"
> "Nomen alias quære."

In the ante-chapel is a ftatue of the founder, by Bacon, erected in 1786; the fum of 600*l.* having been bequeathed for that purpofe by the Rev. Edward Betham, fellow of the coll ge, who died in 1783: and a monument of the young earl of Waldegrave, who was drowned when at Eton fchool, in 1794.

The college library contains a very large and valuable collection of books, having been from time to time enriched by munificent bequefts.

In 1452 the college had a charter for a market on Wednefdays, with confiderable privileges; but it has been long difufed. Two fairs were granted by the charter of 1444: one for the three days following Afh-Wednefday, the other for fix days next after the 13th of Auguft. There is now only one fair, held on Afh-Wednefday. The parifh church of Eton, called in ancient records Eton-Gildables, having been fuffered to fall to decay, the inhabitants are permitted to attend divine fervice in the college chapel. The provoft is always rector, and has archideaconal jurifdiction within the parifh. There is a chapel of eafe in the village ferved by one of the conducts of the college; it was built for the ufe of the inhabitants by William Hetherington, who had been one of the fellows, and was a very liberal benefactor to the blind and to the poor of other defcriptions.

Eton is fituated on the northern banks of the Thames, oppofite to Windfor, with which it is connected by a bridge. It is 22 miles diftant from London; confifts chiefly of one ftreet; and contains 290 houfes, and 2026 inhabitants. Lyfons's Magna Britannia, vol. i. Beauties of England and Wales, vol. i.

ETORPU, one of the Kurifkoy or Kurile iflands, lying 30 verfts from Urup; and about 300 verfts in extent. The whole ifland is covered with lofty mountains; one of which, at the northern extremity, emits a continual fmoke, and occafionally flames. The fummits of the mountains are bald, with fteep cliffs and heaps of rubbifh. Here are forefts, confifting of the fame trees with thofe of the ifland Urup.

Urup. In the fouthern half, near about the centre of the ifland, grew larch-trees, in the proximity of the fea, but flender, though further inland, in the plains of the vallies, good timber trees, fit for the purpofes of building. Here are likewife black bears, and in the forefts fables and foxes are met with. Of rats there is no fcarcity; fifh-otters haunt the ftreams; and the brooks abound in fifh. During the ftorms that happen here, whales and large dolphins are thrown afhore by the fea. The fea-otter is not feen here, but fea-lions, though not of any great dimenfions. The inhabitants are hairy Kurils, who dwell together in villages. They are numbered in the capitation-tax at 92 perfons.

ETRETPAGNY, or Estrepagni, a fmall town of France, in the department of the Eure, chief place of a canton in the diftrict of Les Andélys, with a population of 1201 individuals. It is fituated 9 miles from les Andélys, and 9 miles W. of Gifors; its canton contains 10,442 inhabitants, difperfed in 26 communes, on a territorial extent of 140 kiliometres.

ETRIGNY, a town of France, in the department of the Saone and Loire, and diftrict of Chalons fur-Saone; $3\frac{1}{2}$ leagues S. of Chalons.

ETRIS, a town of Egypt; 18 miles N.W. of Cairo.

ETROEUNG, a town of France, in the department of the North, and diftrict of Avefnes; $1\frac{1}{4}$ league S. of Avefnes.

ETRURIA, in *Ancient Geography*, a country of Italy, feparated on the weft from Liguria by the river Macra; from Latium and Umbria on the eaft by the Tiber; on the north-eaft by a part of the Apennines from the country of the people called Boii and Senones; and on the fouth-weft wafhed by a portion of the Mediterranean fea, called Mare Tufcum, or Tyrrhenum, the Tyrrhenian fea. This country was once more extenfive than the prefent Tufcany, as it reached as far as the Tiber. The inhabitants of Etruria, who for a long time poffeffed a great part of Italy, were denominated Tufci or Etrufci. (See Etrusci.) The principal rivers of this country were the Arnus, the Umbro, the Clanis, and the Tiber. The chief lakes were the Lacus Trafimanus, and Vulfinienfis. Among the moft confiderable cities we may reckon Luna, Pifæ, Luca, Pittoria, Florentia, Fefulæ, Portus Herculis, Labronis, Voluterræ, Sena Julia, Arretium, Cortona, Perufia, Clufium, Vetularii, &c. &c.

Etruria, in *Geography*, a country fituated between the Mediterranean, the Tiber, and the Apennines; bounded on the eaft by the dominions of the pope, on the north and north-eaft by the kingdom of Italy, on the weft by the republic of Lucca, and on the fouth-weft by the Mediterranean; about 115 miles in length, and 80 in breadth. The face of this country is beautifully varied with hills and vallies, and the foil which is rich and fertile produces abundance of corn, and excellent fruit, oranges, lemons, olives and grapes. The air is in feveral parts rendered infalubrious by fens and moraffes; the falt-pits are rich. Manna is gathered in the marfh-lands near the fea; and the mountainous parts are rich in mines and minerals. Several medicinal fprings have been difcovered befides thofe of Pifa. Arno is the principal river; and Florence is the capital. After feveral revolutions, Etruria became a republic, and deriving its name from its capital, was called Florence. And in this republic the Medici family obtained by commerce the wealth and rank of princes. It was alfo denominated *Tufcany*, which fee; and in 1569, Cofmo I. was declared duke of Tufcany by pope Pius V., which title was ratified by the emperor Maximilian II. in the year 1575, on condition of his enjoying and holding it as a fief of the empire. By the fifth article of the quadruple alliance, made in 1718, it was ftipulated that, with the confent of the Germanic body, the emperor fhould confer it as a fief on the king of Spain's eldeft fon by the fecond marriage, and that it fhould devolve to his male defcendants, and on their failure to the younger brother and his heirs. In 1737 the duchy of Tufcany became annexed to the houfe of Auftria. By the fifth article of the treaty of Luneville in 1801, the duchy of Tufcany was ceded to the duke of Parma, and erected into a kingdom, under the name of Etruria. It has fince been annexed to the kingdom of Italy.

ETRUSCA Terra, in the *Materia Medica*, a kind of bole of which there are two fpecies, the white and the red; thefe are called by many authors the *terra figillata alba & rubra magni ducis*, as they are brought to us fealed with different impreffions.

The *white Tufcan earth* is a denfe and compact fubftance of a dull deadifh white, which in drying acquires fome degree of yellownefs; it is of a fmooth furface, and does not ftain the fingers in handling. It is not eafily broken, and but flightly adheres to the tongue, and freely melts into a fubftance like butter in the mouth. It makes a flight effervefcence with acid menftruums.

The *red Tufcan earth* is a pure bole, very heavy, and of a compact texture, and of a dull brownifh red colour. It is naturally of a fmooth furface, breaks eafily between the fingers, and does not ftain the hands; it adheres ftrongly to the tongue, and melts freely in the mouth, and has a ftrong aftringent tafte, and leaves no fandy harfhnefs between the teeth. It makes an effervefcence with acid menftrua. This is made up of fmall flat cakes, and impreffed with a fhield bearing a ducal coronet, &c. Thefe are the characters by which both thefe earths may be known from others of the fame colour: they are both dug in feveral parts of Italy, particularly in the neighbourhood of Florence: they are kept in the fhops there, and prefcribed with fuccefs in fevers of many kinds, and in diarrhœas, dyfenteries, and the like cafes.

ETRUSCI, Etruscans, in *Ancient Geography*, a people of Italy, who inhabited that part which is now called Tufcany; though it was formerly much more extenfive under the name of *Etruria*. The Etrufcans, in very ancient times, are fuppofed to have been mafters of almoft all Italy; for the whole region called Italia by the Latins was denominated by the more ancient Greeks Tyrrhenia, according to Dionyfius Halicarnaffenfis (Antiq. Rom. lib. i.); whence it is inferred, that it was formerly fubject to the Tyrrhenians, or Etrufcans, and from them received that denomination. Livy and Plutarch intimate, that the feas, which partly furround Italy, *viz.* the Tyrrhenian, Ionian, and Adriatic, were anciently denominated the Etrufcan fea; and that the Etrufcans poffeffed the whole large tract extending from the Alps to the ftraits feparating Italy from Sicily. They built twelve cities beyond the Tiber, which were afterwards the boundary of Etruria Proper on one fide; and they were the founders of Nola and Capua, and poffeffed twelve capital cities in the tract terminated by th Po and the Alps. Virgil and Silius Italicus rank Cæfena and Mantua among the cities of Etrufcan extraction; and we learn from Livy, that this ancient nation in very early times occupied the whole tract between the Alps and the Apennines. According to Pliny, Bononia, or Bologne, was anciently regarded as the principal city of Etruria; and we may obferve, that many Etrufcan relics and fragments of antiquity have been dug up in various provinces of the kingdom

dom of Naples, Verona, Padua, &c. as well as the duchy of Tufcany, or the Proper Etruria. The kingdom of Latium was probably a colony of the Etrufcans; and the firft traces of the city of Rome may poffibly have been owing to that nation. However, in procefs of time, the Gauls made feveral irruptions into Etruria, and feized upon that part of it which lay between the Alps and the Apennines. The firft of thefe irruptions happened about 600 years B.C. and the laft a little before the taking of Rome by Brennus. Several colonies of Greeks made fettlements in the fuperior part of Etruria; and from them it was denominated Magna Græcia. The Etrufcans were likewife difpoffeffed of a large extent of territory by the Samnites and Ligurians, long before they fubmitted to the Romans; fo that at laft they found themfelves confined within the limits of Etruria Propria, where for feveral ages they made a very confiderable figure. Etruria was called by the moft ancient Greeks Tyrfenia; but Polybius, and thofe who lived after him, denominated this country Tyrrhenia. Tyrfenia is faid to be the true name, as it correfponds with that of the Lydian prince, Tyrfenus, under whofe conduct, according to Herodotus, the Tyrfeni, or Tyrrheni, firft made a fettlement in Italy. Etruria was divided into twelve ftates or dynafties, each of which had its peculiar city. Each ftate or tribe was governed by its own prince, called in the Etrufcan language "Lucumo," and received its denomination from the capital city. See ETRURIA.

The Tyrfeni, or Etrufcans, were a branch of the Pelafgi, that migrated into Europe, according to Dionyfius Halicarnaffenfis, not many ages after the difperfion. Thofe who marched by land as far as Lydia detached a colony under the conduct of Tyrfenus to Italy. This colony feems to have been joined by a body of Pelafgi, previoufly fettled in fome of the iflands of the Archipelago. Hence fome have concluded that the Lydian Pelafgi, or Etrufcans, conducted by Tyrfenus into Italy, and the firft Pelafgi that inhabited Greece, were the fame people; but Dionyfius Halicarnaffenfis makes the Tyrfenians and Pelafgi two different nations. The Etrufcans denominated themfelves Rafeni, from their leader Rafan, or Rafen; and Tyrfenus, or Tyrfen, is faid to be only the name Refen, with the fervile letter T fuperadded. This circumftance ferves to evince, not only that the Etrufcan name of the people under confideration agreed with that of the Greeks, but likewife that they were both of oriental extraction. See PELASGI.

The Etrufcans feem to have derived their appellation from Etruri, or Etuni, as they were anciently denominated; and that this appellation was deduced from Athuria, or Aturia, that of their parental country, may be proved from Dionyfius Halicarnaffenfis, Strabo, and Dio. Moreover, Aturia and Affyria differ merely in dialect; the former being equivalent to the Chaldæan word אתוריא, and the latter to the Hebrew אשור, as may be evinced from Bochart (Phaleg. L ii. c. 3.) and others. Since, therefore, nothing is more frequent than the permutation of A and E in oriental words, efpecially when written in Greek letters, Atura and Etura muft be regarded as the fame word, and as the ancient name of Etruria. More efpecially if we confider that Refen was a city of Aturia or Affyria, whence, probably, the leaders of the Etrurian or Etrufcan colony were denominated Rafeni, or Refeni; and that, from the facred hiftorian, we may conclude Afhur to have been the brother of Lud, or great anceftor of the Lydians. The term Tufci, or Thufci, is of a later date, and feems to have been given to the Etrufcans by the Greeks. The facrifices, or ufe of frankincenfe, that prevailed among the Tufcans in after ages, probably fuggefted this appellation to that people.

As each of the twelve tribes, or cantons, called in the Tufcan language "Lucumonin," was governed by its own prince, a king prefided over the whole; and whilft the lucumo affumed the adminiftration of affairs in his own province, the king was confulted on all extraordinary occafions, and convened the general diet of the twelve nations on all preffing emergencies. This diet was held at the temple of Voltumna, which was a celebrated city of Etruria, feated on the fpot which is occupied, according to Cluverius, by the prefent city of Viterbo; and in this temple meafures were concerted for making war upon, or concluding peace with their neighbours. Although the power of each lucumo was limited, the Etrufcan kings feem to have been vefted with a fort of abfolute authority, confonant to the firft oriental form of government.

Some of the principal Tufcan laws were fuch as follow: 1. By the original conftitution of Etruria, no fingle ftate, or lucumony, could enter upon a war, or conclude a peace, with any neighbouring power, without the participation of the whole Etrufcan body. 2. The Etrufcans, by a particular law (Athen. Deipnof. l. i. p. 23.) admitted their women to all nocturnal entertainments; in which they were afterwards followed by the Romans. 3. They obliged themfelves to treat all foreigners with the utmoft humanity. 4. They gave all poffible encouragement, as it fhould feem, by virtue of their conftitution, to all polite arts and artificers. 5. In order to deter people from contracting larger debts than they were able to pay, the Tufcan boys, by way of ridicule, followed all infolvent debtors with an empty purfe. 6. They muft have had many good moral inftitutions, fince from them the Romans received a fupplement to their Twelve Tables. 7. The jura fecialia were firft obferved by the Etrufcans. 8. The Etrufcan polity, in general, feems to have been founded upon maxims of the moft confummate wifdom, as may be collected from Ariftotle, and Heraclides Ponticus in Athenæus's Deipnos.; to which the curious reader may be referred for further information.

The religion of the Etrufcans was a grofs and multifarious idolatry. In common with the ancient Greeks, and Phœnicians, they worfhipped the Cabiri, or Dii magni majorum gentium. They were alfo initiated in the Samothracian or Cabirian myfteries.

Befides the Greek and Roman deities, they had feveral peculiar to themfelves; fome of which were confined to particular towns or diftricts. The divine fervice and facred myfteries of the old Etrufcans agreed, in feveral points, with thofe of the Greeks, but in others differed from them, and thefe they communicated to the Romans long before that nation had any intercourfe with the Greeks. The feftivals, holy days, and ftated times of public worfhip of the Romans and Etrufcans, muft alfo have agreed in feveral particulars, as the Romans, before they became acquainted with the Greeks, received every thing relating to religion, and even their calendar itfelf, from the Etrufcans. The latter borrowed of the Egyptians, or rather the Phœnician fhepherds expelled Egypt, their public fupplications, pomps, and folemn proceffions, which occurred in fome of their principal feftivals. The rites and ceremonies ufed by the harufpices, augurs, and pontifices at Rome, were derived from the Etrufcans, who feem to have been the moft celebrated nation in the Pagan world for fkill in augury, and divination, as well as knowledge of the nature of facrifices, to which all rites and ceremonies neceffarily relate. This, however, was their character among the Romans, as Cicero and Livy have teftified. Hence this branch of fcience was emphatically ftyled at Rome "Ars Etrufca," and "Difciplina Etrufca;" fo that Etruria was denominated by Ar-

nobius

nobius the mother of ſuperſtition. It is obſervable, that neither the Etruſcans nor the Romans had any magnificent temples in the earlier ages. The Etruſcans had ſome peculiarities in their religion, which diſtinguiſhed it from that of every other nation; but the ancient Egyptian and Phœnician modes of worſhip were the ſame with thoſe, for many of the earlieſt ages, uſed in Etruria; nor can any material difference be found between the oldeſt oriental and Etruſcan divinities. With regard to the theological notions of the Etruſcans, they believed one ſupreme Being, whom they called Jave, or Jove; they conſidered him as the great governor of the univerſe, as the principle of life and motion. They were firmly perſuaded of the immortality of the ſoul, and therefore believed a future ſtate of rewards and puniſhments; though in later times they ſeem to have followed the ſyſtem of Pythagoras, and conſequently to have adopted the metempſychoſis of that philoſopher. However, the generality of the Tuſcans adhered to the Sabian ſuperſtition, in common with moſt of the inhabitants of the Eaſt.

The Etruſcan language muſt have been the ſame, or nearly ſo, with the Hebrew and Phœnician. The firſt Pelaſgic ſettlements in Etruria could not have taken place many centuries after the deluge, and very few after the diſperſion; and at that time the languages, or rather dialects of the Egyptians, Aſſyrians, Babylonians, Celtes, Syrians, and Arabs, muſt have approached extremely near to the Hebrew and Phœnician, which the learned allow to have been almoſt the ſame. In ſhort both ſacred and profane hiſtory concur in ſhewing the Hebrew, Phœnician, and Etruſcan tongues to have been, in the earlier ages, nearly the ſame. This alſo appears from the letters and manner of writing anciently uſed in Etruria. The letters are almoſt the ſame with thoſe of the earlieſt Greeks, brought by Cadmus out of Phœnicia. The manner of writing is purely oriental, the letters being drawn from the right hand to the left, agreeably to the practice of the eaſtern nations. The former point is rendered indiſputable by the Eugubian tables, in conjunction with the Sigæan inſcription; and the latter by merely peruſing the Etruſcan inſcriptions. The very remote antiquity of the firſt colonies that ſettled in Etruria, as well as of the Etruſcan language and alphabet, may be eaſily inferred from theſe inſcriptions; for as the Pelaſgic alphabet, that prevailed in Greece before the age of Deucalion, conſiſted of ſixteen letters, the Etruſcan or Pelaſgic alphabet, firſt brought into Italy, compoſed only of thirteen letters, muſt have preceded the reign of that prince. The high, and indeed the almoſt incredible antiquity of the Etruſcan language and alphabet, has been clearly evinced in two diſſertations, printed at Oxford in the year 1746. For other particulars relating to this ſubject, we refer to Dempſter's "Etruria regalis," Gori in his "Muſeum Etruſcum," publiſhed at Florence in 1737; M. Bourguet's Diſſertation publiſhed in 1733, and Buonarota's of Florence in 1726; and Swinton's Etruſcan alphabet, publiſhed at Oxford; and for an abſtract, Anc. Un. Hiſt. vol. xviii.

The Etruſcans were extremely well verſed in all the arts of war and peace, and from them the Romans derived thoſe arts and ſciences that paved the way to the empire of the world. In the beſt ages of Rome, the Romans imitated the Etruſcans; nevertheleſs, in after-ages the Etruſcans became thoroughly debauched both in principle and practice. Augury, and every kind of divination; all the principal religious inſtitutions, temples, ſtatues of gods and heroes, the manner of forming or building cities, fortifications, conſecrations, and nuptial rites were tranſmitted to the Romans by the Etruſcans. Every thing alſo that bore any relation to civil government at Rome, ſuch as enſigns of royalty, the diſtinction of nobles from plebeians, the ſecures and faſces, the lictors, &c. was derived from the ſame ſource. Arms, inſtruments of military muſic, military accoutrements and decorations, trophies, triumphs, chariots, crowns, &c. and in ſhort every thing belonging to the art of war, or military exerciſes, that prevailed at Rome, were brought from Etruria. This was alſo the caſe with reſpect to money, locks and keys, lamps, candleſticks, glaſſes, cups, drinking veſſels, together with the laws and cuſtoms relating to banquets and entertainments. Agriculture, planting of vines, all inſtruments requiſite in huſbandry, mills, architecture, muſic, and a variety of muſical inſtruments, many ſorts of diverſions, eſpecially tragedies, various kinds of garments, and even the rudiments of phyſic, ſeem to have been introduced into Italy by the Etruſcans. Scenical amuſements, maſks, pantomimes, wreſtlers, the cuſtom of anointing their bodies, the uſe of wool, plaſtic ſtatuary, the fabulæ oſcæ or Atellanæ, nuptial verſes, or verſus Feſcenini, and the art of making earthenware, were alſo derived from the Etruſcans. The art of conſtructing ſhips and of navigating them, the method of equipping fleets, and all kinds of naval armaments, were known to the Etruſcans before the time of Romulus; and hence we may conclude, that this nation muſt have been a maritime power, and that it muſt have poſſeſſed an extenſive commerce in the earlier ages of the world. The Etruſcans, who were followers of Pythagoras, and who cultivated the principles of the Italian philoſophy, muſt have cultivated the art of muſic and poetry, and muſt have been well verſed in natural philoſophy and aſtronomy. Tragedy is ſaid to have owed its birth to this nation; or at leaſt they firſt communicated it to the Romans. The firſt actors who appeared upon the ſtage of Rome were ſent for from Etruria. Beſides, the ancient Etruſcans, valuing themſelves upon being the diſciples of Pythagoras, could not be ſtrangers to geometry, nor indeed to any of the mathematical ſciences. For military learning they were famous, and eſpecially for the art of drawing up an army, and making diſpoſitions for an engagement. Athenæus informs us, that the formation of the phalanx, and manner of fighting conſequent upon it, was invented by the Etruſcans, or at leaſt borrowed from them by the Romans. To all the other branches of literature and ſcience for which the Etruſcans were diſtinguiſhed, we may add that they excelled in the knowledge and compoſition of hiſtory.

The firſt perſon who fixed monarchical government in Etruria was Janus, ſuppoſed by ſome to be the Javan of ſcripture, or one of his poſterity, and in ſubſequent ages deified by his ſubjects as a ſingular benefactor. The hiſtory of their ſucceeding kings is intermixed with much fable, and, of courſe, very obſcure and uncertain. It appears, however, that they were a maritime power in the time of the Argonauts; and that they commanded reſpect as ſuch at leaſt a generation before the Trojan war, and made a figure at ſea before the Greeks. That the Etruſcans were a powerful and poliſhed nation, when Romulus founded or rather reſtored Rome, appears from ſome approved authors. That prince could not carry the deſign he had formed into execution, without the aſſiſtance of the Etruſcans. From them he derived all his civil and religious inſtitutions. Anc. Un. Hiſt. vol. xviii.

ETSED, in *Geography*, a town of Hungary, 40 miles N.W. of Zatmar. N. lat. 48° 2'. E. long. 21° 51'.

ETTENHIEM, a town of Germany, in the biſhopric of Straſburg; 12 miles S.S.E. of Straſburg.

ETTENSTATT, a town of Germany, in the principality of Anſpach; 5 miles N.E. of Weiſſemburg.

ETTERSHAUSEN, a town of Germany, in the principality of Wurzburg; 3 miles N. of Volckach.

ETTLSTORFF, a town of the archduchy of Auſtria; 9 miles W. of Sonneberg.

ETTRICK, a river of Scotland, which originates in the S.W. angle of the ſhire of Selkirk, and runs N.E. augmented by many ſmall ſtreams in its progreſs through a pleaſant valley to the Tweed, into which it falls near Sunderland-hall, 1½ mile below Selkirk. The banks of this river were formerly ſhaded with woods, whence the county obtained the name of Ettrick foreſt.

ETUEND, a mountain of Perſia, in the province of Irak; 60 miles S.E. of Hamadan.

ETYMOLOGICON, is uſed for a book, containing the etymologies of many languages. See ETYMOLOGY.

ETYMOLOGY, (from the Greek ετυμος, *true*, and λογος, *a word*,) means a true or real account of words: and as this true account is obtained by tracing them to their origin, etymology hence ſignifies that part of grammar which teaches the derivation of words.

Etymology is an eſſential and uſeful branch of philology; but from partial views, and an inattention to the principles which it implies, it is regarded by many as the fruitleſs ſtudy of words, in which neither knowledge nor certainty is attained. In order to limit, as much as poſſible, the province of etymology, and to remove the objections which have been made againſt it, we ſhall here briefly ſtate the laws which direct, and the conſiderations which give it the preciſion and the fixedneſs of a ſcience.

1. Etymology implies a due attention to the ſtructure of the vocal organs, or to the affinities of elementary ſounds. All men have the ſame organs of ſpeech, and the ſame letters are ſounded by a ſimilar modification of thoſe organs. Letters pronounced by the ſame organs, or the ſame parts of the mouth, approximate in ſound to each other, and from this conſideration become more eaſily corrupted and changed one for another. Thus all the vowels, whatever peculiarity in character and ſound they preſent to a perſon familiar with them, have yet a cloſer affinity to each other than to other letters; and hence are even interchanged. The more modern art of printing, indeed, has contributed to fix the fluctuating ſounds of the vowels, by uniformly preſenting them to the eye under diſtinct characters; but ſtill in an etymological view they are utterly to be diſregarded, or to be regarded only as one capricious, ever fluctuating impulſe of the voice.

The juſtneſs of theſe obſervations will immediately appear to any one who conſiders thoſe words in Latin, which are evidently derived from the Greek; or thoſe in French and in Italian, which are derived from the Latin; or thoſe in modern Engliſh, which are borrowed from the Gothic and Saxon tongues, and are ſtill farther diverſified in the Scotch, Iriſh, and Welſh dialects.

While the vowels form, as it were, the ever corrupting fleſh, or the ever varying complexion of language, the conſonants are the ſinews and bones which impart to it ſtrength and firmneſs, and which alone render it a ſubject of philoſophical inveſtigation. But the conſonants have a cloſer alliance to ſome than to other letters; and their affinity depends on the manner in which they are enunciated. Thus, *p*, *b*, *f*, *v*, *w*, *m*, or φ in Greek, are kindred letters, being produced principally by the *lips*, and are therefore often changed one for another, as caprice or cuſtom ſhall dictate. The ſame obſervation holds in regard to the letters *ſ*, *t*, *d*, *r*, *l*, which being produced by the tongue, impreſſed in various degrees on the extremity of the upper teeth, are called *dentals*; to thoſe which are produced by the tongue and the roof of the mouth and the palate, ſuch as *g*, *j*, *z*, *ch*, and finally to the gutturals, which, though they exiſt not in our tongue, form an important claſs of letters in moſt other languages. To this diſtribution of the conſonants into *labials*, *dentals*, *palatines*, and *gutturals*, the ſcientific etymologiſt will pay a ſtrict attention, and obſervation will ſoon teach him that, however perfect any alphabet may be in regard to etymology, each claſs is but a variation of the ſame letter.

2. Etymology ſuppoſes a ſtrict attention to be paid to *analogy*, that is, to thoſe general principles by which any language is formed in regard to its internal ſtructure, to the diſtinguiſhing terminations of its nouns and verbs, to its general mode of combining words, and to thoſe changes which words uſually undergo after they have been imported and naturalized, as it were, from any foreign tongue. In order to diſcover the nativity and parentage of any term, we muſt, as it were, ſtrip it of the dreſs with which the cuſtom of the country has clothed it, and we can trace it to its true origin, only when we view it ſeparated from the termination by which it is diſguiſed: thus μηνη, when imported into Engliſh, appears under the form of *moon*, having dropped η, its peculiar termination; and when expreſſing that period of time which comprehends one revolution of the moon, it aſſumes the termination *th*, which the analogy of the language hath warranted *month*; while in Latin it exiſts in the ſhape of *men-ſis*. And here it is to be obſerved, that the general principles of analogy, as in natural philoſophy, ſo in etymology, are to be collected by *induction* from inſtances that are ſimple, unequivocal, and definite, and then applied to words that are not ſo. The propriety and juſtice of theſe remarks it will be neceſſary to illuſtrate by a few examples.

Suppoſe we were aſked the derivation of οινος, *wine*, ὁν, or ἑ, *ſelf*, ανασσω, *to rule*, in Greek; we ſhould be able to aſcertain this only by unfolding a general principle in the ſtructure of that language. The oriental tongues, to which the Greek owes its origin, abound with gutturals, which by degrees ſoftened down into an aſpirate in many of thoſe words derived from them; while in others they melted into ſimple vowels, or were replaced by a labial, ſuch as φ, *f*, *b*, *v*, or *w*. Thus חי, *khee*, *life*, *ſelf*, became ὁν, חאן, *khaan*, *a king*, ανασσω, *to rule*, and יין, *yeen*, οινος. In theſe derivations our conviction would be complete, becauſe it is juſtified by a general principle that holds in a thouſand other inſtances.

Suppoſe, farther, we were aſked what were the origin of the Latin *vicus*, *a village*; *video*, *to ſee*; *vinum*, *wine*; *ovis*, *a ſheep*; or of *wheel*, *year*, *well*, *weal*, in our own tongue; we anſwer that the ſubſtitution of a labial for an aſpirate or a guttural, or a diphthong, forms a general principle which pervades the Latin tongue in its formation from the Greek. Hence *vicus* is from οικος; *vinum* from οινος; *ovis*, from οις; *video* from ειδω. With reſpect to our own language a ſimilar analogy obtains, which has converted a guttural into a labial; thus *laugh* is pronounced *laff*; *enough*, *enuff*; and moſt of thoſe words which begin or end with *y* and *w*, whether derived from Hebrew, Greek, or Gothic, began or ended with a guttural. On this general principle *year* may ſafely be ſaid to be derived directly or indirecty from γυρος, *a circle*, and means a period or revolution of time; *wheel*, from κυλιω, *to roll*; *well*, from גיל, *geel*, *a fountain*; and *weal* from חיל, *kheel*, *ſtrength*, which alſo has given birth to the words *heal*, and *health*.

Moreover, if we were aſked the origin of *ſperno*, *to deſpiſe*, we ſhould ſay that it comes from πτερνη, *the heel*, for the prefixing of the letter *s* to Greek words is a principle that pervades the Latin tongue; thus the primary ſenſe of *ſperno*, is is to put the heel upon; on the ſame principle is *ſalio*, *inſilio*, *inſult*, taken from ἁλλομαι. The French generally drop the gutturals either in the middle or at the end of words; hence we ſhould be juſtified by an invariable analogy in ſaying, that *eau*, *water*, is from *aqua*, and *ſeul* from *ſingulus*. The Italians generally drop the liquid *l*; agreeably to this cuſtom of the language, *fiume* is derived from *flumen*, *a ſtream*, and *piano* from *planus*, *a plain*. In German moſt of thoſe words which have *t* in Engliſh are uſed with an *s*; as *waſer*, *water*; *beſſer*, *better*; *es*, *it*: and the corruption of *m* into *f*, or *v*, is a principle that runs through the Welſh tongue; thus, *ve*, *voer*, and *vayr*, are but the Latin words *me*, *mare*, and *major*.

3. Etymology, in order to claim its proper rank as a branch of ſcience, requires a ſtrict attention to the *aſſociation of ideas*, the great law which regulates the human mind. The opinions and cuſtoms of men, it is well known, greatly influence their language; and this influence is produced by the ſecret and unerring impulſe of aſſociation; and the reaſon why this branch of philology has been ſo much abuſed or called in queſtion, is, that little or no regard has been hitherto paid to its connection with that grand invariable principle which governs the human underſtanding. He who attempts at etymology in any language muſt know the philoſophical, the religious, and the political notions of the people who uſe it; he muſt be acquainted even with the phyſical peculiarities of their country, and from an acquaintance with the laws of the human mind he ſhould be able to trace the ſecret proceſs by which thoſe circumſtances influence their ſpeech. We will give a few examples in illuſtration of theſe remarks.

In the early ages of the world, the principal idea under which the character of *God* preſented itſelf was that of *ſuperior power*; and, accordingly, the feelings which it awakened in the beholder were chiefly thoſe of *fear*. And even the Jews, who had far more rational notions of the Deity than the Gentiles, apprehended that no one could ſee God and live. Accordingly moſt of thoſe names, which ſignify a god, are in Greek either immediately derived from a word which ſignifies *fear*, or both from a common origin; thus, from באב, *baab*, *the firſt principle of things*, are taken φοιβος, ποποι, *Gods*; and φοβος, *fear*; ταρβος, *terror*, owes its origin to the Chaldæan תרף, *Terph*, *a houſehold god*. Παν, the god *Pan*, is only the Hebrew פון, *pon*, *conſternation*: δειμων is the *god of terror*, and hence δαιμων, *an inviſible ſpirit*, which was an object of *fear*, and δεισιδαιμων, *the fear of the dæmons*, *religion*. It was the common notion that thoſe dæmons produced violent paſſions and diſorders in the mind and body: hence came the verb δαιμονιαω, *to be mad*. It was thought, too, that they were the agents of God in preſiding over men; hence ευδαιμων, *one who had a good dæmon for his guardian angel*, and κακοδαιμων, *one who had an evil one*.

The introduction of evil into the creation could not be accounted for by the heathen philoſophers, only by ſuppoſing the exiſtence of two principles equal in power, and oppoſite in character and operation. The good principle they naturally aſſimilated to the *ſun*, the moſt ſplendid body in nature, whilſt the evil they called *darkneſs*; hence the ſaying *God is light*: זי, is pronounced by the Perſians *tzee*, but by the Arabians *tdee*, or *tdeio*, *light*; hence ζευς from the former mode of pronunciation, and θεος from the latter. On this principle the Chaldean אזא, *aza*, *to make hot*, the action of the ſun, gave birth to αζω, *to worſhip*, or *reverence*. The general opinion among the philoſophers was that water is the firſt principle of things. Hence the Arabic *mao* came, in Perſian, with little variation, to ſignify *fruit*, *wine*, and in Greek, μαια, *the goddeſs of birth*, and in Engliſh the producing month, *May*. The ſame word in Hebrew, by aſſuming *t* after the analogy of feminine nouns, is מות, *mot*, *death*, which means *reſolution into water*; hence the Egyptian *mot*, (whence Moſes is ſuppoſed to have been taken,) and *mud*, what is waſhed together by water, juſt as *lutum*, *clay*, is the ſupine of *lavo*, or *luo*, *to waſh*.

In eaſtern countries, where the heat of the ſun is violent and long continued, rain is deemed the greateſt bleſſing, and all the terms expreſſive, in moſt of the Aſiatic tongues, of plenty, ſucceſs, and joy, are generally borrowed from the names of water; hence the Hebrew ברך, *berek*, *to bleſs*; in Greek is βρεχω, *to rain*; in Latin *precor*, *to aſk for bleſſing*, *parco*, *to give bleſſing*; *ſpare*, and *ſpargo*, *to ſhed as the dew*, *or ſcatter as ſeed*. The ſame root exiſts in Engliſh in the form of *brook*, the effect of rain.

4. Etymology, in order to become a rational ſtudy, implies an extenſive and an accurate acquaintance with languages. It is not ſufficient to be acquainted with Latin to know Greek; nor to know Italian to be acquainted with Latin, nor to know Engliſh to be acquainted with the Saxon or Gothic; but to be a good etymologiſt in either of theſe, a man muſt comprehend them all. So manifold is the intercommunity between all languages, that no language exiſts derived from one and the ſame ſource. Words exiſt in Engliſh which exiſt alſo in moſt other tongues, under differences of character and termination; and they are derived not from each other, but from a common origin; and a ſcientific etymologiſt, inſtead of deriving them from each other, will trace them all till they meet in a few primitive terms. It would probably be wrong, or at leaſt it would be very doubtful to ſay, that *hand* comes from the Latin obſolete *hendo*, *to catch with the hand*, or from χανδω, the parent of *hendo*, but it would be right to ſay that theſe are *connate*, or *kindred* terms, ſprung, if not from each other, from ſome common root. In Hebrew, Perſian, and Arabic כף, *caph*, *is the hand*. The action of this is two-fold, as it *imparts*, or as it *receives*. In the former ſenſe it gave birth to the Saxon or Gothic *giff*, and hence *if*; in the latter to *capio*. *To take in hand is to begin a thing*; hence the ſame word exiſts in the form of *Cæpio*; and paſſing into Greece it produced κωπη, *a handle*.

And here it is obvious to remark, that as the root, paſſing into different countries, produces as it were new branches; thoſe branches will not continue long till they in their turn become the ſtems of more numerous and diverſified ſhoots; and as they thus multiply by accident, the progreſs of knowledge, the multiplication and diſtinction of ideas attendant thereon, ſeize, as it were, theſe wild and promiſcuous offspring, and give them the ſanction of cuſtom, the ſupreme arbiter of ſpeech, thus conſidering as genuine, words which at firſt were mere *corruptions*. Thus in our own tongue *guſt* is wind; hence *ghoſt*, what conſiſts of *wind*, *ſpectre*, *a-ghaſt*, *ghoſtly*, like a ſpectre, and *gas*, an aeriform fluid, ſo denominated from ghoſt, firſt by Van Helmont. Thus alſo in Latin, from πηγω, *to join together*, is *pango*, *to faſten*, *paco*, *to unite in concord*, *pacify*. To paint is to faſten adventitious colours on a thing; hence *pingo*, and to give to falſehood the adventitious colours of truth is *fingo*, *to feign*. Again, from μενος is *men's mind*, *force*, *eſſence*, *memini*, *to call to mind*, *moneo*, *to put in mind*; *manus*, *force*, or that organ in which the ſtrength of the human body chiefly conſiſts, *manes*, *the ſouls or departed ſpirits*, ſpirit being the eſſence of man; and *maneo*, *to exiſt*, the ſoul being that which exiſts after the deſtruction of the body.

Etymology, then, to be raiſed above the caprice of fruitleſs ſtudy, and to be claſſed among the uſeful and ſolid

I branches

branches of fcience, muft be founded on a juft regard to the affinities of letters, and to the ftructure of the organs of fpeech. It fuppofes an acquaintance with the philofophy of the human mind; with the analogies which form and diftinguifh each language; with the hiftory of mankind, philofophical, religious, and political. From thefe, its qualifications, refults its utility as a department of human knowledge. Etymology, it is evident, furnifhes the readieft and moft effectual means to acquire the knowledge of language; and as language is but the drefs of our ideas, it holds up a mirror to delineate and reflect the operations of the human mind. It helps to afcertain the pofitions of ancient places, to clear obfcurities in the antiquities of nations and families. What is more, when confined within its proper limits, and purfued to its full extent, it will throw much light and additional evidence on the truth of the Mofaic hiftory, refpecting the origin and propagation of mankind.

EU, or Eo, in *Geography*. See Eo.

Eu, a fea-port town of France, and chief place of a canton, in the department of the Lower Seine, and diftrict of Dieppe, feated on the Breffe, near the coaft of the Englifh channel; 15 miles N. of Dieppe. The place contains 3400 and the canton 12,810 inhabitants, on a territorial extent of 182½ kiliometres; and in 27 communes.

EVA, in *Ancient Geography*, a town of the Peloponnefus, in Arcadia.—Alfo, a hill of the Peloponnefus, in Laconia, near Sellafia. Polybius.

EVACUANTS, in *Medicine*, are thofe remedies which operate by diminifhing the quantity of fluids in the body. This effect may be produced either directly, by an artificial opening into the veffels or cavities containing the fluid to be evacuated; as by blood-letting, by means of the lancet, or by cupping; by tapping; &c. Or the evacuation may be accomplifhed indirectly, by exciting the action of the veffels, which are naturally deftined to throw off redundant fluids, on the one hand; or by producing inflammation, and a confequent difcharge of fluids, from parts not naturally fecreting them. Evacuants acting upon the natural emunctories, as the organs of excretion have been called, are of various quality and denomination, according to the parts upon which their action is exerted: thus, fome ftimulate the veffels which open into the cavity of the inteftines, and carry off the fluids by ftool, and are called *purgatives*, *laxatives*, or Cathartics; others excite the veffels of the kidnies to increafed action, and are denominated Diuretics; others augment the perfpiration, and are termed Diaphoretics and *fudorifics*; others again ftimulate the falivary glands, and produce a great difcharge of faliva, whence they are called Sialogogues; and others excite an increafed difcharge of the mucus of the noftrils, and are termed Errhines. All thefe kinds of evacuant medicines are occafionally employed, with a view to relieve the conftitution at large, or fome part of the body, from an inflammatory or febrile condition; or to remove local congeftions in particular organs, &c. See Bleeding, Cupping, and the words in capitals; under which heads the principles of the evacuation, thus varioufly effected, are explained.

EVACUATION, fee the preceding article.

Evacuation, in a *Military Senfe*, relates to the withdrawing of troops from any fortrefs or poft, not befieged, but intended to be relinquifhed, or eventually to be difmantled. This term is fometimes erroneoufly ufed in capitulations, where it is expreffed that the garrifon fhall evacuate within a certain number of hours. Now, as it is in almoft every cafe, a ftipulation on the part of the victors, that they fhall be put in poffeffion of certain gates, or defences, previous to the garrifon marching out; thereby fecuring every advantage that may have been obtained; it ftands to reafon, that the term evacuation is incorrectly applied. We have, indeed, but rarely inftances wherein it is properly introduced; one very recent cafe is however very prominent; namely, the evacuation of certain fortreffes in Pruffia by the French troops; for, if we are correctly informed, the Pruffian forces did not, in fome inftances, attempt to enter until their *friends* had completely withdrawn.

It is fometimes made a condition, that particular approaches, lines, or pofts, fhall be evacuated; there we fee the term appropriately ufed; becaufe fuch approaches, and lines efpecially, are not confidered as permanent works; therefore are intended to be difmantled fo foon as thofe who erected them fhould retire.

Where a place is to be evacuated under the exprefs condition of all damages being paid for, it becomes the duty of the future poffeffors to be very correct in caufing an enquiry to be made into all depredations and grievances, before the forces about to retire quit the place. Commiffioners on both fides are neceffary; in order that every matter may be adjufted at the moment, fo as to obviate future difagreements. This appears to have been attended to when the Portuguefe territory was evacuated by Junot; though we have ftrong reafon to apprehend that great evafion, and many highly nefarious acts, were practifed by the French on that occafion.

EUÆMIA, of ευ, *well*, and αιμα, *blood*, is ufed by Tremelius and fome other writers, to denote a good and healthy ftate of the mafs of blood.

EUÆMON, in *Ancient Geography*, a town of Greece, placed by Steph. Byz. in the territory of the Orchomenians.

EVAGRIUS, in *Biography*, patriarch or bifhop of Conftantinople, who fucceeded Eudoxus in 370, and whofe election was much refented by the emperor Valens. From this event commenced a cruel perfecution againft the Catholics, which did not terminate till the acceffion of Gratian to the throne. Evagrius probably died in exile during this period.

Evagrius, bifhop of Antioch, fucceeded Paulinus in the year 389; in confequence of whofe election, in oppofition to Flavianus, the fchifm in the church of Antioch, that has been much lamented by the orthodox, was continued. However, by the influence of Siricius bifhop of Rome, in the council of Capua, held in 390, Evagrius's election was approved. Two years afterwards Evagrius died, and the fchifm terminated. Evagrius was the friend and companion of St. Jerome, who reprefents him as a perfon of an active and ardent fpirit, and as the author of various writings, which he had perufed. None of thefe that deferve particular mention are now extant. Cave. Dupin.

Evagrius, furnamed *Ponticus*, and by St. Jerome *Hyperborita*, on account of the fituation of the place of his nativity near the Euxine fea, flourifhed near the clofe of the fourth century. Having been ordained deacon of Conftantinople by St. Gregory Nazianzen, he was inftructed by this bifhop in biblical learning, and advanced to the office of his archdeacon. His perfon and manners recommended him to the favour of the ladies; and being fufpected of an improper intimacy with the wife of a man of confequence, he was obliged to retire from Conftantinople in the year 385, and to remove to fome diftant place. At Jerufalem he embraced the monaftic life, and paffed 15 years at a monaftery amidft the deferts of Nitria in Egypt.

Whilft

Whilst he was in this situation he refused the episcopal dignity which was offered him by Theophilus bishop of Alexandria. He afterwards defended the opinions of Origen, and laid the foundation of the tenets which, in the course of a few years, were propagated by Pelagius and his followers. He lived to an advanced age, but the time of his death has not been ascertained. Sozomen speaks of him as a man, distinguished by his learning, judgment, and eloquence; and represents him as devout, humble, abstemious, and irreproachable in his manners. Some of his writings are found entire in the "Bibliotheca Patrum," and in "Cotelerius's Monum. Eccl. Græc.;" but fragments only of the greater number are dispersed in the works of Socrates and other authors. Socrates' Hist. Eccl. Cave. Dupin. Another monk of this name flourished among the ecclesiastical writers of the fifth century. Cave. Dupin.

Evagrius, an ancient ecclesiastical historian, was born at Epiphania, a city of Syria in 536 or 537. From the study of rhetoric and the profession of an advocate, in which he acquired considerable reputation, he derived the surname of *Scholasticus*. At Antioch he lived in habits of intimacy with Gregory, patriarch of that city, and when Gregory was charged with the crime of incest, and made an appeal to the emperor and a synod, Evagrius attended him to Constantinople, where his abilities and character were held in high estimation; nor was he less respected at Antioch, the place of his customary residence. The intervals of leisure which he could gain from the public duties of the several offices which he sustained, were devoted to the composition of his "Ecclesiastical History, in 6 books," comprehending the period from the year 430 to 594, and including the events that occurred from the close of the histories of Theodoret and Socrates till the twelfth year of the emperor Mauricius. His books of "Epistles, &c." and "Panegyrical Oration on Mauricius," &c. are lost. His history is, upon the whole, a work of industrious research, general information, and considerable merit; though it manifests, on the part of the author, a great degree of credulity. The writers of the Romish church extol him as the only Greek ecclesiastical historian who has maintained the doctrine of the true faith; and Photius represents his style as sometimes elegant and beautiful, often too redundant and luxuriant.

The original Greek of this history was published at Paris in 1544, in folio, by Robert Stephens; in 1612 at Geneva, in folio, accompanied with a Latin version; in 1679 by Valesius, with a new version and notes; and in 1720 this last edition was republished at Cambridge in folio, with many additional notes. Cave. Valesii Præf. Dupin.

EVANDRIA, in *Ancient Geography*, a small town of Spain, in Lusitania, according to Ptolemy; supposed to be "Talavera la Veja."

EVANDRIUS Mons, one of the seven mountains, forming the site of the city of Rome, called also mount Palatine.

EVANGELICAL *Harmony* and *Economy*. See the substantives

EVANGELISTS, the inspired authors of the Gospels. See Matthew, Mark, Luke and John. The symbols of these in the order now recited, according to Jerom, are a man, a lion, a calf or ox, and an eagle. According to St. Augustine, in his interpretation of Ezekiel, ch. i. 5.—10. and Rev. iv. 7, they are a lion, a man, an ox, and an eagle.

The word is derived from the Greek, ευαγγελιον, formed of ευ, *bene*, *well*, and αγγελος, *angel*, *messenger*.

The denomination evangelists was likewise given in the ancient church to such as preached the Gospel up and down, without being attached to any particular church, being either commissioned by the apostles to instruct the nations, or of their own accord, abandoning every worldly attachment, consecrated themselves to the sacred office of preaching the Gospel.

In which sense some interpreters think it is that St. Philip, who was one of the seven deacons, is called the evangelist, in the twenty-first chapter of the Acts of the Apostles, ver. 8. Again, St. Paul writing to Timothy, Ep. ii. chap. iv. ver. 5. bids him do the work of an evangelist. The same apostle, Eph. iv. 11. ranks the evangelists after the apostles and prophets.

Evangelists, in *Geography*, four small islands at the western extremity of the Straits of Magellan, near the coast of South America; three are low, and one, at some distance, appears like a hay-stack. S. lat. 52° 45'. W. long. 67° 16'.

EVANIA, in *Entomology*. See Sphex.

EVANID, a name which some authors give to those colours which are transient, or not of long duration; as those in the rainbow, in clouds, before and after sun-set, &c.

Evanid colours are the same with those otherwise called fantastical and emphatical colours. Some authors also use the same term to express those flowers of plants whose petals fall off as soon as they are opened.

EVANS, John, in *Biography*, was born at Wrexham, Denbighshire, in the year 1680. His father was one of the ejected ministers in 1662, who, on account of his nonconformity, being driven from the established church, became minister to an independent congregation at Wrexham. The son was educated with great care, and inducted to the different branches of literature necessary to qualify him for the office of the ministry, which he afterwards exercised in London, first as an assistant, and afterwards as successor to Dr. Daniel Williams. He died in the year 1730, in the fifty-first year of his age, highly esteemed by all who knew him. He had ever been eminent for piety, integrity, and public spirit; in his principles he was orthodox, but disposed to think well of, and to honour, those who differed from him, without any regard to the sentiments which they might hold. He received a diploma of doctor in divinity from the universities of Edinburgh and Aberdeen. His principal work as an author consisted of two volumes of sermons, entitled "Practical Discourses concerning the Christian Temper," which are still in considerable estimation. The celebrated Dr. Watts characterized them as "the most complete summary of those duties which make up the Christian life." Gen. Biog.

Evans's *island*, in *Geography*, a small American island, near the coast of Main. N. lat. 44° 31'. W. long. 67° 3'.

EVANSHAM, a town of America, the capital of Wythe county, in Virginia, situated on the E. side of Reedy creek, which falls into the Great Kanhaway, Woods or New River. It contains a court-house, gaol, and about 25 houses; 40 miles W. by S. from Christiansburg.

EVANTES, in *Antiquity*, the priestesses of Bacchus, thus called, because in celebrating the orgia they ran about as if distracted, crying *evan, evan, ohe evan!*

The word is formed from Ευαν, a title or appellation of Bacchus.

EUANTHI Colores, in *Painting*, a term used by the Greeks to express what the Romans call the *floridi colores*; these were such colours as had a remarkable brightness in their works. The other duller and coarser colours the Romans called *austeri colores*, and the Greeks *bathyci*.

Of

Of the firſt ſort were cinnabar, lapis armenus, chryſocolla, minium, indigo, and purpuriſſa, according to the Romans; but the Greeks, as we find by Dioſcorides, made cinnabar one of the auſtere colours.

EUA'PHION, (from ευ, *eaſe*, and αφη, *the touch*,) in *Surgery*, a medicine for the hemorrhoids, named from its gentleneſs. Galen.

EVAPORATION, in *Natural Philoſophy*, is that proceſs by which water and other liquids are converted into vapour or ſteam, an elaſtic fluid, and diſſipated in the atmoſphere. Certain ſolid bodies, too, are ſubject to a ſimilar diſſipation in air; this is uſually denominated *exhalation*: but as the cauſe is no doubt the ſame in both caſes, it may be properly conſidered under this head.

The ſpontaneous evaporation of water, or that which is conſtantly going on in a greater or leſs degree from all parts of the ſurface of the globe, has always been an intereſting phenomenon to the ſpeculative philoſopher. Various hypotheſes have been advanced to account for the aſcent of water into the atmoſphere in an inviſible form, and for its ſubſequent deſcent in the form of rain; but the opinions of early writers on this ſubject are of little importance, as they were not acquainted with the principal facts and experiments which ought to guide us in the inveſtigation. Ariſtotle ſeems to have aſcribed the formation of vapour to the action of fire; and ſo far his notion was correct. Halley ſuppoſes ſmall hollow ſpheres of water to be filled with a ſubtile elaſtic fluid, ſo as to make them ſpecifically lighter than air; he alſo hints at a chemical affinity between air and water, ſimilar to that between water and ſalts. Deſaguliers, after having ſhewn the inſufficiency of former hypotheſes, propoſes a new one; he aſſerts that water is capable of being converted by heat into an elaſtic fluid much lighter than air, and refers to the ſteam engine as a proof; he ſhews, too, that a glaſs veſſel filled with water, and inverted in another veſſel of water, and then expoſed to the heat of ebullition, has its water expelled, and ſteam, an elaſtic inviſible fluid, takes its place. This ſteam, he ſhews, is again condenſed into water as the veſſel cools. He argues that ſteam is 16½ times lighter than air, and that when formed at a low temperature it muſt aſcend in the atmoſphere till it meets with air of the ſame denſity, and there it will ſtop; but when accumulated, the cold condenſes a portion of it into drops of water: hence clouds and rain. This notion, which goes to identify vapour in the air, with the ſteam or vapour of water formed by heat in a vacuum, is ingenious and apparently original, but how the vapour ſhould aſcend till it arrives at air of the ſame denſity, is not very eaſily conceivable: for the vapour, in aſcending, muſt expand as the preſſure is diminiſhed, according to the eſtabliſhed laws of elaſtic fluids, and therefore never can obtain the ſame denſity as the air. The vapours might indeed aſcend to the top of the atmoſphere, and form a diſtinct ſtratum, as ſome have imagined with reſpect to hydrogen gas. The author has extravagantly under-rated the ſpecific gravity of ſteam, or aqueous vapour, which is certainly at leaſt one-half that of atmoſpheric air. Upon the whole, this hypotheſis was more plauſible than that adopted by Halley.

As the ſcience of chemiſtry gradually expanded, the phenomena of evaporation began to be conſidered as moſt nearly allied to thoſe of chemical ſolution. From the year 1743 to 1766 the eſſays of Nollet, Franklin, Roi, Hamilton and others, tended to eſtabliſh the opinion that water is taken up into the air by chemical ſolution, in a ſimilar way to that in which water and other liquids diſſolve ſalts. In the 55th vol. of the Philoſophical Tranſactions, there is an eſſay of Profeſſor Hamilton on evaporation, in which he inſiſts at large on the hypotheſis of ſolution. Hot water, he obſerves, diſſolves ſalts ſooner and in greater quantities than cold water, and depoſits a part of the ſame on cooling: ſo warm air takes up more water than cold air; but the water is depoſited again when the air cools, or by the contact of a cold body, as a glaſs of cold water. Evaporation always produces cold; this is obſerved when any part of the human body is moiſtened with water, and the ſame ſuffered to evaporate, but ſtill more remarkably when moiſtened with ether or other fluids more evaporable than water; in like manner, certain ſalts diſſolved in water conſtantly produce cold. In ſhort, the points of reſemblance between evaporation and chemical ſolution are ſo numerous and ſtriking, that the generality of philoſophers ſeem to have adopted the idea that air poſſeſſes a chemical affinity for water, and attaches a portion of it to itſelf, which becomes incorporated with the elaſtic maſs of the atmoſphere, under the denomination of vapour, till cold, or ſome other cauſe, reduces it again to the ſtate of water.

In the year 1783, Sauſſure of Geneva publiſhed his celebrated eſſays on hygrometry, in which the ſubject of evaporation is diſcuſſed much more largely than had been previouſly done. This author does not claim the merit of any new theory; for, he ſays, "the converſion of water into elaſtic vapour has been known time immemorial; the diſſolution of water in air was diſcovered by Roi, and the veſicules, which compoſe fogs and clouds, were conceived by Halley, and ocularly demonſtrated by Kratzenſtein. But no philoſopher has, I believe, clearly diſtinguiſhed the different modifications of vapours: all the ſyſtematic authors have endeavoured to reduce all vapours to one and the ſame ſpecies, whilſt in reality they exiſt under forms abſolutely different. It had not been perceived that water, on being diſſolved in the air, is converted into an elaſtic fluid; but I have ſhewn this to be the fact by the moſt exact experiments; and further, the preciſe effect which the ſolution of a given quantity of water in air has upon the ſpecific gravity of the air. Finally, the laws according to which the humidity of the air varies in proportion to its condenſation and rarefaction, form an entirely new ſubject, on which our ideas hitherto have been vague and erroneous. Theſe, I believe, will be found to have received a ſatisfactory elucidation." Preface, page 10. Before we examine the concluſions of Sauſſure, it may be proper to advert to the facts which are alluded to above. Having procured a large glaſs balloon, containing 4¼ cubic feet of air, Sauſſure adapted to it a manometer or inſtrument to meaſure the force of elaſtic fluids; the balloon being filled with air of the natural humidity, the manometer, or thermometer, and a veſſel containing cauſtic alkali of a given weight, were all encloſed in the balloon, and confined from the action of the external air. The cauſtic alkali abſorbed the vapour in the balloon; and the manometer ſhewed the diminution of elaſticity conſequent thereon; after the experiment was carried as far as was deſired, the balloon was opened, and the increaſe of weight of the alkaline veſſel was aſcertained. Hence were derived data for calculating the influence of vapour on the elaſticity of the air, and likewiſe the whole quantity of water in a ſtate of vapour in a given bulk of air. This might be called the analytic experiment; but the ſynthetic one was alſo made. By encloſing a piece of wet linen of a given weight in the balloon containing air as dry as poſſible, along with the other inſtruments, the moiſture of the linen evaporating increaſed the elaſticity of the confined air a quantity which could be obſerved; and at the cloſe of the experiment the loſs of weight of the linen indicated the quantity of water which had been evaporated, and had increafed the elafticity. The two methods were thus found to corroborate each other remarkably well. The refults were, that at the temperature of 64°, a quantity of extremely dry air acquires an increafe of $\frac{1}{74}$th in elafticity in attaining extreme humidity; and *vice verfâ*: that a cubic foot of air takes up 10 grains of water in paffing from extreme drynefs to extreme humidity; and that confequently it diminifhes the fpecific gravity of the air, as if a volume of elaftic fluid, equal in weight to 10 grains, and of $\frac{3}{4}$ths the fpecific gravity of air were added to it. Of the general accuracy of thefe refults there is no room for doubt. They form a valuable acquifition to this branch of fcience. One important fact was ftill wanting; as air was fuppofed to diffolve water by virtue of an affinity, it was reafonable to expect that every fpecies of air would have its peculiar affinity, or take up a certain portion of water peculiar to itfelf, agreeably to what is obferved in other cafes of chemical faturation. Sauffure afcertained this point clearly in regard to inflammable and fixed air, that is, hydrogen and carbonic acid. Both thefe gafes were found in their pure ftate, and when mixed with any proportion of common air, to affect the hygrometer in the fame way as common air, and to promote evaporation in the fame degree. In fhort, there was not any appearance to indicate that they contained either lefs or more vapour than common air in like circumftances. Sauffure found that evaporation was accelerated in proportion to the rarefaction of the air; this circumftance he accounted for by obferving that the preffure of the atmofphere retards evaporation; however, upon the principle of folution, it might have been expected that the greater quantity and denfity of the folvent would have compenfated for the greater preffure. The condenfation of air, on the contrary, uniformly tends to make it depofit moifture, and retards evaporation. This he explains by obferving, that the folvent power of air does not increafe quite fo rapidly as its denfity; continued condenfation therefore muft firft faturate the air with moifture, and then make it depofit a portion. Sauffure found that warm and denfe air required more vapour to faturate it than cold and rare air; he was led too haftily to afcribe the folvent power of the air partly to its temperature and partly to its denfity; but it has fince been proved that temperature alone is concerned, and the denfity has no effect whatever. On the head of rarefaction and condenfation, Sauffure adverts to a curious fact, known by every philofopher, but not fatisfactorily explained by any one; namely, the abundant and inftantaneous formation of a cloud or mift upon exhaufting a receiver by the air-pump. As the rarefaction of air is found to promote evaporation, it appears aftonifhing at firft fight that the air fhould exhibit figns of fuperfaturation at the fame inftant. When the pump plate is covered with wet leathers the above appearance never fails; but the abbé Nollet found it to take place when water was totally excluded. Sauffure, however, denies this to be the fact; he thinks that water muft not have been excluded with fufficient care in Nollet's experiments; and affirms that from his own experience no appearance of mift was found upon exhauftion, when the pump was carefully dried. The hygrometer at the time was 70°, extreme moifture being 100°. As the two authors here appear to be at iffue as to the fact, the writer of this article, from his own experience, can venture to affirm that both of them may ftill be correct. When care is taken to exclude water from the pump and receiver, the mift is by no means fo copious as otherwife; it is alfo more diminutive as the air is dry or far from extreme humidity; with both thefe circumftances and a large receiver, no mift will appear by a moderate rate of exhauftion; but it may always be produced by ufing a fmall receiver, and rapid exhauftion. Sauffure's explanation of the fact is very inadequate, and unworthy of repetition; he further notices the dew obferved on the receiver of an air-pump after letting in the air, and very juftly afcribes it to the condenfation of the vapour raifed up into the receiver after exhauftion; the air taking in with it nearly as much vapour as it is capable of holding. Upon liberating condenfed air a great mift is obferved in the receiver; Sauffure explains this in the fame unfatisfactory manner as before, and that in one cafe only, namely, when the receiver contains water; but his explanation does not apply when the receiver is perfectly dry; yet the phenomenon of mift is equally apparent in that cafe. The true explanation is, that a great but momentary cold, of 50° or more, occafions the precipitation of vapour, both upon rarefying air and liberating condenfed air. The fact has fince been demonftrated by Mr. Dalton; but it was hinted at by Lambert, as quoted by Sauffure, page 331.

Though Sauffure does not affect to introduce any new theory on the fubject of evaporation, he certainly advances fome notions on the fubject that were not previoufly held by others, efpecially by thofe who adopted the chemical folution of water in air. He fays, "evaporation, properly fpeaking, is the refult or rather the effect of the intimate union of elementary fire with water; by this union the water and fire combined form an elaftic fluid fpecifically lighter than air, and which is peculiarly diftinguifhed by the name of *vapour*. This vapour being formed in a vacuum, or otherwife when the heat is fufficient to give it force fuperior to atmofpheric preffure, fo as to expel the air from any veffel in which it is formed, is called *pure elaftic vapour*." Page 361. This reprefentation is, in all probability, correct, and will be generally adopted without hefitation. He proceeds: "but when the vapour cannot entirely furmount the preffure of the air, it penetrates it, mixes with it, undergoes a true folution, and may then be properly called *diffolved elaftic vapour*." Page 362. Certainly the advocates for the folution of water in air cannot adopt this language. Pure elaftic vapour is firft formed; then by means of fuch force as it happens to have, which is generally fmall, it penetrates and mixes with the air; afterwards it is diffolved by the air; that is, the particles of air finding thofe compound particles of water and fire amongft them, attract them, and form triple compounds of air, water, and fire. Here the bufinefs for which folution is called in is performed before hand; for we muft fuppofe it to be the affinity of air for water which enables the latter to rife at all againft fo fuperior a preffure. If the vapour can, by virtue of its elafticity, penetrate the air, why may it not continue there by virtue of the fame elafticity? Sauffure proceeds; "when afterwards the air faturated lets fall the water which it contains, this water fometimes takes the form of veficules or bubbles; thefe veficules, filled and furrounded with a fubtile elaftic fluid, are fupported in the air, and even fometimes rife in it, by their lefs fpecific gravity. Thefe veficules are effentially diftinct from the air, as well as from the vapour above defined; but according to cuftom I have arranged them in the clafs of vapours, and diftinguifhed them by the name of *veficular vapour*. Finally, when the elaftic vapour, or the veficules themfelves, condenfe into folid drops, which only differ from drops of rain by their extreme fmallnefs, they are ftill very different from vapours properly fpeaking. Notwithftanding, as thefe fmall particles float in the air, and can even be fupported in it for fome time, by its agitation and vifcofity, I have claffed them alfo amongft vapours, and given them the name of *concrete vapours*."

Page

Page 363. It may be proper to obferve here, that the vefi-cular vapour of Dr. Halley was fuppofed to be tranfparent, and therefore to correfpond to the *diffolved elaftic vapour* of Sauffure. It was moreover hypothetical; but Kratzenftein and Sauffure affirm that the fmall vifible particles floating over fteaming water, as well as thofe of certain fogs, are difcernible by a microfcope to be hollow or veficular. Thefe vifible particles are the *veficular vapour* of Sauffure. Though it is by no means improbable that the vapour iffuing from warm water is enveloped in a film of water, juft as we fee it in ebullition, and that the fame bubble of fteam on cooling may fhrink into a veficule, containing an atom of air, the original nucleus of the fteam; yet it is not equally probable that in the condenfation of pure vapour a veficule fhould be formed: ftill lefs likely is it that fometimes veficules, and at other times folid drops, fhould be formed. Microfcopic obfervations on atoms dancing about in the air are fcarcely to be relied on. But whatever may be the fact as to the conftitution of condenfed vapour, that is, whether the particles are hollow or folid, there is not any fufficient reafon for fuppofing them conftituted of any other principles than water and atmofpheric air. The only one that has been advanced in fupport of the hypothefis is, that without fome fubtile elaftic fluid, internal or external, the watery particles conftituting clouds muft conftantly defcend; whereas clouds are feen to remain ftationary and fometimes even to afcend, which, it is alleged, could not take place. were not the particles of lefs fpecific gravity than the air. Now the afcent of clouds is in all probability an optical deception. It is occafioned by the diffolution or evaporation of the under furface of the cloud, and the fuperior new formation of a cloud. We have no fufficient reafon for believing that the individual particles of clouds afcend; yet they frequently defcend with a velocity almoft imperceptible; this arifes from the refiftance the air makes to the motion of fmall bodies, which, it is well known, increafes in proportion as their diameters decreafe. The epithet *vapour*, which denotes an elaftic fluid, cannot, with philofophical propriety, be applied to the vifible particles of water conftituting clouds.

Mr. Pictet of Geneva publifhed an ingenious effay on fire, which was tranflated into Englifh and publifhed in 1791. This gentleman, impreffed with fuch ideas of the powers of fire in every thing which relates to evaporation, is tempted to look upon it as the fole agent in this clafs of phenomena, and to renounce the idea that air acts in the manner of chemical *diffolvents*. He obferves, " the very fpecious arguments of my learned colleague (Sauffure,) in his hygrometry in favour of that opinion, had long feduced me; but the charming fimplicity which the theory of evaporation would acquire if we could diveft it of the agency of air; the poffibility I perceive of reducing the whole to the action of fire; the probability which increafes with the fimplicity of every natural hypothefis, attract me, I confefs, ftill more forcibly." Page 222.

In the Philof. Tranfac. for 1792, there is an effay of De Luc on evaporation. This acute philofopher diftinctly maintains that vapour in the air is precifely the fame as vapour in vacuo, and in both cafes is formed by the intimate union of fire with water; he denominates it *fteam*, and fhews that fteam in air of any denfity, and fteam in vacuo, affect the hygrometer alike, provided the fteam has the fame temperature and elafticity, at leaft within the ordinary range of atmofpheric temperature. He ftrengthens his opinion of fteam in air, and in vacuo being the fame from the fact that cold is produced, or heat abforbed, by evaporation in both cafes. From the facts as afcertained refpecting fteam, by Mr. Watt and others he juftly infers, that there is a certain minimum diftance of the particles of fteam for each temperature, at which they retain their elafticity; if they are condenfed by any mechanical force within the limit of this diftance, they lofe their elafticity and become water; if not, they retain it, and act as any other permanently elaftic fluid. In fpeaking of fteam in air, he obferves, " that no mechanical caufe can produce the decompofition (condenfation) of that fluid, but by forcing its particles to become nearer each other than the actual temperature can admit, which cannot happen in the atmofphere, except by the accumulation of fteam itfelf in fome part of it." " He concludes that the product of evaporation is always of the fame nature, namely, an expanfible fluid, which either alone, or mixed with air, affects the manometer by preffure, and the hygrometer by moifture, without any difference arifing from the prefence or abfence of air, at leaft without any perceived hitherto."

In 1793, Mr. Dalton publifhed a volume of meteorological effays, in which he gives a theory of vapour, very nearly allied to that of De Luc above-mentioned, and to the opinion of Pictet, though he feems to have been unacquainted with thefe circumftances. From the refults of certain experiments and obfervations he concludes, " that the vapour of water (and probably of moft other liquids) exifts at all times in the atmofphere, and is capable of bearing any known degree of cold without a total condenfation, and that the vapour fo exifting is one and the fame thing as *fteam* or vapour of 212° or upwards. The idea, therefore, that vapour cannot exift in the open atmofphere under the temperature of 212°, unlefs chemically combined therewith, I confider as erroneous; it has taken its rife from a fuppofition that *air* preffing upon vapour condenfes the vapour equally with *vapour* preffing upon vapour, a fuppofition we have no right to affume, and which, I apprehend, will plainly appear to be contradictory to reafon and unwarranted by facts; for, when a particle of vapour exifts between two particles of air, let their equal and oppofite preffures upon it be what they may, they cannot bring it nearer to another particle of vapour, without which no condenfation can take place, all other circumftances being the fame; and it has never been proved that the vapour in a receiver from which the air has been exhaufted, is precipitated upon the admiffion of perfectly dry air. Hence then we ought to conclude, till the contrary can be proved, that the condenfation of vapour expofed to the common air does not in any manner depend upon the preffure of the air." Effays, p. 201.

In 1802, Mr. Dalton publifhed, in the fifth vol. of the Manchefter Memoirs, a feries of interefting effays relative to evaporation; he found, 1ft. The expanfive force of pure fteam over water in vacuo at all temperatures from 32° to 212°; 2d. The expanfive force of dry air for the fame range of temperature; and, 3d. The expanfive force of dry air in contact with water for the like range. From a comparifon of thefe experiments it appeared that the obfervation of De Luc was univerfally true; namely, that fteam in vacuo and fteam in air are precifely of the fame force at the fame temperature. The law was found to apply equally to the fteam from ether and other liquids, and to other elaftic fluids, as well as common air. Mr. Dalton confiders thefe facts to be decifive as to the nature of the connection between fteam and air, and infers that fteam forms a mechanical mixture with air, and not a chemical compound, as fome have fuppofed. This conclufion was confirmed by experiments upon the quantity of water evaporated at different temperatures; which was always in proportion to the elaftic force of vapour at the temperature. For inftance, water at 212°, or kept juft boiling, evaporates twice as faft as water of 180°, and this twice as faſt as water of 150°; and the forces of pure ſteam at thoſe temperatures are 30, 15, and $7\frac{1}{2}$ inches of mercury reſpectively. The rule, however, does not apply without a correction for low temperatures; becauſe the ſteam already in the air prevents in degree the aſcenſion of freſh ſteam; whereas in high temperatures, the ſmall portion of ſteam commonly in the air is too trifling to have any obſervable effect. Mr. Dalton has given a table founded upon experience, and adapted to the above-mentioned law, by which not only the actual quantity of water evaporated in atmoſpheric temperatures may be aſcertained, but alſo the quantity of vapour exiſting in the air may be found, provided the rate of evaporation is given. The following is an abſtract of it.

The firſt column of the table expreſſes the temperature; the ſecond, the correſponding force of vapour in vacuo, derived from experiment; the third column expreſſes the number of grains of water evaporated per minute, from a ſurface of $28\frac{1}{4}$ ſquare inches, in a moderate current of air or nearly calm; the fourth is the like evaporation in a medium current; and the fifth is the evaporation when a ſtrong breeze exiſts, or a rapid current of air ſweeps over the evaporating ſurface. The air is ſuppoſed to be perfectly dry or free from vapour; otherwiſe every particular ſtate of atmoſpheric vapour would require a table. The table is intended to be uſed when we want to find the quantity of water evaporated from a given ſurface by the ſlow and gradual operation of the atmoſpheric temperature, or what has been called *ſpontaneous* evaporation. But as it is adapted to air perfectly free from vapour, it cannot be of any practical utility without further data. The force of vapour actually exiſting in the atmoſphere at the time muſt be firſt aſcertained, by determining the temperature at which dew begins to be formed on a glaſs, &c. containing cold water or a cold mixture. Then the force due to that temperature muſt always be ſubtracted from the whole force due to the given temperature of the evaporating water.

Table.

Temperature	Force of vapour in Inch. of Mer.	Grains of Water evaporated.		
		Loweſt	Mean	Higheſt
212°	30.00	120	154	189
20°	.129	.52	.67	.82
25	.156	.62	.79	.97
30	.186	.74	.95	1.17
35	.221	.80	1.14	1.39
40	.263	1.05	1.35	1.65
45	.316	1.26	1.62	1.99
50	.375	1.50	1.92	2.36
55	.443	1.77	2.28	2.78
60	.524	2.10	2.70	3.30
65	.616	2.46	3.16	3.87
70	.721	2.88	3.70	4.53
75	.851	3.40	4.37	5.34
80	1.000	4.00	5.14	6.29
85	1.17	4.68	6.07	7.46

Problem 1.—Having given the quantity of force of atmoſpheric vapour, to find the rate of evaporation,—

Suppoſe that atmoſpheric vapour begins to be condenſed at 50°, and the temperature of the air is 60°; query the rate of evaporation, with a medium breeze?

Whole evaporating force, per table, for 60°	=	2.70 grains.
Exiſting force of atmoſpheric vapour for 50°	=	1.92 grains.
Remainder - -		.78 grains.

Hence a ſurface of $28\frac{1}{4}$ inches would loſe $\frac{78}{100}$dths of a grain in each minute.

Again; ſuppoſe the atmoſpheric vapour to be at 20°, with a ſtrong breeze, in one caſe, the air being 32°; and the atmoſpheric vapour to be at 50°, in another caſe, with calm air at 58°; query the rates of evaporation in thoſe two caſes?

1ſt Caſe. Whole evaporating force per table, for 32° - - -	=	1.26 grains.
Exiſting force of atmoſ. vap. for 20°	=	.82 grains.
Remainder, or rate of evaporation	=	.44 grains.

2d Caſe. Whole evaporating force, per table, for 58° - - -	=	1.96 grains.
Exiſting force of atmoſ. vap. for 50°	=	1.50 grains.
Remainder, or rate of evaporation	=	.46 grains.

Hence it appears that under the circumſtances above-mentioned the evaporation would be nearly the ſame in both caſes.

Problem 2.—Having given the rate of evaporation, to find the quantity or force of amoſpheric vapour.

Suppoſe the evaporation from a ſurface of $28\frac{1}{4}$ inches is found to be one grain in a minute, with a medium breeze, the temperature being 70°; query the quantity and force of atmoſpheric vapour?

Whole evaporating force, per table, at 70°	=	3.70 grains.
Obſerved evaporating force - -	=	1.00 grains
Remainder = exiſting atmoſpheric force		2.70 grains,

which correſponds to 60°, for the temperature at which the atmoſpheric vapour would be found to be condenſed at the time.

Mr. Dalton contends that all the different gaſes conſtituting the atmoſphere, namely, azotic, oxygenous, carbonic acid, and ſteam, are independent of each other; ſo that they preſs the ſurface of the earth and other bodies with their own weight only, when in a ſtate of equilibrium. Whence he conſiders the *quantity* and *force* of ſteam in the atmoſphere as ſynonymous terms. Thus in the above example, the force of ſteam of 60° being repreſented by .524 parts of an inch of mercury, the weight of the incumbent atmoſphere of ſteam muſt be the ſame, or equal to 7 inches of water nearly. This notion, concerning the whole quantity of ſteam in the atmoſphere incumbent upon any place, is entirely new; and, if correct, muſt be of the firſt importance in meteorology.

Though the reaſons aſſigned by De Luc and Dalton for the non-condenſation of ſteam, already exiſting in air, appear to be incontrovertible, yet from what has been ſaid above, no ſufficient reaſon has been given by either of them for the *entrance* of ſteam of low temperatures into the atmoſphere. How does ſteam of $\frac{1}{60}$th part of the force of the atmoſphere at firſt penetrate it? Even Sauſſure ſpeaks of the fact, and as if there were no difficulty attending it. De Luc does not attempt any explanation. Dalton ſeems to have been fully aware that the hypotheſis of pure ſteam exiſting in air was not tenable without obviating this difficulty. Accordingly he conceived that the particles of ſteam are not repulſive to thoſe of air, but only to other particles of ſteam; hence the new formed ſteam has a kind of vacuum, to enter in the pores or interſtices of the air. But this, it is thought by many, is going into the other extreme, and making the facility much too great; befides, there is no notion fo general and fo probable, as the one that heat is the caufe of repulfion; and if this notion be true, the particles of fteam cannot be admitted to be repulfive of each other, and indifferent to thofe of air. Mr. Dalton, it feems, now confiders the inequality in the fize of the ultimate particles of different elaftic fluids to be the caufe why they are conftantly diffufing themfelves through each other, and never obtain a proper equilibrium till their particles take the arrangement, which they would do in a vacuum; and the elevation of fteam from the furface of water, he fuppofes, takes place, becaufe certain particles of the furface are in a great meafure exempt from the preffure of the atmofphere. See New Syftem of Chemical Philofophy, p. 190.

From the experiments of Mr. Watt on fteam, it appears that evaporation at high and low temperatures is much the fame as to the expenditure of heat for a given weight of water.

The evaporation from ice of 32° does not differ materially from that of water, at the fame temperature. Electricity is faid to promote evaporation in fome degree.

Evaporation in Meteorology.—With refpect to the natural evaporation of water from the furface of the earth, the experiments of Mr. Hoyle and Mr. Dalton, of Manchefter, are nearly the only ones that are fufficiently numerous from which to draw any conclufions. They took a cylindrical veffel of tinned iron, 10 inches in diameter, and three feet deep; there were two pipes foldered into it, one at the bottom, the other at the top, for the water to run off into bottles. The veffel was filled with gravel, fand, and foil, and fubfequently the foil was covered with grafs and other living vegetables. It was nearly buried in the ground in an open fituation, and provifion made for placing bottles to the two pipes. In this manner it was expofed to receive the rain, and to fuffer evaporation from the furface, the fame as the furrounding green ground. A regular regifter was kept of the water which percolated through the foil and gravel into the bottles; and a rain gage of the fame furface was kept clofe by, for the fake of comparifon. The refults are contained in the table below, together with the mean evaporation from a like furface of water, for the three fucceeding years.

Water through the two Pipes.	1796	1697	1798	Mean.	Mean Rain.	Mean Evap. from Ground	Mean Evap. from Water.
	Inch.	Inch.	Inch.	Inch.	Inch.	Inch.	Inch.
January	1.90	.68	1.77	1.45	2.46	1.01	1.50
February	1.78	.92	1.12	1.27	1.80	.53	2.00
March	.43	.07	.34	.28	.90	.62	3.50
April	.22	.30	.18	.23	1.72	1.49	4.50
May	2.03	2.44	.01	1.49	4.18	2.69	4.96
June	.17	.73	—	.30	2.48	2.18	6.49
July	.15	03	—	.06	4.15	4.09	5.63
Auguft	—	—	.50	.17	3.55	3.38	6.06
September	—	.98	—	.33	3.28	2.95	3.99
October	—	.68	—	.23	2.90	2.67	2.35
November	—	1.04	1.59	.88	2.93	2.05	2.04
December	.20	3.08	1.88	1.72	3.20	1.48	1.50
	6.88	10.95	7.39	8.41	33.55	25.14	44.43
Rain	30.63	38.79	31.26				
Evap.	23.75	27.84	23.87				

From this table it appears that the evaporation from a furface of water, is nearly twice as much as from green ground; alfo, that about eight or nine inches of rain are left for the fupply of fprings and rivers. This furplus of water muft be evaporated from the fea, and return to it again by the rivers.

Evaporation in Chemiftry.—When artificial heat is applied, the quantity evaporated will be nearly in geometrical progreffion to the excefs of temperature, above that of the air. It is always nearly in proportion to the furface expofed. When the liquid is much below the margin of the veffel, the evaporation is greatly retarded.

Evaporation in the Arts. In certain arts, fuch as dyeing, printing, &c. quick evaporation is expedient. This is effected by expofing the wet pieces in a ftove, which has commonly a fire and long flues from which the heat is diffipated into the room. The cold air fhould be admitted into the room as near the fire and flues as poffible; and feveral fmall openings at the top of the ftove fhould be made to fuffer the vapoury air to efcape.

See the articles Clouds, Dew, Distillation, Hygrometer, Rain, Steam, &c.

Evaporation, in *Pharmacy, Chemiftry*, &c. denotes an operation by which the more aqueous and volatile parts of fluids are fpent, or driven away in fteam, fo as to leave the remaining part ftronger, or of a higher confiftence than before.

Evaporation is effected by fetting a liquor over a gentle heat, to carry off the moft fluid and volatile parts, without leffening the quantity of the other matters with which the liquor is impregnated.

The veffels ufed for this purpofe are bafons, tefts, or crucibles, which are made of glafs, metal, or earth, according to the nature of the bodies on which the operation is to be performed. They are flat, fhallow, and wide, fo that the body from which the evaporation is to be made may prefent a large furface to the air. In all evaporations the degree of heat ought to be proportioned to the volatility of the fubftance to be evaporated, and to the degree of fixity of the fubftance intended to be left, and of its adhefion to the volatile parts. In fome cafes, as in obtaining oil from rectified fpirit of wine and ether, the liquors ought to be evaporated upon the furface of water in open air, without any other heat than that of the atmofphere; in others, when the part to be evaporated is not very volatile, and when the remaining fubftance is very fixed, and does not adhere much to the volatile part, as in the purification of gold by antimony, a ftrong heat may be applied, and a current of air directed upon the furface of the body. Macquer.

EVARCHUS, in *Ancient Geography*, a river of Afia, forming the boundary between Paphlagonia and Cappadocia. Valerius Flaccus affigns it to Scythia, and fays it abounded with fwans.

EVARISTUS, in *Biography*, bifhop of Rome, was elected to that office about the year 100, in which he continued eight or nine years. Much has been faid of him with regard to his decretals; his diftribution of Rome into parifhes, his prefenting Adrian with a book concerning the excellence of the Chriftian religion, and his martyrdom under the reign of that emperor; but thefe and other facts collected by modern writers do not ftand on fufficient authority to obtain credit. Moreri.

EVASION, Evasio, in *Law*, is ufed for any fubtile endeavour to fet afide truth, or to efcape the punifhment of the law, which will not be endured. Thus, if a perfon fays to another that he will not ftrike him, but will give

him

him a pot of ale to ſtrike him firſt; and accordingly he ſtrikes, the returning of it is puniſhable; and if the perſon firſt ſtriking be killed, it is murder; for no man ſhall evade the juſtice of the law by ſuch a pretence to cover his malice. 1 Hawk. P. C. 81.

EUASPLA, in *Geography*, a river of India, in the northern part of the mountain Paropamiſus, which ran S.E. into the Indus.

EVATES, a branch or diviſion of the ancient Celtic philoſophers, the Druids.

Strabo diſtributes the philoſophers among the Britons and Gauls into three ſects; Βαρδοι, *Bards*, Ουατεις, *Evates*, and Δρυιδαι, *Druids*. He adds, that the Bards were poets and muſicians; the Evates, prieſts and naturaliſts; and the Druids, moraliſts as well as naturaliſts. But Marcellinus, Voſſius, and Hornius, reduce them all to two ſects, *viz.* Bards and Druids. Laſtly, Cæſar, lib. vi. comprehends them all under the name of *Druids;* which ſee.

The Evates or Vates of Strabo might probably be what other authors, and particularly Ammian. Marcellin. calls *Eubages;* but Mr. Bouche, in his Hiſt. de Provence, lib. ii. chap. 2. diſtinguiſhes between them. The Vates, he ſays, were ſuch as took care of the ſacrifices and other ceremonies of religion; and the Eubages, thoſe who ſpent their time in the ſearch and contemplation of the great myſteries of nature.

EVAUX, in *Geography*, a town of France, in the department of Creuſe, and chief place of a canton, in the diſtrict of Aubuſſon; 26 miles E. of Gueret. The number of inhabitants in the place is 2,081, and in the canton 8,036, and the territorial extent of 232½ kiliometres includes 12 communes. Near it are a mineral ſpring and baths. N. lat. 46° 10′. E. long. 3° 33′.

EVAX, in *Botany*, Gærtn. v. 2. 393, ſee FILAGO.

EVAZA, in *Ancient Geography*, an epiſcopal ſee of Aſia propria, under the metropolis of Epheſus; mentioned in the acts of the council of Epheſus.

EUBAGES, an order of prieſts or philoſophers among the ancient Celtæ or Gauls. Chorier takes the Eubages to be the ſame with the Druids and Saronidæ of Diodorus. Others will have the Eubages to be thoſe whom Strabo, lib. iv. p. 197. calls Ουατεις, *Evates*, or *Vates*, on which principle there is room to conjecture, that the word ſhould be written Ουαγεις, it being eaſy to miſtake a Γ for a T. See DRUID.

EUBELSTADT, in *Geography*, a town of Germany, in the biſhopric of Wurzburg, on the Maine; three miles S. of Wurzburg.

EUBŒA, in *Ancient Geography*, one of the moſt conſiderable of the Greek iſlands, formerly joined to Bœotia, as Pliny informs us, by an iſthmus, ſo narrow is the Euripus in ſome places, which ſeparates it from the continent; and extending from north-eaſt to ſouth-weſt 150 miles, but where broadeſt being only 40 miles, and 20 where it is narroweſt. In compaſs it is eſtimated at 365 miles. This iſland was anciently denominated Chalcis, Ellopia, Aonia, Abantis or Abantia, Macris, Oche, Bomo, &c. Its appellation Eubœa is ſaid to be derived from a famous cave on the eaſtern coaſt of the iſland, called by the Greeks αυλη βοος, or the ox-ſtall, and this name was probably deduced from its excellent paſtures. Eubœa had ſeveral remarkable promontories, which ſtretched far into the ſea; of theſe Pliny and Mela mention three, *viz.* Geraſtus and Caphareus to the ſouth, and Cenæum to the north; and Strabo mentions a fourth, which he calls Petalia, over-againſt Sunium. Cenæum, now Capo Liter, and Geraſtus, now Capo Roſſo, are, according to Strabo, 1200 furlongs diſtant from each other, which meaſure exactly the length of the iſland, as it is ſet down by Pliny. The mountains of Eubœa are high, and covered during a great part of the year with ſnow. The famous city of Chalcis was ſituated under one of them of the ſame name, and on another, called Dryphis, was a temple dedicated to Diana. The following rivers are mentioned by Strabo, *viz.* Callas, Budarus, Cireceus, and Neleus or Melas. The champaign country was exceedingly fertile, and yielded great plenty of corn, wine, oil, and all ſorts of delicious fruits; but it was chiefly famous for its rich paſtures. This iſland had in former times many cities of great note, which are mentioned by Strabo, Pliny, Ptolemy, and Mela. On the eaſtern coaſt ſtood the cities of Geraſtus, which was a famous haven, Petalia, and Caryſtus, near which were the celebrated quarries of Caryſtian marble, ſo much valued by the Romans, and alſo of Amianthus or Aſbeſtos. About five miles from Caryſtus was the village of Amarynthus, famous for a temple of Diana. On the ſame coaſt ſtood Eretria and Chalcis, which ſee reſpectively. Between Chalcis and the promontory Cenæum, ſtood the cities of Edepſum and Oreos; the former being famous for its hot-baths, and the latter one of the moſt powerful cities of Eubœa during the Trojan war, and occupying the fourth part of the iſland, in the time of Philip, the father of Alexander. The name Oreos was changed by the Athenians, when they became maſters of the iſland by means of Pericles, into that of Iſtiæa, or Heſtiæa, which was the name of their tribe. On the north ſide of the iſland, oppoſite Theſſaly, and extending from Cenæum to Artemiſium, ſtood Dia, or Athenæ Diades; and on the coaſt, waſhed by the Ægean ſea, ſtood the maritime city of Cerinthus. The inland cities mentioned by Strabo, Pliny, Ptolemy, &c. were Ellopia, Nyſa, Eubœa, Orabiæ, Rhamnus, Porthmus, Algæ, and Tamyna.

Eubœa was probably one of the iſlands in which the firſt Orientals, who paſſed from the continent of Aſia towards the coaſts of Greece, made a ſettlement. It muſt have formed a very powerful ſtate at an early period, ſince its king Elephenor conducted 40 ſhips to the war of Troy. Solinus aſcribes the commencement of this monarchy to the Titans. Others ſuppoſe Abas to have been the firſt ſovereign of Eubœa. The ſucceſſion of its ſovereigns is little known. In the time of Darius Hyſtaſpis, the cities of Chalcis, Eretria, Caryſtus, and Oreos, formed diſtinct republics, governed by the nobles, whom they called hippobates, or horſemen; none being received into the government who were not able to maintain a certain number of horſes. This oligarchy was not of long duration; but it was ſucceeded by a democracy, compoſed of domeſtic tyrants, who ſeized all power to themſelves, and ruled in their ſeveral cities without controul. At length the Eubœans ſubmitted firſt to Philip of Macedon, and then to his ſon Alexander, on whoſe death they endeavoured to ſhake off the Macedonian yoke; but they were again brought under ſubjection by Antigonus. When the Romans firſt paſſed into Greece, the kings of Macedon held this iſland in ſubjection; but it was ſoon after declared free by the ſenate, in order to weaken the power of Philip in theſe parts. But not being ſupplied with forces, they were unable to maintain their liberty; and fell under the power of Antiochus the Great, and Mithridates king of Pontus. The Romans, however, prevailing in the Eaſt, reſtored the Eubœans to their former ſtate of liberty. It was not long before Marc Antony ſubjected them to Athens; but Auguſtus, incenſed againſt the Athenians for aſſiſting his rival, firſt gave freedom to the city of Eretria, and ſoon after to the whole iſland, which remained in a flouriſhing condition, under its own laws, till the

the reign of Veſpaſian, when it underwent the ſame fate as the other ſtates of Greece.

Eubœa, the name of ſeveral towns in the iſland of Eubœa, Corcyra, and Lemnos.

EUBULIDES, in *Biography*, a native of Miletus, was a ſucceſſor of Euclid in the Megaric ſchool. He was a ſtrong opponent of Ariſtotle, and ſeized every occaſion of cenſuring his writings and calumniating his character. He introduced new ſubtleties into the art of diſputation, ſeveral of which, though often mentioned as proofs of great ingenuity, deſerve only to be remembered as examples of egregious trifling. They belong to that ſophiſtical mode of reaſoning, called by Ariſtotle eriſtic ſyllogiſms. A ſingle ſpecimen will be ſufficient. It ſhall be of the ſophiſm, called from the example, "the Lying :" if, when you ſpeak the truth, you ſay you lie, you lie ; but you ſay you lie, when you ſpeak the truth ; therefore in ſpeaking the truth, you lie. Theſe ſilly inventions for perplexing plain truth were formerly in ſuch high repute, that Chryſippus wrote ſix books upon the above mentioned ſophiſm ; and Philetas, a Choan, died of a conſumption which he contracted by the cloſe ſtudy he beſtowed upon it. The inſcription upon his tomb was Ὁ ψευδόμενος, "The Deceived." Brucker's Hiſt. Phil. by Enfield, vol. i. p. 192.

EUCALYPTUS, in *Botany*, from ευ, *well*, and καλυπτος, *covered*, alluding to the peculiar lid which covers the calyx and encloſes the organs of impregnation. L'Herit. Sert. Angl. 18. Ait. Hort. Kew. v. 2. 157. Willd. Sp. Pl. v. 2. 976. Mart. Mill. Dict. v. 2. Sm. Bot. of N. Holl. 39. Juſſ. 451. Claſs and order, *Icoſandria Monogynia*. Nat. Ord. *Heſperideæ*, Linn. *Myrti*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, abrupt, entire, permanent, cloſed before impregnation with a convex or conical, entire, deciduous lid, which is ſometimes, if not always, of two or three layers. *Cor.* none. *Stam.* Filaments numerous, thread-ſhaped, equal, inſerted into the margin of the calyx within the lid, and not expanding till after it falls, anthers roundiſh, two-lobed, ſmall. *Piſt.* Germen inferior, urceolate, firmly united with the baſe of the calyx, ſometimes angular ; ſtyle ſimple, columnar, about as long as the full-grown ſtamens ; ſtigma ſimple, bluntiſh. *Peric.* Capſule roundiſh, crowned with the rim of the calyx, of three or four cells, opening at the top. *Seeds* numerous, angular, ſmall.

Eſſ. Ch. Calyx ſuperior, permanent, truncated, covered before flowering with an entire lid, which ſoon falls off. Capſule of three or four cells, opening at the top. Seeds numerous.

This genus was founded by the late M. L'Heritier in his Sertum Anglicum, upon a ſingle ſpecies, from Van Diemen's land, named by him *obliqua*, and figured in the 20th plate of that work. Its deſcription never appeared. The generic characters were by him communicated to the Hortus Kewenſis, and adopted, with ſome neceſſary corrections, in Dr. Smith's Botany of New Holland, where a ſecond ſpecies is figured, *E. robuſta*, t. 13. This is called New Holland Mahogany, or Brown Gum Tree, and is one of the loftieſt trees about Port Jackſon, being often 100 feet high, and proportionably thick. The wood hard, heavy, ſtrong, red and very reſinous. *Leaves* alternate, ſtalked, ovate, entire, a little oblique and unequal. *Flowers* in denſe ſimple umbels, of a tawny yellow, on ſimple or divided angular ſtalks, growing in a corymboſe manner about the ends of the branches. The *lid* in this ſpecies is conical, as long as the calyx and germen, with a ſtricture in the middle ; that of the former is ſhort and hemiſpherical, with a minute point. Four more ſpecies from New South Wales are deſcribed in the work laſt mentioned, and ſix additional ones by the ſame author in the Tranſ. of the Linn. Soc. v. 3. p. 283—288. All theſe 12 are adopted by Willdenow in his Sp. Pl. A new one, *E. marginata*, was added to this liſt by Dr. Smith in Tr. of Linn. Soc. v. 6. 302, who has ſince figured and fully deſcribed one of the moſt important of the former, *E. reſinifera*, the Red Gum Tree, in his Exotic Botany, v. 2. 49. t. 84. This bloſſomed in Lady De Clifford's greenhouſe at Paddington. The *flowers* are green with white ſtamens. *Lid* conical, twice as long as the calyx and germen, conſiſting of three coats, of which the outermoſt is formed of three ribs originating from the angles of the germen.—The tree produces an aſtringent reſin of a fine deep red, whoſe probable uſes in medicine or the arts merit enquiry. Many more ſpecies of this genus are ſaid to abound in New Holland, all lofty trees, deſtitute of hairineſs, with ſimple, lanceolate, or ſomewhat ovate, pointed, entire leaves, generally oblique, and often unequal, at the baſe ; without ſtipulas. They are commodiouſly divided into two ſections, by their hemiſpherical or conical lids.

EUCARPIA, in *Ancient Geography*, a town of Aſia, in Greater Phrygia, according to Ptolemy and Strabo.

EUCERA, in *Entomology*, a genus of Hymenoptera, propoſed by Scopoli, and adopted by various late writers. Under this denomination are comprehended thoſe of the Linnæan genus Apis (bee), which have the mandibles horny, incurvated, acute, and toothleſs ; jaw elongated, and membranaceous at the tip ; lip horny, five-cleft ; tongue inflected and ſeven-cleft ; antennæ cylindrical, thoſe of the male very long, and often exceeding the length of the body ; the abdomen ſhort and downy ; tail of the female armed with a ſting. The inſects of this genus form cylindrical cavities in the earth, in which they depoſit their eggs, each included in a ſeparate cell, and furniſhed with a ſuitable proviſion of honey for the ſubſiſtence of the young when hatched. In the winged ſtate the Euceræ fly with great rapidity, and like the bee, collect the farina and nectar of flowers with great induſtry and activity. The females commonly differ much in appearance from the males of the ſame ſpecies, independently of the length of the antennæ.

Species.

Longicornis. Black ; ſummit of the head, thorax, and two firſt rings of the abdomen above grey-downy ; reſt of the abdomen nearly glabrous. Latreille. *Eucera longicornis*, Fabr. Kirby. Ap. Angl.

Native of Europe. The female of this ſpecies is not diſtinctly aſcertained. Mr. Kirby ſeems to entertain no doubt of its being the inſect figured by Panzer under the name of Andrena ſtrigoſa. Since his obſervations appeared, however, Latreille has written on the ſame ſubject, and though he does not refer to the remark of Mr. Kirby, he evidently alludes to it in the following paſſage, " Je doute que l'andrene, que Panzer nomme *ſtrigoſa*, ſoit la femelle de cette eſpèce. Son abdomen eſt très-different par ſes taches de celui de *l'eucere longicorne* et cet inſecte ne paroît qu'au milieu du l'ete, tandis que le dernier ne ſe voit, qu'au printemps." The difference of the abdomen may perhaps be conſidered in this ambiguous race leſs definitive than the time of its appearance in the winged ſtate ; for if the firſt be conſtantly found only in the middle of the ſummer, and the other in ſpring, we ſhould admit them to be diſtinct. It further merits obſervation that Latreille deſcribes an inſect which he imagines to be the true female, " La femelle, &c."—" The female, or, at leaſt, that which I regard as ſuch, and of which I have

have feen an individual in the collection of the naturalift Baumhaaver, differs only in the fhortnefs of the antennæ; the head entirely black, and the pofterior feet very downy." The fpecies inhabits Europe.

ATRICORNIS. Antennæ black, as long as the body, which is hairy and ferruginous. Fabr.

Native of Barbary.

GLAUCA. Antennæ ferruginous, as long as the body, the latter hairy and glaucous. Fabr. Sp. Inf. &c.

Inhabits the Eaft; two firft fegments of the abdomen with a black band.

LINGUARIA. Antennæ black, length of the abdomen; thorax cinereous; abdomen black. Fabr.

Native of Europe, on flowers.

TUMULORUM. Antennæ length of the abdomen: body black; legs and jaws yellowifh. Linn. Fn. Suec. *Eucera tumulorum*, Fabr.

An European infect, alfo found on flowers.

GRISESCENS. Antennæ black, as long as the body; the latter hairy and cinereous. Fabr.

Inhabits Barbary.

ANTENNATA. Antennæ as long as the body; abdomen black, with whitifh ftreaks. Fabr.

A fmall infect, found in abundance in the environs of Paris in autumn, and alfo in other parts of Europe. The lip is marked with a trilobate fpot of yellow; the head and thorax cinereous; abdomen glabrous; edges of the fegments fringed with white, legs teftaceous.

CURVICORNIS. Blackifh-grey; antennæ convoluted, fub-clavated; abdomen roundifh; margin of the wings black. Scopoli. Native of Carniola.

BREVICORNIS. Ferruginous hairy; abdomen braffy; antennæ fhort and black. Fabr. Suppl.

This is an inhabitant of Italy, and is defcribed by Fabricius from the cabinet of Dr. Allioni. The head, thorax, and legs with ferruginous hairs.

CRASSIPES. Hairy cinereous; abdomen black, with the margins of the fegments greenifh; pofterior thighs thick. Fabr. Suppl.

Native of Tranquebar in the cabinet of Lund. The antennæ of this infect are fhort; the wings are dufky with fufcous tip; legs yellowifh; thighs of the pofterior pair thick, dentated, and black; fhanks incurvated, toothed, and yellow. Whether this and the fpecies immediately preceding ought ftrictly to be placed with the Euceræ, (fo named from the length of their antennæ,) if they fhould be of the male kind, may be fubmitted with deference; the fex is not mentioned in either inftance. Fabricius defcribed them as Euceræ, and they agree in every refpect with that genus, except in the remarkable brevity of the antennæ.

EUCHARIST, EUCHARISTIA, the facrament of the Supper, or a participation of the body and blood of Chrift, under the fpecies or figures of bread and wine. See COMMUNION, SACRAMENT, SPECIES, TRANSUBSTANTIATION, and CONSUBSTANTIATION.

The word in its original Greek, Ευχαριϛια, literally imports *thankfgiving*, being formed of ευ, *bene*, *well*, and χαρις, *gratia*, *thanks*.

EUCHENDORF, in *Geography*, a town of Lower Bavaria, on the Vils; 14 miles W. of Vilzhofen.

EUCHERIUS, in *Biography*, a bifhop of Lyons in the fifth century, began his career in fecular life, in the various offices of which he acquired wealth. He fuftained the rank of fenator, and having married, had feveral children, among whom were two fons, whom he lived to fee advanced to the epifcopal dignity. Wearied with the purfuits of the world, he embraced a monaftic life, which he quitted for the bifhopric of Lyons in the year 434. He attended the deliberations of the firft council of Orleans in the year 441, and was diftinguifhed for his learning and fagacity. He was a popular preacher, upon thofe principles of grace which were vindicated by St. Auguftine. He died about the year 454. Among the various pieces attributed to Eucherius, may be noted "Epiftola de Laude Eremi, feu de Vita Solitaria," intended to extol the advantages of afcetic life, written, for the times, with uncommon beauty and purity of language: "Epiftola Parænetica de contemptu Mundi, et Sæcularis Philofophiæ ad Valerianum Cognatum fuum," which was publifhed by Erafmns, with annotations, at Bafil in the year 1520, and pronounced to be one of the moft elegant pieces of antiquity. To thefe may be added two treatifes intended to illuftrate difficult paffages of Scripture, of lefs value than thofe mentioned above. Thefe, and fome others attributed to Eucherius, were collected and publifhed at Bafil in 1531, at Rome in 1564, and are likewife to be found in the fixth volume of the "Bibliotheca Patrum." There was another Eucherius who was likewife a bifhop of Lyons, and affifted at the fecond council of Orleans about the year 529. Moreri.

EUCHITES, or EUCHITÆ, in *Ecclefiaftical Hiftory*, a fect of ancient heretics, who were firft formed into a religious body towards the end of the fourth century, though their doctrine and difcipline fubfifted in Syria, Egypt, and other eaftern countries before the birth of Chrift; they were thus called becaufe they prayed without ceafing, imagining that prayer alone was fufficient to fave them.

Their great foundation was thofe words of St. Paul, Epift. i. to the Theffalonians, chap. v. ver. 17. *pray without ceafing*.

The word is formed of the Greek, ευχη, *prayer*, whence ευχιται, the fame with the Latin, *precatores*, *prayers*. They were alfo called *Enthufiafts* and *Meffalians*, a term of Hebrew origin, denoting the fame as Euchites.

The Euchites were a fort of myftics who imagined, according to the oriental notion, that two fouls refided in man, the one good and the other evil; and who were zealous in expelling the evil foul or dæmon, and haftening the return of the good fpirit of God, by contemplation, prayer, and finging of hymns. They alfo embraced the opinions nearly refembling the Manichean doctrine, and which they derived from the tenets of the oriental philofophy. The fame denomination was ufed in the twelfth century, to denote certain fanatics who infefted the Greek and Eaftern churches, and who were charged with believing a double Trinity, rejecting wedlock, abftaining from flefh, treating with contempt the facraments of Baptifm and the Lord's Supper, and the various branches of external worfhip, and placing the effence of religion folely in external prayer, and maintaining the efficacy of perpetual fupplications to the Supreme Being for expelling an evil being or genius, which dwelt in the breaft of every mortal. This fect is faid to have been founded by a perfon called Lucopetrus, whofe chief difciple was named Tychicus. By degrees it became a general and invidious appellation for perfons of eminent piety and zeal for genuine Chriftianity, who oppofed the vicious practices and infolent tyranny of the priefthood; much in the fame manner as the Latins comprehended all the adverfaries of the Roman pontiff under the general terms of *Waldenfes* and *Albigenfes*. Mofh. Eccl. Hift. Eng. edit. 8vo. vol. i. p. 350. and vol. ii. p. 441.

St. Cyril of Alexandria, in one of his letters, takes occafion to cenfure feveral monks in Egypt, who, under pretence of refigning themfelves wholly to prayer, led a lazy,

lazy, fcandalous life. A cenfure likewife applicable to monafteries in general.

EUCHOLOGIUM, Ευχολογιον, a Greek term, fignifying, literally, *a difcourfe on prayer*.

The word is formed of ευχη, *prayer*, and λογος, *difcourfe*.

The Euchologium is properly the Greek ritual, wherein are prefcribed the order and manner of every thing relating to the order and adminiftration of their ceremonies, facraments, ordinations, &c.

Fa. Goaar has given us an edition of the Greek Euchologium in Greek and Latin, with notes, at Paris.

EUCHROO'N, in *Surgery*, a plafter mentioned by Scribonius Largus.

EUCHYMIA, from ευ, *good*, and χυμος, *juice*, in *Medicine*, a good temper of the blood, or other juices and fluids in an animal body.

EUCLABRIS, in *Antiquity*, a table whereon the flaughtered victim was fpread, in order to have its inteftines carefully infpected. It was from this table that the veffels ufed in facrifices were called *euclabria*.

EUCLASE. The colour of this mineral is a very clear fea-green. It occurs only cryftallized. Its primitive form is that of an oblique quadrilateral prifm, but its fummits are generally fo complicated by truncatures and bevellings as to render a mere verbal defcription of it wholly unintelligible: in this ftate it refembles certain varieties of topaz, but may readily be diftinguifhed by meafuring the obtufe angles of the prifm, which in this mineral are 133°, whereas in the topaz they are 124°; its lamellæ alfo are not perpendicular to the axis of the prifm. It has a brilliant vitreous luftre. Its fracture in the direction of its axis and parallel to the fmall diagonal of its bafe is perfectly lamellar; but when parallel to the large diagonal is very imperfectly fo. Its crofs fracture is fomewhat conchoidal. It is tranfparent and has a double refraction. It is fufficiently hard to fcratch quartz, but is remarkably brittle. Sp. gr. = 3.06.

When expofed to the blowpipe, it firft lofes its tranfparency, and then melts into a white enamel. It has been analyfed by Vauquelin, with the following refult:

Silex - - - -	35 to	36
Alumine - - - -	18 —	19
Glycine - - - - - -	14 —	15
Iron - - - -	2 —	3
	69 —	73
Lofs - - - - -	31 —	27
	100 —	100

This mineral is fo very rare that only a fmall portion could be afforded for analyfis; of the lofs, Vauquelin attributes the greateft part to water of cryftallization, and the reft is probably alkali.

The euclafe was found in Peru by Dombey, and all the fpecimens in the cabinets of Europe were brought over by this naturalift.

EUCLEA, in *Botany*, is derived by Profeffor Martyn from ευκλεια, *glory*, or *celebrity*, which feems in no refpect applicable to this plant. We would rather explain it by ευ, *well*, and κλειω, *to fhut up*, becaufe of the manifold coverings of the feeds, each of which is enclofed in an arillus, within the cell of a capfule, whofe outfide moreover is protected with a covering of pulp. To all this indeed L'Heritier firft adverted, and not Linnæus nor Thunberg, one of whom probably invented the name. Linn. Suppl. 67. Thunb. Nov. Gen. 84. L'Herit. Sert. Angl. 31. Schreb. 699, 700. Juff. 432. Clafs and order, *Dioecia Dodecandria*, or perhaps, as the Linnæan Syftem now ftands, *Polygamia Monoecia*. Nat. Ord. uncertain, Juff.

Gen. Ch. *Cal.* Perianth inferior, fmall, with five teeth, permanent. *Cor.* of one petal, larger than the calyx, in five deep, ovate, obtufe, equal, fpreading fegments. *Stam.* Filaments about fifteen, fhort, inferted into the receptacle; anthers erect, fquare, flightly downy, fhorter than the corolla. *Pift.* Germen fuperior, ovate, fomewhat pyramidal; ftyles two, the length of the ftamens; ftigmas fimple. *Peric.* Capfule with a pulpy coat, roundifh, with three horns, three cells, and three valves. *Seeds* folitary, roundifh, each enclofed in an arillus; one or two of them frequently proving abortive.

Eff. Ch. Calyx with five teeth. Corolla in five deep equal fegments. Stamens 15. Styles two. Capfule fuperior, of three cells, pulpy-coated. Seeds folitary, enclofed in an arillus.

Obf. L'Heritier, from whom the above characters are taken, remarks that fome flowers have an abortive germen, but he never faw any that were entirely female without ftamens. Thunberg defcribes diftinct male and female flowers, and afferts that the former are moft frequently five-cleft, the latter four-cleft. Linnæus does not advert to any fuch difference.

Thunberg defines three fpecies, all natives of the Cape of Good Hope, in his Prodromus, p. 85.

1. E. *lancea*. " Leaves lanceolate, flat."

2. E. *racemofa*. " Leaves ovate, flat."—E. racemofa; Linn. Suppl. 428. L'Herit. Sert. Angl. 32. Ait. H. Kew. v. 3. 411. (Padus foliis fubrotundis, fructu racemofo; Burm. Afric. 238. t. 84. f. 1: and Euonymus foliis fubrotundis integris, fructu corniculato; ibid. 260. t. 97. f. 1. E. africanus, foliis laurinis, fructu aculeato; Breyn, Ic. 31. t. 22. f. 3.) A fmooth branching fhrub, with alternate, obovate, thick, fomewhat revolute *leaves*, about an inch long, on fhort footftalks. *Flowers* eight or ten in each axillary drooping clufter, about as long as its correfponding leaf. *Petals* fnow-white. *Fruit* red, the fize of a pea.

3. E. *undulata*. " Leaves ovate, undulated."—Much like the laft in general afpect. Its red fruit is eaten by the Hottentots, who call the plant Guarri-bofches.

EUCLID, in *Biography*, a native of Megara, and founder of the Megaric or Eriftic fect, was diftinguifhed by his fubtle genius, and early application to the ftudy of philofophy. Having acquired fome knowledge of the art of difputation from the writings of Parmenides, he was induced by the fame of Socrates to remove from Megara to Athens, where he became the auditor and difciple of this eminent philofopher. Notwithftanding the terror of the decree which enacted, that any inhabitant of Megara who fhould be feen at Athens fhould forfeit his life, he frequently came to Athens by night, from the diftance of about 20 miles, concealed in a long female cloak and veil, to vifit his mafter. He alfo frequently engaged in the bufinefs and difputes of the civil courts, by which proceeding he offended Socrates, who defpifed forenfic contefts; and this circumftance feems to have occafioned a feparation between them. Afterwards he put himfelf at the head of a fchool in Megara, where his chief employment was to teach the art of difputation. Although he was much addicted to vehement debates, he poffeffed fo great a command of temper, that in a quarrel with his brother, who faid to him, " Let me perifh if I be not revenged upon you," Euclid replied, " And let *me* perifh, if I do not fubdue your reſentment by forbearance, and make you love me as much as ever."

Averſe from the analogical method of reaſoning, Euclid was of opinion that legitimate argumentation conſiſts in deducing fair concluſions from acknowledged premiſes. He held, that there is one ſupreme good, which is called by the different names of Intelligence, Providence, God; and that evil, conſidered as an oppoſite principle to the ſovereign good, has no phyſical exiſtence. The ſupreme good he defined to be that which is always the ſame. Good he therefore conſidered abſtractedly, as reſiding in the Deity, and he ſeems to have maintained, that all things which exiſt are good by their participation of the firſt good, and that in the nature of things there is no real evil. When Euclid was aſked his opinion concerning the gods, he replied, "I know nothing more of them than this: that they hate inquiſitive perſons." Brucker's Hiſt. Phil. by Enf. v. i.

Euclid, known to every well educated youth by his "Elements," was, according to the teſtimony of Pappus and Proclus, a native of Alexandria, in Egypt, where he flouriſhed and taught the mathematics in the reign of Ptolemy Lagus, about 300 years before Chriſt His was the firſt mathematical ſchool in that far famed city, where, till its conqueſt by the Saracens, moſt of the eminent mathematicians were either born, or ſtudied. To Euclid, and to thoſe immediately educated by him, the world has been indebted for Eratoſthenes, Archimedes, Apollonius, Ptolemy, &c. "The Elements," to which we have already referred, are not to be wholly attributed to Euclid, many of the invaluable truths and demonſtrations contained therein were diſcovered and invented by Thales, Pythagoras, Eudoxus, and others; but Euclid was the firſt who reduced them to regular order, and who probably interwove many theorems of his own, to render the whole a complete and connected ſyſtem of geometry. "The Elements" conſiſt of fifteen books, but the laſt two are ſuſpected to have been written 200 years after Euclid's death, by Hypſicles of Alexandria. The beſt edition publiſhed in this country is that printed at Oxford, in folio, in 1703; but the moſt common edition in our ſchools is that by the late learned Dr. Simſon. Euclid is ſaid to have been a perſon of agreeable and pleaſing manners, and admitted to habits of friendſhip and familiarity with king Ptolemy, who once demanded of the mathematician if he could not direct him to ſome ſhorter and eaſier way of acquiring a knowledge of geometrical truths, than that which he had exhibited in his "Elements," to which Euclid replied, that "there was no royal road to geometry."

Euclid, as a writer on muſic, has ever been held in the higheſt eſtimation by all men of ſcience who have treated of harmonics, or the philoſophy of ſound. As Pythagoras was allowed by the Greeks to have been the firſt who found out muſical ratios, by the diviſion of a monochord, or ſingle ſtring, a diſcovery which tradition only had preſerved, Euclid was the firſt who wrote upon the ſubject, and reduced theſe diviſions to mathematical demonſtration.

His "Elements" were firſt publiſhed at Baſil, in Swiſſerland, 1533, by Simon Grynæus, from two MSS. the one found at Venice, and the other at Paris. His "Introduction to Harmonics," (Εισαγωγη ἁρμονικη,) which in ſome MSS. was attributed to Cleonidas, is in the Vatican copy given to Pappus; Meibomius, however, accounts for this, by ſuppoſing thoſe copies to have been only two different MS. editions of Euclid's work, which had been reviſed, corrected, and reſtored from the corruptions incident to frequent tranſcription by Cleonidas and Pappus, whoſe names were, on that account, prefixed. It firſt appeared in print with a Latin verſion, in 1498, at Venice, under the title of "Cleonidæ Harmonicum Introductorium:" who Cleonidas was, neither the editor, George Valla, nor any one elſe pretends to know. It was John Pena, a mathematician in the ſervice of the king of France, who firſt publiſhed this work at Paris, under the name of Euclid, in 1557. After this, it went through ſeveral editions with his other works.

His "Section of the Canon," (Κατατομη κανονος,) follows his "Introduction;" it went through the ſame hands and the ſame editions, and is mentioned by Porphyry, in his Commentary on Ptolemy, as the work of Euclid. This tract chiefly contains ſhort and clear definitions of the ſeveral parts of Greek muſic, in which it is eaſy to ſee that mere *melody* was concerned; as he begins by telling us, that the ſcience of *harmonics* conſiders the nature and uſe of melody, and conſiſts of ſeven parts: ſounds, intervals, genera, ſyſtems, keys, mutations, and melopœia; all which have been ſeverally conſidered in the diſſertation.

Of all the writings upon ancient muſic, that are come down to us, this ſeems to be the moſt correct and compreſſed: the reſt are generally looſe and diffuſed; the authors either twiſting and diſtorting every thing to a favourite ſyſtem, or filling their books with metaphyſical jargon, with Pythagoric dreams, and Platonic fancies, wholly foreign to muſic. But Euclid, in this little treatiſe, is like himſelf, cloſe and clear; yet ſo mathematically ſhort and dry, that he beſtows not a ſyllable more upon the ſubject than is abſolutely neceſſary.

His object ſeems to have been the compreſſing into a ſcientific and elementary abridgment, the more diffuſed and ſpeculative treatiſes of Ariſtoxenus. He was the D'Alembert of that author, explaining his principles, and, at the ſame time, ſeeing and demonſtrating his errors. The muſical writings of Rameau were diffuſed, obſcure, and indigeſted; but M. D'Alembert, extracting the eſſence of his confuſed ideas, methodized his ſyſtem of a *fundamental baſe*, and compreſſed, into the compaſs of a pamphlet, the ſubſtance of many volumes. See Elemens de Muſique, ſuivans les Principes de Rameau.

According to Dr. Wallis, (Phil. Tranſ. No. 242, and Lowthorp's Abridg. v. i.) Euclid was the firſt who demonſtrated that an octave is ſomewhat leſs than *ſix whole* tones; and this he does in the 14th theorem of his "Section of the Canon." In the 15th theorem he demonſtrates that a fourth is leſs than two tones and a half, and a fifth leſs than three and a half; but though this proves the neceſſity of a temperament upon fixed inſtruments, where one ſound anſwers ſeveral purpoſes, yet he gives no rules for one, which ſeems to furniſh a proof that ſuch inſtruments were at leaſt not *generally* known or uſed by the ancients.

What Ariſtoxenus called a *half-tone*, Euclid demonſtrated to be a ſmaller interval, in the proportion of 256 to 243. This he denominated a *limma*, or *remnant;* becauſe giving to the *fourth*, the extremes of which were called *ſoni ſtabiles*, and were regarded as fixed and unalterable, the exact proportion of 4 to 3, and, taking from it two major tones $\frac{8}{9} \times \frac{8}{9}$, the limma was all that remained to complete the diateſſaron. This diviſion of the diatonic genus being thus, for the firſt time, eſtabliſhed upon mathematical demonſtration, continued in favour, ſays Dr. Wallis, for many ages. But this is further explained in other articles.

EUCOMIS, in *Botany*, from ευκομης, *having beautiful hair*, alluding to the leafy tuft of barren bracteas, which crowns the ſpike of flowers. See Coma.—L'Herit. Sert. Angl. 17. Ait. Hort. Kew. v. 1. 432. Schreb. 798. Willd. Sp. Pl. v. 2. 92. Mart. Mill. Dict. v. 2. (Baſilæa; Lamarck Encycl.

Encycl. v. 1. 382. t. 239. Juff. 52. Venten. v. 2. 163. Fritillaria; Linn. Gen. 164.) Clafs and order, *Hexandria Monogynia*. Nat. Ord. *Coronariæ*, Linn. *Afphodeli*, Juff.

Gen. Ch. *Cal.* none. *Cor.* of one petal, inferior, bell-fhaped, regular, permanent, in fix deep, equal, oblong, obtufe, fpreading fegments. *Stam.* Filaments fix, fhorter than the corolla, awl-fhaped, dilated at the bafe and united by that part into a concave nectary, attached to the bottom of the corolla; anthers oval. *Pift.* Germen fuperior, ovate, with three furrows; ftyle awl-fhaped; ftigma fimple. *Peric.* Capfule ovate, three-lobed, of three cells. *Seeds* numerous, fmall, ovate.

Eff. Ch. Calyx none. Corolla inferior, in fix deep, fpreading, permanent, equal fegments. Filaments united at their bafe into a concave nectary, attached to the corolla.

1. E. *nana*. Ait. Hort. Kew. v. 1. 432. Jacq. Hort. Schoenbr. v. 1. 47. t. 92. (Fritillaria nana; Linn. Mant. 223.) Stalk club-fhaped. Leaves numerous, broad-lanceolate, crenate. Barren bracteas elliptical.—Native of the Cape of Good Hope, as are all the known fpecies. *Bulb* ovate, rather large. *Leaves* radical, about eight, pale-green, fpreading, recurved, obovato-lanceolate, fomewhat acute. *Stalk* folitary, a fpan high, green, fwelling confiderably upwards, bearing a fhort fpike of green drooping *flowers*, furmounted with a tuft, about as long as the fpike, confifting of elongated, elliptical, barren *bracteas*. It is kept in the greenhoufe, and flowers in the fpring, but is fcarcely cultivated except for the fake of curiofity.

2. E. *bifolia*. Jacq. Ic. Rar. v. 2. t. 449. Coll. v. 4. 215. Curt. Mag. t. 840. (Melanthium maffoniæfolium; Andr. Repof. t. 368.)—Stalk club-fhaped. Leaves two, elliptical, depreffed. Bracteas all longer than the flowers, pointed, recurved.—The *leaves* are ribbed, entire, very broad. *Stalk* very fhort, green. Barren and fertile *bracteas* uniform, and all longer than the *flowers*, which are feffile and erect.

3. E. *purpurea*. (E. purpureocaulis; Andr. Repof. t. 369.) Stalk club-fhaped. Leaves numerous, obovate, obtufe, depreffed. Fertile bracteas fhorter than the flowers; barren ones linear-lanceolate.—Drawn by Mr. Andrews in the garden of G. Hibbert, efquire.—The broad, depreffed, numerous *leaves*; thick, violet *ftalk*; and numerous, narrow, purple-edged leaves of the crown, readily diftinguifh this fpecies.

4. E. *regia*. Ait. H. Kew. v. 1. 433. (Fritillaria regia; Linn. Sp. Pl. 435. Corona regalis, lilii folio crenato; Dill. Elth. t. 92, 93.)—Stalk cylindrical. Leaves tongue-fhaped, crenate, depreffed. Barren bracteas elliptical.—This moft refembles the firft fpecies in fize, habit, colour, and the crenate edges of its *leaves*; but differs in its longer cylindrical *ftalk*. It has been much longer cultivated than any other of the genus.

5. E. *undulata*. Ait. ibid. Curt. Mag. t. 1083. (E. regia; Redout. Liliac. v. 3. t. 175. Bafilæa; Lamarck f. 1.)—Stalk cylindrical. Leaves ovate-oblong, undulated, fpreading. Barren bracteas almoft as long as the fpike.—Introduced in 1760 by Mr. Miller, who, from its bloffoming in autumn, which is not invariable, named it *Fritillaria autumnalis*. *Stalk* taller than in the laft. *Leaves* narrower and longer. Mr. Gawler obferves that their undulations difappear as they decay.

6. E. *punctata*. L'Herit. Sert. Angl. t. 18. Curt. Mag. t. 913. (Bafilæa; Lamarck f. 2.)—Stalk cylindrical. Leaves lanceolate, channelled, fpreading. Spikes many times longer than the barren bracteas.—The long narrow *leaves*, *ftalk* elegantly fpeckled with violet, and efpecially the great extent of the *fpike*, which is about a foot in length, render this fpecies very diftinct. The *corolla* is of a very pale green. *Germen* violet. The bafes of the *leaves* are externally fpotted like the ftalk. It flowers in June or July, and is eafy of cultivation.

EUCRASY, of ευ, *well*, and κρασις, *temperature*, an agreeable, well-proportioned mixture of qualities, whereby a body is faid to be in good order, and difpofed for a good ftate of health.

EUCRYPHIA, in *Botany*, from ευ, *well*, and κρυφιος, *covered*, becaufe the flower-buds are concealed by a peculiar covering. Cavan. Ic. v. 4. 48. Clafs and order, *Polyandria Polygynia*. Nat. Ord. *Tiliaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of five minute, ovate, equal, permanent leaves. *Cor.* Petals five, large, obovate, equal, fpreading; covered before expanfion with a deciduous veil, feparating from the bafe into four fegments. *Stam.* Filaments inferted into the receptacle, numerous, awl-fhaped, fhorter than the petals; anthers roundifh, of two cells. *Pift.* Germen fuperior, ovate, ftriated; ftyles about 12, fhorter than the ftamens; ftigmas fimple. *Peric.* Capfule ovate, with a woody furrowed bark, burfting at the top and bottom into as many cells as there are ftyles, each remaining attached by two fibres to the receptacle. *Seeds* feveral, obovate, imbricated, each terminated by a fmall membranous wing.

Eff. Ch. Calyx of five fmall leaves. Petals five, covered before expanfion with a deciduous veil. Capfule of many cells, feparating at top and bottom. Seeds winged, imbricated.

1. E. *cordifolia*. Cavan. Ic. v. 4. 49. t. 372.—A fine tree gathered in Chili, by Louis Née, from whofe herbarium Cavanilles defcribed it. *Wood* red. *Branches* downy when young. *Leaves* oppofite, on fhort ftalks, ovate, obtufe, undulated and bluntly crenate, veiny, coriaceous; heart-fhaped at the bafe; fmooth above; downy and white beneath; fcarcely two inches long. *Stipulas* none. *Flowers* axillary, folitary, each on a ftalk about an inch long, with a few fcales at its bafe. *Petals* white, turning red in drying. *Veil* of the flower externally downy.—It is commonly called in the country *Roble di Chile*, or Chili Oak.

EUDEMIA, in *Ancient Geography*, a fmall ifland of the Ægean fea, placed by Pliny in the Thermaic gulf.

EUDÆMON, John Andrew, in *Biography*, a learned Jefuit, was a native of Candia, and went to Rome in purfuit of knowledge, where he entered himfelf a member of the fociety of Jefus. He was afterwards profeffor of philofophy, and then of theology in the univerfity of Padua. He was honoured with the efteem and friendfhip of Pope Urban VIII. who appointed him the chaplain to his own nephew cardinal Barberini, when he was fent papal legate into France. He died at Rome in 1625, leaving behind him in various publications many teftimonials to his talents and learning. He was fufpected to be the author of a work entitled "Admonitio ad Regem Ludovicum XIII." which attacked the authority of the kings of France, in matters of an ecclefiaftical nature. This treatife brought the fociety, of which Eudæmon was a member, into great and general difrepute; it was likewife cenfured by the faculty of the Sorbonne, and the affembly of the clergy at Paris, and condemned by the parliament. Moreri.

EUDEMUS, in *Biography*, a name, it would appear, common to feveral phyficians in different ages, of whom little is known with any degree of certainty or precifion. One Eudemus is mentioned by Galen as contemporary with Herophilus, in the 37th age, and is compared with the latter in refpect to his anatomical fkill, efpecially relative to the

the nerves. Another Eudemus is said to have suffered death for his crimes, in the year 31 of the Christian era. And others of the same name, as Eudemus the vender of antidotes, Eudemus of Chio, are occasionally mentioned. See Eloy. Dict. Hist.—Le Clerc Hist. de la Medecine.

Eudemus of Rhodes was a pupil of Aristotle. The Ethics of Aristotle are inscribed to him, and some suppose them to have been written by him.

EUDES, duke of Aquitain, succeeded to his dukedom towards the close of the seventh century. When Pepin Heristal laid claim to the royal authority in France, Eudes declared himself independent, and seized upon the remainder of Aquitain, and in a short time by force of arms made himself master of all the country lying between the Loire, the Ocean, the Pyrenées, Septimania, and the Rhone. In 721 he defeated Zama, lieutenant of the Saracen caliph, who had invaded Gaul, under the walls of Toulouse, but in a few years afterwards he found it necessary to make an alliance with Munuza, another Saracen general, to whom he gave his daughter in marriage. After this his country was completely over-run by the Saracens, over whom, by the aid of Charles Martel, he obtained, in 732, a complete victory, which delivered France from the Mahometan yoke. Eudes died in 735, leaving behind him three sons by his wife Valtrude, who was the near relation of Pepin. Moreri. Univer. Hist.

Eudes, John, born at Rye in Lower Normandy, in the year 1601, was brother of the celebrated historian Mezerai, and received his education at Caen, under the care of the Jesuits, where he was afterwards entrusted with the superiority of the house belonging to the congregation. In 1643 he quitted the duties of this institution, and undertook the establishment of another, of which he became the first superior as well as founder. This was denominated "The congregation of Jesus and Mary," and the principal object of it was to provide a seminary for the instruction of young persons in piety and sacred knowledge, and to form a body of religionists, influenced by greater fervour and exaltation in their devotional feelings, than was encouraged by the regulations of the society of which he had been a member. He died in 1680, at the age of seventy-nine. He is described as having been an excellent and well meaning man, but mystical and highly enthusiastic. As a preacher and instructor of youth, he was very popular; but his writings evince little knowledge and less judgment, though they exhibit a devotional spirit, tinctured with large portions of superstitious credulity. The most remarkable of his pieces are (1) A treatise "On the Devotion and Office of the Heart of a Virgin; (2) "Man's contract with God;" and, (3) some particulars concerning a peasant in Normandy, whom he regarded as under divine inspiration, entitled "The life of Mary of the Vallies." Moreri.

EUDIOMETRY. This term is applied to those processes which have been employed to ascertain the purity, or, in other words, the degree of oxygenation of any gaseous mixture, and especially of atmospherical air.

A considerable variety of methods have been used by chemists, all of which, though essentially different, agree in acting upon the oxygenous portion alone, the azot being in all cases left as the unchanged residue. The following are the several methods employed.

Of nitrous gas as an eudiometer.—This was the first eudiometer used by Dr. Priestley in his original experiments on air, which immediately followed the discovery of oxygen by this illustrious philosopher. If nitrous gas be mixed with *oxygen gas*, in a glass jar over water, in the proportions in which they saturate each other, to form nitric acid, the gases will totally disappear, a ruddy fume is seen at the moment of mixture, and the water will rise to the top of the jar, leaving unabsorbed only the unavoidable impurities of the gases. If, on the other hand, nitrous gas be mixed with *atmospherical air*, or any other admixture of oxygen and azot, the former alone of the two will be condensed by and with the nitrous gas, and the azot will remain unaltered. Hence by measuring the respective quantities of the gases employed, and the quantity absorbed, the purity of the atmospherical air may be ascertained, (supposing it known by previous experiment what are the exact proportions in which nitrous gas and oxygen saturate each other, and become totally absorbable by water.) Thus, for example, if 100 measures of nitrous gas be added to the same quantity of common air, and the two compleatly mixed, the bulk after such mixture will not be 200 measures, but only about 108, and consequently 92 measures will have been absorbed; which last, therefore, consist of all the oxygen of the air, with so much of the nitrous gas as has been employed to saturate it. This result Dr. Priestley was in habit of denoting, for brevity sake, by the expression that the air was of the purity of 108, by which he always meant that when 100 of nitrous gas, and 100 of the air to be examined were mixed, the residue after the mutual action of the airs was over, was of the number specified. The quantity of the two airs absorbed being known, the portion which is estimated to belong to the oxygen must therefore depend on the proportion in which nitrous and oxygen gases saturate each other, which requires another elementary experiment. Thus in the instance before us, if three parts of nitrous gas saturate one part of oxygen, the 92 parts which have disappeared are composed of 69 of the former gas, and 23 of the latter, and hence the composition of the 100 parts of atmospherical air examined, will be 23 of oxygen, and the remainder unabsorbed residue chiefly azotic.

A number of valuable experiments by Fontana, Ingenhouz, and especially by Mr. Cavendish, made on this subject, have shewn that different portions of the very same mixture of nitrous gas and oxygen will experience a prodigious difference of absorption according to the width of the tube in which they are mixed, the order of mixture, the time of standing together, the degree of agitation used, and other manipulations. Thus Mr. Cavendish observed, that if one measure of nitrous gas and as much common air be rapidly mixed, and immediately shaken, the absorption will be nearly half the entire contents, but if the airs are suffered to remain in contact for about a fourth of a minute before they are shaken, the absorption will be no more than about .8. The nature of the water also in which the experiment is made is found very materially to influence the result. By attending to every circumstance of the kind, Mr. Cavendish, with that admirable accuracy which distinguishes all the researches of this eminent philosopher, was enabled to obtain very satisfactory results as to the uniform nature of atmospherical air.

Still, however, the difficulties of employing this mode of analysis with sufficient precision in all admixtures of oxygen and azot have been found so great, and the apparent anomalies so numerous, that it has been long nearly abandoned by chemists, till of late the subject has been revived by Mr. Dalton, who has added some important observations, which require some notice in this place. (See the Manchester Transactions. New series.)

Mr. Dalton gives the following experiments:

If 100 measures of common air be thrown up to 36 measures of nitrous gas in a tube only 3-10ths of an inch wide,

wide, and 5 inches long, and no agitation be ufed, in a few minutes the whole will be reduced to 79 or 80 meafures, and exhibit no figns of either oxygen or nitrous gas, but will confift entirely of azot.

If on the other hand 100 meafures of common air be thrown up to 72 of nitrous gas, in a wide veffel over water, fuch as to form a thin ftratum of air, and an immediate agitation be ufed, both the oxygen and the nitrous gas will, as before, totally difappear, and the refidue, as before, will alfo be 79 or 80 meafures of azot.

If in the laft experiment lefs than 72 meafures of nitrous gas be ufed, there will be a refiduum containing fome oygen; if more, the refidue will contain nitrous gas.

From thefe elementary experiments Mr. Dalton infers that the oxygen, contained in 100 parts of common air, may unite totally either with 36 parts of nitrous gas, or with 72, double that quantity, but with no intermediate portion. To infure the former effect, the gafes muft be mixed in a narrow veffel without agitation; to infure the latter the veffel muft be large, and the points of contact between the ingredients muft be increafed by agitation. But in the ordinary circumftances of the experiment, Mr. D. fuppofes that both thefe effects partially take place, fo that one part of the oxygen unites with the nitrous gas in the fmaller proportion, and another in the larger; and hence he accounts in a very ingenious and fatisfactory manner for the greater part of the apparent anomalies which have been obferved in the employment of nitrous gas in eudiometry. Therefore, he obferves, to ufe nitrous gas for the purpofe of eudiometry, we muft attempt to form one or other of thefe combinations wholly, and he prefers that with the fmalleft proportion of nitrous gas, in the following way:

Take a narrow tube of the dimenfions above given, add 100 parts of common air to about 36 of nitrous gas, and when the diminution is complete, without agitation, transfer the refidue to another tube and meafure it; then 7-19ths of the lofs will be due to the oxygen prefent.

But a ftronger objection arifes againft the employment of nitrous gas in its aeriform ftate, owing to the difficulty of obtaining this gas of uniform purity. From a very elaborate feries of experiments on this fubject, undertaken by Humboldt and Vauquelin, (Ann. Chem. tom. 28.) it appears that when nitric acid of any ftrength is poured upon copper wire (which is the ufual mode of obtaining nitrous gas,) an effervefcence more or lefs vehement takes place, and a gas is difengaged, confifting of nitrous gas, but always mixed with more or lefs of azotic gas, and fometimes nitrous oxyd, and it is this varying portion of azot which conftitutes the chief difficulty and trouble in the employment of nitrous gas in eudiometry. The quantity of azot is found to depend largely on the ftrength of the acid being from about one-tenth or lefs to nearly half the entire gas. According to Humboldt, the degree of ftrength of acid which produces the pureft nitrous gas, is that in which the fpecific gravity is about 1.15 to 1.17, or from 17 to 21 of Beaume's areometer. Mr. Dalton finds that nitric acid diluted with an equal bulk of water poured on copper and mercury, without any artificial heat being ufed, gives a nitrous gas nearly pure, or with only from two to three per cent. of azot.

The proportion of azotic impurity in any mixture of this with nitrous gas, is moft conveniently afcertained by agitating the gas with a folution of green fulphat of iron, which abforbs the nitrous gas without materially affecting the other. This experiment was firft made by Dr. Prieftley, who found that the folution of iron acquired thereby a reddifh or olive brown colour, and a very acid ftyptic tafte. Other chemifts have alfo found a certain quantity of ammonia in the folution.

To obviate the objections brought againft the ufe of nitrous gas, in the gafeous form, as an eudiometer, Mr. Davy has ingenioufly applied to this purpofe the folution of fulphat or muriat of iron, faturated with nitrous gas as above-mentioned, and this, with a few precautions, is found to anfwer with great precifion, and to be applicable with little trouble to all cafes of the analyfis of gafes where oxygen is one of the fubftances fought for. The mode of ufe in ordinary cafes is as fimple as poffible. The gas is put into a graduated eudiometer tube, fome of the folution is poured in, and by very gentle agitation for about a minute, the whole of the oxygen is abforbed. The chief precautions required are, not to ufe the fame folution twice, to keep it in a well-ftopped bottle, and particularly to remove it from the gas under analyfis as foon as the utmoft degree of abforption is produced, as after this time a fmall increafe of bulk is again obfervable in the refidue, owing probably to fome evolution of gas from the folution. It is alfo found that if the folution be very highly impregnated with the nitrous gas, and much hafty agitation be ufed, a little of the nitrous gas efcapes in the gafeous form into the eudiometer tube, which may be removed by the application of a little fulphat or muriat of iron. One cubic inch of the impregnated folution of moderate ftrength will abforb about five or fix cubic inches of oxygen gas.

Of the fulphurets as eudiometers.—The eudiometer firft employed by the illuftrious Scheele, in his original experiments on the conftitution of the atmofphere, fo early as the year 1779, was a mixture of iron filings and flowers of fulphur, moiftened with a little water. By confining a cup of this mixture under a jar of common air over water, this excellent chemift obferved an abforption foon to begin, the water gradually rifing in the jar for about eight hours, after which no further diminution took place, and the refiduary gas confifts chiefly of azot.

This valuable elementary experiment has been employed in eudiometry with great advantage, but modified confiderably, and a few precautions muft be taken to avoid inaccuracies. In the firft place it is to be obferved that this mixture of iron filings and fulphur is flow in its operation, and moreover, a quantity of hydrogen gas is given out towards the end, which mixes with the refiduary azotic gas. To leffen the duration of the experiment the liquid alkaline or earthy fulphurets have been fubftituted to the mixture of iron filings and fulphur, with great advantage. When atmofpherical air, confined in a tube, is fhaken for a few minutes with a little of the liquid fulphuret of lime, potafh, or foda, the whole of the oxygen is abforbed in a few minutes.

Guyton has propofed to haften the abforption by heating the folution, but it has been found that in this cafe there is fome danger of expelling from it a portion of fulphurated hydrogen gas, which would impair the accuracy of the experiment.

A more important fource of error has been mentioned by Marti, (Journal de Phyfique, tom. 52.) which muft be avoided. It appears from his experiments that liquid fulphuret of lime, (and probably the other liquid fulphurets,) when recently made, is capable of abforbing a portion of azot as well as oxygen, which, though fmall, is fufficient to affect materially the refult of a delicate experiment. Marti found that when one meafure of common air was fhaken with 20 meafures of the liquid fulphuret of lime, the entire abforption amounted to as much as 26 per cent. of the air. But of thefe it is known that only about 21 can be be oxygen, and confequently about 5 of azot muft have been abforbed. The experiment being repeated with the fame folution, only 21 per cent. were now abforbed, fo that the folution had been faturated with azot by the previous experiment. The fame folution was then fhaken with pure azot, but no abforption took place, which confirmed the fact of the previous faturation of the fulphuret with azot. On the other hand, when a perfectly frefh folution was ufed, which immediately after being prepared, had been allowed to cool in a well-clofed bottle, and only a twentieth of its bulk of common air was confined with it, the latter in a few minutes had diminifhed full one-half.

It is eafy to avoid errors from this circumftance. All that is neceffary is, previoufly to ufing the liquid fulphuret as an eudiometer, to fhake it for a few minutes in a bottle of common air, and it is never neceffary to ufe more than about two meafures of the fulphuret to one of common air. With thefe precautions, the fulphuret proves a very ufeful and accurate eudiometer.

Of hydrogen gas as an eudiometer.—This ingenious method was propofed and employed with great fuccefs by the celebrated Volta. It confifts in mixing known proportions of pure hydrogen gas with the air to be examined in a very ftrong glafs tube, through which a metallic communication is made, and detonating the contents by the electric fpark. After the fhock, a fudden diminution takes place, owing to the production of water by the detonation of the hydrogen with the oxygen contained in the air examined. The exact faturating proportion between the two gafes has been varioufly given, but an excefs of hydrogen fhould be ufed. One hundred parts of oxygen require at the higheft eftimation fomewhat lefs than 200 of hydrogen for faturation; fo that when equal bulks of hydrogen and *atmofpheric air* are ufed, there is an abundant allowance of hydrogen. Mr. Dalton finds 60 of the latter fufficient for 100 of common air, and the diminution is very uniformly 60 parts with the above proportions; and hence, if common air contains 21 per cent. of oxygen, the faturating proportions of oxygen and hydrogen are 21 of the former to 39 of the latter.

The chief objection to the univerfal ufe of Volta's eudiometer is, that it requires an apparatus to give the electric fpark, which cannot be always procured; and in all experiments of this kind it is particularly defirable to employ one uniform mode of experimenting where general refults are to be eftablifhed.

Of phofphorus as an eudiometer.—Phofphorus has two diftinct modes of combuftion in common air, according to the temperature to which it is raifed. One of thefe is rapid, and attended with the evolution of a prodigious quantity of light and heat, and it occurs when phofphorus is heated a little above its melting point, or in common language is fet fire to. The other takes place in a temperature not exceeding from 90° to 100° at the utmoft, and is that in which the phofphorus emits copious fumes, white in the day-time but highly luminous in the dark, and without any fenfible emiffion of heat. In either cafe the phofphorus is *confumed*, or oxygenated; but it is the flow combuftion without fenfible heat that is alone employed in eudiometry. The whole apparatus required for the purpofe is fimple and convenient of application. Nothing more is neceffary than to fix a ftick of phofphorus in a portion of glafs tube run through a cork, which loofely fits the open end of the fmall jar which is to contain the air to be analyzed, and confine it by water. If the temperature is very cold, the procefs may be affifted by the warmth of the hand. The phofphorus is immediately furrounded by the white luminous fume, which flowly falls down to the furface of the water, during which time the oxygen of the air is gradually abftracted by the vaporized phofphorus, and in confequence the bulk of the contained air is diminifhed. The abforption of oxygen is complete when the contained gas is no longer luminous, which, in a fmall jar with a ftick of phofphorus that traverfes nearly its whole length, requires about half an hour at the heat of from 70° to 80°. The procefs fucceeds equally well at a lower temperature, though a longer time is required. The heat cannot be fafely raifed more than about 85° or 90°, without danger of kindling the phofphorus, which may be avoided by obferving that it melts and becomes gloffy juft before it catches fire.

The exact operation of the flow combuftion of phofphorus ufed in this experiment has been very happily explained by Goettling and Berthollet. When phofphorus is expofed to air at any temperature below that of rapid combuftion, the firft effect feems to be a folution of the furface in the azot of the furrounding air, and this phofphorized azot inftantly unites with the oxygen, becomes thereby luminous, and phofphorus acid abforbable by water is generated. Hence it is (ftrictly fpeaking) only that portion of phofphorus which becomes diffolved in the azot which is the eudiometrical fubftance; and in confirmation of this it may be added that phofphorus inclofed in pure oxygen gas is not in any degree luminous, but remains perfectly inactive till the heat is raifed to the point of ftrong combuftion. On the other hand, if the pureft poffible azot is paffed into a jar full of water, and containing a ftick of phofphorus, the gas only becomes luminous for a very fhort time, after which this appearance ceafes, but the azot continues to faturate itfelf with phofphorus. If now a bubble of common air or oxygen is let up into this phofphorized azot, the luminous appearance immediately returns, and continues fo till all the oxygen is exhaufted. Phofphorus, therefore, furnifhes alfo an ufeful teft of the purity of azot, by not becoming luminous in it, but by enabling it to become luminous as foon as a particle of oxygen is added.

One circumftance of importance fhould be added, which is, that azotic gas in faturating itfelf with phofphorus is found to expand about 1-40th of its bulk, which accounts for the apparent difference in the compofition of common air as determined by phofphorus or by other eudiometrical fubftances. After all abforption has ceafed, when phofphorus is ufed, the apparent lofs is not more than from 20 to 21 per cent. of the atmofpherical air employed, whereas with all the other eudiometrical proceffes the lofs is from 21 to 22 per cent., but this difference may be chiefly accounted for by the expanfion of the refidual azot from its faturation with phofphorus. It is therefore more accurate to diminifh the bulk of the refiduum by 1-40th, and this diminution muft be thrown into the fide of the oxygen abforbed. In analyzing an air much more oxygenous than the atmofphere, in proportion as the azotic ingredient diminifhes, the operation of the phofphorus in removing the oxygen becomes lefs rapid and powerful, and hence either a dilution with pure azot is adviseable, or fome other eudiometrical teft fhould be preferred.

The general refults of all the operations of atmofpherical air have eftablifhed it as an inconteftible truth, that fcarcely any difference exifts in the proportion of oxygen, whatever be the height, feafon of the year, climate, and temperature at which the experiment is made, and even where the greateft changes would be expected from vitiation of air by the refpiration of crowded affemblies of people, and the like, the lofs of oxygen is much lefs than would have been generally expected. Hence the utility of eudiometry as a meafure of the purity of the atmofphere has much diminifhed fince this

fact

faſt has been eſtabliſhed, but the numerous and acute reſearches to which the ſubjeſt has led, have been of high importance to this difficult part of chemical reſearch.

Several kinds of apparatus are uſed in eudiometrical experiments, ſome of which may be here deſcribed.

Dr. Hope's eudiometer is the following. (*Plate* X. *Chemiſtry*, *fig.* 1.) It conſiſts of two parts, the lower of which is a ſhort thick bottle, with an upper and a ſide opening, the latter cloſed by a glaſs ſtopper, and the other receiving a graduated tube cloſed at the top, and accurately fitted by grinding. To uſe it, take off the tube, and fill it quite full of the gas to be examined, and alſo fill the bottle with liquid ſulphuret of lime, and, without ſhaking, ſink it in water, and then immerſe the open end of the graduated tube in the ſame water, and ſlide it upon the bottle and thruſt it in. Then take out the bottle and tube, and ſhake them, to bring the ſulphuret thoroughly in contaſt with the contained gas, and immerſe the bottle from time to time in water, opening the ſide ſtopper to allow the water to ruſh in, and ſupply the vacuum made by the abſorption of oxygen. This will indeed ſomewhat dilute the eudiometrical liquor, but not ſo much as to prevent it from aſting. When all abſorption is over, the quantity of reſidual gas is found by inſpeſtion of the ſcale of the graduated jar.

The apparatus for detonating oxygen and hydrogen, which forms Volta's eudiometer, conſiſts of a very thick graduated glaſs tube, open at bottom, and towards the top are two ſealed holes, admitting the wires by which the eleſtric ſpark is taken. A very uſeful improvement in this apparatus has been introduced by Mr. Pepys, to prevent the violence of the ſhock, either from breaking the glaſs (with moderate quantities) or from throwing out any of the mercury when confined by this fluid. In this improved apparatus, the thick graduated jar is fixed to a heavy iron ſtand, which has a ſtrong ſpring near the foot, that draws out in the manner of the ſteel-yard, when the concuſſion is given, and thus takes off the recoil. *Fig.* 2.

An improved and very uſeful apparatus for nice eudiometrical experiments, is given by Mr. Pepys in the Phil. Tranſ. for 1807, to which we ſhall refer our readers for a full deſcription. It conſiſts of a graduated tube, an elaſtic gum-bottle, furniſhed with a perforated glaſs ſtopper, cloſely fitting to the end of the tube, and another very ſmall tube with a ſurrounding jar for the purpoſe of meaſuring quantities leſs than the ſmalleſt ſubdiviſions of the larger graduated tube. The eudiometrical liquor is put into the elaſtic gum-bottle, and by preſſure is injeſted ſtrongly up into the larger tube, by which means the aſtion is facilitated, and none of the liquor is ſpilled or waſted.

EUDOCIA, in *Biography*, a Roman empreſs, wife of Theodoſius the younger, was daughter of Leontius, an Athenian philoſopher. She was educated in the ſciences and religion of ancient Greece, and ſo great were her mental acquirements and perſonal beauty, that Leontius divided his property between his ſons, conceiving ſhe could ſtand in need of nothing to recommend her to a proper huſband. About the year 421 ſhe was married to Theodoſius, when ſhe renounced the errors of paganiſm, and received the baptiſmal name of Eudocia, having previouſly been called Athenais. She was reconciled to her brothers; and, having invited them to court, conferred upon them offices of rank and power. Upon the throne, as in a more humble ſtation, ſhe cultivated letters, and employed her talents in the ſervice of the religion to which ſhe was a convert. She put into verſe ſeveral of the books of the Old Teſtament, and wrote paraphraſes on ſome of the Jewiſh prophets. She lived for a conſiderable time in harmony with her conſort; and after the marriage of her daughter to the emperor Valentinian III. ſhe was permitted to pay her vows in a ſplendid pilgrimage to Jeruſalem; and at Antioch ſhe pronounced an oration to the ſenate from a throne of gold. After her return, ſuſpicions were excited of her fidelity in the breaſt of her huſband by his ſiſter Pulcheria, who had been the means of bringing them together by marriage. The objeſt of theſe ſuſpicions was Paulinus, a handſome and accompliſhed man, who held high offices at court, and who was put to death on the occaſion. Eudocia was reduced to a private condition, and allowed to ſeek a retreat in the Holy Land, where ſhe had formerly obtained a high degree of credit by the magnifience of her preſents. Here ſhe devoted herſelf to religious and devotional ſtudies, and died in 460 at the age of 67. In her laſt illneſs, ſhe aſſerted in the moſt ſolemn manner her innocence of the crime for which ſhe had been dethroned and ſuffered baniſhment. Moreri. Gibbon's Hiſt.

EUDOCIAS, in *Ancient Geography*, an epiſcopal town of Aſia, in Pamphylia.—Alſo, an epiſcopal town of Aſia, in the ſecond Galatia.

EUDON, a river of Aſia, in Caria.

EUDOXIANS, a party or ſeſt of heretics in the fourth century, ſo denominated from their leader Eudoxius, a native of Arabiſſus in Armenia Minor, and patriarch of Antioch, to which he was advanced in 356, and Conſtantinople, to which he was promoted in 359, and which he retained till his death, in 370. He was a great defender of the Arian doſtrine, though repreſented as ſomewhat fluſtuating and unſteady in his principles. He is charged with being a bitter perſecutor of the Catholics. Of his works, no remains are extant, except ſome fragments of a treatiſe "De Incarnatione Dei verbi;" to which Cave (Hiſt. Lit.) has referred.

The Eudoxians adhered to the errors of the Arians and Eunomians, maintaining that the Son was created out of nothing; that he had a will diſtinſt and different from that of the Father, &c.

EUDOXIOPOLIS, in *Ancient Geography*, an epiſcopal town of Aſia, in Piſidia.

EUDOXUS, the *Cnidian*, in *Biography*, was celebrated as an aſtronomer, a geometrician, a phyſician, and legiſlator, but was moſt particularly diſtinguiſhed in the firſt of theſe charaſters. His firſt preceptor was Archytas, by whom he was inſtruſted in the principles of geometry and philoſophy: about the age of 23 he came to Athens. His knowledge of medicine is ſaid to have been obtained in this way. A phyſician, named Theomodonus, obſerving the ardent deſire which he manifeſted for ſtudy, notwithſtanding his extreme poverty, preſumed that he poſſeſſed talents which deſerved cultivation, and therefore took him to his houſe, and afforded him every means of accompliſhing his wiſhes, enabling him, as his own patrimony was ſmall, to attend the ſchools of the philoſophers, particularly that of Plato. Eudoxus afterwards went into Egypt, accompanied by a pupil, named Chryſippus, and here he was introduced by Ageſilaus to king Neſtanebis II., and by him to the Egyptian prieſts. He is highly celebrated by the ancients for his ſkill in aſtronomy; but none of his writings on this or any other ſubjeſt are extant. Aratus, who has deſcribed the celeſtial phenomena in verſe, is ſaid to have followed Eudoxus; to whom is attributed the honour of bringing the celeſtial ſphere and the regular aſtronomy from Egypt into Greece. Having left Egypt he taught aſtronomy and philoſophy with great applauſe at Cyzicus, on the Propontis; and he afterwards removed to Athens, where he opened a ſchool, and gained ſo high a degree of reputation,

reputation, that he was consulted on subjects of policy as well as sciences, by deputies from all parts of Greece. His death is generally referred to the first year of the 107th olympiad, 352 years before Christ. See Le Clerc. Hist. de la Med. Eloy.

Eudoxus is said by Fabricius (Bibl. Græc. lib. iii. c. 5.) to have written upon music, and he gathers from Theon of Smyrna, p. 94, that Eudoxus was the first who expressed the ratios of concords by numbers, and who discovered that grave and acute sounds depend on the slow or quick vibrations of the sounding body.

EUDRACINUM, in *Ancient Geography*, a town placed by the Itinerary of Antonine on the Alps, between Summus Penninus and Augusta Prætoria.

EUDRAPA, Eder, or *Edir*, a town of Asia, situated in Mesopotamia, W.S.W. from the town of Carmanda.

EUDROME, in the *Ancient Music*, the name of an air played by hautbois at the Sthenian games, instituted at Argos in honour of Jupiter. Hicorax the Argian was the inventor of this air.

EVE, the first woman, and mother of the human race. The history of her formation and other particulars is recorded in the Hebrew Scriptures (Gen. ii. iii. iv.); and it is needless to recite from Bayle and others the absurd fables invented concerning her by the Jewish rabbis.

Eve. See Vigil.

EVEA, or Eva, in *Ancient Geography*, the ancient name of Byblos, a town of Phœnicia.

Evea, in *Botany*, Aublet Guian. v. 1. 100. t. 39. Juss. 208. See Callicocca, spec. 10.

EVECTION, in *Astronomy*, the most considerable of the lunar irregularities, and the first that was known to the ancient astronomers. It was discovered by Ptolemy. Its general and constant effect is to diminish the equation of the centre in the syzygies, and to increase it in the quadratures. If this diminution and augmentation were always the same, the evection would depend alone on the angular distance of the moon from the sun; but the absolute value of the evection depends likewise on the distance of the moon from the perigee of her orbit. After a number of trials and observations, it was found that this inequality could be represented very exactly by supposing it proportional to the sine of double the angular distance of the moon from the sun, *minus* the mean anomaly of the moon. The co-efficient to this proportion is 1° 20′ 30″.

The period of the evection differs but little from the periodic revolution of the moon: it is 27.178533 days. The evection is caused by the action of the sun upon the moon, and may be explained by supposing a change to take place in the excentricity of the moon's orbit, and at the same time a motion in the apogee.

Ptolemy supposed the epicycle of the moon to be carried along in an excentric circle, and that it was nearer to us in the quadratures than in the conjunctions and oppositions; so that to explain this inequality at the same time with the equation of the centre, he imagined an excentric and an epicycle. It is curious to trace the progress of these discoveries, and the history of the first observations of the evection has been transmitted in the words of Ptolemy himself. (Almagest. lib. v. cap. 1.)

In observing, says he, with care, the order of this inequality, we took notice that there was no other than the first and simple inequality in the conjunctions and oppositions, and even in the quadratures when the moon was in apogee or perigee, (meaning by the simple inequality the equation of the centre); but we may be assured that this is not sufficient to calculate the particular motion of the moon in other aspects. The second inequality, (*i.e.* the evection,) is connected with the distance of the moon from the sun, and is re-established and disappears in the conjunctions and oppositions, and is greatest in certain quadratures. We discovered this inequality by the observations transmitted by Hipparchus, and by those which we have made by means of an instrument constructed for the express purpose of measuring the difference of longitude on the zodiac between the moon and the sun.

Ptolemy found that there was a difference of $2\frac{2}{3}°$ between the observed and the calculated place (when the first inequality or equation of the centre was only used) when the moon in quadrature was three signs from the apside. (Almagest. v. 3.) Then the sun being in the apogee or perigee of the moon, the inequality, which should have been 5°, was found $7\frac{2}{3}°$; to explain which he supposed the epicycle as above-mentioned.

Copernicus, to explain the evection, employed two epicycles. The small epicycle is supposed to describe the circumference of the great one in the space of an anomalistic revolution, and contrary to the order of the signs; while the moon describes the small epicycle contrary to the order of the signs in $14^d\ 18^h$, or in the space of half a synodical revolution.

It was in this manner that the second inequality of the moon, called now the evection, was explained till the time of Tycho. It was called by Ptolemy "προσνευσιν, epicycli quasi annutum," by Copernicus "prostaphæresim secundi vel minoris epicycli," by Tycho "prostaphæresim excentricitatis," and by Bouilliaud "evection," which name it still retains.

The evection was explained in a different manner by Horrox about the year 1640; but his theory was not made known till 1673, when Flamstead calculated his new tables of the moon, upon the principles and numbers given him by Horrox. These tables were published in the posthumous works of Horrox in 1673. This hypothesis is the same with that of Arzachel, an astronomer who flourished in Spain in 1080, when that country was possessed by the Arabians, and who applied it to the motion of the sun. Let T be the centre of the earth (*Plate* XII. *Astronomy*, *fig.* 107.), C the mean place of the centre of the orbit which a planet is supposed to describe; so that T C A may be the line of the apsides, and T C the excentricity of the planet. If the centre of the orbit, instead of being fixed in C, be supposed to describe the circumference of a small circle A C B, there will result a double effect: 1. The line of apsides T A will change its position, and instead of remaining constantly in the direction T C A, it will pass, for example, into the position T G, and will make with the first position an angle A T G. 2. The excentricity, instead of being equal to the original quantity T C, will become T G, T B, &c. This hypothesis was invented by Arzachel to explain a supposed diminution of the excentricity of the sun's orbit, which he had inferred from some defective observations, and has not only been adopted by Horrox to deduce this inequality of the moon, but by Flamstead, Halley, and Newton, for the same purpose.

Kepler had already announced that he employed an excentricity of the lunar orbit which varied every year; but Horrox was led likewise to this hypothesis by observations of the diameter of the moon; for about this time the application of micrometers to telescopes enabled astronomers to determine the apogee and perigee of the moon much more exactly than formerly. From these observations he perceived that the apogee of the moon was about 25° more advanced when the distance from the sun to the apogee of of the moon was 45° or 225°, than when it was 135° or 315°; hence the motion of the apogee, inftead of being uniform, feemed to have an annual libration of more than 12°. This variation in the motion of the apogee being once known, its connection with a change of excentricity was not difficult to be difcovered. Both Halley and Newton employed the above hypothefis. According to the method of Newton the centre A of the orbit of the moon (*fig.* 108.) defcribes a circle A C B, the earth being at T. Thus T C expreffes the mean excentricity of the moon; T A the greateft excentricity, and T B the leaft; T C being to C B as the mean excentricity is to its difference from the leaft, or as the total fine is to the fine of $12^\circ\ 18'$, which is the greateft equation of the apogee. It is likewife fuppofed that if the angle A C G be taken equal to double the annual argument, or the diftance between the fun and the mean apogee of the moon for a given time, the angle C T G will be the equation of the apogee, and T G the excentricity for the fame time. Then in the triangle T C G, the two fides and included angle being given, we have the fum of T C, and C G is to their difference as the tangent of half A C G, (or the annual argument, whofe double is A C G,) is to the tangent of half the difference of the unknown angles. This is reduced to a conftant logarithm, which added to that of the tangent of the mean annual argument, gives the annal argument corrected; and this, added to the place of the fun, gives the true place of the apogee of the moon. This is the form which Halley employed in his lunar tables.

It efcaped the obfervation of Flamftead, Halley, and Newton, that this equation might be calculated without fuppofing a variable excentricity and libration of the apogee. Euler employed this method, of which the following is the demonftration.

Let L (*fig.* 109.) be the moon, T the earth, C the mean centre of the lunar orbit, G the centre for a given moment; C T the mean excentricity of the moon, C L T the half of the mean equation of the orbit, becaufe it is the double excentricity which produces the whole equation; G L T the half of the evection for the time given, and reprefented in Newton's method by an augmentation of excentricity; C L G is the difference of thefe two equations, or the effect which the change of excentricity, and the libration of the apogee, produce upon the half equation. To find by a fimple operation this angle C L G, which is the half of the evection, it muft be remembered that when this angle is the greateft, or when L C is perpendicular to C G, the angle C L G is 40′, that is, the conftant relation between C L and C G is fuch, that the value of L can only be 40′ when it is the greateft, or $1^\circ\ 20'$ for the whole evection. When the angle L C G is oblique, the angle C L G will diminifh, and that in the ratio of the perpendicular G D to the line C G, or as the fine D C G to radius. Hence the evection will be 80′ fin. D C G; but the angle D C G = A C L − A C G is the mean anomaly of the moon, minus twice the diftance of the fun from the moon's apogee, or what is the fame, twice the diftance of the moon from the fun, minus the mean anomaly of the moon, which forms the argument of evection.

The half evection, or angle G L C, is equal 40′ fin. (2 dift. ☾ ☉ — m. anom. ☽.) This is the form in which it is ufually found in the lunar tables.

When we come to treat of the theory of the moon, and the lunar inequalities, we fhall have occafion to refume this fubject, and to fhew how correctly this equation is derived from the law of univerfal gravitation; we fhall confine ourfelves at prefent to a very general explanation of the phyfical caufe of this phenomenon.

When the fun correfponds to the apogee or perigee of the moon, that is, when the line of apfides of the moon coincides with the line of the fyzygies, the central force of the earth upon the moon, which is the weakeft in the fyzygy apogee, receives the greateft diminution, and the central force, which is the ftrongeft at the fyzygy perigee, there receives the leaft diminution, therefore the difference between the central force perigee and the central force apogee will then be the greateft, and the difference of the diftances will be augmented, that is, the excentricity will become greater, and obfervation fhews that the equation is then $7^\circ\ 40'$, whereas it does not exceed 5° when the line of the quadratures coincides with the line of the apfides.

The formula for the evection in the lateft tables is $1^\circ\ 20'\ 28''$ fin (2 dift. ☾ ☉ — mean anomaly ☽); from which it is eafy to follow the fucceffive variations of this equation, for it is only requifite to confider the different values which its argument can take. If it be required, for inftance, to determine when it arrives at its maximum, we have only to inveftigate the cafe in which the angle 2 dift. ☉ ☽ — m. anom. ☽ becomes equal to 90°, or 270°, or its fine equal to unity, the evection will then be equal $1^\circ\ 10'\ 21''$: the firft of thefe values will happen in the quadratures, when the mean anomaly is equal 90°, for then 2 dift. ☾ ☉ = 180° 2 dift. ☉ ☽ — m. anom. ☽ = $180^\circ - 90^\circ = 90^\circ$; on the contrary, the evection will difappear, when the argument is zero or 180°, this will happen in the fyzygies when the moon is either perigee or apogee, for then the diftance of the moon from the fun is equal 0° or 180°, and the fame of the mean anomaly. But by the various combinations of the two angles which form the argument of evection, the greateft and leaft values will arrive, even in feveral other points of the orbit. In general, in the conjunctions, the evection will have a contrary fign to the equation of the centre, for its argument is reduced to — mean anom. ☽, which gives a negative fign if the anomaly is lefs than 180°, and a pofitive fign if it is greater; but in the firft cafe the equation of the centre is additive, and in the fecond it is fubtractive. It is eafy to comprehend that it will be the fame in the oppofitions, hence it follows that in the fyzygies the evection is fubtractive from the equation of the centre, on the contrary it is additive in the quadratures. Thus the firft obfervers that examined the theory of the moon's motion only by means of eclipfes, and with no other view but to predict thofe phenomena, always found the equation of the centre too fmall, by the quantity of the evection in the fyzygies.

It is not difficult to find the period of the evection from the variations of the value of the angle on which it depends; it is fufficient to calculate the variations of this angle in a given time; and to conclude, by a fimple proportion, the number of days neceffary for it to vary 360°.

The fynodical motion of the moon in one century is $445267^\circ\ 6'\ 55''.46$, multiplying this by two, we have $890534^\circ\ 13'\ 50''.92$ for the double of the diftance of the moon from the fun, after a hundred Julian years. If from this we take the anomaliftic motion of the moon, in the fame interval, or $477198^\circ\ 41'\ 30''.6$; the difference $413335^\circ\ 32'\ 20''.3$ will be the value of the argument of evection, after 100 Julian years; from whence it appears, that this argument increafes 360° in a number of days expreffed by 360.36525, or 27.178533 days; this is the period of the evection, after which period it fucceffively takes again the fame values.

From this it appears, that fubftituting, inftead of thefe angles, their values calculated as above, the argument may be put in the form of a quantity proportional to the time; for

E V E

For example, if we name the number of days elapſed ſince a given epoch as that of the tables t. The angle 2 diſt. ☽ ☉ —m. anom. ☽ will become $\frac{t \cdot 360}{27.178533}$, and the evection may be repreſented under this form $1° \; 20' \; 28'' \left(\frac{360 \cdot t}{27.178533}\right)$ or ſimply $1° \; 20' \; 28''$ ſin. m. t. making $m = \frac{360}{27.178533}$.

EVEILLON, James, in *Biography*, was born at Angers in the year 1542; he was diſtinguiſhed at a very early age for his literary acquirements, and obtained conſiderable eccleſiaſtical preferment, in the place of his birth, till at length he was made grand-vicar to the biſhop. Eveillon was looked up to for his ſuperior knowledge of the rights and uſages of the church; and of every ſubject connected with the councils, the fathers, and the canon law. He was not unfrequently employed in matters relating to church diſcipline, the reformation of breviaries, rituals, and monaſtic inſtitutions. His principal works were entitled "De Proceſſionibus Eccleſiaſticis, in quo earum Inſtitutio, Significatio, Ordo, et Ritus explicantur."—"De recta Pſallendi Ratione;" and "A Treatiſe on Monitions and Excommunications," which has borne a high character in the Catholic communion. Eveillon died at the age of 79, in the year 1621. He was a man of extenſive benevolence, having obtained the title of father to the friendleſs, and the poor, to whoſe relief he devoted the whole of a liberal income, excepting what was abſolutely neceſſary for his own ſupport. Moreri.

EUELPIDIUM, a kind of fluid collyrium.

EUELPISTI, a plaſter deſcribed by Scribonius Largus.

EVELYN, John, in *Biography*, the ſon of Richard Evelyn, eſq. was born at Wotton, in Surrey, in 1620. He received the early part of his education at Lewes, from thence he went to Chriſt church, Oxford. During the civil wars he ſpent his time on the continent, particularly in France and Italy. He married in the year 1647 the only daughter of ſir Richard Browne, the king's miniſter at Paris, and returned to England about the year 1651, where he employed himſelf in literary occupations, chiefly in tranſlating from the French and Latin. He was much inclined to a life of learned leiſure; and in his zeal to forward a ſimilar plan for others he formed a ſcheme for the erection of a college, where perſons might live together in philoſophical retirement, and in the purſuit of common ſtudies. In 1657 he publiſhed a favourable account of the king's character, with a view of preparing his countrymen for the reſtoration of monarchy, and on the return of the exiled Charles, he was graciouſly received, and introduced into public life, though without abandoning his literary purſuits. In 1662 he publiſhed a curious and learned work, containing much uſeful and important information, entitled "Sculptura, or the Hiſtory and Art of Chalcography, or Engraving on Copper." This piece was reprinted in 1755, with additions. Mr. Evelyn practiſed the art himſelf, and is introduced by Mr. Walpole into his catalogue of Engliſh engravers. On the inſtitution of the Royal Society, he was nominated among the firſt fellows and members of the council, and he ever after continued a zealous and truly active member of that learned body. At ſome of the early meetings of the ſociety was read his diſcourſe on foreſt trees, which was the baſis of the treatiſe entitled "Sylva, or a Diſcourſe of Foreſt Trees, and the propagation of Timber in his Majeſty's Dominions, to which is annexed Pomona, or an Appendix concerning Fruit Trees, in relation to Cyder, &c." As a ſequel to this work, he afterwards publiſhed his "Terra, a Philoſophical Diſcourſe of Earth, relating to the Culture and Improvement of it for Vegetation, and the Propagation of Plants." Both theſe works have been reprinted ſeveral times. The edition of the Sylva by Dr. Andrew Hunter, of York, is with plates of all the trees, in which their parts of fructification are accurately diſplayed according to the Linnæan ſyſtem. Mr. Evelyn was appointed, at the deſire of the king, in 1664, one of the commiſſioners of the ſick and wounded ſeamen, and likewiſe a commiſſioner for rebuilding St. Paul's cathedral. How well fitted he was for the latter office was ſhewn by a work which he publiſhed, entitled "A Parallel of the Ancient Architecture with the Modern," tranſlated from the French of Roland Freart, ſieur de Chambray; with additions from Alberti and others. He reſided at this period at his houſe of Sayes-court, near Deptford, which he had in right of his wife; here he cultivated a garden, and was regarded as a great improver of the art of horticulture, and celebrated for the pains which he took in the introduction of exotics into this country. During the reign of Charles, a board of trade was formed, and Mr. Evelyn was appointed one of its members. On this occaſion he drew up a ſmall treatiſe on the origin and progreſs of navigation and commerce, with an aſſertion of the king's title to the dominion of the ſea. Among the papers which he communicated to the Royal Society is a curious letter, given at length in the Biographia Britannica, deſcribing the miſchiefs done to his garden by the ſevere winter of 1683–4. This letter will be read with intereſt, as affording information of the perennials at that time chiefly cultivated in England, and as ſtating the dire effects of rigorous froſt. We ſhall give the concluding paragraph:

"The vines have eſcaped, and of the eſculent plants and ſallads, moſt, except artichokes, which are univerſally loſt; and what I prefer before any ſallad whatever, eaten raw when young, my ſampier is all rotted to the very root. The arboreſcent and other ſedums, aloes, &c. though houſed, periſhed with me, but the yucca and opuntia eſcaped. Tulips, many are loſt, and ſo the Conſtantinople-narciſſus, and ſuch tuberoſæ as were not kept in the chimney corner, where was a continual fire. Some anemonies appear, but I believe many are rotted. My tortoiſe, which by his conſtant burying himſelf in the earth at the approach of winter, I looked upon as a kind of plant animal, happened to be obſtructed by a vine-root from mining to the depth he was uſually wont to inter, is found ſtark dead, after having many years eſcaped the ſevereſt winter. Of fiſh I have loſt a few, and the nightingales, which for being a ſhort winged bird, and ſo exceedingly fat at the time of the year, we commonly ſuppoſe them to change the climate, whereas indeed they are then hardly able to fly an hundred yards, are as briſk and frolic as ever; nor do I think they alter their ſummer ſtations whatever may become of them all the winter."

In the reign of James II. Mr. Evelyn was, during the abſence of the earl of Clarendon in Ireland, made one of the commiſſioners for executing the office of lord privy ſeal, and after the revolution he was appointed treaſurer of Greenwich hoſpital. In 1697 he publiſhed a diſcourſe on medals, entitled "Numiſmata, &c." and his laſt work was "Acetaria, a Diſcourſe of Sallets," in which he treats of the nature and properties of all plants which have been employed as ſallad herbs. This diſcourſe was inſcribed to lord chancellor Somers. The dedication, which is written with much elegance, was intended to procure, if poſſible, a public eſtabliſhment for the Royal Society. Mr. Evelyn died in Feb. 1706 in his 86th year, having paſſed his days in uſeful and elegant purſuits, and diſtinguiſhed by benevolence, piety, and integrity. Biog. Brit.

Evelyn, John, ſon to the former, was born Jan. 14, 1654, at his father's houſe at Deptford. He was at a very early age admired for his rapid progreſs in knowledge, ſo that in the year 1666 he was ſent to Oxford under the ſpecial care of Dr. Bathurſt, till he could be admitted a gentleman commonner, which was in the Eaſter term, 1688. It does not appear that he took his degrees there, but returned to his father's houſe, where he proſecuted his ſtudies with much diligence and ſucceſs. During his reſidence in Trinity college, he is ſuppoſed to have written the elegant Greek poem which is prefixed to the ſecond edition of the Sylva. He became deeply learned in the ancient and modern languages, and cultivated poetry, of which there is evidence by a tranſlation "Of Gardens, firſt written in Latin by Renatus Rapinus." This was publiſhed when the tranſlator was a youth of nineteen years of age only. He afterwards tranſlated Plutarch's life of Alexander the Great from the Greek; and from the French he gave a tranſlation of "The Hiſtory of the Grand Viziers, Mahomet, and Achmet Coprogli." He was likewiſe author of ſeveral poems, two of which have been chiefly admired, the one "On Virtue," and the other was entitled "The Remedy of Love," and have been inſerted in Dryden's Miſcellanies. Mr. Evelyn was a man of buſineſs as well as a cultivator of literature, and was appointed one of the commiſſioners of the revenue of Ireland. He died in the prime of life, in London, March 24, 1698, in the forty-fifth year of his age, leaving behind him two ſons and three daughters. Biog. Brit,

EUE'MBOLOS, (from ευ *well*, εν, *in*, and βαλλω, *to caſt*,) a perſon ſkilful in ſetting bones.

EVEN Foot, in *Poetry*. See Foot.

Even *number*, is that which may be divided into two equal parts or moieties. See Number.

EVENELADS, in *Geography*, a river of England, in the county of Oxford, which runs into the Iſis, about 5 miles W. of Oxford,

EUENES, a town of Norway, 18 miles N. of Drontheim.

EVENING Star, in *Aſtronomy*. See Vesper.

Evening *iſland*, in *Geography*, a ſmall iſland in the Pacific ocean. N. lat. 2° 46'. W. long. 133° 17'.

EVENLY *even number*, is that which is exactly diviſible by an even number taken an even number of times; ſuch is 32, ſince it is diviſible by 8, taken four times.

Evenly *odd number*, is that which an even number meaſures by an odd one; as 30, which is meaſured by 6, taken five times.

EVENUS, in *Ancient Geography*, a river of Aſia Minor, according to Pliny, who ſays that the towns of Lyrneſſa and Miletus were built upon its banks. The inhabitants of Adramyttium drew water from this river by means of canals. Strabo.

Evenus, *Fidari*, a river of Greece, in Ætolia, which took its riſe towards the north-eaſt in mount Pindus, on the frontiers of Theſſaly, and paſſing through the territories of the Bomiæi, Ophienſes, and Apodoti, watered Calydon, and diſcharged itſelf into the ſea; to the weſt is the town called Chalcis. It was on the banks of the Evenus that Hercules, according to the fable, ſlew the centaur Neſſus.

EVERARD'S *ſliding rule*. See Sliding.

EVERBODE, in *Geography*, a town of France, in the department of the Dyle; 5 miles N. of Dieſt.

EVERDINGEN, Cæsar Van, in *Biography*, a painter of hiſtories, portraits, and landſcapes, born at Alkmaer in 1606. The maſter under whom he ſtudied, Van Bronkhorſt, ſoon obſerved and encouraged his ſuperior talents from among the reſt of his diſciples. He had a lively invention, and painted with freedom and firmneſs, and a good force of colouring.

Many of his pictures are ſpoken of in terms of praiſe; but the one ſelected as his principal performance is the repreſentation of the victory of David over Goliath. It was painted on the folding doors of the organ in the great church at Alkmaer; and the ſketch of it was preſerved in the council chamber of that city; it was painted in 1648. He died in 1679, aged 73.

Everdingen, Aldret Van, a landſcape painter, whoſe merit was very conſiderable. He was the nephew of Cæſar Van Everdingen, and was born in the ſame city, Alkmaer, in 1621. Having firſt attended to the inſtructions of Roland Savery, he afterwards greatly improved by thoſe of Peter Molyn; whom at laſt he ſurpaſſed in ſkill. He delighted moſt in the grand ſcenes of nature, or rather her more romantic features, ſuch as rocks, torrents, and cataracts, which he executed with great freedom and variety of touch. In his time he had no ſuperior, but Jacob Ruyſdael followed him immediately, was indeed partly contemporary with him, and in his own ſtyle left him far behind in the brilliancy and force of his colours and execution, and the choice of his forms. However, Everdingen is highly deſerving of great praiſe for the care which he took to make himſelf acquainted with the effects of nature, and the truth with which he marked them. He made a voyage up the Baltic, and was much gratified by and made much uſe of the ſcenery, which the romantic coaſts of that ſea, and of Norway, (which he alſo viſited) afforded him. He died in 1675, and left behind him a great number of drawings, both of real views and compoſitions, which are very freely wrought. He was thought not to ſucceed ſo well in large works as in ſmaller ones, thoſe coming more within the management of the neatneſs of pencilling, which characterizes his ſtyle of execution. The latter are very highly and very deſervedly valued in Flanders and Holland.

Everdingen, in *Geography*, a town of Holland, in Guelderland; three miles W. of Culemburg.

EVERET'S Bridge, a place of Nanſemond county, in Virginia; where is a poſt-office; 266 miles from Waſhington.

EVERGEM, a town of France, in the department of the Eſcaut, and chief place of a canton in the diſtrict of Gand. The place contains 6878, and the canton 13,176 inhabitants, on a territory of $67\frac{1}{2}$ kiliometres and four communes.

EVERGETÆ, in *Ancient Geography*, a people of Aſia, placed by Strabo in the vicinity of Drangiana.

EVERGETES, Ευεργετης, a Greek term, ſignifying *benefactor*, being formed of ευ, *bene*, *well*, and εργον, *opus*, *work*. It is ſtill retained in our language by way of addition or epithet given to two princes or kings of Syria and Egypt, who ſucceeded Alexander. Thus we ſay Ptolemy Evergetes, king of Egypt, Antiochus Evergetes king of Syria.

EVERGREEN Thorn, in *Gardening*. See Mespilus *Pyracantha*.

Evergreen *Trees*, are ſuch trees, whether of tall or ſhrubby growth, as conſtantly retain their leaves during the whole year. There is a great number of this ſort of

plants,

plants, which will be particularly defcribed under their proper genera.

Thefe kinds of trees, fhrubs, &c. are increafed in different modes, according to their particular nature, as by feeds, layers, cuttings, fuckers, &c. which is fully fhewn under the culture of the different forts, but principally in the fpring feafon, though occafionally in the fummer, and frequently in the early autumn.

The proper feafons for planting them out are the early autumn or latter fpring months, according to the nature of the foil. Where the foils are of the more ftiff, retentive, moift kind, the more advanced fpring months are the beft; but where they are of the light, dry, loofe defcription, the beginning of the autumn is the moft proper period; as in the former cafe the plants will be in no danger of being injured by ftagnant moifture in the winter, and in the latter there will be no rifk of their being deftroyed by the heat and drynefs of the fummer, before they become perfectly eftablifhed in the ground.

In the planting of evergreen trees, it is feldom neceffary to put them into any great depth, as they are very liable to be deftroyed by deep planting. There is likewife another circumftance that ought to be regarded, which is that of having the mould in which they are to be fet fufficiently fine, and the roots well bedded in it, without being too much cut in or retrenched. In all cafes the loofe mould fhould be well trodden in about them; and the more tall growing kinds well fupported with ftrong ftakes, fo as to keep them perfectly fteady in their fituations. Numbers of trees of this, as well as other forts, are deftroyed for want of attention in this refpect, as when once they get loofe they foon die by the motion which takes place. The pruning or cutting in of this fort of trees, where it is neceffary, fhould be performed either in the more advanced fpring feafon, or the latter part of the fummer, but never in the winter feafon, as they are liable to much injury from cold. This is equally neceffary to be regarded in the clipping of hedges conftituted of plants of this fort.

Many of thefe forts of trees and fhrubs are fufficiently hardy to admit of being planted in moft forts of foils and fituations. The tall-growing kinds are well adapted for affording ornament and variety in mixture with thofe of the deciduous clafs in extenfive plantations, and fuch as are of a fhrubby growth in the borders, clumps, and other parts of ornamented grounds. In thefe fituations they fhould be fuffered as much as poffible to take their natural growth, efpecially the fir kinds, and in the others only very little cut in, and the dead wood removed from them.

In the forming of hedges various plants of this fort are employed; but the beft are thofe of the holly, yew, evergreen privet, and box kind; though the common laurel and lauruftinus may be the moft advifeable, where they are required to be lofty. Thefe are likewife capable of being trained fo as to cover naked walls, palings, or other unpleafant objects. Hedges formed of thefe plants fhould be clipped once or twice during the fummer feafon, fo as to keep them in perfect neat order.

Various ornamental devices were formerly made with thefe and other forts of evergreens in gardens; but thefe are at prefent little in ufe, as a better and lefs troublefome tafte prevails.

It has been remarked by the author of "The Philofophy of Gardening," that in thefe forts of trees and fhrubs the buds rife in the bofoms of the leaves, which, as they are not fhed in the autumn, continue to oxygenate the juice of the plants, and fupply nutriment to the buds during the fine days in the winter and fpring feafons, furviving till nearly the middle of fummer, when the new buds have expanded leaves of their own. It is hence conjectured, that evergreens provide no ftore of nourifhment in their roots, or alburnum in the fummer for the fupport of their enfuing vernal buds, and of courfe have probably no bleeding feafon, as is the cafe with thofe of the deciduous kind.

And there is another circumftance which has been ftated by Dr. Milne, in his botanical dictionary, to take place in refpect to evergreen trees, which is, that when they are engrafted on thofe of the deciduous fort, it determines the latter to retain their leaves. This is afferted to be confirmed by repeated experience, in grafting the laurel, (*lauro-cerafus*) an evergreen, on the common cherry, (*cerafus*), and the (*ilex*), an evergreen oak, on the common oak. And it is probable that many other facts of the fame kind may exift, though they have not been noticed by common gardeners.

EVERLASTING. See GNAPHALIUM.

EVERLASTING *Pea*. See LATHYRUS.

EVERLASTING *Pea*, in *Agriculture*, is the common name of a perennial plant of the vetch kind, which grows naturally in fome fituations in this country; and is capable of being cultivated with great care and advantage as a green food for cattle or other ftock, where the foils are inclined to be of the more heavy loamy kinds; as it affords a large produce of the moft nutritious fort of fodder. Where it is fuffered to ftand till the feeds are formed, it has been found in the few trials that have been made with it to poffefs a highly fattening property when confumed by animals.

EVERRIATOR, derived from *ex* and *verro, I cleanfe*, in *Antiquity*, an officer who was obliged in a folemn manner to cleanfe fuch houfes as were defiled by dead bodies, called *domus funeftæ*.

EVERRICULUM, (from *everro, to fweep away*,) a kind of inftrument, in *Surgery*, refembling a fpoon, and ufed for taking away any fmall fragments of the ftone, which may remain behind in the bladder, in the operation of lithotomy.

EVERS, in *Rural Economy*, a term fometimes provincially applied to thofe ftiles which open; in which cafe the top rail has a bolt of iron driven through it at one end, the other falling into a notch in the oppofite poft, by which contrivance an opening can occafionally be readily made.

EVERSBERG, in *Geography*, a town of Germany, in the kingdom of Weftphalia; 34 miles N. of Cologn.

EVERY YEAR'S-LAND, in *Agriculture*, is a term applied to fuch lands as have been cropped with what are termed brown and white crops, or pulfe and grain crops, in alternation or fucceffion for a very great length of time, without the intervention of any fort of fallow. Mr. Marfhall has remarked that extenfive common fields in Gloucefterfhire have been conducted under this fort of management for "perhaps centuries:" and the fame is the cafe in fome other countries.

EVES-DROPPERS, in *Law*. See EAVES-DROPPERS.

EVESHAM, or ESAM, in *Geography*, is a borough and market town, pleafantly fituated upon a rifing ground, above the banks of a navigable river, named the Warwickfhire Avon, in the hundred of Blakenhurft, and county of Worcefter, diftant from London ninety-fix miles. This place claims high antiquity, and is not lefs notable for its fubfequent celebrity. The firft notice of it upon record, like the origin of moft towns referable to the Saxon period, is the account of Egwin, bifhop of Worcefter, having founded a monaftery here in the year 709: and amply endowed it by the affiftance of Kenred, fon of Wulpher, king of Mercia. This was one of the mitred abbies; its abbot fat in the houfe of peers as a baron of the realm; its privileges were numerous and extenfive, and the revenues on the diffolution were valued at the annual fum of 1183*l.* Of the building, which from records appears to have been immenfe, few veftiges remain. The large elliptical arch, decorated with rich but mutilated imagery, is ftill ftanding; and the tower noticed by Leland. "Clement Lichfeild the laft abbot of Evefham fave one, did very much coft in buildinge of the abbey and other places longing to it.—He made a right fumptuoufe and high fquare towre of ftone in the cemitery of Eovefham. This tower had a great bell in it, and a goodly clocke, and was as a gatewav to one piece of the abbey." Itinerary, vol. iv. p. 108. This tower is a regular and beautiful ftructure, twenty-two feet by twenty-two, and one hundred and feventeen in height; and is generally confidered the laft monaftic building erected under papal influence in England. Though the churches have towers, this ftill continues the ftation for the clock and bells.

In that part of the town called Bengeworth, which may be viewed as a fuburb on the eaftern fide of the river, over which the communication is formed by a handfome ftone bridge of feven arches, ftood an ancient caftle, probably erected foon after the Norman conqueft. For in the year 1152, abbot William de Audville gained this fortrefs from lord William de Beauchamp, who held it for king Stephen, razed it level with the ground, and converted the fite into a place of interment.

Evefham is a very ancient borough, enjoying numerous privileges, both by prefcription and charter. It was one of the towns fummoned by writ to fend members to parliament, in the twenty-third year of king Edward the Firft's reign, when he bafely pretended to reftore the Saxon conftitution; and was one of the eight boroughs which had their elective franchife reftored in the time of James the Firft. That monarch at the fame time granted a charter to the town to be governed by a mayor, feven aldermen, twelve burgeffes, and twenty-four affiftants, recorder, chamberlain, who are alfo of the common council, and other fubordinate officers. The mayor and four fenior aldermen are juftices of the peace, form a *quorum*, and have power to hold a feffions of *oyer* and *terminer*, and gaol delivery, to punifh all crimes, except high treafon, and execute felons within their liberty.

The town is much altered fince Leland vifited it; the houfes, which then were what are called *half-timbered*, that is, timber frames, having the open parts filled up with wattle and dab, are moftly well built with brick, the ftreets are wide and fpacious, and the falubrity of the air, with the beauty of the fituation, induce many genteel families to take up their refidence here. In the town are three parifh churches, two in the part ufually called Evefham, and one in Bengeworth; a well endowed free grammar fchool, charity fchool, and alms-houfe. The market, held on Mondays, is well fupplied, and four annual fairs are held Febuary the fecond, the firft Monday after Eafter, Whit-Monday, and the twenty-firft of September. From the late returns to government under the Population act, the number of houfes appear to be 616, and of inhabitants 2837. The richnefs of the foil in the vicinity has been long an inducement to turn many of the fields into garden ground, and the peculiar finenefs of the vegetable productions of this place has rendered Evefham gardeners proverbial for unrivalled fkill. They not only fupply the neighbourhood, but alfo the city of Worcefter, fourteen miles diftant; Birmingham, thirty; and during the afparagus feafon Bath and Briftol, more than fifty. Tindal's Hiftory and Antiquities of Evefham.

Evesham, *Vale of.* The fine tract of land comprized under this denomination, unrivalled in fame or fertility, is fituated on the eaftern and weftern banks of the river Avon, extending for feveral miles in various directions into Warwickfhire, where it is bounded by the high land of the Ridgeway, and into Gloucefterfhire, where the Cotfwold hills form a terminating barrier; and the fouth is wafhed by the river Severn.

It is defcribed in Monaftic hiftory as having derived the name, which it gives to the town already defcribed, from *Eoves*, a Saxon, fwine-herd to Egwin bifhop of Worcefter, in the latter end of the feventh century: this ham having been Egwin's property till he was dethroned by the pope, and his eftates confifcated. Previoufly to this it was called Heth-holme, or Heath-field.

To thofe who wifh to fee what "fun and foil," unaffifted by art, can do, parts of this diftrict will furnifh ftriking fpecimens. And to the admirers of agriculture other portions will evince what wonders may be effected from aiding the efforts of nature by the application of art. The foil is principally a deep heavy loam, or rich loamy clay, of inexhauftible depth, equally calculated for corn, or pafturage. And whether it be placed under an arable, or a grazing fyftem, the produce and the profits alike exceed analogical belief. The vale of Evefham, fays Leland, "is, as it were, for fuch an angle, the horreum of Worcefterfhire, it is fo plentiful of corn;" and juftly has he characterized this prolific fpot. For the abundance of herbage is not equalled by the famous Tilney fneeth in the hundred of Marfhland and county of Norfolk; nor can the crops of corn be furpaffed, except by thofe defcribed in Brydone's Tour as produced in the vales of Sicily. The rent of lands in the farms of this diftrict is equal to that of accommodation lands in moft other parts of the kingdom; yet perfons who have occupied eftates in fome others, at an exceeding low rate on a comparifon of the net proceeds from both, do not hefitate in deciding in favour of the higher rental. In this vale, about a mile diftant from the town of Evefham, was fought the moft memorable battle recorded in the annals of Englifh hiftory, between Simon de Montfort, the powerful earl of Leicefter, and prince Edward, afterwards king Edward the Firft; in which the earl was completely defeated, and the refractory barons, with moft of their adherents, taken or flain. He has been not unaptly compared to the Roman confpirator Catiline, for, like him, he verified in his conduct the remark of Tiberius, recorded in Tacitus Ann. l. iv. c. 18. "Beneficia eo ufque læta funt, dum videntur exfolvi poffe." "Favours are only fo long properly beftowed as there appears a probability, or at leaft a capability of return." After king Henry the Third had conferred upon him an accumulation of honours and emoluments, and even permitted him to marry the princefs, his fifter; he experienced from the earl the moft ungrateful requital. He purfued the monarch with the moft inveterate hatred; and by inflammatory fpeeches, and other overt acts, excited the moft perplexing commotions, and diftreffing inteftine warfare, the kingdom ever experienced; under a pretence of reftraining the prerogative, reforming the government, and afcertaining and fecuring the liberties of the fubject. The conteft, however, was productive of good, intended by neither of the parties. The prince, when he had afcended the throne, determined to ftill further curtail the enormous power of the barons; and by his writs fummoned together, as his advifers, reprefentatives from numerous cities and boroughs, as well as counties; the battle of Evefham therefore may be confidered "as the origin of our prefent houfe of commons."

Evesham, a townfhip of America, in Burlington county, New

New Jerfey, fituated between the forks of Moore's creek, which runs north-wefterly to Delaware-river; 16 miles E. of Philadelphia.

EVESPERIDES, in *Ancient Geography*, a people of Africa, in the maritime part of Libya, to the weft of the Aufchifes: whofe country, according to Herodotus, was fingularly fertile; whence it has been fuppofed that the famous garden of the Hefperides was found in their territory. This name, in its grammatical acceptation, fignifies Occidentals.

EVESPERIS, a town on the coaft of Africa, which afterwards took the name of Berenice.

EVEST, in *Geography*, a river of Ruffia, which runs into the Dwina, near Kreutzburg.

EUEXIA, from ευ, *well*, and εξις, *habit*, in *Medicine*, a good found habit of body.

EUFEMIA, St., in *Geography*, a town of Naples, in the province of Otranto, two miles N.N.E. of Aleffano. —Alfo, a town of Naples, in Calabria Ultra, fituated on a bay of the Mediterranean, to which it gives name. N. lat. 39° 2'. E. long. 16° 30'.

EUFRA, a town of South Finland; 12 miles N.N.E. of Abo

EUGALENUS, Severinus, in *Biography*, a phyfician of Doccum, in Friefland, known chiefly as the author of a treatife on the fcurvy, which once maintained a confiderable character, and paffed through many editions. Its title is "De Scorbuto Liber, cum Obfervationibus quibufdam, brevique et fuccinctâ cujufque curationis indicatione, 1604." But the treatife of Dr. Lind, on the fame fubject, in which the abfurdities and ignorance of Eugalenus are pointed out, has fuperfeded it. Eloy. Mangeti Bibl. Script. Med.

EUGANEI, in *Ancient Geography*, a people of Italy, towards the Alps.

EUGANO, in *Geography*, a mountain of Italy, in the weft part of the Paduan, bordering on the Vicentin.

EUGENE, Francis, of Savoy, in *Biography*, generally denominated prince Eugene, grandfon of Charles-Emanuel, duke of Savoy, was born at Paris in 1663, and deftined for the church. His mother, on account of her ill-conduct, was obliged to leave Paris. She retired to Bruffels, and young Eugene being deprived of her fupport, and having been difappointed in his expectations of preferment, went as volunteer to ferve in Germany againft the Turks. He, with other French volunteers, was recalled on pain, in cafe of difobedience, of perpetual banifhment. He fet the order at defiance, and fo much diftinguifhed himfelf in his firft campaign that the emperor gave him a regiment. After the fiege of Vienna was raifed, he ferved in Hungary under the command of the duke of Lorrain and the elector of Bavaria. From this time his reputation increafed, with every action in which he engaged, till, in the year 1697, he was appointed to the command of the imperial army. In the autumn of this year he entirely defeated the Turks at the battle of Zeuta, in which the grand vizier and more than 20,000 men were left on the field, and the grand feignior was obliged to make a precipitate retreat with the broken relics of his army. Eugene had hazarded this engagement contrary to the exprefs orders of the imperial court; but he fo completely juftified his conduct, that Leopold gave him a written authority to act thenceforth according to his own judgment. He was now oppofed by all the great French generals, but in every battle his exertions and prowefs were crowned with fuccefs, and on returning to Vienna the emperor created him prefident of the council of war, and entrufted the military cheft to him; but that cheft was frequently ill fupplied, which occafioned him more trouble than the moft vigorous oppofition in the field. He was ftrictly united with the duke of Marlborough, and by their talents and concert they obtained a decifive fuperiority over the French in Germany. At the celebrated battle of Blenheim, Eugene commanded the imperial part of the army, and had no fmall fhare in the fuccefs. In 1705, he was defeated in Italy, but in the following campaign he regained his reputation by marching acrofs Lombardy in the face of the French army, and attacking the French in their intrenchments at Turin, over whom he obtained a complete victory, which fecured the duke of Savoy and reftored all the Milanefe to the emperor. In 1707, he invaded France, but without obtaining any decifive advantage, and in 1708 he was with the duke of Marlborough at the battle of Oudenard, and the capture of Lifle. He commanded the centre at the bloody battle of Malplaquet, where he was grievoufly wounded, but refufed to retire from the field, faying, "Of what ufe will it be if we are to die here;—if we are to furvive it will be time enough in the evening to be dreffed." When the politics of England took a turn and peace was determined on, Eugene carried on the war alone, till it was concluded by the peace of Radftadt in 1714. Shortly after this he was called on to contend again with the Turks, whom he fignally defeated in the year 1716. In the following year he undertook the fiege of Belgrade, when the Turks came to its relief, and invefted him in his camp. He fuffered them to approach very near, and then fuddenly quitting his lines fell upon them with fo much vigour, that he killed 20,000 men, aud poffeffed himfelf of their cannon and camp equipage. Belgrade immediately furrendered, and an advantageous peace was the refult of this important victory. Eugene now retired to Vienna covered with glory, and juftly confidered as the faviour of the empire, and the greateft benefactor to the houfe of Auftria. He was great in retirement, as he had been heroic and magnanimous in war. In the year 1733 he attempted new exploits, in confequence of the difputed election to the Polifh crown; but he was no longer the great, the enterprizing Eugene. He died in 1736 at Vienna, aged feventy-three. As a man he was cold and referved in his manner, and ferious in his afpect: as a friend he was liberal, free from pride, faithful to his promifes, and ever ready to do a kind action. As a general he was regarded by thofe under him in the character of a father and protector: in his military capacity he was enterprifing, full of refources, and though he fometimes committed faults, he rarely failed to redeem his credit by new and brilliant fucceffes. Moreri. Modern Univerfal Hift. Hift. of England. See alfo the article Churchill in this Dictionary.

EUGENIA, in *Botany*, fo named by Micheli in compliment to the heroic prince Eugene of Savoy, who fent him from Germany almoft all the plants defcribed by Clufius, and who had a celebrated botanic garden. Mich. Gen. 226. t. 108. Linn. Gen. 247. Sm. Tr. of Linn. Soc. v. 3. 280. Schreb. 333. Willd. Sp. Pl. v. 2. 959. Mart. Mill. Dict. v. 2. Juff. 324. (Syzygium; Gærtn. t. 33.). Clafs and order, *Icofandria Monogynia*. Nat. Ord. *Hefperideæ*, Linn. *Myrti*, Juff.

Gen. Ch. *Cal.* Perianth fuperior, in four deep, oblong, obtufe, concave, permanent fegments, the orbicular centre between them elevated, and fomewhat downy. *Cor.* Petals four, twice as large as the fegments of the calyx, oblong or roundifh, obtufe, concave. *Stam.* Filaments numerous, inferted into the elevated ring of the calyx, about as long as the corolla; anthers fmall, roundifh. *Pift.* Germen inferior, turbinate; ftyle fimple, the length of the ftamens;

ftigma

ftigma fimple. *Peric.* Berry roundifh or angular, crowned with the calyx, of one cell. *Seed* folitary, roundifh, fmooth and even.

Eff. Ch. Calyx fuperior, in four deep fegments. Petals four. Berry of one cell, with one feed.

Obf. The number of petals, and fegments of the calyx, is frequently five, in one inftance eight. The germen has, in fome fpecies at leaft, two cells, though one of them becomes obliterated as the fruit ripens.

This is an extenfive genus, chiefly from the Eaft and Weft Indies, whofe fpecies are as difficult to define as the rofes in our European gardens. Their habit is akin to the myrtle, but often more ftout and arborefcent. *Leaves* fimple, oppofite, ovate or elliptical, entire, without ftipulas, moft frequently fmooth, paler beneath, evergreen. *Flowers* either terminal or axillary, white or reddifh. *Fruit* not unwholefome, but fcarcely ever very grateful to the palate; in fome cafes highly fragrant. Willdenow has 30 fpecies, a number far fhort of what are known, and yet two of them (*acutangula* and *racemofa*), are fcarcely true *Eugeniæ.* There is alfo fome confufion between this genus and *Plinia*, the original *E. uniflora*, Linn. Sp. Pl. 673, being not only *Myrtus brafiliana*, ibid. 674, but alfo *Plinia rubra*, Linn. Mant. 243; as well as *P. pedunculata*, Linn. Suppl. 253; under which laft name it is figured in Curt. Mag. t. 473, with a wrong quotation of Linn. Mant. Whatever the *Plinia* of Plumier may be, this plant is the original *Eugenia* of Micheli's figure, and is well known in the Brafils and Weft Indies, its fruit refembling an indifferent cherry in fize, tafte, and colour, though different in being externally furrowed. This fruit fometimes ripens in ftoves in England, but the plant is no general favourite, being a meagre reprefentative of the common myrtle.

E. *Jambos.* Linn. Sp. Pl. 672. (Malacca Schambu; Rheede Hort. Mal. v. 1. t. 17.), is much celebrated for the fragrance of its fruit, which refembles that of a rofe, or rather rofe-water. It is alfo of an extremely fine yellowifh colour with a rofy tint, and though not pleafant to the tafte, is frequently brought to table in the Indies, for the fake of its perfume.

E. *malaccenfis.* Linn. Sp. Pl. 672. Sm. Exot. Bot. t. 61, a beautiful Eaft Indian fpecies, is efteemed for the elegance of its red cluttered flowers, as well as the flavour and cooling quality of its fruit.

EUGENIUS I. in *Biography*, pope, was born at Rome, and raifed to the higheft dignity in the church in the year 634, on the depofition of pope Martin. He owed his elevation to the choice of the Roman people and clergy, and their choice was confirmed by the emperor Conftans. At this period the weftern and eaftern churches were furioufly contending with each other upon the queftion whether Chrift poffeffed one will or two. Eugenius, after his promotion, took pains to quiet the minds of the difputants.. A compromife was entered into between the parties, but it was not of that nature to command general approbation: it was unfatisfactory to the Roman people and clergy, who oppofed the admiffion of the patriarch Peter's confeffion of faith. Peter had taken the other fide of the queftion, and in his confeffion he took no notice of the will and operations in Chrift. So vehement was this party that they refufed to permit the pope to perform divine fervice in the church of St. Mary, until he had publicly declared his condemnation of it. We have no other particulars relating to this pope, who died in the year 657, but he was commended by his contemporaries and fucceffors for piety, mildnefs, humanity, and generofity. Moreri. Bower.

EUGENIUS II. pope, was a Roman by birth, and from being archprieft of St. Sabina, was made bifhop of Rome in the year 824. This election was oppofed by the people, who made choice of a different perfon for pope. The double election excited confiderable difturbances at Rome, which occafioned the interference of Lewis the Debonnaire, who decided for Eugenius, and confirmed him in his high office. The monarch took this opportunity of reviving feveral ancient cuftoms and laws, declaratory of the dependence of the bifhops of Rome on the imperial power, and determining the limits of the fubmiffion and obedience which were paid to them. Eugenius, to fecure his own power, took the oath of fidelity to Lewis and his fon Lotharius, in which was included their folemn engagement that no future pope fhould be confecrated with their confent, but in the prefence of the emperor's deputy, and after the exaction of a fimilar oath to what was at that time adminiftered. During the pontificate of Eugenius, a council was affembled in France under the aufpices of Lewis and the Greek emperors Michael and his fon Theophilus, to examine the doctrine of the Greek church, in relation to images. This was in the year 825, and at the conclufion of the council the bifhops wrote a letter to Lewis, giving fentence againft both parties, *viz.* the churches of Conftantinople and Rome; the former for breaking images, whence they were denominated "Iconoclaftæ," and the latter for worfhipping them, whence they obtained the title of "Iconolatræ," declaring at the fame time that it was a far greater crime to worfhip than to break images. The emperor was alfo exhorted by the council to interfere with the pope, and to intreat him to abolifh the fuperftitious worfhip of images, which was the caufe of much offence to all good men. Lewis wrote to the pope, and deputed two bifhops to reafon with him on the fubject, but to little or no purpofe; he continued not only to promote, but to juftify the practice of image worfhip. In the following year Eugenius held a council at Rome, in which a number of decrees were paffed, intended to reform the ftate of ecclefiaftical difcipline and to encourage the progrefs of literature both facred and profane, but he died in the year 827, before he could carry his plans into effect. He was highly fpoken of by Catholic writers, and applauded for his humility, his beneficence, and the humane policy of his government. He is reprefented as excelling in mental and corporeal endowments. As a writer, two of his epiftles, and eleven of his decrees, are extant in the feventh volume of the "Collectio Conciliorum." It has been reported, and not greatly to the credit of Eugenius, that he was the inftitutor of the ordeal by cold water. See ORDEAL. Moreri. Bower.

EUGENIUS III. pope, fo called upon his elevation to the popedom, from his ufual name Bernard, was a native of Pifa, and a difciple of St. Bernard. On the death of Lucius II. in the year 1145, Bernard was unanimoufly fixed on by the cardinals as the new pope, and was enthroned with the ufual ceremony under the title of Eugenius III. The people, who had been long ftruggling to wreft from the popes the fovereignty which they had acquired over them in temporal matters, would not fuffer Eugenius to be confecrated, unlefs he refigned all pretenfions to dominion, otherwife than as connected with his fpiritual rank, and would be contented with the revenue to be derived from tithes, and the voluntary contributions of the faithful. Unwilling to make thefe conceffions, he privately withdrew to the Benedictine monaftery of Farfa in Sabina, whither he was followed by the cardinals, and confecrated. Not daring to return to Rome, he removed from Farfa to Viterbo, where he continued for fome months. During his abode there embaffadors arrived from the Crufaders in the Eaft, to implore

plore affiftance from the pope and the weftern princes againft the Turks, who had gained fome important advantages over them. Eugenius fupplicated the affiftance of Lewis VII. king of France, ftrongly urging him to march in perfon to the relief of the Chriftians in the Holy Land, and conferring on thofe who fhould attend him the privileges which his predeceffors had granted to fuch as engaged in the holy war. Lewis embarked, and Eugenius now took meafures to reduce the Romans to fubmiffion, which he effected in a fhort time, and forced them to acknowledge him as their temporal as well as fpiritual lord. His triumph was of no long duration, for an infurrection obliged him to feek for perfonal fafety in flight. He went to Treves, where he held a council in the year 1146. In the following year he was refpectfully entertained at Paris by the king; and here he was allowed to hold a council, in which William, archbifhop of York, was depofed from his dignity. From Paris he went to Rheims, where, in 1148, he held that council before which the fanatic Eon was examined. See Eon. He next returned to Italy, and, with the affiftance of the king of Sicily, once more fubdued the people of Rome, in the year 1149. Shortly after this he was obliged to retire into Campania, where he remained till the year 1152. During this period he was not inactive, but fent a legate into Ireland, by whom he eftablifhed the four archbifhoprics in that kingdom. He was now permitted to return to Rome, where he lived in peace till his death in 1153. His virtues have been highly commended by his contemporaries. By fome writers his chief merit arifes from his zeal and fufferings in promoting the interefts of the holy fee, and in combating the errors of heretics: by more modern hiftorians his memory has been held in abhorrence on account of the active part which he took in promoting the Crufades, by which great calamities overwhelmed Europe and the eaftern world. Moreri. Bower. See Croisade.

Eugenius IV. pope, was a native of Venice, and of plebeian rank, though defcended from an ancient family. His original name was Gabriel Condelmerio, and while he was very young he accompanied a nephew of pope Gregory XII. to Rome, where he took the Celeftine habit. He was afterwards made treafurer to the pope himfelf, and then bifhop of Sienna. In 1408 he was advanced to the office of cardinal prefbyter of St. Clement. While Martin V. was pope he was fent delegate into the Marche of Ancona, and afterwards to Bologna, and performed the duties repofed in him with great ability and reputation. On the death of Martin in 1431, he was elected to the papal fee, when he affumed the name of Eugenius IV. Immediately upon his elevation he involved himfelf, and the city of Rome, in the moft alarming difficulties, by attempting to feize upon treafures faid to have been left by his predeceffors; and no fooner was he extricated from the dangers refulting from this conduct, than he drew upon himfelf frefh troubles with the council of Bafil, which he determined to diffolve on account of their conciliating meafures with the Huffites of Bohemia. His legate, cardinal Cæfarini, whom he empowered to act on the occafion, a man of much difcretion, forewarned him of the troubles he was likely to bring on himfelf by the act. Eugenius had, however, made up his mind, and in 1431 iffued his bull, declaring the council of Bafil to be diffolved, and appointing another to be convened in eighteen months at Bologna. The emperor urged the pontiff to revoke his decree, fetting forth in ftrong and very preffing terms the evils into which he would otherwife plunge the Chriftian world; and he added that he was fure the affembled bifhops would not fubmit to be difappointed of the object of their meeting, and that he, as protector of the church, was bound to afford them his fupport. Eugenius was immoveable, and the council were alike determined to fet his power at defiance. After confirming the decrees of the council of Conftance, which declared the papal power to be fubordinate to that of a general council, and bound by its ftatutes and mandates they voted that no power on earth could diffolve them without their confent, and that none fhould withdraw from them without their leave; and they went fo far as to fummon the pope to appear in perfon before them within a limited time, or to fend legates with full authority to act in his name. The firmnefs of the council, after much altercation, brought the pope to fubmiffion, and in the year 1433 he iffued a bull, declaring null and void whatever had been done by him, or in his name, in derogation of the council general of Bafil. In the fame year Eugenius received the emperor Sigifmond at Rome with great magnificence, and crowned him there. Shortly after this he was attacked by Philip duke of Milan, who laid wafte the territory of Rome, and when the inhabitants laid their complaints before the pope, he referred them to the cardinal his nephew, who, regardlefs of every thing that did not contribute to his own eafe and pleafure, treated their fufferings with neglect and contempt. Enraged at this behaviour they took up arms, and produced a temporary revolution at Rome. It was with the utmoft difficulty that Eugenius efcaped from their fury, and took refuge at Florence; a reconciliation was effected, which was farther confirmed through the mediation of the council of Bafil, who difpatched fome of their body to offer friendly advice on the occafion. In 1437 frefh diffenfions arofe between the council and the pope, which terminated in their final rupture, and a new council was appointed to meet at Ferrara, whofe firft act was to declare the congregation of Bafil an unlawful affembly, and themfelves the only oecumenical council lawfully affembled, and they ordered all bifhops who ftill remained at Bafil to withdraw from that city within thirty days, on pain of excommunication, and the forfeiture of their dignities and benefices. The council of Bafil, on the other hand, paffed a decree or fentence of fufpenfion againft Eugenius from papal jurifdiction, forbidding all ecclefiaftics, on pain of excommunication, to obey him. Early in the year 1439, a contagious diforder breaking out at Ferrara, the pope tranflated the council to Florence, where a pretended union was effected between the Greek and Latin churches, which, being violently oppofed at Conftantinople, was rendered null and void. In the mean time the council of Bafil, after declaring the fuperiority of councils over the pope to be an article of the Catholic faith, proceeded to depofe Eugenius from the papacy, as difobedient to the commands of the church, a contemner of the canons, a difturber of the unity of the church, and an obftinate heretic; and they difpatched nuncios to the different courts of the Chriftian princes to acquaint them with the meafures which had been adopted. Eugenius thundered out his excommunications againft the fathers at Bafil, but they held his decrees in derifion, and raifed to the papal throne Amadeus, duke of Savoy, who affumed the name of Felix V. The rival popes and rival councils anathematized each other, laying claim to the true apoftolic powers. Eugenius was fupported by France, Italy, Spain, Portugal, Hungary, and England, but Felix was defended by the people of Savoy, by the Swifs, and by the dukes of Bavaria and Auftria. The German princes chofe to preferve a neutrality till the year 1447, when they declared for Eugenius, determining that he was the only true vicar of Chrift upon earth. In the midft of the public rejoicings on this occafion, he died in

his

his ſixty-fourth year. His character as a pope is eaſily gathered from what has been ſaid; he was ambitious, intriguing, and a decided enemy to reform. In his laſt illneſs he is ſaid to have been painfully affected with reflections on his paſt life; "Oh Gabriel," exclaimed the dying pontiff, "how much better had it been for thy ſoul's ſafety, hadſt thou never been promoted to the dignity of cardinal or pope!" He was a patron of literature and learned men, though he had no pretenſions to learning himſelf; his epiſtles and bulls are to be found in volumes xii. and xiii. of the "Collectio Conciliorum." He was a handſome man, of a venerable aſpect, and always looked downwards when he appeared in public. He was frugal and temperate in his own perſon, but was liberal and hoſpitable; and at his table there was a princely magnificence. In this reign the cardinals began to indulge in the ſports of the field, and to abandon themſelves to all kinds of luxury. Bayle. Moreri. Bower.

Eugenius, Catholic biſhop of Carthage, was raiſed to that ſituation in the year 481, at the requeſt of the emperor Zeno, who had entered into a treaty of peace with Hunneric, at that time the reigning monarch. In the year 483, he was ſummoned, with the other Catholic biſhops, by the king, to Carthage, to maintain a public debate in defence of their principles againſt the Arian biſhops, whom he patronized. Eugenius undertook to draw up a treatiſe, explanatory of the Catholic faith, which was approved by all the biſhops of his party, and preſented to Hunneric, and he offered to defend the principles contained in it by an appeal to the ſacred writings, as well as to the ſentiments of the fathers. He alſo delivered a petition to that prince, in the form of an apology, the deſign of which was, to obtain peace for the Catholics. It was, however, of no avail; the biſhops of that party were all ſentenced to baniſhment, and Eugenius was ſent into exile, amidſt the dreary deſerts of Tripoli. In the following year Hunneric died, and Eugenius was permitted to return to Carthage, but was again baniſhed, on the acceſſion of Thraſamund, and ſent into Gaul. He died at Albi, in the year 505. His principal works are, "Expoſitio fidei Catholicæ," "Apologeticus pro fide;" "Altercatio cum Arianis;" and a letter to his people, exhorting them to conſtancy in the orthodox faith. Moreri.

Eugenius, biſhop of Toledo, in the ſeventh century, was attached to the monaſtic life, but compelled, by order of the prince, to accept of the epiſcopal dignity in the year 646. He filled that ſee ſeveral years, and made a figure at the councils of Toledo, which were held in the years 653, 655, 656. He was author of a treatiſe "On the Trinity," and two books on miſcellaneous ſubjects. He reviſed and improved Dracontius's work on the creation of the world, which was publiſhed at Paris, together with his "Opuſcula," in the year 1619. Moreri.

EUGHTGUR, in *Geography*, a town of Hindooſtan, in the circar of Kitchwara; 15 miles E. of Ougein.

EUGIA, in *Ancient Geography*, a ſmall country of the Peloponneſus, in Arcadia.

EUGMO, in *Geography*, a ſmall iſland on the eaſt ſide of the gulf of Bothnia. N. lat. 63° 49′. W. long. 22° 42′.

EUGUBIO. See Gubbio.

EUHYDRIUM, in *Ancient Geography*, a town of Greece, in Theſſaly, according to Livy.

EVIAN, in *Geography*, a town of France, in the department of the Leman, on the coaſt of the lake of Geneva, containing two pariſhes and two convents. The place includes 1502, and the canton 12,911 inhabitants, on a territory of 280 kiliometres, and in 19 communes. Near Evian are ſome mineral waters, which render it in ſummer a place of reſort. It is ſituated 23 miles N. E. from Geneva. N. lat. 46° 25′. E. long. 6° 24′.

EVICTION, from *evinco*, *I overcome*, in *Law*, ſignifies a recovery of lands or tenements by law.

EVIDENCE, a quality in things whereby they become viſible and apparent to the eyes, either of the body or the mind.

The ſchoolmen diſtinguiſh evidence into *formal* and *objective*. The former is the act of the intellect, conſidered as clear and diſtinct; the latter conſiſts in the clearneſs and perſpicuity of the object; or it is the object itſelf ſo conſtituted as that it may be clearly and diſtinctly known.

Others divide evidence into *moral*, *phyſical*, and *metaphyſical*. A thing is ſaid to be *morally evident*, ſo far as we have a diſtinct notion or knowledge thereof, by unexceptionable witneſſes; *phyſically*, ſo far as natural ſenſe and reaſon, pointing out any thing, convince us thereof; *metaphyſically*, when we enter fully and clearly into the eſſence of any thing.

Evidence is the eſſential and infallible character or criterion of truth, and is that in effect which with us conſtitutes truth.

If evidence ſhould be found in propoſitions that are falſe, we ſhould be compelled into error, ſince the aſſent we give to evidence is neceſſary: whence would follow this impious poſition, that God who made us is the author of our errors, as he has conſtituted us ſo as to put us under a neceſſity of falling into them.

It may be added that as we neceſſarily love truth and hate error, it ſeems inconſiſtent with the nature of a beneficent being to form us with a love of what we could not obtain, or not know whether we did obtain it or not; beſides, that if we ſhould err in things that are evident, as well as in thoſe that are not ſo, we ſhould ſometimes find contradictions in evident propoſitions, as we commonly do in things that are obſcure.

Evidence, therefore, muſt be allowed the mark of truth; and thoſe things muſt be allowed true which carry with them ſuch a degree of evidence as obliges us to aſſent to them. Whatever we ſee evidently agreeable to things whereof we ſpeak, that we muſt acknowledge to be true.

The Epicureans allow of no other evidence but that of ſenſe, or that ariſing from ſenſe, it being a fundamental principle with them, that ſenſe is the firſt and primary criterion of all truth. By evidence of ſenſe, they mean that ſpecies or image exhibited by the ſenſe or phantaſy; which, when all impediments to a juſt judging, as diſtance, motion, medium, &c. are removed, cannot be contradicted or gainſaid; wherefore, the queſtion being put, whether or not a thing be ſuch as it appears; the anſwer is not to be given, till it has been tried and examined in all the ways, and by all the ſenſes, of which it can be an object. See Error.

There are certainly other ſuperior and leſs fallible ſources or grounds of evidence than ſenſe: ſuch is that inward conſciouſneſs by which we learn what belongs to the mind, or that which Mr. Locke calls reflection; of which ſuch are intelligence, intuition, and common ſenſe, principally relating to thoſe abſtracted, or other propoſitions that carry their own evidence with them, and admit no doubt about them; whence we derive our aſſent to propoſitions called axioms and maxims: ſuch is alſo reaſoning, whereby we infer one truth from others by natural and juſt methods of argument, whence reſults ſcience: ſuch is likewiſe the teſtimony of others, on which we found the evidence of Faith (ſee alſo Testimony): to which we may alſo add inſpiration, infpiration, or that impreffion made on the mind by God himfelf, which gives a convincing and indubitable evidence of the truth of any propofition, and attefted to others, either by prophecy or miracles. Watts's Logic, part ii. chap. ii. § 9.

By thus confidering the various fources whence our perception and belief of any truth are derived, we may be led to diftinguifh evidence into intuitive and deductive, and that founded on teftimony. Intuitive evidence comprehends that of pure intellection, of confcioufnefs, and of common fenfe, under the laft of which that of memory is included. (See Intuitive.) Deductive evidence is divided into fcientific and moral; the latter of which includes thofe kinds of evidence that are deduced from experience, analogy, and teftimony, to which may be added a mixed fpecies, derived from the calculation of chances. (See Deductive.) See alfo each of the above-mentioned fubjects. See Campbell's Phil. of Rhet. book i. chap. 5.

The evidences of the Chriftian religion are diftinguifhed into two kinds, the direct and collateral: the direct evidences are external and internal; the external are miracles and prophecy; the internal evidence is deduced from its excellence, confidered in reference to the main and principal end of Chriftianity. Whatever does not either belong to its excellence confidered in this light, or fall under the head of miracles wrought on purpofe to atteft it, or of prophecies fulfilled, and yet affords a proof or any real prefumption of its truth and divinity, is a collateral evidence for it. All the collateral evidences of the truth of Chriftianity are in one fenfe internal evidences, becaufe they all arife from fome particulars in the nature of this religion, from fome circumftances which have attended its reception, or fprung from it, or from fome remarkable facts connected with it, and related in the gofpel hiftory. Of this kind is the argument deduced from its great efficacy at its firft appearance, in banifhing polytheifm, idolatry, fuperftition, and the arts of magic; in foftening the rigour of defpotifm, introducing moderation into government, excluding many inconvenient civil laws once generally prevalent, giving rife to others of a very happy tendency, refifting the laws of war, humanizing the manners, and improving the cuftoms of nations, and reforming the temper and conduct of thofe who embraced it.

Another clafs of collateral arguments for the truth of the Chriftian religion, arifes from particulars in its nature or effects produced by it, or from facts in the Gofpel hiftory, which cannot be at all accounted for but on the fuppofition of a Divine original; or which are, at leaft, moft naturally explicable on that fuppofition. To this clafs may be referred thofe prefumptive arguments deduced from the character of Jefus, fo exalted, and yet fo uniformly fupported; the nature of his laft difcourfes with his difciples; the character of fome of his apoftles; that of Judas the traitor; the controverfies among Chriftians in the apoftolic age; and the method ufed by Chrift and his apoftles, of referring their claims to the impartial inquiries of men. Other collateral arguments have an affinity to the external evidences of Chriftianity: fuch are thofe derived from the miraculous converfion of the apoftle Paul and his fubfequent conduct; from the character of the man of fin foretold by Paul; from the quick and extenfive propagation of the Gofpel; from the continuance and prefent ftate of the nation of the Jews. Some of thefe arguments have an immediate relation to the proof of Chriftianity from prophecies; others are related to the proof from miracles. Other arguments have an equal relation to the internal and external evidence of Chriftianity; fuch is that deduced from the manner in which Chrift and his apoftles propofed the evidences of their miffion, and the advantage they have gained in confequence of the oppofition and fcrutiny of unbelievers. See on this fubject Lord Lyttelton's Obfervations on the Converfion and Apoftlefhip of St. Paul, Duchal's Prefumptive Arguments for the Truth of the Chriftian Religion, and Gerrard's Differtation on the genius and evidences of Chriftianity.

Evidence, in *Law*, is any proof, whether by teftimony of men on oath, or by writings and records; the former called *parol evidence*, that is, by word of mouth, and the latter *written evidence*.

It is thus called, becaufe the point in iffue is hereby made evident to the jury. Evidence in the trial by jury includes not only that which is given in proof, but that which the jury may receive by their own private knowledge; for an account of which fee the fequel of this article.

With regard to parol evidence, or witneffes, we may obferve in general, that all witneffes, whatever be their religion or country, that have the ufe of their reafon, are to be received and examined, except fuch as are *infamous*, or fuch as are *interefted* in the event of the caufe. All others are competent witneffes; though the jury from other circumftances will judge of their credibility. Infamous perfons are fuch as may be challenged as jurors, *propter delictum*; and, therefore, never fhall be admitted to give evidence to inform that jury, with whom they were too fcandalous to affociate. Interefted witneffes may be examined upon a *voir dire*, if fufpected to be fecretly concerned in the event; or their intereft may be proved in court. A party interefted in a fuit, or a wife for or againft her hufband, a hufband againft his wife, except in cafes of treafon, an alien infidel, perfons *non fanæ memoriæ*, thofe that are attainted of confpiracy, or in a præmunire upon ftat. 5 Eliz. cap. 1. popifh recufants convict on ftat. 3 Jac. I. cap. 5. (See contra 1 Hawk. P. C. c. 12. § 6.) perfons convicted of felony, perjury, &c. thofe who by judgment have ftood on the pillory, or been whipped, whilft the judgment is in force, are difabled from giving evidence: but kinfmen, though ever fo near, tenants, fervants, mafters, attornies for their clients, but not againft them, becaufe they are obliged to keep their fecrets, one of the jurors upon trial, and all others that are not infamous, who want not underftanding, or are no parties in intereft, may give evidence in a caufe, though the credit of fervants is left to the jury. (2 Rol. Abr. 685. 1 Vent. 243.) If after a man hath ftood in the pillory, &c. he be pardoned, he may be an evidence; and though judgment of the pillory infers infamy at common law, by the civil and canon law it imports no infamy, unlefs the caufe for which the perfon was convicted was infamous; and, therefore, fuch may be a good witnefs to a will, if not convicted of any infamous act. (3 Lev. 426, 427.) It has been held, that it is not ftanding in the pillory which difables a perfon for giving evidence; but ftanding there upon a judgment for an infamous crime, as forgery, &c. If for a libel, a man may be a witnefs. (5 Mod. 74. 3 Nelf. Abr. 557.) Perfons excommunicated cannot be witneffes; but perfons outlawed may be witneffes, becaufe the outlawry has no influence on their credibility. (Bull. N. P. 292, 3.) A man convicted of felony, and afterwards pardoned, may be a good evidence. (Raym. 369.) Burning in the hand is faid to reftore a perfon to his credit. (Ibid. 330.) A perfon condemned to be hanged for burglary, but having a pardon for tranfportation, hath been allowed to be a good evidence. (5 Mod. 108.) One outlawed for treafon and pardoned may be an evidence. (State Trials, vol. iii. 515.) Perfons acquitted, or guilty of the

fame

ſame crime, while they remain unconvicted, may be evidence againſt their fellows. (Kel. 17.) Although no evidence ought to be given of what an accomplice hath ſaid, who is not in the ſame indictment; (State Trials, vol. ii. 414.) an informer may be a witneſs, though he is to have part of the forfeiture, where no other witneſſes can be had. (Wood's Inſtit. 598.) If an action is brought againſt many perſons for taking of goods, one of them may be admitted as an evidence againſt the reſt. (Comberb. 367. 1 Mod. 282.) In criminal caſes, as of robbery on the high way, in action againſt the hundred; in rapes of women, or where a woman is married by force, &c. a man or a woman may be an evidence in their own cauſe. (1 Vent. 243.) And in private enormous cheats, a perſon may give evidence in his own cauſe, where nobody elſe can be a witneſs of the circumſtances of the fact but he that ſuffers. (1 Salk. 286.) Upon an information on the ſtatute againſt uſury, he that borrows the money, after he hath paid it, may be an evidence, but not before. (Raym. 190.) Although an alien infidel may not be an evidence, a Jew may, and be ſworn on the Old Teſtament. (1 Inſt. 6.) A quaker ſhall not be an evidence in any criminal cauſe unleſs he will take an oath: though on other occaſions his affirmation ſhall be accepted inſtead of an oath. Stat. 7 and 8 W. III. c. 34. See Quaker.

The oath of a Gentoo, ſworn according to the circumſtances of his religion, has been admitted in a civil matter. (1 Atk. 21.) And by Willes C. J. an infidel in general is an admiſſible witneſs, for the term does not imply that he is an atheiſt; but whenever it appears that a witneſs hath no idea of a God or religion, he ſhall not be permitted to give his teſtimony. (1 Atk. 40. 45.) When perſons that are competent witneſſes are ſerved with a writ of *ſubpœna ad teſtificandum*, they are bound to appear at the trial on pain of 100*l.* to be forfeited to the king, to which the ſtat. 5 Eliz. cap. 9. has added a penalty of 10*l.* to the party aggrieved, and damages equivalent to the loſs ſuſtained by want of their evidence: but no witneſs, unleſs his reaſonable expences be tendered him, is bound to appear at all; nor if he appears, is he bound to give evidence till ſuch charges are actually paid him, except he reſides within the bills of mortality, and is ſummoned to give evidence within the ſame. In a criminal cauſe, if a witneſs refuſe to appear, and give evidence, being ſerved with proceſs, the court will put off the trial, and grant attachment againſt him; and as refuſing to give evidence is a great contempt, the party may be committed and fined. (1 Salk. 278.) Preventing evidence to be given againſt a criminal is puniſhable by fine and impriſonment; and perſons diſſuading a witneſs from giving evidence, &c., and jurors or others, diſcloſing evidence given, are likewiſe offences puniſhed in the ſame manner. (2 Hawk. P. C. c. 22.) Members of either houſe of parliament may be witneſſes on impeachments. (State Trials, vol. ii. 612.) A perſon who hath a legacy in a will, is not a good witneſs to prove the will; but if he releaſe his legacy, he may be a good evidence. (Skin. 704.) Thus alſo, a perſon who claims any benefit by a deed, may not be an evidence to prove that deed; and a perſon concerned in the ſame title of land in queſtion will not be admitted as evidence. (Ibid. 705.) If a legatee is permitted to be ſworn and examined, the counſel cannot afterwards except againſt his evidence. (1 Lord Raym. 730.) To obviate all difficulties, it is enacted by ſtat. 25 Geo. II. c. 6. that any deviſe to a perſon being witneſs to any will or codicil ſhall be void, and ſuch perſon ſhall be admitted as a witneſs; and that any creditor atteſting a will or codicil, by which his debt is charged upon land, ſhall be admitted as a witneſs to the execution, notwithſtanding ſuch charge: the credit of every ſuch witneſs being left to the conſideration of the court and jury. The ſon of a legatee is no witneſs to a will in the ſpiritual court; but it is held he may be a good evidence to prove a nuncupative will, within the intent of the ſtatute of frauds. (1 Lord Raym. 85.) See Will.

One credible witneſs is ſufficient evidence to a jury of any ſingle fact in all civil actions, though the concurrence of two or more corroborates the proof; but in caſes of high-treaſon, petit-treaſon, and miſpriſion of treaſon, by ſtatutes 1 Edw. VI. cap. 12. 5 and 6 Edw. VI. cap. 11. and 1 and 2 Ph. and Mar. cap. 10. *two* lawful witneſſes are required to convict a priſoner, except in caſes of coining and counterfeiting the ſeals, or unleſs the party ſhall willingly and without violence confeſs the ſame: and by ſtat. 7 W. III. cap. 3. the confeſſion of the priſoner muſt be in open court; and both witneſſes muſt be to the ſame overt-act of treaſon, or one to one overt-act, and the other to another overt-act of the ſame ſpecies of treaſon. Baron Monteſquieu, indeed, lays it down for a rule, Spirit of Laws, book xii. chap. 3. that thoſe laws which condemn a man to death *in any caſe*, on the depoſition of a ſingle witneſs, are fatal to liberty.

All evidence is to be given in open court, in the preſence of the parties, their attornies, the counſel and all by-ſtanders, and before the judge and jury: many advantages attend this way of giving teſtimony, *ore tenus*, a method familiar among the ancient Romans, as may be collected from Quintilian, Inſt. Orat. lib. v. cap. 7. and it was continued as low as the time of Adrian; but the civil law, as it is now modelled, rejects all public examination of witneſſes.

No witneſs is bound to give any anſwer by which he confeſſes or accuſes himſelf of any crime. The court in criminal caſes is to examine the witneſſes, and not the priſoner or proſecutors. A witneſs ſhall not be permitted to read his evidence, but he may look at his notes to refreſh his memory. A witneſs may not recite his evidence to the jury, after having gone from the bar, and he hath given his evidence in court; if he does, the verdict may be ſet aſide. (Cro. Eliz. 159.) One that is to be an evidence at a trial, ought not to be examined before the trial, but by the conſent of both parties, and a rule of court for that purpoſe. No evidence ought to be produced againſt a man, in a trial for his life, but what is given in his preſence. State Trials.

Poſitive proof is always required whenever the nature of the caſe poſſibly admits of it.

Sometimes violent preſumption will be admitted for evidence without witneſſes; as where a perſon is run through the body in a houſe, and one is ſeen to come out of the houſe with a bloody ſword, &c. but on this the court ought not to judge haſtily, 1 Inſt. 6. 673; and though preſumptive and circumſtantial evidence may be ſufficient in felony, it is not ſo in treaſon. State Trials.

Though all preſumptive evidence of felony ſhould be admitted cautiouſly, for the law holds that it is better that ten guilty perſons eſcape, than that one innocent ſuffer. (See Presumption.) Sir Matthew Hale lays down two rules, moſt prudent and neceſſary to be obſerved. 1. Never to convict a man for ſtealing the goods of a perſon unknown, merely becauſe he will give no account how he came by them, unleſs an actual felony of ſuch goods be proved: and, 2. Never to convict any perſon of murder or manſlaughter, till at leaſt the body be found dead; on account of two inſtances, which he mentions, where perſons were executed for the murder of others, who were then alive, but miſſing. 2 Hal. P. C. 200.

Evidence by writings and records, is where acts of parliament, statutes, judgments, fines, and recoveries, proceedings of court, and deeds, &c. are admitted as evidence. The printed statute-book is good evidence upon a general act of parliament, which need not be pleaded; but in the case of a private act, it is otherwise; for there it must be pleaded and examined by the records of parliament before it can be admitted in evidence. Records and enrolments prove themselves; and a copy of a record or enrolment, sworn to, may be given as an evidence. (Co. Litt. 119. 262.) A record of an inferior court has been rejected in evidence; and the proceedings in county-courts, courts-baron, &c. may be denied, and then tried by a jury. But court-rolls of a court-baron, when shewn, are good evidence; and, in many cases, copies of the court-rolls are allowed as evidence. An ancient deed of thirty years standing proves itself; but modern deeds, and other writings, must be attested and verified by parol evidence of witnesses. The counterpart of a deed is no evidence, when the original is in being, and can be procured; though it may be, when the original cannot be procured. (Co. Litt. 225. 10 Rep. 92.) The counterpart of an ancient deed hath been admitted as evidence. (Mod. Caf. 225.) In case of a fine, a counterpart is good evidence of itself. (1 Salk. 287.) Although a witness swear to the hand and contents of a letter, if he never saw the party write, it will not be good evidence. If all the witnesses to a deed are dead, continual and quiet possession is presumptive evidence of the truth of it; yet it may receive farther credit by comparison of hands and seals. (Wood's Inst. 599.) When witnesses to deeds are dead, their hand-writing must be proved. (2 Inst. 118.) If one of several witnesses survive, a subpœna must be taken out against the living witness, and strict inquiry made after him, and affidavit made that he cannot be found, before the hand-writing of the deceased witnesses is to be proved. (1 Litt. 556.) And a shop-book may not be given in evidence for goods sold, &c. by 7 Jac. I. cap. 12. after one year, before the action brought, except there be a bill, &c. for the debt; unless between merchant and merchant in the usual intercourse of trade. In order to make books evidences, if the servant who was accustomed to make entries in it be dead, his hand must be proved; and this, when accompanied with other collateral proofs of fairness and regularity, is the best evidence that can then be produced. In debt, a release may be given in evidence; so may any matters of fact, tampering with witnesses, or fraud.

In order to prove a lease for years, nothing shall be admitted but the very deed of lease itself, if in being; but if that be positively proved to be burnt or destroyed, then an attested copy may be produced, or parol evidence given of its contents. No evidence of a discourse with another will be admitted, but the man himself must be produced: yet in some cases, as in proof of any general customs or matters of common tradition or repute, the courts admit of *hearsay* evidence, or an account of what deceased persons have declared in their life-time; but such evidence will not be received of any particular facts. The probate of a will, when it concerns merely personal estate, may be given in evidence; but where title of lands is claimed under a will, the original will must be shewn, not the probate, though if the will be proved in the Chancery, copies of the proceedings there will be evidence. (2 Rol. Abr. 687. Trials per pais, 234. 1 Salk. 286. Raym. 335.) In some cases the ledger-book of the ecclesiastical court in which the will is entered is sufficient evidence, being a roll or record of the court. (Bull. N. P. 245, 6.) Depositions of witnesses in Chancery between the same parties may be given as evidence at law, if the witnesses are dead, and the bill and answer proved. Depositions before a coroner are admitted as evidence, the witnesses being dead, or gone beyond sea. (1 Lev. 18). 2 Nelf. Abr. 760.) The confession of a prisoner before a magistrate, &c. may be given in evidence against him. (See 2 Hawk. P. C. c. 46.) See Baron Gilbert's Treatise of Evidence, or the Introduction to the Law of Nisi Prius, 4to. 1767.

From this treatise the following rules of evidence are extracted. 1. In general, the best evidence must be given that the nature of the thing will admit of. 2. No person interested in the question can be a witness. To this rule there are some exceptions; as, 1. A party interested may be admitted in a criminal prosecution in most instances. 2. He may be admitted for the sake of trade in the common usage of business, as porters, apprentices, &c. 3. Where no other evidence is reasonably to be expected. 4. Where he acquires his interest by his own act, after the party who calls him as a witness has a right to his evidence. 5. Where the possibility of interest is very remote. 3. The third general rule is that hearsay is no evidence. 4. In all cases where a general character or behaviour is put in issue, evidence of particular facts may be admitted; but not where it comes in collaterally. 5. In every issue the affirmative is to be proved. 6. No evidence need be given of what is agreed by the pleadings, &c. &c. See Pleading.

Sir Thomas Smith restrains evidence to authentic writings of contracts, written, sealed, and delivered. De Rep. Ang. lib. ii.

Evidence, *demurrer to*. See Demurrer.

Evidence, *exception to*. See Exception.

EVIL, Malum, in *Ethics*, a privation or absence of some proper or necessary good, or of some measure or degree thereof.

Evil is either *natural* or *moral*; between which there is this relation, that moral evil produces natural.

Evil, *moral*, is defined a deviation from right reason; a discernment of right from wrong, being given us as a guide of our actions; or it is the disagreement between the actions of a moral agent and the rule of those actions, whencesoever it is derived, and howsoever made known; and no action can be morally evil unless the agent be properly such, intelligent and free, and capable of distinguishing, choosing, and acting for himself. This the philosophers call *inhonestum*, and *turpe*, as staining the image of God, and sullying our original beauty; likewise *malum culpæ*.

Evil, *natural*, is a want of something necessary to the *bene esse*, or perfection of a thing, or to its answering all its purposes; such are defects of the body, blindness, lameness, hunger, diseases, death. This species is denominated *triste*, *injucundum*, *noxium*, and *malum pœnæ*.

Good and evil, says a learned writer, are opposites, and arise from the relations which things have to each other: for since there are some things which profit, and others which prejudice one another; and since some things agree, and others disagree; we call the former good and the latter evil. Whatever, therefore, is incommodious or inconvenient to itself or any thing else; whatever becomes troublesome or frustrates any appetite implanted by God; whatever forces any person to do or suffer what he would not, that is *evil*. These inconveniencies appear to be of three kinds: those of imperfection; those that are natural; and those that are moral. By the evil of imperfection we may understand the absence of those perfections or advantages which exist elsewhere, or in other beings; by natural evil, pains and uneasinesses, inconveniencies and disappointments of appetites arising from natural motions; and by moral evils, vicious elections, that is, such as are hurtful to ourselves,

or

or others. This opinion is otherwife ftated in the following manner: all evil is inconveniency, but fome inconveniencies arife from the feries of natural caufes without our confent, and fometimes our knowledge; thefe we call natural evils: but others happen from the abufe of elections, when an undue choice occafions them; and in this cafe, befides the natural evil that arifes from them, there is likewife an obligation on the perfon that makes the choice to anfwer for the hurt he has done by it. Now thefe choices that bring inconveniencies are called moral evils; and the difference between natural and moral evil is not their both bringing inconveniencies and injury to ourfelves or others, for this conftitutes the nature of their evil, but that the ill effects of the one proceed from the choice, thofe of the other from natural caufes; and hence the author of that choice is anfwerable for the one, but nobody for the other. Moral evil, therefore, is natural evil, with choice fuperadded. See archbifhop King's "Effay on the origin of Evil," by Law, vol. i. and ii. Sherlock, alfo, in his "Treatife on Judgment," p. 20, &c. diftinguifhes in a fimilar manner between moral and natural good and evil; the only difference between them, he fays, is this, "that moral good and evil is in the will and choice, natural good and evil is in the nature of things; that which is good or hurtful to ourfelves or others is naturally good or evil; to love, to choofe, to do that which is good or hurtful to ourfelves or others, is morally good or evil, or is the good or evil of our choice or actions. If you will but recollect yourfelves, you will find that you have no other notion of good or evil but this; when you fay fuch a man has done a very good or very evil action, what do you mean by it? Do you not mean, that he has done fomething very good or very hurtful to himfelf or others? When you hear that any man has done good or evil, is not the next queftion, what good or what hurt has he done? And do not you mean by this, natural good or evil? which is a plain evidence that you judge of the moral good or evil of actions by the natural good or evil which they do."

The ingenious author of the "Enquiry into the Origin of our Ideas of Beauty and Virtue," gives the following ftatement of the nature of moral good and evil, and of the difference between thefe and natural good and evil. Moral evil, according to this philofopher, denotes our idea of a quality apprehended in actions which excites averfion and diflike towards the actor, even from perfons who receive no difadvantage thereby; as moral goodnefs denotes our idea of a contrary quality which procures approbation and love towards the actor, even in perfons unconcerned in its natural tendency. This notion fuppofes an univerfally acknowledged difference of moral good and evil from natural. Moral good, we all know, procures love towards thofe we apprehend poffeffed of it; whereas natural good does not. How differently, for inftance, are we affected towards thofe we fuppofe poffeffed of honefty, faith, generofity, &c. when we expect no benefit from thofe qualities, and thofe poffeffed of the natural goods, as houfes, lands, gardens, health, ftrength, &c. So whatever quality we apprehend morally evil, raifes our hatred towards the perfon in whom we obferve it; as treachery, cruelty, ingratitude, &c. whereas we love and pity many expofed to natural evils, as pain, hunger, ficknefs, &c.

The origin of thefe different ideas of actions has greatly puzzled the moralifts: fome make felf-intereft, or felf-love, the fource of them all; we approve the virtue of others as it has fome fmall tendency to our happinefs, either from its own nature, or from this general confideration, that a conformity to nature and reafon is in the general advantageous to the whole, and to us in particular; and on the contrary, difapprove the vice of others, as tending at the long run to our particular detriment.

Others fuppofe an immediate natural evil in the actions called *vicious*, that is, that we are determined to perceive fome deformity or difpleafure in fuch actions, without reflecting on any difadvantage that may any way redound to us from the action; and that we have a fecret fenfe of pleafure accompanying fuch of our own actions as are called *virtuous*, when we expect no farther advantage from them; but then they add, that we are excited to perform thofe actions, even as we purfue or purchafe pictures, ftatues, landfcapes, &c. from felf-intereft, to obtain the pleafure which accompanies the action.

But the author juft mentioned maintains that fome actions have to men an immediate goodnefs, and others an immediate evil, *i. e.* we perceive pleafure in fome and pain in others, and are determined to love or hate the doers, without any view of natural advantage, without any view to future rewards or punifhments, or even without any intention to obtain the fenfible pleafure of the good, but from a very different principle, *viz.* an internal moral fenfe, or a natural determination of the mind to receive amiable or difagreeable ideas of actions, when they fhall occur to our obfervation, antecedently to any opinion of advantage or lofs to redound to ourfelves from them, even as we are pleafed with a regular form or an harmonious compofition, without any knowledge of the mathematics, or feeing any advantage in that form or compofition different from the immediate pleafure. But according to this account of Dr. Hutchefon, however plaufible, moral good and evil fignify nothing in the objects themfelves, to which they are applied, any more than agreeable and harfh, fweet and bitter, &c. but only certain effects in us; and virtue is a mere affair of tafte; whereas it feems to be much more juft to conclude, that right and wrong, or good and evil, are real qualities of actions, and not merely of our minds; and that the power whereby we perceive thefe qualities is not any arbitrary fenfe but the underftanding: or to fuppofe with another excellent writer, that moral good, confidered as fynonymous with virtue, denotes the doing good to mankind, in obedience to the will of God, and for the fake of everlafting happinefs, and moral evil or vice, the contrary. Price's Original of our Ideas, &c. p. 13, and p. 59, &c. Paley's Principles of Moral and Political Philofophy, vol. i. p. 41. See farther under Deformity, Sense, Good, Virtue, and Vice.

The queftion concerning the origin of evil has very much perplexed philofophers and divines, both ancient and modern. Plato, for the folution of this queftion, maintained, that matter, from its nature, poffeffes a blind and refractory force, from which arifes in it a propenfity to diforder and deformity; and that this is the caufe of all the imperfection which appears in the works of God, and the origin of evil. Matter, he conceives, refifts the will of the fupreme artificer, fo that he cannot poffibly execute his defigns; and this is the caufe of the mixture of good and evil, which is found in the material world. "It cannot be," fays he, (Theæt. t. i. p. 176.) "that evil fhould be deftroyed, for there muft always be fomething contrary to good;" and again, "God wills, *as far as it is poffible*, every thing good, and nothing evil." What is that property of matter which oppofes the wife and benevolent intentions of the firft intelligence, Plato has not clearly explained, but he fpeaks of it as Σύμφυτος ἐπιθυμία, an innate propenfity to diforder, (Phileb.) and fays, "that before nature was adorned with its prefent beautiful forms, it was inclined to confufion and deformity, and that from this habitude

I

bitude arises all the evil which happens in the world." Plutarch supposes the Platonic notion to be, that there is in matter an unconscious irrational soul; and this supposition has been adopted by several modern writers. But the writings of Plato afford no evidence, that he conceived the imperfection of matter to arise from any cause distinct from its nature. Such a notion is incongruous with Plato's general system, and it is contrary to the doctrine of the Pythagorean school, to which he was probably indebted for his notions on this subject; for the philosophers of that sect held, that motion is the effect of a power essential to matter. Some of the Stoics adopted the notion of the Platonists concerning the origin of evil, and ascribed it to the defective nature of matter, which it is not in the power of the great artificer to change; asserting, that imperfections appear in the world, not through any defect of skill in its author, but because matter will not admit of the accomplishment of his designs. But it was perceived by others, that this hypothesis was inconsistent with the fundamental doctrine of the Stoics concerning nature. For since, according to this system, matter itself receives all its qualities from God, if its defects be the cause of evil, these defects must be ultimately ascribed to him. No other way of relieving this difficulty remained, but to have recourse to fate, and say, that evil was the necessary consequence of that eternal necessity, to which the great whole, comprehending both God and matter, is subject. Thus, when Chrysippus was asked, whether diseases were to be ascribed to divine Providence, he replied, that it was not the intention of nature that these things should happen; nor were they conformable to the will of the author of nature and parent of all good things; but that, in framing the world, some inconveniences had adhered, by necessary consequence, to his wise and useful plan. To others the question concerning the origin of evil appeared so intricate and difficult, that finding themselves unequal to the solution of it, they denied either that there is any God at all, or, at least, any author or governor of the world. The Epicureans belonged to this class; nor does Lucretius allege any other reason for denying the system of the world to be the production of a deity besides its being so very faulty. Others again judged it to be more rational to assign a double cause of visible effects than to assign no cause at all; as nothing, indeed, can be more absurd than to admit actions and effects without any agent and cause. These persons, perceiving a mixture of good and evil, and being persuaded that so many inconsistencies and disorders could not proceed from a good being, supposed the existence of a malevolent principle, or God, directly contrary to the good one; hence they derived corruption and death, diseases, griefs, mischiefs, frauds and villanies, whilst from the good being they deduced nothing but good. This opinion was held by many of the ancients; by the Persian magi, Manichæans, Paulicians, &c. &c. See these articles, and also ZOROASTER. Absurd as this hypothesis was, it very long and generally prevailed, not only in the Heathen but in the Christian world; nor have the light and influence of Christianity yet availed to its total extermination, so that no trace or remnant of it remains. Those who wish to find a satisfactory refutation of it, may consult "King's Origin of Evil," vol. i. and the annexed notes of the editor.

The excellent Dr. Clarke, in his "Demonstration of the Being and Attributes of God," deduces from the possibility and real existence of human liberty an answer to the question, what is the cause and original of evil? "For liberty," he says, "implying a *natural* power of doing evil, as well as good; and the imperfect nature of finite beings, making it possible for them to abuse this their liberty to an actual commission of evil; and it being necessary to the order and beauty of the whole, and for displaying the infinite wisdom of the Creator, that there should be different and various degrees of creatures, whereof, consequently, some must be *less perfect* than others; hence there necessarily arises a possibility of evil, notwithstanding that the Creator is infinitely good. In short thus: all that we call *evil*, is either an *evil of imperfection*, as the *want of certain faculties and excellencies which other creatures have*; or *natural evil*, as *pain*, *death*, and the like; or *moral evil*, as all kinds of *vice*; the *first* of these is not properly an evil. For every power, faculty, or perfection, which any creature enjoys, being the free gift of God, which he was no more obliged to bestow, than he was to confer being or existence itself; 'tis plain the want of any certain faculty or perfection in any kind of creatures, which never belonged to their nature, is no more an evil to them, than their never having been created or brought into being at all, could properly have been called an evil. The *second* kind of evil, which we call *natural evil*, is either a necessary consequence of the former; as *death*, to a creature on whose nature immortality was never conferred; and then 'tis no more properly an evil than the former; or else 'tis counterpoised, in the whole, with as great or greater good; as the *afflictions and sufferings of good men*; and then also it is not properly an evil; or else, lastly, 'tis a *punishment*; and then 'tis a necessary consequent of the *third* and last sort of evil, *viz.* *moral evil*. And this arises wholly from the abuse of *liberty*, which God gave to his creatures for other purposes, and which 'twas reasonable and fit to give them for the perfection and order of the whole creation: only they, contrary to God's intention and command, have abused what was necessary for the perfection of the whole, to the corruption and depravation of themselves. And thus all sorts of evils have entered into the world, without any diminution to the infinite goodness of the Creator and Governor thereof.

EVIL, or *King's* EVIL, the appellation formerly given to *scrofula*, in consequence of the supposed power possessed by the kings of England and France of curing this disease by *touching* the sick.

The origin and first exercise of this royal faculty are not agreed upon by historians; those of France are disposed to maintain, that it was originally inherent in their kings, some asserting that St. Louis, others that king Robert, was the first who was thus gifted; but by most other writers it is assigned as an earlier prerogative of the English crown. Edward the Confessor is generally mentioned as the first possessor of this miraculous power: and it was disputed in the days of Malmsbury, who lived not long after his reign, whether this faculty were a peculiar reward from heaven for that king's sanctity, or hereditarily resident in the English crown. Polydore Virgil has noticed this gift to Saint Edward, and its continuance in the line of his successors; and Dr. Harpsfield, in his Ecclesiastical History of England, after describing the miracles of the Confessor, observes, "quam strumosos sanandi admirabilem dotem in posteros suos Anglorum reges, ad nostra usque tempora transfudisseet perpetuasse, merito creditur." The practice was long continued, and seems to have reached its greatest height in the reign of Charles II. to whom multitudes flocked to receive the benefits of the royal touch; insomuch, that after his restoration, he is said to have laid his hands upon more than six thousand persons in one year. His majesty was therefore obliged to make some restrictions with regard to the times of healing, and the number of patients. All persons were obliged to go to the king's surgeon, whose duty it was to examine

examine their certificates from the minifter and church-wardens of their parifh, to determine whether they were proper objects, to give them tickets of admiffion to the royal prefence, and to introduce every one to the king's facred hand to be touched. The king ufually gave public notice of the day of healing; in the winter the ceremony was always held at Whitehall; in the fummer fometimes at Whitehall, and fometimes at Windfor.

The following curious paragraphs were made public in 1660.

"The kingdom having been for a long time troubled with the evil, by reafon of his majefty's abfence, great numbers have lately flocked for cure. His facred majefty, on Monday laft, touched 250 in the Banqueting houfe; among whom, when his majefty was delivering the gold, one fhuffled himfelf in, out of an hope of profit, which had not been ftroked, but his majefty quickly difcovered him, faying, this man hath not yet been touched. His majefty hath for the future appointed every Friday for the cure, at which 200, and no more, are to be prefented to him, who are firft to repair to Mr. Knight, the king's furgeon, &c. Parliamentary Journal, July 2—9, 1660.

"Saturday being appointed by his majefty to touch fuch as were troubled with the evil, a great company of poor afflicted creatures were met together, many brought in chairs and flafkets; and being appointed by his majefty to repair to the Banqueting-houfe, his majefty fat in a chair of ftate, where he ftroked all that were brought to him, and then put about each of their necks a white ribbon, with an angel of gold on it. In this manner his majefty ftroked above fix hundred; and fuch was his princely patience and tendernefs to the poor afflicted creatures, that though it took up a very long time, his majefty, who is never weary of well-doing, was pleafed to make inquiry whether there were any more that had not yet been touched. After prayers were ended, the duke of Buckingham brought a towel, and the earl of Pembroke a bafon and ewer, who, after they had made obeifance to his majefty, kneeled down till his majefty had wafhed." Mercurius Politicus, June 21—28, 1660.

An exact regifter was at that time kept of the number of cafes that came for relief, and the whole amount is very great. From 1660 to 1664 inclufive, a period of five years, 23,601 perfons were touched by Charles II.: and from May 1667 to May 1684, the number of perfons touched amounted to 68,506; making all together 92,107. For the intervening years, 1665 and 1666, no regifter was made, the king having removed from the metropolis on account of the plague.

This fuperftitious practice was dropped by the prefent royal family, "who obferved (fays Hume) that it could no longer give amazement, even to the populace, and was attended with ridicule in the eyes of all men of underftanding." Rapin indeed remarks, that "the late king William III. of glorious memory, was fo perfuaded he fhould do no injury to perfons afflicted with this diftemper, by *not* touching them, that he refrained from it all his reign." The practice continued in vogue in the reign of queen Anne; it is recorded of Dr. Johnfon, that he was touched by that princefs, but without effect.

It is extraordinary that this belief in the efficacy of the royal touch in the cure of this fevere difeafe was by no means confined to the vulgar, nor to perfons unacquainted with the nature and cure of difeafes. Dr. Johnfon's mother is faid to have been inftigated by the advice of a celebrated phyfician, fir John Floyer, to bring her fon to London for the purpofe of receiving the remedy. And Wifeman and Browne, eminent furgeons of their day, and furgeons to the king (Charles II.) have given their ftrongeft teftimony in favour of the fuperiority of the royal remedy, over any which their art poffeffed. "I muft needs profefs," fays Wifeman, "that what I write will do little more than fhew the weaknefs of our ability, when compared with his majefty's, who cureth more in any one year, than all the chirurgeons of London have done in an age. However, that this attempt may not feem to want precedent, give me leave to tell you, that it is no more than the French kings' chirurgeons have done before me, or than old Mr. Clows did in queen Elizabeth's days, and all other general writers in chirurgery have done more or lefs." And he affirms that he had been "a frequent eye-witnefs of many cures performed by his majefty's touch alone, without any affiftance of chirurgery; and thofe many of them fuch as had tired out the endeavours of able chirurgeons before they came thither."

The other furgeon royal juft mentioned has left us the moft circumftantial account of this royal healing, in a publication, entitled "Adeno-choiradelogia; or, an Anatomick-Chirurgical Treatife of Glandules and Strumæs, or King's-evil-fwellings, together with the Royal Gift of Healing, or Cure thereof, by Contact or Impofition of Hands, performed for above 640 years by our kings of England; continued with their admirable effects and miraculous events; and concluded with many wonderful examples of Cures by their facred touch. All of which are fuccinctly defcribed by John Browne, one of his Majefty's Chirurgeons in Ordinary, and Chirurgeon of his Majefty's Hofpital, London, 1684." His offices evince that the author was a man of character, and his book is approved, as was the cuftom of his time, by the prefident and feveral fellows of the College of Phyficians. Like Wifeman, he feems to have been a ftaunch loyalift, and a vehement defender of the divine right of kings; he detefted all diffenters, and confidently afferts that the ufurper, Cromwell, tried in vain to exercife this royal prerogative, "he having no more right to the healing power, than he had to the regal jurifdiction." The third part of the treatife of Browne, which is devoted to the hiftory and nature of the royal gift, is entitled *Charifma Bafilicon*. Befides an hiftorical view of this prerogative, it contains rules for the meaneft capacity to find out the difeafe, which were deemed expedient to prevent poor people from unneceffary journeys; and fixty admirable cures, performed with or without gold, are circumftantially detailed, as well as feveral cafes of fcrofulous tumours and fores, which difappeared on being touched with handkerchiefs dipped in the blood of Charles I.

Some fhrewd fufpicions had, indeed, been thrown out, that the piece of gold, given by the king on the occafion, was the moft efficacious remedy employed; and the above mentioned writers are anxious to refute fuch a flander on the royal qualifications. The author of a late treatife tells the following ftory, which may, in fome degree, account for the numbers regiftered at Whitehall. "An old man, who was witnefs in a caufe, had by his evidence fixed the time of a fact, by queen Anne having been at Oxford, and touched him while a child, for the cure of the *evil*. When he had finifhed his evidence, the relator had an opportunity of afking him whether he was really cured. Upon which he anfwered, with a fignificant fmile, that he believed himfelf never to have had a complaint, that deferved to be confidered as the *evil*; but that his parents were poor, *and had no objection to the bit of gold*." See Wifeman's Chirurgical Treatifes, book iv. chap. 1. Browne above cited. Edin. Med. and Surg. Journal, vol. iii. p. 185.

EULER, LEONARD, in *Biography*, a great mathematician, was born at Bafil in the year 1707, where he was educated. He performed his academical tafks with fo much rapidity, that he had a good portion of time left at his own command, which he confecrated to the ftudy of the mathematics. In the purfuit of this kind of knowledge, he was affifted by John Bernouilli, who was regarded as one of the chief mathematicians of Europe, and whofe diftinguifhed attention and efteem he obtained, by his early proficiency and unwearied application. In 1723, M. Euler was admitted to the degree of M. A. on which occafion he obtained great applaufe by delivering a Latin difcourfe, wherein he drew a comparifon between the philofophy of Newton and the Cartefian fyftem. In compliance with his father's defire, he applied himfelf to theology and oriental literature, in which he made no inconfiderable progrefs, but his predominant bias ftill leading him to the mathematics, his father allowed him to follow the bent of his inclination. In the courfe of his ftudies under Bernouilli, he contracted an intimate friendfhip with his two fons, Nicholas and Daniel, which proved to be of the higheft advantage to him in after life. Thofe two celebrated mathematicians having been invited to Peterfburgh, in the year 1725, by Catharine I. for carrying into execution the project of Peter the Great, for the eftablifhment of an academy of fcience, promifed Euler to ufe their endeavour to find him a fituation in that city. By their advice he applied himfelf diligently to the ftudy of natural knowledge, and attended the lectures of all the eminent profeffors of Bafil. While engaged in thefe purfuits he compofed a differtation "On the nature and propagation of Sound;" and alfo an anfwer to a prize queftion, "Concerning the mafting of Ships," which obtained the fecond prize. By this circumftance his attention was early drawn to the curious and important ftudies of naval architecture and navigation, which he contributed greatly to enrich in the fubfequent periods of his life. He now joined his friends the Bernouillis at Peterfburgh, and was appointed with them a joint profeffor in the univerfity of that city. In this fituation his talents and genius were fo far called into exercife as to entitle him to rank among the moft eminent mathematicians. He contributed many memoirs to the academical collection, which excited a noble fpirit of emulation between him and his two friends, unalloyed by the leaft mixture of envy or jealoufy, and fuch as produced no alteration in their friendfhip. The integral calculus he carried to new degrees of perfection; invented the calculation of fines; fimplified analytical operations, and in this way threw new light on all the branches of mathematical fcience. In 1730, M. Euler was appointed profeffor of natural philofophy; and, in 1733, he fucceeded his friend Daniel Bernouilli, in the mathematical chair. In 1735, the academy propofed an intricate and important problem for folution, which Euler completed in three days, though it was fuppofed to be the labour of many months. The exertion on this occafion was fo violent that it produced a fever which endangered his life, and deprived him of the ufe of one of his eyes. In the year 1740, the Academy of Sciences at Paris propofed for folution the important fubject of "The flux and re-flux of the fea." To this Euler applied the force of his genius, and produced a memoir, which was allowed to be a mafter piece of analyfis and geometry. He had, however, as competitors, Daniel Bernouilli, and our countryman, Colin Maclaurin, with whom he fhared the prize. In 1741, Euler, at the exprefs invitation of the king of Pruffia, repaired to Berlin, where his induftry and talents appeared to great advantage. He furnifhed many effays for the memoirs of the Pruffian academy, without withholding his contributions from the academy of Peterfburgh, which was now encouraged by the patronage and munificence of the emprefs Elizabeth. In 1742, he obtained a penfion from the academy at Peterfburgh, and in 1766, by permiffion of the king of Pruffia, he returned to that city, to fpend the remainder of his days; when the munificence of Catharine II. liberally rewarded him for the preference which he exhibited towards his Peterfburgh connections. Shortly after his return he loft the fight of the other eye, yet in this deplorable fituation he dictated to his fervant, an unlettered youth, and who was entirely unacquainted with mathematical knowledge, his "Elements of Algebra," a work of high merit, and which has been tranflated into the Englifh language. At this period he was elected one of the very few foreign members of the Academy of Sciences at Paris. After this he received from them the prize for his differtations "Concerning the inequalities in the motions of the planets:" alfo two prizes for queftions propofed relative to "A more perfect theory of the moon." He next reviewed his whole theory with the affiftance of his fon, and Meffrs. Krafft and Lexell; and purfued his refearches till he had conftructed the new tables which appeared with the great work in 1772. "This work alone," fays his biographer, "would be fufficient to render his name immortal, and when it is confidered that it was completed after he was totally blind, and at a time in which he was embarraffed in his domeftic circumftances by a dreadful fire, that had confumed great part of his fubftance, and forced him to quit the ruined houfe; it is impoffible not to be ftruck with admiration and aftonifhment at the powers of his genius and memory, and the perfeverance, fortitude, and tranquillity of mind which he muft have poffeffed." Some time after this he underwent the operation of couching, which reftored to him his fight; but either too eager to benefit by the organ, or by the negligence of his furgeon, he was a fecond time deprived of his fight, and the relapfe was attended with much tormenting pain. Still he he was active in the purfuit of fcience, and in the courfe of feven years tranfmitted to the academy of Peterfburgh feventy diftinct memoirs, and left behind him two hundred more, which were afterwards revifed and completed. In the beginning of September, 1783, he was feized with feveral attacks of a vertigo; thefe, however, did not prevent his calculating the motion of air-balloons, which then began to engage the attention of the philofophical world; but on the 7th of the fame month, while he was amufing himfelf with his grand-children, an apoplectic fit terminated his illuftrious career, at the age of 76. Befides being foreign member of the Royal Academy of Sciences at Paris, M. Euler was member of the Imperial Academy of Peterfburgh, ancient director of the Royal Academy of Berlin, and fellow of the Royal Society of London. His works were very numerous; his knowledge was not confined to his favourite ftudies of the mathematics and aftronomy, of which he has fecured to himfelf an imperifhable fame. He had made much progrefs in medical, botanical, and chemical fcience. He alfo poffeffed, in a high degree, what is generally called erudition. He had read with attention and tafte the moft eminent Latin claffics, and was familiarly acquainted with the civil and literary hiftory of all ancient and modern nations. His uncommon memory feemed to retain every idea that was conveyed to it either from reading or from meditation. The Æneid of Virgil he could repeat from the beginning to the end, and point out to his hearers the firft and laft line of every page in the edition which he ufed. He enjoyed a vigorous conftitution, and a furprifing fhare of health, confidering the intenfity and ardour of his application. His manners were unaffected and pleafing, his temper lively and cheerful, and his converfation both inftructive and entertaining. The evening of his days was calm and ferene, fweetened in no fmall degree by the fame that follows genius, the univerfal efteem and refpect that were due to his exemplary virtues, and the fatisfaction which he received from the kind offices of friendfhip, and the endearments of domeftic felicity.

This great geometrician had beftowed much meditation, early in life, on harmonics, or the philofophy of found; for in 1739, at the age of 32, he publifhed at Peterfburgh, in Latin, a work in 4to. under the title of "Tentamen novæ Theoriæ Muficæ ex certiffimis harmoniæ principiis dilucidé expofitæ, auctore Leonardo Eulero." This work, being written in Latin, and requiring in the reader, befides that language, a knowledge in geometry, algebra, and fluxions, was little noticed by the public at large on its firft appearance, and ftill lefs underftood by muficians, for whofe ufe it muft have been chiefly intended. It, however, fet mathematicians and men of fcience to work, and ftarted many curious fubjects of meditation to fuch as interefted themfelves in the ftudy of harmonics.

But we do not very well fee how the author could with propriety call his treatife an attempt at a *new* theory of mufic. The ratios were all known ever fince the time of Euclid. Indeed he has followed the proportions which Zarlino tried to eftablifh in his "Inftitutioni," which had been adopted by Des Cartes, Rameau, Tartini, &c.; and Des Cartes, and others after him, had accounted for the pleafure which we receive from concords, by the fimplicity of the ratios between the founds which form them. There is a plate, p. 35, reprefenting, we thought, in a new and ingenious manner to the eye, the pulfations of two ftrings; the one fixed to a given tone, and the other tuned progreffively to all the confonant intervals, which clearly fhews the coincidences of vibration, upon the frequency of which the degree of fweetnefs and perfection in concords depends. We believe, however, that this was done in the 17th century, but in a lefs elegant manner, by our countryman lord keeper North, in a quarto pamphlet of only twenty-five pages, intitled, "A Philofophical Effay of Mufick directed to a Friend;" London, 1677.

In this little tract the vibrations of each confonance are reprefented to the eye, and the coincidences with the fixed tone, its bafe or principal, in the fame manner as in the work of the great geometrician Euler, who has pufhed ratios as far as our perception and appreciation can go, extending the whole compafs of our mufical fyftem to eight octaves. See COMPASS.

The degrees of fuavity in confonance from the fimplicity of ratios and frequency of coincidence, had, we believe, been fettled before the year 1739, when this treatife was publifhed.

The following is a tranflation of the titles of the feveral chapters of this work. After a preface of twenty pages,

Chap. I. treats of found, and the auditory fenfe.
II. Of the fweetnefs and principles of harmony.
III. Of mufic in general.
IV. Of concords.
V. Of concords in fucceffion.
VI. Of a feries of concords.
VII. Of intervals, and their names.
VIII. Of the genera of mufic.
IX. Of the diatonico-chromatico genus.
X. Of other more compounded genera.
XI. Of the concords in the diatonico-chromatico genus.
XII. Of the modes or keys and fyftems in the diatonico-chromatico genus.
XIII. Of the ratio of compofition in a given mode and fyftem.
XIV. Of the modes and fyftems in tranfpofed keys.

In the 13th chap. on the laws of compofition, and the poffible combinations in any given mode, key, or fyftem, fome of thefe combinations employ every note in the fcale, feemingly at once, which would be extremely offenfive if heard together. The author probably means, that all thefe founds may be heard fucceffively in melody, provided they are in tune, and have a fundamental bafe.

Upon the whole, Euler feems not to have invented much in this treatife; and to have done little more than arrange and methodize former difcoveries in a fcientific and geometric manner. He may, indeed, not have known what antecedent writers had difcovered before; and though not the firft, yet to have imagined himfelf an inventor.

EULER's *Logarithms*, or *Binary Logarithms*, are a fpecies of artificial numbers contrived by M. Euler to facilitate the calculation and comparifon of mufical intervals, which they do, by reprefenting each interval in *decimal parts* of the octave, which is 1 in this notation, the fucceffive octaves or powers of 2 being reprefented by 2, 3, 4, &c. as in the following table, for the firft 10 numbers, *viz.*

1 = 0.000000	6 = 2.584963
2 = 1.000000	7 = 2.807356
3 = 1.584963	8 = 3.000000
4 = 2.000000	9 = 3.169925
5 = 2.321928	10 = 3.321928

By help of the primes which compofe mufical ratios, and their binary logarithms in this table, the Euler's logarithm may be found, which anfwers to any interval: as the names of the feveral intervals occur, we fhall give their binary logarithms.

EULISIA, in *Ancient Geography*, a country of Scythia, towards the Palus Mæotis.

EULOGIUS, in *Biography*, patriarch of Alexandria, was, at firft, prefbyter of the church of Antioch, and diftinguifhed himfelf by his zeal for the Catholic doctrines in a letter which he wrote to Eutychius, patriarch of Conftantinople, containing an expofition of the true faith. He was elevated to the fee of Alexandria in the year 581, and became very active in rooting out herefy, not only by the allowable and fair weapons of reafon and argument, but by expelling from their fituation all ecclefiaftics who were advocates for the doctrine of one nature in Chrift. He lived in habits of intimacy with Gregory the Great, whofe fentiments and difpofition were congenial to his own. He died in 608. Of his works only fragments are remaining. Moreri.

Eulogius, elected archbifhop of Toledo in the ninth century, was born at Cordova about the year 800. He was educated for the priefthood, and difcharged the duties of that office with zeal and activity till the year 844, when he was driven into exile by the Saracens for his boldnefs in maintaining the principles of the Catholic faith. After much fuffering he ventured to return to Cordova, where, in the year 850, he was thrown into prifon on account of his religion. In the dungeon he employed himfelf in writing animating exhortations to the Chriftians, to fupport and confole them under their perfecution, for confcience fake, and to encourage them to undergo the fevereft trials rather than difgrace themfelves by apoftacy. He was afterwards liberated, and by his perfonal labours, as well as writings, perfevered in fortifying his fellow Catholics againft the arts and terrors of their enemies. As a reward for his exertions in this hazardous employment, he was chofen to fill the vacant fee of Toledo; but he was put to death before he could receive the epifcopal confecration. The accufation againft him was the having converted a young Mahometan female to the Chriftian faith: he was beheaded in 859. He was author of "Memoriale Sanctorum, five Libri III. de Martyris Cordubenfibus;" "Apologeticus pro Martyribus, &c.;" "Exhortatio ad Martyrium;" and fome moral epiftles. Thefe were collected and printed with notes by Ambrofius Moralis in 1554, and again in a more correct form by Poncius Leo in 1574. Moreri.

EULOGY, Eulogia, in *Church Hiftory*. When the Greeks have cut a loaf, or piece of bread, to confecrate it, they break the reft into little bits, and diftribute it among the perfons who have not yet communicated, or fend it to perfons that are abfent; and thefe pieces of bread are what they call eulogies.

The word is Greek, ευλογια, formed of ευ, *bene*, *well*, and λεγω, *dico*, *I fay*, *fpeak*; q. d. *benedictum*, *bleffed*.

The Latin church has had fomething like eulogies for a great many ages; and thence arofe the ufe of their holy bread.

The name eulogy was likewife given to loaves or cakes brought to church by the faithful to have them bleffed.

Laftly, the ufe of the term paffed hence to mere prefents made a perfon, without any benediction. See the Jefuit Gretfer, in his Treatife de Benedictionibus & Maledictionibus, lib. ii. cap. 22. 24, &c. where he treats of eulogies thoroughly.

From a paffage in Bollandus, on the Life of S. Melaine, cap. 4. it appears, that eulogies were not only of bread, but any kind of meat bleffed and hallowed for that purpofe. And that almoft every body bleffed and diftributed eulogies; not only bifhops and priefts, but even hermits, though laymen, made a practice of it. Women alfo would fometimes fend eulogies.

The wine fent as a prefent was alfo held an eulogy. Bollandus remarks farther, that the eucharift itfelf was alfo called eulogy.

Eulogy, likewife, means an encomium on any perfon, on account of fome virtue or good quality.

EUMARIDES, of ευμαρης, *eafy*, among the *Ancients*, a kind of fhoes common to men and women.

The eumarides were ufed for pomp and delicacy, being neat, and painted with various colours.

EUME, in *Geography*, a river of Spain, which runs into the fea near Corunna.

EUMECES, in the *Writings of the Ancient Naturalifts*, the name of a ftone which Pliny tells us refembled a flint, and was found in Bactria; the ancients had an idle opinion, that, if laid under the head, it occafioned true and prophetic dreams, foretelling to the perfon the more remarkable future events of his life. Hift. Nat. lib. xxxvii. cap. 10.

EUMENES, in *Biography*, a captain under Alexander the Great, was a native of Cardiopolis, in the Thracian Cherfonefe. His father was of a low ftation, but one in a condition to have entertained at his houfe Philip king of Macedon, who became the patron of his fon. So well did the youth approve himfelf as fecretary to the monarch, that his fon Alexander continued him in the fame office, and gave him a command in the cavalry. According to Plutarch, Eumenes took every advantage that his ftation afforded him of accumulating money, for his tent being fet on fire by the private orders of his fovereign, to whom he had refufed the loan of three hundred talents; there was found to the value of more than one thoufand talents in melted gold and filver. After the death of Alexander, when the provinces were divided among the principal commanders, the government of Cappadocia, Paphlagonia, and the country bordering on the Euxine fea, as far as Trapezius, which as yet were unconquered, were affigned to Eumenes. Eumenes attached himfelf to Perdiccas, who made him his chief minifter, and gave directions to Antigonus and Leonatus to put him in poffeffion of his government. Antigonus paid no attention to the order, but Leonatus, pretending to comply, marched an army feemingly for the purpofe, which Eumenes joined. His defign was, however, to feize the kingdom of Macedon for himfelf; but upon making it known, Eumenes deferted him by night, after feizing his treafures, and repaired to Perdiccas. In reward for his fidelity, Perdiccas himfelf made an expedition in Cappadocia, and after defeating and killing the king Ariathes, left Eumenes mafter of the country. He was next appointed prefect of Afia, between mount Taurus and the Hellefpont, and was entrufted with the care of oppofing the army expected to march againft him out of Greece under Antipater and Craterus. On the approach of thefe great commanders, Eumenes concealed from his army that they were about to contend with Craterus, for whom they entertained the moft profound refpect and veneration, and giving battle to him and Neoptolemus, he flew the latter with his own hand, while Craterus was mortally wounded, fighting at the head of his phalanx. Eumenes, who felt for him emotions of the fincereft friendfhip, grafped his hand as he was expiring, wept over his remains, and honoured him with a magnificent funeral. After the murder of Perdiccas by his own army, Eumenes was declared a public enemy, and Antigonus was fent to conduct the war againft him. Eumenes was routed, but able to retire to the impregnable caftle of Nora, which he defended with great ability. He was abundantly fupplied with corn, and though without

out any other kind of provifions, he kept his men in good humour, by his affable and cheerful demeanour. Another fcene opened itfelf for the ambition of Antigonus, and Eumenes was fet at liberty. He inftantly began to levy troops, and in a fhort time was declared royal general of Afia, and there was affigned to him a guard of Argyrafpidæ, or filver fhields. To infpire his troops with a fort of religious enthufiafm in the caufe, he pretended to have feen Alexander in a vifion, by whofe direction he erected a royal tent, containing a throne of gold, with all the enfigns of majefty, where the captains were to offer incenfe, and then deliver their orders in a common council. After this there were difputes about the chief command, but when Antigonus approached all agreed that Eumenes was the only general, under whom they would fight. His fituation was difficult and precarious, he was aware that many of the other commanders were defirous of getting rid of him, as the chief obftruction to their ambitious defigns. From thofe whom he moft fufpected he borrowed large fums of money, that by fuch a pledge he might give them an intereft in his fecurity. The war was protracted with various fuccefs to a fecond campaign, when a battle enfued, in which Eumenes routed the enemies' infantry, but in the mean time his cavalry took poffeffion of the camp of Eumenes. This circumftance occafioned fo much difcontent in the army, that when Antigonus fent an offer to reftore the foldiers, their wives and property, on condition of their delivering Eumenes into his hands, the Argyrafpidæ furrounded him, feized his fword, tied his arms behind him, and gave him up prifoner. Antigonus being afked how he fhould be kept? As you would keep a lion or a wild elephant, he replied. All the Afiatic chiefs fubmitted upon this event, and it remained only to determine the fate of the illuftrious captive. This was fo long kept in fufpence, that Eumenes expreffed his furprife that Antigonus had neither the courage to put him to death, nor the generofity to make him his friend by fetting him at liberty. A party in the army, headed by Demetrius, favoured the laft meafure, but the majority urged Antigonus to remove fo formidable a rival. This counfel prevailed, and orders were given to deprive him of food. He had fuffered the pains of hunger two or three days, and was faft approaching his end, when the army being fuddenly obliged to decamp, an executioner was fent to difpatch him. His remains were treated with funeral honours, and his afhes were enclofed in a filver urn, and fent to his family. This was in the year 315 B. C. Eumenes had a fine perfon, was highly accomplifhed, and poffeffed the manners and fentiments fuited to an elevated ftation; he was faithful to the caufe of his deceafed mafter, and it was not till after his death that the captains who divided the Macedonian empire among them openly affumed the ftyle of independent fovereigns. Eumenes perifhed in his forty-fifth year. Univer. Hift. Plutarch.

Eumenes II. king of Pergamus, fucceeded his father Attalus in the year B. C. 197. He cultivated the friendfhip of the Romans, who were now beginning to extend their influence into Afia, urging them to check the ambitious projects of Antiochus the Great, of which he feared he fhould be the victim. Eumenes joined his fleet to that of the Romans, and by his perfonal bravery greatly contributed to a naval victory, which was gained over that king; nor was he lefs ufeful at the decifive battle of Magnefia. On account of his important fervices he was rewarded by an acceffion to his dominions, of all the countries weft of mount Taurus, which had belonged to Antiochus, and alfo of all the provinces lying between that mountain and the river Meander, except Lycia and Caria, which were given to the people of Rhodes. Eumenes, now one of the moft potent princes in Leffer Afia, was involved in a war with Prufias, king of Bithynia, in which he was defeated both by land and fea. Peace was made, and another conteft took place between Eumenes and Pharnaces; in this the latter was obliged to fue for peace. Eumenes now made an alliance with Antiochus, fon of his old enemy Antiochus the Great, and in conjunction with his brother Attalus placed that prince on the throne of Syria, from which he had been driven by an ufurper. Perfes, king of Macedon, by increafing his military force, excited the jealoufy of his neighbours, and Eumenes took a journey to Rome, for the purpofe of acquainting the fenate with all he had difcovered of his dangerous projects. On his return, Eumenes, going to offer facrifice at the temple of Delphi, had nearly loft his life by affaffins hired by Perfes to deftroy him. He received fo much injury that he was carried almoft lifelefs on board his fhip, and it was generally believed that he was actually dead. Attalus his brother, giving credit to the news, affumed the royal enfigns, and even married the queen Stratonice. Eumenes, after his recovery, gave his brother a friendly reception, advifing him not to marry his wife again till it was certain he was dead. From this period he was engaged in contefts with the Romans, who began to regard him with fufpicion, and it is thought they encouraged Attalus to feize upon his brother's kingdom for himfelf. Eumenes died in the year 159 B.C. leaving an infant fon to the protection of his brother and fucceffor Attalus. Eumenes was liberal, and even magnificent towards his friends. He was a patron of letters, and made confiderable additions to the celebrated library of Pergamus. Univer. Hift.

Eumenes, an orator, was an Athenian by defcent, but was born at Autun in Gaul, where he was for a confiderable time profeffor of rhetoric, and acquired great reputation. He was fecretary to the emperors Maximian and Conftantius, and was much efteemed by Conftantine the Great, whom he harangued in favour of the inhabitants of Autun in 311. He delivered an oration before the prefect of Lyonefe Gaul, in favour of the reftoration of the public fchools in the province, towards which he nobly offered to contribute his own falary, as fecretary, probably, as well as profeffor. He died about the middle of the fourth century. Fragments of his orations are printed in the "Panegyrici Veteres." Moreri.

EUMENIA, in *Ancient Geography*, a town of Afia, in the Greater Phrygia, feated on the Cludrus.—Alfo, a town of Afia Minor, in Caria.—Alfo, a town of Thrace, on the confines of Lower Mœfia.

EUMENIDEIA, Ευμενιδεια, an annual feftival obferved in honour of the Furies. It was otherwife called σεμνων εορτη, becaufe the Athenians called the Furies σεμναι θεαι, *i. e. venerable goddeffes.*

EUMENIDES, in *Antiquity*. See Furies.

EUMETRES Beli, in *Natural Hiftory*, the name given by the ancients to a gem which the Affyrians held facred to their god, and which many other nations learned from them to fuppofe very powerful againft magic. Many have fuppofed this to be the one we now call oculus Beli: but this is an error, fince Pliny, in his account of the eumetres, fays, that it was of a very fine green. It was probably a gem of the emerald kind, that ftone having ever been in very high efteem in the Eaftern part of the world, as it is alfo to this day.

EUMINACUM, in *Ancient Geography*, a town of Mœfia, Mœsia, marked in the Itinerary of Antonine; 24 miles from Viminiacum.

EUMME' Faregge', or *Omm Faredje*, a canal of Egypt, joining lake Manzaleh with the Mediterranean; supposed to be the mouth of that ancient canal, called the Tanitic or Saitic branch of the Nile.

EUMOLPIDES, in *Antiquity*, priests of Ceres, who had the power among the Athenians of initiating into the mysteries of this goddess, or excluding from them.

EUMOLPUS, in *Biography*, a disciple of Orpheus, who, tracing the footsteps of his father Musæus, wrote concerning the mysteries of Ceres.

EUNAPIUS, a native of Sardis, in Lydia, flourished in the fourth century, and was a kinsman of the celebrated sophist Chrysanthius, at whose request he wrote the lives of the philosophers of his time. This work has been characterized by Brucker "as a mass of extravagant tales, discovering a feeble understanding, and an imagination prone to superstition;" besides being a sophist, he was an historian, and practised physic. In his writings he seems to have entertained a great prejudice against Christianity, the martyrs to which he treats with a contempt that has given just offence to contemporary ecclesiastical writers. He wrote a history of the Cæsars from Claudius II. to Arcadius and Honorius, of which only a fragment, "De Legationibus," is remaining. The "Vitæ Philosophorum" was published with a Latin translation by Junius in 1596. Moreri.

EUNILAK, in *Geography*, a place of East Greenland. N. lat. 61° 4'. W. long. 46°.

EUNOFIUS, a name given by some authors to the ætites, or eagle-stone.

EUNOMIANS, in *Ecclesiastical History*, a sect denominated from Eunomius, bishop of Cyzicus, who, in the fourth century, maintained most of the errors of Arius, and added others to them. He was a native of Dacora, a town of Cappadocia; and removing to Constantinople, gained his subsistence first as a notary, and afterwards as a schoolmaster. At Alexandria he became a disciple of Aetius, whose opinions he adopted and strenuously defended. Having been ordained a deacon by Eudoxius, bishop of Antioch, he was deputed to the court of the emperor Constantius for the purpose of defending Eudoxius against the accusations of Basil, bishop of Ancyra; but in his way thither he was seized by the partizans of Basil, and banished to Myda, a city in Phrygia. In the year 360 he was ordained bishop of Cyzicus; but boldly avowing his opinions, he became obnoxious to the orthodox party, and underwent various and severe persecutions. At the command of the emperor Constantius, he was at length condemned and deposed by Eudoxius. At Chalcedon, whither he retired, his enemies pursued him, and he was afterwards banished by the emperor Valens to Mauritania. At the close of the reign of this emperor, after he had been allowed to return to Constantinople, he was charged with disturbing the peace of the church, and again banished to the island of Naxos. When Valens died, he returned to Chalcedon, but was soon sent into exile by the emperor Theodosius. Wearied by incessant and grievous persecution he obtained leave from the court to retire to the place of his nativity, where he died at an advanced age, about the year 394. He was the author of various works, most of which are now lost. Those that are extant are "Eunomius's Creed," presented to the emperor Theodosius in the year 383, and his "Apologeticus," or Defence of his Doctrine, in which, according to Dr. Cave, the sly arch-heretic reasons shrewdly. Fabricius has published this piece entire, and an English version of it may be seen in the 1st volume of Whiston's "Primitive Christianity revived." Socrates Hist. Eccles. Cave's H. L. Fabr. Bib. Græc. vol. viii. Lardner.

EUNOMIŒUPSYCHIANS, a sect of heretics of the fourth century, mentioned by Nicephorus, lib. xii. cap. 30. being the same with those called Eutychians by Sozomen, lib. vii. cap. 17. See Eutychians.

EUNUCH, Ευνουχος, a term applied in the general to all who have not the faculty of generating, either through imbecility or frigidity; but more particularly to such as have been castrated, or have lost some of the parts necessary for that purpose.

The word is formed of ευνην εχει, q. d. *lecti curam habet, guardian*, or *keeper of the bed.*

In England, France, &c. eunuchs are never made but on occasion of some disease which renders such an operation necessary; but in Italy they make eunuchs for the sake of preserving the voice; and in the East they make eunuchs to be guards or attendants on their women.

Great numbers of children, from one to three years of age, are yearly castrated in Italy to supply the operas and theatres, not only of Italy but other parts of Europe, with singers; though it is not one in three, that, after having lost their virility, have a good voice for a recompence. See Conservatorios.

Tavernier assures us, that in the kingdom of Boutan, in the East Indies, there are every year made twenty thousand eunuchs, and sold thence into other countries.

The seraglios of the Eastern emperors are chiefly served and guarded by eunuchs; and yet we have very good testimonies, that the rich eunuchs in Persia and other countries keep seraglios for their own use. This is a punishment of crimes in some countries. See Adultery.

By an arret of the grand chamber of Paris in 1665, it is adjudged that an eunuch could not marry, not even with the consent of the woman, and all the parties on both sides.

Claudian has a very severe satire against the eunuch Eutropius, who had been elected consul of Rome. He represents him as an old woman, dressed up in the honours of the consulate.

In the council of Nice those were condemned who, out of an indiscreet zeal, and to guard themselves from sensual pleasures, should make themselves eunuchs. Such as thus mutilated their bodies were excluded from holy orders; witness Leontius, bishop of Antioch, who was deposed for having practised this cruelty on himself; and the bishop of Alexandria excommunicated two monks who had followed his example, on pretence of securing themselves from the impetuous motions of concupiscence.

Several of the emperors made very severe prohibitions against the making of eunuchs, or people's castrating themselves. See Castration.

Eunuchs, *Eunuchi*, in *Ecclesiastical History*, is also the denomination of a sect of heretics in the third century, who had the folly or madness to castrate not only those of their own persuasion, but even all they could lay hands on.

They took their rise from the example of Origen, who, upon a misunderstanding of our Saviour's words in St. Matthew, chap. xix. ver. 12. made himself an eunuch, by cutting off the offending part, as some say; or as others (particularly St. Epiphanius), by the use of certain medicines. These heretics were also called *Valesians.*

EVOCATI, among the Romans, soldiers, who having served their time in the army, went afterwards volunteers at the request of some favourite general.

EVOCATION, Evocatio, among the Romans, a religious ceremony always observed by them at undertaking the

the siege of a town, wherein they solemnly called upon the gods and goddesses of the place to forsake it and come over to them. Without the performance of this ceremony, they either thought that the place could not be taken, or that it would be a sacrilege to take the gods prisoners.

The form of evocation used at taking the city of Carthage is related by Macrobius, Sat. III. 9.

They always took it for granted that their prayer was heard, and that the gods had deserted the place and came over to them, provided they were able to make themselves masters of it. The ancients had also two other sorts of evocation; one was a magical operation, which they used in order to call up departed souls. This custom of raising the manes, or conjuring up souls departed, was so ancient, that its origin is traced as high as the earliest periods of time; and all the anathemas denounced by the sacred authors against those who consulted familiar spirits are proofs of the antiquity of this practice. Among the different sorts of magic prohibited by Moses, that of calling up the dead is expressly specified. (See Witch *of Endor.*) Prophane authors look upon Orpheus as the inventor of this art, in evidence of which it is alleged, that the hymns which are ascribed to him are mostly real pieces of conjuration, but it is probable that this practice was derived from the people of the East, and was carried into Greece with other religious ceremonies, by colonies which came and settled here. It is certain, however, that in the time of Homer, this sort of conjuration was practised, as it is mentioned in some passages of the Iliad. At that time it was not reckoned odious or criminal, since there were persons who made public profession of conjuring up ghosts, and there were temples where the ceremony of conjuration was to be performed. Pausanias (in Bœot.) speaks of that which was in Thesprotia, where Orpheus came to call up the soul of his wife Eurydice. Ulysses's travels into the country of the Cimmerians, whither he went to consult the ghost of Tiresias, described by Homer in the Odyssey (l. xi.) seems to indicate a kind of conjuration. Historians, as well as poets, have mentioned this species of conjuration. Another sort of evocation was that which was used in calling up the gods. In order to understand this practice, it should be recollected, that it was a doctrine of the Pagan theology, that the gods presided in a peculiar manner over certain places, and that several of these places were under the protection of the same god; and as it was impossible for him to be in them all at the same time, it was necessary to use the ceremony of evocation, when his presence was thought needful. They had hymns proper to this operation, which they called κλετικοι, such as were most of those ascribed to Orpheus, and those of the poet Proclus. When they thought the patron god was arrived, they celebrated the festival named επιδημιαι. As soon as the danger, which made them invoke the gods was passed, they gave them liberty to go any where else; and they had other hymns for celebrating their departure, which hymns were called αποπεμπτικοι.

EVOCATORIÆ Epistolæ, among the Romans, letters sent by the emperors to command the attendance of any person; or letters granting licence to any one to wait on the emperor; every person not being allowed this privilege till they had desired and obtained the evocatoriæ epistolæ.

EUODIA, in *Botany*, from ευωδια, *a sweet smell*, Forst. Gen. 7. t. 7. See Fagara.

EVOLI, in *Geography*, a town of Naples, in Principato Citra; 15 miles E.S.E. of Salerno.

EVOLVENT, in *Geometry*, a term which some writers use for the curve resulting from the evolution of a curve; in contradistinction to the evolute, which is the curve supposed to be opened or evolved.

The evolute always both touches and cuts the evolvent at the same time: the reason is, that it has two of its infinitely small sides in common with the evolvent; or, rather exactly placed on two equal sides thereof; one of them within-side that of the evolvent, *i. e.* on the concave side thereof; and the other on the convex side of its correspondent side; so that the evolute touches the evolvent in two points; whence, instead of being a tangent, it is said to osculate the evolvent; and, hence, it is also called *osculator*, and *circulus osculator.*

There is one, and but one osculator, to each point of the evolvent; but to the same point there is an infinity of other circles which only touch, and do not osculate. The osculator, and the evolute, make no angle in the place where they touch and cut; nor can any curve line be drawn between, as there may between a tangent and a curve.

EVOLUTE, Evoluta, in the *Higher Geometry*, a curve first proposed by Mr. Huygens, and since much studied by the latter mathematicians. See Curvature.

The evolute is a curve, supposed to be evolved, or opened; and which, in opening, describes other curves.

To conceive its origin and formation, suppose a flexible thread, wound exactly over the convexity of any curve, as A B C G (*Plate* VI. *Analysis*, *fig.* 1.) and suppose the thread fixed in G, and every where else at liberty, to A. Now, beginning to unwind the thread from the point, and continuing it to D, and, throughout, keeping it tight on the curve surface A B C G, when the thread is become quite straight, and is only a tangent, F G, to the curve in the point G, it is evident the extremity A, in its progress to F, has described another curve line A D E F.

Here, the first curve A B C G is called the evolute; each of its tangents B D, C E, &c. comprehended between it and the curve A D E F, called the *involute*, is called a *radius of the evolute*, or *radius osculi*, *radius osculator*, or radius of curvature, of the curve A D E F, in the respective points D, E, &c. And the circles, whereof the osculators B D, C E, &c. are radii, are called *circuli osculatores* of the curve A D E F, in D, E, &c. And, lastly, the new curve resulting from the evolution of the first curve begun in A, is called the *curve of evolution*, or *curve described by evolution.*

Evolute, *the radius of the*, then, is the part of the thread comprized between any point where it is a tangent to the evolute, and the correspondent point where it terminates in the new curve. Which appellation, *radius*, is the more proper, as one may actually consider this part of the thread in every step it takes, as if it described an arc of an infinitely small circle, making a part of the new curve, which thus consists of an infinite number of such arcs, all described from different centres, and with different radii.

Every curve, therefore, may be conceived as formed by the evolution of another. And we are to find that, whose evolution formed it; which amounts to the finding of the radius of the evolute in any point; for, as it is always a tangent to the generating curve, it is, properly, no more than one of its infinitely small parts, or sides, prolonged; and all its sides, whose positions are determined of course, are no other than the generating curve itself.

The same thread is also called *radius curvedinis*, or *radius osculi*, because a circle described hereby, from the centre G, is said to osculate, or kiss it, as both touching and cutting at the same time, *i. e.* touching both the inside and the out.

Hence, 1. The evolute B C F (*fig.* 35.) is the place of all

all the centres of the circles that ofculate the curve A M, defcribed by evolution. 2. When the point B fall on A, the radius of curvature, or radius of the evolute, M C, is equal to the arc B C; or to the aggregate of A B, and the arc B C. 3. Since the element of the arc M m, in the curve defcribed by evolution, is an arc of a circle defcribed by the radius C M; the radius of the evolute C M is perpendicular to the curve A M, or to a tangent at the point M. 4. Since the radius of the evolute M C is always a tangent to the evolute B C F, curves by evolution may be defcribed through innumerable points, if only tangents be produced in the feveral points of the evolute, till they become equal to their correfpondent arcs.

The finding of the radii of evolutes is a thing of great importance in the higher fpeculations of geometry; and even, fometimes, is of ufe in practice as the inventor of the whole theory, Huygens, has fhewn, in applying it to the pendulum. (Horol. Ofcill. part 3.) The doctrine of the ofcula of evolutes is owing to M. Leibnitz, who firft fhewed the ufe of evolutes in the meafuring of curves.

We fhall here fubjoin a brief account of the method of finding the radius of the evolute in different kinds of curves and equations expreffing the nature of evolutes.

1. To form a general expreffion for (B E) the radius of the evolute, or of curvature at any point B in the involute curve A B Y, whofe axis is A X, and evolute D E, *fig.* 3.

With the radius E B defcribe the circular arc B K, which will have the fame curvature with the involute curve A B at the point B. Draw the radius E K parallel to the axis A X, and produce the ordinate B C to L, to which draw A N parallel: let the abfcifs A C be $= x$, the ordinate C B $= y$, radius E B or E K $= r$, K N $= a$, and N A $= b$; then L E $= r - a - x$. If the abfcifs x be fuppofed to increafe uniformly, and B m to be a tangent at the point B; and $m\,n$ be drawn parallel to B C, and B N parallel to A X; B n, $n\,m$, and m B, which are the contemporary increments of the abfcifs, ordinate, and curve, will be as their fluxions refpectively; or B n will be as $\dot{x}$, $n\,m$ as $\dot{y}$, and B m $(= \overline{Bn^2 + nm^2}|^{\frac{1}{2}})$ as $\overline{\dot{x}^2 + \dot{y}^2}|^{\frac{1}{2}}$.

Farther, the triangles B $n\,m$ and B L E are fimilar; therefore B n : $n\,m$ :: B L : L E, *i. e.* $\dot{x} : \dot{y} :: y + b : r - a - x$; confequently, $r\dot{x} - a\dot{x} - x\dot{x} = y\dot{y} + b\dot{y}$: the fluxion of which equation (fuppofing $\dot{x}$ invariable, and therefore, the direction of the curve A B continually approaching towards a parallelifm with its axis, the fluxion of $\dot{y}$ as negative) is $-\dot{x}^2 = \dot{y}^2 - y\ddot{y} - b\ddot{y}$; and $\dot{x}^2 + \dot{y}^2 = \overline{b + y} \times \ddot{y}$.

Again, L B : B E :: n B : B m, *i. e.* $b + y : r :: \dot{x} : \overline{\dot{x}^2 + \dot{y}^2}|^{\frac{1}{2}}$; therefore $b + y = \dfrac{r\dot{x}}{\overline{\dot{x}^2 + \dot{y}^2}|^{\frac{1}{2}}}$, and fubftituting this expreffion for $b + y$, the above equation will become $\dot{x}^2 + \dot{y}^2 = \dfrac{r\dot{x}\ddot{y}}{\overline{\dot{x}^2 + \dot{y}^2}|^{\frac{1}{2}}}$; confequently, $\overline{\dot{x}^2 + \dot{y}^2} \times \overline{\dot{x}^2 + \dot{y}^2}|^{\frac{1}{2}} = r\dot{x}\ddot{y}$, *i. e.* $\overline{\dot{x}^2 + \dot{y}^2}|^{\frac{3}{2}} = r\dot{x}\ddot{y}$, and $\dfrac{\overline{\dot{x}^2 + \dot{y}^2}|^{\frac{3}{2}}}{\dot{x}\ddot{y}} = r =$ B E. In deducing this expreffion, the increment of the ordinate y, or the velocity or fluxion with which it flows, is fuppofed continually to decreafe, therefore its fecond fluxion is negative: but when y increafes with an accelerated motion, its fecond fluxion will be affirmative; and the above expreffion will be $\dfrac{\overline{\dot{x} + \dot{y}^2}|^{\frac{3}{2}}}{-\dot{x}\ddot{y}}$. By fubftituting 1 for $\dot{x}$, which is invariable in thefe expreffions, they will become $\dfrac{\overline{1 + \dot{y}^2}|^{\frac{3}{2}}}{\ddot{y}}$ and $\dfrac{\overline{1 + \dot{y}^2}|^{\frac{3}{2}}}{-\ddot{y}}$ refpectively; the former taking place when the curve is concave, and the latter when it is convex towards the axis, and the fign of $\ddot{y}$ fhewing the pofition of the evolute and radius of curvature with refpect to the curve and axis. By reducing thefe expreffions from the nature and properties of the curve, and always fubftituting 1 for $\dot{x}$, we fhall obtain the value of B E, or the radius required. The vertical diftance or radius A D may be eafily obtained by fubftituting for $\dot{x}$, 1, and for $\dot{y}$ its proper value in the expreffion for the fubnormal C H, which is evidently $\dfrac{y\dot{y}}{\dot{x}}$. *E. gr.*

1. To find the radius of curvature at any point B in the parabola A Y, *fig.* 4.

Let the parameter be $= a$, abfcifs A C $= x$, and ordinate C B $= y$: then, by the nature of the curve $ax = y^2$, and therefore $a\dot{x} = 2y\dot{y}$ (fee Fluxion), and making $\dot{x} = 1$, $a = 2y\dot{y}$, and $\dot{y} = \dfrac{a}{2y} = \dfrac{a}{2 \times \overline{ax}|^{\frac{1}{2}}}$. But the fluxion of this equation will be $-\ddot{y} = \dfrac{-a^2}{4 \times \overline{ax}|^{\frac{3}{2}}}$, or $\ddot{y} = \dfrac{a^2}{4 \times \overline{ax}|^{\frac{3}{2}}}$, and $\dot{y}^2$ being equal to $\dfrac{a^2}{4ax} = \dfrac{a}{4x}$, we fhall have, by fubftituting thefe values in the expreffion $\dfrac{\overline{1 + \dot{y}^2}|^{\frac{3}{2}}}{\ddot{y}}$ for $\dot{y}^2$ and $\ddot{y}$,

$$\frac{\overline{1 + \frac{a}{4x}}|^{\frac{3}{2}} \times \overline{4 \cdot ax}|^{\frac{3}{2}}}{a^2} = \frac{4}{a^2} \times \overline{\frac{4x + a}{4x}}|^{\frac{3}{2}} \times \overline{ax}|^{\frac{3}{2}} = \frac{4}{a^2} \times \overline{\frac{4ax^2 + a^2x}{4x}}|^{\frac{3}{2}} = \frac{4}{a^2} \times \overline{\frac{1}{4}}|^{\frac{3}{2}} \times \overline{4ax + a^2}|^{\frac{3}{2}} = \frac{4}{a^2} \times \frac{1}{8} \times \overline{4ax + a}|^{\frac{3}{2}} = \frac{\overline{4ax + a^2}|^{\frac{3}{2}}}{2a^2}.$$

Then if a femicircle be defcribed through the point B, C n be bifected in H, and H r be made equal 2 A C, and r E be a perpendicular at r, produced till it meets a line B E, drawn from B through H, this line B E will be the radius of curvature required: for B C^2 = A C $\times$ C n, 35 E. 3. or $\dfrac{\text{B C}^2}{\text{A C}}$ = C n, *i. e.* $\dfrac{ax}{x} = a =$ C n, and C H $= \frac{1}{2}a$, and C $r = \frac{1}{2}a + 2x$; and by 47 E. 1. $\overline{\text{C H}^2 + \text{C B}^2}|^{\frac{1}{2}}$ = B H, *i. e.* $\overline{\frac{1}{4}a^2 + ax}|^{\frac{1}{2}}$ = B H; and by 4 E. 6. C H : H B :: C r : B E; *i. e.* $\frac{1}{2}a : \overline{\frac{1}{4}a^2 + ax}|^{\frac{1}{2}} :: \frac{1}{2}a + 2x : \dfrac{a + 4x}{a} \times \overline{\frac{1}{4}a^2 + ax}|^{\frac{1}{2}} = \dfrac{\overline{a^2 + 4ax}|^{\frac{3}{2}}}{2a^2}$ = B E as before. A D the vertical diftance, or, $\dfrac{y\dot{y}}{\dot{x}}$, is in this cafe, putting $\dfrac{a}{2y}$ for $\dot{y}$, and 1 for $\dot{x}$, equal to $\dfrac{a}{2}$; and this likewife appears, by confidering, that in the expreffion for the radius when the radius becomes equal to the vertical diftance, the abfcifs x vanifhes, and it becomes $\dfrac{\overline{a^2}|^{\frac{3}{2}}}{2a^2} = \dfrac{a^3}{2a^2} = \dfrac{a}{2}$.

E. gr. 2. To find the radius of curvature at any point B in the cycloid A B D, *fig.* 5.

Put the radius O F or O D $= a$, abfcifs A C $= x$, ordinate

nate C B $= y$, sine I G $= s$, and arc F G $= z$. Now by 35 E. 3. I G $= \overline{DI \times IF}^{\frac{1}{2}}$, that is, $s = \overline{2ay - y^2}^{\frac{1}{2}}$; the fluxion of which equation is $\dot s = \frac{a\dot y - y\dot y}{\overline{2ay-y^2}^{\frac{1}{2}}}$; and by the nature of the cycloid, arc D G = G B; and therefore, arc F G = G I + A C, or A C = arc F G − G I, that is, $x = z - s =$ (by substituting for s its above value) $z - \overline{2ay - y^2}^{\frac{1}{2}}$; and the fluxion of this equation, making $\dot x = 1$, is $1 = \dot z + \frac{y\dot y - a\dot y}{\overline{2ay - y^2}^{\frac{1}{2}}}$.

But $\dot z = \overline{\dot s^2 + \dot y^2}^{\frac{1}{2}}$ = (by writing for $\dot s$ its above value); $\overline{\frac{\overline{a\dot y - y\dot y}^2}{2ay - y^2} + \dot y^2}^{\frac{1}{2}} = \frac{a\dot y}{\overline{2ay - y^2}^{\frac{1}{2}}}$; which, substituted for $\dot z$, makes the above equation $1 = \frac{a\dot y}{\overline{2ay - y^2}^{\frac{1}{2}}} + \frac{y\dot y - a\dot y}{\overline{2ay - y^2}^{\frac{1}{2}}}$; that is, $1 = \frac{y\dot y}{\overline{2ay - y^2}^{\frac{1}{2}}}$; therefore, $\dot y = \frac{\overline{2ay - y^2}^{\frac{1}{2}}}{y}$; and the fluxion of this equation (the fluxion of $\dot y$ being negative), is $-\ddot y = \frac{\frac{ay\ddot y - y^2\ddot y}{\overline{2ay - y^2}^{\frac{1}{2}}} - \dot y \cdot \overline{2ay - y^2}^{\frac{1}{2}}}{y^2} = \frac{-a\dot y}{y \cdot \overline{2ay - y^2}^{\frac{1}{2}}} =$ (by writing for $\dot y$ its equal), $-\frac{a}{y^2}$; that is, $\ddot y = \frac{a}{y^2}$.

Now, by substituting $\frac{2ay - y^2}{y^2}$ for $\dot y^2$, and $\frac{a}{y^2}$ for $\ddot y$, we have $\frac{\overline{1 + \dot y^2}^{\frac{3}{2}}}{\ddot y} = \frac{\overline{1 + \frac{2ay - y^2}{y^2}}^{\frac{3}{2}} \times y^2}{a} = \frac{\overline{2ay}^{\frac{3}{2}}}{ay} = \frac{2ay \times \overline{2ay}^{\frac{1}{2}}}{ay} = 2 \cdot \overline{2ay}^{\frac{1}{2}}$ = B E, the radius of curvature required.

Construction.—Make F H = G B; and through the point H draw the right line B E, making B H = H E = chord F G; then will B E be the radius of curvature at the point B; for a tangent to the point B is parallel to the chord D G, and the radius of curvature is always perpendicular to the tangent; therefore, because by 31 E. 3. the ∠ D G F is right, B E must be parallel to the chord F G. Now, by 4 and 8 E. 6. D F : F G :: G F : F I, or C B, ∴ G F $= \overline{DF \times CB}^{\frac{1}{2}} = \overline{2ay}^{\frac{1}{2}}$, and $2\,GF = 2 \cdot \overline{2ay}^{\frac{1}{2}}$ = B E.

2. To form a general expression for the radius of curvature in spirals, or curves whose ordinates are referred to a fixed or central point:

Let C B Y, (*fig.* 6.) be the curve, C the central point, or that from which all the ordinates issue; and B E the radius of the curvature at the point B, that is, let the point E be supposed in the evolute curve: conceive C b and E b indefinitely near to C B and E B, that is, let the points B and b be supposed indefinitely near to each other; and let C F and C f be perpendicular to E B and E b respectively, then will the points F and r be indefinitely near to a coincidence; and therefore B r and C r may be taken as equal to B F and C F. Now, if with the ordinate C B as a radius, the little circular arc B n be described and considered as a little right line perpendicular to C b, and the increment B b be considered as coinciding with the tangent to the point B, then the little right-angled triangle B n b will be similar to the right-angled triangle B F C; (for ∠ C B n = ∠ E B b; and therefore ∠ E B n being common, the ∠ C B F = ∠ n B b; and, consequently, the angles at F and n being right, ∠ B C F = ∠ B b n); therefore by 4 E. 6. b B : B n :: C B : B F; that is, (if we put the ordinate C B $= y$, B $n = x'$, and $n\,b = y'$, when, by 47 E. 1 B b will be $= \overline{x'^2 + y'^2}^{\frac{1}{2}}$,) $\overline{x'^2 + y'^2}^{\frac{1}{2}} : x' :: y : \frac{x'y}{\overline{x'^2 + y'^2}^{\frac{1}{2}}}$ = B F or B r; and B b : b n :: B C : C F, that is, $\overline{x'^2 + y'^2}^{\frac{1}{2}} : y' :: y : \frac{yy'}{\overline{x'^2 + y'^2}^{\frac{1}{2}}}$ = C F or C r; the increment of which is $r\,f$; that is, supposing x' to be invariable) $\frac{\frac{\overline{y'^2 + yy''} \times \overline{x'^2 + y'^2}^{\frac{1}{2}} - y'y'' \times yy'}{\overline{x'^2 + y'^2}^{\frac{1}{2}}}}{x'^2 + y'^2} = \frac{x'^2y'^2 + y'^4 + yx'^2y''}{\overline{x'^2 + y'^2}^{\frac{3}{2}}} = rf$. Again, the triangles E B b and E r f being similar, B b − rf : B b :: (B E − r E, or) r B : B E; that is, $\left(\overline{x'^2 + y'^2}^{\frac{1}{2}} - \frac{x'^2y'^2 + y'^4 + yx'^2y''}{\overline{x'^2 + y'^2}^{\frac{3}{2}}} =\right) \frac{x'^4 + x'^2y'^2 - yx'^2y''}{\overline{x'^2 + y'^2}^{\frac{3}{2}}} : \overline{x'^2 + y'^2}^{\frac{1}{2}} :: \frac{x'y}{\overline{x'^2 + y'^2}^{\frac{1}{2}}} : \frac{y \times \overline{x'^2 + y'^2}^{\frac{3}{2}}}{x'^3 + x'y'^2 - yx'y''}$ = B E, or B E $= \frac{y \times \overline{\dot x^2 + \dot y^2}^{3}}{\dot x^3 + \dot x\dot y^2 - y\dot x\ddot y}$; which is a general expression for the radius of curvature of all curves referred to a fixed or central point, when x' or $\dot x$ is invariable.

Hence, if $\dot x$ be made = 1, the general expression for the radius of curvature will be $= \frac{\dot y \times \overline{1 + \dot y^2}^{\frac{1}{2}}}{1 + \dot y^2 - y\ddot y}$. Wherefore, if we put the equation of the given spiral into fluxions, making $\dot x = 1$, and put this fluxional equation into fluxions again; and from thence, or from the nature of the curve, find the values of $\dot y^2$ and $\ddot y$: then, if for $\dot y^2$ and $\ddot y$ we substitute these their values in this general expression, we shall have B E the radius of curvature required.

Otherwise. Let A R B be the proposed curve, (*fig.* 7.) P the point, or centre, to which its ordinates are referred. N O L the evolute, and R O the ray of curvature at R. Moreover, let P H be perpendicular to R O; and supposing the ordinate P R (y) to become variable by the motion of the point R along the curve, let the fluxions of A R and P H (p), expressing the celerities of the points R and H in directions perpendicular to R O, be denoted by $\dot z$ and $\dot p$ respectively: the fluxions of quantities being always as the celerities by which the quantities themselves increase in magnitude. (See FLUXION).

Therefore the celerities of any two points, in a right line revolving about a centre, being as the distances from that centre, it follows that $\dot p : \dot z$ :: O H : O R; whence by division (putting R H $= v$) we have $\dot z - \dot p : \dot z :: v$ (R H) : R O $= \frac{v\dot z}{\dot z - \dot p} = \frac{vp\dot z}{p\dot z - p\dot p}$, But $p\,\dot z = y\,\dot y$.

and

and therefore $RO = \frac{vy\dot y}{y\dot y - p\dot p}$; which, because $y^2 - p^2$ is $= v^2$ (and therefore $y\dot y - p\dot p = v\dot v$) will also be $= \frac{vy\dot y}{v\dot v} = \frac{y\dot y}{\dot v}$.

E. G. 1. Let the given curve A R (*fig.* 7.) be the logarithmic ſpiral, whoſe nature is ſuch, that the angle P R Q (or R P H) which the ordinate makes with the curve, is every where the ſame.

Then (denoting the ſine of that angle by b, and the radius of the tables by a) we have $RH\ (v) = \frac{by}{a}$, and therefore $RO\ \left(\frac{y\dot y}{\dot v}\right) = \frac{ay\dot y}{b\dot y} = \frac{ay}{b}$; which being to P R ($y$) in the conſtant ratio of a to b, or of P R to R H, the triangles R O P and R P H muſt therefore be ſimilar, and ſo the angle P O H, which the ordinate P O makes with the evolute, being every where equal to P R Q, will likewiſe be invariable. Whence it appears that the evolute is alſo a logarithmic ſpiral, ſimilar to the involute; and that a right line drawn from the centre, perpendicular to the ordinate of any logarithmic ſpiral, will paſs through the centre of curvature.

E. G. 2. To find the radius of curvature at any point B the ſpiral of Archimedes, C B, &c *fig.* 8.

Put the circumference of the generating circle A F, &c. $= a$, and its radius $CA = b$; ordinate $CB = y$, arc $AF = z$. Let Cf be ſuppoſed indefinitely near to C F, that is, let the ∠ F C f be ſuppoſed indefinitely ſmall; and with the ordinate C B as a radius deſcribe the little circular arc B n, which put $= x'$; alſo put $Ff = z'$. Now, by the nature of the curve, $a : b :: z : y$, or $z = \frac{ay}{b}$, the fluxion of which equation is $\dot z = \frac{a\dot y}{b}$; and by the ſimilar ſectors C B n and C F f, $y : x' :: b : z' = \frac{bx'}{y}$, or, $\dot z = \frac{b\dot x}{y}$. Hence, $\frac{a\dot y}{b} = \frac{b\dot x}{y}$; that is, (making $\dot x = 1$) $\frac{a\dot y}{b} = \frac{b}{y}$; from which equation we have $\dot y = \frac{b^2}{ay}$; therefore $\dot y^2 = \frac{b^4}{a^2y^2}$, and $\ddot y = \frac{-ab^2\dot y}{a^2y^2} =$ (by writing for $\dot y^2$ its value), $\frac{-b^4}{a^3y^3}$; and if we ſubſtitute for $\dot y^2$ and $\ddot y$ theſe their values, we ſhall have $\frac{y\times\overline{1+\dot y}\big|^{\frac12}}{1+\dot y^2 - y\dot y}$

$$= \frac{y\times\overline{1+\frac{b^4}{a^2y^2}}\Big|^{\frac32}}{1+\frac{b^2}{a^2y^2}+\frac{b^4}{a^2y^4}} = \frac{\overline{a^2y^2+b^4}\big|^{\frac32}}{a^2y^2+2ab^2} = BE,$$

the radius of curvature ſought.

Conſtruction.—Through the centre C draw the indefinite right line H v perpendicular to the ordinate C B; draw the tangent T B, perpendicular to which draw B H; produce B C to V, making $BR = TH$ and $RV = CH$; with B V and B R as radii, deſcribe the arcs V v and R r; draw the right line v B; and from the interſecting point r draw r E parallel to v H; then will B E be the radius of curvature at the point B: for, $CT = \frac{yz}{b}$, that is, by ſubſtituting $\frac{ay}{b}$ for z, $CT = \frac{ay^2}{b^2}$; and by 8 and 4 E. 6. T C : C B :: C B : C H, that is, $\frac{ay^2}{b^2} : y :: y : \frac{b^2}{a} = CH$; therefore $TH = BR = Br = \frac{ay^2}{b^2} + \frac{b^2}{a}$, and $BV = Bv = \frac{ay^2}{b^2} + \frac{2b^2}{a}$; and by 47 E. 1. $HB = \overline{BC^2 + CH^2}\big|^{\frac12} = \overline{y^2 + \frac{b^4}{a^2}}\big|^{\frac12} = \frac{\overline{a^2y^2+b^4}\big|^{\frac12}}{a}$: again, by 4 E. 6. $Bv : BH :: Br : BE$, that is, $\frac{ay^2}{b^2} + \frac{2b^2}{a} : \frac{\overline{a^2y^2+b^4}\big|^{\frac12}}{a} :: \frac{ay^2}{b^2} + \frac{b^2}{a} : \frac{\overline{a^2y^2+b^4}\big|^{\frac12}}{a} \times \frac{a^2y^2+b^4}{a^2y^2+2b^4} = \frac{\overline{a^2y^2+b^4}\big|^{\frac32}}{a^3y^2+2ab^4} = BE$.

3. To find an equation that ſhall expreſs the nature of the evolute of a given involute curve.

Let B E be the radius of evolution or curvature at any point B in the involute curve A B, *fig.* 9. whoſe abſciſs is $AC = x$, and ordinate $CB = y$. Parallel to H A draw E N; produce B C to L; and equal and parallel to C L, draw D N from the vertex of the evolute D E; then will the triangles B H C and B E L be ſimilar: and therefore, by 4 E. 6. B H : H C :: B E : E L, that is, $\frac{\dot y}{\dot x}\times\overline{\dot x^2+\dot y^2}\big|^{\frac12} : \frac{y\dot y}{\dot x} :: \frac{\overline{\dot x^2+\dot y^2}\big|^{\frac32}}{\dot x\ddot y} : \dot y \times \frac{\dot x^2+\dot y^2}{\dot x\ddot y} = EL$; and H C : C B :: E L : L B, that is, $\frac{y\dot y}{\dot x} : y :: \dot y\times\frac{\dot x^2+\dot y^2}{\dot x\ddot y} : \frac{\dot x^2+\dot y^2}{\ddot y} = LB$. Now, theſe are general expreſſions for E L and L B, when $\dot x$ is conſidered as invariable, and the fluxion of $\dot y$ as negative. Hence, therefore,

If $\dot x = 1$, and the fluxion of $\dot y$ be negative, the general expreſſion for B L will be $= \frac{1+\dot y^2}{\ddot y}$, and this multiplied by $\dot y$ is $\dot y \times \frac{1+\dot y^2}{\ddot y} =$ the general expreſſion for L E. Now, by help of the equation of the given involute curve, exterminate $\dot y$, $\dot y^2$, and $\ddot y$, out of theſe expreſſions, and find the vertical diſtance A D. Then, if we put the abſciſs of the evolute $DN = u$, and its ordinate $NE = v$; by help of theſe two equations, $u = BL - BC$, and $v = AC - AD + LE$, we may get the nature of the evolute curve D E required.

Note.—If the given involute be convex towards its axis, and x and y increaſe together, or the fluxions of x and $\dot y$ be both affirmative, then the general expreſſions for B L and L E will be $\frac{1+\dot y^2}{-\ddot y}$; and $\dot y \times \frac{1+\dot y^2}{-\ddot y}$ reſpectively; wherein the negative ſign ſhews, that the points L and E muſt be taken on the concave ſide of the involute curve, that is, on the other ſide of it with regard to x and y.

E. gr. To find the nature of the curve A E P (*fig.* 10.) by whoſe evolution the cycloid A B D is deſcribed.

Put $AC = x$, $CB = y$, arc $FG = z$, and O D or $OF = a$; then by Ex. 2. art. 1. above, $\dot y = \frac{\overline{2ay-y^2}\big|^{\frac12}}{y}$, $\dot y^2 = \frac{2ay-y^2}{y^2}$, and $\ddot y = \frac{a}{y^2}$; wherefore, $BL =$

1 +

$$\frac{1+\dot{y}^2}{\dot{y}} = \frac{\overline{1+\frac{2ay-y^2}{y^2}} \times y^2}{a} = 2y, \text{ and } LE = \dot{y} \times$$

$BL = \frac{\overline{2ay-y^2}|^{\frac{1}{2}}}{y} \times 2y = 2 . \overline{2ay-y^2}|^{\frac{1}{2}}$. Hence, if we put the abſciſs $AN = u$, and ordinate $NE = v$, we have $u\ (= BL - CB =)\ 2y - y = y$, and $v = (AC + LE =)\ x + 2 . \overline{2ay-y^2}|^{\frac{1}{2}}$ that is, (becauſe $x = z - \overline{2ay-y^2}|^{\frac{1}{2}}$) $v = z + \overline{2ay-y^2}|^{\frac{1}{2}}$, or, (writing u for y its equal,) $v = z + \overline{2au-u^2}|^{\frac{1}{2}}$. Wherefore, the evolute curve A E P is a cycloid, and equal to the given cycloid A B D; for, let $AS = SV = a$, then (A N being $= FI$,) $AT = FG = z$, and $NT = \overline{2au-u^2}|^{\frac{1}{2}} = IG$; and therefore, $AT + TN = z + \overline{2au-u^2}|^{\frac{1}{2}}$, that is, $AT + TN = NE$, which is the property of the cycloid; therefore, the evolute A E P is a cycloid; and becauſe $AV = FD$, therefore the cycloids A E P and A B D are equal. See Cycloid.

The evolute of a ſpiral, or indeed of any other curve, may be deſcribed by finding the radii of curvature at ſeveral points in the involute; for then we ſhall have as many points in the evolute, through which if a curve line be drawn, it will be the evolute ſought.

Wolf. Elem. Math. tom. i. p. 524, ſeq. or the Infinim. Petites of M. le Marquis de l'Hopital. Simpſon's Fluxions, vol. i. p. 71, &c. And Rowe's Fluxions, edit. 3. 1767, chap. vi. and vii. p. 103—132.

Since the radius of an evolute is either equal to an arc of an evolute, or exceeds it by ſome given quantity, all the arcs of evolutes may be rectified geometrically, whoſe radii may be exhibited by geometrical conſtructions; whence we ſee why an arc of a cycloid is double its chord; the radius of the evolute being double the ſame, and the evolute of a cycloid being itſelf a cycloid, equal and ſimilar to the involute.

M. Varignon has applied the doctrine of the radius of the evolute to that of central forces; ſo that having the radius of the evolute of any curve, one may find the value of the central force of a body; which, moving in that curve, is found in the ſame point where that radius terminates; or reciprocally, having the central force given, the radius of evolute may be determined. Hiſt. de l'Acad. Roy. des Sciences, an. 1706.

The variation of curvature of the line deſcribed by the evolution of a curve, is meaſured by the ratio of the radius of curvature of the evolute, to the radius of curvature of the line deſcribed by the evolution. See Maclaurin's Flux. art. 402. prop. 36.

Evolute, *imperfect*. M. Reaumur has given a new kind of evolute, under this denomination. Hitherto the mathematicians had only conſidered the perpendiculars let fall on the points of the convex ſide of the curve; if other lines not perpendicular were drawn upon the ſame points, provided they were all drawn under the ſame angle, the effect would be the ſame; that is, the oblique lines would all interſect within the curve; and by their interſections, form the infinitely ſmall ſide of a new curve, whereof they would be ſo many tangents.

This curve would be a ſort of evolute, and would have its radii; but an imperfect evolute, ſince the radii are not perpendicular to the firſt curve. Hiſt. de l'Acad. &c. an. 1709.

EVOLUTION, in *Geometry*, the unfolding or opening of a curve, and making it deſcribe an evolvent.

EVO

The word *evolutio* is formed of the prepoſition *e*, *out*, and *volvo*, *I roll*, or *wind*; q. d. an *unwinding*, or *unrolling*.

The equable evolution of the periphery of a circle, or other curve, is ſuch a gradual approach of the circumference to rectitude, as that its parts do all concur, and equally evolve, or unbend; ſo that the ſame line becomes ſucceſſively a leſs arc of a reciprocally greater circle, till at laſt they change into a ſtraight line. In the Philoſophical Tranſactions, N° 260, a new quadratrix to the circle is found by this means, being the curve deſcribed by the equable evolution of its periphery.

Evolution, in *Algebra*, is alſo uſed for the extraction of roots out of powers. In which ſenſe it ſtands oppoſed to involution. See Extraction *of roots*.

Evolution, as relating to *Military* operations, muſt be underſtood to be founded on the principles of Tactics (which ſee), and be conſidered indiſpenſably neceſſary to the ſafety, the progreſs, and the ſucceſs of all bodies of men, whether large or ſmall. The term is generally uſed as ſynonymous with manœuvre, but in ſtrictneſs they are by no means to be ſo accounted; for an evolution rather relates to an open, candid, and undiſguiſed movement, made either for a change of poſition, or for the general purpoſes of attack and defence; while a manœuvre applies abſtractedly to deceptious movements, to feints, and to that kind of trick which gives riſe to the ſaying ſo common among us, "I have out-manœuvred him." Thus the French, from whom we have directly borrowed the term, ſay, "un ruſé manœuvre," *i. e.* a cunning fellow; and among them a ſkilful ſeaman is deſignated "un manœuvrier."

In every ſervice, both in the military and naval departments, certain regulations exiſt which direct, that all candidates for promotion ſhould be acquainted, not ſimply with the ſeveral motions of the firelock, and the ordinary duties of individuals, but with a variety of movements to be made by entire battalions, or armies, and by either ſingle ſhips, ſquadrons, diviſions, or fleets reſpectively. It being our intention to amplify under the head of Tactics, *military* and *naval*, we ſhall in this place confine ourſelves to thoſe evolutions which, forming a part of the Britiſh diſcipline, ought to be thoroughly underſtood by every perſon whoſe purſuits tend towards the goal of martial celebrity; and ſhould be thoroughly underſtood by every officer, of whatever rank.

The following nineteen changes will be ſufficient for the purpoſe, under the remark, that we pre-ſuppoſe a battalion to be arranged at cloſe order, and all in readineſs for performing the required evolutions.

Evolution 1.

On a rear diviſion.	Form cloſe column of companies behind grenadiers. Form cloſe column of two companies. Face and march to the right. Deploy on the rear diviſion.	*Explanation.*—The column marches *quick*, 20 or 30 paces to the right, and, without halting, begins to deploy into line on the rear diviſion. The commanding officer of the battalion gives the word, for each diviſion to halt, front.

Evolution 2.

On a front diviſion.	Form cloſe column of companies in front of the left. Form cloſe column of two companies. Face and march to the left. Deploy on the front diviſion.	The column marches *quick*, 30 or 40 paces to the left, and, without halting, begins to deploy on the front diviſion. The commanding officer of the battalion gives the word for each diviſion to halt, front.

Evolution

Evolution 3.

On a central divifion.

Form clofe column of companies on a central company, either flank in front, and facing to the rear.
Countermarch of each divifion in clofe column.
Deploy on any central named company.

The clofe column is formed facing to the rear. It then countermarches each divifion, fo as to return to the proper front. In the central deployment by companies, the company officers give the words refpectively to halt, front.

Evolution 4.

Change of pofition in open column.

Wheel back into open column of companies, the right in front.
March forward 30 or 40 paces.
Enter an oblique line (the three or four leading companies), by wheeling fucceffively to the left, a half-wheel.
Halt.
The rear companies file into column.
Wheel up into line.

The battalion, thus, at an intermediate point, enters an alignment, on which it is to form.

Evolution 5.

Wing thrown back.

The left company is wheeled back till parallel with the original pofition. The reft of the companies wheel into echellon.
March to the rear.
Form on the left company.

The whole companies wheel back at the fame time; the left company twice the number of paces that the others do. Should it be neceffary for the fubfequent movements, the line may retire 50 or 60 paces, and then front.

Evolution 6.

Countermarch, and change of pofition.

Wheel back into open column, the right in front.
Countermarch companies by files.
March in column 30 or 40 paces.
Head divifion halts clofe to the head of column.
Form fquare, and prepare for firing.
Re-form in clofe column.
Open out to open column from the rear, and halt.
Change head of column, by the countermarch of companies, from the rear to the front.
Column moves on and halts.
Wheel up into line.

After the countermarch by files, the column ftands with its left in front. The column clofes in quick time. The fquare is formed, and clofe column re-formed. The column opens out in quick time from its rear divifion, and halts. The countermarch by companies, from the rear to the front, is in ordinary time. When the line is formed, it is then confiderably to the reviewing general's right, and with its rear to him.

Evolution 7.

Countermarch by files on the centre of the battalion.

This brings back the battalion to its original front.

Evolution 8.

March in open column.

Form open column behind the left company, which is put in march when the third company has taken its place in column.
The right fub-divifions double.
The column halts, and pivots are corrected.
Wheel up into line.

The companies that are filing incline towards the head of the column; fucceffively front at their wheeling diftances, afcertained as ufual by their ferjeants; take up the ordinary ftep, and follow in open column. When the column is marching fteadily, the whole fub-divifions double at once, at one command, and again move up at another.

Evolution 9.

Echellon change of pofition.

Wheel back into open column, the left in front.
The third company is wheeled back, the 8th of a circle, and each of the others 3-16ths of the circle.
Form line on the third company by the echellon-march.

The line is thus formed oblique, from open column, on a central company, by the echellon-march.

Evolution 10.

Change of pofition.

The left company is wheeled up the 8th of a circle, and each of the others 1-16th.
Form line by the echellon-march.

The line thus changes pofition to the front, on the left company, by the echellon-march.

Evolution 11.

Change of pofition.

The battalion faces to the right.
March in file 50 or 60 paces.
Halts.
Wheels up into line, except the light company, which files quickly to the right, and forms behind the colours.

The column of companies is formed by the rear men of each moving up quickly to the left of their leaders, and of each other: the officers move to pivot flanks, and pivots are inftantly corrected. The column halts when the colours are oppofite to the general.

Evolution 12.

Retreat in line.

The battalion retires (50 paces).
Halts; fronts.
Fire twice by companies from centre to flanks.
Retire by alternate companies in two lines (250 paces, each retreat about 50 paces.)
Form line.
Retire in line (50 paces).
Halt; front.

The light company, being previoufly fubdivided and prepared, acts in the retreat by alternate companies, filling up, or at leaft occupying the intervals in the firft line, and retiring with it to the fecond, in which it continues to fet in like manner, and thus alternately. When the line halts, and fronts, it refumes its place on the left.

Evolution 13.

March to flank in echellon.

Companies make a half wheel to the right.
March in echellon, (250 paces.)
Wheel back on the march into parallel line.
Forward (100 paces.)
Halt.
Fire thrice by companies, from flanks to centre.

At the word "wheel back into line," the pivot flanks mark time, and the divisions wheel back in ordinary time. At the proper instant, when the battalion is formed, the commander gives the word "Forward," for the whole to advance by the colours, and to correct any irregularity there may be in the battalion.

[Hitherto the battalion may have been *two* deep, but if its companies can muster ten files each, the corps may now be formed *three* deep.]

Evolution 14.

Movements in the square.

Form square.
March the square by the left.
Angle of the front face (50 paces.)
Halt; form square.
March square by the left face.
Halt; form square.
March square by the rear face.
Halt; form square.
Fire in square by companies.
Form the line.

The square is formed by the echellon march of companies. After the march by the left face, the square is formed when opposite the general. The line is formed by the echellon wheel-up, and march of companies. When the order is given to form line, the light company marches quickly, and places itself two deep, and in two divisions, ten or twelve paces behind the two centre companies.

Evolution 15.

Retiring, and filing to the rear.

Retire in line (100 paces.)
File by companies from the proper right.
Halt in open column, the right in front.
Wheel up into line.

When the line has passed the light company twenty paces, that company extends to cover the centre of the battalion, and follows at 50 or 60 paces distance; and when the column halts to form, the light company passes quickly through and beyond it. The companies file quickly to the rear.

The battalion forms line at the extremity of its ground; the light company 30 paces in its rear.

Evolution 16.

Filing, advancing, and charging to the front.

Advance in line (50 paces.)
File from the right of companies to the front (50 paces.)
Halt in open column, the left in front.
Wheel up into line.
Advance in line (50 paces.)
Advance by alternate half battalions, and fire four times.

Before the line advances, the light company quickly forms, extended 30 paces before the centre, and preserves that distance in advancing. When the column halts to form, the light company passes quickly to the rear, and assembles half of it behind each flank, then moves relatively with the flank-companies, till after the charge of bayonets. The alternate half-battalions fire, the two first ranks standing.

Evolution 17.

Charge and pursuit.

Form line. Advance (50 paces.)
Fire volley. Advance (50 paces.)
Fire volley. Charge bayonets (50 paces.)
Halt. Load.

After the volley, bayonets are ported; the battalion advances firm by the centre at the quick step, and at the word "Halt," the front rank comes down to the charging position. The word "Prime and Load" is then given, and the light company, issuing from behind the flanks, pursue, return, and assemble, and join on the left of the battalion.

Evolution 18.

Retiring in line.

Retire in line (100 paces.)
Retire by alternate half battalions.
Fire four times.
Retire in line (100 paces, or more.)
Halt. Front.

The whole battalion being assembled, the alternate half-battalions fire, the two front ranks standing.

Evolution 19.

Advance in line and salute.

Advance in line (100 paces.)
Halt.
Fire two vollies.
Port arms at the last one, and half cock.
Open ranks.
Advance within 50 paces of reviewing general.
Halt.
General salute.

In the vollies the front rank kneels.

The music may occasionally play, and the drums roll, as the line advances.

The music will play while advancing at open ranks.

We have selected this portion of the discipline ordered for the British army, because it comprizes sufficient changes to give our readers a correct idea of what are termed *evolutions*. These are so contrived as to be performed on a very moderate extent of ground; each evolution serving to correct any obliquity, or lateral change of position, and confining the regiment within certain limits.

It may be proper to remark, that though the foregoing relate in this instance to a single regiment under review, the whole of the charges may be considered as representing those made by a large army; the several companies being the representatives of regiments, or of larger bodies. See BATTALION.

Fa. Hoste, a Jesuit, in 1697, printed a Treatise on Naval Evolutions, in folio. By naval evolutions he means the motions made by a fleet, squadron, or naval armament, in order to put themselves in a proper disposition for attacking the enemy, or defending themselves with the most advantage. See TACTICS.

EVOLVULUS, in *Botany*, from *evolvo*, *to roll out or unfold*, in opposition to *Convolvulus*, with which the present genus agrees in habit, except in not having a convoluted stem. Linn. Gen. 152. Schreb. 204. Willd. Sp. Pl. v. 1. 1516. Juss. 134. Class and order, *Pentandria Tetragynia*. Nat. Ord. *Campanaceæ*, Linn. *Convolvuli*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, acute, permanent segments. *Cor.* of one petal, regular, wheel-shaped, plaited, slightly five-cleft. *Stam.* Filaments five, capillary, spreading, almost as long as the corolla; anthers rather oblong. *Pist.* Germen superior, nearly globular; styles four, capillary, spreading, the length of the stamens; stigmas simple fimple. *Peric.* Capfule nearly globular, of four cells and four valves. *Seeds* folitary, roundifh, angular on the inner fide.

Eff. Ch. Calyx of five leaves. Corolla five-cleft, wheel-fhaped. Capfule fuperior, of four cells. Seeds folitary.

Willdenow has feven fpecies, five of which were known to Linnæus. Among the latter is *E. linifolius*, Linn. Sp. Pl. 392. (Convolvulus linifolius; Am. Acad. v. 4. 306. Syft. Nat. ed. 10. v. 2. 923. Brown. Jam. t. 10. f. 2.) whence he informs us he derived the above generic character, having the plant alive under his own infpection. It is a fmall inconfpicuous annual, with flender, ftraight, fpreading ftems; narrow, lanceolate, hairy leaves; and little, blue, axillary flowers; native of low ground in Jamaica.

The other fpecies have rounder leaves, but otherwife agree very much with the above. They grow in the Eaft or Weft Indies, and are annuals of humble growth, and no confpicuous attractions, being inferior in beauty to the meaneft fpecies of *Convolvulus*.

E. *tridendatus*, Linn. Sp. Pl. 392, is now returned to *Convolvulus*, fee that genus, fp. 19.

EUONYMUS, ευωνυμον of Theophraftus, fo called by antiphrafis, from ευωνυμος, *having a good name*, becaufe the plant was *infamous* for its ftrong fœtid fmell, and its poifonous quality to cattle. Spindle-tree. Linn. Gen. 107. Schreb. 148. Willd. Sp. Pl. v. 1. 1130. Juff. 377. Gærtn. t. 113. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Dumofæ*, Linn. *Rhamni*, Juff.

Gen. Ch. *Cal.* Perianth inferior, flat, in four or five deep, equal, roundifh, concave fegments. *Cor.* Petals four or five, ovate-oblong, flat, fpreading, longer than the calyx. *Stam.* Filaments four or five, awl-fhaped, erect, fhorter than the petals, inferted, alternately with them, into a glandular receptacle; anthers two-lobed. *Pift.* Germen fuperior, pointed; ftyle fhort, fimple; ftigma obtufe. *Peric. Capfule* fucculent, coloured, depreffed, with four or five angles, and as many cells and valves. *Seeds* folitary, ovate, each wrapped up in a pulpy arillus.

Eff. Ch. Calyx flat. Petals five. Capfule fuperior, five-fided, coloured, of five cells and five valves. Seeds in a pulpy covering.

A genus of extra-tropical fhrubs, the produce of Europe, North America and Japan. Willdenow has feven fpecies. They are deftitute of hairinefs, and have oppofite branches and leaves; the latter fimple, deciduous, more or lefs elliptical, entire or toothed, with fcarcely any ftipulas. Flowers of a dull or greenifh hue, in axillary forked panicles, not ornamental. Fruit much more confpicuous and often very beautiful, on account of the pink, waxy hue of the capfule, varying occafionally to white, and orange coverings of the feeds.

E. Tobira. Thunb. Jap. 99. (Tobira; Kæmpf. Am. Exot. 796, cum ic.), a native of Japan, has terminal flowers, and in many other refpects feems not perfectly to accord with this genus.

E. europæus. Sm. Fl. Brit. 262. Engl. Bot. t. 362; and *E. verrucofus*, Jacq. Auftr. t. 49; alfo *E. latifolius*, Jacq. Auftr. t. 289; are good examples of it. Linnæus confounded them together as varieties, but Scopoli, and afterwards Jacquin, have well diftinguifhed them. The laft fpecies in particular is very remarkable for its warty branches, flender habit, reddifh flowers, and fmall pale capfules, out of which the black feeds, partially clothed with their fcarlet arillus, hang by flender threads. The wood of all of them is tough, and ufed for fkewers and fpindles. It fhould be cut in the fummer. The fruit ferves in many places to decorate churches and ruftic kitchens at Chriftmas-time. It is reported to be dangeroufly emetic and purgative.

Euonymus, in *Gardening*, comprehends plants of the hardy flowering fhrubby kind, of which the fpecies cultivated are, the common fpindle-tree (*E. europæus*); the warted fpindle-tree (*E. verrucofus*); the purple-flowered fpindle-tree (*E. atropurpureus*); the ever-green fpindle-tree (*E. americanus*); and the broad-leaved fpindle-tree (*E. latifolius.*)

The evergreen fort of fpindle tree has a variety with variegated leaves.

Method of Culture.—All the four more common forts may be propagated either by feeds, layers, or cuttings of the young fhoots; but the evergreen kind requires a different method.

In the firft mode, the feeds fhould be fown in the clumps or borders in the early autumn, covering them well in. In the following autumn the plants fhould be removed, and fet out in nurfery rows, being kept well cleared from weeds during the fummer. After two or three years growth in this fituation, they will be fit to plant out for good, in proper fituations.

With refpect to the young fhoots, they may be laid down in the autumn, a flit being made at the joint placed the deepeft in the ground. In the following autumn they will be well rooted, and may be taken off and planted out in the manner of the feedling plants.

The cuttings fhould be made eight or ten inches in length, and planted in a fhady border in the autumn. When they have ftruck full root, they fhould be carefully removed, and managed as thofe raifed from the feed.

But the two laft methods, and thofe of budding and grafting, are the only ones by which the green variety can be continued with certainty and fuccefs.

With regard to the laft fpecies, it is beft increafed by laying down the young branches after being tongued in the autumn, managing them afterwards in the fame manner as the others.

Thefe plants are fufficiently hardy to bear the open air, when planted in warm fheltered fituations.

They are all very ornamental plants; the four common forts producing a fine effect by their berry-like feeds, and the laft fort but one by its evergreen leaves; the chief objection to the former kinds being their great aptitude to have their leaves compleatly eaten up by the caterpillars foon after they are fully expanded.

EVORA, or Elvora, anciently *Ebora*, in *Geography*, an ancient, walled and fortified, large but not populous, city of Portugal, the capital of the province of Alentejo, and an archbifhop's fee, fituated on a gentle eminence in a fruitful plain, furrounded by hills, near the centre of the province; 65 miles E. Lifbon. The ftreets are narrow, crooked, and full of angles. It has no trade or manufactures; but contains five parifh churches, twenty-three religious houfes, and about twelve thoufand inhabitants. The cathedral and other buildings are high and in the Gothic ftyle. This city is faid to have been founded by the Phœnicians, and walled round by Sertorius, who fupplied the town with water by means of a beautiful aqueduct, (fince entirely rebuilt by John III.,) and who, after having refided there for a confiderable time, was buried, as tradition reports, in this place. Julius Cæfar conftituted it a municipium, and named it Liberalitas Julia. It was taken by the Moors in the year 715, and retaken by the Chriftians under Giraldo, whofe heroic conduct is celebrated by Camoens in his Lufiad, in 1166, and then reduced under the dominion of Alphonfo Henriques. In 1540 it was erected into

into an archiepiscopal see by pope Paul III.; and the first prelate founded an university, now fallen into decay. In this city are the remains of a temple of Diana, 7 pillars of which are standing, of the Corinthian order, connected by a plaster-wall. This edifice, at first a pagan place of worship, was converted into a Moorish mosque, and is now the butchers shambles. There are many other Roman vestiges, inscriptions, &c. particularly in the great square, which indicate the antiquity of this place. Its fortifications are 12 bastions, and two demi-bastions, and a castle in ruins. On the north side of Evora the hills rise, being round the town adorned with gardens, and on their summits with evergreen oaks. The road from hence to Montemor o novo, which lies at the distance of five leagues, passes over granite hills, partly covered with corn fields, and partly with fine woody or evergreen oaks and pastures. N. lat. 38° 30'. W. long. 7° 42'.

EVORAMONTE, a town of Portugal, in the province of Alentejo, seated on a rock, and containing about 800 inhabitants; 15 miles N.E. of Evora. N. lat. 38° 42'. W. long. 7° 31'.

EVORIA, a town of European Turkey in Livadia; 24 miles N. of Lepanto.

EUOSMA, in *Botany*, from ευοσμος, *sweet-smelling*, because the flowers have the scent of hawthorn-blossoms. Jackson in Andr. Repos. t. 520. Class and Order, *Pentandria Monogynia*. Nat. Ord. *Rotaceæ*, Linn. *Gentianæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in five deep, obovate, concave, equal, permanent segments. *Cor.* of one petal, bell-shaped; tube dilated, as long as the calyx, pervious; limb in five broad, short, obtuse, spreading lobes. *Stam.* Filaments five, awl-shaped, shorter than the tube, inserted into its lower part, alternate with the lobes of the limb; anthers incumbent, roundish, compressed. *Pist.* Germen superior, oval, two lobed; style very short and thick; stigma capitate, four-lobed, on a level with the anthers. *Peric.* Capsule ovate, pointed, with a longitudinal furrow on each side, swelling irregularly from the projection of the seeds, of two valves, whose inflexed edges divide it into two cells; receptacles one in each cell, linear, triangular, parallel to the valves and close to the partitions. *Seeds* five or six in each cell, in two rows, oval, flattened on the inner side, all over rough with minute tubercles.

Eff. Ch. Calyx deeply five-cleft. Corolla bell-shaped, with a five-cleft border. Stigma four-lobed. Capsule superior, with two furrows and two cells, bursting at the top. *Seeds* several, oval, rough, affixed to a triangular receptacle.

1. *E. albiflora*. Andr. Repos. t. 520. Native of New South Wales, in the country near Port Jackson, from whence specimens and seeds were long ago sent by Dr. White. It is said to bear our winters in the open ground, flowering in April. *Stem* shrubby, with numerous, opposite, slender, square, leafy, slightly downy branches. *Leaves* opposite, on short stalks, lanceolate, acute, entire, smooth; shining and deep green above; paler, opaque, and somewhat glaucous beneath. *Stipulas* small, bristle-shaped, in pairs at the base of each footstalk, somewhat hairy. *Flowers* in dense, axillary, bracteated panicles, much shorter than the leaves; snow-white, small, but copious, and very fragrant. *Capsules* about a quarter of an inch long, obtuse, rugged, tipped with the short permanent style.

The characters above given will, we believe, distinguish this genus from *Exacum*, to which it is most allied of any in the same natural order. See EXACUM.

EVOVÆ, a barbarous word, says Rousseau, formed of the six vowels, which begin the syllables of the words *seculorum amen*, and which is only used in canto fermo. It is from the letters of this word that the tone is found in the psalms and antiphonaria of the Roman catholic church, and the notes by which the verses of the psalms and canticles must be terminated.

The evovæ always begins by the dominant of the mode and ends upon the final.

EVOUTS, in *Geography*, a small island in the Southern Pacific ocean; 15 miles S. from Terra del Fuego. S. lat. 55° 33'. W. long. 67° 36'.

EUPAREA, in *Botany*, ευπαρεια, *having beautiful cheeks*, in allusion probably to the scarlet colour of the flowers, said to resemble *Anagallis arvensis*. Gærtn. v. 1. 230. t. 50. Schreb. 156. Willd. Sp. Pl. v. 1. 1183. Mart. Mill. Dict. v. 2. Class and order, *Pentandria Monogynia*. Nat. Ord. *Lysimachiæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, acute leaves. *Cor.* Petals from five to twelve, lanceolate, spreading, longer than the calyx. *Stam.* Filaments five; anthers. *Pist.* Germen roundish, superior; style bristle-shaped, long; stigma simple. *Peric.* Berry dry, globose, crowned with the permanent style, of one cell. *Seeds* numerous, roundish, small, affixed to a globose, fungous, central receptacle.

Eff. Ch. Calyx of five leaves. Petals from five to twelve. Berry superior, dry, of one cell, with many seeds. Receptacle globose.

E. *amœna* is the only known species, gathered in New Holland by sir Joseph Banks and Dr. Solander. Gærtner describes it as a procumbent plant, resembling *Lysimachia nummularia*, but about one-fourth its size. Flowers of the colour of the Scarlet Pimpernel. He adds that "the seed-vessel, which-ever way pressed, would not open by regular valves, so that it is very nearly allied to *Trientalis*." Indeed his figures betray the very close affinity, even the identity of these two genera, except that one is described as polypetalous, the other monopetalous, and that the stamens of *Euparea* are not said to equal the petals in number, when the latter are more than five.

EUPATORIA, formerly KOSLOF, or *Gosleve*, in *Geography*, a town and district of Russia, in the province of Taurida or Crim Tartary, near the Black sea. N. lat. 45° 40'. E. long. 33° 14'.

EUPATORIA, or *Pompeiopolis*, in *Ancient Geography*, *Akmetschid*, a town in the N.W. part of the Tauris Chersonesus.

EUPATORIA, *Amid*, a town of the kingdom of Pontus, situated in the gulf of Amisa, and contiguous to a town of the same name. Mithridates Eupator is said to have built it, and to have given it his name.

EUPATORIUM, in *Botany*, ευπατωριον of Dioscorides, from Mithridates, surnamed Eupator, who is reported to have brought this plant into use as a counter-poison. Linn. Gen. 413. Schreb. 546. Willd. Sp. Pl. v. 3. 1748. Sm. Fl. Brit. 859. Mart. Mill. Dict. v. 2. Juss. 178. Gærtn. t. 166. Class and order, *Syngenesia Polygamia-æqualis*. Nat. Ord. *Compositæ discoideæ*, Linn. *Corymbiferæ*, Juss.

Gen. Ch. *Common Calyx* oblong, imbricated; scales linear-lanceolate, erect, unequal, unarmed. *Cor.* compound, uniform, discoid; florets all uniform, perfect, fertile, monopetalous, funnel-shaped, with a regular, five cleft, spreading border. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen minute; style thread-shaped, very long, cloven down as far as the top of the anthers, straight; stigmas slender, bluntish,

 straight.

ſtraight. *Peric.* none, except the permanent calyx. *Seeds* ſolitary, oblong, angular; down long, rough, or feathery. *Recept.* naked.

Eff. Ch. Receptacle naked. Down rough or feathery. Calyx imbricated, oblong. Style prominent, cloven half way down, divaricated.

A large genus, chiefly, though not entirely, American. The *roots* are perennial. *Stem* ſometimes ſhrubby. *Leaves* oppoſite, moſtly ſimple, and ſtrongly ſerrated. *Flowers* corymboſe, terminal, numerous, white, bluciſh, or reddiſh. Whole plant, roughiſh, bitter, or aromatic. Willdenow has 71 ſpecies.

E. *cannabinum*, Engl. Bot. t. 428, ſingular for having fingered leaves, which indeed are ſometimes found undivided, is the only Britiſh ſpecies. It grows in watery places about the banks of rivers, or in mountainous boggy thickets, where it with us ſupplies the place of the Swiſs *Cacalia alpina*, which its pink flowers ſomewhat reſemble.

Several of the American ſpecies are eſteemed in that country, on account of their aromatic and tonic qualities, and known by the name of Fever root, or Fever weed. Among theſe, we believe, are E. *ſeſſilifolium*, *perfoliatum*, and *aromaticum*, but we want further information on this ſubject.

E. *Aya-pana*, Venten. Jard. de la Malmaiſon, t. 3. a native of the banks of the river of the Amazons, is ſaid to be "an excellent ſudorific and alexipharmic;" partaking therefore, no doubt, of the virtues of the above-mentioned ſpecies. Its *leaves* are lanceolate, nearly entire, and not accurately oppoſite. The *flowers* are purpliſh.

E. *zeylanicum*, Linn. Sp. Pl. 1172, has decidedly alternate leaves, ſo as to have raiſed a doubt in the mind of Linnæus whether it could belong to this genus; yet its fructification ſeems altogether like the generality of the ſpecies.

EUPEGIUM, in *Ancient Geography*, a town of Greece, in the Peloponneſus.

EUPEN, or Oepen, in *Geography*, a town of France, in the department of the Ourthe, and chief place of a canton in the diſtrict of Malmedy; 4 miles E.N.E. of Limburg. The place contains 6,749, and the canton 12,616 inhabitants, on a territorial extent of 102½ kiliometres and ſeven communes. Here is a conſiderable manufacture of cloth.

EUPETALOS, in *Natural Hiſtory*, the name of a gem deſcribed by the ancients as famous for its variety of colours. Pliny, lib. xxxii. cap. 10. tells us, that it ſhewed at once blue, fire-colour, red-lead colour, and yellow. It ſeems to have been the opal, and that Pliny's deſcription of it in this place was taken from ſome author he did not perfectly underſtand, as is the caſe in many of his accounts from the Greeks.

EUPHASEE, in *Geography*, the ancient name of Hiwaſſee river in Teneſſee, N. America; alſo the name of an Indian town on its S.W. bank, 28 miles from its mouth. See Hiwassee.

EUPHEMISMUS, Ευφημισμος, of ευ, *well*, and φημι, *I ſpeak*, in *Rhetoric*, a figure which expreſſes things in themſelves diſagreeable and ſhocking, by terms implying the contrary quality; that is, the Pontus, or Black ſea, having the epithet of αξενος, (i. e. *inhoſpitable*) given it on account of the ſavage cruelty of thoſe who inhabited the neighbouring countries; this name, by euphemiſm, was changed into that of Euxinus. Thus Ovid. Triſt. lib. iii. eleg. 13.

"Dum me terrarum pars pene noviſſima Ponti
Euxinus falſo nomine dictus habet."

In which ſenſe it only makes a ſpecies of irony. But every euphemiſm is not irony; for we ſometimes uſe improper and ſoft terms in the ſame ſenſe with the proper and harſh. See Voſſ. Rhet. lib. iv. cap. 186, ſeq.

EUPHEMIUS, in *Biography*, ſucceeded to the high dignity of patriarch of Conſtantinople in the year 490. He was zealouſly attached to the doctrines of the Catholic church, of which he gave proof by ſtriking out from the liſts of perſons in communion with the church, the name of Peter Mongus, patriarch of Alexandria, becauſe that prelate had pronounced an anathema againſt the council of Chalcedon. This circumſtance produced a violent ſchiſm between the two patriarchs, who convened their reſpective ſynods, in which they mutually procured excommunications of each other to be iſſued. In the year 491, on the death of Zeno, when Anaſtaſius was taking meaſures to ſecure the imperial throne, Euphemius warmly oppoſed him, on account of his known Arian principles, and when he found his oppoſition fruitleſs, he refuſed to crown the new emperor till he had delivered to him a written confeſſion of orthodox faith, and engaged under his hand, and by the ſanctity of an oath, to maintain the principles of the Catholic doctrine, as eſtabliſhed by the council of Chalcedon. In the year 493, Theodoric, having become maſter of Italy, ſent ambaſſadors to Anaſtaſius to treat for peace, to which Euphemius was thought to be the chief obſtacle. In a ſhort time afterwards Anaſtaſius having confidentially informed the patriarch of his deſire to terminate in an honourable manner the war in which he was engaged with the Iſaurians, Euphemius betrayed his ſecret to the patrician John, the father-in-law of Athenodorus, one of the chiefs of the Iſaurians. The emperor was made acquainted with the patriarch's conduct, and laid the caſe before an aſſembly of biſhops, who were convened at Conſtantinople in the year 495, and by his influence with them, obtained a decree that Euphemius ſhould be depoſed, and cut off from the communion of the church. He afterwards obtained a ſentence of baniſhment againſt Euphemius, who died at Ancyra in the year 515. Moreri.

EUPHON, in *Acouſtics*, a muſical inſtrument lately contrived by Dr. Chladni of Wittemberg, who, in conſequence of a variety of experiments on the longitudinal vibrations of claſtic bodies, conſtructed this inſtrument, ſo called from its pleaſant ſound, which conſiſts of glaſs tubes diſpoſed in a proper frame, and expreſſing their ſounds by being rubbed longitudinally. The euphon has ſome reſemblance to a ſmall writing deſk. When opened, the glaſs tubes, of the thickneſs of the barrel of a quill, and about 16 inches long, are ſeen in an horizontal poſition. They are wetted with water by a ſponge, and ſtroked with the wet fingers in the direction of their length, ſo that the increaſe of the tone depends merely on the ſtronger or weaker preſſure, and the ſlower or quicker movement of the fingers. The number of tubes is 42. In the back part there is a perpendicular ſounding-board divided in the middle, through which the tubes paſs. From this conſtruction it appears, that the euphon ſhould not be conſidered as an altered or improved harmonica, (See Armonica), but as a totally new and different inſtrument. In regard to ſweetneſs of ſound, it approaches very near to the harmonica; but it poſſeſſes ſeveral advantages, peculiar to itſelf. It is ſimpler, with regard both to its conſtruction and the movement neceſſary for producing the ſound, as neither tuning nor ſtamping is required, but merely the movement of the finger. It produces its ſound more ſpeedily; ſo that as ſoon as it is touched you may have the tone as full as the inſtrument is capable of rendering it; whereas in the harmonica, the tones, particularly the lower ones, muſt be made to increaſe gradually.

It

It has alſo greater diſtinctneſs in quick paſſages, becauſe the tones do not reſound ſo long as in the harmonica, where the ſound of one low tone is often heard when you wiſh only to hear the following tone. The uniſon is purer than is generally the caſe in the harmonica, where it is difficult to have perfect glaſſes, which in every part give like tones with mathematical exactneſs. It is however as difficult to be tuned as the harmonica. It does not affect the nerves of the performer; for a perſon ſcarcely feels a weak agitation in the fingers; whereas in the harmonica, particularly in concords of the lower notes, the agitation extends to the arms and even through the whole body of the performer. This inſtrument is leſs expenſive than the harmonica; when one of the tubes breaks, or any other part is deranged, it can ſoon be repaired, and at very little expence: whereas, when one of the glaſſes of the harmonica breaks, it requires much time and is very difficult to procure another capable of giving the ſame tone as the former, and which will correſpond ſufficiently with the ſeries of the reſt. For an account of the experiments that led the author to the conſtruction of this inſtrument, and of the various ſtages of his progreſs in the improvement of it, we refer to the Philoſophical Magazine, vol. ii. p. 391, &c.

EUPHONIC Accent. See Accent.

EUPHONY, in *Elocution* and *Compoſition*, that ſweet or pleaſing quality in the ſucceſſive ſounds of language, which reſults from happy combinations of the enunciative elements, ſuch eſpecially as, though eſſentially different in their characteriſtic powers, melt eaſily into each other ſo as to preſerve an uninterrupted flow of utterance through the reſpective members of a ſentence, without labour to the ſpeaker, or offence to the hearer. The word is formed of ευ, *bene*, *well*, and φωνη, *vox*, *voice*. Quintilian calls *euphonia*, *vocalitas*; Scaliger, *facilis pronunciatio*. The moſt obvious rule with reſpect to euphonic compoſition is that a due mixture ſhould be made of conſonants and vowels; and the principle of this rule may be at once explained and illuſtrated by the following parody on a famous but ſophiſtical couplet in Pope's Eſſay on Criticiſm,

> "Your conſonants with vowels well combine,
> And twelve ſmall words may flow in one ſmooth line."

But this is not all that is requiſite for perfect euphony: every vowel does not blend with equal grace and facility with every conſonant; nor is every ſucceſſion of mere vowels, or every ſucceſſion of conſonants, equally offenſive or cacophonous. Words or ſyllables, for example, terminating with thin vowels, may be followed by other words or ſyllables, commencing with broad or open vowels, or the reverſe, with very happy effect; and ſome conſonants may be brought together, in immediate ſucceſſion, even as terminative and initial elements of following ſyllables or words, in ſuch way as rather (while they increaſe the ſonorous energy of ſuch compoſition,) to diverſify the time and expreſſion, than to diſturb the euphony of the ſentence. All the liquids eſpecially (thoſe that properly ought to be, as well as thoſe that commonly are ſo called) combine with almoſt equal facility with other liquids, and with vowels or with the conſonants, whether ſemi-liquids, ſibilants, or mutes. (See Liquid, Mute, &c.) Which of theſe, and under what circumſtances, may be thus brought together, with the happieſt effect of euphony and expreſſion, it would require a much longer diſcuſſion than we have ſpace for, to aſcertain; and, after all, much muſt be left to the taſte, the ear, and the experimental diſcrimination of the writer. But it is not upon the writer alone, that the effect of euphony depends. The reader or reciter muſt alſo do his part, for though it is very poſſible ſo to write, that no organs, and no management of thoſe organs, can elicit in the delivery, any thing but the diſſonance of cacophony; there are ſome pedants who contrive to render even the ſmootheſt compoſitions harſh and cacophonous, and then aſcribe to their native language, (of the very elements and genius of whoſe oral compoſition they are utterly ignorant,) the diſguſting diſſonance which does, in reality, belong to their own jargonized utterance. Euphony in the reader or ſpeaker depends principally upon his ſkill and management in the articulation and implication of the ſucceſſive elements, ſyllables, and words as explained under the term Enunciation; and upon his giving full tune, and ſufficient quantity to the liquids and liquifiable conſonants. Cacophony (the antagoniſt of Euphony) on the contrary, reſults in the reader, from the laboured ſeparation of terminatives and initials, that might eaſily have been implicated; from giving unneceſſary impulſe and force to the mutes, from hurrying over the liquids, and partially tuneable elements, as if they were mere mutes, and from perpetual unneceſſary interruptions in the ſtream of enunciative delivery.

EUPHORBIA, in *Botany*, ευφορβιον of Dioſcorides, ſo named after Euphorbus, phyſician to Juba king of Lybia. Spurge. Linn. Gen. 243. Schreb. 326. Willd. Sp. Pl. v. 2. 881. Sm. Fl. Brit. 513. Mart. Mill. Dict. v. 2. Juſſ. 385. Claſs and order, *Dodecandria Trigynia*. Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, inflated, ſomewhat coloured, with four, in ſome few inſtances five, marginal teeth, permanent. *Cor.* Petals, or Nectaries, four, ſometimes five, turbinate, gibbous, thick, abrupt, unequal in ſituation, alternate with the teeth of the calyx, inſerted into its margin by their claws, permanent, bearing plenty of honey. *Stam.* Filaments numerous, 12 or more, thread-ſhaped, jointed, longer than the corolla, inſerted into the receptacle, coming to maturity at different periods, ſeparated by briſtly ſcales; anthers roundiſh, of two diſtinct lobes. *Piſt.* Germen ſuperior, roundiſh, three-ſided, elevated on a ſtalk above the margin of the calyx; ſtyles three, cloven; ſtigmas obtuſe. *Peric.* Capſule ſtalked, roundiſh, three-lobed, of three cells, and three valves which ſeparate elaſtically. *Seeds* ſolitary, roundiſh.

Obſ. The petals or nectaries are for the moſt part four, in ſome flowers five, which often happens on the ſame plant, ſuch flowers being furniſhed with ſtamens only, without a piſtil, and coming forth earlier than the reſt. In many the petals are glandular, in others creſcent-ſhaped, or toothed; in ſome few thin and membranous; they are commonly ſituated as it were on the outſide of the calyx. The capſule is either ſmooth, or hairy, or warty.

Eſſ. Ch. Calyx of one leaf, inflated, inferior. Nectaries four or five, inſerted into the calyx. Capſule ſtalked, three-lobed.

A vaſt, but very natural, genus, whoſe ſpecies amount in Willdenow's work to 124. They are divided into ſeveral ſections. All abound with an acrid milk.

Thoſe of the firſt ſection have a very peculiar thick, ſhrubby, fleſhy, angular ſtem, armed with ſpines, and bearing few or no leaves. To this belongs *E. officinarum*, probably the original ſpecies. See its figure in Commelin's Hort. Amſt. v. 1. t. 11. Alſo *E. antiquorum*, ib. t. 12, an Eaſt Indian plant, which ſeems very improperly named, as neither agreeing with the deſcriptions of the ancients, nor growing in the country whence they procured their ευφορβιον.

The ſecond ſection has ſhrubby ſtems without thorns, neither forked nor umbelliferous. As *E. Caput Meduſæ*, Comm. Hort. t. 17, common in Green-houfes; and *E. petiolaris*, Curt. Mag. t. 883.

The third has forked ftems, not umbelliferous, and the plants are moftly herbaceous and annual, as *E. picta*, Jacq. Ic. Rar. t. 477, and *pilulifera*, t. 478; alfo *E. Peplis*, Engl. Bot. t. 2002, common on the fea fhores of the fouth of Europe.

The fourth has the flowers in an umbel, three-branched in the firft inftance, and the branches fubfequently forked repeatedly, each fubdivifion of the inflorefcence accompanied by a pair of heart-fhaped, unequal-fided, fomewhat coloured bracteas, as our common weed *E. Peplus*, Curt. Lond. fafc. 1. t. 35. Engl. Bot. t. 959.

The fifth has a four-branched umbel, as the great *E. Lathyris* of the gardens, commonly called the Caper tree, remarkable for its long, dark, four-rowed leaves. There are but few fpecies in this fection.

The fixth, a numerous fection, has a five-branched umbel, like the common *E. heliofcopia*, Curt. Lond. fafc. 1. t. 36. Engl. Bot. t. 883; and the rare and fplendid *E. punicea*, Sm. Ic. Pict. t. 3, a fhrubby Jamaica plant, of which a moft miferable fpecimen is drawn in Jacq. Ic. Rar. t. 484.

The feventh and laft fection confifts of fuch fpecies as have numerous rays to the common umbel, like *E. Cypariffias*, Engl. Bot. t. 840, frequent in gardens, and *amygdaloides*, t. 256, very common in woods.

EUPHORBIA, in *Gardening*, comprehends plants of the herbaceous, fhrubby, fucculent kinds, the principal cultivated fpecies of which are; the triangular fpurge (E. antiquorum); the Canary fpurge (E. canarienfis); the officinal fpurge (E. officinarum); the Medufa's head fpurge (E. caput Medufæ); the myrtle-leaved fpurge (E. tithymaloides); the feven-angled fpurge (E. heptagona); the warty-angled fpurge (E. mammilaris); and the Cape fpurge (E. lathyris): the firft fpecies is a large plant, of which there is a variety with a naked three-cornered compreffed ftalk, fending out a great number of erect branches, which are likewife generally three-cornered, but fometimes four-cornered; armed with fhort crooked fpines, having no leaves. The plants have not, we believe, yet produced flowers in this climate. This variety, like the fpecies from which it is produced, is a native of the Eaft Indies.

The fourth fpecies has alfo a variety frequently denominated the "Little Medufa's head," which has a thick fhort ftalk, feldom more than eight or ten inches in height, from which come out a great number of flender trailing branches, about a foot in length, intermixing, and having the fame appearance with the other, but fmaller and much fhorter; the ends are befet with narrow leaves, between which the white flowers come out and appear. Its native fituation is the fame as that of the fpecies from which it is derived. According to fome there are likewife a double branching, a dwarf trailing, and other varieties.

The fifth fort has alfo laurel leaved and variegated leaved varieties.

Method of Culture.—Thefe different forts of plants may be raifed by planting cuttings, which have been made at a joint, five or fix inches in length, after having been rolled in fand, and laid upon a fhelf for fome days to have the wounds healed over, in the fummer feafon about the middle, choofing fmall pots for the purpofe filled with light, dry, fandy mould, with fome rubbifh at the bottoms, fuch as that formed of one fourth part of lime-rubbifh which has been well fcreened, the fame quantity of fea fand, and one half of the whole of light frefh vegetable earth, which fhould be very well mixed and incorporated together, by being often turned over; then plunging the pots in the bark hot bed, giving due fhade when the weather is hot and funny, with a little water occafionally once or twice a week. As foon as the plants have ftricken root, air fhould be admitted to them pretty freely in the fituation in which they may be; or they may, in order to be hardened, be removed into the ftove.

In the after management they fhould be allowed larger pots annually as they advance in growth, and be often refrefhed with water during the fummer months, but very fparingly in the winter feafon.

It may be remarked that moft of thefe forts of plants are capable of being kept in the hot-houfe, on the fhelves, and fome of them, as the fifth, fixth, and feventh forts, in a dry airy green-houfe, or glafs cafe, during the winter months, great care being taken to protect them well from the frofts; being fet out in the fummer in the open air: but the fourth fpecies requires fome fort of fupport in order to prevent the branches, by their weight, forcing it upon the pots; as by this fort of treatment the plants will rife to the height of four or five feet, throwing out a great number of fide branches. The eighth kind, however, requires little or no particular care after it has been once introduced, except merely that of keeping the young plants clean, as it will be continued by its fcattering the feeds.

All thefe plants, with the exception of the laft, afford great variety in collections of the hot and green-houfe kinds; and that alfo in the clumps and borders of the pleafure grounds, among others of the lefs hardy forts.

EUPHORBIÆ, in *Botany*, the 96th natural order in Juffieu's fyftem, or the 1ft of his 15th clafs. The definition of this clafs is,—Cotyledons two. Petals none. Stamens in a feparate flower from the piftils. Its characters are thus more fully explained. Flowers either monoecious, that is, males and females together on the fame plant, or dioecious, on feparate ones; very rarely hermaphrodite. Calyx in all of one leaf, or a fcale fupplying its place. Corolla none, except occafionally fome fcales, or internal divifions of the calyx, refembling petals. In the male flowers the ftamens are inferted either into the upper or lower part of the calyx, or fcale which fupplies its place, definite, or rarely indefinite, in number; their filaments diftinct, or rarely united into a central ftalk, originating from the middle of the calyx. Germen in the females fimple, or fometimes more than one, fuperior, or rarely inferior; ftyle one, or feveral, rarely wanting; ftigma either folitary or more than one. Fruit either fuperior or inferior, various in the ftructure and number of its cells.

The learned author, by his fubfequent remarks and explanations, is evidently aware of the difficulties attending this clafs, which indeed is in no fenfe really a natural one, its orders having little or no affinity to each other, except the two laft *Amentaceæ* and *Coniferæ*.

The characters of the order of *Euphorbiæ* are, *Flowers* monoecious or dioecious, or rarely hermaphrodite. *Calyx* of each tubular, or deeply divided, fimple or double, the internal fegments occafionally refembling petals. *Petals* none, except the fegments juft mentioned. *Stamens*, in the male flowers, definite or indefinite in number, their filaments inferted either into the receptacle, or the centre of the calyx, diftinct or united, fometimes branched, fometimes jointed. In fome there are chaffy fcales between the filaments. *Germen*, in the female flowers, folitary, fuperior, feffile or ftalked; ftyles in fome cafes feveral, often three, with an equal number of cells to the capfule, each containing one or two feeds; in others the ftyle is fimple, with three or more ftigmas, the fruit of feveral

veral cells, equalling the ſtigmas in number, with one or two ſeeds in each. In all the cells are furniſhed with two internally elaſtic valves; the ſeeds have a partial covering, and are attached at the upper part to the permanent central axis of the fruit. Corculum flat, enveloped in a fleſhy albumen. The plants are either herbaceous, or ſhrubby, or arboreſcent; ſome of them milky. Leaves alternate or oppoſite, (in ſome few inſtances wanting,) either with or without ſtipulas. The firſt ſection conſiſts of ſuch genera as have ſeveral ſtyles, moſtly three. Theſe are *Mercurialis*, *Euphorbia*, *Argythamnia* of Browne's Jam. 338. Sw. Prod. 39, *Cicca*, *Phyllanthus*, *Xylophylla*, *Kirganelia*, *Kiggellaria*, *Clutia*, *Andrachne*, *Agyneia*, *Buxus*, *Securinega* of Commerſon, *Adelia*, *Mabea*, Schreb. 641, *Ricinus*, *Jatropha*, *Dryandra*, *Aleurites*, *Croton*, *Acalypha*, *Caturus* and *Excœcaria*. The ſecond ſection, with a ſolitary ſtyle, contains *Tragia*, *Stillingia*, *Sapium of* Browne, *Hippomane*, *Ægopricon*, *Sechium* of Browne, *Hura*, *Omphalea*, *Plukenetia* and *Dalechampia*.

The ſeeds of theſe plants are mild and eatable in many inſtances, if freed from their integuments and corculum, the latter being very dangerouſly purgative, as in *Euphorbia* and even *Ricinus*, proving mild in the latter only from the copious oil of the cotyledons. *Euphorbia*, which gives its name to this natural order, can only by a very bold analogy, or rather hypotheſis, be ſaid to have no corolla, and is very imperfectly polygamous, not monoeecious; indeed Juſſieu allows it to be hermaphrodite. See EUPHORBIA.

EUPHORBIUM, is a moſt acrid gum reſin, which exudes from the *Euphorbia officinarum* and other ſhrubs of the ſame genus, and was formerly uſed in pharmacy, but is now nearly, if not, entirely rejected.

This gum is brought from Barbary and other parts of the Mediterranean in tears or drops of an irregular form, generally entangling much impurity; of a pale yellow colour without, and white within. Euphorbium has no ſmell: when taken into the mouth it gives at firſt no taſte, but after a little time a moſt acrid biting ſenſation is felt, which increaſes to an intolerable degree, and if not immediately rejected it proceeds to corrode the ſkin of the tongue and fauces. The ſame acrimony is ſhewn when applied to the body in any other manner. In reducing it to powder the duſt that flies off will excite the moſt violent ſneezing, and often bleeding from the noſtrils and throat, ſo that particular precautions muſt be taken. When laid for ſome time on the ſkin it bliſters.

The ſpirituous tincture of euphorbium is ſtill more acrid.

This gum reſin, on account of its extreme acrimony, can hardly be uſed with ſafety as an internal medicine, as it is liable to produce violent diarrhœa and bloody ſtools, and much inflammation. The only purpoſe for which it has been employed in the later diſpenſatories has been in mixture with cantharides to increaſe the veſicating and irritating property, but euphorbium is now altogether diſuſed.

EUPHORIA, in *Botany*, ſo named by Commerſon from ευφορος, *fertile*, a genus comprehending the two Chineſe fruits Lit-chi and Longan, to which Juſſieu ſuſpects Forſter's *Pometia* may alſo belong. See SCYTALIA.

EUPHORY, ſignifies the ſame as *Eucracy*.

EUPHRASIA, in *Botany*, from ευφραινω, *to exhilarate*, or *delight*, alluding to the brightneſs or gaiety of the bloſſoms. Eye-bright. Linn. Gen. 304. Schreb. 401. Willd. Sp. Pl. v. 3. 192. Tournef. t. 78. Sm. Fl. Brit. 650. Mart. Mill. Dict. v. 2. Juſſ. 100. Gærtn. t. 54. Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Pediculares*, Juſſ.

Gen. Ch. *Cal.* perianth of one leaf, inferior, cylindrical, four-cleft, equal, permanent. *Cor.* of one petal, ringent; tube as long as the calyx; upper lip concave, notched; lower ſpreading, deeply three-lobed, its lobes equal, obtuſe, notched. *Stam.* Filaments four, thread-ſhaped, ſituated cloſe under the upper lip; anthers of two lobes, the lobes unequally ſpinous at their lower extremities. *Piſt.* Germen ſuperior, ovate; ſtyle thread-ſhaped, agreeing in form and ſituation with the ſtamens; ſtigma obtuſe, undivided. *Peric.* Capſule ovate-oblong, compreſſed, of two cells and two valves; the partition contrary to the valves. *Seeds* numerous, minute, roundiſh, longitudinally ſtriated.

Eſſ. Ch. Calyx cylindrical, four-toothed, equal. Upper lip of the corolla cloven; lower three-lobed, the lobes cloven. Anthers bearded with unequal ſpines. Capſule ovate-oblong. Seeds ſtriated.

Botaniſts are not perfectly agreed about the limits of this genus, and its near allies *Bartſia* and *Rhinanthus*. The firſt of Willdenow's twelve ſpecies, E. *latifolia*, Linn Sp. Pl. 841, is *Bartſia latifolia*, Sm. Prod. Fl. Græc. Sib. 428, a beautiful native of the ſouth of Europe. His ſixth, E. *odontites*, is *Bartſia odontites* of Hudſ. Fl. Angl. 268, and Sm. Fl. Brit. 648. Engl. Bot. t. 1415.

E. *officinalis*, Linn. Sp. Pl. 841. Engl. Bot. t. 1416. Curt. Lond. faſc. 5. t. 42. common in heathy and mountainous paſtures, which its gay bloſſoms greatly enliven in autumn, is a genuine and original example of the genus. This is a ſmall, upright, annual plant, with ovate ſharply ſerrated *leaves*. The *flowers* are white, ſtrongly ſtreaked with purple, having a yellow ſpot on the lip. On the Alps they are often larger, light purple, and ſtill more beautiful.

The dazzling brilliancy of theſe little bloſſoms ſeems to have given riſe to the vulgar opinion, that the plant was good for the eyes; whence its Engliſh name Eye-bright.

EUPHRATENSIA, in *Ancient Geography*. See COMMAGENE.

EUPHRATES of Alexandria, in *Biography*, a Stoic philoſopher, who flouriſhed in the ſecond century, was a friend of Dio and of Apollonius Tyanæus, who introduced him to Veſpaſian. Although a violent quarrel aroſe between the latter philoſopher and Euphrates, in conſequence of which Philoſtratus, the panegyriſt of the former, inveighs with great ſeverity againſt the latter, it appears from the teſtimony of Epictetus, Pliny the younger, and Euſebius, that Euphrates was univerſally eſteemed for his talents and virtues, and that the cenſures of Philoſtratus deſerve only contempt. Pliny's character of him is highly intereſting. "If ever," ſays he (Ep. l. i. ep. 10.), "polite learning flouriſhed at Rome, it certainly does at preſent. Of this I could give you many inſtances; but I will content myſelf with naming only Euphrates the philoſopher. When, in my youth, I ſerved in the army in Syria, I had an opportunity of converſing familiarly with this excellent man, and took ſome pains to gain his affection, though that indeed was not difficult; for he is exceedingly open to acceſs, and full of that gentleneſs of manner which he teaches. Euphrates is poſſeſſed of ſhining talents, which cannot fail to intereſt even the unlearned. He diſcourſes with great accuracy, dignity, and elegance; and frequently riſes into the ſublimity and luxuriance of Plato himſelf. His ſtyle is copious and diverſified, and ſo wonderfully ſweet, as to captivate even the moſt reluctant auditor. Add to all this, his graceful form, comely aſpect, long hair, and large white beard; circumſtances which, though they may probably be thought trifling and accidental, contribute, however, to procure him much reverence. There is no diſguſting negligence in his dreſs; his countenance is grave, but not auſtere; his approach commands reſpect, without exciting awe. With

With the ſtricteſt ſanctity, he unites the moſt perfect politeneſs of manner. He inveighs againſt vice, not againſt men; and, without chaſtiſing, reclaims the offender. You liſten with fixed attention to his exhortations, and even when convinced, ſtill hang with eagerneſs upon his lips."

In conformity to the principles of the Stoic philoſophy, Euphrates, when he found his ſtrength worn out by diſeaſe and old age, voluntarily put a period to his life by drinking hemlock, having firſt, for ſome unknown reaſon, obtained permiſſion from the emperor Adrian. Brucker's Hiſt. Phil. by Enfield, vol. ii.

Euphrates, the reputed founder of a religious ſect in the ſecond century, ſometimes called "Ophians," or "Ophites," and ſometimes "Serpentinians," names derived from the peculiar tenet which he held, that the ſerpent, by which our firſt parent was deceived, was either Chriſt himſelf, or "Wiſdom" concealed under the form of that animal, and that he was the occaſion of all the knowledge which men had received. Hence he is ſaid to have inculcated a particular veneration for the ſerpent, preſerving a living one, offering to it a ſubordinate kind of divine honour, and bringing it out to partake of or to conſecrate the euchariſt. Origen and others contend that the followers of Euphrates were not Chriſtians, but calumniators of Jeſus Chriſt, and oppoſers of his doctrine: but Dr. Lardner, who has taken ſome pains in inveſtigating the ſubject, conſiders them as believers in Chriſtianity, and maintaining that Jeſus, who was born of a virgin, was a moſt excellent man, and that, having by his miracles and inſtructions manifeſted himſelf to be the true Meſſiah, was crucified, and afterwards raiſed from the dead, received into heaven, where he ſits on the right hand of God. He conceives that what ſome have ſaid of them, reſpecting the ſerpent being Chriſt, muſt be a miſtake, founded on an opinion that the brazen ſerpent in the wilderneſs was a type or figure of Chriſt. The other accounts of worſhipping the ſerpent, &c. this judicious and learned writer rejects without heſitation. Moreri. Lardner.

Euphrates, in *Ancient Geography*, one of the moſt conſiderable and beſt known rivers of Aſia, the ſource of which was in the mountains of Armenia north of Abus, which after receiving ſeveral ſtreams in this part of Armenia, at the towns of Elegia, Gymnias, and Brapus, purſued its courſe towards the ſouth-weſt, ſeparating Armenia Major, on the eaſt, from Armenia Minor on the weſt. It then proceeded ſouth-eaſtward, waſhing the ſkirts of Syria, and dividing Arabia from Meſopotamia; and afterwards directing its courſe towards the north-eaſt, it ſeparated Chaldæa and Babylonia from Meſopotamia, till at length mixing its waters with thoſe of the Tigris, with which it previouſly communicated by ſeveral canals, it emptied itſelf into the Perſian gulf. The Euphrates, according to Ptolemy, above Babylon, near a town in Meſopotamia, called Sipphara, divided itſelf into two branches, one running to Babylon, and the other to Seleucia, where it fell into the Tigris. Pliny ſays the latter was partly artificial; for he places Seleucia at the confluence of the Tigris and Euphrates, adding that the Euphrates was conveyed to it by a canal. Prideaux, on the authority of Pliny, ranks this artificial branch among the ſtupendous works of Nebuchadnezzar. Between theſe two branches a canal was cut from the Euphrates, above Babylon, to the Tigris at Apamea, 60 miles below Seleucia. This canal was denominated *Naarmalcha*, and was dug by Nebuchadnezzar, as Abydenus informs us, to convey the waters of the Euphrates, when it overflowed, into the Tigris, before they reached Babylon. At the diſtance of 800 furlongs from Babylon to the ſouth was another canal, called by Arrian Pallacopes, and by Appian Pallacotta, derived from the branch of the Euphrates that paſſed through Babylon, and continued to certain lakes or marſhes in Chaldæa. On this canal, or river, as Arrian calls it, Alexander ſailed from the Euphrates to the above-mentioned lakes. But it is impoſſible, at this diſtance of time, and after the changes that have occurred, to trace out the numerous branches and canals which watered the ancient country of Babylon. This great river moved ſlowly through a great part of its courſe, and was ill adapted for navigation, as ſome parts of it were ſhoal and others rocky. Thevenot, however, is of opinion, that the Euphrates might, with little trouble, be made navigable, even by great barks, quite to the Tigris, only by clearing the channel of the ſtones with which it is choked in ſome places. The ancient mode of navigating this river was very extraordinary. The veſſels were round, without diſtinction of head or ſtern, and no better than great wicker baſkets, covered over with hides, guided by two oars or paddles. They were capable of carrying a very conſiderable weight; and when they had unloaded their cargo at Babylon, they were ſold, but the hides were kept: and loading their aſſes with them, the navigators returned home by land, the rapidity of the ſtream not allowing them to return by water.

Euphrates, in *Modern Geography*, a river of Aſiatic Turkey, which riſes from the mountains of Armenia, as ſome have ſaid, in two ſtreams, a few miles to the N.E. of Erzeron, the ſtreams uniting to the S.W. near that city; and chiefly purſuing a S.W. direction to Semiſat, where it would fall into the Mediterranean, if not prevented by a high range of mountains. In this part of its courſe the Euphrates is joined by the Morad, a ſtream almoſt doubling in length that of Euphrates, ſo that the latter river might more juſtly be ſaid to ſpring from mount Ararat, about 160 Britiſh miles to the eaſt of the imputed ſource. At Semiſat, the ancient Samoſata, this noble river aſſumes a ſoutherly direction; then runs an extenſive courſe to the S.E., and after receiving the Tigris, falls by two or three mouths into the gulf of Perſia, about 50 miles S.E. of Baſſora. N. lat. 29° 50'. E. long. 66° 55'. The comparative courſe of the Euphrates may be eſtimated at about 1400 Britiſh miles. This river is navigable for a conſiderable diſtance from the ſea. This river in its courſe ſeparates Aladulia from Armenia, Syria from Diarbekir, and Diarbekir from Arabia, and paſſing through the Arabian Irak, there joins the Tigris.

Euphrates, a river of Africa, in the country of Whidah, on the Slave coaſt.

EUPHROSYNE, in *Mythology*, one of the three Graces. See Graces.

EUPHROSYNUM, in *Botany*, a name uſed by Pliny and ſome others for the common borrage. See Borrage.

EUPILIS, in *Ancient Geography*, *Puſſiano*, a lake of Italy, in Gallia Ciſalpina, whence, according to Pliny, iſſued the river Lambrus.

EUPNŒA, of ευ, *well*, and πνεω, *I breathe*, in *Medicine*, is a right and natural reſpiration.

EUPOLIS, in *Biography*, an Athenian who flouriſhed B.C. 440, was known as a comic writer, and one of that claſs who marked out by name the objects of their ſatire, which rendered him extremely popular with the many, as he was dreaded by the great. He is mentioned by Horace and Quintilian, who put him in the ſame claſs with Cratinus and Ariſtophanes. His comedies were of a political caſt, in one of which Alcibiades was ſo ſeverely attacked, that he is ſaid to have hired aſſaſſins to throw him into the ſea. The plot did not ſucceed, for Eupolis wrote ſeveral comedies after the period aſſigned to this fact, and Ælian relates that

that he died at Ægina. Fragments of his works have come down to us, and titles of twenty of his plays. Gen. Biog.

EUPORIA, in *Ancient Geography*, a town of Macedonia, placed by Ptolemy in Bisaltia.

Euporia, of ευ and πορος, *passage*, in *Medicine*, is an easy preparation of medicines, or the easiness of their operation.

EUPSYCHIANS. See Eunomioeupsychians.

EURA, in *Geography*, a town of Sweden, in the government of Abo; 17 miles N.E. of Abo.

EVRA, a town of Abyssinia; 12 miles S.E. of Siré.

EVRACMINNA, a town of Sweden, in the government of Abo; 17 miles S. of Biorneborg.

EVRAN, a town of France, in the department of the North Coasts, and chief place of a canton in the district of Dinan, four miles S. of it. The place contains 3573, and the canton 9175 inhabitants, on a territorial extent of 117½ kiliometres and seven communes.

EURAN Islands, a cluster of small islands, on the east side of the gulf of Bothnia. N. lat. 63° 54'. E. long. 22° 39'.

EURANIUM, in *Ancient Geography*, a town of Asia Minor, in Caria.

EURE, in *Geography*, a river of France, which has its source in the forest of Logny, and terminates in the Seine, above Pont de l'Arche. Its course is northward, and extends 36 leagues.

Eure, formerly *Ouche*, a department of the second or northern region of France, in 49° N. latitude, bounded on the north by the department of the Lower Seine, on the east by that of the Oise, on the south by the departments of the Eure and Loire and the Orne, and on the west by the department of the Calvados. It takes its name from the river Eure, which traverses it; and its capital is Evreux. It contains 307 square leagues, and 415,574 inhabitants in five districts, *viz.* Pontaudemer, Louviers, Les Andelys, Evreux, and Bernay, 35 cantons, and 843 communes. Its fertile soil yields grain, hemp, flax, and pastures; and it has considerable forests.

Eure *and Loire*, a department of the second or northern region of France, in 48° 15' N. lat. composed of a part of *Beauce* and of *Perche*, bounded on the N.W. by the department of the Eure, on the east by the departments of the Seine and Oise and the Loiret, on the south by the departments of the Cher and Loiret, and on the west by the departments of the Orne and Sarte. It takes its name from the rivers Loire and Eure, which water it; and its capital is Chartres. It contains 300 square leagues, and 259,967 inhabitants. It is divided into four districts, *viz.* Nogent-le-Rotrou, Chartres, Chateaudun, and Dreux; 23 cantons, and 460 communes. This department, on account of its great fertility, is called the granary of Paris, and it abounds in fruits and rich pastures

EVRE, or Yevre, a river of France, which discharges itself into the Cher by two streams, one near Vierson, the other at Bourges.

EVRECY, a town of France, in the department of the Calvados, and chief place of a canton in the district of Caen; seven miles S.W. of Caen. The place contains 850, and the canton 13,110 inhabitants, on a territorial extent of 145 kiliometres, and 29 communes.

EVREGNIES, a town of France, in the department of Jemmappe; nine miles N.N.W. of Tourney.

EUREOS, in *Natural History*, the name of a stone, described by Pliny, and seeming plainly to be the same with the tecolithus, which he mentions in another place, and to be the stone now called *lapis Judaicus*, and known at this time to be the petrified spine of a sort of echinus marinus, or sea urchin.

EVREUX, Mediolanum, *Eborice*, or *Civitas Evergorum*, in *Geography*, a town of France, in the department of the Eure, of which it is the capital, and chief place of a district. Its north division contains 4200, and the canton 10,458 inhabitants, and the south division 4226, and its canton 10,853 inhabitants; the territorial extent comprehends 345 kiliometres, and each division includes 30 communes. Before the revolution this was the see of a bishop, suffragan of Rouen; containing nine parish churches, two abbies, and ten convents. This is an ancient and considerable town, with large suburbs, situated in a deep and fruitful vale on the river Eton, 23 miles N.W. from Paris. Its cathedral is a fine Gothic structure. The manufactures of Evreux consist of woollen and linen cloth, and its trade of rice, grain, wine, and cyder; but they are not considerable. N. lat. 49° 2'. E. long. 1° 15'.

EURIA, in *Ancient Geography*, a town of Greece, in Epirus.

EURIPIDES, in *Biography*, the contemporary and rival of Sophocles, and one of the most ancient Greek tragedians, was born in the isle of Salamis, in the first year of the 75th olympiad, B.C. 480, according to many writers, though the Arundelian marble places his birth five years earlier. His father's name was Mnesarchus, an Athenian, and that of his mother was Clito, a seller of herbs, according to the report of Aristophanes, the avowed enemy of Euripides; but by the testimony of later grammarians, founded on the authority of Philochorus, an ancient writer, she was of noble descent. Before the birth of his son, Mnesarchus is said to have consulted the oracle of Apollo concerning his future destiny, and to have received for answer, "that the child who should be born to him would reach the summit of glory, and gain the honour of the sacred garland," which was understood to signify the crown of victory at the olympic games. When Greece was invaded by Xerxes, Mnesarchus and his wife retired for safety, among other Athenians, to the island of Salamis. In the autumn of the year 480 B.C. when this invasion took place, the fate of Greece was in a great measure decided by the naval victory of Salamis over the Persians; and on the same day, it is said, Euripides was born, who in memory of this battle, fought in the narrow channel, or *Euripus*, which divides Salamis from the continent, received his name. Euripides, at subsequent periods of his life, was accustomed to frequent the island of his nativity, where was shewn a cave, in which some of his tragedies are said to have been composed. Euripides, in conformity to the suggestion of the oracle, and also to the custom of the country, qualified himself for honourable and successful contest at the public games, by an early initiation in the usual gymnastic exercises; but his views were directed to nobler pursuits. Accordingly, whilst he paid some attention to the art of painting, he studied rhetoric under Prodicus, celebrated for the allegory of the choice of Hercules, preserved by Xenophon, and received instructions in physics from Anaxagoras, and in morals from Socrates. In his 18th year he first applied himself to the composition of tragedies, the number of which, during the course of his life, amounted, as some say, to 75, but according to others, to 92. He does not appear, however, to have been very successful in his exhibitions on the theatre, for no more than five of his performances gained the prize at the olympic games: but they were privately read with avidity and highly applauded by his countrymen. To this purpose we may mention the following fact. After the

 unfortunate

unfortunate expedition of the Athenians againſt Syracuſe, ſeveral captives were kindly treated by the Sicilians, and obtained relief from indigence and wretchedneſs, by going about from place to place, reciting and ſinging the verſes of Euripides. Upon their return to their own country, the poet received their perſonal acknowledgments. Socrates was the friend of Euripides, and is ſaid to have given him advice and aſſiſtance in the compoſition of ſome of his dramas; and he occaſionally attended the public exhibition of them. In the character of Palamedes the poet was ſuppoſed to have delineated that of Socrates; and ſome verſes are quoted addreſſing the Greeks as having ſlain the beſt and wiſeſt of their nation, which the audience applied to the fate of this philoſopher, burſting into tears at the recollection of their crime. As Socrates had become an object of public perſecution and calumny before the repreſentation of the Palamedes, ſome application of the character to his circumſtances might probably have been intended by the poet. But his death could only be alluded to by way of probable anticipation, as he ſurvived Euripides ſome years. The remarkable effect aſcribed to the paſſage of the Palamedes juſt mentioned might poſſibly have taken place at ſome repreſentation of that play ſubſequent to the death of Socrates. Euripides was the conſtant rival of Sophocles, and their mutual jealouſy ſeems to have degenerated into declared enmity. Our poet was frequently the object of raillery to Ariſtophanes. Euripides was twice married; but as he was diſappointed in his expectation of domeſtic happineſs, he is ſaid to have indulged a kind of antipathy to women, for which this circumſtance has been pleaded as an apology. Hence he obtained the name of Μισογυνης, *woman-hater*, though his editor, Barnes, ſtrenuouſly defends him from the charge implied in this appellation, obſerving, that if he has deſcribed ſome females with all the vices incident to human nature, yet he has delineated many others with all the virtues that can adorn their ſex; and Sophocles is ſaid to have obſerved, that the hatred which he expreſſed againſt women was confined to the ſtage. In advanced life he enjoyed ſo little felicity at Athens, that he accepted an invitation to the court of Archelaus, king of Macedonia, where he was honourably treated, though he did not altogether eſcape the effects of malicious jealouſy. To the conſequence of a quarrel from this cauſe ſome have aſcribed his tragical death; for as he was walking in a wood, the king's hounds were let looſe upon him, and tore him in pieces. Others ſay that his death was owing to natural decay. He died at the age of about 75 years. The Athenians ſent embaſſadors to Macedonia, to requeſt the removal of his body to his native country; but Archelaus refuſing to comply with their requeſt, cauſed him to be interred with great magnificence, and erected in honour of him a noble monument in the vicinity of Pella, his chief city. The Athenians appointed a public mourning on occaſion of his death, and erected in memory of him a cenotaph on the road leading from the city to the Piræus. The following epitaph is aſcribed to Thucydides, the hiſtorian.

> " Μναμα μεν Ελλας απασ' Ευριπιδου· ος̣α δ'ισχει
> Γη Μακεδων, ἡ γαρ δεξατο τερμα βιου.
> Πατρις δ'Ελλαδος Ελλας Αθηναι· πλειςα δε Μουσαις
> Τερψας, εκ πολλων και τον επαινον εχει."

"All Greece is the monument of Euripides; the Macedonian land poſſeſſes his bones, for there he reached the boundary of his life. His country is Athens, the Greece of Greece; having afforded general delight by his muſe, he enjoys the recompence of general praiſe."

It has been recorded to the reproach of Euripides, that many of the maxims which he attributes to his dramatic characters are favourable to vice; and though he cannot be wholly exculpated from this charge, he abounds with moral maxims, expreſſed in noble and elegant language, which deeply impreſs the mind of the reader. He has been alſo charged with moroſeneſs of temper; but however this be, he introduces numerous paſſages of tender and delicate pathos. As a tragedian, when compared with Sophocles, it ſeems to be the general opinion, that with leſs pomp of diction, leſs force and elevation of character, and leſs knowledge of dramatic effect than his rival, he more excels in tenderneſs, ſuavity, and moral ſentiment. Ariſtotle calls him the "moſt tragical" of all the poets, meaning either that he was the moſt ſkilful in the drama, or the moſt pathetic. Euripides, it ſhould be recollected, was the favourite poet of Milton. Poſſeſſing a high notion of the preceptive office of the theatre, he was once deſired by the auditors to retrench a paſſage in one of his plays, but he ſtepped forward and ſaid, "I do not write in order to learn from you, but to teach you." Of his works nineteen compleat plays, and the commencement of a twentieth, are ſtill remaining. Of theſe, both ſingly and collectively, there are ſeveral editions. The beſt of the whole works are thoſe of Baſil, 1551, of Plantin, 1571, of Commelin, 1597, of Paul Stephens, 1604, 1611, of Barnes, *Camb.* 1694, and of Muſgrave, Oxf. 1778. Bayle. Moreri. Barnes. Gen. Biog.

EURIPUS, Ευριπος, in *Hydrography*, properly ſignifies a certain ſtrait of the ſea which divides Eubœa from Attica, Bœotia, and Locris, where the currents are ſo ſtrong that the ſea is ſaid to ebb and flow ſeven times a day; in which place, as the ſtory commonly goes, Ariſtotle drowned himſelf out of chagrin, for not being able to account for ſo unuſual a motion. This ſtrait was ſo narrow overagainſt Chalcis as ſcarcely to admit a galley. It is now called the gulf of Negropont.

Euripus has ſince become a general name for all ſtraits, where the water is in great motion and agitation.

The ancient circuſes had their Euripi, which were no other than pits or ditches, on each ſide of the courſe, into which it was very dangerous falling with their horſes and chariots as they ran races. The term Euripus was more particularly applied by the Romans to three canals or ditches which encompaſſed the circus on three ſides, and which were filled occaſionally, to repreſent naumachiæ or ſea-battles.

The ſame people called their ſmaller fountains or canals in their gardens Euripuſes; and their largeſt, as caſcades, &c. *Niles.*

EUROCLYDON, of Ευρος, *eaſt-wind*, and κλυδων, *wave*, is a ſpecies of wind, of which we have an account only in Acts, xvii. 14 and concerning the nature of which critics have been much divided. Bochart, Grotius, Bentley, and others, ſubſtitute another reading, ſupported by the Alexandrian MS. and the Vulgate, *viz.* Ευρακυλων, or *Euroaquilo*; but Mr. Bryant defends the common reading, and conſiders the Euroclydon, *i. e.* Ευρος κλυζων, as an eaſt-wind that cauſes a deep ſea or vaſt inundation. He maintains, in oppoſition to Dr. Bentley's reaſoning, who ſuppoſes that the mariners in the ſhip, the voyage of which is recited in this paſſage, were Romans, that they were Greeks of Alexandria, and that the ſhip was an Alexandrine ſhip, employed in the traffic of carrying corn to Italy; and therefore, that the mariners had a name in their own language for the particular typhonic or ſtormy wind here mentioned. He alſo ſhews from the paſſage itſelf, that the tempeſtuous wind called Euroclydon, beat (κατ' αυτης) upon the iſland of Crete; and therefore, as this is a relative expreſſion, referring to the

the situation of the person who speaks of it, who was at that time to the windward, or south of it, the wind blew upon shore, and must have come from the south or south-east; which, he adds, is fully warranted from the point where the ship was, and the direction it ran in afterwards, which was towards the north and north-west. Bryant's Observations, &c. 1767, p. 1. &c.

EURO-Auster. } See Winds.
Euro-*Notus.* }

EUROMA, in *Ancient Geography*, a town of Asia, in Phœnicia.

EUROMUS, a town of Asia, in Caria; situated E. of mount Grius, N. of mount Latmus, and N.W. of the town of Mylasa. It had a theatre and a magnificent temple.

EVRON, in *Geography*, a town of France, in the department of the Mayenne, and chief-place of a canton, in the district of Laval; 15 miles E.N.E. of Laval. This place contains 4044 and the canton 13,213 inhabitants, on a territorial extent of 205 kiliometres and 11 communes. The fairs of this town are frequented.

EUROPA, in *Mythology*, daughter of Agenor, king of Phœnicia, by his wife Telaphassa, who was so beautiful, that, according to the fable, Jupiter is said to have fallen in love with her, and to have ordered Mercury to convey her to the sea-shore, where that god, having transformed himself into a bull, took her upon his back, and transported her into Crete. Some have explained this fable by alleging that a captain of Candia, named Taurus, carried off that princess, after he had taken the city of Tyre from Agenor; but others, with greater probability, assert, that some merchants of Crete, having arrived upon the coasts of Phœnicia, and seen the young Europa, were so much struck with her beauty, that they carried her off for their king Asterius; and as their ship bore upon the fore-castle a white bull, and that king of Crete had assumed the name of Jupiter, it was hence fabled that the god had transformed himself into a bull, in order to carry off the princess. Asterius is said to have married her, and to have had by her three sons; after which she is reported to have engaged the attachment and esteem of the Cretans to such a degree, that they worshipped her after her death as a divinity. They even instituted a feast in honour of her, which was called Hellotia. They afterwards gave her the surname of Minerva, and celebrated to her honour that festival which was consecrated to that goddess among the Cretans. Several authors have been of opinion that Europe took its name from this princess; but the learned Bochart believes that this part of the world was so denominated from the whiteness of its inhabitants. M. Gebelin, however, deduces the name of Europa from *Wrab*, signifying Occidental, and expressing its situation with regard to Asia.

Europa *rocks*, in *Geography*, rocks in the strait of Mozambique. S. lat. 21° 30′. E. long. 40° 16′.

EUROPE, one of the four grand divisions, or quarters, as they have been somewhat improperly called, of the terraqueous globe. Although Europe be less considerable in extent than Asia, or America, or even Africa, it claims on a variety of accounts our more particular attention. In modern times it has been the seat of literature and science; in this part of the globe every kind of cultivation and improvement has made the most rapid progress, and it has been distinguished, not only by the general temperature of its climate, the fertility of its soil, and the abundance of its productions for the supply of necessity and the gratification of luxury, but more especially for the wisdom, strength, and courage of its inhabitants, and for the excellence of its government, laws, and religion. The boundaries of Europe were very inaccurately ascertained by the ancient geographers, and the name itself seems to have originated in a small district near the Hellespont. More than a third part of Europe, towards the north and east, has only been known with precision in modern times. It lies chiefly in the temperate zone, north of Africa, and north-west of Asia, between 35° 25′ and 71° 23′ N. lat. and between 9° 40′ W. and 61° 5′ E. longitude. From the Portuguese cape, denominated by our mariners the rock of Lisbon, in the west, to the Uralian mountains in the east, the length may be about 3,300 British miles; and the breadth from Cape Nord in Danish Lapland to Cape Matapan, the southern extremity of Greece, may be about 2,350. The contents in square miles have been variously estimated, but at a medium may be stated at about $2\frac{1}{2}$ millions. On the south, Europe is bounded by the Mediterranean sea, on the west by the Atlantic, which contains the most remote European islands, the Azores and Iceland, Greenland being regarded as a part of North America. On the north the boundary is the Arctic ocean, comprehending the remote isles of Spitzbergen, and Novaya Zemlia, or the New Land. "Toward the east the limits, (says Mr. Pinkerton,) admit of some discussion: the Uralian mountains, a grand natural limit, not extending to the Arctic ocean, the river Cara, which flows into the sea of Karshoye, is admitted as a boundary. The Uralian limit extends to about 56° of N. latitude; to the south of which the grand confines of Europe and Asia have been sought in the petty distinctions of Russian governments. More natural limits might be obtained by tracing the river Ousa from its source, to its junction with the Belaia. Thence along the Kama to the Volga, which would constitute a striking natural division, to the town of Sarepta; whence a short ideal line, the only one admitted in this delineation, will lead due west to the river Don, which would complete the unascertained boundary; that on the north and west of the Euxine being clear and precise."

The ancient inhabitants of Europe consisted of Celts in the west and south; Fins in the north-east; and Laps or Laplanders, resembling the Samoieds of Asia in the farthest north, who enriched their rude language by adopting that of the more civilized Fins. The ancient inhabitants, who seem to have been thinly scattered, were driven towards the west and north by the Scythians or Goths from Asia, whose descendants occupy the greater part of Europe; by the Sarmatians or Slavonic tribes, also from Asia, the ancestors of the Russians, Poles, &c. and who were accompanied by the Heruli, using what is now called the Lettic speech, to be found in Prussia, Lithuania, Samogitia, Courland, and Livonia, somewhat akin to the Slavonic language, with various shades of distinction. The colony of Iberi, northern Mauretani, passed into Spain at a very early period; and the later accession of Hungarians and Turks from Asia may likewise be commemmorated. The present population of Europe is commonly estimated at 150,000,000; and though some writers have asserted that this quarter of the globe was anciently more populous than it is now, the opinion does not seem to be well founded. It will not readily be adopted by those who duly consider the number and magnitude of modern cities, towns, and villages; the abolition of feudal wars; the adoption of a mode of combat less destructive than that which formerly prevailed; the gradual extirpation of superstition, fanaticism, barbarity, and slavery; and the many extensive improvements made in agriculture, by eradicating forests, draining marshes, cultivating wastes, and opening canals of communication in the interior countries.

countries. It is generally allowed, that, notwithftanding the ravages of war, and emigrations to foreign parts, the population of moft European ftates has been, for fome time paft, increafing. The prevalence of the Chriftian religion throughout Europe, except in fome parts of Turkey, has been favourable to knowledge, induftry, and civilization; and it has contributed to conftitute the whole of Europe, as it were, into one republic, fo that any ufeful difcovery made in one ftate paffes rapidly to the reft. The mutual intercourfe between the different ftates of Europe is very much facilitated by its inland feas, as well as navigable rivers and canals. Of the inland feas the principal are the Mediterranean, the Baltic, and the White fea, which fee refpectively. Its other feas are the German, often ftyled the North fea, the Irifh fea, and various parts of the Atlantic. The gulfs and bays of Europe are very numerous, among which we may reckon the following, *viz.* the Bothnian and Finland gulfs; the Murray frith, and Frith of Forth, on the eaft coaft of Scotland; the bay of Bifcay, a large inlet of the Atlantic, on the eaft bounded by France, and on the fouth by Spain; the gulfs of the Mediterranean, *viz.* that of Lyons, S. of France; that of Genoa, between Corfica and the Genoefe republic; the gulf of Venice, between Italy and Greece; the gulf of Lepanto, N. of Morea; the Archipelago between Greece and Afia Minor; the fea of Marmara between Europe and Afia; and the fea of Azoph on the north coaft of the Euxine. The moft confiderable ftraits are that of Waygatz at the N. E. extremity of Europe; the found of Elfinore between the ifland of Zealand and Sweden; the Little Belt between Funen and Jutland; the Categat, or entrance into the Baltic; the ftrait of Dover, or Englifh channel, between England and France; the Briftol channel, between England and Wales; St. George's channel, between Great Britain and Ireland; Pentland frith, between Scotland and the Orkney Ifles; the ftrait of Gibraltar, between Spain and Africa; the ftrait of Meffina, between Italy and Sicily; the Dardanelles ftrait, or fouth entrance into the fea of Marmara; the ftrait of Conftantinople, that forms a communication between the fea of Marmara and the Euxine; and the ftrait of Caffa, between the Euxine and the fea of Azoph. The moft remarkable capes are North Cape, the extreme point of Lapland; Cape Finifterre, on the N. W. coaft of Spain; Cape St. Vincent, the S. W. extremity of Portugal; and Cape Matapan, the S. point of the Morea. Its principal lakes are thofe of Onega, Ladoga, and Peipus, in Ruffia; thofe of Geneva and Conftance, S. W. and N. of Switzerland; Lago Maggiore, and others, in the northern parts of Italy. The largeft rivers are the Volga, Don, and Dwina, in Ruffia; the Dnieper on the eaft border of Poland; the Danube, between Hungary and European Turkey; the Rhine and Elbe in Germany; the Rhone in France; the Po and Tyber in Italy; the Tago in Spain; the Scheldt and Meufe in the Netherlands; the Thames and Severn in England; the Tay in Scotland, the Shannon in Ireland, &c. &c. The principal chains of mountains are the Carpathian or Krapach mountains, between Poland and Hungary; the Alps, between France, Switzerland, and Italy; the Apennines, in Italy; the Pyrenées between France and Spain; and the extenfive ridge that feparates Norway from Sweden. The moft diftinguifhed iflands are Great Britain and Ireland, the Orkney Ifles, the Hebrides, Zealand, and Funen, in the Baltic; Iceland, in the North fea; and in the Mediterranean, Ivica, Majorca, Minorca, Sardinia, Corfica, Sicily, Malta, Candia, and the iflands of the Archipelago.

The principal European ftates are the Britifh empire, including England, Scotland, and Ireland; the ftates of Denmark, comprehending Denmark with the adjacent iflands, Norway and Iceland; Sweden; Ruffia, formerly called Mufcovy; Holland; France, including the Netherlands, Italian ftates, and other late acquifitions; Switzerland; Germany and Auftria; Pruffia; Bohemia and Hungary; Poland, now difmembered; Spain; Portugal; Sicily; Malta; and Turkey in Europe. See each under its appropriate title.

EUROPEAN Hours. See Hour.

European *Ocean*. See Ocean.

EUROPUS, in *Ancient Geography*, a town of Afia, in Parthia, founded, as Strabo fays, by Nicator, and called by the Parthians *Arfacia*.—Alfo, a town of Afia, in Syria, fituated on the banks of the Euphrates, E. of Hicropolis, and S. of Zeugma.—Alfo, a town of Afia, in Caria.—Alfo, a town of Macedonia.—Alfo, a river of Greece, in Theffaly, which rofe in mount Citarius, and flowed into the Peneus.

EUROTAS, a river of Laconia, which commenced on the frontiers of Arcadia, watered Sparta, and proceeding fouthward, difcharged itfelf into the Laconic gulf.—Alfo, a river of Greece, in Theffaly, near mount Olympus.—Alfo, a river of Italy, near Tarentum, the fame with the river Galefus, according to Polybius.

EURUS, in *Mythology*, the genius of the fouth-eaft wind, according to the Grecian divifion of the compafs into eight points; but according to the Roman divifion into four, Eurus was the intelligence that prefided over the whole eaftern quarter of the heavens. (See Wind.) "Eurus," fays Spence, "according to the Roman poets, feems to have his character compofed from the Apeliotes and Eurus of the Greeks: by one defcription of him he fhould have a look that feems delighted, and in another he is fpoken of as playful and wanton. He is fometimes defcribed as impetuous, and fometimes as difordered with the ftorm he has been driving along the fea. Horace gives us a picture of the former, and Valerius Flaccus of the latter. I fhould be apt to imagine, from fome expreffions in the poets, that he was fometimes reprefented on horfeback, or perhaps in a chariot, whirling through the air; but there are fo few remains of the ancient artifts relating to thefe airy beings, that we have nothing from them to confirm any fuch conjecture."

EURYA, in *Botany*, fuppofed to be from ευρυς, *broad* or *ample*, the application of which to this plant we do not, from any part of the defcription or figure, perceive. Thunb. Jap. 11. Schreb. 321. Willd. Sp. Pl. v. 2. 856. Mart. Mill. Dict. v. 2. Juff. 432. Clafs and order, *Dodecandria Monogynia*. Nat. Ord. uncertain, Juff.

Gen. Ch. *Cal.* Perianth inferior, of five ovate, concave, obtufe, fmall leaves, with two leffer ones at its bafe. *Cor.* Petals five, roundifh-ovate, concave, the fize of the calyx. Nectary a glandular ring round the bafe of the germen. *Stam.* Filaments thirteen, extremely fhort; anthers erect, fquare, almoft as long as the corolla. *Pift.* Germen fuperior, roundifh, fmooth; ftyle awl-fhaped, fhorter than the ftamens; ftigmas three, reflexed. *Peric.* Capfule globofe, tipped with the permanent ftyle, fmooth, of five valves and five cells, fcarcely fo big as a pepper-corn. *Seeds* feveral, obfcurely triangular, dotted, brown, deftitute of pubefcence.

Obf. Thunberg obferved the flowers to be moft frequently dioecious.

Eff. Ch. Calyx double; the inner of five equal leaves; the outer of two fmaller ones. Petals five. Capfule fuperior, of five cells and five valves. Seeds numerous.

E. *japonica.* Thunb. Jap. 191. t. 25. (Fisakaki; Kæmpf. Amœn. Exot. 778.) A Japanese shrub, common on the hills about Nagasaki, flowering in September and October, and cultivated in gardens for the sake of its elegance. It is smooth in every part. *Branches* slender, alternate, leafy. *Leaves* alternate, stalked, elliptic-lanceolate with a blunt point, serrated, compared by Kæmpfer to those of tea, evergreen, yellowish beneath, an inch or two long. *Flowers* axillary, in pairs, stalked, small, white or reddish. Thunberg describes the fruit as above; but Kæmpfer says "the *berries* resemble those of juniper, and are juicy, giving a stain like ultramarine, and containing from ten to twenty hardish brown seeds, crackling under the teeth." If Thunberg adverted to this description, he might perhaps deduce the generic name, though incorrectly, from ευ, *well*, and ρυας, *a flowing of juice*, or *a falling of berries*.

EURYALE, in *Mythology*, one of the Gorgons, daughter of Phorcys, and sister of Medusa: she was subject neither to old age nor death.

EURYAMPUS, in *Ancient Geography*, a town of Macedonia, in Magnesia.

EURYANDRA, in *Botany*, from ευρυς, *broad*, and ανηρ, *a male*, because the male organs, or stamens, are dilated at the summit. Forst. Gen. t. 41. Schreb. 367. Juss. 280. See TETRACERA; to which genus Schreber, in his emendanda, 833, and Willdenow, Sp. Pl. v. 2. 1242, have at the recommendation of Solander referred it.

EURYDICE, in *Mythology*, the wife of Orpheus, who, flying from Aristæus that endeavoured to ravish her, was slain by a serpent. Her husband went down to the shades, and by the force of his music persuaded Pluto and Proserpine to give him leave to carry back his wife; which they granted, provided he did not look on her till he came to the light; but he, breaking the condition, was forced to leave her behind him.

EURYMEDON, in *Ancient Geography*, *Zacuth*, a river of Asia, in ancient Pamphylia, which had its source in mount Taurus, passed the town of Aspenus, and discharged itself into the sea of Pamphylia.

EURYMENÆ, a town of Greece, in Thessaly.

EURYNOME, in *Mythology*, the mother of the three Graces.

EURYNOMIA, Ευρυνομεια, in *Antiquity*, an anniversary solemnity in honour of Eurynome, by some thought to be the same with Diana, by others one of Oceanus's daughters.

EURYPHON, the Cnidian physician, in *Biography*, was a contemporary of Hippocrates, but probably older in years, since he is deemed the author of the Cnidian aphorisms, which are quoted by Hippocrates. These two physicians are said by Soranus to have met in consultation in the presence of king Perdiccas. Euryphon is mentioned by Plato the comedian, as having produced many scars on the skin of Cinesias, the son of Evagoras, by the employment of actual cauteries for the cure of empyema, or pulmonary consumption; a practice which Hippocrates pursued. See Le Clerc Hist. de la Med.

EURYTHMIA, from ευ and ρυθμος, *order*, an old term in *Surgery*, signifying adroitness in handling instruments.

EURYTHMY, Ευρυθμια, in *Architecture*, *Painting*, and *Sculpture*, a certain majesty, elegance, and easiness, appearing in the composition of divers members or parts of a body, building, or painting, and resulting from the fine proportions thereof.

The word is Greek, and signifies literally a *consonance* or *fine agreement*, or, as we call it, a *harmony of all the parts*, being compounded of ευ, *well*, and ρυθμος, *rythmus*, *cadence*, or *agreement of numbers*, *sounds*, or the like things.

Vitruvius ranks eurythmia among the essential parts of architecture; he describes it as consisting in the beauty of the construction or assemblage of the several parts of the work, which renders its aspect or whole appearance graceful; *e. gr.* when the height corresponds to the breadth, and the breadth to the length, &c.

"From these three ideas or designs, *viz.* orthography, scenography, and profile, it is that eurythmy, *majestica*, and *venusta species edificii*, do result, which creates that agreeable harmony between the several dimensions, so as nothing seems disproportionate, too long for this, or too broad for that, but corresponds in a just and regular symmetry, and consent of all the parts with the whole." Evelyn's Account of Archit. &c.

EUSCOM, in *Geography*, a river of Canada, which runs into lake St. Clair. N. lat. 42° 45′. W. long. 82° 25′.

EUSDALE, or EYSDALE, a small island on the W. coast of Scotland, noted for its quarries of slate. N. lat. 56° 13′. W. long. 5° 48′.

EUSEBES, the name of a species of marble mentioned by Pliny: he has given us no description of it, but only tells us, that there was a seat made of it in the temple of Hercules at Tyre, from which the priests pretended that the gods used to arise.

EUSEBIANS, a denomination given to the sect of Arians, on account of the favour and countenance which Eusebius, bishop of Cæsarea, shewed and procured for them at their first rise; or rather from the protection afforded to Arius, and the adoption of his opinions by Eusebius bishop of Nicomedia. See ARIANS.

EUSEBIUS, pope, in *Biography*, a native of Greece, son of a physician, perhaps he himself at one period was a physician, succeeded Marcellus in the see of Rome. It is believed that he filled the pontificate but a very few months. He was a violent opponent to the re-admission of lapsed Christians to communion, and his conduct on this head created great dissensions at Rome, to put an end to which the emperor Maxentius banished him to Sicily. Moreri. Bower.

EUSEBIUS, surnamed *Pamphilus*, was born at Cæsarea in Palestine, of which he was afterwards bishop, about the year 270. Of his parents, and his instructors in early life, we have no account; nor is any thing recorded concerning his family. His talents and learning may, however, be justly appreciated by his numerous and valuable works. Having been ordained presbyter, probably, by Agapius, bishop of Cæsarea, he set up a school in that city, which produced many learned men, and whilst he was in this situation he formed an intimate acquaintance and friendship with Pamphilus, a learned presbyter of the same church, who is supposed to have afforded him much assistance in his studies. When Pamphilus was imprisoned in the year 307, Eusebius attended him to animate his fortitude and comfort him in his distress: and after the martyrdom of his friend in 309, he removed to Tyre, where he witnessed the firmness and patience with which many Christians endured the severity of persecution. From thence he went to Egypt, where the same scene was exhibited, and where he himself was imprisoned. As he did not suffer in common with others, some persons have insinuated, that he procured his liberty by sacrificing, or by some other mean compliance, unbecoming his Christian principles and profession. But Dr. Lardner has alleged several circumstances which evince this accusation to be altogether unfounded. At the close of the Dioclesian persecution, Eusebius returned to Palestine, and succeeded Agapius, according to the more general opinion, as bishop of Cæsarea in the year 315. It is certain, however, that he was bishop of Cæsarea in the year 320 at the latest. After this period he was present at most of the synods held in that part of the world; and on all occasions distinguished himself by recommending peace and mutual forbearance. At the famous council of Nice in 325, he was placed by command of Constantine on the right hand of the throne, and opened the meeting by a panegyrical address. At this council he seems to have been desirous of compromising the dispute between Arius, to whose sentiments he probably inclined, and the orthodox party; and with this view proposed a creed, which all the fathers allowed to be unexceptionable. Some of the most zealous partizans, however, suggested the propriety of introducing the word ὁμοουσιος, or *consubstantial*, as applicable to the Son; and the motion for this purpose was carried by a majority. Eusebius for some time demurred, alleging that the expression was unscriptural; but at length, being allowed to subscribe to the term in his own sense of it, he submitted; and the word became afterwards the test of orthodox belief, but very ineffectual for allaying the dissensions of the Christian church. In the year 330 Eusebius concurred with the council at Antioch in deposing Eustathius the bishop; but though the bishops and people concurred in electing him for this see, which was more honourable and profitable than that of Cæsarea, he peremptorily refused the acceptance of it. Although they applied to Constantine for the interposition of his authority, Eusebius wrote to the emperor, and obtained his permission to decline it, accompanied with encomiums on his moderation and disinterestedness, which he justly merited. At the council of Tyre in 335 he joined those bishops who condemned the proceedings of Athanasius, bishop of Alexandria; and he was deputed to attend the emperor, in order to justify the measures that had been adopted against that prelate. On occasion of this visit to Constantinople, he pronounced his panegyric on the emperor, and obtained singular marks of Constantine's condescension and favour. After his return to Cæsarea, the emperor kept up an epistolary correspondence with him, specimens of which are preserved in Eusebius's life of that prince. This work was written soon after the death of the emperor; nor did the bishop long survive, for he died in the year 339 or 340. Of the learning and application of Eusebius, his works afford ample evidence. "From his works it appears," says Tillemont, "that he had read all sorts of Greek authors, whether philosophers, historians, or divines, of Egypt, Phœnicia, Asia, Europe, and Africa." Eusebius had opportunities for conversing with the most learned men of his time, and he had access to the best libraries: so that from these different resources he was able to compile works of various kinds, in which he exercised a laudable caution with respect to his authorities and facts, and in which he also manifests a considerable degree of candour and impartiality. His works, however, as compositions, claim no very high commendation, as they are destitute of elegance and perspicuity. Upon the whole we may observe, that he was a good man as well as a learned scholar; zealously attached to religion, without bigotry; an enemy to ecclesiastical tyranny and discord, and always desirous of accommodating differences, and reconciling contending parties. Nevertheless Dr. Lardner mentions with disapprobation his concurrence with the Arian party in the harsh treatment given to Eustathius, bishop of Antioch, Athanasius of Alexandria, and Marcellus of Ancyra. As to his sentiments with regard to the doctrine, warmly controverted in his time, Dr. Jortin inclines to think, that he was neither an Arian nor an Athanasian, but that he endeavoured to steer a middle course, and yet inclining more to the Arians than to the Athanasians. Dr. Lardner, with his usual caution, observes, that this is a question which cannot be easily decided.

Of the works of Eusebius we can here enumerate only the principal, referring for an account of the rest to the writers cited at the close of this article. The first that deserves mention is the "Ecclesiastical History," in ten books, published in 326, and containing the history of the Christian church from the birth of Christ to his own times. The best edition is that of Valesius, published at Cambridge by Reading in three volumes folio. This contains Eusebius's "Life of Constantine," in four books, written in 337 or 338, and other ecclesiastical historians, Socrates, Theodoret, &c. In this history we have several passages concerning the canon of scripture; in which the author treats of the order of the gospels; of the scriptures universally acknowledged, and of those that are not such; of the epistles, &c. (See CANON.) Eusebius's "Chronicle" was a work of prodigious labour and learning; and is preserved only in a Latin version of Jerome. The "Evangelical Preparation," in 15 books, and ten books of the "Evangelical Demonstration," which originally comprehended 20 books, are still extant; and contain the most learned defence of Christianity against both Jews and Pagans, transmitted to us from antiquity. A beautiful edition of these valuable works was published in Greek, by Robert Stephens, in 1544 and 1545, in 2 vols. fol., and reprinted at Paris, in 1628, in 2 vols. fol., with a Latin version of the former, and various readings from different MSS. and notes by Francis Vigerius, and Donatus's Latin version of the latter. Eusebius was also the author of a "Commentary upon the 150 Psalms," published by Montfaucon in 1705, as far as the 119th psalm: "A Commentary upon the Prophecies of Isaiah," published likewise by Montfaucon: "An Exposition of the Song of Songs," published by Meursius in 1627; "A Treatise against Hierocles" who had made a comparison of Apollonius Tyanæus with Jesus Christ, still extant in the original Greek; "Two books against Marcellus," who revived the heresy of Sabellius, and "Three books of Ecclesiastical Theology," written in 336; "An Apology for Origen," in 6 books, the joint work of Eusebius and Pamphilus, now existing in a Latin version; "Ten Evangelical Canons," or rules for harmonizing the gospels; the "Topics," in two books, being a kind of dictionary of places mentioned in the Scriptures; "A description of the Church of the Sepulchre at Jerusalem, &c." composed in 335; "An Oration in praise of Constantine," which is as much an argument for the truth of the Christian religion, as a panegyric upon the emperor, and much commended by Du Pin and Lardner; the "Life of Constantine," in 4 books, already mentioned: "Fourteen small pieces in Latin," published by James Sirmond in 1643, 8vo. and many other treatises, that are no longer extant. Fabr. Bibl. Græc. v. vi. Cave's H. L. vol. i. Lardner's Works, vol. iv. Jortin's Rem. on E. H. vol. ii.

EUSEBIUS, first of all bishop of Berytus in Phœnicia, and afterwards of Nicomedia, in Bithynia, was advanced to the see of Constantinople in 338 or 339. He was a relation of the emperor Julian, who was educated by him, and probably also of Constantine: and as he was a man not only distinguished by his abilities and learning, but favoured with free access to the court, his influence on behalf of the Arian party,

party, to which he was attached, was always of great importance to their caufe. From the protection afforded to Arius and his followers by Eufebius they were frequently denominated "Eufebians." Although he remonftrated againft the proceedings of the court of Nice in 325, at which he was prefent, he fubfcribed the creed, probably with the fame explanation which was given by the bifhop of Cæfarea of the fame name. That this was the cafe we may infer from the patronage which he afforded to the Arians, and which caufed Conftantine to depofe him from his fee and to fend him into exile. He was afterwards, *viz.* in 328 or 329, recalled, and reftored to his fee, as well as to the favour of the emperor. Afterwards, when the Arian party became triumphant at the court of Conftantinople, he encouraged the perfecution of thofe who had been the perfecutors of Arius. Having maintained his credit and influence with Conftantine till his death, he gained in an equal, if not greater, degree, the confidence of his fon Conftantius; who promoted him, in 338, to the fee of Conftantinople. In this high ftation he was active in promoting the Arian interefts, and in perfecuting the Catholics. Soon after the council of Antioch, held in 341, probably in the fame or the fucceeding year, he terminated his career. Eufebius was eminent for his abilities and learning; and his friends have extolled his piety and virtue: but no fufficient apology can be offered for his intolerance. His writings were numerous, but none of them remain, except a "Letter concerning Arius and his Opinions," preferved by Theodoret. Fabr. Bibl. Græc. vol. vi. Cave's H. L. vol. i. Lardner's Works, vol. iv.

Eusebius, bifhop of Emefa, who flourifhed about the year 340, was defcended of a very honourable family, and born at Edeffa in Mefopotamia, at which place he enjoyed the benefit of a learned education, and of early inftruction in the facred fcriptures. He afterwards removed to Paleftine, where he ftudied under Patrophilus of Scythopolis, and Eufebius of Cæfarea. He likewife went to Antioch, and from thence to Alexandria, in which city he ftudied philofophy, and then returned to Antioch. Some time after that, having refufed the offer of the fee of Alexandria, from which Athanafius was depofed in 341, he was appointed bifhop of Emefa; where his diftinguifhed proficiency in literature and the fciences led the ignorant populace to charge him with the practice of magical arts. Under this accufation, he was obliged to retire to Laodicea, and to feek the protection of George, bifhop of that city, who was afterwards his biographer. When the prejudices of the mifguided people at Emefa fubfided, he returned thither, and here he fpent the greater part of the remainder of his life, which terminated at Antioch about the year 360. He is generally thought to have embraced the Arian tenets: though Cave thinks that he fhould be ranked among the Semi-Arians. However this be, his character was held in high eftimation for virtue and piety, as well as for learning and eloquence. Although he was great and good, as Sozomen fays, he experienced the envy of thofe who are offended at other men's virtues. The emperor Conftantius, however, was much pleafed with him, and his attendance was always required by that prince in his expeditions againft the Perfians. He wrote a great number of books, which were chiefly treatifes againft the Jews, againft the Novatians, and againft the Manichæans; 10 books upon the epiftle to the Galatians; and many fhort homilies upon the gofpels. His works are in general loft. His treatife againft the Jews is faid to be ftill extant in a Greek MS. in the library at Vienna. The homilies, that have been publifhed under his name at Paris in 1575, and at Antwerp in 1602, 8vo. are now allowed to be the productions of other writers. Socr. Hift. Eccl. l. iii. Cave's H. L. vol. i. Lardner's Works, vol. iv.

Eusebius, bifhop of Verceil, or Vercelli, in Italy, was born in Sardinia; and flourifhed about the year 354. In this year he was deputed by pope Liberius to plead the caufe of Athanafius, after his expulfion from Alexandria, before the emperor Conftantius; and in the council at Milan he was a zealous advocate for the depofed bifhop, and for the Nicene creed. The Arian party, however, prevailed, and a decree was paffed for condemning the conduct of Athanafius. Eufebius refifted, and for his unyielding fteadinefs he was banifhed to Scythopolis in Syria, afterwards to Cappadocia, and laft of all into the Upper Thebais. The caufe of orthodoxy, nothwithftanding all his fufferings, found him an undaunted and perfevering advocate. Upon the acceffion of Julian to the empire, he and other friends were allowed to return home; and during the remainder of his life he maintained his invincible attachment to the Catholic doctrine, and his zeal in promoting it. He died about the year 370, or foon after. Moft of his works have been loft: but it is faid that in the cathedral church at Verceil there is a MS., containing a Latin verfion of the four Gofpels, which is inferted in the "Evangeliarium Quadruplex Latinæ Verfionis Antiquæ, feu veteris Italicæ," publifhed by Jofeph Bianchini, at Rome, in 1749. Cave's H. L. vol. i. Lardner's Works, vol. iv. chap. 90.

Eusebius, bifhop of Dorylæum in Phrygia in the fifth century, was at firft an eminent advocate at Conftantinople, but embracing the ecclefiaftical life, he obtained the above-mentioned fee, and diftinguifhed himfelf by his oppofition to the Eutychians. Some few of his works remain, which are of a polemical nature, and not worth mentioning. Cave's Hift. Lit. vol. i.

EUSENE, in *Ancient Geography*, a town of Afia, in Paphlagonia. Ptolemy.

EUSHAR, in *Geography*, a town of Afiatic Turkey, in Natolia; 24 miles E. of Ifharteh.

EUSHEIM, a town of Germany, in the principality of Wurzburg; 3 miles N.W. of Volckach.

EUSIMARA, in *Ancient Geography*, a town of Afia, in Melitenè, a country of Cappadocia, feated on the bank of the Euphrates. Ptolemy.

EUSKIRCHEN, in *Geography*, a town of France, in the department of the Roer; 20 miles S.E. of Juliers.

EUSTACE, or Eustatia, an inconfiderable American ifland, about 20 miles in circuit, forming with a long point of land the entrance to the harbour of St. Auguftine, in Eaft Florida. It was alfo called Metanzas, or Slaughter, from a butchery made upon it by the Spaniards.

EUSTACHE, David, in *Biography*, a French proteftant minifter, at Montpellier, affifted at the national fynod held at London in 1659, as deputy of the province of Lower Languedoc, and was nominated by the affembly to prefent to the king the letter which they had addreffed to him. He performed the tafk much to the fatisfaction of thofe who had appointed him to the office. He was author of many theological pieces and fermons; the titles of fome of the former are "Salutary Remedies againft a Departure from God;" "The Triumph of Faith;" "An Anfwer to the Queftion afked of the Proteftants, where was your Church before Luther;" "The Orator Tertullus convicted;" which was a reply to the harangue fuppofed to be made by the wife men of the pretended reformed religion to the queen Maria Therefa, upon her entrance into the kingdom, in which they declared that being informed fhe had expreffed great concern that part of the king her hufband's fubjects were

were heretics, they came to leffen that concern by embracing her majefty's religion, and that this they did after having been fatisfied, by the teftimony of their moft famous authors; that one may be faved in the Romifh religion. Moreri. Bayle.

EUSTACHIAN Tube, in *Anatomy*, is the paffage by which air is conveyed from the fauces to the tympanum of the car, fo called from an Italian anatomift. See Ear.

Eustachian *valve*, is a part formed in the right auricle of the heart. See Heart.

EUSTACHIUS, Bartholomew, in *Biography*, one of the moft celebrated anatomifts of the fixteenth century, was a native of a little village in Italy, called San Severino. He purfued his ftudies at Rome, where he firft conceived a bias in favour of medicine, and efpecially of anatomy, which he cultivated with fuch fuccefs, that he was appointed to the profeffor's chair in that college. This is nearly the fum of our knowledge refpecting the life of this celebrated man: he died at Rome in 1574. Euftachius was the author of feveral works, the greater part of which is loft. His treatife "De Controverfiis Anatomicorum," which was one of the moft confiderable of his productions, is much regretted. Thofe of his writings, which remain, confift of his Opufcula, which appeared under the following titles, "Opufcula Anatomica, nempe de Renum ftructura, officio, et adminiftratione: de auditûs organo: offium examen: de motu capitis: de vena quæ azygos dicitur, et de alia, quæ in flexu brachii communem profundam producit: de dentibus." Venet. 1563, and again in 1674, with the notes of Pinus. An edition was alfo publifhed at Leyden, 1707, under the fuperintendance of Boerhaave.

Euftachius was the author of feveral difcoveries in anatomy; he was the firft who defcribed the renal capfules, and the thoracic duct; and his name, ftill attached to the paffage leading from the throat to the internal ear, (the Euftachian tube,) announces the origin of our knowledge on that fubject. A feries of figures engraved on copper were mentioned in his Opufcula as nearly finifhed; but they were loft for more than 150 years, and were difcovered, and publifhed at Rome in 1714, by Lancifi, phyfician to pope Clement XI. in one volume folio. Thefe plates were again publifhed, but not well printed, at Geneva in 1717. The edition of Rome in 1728 is excellent; but the one publifhed at the fame city, 1740, by Petrioli, is lefs valuable. The fame work was twice publifhed at Leyden, under the direction of Albinus, *viz.* in 1744 and 1762.

Euftachius edited the lexicon of Erotian at Venice in 1666, under the title of "Erotiani, Græci fcriptoris vetuftiffimi, vocum, quæ apud Hippocratem funt, collectio, cum annotationibus Euftachii," in 4to. Eloy. Dict. Hift.

EUSTATHIANS, in *Ecclefiaftical Hiftory*, a name given to the Catholics of Antioch in the fourth century, on occafion of their refufal to acknowledge any other bifhop befide St. Euftathius, bifhop of Sebafté in Armenia, depofed by the Arians.

The denomination was given them during the epifcopate of Paulinus, whom the Arians fubftituted for St. Euftathius, about the year 330, when they began to hold their affemblies apart About the year 350, Leontius of Phrygia, called the Eunuch, who was an Arian, and was put in the fee of Antioch, defired the Euftathians to perform their fervice in his church; which they accepted; and the church of Antioch ferved indifferently thus both for the Arians and Catholics.

This, we are told, gave occafion to two inftitutions, which have fubfifted in the church ever fince; the firft was pfalmody in two choirs; though Mr. Baillet thinks, that if they inftituted an alternate pfalmody between two choirs, it was between two Catholic choirs, and not by way of refponfe to an Arian choir. The fecond was the doxology, *Glory be to the Father, and the Son, and the Holy Ghoft.*

This conduct, which feemed to imply a kind of communion with the Arians, gave great offence to abundance of Catholics, who began to hold feparate meetings, and thus formed the fchifm of Antioch. Upon this the reft, who continued to meet in the church, ceafed to be called Euftathians; and that appellation became reftrained to the diffenting party.

St. Flavianus, bifhop of Antioch, in 381, and one of his fucceffors Alexander, in 482, brought to pafs a coalition or re-union between the Euftathians and the body of the church of Antioch, defcribed with much folemnity by Theodoret, Eccl. lib. iii. cap. 2.

Eustathians were alfo a fect of heretics in the fourth century, denominated from their founder Euftathius, a monk fo foolifhly fond of his own profeffion, that he condemned all other conditions of life. Whether this Euftathius was the fame with the bifhop of Sebafté and chief of the Semiarians, it is not eafy to determine.

He excluded married people from falvation; prohibited his followers from praying in their houfes, and obliged them to quit all they had as incompatible with the hopes of heaven.

He drew them out of the other affemblies of Chriftians to hold fecret ones with him, and made them wear a particular habit; he appointed them to faft on Sundays; and taught them that the ordinary fafts of the church were needlefs, after they had attained to a certain degree of purity which he pretended to. He fhewed great horror for chapels built in honour of martyrs, and the affemblies held therein.

Several women, feduced by his reafons, forfook their hufbands, and abundance of flaves deferted their mafters' houfes.

He was condemned at the council of Gangra, in Paphlagonia, held between the years 326 and 341. Socr. lib. ii. cap. 43 and Sozom. lib. iv. cap. 24. Hard. Concil. Coll. tom. i. p. 530.

EUSTATHIUS, in *Biography*, a faint in the Greek and Roman churches, and bifhop of Antioch, was tranflated to that fee from the bifhopric of Beræa, in Syria, about the year 323. He was a ftrenuous opponent of the Arian doctrine, and is faid to have been the firft ecclefiaftic of confequence who wrote againft it. He was diftinguifhed by his zeal at the council of Nice in 325, and by his exertions in carrying the decifions of that council into effect. This conduct fo much exafperated the Arian bifhops, that they got him accufed of adhering to the doctrine of Sabellius, rather than to that of the council of Nice. His enemies alfo fuborned an infamous woman to appear before the fynod of the Eaftern bifhops, to charge Euftathius with being father of a child which fhe held in her arms: other charges, equally difreputable, were made againft him: of thefe he was declared guilty, and depofed from his paftoral office. He was afterwards banifhed to Trajanopolis in Thrace, where he died. Of his numerous writings we have few remains, excepting the fragments collected by Fabricius. Jerome thought highly of his talents; Sozomen commends him for his piety and eloquence, and fays that his works were in high eftimation in his time. By Theodoret he is called the great Euftathius: but Socrates and others fpeak very flightingly of his talents, and Socrates fays he is one of thofe obfcure perfons who had endeavoured to raife his own reputation by oppoſing Origen. He is generally admitted to have been the author of "A Diſſertation concerning the Ventriloquiſt or Pythoneſs," mentioned in Samuel, firſt book, chap. xxvii. written againſt Origen on that ſubject. This was publiſhed by Allatius in Greek, with a Latin verſion, in 1629, and may be found in the 29th volume of the "Bibliotheca Patrum," and in the eighth volume of the "Critici Sacri." Fabr. Bib. Græc. vol. viii. Cave's H. L. vol. i. Lardner's Works, vol. iv.

EUSTATIA, or Eustatius, *St.*, in *Geography*, one of the leeward Caribbee iſlands; which is a huge pyramidal rock riſing out of the ſea, about 29 miles in compaſs; but for its ſize the Dutch, by their induſtry, rendered it one of the moſt valuable of the Caribbees. The ſides of the mountains are laid out in pretty ſettlements; but they have neither ſprings nor rivers. Sugar and tobacco have been the chief produce of this iſland, which the Dutch have cultivated even to the top of the pyramid, which terminates in a plain ſurrounded with woods, having a hollow in the middle that ſerves as a den for wild beaſts. This iſland has afforded ſubſiſtence for five thouſand white people, and fifteen thouſand negroes, who rear hogs, kids, rabbits, and all kinds of poultry in ſuch abundance, that they have been able to ſupply even their neighbours. It has but one landing place, which the original occupiers, finding difficult of acceſs, fortified, ſo as to render it almoſt impregnable. Such for many years was the policy of the Dutch in the government of this iſland, that they have been jealous of admitting any ſtrangers into their harbour, and kept them ignorant of its internal riches, whilſt it has ſerved as a ſtorehouſe for all European commodities. The property of it was firſt granted by the States-General to certain merchants of Fluſhing. It was firſt ſettled about the year 1600; but in the wars between the Engliſh and Dutch in 1665, the latter were diſpoſſeſſed of it by an armament from Jamaica. The Engliſh were afterwards diſpoſſeſſed by the combined forces of the Dutch and French; and the latter kept poſſeſſion of it till it was reſtored to the Dutch by the treaty of Breda. Soon after the revolution, the French ejected the Dutch from this iſland, whence they were again driven by the Engliſh under ſir Timothy Thornhill, who, with a view to the protection of the Dutch, left a ſmall Engliſh garriſon in the fort. The peace of Ryſwick reſtored the Dutch to the entire poſſeſſion of the iſland. In the year 1781 this iſland was obliged to ſurrender to the Engliſh under admiral Rodney, who confiſcated the private property of the inhabitants under a plea that they had aſſiſted France and the United States with naval and other ſtores. Before the cloſe of the year it was retaken by the French under the command of the marquis de Bouille; but reſtored to the Dutch at the peace in 1783. It is diſtant 9 miles N. W. from St. Chriſtopher's. N. lat. 17° 30′. W. long. 63° 8′.

Eustatia, is alſo the name of a town in the fore-mentioned iſland.

EUSTATIUS, in *Biography*, archbiſhop of Theſſalonica, flouriſhed in the 12th century, under the emperors Manuel, Alexius, and Andronicus Comnenus. He is celebrated for his great learning as a grammarian and critic, and is eſpecially known as a commentator on Homer and Dionyſius the geographer. His annotations on the former are copious, and abound in hiſtorical and philological deſcriptions: they were publiſhed at Rome in four volumes folio, between the years 1542 and 1550, and have been re-printed, particularly at Florence in 1730, with the notes and tranſlations of Politi and Salvini. The commentaries on Dionyſius were firſt printed in the Greek, by Robert Stephens in 1547, and have been ſeveral times re-printed. A Latin verſion of them was given by Politi in 1742, at Geneva, in two volumes octavo. Moreri.

EUSTEPHIA, in *Botany*, ευϛεφιος, *wearing a beautiful crown*, alluding to the coronet formed in the mouth of the flower, by the tranſverſe ſegments of the ſtamens. Cavan. Ic. v. 3. 20. Willd. Sp. Pl. v. 2. 48. Vent. Regn. Veg. v. 2. 282. Claſs and order, *Hexandria Monogynia.* Nat. Ord. *Spathaceæ*, Linn. *Narciſſi*, Juſſ.

Gen. Ch. *Cal.* Sheath oblong, divided to the baſe into four acute ſegments, withering. *Cor.* ſuperior, of one petal, tubular, regular, in ſix deep, linear, obtuſe, nearly equal ſegments, three of which are internal; without any appendage at the mouth. Nectary ſix little cavities in the baſe or tube of the corolla. *Stam.* Filaments ſix, inſerted into the bottom of the corolla, juſt above each nectariferous pore, linear, flat, ſomewhat longer than the corolla, and three-cleft juſt where they emerge from it, the middle ſegment longeſt, erect, ſlender, bearing the anther, the lateral ones ſhort, and horizontally divaricated, forming a crown in the mouth of the corolla; anthers incumbent, ovate. *Piſt.* Germen inferior, turbinate, triangular; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma ſwelling, undivided. *Peric.* as far as can be judged from the germen, a capſule of three cells. *Seeds* . . . .

Eſſ. Ch. Calyx a divided ſheath. Corolla ſuperior, regular, tubular, cylindrical, in ſix deep ſegments. Nectary ſix pores in the baſe of the corolla. Filaments with two lateral points.

1. E. *coccinea*, Cavan. Ic. t. 238. Flowered in the royal garden at Madrid in May 1794, but its native country is unknown. *Root* perennial, bulbous. *Leaves* radical, ſeveral, linear, obtuſe, ſomewhat falcated. *Stalk* ſolitary, above a foot high, ſtout, ſmooth, ſlightly compreſſed. *Flowers* four in a terminal umbel, drooping, ſcarlet, reſembling thoſe of *Cyrtanthus anguſtifolius*, but very diſtinct in their ſtructure. *Sheath* nearly as long as the partial flower-ſtalks and flowers together.

EUSTOCHIUM, or Eustochia, in *Biography*, a Roman lady in the 4th century, who is highly ſpoken of by St. Jerome, was a deſcendant from the families of the Scipios and Paulus Æmilius, and rendered herſelf celebrated for the proficiency which ſhe had made in literature. She was well acquainted with the Hebrew and Greek, as well as the Latin tongues, and converſant with the moſt important theological ſubjects. In the Catholic world her memory is cheriſhed on account of her early devotedneſs to a religious courſe. She profeſſed herſelf a diſciple of St. Jerome, whom ſhe followed from Rome to Cyprus, and thence to Antioch, Egypt, and numerous other places, and at length fixed her reſidence in a monaſtery at Bethlehem. Her mother Paula deſerted a young family to accompany her in theſe excurſions. Moreri.

EUSTRATIUS, a preſbyter of the church of Conſtantinople, flouriſhed about the year 578, and was author of "A Treatiſe concerning the Souls of the Dead," intended to prove that the ſouls of all men are active after their ſeparation from the body, and that they act differently according to the difference of their merits. He was author alſo of "The Life of the Patriarch Eutychius," which appears to have been a funeral oration pronounced by Euſtratius in the great church at Conſtantinople, a ſhort time after the death of the ſubject of it.

Eustratius, archbiſhop of Nice in the twelfth century, is mentioned by Anna Comnena, and other Latin writers, as a perſon of profound learning and ſkill, as well in civil as eccleſiaſtical affairs. He was author of "A Treatiſe againſt Chryſolanus concerning the proceſſion of the

Holy

Holy Spirit," and of other unpublished treatises. The only works of his which have been committed to the press are "Commentaries on the latter Analysis of Aristotle," published in Greek at Venice, in 1534: and "Commentaries on the Ethics of Aristotle," published likewise in Greek at the same place, 1536, and at Paris in Latin, 1543. Moreri.

EUSTYLE, formed of ευ, *bene*, *well*, and ϛυλος, *column*, in *Architecture*, a kind of edifice, where the columns are placed at a most convenient distance one from another, the intercolumniations being all just two diameters and a quarter of the column, except those in the middle of the fronts, before and behind, which are three diameters distant.

The eustyle is a medium between the pycnostyle, and arcostyle.

Vitruvius, lib. iii. cap. 2 observes, that the eustyle is the most approved of all the manners of intercolumniation, and that it surpasses all the rest in conveniency, beauty, and strength.

EUTACA, in *Geography*, a mountain of Egypt, near the Red sea; 12 miles S. of Suez.

EUTAM, a small island of the West Indies, near the east coast of Porto-Rico. N. lat. 18° 18'. W. long. 64° 41'.

EUTERPE, in *Botany*, ευτερπης, *pleasing or agreeable*. Gærtn. v. 1. 24. t. 9. Juss. 453. Supposed by Jussieu to be the same with his *Corypha Sabal*, see our CORYPHA, sp. 3, which Adanson likewise made a distinct genus. If it be so, Gærtner's classical appellation may well take place of the barbarous Sabal.

EUTERPE, of ευ, *well*, and τερπω, *I delight*, in *Mythology*, one of the nine Muses, which presided over wind-instruments: she is represented with a crown of flowers, playing on a double flute, with Cupid at her knees. Sometimes she has a mask in her left hand, and a club in her right. To her the invention of tragedy is ascribed.

EUTHIA, a term in the *Ancient Music*, which implies a succession of notes proceeding from grave to acute. Euthia was one of the parts of the ancient Melopœia.

EUTHYMIA, Ευθυμια, among the Greeks, signified such a disposition or state of the mind, as could not be ruffled either by good or bad fortune, by sickness or health, good or evil. Mem. Acad. Inscript. vol. xiv. p. 131.

EUTHYMIUS, in *Biography*, flourished in the tenth century, first as a monk, and afterwards, by his talents and virtues, he so far recommended himself to notice, that he obtained the appointment of "Syncelle," an office of high rank under the patriarch, and he was also chosen confessor by the emperor Leo VI. In 906 the patriarch Nicholas was deposed by the emperor, and Euthymius was elevated to it in his stead. Upon the death of Leo, his successor Alexander II. re-established Nicholas in the patriarchal chair, and sentenced Euthymius to banishment, a punishment which he bore with fortitude and patience till his death, in or about the year 920. Another patriarch of Constantinople, of the name of Euthymius, obtained that dignity in the year 1410, and enjoyed it till his death in 1416. Moreri.

EUTHYMIUS ZIGABENUS, was a monk of the order of St. Basil, who flourished at Constantinople about the beginning of the twelfth century. By his superior talents he acquired the patronage and esteem of the emperor Alexius Comnenus, at whose command he drew up his Panoplia, or defence of the orthodox faith against all heresies. It consists chiefly of passages selected from the writings of the ancient Greek fathers on different points, in which heretics have departed from the Catholic doctrine. Euthymius was also the author of "A Commentary upon the Psalms and Canticles," of which a Latin version was published by Saulius in 1530, and since that time more than once reprinted; "A Commentary on the four Evangelists," selected from the ancient fathers; "Commentaries on the Epistles of St. Paul;" "A Treatise against the Heresies of the Massalians, &c." Moreri.

EUTHYPOROS, from ευθυς, *straight*, and ποριζω, *to pass into*, among the old terms of *Surgery*, meant extension, made in a straight line, in order to reduce fractures, and dislocation.

EUTIN, in *Geography*, a town of Germany, in the bishopric of Lubeck, situated by the side of a lake, the usual residence of the prince bishop, the bishopric, like that of Osnaburg, being secular; 20 miles N. of Lubeck. N. lat. 54° 10'. E. long. 10° 32'.

EUTOCIUS, in *Biography*, a considerable mathematician, who lived at the time of the decline of the sciences in Greece, was a native of Ascalon, in Palestine, and a disciple of Isidorus, one of the celebrated architects employed by the emperor Justinian. He probably flourished about the commencement of the sixth century, though we have no particulars respecting his life; but his works reflect much honour on his memory. He wrote elaborate and perspicuous "Commentaries on the books of Archimedes concerning the Sphere and Cylinder;" and also on the first four books of the Conics of Apollonius Pergæus. These commentaries have not only elucidated many difficult passages in those profound writers, but have tended to throw light on the history of mathematics. There have been many editions of them, but the most magnificent was that in the edition of the works of Archimedes, printed at Oxford in folio, in the year 1792, which was prepared for the press by Torelli of Verona; and that in Dr. Halley's edition of the eight books of Apollonius, published at Oxford in 1710. Moreri. Montucla.

EUTROPIUS, a Latin historian of the fourth century, is supposed to have been a native of Acquitain. He bore arms under Julian, in his expedition against the Persians, and is said to have risen to the senatorian rank. He wrote several works, of which the only one remaining is an abridgment of the Roman history, in ten books, from the foundation of the city to the reign of the emperor Valens. This is a neat compendium, and has long since been received as a school-book. Moreri.

EUTROPIUS, the eunuch minister of the emperor Arcadius, who rose by base and infamous practices from the vilest condition to the highest pitch of opulence and power, was probably a native of Asia. In the year 395 he was made great-chamberlain to Arcadius, emperor of the East. After the fall of Rufinus, he succeeded that minister in the confidence of his master, and rose to unlimited authority. All persons of whatever rank humbled themselves before the favourite, who became the capricious disposer of honours and emoluments of every kind, and in 399 he, an eunuch, even assumed the dignity of consul, a disgrace to Rome never before equalled. Honours, if such they may be denominated, of every kind were accumulated upon him: the towns were filled with his statues, and he was entitled the third founder of Constantinople. His predominant passion was the love of money, and of course the most shameful venality directed all appointments to the high offices of the state. As a security to his person, a law of treason was passed, which extended the penalties of that crime to every attempt against the ministers and servants, as well as against the person of the emperor. Such a shield was not sufficient to defend him from the influence of court intrigue. An in-

sult

ſult which he offered to the empreſs cauſed her to implore the protection of her huſband, and at the ſame moment complaints were offered againſt him from other quarters, which induced the emperor to ſign his condemnation, and the fallen and juſtly execrated favourite was obliged to ſeek refuge in the ſanctuary of a church, from the pulpit of which Chryſoſtom pronounced an eloquent diſcourſe, pointing him out to the people as an example of the inſtability of human grandeur. He afterwards ſurrendered himſelf on promiſe that his life ſhould be ſpared, and was condemned to perpetual exile in Cyprus. Thither he was conveyed, but being haſtily brought back and tried on another charge, he was condemned and beheaded in the year 399. Gibbon.

EUTYCHIA, in *Ancient Geography*, an iſland of the Ægean ſea, before the Pagaſci gulf.

EUTYCHIANS, in *Eccleſiaſtical Hiſtory*, ancient heretics, who denied the duplicity of natures in Chriſt; thus denominated from Eutyches, the archimandrite, or abbot of a monaſtery at Conſtantinople, who began to propagate his opinion A. D. 448.

The averſion Eutyches bore to the hereſy of Neſtorius threw him into another extreme not leſs dangerous than that he ſo warmly oppoſed; though ſome paſſages in St. Cyril, which raiſed the unity of the perſon of Jeſus Chriſt very high, contributed likewiſe to his deluſion. At firſt he held that the *Logos*, *Word*, brought his body down with him from heaven; which was a near approach to the hereſy of Apollinarius; and, though he afterwards teſtified the contrary, in a ſynod at Conſtantinople, wherein he was condemned, yet he could not be brought to acknowledge that the body of Jeſus Chriſt was conſubſtantial with ours.

In effect, he did not ſeem quite ſteady and conſiſtent in his ſentiments; for he appeared to allow of two natures, even before the union; which was apparently a conſequence he drew from the principles of the Platonic philoſophy, which ſuppoſes a pre-exiſtence of ſouls; accordingly he believed that the ſoul of Jeſus Chriſt had been united to the divinity, before the incarnation; but then he allowed no diſtinction of natures in Jeſus Chriſt ſince his incarnation.

See the diſſertation of H. Hardouin, "De Sacramento Altaris;" wherein that Jeſuit endeavours to unfold all the ſentiments of the Eutychians.

This hereſy was firſt condemned in a ſynod held at Conſtantinople, by Flavian, in 448, approved by the council of Epheſus, called *Conventus latronum*, in 449, and re-examined and fulminated, in the general council of Chalcedon, in 451. The legates of pope Leo, who aſſiſted at it, maintained, that it was not enough to define, that there were two natures in Jeſus Chriſt, but inſiſted ſtrenuouſly, that, to remove all equivocations, they muſt add theſe terms, *without being changed, or confounded, or divided.*

The hereſy of the Eutychians, which made a very great progreſs throughout the Eaſt, at length became divided into ſeveral branches. Nicephorus makes mention of no fewer than twelve; ſome called *ſchematici*, or *apparentes*, as only attributing to Jeſus Chriſt, a phantom, or appearance of fleſh; and no real fleſh; others *Theodoſians*, from Theodoſius, biſhop of Alexandria; others *Jacobites*, from one James, *Jacobus*, of Syria; which branch eſtabliſhed itſelf principally in Armenia, where it ſtill ſubſiſts. Others were called *Acephali*, q. d. *without head*; and *Severians*, from a monk called Severus, who ſeized on the ſee of Antioch in 513.

Theſe laſt were ſubdivided into five factions, *viz.* *Agnoetæ*, who attributed ſome ignorance to Jeſus Chriſt; the followers of Paul; Μελαινοι, that is, the *black Angelites*, thus called from the place where they were aſſembled; laſtly, *Adrites*, and *Cononites*.

Eutychians was alſo the name of another ſect, half Arian, half Eunomian, which aroſe at Conſtantinople in the fourth century.

It being then a matter of mighty controverſy among the Eunomians at Conſtantinople, whether or no the Son of God knew the laſt day and hour of the world, particularly with regard to that paſſage in the Goſpel of St. Matthew, chap. xxiv. ver. 36. or, rather, that in St. Mark, xiii. 32. where it is expreſſed, that *the Son did not know it, but the Father only*; Eutychius made no ſcruple to maintain, even in writing, that the Son did not know it; which ſentiment diſpleaſing the leaders of the Eunomian party, he ſeparated from them, and made a journey to Eunomius, who was then in exile.

That heretic acquieſced fully in Eutychius's doctrine, and admitted him to his communion; Eunomius dying ſoon after, the chief of the Eunomians at Conſtantinople refuſed to admit Eutychius; who, upon this, formed a particular ſect of ſuch as adhered to him, called *Eutychians*.

This ſame Eutychius, and one Theophronius, as was ſaid in Sozomen's time, were the occaſions of all the changes made by the Eunomians in the adminiſtration of baptiſm; which conſiſted, according to Nicephorus, in only uſing one immerſion, and not doing it in the name of the Trinity, but in memory of the death of Jeſus Chriſt.

Nicephorus calls the chief of that ſect not Eutychius, but Eupſychius, and his followers Eunomioeupſychians.

EUTYCHIANUS, in *Biography*, biſhop of Rome, ſucceeded to that high office on the death of Felix, in the year 275, and preſided over the church about eight or nine years, when he died. Catholics have conſidered him as a martyr to the cauſe of truth; but hiſtorians, in general, infer, from the unmoleſted ſtate of Chriſtians, at that period, in Rome, that he died a natural death. There are two decretal epiſtles of this pope extant, relative to ſubjects of eccleſiaſtical diſcipline. Moreri. Bower.

EUTYCHIUS, patriarch of Conſtantinople, was born in the year 512. He was brought up to the eccleſiaſtical profeſſion, and obtained in early life the epiſcopal dignity in a town of Pontus, which he afterwards relinquiſhed, and entered into a monaſtery in the city of Amaſæa. In 552 he was deputed by the biſhop of that city to Conſtantinople, as his repreſentative, in the approaching general council that was to be held there. Before the meeting of the council, he obtained the favour of Juſtinian, who raiſed him to the patriarchate of Conſtantinople, which became vacant in the year 553, by the death of Mennas. Almoſt immediately after he had aſſumed the new character, he preſided at the council in which the opinions of Origen and his followers were condemned. Some years after, *viz.* in the year 564, Juſtinian endeavoured to obtain the patriarch's ſanction to a doctrine which he had adopted, *viz.* that the body of Jeſus Chriſt was rendered incorruptible before his reſurrection, by the union of the divine and human natures; but when Eutychius ſteadily refuſed to countenance the opinion, the emperor depoſed him from the patriarchate and ſent him into exile. In 578, he was reinſtated in the ſee of Conſtantinople, by the emperor Tiberius II. and he died in the year 585, at the age of 73. There is extant, in the fifth volume of the "Collectio Conciliorum," an epiſtle of his to pope Vigilius.

He was author of other pieces; of thefe a fragment of one only remains, "Concerning the Souls of the Dead." Moreri.

EUXINE SEA, called the *Black Sea*, as it is faid, either from its black rocks, or dangerous navigation, an inland fea, fituated partly in Europe, and partly in Afia; bounded on the north by the government of Caucafus and Ekatarinoflaf, on the eaft by Mingrelia and Georgia, on the fouth by Natolia, and on the weft by European Turkey. This fea is divided into the Euxine proper, the Pontus Euxinus, computed to be 1000 verfts in length, and 500 in breadth, and the fea of Azof, (fee AZOF) the Palus Mæotides of the ancients, which, without including the bay of Taganroh, is ftated to be 200 verfts long, and 160 verfts broad. Both thefe are now entirely within the confines of the Ruffian empire. The fea of Azof, called palus, or a marfh, by the ancients, becaufe it was polluted by mud, is united to the Euxine by the ftraits of Caffa, or the ancient Cimmerian Bofphorus. The moft important of the bays formed by thefe feas are the Liman, at the mouth of the Dnieper, the bay near Perekop, and that clofe to Yenikalé. The moft confiderable ifland belonging to thefe feas in the vicinity of the Ruffian coafts, is Taman. The principal harbours are Caffa, now Theodofia, Sebaftopol, Koflof, Balaklava, and fome others. At the weftern extremity of thefe feas, within the province of Taurida, is a very large pool, called Sivafh, or the Putrid fea, which is about 140 verfts long, and 54 broad. The chief rivers that fall into the Euxine, are the Kuban, or Hypanis of the ancients, the Don, or ancient Tanais, the Dnieper or Boryfthenes of ancient geographers, and the Bogur, which rifes in Poland, parting that kingdom, and a portion of European Turkey from Ruffia, and at Otchakof, falls into the Euxine. The Euxine fea was formerly denominated αξινος, or *inhofpitable*, on account of the barbarity of the inhabitants of its coafts; but when they became civilized by their commerce with the Greeks, the name was changed into ευξινος, i. e. *hofpitable*, or favourable to ftrangers.

EUZET, a town of France, in the department of the Gard; nine miles W. N. W. of Uzes.

EUZOIUS, in *Biography*, was in early life a deacon of the church of Alexandria, from which office he was expelled by Alexander, bifhop of that fee, at the fame time with Arius, on account of his efpoufing the principles of that celebrated character. They were both involved in the like condemnation at the council of Nice. About the year 355, he prefented a confeffion of faith to the emperor Conftantine, which met with the approbation of that fovereign, and which was the means of bringing him into confequence at the imperial court, when the orthodox party were thrown in the back ground. He was appointed to the fee of Antioch, and called upon to baptife the emperor Conftantius. His influence was now very confiderable, and to this the friends of Athanafius attribute much of the perfecution by which that bifhop was harraffed. Moreri.

EUZOIUS, bifhop of Cæfarea, was educated in that city at the fame time with Gregory Nazianzen. On the death of Acacius he obtained the bifhopric of Cæfarea, after maintaining a violent conteft with the different rival candidates. He was in principle an Arian, or nearly fo, and on that account was depofed from his fee under the reign of the emperor Theodofius, about the year 380. He was author of numerous treatifes now loft; poffeffed with much learning, and was very diligent in the difcharge of his epifcopal functions; but he is principally celebrated on account of his great exertions in promoting the interefts of fcience and literature. He manifefted much zeal in the reftoration and improvement of the library at Cæfarea, which had been originally collected by Origen and Pamphilus, and was at this period fallen into decay. To this object he devoted his time and labour, taking care that faithful tranfcripts fhould be procured of fuch books as were in a perifhing ftate, and increafing their numbers by new collections. Moreri.

EWAGE, *Ewagium*, in our *Old Writers*, the fame with *aquage*, which is toll paid for water-paffage. It is derived from the French *eau*, water.

EWALD, JOHN, in *Biography*, a Danifh poet, was born at Copenhagen in the year 1743. His father was a clergyman, and when he found his own end approaching he fent his fon for education to Slefwick, and died in a few hours after. Licht, the perfon to whofe care young Ewald was entrufted, treated him in every refpect as his own fon, and gave him free accefs to his library. The books moft agreeable to his tafte were romances, which he read with the greateft avidity. The adventures of Tom Jones and Robinfon Crufoe, particularly the latter, had made fuch an impreffion on his mind, and had excited his paffions fo ftrongly, that he eloped from Slefwick in his thirteenth year, in order to proceed to Holland, that he might undertake a voyage to Batavia, in the hope of being fhipwrecked and thrown on fome defert ifland. Scarcely had he travelled four miles, before he was overtaken by his preceptor and friend, who carried him back by force. At another time having read and heard of many romantic tales refpecting faints and martyrs, he was defirous of becoming a martyr for the caufe of Chriftianity. At length he refolved upon the profeffion of a foldier, which being oppofed by his friends, he left home, in company with his brother, and joined the Pruffian fervice, from this he deferted to the Auftrian army, in which he was firft a drummer, and then a ferjeant. A commiffion was offered him, provided he would embrace the Catholic religion, which he abfolutely refufed, and in a fhort time deferted again. On his return to Denmark he devoted himfelf to theology, and ftudied with fo much deligence as to be fit for examination in the courfe of a year. He had paid his addreffes to a lady, who, fufpecting him not to be in earneft, gave her hand to another: this fo affected Ewald as to produce a complete change in his difpofition, and to give his ideas a melancholy caft. He now abandoned himfelf to pleafure, and injured his conftitution. To give vent to the effufions of his mind, he wrote a piece, called "The Temple of Good Fortune," which proved the fource of all his future fame. It obtained the approbation of the fociety of Belles-lettres; and procured him the friendfhip of M. Carftens, a zealous votary of the mufes, which he enjoyed, without interruption, during the remainder of his life. On the death of Frederic V. in 1766, he compofed an elegy, which was received with univerfal approbation, and Ewald, intoxicated with the praifes beftowed upon his work, began to confider himfelf one of the greateft poets that Denmark had ever produced. The fociety of Belles-lettres propofed as the fubject of a prize the beft ode on any of the attributes of the deity, and Ewald, determined to try his fortune, made choice of the divine goodnefs, and had already formed his plan, when he learned that Benzon, one of his moft intimate friends, was employed on the fame fubject. Unwilling to enter the conteft with a friend he abandoned his fubject, and wrote his Adam and Eve, a fort of half drama, in one act, which poffeffed much merit, but without order or any regard to the laws of compofition. He hoped that this might obtain the prize, but was difappointed, and began to ftudy poetry, being now refolved to read; and not to write any more for two years. The works of Corneille and Klopſtock fell into his hands, and gave his taſte a new direction. His next work was "Rolfe Krage," a tragedy in the ſtyle of Oſſian, and "The ſongs of Skalden," which he wrote under the eye of Klopſtock, who had a very great and ſincere affection for him. During the time he was employed on this piece, he was attacked by a diſeaſe, under which he languiſhed for ten years. It proceeded from the gout, and was often attended with excruciating pain, yet his ſpirits and cheerfulneſs rarely forſook him, and he wrote in the intervals of his eaſe ſome ſmall theatrical pieces, which in part related to preſent times and manners, and which abounded with humour and the keeneſt ſatire. Ewald had obtained from the king a penſion of a hundred dollars, but this being inſufficient for his maintenance, he was obliged, by writing temporary poems, to gain a part of his livelihood, till the profits ariſing from the repreſentation of his theatrical pieces, and from the ſale of his works, ſhould place him beyond the fear of want. He died at Copenhagen in March 1781, in the thirty-eighth year of his age. In ſtrength of imagination, ſpirit and originality, Ewald ſurpaſſes all the other Daniſh poets. His excellent qualities gained him the affection of thoſe who knew him. He never proſtituted his muſe to improper purpoſes, and never, ſays his biographer, did an immoral or pernicious line flow from his pen. A complete edition of his works was publiſhed at Copenhagen between the year 1781—1791. Gen. Biog.

EWANICZOW, in *Geography*, a town of Poland, in the palatinate of Kaminiec; 64 miles N.N.W. of Kaminiec.

EWANO, a town of Poland, in Galicia; 36 miles S.E. of Halicz.

EWE, a ſmall iſland on the W. coaſt of Scotland, at the entrance of Loch Ewe. N. lat. 57° 53′. W. long. 5° 37′.

EWE, in *Rural Economy*, the female of the ſheep kind of animals. It is of very great importance in the forming of this ſort of ſtock to have good ewes. (See SHEEP.) It is the practice in ſome of the more northern diſtricts to have recourſe to the milking of the ewes in order to make cheeſe from it. But it is ſaid to have been lately found ſo injurious to the animals, and to be attended with ſo little profit, that it is, at preſent, much on the decline.

EWE-*Cheeſe*, is that ſort of cheeſe which is prepared from the milk of the ewe. It is a very ſtrong pungent kind of cheeſe, which is not well reliſhed by many. Some, however, conſider it as very rich and excellent, preferring it to the other ſorts of cheeſe. In ſome places theſe cheeſes are made of a conſiderable ſize, perhaps, nearly as large as thoſe of the Cheſhire dairies, one, two, or three hundred ewes being milked regularly for the purpoſe. See CHEESE.

EWELL, in *Geography*, is a market town in the hundred of Copthorne, and county of Surry, ſituated at the foot of Banſtead downs, diſtant S.E. by E. of London 13 miles. The weekly market is held on Thurſdays, and it has two annual fairs, one the 12th of May, the other the 29th of October. The number of houſes, according to the returns in 1801, is 194, and of inhabitants 1112. Here is the head of an extraordinary ſpring, which forms a curious natural jet d'eau, breaking out in ſeveral places. After watering Epſom-court meadows it flows in a fine ſtream called the Malden, and falls into the river Thames at Kingſton.

Near this town ſtood the magnificent palace, from its grandeur and ſplendid decorations, denominated "None-Such," erected by king Henry the Eighth. Charles the Second having conferred it upon his favourite miſtreſs, the infamous ducheſs of Cleveland, ſhe cauſed it to be taken down, and ſold the materials.

EWENNY, a river which has its ſource in the mountains to the north of Peterſton ſuper montem, and paſſing by Coychurch and Ewenny priory, joins the river Ogmore near Merthyr Mawr, below which it falls into the Briſtol channel. A phenomenon on this ſtream has given riſe to a geological error, which has generally been credited without proper inveſtigation, that the river makes a "dip under a mountain, appearing again near Nevern bridge, after a ſubterraneous paſſage of two miles." "Mr. Lethieuller obſerves, "that between Merthyr Mawr, near which alſo were deep ſands, and New-inn bridge, the river Ogmore, or rather a branch of it, runs a quarter of a mile under the hill, paſſing alſo under ſeveral natural bridges; after which, iſſuing out with great violence, it joins the main ſtream. The maps again here miſtake in giving this river the name of Ogmore before its junction with the Ewenny, after which only it aſſumes that name, being called before the Bridgend river, as it comes from Bridgend, where it runs under ground a a little to the north of that place, and appears again from under Ogmore hill." See Archæologia, vol. iv. p. 27. It occurs near the junction of the Ewenny with the river Ogmore. From the foot of a long ridge of down, where the hill makes a bold eſcarpement to the vale, iſſues a large body of water, exceeding the quantity previouſly flowing down the river, except after rains. In its paſſage from under the hill it is heard to boil and rage, and ruſhes out with foaming impetuoſity, as though it had met with violent interruption in its courſe; and forms two ſtreams, which immediately appear different in the velocity of their motions and quality of their contents; one being what is vulgarly called *hard*, and the other *ſoft* water. The ſtream to the ſouthward is ſought for culinary, and that to the northward for lavatory purpoſes. In trying it, Mr. Evans obſerves, "the water from the oppoſite ſides of the ſtream had a different effect upon the tongue and palate, and by a brief analyſis it was diſcovered, that the one contained a portion of calcareous matter in ſolution; and the other left but little reſidue, which was of an argillaceous nature." An attempt was then made to aſcertain whether the river might not enter ſome other part of the hill, and by a ſubterraneous paſſage here ſeek daylight again, as is reported of the Deveril in Wiltſhire, and the Mole in Surry. But after a fruitleſs ſearch the ſmalleſt veſtige of ſuch a ſubterraneous courſe could not be traced. The phenomenon therefore in queſtion appears to proceed from two powerful ſprings, riſing in the internal parts of the hill, the ſtreams of which having flowed ſeparately, here unite, but without intermingling their waters, till they join the Ewenny. Evans's Tour in South Wales.

EWENNY *Priory*, in *Antiquity*, was a monaſtery of the Benedictine order, founded by John Maurice de Lundres, Lord of Ogmore, A. D. 1140; and given as a cell to Glouceſter Abbey. Its revenues, as valued at the diſſolution, were 78*l.* 0*s.* 8*d.* It ſtands cloſe to the road leading from Newton to Pyle in Glamorganſhire, South Wales, in a marſhy plain, near the banks of the river Ewenny. It was ſurrounded by ſtrong embattled walls, having two gateways; and the one forming the principal entrance had two portculliſes: theſe, with parts of maſſive towers viſible among its ruins, indicate it was intended as a place of ſecurity, as well as religious retirement. The buildings appear to have been very extenſive, and ſome rooms, which formed the abbot's lodge yet remaining, are large and ſtately; particularly the great hall or refectory. But the abbey church, ſtill ſtanding, is a noble edifice, the ſimple and uniform architecture of which muſt be gratifying to every admirer of the arts. It is a maſſive building of a cruciform ſhape, conſiſt-

 ing

ing of a nave, two tranfepts, and a choir; in which heavy circular arches reft upon round bulky columns with fimple capitals: the windows alfo and door-ways have all the circular arch, which have induced fome to refer it to a Saxon period. The whole certainly denotes the earlieft Norman ftyle of architecture. The curious ftone vaulted groined roof of the choir claims particular attention; and the neglected effigies of the founder, bearing this infcription, "Ici gift Morice de Lundres le fundur, Deu li rende fun labur. Am." In the fouth tranfept lies another rude ftone figure of a knight in armour, which has generally been thought commemorative of Pain de Tuberville lord of Coity. But fir Richard Hoare has fhewn this ftatement, which originated with Camden, to be erroneous. After having the tomb cleaned, he was enabled to read the infcription thus,

"Sire Roger de Remi gift ici
Deu de fon alme eit merci am."

The perfon here named "De Remi," fir Richard fuppofes to have been fome friend, and follower of Morice de Lundres. The floor of the church has been paved with glazed porcelain tiles, ornamented with various devices, fuch as are feen in other buildings of a fimilar nature; but few now remain. The nave is at prefent ufed as the parifh church for divine worfhip, and the choir has a cemetery for diftinguifhed families in the vicinity: monuments for whom, particularly that of Carne, adorn its walls. It muft be matter of regret to thofe interefted in ancient buildings, to fee the prefent dilapidated ftate of this once noble ftructure: in many places rooflefs, the windows unglazed, the roof of the choir cracked, the fepulchral monuments broken, and thrown carelefsly about; and this noble fanctuary, which has ftood near feven hundred years, and exhibits the moft perfect fpecimen of early Norman architecture of any church in the kingdom, rapidly approaching to its diffolution. Evans's Tour in South Wales, and the Tranflation of Gyraldus's Itinerarium by fir Richard Colt Hoare.

EWER, in *Rural Economy*, a term fometimes provincially applied to the udder of the cow, or other animal. See UDDER.

EWES, or EUS, in *Geography*, a river of Scotland, which joins the Efk at Langholm, in Dumfries-fhire; and the valley through which it paffes is called Ewefdale.

EWRY, an office in the king's houfhold, where they take care of the linen for the king's table; lay the cloth, and ferve up water in filver ewers after dinner, whence the office takes its name.

EXACERBATION, in *Medicine*, fignifies the increafe or return of the fymptoms in thofe fevers of the remittent, intermittent, or even continued clafs, in which the febrile condition is renewed at regular periods, or becomes augmented. It is nearly fynonymous with *Paroxyfm*; but is more particularly reftricted to the periodical increafe of the remittent, or continued fevers, in which there is no abfolute ceffation of the febrile ftate. The evening exacerbation of hectic fever is a familiar example. Dr. Cullen afferts his belief, that there are commonly two exacerbations and remiffions both of hectic and of continued fever in the day; the one in the forenoon, the other in the evening: that of the morning, however, if it really occurs, is lefs diftinct, and many practitioners have been unable to detect it. See FEVER, and HECTIC.

EXACHORD. See HEXACHORD.

EXACHORDE, *Fr.* ESSACORDO, *Ital.*, an inftrument with fix ftrings, or a fyftem compofed of fix founds, fuch as the hexachord of Guido, which fee.

EXACTION, in *Law*, a wrong done by an officer, or one pretending to have authority: in taking a reward, or fee, for that in which the law allows not of any.

The difference between exaction and extortion, confifts in this; that extortion is, where the officer takes more than his due; and exaction, where he wrefts a fee, or reward, where none is due.

EXACTIS, in *Natural Hiftory*, a name given by Linkius, and fome other authors, to a fpecies of ftar-fifh, of the more branched kind, whofe rays are fix in number, when they firft part from the body, but very foon branch out into a great number more. See STAR-*fifh*.

EXACTOR REGIS, in *Law*, the king's exactor, or collector. Sometimes it is taken for the fheriff. But generally, "quicunque publicas pecunias, tributa, vectigalia & res fifco debitas exigit, proprie nominatur exactor regis."

EXACUM, in *Botany*, a name which Pliny fays has been given to the Leffer Centaury, becaufe it carries off all bad medicines by ftool, apparently from ἐξ, *out of*, and ἀκόω, *to drive*, or *force onward*. Linn. Gen. 57. Schreb. 77. Willd. Sp. Pl. v. 1. 634. Sm. Fl. Brit. 182. Mart. Mill. Dict. v. 2. Juff. 142 Gærtn. t. 114. Clafs and order, *Tetrandria Monogynia*. Nat. Ord. *Rotaceæ*, Linn. *Gentianæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, in four deep, ovate, flightly fpreading, permanent fegments. *Cor.* of one petal, permanent, falver-fhaped; tube inflated, the length of the calyx; limb in four deep, roundifh, fpreading lobes. *Stam.* Filaments four, thread-fhaped, inferted into the tube, not fo long as the limb; anthers roundifh. *Pift.* Germen fuperior, oval, filling the tube; ftyle thread-fhaped, rather oblique, the length of the ftamens; ftigma capitate. *Peric.* Capfule elliptical, as long as the calyx, compreffed, with a longitudinal furrow at each fide, of two cells, burfting at the top. *Seeds* numerous, fmall, roundifh, affixed to a central receptacle which forms the partition of the capfule.

Eff. Ch. Calyx in four fegments. Corolla falver-fhaped, with an inflated tube. Capfule fuperior, with two furrows, two cells, and many feeds, burfting at the top. Stigma capitate.

Obf. The flowers in fome fpecies are five-cleft, with a correfpondent number of ftamens.

Since this genus was founded by Linnæus on the examination of fome dried Eaft Indian fpecimens of his *E. feffile* and *pedunculatum*, Sp. Pl. 163, feveral fpecies have been added to it by different botanifts, either entire new difcoveries, or feparated from the old genus of *Gentiana*. Vahl has alfo referred hither the *Coutoubea* of Aublet, Guian. t. 27, 28, with unqueftionable propriety, though Juffieu and Schreber have kept it feparate, the latter by the name of *Picrium*, alluding to its bitternefs.

Our only Britifh fpecies is *E. filiforme*, Engl. Bot. t. 235, found in fpongy or fandy bogs, in Dorfetfhire, Devonfhire, and Cornwall, flowering in July. This is a fmall, flender, inconfpicuous annual, with a branched *ftem*; oppofite, feffile, lanceolate *leaves*; and fmall, terminal, folitary, yellow *flowers*, expanded only while the fun fhines bright upon them. It was the *Gentiana filiformis* of Linnæus and all following authors, till referred to *Exacum* in Engl. Bot.

E. *vifcofum*. Sm. Ic. Pict. t. 18. (Gentiana vifcofa; Ait. Hort. Kew. v. 1. 321.) has pentandrous five-cleft flowers. This is a handfome green-houfe plant, brought from the Canary iflands by Mr. Maffon. The *ftem* is fhrubby, three feet high, with oblong ribbed *leaves*, and large terminal panicles of yellow *flowers*.

The annual fpecies are fcarcely to be cultivated, no fuccefsful cessful method of raising them from seed in a garden having yet been discovered.

EXÆRESIS, from ἐξ, *out of*, and αἱρεῖν, *to remove*, in *Surgery*, was divided by the ancients into six branches, namely, synthesis, diæresis, exæresis, aphæresis, prosthesis, and diorthrosis. Exæresis implied all such methods and operations, as had for their object the removal of diseased, redundant, or extraneous substances from the body.

EXAGGERATION, in *Rhetoric*, a figure whereby we enlarge or heighten things; making them appear more than they really are, whether as to goodness, badness, or other qualities.

The word is formed of the Latin *exaggero*, *I exaggerate*; which is a compound of *ex* and *agger*, *a mound*, or *elevation of earth*. See Hyperbole.

Exaggeration, in *Painting*, is a method of representing things, wherein they are loaded too much, or marked too strongly; whether in respect of the design, or the colouring, or the position of the object.

Exaggerating differs from caricaturing, in that the latter perverts, or gives a turn to the features, &c. of a face which they had not; whereas the former only improves, or heightens what they had.

The latter is a kind of burlesque on the object, and is generally meant to ridicule: the former is usually an exalting or enlivening of the beauties of the object, beyond what nature allows. The painter is obliged to have recourse to an exaggeration of colours, both on account of the surface of his ground, the distance of his work, and of time, and the air, which diminish and weaken the force of the colours; but this exaggeration must be conducted in such a manner, as not to put the objects out of their natural characters. The term exaggeration is not now in use. See Style in *Painting*.

EXAGON. See Hexagon.

EXA'LMA, from ἐξάλλω, *to leap out*, in *Surgery*, a dislocation of the vertebræ, according to Hippocrates.

EXALTACION, in *Geography*, a town of South America, in the government of Moyes; 50 miles S. of Trinidad.

Exaltation *of the Cross*. See *Exaltation of the* Cross.

EXALTATION, Elevation, is chiefly used in a figurative sense, for the raising or advancing a person to some ecclesiastical dignity; and particularly to the papacy.

The term exaltation is, in some measure, appropriated to the pope; and expresses his inauguration, coronation, taking possession, and the beginning of his pontificate.

We shall here add, that the cross was delivered up by a treaty of peace made with Siroes, Chosroes' son. The institution of this treaty is commonly said to have been signalized by a miracle; in that Heraclius could not stir out of Jerusalem with the cross, while he had the imperial vestments on, enriched with gold, and precious stones; but bore it with ease, in a common dress.

But, long before the empire of Heraclius, there had been a feast of the same denomination observed both in the Greek and Latin churches, on occasion of what our Saviour said in St. John, xii. 32. "And I, if I be exalted, or lifted up, will draw all men unto me." And again, in ch. viii. ver. 28. "When ye have exalted, or lifted up, the Son of man, then shall ye know that I am he." F. Du Soulier assures us, that M. Chastelain was of opinion, this feast had been instituted, at least at Jerusalem, two hundred and forty years before Heraclius.

The feast of the dedication of the temple built by Constantine, was held, says Nicephorus, on the fourteenth of September, the day on which the temple had been consecrated, in the year 335; and this feast was also called the exaltation of the cross, because it was a ceremony therein, for the bishop of Jerusalem to ascend a high place, built by Constantine for that purpose, in manner of a pulpit, called by the Greeks, the "sacred mysteries of God," or, "the holiness of God," and there hoist up the cross, for all the people to see it.

Exaltation, in *Physics*, denotes the act, or operation, of elevating, purifying, subtilizing, or perfecting, any natural body, its principles and parts; also the quality, or disposition, which bodies acquire by such operation.

The term exaltation has been peculiarly affected by the ancient chemists and alchemists; who imagining it to have some extraordinary emphasis, are employing it on every occasion.

Exaltation, in *Astrology*, is a dignity which a planet acquires in certain signs, or parts of the zodiac; which dignity is supposed to give it an extraordinary virtue, efficacy, and influence. The opposite sign, or part of the zodiac, is called the dejection of the planet.

Thus, the 15th degree of Cancer is the exaltation of Jupiter, according to Albumazar, because it was the ascendant of that planet at the time of the creation; that of the sun is in the 19th degree of Aries; and its dejection in Libra; that of the moon is in Taurus, &c. Ptolemy gives the reason of this in his first book De Quadrup.

EXAMEN, or Examination, an exact and careful search, or inquiry, in order to discover the truth or falsehood of a thing.

EXAMILION, &c. See Hexamilion, &c.

EXAMINATION, Self, is a point much insisted on by divines, and particularly the ancient fathers, by way of preparation to repentance. St. Ignatius reduces it to five points; *viz.* 1. A returning of thanks to God for his benefits. 2. A begging of grace and light, to know and distinguish our sins. 3. A running over all our actions, occupations, thoughts, and words, in order to learn what has been offensive to God. 4. A begging of pardon, and conceiving a sincere sorrow for having displeased him. And, 5. Making a firm resolution not to offend him any more; and taking the necessary precautions to preserve ourselves from it.

Examination *of Bankrupt*, in *Law*. See Bankrupt.

Examination *of Prisoners*. See Commitment.

Examination, or Inspection, *Trial by*, is when, for the greater expedition of a cause, in some point or issue being either the principal question, or arising collaterally out of it, but being evidently the object of sense, the judges of the court, upon the testimony of their own senses, shall decide the point in dispute. Thus, in case of a suit to reverse a fine for non-age of the cognizor, or to set aside a statute or recognizance entered into by an infant; in this, and in similar cases, a writ shall issue to the sheriff (9 Rep. 31.), commanding him that he constrain the said party to appear, that it may be ascertained by the view of his body by the king's justices, whether he be of full age or not. If, however, the court, upon inspection, has any doubt of the age of the party, it may proceed to take proofs of the fact; and, particularly, may examine the infant himself upon an oath of *voir dire*, *veritatem dicere*, that is, to make true answer to such questions as the court shall demand of him; or the court may examine his mother, his godfather, or the like. (2 Roll. Abr. 573.) In like manner, if a defendant pleads in abatement of the suit that the plaintiff is *dead*, and one appears and calls himself the plaintiff, which the defendant denies; in this case the judges shall determine, by inſpection and examination, whether he be the plaintiff or not. (9 Rep. 30.) Alſo, if a man be found by a jury an idiot, *à nativitate*, he may come in perſon into the chancery before the chancellor, or be brought there by his friends, to be inſpected and examined, whether idiot or not; and if, upon ſuch view and inquiry, it appears he is not ſo, the verdict of the jury, and all the proceedings thereon, are utterly void and inſtantly of no effect. (Ibid. 31.) The trial by inſpection may be alſo uſed, upon an appeal of maihem, when the iſſue joined is whether it be maihem or no maihem, this ſhall be decided by the court upon inſpection, for which purpoſe they may call in the aſſiſtance of ſurgeons. (2 Roll. Abr. 578.) And by analogy to this, in an action of treſpaſs for maihem, the court (upon view of ſuch maihem as the plaintiff has laid in his declaration, or which is certified by the judges who tried the cauſe to be the ſame as was given in evidence to the jury) may increaſe the damages at their own diſcretion (1 Sid. 108); as may alſo be the caſe upon view of an atrocious battery. (Hardr. 408.) But then the battery muſt likewiſe be alleged ſo certainly in the declaration, that it may appear to be the ſame with the battery inſpected. Alſo, to aſcertain any circumſtances relative to a particular day paſt, it hath been tried by an inſpection of the almanac by the court. Thus, upon a writ of error from an inferior court, that of Lynn, the error aſſigned was that the judgment given was on a Sunday, it appearing to be on the 26th February, 26 Eliz. and upon inſpection of the almanacs of that year, it was found that the 26th of February in that year actually fell upon a Sunday: this was held to be a ſufficient trial, and that a trial by a jury was not neceſſary, although it was an error in fact, and ſo the judgment was reverſed. (Cro. Eliz. 227.) But, in all theſe caſes, the judges, if they conceive a doubt, may order it to be tried by a jury. Blackſt. Com. vol. iii.

Examination *of witneſſes*, in the trial by jury, derives peculiar advantage from its being conducted openly, *vivâ voce*, in the preſence of all mankind. This mode of examination is much more conducive to the clearing up of truth, than the private and ſecret examination taken down in writing before an officer or his clerk, in the eccleſiaſtical courts, and all others that have borrowed their practice from the civil law, where a witneſs may frequently depoſe that in private, which he will be aſhamed to teſtify in a public and ſolemn tribunal. Beſides, the occaſional queſtions of the judge, the jury, and the counſel, propounded to the witneſſes on a ſudden, will ſift out the truth much better than a formal ſet of interrogatories previouſly penned and ſettled; and the confronting of adverſe witneſſes is alſo another opportunity of obtaining a clear diſcovery, which can never be had upon any other method of trial. Nor is the preſence of the judge, during the examination, a matter of ſmall importance; for, beſides the reſpect and awe with which his preſence will naturally inſpire the witneſs, he is able by uſe and experience to keep the evidence from wandering from the point in iſſue. In ſhort, by this method of examination, and this only, the perſons who are to decide upon the evidence have an opportunity of obſerving the quality, age, education, underſtanding, behaviour, and inclination of the witneſs; in which points all perſons muſt appear alike, when their depoſitions are reduced to writing, and read to the judge, in the abſence of thoſe who made them; and yet as much may be frequently collected from the manner in which the evidence is delivered as from the matter of it. See Evidence.

Examination *of witneſſes* in Chancery is done with a view to the proof of facts that are diſputed, and their depoſitions are taken in writing, according to the manner of the civil law. For this purpoſe interrogatories are formed, or queſtions in writing; which, and which only, are to be propoſed to, and aſked of, the witneſſes in the cauſe. For the examination of witneſſes in or near London, there is an examiner's office appointed; but for ſuch as live in the country, a commiſſion is granted to four commiſſioners, two named on each ſide, or any three or two of them, to take the depoſitions there. And if the witneſſes reſide beyond ſeas, a commiſſion may be had to examine them there upon their own oaths, and (if foreigners) upon the oaths of ſkilful interpreters. And it hath been eſtabliſhed that the depoſition of an heathen who believes in the Supreme Being, taken by commiſſion in the moſt ſolemn manner according to the cuſtom of his own country, may be read in evidence. The commiſſioners are ſworn to take the examinations truly and without partiality, and not to divulge them till publiſhed in the court of chancery; and their clerks are alſo ſworn to ſecrecy. The witneſſes are compellable by proceſs of *ſubpœna*, as in the courts of common law, to appear and ſubmit to examination. And when their depoſitions are taken, they are tranſmitted to the court with the ſame care that the anſwer of a defendant is ſent. See Commission *to examine witneſſes*, and Interrogatories.

EXAMINERS, in *Chancery*, are two officers, whoſe buſineſs is to examine, on oath, the witneſſes produced on both ſides, upon ſuch interrogatories as the parties to the ſuit do exhibit for the purpoſe.

EXAMPLE, in *Rhetoric*, denotes an imperfect kind of induction or argumentation; whereby it is proved, that a thing which has happened on ſome other occaſion, will happen again, on the preſent one, from the ſimilitude of the caſes. That is uſually called an example, which is brought either to prove or illuſtrate ſome general aſſertion, as if one ſhould ſay, that "human bodies may be brought to ſuſtain the greateſt labours by uſe and exerciſe:" and in order to prove this ſhould relate what is ſaid of Milo of Croton, that "by the conſtant practice of carrying a calf ſeveral furlongs every day, he ſhould carry it as far after it was grown to its full ſize." (Eraſm. Chil. p. 193.) But the word example is uſed in oratory for any kind of ſimilitude; or, as Voſſius defines it (Orat. Partit. l. iii. c. 7. § 16.), "When one thing is inferred from another, by reaſon of the likeneſs which appears between them." Hence it is called an "imperfect induction," which infers ſomething from ſeveral others of a like nature. With regard to examples, we may obſerve, that thoſe have the greateſt force in reaſoning, which are taken from facts. See Induction.

EXANIA, from *ex*, *out of*, and *anus*, the complaint now more commonly named by practitioners in ſurgery prolapſus ani. See Prolapsus.

EXANNUAL Roll. In the old way of exhibiting ſheriff's accounts, the illeviable fines and deſperate debts were tranſcribed into a roll, under this name, which was yearly read, to ſee what might be gotten by it.

EXANTHEMA, in *Medicine*, ſynonymous with *efflo-reſcence*, from ἐξ, and ἄνθος, *a flower*, a term applied by the older writers nearly in the ſame ſenſe in which we now employ the word *eruption*, and comprehending every ſpecies of ſpot, diſcolouration, or elevation of the ſkin. The ſyſtematic noſologiſts at preſent underſtand by this word all eruptions on the ſkin, which are accompanied with fever; ſuch as the ſmall-pox, meaſles, ſcarlet fever, &c. Dr. Willan uſes the term in a more limited ſenſe, *viz.* to expreſs that appearance only which is in Engliſh denominated a *raſh*; which is a bluſh or "redneſs of the ſkin, varying as to extent, continuity, and brightneſs of colour, and occaſioned by an unufual quantity of blood diftributed to feveral of the cutaneous veins, in fome inftances with partial extravafation." The exanthemata conftitute the third order of Dr. Willan's claffification of cutaneous difeafes, including the meafles, fcarlet fever, nettle-rafh, rofeola, purpura, and erythema. See Cutaneous *difeafes*, and thefe words refpectively. See alfo Cullen Nofol. Method. clafs i. order iii. Willan on Cutan. Dif. ord. iii.

EXARCH, Ἔξαρχος, in *Antiquity*, an appellation given, by the emperors of the Eaft, to certain officers fent into Italy, in quality of vicars, or rather prefects, to defend that part of Italy which was yet under their obedience; particularly the city of Ravenna, againft the Lombards, who had made themfelves mafters of the greateft part of the reft.

The refidence of the exarch was at Ravenna; which city, with that of Rome, were all that was left to the emperors. The firft exarch was Longinus, who was fent in the year 568 by the emperor Juftin II. the fucceffor of Juftinian, to govern Italy in the room of Narfes. Longinus, being invefted with abfolute authority and power, fuppreffed the magiftrates, who had been previoufly appointed to govern the provinces of Italy; and he himfelf took the title of exarch, which by the Greeks was given to thofe who prefided over a diocefe, and confequently over the numerous provinces of which the diocefe was compofed. This title was adopted by the fucceffors of Longinus, who, refiding, as he had done, at Ravenna, were on that account called the exarchs of Ravenna. They governed all Italy, naming and removing the magiftrates, called dukes, at their pleafure; and to them the people had recourfe in all matters of confequence. Longinus was fent by Juftin to rule all Italy; but a great part of that country, in the firft year of his government, was feized on by the Lombards, who had been called in by Narfes. This magiftrate maintained the power and authority of the emperors of the Eaft in Italy for the fpace of 183 years, that is, from the year 568, when Longinus was fent into Italy, to the year 751, when Eutychius, the laft exarch, was expelled, and Ravenna taken by Aftulphus, or Aftolphus, king of the Lombards. See Lombards.

According to Gibbon (Decline and Fall of the Roman Empire, vol. vii.) Narfes was the firft and moft powerful of the exarchs, and adminiftered above fifteen years the kingdom of Italy. A duke was ftationed for the defence and military command of each of the principal cities of Italy; and the eye of Narfes pervaded the ample profpect from Calabria to the Alps. During a period of 200 years, fays the hiftorian, (vol. viii.) Italy was unequally divided between the kingdom of the Lombards and the exarchate of Ravenna; and 18 fucceffive exarchs were invefted, in the decline of the empire, with the full remains of civil, of military, and even of ecclefiaftical power. Their immediate jurifdiction, which was afterwards confecrated as the patrimony of St. Peter, extended over the modern Romagna, the marfhes or vallies of Ferrara and Commachio, five maritime cities from Rimini to Ancona, and a fecond, inland Pentapolis, between the Adriatic coaft and the hills of the Apennines. Three fubordinate provinces, of Rome, of Venice, and of Naples, which were feparated by hoftile lands from the palace of Ravenna, acknowledged, both in peace and war, the fupremacy of the exarch. The remainder of Italy was poffeffed by the Lombards. When Aftulphus, as we have already mentioned, had made himfelf mafter of the exarchate, he thought that he had a juft title to all the places depending on that domain, and confequently to the Roman dukedom and to Rome itfelf. He, therefore, required by a meffenger the inhabitants of that city to acknowledge him for their fovereign; and at the fame time began his march towards Rome. The pope, Stephen II., was alarmed, and attempted to divert Aftulphus from his declared purpofe of plundering Rome and maffacring the inhabitants, by a folemn embaffy; but the king, rejecting the prefents accompanying this embaffy, infifted upon being acknowledged by the pope and the Romans for their fovereign. The pope in this diftrefs applies to the emperor; but Conftantine was not in a condition to affift him. He then determined to recur to the protection of France, which had been transferred, fome years before, from the Merovingian to the Carlovingian line; and the celebrated Pepin, fon to Charles Martel, was then king. Indeed Pepin had previoufly promifed to pope Zachary, that he would protect his fee againft all its enemies, efpecially againft the Lombards. Pope Stephen vifited France in perfon; and having ftated the deplorable condition to which he was reduced by the Lombards, and implored his affiftance and protection, Pepin promifed to affift him againft the Lombards with the whole ftrength of his kingdom, and to drive them out of the exarchate and Pentapolis, which were to be reftored, as Pepin underftood, to the emperor, from whom the Lombards had taken them; but the pope, finding the king well-difpofed, took advantage of this favourable opportunity for aggrandizing himfelf; and, therefore, infinuated to Pepin, that he could not better acquit himfelf of his obligations to the apoftolic fee, confult the welfare of his foul, or reward him for the dangers he had undergone, and the pains he had taken for the fafety of Italy, and the church, than by granting both the exarchate and Pentapolis to St. Peter, that is, to himfelf. The pope, at the fame time, pretended that Conftantine had forfeited all right to thofe countries, by forfaking the protection of Italy, and perfecuting the church. Pepin not only put him in poffeffion of the exarchate and Pentapolis, if he fhould fucceed in expelling the Lombards, but confirmed his promife with an oath, in which his fons Charles and Carloman concurred. In confequence of this engagement Pepin marched with his army againft the Lombards, and having routed them, Aftulphus fled precipitately to Pavia. Pepin purfued him, and having befieged his capital, granted him peace on condition of his reftoring the places which he had feized in the Roman dukedom, together with the exarchate and Pentapolis, to the pope. Hoftages were alfo delivered in order to fecure the fulfilment of this condition. Aftulphus, regardlefs of his oath and hoftages, invaded the Roman dukedom, feized feveral cities, and befieged Rome itfelf. In this extremity, Stephen had again recourfe to his protector, who, highly incenfed at the treachery of Aftulphus, marched again into Italy, and clofely invefted Pavia, into which the Lombard king had retired. Aftulphus once more fued for peace, which was granted him upon his promifing to perform immediately the treaty made the year before, and, befides, to furrender to the pope the city of Commachio, which was then a place of great importance. Pepin then renewed his donation; and having caufed a new inftrument to be drawn up, he caufed it to be delivered, figned by himfelf, by his two fons, Charles and Carloman, and by the chief barons and prelates of France, into the pope's hands. He then left Italy, and returned with his army to France. The exarchate comprifed, according to Sigonius (ad ann. 756) the following cities, *viz.* Ravenna, Bologna, Imola, Faenza, Forlimpopoli, Forli, Cefena, Bobbio, Ferrara, Commachio, Adria, Servia, and Secchia, which were all delivered to the pope, except Faenza and Ferrara. Pentapolis, or Morca d'Ancona, comprehended Rimini, Pefaro, Pesaro, Conca, Fano, Sinigaglia, Ancona, Osimo, Umana, Jesi, Fossombrone, Monteferetro, Urbino, the Balnesian territory, Cagli, Luceoli, and Eugubio, with their territories and districts, as appears by the donation of Lewis the Pious, by which Pepin's donation was confirmed. The pope committed the government of the exarchate to the archbishop of Ravenna, who thereupon took the title of exarch, not as archbishop, but as an officer of the pope, now a temporal prince. Thus was the sceptre added to the keys, the sovereignty to the priesthood, and the popes were enriched with the spoils of the Lombard kings, and the Roman emperors. As those countries belonged, without doubt, to Constantine their emperor, some authors have thought that this donation was made in his name, and that this gave rise to the fable of the donation of Constantine the Great. Hence it appears that the popes by degrees became sovereigns of Rome. The exarchate of Ravenna, says Petrus de Marca, being yielded to the pope, the government of Rome, of course, devolved upon him; for the Roman dukedom had been always subject to the exarch. The pope, therefore, when he became master of the exarchate, claimed the administration, and continued to govern Rome, not as sovereign, but only with the authority that had been vested in the exarch, till the year 876, when the authority of the emperors, successors of Charlemagne, declining in Italy, Charles the Bald yielded all his claim to, and sovereignty over Rome, to the apostolic see. Hence Constantine Porphyrogenitus, describing the state of Europe in his time, that is, about the year 914, writes, that Rome was subject to the pope, as its sovereign. It was upon the declension of the western empire, when it was confined to Germany alone, that the pope, as well as the several princes of Italy, assumed the sovereignty, which they afterwards enjoyed. The donation of Pepin was confirmed by Charlemagne at the request of pope Adrian; for having ordered Iterius, his secretary, to draw up a new instrument, he signed it himself, caused it to be signed by the abbots, bishops, and other great men, who had attended him to Rome, and, with his own hand, laid it on the altar of St. Peter.

F. Papebroch, in his Propylæum ad Acta Sanct. Maii, has a dissertation on the power and office of the exarch of Italy, in the election and ordination of the pope.

The emperor Frederic created Heraclius, archbishop of Lions, a descendant of the illustrious house of Montboissier, exarch of the whole kingdom of Burgundy; a dignity, till that time, unknown any where but in Italy, particularly in the city of Ravenna. Menestrier. Hist. de Lyons.

Homer, Philo, and other ancient authors, give likewise the name exarchus to the choragus, or master of the singers, in the ancient choruses, or him who sung first; the word αρχω, or αρχομαι, signifying equally *to begin*, and *to command*.

EXARCH *of a diocese*, was anciently the same with primate. This dignity was inferior to the patriarchal, yet greater than the metropolitan.

EXARCH also denotes an officer still subsisting in the Greek church; being a kind of deputy or legate *a latere* of the patriarch, whose office it is to visit the provinces allotted him, in order to inform himself of the lives and manners of the clergy; take cognizance of ecclesiastical causes; the manner of celebrating divine service; the administration of the sacraments, particularly confession; the observance of the canons; monastic discipline; affairs of marriages, divorces, &c. but, above all, to take an account of the several revenues which the patriarch receives from several churches; and particularly as to what regards the collecting of the same.

The exarch, after having greatly enriched himself in his post, frequently rises to the patriarchate itself.

EXARCH is also used, in the *Eastern Church Antiquity*, for a general, or superior over several monasteries; the same that we otherwise call archimandrite: being exempted, by the patriarch of Constantinople, from the jurisdiction of the bishops; as are now the generals of the Romish monastic orders.

In 493, Sebas was established exarch, or chief, of all the anchorets within the territory of Jerusalem. Du Bois.

EXA'RMA, from εξαιρομαι, *to be elevated*, in *Surgery*, a high, prominent, swelling.

EXARTHRE'MA, from εξ, *out of*, and αρθρον, *a joint*, an old term, having the same signification as the word dislocation. See LUXATION.

EXA'RTHROS, from εξ, *out of*, and αρθρον, *a joint*, a term denoting a person whose joints are so large and mis-shapen, that they look as if they were luxated.

EXARTICULATION, a dislocation of some of the jointed bones; or a breach of articulation. See LUXATION.

EXAUCTORATIO, among the Romans, differed from *missio*, or a discharge. In the latter, the soldiers were quite dismissed from the service; and this was done after they had served twenty years: but in the former case, they only lost their pay, being still kept under their colours or *vexilla*, though not under the eagle, *aquila*, which was the standard of the legion. Whence, instead of *legionarii*, they were called *subsignani*, and were still retained till they had either served out their time, or had lands assigned them. The exauctoratio commonly took place after they had served seventeen years.

EXAUDET, in *Biography*, a performer on the violin in the opera band at Paris from 1749 to 1760; remarkable for nothing as a composer, but for the minuet which bears his name in France, and which in England is better known by the title of "Marshal Saxe's Minuet," the best "Minuetto per ballo," or for dancing, perhaps, that ever was composed.

EXCALCEATION, *ex*, *off*, and *calceus*, *shoe*, *discalceation*, or the act of putting off the shoes.

Among the Hebrews there was a particular law, whereby a widow, whom her husband's brother refused to marry, had a right to summon him into a court of justice; and, upon his refusal, might excalceate him, *i. e.* pull off one of his shoes, and spit in his face; which were both actions of great ignominy among that people.

The house of the person who had undergone them was thenceforward called the house of the excalceated.

EXALCED, EXCALCEATI, different orders of friars, hermits, and nuns, who amongst their other austerities went barefooted, or wore nothing on their feet but sandals, were distinguished by the name of excalced, as the Franciscans, Carmelites, Poor Clares, &c. whilst other branches of the same institute, but less rigid, were called calced, from their members wearing shoes. A particular branch of the Waldenses, Vaudois, or poor men of Lyons, in the 12th century, laid great stress on the wearing of sabots or wooden clogs instead of shoes, and therefore obtained the name of Sabatati and Insabatati.

EXCAMBIATOR. See EXCAMBIO, and EXCHANGE.

EXCAVATION, formed of *ex*, and *cavus*, *hollow*, or *cave*, a *pit*, &c. the act of hollowing or digging a cavity, particularly in the ground.

The excavation of the foundations of a building, by the Italians

Italians called *cavatione*, is ſettled by Palladio at a ſixth part of the height of the whole building: unleſs there be cellars underground, in which caſe he would have it ſomewhat more.

Excavation *of Vallies*, in *Geology*, is a ſubject which has exerciſed the thoughts of many ingenious men, the greater part of whom have ſuppoſed that theſe ſtupendous and important operations were effected by violent currents of water, which at ſome period made their way down them: but a more careful examination has ſhewn, that in ſcarcely any inſtances are the excavated materials to be found, or any part of them, as muſt inevitably have happened at the bends and junctions of vallies, particularly thoſe which lie far inland, had the mere waſhing of water been the cauſe of vallies: but Mr. Farey, and Dr. William Richardſon, have of late, and ſeparately as it ſhould ſeem, come to the concluſion (Philoſophical Magazine, vol. xxxiii. p. 204 and 262.) that theſe excavations were effected by cauſes acting "from above the ſurface of the earth," which completely carried off the matter which once filled up the vallies, and originally joined thoſe correſponding parts of ſtrata, whoſe edges are now in a great number of inſtances to be traced in their oppoſite ſides: theſe opinions of the former gentlemen have been already ſlightly noticed, and referred to, in our articles Coal, Colliery, and others.

EXCELLENCY, a quality, or title of honour given to ambaſſadors, and other perſons, who are not qualified for that of highneſs, as not being princes; and yet are to be elevated above the other inferior dignities.

In England, and France, the title is now peculiar to ambaſſadors: but it is very common in Germany and Italy. Thoſe to whom it was firſt appropriated were the princes of the blood of the ſeveral royal houſes; but they quitted it for that of highneſs, upon ſeveral great lords aſſuming excellency.

The ambaſſadors have only borne it ſince the year 1593, when Henry IV. of France ſent the duke de Nevers ambaſſador to the pope, when he was firſt complimented with excellency. After that, the ſame appellation was given to all the other ambaſſadors reſiding at that court; from whence the practice ſpread through the other courts.

The ambaſſadors of Venice have only had it ſince the year 1636, when the emperor and king of Spain conſented to allow it them.

The ambaſſadors of the crowned heads diſpute the giving of that title to the ambaſſadors from the princes of Italy; where the practice is not eſtabliſhed.

The court of Rome never allowed the quality of excellency to any ambaſſador who was a churchman, as judging it a ſecular title. The common rules and meaſures of excellency were a little variable, with reſpect to the court of Rome. The ambaſſadors of France, at Rome, anciently gave the title of excellency to all the relations of the pope then reigning; to the Conſtable Colonna; to the duke of Bracciano, and the eldeſt ſons of all thoſe lords; as alſo the dukes of Savelli, Ceſarini, &c. But they have been ſince more reſerved in this reſpect; though they ſtill honoured all the Roman princeſſes with excellency.

The court of Rome, in their turn, and the Roman princes, beſtowed the ſame title on the chancellor, miniſters, and ſecretaries of ſtate, and preſidents of the ſovereign courts of France; the preſidents of the councils in Spain; the chancellor of Poland; and thoſe of the firſt dignities of other ſtates, if they were not eccleſiaſtics.

The word excellency was, anciently, a title of kings and emperors; accordingly Anaſtaſius the library-keeper calls Charlemagne his excellency. The ſame title is ſtill given to the ſenate of Venice: where, after ſaluting the doge under the title of *ſereniſſimo*, the ſenators are addreſſed under thoſe of your *excellencies*. The Liber Diurnis Pontif. Rom. gives the title excellency to the exarch and patricians.

The Italian and French have improved on ſimple excellency; and made *excellentiſſimo*, and *excellentiſſime*, which have been beſtowed on certain popes, kings, &c.

EXCELSIS. See Gloria *in excelſis*.

EXCENTRIC, in *Geometry*, is applied where two circles, or ſpheres, though contained, in ſome meaſure, within each other, yet have not the ſame centre; and, conſequently, are not parallel; in oppoſition to concentric, where they are parallel, having one and the ſame common centre. The ſun's orbit is excentric, with regard to the globe of our earth: Mars is very excentric, with regard to the ſun; that is, his motion is about a very different centre.

Excentric *Theory*, in *Ancient Aſtronomy*, one of the theories adopted by the ancient aſtronomers to explain and calculate the different irregularities which they had obſerved to take place in the motions of the heavenly bodies.

It is not exactly aſcertained at what period practical aſtronomy had attained ſufficient perfection to indicate the neceſſity of ſuch a theory. Probably both the Indian and Egyptian aſtronomers were early acquainted with the more obvious inequality in the ſun's orbit; but Hipparchus is the firſt aſtronomical writer who ſeems to have aimed at determining it with any degree of preciſion.

The theory embraced by Hipparchus is ſaid to have been firſt taught in Greece by the diſciples of Pythagoras. Though their knowledge on the ſubject is ſuppoſed to have been derived from the oriental nations, yet it is highly probable they contributed to ſtrengthen the prejudices in favour of circular and uniform motion, which afterwards proved the ſource of ſo much difficulty and error in all the ſyſtems of ancient aſtronomy. It was from this prejudice, early aſſumed as a principle, that nature could not, conſiſtently with the obſerved ſimplicity of her deſigns, adopt any other form for the celeſtial orbits than that of perfect circles, nor any other motion than what was perfectly uniform. The problem, therefore, that occupied the aſtronomers and philoſophers of thoſe days, was to explain the various irregularities which they obſerved in the planetary motions, without infringing on the above principle.

There were two theories choſen for this purpoſe, nearly equivalent in their principle, the concentric and the excentric.

In the concentric theory the earth was ſuppoſed to be placed in the centre of a circle, on the circumference of which the centre of another circle revolved, and on the circumference of this ſecond circle, called an epicycle, the planet was ſuppoſed to move. The firſt circle was called the *deferent*, and by aſſigning a ſuitable ratio to the deferent circle, and to its correſponding epicycle, ſome of the more obvious irregularities were pretty accurately repreſented. *Fig.* 110. *Plate* XIII. *Aſtronomy*, is the repreſentation of the concentric theory. Let C be the centre both of the earth and of the circle F B D, and let H G K be a ſmaller circle, or epicycle, whoſe centre B moves uniformly in the circumference F B D, from weſt to eaſt, or *in conſequentia*, while the ſun moves alſo uniformly and with the ſame velocity in the circumference of the epicycle, *in antecedentia* in the upper part, but *in conſequentia* in the lower part. If the point G of the epicycle, called its apogee, as being moſt diſtant from the earth, be ſuppoſed at the beginning of the anomaliſtic revolution to be placed in the point A of C F produced; and if when it comes to G, the arc G H be taken ſimilar to F B, the point H will be be the place of the ſun when the centre of the epicycle has moved from F to B. If then in C F, to which B H is parallel, we take C E = B H, and on E as a centre, with the diſtance E A = C F, deſcribe the circle A H P, the ſun would be ſeen from E to move in this circle equably; for the angle A E H is equal to the angle F C B; but ſeen from C, the centre of the earth, it will appear to move in it inequably; for the angle A C H, in the firſt circle of anomaly, that is, in the paſſage of the ſun from A to P, is always leſs than A E H or F C B; and its true place H will be leſs advanced in longitude than its mean place B. When again the centre of the epicycle or the mean place of the ſun, having deſcribed a ſemicircle, ſhall have come to D, the ſun, having deſcribed a ſemicircle of the epicycle, will be found in P, the perigee of the orbit A H P, and its mean and true places B and H will be ſeen from C to coincide as they did in the apogee A. But in the ſun's paſſage from P to A, that is, in the ſecond ſemicircle of anomaly, his true place H, as ſeen from C, will be always more advanced in longitude than his mean place B: for in this ſemicircle the angle P C H is always greater than P E H or D C B. The angle E H C or B C H, which is the difference between the mean and true places of the ſun, is called the equation of the orbit, and it is evident that this equation will be greateſt in N or M, where the centre B of the epicycle is 90° diſtant from either of the apſides.

It was thus that the ancients originally proceeded in their repreſentation of the ſolar inequalities, and the repreſentation ſeemed to be ſufficiently juſtified by obſervation: at leaſt, till the days of T. Brahé, no obſervations had been made with ſufficient accuracy to ſubject it to ſuſpicion. Their ſucceſs alſo, while no lunar inequality except the ſimple anomaliſtical one was diſcovered, was equal in the application of the ſame concentric theory to the motions of the moon: and having, in two caſes, thus ſucceſsfully, by means of one ſubordinate ſphere or epicycle, reconciled apparent inequality of motion with real uniformity, it was natural to ſuppoſe that other inequalities, though more various and complicated, might be explained in a ſimilar manner, and required only the addition of other epicycles. The ſame method of procedure, therefore, was continued, and every new inequality which obſervation diſcovered, was accounted for by a new ſphere or epicycle producing it, till the whole number employed in the ſyſtem amounted to 34. Ariſtotle, on narrower examination, found theſe inſufficient, and added to them 22: but ſtill they were deemed inſufficient; and the number was at laſt increaſed to 72. But though it was not till long after the days of Ariſtotle, that the theory was carried to ſuch a degree of extravagance, the multiplication of epicycles rendered it, even in his time, almoſt as intricate and complex as the appearances which it was intended to explain. Some examples of this kind will occur on the revival of it by Copernicus and T. Brahé: and when Hipparchus and Ptolemy introduced excentric orbits, and by means of them ſomewhat diminiſhed the multiplicity of the ſpheres employed by their predeceſſors, they were thought to do a ſignal ſervice to aſtronomy.

The manner in which Hipparchus explained the ſolar inequalities, in his excentric theory, was to this purpoſe. Let O (*fig.* 111.) be the centre of the earth and of the ſtarry ſphere. Let B C D E be the ecliptic, or great circle in the *primum mobile* in which the ſun ſeems to perform his annual revolutions; and, in the ſame plane, but on a different centre Z, let the circle A L P be deſcribed. This is the circle, or orbit, in which the ſun is ſuppoſed actually to move, and to deſcribe round its centre equal arcs or angles in equal times: or rather, he is ſuppoſed to be carried round by the equable motion of the circle itſelf; which, becauſe its centre is not occupied by the earth, is called an excentric circle. It is evident, in this repreſentation, that if the earth were placed in Z, a ſpectator on it would perceive the ſun, ſince he is ſuppoſed to move uniformly in the excentric, to move alſo uniformly in the ecliptic. But the earth is placed in O, at the diſtance O Z from the centre of the excentric; and therefore, when his motions are referred to the ecliptic by a ſpectator in O, they muſt appear unequal. When, for example, he departs from A the apogee of the excentric, and comes to K, he would be ſeen from Z in the point R of the ecliptic; but from O, the centre of the earth, he is ſeen in C, a point leſs advanced in longitude. On the contrary, when he departs from P, the perigee of the excentric, and comes to N, his place in the ecliptic, as ſeen from Z, is the point V; but ſeen from O it is the point F, more advanced in longitude than V. Any line, as Z K, drawn from the centre of the excentric to the ſun, or any parallel to it drawn from O, is called the line of mean motion, and determines the mean anomaly A Z K; and any line, as O K, drawn from the ſun to the centre of the earth, is called the line of true motion, and determines the true anomaly A O K; and the angle O K Z, which is the difference between the mean and true anomalies, is the equation of the orbit. In the apogee and perigee this equation vaniſhes, in the ſame manner as in the concentric theory, becauſe there the lines of mean and true motion coincide; and at the points L, L, where a perpendicular to the line of apſides, drawn through O, meets the excentric, it comes to its greateſt amount. Thus, by the ſingle ſuppoſition that the ſolar orbit was excentric to the earth, Hipparchus ſupplied the place of the epicycle added to the concentric: nor is it difficult to perceive that the repreſentations, given by both theories of the ſolar inequalities, were in their effects preciſely the ſame.

In both theſe theories, it is evident that the inequalities of the ſun were conſidered as purely optical: and what was principally required was to find the point O, in the line A P of the apſides, in which the earth muſt be ſituated, in order to give to the ſolar motions the juſt inequality which obſervation required; and to determine the longitude A of the ſolar apogee, that is, the point B of the ecliptic to which it is referred from O. Without finding the juſt excentricity O Z, the calculated differences, or equations, between the ſun's mean and true places, would not correſpond with the obſerved differences: and without diſcovering the poſition of the apogee, the calculated equations, however accurate, would not be applied in their proper places. In theſe inveſtigations the procedure of Hipparchus was as follows.

Let B (*fig.* 112.) be the place of the ſun at the vernal equinox, B D an arc of the excentric equal to his mean motion for $94\frac{1}{2}$ days, that is, from the vernal equinox to the ſummer ſolſtice, D F an arc equal to his mean motion for $92\frac{1}{2}$ days, or from that ſolſtice to the autumnal equinox: let the chord B F be drawn, and from D another chord D E G perpendicular to B F. The point E of the interſection of theſe chords is evidently the point where the earth muſt be ſituated: for it is the only point from which B, D, F, G, can appear at the diſtance of 90° from one another, and as they appear actually in the heavens.

It was required, therefore, to determine the excentricity E C, or the diſtance of the point E from C, the centre of the ſolar orbit. Since the arc B D F of the mean motion, and which the ancients ſuppoſed to be the only real motion of the ſun, from B the vernal to F the autumnal

nal equinox, is given by means of the annual revolution, and confifts of 184° 20′, its half B H will confift of 92° 10′. Through H draw the diameter H C; and through C the centre of the orbit, the diameter C K perpendicular to H C, and meeting D E in L; and join C E. If from B D, the mean motion for $94\frac{1}{2}$ days, and = 93° 9′ we fubtract B H = 92° 10′, the remainder D H will be found = 59′: and if from B H we fubtract the quadrant K H, the remainder B K will be = 2° 10′. Therefore C L and E L, the fines of the arcs D H, B K, will be given in parts of C D = 10,000; the former to wit = 172, and the latter = 378. Therefore the excentricity E C, being the hypothenufe of the right-angled triangle E L C, will be found in the fame parts: for $EC^2 = CL^2 + EL^2$, and therefore E C = 415.

By producing E C to meet the excentric in A and P, we fhall have the line A P of the apfides: and the longitude of A the apogee will be found from the fame triangle E L C; for C E : E L : : R : fin. E C L = K C A = B E A = 65° 30′. Since B therefore reprefents the point of Aries, the place A of the apogee fell fhort of the folftitial point D, 24° 30′, in the days of Hipparchus. It is now between 9° and 10° more advanced.

When the excentricity and the longitude of the apfides were thus determined, the equations of the orbit, or the differences between the mean and true places of the fun, were obtained by a very fimple trigonometrical computation. For in the excentric theory, (*fig.* 111.) when this equation comes to its greateft magnitude, in the points L, L, or M, M, where perpendiculars to the line of apfides drawn through O or Z meet the excentric, the excentricity O Z becomes the tangent of the angle Z M O to the radius of the orbit Z M: and at any other point K, with the excentricity O Z, the radius Z K, and the angle K Z O the fupplement of the mean anomaly A Z K, the equation Z K O will be found by the analogy K Z + Z O : K Z − Z O : : tan. $\frac{1}{2}$ A Z K : tan. $\frac{1}{2}$ (Z O K − Z K O). The calculation will be precifely the fame in the concentric theory if E C be taken in C A, (*fig.* 110.) equal to the radius of the epicycle, that is, to the excentricity O Z, (*fig.* 111.) and will produce the fame refults: and the excentric theory will be found to differ from the concentric only in fimplicity. It is probably needlefs to obferve that the parallels O L and Z M will mark the fame point in the zodiac.

Though thefe theories were thought fufficient to explain the folar motion, in that imperfect ftate of practical aftronomy, yet they were found entirely to fail when applied to the obferved motions of the moon and planets. A new fcheme was therefore adopted by Ptolemy, in which, however, the principle of uniform motion was in fact abandoned. This confifted in affuming an imaginary point as the centre of a new circle, called the equant; and it was fuppofed that to a fpectator fituated in that point the motion of the planet would appear to be uniform. It is not now exactly known if the Greek aftronomers invented this theory, or if they received it by tradition from the eaftern nations, but it is a curious circumftance to obferve, in the hiftory of the fcience of aftronomy, how very near the truth the ancients arrived by trial and obfervation; for their deferent circle and epicycle reduced the figure of the orbit really to an oval form, and the two points in which they placed the earth and the centre of the equant were many centuries afterwards difcovered to be no other than the foci of an elliptic orbit. The true theory was kept out of fight by an obftinate adherence to an ancient prejudice, for what a fingular method was nature fuppofed to take, in order to adhere to this principle of uniform and circular motion; after a number of unmeaning efforts, fhe only accomplifhed an *apparent* uniform motion round an imaginary point, in which no fpectator could ever poffibly be placed to admire the beauty of the contrivance:

The mode of determining the equant was as follows.

Let A be the centre of the earth, (*fig.* 113.) fuppofe the centre of the world D, the centre of the orbit of a planet, or of the excentric circle, F K M L E, called the deferent, (fee Epicycle.) Upon the point F is defcribed the epicycle G Q, and above D a point E is affumed, equal to the excentricity A D, and from the point E another circle is defcribed, R K O L R, of the fame magnitude as the deferent. This fecond circle is called the equant, becaufe the centre of the epicycle, which moves upon the deferent, has neverthelefs an equal motion round the centre E of the equant, for the epicycle defcribes its deferent with an unequal motion, which fhould difappear when referred to the centre of the equant, fo that the angle, fuch as F E I, formed by the line of apfides A F, and by the line drawn to the centre of the epicycle, arrived at I, may be always equal in equal times; for this reafon Ptolemy calls the point E the point of equality. The angle F A I is the true anomaly of the excentric, the angle F E I the mean anomaly, and which is always formed at the centre of the equant.

Kepler had endeavoured to explain phyfically the caufe of the equant, that is, why there fhould be a point E different from the point D, about which the motion was regular and uniform, (Myfter. Cofmogr. c. 22.) He was perfuaded the caufe was general, and that the equant muft take place in the orbit of the earth, as well as in the other planets. Neither Tycho nor Copernicus had employed an equant, but Kepler was perfuaded that the points E and D in an excentric were not the fame, particularly when Tycho informed him that the annual orbit, or excentric of the fun, appeared to him not to be always the fame.

Kepler fufpected that this variation arofe from the point of equality not being the centre of the circle; and in the courfe of his inveftigation of this queftion, he was led to the difcovery of the bifection of the excentricity in the cafe of the earth, whereas the ancients only admitted it in the cafe of the fuperior planets. See Excentricity, *bifection of.*

EXCENTRICITY *of the Orbit of a Planet*, in *Aftronomy*, is the diftance between the centre and the focus of the ellipfe in which it revolves. The difcovery of the excentricity in the orbits of the fun and moon is attributed to Hipparchus, who wrote a treatife on this fubject 150 years before our era.

The excentricity of the orbit is computed from the greateft equation of the centre, by the following proportion: As 57° 17′ 44.″8, (the arc = rad.) is to half the greateft equation, fo is rad. = 1 to the excentricity. See Equation, and Elliptic *Motion.*

But when the greateft equation has been found, and accurately determined by obfervation, the excentricity may be practically deduced by ufing the rule of falfe pofition, or by fuppofing the excentricity known, and finding by trial the greateft equation correfponding to it

The excentricities of the planetary orbits are ufually calculated on a fcale which fuppofes the mean diftance of the earth from the fun divided into one hundred thoufand parts, and the excentricity is expreffed in proportional parts of that fcale.

The following formula for calculating the excentricity is given by Lambert in the Ephem. de Berlin.

Let

Let E be the greateſt equation of the centre, e the excentricity, make $\frac{E}{57.} = \alpha$.

The excentricity will then be expreſſed by the following ſeries.

$$e = \frac{1}{2}\alpha - \frac{11}{768}\alpha^3 - \frac{587}{93040}\alpha^5 - \frac{40583}{2642411520}\alpha^7 -, \&c.$$

The quantity α is always a ſmall fraction, particularly for the ſun; if we ſuppoſe with La Place, $E = 2^\circ.1409$ decimal for 1750. Then,

$$\alpha = \frac{2.1409}{63.6620} = 0.033629$$

$$\tfrac{1}{2}\alpha = 0.016814.$$

The ſecond term, $\frac{11}{768}\alpha^3$, is leſs than 0.000001, and may therefore be entirely neglected.

Table *of Excentricities according to different Authors.*

Planets.	Kepler.	Caſſini.	Halley.	La Lande.	Log. of Excen. in parts of the mean diſtance.
Mercury	8150	$8092\frac{1}{2}$	7970	7955.4	9.3128399
Venus	501	517	504.985	498	7.8378910
The Sun	1800	169	1691.90	1681.395	8.2253628
Mars	14115.5	14155	14170	14183.7	8.9688921
Jupiter	25074	2506	25078.6	25013.3	8.6819346
Saturn	54143.5	5432	54381.4	53640.42	8.7499109
Herſchel				90804	8.6774873

The following table of excentricities in parts of the major axis is taken from the "Syſtem of the World," by La Place.

Mercury	-	0.205513
Venus	-	0.006885
Earth	-	0.016814
Mars	-	0.093808
Jupiter	-	0.048877
Saturn	-	0.056223
Uranus	-	0.046683

The ſecular variation of theſe numbers is as follows: (the ſign — indicates a diminution.)

Mercury	-	+ 0.000003369
Venus	-	— 0.000062905
The Earth	-	— 0.000045572
Mars	-	+ 0.000090685
Jupiter	-	+ 0.000134254
Saturn	-	— 0.000261553
Uranus	-	— 0 000026228

Excentricity, *biſection of.* The biſection of the excentricity is a curious principle aſſumed by Ptolemy, and the ancient aſtronomers, to explain the irregularities of the planetary motions. It is thus deſcribed by Dr. Small.

The inequalities of the planets were ſo various and intricate, that the explications of them were for a long time extremely imperfect, and ſo partial, that no Grecian aſtronomer before Ptolemy had ſuppoſed it practicable to give a compleat theory of all. In the more ancient times the explications of them appear to have been made by orbits concentric to the earth, and charged with epicycles: but, as Ptolemy had found no method of repreſenting the ſecond inequalities, except by means of epicycles, ſo, to avoid the perplexity occaſioned by the multiplication of them, he gave the preference to an excentric orbit for the repreſentation of the firſt; and, by the ſuperior ſimplicity of the repreſentation, the authority of the excentric theory was for many centuries eſtabliſhed. With reſpect to thoſe firſt inequalities, at leaſt of the ſuperior planets, it appears to have been originally ſuppoſed, that they might be ſufficiently accounted for by the more ſimple ſolar hypotheſis. For, if the planet, in conſequence of its ſecond inequalities, be repreſented as moving in the circumference $a\,b\,c$ (*fig.* 111) of an epicycle, the centre A L P Q, of this epicycle, will repreſent the places which it would occupy, if it were diveſted of all ſecond inequality: and it was thought a ſufficient explication of the firſt inequality, to ſuppoſe that this centre moved equally round Z, the centre of the orbit, and conſequently inequably round O, the centre of the earth. But when, according to Kepler's conjectures on this ſubject, they endeavoured to account for the inequality of the latitudes in oppoſition, and of the digreſſions of the planets, eſpecially their greateſt digreſſions, from the point oppoſite to the ſun, by variations of their diſtances from O, it appeared that the point Z, round which the planet moved equably, could not be the ſame with the centre of the orbit; for, both the latitudes, and alſo the angles $a\,O\,c$, $d\,O\,f$, which the epicycle ſubtended at the centre of the earth, were found to be greater at the apogee, and leſs at the perigee than the limits of the excentric A L P Q permitted; and that, conſequently, the centre of the orbit occupied a place nearer than Z to the centre of the earth. It was therefore a matter of much greater difficulty to form an hypotheſis for the motions of the planets, than for thoſe of the ſun: for, if their firſt inequalities required one determined excentricity, or diſtance between the centre of uniform motion and the centre of the earth, the variations of their latitudes, and of their ſecond inequalities, ſhewed that this was not the excentricity of the orbit in which the epicycle moved, and that this orbit evidently required another. In what proportion the diſtance Z O between the centre of uniform motion and the centre of the earth ought to be divided by the centre of the orbit, appears to have been for a long time a matter of much uncertainty. But Ptolemy tells us that, on applying himſelf to inveſtigate the meaſure of the approach of the centre of the epicycle, within the circle A L P O at the apogee, and its conſequent withdrawing from it beyond the perigee, he found, by multiplied obſervations, that the centre of the orbit lay preciſely in the middle, between Z the centre of uniform motion, and O the centre of the earth. This is the famous principle, known by the name of the biſection of the excentricity: and, as Ptolemy gives no account of the means by which it was diſcovered, nor of the obſervations from which it was inferred, his aſſuming it has juſtly excited the wonder of all aſtronomers. The greater part believed him to have aſſumed it merely from conjecture, and not to have derived it, as Kepler more generouſly ſuppoſed, from any obſervations; and there ſeems to be ſome reaſon for thinking that it came to him by tradition, from the more ancient aſtronomy of the Eaſt.

EXCEPTIO, in the *Roman Law*. See Pleading.

EXCEPTION, ſomething reſerved, or ſet aſide, and not included in a rule.

It is become proverbial, that there is no rule without an exception; intimating, that it is impoſſible to comprehend all the particular caſes under one and the ſame maxim. But it is dangerous following the exception preferably to the rule.

Exception, in *Law*, is a ſtop or ſtay to an action.

The term is uſed indifferently, both in the civil and common

mon law; and in each exceptions are divided into *dilatory* and *peremptory*.

In law proceedings, exception is a denial of a matter alleged in bar to the action; and in chancery it is that which is alleged againft the fufficiency of an anfwer, &c. Exception, in a general fenfe, includes all the kinds of defence, or vindication, which a perfon, againft whom a procefs is brought, makes ufe of to prevent or retard its effect.

The civilians reckon three kinds of exceptions; *viz. declinatory*, whereby the authority of the judge or court is difallowed; *dilatory*, intended to defer or prevent the thing from coming to an iffue; and *peremptory*, which are proper and pertinent allegations, founded on fome prefumption that ftands for the defendant; as want of age, or other quality, in the party; or other matter that may be decided, without entering into a full difcuffion of the merits of the caufe.

Exception *to evidence*, is where a demurrer is offered in any civil caufe, on account of the infufficiency of the evidence given, and the court does not agree to it; in which cafe the court or judge are required to feal a bill of exceptions, by ftat. Weftm. 2. 13 Edw. I. cap. 31. which is in the nature of an appeal, examined in the next immediate fuperior court, upon a writ of error after judgment given in the court below. See Demurrer, and Evidence.

Exception, *in deeds and writings*, is the faving of a particular thing out of a general one granted by deed, as a room, fhop, or cellar, out of a houfe; a field, or timber-trees, out of land, &c. Exceptions of this kind muft not crofs the grant, nor be repugnant to it, or elfe they are void of courfe; yet there may be a kind of exception, or faving out of an exception, fo as to make a thing as if never excepted; as where a leafe is made of a rectory, excepting the parfonage-houfe, faving to the leffee a chamber, this fhall pafs by the leafe.

EXCEPTIVE Conjunction. See Conjunction.

Exceptive *propofitions*, are thofe wherein fomething is affirmed of a whole fubject, abating fome one of the parts thereof, which is *excepted* by a particle, thence called an exceptive particle, or particle of exception.

Thus, "All the fects of the ancient philofophers, except the Platonifts, held God to be corporeal. Covetoufnefs is inexcufable in refpect of every thing, but time."

EXCESS is diftinguifhed into *natural* and *moral*: the firft, is a part whereby one quantity is greater than another. Thus, we fay, this line is longer than that; but the excefs is inconfiderable.

The latter is an intemperance, or going beyond the juft bounds and meafures prefcribed for any thing. Thus, we fay, excefs in wine, women, &c. is prejudicial to the health.

EXCESSIVE, in *Mufic*, is ufed as a prefix to denote the excefs of certain tempered intervals above the true intervals of the fame name; it is generally oppofed to defective, *viz.* when there is a deficiency to the fame extent as there is here an excefs; but their ufe is not limited to any certain quantity of excefs or defect, they being fometimes applied in conjunction with or to reprefent the diafchifm, fometimes with enharmonic diefis, at others with minimum femitone, &c.; whereas the prefixes, redundant and deficient, are ufed only with the major comma, and hence the word comma is fometimes omitted; and in like manner the prefixes fuperfluous and diminifhed are confined to the minor femitone, which laft word is therefore fometimes omitted in naming the clafs of intervals, which are increafed or leffened by a minor femitone.

EXCHANGE, in *Commerce*, and *Political Economy*, is the act of paying or receiving money in one country for its equivalent in the money of another country, by means of bills of exchange.

This fcience, therefore, comprehends both the reduction of monies, and the negociation of bills: it determines the relative value of the currencies of all nations, and fhews how foreign debts are difcharged, loans and fubfidies paid, and other remittances made from one place to another, without the rifk or expence of tranfporting fpecie.

This important fubject may be confidered under the five following heads, namely:

1. Bills of exchange.—2. Par of exchange.—3. Courfe of exchange.—4. Monies of exchange.—5. Arbitration of exchange.

Bills of exchange.—A bill of exchange is a written order for the payment of a certain fum of money at an appointed time. It is a mercantile contract in which four perfons are moftly concerned, *viz.* 1. The *drawer*, who receives the value. 2. His debtor in a diftant place, upon whom the bill is drawn, who is called the *drawee*, and who is to accept and pay it. 3. The perfon who gives value for the bill, and who is called the *buyer* and *remitter*; and, 4. The perfon to whom it is ordered to be paid, who is called the *payee*, and who may, by indorfement, pafs it to any other holder.

Moft mercantile payments are made in bills of exchange, which, until due, generally pafs from hand to hand, like any other circulating medium. The laws of all trading nations afford the moft ready and effectual means of enforcing the payment of bills, and hence that credit which they fo univerfally obtain, and which greatly facilitates the operations of commerce.—For the laws, cuftoms, and regulations of bills of exchange, fee Bill *of exchange*, and *Mercantile* Law. See alfo Agio, Usance, and Days *of Grace*.

Bills are diftinguifhed into inland and foreign, according as they are made payable in the country where they are drawn, or in a foreign country. Their functions, however, are fimilar in both cafes, and therefore in explaining the theory of exchange, we fhall begin with the operations of inland bills as the moft fimple and familiar.

Suppofe A. of London is creditor to B. of Edinburgh 100*l.* and C. of London debtor to D. of Edinburgh 100*l.* thefe two debts may be difcharged by the operation of one bill: thus, A. draws on B. and fells his bill to C. who remits it to D. and the latter receives the amount from B. when due. Here, by a transfer of claims, the London debtor pays the London creditor, and the Edinburgh debtor the Edinburgh creditor.

By the foregoing example it appears that reciprocal and equal debts due between two places, may be difcharged without any cafh remittance, and it may be fuppofed that fuch an operation is of equal convenience to the parties concerned, in both places; but when debts are unequal, the advantage muft be likewife different, as the obligation of remittance is no longer mutual; for the debtor place muft pay its balance either by fending cafh or bills; and as the latter mode is generally preferred for feveral reafons, an increafed demand for fuch bills muft be the confequence; and this enhances their price, as it would that of any other faleable article.

This is the plain principle of exchange which is conftantly exemplified in the premium paid for inland bills on London; for this city, being the grand emporium of commerce that furnifhes moft other places of the kingdom with foreign merchandize, and being alfo the refidence of numerous

numerous landlords whofe rents muft be remitted to them from the country, it has generally a large balance of debt in its favour, a great part of which muft be fent in bills; this creates a demand, and confequently a premium which is moftly commuted for time; thus, if A. of London be creditor to B. of Edinburgh 200*l.* and C. of London debtor to D. of Edinburgh only 100*l.* the balance of 100*l.* againft Edinburgh cannot be cancelled by a transfer of claims, but muft, we will fuppofe, be remitted by a bill, which can be only obtained at a certain number of days after date. The moft general term for bills from Edinburgh on London is 40 days, and the intereft for this time is about $\frac{1}{2}$ *per cent.* The number of days here is called the exchange, which has been known to vary confiderably according to the balance of debt, or the plenty or fcarcity of bills. A fimilar premium or date is allowed for bills from all other places of Great Britain on the capital, but bills at fight on any of thofe places may be generally had in London without any premium whatever.

Although the principle of foreign exchange is the fame as that of inland, yet the former is more complicated in its operations than the latter, owing to the denominations of money not being the fame. This caufes a difference in the mode of paying the premium for bills; in which, however, the date is taken into confideration as well as the comparative rates at which the monies are valued.

In foreign exchange one place always gives another a fixed fum or piece of money for a variable price, which fluctuates according to the balance of debt, as before ftated: the former is called the certain price, and the latter the uncertain price. Thus London is faid to give to Paris the certain for the uncertain; that is, the pound fterling for a variable number of francs; and to give to Spain the uncertain for the certain; that is, a variable number of pence fterling for the dollar of exchange.

Whatever the uncertain price is, at any time, is called the courfe of exchange. Now fuppofe Paris gives London 25 francs for the pound fterling, and that this fum is found to contain the fame quantity of pure filver as 20 fhillings, then the exchange is faid to be at par; but if France fhould give a higher price, it is faid to be in favour of London, and *vice verfâ.* This is the common mode of judging whether the exchange be favourable or unfavourable to a place, though it is not always the correct method, nor that which merchants generally act upon. But before we enter into any further explanation of the courfe of exchange, or the caufes of its fluctuation, it will be neceffary to explain more fully what is to be underftood by the par of exchange, a fubject on which there is fome difference of opinion, even among writers of the firft authority.

Par of Exchange.

The par of exchange may be confidered under two general heads; namely, the *intrinfic par,* and the *commercial par,* each of which admits of fubordinate divifions and diftinctions.

The intrinfic par of exchange is the value of the money of one country compared with that of another, with refpect both to weight and finenefs. Thus, two fums of different countries are intrinfically at par when they contain an equal quantity of the fame kind of pure metal, feparated from its alloy, which is always deemed of no value. See Coin.

There fhould be two intrinfic pars, the one between gold coins, and the other betweeen filver coins; and hence the intrinfic par of exchange can be only determined with accuracy between places which pay their bills in the fame kind of metal, as between England and Portugal, that pay in gold coin; or between France and Spain, that pay in filver coin, for the relative value between thefe metals is fcarcely ever the fame in any two countries.

It may be even obferved, that the value of the fame metal differs confiderably in different countries, and therefore this intrinfic par of exchange cannot be always confidered as a true equality in the value of monies; thus in the cafe of France and Spain, where the latter country fupplies the former with the materials of her filver coinage, filver muft be moft valuable in France, and the difference fhould be equivalent to the charges attending the removal, fuch as the duty paid (in time of peace) to the Spanifh government, for the exportation of dollars, the expences of carriage, infurance, commiffion, intereft, &c. all of which amount to nearly 7 *per cent.*

A fimilar computation might be made between gold in England and in Portugal, as the latter country fupplies the former with the materials of her gold coinage.

But where one country pays its bills in gold, and another in filver, no intrinfic par of exchange whatever can be permanently eftablifhed. An equivalency can be only afcertained by valuing as merchandize the gold of one place, and the filver of the other, according to the market price of the day; but this is the commercial par, which fhall be more fully explained below.

In afcertaining the intrinfic par between coins of the fame metal, a queftion occurs, whether the computation fhould be made according to the mint regulations of the refpective countries where the monies are ftruck, or according to actual affays. The former is the moft general method, though the latter is certainly the moft correct; for while fome governments make coins according to their full ftandard, as in England, others take advantage of the allowance for remedy, and fometimes make it a fource of confiderable emolument.

There are fome countries with which no par of exchange, either intrinfic or commercial, can be permanently fixed. Thefe are fuch as pay their bills in paper, which muft have a fluctuating and precarious value. Even the bank money of Amfterdam and Hamburgh comes in a certain degree within this defcription, as it bears a fluctuating agio againft currency.

The *commercial par* is the comparative value of the monies of different countries, according to the weight, finenefs, and market price of the metals. This is the par which merchants generally confider of importance in their exchange fpeculations, and we cannot define it better than in the following paffage, taken from the Minutes of the Committee of the Houfe of Commons, appointed in 1804, to enquire into the ftate of exchange between Ireland and England. Several of the moft intelligent merchants of both countries were examined on the occafion, and their evidence produced much new and practical information.

In the examination of Benjamin Winthrop, efq. governor of the bank of England, an interefting enquiry and inveftigation took place refpecting the par of exchange, from which the following appropriate queftion and anfwer are extracted.

Queftion.—"When a fum of Hamburgh currency, which will buy a pound of bullion of given purity in the market of Hamburgh, can purchafe a bill for a fum of Englifh currency, which will buy a pound of bullion of the fame ftandard in the Englifh market, is not then the exchange at par between thofe two countries?"

Anfwer.

Anſwer.—" I confeſs it does appear to be a complete par of exchange."

This par of exchange is variouſly denominated by different writers on political economy; thus it is called the *current*, the *momentary*, the *political*, and the *eventual par*; and though each of theſe terms ſeems to convey a correct idea of the ſubject, yet we have adopted the word *commercial* as equally appropriate and more generally underſtood.

Some notice might be here taken of what is called a *monetary par*, in which an allowance is made for ſeignorage and mint expences, and alſo of a *common* or *eſtimate par*, which generally differs from the true one; thus the pound ſterling of England is eſtimated at 11 guilders current of Holland; but ſuch definitions are of little utility in the illuſtration of exchange.

The following opinion on the par of exchange ſeems to deſerve quotation. It is tranſlated from the preface of a moſt elaborate work, entitled " Dictionaire des Arbitrages," by Francois Corbaux, publiſhed at Paris in 1802.

" Without dwelling any longer," ſays this author, " on the arbitrary notions which have been formed of the par of exchange, and without ſeeking to adopt new ones, which might be rendered very numerous, we ſhall conclude by obſerving, that although the intrinſic or pretended real par is made the foundation and principal element in the determination of the price of exchange, yet not being the ſame in the gold as in the ſilver coins, the pars of theſe two metals ſhould be kept totally diſtinct; and that beſides, as neither of them finds any direct application in the common courſe of exchange affairs, it is through ignorance that ſo much importance has been attached to them, and that they have been conſidered as the moſt correct expreſſion of the relative value of the monies of two countries. In ſhort to ſeek for a true and rational par is to ſuppoſe what cannot exiſt, that is, the fixing of different principles and elements which are ſubject to continual variation, and, after all, if this could be accompliſhed, it would preſent no object of real utility."

However well-founded the opinion of Monſieur Corbaux may be, we think it muſt be at leaſt ſatisfactory to merchants to underſtand the intrinſic par of exchange, and therefore we ſhall give new tables of it at the concluſion of the preſent article, computed both in gold and ſilver, with rules and examples for performing all ſuch calculations; and ſhall now proceed to the explanation of the courſe of exchange, which is a ſubject of great importance, whether we conſider it in a commercial or political point of view.

Courſe of Exchange.

The courſe of exchange is the current price or proportion between the monies of two places; which is always fluctuating according to circumſtances.

When merchants have occaſion to draw or remit foreign bills, they meet upon the Royal Exchange, where this kind of buſineſs in London muſt be tranſacted. The market is conſtantly attended by exchange-brokers, to whom the wants of the parties who wiſh to buy or ſell bills are privately communicated. Theſe brokers, whoſe confidential ſituation demands ſtrict impartiality, bring parties together; and ſettle the courſe of exchange for the day, as ſoon as they learn how the market ſtands with reſpect to the number of drawers and remitters. The commiſſion for this buſineſs throughout Europe, is one *per mille* (or thouſand) which is equally paid by the buyers and ſellers of bills.

When the courſe of exchange riſes above par againſt any country, it is then concluded that the balance of trade is againſt that place. Now, if England ſhould import from France goods to the value of 100,000*l.*, and export only to the value of 80,000*l.*, it may coſt England 120,000*l.* to pay the whole debt, if it ſhould be publicly known that ſo great a balance exiſts, and therefore ſecrecy is of peculiar importance in this kind of buſineſs.

The fluctuations of exchange are moſtly greater or leſs according to the known amount of the balance, and the expence and difficulty of conveying ſpecie. By the expence of ſuch conveyance is meant the carriage and inſurance, and by the difficulty the hazard of evading thoſe prohibitory regulations which, in moſt countries, impede the exportation of coin; and ſo powerful is the operation of theſe cauſes, that the exchange is ſometimes very high, or unequal, even between neighbouring countries, affording room for very profitable ſpeculations for thoſe merchants who circulate bills in the way of arbitration of exchange.

An unfavourable ſtate of the exchange with a country furniſhes a motive for exporting commodities to it. The merchant under theſe circumſtances can afford to ſell his goods as much cheaper as the premium which he receives for his bill amounts to. Hence the courſe of exchange tends to correct itſelf, and, in peace, it ſeldom continues, for any length of time, more unfavourable than the amount of the expences which might be incurred by tranſporting bullion to pay the balance which is to be remitted; for bullion may be conſidered the univerſal currency of merchants, though it is not always of ready or immediate application.

Although an unfavourable balance of trade has been generally conſidered an invariable cauſe of an unfavourable courſe of exchange, yet recent experience has ſhewn that this is not always the caſe. Thus, in the inveſtigation already alluded to, which took place in the Houſe of Commons relating to the exchange between England and Ireland, it was demonſtrated that the balance of trade was in favour of Ireland, while the courſe of exchange was highly unfavourable; it was, however, ſhewn in ſubſequent publications on the ſubject by Meſſrs. Parnell and Forſter, that though the balance of trade was in favour of Ireland, the balance of debt was unfavourable, or, in other words, the balance of remittance, on account of the number of Iriſh abſentees reſident in England; but perhaps the political ſtate of the country was the chief cauſe.

In time of war the fluctuations of the courſe of exchange are ſometimes very great, particularly where large remittances are to be made in the way of foreign loans or ſubſidies. The exchange is likewiſe lowered by any debaſement of the coin of a country, or by the depreciation of any other circulating medium. Even an exceſs of currency has the effect of turning the rate of exchange againſt that place where it prevails, as the exceſs raiſes the price of all commodities beyond their value in thoſe places where no ſuch redundancy exiſts. It may, however, be obſerved, that the nature of exchange operates to effect the general diſtribution of the ſurplus ſpecie, and to maintain the level of money throughout the commercial world. In ſhort, in all caſes, the exchange tends to an equilibrium.

Although the depreciation of the circulating medium of a country raiſes the courſe of exchange againſt it, the circumſtance is not always a diſadvantage. Thus, before the reformation of our ſilver coinage, in the reign of William the Third, the exchange between England and Holland, computed by the ſtandard of their reſpective mints, was 25 *per cent.* againſt England, but the current coin of England was more than 25 *per cent.* below its nominal or ſtandard value; and therefore the exchange was virtually in favour of of England, according to the ftatement of Dr. Adam Smith.

It may be further obferved, that the wealth of a country will fometimes raife the courfe of exchange againft it, on account of its importations of luxuries from abroad. Rich countries are likewife liable to have the courfe of exchange turned againft them by the fubfidies which they may have to remit to lefs opulent ftates, as before noticed.

Thus in 1793, the trade between Holland and England was completely open; and yet the courfe of exchange was 10 or 12 *per cent.* againft Amfterdam, owing probably to the balance of trade being fo much in favour of London. But, in 1794, when England undertook to fubfidize Pruffia, large remittances of bills were made through Amfterdam, which caufed an immediate fall in the courfe of exchange between that place and London, even below par: and therefore at fubfequent periods of the war, it has been thought prudent by the Englifh government to export fpecie on fuch occafions, rather than to turn the courfe of exchange againft London by the operation of remitting large fubfidies in bills. During the prefent war between France and Auftria (1809) the latter power has been fubfidized by the Englifh government, which has been chiefly done in bills, and this has tended to raife the exchange againft England, in the places where thofe bills were negociated. But the caufe which has operated more powerfully to produce this effect is the great exportation of goods to England, from Germany, France, and Holland, without any adequate importation of Englifh merchandize. Hence the exchange with London has been for fome time greatly in favour of thofe places, while between London and moft of the other parts of Europe it has continued nearly at par.

From what has been faid refpecting the caufes, both commercial and political, which produce the fluctuations of exchange, and which frequently counteract each other, the following fimple conclufion may be drawn; that whatever produces a demand for bills on any place tends to enhance their value, and therefore the courfe of exchange rifes and falls according to the proportion which exifts between the plenty and fcarcity of bills, that is, between the demand and the fupply.

Monies of Exchange.

The following tables contain the monies of exchange of the principal trading places of Europe, in all their varieties and combinations. Explanations are alfo given of the quotations or lifts of the courfes of exchange, which are tranfmitted from one country to another for the government and advice of merchants. Thefe quotations feldom give more than the figures of the uncertain prices, omitting the denominations of money and the certain prices, all of which are here explained.

Note.—In all the uncertain prices the words *more or lefs* are to be underftood.

Amsterdam.

Monies of Exchange.

Exchanges are computed in florins, ftivers, and pennings; or in pounds, fhillings, and pence Flemifh.

16 Pennings	=	1 Stiver
20 Stivers	=	1 Florin or guilder
2 Grotes or pence Flemifh	=	1 Stiver
12 Grotes or 6 ftivers	=	1 Shilling Flemifh
20 Shillings Flemifh, or 6 florins	=	1 Pound Flemifh.

There are two forts of money in Holland; namely, *banco* and *currency:* banco generally bears a premium againft currency of 4 or 5 *per cent.* which is called *agio.*

Quotation explained.

Amfterdam gives to	Uncertain prices.		Certain prices.
London	34 fhillings 8 grotes Flemifh	for	1 Pound fterling
France	54 Grotes Flemifh	—	3 Francs
Spain	99 Ditto	—	1 Ducat of exch.
Portugal	44 Ditto	—	1 Old crufade
Genoa	86 Ditto	—	1 Pezza of $5\frac{3}{4}$ lire
Leghorn	92 Ditto	—	1 Pezza of 8 reals
Hamburgh	34 Stivers	—	2 Marks
Vienna	20 Ditto	—	1 Rixdollar
receives from			
Antwerp	104 Florins	—	100 Florins
Breflau	144 Rixdollars	—	100 Rixdollars
Venice	96 Soldi piccoli	—	1 Florin

N. B. The exchanges of Amfterdam are always tranfacted in banco, unlefs otherwife expreffed.

Augsburg.

Monies of Exchange.

Exchanges are computed in florins and creutzers, and alfo in rixdollars and creutzers.

60 Creutzers	=	1 Florin
$1\frac{1}{2}$ Florin or 90 creutzers	=	1 Rixdollar of account.

Two forts of money are ufed here; giro, that is, money of exchange, and currency.

100 Florins of exchange = 127 Florins current.

Quotation explained.

Augfburg gives to	Uncertain prices.		Certain prices.
Amfterdam	113 Rixdollars of exchange	for	100 Rixdollars
Hamburgh	118 Ditto Ditto	—	100 Ditto
Francfort	102 Rixdollars cur.	—	100 Ditto
Leipfic	99 Ditto Ditto	—	100 Ditto
London	10 Florins 45 creutzers	—	1 Pound fterling
Paris	120 Florins current	—	300 Francs
Nuremberg	101 Florins Ditto	—	100 Florins
receives from			
Genoa	62 Soldi fuori banco	—	1 Florin
Leghorn	57 Soldi moneta buona	—	1 Ditto
Vienna	128 Florins	—	100 Ditto.

Berlin.

Monies of Exchange.

Exchanges are computed in rixdollars, good grofchen, and pfenings currency.

12 Pfenings	=	1 Good grofche
24 Good grofchen	=	1 Rixdollar of account.

Quotation explained.

Berlin gives to	Uncertain prices.		Certain prices.
Amfterdam	154 Rixdollars	for	100 Rixdollars
Breflau	$100\frac{1}{2}$ Ditto	—	100 Ditto
Hamburgh	158 Ditto	—	100 Ditto
Konigfberg	$100\frac{1}{2}$ Ditto	—	100 Ditto
Francfort	105 Ditto	—	100 Ditto
Leipfic	104 Ditto	—	100 Ditto
London	$6\frac{1}{2}$ Ditto 12 grofchen	—	1 Pound fterling
Paris	83 Rixdollars	—	300 Francs.
Augfburg	106 Ditto	—	100 Rixdollars
Vienna	60 Ditto	—	100 Ditto.

Bologna.

Bologna. See Rome.

Bremen.

Monies of Exchange.

Exchanges are computed in rixdollars, grotes, and ſwares

5 Swares = 1 Grote
72 Grotes = 1 Rixdollar of account.

Quotation explained.

Bremen gives to	Uncertain prices.		Certain prices.
Amſterdam	143 Rixdollars	for	100 Rixdollars
Hamburgh	142 Ditto	—	100 Ditto
Francfort	110 Ditto	—	100 Ditto
Leipſic	104 Ditto	—	100 Ditto
London	605 Ditto	—	100 Pounds ſterling
Nuremberg	104 Ditto	—	100 Rixdollars
Paris	20 Grotes	—	1 Franc
Vienna	90 Rixdollars	—	100 Rixdollars.

Breslau. See Berlin.

Cadiz.

Monies of Exchange.

Exchanges are computed in dollars, reals, and maravedis of old plate; alſo in ducats of exchange, and in dobloons of plate, or piſtoles of exchange.

34 Maravedis = 1 Real
8 Reals = 1 Dollar of plate
375 Maravedis of plate = 1 Ducat of exchange
4 Dollars of plate = 1 Piſtole of exchange.

N. B. Vellon, the current money of Spain, is to old plate as 17 to 32; that is,

32 Reals or maravedis vellon = {17 Reals or maravedis of old plate.

Quotation explained.

Cadiz gives to	Uncertain prices.		Certain prices.
Genoa	121 Dollars of plate	for	100 Pezze of $5\frac{3}{4}$ lire
Leghorn	130 Ditto	—	100 Pezze of 8 reals
Naples	{290 Maravedis of plate}	—	1 Ducat regno
receives from			
Amſterdam	97 Grotes Flemiſh	—	1 Ducat of exch.
London	42 Pence ſterling	—	1 Dollar of plate
Paris	78 Sous tournois	—	1 Ditto
Hamburgh	90 Grotes Flemiſh	—	1 Ducat of exch.
Liſbon	2470 Rees	—	1 Dobloon of plate

Constantinople.

Monies of Exchange.

Exchanges are computed in piaſtres, paras, and aſpers; or in piaſtres and aſpers.

3 Aſpers = 1 Para
40 Paras or 120 aſpers = 1 Piaſtre or dollar.

Quotation explained.

Conſtantinople gives to	Uncertain prices.		Certain prices.
London	17 Piaſtres	for	1 Pound ſterling
Vienna	50 Paras	—	1 Florin
Leghorn	145 Ditto	—	1 Pezza of 8 reals
Genoa	24 Ditto	—	1 Lirafuoribanco
Amſterdam	65 Ditto	—	1 Florin current
Paris	200 Piaſtres	for	300 Francs
Venice	360 Paras	—	{1 Sequin of 22 lire
receives from			
Marſeilles	{1 Franc, 50 centimes}	—	1 Piaſtre
Hamburgh	{25 Grotes Flemiſh}	—	1 Ditto
Smyrna	110 Piaſtres	—	100 Ditto.

Copenhagen.

Monies of Exchange.

Exchanges are computed in rixdollars, marks, and ſkillings Daniſh; and ſometimes in rixdollars, marks, and ſkillings lubs or Hamburgh. Pfenings are alſo ſometimes reckoned.

12 Pfenings = 1 Skilling
16 Skillings = 1 Mark
6 Marks Daniſh, or 3 marks lubs = 1 Rixdollar
2 Marks or ſkillings Daniſh = 1 Mark or ſkilling lubs.

Quotation explained.

Copenhagen gives to	Uncertain prices.		Certain prices.
Amſterdam	143 Rixdollars	for	100 Rixdollars

Naples	103 Ditto	—	1 Ducat regno
Hamburgh	45 Ditto	—	1 Mark
Vienna	30 Ditto	—	1 Florin
Augsburg	62 Ditto	—	1 Ditto
receives from			
Venice	33 Soldi piccoli	—	1 Lira
Palermo	36 Grani	—	1 Ditto
Amsterdam	85 Grotes Flemish	—	1 Pezza
France	94 Sous in francs	—	1 Ditto

Genoa receives from	Uncertain prices.		Certain prices.
Spain	620 Maravedis of plate	for	1 Gold crown
Lisbon	718 Rees	—	1 Pezza
Milan	87 Soldi	—	4 Lire
London	48 Pence sterling	—	1 Pezza

HAMBURGH.

Monies of Exchange.

Exchanges are computed in marks, schilling lubs, and pfenings; or in pounds, shillings, and pence Flemish; also in rixdollars, marks, &c.

12 Pfenings	=	1 Schilling lubs
16 Schillings	=	1 Mark
3 Marks	=	1 Rixdollar
6 Pfenings	=	1 Grote or penny Flemish
12 Grotes	=	1 Shilling Flemish
20 Shillings Flemish	=	1 Pound Flemish
Thus, 6 Schilling lubs	=	1 Shilling Flemish
7½ Marks	=	1 Pound Flemish.

There are two sorts of money in Hamburgh, called *banco* and *currency.* Banco bears an agio or premium against currency, which is generally from 20 to 25 *per cent.*

Quotation explained.

Hamburgh gives to	Uncertain prices.		Certain prices.
London	33 Shillings 7 Grotes Flem.	for	1 Pound sterling
France	26 Schilling lubs	—	3 Francs
Spain	91 Grotes Flemish	—	1 Ducat of exch.
Portugal	43 Ditto	—	1 Old crusade
Genoa	80 Ditto	—	1 Pezza of 5¾ lire
Leghorn	86 Ditto	—	1 Pezza of 8 reals
Basil	25 Schilling lubs	—	1 Ecu of 3 francs
receives from			
Amsterdam	33 Stivers	—	2 Marks
Breslau	139 Rixdollars	—	100 Rixdollars
Copenhagen	149 Ditto	—	100 Ditto
Vienna	310 Florins	—	100 Ditto
Venice	82 Soldi piccoli	—	1 Mark.

N. B. The exchanges of Hamburgh are always transacted in banco, unless otherwise expressed.

LEGHORN.

Monies of Exchange.

Exchanges are computed in pezze, soldi, and denari di pezza; sometimes in lire, soldi, and denari di lira, moneta buona.

12 Denari di pezza	=	1 Soldo di pezza
20 Soldi di pezza	=	1 Pezza of 8 reals
12 Denari di lira	=	1 Soldo di lira
20 Soldi di lira	=	1 Lira
5¾ Lire, moneta buona	=	1 Pezza of 8 reals.

Quotation explained.

Leghorn gives to	Uncertain prices.		Certain prices.
Vienna	30 Soldi moneta buona	for	1 Florin
Novi	186 Pezze	—	100 Scudi d'oro marche.

Leghorn receives from	Uncertain prices.		Certain prices.	
Rome	128 Bajocchi	for	1	Pezza of 8 reals
Naples	118 Ducats regno	—	100	Ditto
Palermo	11 Tari 15 grani	—	1	Ditto
Genoa	125 Soldi fuori banco	—	1	Ditto
Milan	136 Soldi correnti	—	1	Ditto
Florence	124 Soldi	—	1	Ditto
Turin	93 Soldi	—	1	Ditto
Venice	$10\frac{1}{2}$ Lire piccole	—	1	Ditto
France	104 Sous in francs	—	1	Ditto
London	54 Pence fterling	—	1	Ditto
Amfterdam	95 Grotes Flemifh	—	1	Ditto
Hamburgh	89 Grotes-Flemifh	—	1	Ditto
Lifbon	855 Rees	—	1	Ditto
Spain	140 Dollars of plate	—	100	Ditto
Augfburg	204 Florins current	—	100	Ditto
Bologna	96 Bolognini	—	1	Ditto
Ancona	132 Bajocchi	—	1	Ditto
Geneva	109 Ecus of 3 livres	—	100	Ditto
Peterfburg	190 Rubles	—	100	Ditto.

LEIPSIC. See BERLIN.

LISBON.

Monies of Exchange.

Exchanges are computed in rees and milrees, and alfo in old crufades.

1000 Rees = 1 Milree
400 Rees = 1 Old crufade.

Quotation explained.

Lifbon gives to	Uncertain prices.		Certain prices.
Paris	470 Rees	for	3 Francs
Genoa	746 Ditto	—	1 Pezza of $5\frac{3}{4}$ lire
Leghorn	810 Ditto	—	1 Pezza of 8 reals
Vienna	360 Ditto	—	1 Florin
Venice	66 Ditto	—	1 Lira piccola
Spain	2430 Ditto	—	1 Dobloon of plate
receives from			
London	66 Pence fterling	—	1 Milree
Amfterdam	45 Grotes Flemifh	—	1 Old crufade
Hamburgh	43 Ditto	—	1 Ditto.

MADRID.

Monies of Exchange. See CADIZ.

Quotation of Madrid on Paris explained.

Madrid receives from	Uncertain price.		Certain price.
Paris	15 Francs 40 centimes	for	1 Dobloon of plate.

The other exchanges of Madrid are fimilar to thofe of Cadiz.

MILAN.

Monies of Exchange.

Exchanges are computed in lire, foldi, and denari correnti or imperiali.

12 Denari = 1 Soldo
20 Soldi = 1 Lira
106 Lire or foldi imperiali = 150 Lire or foldi correnti
117 Soldi imperiali = 1 Scudo or crown.

Quotation explained.

Milan gives to	Uncertain prices.		Certain prices.
France	55 Soldi imperiali	for	3 Francs
Genoa	86 Soldi correnti	—	4 Lire fuori banco
Rome	138 Ditto	—	1 Roman crown
Leghorn	135 Ditto	—	1 Pezza of 8 reals
Augfburg	66 Ditto	—	1 Florin current
Venice	84 Ditto	—	1 Ducat current
Vienna	55 Ditto	—	1 Florin current
Amfterdam	57 Ditto	—	1 Florin banco
London	31 Lire correnti	—	1 Pound fterling
Hamburgh	49 Soldi correnti	—	1 Mark.

NAPLES.

Monies of Exchange.

Exchanges are computed in ducats and grains, or in ducats, carlins, and grains.

10 Grains = 1 Carlin
10 Carlins or 100 grains = 1 Ducat regno.

Quotation explained.

Naples gives to	Uncertain prices.		Certain prices.
Leghorn	120 Ducats regno	for	100 Pezze

Milan	81 Roman crowns	—	100 Scudi imperiali
Ancona	99 Ditto	—	100 Crowns
Bologna	98 Ditto	—	100 Ditto
Leghorn	98 Bajocchi	—	1 Pezza of 8 reals
Amſterdam	44 Ditto	—	1 Florin

Rome receives from	Certain prices.		Uncertain prices.
Naples	122 Ducats regno	for	100 Roman crowns
Venice	11 Lire 10 ſoldi piccoli	—	1 Ditto
Genoa	124 Soldi fuori banco	—	1 Ditto
Paris	105 Sous in francs	—	1 Ditto
London	51 Pence ſterling	—	1 Ditto

ROTTERDAM.

Monies of Exchange. See AMSTERDAM.

Quotation on London explained.

Rotterdam gives to	Uncertain price.		Certain price.
London	11 Florence current	for	1 Pound ſterling.

For the other exchanges of Rotterdam, ſee AMSTERDAM.

STOCKHOLM.

Monies of Exchange.

Exchanges are computed in rixdollars, ſkillings, and fenings.

12 Fenings or Oers	=	1 Skilling
48 Skillings	=	1 Rixdollar.

Quotation explained.

Stockholm gives to	Uncertain prices.		Certain prices.
Amſterdam	44 Skillings	for	1 Rixdollar
Copenhagen	36 Ditto	—	1 Ditto
Dantzic	$9\frac{1}{2}$ Ditto	—	1 Florin
Hamburgh	47 Ditto	—	1 Rixdollar
Leghorn	40 Ditto	—	1 Pezza of 8 reals
London	$4\frac{1}{2}$ Rixdollars	—	1 Pound ſterling
Paris	24 Skillings	—	1 Ecu of 3 livres
Spain	42 Ditto	—	1 Ducat of exch.

TRIESTE. See VIENNA.

TURIN.

Monies of Exchange.

Exchanges are computed in lire, ſoldi, and denari.

12 Denari	=	1 Soldo
20 Soldi	=	1 Lira

Quotation explained.

Turin gives to	Uncertain prices.		Certain prices.
Amſterdam	37 Soldi	for	1 Florin
Augſburg	42 Ditto	—	1 Ditto
Geneva	82 Ditto	—	3 Livres
Genoa	9 Lire 8 ſoldi	—	1 Sequin
Leghorn	86 Soldi	—	1 Pezza of 8 reals
London	19 Lire 10 ſoldi	—	1 Pound ſterling
Milan	92 Soldi	—	$7\frac{1}{2}$ Lire correnti
Paris	20 Lire	—	24 Francs
Rome	87 Soldi	—	1 Roman crown
Venice	94 Ditto	—	1 Ducat current.

VENICE.

Monies of Exchange.

Exchanges are computed in lire, ſoldi, and denari, moneta piccola; and alſo in ducats.

12 Denari	=	1 Soldo
20 Soldi	=	1 Lira
6 Lire 4 ſoldi	=	1 Ducat current, or of account
8 Lire	=	1 Ducat effective

Quotation

Quotation explained.

Venice gives to	Uncertain prices.		Certain prices.
London	56 Lire piccole	for	1 Pound ſterling
Amſterdam	4 Lire 18 ſoldi ditto	—	1 Florin
Augſburg	4 Lire 16 ſoldi ditto	—	1 Ditto
Conſtantinople	3 Lire 6 ſoldi	—	1 Piaſtre
Paris	2 Lire 5 ſoldi	—	1 Franc
Genoa	38 Soldi	—	1 Lira fuori banco
Hamburgh	4 Lire 6 ſoldi	—	1 Mark
Leghorn	11 Lire 18 ſoldi	—	1 Pezza
Milan	34 Soldi	—	1 Lira corrente
Naples	9 Lire 18 ſoldi	—	1 Ducat regno
Vienna	4 Lire 8 ſoldi	—	1 Florin
Rome	12 Lire 10 ſoldi	—	1 Roman crown.

VIENNA.

Monies of Exchange.

Exchanges are computed in florins and creutzers, or in rixdollars and creutzers; pfenings are ſometimes uſed.

4 Pfenings	=	1 Creutzer
60 Creutzers	=	1 Florin
90 Creutzers, or $1\frac{1}{2}$ florin	=	1 Rixdollar of account.

Quotation explained.

Vienna gives to	Uncertain prices.		Certain prices.
Amſterdam	286 Rixdollars	for	100 Rixdollars current
Augſburg	$202\frac{1}{2}$ Ditto	—	100 Ditto
Hamburgh	300 Ditto	—	100 Ditto banco
London	19 Florins	—	1 Pound ſterling
Paris	47 Creutzers	—	1 Franc
Conſtantinople	112 Florins	—	1 Piaſtre
Venice	184 Ditto	—	500 Lire piccole
Prague	$99\frac{1}{2}$ Ditto	—	100 Florins
receives from			
Genoa	30 Soldi fuori banco	for	1 Florin
Leghorn	28 Soldi moneta buona	—	1 Ditto
Milan	33 Soldi correnti	—	1 Ditto.

AMERICA.

Monies of Exchange.

Exchanges are computed in dollars, dimes, and cents; and in ſome places in pounds, ſhillings, and pence currency.

10 Cents	=	1 Dime
10 Dimes, or 100 cents	=	1 Dollar,
12 Pence currency	=	1 Shilling ditto
20 Shillings currency	=	1 Pound ditto.

American Quotations explained.

New York gives to	Uncertain prices.		Certain prices.
London	177 Pounds currency	for	1 Pound ſterling
Amſterdam	42 Cents	—	1 Guilder
Hamburgh	35 Cents	—	1 Mark
Bremen	78 Cents	—	1 Rixdollar
receives from			
Paris	5 Francs 30 cent.	—	1 Dollar.

Philadelphia gives to	Uncertain prices.		Certain prices.
Amſterdam	43 Cents	for	1 Guilder
Hamburgh	35 Cents	—	1 Mark
receives from			
London	4*s*. 6*d*. ſterling *at par*	—	1 Dollar

Baltimore gives to	Uncertain prices.		Certain prices.
Amſterdam	40 Cents	for	1 Guilder
Hamburgh	33 Cents	—	1 Mark
London	101 Cents	—	4*s*. 6*d*. ſterling.

Theſe American quotations have been copied from a New York paper of March 1809. All the other quotations may be likewiſe relied on, having been taken from genuine and recent authorities.

LONDON.

Monies of Exchange.

Exchanges are computed in pounds, ſhillings, and pence ſterling; and farthings are ſometimes reckoned.

4 Farthings	=	1 Penny
12 Pence	=	1 Shilling
20 Shillings	=	1 Pound.

Lloyd's Liſt explained.

London gives to	Uncertain prices.		Certain prices.
Madrid	42 Pence ſterling	for	1 Dollar of plate
Genoa	$47\frac{1}{2}$ Ditto	—	1 Pezza of $5\frac{3}{4}$ lire
Leghorn	$51\frac{1}{2}$ Ditto	—	1 Pezza of 8 reals
Liſbon	68 Ditto	—	1 Milree
Naples	42 Ditto	—	1 Ducat regno
Palermo	90 Ditto	—	1 Ounce
receives from			
Amſterdam	34 Shillings Flem.	—	1 Pound ſterling
Rotterdam	11 Florins current	—	1 Ditto
Hamburgh	33 Shillings Flem.	—	1 Ditto
Paris	23 Livres 10 ſous	—	1 Ditto
Venice	52 Lire piccole	—	1 Ditto
Dublin	10 per cent, that is, 110*l*. Iriſh	—	100 Ditto.

Examples for calculating the exchanges of London with the above places are here given; whence the method of computing the exchanges of other places one with another may be eaſily comprehended, as all operations of this kind may be performed by the Rule of Three Direct.

LONDON and AMSTERDAM.

Engliſh money is reduced to Dutch by ſaying; as 1*l*. ſterling is to the rate of exchange, ſo is the given ſum to the ſum ſought.

Reduce 782*l*. 12*s*. 6*d*. ſterling to Dutch money, exchange at 34 ſhillings and 8 pence Flemiſh *per* pound ſterling.

```

Irifh money is reduced to Englifh by reverfing the foregoing analogy; thus,

			£.	s.	d.		£.	s.
As $111\frac{5}{8}$	:	100 ::	879	6	6 Ir	:	787	15 Eng.

When the exchange between the two countries is at par, Englifh money is turned to Irifh by adding $\frac{1}{12}$, and Irifh to Englifh by fubtracting $\frac{1}{13}$.

Thus reduce 787*l.* 15*s.* Englifh to Irifh money at par.

```
12)787  15   0  Englifh
    55  12  11
   -----------
13)853   7  11  Irifh
    65  12  11
   -----------
   787  15   0  Englifh.
```

Arbitration of Exchange.

Arbitration of exchange is a comparifon between the courfes of exchange of feveral places in order to afcertain the moft advantageous method of drawing or remitting bills. It is diftinguifhed into fimple and compound arbitration; the former comprehends the exchanges of three places only, and the latter of more than three places.

Simple Arbitration

Is a comparifon between the exchanges of two places with refpect to a third; that is to fay, it is a method of finding fuch a rate of exchange between two places, as fhall be in proportion with the rates quoted between each of them and a third place. The exchange thus determined, is called the *arbitrated price*, and alfo *proportional exchange*; and the *proportional par*.

If, for example, the courfe between London and Paris be 24 francs for 1*l.* fterling, and between Paris and Amfterdam 54*d.* Flemifh for 3 francs, (that is, 36*s.* Flemifh for 24 francs,) the arbitrated price between London and Amfterdam, through Paris, is evidently 36*s.* Flemifh for 1*l.* fterling: for as 3 fr. : 54*d.* Flem. :: 24 fr. : 36*s.* Flem.

Now when the actual direct price (as feen by a quotation or otherwife advifed,) is found to differ from the arbitrated price, advantage may be made by drawing or remitting indirectly, that is, by drawing on one place through another, as on Amfterdam through Paris; which may be performed in three different ways.

1ft. London may draw on Paris, and order his correfpondent there to draw on Amfterdam.

2d. London may draw on Paris, and order his correfpondent in Amfterdam to remit the fame fum to Paris.

3d. London may order his correfpondent at Paris to draw on Amfterdam, and to remit the value to London.

The operation of remitting indirectly, or of remitting to one place through another, may be likewife performed in three different ways:

1ft. London may remit to Paris, and order his correfpondent there to remit the fum to Amfterdam.

2d. London may remit to Paris, and order his correfpondent in Amfterdam to draw on Paris.

3d. London may take bills on Paris, and remit them to Amfterdam, there to be negociated.

To exemplify this by familiar illuftrations, fuppofe the arbitrated price between London and Amfterdam to be as before ftated, 36*s.* Flemifh for 1*l.* fterling; and fuppofe the direct courfe, as given in Lloyd's lift, to be 37*s.* Flemifh, then London, by drawing directly on Amfterdam, muft give 37*s.* Flemifh for 1*l.* fterling; whereas, by drawing through Paris, he will give only 36*s.* Flemifh for 1*l.* fterling: it is therefore the intereft of London to draw indirectly on Amfterdam through Paris.

On the contrary, if London remits directly to Amfterdam, he will receive 37*s.* Flemifh for 1*l.* fterling; whereas, by remitting through Paris, he will receive only 36*s.* Flemifh: it is the intereft of London therefore to remit directly to Amfterdam.

Example 2.—Suppofe the exchange of London on Lifbon to be at 68*d.* *per* milree, and that of Lifbon on Madrid 500 rees *per* dollar, the arbitrated price between London and Madrid is 34*d.* ft. *per* dollar; for as 1000 rees : 68*d.* :: 500 rees : 34*d.* But if the direct exchange of London on Madrid be 35*d.* fterling *per* dollar, then London, by remitting directly to Madrid, muft pay 35*d.* for every dollar; whereas by remitting through Lifbon he will pay only 34*d.*: it is therefore the intereft of London to remit indirectly to Madrid through Lifbon.

On the contrary, if London draws directly on Madrid, he will receive 35*d.* fterling *per* dollar; whereas, by drawing indirectly through Lifbon, he would receive only 34*d.*: it is therefore the intereft of London to draw directly on Madrid.

From thefe examples, the two following rules are manifeft.

Rule 1.—Where London gives the certain price, draw through that place which gives the loweft arbitrated price, and remit through that which produces the higheft.

Rule 2.—Where London gives the uncertain price, draw through that place which produces the higheft arbitrated price, and remit through that which gives the loweft.

What is faid here of London will equally apply to any other place from whence the operation is made.

Suppofe the exchange of London on Amfterdam to be 34.6; on Genoa, 47; on Leghorn, 52; and the exchange of Amfterdam on Genoa, 86; on Leghorn, 93; what is the moft advantageous method for London to remit to, or draw on Amfterdam?

1ft.—Becaufe 47*d.* ft. give 1 pezza in Genoa, and this pezza in Amfterdam gives 86*d.* Flemifh, fay, as 47*d.* ft. : 86*d.* Flemifh :: 240*d.* ft. : 439*d.* Flemifh, or 36*s.* 7*d.* Flemifh, which is the arbitrated price through Genoa.

2d.—Becaufe 52*d.* ft. give 1 pezza in Leghorn, and this pezza in Amfterdam gives 93*d.* Flemifh, fay, as 52*d.* ft. : 93*d.* Flemifh :: 240*d.* ft. : 429*d.* Flemifh, or 35*s.* 9*d.* Flemifh, which is the arbitrated price through Leghorn.

Hence, according to the firft rule, the intereft of London is *to draw* directly on Amfterdam, inftead of drawing through Genoa or Leghorn; and *to remit* through Genoa, inftead of remitting directly to Amfterdam, or indirectly through Leghorn.

And according to the fecond rule, the intereft of Amfterdam would be *to remit* directly to London, and *to draw* on London through Genoa.

Compound

Compound Arbitration

Is a compariſon between the exchanges of more than three places in order to find how much a remittance paſſing through them all will amount to at the laſt place, or to find the arbitrated price between the firſt place and the laſt, and thus to determine on the moſt advantageous mode of negociating bills.

Compound arbitration is therefore a repetition of ſimple arbitration, and may be ſolved by a continuation of ſeveral ſtatings in the Rule of Three; but all ſuch operations are beſt performed by conjoint proportion; commonly called the "Chain rule," which ſhall be here explained and demonſtrated, after giving an example of compound arbitration by the Rule of Three.

Suppoſe the exchange between London and Amſterdam to be 35 ſhillings Flemiſh for 1 *l.* ſterling; between Amſterdam and Liſbon, 42 pence Flemiſh for 1 old cruſade; and between Liſbon and Paris, 480 rees for three francs, what is the arbitrated exchange between London and Paris?

1ſt. As 35*s.* Flem. : 1*l.* :: 42*d.* Flem., or 3½*s.* Flem. : 2*s.* ſt. = 1 old cruſade.

2dly. As 1 old cruſade, or 400 rees : 2*s.* ſt. :: 480 rees : 2*s.* 4$\frac{4}{5}$*d.* ſt. = 3 francs.

3dly. As 2*s.* 4$\frac{4}{5}$*d.* ſt. : 3 francs :: 240*d.* ſt. : 25 francs.

Hence the arbitrated price is 25 francs for 1 *l.* ſterling.

The Chain Rule explained and demonſtrated.

Diſtinguiſh the ſeveral courſes of exchange into antecedents and conſequents, and place them in two columns, the antecedents to the left and the conſequents to the right, by way of equation.

The firſt antecedent muſt be of the ſame denomination as the quantity of which the value is required.

The firſt conſequent muſt be of the ſame denomination as the ſecond antecedent, and the ſecond conſequent as the third antecedent; and ſo on throughout.

The laſt conſequent muſt be of that denomination in which the anſwer is required.

The terms being thus arranged, the antecedents muſt be multiplied continually for a diviſor, and the conſequents for a dividend; and the quotient will be the anſwer.

The calculation may be abridged by expunging ſuch antecedents and conſequents as are alike, and reducing ſuch their loweſt terms as admit of a common diviſor.

Example from the foregoing Queſtion.

1 *l.* Sterling	=	35 Shillings Flemiſh.
3½ Shillings Flemiſh	=	400 Rees
480 Rees	=	3 Francs.

How many francs will 1*l.* ſterling give?

$$\frac{3 \times 400 \times 35}{1 \times 480 \times 3\frac{1}{2}} = \frac{42000}{1680} = 25 \text{ francs.}$$

In this example, 480 and 400 have the common diviſors 8 and 10, and they may therefore be reduced to 5 and 6; again the antecedent 6 may be reduced to 2, by ſtriking out the firſt conſequent 3; the fraction is therefore reduced to $\frac{5 \times 35}{2 \times 3\frac{1}{2}} = \frac{175}{7} = 25$, as before.

Demonſtration of the Chain Rule.

Let A, B, C, D, &c. be ſeveral denominations of money, and *m*, *n*, *p*, *q*, &c. the numbers or quantities of thoſe denominations, and let them ſtand thus:

Antecedents.		*Conſequents.*
m A	=	n B
p B	=	q C
r C	=	s D
t D	=	v E

Now to find what number of the laſt denomination (E) is equal to a given number of the firſt denomination (A) let z times the laſt term = y times the firſt, that is, let $z\,E = y\,A$.

Multiply all theſe equations together, the antecedents by the antecedents, and the conſequents by the conſequents, which will give $m\,A \times p\,B \times r\,C \times t\,D \times z\,E = n\,B \times q\,C \times s\,D \times v\,E \times y\,A$, and this equation reduced is $mprtz = nqsvy$.

Now if the number of the laſt denomination be required, $z = \frac{nqsvy}{mprt}$; but if the number of the firſt denomination be required, $y = \frac{mprtz}{nqsv}$. *Q. E. D.*

Example 2.—If London remit 1000*l.* ſterling to Cadiz by way of Holland at 35 *s.* Flemiſh *per* pound ſterling; thence to France at 58 *d.* Flemiſh *per* ecu of 3 francs; and thence to Cadiz at 15½ francs *per* doubloon of 4 dollars, what is the price between London and Cadiz reſulting from the operation? and how many dollars will the 1000*l.* amount to in Spain?

1 Pound ſterling	=	35 Shillings Flemiſh
1 Shilling Flemiſh	=	12 Pence Flemiſh
58 Pence Flemiſh	=	3 Francs
15½ Francs	=	1 Doubloon
1 Doubloon	=	4 Dollars

How many dollars are equal to 1000*l.* ſterling?

$$\frac{35 \times 12 \times 3 \times 4 \times 1000}{58 \times 15\frac{1}{2}} = \frac{5040000}{899} = 5606 \text{ dollars, 1 real,}$$

28 mar. which gives the exchange at 42¾ *d.* nearly.

The indirect courſe of exchange between London and Cadiz may be alſo found by an inverſe operation, called the *Doctrine of Contraries*: thus,

4 Dollars	=	1 Doubloon
1 Doubloon	=	15½ Francs
3 Francs	=	58 Pence Flemiſh
12 Pence Flemiſh	=	1 Shilling Flemiſh
35 Shillings Flemiſh	=	240 Pence ſterling.

How many pence ſterling equal 1 dollar?

$$\frac{240 \times 58 \times 15\frac{1}{2}}{4 \times 3 \times 12 \times 35} = \frac{58 \times 15\frac{1}{2}}{3 \times 7} = \frac{899}{21} = 42\tfrac{17}{21}d.$$

Now if the direct courſe of exchange was above the indirect, the circular remittance would be moſt advantageous; but if under, the direct operation would be preferable.

In computing the profits or loſſes of exchange operations, allowance ſhould be made for the expences, commiſſion, and intereſt of money, all of which may be compriſed in the ſtatement by the Chain Rule; that is, by deducting them from thoſe terms of the conſequents to which they may relate; thus, in the following example, the *per centage* is ſubtracted from 100 in the laſt place of the conſequents.

Example 3.—London takes bills on Madrid at 33½*d. per* dollar of exchange, remits them to Amſterdam, with orders to negociate at 90¼ grotes *per* ducat of exchange, and make the returns in bills on Paris at 51⅜ grotes *per* ecu of 3 francs: what does London gain or loſe *per cent.* by this operation, ſuppoſing the bills on Paris are negociated at 25 livres 18 ſous *per* pound ſterling; and that all the charges, including intereſt for the time that London is out of its money, amount to 1⅛ *per cent.*?

33½ Pence ſterling	=	272 Maravedis
125 375 Maravedis	=	90¼ Grotes

51⅜

	$51\frac{3}{8}$ Grotes	=	$\cancel{4}$	Francs
4	$\cancel{80}$ Francs	=	81	Livres
	1 Livre	=	$\cancel{20}$	Sous
259	$\cancel{518}$ Sous	=	$\cancel{240}$	Pence sterling 120
	$\cancel{100}$ Pence sterling	=	$98\frac{7}{8}$	On account of charges.

How much does $\cancel{100}$ *l.* sterling give?

$$\frac{272 \times 90\frac{1}{4} \times 81 \times 98\frac{7}{8}}{33\frac{1}{2} \times 125 \times 51\frac{3}{8} \times 4 \times 259 \times 100} = 105,853, \text{ anfwer.}$$

The profit is therefore 5*l.* 17*s.* $0\frac{3}{4}$*d.* *per* 100*l.* fterling.

Operations in compound arbitration may be greatly facilitated by the help of logarithms: thus, "from the fum of the logarithms of the confequents, fubtract the fum of the logarithms of the antecedents; the difference will be the logarithm of the anfwer."

In this cafe, however, the reduction of the numbers as above is fuperfluous, as it is as eafy to find the logarithm of a large as of a fmall number; but when equal terms are on both fides they fhould be ftruck out; and if a common divifor can be found which will reduce any term to unity, it will likewife fhorten the operation.

In queftions of this kind much time and labour may be fometimes faved by making ufe of *fixed numbers*; thus, where feveral terms are unchangeable in both the antecedents and confequents they can be reduced to one; and the conftant logarithm of this number may be ufed with thofe that vary; fuch as the logarithms of the rate of exchange, the amount of the charges, &c.

Befides the foregoing rules for facilitating the arbitration of exchange, various other methods have been propofed for fhortening and illuftrating the fubject; even triangles and other diagrams have been conftructed for this purpofe; (fee Poftlethwait's Commercial Dictionary, vol. i. p. 94.) but geometrical projections do not feem well adapted to elucidate this rule.

A graphic operation, however, of a very ufeful and ingenious defcription, has been lately executed in London, in which fcales of the monies of exchange of the principal places in Lloyd's lift are fo graduated and arranged, that the arbitrated price between any two of them, with refpect to a third place, may be immediately found by the application of a right line. The invention is by William Wollafton, M.D. S. and F.R.S.

We fhall conclude this article by giving rules for calculating the intrinfic par of exchange, and alfo tables of the fame in gold and filver according both to mint regulations, and to affays.

The intrinfic par of exchange may be calculated by the rules laid down for computing the value of coins. (See Coin.) But the operation may be performed with greater precifion by the Chain rule, as in the following examples.

Example 1.—What is the intrinfic par between London and Lifbon, in *gold*, when taken from the Johanefe of 6400 rees, which, according to the mint regulations of Portugal, contains $221\frac{2}{5}$ grains of Englifh ftandard gold?

6400 Rees	=	$221\frac{2}{5}$ Grains of ftandard gold
480 Grains ftandard gold	=	$934\frac{1}{2}$ Pence fterling.

How many pence fterling will 1000 rees give?

Striking out the common divifor 1000, $\dfrac{221\frac{2}{5} \times 934\frac{1}{2}}{64 \times 48} =$ 67,35*d.* fterling for the milree.

Example 2.—What is the intrinfic par between London and Madrid, in *filver*, the weight of the dollar being 17 dwt. 8 gr. Troy, and its finenefs 8 dwt. worfe than Englifh ftandard, according to average affays lately made at his majefty's mint at the Tower of London.

85 Dollars of exchange	=	64 Hard dollars
1 Hard Dollar	=	416 Grains Troy
222 Grains in dollars	=	214 Grains ftandard
480 Grains ftandard	=	62 Pence fterling.

How many pence fterling does 1 dollar of exchange give?

Striking out the common divifor 64, $\dfrac{416 \times 214 \times 62}{85 \times 111 \times 15} =$ 39*d.* fterling for the dollar of exchange.

Example 3.—What is the intrinfic par between London and Amfterdam, in *filver*, when taken from the rixdollar current, which weighs 18 dwt. Troy, and is (according to affays) 16 dwt. worfe than Englifh ftandard, taking the agio of banco on currency at 4 *per cent.*

62 Pence fterling	=	20 Dwt. ftandard filver
202 Dwt. ftandard	=	222 Dwt. in rixdollars
18 Dwt. or 1 rixdollar	=	50 Stivers currency
1 Stiver	=	2 Grotes
12 Grotes	=	1 Shilling Flemifh
104 Shillings Flemifh currency	=	100 Shillings Flemifh banco.

Howmany fhillings Flemifh banco do 240 pence fterling give?

Brought down and reduced.

31	$\cancel{62}$	$\cancel{20}$	5
103	$\cancel{206}$	$\cancel{222}$	37
3	$\cancel{18}$	50	50
	$\cancel{12}$	$\cancel{2}$	
13	$\cancel{104}$	$\cancel{100}$	25
		$\cancel{240}$	20

$$\frac{5 \times 37 \times 50 \times 25 \times 20}{31 \times 103 \times 3 \times 13} = 37s.\ 2d. \text{ Flemifh for the pound fterling.}$$

Table of the intrinfic par of exchange between London and the principal places in Lloyd's lift, gold againft gold, and filver againft filver, calculated according to the mint regulations of each place refpectively.

From the two foregoing tables it appears, that the par in gold generally varies from that in ſilver, and in ſome places very conſiderably.

It alſo appears that the aſſays do not differ eſſentially from the mint regulations; but where any difference is found to exiſt, it is moſtly in deficiency.

The intrinſic par of exchange between any other places, beſides the above, may be determined by the foregoing rules, and from the money tables in the preſent article, with thoſe given in the article Coin.

It ſhould be obſerved, that in the calculation of the par for Amſterdam, the ducat is reckoned at 5 florins 5 ſtivers currency, but this price is ſubject to alteration, and therefore no permanent par in gold can be eſtabliſhed with Holland, even if the agio were fixed. It ſhould be alſo remarked, that in computing the par with Hamburgh the ducat is reckoned at 6 marks Hamburgh banco, and the Cologne mark of fine ſilver at $27\frac{5}{8}$ marks banco, which are the common, but not conſtant prices, and therefore no permanent par can be eſtabliſhed with Hamburgh, any more than with Amſterdam.

Authors on exchange are very numerous, though few can be mentioned that have produced full and accurate ſyſtems: the principal are, Kruſe of Hamburgh; Ricard of Amſterdam; Gerhardt of Berlin; Marien of Spain; Senebier of Geneva; Giraudeau, Ruelle, Reiſhammer, and Corbaux of France; and Duboſt of London. Among the productions of thoſe writers Kruſe's Hamburgh Contoriſt has been the moſt univerſally approved; an Engliſh tranſlation of this ſyſtem of exchanges, monies, weights and meaſures, with conſiderable additions and alterations, is now nearly printed, and will be ſhortly publiſhed, under the title of the "Univerſal Cambiſt;" from which the preſent article has been chiefly extracted.

Exchange alſo denotes a public place, in moſt conſiderable cities, wherein the merchants, negociants, agents, bankers, brokers, interpreters, and other perſons concerned in commerce, meet, on certain days, and certain times thereof, to confer, and treat together of matters relating to exchanges, remittances, payments, adventures, aſſurances, freightments, and other mercantile negociations both by land and ſea.

In Flanders, Holland, and ſeveral cities of France, theſe places are called *bourſes;* at Paris and Lyons, *places de change;* and in the Hanſe towns, *colleges of merchants.*

Theſe aſſemblies are held with ſo much exactneſs, and merchants and negociants are ſo indiſpenſably required to attend at them, that a perſon's abſence alone makes him be ſuſpected of a failure or bankruptcy.

The moſt conſiderable exchanges in Europe are that of Amſterdam, and that of London, called the Royal Exchange. For an account of the latter, ſee Royal *Exchange.*

The former is a large building, 230 feet long and 130 broad, round which runs a periſtyle or portico, 20 feet wide. The columns of the periſtyle, amounting to 46, are numbered, for the convenience of finding perſons.

That of Antwerp was little inferior to either of them, till a variety of circumſtances concurred to effect its ruin, and to transfer its trade to Amſterdam; the era of this important event in commercial hiſtory is about the year 1585.

Even in the time of the ancient Romans there were places for the merchants to meet, in moſt of the conſiderable cities of the empire. That ſaid by ſome to have been built at Rome in the year of the city 259, 493 years before our Saviour, under the conſulate of Appius Claudius and Publius Servilius, was called *collegium mercatorum;* whereof it is pretended there are ſtill ſome remains, called by the modern Romans *loggia*, the lodge; and now, uſually the "Place of St. George."

This notion of a Roman exchange is ſuppoſed to be founded on the authority of Livy, whoſe words are as follow; *viz.* "Certamen conſulibus inciderat, uter dedicaret Mercurii ædem. Senatus a ſe rem ad populum rejecit utri eorum dedicatio juſſu populi data eſſet, eum præeſſe annonæ, mercatorium collegium inſtituere juſſit." Liv. lib. ii. But it muſt be here remarked, that *collegium* never ſignified a building for a ſociety in the purer ages of the Latin tongue; ſo that "collegium mercatorum inſtituere" muſt not be rendered to build an exchange for the merchants, but to incorporate the merchants into a company. As Mercury was the god of traffic, this ædes Mercurii ſeems to have been chiefly deſigned for the devotions of this company or corporation.

Exchange, in *Law*, is a mutual grant of equal intereſts in lands or tenements, the one in conſideration of the other; and in our common law it more particularly denotes the compenſation which the warrantor muſt make the warrantee, value for value, if the land warranted be recovered from the warrantee. Bracton, lib. ii.

The word "exchange," is ſo individually requiſite and appropriated by law to the caſe now ſtated, that it cannot be ſupplied by any other word, or expreſſed by any circumlocution. (Co. Litt. 50, 51.) The eſtates exchanged muſt be equal in quantity (Litt. § 64, 65.), not of *value*, for that is immaterial, but of *intereſt;* as fee-ſimple for fee-ſimple, a leaſe for 20 years for a leaſe of 20 years, and the like. And the exchange may be of things that lie either in grant or in livery. (Co. Litt. 51.) But no livery of ſeiſin, even in exchanges of freehold, is neceſſary to perfect the conveyance (Litt. § 62.); for each party ſtands in place of the other and occupies his right, and each of them hath already had corporal poſſeſſion of his own land. But entry muſt be made on both ſides; for, if either party die before entry, the exchange is void for want of ſufficient notoriety. (Co. Litt. 50.) And ſo alſo, if two parſons, by conſent of patron and ordinary, exchange their preferments; and the one is preſented, inſtituted, and inducted, and the other is preſented, and inſtituted, but dies before induction; the former ſhall not keep his new benefice, becauſe the exchange was not completed; and therefore he ſhall return back to his own. (Park, § 288.) For if, after an exchange of lands or other hereditaments, either party be evicted of thoſe, which were taken by him in exchange, through defect of the other's title, he ſhall return back to the poſſeſſion of his own, by virtue of the implied warranty contained in all exchanges. Blackſt. Comm. book ii. See WARRANTY.

EXCHANGE *of goods and chattels*. See SALE.

EXCHANGE, *the king's*, is the place appointed by the king for exchange of plate, or bullion for the king's coin. Theſe places have formerly been diverſe: but now there is only one, *viz.* that of the Tower of London, joined with the Mint.

EXCHANGE, *bill of*. See BILL *of Exchange*.

What we call re-exchange, is the due, or premium of a ſecond exchange, when a bill is proteſted. See RE-EXCHANGE.

EXCHANGE *brokers*. See *Exchange* BROKERS.

EXCHANGE *of Priſoners*. This meaſure, which is dictated both by humanity, and, in general, by mutual intereſt, is frequently adopted by two hoſtile nations, for the purpoſe of eaſing themſelves from the great charge incurred by the retention of priſoners of war in priſons, depots, &c. Sometimes an exchange becomes a conſideration while drawing up the articles of a capitulation; eſpecially where the beſiegers conſider it a matter of policy to get poſſeſſion of a fortreſs, without being too ſtrict in the conditions of ſurrender.

Thus we frequently obſerve, that a garriſon is allowed to retire, under the expreſs ſtipulation, that "no part thereof ſhall ſerve again until regularly exchanged." In ſuch caſe, an immediate liberation of an equal number of thoſe confined in the enemy's priſons ought inſtantly to take effect, and the perſons thus diſcharged ſhould be forwarded to their country; but if, as ſometimes occurs at the very commencement of a war, when one party has been extenſively ſucceſsful, the other may not have the means of equalization in regard to the liberation of priſoners, it may occur, that months, or even years, may elapſe, before ſuch reſtriction may be removed.

This, indeed, is not the only point on which the matter may reſt: it may ſometimes happen, that a prince may feel it to be his intereſt not to carry an exchange into effect; and this he may juſtify under the ordinary circumſtances attendant upon capitulation. Say, that an army ſurrenders ſimply under this condition; "that it ſhall not ſerve until duly exchanged." Here we ſee no obligation on the part of its ſuperiors to make any exchange: therefore, when policy dictates ſuch forbearance, we cannot affix any imputation on the prince, power, &c., if no exchange takes place.

If, indeed, the garriſon are allowed to return to their country, or to retire unmoleſted, on condition that "they *ſhall* be exchanged," then, we naturally expect, that no time will be loſt in liberating an equal number; adverting to the ſeveral claſſes of thoſe allowed to retire, and pairing them off in a correct manner.

We have heard of evaſions contrived for the expreſs purpoſe of detaining ſome individual, who, by his prowcſs, or abilities, may have become highly obnoxious to the enemy. This, however, can only take place where there is no perſon of correſponding rank, againſt whom he can be paired off; then the exchange neceſſarily becomes in a degree arbitrary; though it is a matter of courteſy, to form ſome equivalent, in ſuch manner as may ſuit the wiſhes of his own government.

With a view to facilitate the exchanges occaſionally ordered, as well as to obviate the million of frivolous complaints which would elſe be made, it is cuſtomary for powers at war either to receive agents, or to appoint ſupervisors, whoſe duty is confined ſolely to ſuch matters as relate to the due ſubſiſtence of the priſoners, and to conducting whatever may relate to exchanges. Through this medium a government may always avail itſelf of the means of releaſing any particular perſons, confined as priſoners of war in the enemy's country; but, to effect this, at leaſt to be able to command it, there muſt be in its power ſome equivalent: for it would be unreaſonable to expect that a general officer ſhould be given up, when only a colonel could be offered in exchange; but a general may be liberated by any government, for the purpoſe of liberating any officer of inferior rank then in the power of the enemy: and ſo throughout.

EXCHANGERS are thoſe who return money beyond ſea, by bills of exchange, &c. called anciently alſo *excambiators*, and ſince *remitters*.

EXCHEQUER, or ſimply *Chequer*, originally denotes a cheſs-board; or a frame divided into ſixty-four ſquares, of two colours, whereon to play at draughts, cheſs, &c. See CHESS, &c.

The word is formed from the French *eſchequier*, which ſignifies the ſame. Hence, trees are ſaid to be planted chequer-wiſe, *in quincuncem*, when diſpoſed ſo as to form diverſe ſquares repreſenting a chequer.

EXCHEQUER is more particularly uſed for a chamber, or apartment, in Weſtminſter-hall, conſiſting of two parts; the court of exchequer and the lower exchequer. See COURT *of Exchequer*, and COURT *of Exchequer-chamber*.

EXCHEQUER-*bills* are a ſpecies of paper firſt eſtabliſhed by Mr. Montague, in 1696, as a more convenient kind of ſecurity than the tallies and orders for repayment then in uſe, and alſo to ſupply the want of circulating caſh, during the re-coinage at that period. They were then taken at the exchequer for all payments of the revenue, and, when re-iſſued, they were allowed 7*l.* 12*s. per cent.* intereſt. They have ſince been iſſued yearly for anticipating the produce of particular taxes; and they have almoſt conſtantly formed the principal article of that part of the public debt called the unfunded debt. Of late years the total amount of outſtanding exchequer bills (excluſive of thoſe charged on ſpecific branches of the revenue) has uſually been about 12 millions. The bank of England, ever ſince the year 1706, have been the contractors for their circulation, at a certain premium. The commiſſioners of the treaſury are empowered, by various ſtatutes, to borrow money, within a ſpecific ſum, limited by thoſe ſtatutes, by iſſuing exchequer bills on the credit of certain duties; which bills, by 12 Anne, cap. 11. and 12 Geo. I. cap. 11. bear an intereſt of 2*d.* a day *per cent.* payable to the bearers. But the intereſt payable on them has differed according to the current rate of intereſt at the time when they have been iſſued. Thoſe now in circulation bear intereſt at the rate of 3½*d.* a day *per cent.* They are often made for 100*l.* each, but of late years they have been chiefly for 1000*l.* each, and ſometimes for larger ſums. Theſe bills are numbered arithmetically,

cally, and regiſtered accordingly, ſo that the principal ſums may be paid off in courſe, the time of which is notified by public advertiſement. The ſaid exchequer bills ſhall be current to all receivers and collectors of the cuſtoms, exciſe, or any revenue, and at the receipt of the exchequer; and as any of them are paid or lent into the exchequer, the officers there ſhall cauſe tallies to be levied and delivered to the payers or lenders, as if they had made ſuch payments or loans in ſpecie. The inſtalments on loans are paid into the receipt of the exchequer in exchequer bills, which are received again by the bank as caſh, either for the amount of dividends due, or in repayment of advances. When theſe bills are ſold at a conſiderable diſcount, or any other circumſtance indicates that too many of them are in circulation, it is uſual to fund a part of them, that is, to convert them into a permanent debt by offering the holders of them ſtock in lieu of their bills. This of late has been frequently done. The total amount of exchequer bills iſſued for the public ſervice between the 5th of January 1808 and the 5th of January 1809, and not redeemed within that period, was 39,735,200*l.* The unfunded debt in exchequer bills, outſtanding on the 5th of January 1809, was 40,093,200*l.* The amount of exchequer bills iſſued for the public ſervice in Ireland, between the 5th of January 1808 and the 5th of January 1809, and not redeemed within that period, was 541,666*l.* 13*s.* 4*d.* If any exchequer bills be loſt, upon affidavit before a baron of the exchequer, and certificate from him, and ſecurity given to pay the ſame if found, duplicates are to be made out; and when bills are defaced new ones ſhall be delivered. Forging of theſe bills, or of the indorſements on them, is felony.

Exchequer, *meſſenger of the.* See Messenger.

Exchequer, *Black Book of the*, is a book under the keeping of the two chamberlains of the exchequer; ſaid to have been compoſed in 1175, by Gervaiſe of Tilbury, nephew of king Henry II. and divided into ſeveral chapters.

Herein is contained a deſcription of the court of England, as it then ſtood, its officers, their ranks, privileges, wages, perquiſites, powers, and juriſdiction; and the revenues of the crown, both in money, grain, and cattle. Here we find, that for one ſhilling, as much bread might be bought as would ſerve a hundred men a whole day; that the price for a fat bullock was only twelve ſhillings, and a ſheep four, &c. Larrey, p. i. p. 394. See alſo Domesday.

EXCISE, an inland duty, or impoſition, charged on commodities of general conſumption, and paid ſometimes upon the conſumption of the commodity, or frequently upon the retail ſale, which is the laſt ſtage before the conſumption. This mode of taxation was adopted among the Romans; for Auguſtus, after the civil wars, introduced an exciſe, which, though very moderate, was general. It ſeldom exceeded one *per cent.* but it comprehended whatever was ſold in the markets or by public auction, from the moſt conſiderable purchaſes of lands and houſes, to thoſe minute objects which can only derive a value from their infinite multitude and daily conſumption. Such a tax, however, as it affects the body of the people, has ever been the occaſion of clamour and diſcontent. Auguſtus was obliged to declare by a public edict, that the ſupport of the army depended in a great meaſure on the produce of the exciſe; and Tiberius diminiſhed the exciſe to one-half, though the relief was of very ſhort duration. It has been adopted, in more modern times, as the moſt economical mode of taxing the ſubject; the charges of laying, collecting, and managing the exciſe duties being conſiderably leſs in proportion than in other branches of the revenue. Beſides, it renders the commodity cheaper to the conſumer than charging it with cuſtoms to the ſame amount would do, becauſe this tax is generally paid in a much later ſtage of it. Nevertheleſs, the rigour and arbitrary proceedings of exciſe-laws ſeem hardly compatible with the temper of a free nation. For the frauds that might be committed in this branch of the revenue, unleſs a ſtrict watch is kept, makes it neceſſary, wherever it is eſtabliſhed, to give the officers a power of entering and ſearching the houſes of ſuch as deal in exciſeable commodities, at any hour of the day, and, in many caſes, of the night likewiſe. And the proceedings in caſe of tranſgreſſions are ſo ſummary and ſudden, that a man may be convicted in two days' time in the penalty of many thouſand pounds by two commiſſioners or juſtices of the peace; to the total excluſion of the trial by jury, and diſregard of the common law. Obnoxious as the exciſe duty has always been, it was firſt ſuggeſted by the earl of Bedford, lord treaſurer to king Charles I., but never actually introduced in that prince's reign. Its original eſtabliſhment took place in the year 1643, when it was introduced, on the model of the Dutch prototype, by the long parliament after its rupture with the crown; and its progreſs has been gradual. It was at firſt laid upon thoſe perſons and commodities, where it was ſuppoſed the hardſhip would be leaſt perceivable, *viz.* the makers and venders of beer, ale, cyder, and perry; and though it originated with the long parliament, the royaliſts at Oxford ſoon followed the example of their brethren at Weſtminſter, by impoſing a ſimilar duty; both parties, however, proteſting that it ſhould be continued no longer than to the end of the war, and then be utterly aboliſhed. But the parliament at Weſtminſter ſoon after impoſed it on fleſh, wine, tobacco, ſugar, and ſuch a multitude of other commodities, that it might be fairly denominated general. This was done in purſuance of the plan laid down by Mr. Pymme, who had been intended for chancellor of the exchequer under the earl of Bedford, and who ſeems to have been the father of the exciſe. In his letter to ſir John Hotham (30 May, 1643) he intimates, "that they had proceeded in the exciſe to many particulars, and intended to go on farther; but that it would be neceſſary to uſe the people to it by little and little." Having accuſtomed the people to it for ſome years, the ſucceeding champions of liberty boldly and openly declared (Ord. 14th Auguſt, 1649, ch. 50.) "the impoſt of exciſe to be the moſt eaſy, and indifferent levy that could be laid upon the people;" and accordingly it was continued during the whole uſurpation. Upon the reſtoration of king Charles II., as it had been long eſtabliſhed, and its produce was well known, ſome part of it was given to the crown, in 12 Car. II., by way of purchaſe for the feodal tenures and other oppreſſive parts of the hereditary revenue. (See Revenue.) Notwithſtanding its general unpopularity, it has been impoſed on abundance of other commodities in the reigns of king William III. and of every ſucceeding prince, towards ſupporting the enormous expences occaſioned by our wars on the continent. In the year 1732, the groſs produce of the exciſe-duty amounted to 2,964,617*l.* About this time ſir Robert Walpole, being of opinion, that taxes on conſumable commodities, to which every citizen contributes in proportion to his conſumption, and which, being included in the price of the commodity, are inſenſibly paid, conſtituted the moſt eligible mode of raiſing the revenue neceſſary for the public ſervice, formed a project for the gradual abolition, not only of the taxes on land, houſes, and windows, but alſo of the cuſtoms, by the ſubſtitution of productive exciſe duties. Fully apprized of the abuſes and frauds to which the collection of the cuſtoms was ſubject, and which he had no hope of remedying, he thought that the ſcheme of converting the greater part of the cuftoms into duties of excife, would be equally advantageous to government and to the fair trader; and that the excife laws might be fo ameliorated, that, notwithftanding the odium generally attached to them as arbitrary and oppreffive, no juft ground of complaint fhould remain. With a view to the execution of this plan, he obtained a revival of the falt-duties, which had been repealed fome years before; but upon propofing, in the following year, to transfer the duties on wine and tobacco to the excife, "faction," fays Dr. Smith (Wealth of Nations, vol. iii. p. 358.) "combined with the intereft of fmuggling merchants, raifed fo violent, though unjuft a clamour againft that bill, that the minifter thought proper to drop it." The defeat of this fcheme was celebrated by general rejoicings, as a deliverance from the greateft political danger.

The feveral commodities now fubject to excife duties are ale, beer, cyder, perry, mum, metheglin, and mead; things fold by auction; bricks and tiles; candles; coaches and coachmakers; coffee, tea, chocolate, and cocoa-nuts; glafs; hops; leather; linen cloths, filks, cottons, and callicoes; malt; paper; plate; falt; foap; fpirituous liquors; ftarch, hair-powder, and ftone-blue; fweets; tobacco and fnuff; vinegar and verjuice; wine; and wire. See each of thefe articles.

In the year 1787 the various rates of duty which had been impofed at different times were confolidated; and other regulations were alfo adopted, by which the produce of the revenue was augmented, and the expence of collecting it materially reduced.

By 24 Geo. II. c. 40, all fines, penalties, and forfeitures, impofed by this or any other act relating to the duties of excife, fhall be fued for, levied, recovered, or mitigated by fuch ways and means as any fine, penalty, or forfeiture is or may be recovered or mitigated by any law or laws of excife, or in the courts at Weftminfter, and fhall be half to the king and half to him that fhall inform or fue:—that is to fay, if within the limits of the chief office in London, the offence fhall be determined by the commiffioners (or any three of them, 1 Geo. II. ft. 2. c. 16.) or, in cafe of appeals, by the commiffioners of appeals; in all other places they fhall be heard and determined by any two or more juftices of the peace, refiding near the place where the offence was committed, or forfeiture incurred; and in cafe of neglect or refufal of fuch juftices, for the fpace of fourteen days next after complaint made, and notice thereof given to the offender; then the fub-commiffioners may hear and determine the fame; and if the party find himfelf aggrieved by the judgment given by the faid fub-commiffioners, he may appeal to the next quarter-feffions, whofe judgment therein fhall be final. The faid commiffioners for appeals, and chief commiffioners for excife, and all juftices of the peace and fub-commiffioners aforefaid, are required, upon any complaint or information exhibited of any fuch forfeiture made or offence committed, to fummon the party accufed, and upon his appearance or contempt to proceed to the examination of the fact, and on due proof thereof either by the voluntary confeffion of the party, or by the oath of one credible witnefs, to give judgment or fentence, and to iffue warrants under their hands, for levying the fame on the goods and chattels of the offender, and to caufe fale to be made thereof, if not redeemed in (not lefs than four, nor more than eight days, 27 Geo. II. c. 20.); and for want of fufficient diftrefs, to imprifon the party offending till fatisfaction be made. The juftices, commiffioners, or fub-commiffioners, refpectively, where they fhall fee caufe, may mitigate, compound, or leffen, the forfeiture, penalty, or fine; fo as the fame be not made lefs than double the value of the duty of excife which ought to have been paid, befides the reafonable cofts and charges of fuch officers, or others as were employed therein, to be to them allowed by the faid juftices. (12 C. II. c. 24.) No appeal in any caufe of excife fhall be admitted, till the appellant hath depofited the fingle duty with the commiffioners or fub-commiffioners, and given fecurity to the commiffioners of appeal, or juftices of the peace, where the caufe is to be finally adjudged, for fuch forfeiture as was adjudged againft him. (15 C. II. c. 13.) By the fame ftatute all differences and appeals about the excife fhall be heard in the proper county, and not elfewhere, and appeals within London and its limits, fhall be within two months after judgment, and notice given or left at the dwelling houfe of the party, in all other places in four months and not otherwife.

By 43 Geo. III. c. 69, after fifth of July 1803, all duties, allowances, bounties and drawbacks of excife, and other duties under the management of the commiffioners, granted by any act of parliament then in force, fhall ceafe; except in cafes relating to the recovery of arrears, or of any fine, &c. previoufly incurred. Provided that the act fhall not extend to alter the duties upon malt, mum, cyder, and perry, granted by 43 Geo. III. c. 3. or upon malt, tobacco, and fnuff, continued by 43 Geo. III. c. 4; (except as to the duties on tobacco licences, and on tobacco of Spain and Portugal): nor fhall the act extend to the countervailing duties on importation from Ireland, or the drawbacks payable on exportation thither, according to the "Act of the Union;" (except thofe in refpect of beer, ale, and wines, bricks and tyles, cyder and perry, hops, mead or metheglin, fpirits, vellum and parchment, gilt and filver wire, and gold and filver thread, lace or fringe.) And in lieu thereof fhall be raifed and collected upon the feveral goods, wares, merchandize, and commodities, defcribed in fchedules annexed to the faid act, and for the fales by auction, and upon licences mentioned in one of thefe fchedules, the feveral fums and duties refpectively fet forth in the faid fchedules; and that there be allowed in refpect of goods, &c. for which any duty of excife is impofed, the feveral drawbacks of excife as fet forth in another fchedule, and alfo all allowances directed to be made by any act in force on the faid 1ft of July 1803, except as herein altered. And by 43 Geo. III. c. 81. certain additional duties inferted in an annexed fchedule are directed to be paid, and the drawbacks in another fchedule fhall be allowed; to commence from July 5, 1803, where no date is inferted in the act, and the amount of the additional duties may be added to the price of articles contracted for prior to the act. And the faid new duties fhall be raifed, levied, collected, confumed, paid, recovered, adjudged, mitigated, and allowed, (except where altered by thefe acts or either of them) in the like manner, and by fuch means, ways, and methods as the former duties. And all conditions, regulations, rules, reftrictions, and forfeitures; and every pain, penalty, fine, or forfeiture of any nature or kind whatfoever, for any offence againft any act of parliament then in force; and the feveral claufes, powers, and directions therein contained, (unlefs altered hereby,) fhall extend to and be applied in the execution of thefe acts, in as full and ample manner as if the fame were repeated and re-enacted in the body of thefe acts, 43 Geo. III. c. 69. § 4. c. 81. § 3. And in all cafes where duties are impofed or drawbacks allowed by thefe acts on any fpecific quantity of goods, the fame fhall apply after the fame rate to any lefs quantity. Id.

The excife duties of England are under the management of nine commiffioners, who fit in the general "Excife office," having falaries of 1200*l.* a-year each, and they are obliged, by oath, to take no fee or reward, but from the king only. From thefe commiffioners there lies an appeal to five others, called "Commiffioners of Appeal." The commiffioners

commiffioners of excife in Scotland are five in number, and have falaries of 600*l.* *per annum* each.

The number of officers employed in this branch of the revenue is very great. Befide the commiffioners above-mentioned, and their fubordinate officers, as regifters, meffengers, &c. there is an auditor of the excife, and an auditor of hides, with their clerks, &c. A comptroller of cafh, and another of accompts, with their clerks; a regifter; fecretary; folicitor; receiver-general, with his clerks; clerk of fecurities; ftore-keeper; houfe-keeper; door-keepers; general accomptants, with their affiftants; accomptant for fines, and two accomptants for the London brewery; clerk of the bills of exchange; examiners; clerk for fupervifors diaries; five general furveyors; general furveyors of diftillery; and brandy; examiners of the diftillery, of the brewery, and of foap and candles; furveyors of glafs, of coaches, and plate licences; infpector of fpirituous liquors, licences, and coaches; infpectors general of coffee, tea, &c. and of brewery through England and Wales. Befide which, there are in England and Wales, exclufive of the bills of mortality, within which is the principal head office of excife, to which all other offices in the kingdom are fubordinate and accountable, about fifty collectors, who go their refpective rounds once in fix weeks: the province of a collector comprehends feveral diftricts, within each of which there is a fupervifor, under the infpection of the collector; and each diftrict is parcelled out into out-rides and foot-walks, within each of which there is an inferior officer, conftituted under the hands and feals of the commiffioners, or fub-commiffioners, in their refpective divifions, as neceffity requires, and called gauger, or exciseman, under the infpection of the fupervifor, who every fix weeks draws out a diary of every day's bufinefs, with remarks, and tranfmits it to the chief officer. Every perfon, previous to his appointment to the office of gauger, muft procure a certificate of his age, which muft be between 21 and 30; he muft underftand the four firft rules of arithmetic, ftate what bufinefs he hath followed, and that he is not encumbered with debts, be of the communion of the church of England, and, if married, not have more than two children; he muft nominate two able perfons to be his fureties; and the certificate, containing thefe particulars, and written by himfelf, muft be figned by the fupervifor of the diftrict where he lives, and accompanied with an affidavit, that he has ufed no bribes for obtaining this office. He is then ordered for inftruction, under the care of an experienced officer, and to wait, under the denomination of an "expectant," till a vacancy happens. Upon admiffion of officers of every kind relating to the excife, the oaths of allegiance and fupremacy, and an oath of faithfulnefs in the execution of the particular office, muft be taken, and the declaration againft tranfubftantiation muft be fubfcribed. The officers of excife are appointed, and may be difmiffed, replaced, or altered by the commiffioners under their hands and feals; their falaries are allowed and eftablifhed by the treafury: and by 1 William and Mary, c. 24. § 15. if it be proved by two witneffes that any officer has demanded or taken any money, or other reward whatever, except of the king, fuch offender fhall forfeit his office. Officers of excife, taking a bribe, are liable to a forfeiture of 10*l.* 15 Car. II. cap. 11: and a perfon liable to excife duties offering them a bribe, &c. fhall forfeit 500*l.* 11 Geo. cap. 30. Officers meddling in elections are fubject to a penalty of 100*l.* and an incapacity of holding any office under the king, 5 W. cap. 20. And an officer, either of the excife or cuftoms, dealing in excifeable liquors, fhall forfeit 50*l.* and be incapable of any office in the revenue, 12 Geo. cap. 28. The concealment of excifeable goods is fubject to a forfeiture of thofe goods, and treble value, 11 Geo. cap. 30. Any perfon obftructing an officer in the execution of his duty, fhall forfeit 10*l.* 6 Geo. cap. 21. Actions of affault upon any officer may be tried in any county, 9 Geo. II. c. 35. And if any perfon fhall difturb or oppofe any excife officer in the execution of the powers and authorities by this act granted, or any or either of them, except where other penalties are by the act provided, he fhall forfeit 200*l.* 42 Geo. III. c. 38. And the fame penalty is inflicted by 43 Geo. III. c. 81, in relation to that act. Officers of excife are empowered to fearch at all times of the day, enter warehoufes, &c. And if officers fufpect that excifeable goods are concealed in any place within the limits of the chief office of excife in London, upon oath by fuch officers before the commiffioners, or any two or more of them; or if fuch place be in any other part of Great Britain, on oath before one or more juftices of the county, &c. or fufpected place, fetting forth the ground of fufpicion, the faid commiffioners, or the faid juftice or juftices may, by fpecial warrant, authorife fuch officers by day or night (but if in the night, in prefence of a conftable or other peace officer) to enter into fuch place and to feize all fuch goods; and if any perfon fhall obftruct any fuch officers fo authorifed, or any one acting in the execution of fuch warrant, he fhall forfeit 100*l.* 42 Geo. III. c. 93. The officers, in their permits for removing excifeable goods, fhall exprefs as well the time for which they fhall be in force for removing fuch goods, as the time within which they fhall be received into ftock by the perfon to whom they are fent; and if not removed within the time limited (unavoidable accidents excepted), or, in default of fuch removing, if the permit fhall not be returned to the officer who granted the fame, the perfon procuring the permit fhall forfeit treble value of the goods: and if not received into ftock, within the time limited, by the perfon to whom they were permitted to be fent, they fhall be deemed goods removed without a permit. 21 Geo. III. c. 55. No writ fhall be fued out againft any officer of excife, or his affiftant, for any thing done in the execution of his office, until one calendar month's notice fhall have been delivered to him, or left at his ufual place of abode, clearly and explicitly containing the caufe of action, the name and place of abode of the perfon who is to bring fuch action, and the name and place of abode of his attorney or agent: and the officer may at any time within fuch month tender amends, and plead fuch tender in bar of the action; and if, upon iffue joined, the jury fhall find the tender to have been fufficient, they fhall give a verdict for the defendant; but if the jury find that no amends, or fuch as were not fufficient, were tendered, they fhall give a verdict for the plaintiff, and fuch damages as they fhall think proper with cofts of fuit. 23 Geo. III. c. 70. If any action fhall be brought againft an officer, &c. it fhall be brought within three months after the caufe of action fhall arife, and not afterwards, and fhall be laid in the proper county; and if the plaintiff fhall be nonfuited, or difcontinue, or if upon a verdict or demurrer judgment fhall be given againft him, the defendant fhall recover treble cofts.

The additional duties, which the progrefs of the public expenditure has rendered it neceffary to impofe, have greatly increafed the produce of the excife, and rendered it the moft important branch of the public revenue. The duties which it comprehends are divided into the permanent confolidated duties, the temporary war taxes, and the annual duties; the latter confift of the old annual malt duty, and of an additional malt duty, which, with fome duties on tobacco and fnuff, and fome cuftom duties, have, fince the project for felling the land-tax, been granted annually in lieu thereof.

An Account of the Grofs Actual Receipt in Money, Charges of Management, and Taxes repaid to Officers, Exports, Temporary War Taxes, and Malts and Tobacco, Annual in England, for the Year ended Exchequer, on each Article;—together with the Balance in the Hands of the

The total payments out of the revenue of exciſe, under the authority of warrants from the barons of exchequer, to the receiver-general of crown rents and caſualties in Scotland, from January 5, 1808, to January 5, 1809, are as follow:

	£.	s.	d.
Salaries to the judges and officers of the three courts of ſeſſion, juſticiary, and exchequer, and of the admiralty and commiſſary courts - - - - - - - -	50,340	12	$10\frac{1}{4}$
Paid to thoſe on his majeſty's civil liſt eſtabliſhment, not belonging to the three courts - - - - - - - - - - -	22,727	10	$10\frac{1}{2}$
To Francis lord Napier, commiſſioner to the general aſſembly of the church of Scotland - - - - - - - - - - -	2,000	0	0
To John Connel, procurator for the church of Scotland, to be diſtributed by him among itinerant preachers - -	1,000	0	0
To A. Mundell, without account	1,208	17	6
Total - -	77,277	1	$3\frac{1}{4}$

The total revenue of inland exciſe and licences, together with other fees received by revenue exciſe collectors in Ireland, for one year, ending the 5th of January, 1809, amounted to 1,659,838*l.* 8*s.* $9\frac{1}{4}$*d.* and the total payments for management, militia, bounties, &c. out of the groſs and net revenue of exciſe, during the ſame period, amounted to 531,910*l.* 9*s.* 5*d.* If we add to the above ſum 1,659,838*l.* 8*s.* $9\frac{1}{4}$*d.* the amount of the inland duties, *viz.* 429,824*l.* 11*s.* $0\frac{5}{8}$*d.* the groſs produce will amount to 2,089,662*l.* 19*s.* $9\frac{5}{8}$*d.* and the amount of the net produce was 1,772,615*l.* 16*s.* $2\frac{3}{8}$*d.*

EXCISION, in *Surgery*, is a word often uſed to ſignify the operation of cutting any tumour, or any foreign ſubſtance, off, or out of, a part of the body.

EXCITABILITY, in Dr. John Brown's hypotheſis, or the *Brunonian* hypotheſis, as it has been called, is nearly ſynonymous with the *vital principle* of medical writers in general, and ſignifies that quality or property of living beings, on which the phenomena of life depend.

Life itſelf is, in the opinion of Brown, a *forced ſtate*, ariſing altogether from the action of certain agents, which he denominates *exciting* powers, upon the *excitability*; for death enſues equally, whether the exciting powers are withdrawn, or the excitability is loſt. The exciting powers conſiſt of heat, air, food, drink, and other ſubſtances taken into the ſtomach, the blood, and the fluids ſecreted from it; as well as of certain functions of the ſyſtem itſelf, ſuch as muſcular exertion, ſenſation, thought, and paſſion or emotion. The effect of the exciting powers acting upon the excitability, is denominated *excitement.*

This word "excitability" is to be conſidered as a general term, expreſſive of the facts aſcertained by obſervation, but of the eſſential nature of which we muſt remain ignorant; as in the caſe of gravitation, &c. "We know not what excitability is," ſays Dr. Brown, "or in what manner it is affected by the exciting powers. But whatever it be, whether a quality or a ſubſtance, a certain portion is aſſigned to every being upon the commencement of its living ſtate." He obſerves, however, that ſuch expreſſions as a determinate portion of excitability in each living being, the exhauſtion, or the accumulation of excitability, are neceſſarily borrowed from the qualities of material ſubſtances, in conſequence of the poverty of language; and are not to be received in a ſtrict and literal ſenſe.

Every power, then, that acts on the living frame, according to this doctrine, is ſtimulant, or produces excitement by expending excitability; whence "it follows, that the whole phenomena of life, every ſtate and degree of health and diſeaſe, are alſo owing to ſtimulus, and no other cauſe." By too great ſtimulation weakneſs is induced, becauſe the excitability becomes defective; this is ſaid to conſtitute a ſtate of *indirect debility*; when the exciting powers or ſtimulants are withheld or diminiſhed, weakneſs is likewiſe induced, the excitability being accumulated, or in exceſs; and this is denominated a ſtate of *direct debility*. (See Debility.) For "this mutual relation obtains betwixt excitability and excitement; that the more weakly the powers have acted, or the leſs the ſtimulus has been, the more abundant the excitability becomes;—the more powerful the ſtimulus, the excitability becomes the more exhauſted." It is only then, when a mean degree of ſtimulus operates upon excitability at a medium, that perfect health is produced: in illuſtration of which a ſcale was drawn by Brown, (See Elements of Medicine, chap. iii. § 39. *note*) divided into 80 degrees of excitability oppoſed inverſely to 80 degrees of exciting power, at each end of which is *death*; there being, in the one caſe, 80 degrees of excitability, and no exciting power; and in the other, 80 degrees of ſtimulus and no excitability; whereas *perfect health* holds the middle ſtation, where there are 40 degrees of ſtimulus and of excitability reſpectively. Good health, however, may be conſidered to exiſt within a range of 30 or 40 degrees (15 or 20 on each ſide of the mean) in conſequence of the conſtant variation of ſtimulus, to which man is expoſed, in his food, drink, paſſions of the mind, &c.; but every departure from the mean of perfect health conſtitutes a pre-diſpoſition to diſeaſes of direct or indirect debility. As life is entirely regulated by excitement, and the exciting powers have a ſtimulating effect only, Dr. Brown affirms, that "the notion of health and diſeaſe being different ſtates is diſproved;" the operation of the powers producing or removing each ſtate being perfectly identical: and efficacious remedies being ſuch as oppoſe deficient ſtimulus to exceſſive excitement, and exceſſive ſtimulus to deficient excitement. In a word, there are but *two* forms of diſeaſes; and both are always preceded by pre-diſpoſition; thoſe which ariſe from exceſſive excitement are called *ſthenic* (from σθένος, *ſtrength*,) and thoſe which originate from a deficient excitement, *aſthenic*. The direct tendency of this hypotheſis, therefore, was to reduce the art of medicine to the ſimple regulation of ſtimuli, or of the exciting powers; it required

us

us only to increafe the quantity of ftimulation on the one hand, or to withdraw, or rather diminifh, the ftimuli on the other; as the excitement happened to be too great or too little, above or below the medium of the fcale of health.

As this concife ftatement of a medical hypothefis, which has excited great attention and much controverfy, may, perhaps, be obfcure to thofe who are unaccuftomed to the ftudy of the phenomena of animal life, we fhall cite an illuftration of Brown's fyftem, drawn up by one of his pupils from a familiar operation, by which a conception of his fundamental principles may be facilitated.

"Suppofe a fire to be made in a grate filled with a kind of fuel not very combuftible, and which could only be kept burning by means of a machine, containing feveral tubes, placed before it, and conftantly pouring ftreams of air into it. Suppofe alfo a pipe to be fixed in the back of the chimney, through which a conftant fupply of frefh fuel was gradually let down into the grate, to repair the wafte occafioned by the flame, kept up by the air-machine.

The grate will reprefent the human frame; the *fuel* in it the *matter of life* (the *excitability* of Brown, and the *fenforial power* of Darwin): the tube behind, fupplying frefh fuel, will denote the power of all living fyftems conftantly to regenerate or reproduce excitability; while the air-machine, of feveral tubes, denotes the various *ftimuli*, or exciting powers, applied to the excitability of the body; and the flame, drawn forth in confequence of that application, reprefents *life*, the product of the exciting powers acting upon excitability.

As Dr. Brown has defined *life* to be "a forced ftate," it is fitly reprefented by a flame, *forcibly* drawn forth, from fuel little difpofed to combuftion, by the conftant application of ftreams of air poured into it from the different tubes of a machine. If fome of thefe tubes are fuppofed to convey pure, or *oxygenous* air, they will denote the higheft clafs of exciting powers, fuch as opium, mufk, camphor, fpirits, wine, &c. (the diffufible ftimuli of Dr. Brown) which bring forth for a time a greater quantity of life than ufual, as the blowing in of pure air into a fire will temporarily draw forth an uncommon quantity of flame. If others of the tubes be fuppofed to convey common or atmofpheric air, they will reprefent the ordinary exciting powers, or ftimuli, applied to the human frame, fuch as heat, light, air, food, drink &c.; while fuch as convey impure airs may be ufed to denote what have formerly been termed fedative powers, fuch as poifons, contagious miafmata, foul air, &c. (Sedatives are deemed by Brown ftimulants of a minor force.)

The reader will now be at no lofs to underftand the feeming paradox of the Brunonian fyftem, that food, drink, and all the exciting powers applied to the body, though they *fupport* life, yet they *confume* it; for he will fee, that the application of thefe powers, though it brings forth *life*, yet at the fame time it waftes the excitability, or *matter of life*; juft as air blown into the fire brings forth more *flame*, but wafts the *fuel*, or *matter of fire*. This is conformable to the common faying, "the more a fpark is blown, the brighter it burns, and the fooner it is fpent." A Roman poet has given us an excellent illuftration of the Brunonian fyftem, when he fays,

> "Balneæ, vina, Venus, confumunt corpora noftra;
> Sed vitam faciunt balnea, vina, Venus."
>
> "Wine, warmth, and love our vigour drain;
> Yet wine, warmth, love our life fuftain."

It will be equally eafy to illuftrate the two kinds of *debility*, termed *direct* and *indirect*, which, according to Brown, are the caufes of all difeafes; if the quantity of ftimulus, or exciting power, is proportioned to the quantity of excitability; that is, if no more excitement is drawn forth, than is equal to the quantity of excitability produced, the human frame will be in a ftate of health; juft as the fire will be in a vigorous ftate, when no more air is blown in, than is fufficient to confume the frefh fupply of fuel, conftantly poured down by the tube behind. If a fufficient quantity of ftimulus is not applied, or air not blown in, the excitability in the man, and the fuel in the fire, will accumulate, producing *direct debility*; for the man will become *weak*, and the fire *low*. This, carried to a certain degree, will occafion death to the firft, and extinction to the laft. If again, an over proportion of ftimulus be applied, or too much air blown in, the excitability will foon be wafted, and the matter of fuel almoft fpent: hence will arife *indirect debility*, producing the fame weaknefs in man, and lownefs in the fire as before, and equally terminating, when carried to a certain degree, in death and extinction."

The fimplicity of this doctrine, contrafted with the complicated hypothefes of preceding phyficians, and its happy illuftration of fome of the phenomena of life, (which we have noticed under the word Debility,) fpeedily obtained for it a number of profelytes, in the fchools of medicine, wherever it was introduced. A generalization fo fweeping was, indeed, well calculated to arreft the attention, and gratify the ardour of young minds; and accordingly it was efpoufed with enthufiafm by the moft fanguine and fpeculative ftudents, and was debated and defended with a vehemence and intolerance of oppofition, almoft unknown in fcientific difcuffions; and this not only at Edinburgh, where the doctrine originated, but fucceffively in the different univerfities of the continent to which it was carried. To learn that there were but two forms of difeafe, and therefore but two indications of cure, and two fets of remedies, was particularly gratifying to thofe who preferred indolent hypothefis to the labour of obfervation. It fuperfeded at once the practice and maxims of the Hippocratic fchool of experience and unremitting inveftigation, and reduced the art of medicine within the compafs of a nut-fhell.

But, true as this doctrine of excitement may be, in its application to many of the phenomena of life, it is by no means adequate to the explanation of the whole, and efpecially of the caufes and remedies of numerous difeafes: it is, moreover, inconfiftent with itfelf in fome points, and its advocates are not agreed in the interpretation of thefe difficulties.

There is one inconfiftency fo grofs and obvious, in the Brunonian doctrine, that it is inconceivable how the author could have been infenfible of it, or have perfevered in maintaining it. In the illuftration above quoted, a tube or chimney is provided, by which the fuel, or excitability, is fuppofed to be conftantly replenifhed: but no fuch provifion is mentioned by Brown. He affirms that "a certain portion of excitability is affigned to every being at the commencement of its exiftence, that the action of ftimuli neceffarily exhaufts it, and that life confifts in the inceffant action of ftimuli upon this excitability;" *i. e.* in the inceffant exhauftion of it. With this ftatement the notion of accumulated excitability (which is faid to conftitute *direct* debility) is altogether incompatible: non-confumption, or rather diminifhed confumption, might preferve the excitability, but furely could never increafe it: though fomewhat might be faved, nothing could be gained, by the abftraction of ftimuli; and on the re-application of the difcontinued ftimuli, the excitability fhould never be found increafed or accumulated, but fhould be ftationary at the point of interruption; or, more correctly fpeaking, it muft always be found

found fomewhat wafted, fince, while life remains, it muft be acted upon in fome degree; while, on the other hand, every violent ftimulation fhould, upon the fame principle, rapidly wafte, and haften the irrecoverable exhauftion of the powers of life. The propofition, then, that a determinate portion of excitability is affigned to every individual, being equally inconfiftent with the fubfequent theorems of the fyftem, and with matter of fact, has been either given up, or explained away, by the pfeudo-Brunonians of the prefent day. They admit that the excitability may be partially reftored or renewed by reft and food. But to make the hypothefis confiftent with common fenfe, it requires that the procefs of *generating* excitability be conftantly going; for even during the moft profound fleep, ftimuli, or, in other words, exhaufting powers, are inceffantly applied, the ceffation of all excitement being fynonymous with death.

Another inconfiftence in the hypothefis, fcarcely lefs palpable, is the ftatement, that *indirect* debility, which confifts in exhauftion of the excitability from exceffive ftimulation, is to be cured, *i. e.* the excitability is to be reftored, by a continuance of ftrong ftimuli; namely, by ftimuli "*little fhort* of thofe which produced the over-excitement." But, however managed, it is obvious from the hypothefis, that they muft exhauft excitability, if they act at all; they muft, therefore, wear out what remains of the excitability more and more, and ultimately exhauft the power. No attempts to explain away this incongruity of language can be confidered fuccefsful; the alleged lofs of power in the ftimuli, in confequence of repetition, will only account for the lefs rapidity of the complete exhauftion; but exhauftion of excitability cannot be feparated from the notion of ftimulation.

In its application to the practice of medicine, as well as to the explanation of the action of many caufes of difeafe, the Brunonian fyftem is marked by a grofs neglect or defiance of obfervation and experience. The connections and dependencies of the different functions, the local derangements which take place in the different organs, and the curative indications deduced from thefe, are altogether overlooked; and the variety of phenomena which refult from the fpecific operation of various agents on the animal economy, is equally neglected. The affertion that all powers, which influence the animal body, whether productive or curative of difeafe, are *ftimulant*, is an abufe of language not often equalled by the framers of theories. There is not only not an identity in their action;—there is fcarcely any thing in common. "With regard to contagions," to ufe the words of an intelligent critic, "when we confider the regular and progreffive feries of actions, induced by thefe on the fyftem; when we have obferved that each contagion gives rife to a train of peculiar and characteriftic phenomena, defining the difeafe whence the contagion originated, and terminating often in the formation and feparation of a quantity of morbid matter, alone capable of propagating the fame difeafe in others, we cannot acknowledge that identity in the operation of the exciting powers, which the Brunonians contend for. In difeafes induced by contagions, in the fmall-pox, for example, or in lues venerea, we perceive fomething more than fimple excitement and unvaried ftimulation. Individuals of every defcription, whether predifpofed to fthenia or afthenia, whether labouring under direct or indirect debility, may be infected; and when the difeafe has taken place, it runs its courfe under every poffible modification of the excitability, &c." (See Edinburgh Med. and Surg. Journal, vol. i. p. 369.) And again, with refpect to the agents of the Materia Medica, befides their action upon the excitability, or the degree of excitement and exhauftion which they produce, there are various other peculiarities in their mode of operation. "They differ in the fucceffion of phenomena to which they give occafion; the intoxication produced by wine, opium, and fome other narcotics, cannot be imitated by aromatics, by the preparations of antimony or of mercury; nor the effects of thefe by narcotics: they differ in their power of fpecifically affecting particular organs and functions, as the ftomach, inteftines, kidnies, fkin, falivary glands, abforbent or vafcular fyftem, by emetics, purgatives, diuretics, fudorifics, mercury, digitalis, &c. They differ in their power of oppofing and inducing particular organic changes and morbid affections of the fyftem; as fyphilis and biliary difeafes are cured by mercurials, fcurvy by vegetable acids, and uric difeafes by alkalis: they differ in the durability of effect or change produced; as is obvious by comparing the momentary and fleeting effects of the diffufible ftimuli, with the permanent excitement and vigour produced by tonics, as by cinchona and preparations of iron, by wholefome food and pure air." Loc. cit.

In fhort, it is obvious that the word ftimulant, as applied to all thefe various actions upon the living fyftem, no longer retains any definite meaning; but produces a jargon which may be interpreted by each individual according to his own notions. In this refpect, the theory poffeffes an univerfal fitnefs, like Bayes' prologue, and will do for any practice that may be found moft expedient. Thus mercury will be confidered as the proper *ftimulant* for fyphilis, cinchona and arfenic for intermittents, citric acid for fcurvy, and fo on; for fortunately mankind have ftill good fenfe enough to accommodate their hypothefes to the refults of experience: hence we do not apprehend, that many of the moft implicit believers in this jargon would endanger their patients by applying the fame remedies to typhus, gout, and dropfy, becaufe they ftand in the fame numerical portion of the fcale; or by treating phthifis, apoplexy, and the plague alike, becaufe they are claffed together in the fame way!

Notwithftanding its many inconfiftencies and defects, however, the Brunonian doctrine has had fome beneficial influence on medical fcience, by inducing a particular attention to the degree of excitement, which accompanies many difeafes, although it cannot be confidered as the caufe or effence of them. The regulation of the excitement often conftitutes the moft ufeful means of conducting thefe difeafes through their courfe to a fafe termination, by moderating fymptoms, and keeping action within due bounds on the one hand, or fupporting the languid forces of the fyftem on the other. This is efpecially true with regard to contagious febrile difeafes.

The doctrines of Brown are contained in the "Elementa Medicinæ," which were firft publifhed in Latin, and afterwards tranflated by himfelf. After his death a revifed edition of this tranflation was publifhed by Dr. Beddoes, in 2 vols. 8vo. 1795; and another by the author's fon, Dr. William Cullen Brown, in 3 vols. 8vo. in 1804. See Brown.

EXCITATION, (from the Latin *excito*, I excite,) denotes the act of awakening, of roufing, or of producing fome power or action; thus we hear of the excitation of motion, excitation of heat, excitation of paffions, &c. In natural philofophy this word is principally ufed in the fubjects of electricity and of heat; and of thefe two kinds of excitation the particulars are as follows.

When a piece of amber, or of glafs, or of fulphur, or in fhort, of any other folid, called *electric*, or *non-conductor*, is obferved in common, it does not appear to have any particular power; but if it be rubbed with a dry hand, or with fomething elfe, then after a few ftrokes it will be found that

that it has acquired the electric virtue, ſo that now it will attract ſmall bodies that are preſented to it, and it will alſo exhibit other electrical phenomena (for which ſee the article ELECTRICITY.) In this caſe the electric power in the amber, or glaſs, or ſulphur, is ſaid to have been *excited* by the friction of the hand or other body, which therefore is called the *rubber;* for, previous to the friction, the amber, or ſulphur, &c. ſhewed no ſigns of electricity, that power being, as it were, dormant in it.

Rubbing is the moſt general, and upon the whole, the moſt effectual method of exciting electrics, but there are ſeveral other modes of excitation, and indeed hardly any action, or any motion, takes place among natural bodies, which is not attended with the excitation of electricity. In general, however, the electricity is not produced in quantity ſufficient to affect our ſenſes, without the aid of proper inſtruments, and of courſe it paſſes unnoticed. The principal cauſes of the excitation of electricity are rubbing or friction, heating and cooling, melting or coagulating, evaporation and condenſation, expanſion and contraction, the mere juxtapoſition or contact of certain bodies, ſolution and efferveſcence, and laſtly ſome unknown action of the body in certain aquatic animals. But theſe methods are not indiſcriminately applicable to all ſubſtances. They are confined within certain limits of application as well as of effect; and of theſe particulars we ſhall now give a regular account.

Rubbing, or *friction*.—In the ſcience of electricity the various bodies of the earth are diſtinguiſhed into electric and conductors (ſee ELECTRICS and CONDUCTORS;) and whenever two bodies are rubbed againſt each other, unleſs they be both very good conductors, ſome electricity is always produced; that is, one of the bodies acquires the poſitive or vitreous, and the other acquires the negative or reſinous electricity; for by this means one kind of electricity cannot be produced without the other. The circumſtance which, in the ſuperficial manner of performing the experiment, makes it appear as if one kind only of electricity were produced, is that the beſt conductor of the two bodies concerned, being not inſulated, loſes its electricity as ſoon as it receives it; but when both bodies are inſulated, each of them will become electrified by the friction, one of them acquiring the poſitive, and the other the negative electricity. Even two inſulated perfect conductors, by the leaſt contact or friction againſt each other, acquire a ſlight degree of electricity; but of this hereafter. The friction which is required for this excitation of electricity is not that which can ſcrape off or injure the ſurface, but a gentle preſſure progreſſively applied with a pretty quick motion. The former hard kind of friction generates heat, but little or no electricity.

The very ſame body, by changing the rubber, may be cauſed to acquire either the poſitive or the negative kind of electricity; and the change is often produced by a remarkably ſlight alteration of circumſtances, ſuch as altering the direction of the friction, increaſing or diminiſhing the temperature by a few degrees, and ſo forth. The following table exhibits the principal caſes of this kind of change, *viz.* it ſhews what kind of rubber is required for exciting a given body poſitively, and what kind for exciting it negatively. Thus it appears that ſealing-wax acquires the poſitive electricity when rubbed with a metallic body, and that it acquires the negative electricity when rubbed with furs, leather, woollen cloth, &c. Thus alſo it ſhews that baked wood is excited poſitively by ſilk, and negatively by flannel.

Subſtance rubbed.	*Electricity.*	*Rubber.*
The fur on the back of a cat.	Poſitive	Every ſubſtance with which it has hitherto been rubbed.
Smooth glaſs.	Poſitive	Every ſubſtance hitherto tried, excepting
	Negative	The fur on the back of a cat.
Rough glaſs.	Poſitive	Dry oiled ſilk, ſulphur, metals.
	Negative	Woollen cloth, quills, wood, paper, ſealing-wax, white-wax, the human hand.
Tourmalin.	Poſitive	Amber, air, *viz.* by blowing with the bellows upon it.
	Negative	Diamond, the human hand.
Hare's ſkin.	Poſitive	Metals, ſilk, loadſtone, leather, hand, paper, baked wood.
	Negative	Other finer furs.
White ſilk.	Poſitive	Black ſilk, metals, black cloth.
	Negative	Paper, hand, hairs, weaſel's ſkin.
Black ſilk.	Poſitive	Sealing-wax.
	Negative	Hare's, weaſel's, and ferret's ſkin, the load ſtone, braſs, ſilver, iron, the human hand.
Sealing-wax.	Poſitive	Metals.
	Negative	Hare's, weaſel's, and ferret's ſkin, the hand, leather, woollen cloth, paper.
Baked wood.	Poſitive	Silk.
	Negative	Flannel.

When two electric ſubſtances, equal in every reſpect, are rubbed againſt each other, that ſubſtance which ſuffers the greater degree of friction acquires the *negative*, and the other acquires the *poſitive* electricity. Thus, if a piece of ſilk, A, be drawn acroſs another piece of ſilk, B, in every reſpect equal to A, ſo that the ſurface of the whole piece, A, (*viz.* of one ſide of it,) be ſucceſſively drawn over one part of the piece B, then A will acquire the *poſitive*, and B the *negative* electricity. The reaſon of this probably is the greater degree of heat which the rubbed part of B acquires by the friction, it having been obſerved by Bergman, that heat rather diſpoſes bodies to acquire the negative electricity.

Glaſs, when warmed a little, as about the temperature of 110° of Fahrenheit's ſcale, may be excited more eaſily and more powerfully than at a lower temperature. A great part of this effect probably depends upon the glaſs being leſs apt to attract moiſture in that elevated temperature.

Mr. Henly inſulated ſeveral bodies, and in that ſtate rubbed them, one by one, againſt his woollen garments, or againſt ſilk, by which means they became electrified; but he obſerved very great irregularities in the effects which were produced by fubftances much allied to each other, or of the fame clafs. Thus, a guinea, a fix-pence, and a piece of tin, became negative; a piece of copper, a fteel button, and a filver button, pofitive, at leaft when the cloth was warm; animal fubftances, excepting fhells, generally acquired the pofitive electricity; vegetables became almoft always negative; but the fmooth fkins of bears became pofitive; common pebbles, marble, coal, and jet, acquired the negative electricity; gems and cryftals, the pofitive; glazed wares and writing paper, the pofitive; tobacco pipe, elaftic gum, a tallow candle, oiled filk, Indian ink, and blue vitriol, (*viz.* fulphate of copper,) acquired the negative electricity. Other perfons have extended the lift confiderably farther, but it is ufelefs to fpecify the particulars.

The principal requifite in the fubject of electricity, is to determine the proper conftruction of the rubber, and the method of employing it, fo as to excite the greateft poffible power in a given electric.

The beft rubber for a tube of fmooth glafs, Mr. Cavallo fays, (Treatife on Electr.) is the rough fide of black oiled filk, efpecially when a little amalgam has been rubbed upon it; but the beft rubber for a rough glafs tube, a ftick of baked wood, fealing-wax, or fulphur, is foft new flannel. The rubbers of common electrical machines, wherein a glafs globe, or cylinder, or circular plate is revolved, has been varied and improved progreffively. The more common conftruction confifts of nothing more than a filk cufhion ftuffed with hair, over which is placed a piece of leather, and upon this leather fome amalgam, (fee AMALGAM *for electrical purpofes,*) is fpread fo as to adhere pretty faft to it. Some time ago it was cuftomary, (and the practice even at prefent is not entirely laid afide,) to make the rubber of red bafil fkin ftuffed with hair; but the abovementioned filk one, which was contrived by Dr. Nooth, is much preferable. If this filk cufhion, on account of adapting it to the furface of the glafs, is to be fixed upon a metallic plate, then care fhould be taken to render the plate free from fharp points, edges or corners, and it fhould be concealed or covered over with the filk. In fhort, to conftruct the rubber properly, it muft be made fo, that the fide of it which the furface of the glafs enters in whirling, may be as perfect a conductor as can be made, in order to furnifh an ample and ready fupply of electricity, and the oppofite part fhould be as much a non-conductor as poffible, in order that none of the electricity that has been accumulated upon the glafs may go back to the rubber. A piece of filk is generally fixed to the extremity of the leather which ftands againft the furface of the glafs. The rubber of Mr. Nairne's electrical machine (fee ELECTRICAL *Machine,*) confifts of filk only put over the leather cufhion, the piece of filk projecting a confiderable way beyond the cufhion, and very little amalgam is ufed with it: in truth no amalgam at all is put upon the rubber of this machine; but whilft the clean rubber is on, and the cylinder is turning, a piece of leather, with fome amalgam fpread upon it, is applied for a few feconds to the under part of the cylinder, by which means a fufficient number of particles of amalgam will fly along the furface of the glafs, from the leather to the rubber.

The rubber fhould be fupported by a fpring, by which means it may eafily adapt itfelf to the inequalities of the furface of the glafs, which, with cylinders, often are very confiderable. It fhould likewife be infulated in whatever manner it may be moft convenient; for whenever infulation is not wanted, a chain or wire may be occafionally hung upon it, by which means it will communicate with the ground, or with any other body at pleafure: when there is no poffibility of infulating the rubber, feveral of the moft interefting experiments in electricity cannot be performed with the machine.

Mr. Nicholfon made a great variety of experiments refpecting this mode of excitation, which are defcribed at large in the Philofophical Tranfactions for the year 1789, and from thofe experiments he deduces the following inferences.

"Thofe experiments," he fays, "fhew that the office of the filk is not merely to prevent the return of electricity from the cylinder to the cufhion, but that it is the chief agent in the excitation, while the cufhion ferves only to fupply the electricity, and perhaps increafe the preffure at the entering part. There likewife feems to be little reafon to doubt but that the difpofition of the electricity to efcape from the furface of the cylinder, is not prevented by the interpofition of the filk, but by a compenfation after the manner of a charge, the filk being then as ftrongly negative as the cylinder is pofitive; and, laftly, that the line of light between the filk and the cufhion in weak excitations, does not confift of returning electricity, but of electricity which paffes to the cylinder, in confequence of its not having been fufficiently fupplied, during its contact with the rubbing furface.

"When the excitation was very ftrong in a cylinder newly mounted, flafhes of light were feen to fly acrofs its infide, from the receiving furface to the furface in contact with the cufhion, as indicated by the brufh figure. Thefe made the cylinder ring as if ftruck with a bundle of fmall twigs: they feem to have arifen from part of the electricity of the cylinder taking the form of a charge. This appearance was obferved in a nine-inch, and a twelve-inch cylinder, and the property went off in a few weeks. Whence it appears to have been chiefly occafioned by the rarity of the internal air produced by handling, and probably reftored by gradual leaking of the cement."

In order to determine what takes place in the infide of the cylinder, Mr. Nicholfon undertook a feries of experiments with a plate machine, (fee ELECTRICAL *Machine,*) and from their refult it appears, "that no advantage is gained by rubbing both furfaces, but that a well-managed friction on one furface will accumulate as much electricity as the prefent methods of excitation feem capable of collecting; but that when the excitation is weak, on account of the electric matter not paffing with fufficient facility to the rubbed furface, the friction enables the oppofite furface to attract or receive it, and if it be fupplied, both furfaces will pafs off in the pofitive ftate, and either furface will give out more electricity than is really induced upon it, becaufe the electricity of the oppofite furface forms a charge. It may be neceffary to obferve, that I am fpeaking of the facts or effects produced by friction; but how the rubbing furfaces act upon each other to produce them, whether by attraction or otherwife, I do not here enquire."

From farther experiments with the cylinder, Mr. Nicholfon deduced the following conclufions; "the line, he fays, of light on a cylinder departing from a fimple cufhion, confifts of returning electricity. 2. The projecting part of the cufhion compenfates the electricity upon the cylinder, and by diminifhing its intenfity prevents its ftriking back in fuch large quantities as it would otherwife do. 3. That if there were no fuch compenfation, very little of the excited electricity would be carried off; and, 4. That the compen-

compenſation is diminiſhed, or the intenſity increaſed, in an higher ratio than that of the diſtance of the compenſating ſubſtance; becauſe if it were not, the electricity which has been carried off from an indefinitely ſmall diſtance, would never fly back from a greater diſtance, and from the edge of light.

"I hope the conſiderable intenſity I ſhall ſpeak of will be an apology for deſcribing the manner in which I produce it. I wiſh the theory of this very obſcure proceſs were better known; but no conjecture of mine is worth mentioning. The method is as follows:

"Clean the cylinder and wipe the ſilk.

"Greaſe the cylinder by turning it againſt a greaſed leather till it is uniformly obſcured. I uſe the tallow of a candle.

"Turn the cylinder till the ſilk flap has wiped off ſo much of the greaſe as to render it ſemi-tranſparent.

"Put ſome amalgam on a piece of leather, and ſpread it well, ſo that it may be uniformly bright. Apply this againſt the turning cylinder. The friction will immediately increaſe, and the leather muſt not be removed until it ceaſes to become greater.

"Remove the leather, and the action of the machine will be very ſtrong.

"My rubber conſiſts of the ſilk flap paſted to a leather, and the cuſhion is preſſed againſt the ſilk by a ſlender ſpiral ſpring in the middle of its back. The cuſhion is looſely retained in a groove, and reſts againſt the ſpring only in ſuch a manner, that by a ſort of libration upon it as a fulcrum, it adapts itſelf to all the irregularities of the cylinder, and never fails to touch in its whole length. There is no adjuſtment to vary the preſſure, becauſe the preſſure cannot be too ſmall when the excitation is properly made. Indeed, the actual withdrawing of the cuſhion to the diſtance of one-tenth of an inch from the ſilk, will not materially affect a good excitation.

"The amalgam is that of Dr. Higgins, compoſed of zinc and mercury. If a little mercury be added to melted zinc, it renders it eaſily pulverable, and more mercury may be added to the powder to make a very ſoft amalgam. It is apt to cryſtallize by repoſe, which ſeems in ſome meaſure to be prevented by triturating it with a ſmall proportion of greaſe: and it is always of advantage to triturate it before uſing."

The following curious fact may, perhaps, be referred to the action of friction.—If a ſtick of ſealing-wax be broken into two pieces, the fractured parts, that is, thoſe extremities of the pieces which were contiguous to each other, will be found electrified, one of them poſitively, and the other negatively.

Heating and cooling.—The property of exhibiting electrical phenomena by means of heating and cooling, was firſt obſerved in a hard ſemi-pellucid foſſil, known under the name of tourmalin (called *aſchentrickker* by the Dutch, from its property of attracting aſhes, &c. when laid near the fire. Linnæus, in his Flora Zeylonica, calls it *lapis electricus.*) This ſtone, which generally is of a deep red or purple colour, and ſeldom exceeds the ſize of a ſmall walnut, is common in ſeveral parts of the Eaſt Indies, and eſpecially in the iſland of Ceylon. Tourmalins are alſo found in a great many other parts of the world, and often in pretty large maſſes, but they are moſtly opaque, and then they hardly ever ſhew any peculiar electric properties. (See its mineralogical characters under the article TOURMALIN.) The tourmalin's properties with reſpect to electricity are as follows.

1. The tourmalin, while kept in the ſame degree of heat, ſhews no ſigns of electricity; but it will become electrical by increaſing or diminiſhing its heat, and ſtronger in the latter than in the former circumſtance. An exceedingly ſmall variation of temperature is often ſufficient to render it ſenſibly electrical.

2. The electricity of the tourmalin does not appear all over its ſurface, but only on two oppoſite ſides, which may be called its *poles*, and they are always in one right line with the centre of the ſtone, and in the direction of its ſtrata; in which direction the ſtone is abſolutely opaque, though on the other ſemi-tranſparent.

3. Whilſt the tourmalin is heating, one of its ſides (diſtinguiſhed by A) is electrified plus, or poſitively, and the other ſide B, minus; but when it is cooling A is minus, and B is plus.

4. If it be heated and ſuffered to cool without either of its ſides being touched, then A will appear poſitive, and B negative, all the time of its heating or cooling.

5. If this ſtone be excited by friction, like any other electric, then each of its ſides, or both at once, may be made poſitive.

6. If the tourmalin be heated or cooled upon ſome other inſulated body, that body will be found electrified as well as the ſtone; and will be found poſſeſſed of the electricity contrary to that which is acquired by that ſide of the ſtone which was laid upon it.

7. The electricity of each ſide, or of both, may be reverſed by heating or cooling the tourmalin in contact with various ſubſtances; thus if it be cooled, or heated, in contact with the palm of the hand, that ſide of it, which would have been poſitive if cooled in the open air, is now negative; and that which would have been negative is now poſitive.

8. If a tourmalin be cut into ſeveral parts, each piece will have its poſitive and negative poles, correſponding to the poſitive and negative ſides of the ſtone from which it was cut.

9. Theſe properties of the tourmalin are alſo obſervable in vacuo, but not ſo ſtrongly as in the open air.

10. If this ſtone be covered all over with ſome electric ſubſtance, as ſealing-wax, oil, &c. it will in general ſhew the ſame appearances with this coating as without it.

11. Mr. W. Canton obſerved a very vivid light upon the tourmalin while heating in the dark; and this is ſufficient to point out which end of the ſtone is become poſitive, and which negative. Alſo, when the ſtone is ſtrongly excited, it emits very ſtrong flaſhes from the poſitive to the negative end, in the dark. That ſtone which is commonly called the "Braſilian emerald" from its colour, but which in fact is a tourmalin, alſo emits the abovementioned electrical light.

12. Laſtly, it is to be remarked that the power of the tourmalin is ſometimes injured by the action of a ſtrong fire, at other times it is improved, and frequently it is not at all affected by it. The laws, however, of ſuch uncertain effects, have not yet been inveſtigated.

Moſt of the above-mentioned properties, which were firſt obſerved in the tourmalin, have been found to belong to ſome other bodies; *i. e.* there are ſome other ſubſtances which have the electric virtue excited in them by heating and cooling. It is to be obſerved that ſuch bodies are generally, if not always, in a cryſtallized ſtate; alſo it has been remarked that the parts which exhibit the different ſtates of electricity differ from each other with reſpect to their form, although they are ſimilarly ſituated: while in thoſe cryſtals that are not electric, the ſimilarly ſituated parts correſpond alſo in form. If a cryſtal, for inſtance, conſiſt of a priſm terminated at each extremity by a pyramid,

mid, and these pyramids differ as to the kind of electricity they are capable of acquiring, it will be found that they also differ in their form ; one consisting of a greater number of surfaces than the other ; and the part which has the greater number of faces acquires the positive electricity ; the other the negative. Kidd's Outlines of Miner. vol. i.

The Abbé Haüy says, that the electricity which is produced by heat has been observed in six species of minerals, *viz.* the tourmalin, the borated magnesia or boracite, the topaz, whether from Brazil, from Saxony, or from Siberia, the mesotype of Haüy, or zeolite, the prehnite, and the oxydated zinc, or electrical calamine. See the nature of these minerals under the articles of their peculiar names. We are informed, however, that lately a gentleman, highly versed in electrical experiments, examined a vast number of specimens of the above-mentioned six minerals, and among them, (independent of the tourmalin,) he found two only that became electrical by heating and cooling ; namely, the boracite and the oxydated zinc ; with respect to a specimen of the latter, which had a pyramid at one end, and was truncated at the other end, he particularly observed that whilst cooling, the pyramid became negative, and the truncated side positive ; but whilst heating, the pyramid became positive, though slightly so, and the truncated side did not manifest any sensible degree of electricity.

Melting or coagulating.—Melting or pouring a melted electric substance into another, excites electricity in various instances, and with peculiar phenomena.

If sulphur be melted in an earthen vessel, and be left to cool upon conductors ; then if taken out of the vessel, when cold, it will be found strongly electrical ; but not at all so, if it be left to cool upon electrics.

If sulphur be melted in glass vessels, and afterwards left to cool, they will both acquire a strong electricity, the sulphur negative, and the glass positive, whether they be left to cool upon electrics or upon conductors ; however, they always acquire a stronger power in the former case than in the latter ; and a stronger still, if the glass vessel is coated with metal. It is to be remarked, that the sulphur acquires no electricity till it begins to cool ; its power increases in proportion as it contracts, and is the strongest when in the state of greatest contraction ; but then the electricity of the glass vessel is at the same time the weakest.

If melted sulphur be poured into a vessel of baked wood, it acquires the negative electricity, and the wood the positive ; but if it be poured into sulphur, or rough glass, it does not acquire any sensible degree of electricity.

Melted sulphur poured into a metal cup, and there left to cool, shews no signs of electricity whilst remaining in the cup ; but if separated, they will then appear strongly electrified, the sulphur positively, and the cup negatively. If the sulphur is replaced in the cup, every sign of electricity will vanish, but, if whilst they are separate the electricity of either of them is taken off, then, on being replaced, they will both appear possessed of that kind of electricity which had not been taken off.

Melted wax, poured into glass or wood, acquires the negative electricity, and leaves the glass or wood positive. But sealing-wax poured into sulphur acquires the positive electricity, and leaves the sulphur negative. The wax-chandlers, in making their candles, often find it extremely difficult to prevent the attraction and adhesion of dust and other light bodies, in consequence of the electrified state of the wax.

Chocolate fresh from the mill, as it cools in the pans in which it is received, becomes strongly electrical. When turned out of the pans, it retains for some time this property, but soon loses it by handling. Mr. Henly, who made these observations upon chocolate, found that by melting it again in an iron ladle, and pouring it into the tin pans as at first, would for once or twice more renew its power ; but when the mass became very dry and powdery in the ladle, the electricity could no longer be revived by simple melting. However, he found that if in that state a little olive oil be added and mixed well with the chocolate in the ladle, then on pouring it into the tin pan as at first, the electric power will be found to be completely recovered.

Evaporation and *condensation.*—It was Mr. Volta who first discovered that the evaporation of water, and of most other bodies either solid or fluid that can be converted into smoke or vapour produced electricity, and not long after it was discovered that the condensation of vapour also produced electricity, but of the contrary kind. Thus when water is evaporated from an insulated vessel, that vessel remains electrified negatively, and if the vapour be received and condensed upon an insulated surface, that surface will acquire the positive electricity. These discoveries, besides their affording an easy explanation of the origin of the electricity in the clouds, fogs, &c. seem to point out a general law of nature ; namely, that the capacity of water or other fluids for holding the electric fluid, is increased by the expansion of those bodies into the form of vapour ; and is diminished by the contrary operation, *viz.* by the contraction of the vapour into the form of water. Therefore, in the first case, by imbibing an additional quantity of electric fluid the vapour would leave the bodies from which it departed in a negative state ; and in the second case, *viz.* in the conversion of vapour into water by giving out a quantity of electric fluid, would leave the bodies that touched it in a positive state. And this is analogous to what takes place with respect to caloric and vapour.

The easiest way of shewing the production of negative electricity by evaporation is, to place a metallic cup upon a delicate electrometer, and to put a red-hot coal in it ; then on pouring a few drops of water upon the coal, a sudden evaporation takes place, and the electrometer opens with negative electricity. In order to shew the positive electricity which is produced by the condensation of vapour, let a pretty long wire (*viz.* about a foot long) proceed from the top of the electrometer, and fix some pieces of paper to the farther end of the wire, then if the steam of water which issues out of the spout of a boiling kettle be directed towards the paper, the steam will be condensed upon it, and the electrometer will open with positive electricity.

The production of electricity by evaporation is not, however, always proportional to the quantity of evaporation ; for instance, when water is evaporated from certain substances it produces a considerable quantity of negative electricity, but when evaporated from certain other substances, it produces little of it or none at all. Thus the slaking of quicklime produces a copious evaporation, but no electricity ; and such is likewise the case with a few other substances.

All the experiments that were made, during some years subsequent to the original discovery, shewed, that if evaporation produced any electricity at all, this was of the negative kind ; but at last two remarkable exceptions from this general rule were discovered, *viz.* one by a learned professor of the academy of Mantua, and the other by Mr. Cavallo, and these exceptions seem to point out a more intimate connection between the electric fluid and other bodies.

The first of the above-mentioned gentlemen found that when water is evaporated by being poured over a red-hot piece of very *rusty* iron, it would leave the iron and vessel upon which

which it ſtood electrified poſitively; and the ſame would be the caſe if the red-hot piece of ruſty iron was thrown into the water: ſuppoſing that the latter is contained in an inſulated veſſel. If the iron be clean and free from ruſt, the electricity will be negative; if very ruſty, the electricity will be poſitive, and if partially ruſty, it will acquire little or no electricity; for in this laſt caſe the negative electricity which ariſes from the evaporation of water from over the clean part of the iron, is balanced by the poſitive electricity, which is produced by the evaporation from over the ruſty part. In conſequence of this, a ruſty piece of iron will not ſerve for more than one or two experiments, for, by rendering it red-hot, part of the ruſt is ſhaken off, and at laſt it will act like a piece of clean iron. Gardenii Diſſert. de Electrici Ignis Natura. § 84, 85, 86.

The other exception (which was diſcovered by Mr. Cavallo, and is publiſhed in the 4th edit. of his Treat. on El.) is ſhewn by means of red-hot glaſs. "The various degrees," Mr. C. ſays, "of electric powers that are produced by the evaporation of water from different ſubſtances induced me to diverſify the experiments as much as I could, in order to diſcover, if poſſible, the reaſon why thoſe different effects took place when the evaporation ſeemed to be equally quick and copious. Amongſt other ſubſtances I tried glaſs, and found that it generally produced little or no electricity. The water was ſometimes poured upon the hot glaſs, but in general the hot glaſs was dropped into the inſulated water which was contained in a tin cup. However, the difference of effect was found not to be occaſioned by thoſe two different modes of proceeding. Having repeated this experiment a great many times, I at laſt found that the effect depended upon the different nature of the glaſs. If white and clean flint glaſs be made red-hot, and in that ſtate be dropped into the veſſel of water, a quick evaporation will enſue, and the veſſel is electrified poſitively. If the flint glaſs be not very clear, there will not be any electricity generated by the evaporation. And, laſtly, if the experiment be tried with glaſs more impure, as that of which wine bottles are made, then the negative electricity will be produced.

"In performing this experiment, it is neceſſary to take care that no pieces of coal adhere to the glaſs, which will frequently happen when a piece of glaſs is heated in a common fire; for in that caſe negative electricity will be produced by the evaporation, though the beſt flint glaſs be uſed."

Expanſion and *contraction.*—The mere expanſion of parts produces electricity in various inſtances; ſuch as the diſperſion of powders by projection or blowing; and the electrometer is affected by the ſame. It is owing to this electrified ſtate of the powders, that ſeveral curious phenomena are exhibited by them, which could not otherwiſe be explained. Thus the configurations which are produced by projecting powders upon an electrophorus, or upon any electrified ſurface, are owing, in great meaſure, to this cauſe; thus alſo the duſt upon the roads when properly attended to is often found to expand itſelf more than it apparently ſhould, and to aſſume peculiar movements, in conſequence of its actual electrified ſtate, which may be eaſily diſcovered by means of a very delicate electrometer. For further particulars reſpecting this kind of excitation, ſee the article ELECTRICAL *Experiments*, and the deſcription of Mr. Bennet's gold-leaf electrometer, under the article ELECTROMETER. Mr. Cavallo, in his Treatiſe on Electricity, gives the following directions for exciting powders. "Inſulate," he ſays, "a metal plate upon an electric ſtand, and connect with it a cork-ball electrometer; then the powder which is required to be tried, being held in a ſpoon, or other thing, at about ſix inches above the plate, is to be let fall gradually upon it. In this manner the electricity acquired by the powder, being communicated to the metal plate, and to the electrometer, is rendered manifeſt by the divergency of the threads; and its quality may be aſcertained in the uſual manner."

"It muſt be obſerved, that if the powder is of a conducting nature, like the amalgam of metals, or ſand, &c. it muſt be held in ſome electric ſubſtance, as a glaſs phial, a plate of ſealing-wax, or the like. Sometimes the ſpoon that holds the powder may be inſulated; in which caſe, after the experiment, the ſpoon will be found poſſeſſed of the electricity contrary to that of the powder."

It is, however, proper to remark with reſpect to this kind of excitation, that the production of the electricity is in ſome meaſure due to the friction; for in the act of pouring any ſubſtance in powder from a plate, a veſſel, &c. a degree of friction between the latter and the former muſt neceſſarily take place.

Contact, or *juxtapoſition.*—That the mere contact of two perfect conductors would generate, or excite electricity, is a diſcovery of a very late date. Mr. Cavallo ſeems to have been the firſt who proved that by dropping a piece of metal upon another, a ſlight degree of electricity was thereby produced. (See the 4th edition of his Treatiſe on Electricity, publiſhed in 1795, third vol. Experiments on Metallic Subſtances.) Mr. Bennet alſo, independent of Mr. Cavallo's experiments, ſeems to have a claim to this diſcovery. The electricity thus produced was ſo very ſlight, that it could only be diſcovered by the niceſt methods; but it was the forerunner of a moſt aſtoniſhing diſcovery. In ſhort Mr. Volta, by repeating the contact of metallic ſubſtances, and at the ſame time expoſing them to the action of a ſaline ſubſtance, produced a moſt powerful electrical inſtrument, which has opened a new field of ample and promiſing aſpect, and has furniſhed the chemical philoſopher with the moſt active engine of decompoſition.

This, and the other modes of excitation that have been mentioned ſubſequent to it, *viz.* by means of ſolution, or efferveſcence, and by the action of the animal body, cannot be well explained, nor thoroughly underſtood, without a full, hiſtorical, and circumſtantial account of that new and admirable branch of electricity, which is now commonly called *Galvaniſm;* but which in juſtice ought rather to be called *Voltaiſm;* and as it would be uſeleſs to fill this Cyclopædia with repetitions, we muſt refer our readers to the articles of the two laſt mentioned denominations, wherein thoſe other modes of excitation are particularly deſcribed.

EXCITATION *of Heat.*—The temperature of bodies is raiſed either by the approach of a body hotter than themſelves, or by the extrication of heat from the bodies themſelves, occaſioned by ſome particular action or diſpoſition. The former of theſe methods of elevating the temperature is a mere communication of heat; for that principle continually tends to diſperſe itſelf amongſt ſurrounding bodies, until they all acquire the ſame degree of temperature. The latter is called the *excitation* of heat, ſince an elevation of temperature takes place amongſt bodies which were not hotter than the ſurrounding bodies a ſhort time before. Thus, when a perſon ſtands before a common fire, heat is ſaid to be communicated to him, but with reſpect to the fire itſelf, the heat is ſaid to be excited, or produced by that particular decompoſition of fuel which is called combuſtion. Thus alſo heat is excited by friction, by the mixture of water with ſulphuric acid, and by a great many others.

other means; but it is communicated by the rays of the fun.

The means by which various degrees of fenfible heat are produced and communicated, are not more than eight; *viz.* 1. Animal heat, or that power in animals which keeps them warm, and enables them to communicate heat to other bodies. 2. Compreffion. 3. Friction, or percuffion of hard bodies. 4. Electricity. 5. Mixture. 6. Fermentation, or putrefaction. 7. The fun's rays; and, 8. The inflammation of fuel. However, by excluding the confideration of the fun's rays for reafons already affigned; by comprehending animal heat, fermentation, and inflammation under the general denomination of decompofition; and by referring the action of electricity to friction; the various modes of exciting heat, which demand our confideration in the prefent article, may be reduced to four; namely, compreffion, friction, mixture, and decompofition, and even this number may be diminifhed by two, fince, as it will appear in the fequel, both friction and mixture may be comprehended under the head of compreffion; for in thefe two cafes the excitation of heat feems to be occafioned by the compreffion or concentration of the integrant parts. We fhall, however, for the fake of perfpicuity, treat diftinctly of the above-mentioned four modes.

The flattening or ftretching of metallic fubftances, whether it be effected by means of the hammer, or fcrew preffes, or flattening mills, or wire drawing, or any other fuch like means, is conftantly attended with an excitation of heat, and a compreffion of the metallic fubftance. The former of thefe effects is perceived by the feel, or, more accurately, by the thermometer; the latter by an increafe of fpecific gravity in the fubftance that has been operated upon. Not only the metals, but all other fubftances that are fufceptible of compreffion, fuch as wood, cotton, the aerial fluids, &c. are likewife heated by the fame means. On the other hand, water, hard ftones, and all fuch bodies as cannot be condenfed into a fmaller fpace, at leaft not in any confiderable degree, will not be heated by the above-mentioned means.

The heat, which is thus excited, differs in degree according to the nature of the fubftance, the violence of the preffure, and the quicknefs of the operation; thus a metallic fubftance, powerfully and quickly compreffed, becomes hotter than a piece of wood fimilarly treated, and hotter than if it were preffed gently or flowly; for with a gentle preffure little heat is excited, and when the preffure is applied flowly, the heat is diffipated nearly as faft as it is excited.

A dexterous blackfmith, by giving a dozen or twenty fmart ftrokes with a hammer, to the extremity of a flender iron rod upon an anvil, will render that extremity of the rod vifibly red-hot, even in the day light; and this is the way by which feveral blackfmiths light the fire of their forges when they go to work in the morning. With refpect to this operation, Dr. Black, in his Lectures, remarks, that the fame extremity of the iron rod cannot be rendered red-hot a fecond time by hammering, unlefs it be firft annealed, or foftened in the fire. "On account," he fays, "of this and other facts, I began to fufpect that malleability and ductility of metals depend on a certain quantity of latent heat exifting in them, which being extricated by hammering, the metals remain rigid, and require to be placed in the fire or annealed, in order to recover that latent heat."

A mixture of oxygen and hydrogen gafes, if compreffed, takes fire, and explodes with great violence. The mechanical condenfation of vapour, and of all the aerial fluids, is attended with a confiderable elevation of temperature. The condenfation of common air excites a confiderable degree of heat, and, when quickly performed, it fires a variety of combuftibles, fuch as cotton, charcoal previoufly warmed, tinder, &c.; and upon this principle a curious inftrument has of late been contrived, by which a candle or fire may be lighted. It is nothing more than a fmall fyringe, or little condenfer, about fix inches long, and not much above a quarter of an inch in diameter, (meaning the diameter of its cylindrical cavity.) It has a pifton, the rod of which comes out at one end, and a ftop-cock at the other end; this ftop-cock is not perforated quite through, but only little more than half way, fo that its cavity may either be expofed to the external air, or it may be turned towards the cylindrical cavity of the fyringe. The operation is performed in the following manner: the pifton is firft drawn out as far as the extremity of the fyringe, a little bit of *amadue*, (more commonly known by the name of German tinder,) is placed into the cavity of the ftop-cock, which is afterwards turned towards the cylindrical cavity of the fyringe; this done, the pifton is pufhed in quickly and forcibly, with one fmart ftroke, by which means the fudden condenfation of the air excites a degree of heat fufficient to fet fire to the tinder; and in fact if the ftop-cock be turned outwardly immediately, after having pufhed the pifton in, the tinder will be found burning, and a match may be lighted by it.

From a general confideration of the effects of compreffion, it appears that the caloric, or that principle to which the effects of heat are attributed, is contained within the pores of other bodies, fomewhat like water in the cavities of a fponge, and that by compreffing the body, part of that caloric is difengaged, and becomes fenfible heat. Thus when a mixture of oxygen and hydrogen gafes is quickly and forcibly condenfed, that operation forces the gafes to abandon a quantity of caloric, which becomes fenfible heat, and as it cannot be diffipated immediately, raifes their temperature to a degree fufficient for their inflammation. This explanation is corroborated by the converfe of the above operation, *viz.* by expanfion; for when gafes are expanded, they abforb an additional quantity of heat, which does not raife their temperature.

Friction is well known to excite heat, the degree of which differs in proportion to the nature of the bodies concerned, and the force which is employed. This effect of friction is fo commonly experienced, and fo generally ufed, as to require but little illuftration. Rubbing the hands againft each other, or againft any part of the body in order to excite heat, is a general practice. Filing, turning, grinding, ftriking a piece of fteel againft a flint, the motion of the axles of wheels in their holes, &c. are common and well-known inftances of friction, which excite heat. In thefe cafes the confideration of two remarkable circumftances forcibly lead us to conclude, that the heat is excited by the compreffion of the parts of the bodies concerned. One of the circumftances alluded to is, that compreffion is the neceffary confequence of friction; the other is, that fuch fubftances as are not compreffible, or the compreffibility of which is next to nothing, cannot be heated by means of friction.

Thus Dr. Irvine fays, in his Lectures, "The moft violent agitation of fimple fluids, fuch as water or mercury, will not fenfibly affect the thermometer. Heat is produced by agitation on thofe fluids which are compound, and whofe ftate of exiftence is changed by the agitation; fuch as milk, and the folution of certain falts in water."

It is afferted in Nicholfon's Journal for June 1808, that Dr.

Dr. Joseph Read found that by agitating water in a tin veffel, or in a glafs one for a few minutes, the temperature of that fluid was raifed about eight degrees, as it appeared from a thermometer left in it all that time. We are, however, ftrongly inclined to fufpect that this apparent refult was owing to fome fallacy in the mode of conducting the experiment.

It feems, therefore, moft probable, that friction produces a compreffion, and that the caloric is expelled from the bodies concerned, fo as to become fenfible heat, in confequence of that compreffion.

The greateft opponent to this hypothefis is count Rumford, who inftituted fome capital experiments, which are defcribed at large in the Philofophical Tranfactions, and in which he fucceeded to fet a quantity of water actually a boiling by the friction of metal againft metal. In fhort, the metal fubmitted to friction was encompaffed by water, and air was carefully excluded from the furfaces in motion; yet the water became hot, and was kept boiling a confiderable time. In this experiment the only obvious fource of caloric, from without, as the count imagines, was through the borer employed to produce the friction; if it be true, that the water could not at the fame inftant be in the act of giving out and receiving heat. Mr. Wm. Henry (Tranf. of the Manchefter Society, vol. v. p. 2.) reafoning upon this experiment of count Rumford, fays, "I cannot admit that the argument is demonftrative in proving the evolved caloric not to be derived from external fubftances; for no abfurdity is implied in fuppofing that a body may be receiving caloric in one ftate, and giving it out in another." Thus thefe gentlemen feem to exclude the action of the compreffion between the metallic bodies, which is occafioned by the friction, and upon which the whole effect feems moft probably to depend.

With refpect to this excitation of heat by means of friction, two ufeful practical confiderations naturally occur; *viz.* to determine which kinds of friction are capable of producing the greateft degree of heat, and in what manner the heat which arifes from the friction of the parts of machinery in general, may be prevented.

The production of heat, and of actual fire, by the friction of wood againft wood, feems to be the firft that occurs to the human being, fince the materials neceffary for it are to be met with every where, and do not require any previous preparation, excepting a trifling adaptation of fhape. In fact all rude nations that have any notion of fire, light their fires by this means. For this purpofe, a piece of wood is laid flat nearly in an horizontal fituation, and another flender piece of wood is rubbed with one extremity backward and forward over the furface of the former, until it excites heat enough to fet fire to the duft that has been abraded from the wood itfelf by the friction. Otherwife a blunt pointed piece of wood is held perpendicularly over an horizontal piece, with its point in a little cavity on the furface of the latter, and is worked therein, like a drill, by rolling it between the hands of the operator, after the manner of a chocolate mill. Though this operation may at firft fight appear to be eafy and fimple, and though it be readily performed by the individuals of rude nations; yet certain it is that the practice of it is not eafily acquired; and in fact there are very few perfons in Europe who are able to fucceed in it. Profeffor Bartholdi fays, that the beft kinds of wood for this purpofe are, box-wood rubbed againft mulberry, or laurel againft poplar, or againft ivy. But the ufe of this mode of exciting heat amongft all civilized nations is fuperfeded by the incomparably eafier, and much more effectual method, of ftriking a piece of fteel againft the edge of a filiceous ftone. In this operation fmall particles of the fteel are violently compreffed and fcraped off in an ignited ftate, fo as to fire tinder, gun-powder, &c. The very common and general ufe of this method, for domeftic conveniency, for gun-locks, &c. renders any farther defcriptions of it perfectly ufelefs.

We have ventured to refer the excitation of heat by electricity, to friction, in confideration that electricity does not excite any heat, unlefs it is actually paffing through bodies, which in fome meafure obftruct its free paffage. But we muft refer the reader for the farther confideration of this matter to the articles which relate to electricity.

It is a matter of great importance in mechanics to prevent, or, at leaft, to diminifh the heat which is excited by the friction of the parts of machinery in general; and for this purpofe the common practice is to interpofe fomething of a lubricating quality between the contiguous parts of machines, *viz.* fomething which may hinder the too intimate contact of the parts, and whofe particles are eafily feparated from each other. On various confiderations olive oil has been found fuperior to any thing elfe in metallic machinery, and efpecially in watch or clock-work, when fteel works in metal or in hard ftone. Where wood and metals work againft each other, hog's lard, or mutton-fuet or fuch other fat or greafe, is moftly ufed; and when wood works againft wood, then the powder of black lead is found to be the moft ufeful.

The heat which is excited by the mixture of certain bodies, comes next under confideration: the inftances of this kind are very numerous, and different degrees of heat may be excited by this means, as far as actual inflammation. The following are felected. If fpirit of wine be mixed with water, the mixture will inftantly become hot enough to be perceived not only by means of the thermometer, but likewife by the mere application of the human hand. This heat will be gradually diffipated, fo that in a few minutes' time that mixture will be found to have acquired the temperature of the furrounding bodies. On mixing a quantity of the ftrongeft fulphuric acid with an equal quantity of water, a degree of heat is excited which exceeds that of boiling water. If a mixture of nitric and fulphuric acids be poured upon an inflammable effential oil, fuch as oil of cloves, oil of turpentine, &c.; the latter is thereby fo heated as to burft out in flames. Water mixed with quick-lime excites a confiderable degree of heat. There is a kind of earth found in Derbyfhire, which is called *black-wad.* If a quantity of this earth, as about half a pound or more of it, be fprinkled over with linfeed oil, and be then left undifturbed, and expofed to the air, about an hour after it will be found in a ftate of incandefcence, burning fomewhat like fmall coal.

In all the cafes of the excitation of heat by the mixture of fluids, two remarkable circumftances deferve particular confideration. One is that the heat will be excited only when the fluids have a chemical action upon each other, fuch as between acids and water, fpirituous liquors and water, &c.; whereas, if oil be mixed with water, or water with quickfilver, no heat will be excited, becaufe no real mixture will take place among thefe bodies. The other circumftance is, that whenever heat is excited by the mixture of fluids, an incorporation, or a concentration of the fubftances is obferved; for it is always attended with a diminution of bulk. Thus a pint of alcohol and a pint of water, mixed together, will meafure lefs than two pints. Thefe circumftances feem to indicate, that the affinity, or the mutual attraction of the particles of the bodies concerned, occa-

fions

ſions a kind of compreſſion, in conſequence of which a certain part of the caloric is forced out, and becomes ſenſible heat.

The fourth cauſe of the excitation of heat is decompoſition; and under this head we muſt comprehend the origin of animal heat, fermentation, putrefaction, combuſtion, and all other proceſſes in which the heat is manifeſtly excited in conſequence of the decompoſition of compound bodies. But as theſe proceſſes will be found treated at large under the articles of their peculiar denominations; we ſhall here only add a few remarks on the heat which is produced by decompoſitions in general. In ſhort it ſeems that the caloric, like ſeveral other principles, enters more or leſs into the formation of compound bodies, and that in the decompoſition of theſe bodies, where certain principles are ſet at liberty, and other new combinations enſue, the caloric alſo undergoes its changes; *viz.* it is expelled from certain bodies, and is either ſet entirely at liberty ſo as to become ſenſible heat, or is partially reabſorbed, in which latter caſe but little heat is manifeſted. This liberation of caloric is ſometimes effected ſlowly, as in the proceſs of animal life, in fermentations, &c. or it proceeds ſo quickly and abundantly, as to occaſion actual inflammation. By the concurrence of various favourable circumſtances it happens, not unfrequently, that decompoſitions and ſpontaneous inflammations take place among bodies, which, in general, are not capable of producing ſuch phenomena. Thus, vegetable ſubſtances that have undergone torrefaction, being kept in ſacks of cloth in contact with the ambient air, as coffee, the meal of grain, French beans, &c. have ſometimes been known to take fire. The like effect is alſo produced by the generation of ſulphurated and phoſphorated hydrogen gas. The cauſe of ſubterraneous fires and volcanoes has in great meaſure been attributed to the decompoſition of pyrites, or metallic ſulphurets, buried in the interior of the earth. Theſe maſſes of pyrites are decompoſed by the contact and concurrence of water and air; and the decompoſition is always accompanied by a great extrication of caloric, and a diſengagement of a very inflammable gas, called *ſulphurated hydrogen gas*. This gas is inflamed at an elevated temperature, and communicates the inflammation to other combuſtibles that may be at hand.

With reſpect to the heat which is produced in combuſtions, ſeveral queſtions of economical uſe may be aſked, ſuch as the determination of the cheapeſt and moſt economical mode of employing fuel, the method of preventing the diſſipation of heat, &c. but theſe particulars will be found under the articles Fire, Fuel, and Heat.

EXCITEMENT, in Dr. Browne's ſyſten of *Medicine*, nearly ſynonymous with life. See Excitability.

EXCLAMATION, or Ecphonesis, in *Rhetoric*, a figure, wherein, by raiſing the voice, and uſing an interjection either expreſsly or underſtood, we teſtify an uncommon ardour, commotion, and paſſion of mind; and expreſs the magnitude of the thing, or the importance of the occaſion.

Such is, " O heavens! O earth!" &c. ſuch alſo is that of Cicero againſt Cataline: " O times! O manners! this the ſenate knows, the conſul ſees—and yet he lives! Lives, ſaid I? nay, and comes into the ſenate!"

In Engliſh the interjections O! or oh! alas! or good God! are generally adjoined in an exclamation. In Latin they uſe O! heu! eheu! ah! vah! pro ſuperi! pro ſuperûm atque hominum fidem!" Sometimes, however, the interjection is underſtood, as, Woe is me! Miſerum me! hoccine ſæculum!

Cicero uſes this figure to expreſs a variety of paſſions. It often denotes reſentment or indignation. Thus, after his return from baniſhment, he exclaims, (Pro Sext. c. 12.) " O mournful day to the Senate and all good men; calamitous to the ſtate, afflictive to me and my family; but glorious in the view of poſterity!" At other times it is uſed to expreſs diſdain or contempt. Thus, ſpeaking of Pompey's houſe, which was bought by Mark Antony, he ſays, (Philipp. II. c. 12.) " O conſummate impudence! Dare you go within that houſe! Dare you enter the venerable threſhold, and ſhew your audacious countenance to the tutelar deities which reſide there?" It is no leſs adapted to expreſs grief. Thus, Cicero ſays of Milo, (Pro Milone, ſub fin.) " O that happy country, which ſhall receive this man! ungrateful this, if it baniſh him! miſerable, if it loſe him!" It alſo ſerves to expreſs admiration, as when Cicero, in compliment to Cæſar, ſays, (Pro Ligur. c. 2,) " O admirable clemency! worthy of the greateſt praiſe, the higheſt encomiums, and moſt laſting monuments!" It has its uſe alſo in ridicule and irony. Thus Cicero, in his oration for Balbus, deriding his accuſer, exclaims, " O excellent interpreter of the law! maſter of antiquity! corrector and amender of our conſtitution!" The ſacred writers ſometimes uſe it by way of intreaty or wiſh, Pſ. lv. 6., and at other times in exultation and triumph, ſo St. Paul exclaims, (1 Cor. xv. 25.) " O death, where is thy ſting! O grave, where is thy victory!" It is frequently joined, as in ſome of the preceding inſtances, with the figure " Interrogation." It generally follows the repreſentation of the thing which occaſions it; though it is ſometimes uſed to introduce it, and thus it ſerves to prepare the mind by exciting its attention.

EXCLUSION, the act whereby a perſon or thing is excluded, *i.e.* ſhut out or ſet aſide. A crown imports an excluſion from the papacy: he appointed a ſtranger his heir, in excluſion of his own relations.

Great efforts were made towards the cloſe of the reign of king Charles II. to procure a bill of excluſion, for ſetting aſide the duke of York, the king's brother, on account of his being a papiſt. See Crown.

Exclusions, in *Mathematics*. The method of excluſions, is a way of coming at the ſolution of problems (in numerical caſes) by previouſly ejecting, or excluding out of conſideration, ſuch numbers as are of no uſe in ſolving the queſtion; whereby, of conſequence, the proceſs may be regularly and judiciouſly abbreviated.

EXCLUSIVE, is ſometimes uſed adjectively, for the force or power of excluding; as, a patent carries with it an excluſive privilege.

Sometimes it is alſo uſed adverbially; as, he ſent him all the Gazettes, from N° 195, to N° 300 excluſive; *i.e.* all between thoſe two numbers, which themſelves were excepted.

Exclusive *Propoſitions*, are thoſe wherein the predicate ſo agrees with the ſubject, as to agree with no other. See Proposition. *E. gr.* Virtue alone makes nobility: nothing elſe renders a man truly noble.

EXCŒCARIA, in *Botany*, from *excæco, to deprive of ſight*, becauſe, according to Rumphius, the ſailors who firſt landed on the iſlands of the Eaſt Indies, where this tree grows, were greatly incommoded, and ſometimes even entirely blinded, by the acrid juice which ſpirted forth, as they felled the wood for burning. Linn. Gen. 515. Schreb. 677. Juſſ. 390. Gærtn. t. 108. Claſs and order, *Diœcia Triandria.* Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juſſ.

Gen. Ch. Male, *Cal.* Catkin cylindrical, covered with florets. *Cor.* none. *Stam.* Filaments three, thread-ſhaped; anthers roundiſh. Female, *Cal.* Catkin as in the male. *Cor.* none. *Piſt.* Germen ſuperior, roundiſh, ſomewhat triangular;

angular; ſtyles three; ſtigmas ſimple. *Peric.* Capſule three-lobed, ſmooth, of three valves, each marked with a furrow, and three cells. *Seeds* ſolitary, ſmooth.

Eſſ. Ch. Male, Catkin naked. Perianth none. Corolla none. Female as in the male. Styles three. Capſule three-lobed. Seeds ſolitary.

E. *Agallocha.* Linn. Sp. Pl. 1451. (Arbor excœcans; Rumph. Amb. v. 2. 237. t. 79, 80.) Native of rocky, dry, and ſandy places about the coaſt in Amboina and other Eaſt Indian iſlands, flowering in January and February, as well as occaſionally at other ſeaſons. It forms a crooked inelegant tree. The *leaves* are alternate, elliptical, bluntiſh, ſmooth, more or leſs waved or bluntly crenate. *Catkins* cylindrical, lateral. *Capſules* the ſize of a pea. The acrid milk with which the tree abounds, cauſes the inhabitants of the countries where it grows to hold it in abhorrence; but Rumphius ſays it is chiefly dangerous to the eyes. The bark, as well as the milk, are uſed in medicine, being powerfully purgative. There ſeems to be no propriety in applying the Greek name αγαλλοχον, from Dioſcorides, to this tree.

How far the Cammetti, Rheede Hort. Malab. v. 5. 89. t. 45, is a diſtinct ſpecies from the above, we have not materials to decide. Its *leaves* are more pointed and leſs diſtinctly waved. Koenig gathered it by the ſea ſide on the coaſt of Coromandel, in low ground, overflowed during the rainy ſeaſon, which does not agree with what Rumphius relates of the foregoing.

Loureiro deſcribes what is probably another ſpecies, by the name of E. *cochinchinenſis*, in p. 612. of his Flora Cochinch. This, he ſays, has beautiful ſhining *leaves*, red underneath, for the ſake of which it is cultivated as an ornamental ſhrub. Its qualities are aſtringent and glutinous, nor did he ever hear of its being hurtful to the eyes.

EXCOMMUNICATION, an anathema, or eccleſiaſtical cenſure, and puniſhment; whereby a heretic is cut off from the ſociety of the faithful, or an obſtinate ſinner from the communion of the church, and the participation of the ſacraments.

This cenſure of excommunication was originally inſtituted for preſerving the purity of the church; but ambitious eccleſiaſtics converted it by degrees into an engine for promoting their own power, and inflicted it on the moſt frivolous occaſions.

The power of excommunication properly belongs to the biſhop; but he may delegate it to any grave prieſt, with the chancellor.

Every excommunication ſhould be preceded by three public admonitions, two days at leaſt diſtant from each other; but this is to be underſtood of excommunications impoſed by the eccleſiaſtical judge; for thoſe impoſed by the law are incurred to all intents and purpoſes the moment the action is committed.

Theſe latter are called excommunications *by the canon*, or *latæ ſententiæ*; and are ſo very numerous, that it would be difficult even for the beſt canoniſts to give an exact liſt of them; there are fifty in the Clementines; twenty in the bull *Cœna Domini*, &c. Wilkins's Mag. Brit. Conc. vol. iv. p. 664. Rebuffe, on the Concordat, reckons up ſixty penalties accruing upon excommunication.

Excommunication is founded on a natural right which all ſocieties have, of excluding out of their body ſuch as violate the laws thereof.

Excommunication is either *major* or *minor*, i. e. *greater* or *leſs*; the firſt, which is that underſtood when we ſay, ſimply, excommunication ſeparates, or cuts off, the delinquent, not only from the ſacraments, but from all communion and fellowſhip with other Chriſtians. The ſecond, or leſſer, only excludes from the participation of the ſacraments.

The greater excommunication, called alſo *ab homine*, is when a prelate, or his deputy, excommunicates any man perſonally, and interdicts him all ſociety with the faithful, all uſe of ſacraments, &c.

In the ancient church, the ſentences of the greater excommunication were ſolemnly promulged four times in the year, with candles lighted, bells tolling, the croſs, and other ſolemnities.

The leſſer excommunication is incurred *pleno jure*, by having any communication with a perſon excommunicated in the greater excommunication. And this too imports a privation of communion, but not an interdiction from entering the church, or having commerce with the faithful.

Anciently, the excommunicated were obliged to procure abſolution from their biſhop, and make ſatisfaction to the church in forty days' time; otherwiſe they were compelled to it by the ſecular judge, by a ſeizure of their effects, impriſonment of their perſons, &c. (See EXCOMMUNICATO *Capiendo.*) In France they were allowed a whole year.

By an edict of St. Louis, in the year 1228, vaſſals, tenants, &c. were diſpenſed, or freed from the oath of fidelity, homage, &c. they had taken to their lords, or ſuperiors, when excommunicate, till they had made their ſubmiſſion.

In Spain, to this day, a perſon who is not abſolved from his excommunication in a year's time is deemed a heretic. There was a time, when the people were fully convinced, that the bodies of excommunicated perſons, unleſs they were firſt abſolved, would not rot, but remain entire for ſeveral ages, a horrible ſpectacle to poſterity! as is atteſted by Matthew Paris, and other writers. And the Greeks are ſtill of the opinion, and affirm, they have many proofs thereof, as is ſhewn by Du-Cange, from the teſtimony of a vaſt number of authors.

By the laws, an excommunicated perſon was not to be buried, but the body flung into a pit, or covered with a heap of ſtones; which were called *imblocare corpus*. And by the rubric, in the Book of Common Prayer, the burial office ſhall not be read for any that die excommunicated. See FUNERAL, &c.

In the ancient church, there were diverſe degrees of excommunication. In effect, excommunication did not always import an interdiction of the ſacraments; but frequently, a ſeparation, or kind of ſchiſm, between the ſeveral churches, or a ſuſpenſion of ſpiritual communication between the biſhops. But afterwards the occaſions of excommunications growing more frequent, they began to uſe it with leſs circumſpection and reſervedneſs.

In the ninth century the eccleſiaſtics were continually making uſe of this ſpiritual weapon, to repel any violences or affronts offered them; and time and familiarity rendering offenders more and more obdurate, they proceeded, by degrees, to rigours unknown to antiquity; as the excommunicating of whole families, or provinces; prohibiting the exerciſe of all religion therein; and even accompanying the excommunications with horrible ceremonies, and direful imprecations.

In the tenth and eleventh centuries, the ſeverity againſt the excommunicated was carried to its higheſt pitch: nobody might come near them, not even their own wives, children, or ſervants; they forfeited all their natural legal rights and privileges, and were excluded from all kinds of offices. Thus was an excommunicated king reduced to the condition of a private man. By thus ſtretching the power of the church to extravagance, they rendered it contemptible. Gregory VII. tempered it a little; exempting the wives and children of excommunicated perfons from incurring excommunication by holding converfation with their hufbands and parents.

To render the excommunicated ftill more odious, the prieft was obliged to ftop, and break off divine fervice, if an excommunicated perfon entered the church; nothing of which averfion is any where difcovered in the practice of the primitive church. At prefent we have but little of the terror or refpect of our forefathers for excommunication; and it is even judged, and proclaimed, an abufe, whenever impertinently employed.

The form of excommunication in the Romifh church, as related by Fevret, is to take lighted torches, throw them on the ground with curfes and anathemas, and trample them out under-foot to the ringing of the bells.

"Auctoritate Dei Patris omnipotentis, et Filii, et Spiritus Sancti, et beatæ Dei genetricis Mariæ, omniumque fanctorum, excommunicamus, anathematizamus, et a limitibus fanctæ matris ecclefiæ fequeftramus illos malefactores, N. confentaneos quoque et participes; et nifi refipuerint, et ad fatisfactionem venerint, fic extinguetur lucerna eorum ante viventem in fæcula fæculorum. Fiat: Amen: Amen: Amen." Ex Emendat. Leg. Will. Conquæft.

We have now none of this folly; the fentence is gravely read, and the perfon remains excommunicated without farther ceremony. See the form of excommunication of the Englifh church in Concilia M. Brit. et Hib. vol. iv. p. 663, &c.

Petrus Blefenfis affures us, that in England it was anciently the practice only to excommunicate fuch as had killed an ecclefiaftic; whereas they were put to death who had killed a layman. But the reafon was, they held excommunication a greater punifhment than death.

The caufes with us are contempt of the bifhop's court, herefy, neglect of coming to church, and of receiving the facrament, incontinency, adultery, fimony, &c.

But if the judge of any fpiritual court excommunicates a man for a caufe of which he hath not the legal cognizance, the party may have an action againft him at common law, and he is alfo liable to be indicted at the fuit of the king. (2 Inft. 623.) With us by the common law an excommunicated perfon is difabled to do any act, that is required to be done by one that is "probus et legalis homo." He cannot ferve on juries, cannot be a witnefs in any court, and cannot bring an action, either real or perfonal, to recover lands or money due to him. (Litt. § 200.) Befides, if, within 40 days after the fentence has been publifhed in the church, the offender does not fubmit and abide by the fentence of the fpiritual court, the bifhop may certify fuch contempt to the king in chancery; upon which there iffues out a writ *De* EXCOMMUNICATO *capiendo*; which fee.

We have inftances of bifhops, who have pronounced formal excommunications againft caterpillars, and other infects, after a formal juridical procefs againft them, wherein thofe animals were allowed an advocate, and proctor to defend their caufe. See EXORCISM.

Fevret relates divers inftances of fuch excommunications againft rats, mice, and other animals, for infefting a country. See the form of thefe excommunications in that author, Traité de l'Albus.

In the ancient church there were two different kinds of excommunications in ufe; the one called *medicinal,* whereby perfons convicted of a crime by their own confeffion, were removed from communion; the other, called *mortal,* was fulminated againft rebels, who perfifted obftinately in their errors and impieties.

The power of excommunicating was lodged in the whole church in general; that is, the bifhops and priefts had the adminiftration thereof by and with the confent of the people, which was practifed even in St. Cyprian's time. But afterwards they ceafed to confult the people about the matter; the bifhop and clergy arrogated the whole power to themfelves. Recourfe, however, might ftill be had to the fynod of the province, to judge of the validity of an excommunication.

EXCOMMUNICATION was alfo practifed among the Jews, who ufed to expel from their fynagogue fuch as had committed any grievous crime. See the Gofpel according to St. John, ix. 22. xii. 42. xvi. 2. And Jofeph. Antiq. Jud. lib. ix. cap. 22. and lib. xvi. cap. 2.

The Effeni, when excommunicated, durft not fo much as receive food at any perfon's hand, for fear of violating their oath, but contented themfelves to live on herbs; infomuch that they frequently perifhed and died for want. See Jofeph. de Bell. lib. ii. cap. 12.

Godwyn, in his Mofes and Aaron, diftinguifhes three degrees, or kinds, of excommunication among the Jews. The firft he finds intimated in St. John ix. 22. The fecond in St. Paul Epift. 1 Cor. v. 5. And the third, in the 1ft Ep. to Corinth. xvi. 22. See NIDDUI.

The rule of the Benedictines gives the name excommunication to the being excluded from the oratory, and the common table of the houfe in our inns of court called *difcommoning.* This was the punifhment of fuch monks as came too late.

EXCOMMUNICATION, or a being fecluded, or cut off from a participation in the myfteries of religion, was alfo in ufe under paganifm.

Such as were thus excommunicated were forbidden to affift or attend at the facrifices, or to enter within the temples; and were afterwards delivered over to the dæmons and furies of hell, with certain imprecations; which was called among the Romans, *diris devovere.* See EXECRATION.

The Druids, among the ancient Britons and Gauls, likewife made ufe of excommunication againft rebels; and interdicted the communion of their myfteries to fuch as refufed to acquiefce in their decifions. See DRUIDS.

That this is the true origin of the extenfive and horrid influence of the European and papal excommunication, will appear evident by the following paffage of Cæfar, De Bello Gallico, lib. vi. cap. 13. "Si qui aut privatus aut publicus Druidum decreto non ftetit, facrificiis interdicunt. Hæc pœna apud eos eft graviffima. Quibus ita eft interdictum, in numero impiorum et fceleratorum habentur, ab iis omnes decedunt, aditum eorum fermonemque defugiunt, ne quid ex contagione incommodi accipiant; neque iis petentibus jus redditur, neque honos ullus communicatur."

EXCOMMUNICATO CAPIENDO, fo called from its effects, or *Significavit,* thus denominated from the bifhops' certificate, a writ directed to the fheriff, for the apprehenfion of one who ftands obftinately excommunicated the fpace of forty days.

Such a one not feeking abfolution, hath, or may have, his contempt certified into the chancery; whence this writ iffues for taking him up and imprifoning him in the county gaol, without bail or mainprize, until he is reconciled to the church, and fuch reconciliation is certified by the bifhop.

EXCOMMUNICATO *Deliberando,* is a writ directed to the under fheriff, for the delivery of an excommunicated perfon out of prifon; upon certificate of the ordinary of his conformity to the ecclefiaftical jurifdiction F. N. B. 62.

EXCOMMUNICATO *Recipiendo,* is a writ whereby perfons excommunicated,

excommunicated, being for their obſtinacy committed to priſon, and unlawfully delivered from thence before they have given ſecurity to obey the authority of the church, are commanded to be ſought for and laid up again.

EXCORIATION, in *Surgery*. A part is ſaid to be excoriated, when it is deprived of its cuticle, by reaſon of inflammation, the action of irritating matter, or of ſtimulating ſubſtances, &c. applied to the ſkin.

Very ſuperficial ulcerations are, alſo, frequently denominated excoriations.

In conſequence of inattention to cleanlineſs, and not occaſionally waſhing away the ſebaceous ſecretion, which is naturally produced under the prepuce, the matter acquires an irritating acrid quality, brings on inflammation all round the corona glandis, followed by extenſive excoriations and ſuppuration. This ſort of caſe is ſeriouſly annoying to the patient, on account of the violent itching, and troubleſome ſoreneſs, which always attend the complaint. The diſorder has ſometimes been named the *falſe gonorrhœa*, and the patient is often rendered very uneaſy in his mind by an apprehenſion of the affection being venereal. Indeed, ignorant and careleſs practitioners have occaſionally miſtaken mere excoriations for chancres, and, quite improperly, have preſcribed a courſe of mercury.

The proper treatment conſiſts in waſhing away all the acrid ſecretion under the prepuce with ſome ſoap-ſuds; injecting under the ſame part, four or five times a day, the ſaturnine lotion; and keeping linen, wet with this application, round the extremity of the penis. The excoriations, if very bad, are to be dreſſed with the ſaturnine ointment. The prepuce, if much ſwelled, and in a ſtate of phymoſis, ſhould have two or three leeches put upon it; but the principal means of cure is attention to keeping the parts clean, and tenderly waſhed with plenty of ſoap once or twice a day. As in all other caſes of inflammation the bowels ought to be kept open.

Excoriation of the nipples is a moſt diſtreſſing complaint. It is more common in the firſt, than the ſubſequent nurſings, and when independent of any diſeaſe in the child's mouth, is owing to the irritation occaſioned by the ſuction.

In many inſtances, a cure may be effected by bathing the parts with a little port wine, or brandy. A more effectual remedy is ſaid to be the tincture of opium.

EXCORTICATION, the act of ſtripping off the cortex or bark from any thing; called alſo decortication.

EXCREMENT, in *Chemiſtry*. See FECES.

EXCREMENT, in *Phyſiology*, is the reſidue of our food, after the nutritious particles have been extracted from it, and it has undergone certain changes by its reſidence in the large inteſtine. See DIGESTION.

EXCREMENT is alſo attributed, by way of analogy, to plants. Thus gums, diverſe juices, balms &c. iſſuing ſpontaneouſly from their reſpective trees, are ſometimes called excrements.

EXCRESCENCE, in the language of *Surgery*, implies a preternatural protuberance, or any morbid growth, which *projects out of* the ſubſtance or ſurface of a part. When the diſeaſe is involved in the ſurrounding fleſh, though it may be attended with a conſiderable ſwelling, it does not rank as an excreſcence, which word eſſentially ſignifies that the tumour, or whatever the diſeaſe is, *grows out of* the part. Funguſes, polypi, and warts of all kinds, are very often, and with ſtrict propriety, denominated excreſcences.

Excreſcences, of the nature of warts, are particularly apt to grow about the anus. Some of them are generally regarded by ſurgical authors as venereal complaints, becauſe they ſometimes get well under a courſe of mercury. This, however, is a very fallacious criterion of a diſeaſe being ſyphilitic; for mercury is a cure for numerous affections beſides venereal ones. Some ſurgeons have doubted whether there is any ſuch thing as a really venereal excreſcence; and as far as our obſervations extend, all thoſe warty growths which ariſe about the anus and perinæum, and are commonly reputed to be of a ſyphilitic nature, may be cured upon the ſame principles as any other ordinary tumours, not of a ſpecific kind.

Excreſcences in general, not being original parts of the body, are known to be weak in the vital power, and to be incapable of bearing the action of ſuch ſtimulating applications as would not deſtroy a part, which may be ſaid to enter into the natural compoſition of the body. Hence it is, that ſprinkling on warty excreſcences a powder, conſiſting of ſavin and ærugo æris, in equal proportions, generally effects a cure. The ſwellings are partly diminiſhed by abſorption, and partly by ſloughing. We have never ſeen about the anus any excreſcences which could withſtand this application.

But the plan which we particularly recommend to be adopted, when ſuch excreſcences are large and numerous, as they frequently are, is to remove them at once with a knife, or a pair of ſciſſars. When they grow from a narrow neck, their deſtruction might be accompliſhed by tying them with a ligature. The latter method, indeed, is often practiſed by ſurgeons who are fearful of hæmorrhage, or whoſe patients have a remarkable dread of a cutting inſtrument, even in caſes in which the object could be fulfilled much more eaſily, and with leſs pain, by means of exciſion; that is to ſay, in examples in which the baſe of the ſwellings is rather broad. Indeed, where the excreſcences are connected with the ſkin by a wide root, the mode of removing them with a ligature becomes exceedingly troubleſome and painful; for the practitioner is firſt under the neceſſity of introducing, through the centre of their baſe, a needle armed with a double ligature. The needle being cut off, one ligature is then to be firmly tied over one ſide of the root of the tumour, and the other over the oppoſite one. In this manner the ſupply of blood to the excreſcence is ſuppreſſed, and the part ſloughs away. Sometimes when the baſe of the diſeaſe is very broad, and the ligature has not been applied with due tightneſs, it becomes neceſſary to apply another one, the doing of which is attended with as much, if not more, pain than the firſt operation.

Upon the whole, when the excreſcences are ſmall, we prefer ſtimulating them with the powder of ſavin and ærugo æris; when they are large, we recommend extirpating them with a cutting inſtrument.

EXCRETION, from *excerno*, *I throw off*, or *ſeparate*, is the ſeparation of any ſuppoſed noxious matter from the blood in any of the organs of the animal body. The proceſs itſelf is not eſſentially different from that of ſecretion. But the latter term is applied to thoſe ſubſtances which, when formed, are applied to uſeful purpoſes in the animal economy. Thus the mucus of mucous membranes imparts to them a neceſſary moiſture, and defends them from the action of the foreign matter which comes in contact with them; the ſerous exhalation of ſerous membranes preſerves them conſtantly ſmooth and poliſhed, and therefore in a fit ſtate for their oppoſed ſurfaces to move without any obſtacle, &c. The excretions are matters ſuppoſed to be noxious to the body, and to be ſeparated on that account, as the urine, bile, perſpiration, &c. The matters voided from the large inteſtine, conſiſting of the reſidue of our food, are often called the alvine excretions.

EXCRETORY, is applied to certain little ducts or veffels in the fabric of the glands.

Excretory ducts are the tubes through which the humours feparated in the feveral glands are emitted or difcharged out of the gland, into fome convenient receptacle or emunctory.

A capillary artery, to which a capillary vein is joined, with an excretory duct, convolved or wound together, make up the body of the glands, the organs of fecretion. The excretory ducts fpring from the extremities of the arteries and veins, and carry off a liquor feparated from the blood. Drake.

The lymphatic glands have either lymphæducts for their excretory ducts, or lacteal veffels, as in the mefentery. Idem.

EXCURSION, in *Aftronomy*. See ELONGATION.

EXCURSION, *circles of*. See CIRCLES.

EXCUSABLE HOMICIDE. See HOMICIDE.

EXCUSATI, in *Church Hiftory*, a term ufed to denote flaves, who, flying to any church for fanctuary, were excufed and pardoned by their mafters; but thefe were obliged to take an oath to that purpofe, before they could have them again; and if they broke the oath, they were punifhed and fined as perfons guilty of perjury.

EXDORF, in *Geography*, a town of Germany, in the county of Henneberg; 7 miles S.E. of Meinungen.

EXE, a river in England, has its origin among the wild eminences of Exmoor, in the weftern corner of Somerfetfhire, and after uniting with the Barle, enters the confines of Devonfhire, near Exe bridge; thence flowing near Bampton, it finks into a rich wooded vale, and paffing Tiverton, has its current increafed by the ftreams of the Loman. Soon after, the Creedy, from Crediton, in the north-weft, and the Culm, or Columb, from Cullumpton, in the north-eaft, intermingle their waters with the Exe, and the vale expanding, opens into a beautiful plain, encircled by towering eminences, clothed with wood. Paffing Exeter, the river proceeds through a fine range of meadows to Topfham, where meeting the tide, and fuddenly widening to an extent of more than a mile, it becomes navigable for veffels of feveral hundred tons burthen. Hence fpreading into a grand eftuary, it rolls onward; but its direct courfe being impeded by a vaft fand-bank, called the Warren, it winds to the eaftward, and flows into the Britifh channel near Exmouth, its whole courfe being about 60 miles. See CANAL.

EXEA DE LOS CAVALLEROS, an inconfiderable town of Spain in the province of Aragon, feated between two rivulets, in the northern part of the province. Its furname commemorates the bravery of fome French and Gafcogne cavalry, when Alphonfo I. king of Aragon, took it from the Moors. N. lat. 42° 6'. W. long. 1° 9'.

EXEAT, in *Church Difcipline*, a Latin term ufed for a permiffion which a bifhop grants a prieft to go out of his diocefe; or an abbot to a religious, to go out of his monaftery.

The word is alfo ufed in feveral great fchools for leave given a fcholar or ftudent to go out. His mafter has given him an exeat.

EXECRATION, EXECRATIO, among the *Ancients*, a kind of punifhment, confifting of direful curfes and marks of infamy. Livy relates an inftance of it, which was ufed againft Philip king of Macedon, by the Athenians. A general affembly of the people being called, they made a decree, that all the ftatues and images of that king, and of all his anceftors, both of the male and female fex, fhould be demolifhed, and their very names rafed; that all the feftivals, facred rites, priefts, and whatever elfe had been inftituted in honour of him, fhould be profaned; that the very place where there had been any monument or infcription to his honour, fhould be deteftable, and that nothing fhould be fet up, or dedicated in them, which could be done in clean places; and, laftly, that the public priefts, as often as they prayed for the Athenian people, allies, armies, and fleets, fhould as many times deteft and execrate Philip, his children, kingdom, land, and fea forces, and the whole race and name of the Macedonians.

Cornelius Nepos, in his life of Alcibiades, calls it *devotion*.

At the taking or demolifhing of a city, it was frequent to pronounce direful curfes and execrations upon any perfon who fhould endeavour to rebuild it; which fome imagine was the reafon that Troy could never be raifed out of its afhes, though feveral perfons attempted it, being devoted to eternal and irreparable ruin by Agamemnon. This feems to have been a very ancient cuftom, and derived from the Eaftern nations; for we find Jofhua, at the deftruction of Jericho, to have fixed an imprecation upon the perfon who fhould rebuild it, which was thought to be accomplifhed in Hiel the Bethelite many ages after. Potter, Archæol. tom. ii. p. 97.

EXECREBRONCHOS, in *Surgery*, from ἐξέχω, *to abound*, and βρόγχος, *a throat*, a term which probably fignified a fwelling of the thyroid gland, which affection is now almoft always named bronchocele.

EXECUTANT, Fr. in *Mufic*, a participle ufed fubftantively. A mufician or performer who executes his part in a band, in the fame fenfe as concertant implies a performer in a concert. See CONCERTANT, EXECUTER, and EXECUTION.

EXECUTED *Contract*, *Eftate*, *Fine*, and *Remainder*. See the fubftantives.

EXECUTER, *Fr.* to execute, play, fing, or perform a compofition, or piece of mufic, in all its parts, whether vocal or inftrumental, and to let every note and paffage be heard agreeable to the notation in the fcore.

As mufic is an object for the ear, it can only be judged by its effects in the execution. Many pieces of counterpoint look correct and learned on paper, which no real judge can hear without difguft; and others that look thin, fimple, and common, which in the execution afford the higheft pleafure, by unexpected effects. Vulgar compofers, attentive to fymmetry and the filling up all the parts, often appear to be great contrapuntifts, while they are judged merely by the eyes; and fuch compofers often have the addrefs to employ fo many different inftruments, and fuch a number of parts in their mufic, that it is with great difficulty a fufficient band can be collected to do it juftice in the execution. Rouffeau.

EXECUTION, the act of executing, *i. e.* of accomplifhing, finifhing, or atchieving any thing to be done.

We fay, the execution of a teftament; of a law; of a treaty; of a building, or the like.

EXECUTION, in *Common Law*, fignifies the laft performance of an act; as of a writ, a judgment, or the like.

EXECUTION *of a judgment*, denotes the putting of the law in force, or it is the obtaining the poffeffion of any thing recovered by judgment of law.

This is performed in various ways, according to the nature of the action upon which it is founded, and of the judgment which is had or recovered. If the plaintiff recovers in an action real or mixed, whereby the feifin or poffeffion of land is awarded to him, the writ of execution fhall be an *habere facias feifinam*, or writ of feifin, of a freehold; or an *habere facias poffeffionem*, or writ of poffeffion, of a chattel intereft. (Finch. L. 470.) Thefe are writs directed to the fheriff of the county, commanding him to give actual poffeffion to the plaintiff, of the land fo recovered; in the execution of which the fheriff may take with him the *poffe comitatus*, or power of the county, and may juftify breaking open doors, if the poffeffion be not quietly delivered. But if it is peaceably yielded up, the delivery of a twig, a turf, or the ring of the door, in the name of feifin, is fufficient execution of the writ. Upon a prefentation to a benefice recovered in a *quare impedit*, or affife of *darrein prefentment*, the execution is by a writ *de clerico admittendo;* directed not to the fheriff, but to the bifhop or archbifhop, and requiring him to admit and inftitute the clerk of the plaintiff. In other actions, where the judgment is, that fomething fpecial be done or rendered by the defendant, then, in order to compel him fo to do, and to fee the judgment executed, a fpecial writ of execution iffues to the fheriff, according to the nature of the cafe. As, upon an affife of nufance, or *quod permittat profternere*, where one part of the judgment is *quod nocumentum amoveatur*, a writ goes to the fheriff to abate it, at the charge of the party, which likewife iffues even in cafe of an indictment. (Comb. 10.) Upon a replevin, the writ of execution is the writ *de retorno habendo;* and if the diftrefs be eloigned, the defendant fhall have a *capias in withernam;* but on the plaintiff's tendering the damages, and fubmitting to a fine, the procefs *in withernam* fhall be ftayed. (2 Leon. 174.) In detinue, after judgment, the plaintiff fhall have a *diftringas*, to compel the defendant to deliver the goods, by repeated diftreffes of his chattels, (1 Roll. Abr. 737. Raft. Entr. 215); or alfo a *fcire facias* againft any third perfon in whofe hands they may happen to be, to fhew caufe why they fhould not be delivered; and if the defendant ftill continues obftinate, then (if the judgment hath been by default or on demurrer) the fheriff fhall fummon an inqueft to afcertain the value of the goods, and the plaintiff's damages; which (being either fo affeffed, or by the verdict in cafe of an iffue, Bro. Abr. tit. *Damages*, 29.) fhall be levied on the perfon or goods of the defendant.

Executions in actions, where money only is recovered, as a debt or damages, (and not any fpecific chattel,) are of five forts: either againft the body of the defendant; or againft his goods and chattels; or againft his goods and the *profits* of his lands; or againft his goods and the *poffeffion* of his lands; or againft all three, his body, lands, and goods. The *firft* of thefe fpecies of execution is by writ of Capias *ad fatisfaciendum*, which fee. This writ is an execution of the higheft nature, inafmuch as it deprives a man of his liberty, till he makes the fatisfaction awarded. When a defendant is once in cuftody upon this procefs, he is to be kept in *arcta et falva cuftodia;* and if he be afterwards feen at large, it is an *efcape*, which fee; and the plaintiff may have an action thereupon againft the fheriff for his whole debt. If a *capias ad fatisfaciendum* be fued out, and a *non eft inventus* is returned thereon, the plaintiff may fue out a procefs againft the bail. The *fecond* fpecies of execution is againft the goods and chattels of the defendant, and is called a writ of Fieri *facias*, which fee. A *third* fpecies of execution is by writ of Levari *facias*, which fee. This affects a man's goods and the *profits* of his lands. This writ is now little ufed, the remedy by *elegit* being much more effectual. This writ of *elegit* is the *fourth* fpecies of execution. Moreover, upon fome profecutions given by ftatute, as in the cafe of recognizances or debts acknowledged on ftatutes merchant, or ftatutes ftaple; (purfuant to the ftatutes 13 Ed. I. *de Mercatoribus*, and 27 Ed. III. c. 9.) upon forfeiture of thefe the body, land, and goods may all be taken at once in execution, to compel the payment of the debt. This procefs is the *fifth* fpecies of execution, and is ufually called an *extent*, or *extendi facias*, which fee. It is to be obferved, that all thefe writs of execution muft be fued out within a year and a day after the judgment is entered, otherwife the court concludes *prima facie*, that the judgment is fatisfied and extinct; yet, however, it will grant a writ of *fcire facias*, in purfuance of ftatutes Weftm. 2. 13 Edw. I. c. 45. for the defendant to fhew caufe why the judgment fhould not be revived, and execution had againft him; to which the defendant may plead fuch matter as he has to allege, in order to fhew why procefs of execution fhould not be iffued: or the plaintiff may ftill bring an action of debt, founded on this dormant judgment, which was the only method of revival allowed by the common law. (Co. Litt. 290.) Blackft. Comm. B. III.

Sir Edward Coke, in his Reports, makes two forts of executions; one *final*, another with *a quoufque*, as only tending to an end.

Execution *final*, is that which maketh money of the defendant's goods, or extendeth his lands, and delivers them to the plaintiff; which he accepts in fatisfaction; and this is the end of the fuit, and all that the king's writ commands to be done.

Execution *with a quoufque*, is that which only tends to an end; as in the cafe of a *capias ad fatisfaciendum*, &c. This is not final; but the body of the party is to be taken, to the intent and purpofe to fatisfy the plaintiff; and his imprifonment is not abfolute, but till he doth fatisfy; fo that the body is but a pledge for the debt. 6 Rep. 87.

Execution, *Tenant by*. See Tenant.

Execution *of criminals*, muft be according to judgment; and the king cannot alter a judgment from hanging to beheading, becaufe no execution can be warranted, unlefs it be purfuant to the judgment. (3 Inft. 52. 211. H. P. C. 252.) But there are ancient precedents wherein men condemned to be hanged for felony, have been beheaded by force of a fpecial warrant from the king. (Bract. 104. Staundf. 13.) And the king may pardon part of the execution in judgment for treafon, *viz.* all but beheading. It has been faid by fir Edward Coke, and fir Matthew Hale, that the king cannot change the punifhment of the law, by altering the hanging or burning into beheading. But others have thought (Foft. 270. F. N. B. 244.), and as judge Blackftone fays, more juftly, that this prerogative being founded in mercy, and immemorially exercifed by the crown, is part of the common law. The court may command execution to be done without any writ; (Finch, L. 478.) though fometimes execution is commanded by writ. (2 Hawk. P. C. 463.) Judgment belongs to the judge; but the execution may be done by the fheriff, or his deputy; and an execution cannot be lawfully made by any but the proper officer, whofe warrant for fo doing was anciently by precept of the judge under his hand and feal; as it is ftill practifed in the court of the lord high fteward, upon the execution of a peer; (2 Hal. P. C. 409.) though in the court of peers in parliament, it is done by writ from the king; and if the fheriff, or other officer alters the execution, or any other executes the offender, or if he is killed without the authority of law, it is felony. (2 Hawk. ib.) The ufage now is for the judge to fign the calendar, or lift of all the prifoners' names, with their feparate judgments in the margin, which is left with the fheriff. As for a capital felony, it is written oppofite to the prifoner's name, "let him be hanged by the neck;" formerly,

formerly, in the days of Latin and abbreviation, "ſuſ. per coll." for *ſuſpendatur per collum.* And this is the only warrant which the ſheriff has for ſo material an act, as taking away the life of another. (5 Mod. 22.) Upon this judge Blackſtone obſerves, that it may certainly afford matter of ſpeculation, that in civil cauſes there ſhould be ſuch a variety of writs of execution to recover a trifling debt, iſſued in the king's name, and under the ſeal of the court, without which the ſheriff cannot legally ſtir one ſtep; and yet that the execution of a man, the moſt important and terrible taſk of any, ſhould depend upon a marginal note. The ſheriff, upon receipt of his warrant, is to do execution within a convenient time, which in the country is alſo left at large. In London a more ſolemn and becoming exactneſs is uſed, both as to the warrant of execution, and the time of executing thereof; for the recorder, after reporting to the king in perſon the caſes of the ſeveral priſoners, and receiving his royal pleaſure, that the law muſt take its courſe, iſſues his warrant to the ſheriffs, directing them to do execution on the day, and at the place aſſigned; and in the court of king's bench, if the priſoner be tried at the bar, or brought there by *habeas corpus*, a rule is made for his execution, either ſpecifying the time and place, (State Trials, p. 332. Foſt. 43.) or leaving it to the diſcretion of the ſheriff. And, throughout the kingdom, by ſtatute 27 Geo. II. c. 37. it is enacted, that in caſe of murder, the judge ſhall in his ſentence direct execution to be performed on the next day but one after ſentence paſſed. But otherwiſe, the time and place of execution are by law no part of the judgment, as was held by the twelve judges. (Mich. 10 Geo. III.) Beccaria has well obſerved, (On Crimes, &c. ch. 19.) that it is of great importance, that the puniſhment ſhould follow the crime as early as poſſible; that the proſpect of gratification or advantage, which tempts a man to commit the crime, ſhould inſtantly awake the attendant idea of puniſhment. Delay of execution ſerves only to ſeparate thoſe ideas, and then the execution itſelf affects the minds of the ſpectators rather as a terrible ſight, than as the neceſſary conſequence of tranſgreſſion.

In caſe a man condemned to die, come to life after he is hanged, as the judgment is not executed till he is dead, he ought to be hung up again. (2 Hal. P. C. 412. 2 Hawk. P. C. 463.) For the former hanging was no execution of the ſentence; and if a falſe tenderneſs were to be indulged in ſuch caſes, a multitude of colluſions might enſue. The body of a traitor, or felon, is forfeited to the king by the execution. Execution may be avoided by a *reprieve* or a *pardon*, which ſee reſpectively.

Execution *of decrees*, in *Scots Law*, is effected by diligence, either againſt the perſon, or againſt the eſtate of the debtor. The firſt ſtep of perſonal execution is by letters of horning, which paſs by warrant of the court of ſeſſion, on the decrees of magiſtrates of boroughs, ſheriffs, admirals, and commiſſaries. If the debtor does not obey the will of the letters of horning, within the days of the charge, the charger, after denouncing him rebel, and regiſtering the horning, may apply for letters of caption, which contain a command, not only to meſſengers, but to magiſtrates, to apprehend and impriſon the debtor. All meſſengers and magiſtrates who refuſe their aſſiſtance in executing the caption, are liable *ſubſidiarè* for the debt; and ſuch ſubſidiary action is ſupported by the execution of the meſſenger employed by the creditor, expreſſing that they were charged to concur, and would not. Letters of caption contain an expreſs warrant to the meſſenger, in caſe he cannot get acceſs, to break open all doors, and other lock-faſt places. The law ſecures peers, married women, and pupils, againſt perſonal execution of caption upon civil debts. Such commoners alſo as are elected to ſerve in parliament, are ſecured againſt perſonal execution by the privilege of parliament. No caption can be executed againſt a debtor within the precincts of the king's palace of Holyrood-houſe; but this privilege of ſanctuary afforded no ſecurity to criminals, as that did which was by the canon law conferred on churches and religious houſes. When the perſonal preſence of a debtor, under caption, is neceſſary in any of our ſupreme courts, the judges are empowered to grant him a protection, for ſuch time as may be ſufficient for his coming and going, not exceeding a month. Protection from diligence is alſo granted by the court of ſeſſion, under the late bankrupt ſtatute, when it is applied for, with concurrence of the truſtee, or a certain number of the creditors, as the caſe may require.

Execution, *military*, is the pillage or plundering of a country by the enemy's army.

Execution alſo denotes every kind of puniſhment inflicted on an army by ſentence of a court-martial. This is of various kinds; as tying up to three halberts, and receiving a number of laſhes with a whip compoſed of nine cord-laſhes, and each laſh of nine knots, from the drummer; or running the gantlope through the parade at guard-mounting, drawn up in two lines for that purpoſe. On this occaſion the provoſt marches through with twigs or ſwitches, and every ſoldier takes as many as there are criminals to be puniſhed; the criminal then marches through the two lines, and each ſoldier gives him a hard ſtroke, the major riding up and down, to ſee that the men lay on properly. When a ſoldier is to be puniſhed with death, a detachment of about two hundred men from the regiment to which he belongs forms the parade, and a file of grenadiers ſhoots the priſoner to death. Different nations have different modes of puniſhment. The cat with nine tails is deſigned to puniſh foot-ſoldiers; but dragoons and cavalry-men are generally picketed.

Execution, in *Muſical Performance*, the action of conveying to the ear, by the aſſiſtance of the eye, what has been written in the ſcore. As much muſic is compoſed of many parts ſo interwoven and linked together, that both the time and intonation are very difficult to ſeize, and of which the ſpirit depends more on taſte than notation of ſuch pieces, nothing is ſo uncommon as a perfect execution. The reading of the notes exactly is no great merit, the performer muſt enter into all the ideas of the compoſer, and feel, and make the hearer feel, the fire or pathos of the expreſſion; but above all he muſt be poſſeſſed of a nice and acute ear, always attentive to the effect of the whole. In French muſic the leader muſt be particularly careful to preſs and relax the time according to the taſte of the melody, the power of voice, and the geſticulation of the ſinger; the other parts muſt conſequently be extremely attentive in following him. "The totality of the opera at Paris, where muſic had no other meaſure than the geſtures of the ſinger, muſt, in my opinion, require an admirable muſician indeed to keep all the performers together." N. B. This was written by Rouſſeau near 40 years ago, and at that time little diſputed; but the editors of the late edit. of the Encyc. men of taſte and judgment, will, perhaps, ſay with Moliere, "medicin malgre lui," this may have been ſo formerly, "mais, nous avons changés tout ca."

"If the French," ſays St. Evremond, "compoſe in a bolder ſtyle than formerly by their intercourſe with the Italians, the Italians in their turn have gained by their commerce with the French, by learning of them a more

 agreeable

agreeable touching, and perfect execution." Letter to the duke of Buckingham.

The reader (says the author of the Lettre sur la Muf. Fran.) will, I believe, excuse me if I wave making any remarks on this passage, I shall only observe, that the French think all the world interested about their music; but on the contrary, in three fourths of Italy, Italian musicians are totally ignorant that there exists a music in France different from their own.

A facility of reading and performing a single part is likewise called, if difficult, execution; particularly when rapid passages are played correctly, and without hesitation, at sight.

Execution of this kind depends in an especial manner on two things; the first in having a powerful hand and quick eye; and the second in having read much music, and being able to phrase it at a glance: for while we only look at single notes, we shall hesitate in pronouncing them: a great facility of execution is only acquired by uniting them into meaning, and putting the thing itself in the place of the sign. In this manner the memory of the reader of a book is no less assisted than by his eyes; and what he would read with great difficulty in a foreign language, though written or printed with the same characters as his own.

Execution, in *Painting*, is a technical term signifying the style and manner in which a painter performs his work: in other words, the mechanical part of the art, as far as relates to the handling of the pencil in laying on the colours of a picture.

It is evident from this definition, that without possessing it in some degree, all knowledge of the other branches of the art is totally nugatory; to what purpose would the theory be made perfect, if no practical means of applying it were understood; but besides that degree of execution absolutely requisite to produce any thing in the shape of a picture, it well deserves to be made an object of particular study, as its various modes are productive of much utility in the progress of a picture. A great deal of the character of many objects in painting depends on the manner in which they are wrought, that is, on the peculiarity of the strokes of the pencil; such, for instance, are all skins of beasts; feathers of birds; trees; various kinds of drapery; armour, &c. in producing the effects of which, execution will alone go very far, in spight of bad form and bad colour. There is a charm in it which few perhaps but painters know, and which, unhappily, too many painters feel and value too highly, and desert for it qualities of a much more valuable kind; and are content too often to let their works pass imperfect, even with the knowledge of their imperfections, rather than disturb the beauty of clearness of touch which they may happen to possess.

It is indeed a task of no easy nature fully to obtain this quality, as it requires the utmost precision of judgment so to execute a work of art, that spirit and vigour should be maintained, accompanied with softness and truth. Without which union the display of it is a vice of art instead of an excellence, and damns instead of exalting the work.

Knowledge of the general character of the object about to be represented is the only foundation of a beautiful, decided, and just execution: possessed of that, the artist holds in his hands the master-key of the expression of its qualities, and renders its effect without difficulty. Wanting it he produces his work with heaviness, with bungling, and confusion.

It has been remarked that the countenances of men scarcely differ more than do the characters of their hand-writing, and not far, if at all, short of the variety of either of these, is that of the manner in which painters have executed their works. Each man in this also has his peculiarity; no two are so exactly alike in the execution of their pictures that an able connoisseur would not distinguish between them, and presently attribute each to its respective author.

This discrimination of hands constitutes almost the tout-ensemble of the knowledge of the host of would-be connoisseurs; and unhappily, too many of them have obtained an influence over the opinions of men well able to teach them in better things appertaining to the arts, if common sense were allowed to rule; and this merely by having pored over the works of painters to endeavour to ascertain the distinguishing characteristics of each one's workmanship: a species of knowledge agreeable and useful to a certain degree, but of easy acquirement, and to which those who have a genuine feeling for the really good and valuable qualities pictures may possess, seldom give sufficient attention to obtain an extended information in it. The works of good artists will force themselves upon our notice, and after sufficiently admiring the general effects of beauty, of sublimity, or character they exhibit; we naturally seek to know by what means or in what manner their various parts are executed, and for the purposes of connoisseurship a satisfactory acquaintance soon takes place on that head. The works of those whose power in art is not sufficient to attract by those better qualities are surely not worthy of that close inspection which is required to become acquainted with their peculiarities of execution. But the trick of the connoisseur dealer is, by some fancied resemblance or some slight reality of resemblance, to pass off an inferior work under the sanction of a great name; while, as we have observed, if common sense were allowed to rule, the name would add no value to the picture, the tinsel would still glare under the gold, and the bauble be soon lost.

This indispensable portion of the art of painting requires early tuition in order to possess a ready power over the hand, so that it shall move freely at the command of the will to effect its desires. The same in fact is the case with regard to the acquirement of free execution in any other art, such as music, writing, &c. For though our muscles appear to act merely on our willing that their office should be performed, and without any particular direction of the power of the mind over the particular muscles which produce the motion, yet, in fact, that immediate influence is applied, although from habit and its extreme rapidity, we are insensible of the communication. This is plain when we require the use of muscles, in a direction we are not constantly in the habit of using them in. For instance, a man not accustomed to ride, or first mounting a horse, finds it necessary to exert all his mental influence to cause those muscles to act which are requisite to maintain his seat on the back of the animal, and the communication of that influence is evidently felt; but when habit has confirmed him in his seat on horse-back, though those same muscles continue to act when he is mounted, he is unconscious of constraining them to do so, the dictates of his will are then so instantaneously excited, that the connection between the exertion of its influeuce, and its effect is completely unobservable.

It is therefore requisite for men desirous of making considerable progress in the practical part of an art, early in life to apply themselves earnestly to its attainment. The best mode of obtaining it in painting, is, by copying the works of those most skilful in their display of it, taking care at the same time to lay in a good store of knowledge of the materials requisite for the art, particularly (if historical painting be the course intended to be pursued) of the human figure, the foldings of draperies, &c. &c., and after some

time

time fpent in making copies of fine works, to paint from nature herfelf, keeping in view the manner in which the great painters, whofe works they have imitated, faw her productions; obferving how they difpofed of thofe touches allowed to remain vifible, and decided both of light and of dark; alfo how they characterized by their execution of the different parts; for, in a well executed work no touches are allowed to remain that are not neceffary in fome meafure to determine the character of the object; the reft are all blended or foftened together, and ferve as a bafe to receive thofe finifhing touches (as they are called) which are the decided features of the ftyle of the mafter, (fee STYLE, in *Painting*,) the fpring of energy and vigour in the work, and without which it would appear tame and infipid.

A picture, wherein the colours and forms are blended all over, is fure to appear either folid like a ftone, or have the texture of dough, of fomething foft and fpiritlefs. On the contrary, where no foftening takes place, and every touch remains vifible, confufion inevitably reigns, with the character of tinfel, and a fluttering want of folidity.

While the ftudent is endeavouring to acquire facility of handling his pencil, or of execution, he muft take care not to be led away by its fafcination, but to remember that it is only the means of prefenting to the world, in an agreeable fhape, other more dignified, and more valuable qualities in art, which lie deeper than the furface; and without which this is worfe than an empty nothing. 'Tis the bane of many an ingenious youth who, happening to poffefs it early, and outfhining his companions in years, fatisfies himfelf that he has made a large advance in his art, when in fact he has obtained only a means of doing fomething, which more important part, his vanity leads him to forget to make the ftudies requifite to enable him to perform, *viz.* to acquaint himfelf thoroughly with the nature of bodies, and the happieft and beft modes of combining them in forms and colours: and as he advances in life he is mortified to find himfelf furpaffed by thofe he had regarded with contempt, but whofe more ftcady and better directed minds have purfued attentively more valuable objects of ftudy, and the more ufeful principles of their art, and now foar to a height which leaves his weaker talent far beneath.

It muft, however, be remarked, that a good execution is a highly valuable quality in a picture, which being wrought with judgment, with fpirit, and eafe, acquires thereby an additional relifh to the enjoyments its better properties difpenfe, and raifes the artift in our eftimation.

Of all thofe who have exhibited this talent with fuccefs, Giacomo Robufti, called Il Tintoretto, ftands foremoft for vigour, as has been noticed under the word ENERGY, in *Painting*. He has no competitor in the freedom, the boldnefs, and the finifh of ftyle in which his beft works are executed.

Of this his picture of St. Mark defcending from heaven to refcue a Chriftian flave condemned to torture among the Turks, originally painted for the Scudo di San Marco at Venice, but now among the fpoils adorning the Louvre at Paris, is a moft decided and aftonifhing proof. This picture is an immenfe work containing twenty figures or more, thofe in front larger than life, yet it is wrought all over with the rapidity and eafe generally characteriftic of fmall pictures, or a fketch within the compafs of the hand to perform at once; and at the fame time it has all the effect of rotundity of finifh the moft laboured works poffefs. In the midft of the fine pictures which furround it, it ftands quite alone in its vigour of effect and fplendour of valour; even a work of Rubens, who is extremely fkilful in this as well as in all other branches of the art; even his, appeared comparatively clumfy in its execution, though one of his fineft productions, the opening of the Temple of James, or, as it is ufually called, the Peace and War. Titian, from his fenfe and truth in the St. Peter martyr, beft withftands the power of Tintoretto. The comparifon of thefe two works may be faid to be fomewhat fimilar to that of a man of wit with a man of fenfe: the former fhines for a moment by the brilliancy and gaiety of his genius, but when the latter is attentively heard, and his obfervations confidered, his greater value becomes apparent.

Titian perhaps on the whole is the beft model to follow for execution: he does not, like Tintoretto, leave his heads without a character in the heat of workmanfhip, though they are not always of the beft; they are not wrought too minutely: the lights and darks are freely placed, his pencil is full and rich, and each part is made out to its full relievo, and his finifhing touches are laid on with the niceft difcrimination of truth in direction of light and hue of colour; nothing can exceed the delicacy and fkill his draperies are wrought with as to character; and though not fo ftrong as Tintoretto's, they have fufficient force, and are far more juftly difpofed and characterized. After Titian in imitating him are, Velafquez and Vandyke for excellence in their execution. Of the former, a Spanifh painter, there are but few works in this country, but what there are, fully juftify the remark. The latter in his very fineft works equals his great predeceffor in this refpect, many of whofe pictures he carefully copied. His touch is exceedingly delicate, and his underftanding of his fubject enabled him to place it with the greateft juftnefs and propriety. There is rarely feen in his works a confufion in effect or relievo, and his power in his earlier productions feems to have encreafed with his canvas; the large picture at Wilton of the Pembroke family is wrought in a ftyle fo broad and mafterly, that it appears to have been as eafily managed as any of his fmaller pictures; and he knew how to give with the greateft eafe the juft character of every object he attempted to reprefent. Gout and confequent weaknefs effected a change in his execution fo great, that his hand is hardly cognizable in fome of his latter works by thofe who have only feen his former ones. When he was in Italy, his manner was that of Titian, with fomewhat of Tintoretto; from this bravura ftyle, as it may be termed, he fell afterwards to one more tame and fpiritlefs; foftened, and rounded up, with few of thofe vigorous touches, and with lefs billiancy of effect. Inftances of both thefe, and alfo intermediate degrees, are at the earl of Egremont's at Petworth. Of the firft are whole length portraits of fir Robert and lady Shirley, which he painted when he was very young at Venice; of the others, are portraits of feveral branches of the Pony family, who once poffeffed that noble manfion. Vandyck certainly furpaffed his mafter Rubens in beauty of execution, but was more than equally furpaffed by him in vigour and variety of imagination; yet the execution of Rubens was extremely powerful, but apt to become flovenly, and he is not, generally fpeaking, a good model to be followed on that head.

For thofe who are intent upon yielding the foft, the delicate, and gentle impreffions produced by highly laboured works without minutenefs, Correggio is the exemplar of the whole clafs of that ftyle of painters. In one particular he, and our own fir Jofhua, in fome of their works, ftand unrivalled in execution. Other painters have given a beautiful furface, which, at a proper diftance, deceives the eye, and prefents the full appearance of flefh: thefe two have, we may almoft fay, made flefh itfelf; the clofeft infpection merely confirms the delufion, and the obferver fancies he could indent his finger in the furface, and expect it to fpring again like nature; fuch ſuch is the fullneſs of the texture of the colour wrought with the many varying hues of nature. Guido Rheni follows in this claſs of the pleaſing ſtyle. His pictures of the lighter kind are exceedingly grateful to the eye, from the intelligence and eaſe with which his pencil appears to have been conducted through all the various parts. Annibal Carracci, in a more bold manner, is alſo a maſter of great power in the execution part of the art; but he often appears to have laboured to expreſs his thoughts; his works, however, poſſeſs great beauties of this nature.

In works of a different and ſmaller claſs from thoſe produced by the maſters whoſe names we have mentioned, almoſt the whole of the Dutch and Flemiſh ſchools are wonderfully ſkilful in their execution, particularly Rembrandt, Teniers, Jauſſen, Metzu, Netſcher, &c. and ſtill more minute Gerard Dow, and Meins. In landſcape, Cuyp, Berghem, Both, Ruyſdael, and Hobbima, are all well worthy of the utmoſt attention in this reſpect; and many others, too numerous to be mentioned here, both of theſe and the Italian ſchool, will greatly aſſiſt the ſtudent who attentively examines their productions to form his judgment, on thoſe points wherein lie the greateſt beauties of this neceſſary branch of the art of painting. But as a good execution conſiſts in a free and ready hand, marking with fullneſs of preciſion and truth the characters of the objects repreſented; nothing but an intimate knowledge of nature will ever enable him to apply his obſervations on works of art to any beneficial purpoſe in completing the productions of his own imagination.

EXECUTIONE *facienda*, in *Law*, a writ commanding execution of a judgment.

Executione *facienda in withernamium*, lies for taking the cattle of one who had formerly conveyed out of the county the cattle of another, ſo that the ſheriff cannot replevy them.

Executione *Judicii*, a writ directed to the judge of an inferior court, to do execution upon a judgment therein, or to return ſome reaſonable cauſe wherefore he delays the execution. F. N. B. 20.

If execution be not done on the firſt writ, an *alias* ſhall iſſue, and a *pluries*, with this clauſe, *vel cauſam nobis ſignifices quare*, &c. And if, upon this writ, execution be not done, or ſome reaſonable cauſe returned why it is delayed, the party ſhall have an attachment againſt him who ought to have done the execution, returnable in B. R. or C. B. New. Nat. Br. 43.

EXECUTIVE Power, *Supreme*, is by the conſtitution of theſe kingdoms lodged in a ſingle perſon, the king or queen for the time being. See Crown and King.

EXECUTOR, a perſon nominated by a teſtator, to take care to ſee his will and teſtament executed or performed, and his effects diſpoſed of according to the tenor of the will.

The teſtaments made in Latin, in the fourteenth century, call executors *proviſores teſtamentarii*.

All perſons are capable of being executors that are capable of making wills, and others beſides, as feme-coverts and infants, and infants unborn; (Weſt. Symb. p. 1. § 635.) but no infant can act as executor till he is ſeventeen years of age. This appointment of an executor, either by expreſs words, or by ſuch as ſtrongly imply the ſame, is eſſential to the making of a will; (Weſt. c. 1. Plowd. 281.) but if the teſtator names no executors, or names incapable perſons, or if the executors that are named refuſe to act, the ordinary muſt grant letters of adminiſtration. See Administrator.

A perſon appointed to be executor is not compellable to execute the will; he may refuſe the charge, before he has adminiſtered as executor, or performed ſuch acts, as paying debts due by the teſtator, or receiving debts due to him, or giving acquittances for the ſame; but if he meddles with the goods of the teſtator, as executor, his ſubſequent refuſal is void, and he ſhall be charged as executor. A perſon to whom a legacy is left may be compelled either to ſtand the executorſhip, or to reſign his legacy. The refuſal of executorſhip muſt be entered and recorded in court. If ſeveral executors are named in a will, and ſome of them refuſe, and others prove the will, they who refuſe may afterwards adminiſter and act; and they muſt be joined in all ſuits, where the co-executors are plaintiffs; but not where they are defendants, becauſe the plaintiff in the action is not bound by law to take notice of any beſides thoſe who have proved the will. Such joint-executors, though they are accounted in law but as one perſon, ſhall not be charged by the acts of their companions, any further than for effects *actually* come to their hands. (Moor. 620. Cro. Eliz. 318. 2 Leon. 209.) But if two or more executors join in a receipt (in writing) and one of them only actually receives the money, each is liable for the whole, as to creditors at law, but not as to legatees or next of kin. (1 Salk. 318.) If joint-executors, by agreement among themſelves, agree that each ſhall intermeddle with a certain part of the teſtator's eſtate, yet each ſhall be chargeable for the whole (to creditors) by agreeing to the other's receipts. Hard. 314.

The intereſt, veſted in the executor by the will of the deceaſed, may be continued and kept alive by the will of the ſame executor, ſo that the executor of A.'s executor is to all intents and purpoſes the executor and repreſentative of A. himſelf. (Stat. 25 Edw. III. ſt. 5. c. 5. 1 Leon. 275.) But the executor of A.'s adminiſtrator, or the adminiſtrator of A.'s executor, is not the repreſentative of A. For the power of an executor is founded upon the ſpecial confidence and actual appointment of the deceaſed; and ſuch executor is therefore allowed to tranſmit that power to another, in whom he has equal confidence; but the adminiſtrator of A. is merely the officer of the ordinary, preſcribed to him by act of parliament, in whom the deceaſed has repoſed no truſt at all; and therefore, on the death of that officer, it reſults back to the ordinary to appoint another.

As to the office or duty of an executor, it is to be obſerved that he may do many things before he proves the will, which an adminiſtrator cannot do; becauſe the former derives his power from the will, and not from the probate or appointment of the ordinary, as the latter does. (Comyns. 151. Wentw. ch. 3.) He may maintain actions of treſpaſs, replevin, or detinue; releaſe an action, aſſent to a legacy, be ſued, alien, or otherwiſe intermeddle with the goods of the teſtator: by adminiſtering, the executor is entitled to receive all debts due to the teſtator, and all payments made to him are good, though he ſhould die, and never prove the will; but he cannot maintain a ſuit or action of debt, or the like, before he has proved the will. The ordinary, &c. may cite the executor, either to prove the will, or refuſe the office; and he may ſequeſter the goods of the deceaſed, till the executor has proved it; and if he does not appear on the proceſs, the ordinary may excommunicate him. On the other hand, the ordinary is compellable by mandamus to proceed to probate, when the will is not controverted. The executor muſt bury the deceaſed in a manner ſuitable to the eſtate he leaves behind him; neceſſary funeral expences are allowed, previous to all other debts and charges; but if he be extravagant, he is chargeable with devaſtation, or waſte of the ſubſtance of the deceaſed, which ſhall be only prejudicial to himſelf, and

and not to the creditors or legatees of the deceafed. (Salk. 196. Godolph. p. 2. c. 26. § 2.) He is then to make an inventory of all the goods and chattels, whether in poffeffion or action of the deceafed, which he is to deliver in to the ordinary upon oath, if lawfully required. He is then to collect all the goods and chattels fo inventoried; for which purpofe the law confers on him ample powers, as the reprefentative of the deceafed; (Co. Litt. 209.) and having the fame property in his goods as the principal had when living, and the fame remedies to recover them; and if there be two or more executors, a fale or releafe by one of them fhall be good againft all the reft. (Dyer. 23.) The executor muft in the next place pay the debts of the deceafed, in the order of their priority. See DEBT, and DEBTEE *Executor*.

Among debts of equal degree, the executor (and alfo the adminiftrator) is allowed to pay himfelf firft, by retaining in his hands fo much as his debt amounts to. (10 Mod. 496.) If a creditor conftitutes his debtor his executor, this is a releafe or difcharge of the debt, whether the executor acts or not, (Plowd. 184. Salk. 299.) provided there be affets fufficient to pay the teftator's debts.

If no fuit has commenced againft him, the executor may pay any one creditor in equal degree his whole debt, though he has nothing left for the reft; for, without a fuit commenced, the executor has no legal notice of the debt. After the debts, the executor is to pay the legacies, which he is to pay as far as his affets will extend; but he may not give himfelf the preference herein, as in the cafe of debts. In cafe of a deficiency of affets, all the *general* legacies muft abate proportionably, in order to pay the debts; but a *fpecific* legacy, as of a piece of plate, horfe, &c. is not to abate at all, unlefs there be not fufficient without it. (2 Vern. 111.) If the legatees have been paid their legacies, and debts come in more than enough to exhauft the refiduum, they are afterwards bound to refund a rateable part. (Ibid. 205.) See LEGACY, and DONATION *Caufa Mortis*.

When all the debts and legacies are difcharged, the furplus or refiduum muft be paid to the refiduary legatee, if any be appointed by the will; if there be none, it was formerly underftood to belong to the executor; (Perkins, 525.) but it feems to be now the general opinion, that, if there be an exprefs legacy given to an executor, and no devife of the furplus, fuch furplus fhall not go to the executor; but be difpofed to the next of kin, according to the ftatute of diftributions; the executor ftanding on the fame footing as an adminiftrator. (Prec. Chanc. 323. 1 P. Wms. 7. 544. 2 P. Wms. 338. 3 P. Wms. 43. 194. Stra. 559.) See INTESTATE.

Where no exprefs legacy is given to the executor, the furplus fhall go to the executor, and not otherwife difpofed of by will. When there are feveral executors, and fome of them are dead, the legatary muft fue the furviving executors, and not the executors or adminiftrators of thofe that are dead. And if all the executors are dead, he muft fue the executors or adminiftrators of thofe that died laft, and not thofe of the reft.

By the French law, an executor fhould be feifed of all the moveables of the deceafed during one year; at the end whereof he is to account for them. To the validity of a teftament, it is not neceffary there be an executor nominated therein.

EXECUTOR *de fon tort*, or of his own wrong, is he who takes on him the office of an executor by intrufion, not being conftituted thereto by the teftator or deceafed, nor authorized by the ordinary to adminifter.

If an executor in his own wrong takes upon himfelf the office of an executor, without lawful authority, he is chargeable to the rightful executor, and to all the creditors of the teftator, and likewife to the legatees, fo far as the goods amounted to, which he wrongfully poffeffed; and fuch an executor is made by any act of acquifition, transferring, or poffeffing himfelf of any of the eftate or goods of the deceafed; but not by acts of neceffity, piety, or charity. (2 Nelfon Abr. 793.) Such an executor cannot bring an action in right of the deceafed; but actions may be brought againft him; neither can he retain for his own debt or legacy. In cafe of his death, his executors or adminiftrators are liable to the fuit of the lawful executor, creditors, and legatees, by 30 Car. II. cap 7.

EXECUTOR, *Debtee*. See DEBTEE.

EXECUTORY, that which has, or carries with it a fufficient authority for being executed.

EXECUTORY *contract*. See CONTRACT.

EXECUTORY *devife of lands*, is fuch a difpofition of them by will that thereby no eftate vefts at the death of the devifor, but only on fome future contingency.

It differs from a *remainder* (which fee) in three very material points: 1. That it needs not any particular eftate to fupport it. 2. That by it a fee-fimple, or other lefs eftate, may be limited after a fee-fimple. 3. That by this means a remainder may be limited of a chattel intereft, after a particular eftate for life created in the fame. The *firft* cafe happens, when a man devifes a future eftate to arife upon a contingency; and, till that contingency happens, does not difpofe of the fee fimple, but leaves it to defcend to his heir at law. As if one devifes land to a feme-fole and her heirs upon her day of marriage; here is in effect a contingent remainder without any particular eftate to fupport it; a freehold commencing *in futuro*. This limitation, though it would be void in a deed, yet is good in a will, by way of executory devife. (1 Sid. 153.) For, fince by a devife a freehold may pafs without corporal tradition or livery of feifin, it may therefore commence *in futuro*; becaufe the principal reafon why it cannot commence *in futuro* in other cafes is the neceffity of actual feifin, which always operates *in præfenti*. And fince it may thus commence *in futuro*, there is no need of a particular eftate to fupport it; the only ufe of which is to make the remainder, by its unity with the particular eftate, a prefent intereft. And hence it follows, that fuch an executory devife, not being a prefent intereft, cannot be barred by a recovery, fuffered before it commences. (Cro. Jac. 593.) The *fecond* cafe happens where a devifor devifes his whole eftate in fee, but limits a remainder thereon to commence on a future contingency. As if a man devifes land to A. and his heirs; but if he die before the age of 21, then to B. and his heirs; this remainder, though void in a deed, is good by way of executory devife. (2 Mod. 289.) But in both thefe fpecies of executory devifes, the contingencies ought to be fuch as may happen within a reafonable time; as within one or more life or lives in being, or within a moderate term of years; for courts of juftice will not indulge even wills, fo as to create a perpetuity, which the law abhors. (12 Mod. 287. 1 Vern. 164.) *Thirdly*, by executory devife a term of years may be given to one man for his life, and afterwards limited over in remainder to another, which could not be done by deed; for by law the firft grant of it, to a man for life, was a total difpofition of the whole term; a life eftate being efteemed of a higher and larger nature than any term of years. (8 Rep. 95.) On this fubject, fee Blackft. Comm. vol. ii. p. 176, 8vo.

EXECUTORY *eftate*. See ESTATE.

EXECUTORY *fine*. See FINE.

EXEDENS Herpes. See Herpes.

EXEDRÆ, Ἐξέδραι, among the *Ancients*, were places wherein the philofophers, fophifts, rhetors, &c. ufed to hold their conferences and difputes.

M. Perrault is of opinion, the exedræ were a fort of little academies, where the men of learning met together. See Academy.

Budæus rather thinks, that what the ancients called exedræ, might anfwer to what we call chapters in the cloifters of monks, or collegiate churches.

EXEGESIS, Ἐξήγησις, a term fometimes ufed by the learned, to fignify *explication*.

Several interpreters of the Bible are of opinion, that in the paffages of Scripture, where we meet with Abba Pater, two words, the firft Syriac, and the fecond Greek or Latin, but both fignifying the fame thing; the fecond is only an exegefis, or explanation of the firft.

Exegesis is alfo ufed for an entire difcourfe by way of explication or comment on any thing.

Exegesis *numerofa*, or *linealis*, fignifies the numeral, or lineal folution, or extraction of roots, out of adfected equations, firft invented by Vieta. Ozanam calls it *la rhetique*. See Extraction *of roots*.

EXEGETES, formed of ἐξηγέομαι, *I explain*, among the Athenians, perfons learned in the laws, whom the judges ufed to confult in capital caufes.

EXEGETICA, in *Algebra*, the art of finding, either in numbers or lines, the roots of the equation of a problem, according as the problem is either numerical or geometrical. See Root and Equation.

EXELCOSIS, from ἕλκος, *an ulcer*, in *Surgery*, an incipient ulceration, or an excoriation, which is juft beginning to fuppurate.

EXEMPLAR, a model or original to be imitated or copied.

Exemplar alfo denotes the idea or image conceived or formed in the mind of the artift, whereby he conducts his work. Such is the idea of Cæfar, which a painter has in his mind when he goes to make a picture of Cæfar. The exemplar is ordinarily numbered among the caufes. See Cause.

EXEMPLIFICATION *of Letters Patent*, denotes an exemplar, or copy of letters patent, made from the inrolment thereof, and fealed with the great feal of England.

Such exemplifications are as effectual to be fhewed, or pleaded, as the letters patent themfelves.

EXEMPLIFICATIONE, in *Law*, is a writ granted for exemplification of an original record. Reg. Orig. 290.

EXEMPTION, a privilege, or difpenfation, whereby a perfon is excepted out of fome general rule.

Exemption is particularly applied to churches, chapels, and monafteries, which have a privilege given them by the popes, or princes, whereby they are exempted from the jurifdiction of the bifhop or ordinary.

The council of Conftance revoked all exemptions, to reftore to the general law, weakened and diminifhed by a relaxation of feveral ages, its ancient force and vigour, and make it every where obtain in all its latitude.

The council of Trent prohibited, and declared them null for the future; confirming only fuch as were well founded on legal conceffions from the holy fee.

Exemption, in *Law*, denotes a privilege to be free from fervice or appearance; thus, knights, clergymen, &c. are exempted from appearing at the county courts by ftatute, and peers from ferving on inquefts. (6 Rep. 23.) Perfons feventy years of age, apothecaries, &c. are alfo exempted by law from ferving on juries, and juftices of peace, attornies, &c. from parifh offices. 2 Inft. 247.

EXERCISE, a repetition of any operation, for the ftrengthening or retaining of a habit.

Exercise, or bodily motion, conftitutes, in the language of the older phyficians, one of the fix *non-naturals*, and has been juftly confidered, from the earlieft times, as an important meafure in the prefervation of health, as well as in the cure of feveral difeafes.

The value of corporeal exercifes in the eftimation of the ancient phyficians, from Hippocrates downwards, is manifeft from their writings, in which the various kinds of exercife, as well as the degrees and times in which they are ufeful, are particularly difcuffed. Efculapius himfelf is faid by Galen to have recommended riding on horfeback, and other exercifes, as the means of benefiting invalids. But Herodicus, a Thracian, feems to have been the firft who paid ferious attention to exercife, as a remedy for difeafes. He was mafter of one of the academies, called *Gymnafia*, in which the military and athletic exercifes were taught; and having remarked that his pupils ufually enjoyed high health, he turned his attention to the regulation of the gymnaftic exercifes, with a view to attain or preferve good health; thus adding the *medical gymnaftic* art, to the two others juft mentioned. (See Gymnastic, and Herodicus.) This mafter of the gymnafium, however, went to work empirically, and is accufed by Hippocrates of doing confiderable mifchief, in attempting to cure febrile difeafes by his exercifes. (De Morb. Epidem. lib. vi.) Hippocrates and his commentator, Galen, have left many obfervations relative to the different exercifes, and their particular effects in the alleviation of particular difeafes. Friction, efpecially by means of the *ftrigil*, or flefh brufh, is much inculcated; on which fubject Galen has compofed his fecond book, "De Sanitate Tuenda." The various modes of wreftling, the exercifes of the *corycus*, or hanging ball, &c. are commented on by Hippocrates in lib. ii. De Diæta: and Galen wrote a little treatife *de parva pila*, (the little ball,) which he recommends as an exercife that influences both the body and the mind at the fame time. In his difcourfe to Thrafibulus he difcuffes the queftion, whether the prefervation of the health properly belongs to medicine, or to the gymnaftic art: he inveighs againft the athletic and other violent practices of the gymnafium, but approves of the more moderate exercifes, which he confiders as fubfervient to the purpofes, and confequently a part of the art of the phyfician. Antyllus, and other Greek writers, have treated of the various exercifes in the fame light, as is evinced by the collections of Oribafius. (See Collect. Med. lib. vi.) The Romans even exceeded the Greeks in their attention to the medical gymnaftics. Afclepiades, in the time of Pompey, as Pliny informs us, confidered the different modes of exercife, *viz.* friction, walking, and geftation, as the chief auxiliaries of the phyfician, efpecially when combined with the proper regulation of diet; and by the employment of thefe exercifes, the inftitution of baths, the invention of hanging beds, *lecti penfiles*, and other means of making phyfic agreeable, he is faid to have acquired the general applaufe of all mankind: "univerfum prope humanum genus circumegit in, &c." (Plin. Nat. Hift. lib. xxvi. cap. 3.) Many eminent examples of the benefits of exercife among the Romans are on record. Suetonius ftates that Germanicus was cured of a fort of atrophy of the lower extremities, (crurum gracilitas) by riding. And Cicero himfelf, when reduced to a ftate of infirmity, which rendered it neceffary for him to defift from pleading, recovered his health by travelling, and by exceffive diligence in the ufe of friction. (Plutarch.) Friction was an exercife, indeed, reduced to a regular fyftem among the ordinary habits of the Romans, and was prefcribed to a great extent by their phyficians. See FRICTION.

That exercife, efpecially in the open air, is highly beneficial to the conftitution, is a truth which univerfal experience has eftablifhed. It is fcarcely neceffary, therefore, to appeal to the arguments of phyfiology to corroborate the propofition. It may be fufficient to ftate, that the immediate refult of bodily exertion is an acceleration of the circulation of the blood; a quicker and ftronger contraction of the heart, by which the blood is pufhed more effectually to every part of the fyftem, and efpecially through the fmall and extreme branches of the veffels. Hence a glow is produced on the furface, and the complexion affumes a redder hue, from the diftention of the capillary veffels with blood; and the exhalent arteries begin to pour out the thinner portions of the fluids in perfpiration. In the fame manner, the extreme arteries of all the other parts of the body are diftended, and excited to greater action; whence all the organs of fecretion, which are principally made up of convolutions of the extreme arteries, are neceffarily ftimulated to an active performance of their feveral functions. The veffels of the ftomach pour out the gaftric liquors more abundantly, and the work of digeftion is more perfectly and actively completed; the appetite for a new fupply of aliment quickly returns, and the ftomach is prepared for repeating the digeftive procefs, by the increafed fupply of the digeftive liquor. The liver and the pancreas, in like manner, elaborate their refpective fluids, the bile and pancreatic juice, more copioufly, and thus contribute an increafed aid to the operations of the alimentary canal. The lungs, in the mean time, being called upon for an augmented fupply of the vivifying principle derived from the oxygen of the atmofphere, by the increafed circulation of the blood through them, refpiration is increafed in proportion to the quantity of venous blood which they receive. Thus, notwithftanding the greater rapidity with which the blood is carried to the fecreting organs, it is rendered adequate to the fecretion of the healthy fluids peculiar to each, by the increafed operation of the lungs; as well as to the fupport of the greater mufcular action, in which the exercife confifts.

It muft be obvious, then, that this general activity of the whole fyftem, this free circulation through the moft minute ramifications of the veffels, and through the glands and organs which they compofe, and this prompt feparation of the excrementitious and other parts of the blood, by the fecretions, cannot but contribute to the general health of the body. It is not lefs obvious that it contributes to the evolution and growth of the different parts of the body; whether we confider the great influx of the blood, from which all growth is derived; or obferve the fact, that thofe mufcles and limbs, which are moft actively exercifed, invariably acquire fuperior bulk, as well as fuperior ftrength. The mufcles of the arms in blackfmiths, and thofe of the loins in porters, and all others employed in raifing or carrying great weights, invariably acquire a difproportionate fize; and, on the contrary, thofe mufcles which are little employed are apt to fhrink, and to be comparatively enfeebled, as in the legs of tailors. The effect of exercife in giving ftrength and rigidity of fibre to the mufcular or flefhy part of animals is well known, and daily exemplified in the difference of texture in the wings and legs of birds which we ufe as food. In the common fowls, which feldom ufe the wing, and conftantly employ the legs in walking, the hardnefs of the flefh of the latter, and tendernefs of that of the former, are notorious. From this influence of exercife in contributing to the growth and ftrength of the animal body, we may obvioufly trace the final caufe of that inftinctive difpofition to activity and motion, which the young of all animals poffefs.

Regular exercife, not too violent in degree, nor continued too long, fo as to induce exceffive fatigue, is therefore to be confidered as the moft important preventive of difeafes. It is not eafy to lay down rules by which it fhould be regulated; fince the conftitution, age, ftrength and habits muft modify its effects in different individuals. A fudden tranfition from a ftate of reft to violent exertion is injurious to the invalid, efpecially after a full meal, or if continued until a profufe perfpiration, or great laffitude takes place; for this over-exertion neceffarily leads to a languor and imperfect performance of all the vital actions, every organ partaking of the general fatigue. The various kinds of exercife may be confidered under two claffes, the active and the paffive; the former being the refult of our own mufcular activity, fuch as walking, dancing, running, fwimming, fencing, the military exercife, and different athletic games; the latter the refult of communicated motion, as riding in a carriage, failing, fwinging, friction, &c.; riding on horfeback, or driving a carriage, partakes in fome meafure of both the active and paffive exercifes.

Walking, which feems to be the moft natural exercife, is capable of producing all the effects above detailed, if adapted in degree and duration to the various circumftances. Hence the moft obftinate cafes of hypochondriacal diforders, of indigeftion, and other ftomach complaints, have been frequently removed by perfeverance in walking, efpecially in the open air of the country. But when the exercife of walking is adopted with a view to banifh the complaints juft mentioned, which a fedentary life is apt to induce, it is moft effectual when regularly and ftrenuoufly purfued. That degree of walking, which, when reforted to occafionally, or with confiderable intermiffions, produces great fatigue and languor, and therefore is rather prejudicial than advantageous, would, if daily continued, foon ceafe to fatigue, and would then contribute greatly to reftore the healthy ftate of the functions. It muft be recollected that the animal vigour is confumed, or, to ufe the language of Brown, the excitability is exhaufted, by the mental functions as well as by mufcular exertion; therefore, to carry with us, in our walks in fearch of health, the brooding anxieties and cares of our profeffions,—to attempt to combine ftudy with fuch exercife by reading, or by ferious reafoning in converfation, is to thwart the good effects of the plan. We may obferve that, fo incompatible is deep thought with mufcular exertion, that moft people ftop in the midft of their activity, when their arguments require great reflection. Serenity of mind, and a relaxation from the ferious occupations of life, are therefore neceffary, when walking is reforted to as a remedy.

Of the more violent fpecies of active exercife, which can only be reforted to as a prefervative from difeafe, by thofe who are in a ftate of good health, it is unneceffary to fpeak.

The modes of exercife which are particularly ufeful in the cure of difeafes, or in the reftoration of the health of convalefcents, are the different fpecies of geftation, efpecially riding in carriages, or on horfeback, and failing.

The motion of a fhip produces the moft gentle exercife, and is therefore adapted even to the relief of very infirm conditions of the body, and it has been employed from early times in the cure of confumption. The Romans, in the time of Pliny, ufed to fend their confumptive patients to Egypt; not, as that author takes care to inform us, on account

account of any peculiarity of that country, but in consequence of the length of the voyage. Annæus Gallio, who had been conful, was cured of a confumption by fuch a voyage. (Nat. Hift. lib. xxxi. cap. 6.) Celfus feems to have confidered failing, when reforted to early, as the principal remedy for confumption: "opus eft, fi vires patiuntur, longa navigatione," he fays; and where the ftrength is not equal to it, he recommends fhort voyages, or the ufe of a litter, or other means of gentle geftation. (De Medicina, lib. iii. cap. 22.) The advantages of a fea voyage, efpecially to a warmer climate, are well known to modern phyficians; and inftances of the fuccefs of fuch a voyage to Madeira, Lifbon, &c. when undertaken in the incipient ftage of confumption, as Celfus recommends it, are very numerous. This, however, like all other remedies for confumption, is too often reforted to when the difeafe has already advanced too far to admit of any effectual relief. See CONSUMPTION.

The exercife of geftation by means of a carriage, and the more active exercife of riding on horfeback, being more eafily obtained, are of more importance in our confideration of the fubject. Horfeback exercife was not much adopted by the ancients, with a view to the cure of difeafes; partly becaufe that valuable animal was lefs ufed by the Greeks and Romans, and partly becaufe their mode of riding, without ftirrups, was incompatible with the weaknefs of invalids. (See Fuller, Medicina Gymnaftica, p. 231.) Hence we may underftand the obfervation of Antyllus, that "riding is of little ufe to thofe who are fickly, becaufe a flow pace is productive only of laffitude, efpecially in the loins;" he admits, however, that "a quick pace of the horfe, although it occafions a troublefome fhaking of the whole body, is neverthelefs fomewhat beneficial, and ftrengthens the fyftem, efpecially the ftomach and the organs of fenfe, more than all other exercifes." (Oribafius, loc. cit. lib. vi. cap. 24. de Equitatione.) The great advantages of riding in the prevention and cure of many difeafes are infifted upon in the ftrongeft terms by Sydenham, who, indeed, appears, in feveral parts of his writings, to have confidered it as a remedy of ineftimable value, provided it be perfevered in with conftancy, in the manner which we have inculcated in refpect to *walking*. Speaking of the mode of cure in chronic difeafes, that fagacious phyfician obferves, "nothing, among all the expedients which have hitherto come to my knowledge, fo effectually fupports the fpirits and ftrength, as long and conftant riding on horfeback." (Diff. Epiftolaris.) Again in his Treatife on the Gout, and particularly refpecting the prevention of the paroxyfms by exercife, he fays, "riding on horfeback is far preferable to all other exercifes for this purpofe; in truth I have frequently confidered, that if any perfon were acquainted with a medicine, which he chofe to keep fecret, of equal efficacy in this, and in the greater number of chronic difeafes, with a conftant and perfevering exer ife on horfeback, he would fpeedily accumulate the moft ample wealth." And to exprefs his full conviction of the value of this exercife in confumptive complaints, he ufes thefe ftrong terms: "in fhort, however fatal confumption is deemed to be, and actually is, fince it deftroys two thirds of thofe who die of chronic difeafes, yet I folemnly affirm, that neither is mercury a more effectual remedy for the lues venerea, nor Peruvian bark for agues, than is the exercife juft commended for confumption, provided that the patient be always careful to fleep in dry linen, and that his journey be fufficiently long." The truth of this great encomium is indeed queftioned by modern practitioners in general, however weighty the authority of Sydenham may be. But there are many cafes on record, which feem to juftify this obfervation. Witnefs the cafe of the late Dr. Currie, of Liverpool, as related by himfelf, in the Zoonomia of Darwin. (Vol. ii. clafs ii. Ord. i. 6.) In this cafe, the patient had an hereditary predifpofition to confumption, and was reftored by travelling from a ftate of debility, in which the erect pofture could fcarcely be borne without fainting, to good health; having begun with the exercife of a carriage, and afterwards ridden on horfeback, as his ftrength augmented. Sydenham has related feveral examples of the value of this exercife, and others may be found detailed by Fuller, &c. We cannot therefore doubt, that in many inftances, in which it has feemed to be deftitute of the efficacy afcribed to it by Sydenham, the failure muft be attributed to the imperfect or too late ufe of the remedy. "I muft here repeat," fays Fuller, quaintly, "that when I fpeak of riding, I underftand the *habit of riding*, the want of which diftinction has made it ineffectual to many a man. He that in this diftemper (confumption) above all others rides for his health, muft be like a Tartar, in a manner always on horfeback; and then from a weak condition he may come to the ftrength of a Tartar." (Medicin. Gymnaft. p. 106.) We have dilated upon this topic, from a conviction that many chronic difeafes, which are included under the epithets of bilious and nervous, as well as many morbid conditions of the vifcera, for which drugs, and even the waters of Briftol, Bath, and Cheltenham, are ineffectually fwallowed, might be removed by a fteady and unremitting exercife, in a carriage, or ftill more certainly on horfeback.

It is unneceffary to enter into a particular enumeration and difcuffion of every poffible form of exercife, the principle being the fame with refpect to all. A late intelligent writer has laid down fome ufeful practical precepts on thefe topics, mixed with a good deal of trifling obfervation, and abfurd hypothefis. (See Willich's Lectures on Diet and Regimen, chap. 7.) The following remarks on the injuries occafioned by want of exercife are from that popular writer.

"We are now to confider the confequences arifing from *want of exercife*. This, indeed, is ftill more debilitating than too violent motion. The folid parts of the human frame are relaxed by it; the circulation of the fluids is retarded; they gradually ftagnate in the fmaller capillary veffels; the fecretions are diminifhed; and abundance of moifture or fat is generated, which renders the body, as well as the mind, more indolent and lethargic, relaxation of the mufcles, obftructions of the inteftines, hemorrhoids, apoplectic fits, various fpecies of dropfy, and at length a premature death, are the fad confequences. Men of letters are the moft unhealthy of all human beings, becaufe their bodies have fcarcely any other exercife but the imperceptible motion of the arms. Want of appetite, flatulency, anxiety, at one time obftructions, at another diarrhœa, and the moft diverfified nervous fymptoms are their attendants. Sleep is beyond their reach; a thoufand tormenting inconveniences, hypocondriafis, and at length a complete ftate of melancholy, is too frequently their lot. Temperance alone will not remedy all thefe evils; for, fince we cannot remain vigorous and healthy for two days together, with the fame mafs of blood, a new accefs of the neweft and moft fubtle parts of our fluids muft daily fupport the nervous fyftem, in order to preferve its regular functions. If this be not continually reftored, weaknefs and relaxation of body and mind are the inevitable confequences; with this difference only, that in a ftate of debility from too much bodily exercife, the thick and coarfe particles of the fluids are carried into circulation with the others, and the next meal or the firft fleep after it, foon soon supplies the deficiency in mental labour; on the contrary, digestion is interrupted, the crude and viscid parts of food remain unassimilated, and the body is prevented from receiving proper nourishment. In like manner sedentary mechanics and artificers are affected, particularly shoe makers, tailors, and weavers. They experience maladies similar to those to which men of letters are subject; and it has been frequently observed, that they are very liable to diseases of the mind, and especially to religious fanaticism."

Exercise, *Field*, in *Military Affairs*, relates to the evolutions performed by companies, regiments, or greater bodies of troops, when learning, or practising, those movements necessary to be correctly understood by persons of all ranks in the military profession. See Evolutions and Tactics.

Exercise, *Gun*, relates to the several arrangements, and motions, made for serving either heavy or light artillery, under every circumstance common to military operations. See Gun-*Exercise*.

Exercise, *Manual*, teaches the several motions of the firelock, whereby all act as it were in unison, and perform their duties when drawn up for display, or for service, in an uniform and appropriate manner. See Manual-*Exercise*.

Exercise, *Sword*, refers to the several positions of the sword, adapted either for attack, defence, or compliment. See Sword-*Exercise*.

Exercise, in a *Naval Sense*, is the preparatory practice of managing the artillery and small arms, in order to make the ships' crew perfectly skilled therein, so as to direct its execution successfully in time of battle. The words of command introduced, during the late war, for the exercise of the great guns, are the following: "Silence: cast loose your guns; level your guns; take out your tompions; run out your guns; prime; point your guns; fire; spunge your guns; load with cartridge; shot your guns; put in your tompions; house your guns; and secure your guns." Falconer's Marine Dict. art. *Exercise*.

Exercise may also denote the execution of the movements, which the different orders and dispositions of fleets occasionally require, and which the several ships are required to perform, by means of signals.

Exercises, in the plural, are particularly understood of what is taught young gentlemen in the academies, or riding-schools, &c. As riding the great horse, dancing, fencing, vaulting, drawing fortifications, &c.

EXERGASIA, Ἐξεργασια, *Exposition*, in *Rhetoric*, a figure consisting of several equivalent expressions, or such as are nearly so, in order to represent the same thing in a stronger manner. The warmth and vehemence of the speaker often urge him to recur to this figure, when he is affected with his subject, and there are no words, no expressions, sufficiently forcible to express his sentiments; and he therefore repeats one after another, as his fancy suggests them. This flow of expression, under the conduct of a good judgment, is often attended with advantage; as it warms the hearers, and impresses their minds, excites their passions, and enables them to see things in a stronger light.

EXERGUM, Exergue, or *Exerge*, often denominated by Evelyn *exurge*, among *Medallists*, is the bottom of a coin, commonly separated from the field by a line, upon which the figures of the reverse stand. It is so called from being ἐξ ἐργυ, *out of the* work of the medal. When the letters or words of a medal run round the margin, are on either side of the figure, or upon the exergue, they are denominated a *legend*; but when they occupy the field, they are called an inscription. See Legend and Inscription.

EXETER, in *Geography*, a city in Devonshire, England is of great antiquity, and, as Risdon emphatically styles it. "may be called the emporium and principal ornament of the west." Its Roman name, as it appears in Ptolemy, is *Isca*; and it is conjectured that the second legion of Augusta was stationed here for some time: this was commanded by Vespasian, who was the conqueror of Britannia Prima, in which province this place was included. In the Itinerary of Antoninus, Exeter is called Isca-Danmoniorum, and is the most westerly station he has noticed: though, from the Iters of Ptolemy and Richard; from the remains of Roman roads over, and around Haldon; and from the vestiges of ancient ways through Drew-Teignton to Oakhampton, and perhaps of a road hence over Dartmoor, by Hollow-street in the parish of Chagford; it is apparent that various principal roads ran westward from this city; and, therefore, it is probable that the Romans had other stations west of this. How long Exeter retained the name of Isca-Danmoniorum is uncertain; though it seems probable that it fell into disuse very soon after the Romans quitted the island, about which time it appears to have been re-occupied by the Britons who had preserved their independence by retiring to the wilds of Cornwall. They did not, however, continue in the possession of it many years; for Cerdic, the founder of the kingdom of Wessex, having greatly extended his territories, either by conquest or intrigue, included the most considerable portion of Devonshire within his dominions: and at length Exeter became subjugated to the power of the Saxons. Under their government its name was changed to Evan-Cestre, Ex-Cestre, &c., and thence, through various similar appellations, softened to Exeter.

This city has been several times besieged; but the greatest calamities it experienced were inflicted by the Danes, who, in the reign of Alfred, in violation of a solemn treaty, surprised and routed the king's horsemen, and mounting their steeds, rode to Exeter, and remained there for the winter. Alfred collected all his forces and invested the city by land, while his fleet blocked up the harbour: the Danes capitulated, and agreed to evacuate all the territories of the West Saxons. Between the period of the death of Alfred and the reign of Athelstan, the Cornish Britons had recovered possession of Exeter; but Athelstan having defeated and driven them to the west of the Tamar, they were never afterwards able to oppose the Saxon arms. To secure his conquests he surrounded Exeter with a wall of hewn stones defended by towers: and under his auspices, says Malmsbury, "it became such a place of trade, that it abounded with opulence." He adds that many other remarkable works of Athelstan were to be seen in the city and its neighbourhood. In the year 1003 Exeter was the first sacrifice to the fury of Swein king of Denmark, when he came to revenge the inhuman massacre of his countrymen: being delivered up by the treachery of its governor, after a siege of two months, many of the inhabitants were put to the sword, and most of the buildings destroyed by fire. Before it was well recovered from this calamity, it was again besieged and taken by William the Conqueror. In the reign of Stephen, this city was alternately garrisoned by the forces of the king and the empress. It again became the scene of hostility during the contest between Henry VI. and Edward IV. In the reign of Henry VII. it was closely, though ineffectually, besieged by three thousand men under Perkin Warbeck. The last siege Exeter experienced was in Edward VI.'s reign, when religious innovations occasioned an alarming insurrection in the west of England: the inhabitants, though reduced nearly to famine, so so bravely defended the city for thirty-five days, that the insurgents abandoned their design.

The ground inclosed within the walls of the city is nearly in the form of a parallelogram, of four furlongs in length, and three in breadth: this space is intersected by the four principal streets which meet near the centre, and diverging at right angles, connect the city with the suburbs. The whole extent occupied by buildings is about one mile and three quarters in length, and one mile in breadth. In the year 1769 the surrounding walls were entire; but many parts have been since destroyed. Stukeley speaks of them as being, in his time, in pretty good repair, and having many turrets and towers, various parts of which are still remaining. Leland, speaking of this city, observes, that it is "a good mile and more in cumpace, and is right strongly waullid and maintainid. Ther be diverse fair towers in the toune waul bytwixt the south and the west gate. Ther be four gates in the toune, by the names of est, west, north, and south. The est and the west gates be now the fairest, and of one fascion of building: the south gate hath beene the strongest." In the year 1769 the north gate was taken down, to make a more convenient entrance into the city; and in 1784 the east gate was removed for the same purpose. The south gate, the interior arch of which Dr. Stukeley remarks to be of Roman workmanship, is intended to experience the same fate.

The situation of Exeter is commanding and pleasant: it stands on the acclivity of an eminence on the eastern banks of the river Exe, which flows in a semi-circular direction round the south-west side of the city. "What adds to its wholesomeness and cleanliness," says Stukeley, "is, that the ground is higher on a ridge along the middle of its length declining on both sides. Further, on the south-west and north-west sides it is precipitous; so that with the river, the walls, the declivity of ground, and ditch without side, 'twas a place of very great strength, and well chose for a frontier." In the highest part of the city, on the north side, stand the remains of Rougemont castle, which was formerly the seat of the West Saxon kings, and afterwards of the dukes of Exeter. This building has little to recommend it but its antiquity and pleasant situation. The ruins of the exterior walls are nearly all that remain; these inclose a considerable space, of a pentagonal form, and were defended by four towers; two on the west, and two on the east side. The ramparts of the castle command a most delightful view over the adjacent country. When the castle was erected is unknown; though Grafton's tale, that it was built by Julius Cæsar, is unquestionably false. William the Conqueror either rebuilt, or much repaired, the whole edifice, and bestowed it on Baldwin de Briono, husband of Albreda his niece, whose descendants, by the female line, enjoyed it, together with the office of sheriff of Devon, which seems to have been annexed to it, till the fourteenth year of Henry III.'s reign, when that prince, resuming into his own hands sundry castles and forts in this realm, dispossessed Robert de Courtney, in whose family it had been for three descents. In the civil war of the seventeenth century the castle was completely ruined, when the city withstood a blockade of two months against Fairfax, one of whose forts, Mr. Gough says, still remains in a field to the north. Within the area inclosed by the walls, a small chapel was erected by lady Elizabeth de Fortibus, countess of Devon, who endowed it with lands, called the prebends of Hays and Catton, for the payment of certain weekly services therein to be performed. A sessions-house, of Portland-stone, has been recently built within the area on the north-west side.

Within the walls of the city are fifteen parish churches, and in the suburbs four; but most of them being small, they present nothing worthy of particular description.

The cathedral is a large interesting edifice, and, according to Hooker and some other writers, was five hundred years in building; it consists of a nave with two aisles, a choir with aisles, a north and south transept, which are terminated by lofty towers. On the south side was a large cloister, which is mostly destroyed. To the east of this is the bishop's palace, which, with its gardens, are inclosed within a lofty wall. For a particular history and description with several architectural points, see a large folio work published by the Society of Antiquaries.

The episcopal see of Devon was seated at Crediton previous to its establishment at Exeter; but Leofric, who was bishop of that see, and lord chancellor of England, prevailed on Edward the Confessor to remove it to the latter town in the year 1049. That monarch, in person, with Eadyga, his queen, attended the installation, and placed the bishop in his new see; which at the same time he endowed with the lands and emoluments appertaining to that of Crediton. The see being thus established, it appears probable that a suitable cathedral was soon afterwards erected: but whether it was constructed by the enlargement and alteration of some existing edifice, or whether a separate and entire building was now raised, is uncertain. "It seems not unlikely," observes sir Henry Englefield, "that the first cathedral was not more than about sixty feet in length, and occupied the site of the present chapel of St. Mary." That the chapel, in its present state, was not the Saxon church, is satisfactorily proved by an examination of its architecture. No particular alteration appears to have been made in the cathedral before the time of William Warlewast, the third bishop, who was a Norman, and had been chaplain to the Conqueror, and his two sons, William and Henry; the latter of whom inducted him to this see in 1107. This prelate was a liberal benefactor to his cathedral; and it appears that he considerably enlarged it, and laid the foundation of the present choir: to him the towers yet remaining are probably to be ascribed; they are perfectly similar in style to the buildings of Gundulphus his cotemporary, and bear much more resemblanee to the magnificence of the Norman architects, than to the simplicity of the English Saxons.

Exeter has been from time immemorial, and still is, invested with great privileges. At the period of the Norman survey it enjoyed the same exemption from taxes as London, York, and Winchester. Since that time it has obtained many charters, and grants of immunities, from several monarchs. In the reign of Henry I. the fee-farm rents were granted to Matilda his queen; and in king John's time, Isabel, his consort, held Exeter in dower, with a fair thereunto belonging. In the third year of John's reign, the burgesses paid a fine of 110 marks for a confirmation of their charters; and about this period the city, which had been previously governed by port-reves and bailiffs, was incorporated, and had a mayor for its chief officer. We find in the Notitia Parliamentaria, that "in the reign of Edward I. the burgesses and citizens pleaded that their city was an ancient demesne, and that they held it in fee-farm of the crown, paying 39*l.* 15*s.* 3*d.* To support this claim, they referred to Henry III.'s charter, made to his brother Richard, king of the Romans; whereby they further challenged return of writs, a gallows, pillory, &c. and a fair of four days, besides three weekly markets; which liberties they certified they enjoyed since the time of the conquest; upon which they were allowed." Henry VIII. constituted

conſtituted Exeter a county of itſelf; thus rendering it independent of Devon, and inveſting it with correſponding privileges.

The corporation now conſiſts of a mayor, twenty-four aldermen, a recorder, chamberlain, town-clerk, ſheriff, four ſtewards, and ſeveral inferior officers. The corporate bodies within the city are thirteen, each of which is governed by officers annually choſen from among themſelves. Exeter was one of the firſt cities that returned members to parliament: the right of election is veſted in the magiſtrates and freemen, who are ſuppoſed to amount to about one thouſand perſons. The trade of Exeter is extenſive; yet would probably have been much more ſo, but for a contention between the inhabitants and Hugh Courtenay, earl of Devon, which deprived the city of the uſe of its river for navigable purpoſes during ſeveral centuries. The diſpute is reported by Izacke to have ariſen about ſome pots of fiſh; which, being expoſed for ſale in the market place, were ſeen nearly at the ſame time by the cators of the earl, and of the biſhop of Exeter, both of whom wanted the whole. The mayor, to whom the difference was referred, adjudged one part to the earl, another to the biſhop, and the third he directed to be kept for the uſe of the market. This deciſion, and a ſubſequent determination of the mayor and council, that no freeman of Exeter ſhould wear any foreigner's livery, badge, or cognizance without the mayor's licence, offended the earl, who immediately impeded the navigation of the river, "ſtopping, filling, and quirting the ſame," ſays Hooker, "with great trees, timber, and ſtones, in ſuch ſort, that no veſſel, or veſſels, could paſſe or repaſſe." Previouſly to this occurrence the tides flowed beyond the city; but now they only reach Topſham, a town between three or four miles nearer the ſea, the advantage of which was probably the chief object of the earl's meaſures, as that place was part of his eſtate, and became exceedingly flouriſhing in conſequence. The river was ſo completely choaked up, that though many attempts were made to reſtore the navigation, ſcarcely any thing was accompliſhed till the year 1675, when a canal was cut from Topſham to the city; and about twenty years afterwards the preſent haven was conſtructed: and by means of ſluices and flood-gates, veſſels of 150 tons burthen are now admitted to a good quay, formed near the city walls.

Exeter is ſituated 170 miles W. from London. The number of inhabitants, as returned under the late act, was 17,388; of houſes 2836. The principal employ of the labouring claſſes of people ariſes from the woollen trade; and the city has derived immenſe profits from the exportation of ſerge, kerſeys, and other articles, the value of which together has been computed at the average ſum of 600,000*l. per annum*: the chief markets were, during peace, Spain, Portugal, Germany, and Italy. About 300 perſons are alſo employed in manufacturing cotton, at a large factory eſtabliſhed on the banks of the river. Exeter had anciently a mint, which was granted by king Athelſtan; and money has been coined here ſo late as the reign of William III., the place of coinage being denoted by the letter E under the buſt.

This city has been the birth place of ſeveral very eminent and learned men. Among the moſt diſtinguiſhed are, Joſephus Iſcanus, whoſe writings adorned the commencement of the thirteenth century: John Hooker, ſir William Petre, and ſir Thomas Bodley, who all flouriſhed in the ſixteenth century; and ſir Peter, afterwards lord King, who held the high office of lord chancellor from 1725 to 1733.

In the vicinity of Exeter are ſeveral handſome, and reſpectable ſeats, belonging to the nobility and gentry. The principal of theſe are, Powderham-caſtle, belonging to viſcount Courtney; Mamhead, the ſeat of lord Liſburne; Haldon-houſe, the ſeat of ſir Lawrence Palk, &c.; Mount-Radford, the ſeat of John Baring, eſq.; Peamore, the ſeat of Samuel Kekewich, eſq.; Cleve, the ſeat of Thomas Northmore, eſq.; Cowicke, the ſeat of James White, eſq.; Oxton-houſe, the ſeat of the Rev. John Swete. Polwhele's Hiſtory of Devonſhire, 8vo. Jenkins's Hiſtory and Antiquities of Exeter, 12mo. 1806.

Exeter, a poſt-town of America, in the county of Rockingham and ſtate of New Hampſhire, and, Portſmouth excepted, the moſt conſiderable ſea port town in the ſtate. It is ſituated on the head of the navigation on Swamſcot, or Exeter river, a branch of the Piſcataqua, 15 miles S.W. of Portſmouth. The tide riſes here eleven feet. This town is well ſituated for manufactures, and has already ſix ſaw mills, a fulling mill, ſlitting mill, paper mill, ſnuff mill, two chocolate and ten griſt mills, iron-works, and two printing offices. The ſadlery buſineſs is very conſiderable. Some few veſſels of different burden are built here, and the river is capable of floating thoſe of 500 tons. The ſituation of Exeter is adapted for an extenſive population. The public edifices are, two congregational churches, an elegant building appropriated to the academy, a handſome and capacious court-houſe, and a gaol The public offices of the ſtate are at preſent kept in this place. It contains 1727 inhabitants. The townſhip is of an irregular figure, and about four miles ſquare. It was incorporated in 1638, before which period it was called Swamſcot falls; it lies 50 miles N. of Boſton. N. lat. 42° 59′. W. long. 71°. The academy was founded and endowed by the Hon. John Phillips, L.L.D. of Exeter, and incorporated by act of aſſembly in 1781. It is ſaid to be a reſpectable inſtitution, under the inſpection of a board of truſtees, and the immediate government and inſtruction of a preceptor and an aſſiſtant. Its annual income is 480*l.* and the number of ſtudents is commonly between 60 and 80. In 1794 a building was erected, which, in point of convenience, and perhaps of elegance, is exceeded by few buildings of the kind in the United States. Morſe.

Exeter, the north-weſternmoſt townſhip in Waſhington county, and ſtate of Rhode iſland, in which the ſeveral branches of Wood river unite; containing 2476 inhabitants, of whom 24 are ſlaves.—Alſo, a townſhip in Luzern county, Pennſylvania, including 737 inhabitants.—Alſo, a town in New Hanover county, in Wilmington diſtrict, North Carolina; ſituated on the N.E. branch of Cape Fear, about 36 miles from Wilmington.

EXFOLIATION. This term, in *Surgery*, denotes the proceſs by which the dead part of a bone ſeparates from the living portion. It is alſo not uncommon for ſurgeons to ſignify, by the word *exfoliation*, the piece of bone itſelf that has periſhed, though this is certainly an abuſe of language.

Exfoliation, or the ſeparation of a dead portion of bone from the living, is effected much in the ſame way as a ſlough is thrown off from the ſoft parts. The piece of bone which has periſhed is not detached by becoming rotten; for, in fact, it poſſeſſes conſiderable firmneſs, and at firſt coheres as intimately as ever to the living bone immediately contiguous to it. As Mr. Hunter has accurately obſerved, if the proceſs of exfoliation were not to take place, the dead piece of bone would remain undetached for years, inaſmuch as putrefaction is concerned in producing the ſeparation.

The more the pathologiſt conſiders the diſeaſes of the bones

bones, the more he will find them refemble thofe of the foft parts. This fact, indeed, anatomy would lead one to infer, fince the texture of the bones is the more fimilar to the ftructure of the reft of the body, than an uninformed perfon would fuppofe. The chief difference is, that the bones contain lime, which the foft parts do not.

Mr. Hunter defcribes the procefs of exfoliation as follows; a dead bone (he fays) acts on the fyftem in the fame manner as any other extraneous body. It ftimulates the adjacent living parts, in confequence of which fuch a procefs is begun, as muft end in the dead piece being thrown off. The effects of this ftimulus are; firft, that the living adjacent bone becomes more vafcular, a circumftance which always takes place, when a part has more to do than is juft fufficient for the fupport of life. Secondly, that the earth of the living part, when it is in contact with the dead bone, is abforbed. Hence the bone becomes fofter, and is now only adherent by the animal matter in its texture. Thirdly, that the living animal part is at laft abforbed along the furfaces of contact. This part of the procefs begins long before the laft is finifhed. Both of them begin firft at the furface, though, in their courfe, they do not every where take place, in an equal degree, at the fame time. Fourthly, that, in proportion to the wafte made by the laft part of the procefs, a fungus arifes from the living furface, and fills up the intermediate fpace, fo as to prevent a vacuum. Mr. Hunter obferves, that thefe different ftages, taken together, conftitute ulceration. He remarks, that when any part of a bone is once loofe, it will be pufhed towards the furface of the body, as moft other inanimate fubftances are. This part of the procefs is partly mechanical, and partly a continuation of ulceration. The fame diftinguifhed furgical writer alfo notices, that a proof of the third ftage above mentioned, may be derived from certain cafes, in which people die while exfoliation is going on. A fmall groove, or worm-eaten canal, may then be difcovered, which becomes gradually deeper, and follows the irregularities of the dead and living furfaces. After the application of the trepan, a circular piece of bone is frequently thrown off, which is always lefs than the fpace from which it came. This, fays Mr. Hunter, could never be the cafe, if there were not a lofs of fubftance.

Thus we find that exfoliation, and the procefs by which a flough of the foft parts is detached, are nearly alike. In both inftances, the matter which forms the bond of connection between the dead and living fubftances, is abforbed, the dead part is loofened, and is next pufhed off by the rifing of the granulations.

The bones, on which exfoliations moft frequently occur, are fuch as are of a firm, folid ftructure; thofe which are of a fpongy cellular texture, are more fubject to the affection called caries.

All the old furgical practitioners and writers ufed to promulgate the doctrine, that whenever the furface of a bone was laid bare, and deprived of its periofteum, an exfoliation muft inevitably follow. The practice, which was reforted to in confequence of this notion, did really, for the moft part, occafion a deftruction of a part of the bone, and the progrefs of the cafe feemed a confirmation of the erroneous opinion, refting on experience itfelf for its foundation. For it followed almoft as a matter of courfe with the ancient furgeons that fince they confidered the occurrence of exfoliation unavoidable in the circumftance which we have mentioned, their grand aim was to promote and accelerate the procefs, fo as to fhorten, as they conceived, the duration of the cafe. With this view, they ufed to put on the uncovered part of the bone ftimulating, drying, fpirituous applications, and, very often, the actual and potential cautery. Alfo, fancying that the wound could never heal till the dead piece of bone had come away, they ufed to avoid laying down the flefh, fo as not to leave the furface of the bone a long while expofed, a caufe, of itfelf, quite adequate to the production of an exfoliation.

However, the fact is, that a mere temporary expofure of part of a bone, fuch a tranfient denudation, as need only be permitted in cafes of wounds, is not neceffarily, or even commonly followed by an exfoliation, when a proper method of treatment is purfued.

We have already remarked that the difeafes of the bones are more like thofe of the foft parts, than many would imagine. The expofed furface of a bone will not die, if it be otherwife free from injury, and the furgeon, immediately he is called, take care to lay down the detached flefh in the fituation which it previoufly occupied. Even when the denuded bone, on account of lofs of fubftance, cannot be directly covered again, it will not always exfoliate, provided the furgeon, inftead of ufing the cautery, cauftics, fpirituous, or any other irritating applications, applies only fome plain foft lint, or a pledget of any mild fimple ointment.

When the foft parts are merely divided, the expofed furface will not flough; but when the wound is complicated, with a violent degree of contufion, laceration, &c. the cafe is different, and the fibres, veffels, &c. moft injured, will die and be thrown off. Thefe parts may either be killed at once by the violence, or the mifchief which they have fuftained may give rife to inflammation, which may terminate in floughing. Things are nearly the fame with refpect to the bones. We will bring to our confideration a few circumftances relating to the fubject of wounds of the head, which are, perhaps, more frequently than any other kind of wounds followed by exfoliations. In thefe inftances, if the foft parts be fimply cut, fo as to occafion an expofure of the cranium, without the bone itfelf being violently contufed, the wound may be healed by the firft intention, and no part of the fkull will exfoliate. The fame occurrences may happen, together with a detachment of the pericranium, and yet the fame confequences will follow.

However, when the external violence has affected the bone, as well as the foft parts, the injured part of the fkull will frequently die and exfoliate, notwithftanding the moft judicious treatment.

The procefs by which an exfoliating piece of bone is thrown off, depends almoft entirely upon nature, and the furgeon can interfere very little, with any real utility. The milder and lefs irritating his dreffings are, the better. Sometimes, when the dead part of the bone is loofe, but is fo covered with flefh that it cannot come away, the practitioner may greatly expedite the cure, by making a proper opening for the removal of the piece of bone that has exfoliated. Sometimes, when the procefs of exfoliation is long and tedious, he may render effential aid by occafionally introducing a pair of fmall forceps into fome finus leading down to the affected bone, and moving the exfoliating portion a little every now and then, fo as to accelerate its feparation. This latter proceeding, it is obvious, is only admiffible when the opening in the foft parts is large enough, and when the dead piece of bone either projects, or is of fuch a fhape as will allow of its being taken hold of with a pair of forceps. Sometimes, when the dead piece of bone is prevented from exfoliating, by being overlapped by new offeous matter at its circumference, the furgeon may properly make fome attempt to cut away the portion which is fo wedged, that its fpontaneous detachment would require an unreafonable length of time. Endeavours of this kind, however, on the part

part of the surgeon, should be made with great circumspection and prudence; and, indeed, they can only be justifiable when the affected bone is sufficiently superficial.

EXFOLIATIVUM, from *exfolio, to shed the leaf*, an instrument for scraping exfoliating bones.

EXFREDIARE, in our *Old Writers*, denotes the breaking of the peace, or committing open violence. Leg. Hen. I. cap. 31.

The word is formed from the Saxon, *frede, peace*.

EX GRAVI QUERELA, in *Law*, a writ that lies for him to whom any lands or tenements in fee are devised by will (within any city, town, or borough, wherein lands are deviseable by custom), and the heir of the devisor enters, and detains them from him. (Reg. Orig. 244. Old Nat. Br. 87.) And if a man devises such lands or tenements unto another in tail, with remainder over in fee, if the tenant in tail enter, and is seised by force of the intail, and afterwards dieth without issue, he in the remainder shall have the writ, ex gravi querela, to execute that devise. (New Nat. Br. 441.) Also where a tenant in tail dies without issue of his body, the heir of the donor, or he who hath the reversion of the land, shall have this writ in the nature of a *formedon in the reverter*. Ibid.

If a devisor's heir be ousted by the devisee, by entry on the lands, he may not afterwards have this writ, but is to have his remedy by the ordinary course of the common law. (Co. Litt. 111.) If the claimant's title accrues within 20 years, the most eligible method of proceeding, is now by *ejectment*; which see.

EXHÆREDATIO. See EXHEREDATION.

EXHALATION, a fume or steam exhaling or issuing from a body, and diffusing itself in the atmosphere.

The terms exhalation and vapour are ordinarily used indifferently, but the more accurate writers distinguish them; appropriating the term vapour to the moist fumes raised from water and other liquid bodies; and exhalation to the dry ones emitted from solid bodies, as earth, fire, minerals, sulphurs, salts, &c. In this sense, exhalations are dry subtile corpuscules, or effluvia, loosened from hard terrestrial bodies, either by the heat of the sun, or the agitation of the air, or some other cause, and emitted upwards to a certain height of the atmosphere, where, mixing with the vapours, they help to constitute clouds, and return back again into dews, mists, rains, &c.

Sir Isaac Newton takes true and permanent air to be formed from the exhalations raised from the hardest and most compact bodies. See AIR, DAMP, EVAPORATION, and VAPOUR.

EXHAUSTED RECEIVER, a glass, or other vessel, applied on the plate of an air-pump, and having the air extracted out of it by the working of the engine. (See AIR-*pump*.) Things placed in an exhausted receiver, are said to be *in vacuo*. See VACUUM.

EXHAUSTIONS, in *Mathematics*. Method of exhaustions is a way of proving the equality of two magnitudes, by a *reductio ad absurdum*; shewing, that if one be supposed either greater or less than the other, there will arise a contradiction. The method of exhaustions was of frequent use among the ancient mathematicians, as Euclid, Archimedes, &c. It is founded on what Euclid says in his tenth book, *viz.* that those quantities whose difference is less than any assignable quantity, are equal; for if they were unequal, be the difference ever so small, yet it may be so multiplied, as to become greater than either of them; if not so, then it is really nothing.

This he assumes in the proof of prop. I. book X. which imports, that if, from the greater of two quantities you take more than its half, and from the remainder more than its half, and so continually, there will, at length, remain a quantity less than either of those proposed.

On this foundation it is demonstrated, that if a regular polygon of infinite sides be inscribed in or circumscribed about a circle, the space, which is the difference between the circle and the polygon, will by degrees be quite exhausted and the circle become equal to the polygon.

EXHEBENUM, in *Natural History*, the name of a white and smooth stone, used by the ancient artificers in polishing gold. It seems to be the same with the lapis Samius, a small smooth stone which they often found in the Samian earth.

EXHEREDATION, EXHÆREDATIO, in the *Civil Law*, with us ordinarily called disinheriting, is the father's excluding his son from inheriting his estate.

There are fourteen causes of exheredation expressed in Justinian's Novel; without some one of which causes, he decrees the exheredation null, and the testament inofficious, as the civilians call it.

Indeed, by the ancient Roman law, the father might pronounce exheredation without any cause; but the rigour of this law was restrained and moderated by Justinian.

EXHIBIT, in *Law*. When a deed, acquittance, or other writing is, in a chancery suit, exhibited, to be proved by witness, and the examiner writes on the back, that it was shewed to the witness at the time of his examination; this is called an exhibit.

EXHIBITION, a producing or shewing of titles, authorities, and other proofs of a matter in contest.

Anciently, they used the phrase, exhibition of a tragedy, comedy, or the like; but now we say representation in lieu thereof.

EXHIBITION, *Exhibitio*, in our *Old Writers*, is used for an allowance of meat and drink, such as was customary among the religious appropriators of churches, who usually made it to the depending vicar. The benefactions settled for the maintaining of scholars in the universities, not depending on the foundation, are also called exhibitions.

EXHORTATION, HORTATIO, in *Rhetoric*, differs only from *suasion*, in that the latter principally endeavours to convince the understanding, and the former to work on the affections.

EXHUMATION, of *ex, out of*, and *humus, ground*, the act of digging up a body interred in holy ground, by the authority of the judge.

In France, the exhumation of a dead body is ordered, upon proof that he was killed in a duel. By the French laws, a parson has a right to demand the exhumation of the body of one of his parishioners, when interred out of the parish without his consent.

EXIDEUIL, in *Geography*, a town of France, in the department of Dordogne, and chief place of a canton, in the district of Perigueux; 18 miles N. E. of Perigueux. The place contains 870, and the canton 8378 inhabitants, in 15 communes, and on a territorial extent of 190 kiliometres.

EXIGENCE, or EXIGENCY, that which a thing requires, or which is expedient and suitable thereto.

EXIGENT, or EXIGI FACIAS, in *Law*, a writ which lies where the defendant, in a personal action, cannot be found, nor any thing of his within the county, whereby to be attached, or distrained. It is directed to the sheriff, ordering him to proclaim and call the party five county-court days successively, and charge him to appear, under pain of outlawry.

The

The fame writ alfo lies in an indictment of felony, where the party indicted cannot be found.

It is called an exigent, becaufe it exigit, *i. e.* exacts, or requires the party to appear, or, by forthcoming, to anfwer the law. If he appear not at the laft day's proclamation, he is faid to be *quinquies*, or *quinto exactus*, and then is outlawed. See OUTLAWRY.

EXIGENTERS, four officers of the court of common pleas, who make all exigents and proclamations, in all actions where the procefs of outlawry lies.

Anciently, the making writs of *fuperfedeas* upon fuch exigents as paffed in their offices, did likewife belong to them; but this branch of bufinefs was taken from them under king James I. and committed to a particular officer in the court of common pleas, created by patent. See SUPERSEDEAS.

EXILE, BANISHMENT. See BANISHMENT.

Among the Romans, the word exile, *exilium*, properly fignified an interdiction or exclufion from water and fire; the neceffary confequence of which was, that the interdicted perfon muft betake himfelf into fome other country, fince there was no living without fire and water. Thus Cicero ad Herenn. obferves, that the form of the fentence did not exprefs exile, but only *aquæ & ignis interdictio*. See INTERDICTION.

The fame author remarks, that exile was not properly a punifhment, but a voluntary flying, or avoiding the punifhment decreed: "Exilium non effe fupplicium, fed perfugium, portufque fupplicii." Pro Cæcina.

He adds, that there was no crime among the Romans, as among other nations, punifhed with exile; but exile was a recourfe people flew voluntarily to, in order to avoid chains, ignominy, ftarving, &c.

The Athenians frequently fent their generals, and great men into exile, out of envy of their merits, or diftruft of their too great authority.

EXILE is fometimes alfo ufed for the relegating a perfon into a place, whence he is obliged not to ftir without leave.

The word is derived from the Latin *exilium*, or from *exul*, a banifhed perfon; and that, probably, from *extra folum*, out of his native foil.

Figuratively, we ufe the phrafe, *honourable exile*, for an office, or employment, which obliges a man to refide in fome remote or difagreeable place.

Under the reign of Tiberius, remote employments were a kind of myfterious exiles. A bifhopric, or even a lord-lieutenancy, in Ireland, has been fometimes deemed a kind of exile. A refidence, or embaffy, in fome barbarous country, is alfo a fort of exile. Accordingly, it is faid, that the king cannot even conftitute a man deputy, or lord-lieutenant of Ireland, nor make one a foreign ambaffador againft his will, fince thefe in reality might be no more than honourable exiles. 2 Inft. 46.

EXILES, in *Geography*, a town of France, in the department of the Po, on the river Doria; 5 miles W. S. W. of Sufa. This town was fortified, and guarded one of the paffes into Piedmont; but by the treaty of peace between the French republic and the king of Sardinia, in 1796, the fortifications were to be razed.

EXILIUM, in *Law*, fignifies a fpoiling; and, by the ftatute of Marlbridge, it feems to extend to the injury done to tenants, by altering their tenure, ejecting them, &c. And this is the fenfe that Fleta determines; who diftinguifhes between vaftum, deftructio, and exilium. For he tells us, that vaftum and deftructio are almoft the fame, and are properly applied to houfes, gardens, or woods; but exilium is when fervants are enfranchifed, and afterwards unlawfully turned out of their tenements. Flet. lib. i. cap. 11. Stat. Marlb. cap. 25.

EXIMA, in *Geography*, a tribe or kabyle in the province of Sufa, in the fouthern divifion of Morocco; amounting to about 11,000 perfons.

EXIMENO, ANTONIO, in *Biography*, a Spanifh Ex-Jefuit, who had refided at Rome many years, and publifhed in that city, in 4to. 1744, a work, intitled "Dell' Origene e della Regole della Mufica," in which, too confident of his own powers, he imagined himfelf capable, with four years ftudy only, intuitively to frame a better fyftem of counterpoint than that upon which fo many great muficians had been formed. Poffeffed of eloquence, fire, and a lively imagination, his book has been called in Italy, "a whimfical romance upon the art of mufic, in which is difcovered a rage for pulling down, without the power of rebuilding." The author has certainly, with fhrewdnefs and accuracy, ftarted feveral difficulties, and pointed out imperfections in the theory and practice of mufic, as well as in the particular fyftems of Tartini and Rameau; but his own refources and experience are totally infufficient to the tafk of correcting the errors of the old fyftem, or forming a new one that is more perfect. He has more eloquence of language than fcience in mufic. His reafoning is ingenious and fpecious, even when his data are falfe; but his examples of compofition are below contempt; and yet, they are courageoufly given as models for ftudents, fuperior to thofe of the old great mafters of harmony.

When Sig. Eximeno calls fugues and canons Gothic compofitions, he does not difgrace their ftructure any more than he would our cathedrals, by calling them Gothic buildings. Let fugues be banifhed from the theatres and private concerts, if he pleafes, and let them remain in the church as a diftinct fpecies of compofition, where they were firft generated, and where they can never become vulgar or obfolete. The ftyle being naturally grave, requires mufical learning, and will, by the folemnity of the words and place of performance, continue to be reverenced and refpected. It is allowed that variety is more wanted in mufic than in any other art, and by totally excommunicating canons and fugues from the church, the art will lofe one capital fource of variety, as well as ingenuity; and intelligent hearers will be deprived of a folemn ftyle of mufic, to be heard no where elfe.

EXINANITION, the fame as evacuation.

EXISTENCE, that whereby a thing has an actual effence, or is faid *to be*, *effe*.

The notion of exiftence is applicable not only to a created but an uncreated fubftance: but it muft be added, that the exiftence of created fubftances, and efpecially corporeal ones, implies a refpect to place, time, and even an efficient caufe; whence the fchoolmen generally define it, that whereby a thing is formally and extrinfically without [*extra*] its caufes, and that here, and now.

Exiftence and effence come very near the nature of each other; in effect, they only differ in that we have different manners of conceiving the fame thing.

For, 1. Effence is ufually explained either by the firft, nobleft, and radical attribute of the thing, *e. gr.* that of body, by extenfion; that of mind by thinking, &c. or by fpecifying all the intrinfic attributes; and exiftence, either by fpecifying all place and all time, as in that of God; or by fpecifying fome definite place, and time, together with the caufe, as in the creatures.

2. The foundation and occafion of this diftinction is this

this; that eſſence belongs to the queſtion, *What is it? Quid eſt?* but exiſtence to the queſtion, *Is it? An eſt?*

3. Exiſtence, neceſſarily pre-ſuppoſes eſſence, and cannot be conceived without it; but eſſence may be conceived without exiſtence; in that eſſence belongs equally to things that are in *potentia*, and *in actu;* but exiſtence only to thoſe *in actu.* Note, however, that this does not obtain in God, about whoſe nature and eſſence the mind cannot think without conceiving his exiſtence.

We have divers ways of arriving at the knowledge of the exiſtence of things. Our own exiſtence we know by intuition; the exiſtence of a God, by demonſtration; and that of other things, by ſenſation.

As for our own exiſtence, we perceive it ſo plainly, that it neither needs, nor is it capable of any proof. In every act of ſenſation, reaſoning, or thinking, we are conſcious to ourſelves of our own being, and in this matter come not ſhort of the higheſt degree of certainty.

As to our knowledge of the exiſtence of a God, though he has given us no innate ideas of himſelf, yet, having furniſhed us with faculties of ſenſe, perception, and reaſon, we can never want a clear proof thereof. See God.

The knowledge of the exiſtence of other things, *i. e.* of external objects, bodies, a world, &c. we only have by ſenſation; for there being no neceſſary connection of real exiſtence with any idea a man hath in his memory, nor of any other exiſtence but that of God, with the exiſtence of any particular man; no particular man can know the exiſtence of any other being, but only when, by actually operating upon him, it makes itſelf be perceived by him. The having the idea of any thing in our mind, no more proves the exiſtence of that thing than the picture of a man evidences his being in the world, or the viſions of a dream make a true ſtory. It is, therefore, the actual receiving of ideas from without that gives us notice of the exiſtence of other things, and makes us know that ſomething doth exiſt at that time without us, which cauſes that idea in us, though we neither know nor conſider how it doth it.

This notice which we have by our ſenſes, of the exiſtence of things without us, though it be not altogether ſo certain as intuition and demonſtration, yet deſerves the name of knowledge, if we perſuade ourſelves that our faculties act and inform us right concerning the exiſtence of thoſe objects that affect them.

Now, beſides the aſſurance of our ſenſes themſelves, that they do not err in the information they give us of the exiſtence of things without us, we have other concurrent reaſons, as, 1. It is plain thoſe perceptions are produced in us by exterior cauſes affecting our ſenſes; becauſe thoſe that want the organs of any ſenſe never have the ideas belonging to that ſenſe produced in their minds. 2. Becauſe we find we cannot avoid having thoſe ideas, produced in our minds. When our eyes are ſhut, we can at pleaſure recal to our mind the ideas of light or the ſun, which former ſenſations had lodged in our memories; but if we turn our eyes towards the ſun, we cannot avoid the idea which the light or the ſun then produces in us, which ſhews a manifeſt difference between thoſe ideas laid up in the memory, and ſuch as force themſelves upon us, and we cannot avoid having; beſides, there is no one who doth not perceive the difference in himſelf between actually looking upon the ſun, and contemplating the idea he has of it in his memory; and therefore he hath certain knowledge, that they are not both memory or fancy. 3. Add to this, that many ideas are produced in us with pain, which we afterwards remember without the leaſt offence; thus, the pain of heat or cold, when the idea of it is received in our mind, gives us no diſturbance, which, when felt, was very troubleſome; and we remember the pain of hunger, thirſt, head ach, &c. without any pain at all, which would either never diſturb us, or elſe conſtantly do it, as often as we thought of it, were there nothing more but ideas floating in our minds, and appearances entertaining our fancies, without the real exiſtence of things affecting us from abroad. 4. Our ſenſes, in many caſes, bear witneſs to the truth of each other's report concerning the exiſtence of ſenſible things without us: he that doubts, when he ſees a fire, whether it be real, may feel it too if he pleaſes; and, by the exquiſite pain, may be convinced, that it is not a bare idea or phantom. Such is Mr. Locke's demonſtration of the exiſtence of external bodies.

The ingenious Dr. Berkeley has a different ſyſtem: external bodies, he contends, have no exiſtence, but in a mind perceiving them; that is, they only exiſt, *quatenus,* they are perceived; and of this he has given us what he and ſeveral others account a demonſtration.

In reality, "that neither our thoughts, paſſions, nor ideas formed by the imagination, exiſt without the mind, he obſerves, is allowed; and that the various ſenſations impreſſed on the mind, whatever objects they compoſe, cannot exiſt otherwiſe than in a mind perceiving them, is not leſs evident. This appears from the meaning of the term exiſt, when applied to ſenſible things. Thus, the table I write on, exiſts, *i. e.* I ſee and feel it; and were I out of my ſtudy, I ſhould ſay it exiſted; *i. e.* that were I in my ſtudy I ſhould ſee and feel it as before. There was an odour; *i. e.* I ſmelt it, &c. but the exiſtence of unthinking beings, without any relation to their being perceived, is unintelligible, their *eſſe* is *percipi.*" The notion of bodies, he endeavours to ſhew, is founded on the doctrine of abſtract ideas: "What are light and colours, heat and cold, extenſion and figure; in a word, the things we ſee and feel, but ſo many ſenſations, notions, ideas, or impreſſions on the ſenſe? And is it poſſible to ſeparate, even in thought, any of theſe from perception? The ſeveral bodies, then, that compoſe the frame of the world, have not any ſubſiſtence without a mind: their *eſſe* is to be perceived or known; and as long as they are not perceived by me, nor any other thinking being, they have no ſhadow of exiſtence at all. The things we perceive are colour, figure, motion, &c. that is, the idea of thoſe things; but has an idea any exiſtence out of the mind? To have an idea is the ſame thing as to perceive; that, therefore, wherein colour, figure, &c. exiſt, muſt perceive them. It is evident, therefore, there can be no unthinking ſubſtance or ſubſtratum of thoſe ideas: but you may argue, if the ideas themſelves do not exiſt without the mind, there may be things like them, whereof they are copies or reſemblances, which exiſt without the mind; it is anſwered, an idea can be like nothing but an idea; a colour or figure can be like nothing elſe but another figure or colour. It may be farther aſked, whether thoſe ſuppoſed originals, or external things, whereof our ideas are the pictures, be themſelves perceivable or not? If they be, they are ideas; if they be not, I appeal to any one, whether it be ſenſe to ſay, a colour is like ſomewhat which is inviſible; hard or ſoft, like ſomewhat intangible, &c. Some diſtinguiſh between primary and ſecondary qualities; the former, *viz.* extenſion, ſolidity, figure, motion, reſt, and number, they maintain have a real exiſtence out of the mind; as for the latter, under which come all other ſenſible qualities, as colours, ſounds, taſtes, &c. they allow the ideas we have of them are not reſemblances of any things exiſting exifting without the mind, or unperceived, but depend on the fize, texture, motion, &c. of the minute particles of matter. Now, it is certain, that thofe primary qualities are infeparably united with the other fecondary ones, and cannot even in thought be abftracted from them, and therefore muft only exift in the mind. Can any man conceive the extenfion and motion of a body without its other fenfible qualities? For my part, I find it impoffible to frame an idea of a body extended and moving, without giving it fome colour, &c. In effect, extenfion, figure, and motion, abftracted from all other qualities, are inconceivable; where the others, therefore, are, there thefe too muft be, *i. e.* in the mind, and no where elfe. Again, great and fmall, fwift and flow, are allowed to exift no where without the mind, being merely relative and changing, as the frame or pofition of the organ changes: the extenfion, therefore, that exifts without the mind, is neither great nor fmall, the motion neither fwift nor flow; *i. e.* they are nothing. That number is a creature of the mind, is plain (even though the other qualities were allowed to exift) from this; that the fame thing bears a different denomination of number, as the mind views it with different afpects; thus, the fame extenfion is 1, or 3, or 36, as the mind confiders it, with reference to a yard, a foot, or an inch. Nay, many of the modern geometricians hold, that a finite line may be divided into an infinite number of parts, and each of thefe infinitefimals, into an infinity of others; and fo on, *in infinitum*; fo that the fame thing is either unity or infinity, either no number or all number. In effect, after the fame manner as the modern philofophers prove colours, taftes, &c. to have no exiftence in matter, or without the mind; the fame thing may be proved of all fenfible qualities whatfoever: thus, they fay, heat and cold are only the affections of the mind, not at all patterns of real beings exifting in corporeal fubftances; becaufe the fame body which feems cold to one hand, feems warm to another. Now, why may we not as well argue, that figure and extenfion are not patterns or refemblances of qualities exifting in matter; becaufe to the fame eye, at different ftations, or to eyes of different ftructure, at the fame ftation, they appear various? Again, fweetnefs, it is proved, does not exift in the thing fapid, becaufe the thing remaining unaltered, the fweetnefs is changed to bitternefs, as in a fever, or by an otherwife vitiated palate. Is it not as reafonable to fay, that motion does not exift out of the mind? fince, if the fucceffion of ideas in the mind become fwifter, the motion, it is acknowledged, will appear flower, without any external alteration. Again, were it poffible for folid figured bodies to exift out of the mind, yet it were impoffible for us ever to know it: our fenfes, indeed, give us fenfation of ideas, but do not tell us that any things exift without the mind, or unperceived, like thofe which are perceived: this the materialifts allow. No other way therefore remains, but that we know them by reafon's inferring their exiftence from what is immediately perceived by fenfe. But how fhould reafon do this, when it is confeffed, there is not any neceffary connection between our fenfations and thefe bodies? It is evident, from the phenomena of dreams, phrenfies, &c. that we may be affected with the ideas we have now, though there were no bodies exifting without them; nor does the fuppofition of external bodies at all forward us, in conceiving how our ideas fhould come to be produced. The materialifts own themfelves unable to conceive in what manner body can act on fpirit, or how it fhould imprint any idea on the mind. To fuppofe, therefore, bodies exifting without the mind; is little elfe than to fuppofe God has created innumerable beings entirely ufelefs, and ferving to no purpofe at all. On the whole it appears, that the exiftence of bodies out of a mind perceiving them, is not only impoffible, and a contradiction in terms; but, were it poffible, nay real, it were impoffible we fhould ever know it. And again, that fuppofing that there are no fuch things, yet we fhould have the very fame reafon to fuppofe there were that we now have. Suppofe, *e. gr.* an intelligence affected with the fame train of fenfations, impreffed in the fame order, and with the fame vividnefs, would it not have all the reafon to believe the exiftence of bodies reprefented by his ideas that we have? All our ideas and fenfations are vifibly inactive; nay, the very being of an idea implies paffivenefs and inertnefs; fo that it is impoffible for an idea to do any thing, or, in ftrictnefs, be the caufe of any thing; it cannot, therefore, be the refemblance or pattern of any active being, unlefs oppofites can be faid to refemble one another. Now, we find a continual fucceffion of ideas of the mind; but thefe, it has been proved, do not depend on any external body as their caufe; it remains, therefore, that their caufe is an incorporeal active fubftance or fpirit: for that I am not the caufe of my own ideas, is plain from this, that when I open my eyes in broad day-light, I cannot help feeing various objects. Now, the fixed rules or methods wherein the mind we depend on excites in us the ideas of fenfe, are called *laws of nature*; thefe we learn by experience, which teaches us, that fuch and fuch ideas are attended with fuch and fuch other ideas in the ordinary courfe of things. Ideas are not any how, and at random, produced; there is a certain order and connection eftablifhed among them like that of caufe and effect; and there are feveral combinations of them made in a very regular artful manner, which we call *bodies*; and the fyftem of thofe, *the world*. In ftrictnefs, however, the connection of ideas does not imply the relation of caufe and effect, but only of a mark or fign of the thing fignified: the fire I fee is not the caufe of the pain I feel, but the mark that forewarns me of it; the noife I hear is not the effect of this or that motion or collifion of natural bodies, but the fign thereof. The Cartefians own fomewhat like this: the action of bodies on our organs, fay they, is not the efficient caufe of our ideas and perceptions, but only the occafional caufe, which determines God to act on the mind, according to the laws of the union of the foul and body." (See CAUSE.) Dr. Berkeley, indeed, taking away bodies, takes away what thefe philofophers account the occafions of their ideas: "by an occafion, he fays, muft either be meant the agent that produces an effect, or fomething obferved to accompany or go before it in the ordinary courfe of things; but matter is allowed to be paffive and inert, and cannot therefore be an agent or efficient caufe; and this matter primitively, and in itfelf, is allowed imperceivable, and devoid of all particular fenfible qualities; *i. e.* it has not this or that particular colour, this or that particular figure, &c. but has colour in the general, figure in the abftract, &c. but an abftract is no object of fenfe; matter, therefore, cannot be the occafion of our ideas in the latter fenfe." See Berkel. Princip. of Human Knowl. See ABSTRACTION.

How far the great argument of the maintainers of a material world from the impoffibility of God's deceiving us, and from the evidence that he does fo, if there be no fuch thing, will go againft this reafoning, we leave to the reader. See Stanl. Hift. Philofoph. part xii. p. 816. where the objections of the ancient Pyrrhonift to the exiftence of bodies are recited.

As to the exiftence of fpirits, Mr. Locke allows, that our having ideas of them does not make us know that any fuch things do exift without us; or that there are any finite fpirits, or any other fpiritual beings, but God. We have ground

ground from revelation, and feveral other reafons, to believe with affurance, that there are fuch creatures; but our fenfes, being not able to difcover them, we want the means of knowing their particular exiftence; for we can no more know that there are infinite fpirits really exifting by the idea we have of fuch beings, than by the ideas any one has of fairies or centaurs, he can come to know that things anfwering to thofe ideas do really exift.

EXIT, properly expreffes the departure of a player from off the ftage, when he has acted his part.

The word is alfo ufed in a figurative fenfe, to exprefs an kind of departure, even death.

EXITERIA, Εξιτήρια, in *Antiquity*, oblations or prayers to any of the gods for a profperous expedition or journey. There were alfo feafts under this denomination, which were celebrated by the Greeks, with facrifices and prayers, when their generals undertook expeditions againft any enemy.

EXITURA, from *exeo, to come from*, in *Surgery*, an abfcefs which difcharges matter.

EXITUS, Issues, in *Law*, the yearly rents or profits of lands or tenements. See Issue, &c.

EXLEGALITUS, the fame with an outlawed perfon. See Outlaw.

EXLUNZA, in *Geography*, a town of Spain, in the province of Leon; 5 miles S.E. of Leon.

EX MERO MOTU, in *Law*, formal words ufed in the king's charters and letters patent, fignifying that he does what is contained therein of his own will and motion, without petition or fuggeftion of any other.

The effect of thefe words is to bar all exceptions that might be taken to the inftrument, by alleging that the prince in paffing fuch charter was abufed by falfe fuggeftions.

EXMES, in *Geography*, a town of France, in the department of the Orne, and chief place of a canton in the diftrict of Argentan; 9 miles E. of Argentan. The place contains 618, and the canton 7358 inhabitants, in 31 communes, and on a territorial extent of $147\frac{1}{2}$ kiliometres.

EXMOUTH, though a watering place of confiderable fize and repute, is only a hamlet belonging to the parifh of Littleham, in the county of Devon, England. As its name imports, it ftands near the mouth of the river Exe. The buildings in general are low, but here are fome good houfes inhabited by genteel families. The vicinity is highly picturefque: from an eminence, called Chapel-hill, a line of coaft prefents itfelf, which extends from Exeter to Berry-head, a diftance of about twenty miles. This line is broken by feveral hills, behind which fpring up fome bold towering head-lands.

The plantations of Mamhead and Powderham-caftle heighten the beauty of the profpect; which is additionally embellifhed by the noble buildings connected with thofe eftates. Holinfhed mentions a caftle erected here to defend the entrance of the haven; and fome flight veftiges of embrafures are ftill apparent. Exmouth is fituated 168 miles W. from London; and contains, including the parifh of Littleham, 432 houfes, and 1909 inhabitants, of whom 570 are returned as employed in trade or manufacture. Polwhele's Devonfhire, vol. ii.

EXOACANTHA, in *Botany*, from εξακανθουμαι, *to be armed with fpines*; Mart. Mill. Dict. v. 2. Billard. Pl. Syr. fafc. 1. 10. Willd. Sp. Pl. v. 1. 1378. Clafs and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*.

Gen. Ch. *General Umbel* of many fpreading rays; the inner ones gradually fhorter; the innermoft extremely fhort; *partial* of many rays. *General involucrum* moftly of 12 channelled leaves, with fpinous points; *partial* halved, its intermediate leaf very long, exactly like thofe of the general involucrum. *Perianth* fcarcely perceptible. *Cor.* uniform, of five equal, inflexed, heart-fhaped petals. *Stam.* Filaments five, longer than the corolla; anthers roundifh. *Pift.* Germen inferior, ovate; ftyles two, fhort, ftraight; ftigmas fimple. *Fruit* fomewhat ovate, ftriated, feparable into two parts. *Seeds* two, ovate, convex and ftriated on the outfide, flat on the inner.

1. E. *heterophylla*. Billard. Syr. fafc. 1. t. 2. Gathered by M. La Billardiere near Nazareth. *Root* biennial, tap-fhaped. *Stem* two feet, or more in height, flightly zig-zag, branched, round, ftriated, leafy, fmooth. *Leaves* pinnate, fmooth; leaflets one or two pair with an odd one; thofe of the radical leaves ovate, fharply ferrated, often cut; thofe of the ftem-leaves lanceolate, acute, narrow, entire, the odd ones very long. *Umbels* terminal, folitary, of about 40 rays; the partial ones of about as many, which are equal and crowded. The *involucral* leaves are very long, prominent, curved downwards, each ending in a fharp fpine. *Petals* white. *Anthers* yellowifh. This plant is a-kin to the *Echinophora*, (fee that article,) but differs generically in the want of a perianth, and in having all the flowers perfect and regular, with naked fruit, not imbedded in the involucrum.

EXOCARPUS, from εξ, *out of*, and καρπος, *a fruit*, becaufe the feed ftands naked at the top of a flefhy bafis or receptacle refembling a pulpy fruit. Billard. Voy. Engl. ed. v 1. 167. t. 14. Clafs and order, *Polygamia Monoecia*, or rather, perhaps, *Pentandria Monogynia*. Nat. Ord. *Terebintaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, in five deep roundifh, equal fegments. *Cor.* none. *Stam.* Filaments five, inferted into the calyx between its fegments: anthers fmall, roundifh. *Pift.* Germen fuperior, globular; ftyle, fhort, folitary; ftigma peltate, orbicular. *Peric.* none. *Seed* a roundifh nut, of one cell, ftanding on the top of an elliptical, hollow, flefhy *receptacle*, about thrice its own fize. Some flowers have an abortive germen, others have no ftamens, all on the fame plant.

Eff. Ch. Calyx inferior, in five deep fegments. Corolla none. Stamens five. Piftil one. Stigma peltate. Nut of one cell, ftanding on a hollow flefhy receptacle.

E. *cupreffiformis*, the only known fpecies, is an evergreen tree, found in New Holland by M. La Billardiere, as well as by Dr. White. It bears innumerable, compound, pendulous, angular, leaflefs *branches*, at whofe extremities are fituated the minute greenifh *flowers*, produced in the month of May. The *fruit* is red, not unlike that of the yew in fize, form, and colour, but the feed is perfectly expofed to view. This plant has been raifed from feed in England, but whether it ftill remains in the gardens we know not. Its fingularity entitles it to notice, and, we believe, it is by no means very tender, if not hardy enough to bear our winters in the open air.

EXOCATACŒLUS, in *Antiquity*, a general denomination, under which were included feveral grand officers of the church at Conftantinople; as, the grand œconomus, grand facellarius, grand mafter of the chapel, grand fceuophylax, or keeper of the veffels, grand chartophylax, the mafter of the little chapel, and the protecdicus, or firft advocate of the church.

There are many opinions with refpect to the etymology of this term. F. Goar apprehends, that all the inferior priefts were called Κατακοιλοι, *catacœli q. d.* people of a low condition, and that their fuperiors were called exocatacœli, *q. d.* people out of the number of catacœli, or above them. Upon the whole, however, he adheres to the fentiment of G. Corcfius, who fays, that the patriarchal palace, and the apartments of the fyncellus, and of the monks in the patriarch's patriarch's fervice, were in a very low part of the city which, with regard to the reft, feemed a valley or pit; and that the officers above mentioned had their feveral houfes or palaces ἐξω, out of the valley; whence the name exocatacœli. M. Du-Cange derives the appellation from their being above the level or rank of the other clerks, and feated at church, &c. in more honourable places erected for that purpofe on either fide of the patriarch's throne.

The exocatacœli were of great authority: in public affemblies they had the precedence of bifhops; and in the patriarchate of Conftantinople did the office of deacons, as the cardinals originally did in the church of Rome. Accordingly, in the letter of John IX. to the emperor Bafilius Leo, they are called cardinales.

At firft they were priefts; but fome patriarchs of Conftantinople, whom Codin does not mention, would have them for the future to be no more than deacons. The reafon was, that being priefts, each of them had their feveral churches, wherein they were to officiate on all the grand feftival days; fo that it unhappily fell out, the patriarch, on the moft folemn days, was deferted by all his chief minifters.

EXO'CHAS, or Exoche, from ἐξω, *without*, and ἐχω, *to have*, in *Surgery*, a kind of excrefcence on the outfide of the anus.

EXOCIONITÆ, Exocionites, in *Church Antiquity*. The Arians were firft called Exocionites, becaufe, when expelled the city by Theodofius the Great, they retired into a place called Exocionium, and there held their affemblies. Juftinian gave the orthodox all the churches of the heretics, excepting that of the Exocionites.

The word is derived from Ἐξακιονιον, or Ἐξωκιονιον, the name of the place above mentioned. Codin, in his Origines, fays, that the Exocionium was a place encompaffed with a wall, built and adorned by Conftantine; and that without the circumference of the wall there was a column, with a ftatue of that emperor, whence the place took its name, *viz.* from ἐξω, *without*, and κιων, *column*.

EXOCŒTUS, in *Ichthyology*, a genus of the abdominal kind of fifhes; the head is fcaly; mouth without teeth; jaws connected at each fide; in the gill-membrane ten rays; body whitifh; abdomen angulated; pectoral fins large, and formed for flying; anterior part of the rays carinated. Thefe are the flying fifhes of Englifh authors.

Species.

Volitans. Abdomen carinated each fide. Linn. Amœn. Acad. *Exocœtus*, Gronov. *Winged flying fifh*, Donov. Brit. Fifhes.

This is an inhabitant of the American and Red feas, and alfo thofe of the warmer parts of Europe: in one or more inftances it has been known to appear as far north as Britain. The vaftly difproportionate magnitude of the pectoral fins in this genus of fifhes affords them extraordinary advantage in effecting their efcape when clofely purfued by their voracious enemies in the water; but this facility of efcape expofes them oftentimes to the attacks of other adverfaries, and they not unfrequently elude the purfuit of the bonito, or the porpeffe, in their native element, to become the prey of gulls, corvorants, and other aquatic birds that hover over the water to feize on them in their aerial flight. They remain only for a fhort time fufpended in the air before they again dive into the water, and after a paufe of a few moments emerge again at fome diftance. They often quit the water in fhoals, and fometimes alight on board fhips in great numbers. The flefh is occafionally eaten.

The colour is filvery, with the back rather blueifh; the pectoral fins blueifh, edged with yellow; ventral fins and extremity of the tail fometimes reddifh.

Exiliens. Ventral fin reaching to the tail. Gmel. Bloch. *Swallow fifh*.

A native of the Mediterranean and Red feas. The colour is filvery, blue on the back, with the fins yellowifh at the bafe, with the extremity blueifh. The flefh is in efteem.

Mesogaster. Ventral fins in the middle of the abdomen. Bloch. *Atlantic flying-fifh*.

Native of the Atlantic feas, and was obferved by Plumier about the coafts of the Antilles. The fifh is bright filvery, with the back and fins blueifh. The fpecies is fufficiently diftinguifhed by the fituation of the ventral fins.

Commersonii. Dorfal fin marked with a dark blue fpot.

Cepede. *Commerfonian flying-fifh*. Shaw Gen. Zool.

Defcribed by Commerfon as refembling the firft fpecies, except in having a dark blue fpot on that part of the dorfal fin neareft the tail, and the ventral fins placed beyond the middle of the abdomen, their tips reaching to about the middle of the anal fin.

The laft mentioned fpecies, we are inclined to believe, may not differ fpecifically from the fifh defcribed by Bloch under the name of mefogafter: the evolans and volitans of Linnæus, according to fome writers, conftitute but one fpecies; and we fhould alfo fpeak with diffidence of the fifh denominated exocœtus non volitans by Forfkal; is it a variety of volitans β, as Gmelin confiders, or rather an error arifing from fome accidental circumftance?

EXOCY'STE, or Exocy'stis, from ἐξω, *without*, and κυστις, *the bladder*. Writers define this term of furgery a prolapfus of the lining of the bladder. We are probably to underftand by the word, a protrufion of the lining outward, between the fafciculi of the mufcular coat of this organ, an occurrence which we know does really fometimes take place. Stones have been found protruded in this manner, carrying along with them a part of the lining of the bladder.

EXODIARY, Exodiarius, in the *Ancient Roman Tragedy*, was a droll, or mime, who appeared on the ftage when the tragedy was ended, and performed what they called the exodium, or conclufion of the fhew, to divert the company.

EXODIUM, Ἐξοδιον, in the *Ancient Greek Drama*, was one of the four parts or divifions of a tragedy.

The word is formed from the Greek, ἐξοδος, *going out*, *digreffion*, of ἐξ and οδος, *way*, *road*. Feftus, lib. v. calls it *exitus*.

The exodium, according to Ariftotle, was fo much as was rehearfed after the chorus had ceafed to fing for the laft time; fo that exodium with them was far from being what the epilogue is with us, as feveral people have imagined it was.

The exodium was fo much of the piece as included the cataftrophe and unravelling of the plot; which cataftrophe, &c. in pieces regularly compofed, always began after the laft finging of the chorus, anfwering nearly to our fourth and fifth acts. M. Dacier's Comment. on Ariftotle's Poetics, chap. 12. See Catastrophe and Chorus.

Among the Romans the exodium was a different thing; it was pretty nearly what farces are with us. After the tragedy was over, came a pantomime on the ftage, called the exodiarius, who, by his grimace, jefting, and buffoonery, diverted the people, compofed their minds, and wiped away the tears which the tragic fpectacle had occafioned to be fhed.

Viginere on T. Livy fays, the exodium confifted of certain

tain humorous drolling verses, rehearsed by the youth at the end of the fabulæ atellanæ, and answering to our farces. In another place, the same author says, that the exodia were a kind of interludes in the intervals between the acts, partly fable and pleasantry, partly music, &c. to give time both for the spectators and actors to recover breath. The passage in Livy, whence he takes the notion, is lib. vii. dec. I. "Ridicula intexta versibus, quæ juventus inter se more antiquo jactare cœpit, eaque conferta sunt fabulis potissimum atellanis." See also Juvenal.

"Urbicus exodio risum movet Attellanæ
Gestibus Autonoes."

Exodium, in the *Septuagint*, signifies the end or conclusion of a feast.

The Hebrew text calls the day עצרת, which the Seventy render Ἐξόδιον.

In particular, exodion is used for the eighth day of the feast of tabernacles, which, it is said, had a special view to the commemoration of the Exodus, or departure out of Egypt, though there is nothing of it expressed in Scripture.

Exodium, was also the name of a song sung at the conclusion of a meal or feast.

EXODUS, the second of the five books of Moses.

The word in its original Greek, Ἔξοδος, literally imports a *going out*, or *journey*; and was applied to this book, because the history of the Israelites' passage out of Egypt is related therein. Besides this, it contains the story of what was transacted in Egypt from the death of Joseph to the delivery of the Jews; as well as what passed in the wilderness, and particularly at mount Sinai, to the building of the tabernacle.

The Hebrews call it *veelle semoth*, q. d. *hæc nomina*, these are the initial words of the book; for the same reason they call Genesis, *beresith*, q. d. *in principio*, *in the beginning*.

EX OFFICIO, in *Law*, denotes a power which a person has in virtue of his office, to do certain things without being applied to; as a justice of peace may not only grant surety of the peace, at the complaint or request of any person, but he may demand and take it, ex officio, at discretion, &c. Dalt. 270.

By a branch of statute 1 Eliz. the queen, by her letters patent, might authorize any persons exercising ecclesiastical jurisdiction to administer an oath, ex officio, whereby supposed offenders were forced to confess, accuse, or clear themselves of any criminal matter, &c. but this branch relating to this oath is repealed by 17 Car. I. cap. 11.

Ex officio *Informations*. See Information.

EXOLICETUS, in *Natural History*, a name used among the writers of the middle ages to express a small stone which had such a variety of colours that it dazzled, as they say, people's eyes in looking at them. It is said to have been found in Libya. The name is probably only a corruption of the hexacontalithos of Pliny and the older writers; and this seems to have been no other than a name for the opal.

EXOMIS, of ἐξ, *out of*, and ὦμος, *shoulder*, in *Antiquity*, a straight narrow garment through which the shoulders appeared. It had something in common with the tunic, and something with the pallium. It was worn by slaves, servants, and the lower classes of people among the Romans.

EXOMOLOGESIS, Ἐξομολογησις, formed of Ἐξομολογεω, *I confess*, a term little used but in speaking of the ancient ceremonies of repentance, whereof the exomologesis, by us called *confession*, was a part.

Some of the ancients, and particularly Tertullian, De Pœnit. cap. 9. use the word in a greater latitude, as comprehending the whole of repentance.

A public exomologesis was never commanded by the church for secret sins, as may be seen in the capitulars of Charlemagne, and the canons of divers councils.

EXOMPHALOS, from ἐξ, *out*, and ὀμφαλος, *the navel*, in *Surgery*, an umbilical hernia, or a disease which consists of a protrusion of some of the abdominal viscera at the navel. The subject will be particularly considered in the article Hernia.

EXONCHOMA, from ἐξ, *out*, and ογχος, *a tumour*, any large prominent swelling.

EXONEIROSIS, from ἐξ, *out*, and ονειρος, *dream*, a nocturnal pollution or emission of the semen in dreams. This, if it happens but rarely, is usually a sign only of redundant vigour; but if it happens frequently, is a sign of weakness of the seminal vessels, which is most frequently the case.

EXONERATIONE Sectæ, in *Law*, a writ that lay for the king's ward, to be freed from all suit to the county-court, hundred-court, leet, &c. during the wardship. F. N. B. 158.

EXONYCHOS, of ἐξω, *without*, and ονυξ, *a nail*, in *Botany*, a name given by some of the ancient writers, among whom are Dioscorides and Pliny, to the gromwell or lithospermum. See Ægonychus.

EXOPHTHALMIA, from ἐξ, *out*, and οφθαλμος, *the eye*, in *Surgery*, a disease consisting of a protrusion, or a preternatural projection of the globe of the eye from the orbit, so that the part cannot be duly covered by the eye-lids. The disorder may proceed either from a morbid enlargement of the eye-ball, or what, perhaps, is a still more common cause, some tumour which occupies or diminishes the cavity of the orbit, and consequently displaces the eye.

The affection has several other names besides exophthalmia; as, for instance, buphthalmus, ophthalmoptosis, prolapsus oculi, ecpiesmos, melon, &c.

From the few words already delivered on the subject, it is easy to perceive that exophthalmia may arise from a variety of causes, and must of course require very different modes of treatment in different cases.

One cause of the disorder noticed by writers, is a disease of the fat and cellular substances situated in the orbit, and serving as a support to the eye-ball. In this case the surface of the eye appears more moistened with tears than usual, and the fat and cellular substance becoming thickened and indurated, forces the eye-ball forward out of its socket. As the eye cannot now be properly covered and sheltered by the eye-lids, it inflames, and ulcerates on its surface, and the patient becomes afflicted with very severe and deep-seated pain. This sort of cause is as difficult of removal, when the disease has advanced to a certain extent, as it is difficult of detection at an early period of the case. The famous oculist, Saint Yves, pretends, however, to have sometimes dispersed such thickenings of the cellular substance in the orbit by persevering in the exhibition of calomel and purgative medicines. The same author assures us, that he successfully exhibited the æthiops mineralis to a scrofulous patient for three months, whose eye-ball protruded to the extent of three lines, by reason of a morbid thickening of the cellular substance, and an enlargement of the lachrymal gland.

When the disease does not yield to any remedies, the symptoms may become so urgent as to render the extirpation of the eye indispensably necessary, as is proved by the following case related by Saint Yves. A woman's eye-ball protruded out of its natural situation, in consequence of a morbid thickening of the fat at the bottom of the orbit. The

The difeafe was attended with infupportable pain, and great reftleffnefs. The fymptoms were appeafed by the employment of general means, and the progrefs of the affection was for a time retarded. Three years afterwards, the eye having been left in a projecting condition, Saint Yves was requefted to vifit the patient. She was now labouring under a violent fever, accompanied with fevere head-ach. The globe of the eye was of a leaden colour, and exceedingly prominent, its coats being fwollen, and appearing likely to become gangrenous. The medical practitioners who were in the habit of attending the woman were of opinion that the eye ought to be extirpated. The neceffity for performing the operation, indeed, feemed to them fo urgent, that the proceeding was immediately adopted. The febrile and all untoward fymptoms fubfided on the fourth or fifth day, and, in about three weeks, the cure was complete.

Exophthalmia may alfo be occafioned by fome tumour of the furrounding parts, either of thofe within, or of others on the outfide of, the orbit. The celebrated French furgeon, M. Louis, met with a man, 40 years of age, in whom a carcinomatous fungus, fituated in the antrum, had deftroyed the bony plate which conftitutes the bottom of the orbit, and pufhed the eye-ball almoft entirely on the cheek, fo as to produce a great deformity of the countenance. The upper jaw bone was carious, both towards the palate and nofe, and the patient perifhed of the afflicting complaints, brought on by the carcinomatous ulceration of all the difeafed parts. The exophthalmia was the effect of the prodigious fize of the tumour, the growth of which could not be effectually refifted by the bones. The protrufion of the eye, fays M. Louis, might have been prevented by attacking the firft difeafe at a proper period, on the fide towards the mouth. The growth of the cancerous fungus is reprefented by this diftinguifhed writer as the effect of a difeafe of the bone, which latter affection he defcribes as the confequence of fyphilis, which had not been fkilfully treated.

Raw makes mention of a child whofe left eye was completely protruded from the orbit, and as large as one's two fifts. The difeafe, which had only begun a few months before, proved fatal. On opening the cranium, a fungous fwelling was difcovered, the bafe of which was connected with the dura mater above the orbit, without any difeafe of the cerebrum.

Exophthalmia, however, originates ftill more frequently from the enlargement of an exoftofis, which arifes within the orbit, and forces the eye-ball out, in proportion as it increafes in magnitude. When the bony fwelling is fituated near the edge of the orbit, the tumour may be attacked with beneficial effects, without meddling with the eye itfelf. The truth of what has juft now been obferved is illuftrated by the following cafe. A woman, 30 years of age, had a fiftula lachrymalis, for which fhe had undergone an operation to no purpofe. The bones became enlarged, and, fifteen years afterwards, an exoftofis of the os planum and internal angular procefs of the os frontis had attained the fize of an egg. The globe of the eye, being laterally compreffed, was forced out of the orbit, and, in fome meafure, hung over that part of the cheek which was near the leffer angle. M. Braffant applied a cauftic to the exoftofis; fuppuration enfued, and in the courfe of three or four months an exfoliation of a confiderable portion of the bony fwelling took place, the eye refumed its natural pofition, and the cure was completed a fhort time afterwards.

Exophthalmia is fometimes produced by the formation of a fteatomatous, or fchirrous tumour, at the bottom, or fides of the orbit. Trincavelli, Bonnetus, and Saint-Yves, furnifh us with feveral examples of this fort. Here an operation is requifite; but a great deal of patience and dexterity are effential in its performance. As the recital of facts tends to the elucidation both of precept and practice, we fhall offer an abridged account of a cafe, related by Dr. Hope, in the Philofophical Tranfactions, where every thing refpecting the method of treatment is very perfpicuoufly explained. A young woman, eighteen years of age, was affected, when twelve years old, with a diftortion of her left eye, towards the temple. This circumftance arofe gradually, in confequence of the growth of a tumour between the eye and the orbit. In a few years, the fwelling protruded externally, in the form of a hard tumour, which extended from the greater angle nearly to the leffer one, beneath the lower eyelid, and which reached nearly half an inch over the cheek. This tumour had pufhed almoft the whole eye-ball out of the orbit, fo that the pupil was removed more than three inches from its proper place. The eye was alfo much more prominent than the other, pufhed over the temple, and quite motionlefs, which circumftances, together with the tumour, prefented a frightful appearance. The fight, however, was not loft. Dr Hope, though diffuaded by Monro, undertook the cure of the patient in the year 1744. Having placed her in a convenient pofture, and made the integuments tenfe, he made an incifion about an inch long, from the greater to the leffer angle, following the direction of the fibres of the orbicularis palpebrarum mufcle. The lips of the wound being feparated, he next paffed a crooked needle, armed with fome filk, through the middle of the tumour, and, regularly as he cut all the adhefions with a biftoury, he drew outward the whole mafs of the difeafe. Sciffars were employed for dividing fuch connections, as were the moft deeply fituated. The part which was thus cut out appeared to be furnifhed with a thick membranous fubftance, exclufively of the body of the tumour, which was of a regular, fpherical, fmooth form, and about as large as a fmall pigeon's egg; the interior was of a flefhy ftructure. In detaching the fwelling from its adhefions, feveral callous indurations were met with, attached to the globe of the eye. The tumour being extirpated, Dr. Hope introduced his finger to the bottom of the orbit, where he felt feveral hardneffes and callofities ftill remaining; he kept his finger there, and having by this means paffed in a needle and ligature, he drew them through the bafe of the callofities. Now having directed an affiftant to hold up the ligature, he paffed in the point of a pair of fciffars, on the end of his finger, and made two or three ftrokes with them, in the place where he felt the roots of the callous hardneffes. Thus he fucceeded in cutting away the whole of the indurated parts, fo as to leave the bottom of the orbit, as far as he could afcertain, perfectly fmooth and free from callofity. All the time that the operation lafted, no hæmorrage of any confequence took place: only a large quantity of dark-coloured grumous blood was poured out from the varicous veffels. The wound was dreffed with fome dry lint, which was not removed till the third day. The eyelids and tunica conjunctiva were affected with a flabby kind of fwelling, attended with a flight inflammation and pain in the anterior part of the head. The dreffings confifted of fimple digeftive and refolvent applications. The pain in the head, and the tumefaction continued three days, without any formation of matter. Dr. Hope then touched the bottom of the wound with the lapis infernalis, and, a few hours afterwards, a large quantity of black blood was difcharged. From this period the pain in the head, and the fwelling ſwelling ſubſided; there was alſo emitted, during the two ſucceeding days, a bloody ſanies, which occurrence induced Dr. Hope to make uſe of ſome injections of warm water, mixed with a little ſpirit of wine, and honey of roſes. After the adoption of this plan of treatment, the pus aſſumed a more favourable appearance. Such ſoft, fungous excreſcences as aroſe in the courſe of the cure, were deſtroyed with the lapis infernalis, and it was not long before the wound was entirely healed. The eye, however, remained unalterably immoveable; for the abductor muſcles had been ſo long contracted, while the adductors had been for ſo conſiderable a time ſtretched and tenſe, that they had completely loſt all power of action.

Finding, that by making rather forcible preſſure on the eye-ball, the part could be made to return, in a great degree, into the orbit, though it became protruded again as ſoon as ſuch preſſure was diſcontinued; Dr. Hope conceived, that a bandage which would conſtantly keep up a graduated compreſſion, might be attended with ſome benefit, and determine the muſcles more ſpeedily to reſume their proper tone, by maintaining the eye in its natural ſituation. Conformably to this idea, this gentleman cauſed a ſteel bandage to be conſtructed, with a concave plate proportioned to the convexity of the globe of the eye. This apparatus made preſſure on the ſide of the eye-ball next the temple, by means of a ſcrew. The machine was put on, after gently puſhing back the eye into its natural ſituation with the hand; and then laying a ſoft compreſs between the eye and the plate of copper, Dr. Hope uſed to make the preſſure act on the part by means of the ſcrew, in ſuch a way, that it was impoſſible for the eye to become diſplaced outward again, as it uſually was before. With the aid of this bandage, which the patient wore conſtantly, night and day, and which was gradually tightened more and more, the eye regained its natural poſition in the ſpace of about twenty days, and did not deviate from it again. At the time when the caſe was publiſhed, the eye was capable of motion in every direction, and the patient could ſee quite as well with it as the other. The wound got completely well in about a month, and only ſeven weeks elapſed before the cure was, in every reſpect, perfect.

Reſpecting the foregoing caſe, M. Louis obſerves, that it certainly does honour to the ſkill and intelligence of the gentleman who undertook the treatment.

Le Dran was equally ſucceſsful in the treatment of a ſimilar diſeaſe, though certainly it was not ſo conſiderable as the preceding. The means made uſe of, were the actual cautery and alternative medicines. The ſubject was a young lady, aged eighteen, who, from her infancy, had been ſubject to inflammations about her lips, eyes, and ears. She had had a fiſtula lachrymalis, and, ſome time after the uſual operation for this complaint, there originated, at the leſſer angle of the eye, a fungous excreſcence, which protruded from the orbit, and had been ſucceſſively removed with the knife, and touched with the lapis infernalis; but in vain, as the tumour always made its appearance again. This plan of treatment was not attended with any greater ſucceſs under the hands of Le Dran, and, conſequently, he ſoon made up his mind to attack the excreſcence, by introducing the actual cautery into its centre. For this purpoſe, he took a long, large, ſewing needle, and had it firmly fixed on a handle. The inſtrument, having been made red-hot in the flame of a wax-candle, was puſhed to the depth of about half an inch into the middle of the ſwelling. By repeating the application of the cautery three or four times, at intervals of a few days, Le Dran ſucceeded in deſtroying the tumour as deeply as its root, the action of the fire having extended beyond the parts actually touched with the heated needle. The conſequence was, that the ſwelling never grew again. To render this cure more certain, Le Dran, for a long while, kept the cauteriſed part open, and the patient was ordered to take alterative medicines, the chief of which were calomel and æthiops mineralis.

The two foregoing examples prove what ſurgery can accompliſh, when the diſeaſe is taken in time. However, when the proper kind of treatment has been deferred too long, the affection of the eye becomes of ſuch a deſcription, as to be irremediable. Nothing now remains to be done except extirpating, not only the tumour, but alſo the whole of the eye-ball. Even this formidable operation is often impracticable, particularly when the parietes of the orbit are diſeaſed. For the bones, in conſequence of the preſſure made upon them by the ſwelling, are rendered carious, and very foul ill-conditioned ulcers are produced. In this ſtate there can be but little hope of a recovery, whatever mode of treatment is adopted.

One ſpecies of exophthalmia, which is indeed uncommon, but not the leſs worthy of being known, is that which is occaſioned by an encyſted tumour. In the fourth volume of the Medical Obſervations and Inquiries, there is an inſtance recorded by Dr. Brocleſby. A labouring man of the pariſh of Haſelmere, in Surry, had been for ſeveral years afflicted with a pain and an obſcurity of ſight in one of his eyes. The affection continued, without much attention being paid to it, until, about two or three years afterwards, the man became quite blind on that ſide. At this period, the globe of the eye was protruded outward in ſuch a manner, that almoſt the whole of the inner ſurface of the lower eye-lid was turned out, and hung down over the cheek, ſo as to form a true ectropium.

Several ſurgeons who were conſulted adviſed the patient not to expoſe himſelf to the riſk of an operation, fearful that the diſeaſe might be converted into one of a cancerous nature. Notwithſtanding this counſel, the man did not ceaſe going about to have the advice of all ſuch perſons as ſeemed likely to afford him any aſſiſtance. At length, he applied to Mr. Dale Ingram, who, having carefully examined the diſeaſe, thought, that on compreſſing different places, he felt a decided fluctuation below the globe of the eye. He immediately ſuſpected, that the fluid was contained in a cyſt, and, conſequently, that the patient might receive relief from an operation. However, the above gentleman would not undertake any thing without conſulting Mr. Bromfield.

The latter ſurgeon, after a careful examination, was not againſt the probability of ſucceſs, and he did the operation in the following manner. After having covered the ſound eye, by tying a handkerchief round the head, and put the eye-lids of the affected eye as near together as poſſible, and directed them to be held in this poſition, Mr. Bromfield made an inciſion through the lower eye-lid to the conjunctiva, and thus made a ſufficient opening for the introduction of his finger behind the globe of the eye. In this way he was enabled to put in a very narrow ſharp-pointed knife, for the purpoſe of puncturing the ſubſtance, which was taken to be the cyſt. Mr. Bromfield was not deceived in his expectation; for, as ſoon as the opening was made, nearly a glaſsful of a thin tranſparent fluid was diſcharged. He now waited a little, both in order to give the patient an opportunity of waſhing out of his mouth ſome blood, which had got into it, and for the ſake of conſidering what ſteps could be taken to extirpate the cyſt, which had contained the fluid. At laſt, he determined to proceed as follows: he

paſſed

paſſed into the wound a double kind of tenaculum, with which he took hold of the cyſt, and then diſſected it entirely away. The wound was filled with ſoft lint, and the dreſſings were kept on with a ſuitable bandage.

In leſs than four and twenty hours there appeared on the ſame ſide of the face a conſiderable degree of ſwelling, which ſoon ſubſided, however, on a dilatation of the firſt wound being made, lighter dreſſings being put on, and the bowels opened. In leſs than a month the man got quite well, and returned to his home with infinite ſatiſfaction. Dr. Brocleſby obſerves, that Mr. Ingram was perſuaded, before the operation, that the muſcles would draw back the eye-ball into the orbit, and that even ſome degree of viſion might return. The doctor could hardly ſuppoſe all this poſſible; but, having an opportunity of ſeeing the man, about five months afterwards, he could ſcarcely recognize him. The eye-lids had recovered their original ſtate, and moved as well as thoſe of the oppoſite eye. The man alſo informed Dr. Brocleſby, that, for about the laſt month, he had begun to diſtinguiſh with the affected eye light from darkneſs, and that his power of ſeeing was becoming greater every day. Dr. Brocleſby remarks, that he could not find any caſe of this kind related by authors, except one very analogous inſtance, recorded by Saint Yves in his treatiſe on the diſeaſes of the eyes.

The laſt kind of exophthalmia which we have to notice, is that which Sauvages has termed *traumatic*. In this ſort of caſe, the eye is ſo much protruded from the orbit, that ſurgeons have frequently been induced to remove the diſplaced part altogether, and this ſometimes has been done too inconſiderately for the unfortunate patient. Covillard informs us, in his Chirurgical Obſervations, that he was called to ſee a man, againſt whoſe eye a racket-ball had been ſtruck with ſuch violence, that all the circumference of the globe of the eye was ſeparated from the orbit. A relation of the perſon who was hurt was ſtanding by with a pair of ſciſſars in his hand, ready to cut the reſt of the parts which connected the eye with the head. Covillard entered the room in time, and very fortunately, to reſiſt this proceeding, as a complete cure enſued without having recourſe to it. Indeed, ſuch was the ſucceſs, that the patient's power of ſeeing ſuffered no kind of diminution or impairment. A ſimilar inſtance, though ariſing from a very different cauſe, occurred to Mr. Benjamin Bell. The eye was almoſt knocked out of the orbit by the violence with which a pointed piece of iron had entered betwixt the ſocket and the eye-ball. The iron had paſſed through a portion of the orbit, and remained firmly fixed there for about a quarter of an hour. During the whole of this time, the patient ſuffered inſupportable pain. He had completely loſt the faculty of ſeeing, and the eye-ball protruded in ſuch a manner, that there was every reaſon to fear that the optic nerve was ruptured, and, conſequently, great doubt concerning the propriety of replacing the part, or not. However, as a little delay did not ſeem likely to be dangerous, it was determined to wait a little. On the firſt removal of the dreſſings, and after taking away the iron, which could only be done with difficulty, ſo deeply had it ſtuck, it was with pleaſure and aſtoniſhment that the ſight was found to return immediately, even before the eye had been replaced. The inflammation which followed was ſoon appeaſed by proper remedies, and viſion was re-eſtabliſhed in its original perfection.

Mr. White makes mention of an analogous example in his book of ſurgical caſes, with this difference, however, that the eye was protruded in a ſtill greater degree.

Theſe two inſtances confirm the one recorded by Covillard, and weigh againſt what Maitre Jean has ſtated, namely, that Covillard's caſe is not authentic.

In order to conceive the truth of the foregoing obſervations, we have only to recollect the way in which the eye is retained in, and connected with the orbit. The ſurface of the boundaries of each orbit (ſays M. Louis, in defending Covillard's caſe,) is oblique, and inclines behind more towards the temple than the noſe. The eye-ball is fixed on the ſide towards the noſe, and juts out in front beyond the cavity of the orbit. Hence, it is manifeſt from the ſlighteſt examination, that the globe of the eye, in the natural ſtate, is partly ſituated on the outſide of the orbit. When it is alſo conſidered that the optic nerve is very looſe, in order to be adapted for readily following, without being at all ſtretched, all the rotatory motions of the eye-ball, produced by the action of the different muſcles belonging to this organ, we can then have no difficulty in imagining how the eye may make an immenſe protruſion outward, in conſequence of an inconſiderable ſwelling, and how it may ſeem to be quite diſplaced from its ſocket, without either the optic nerve or the muſcles being torn or lacerated.

EXORCISM, Ἐξορκισμὸς, prayers or conjurations wherewith to exorciſe, *i. e.* to drive out devils or dæmons from perſons apprehended to be poſſeſſed, or to preſerve from danger.

The word is derived from the Greek, ἐξορκίζειν, *adjurare*, *conjurare*, *to adjure*, or *conjure*. In moſt dictionaries, exorciſm and conjuration are uſed as ſynonymous; but in reality, conjuration is only a part of the exorciſm; and the exorciſm the ceremony entire. The conjuration is properly the formula, where the devil is commanded to come forth, &c.

Exorciſms are of great uſe in the Romiſh church; their prelates, &c. are frequently exorciſing dæmoniacal perſons. The prieſts make holy water by exorciſing common water a certain number of times. In reality, the exorciſm is a part in moſt of their conſecrations.

Exorciſms had anciently another and farther purpoſe; being applied by way of trial or purgation to extort the truth from the accuſed.

The exorciſm, in this ſenſe, was a ſort of bread conjured and exorciſed for the purpoſe; and the opinion was, that if the perſon was criminal he could not ſwallow the bread.

This, it ſeems, was a frequent practice in the time of our Edward III. and the bread thus exorciſed was ſaid to be corſned.

Linderbroeck gives inſtances of exorciſms with barley-bread, and others with cheeſe; and hence, probably, might ariſe that popular imprecation, "May this bread choak me, if I tell a lye." See Ordeal and Judicium *Dei*.

EXORCIST, in the *Romiſh Church*, a prieſt, or tonſured clerk, who has received the four leſſer orders, one of which is that of exorciſt.

The term is likewiſe applied to a prelate, or to a prieſt delegated by a prelate, who actually exorciſes a perſon poſſeſſed.

It is a diſpute among divines whether ever the Greeks had any ſuch order as that of exorciſt. Fa. Goar, in his Notes on the Greek Euchologion, has made it probable they had, from ſeveral concurring paſſages in St. Dionyſius and St. Ignatius Martyr.

The ordination of exorciſts is performed in the time of maſs, their principal office being to expel devils. The fourth council of Carthage, can. 7. appoints, that in the ordination of exorciſts, the biſhop, putting the book of exorciſms orcifms in their hands, fhall fay thefe words: "Receive it, and keep it in remembrance, and have power to lay hands on energumeni, whether baptifed or catechumens; which form ftill obtains."

M. Fleury mentions certain people among the Jews who travelled round the country, making profeffion of driving out devils by invocations, which, they pretended, had been taught them by Solomon; thefe were alfo called exorcifts. See Jofeph. Antiq. Jud. lib. viii. cap. Origen. Tract. xxxv. in Matt. 35. 63.

EXORDIUM, in *Oratory*, the preamble or beginning of a difcourfe or fpeech, ferving to prepare the audience and introduce the matter in hand.

The word is formed from the Latin *ordiri*, *to begin*, by a metaphor taken from the weavers, who are faid, *ordiri telam*, *to begin*, or *warp* a web, by difpofing and ordering the threads in a certain manner for the future work. See Warp.

The exordium, on other occafions, is called the *prologue*, *prælude*, and *proem*.

Cicero defines exordium a part of an oration, whereby the minds of the audience are duly prepared for what remains to be faid. The exordium is a part of principal importance, and is to be laboured with extraordinary care; whence Tully calls it "difficillima pars orationis."

Cicero and Quinctilian mention three ends, to one or other of which it fhould be fubfervient; *viz.* "reddere auditores benevolos, attentos, dociles." The firft end, or that of conciliating the good will of the hearers, may be effected by a felection of topics, in caufes at the bar, from the particular fituation of the fpeaker himfelf, or of his client, or from the character and behaviour of his antagonift contrafted with his own; on other occafions, from the nature of the fubject, as clofely connected with the intereft of the hearers; and, in general, from the modefty and good intention with which the fpeaker enters upon his fubject. The fecond end, or that of exciting and engaging the attention of the hearers, may be accomplifhed by giving them fome hints of the importance, dignity, or novelty of the fubject; or fome favourable view of the clearnefs and precifion with which it is to be treated, and of the brevity with which it is to be difcuffed. In order to effect the third end, or to render the hearers docile, or open to perfuafion, the fpeaker muft begin with ftudying to remove any particular prepoffeffions they may have contracted againft the caufe, or fide of the argument which he efpoufes.

The ancient critics diftinguifh two kinds of introduction, which they call "Principium," in which the orator plainly and directly profeffes his aim in fpeaking: and "Infinuatio," where, prefuming the difpofition of the audience to be much againft the orator, he muft gradually reconcile them to hearing him, before he plainly difcovers the point which he has in view. Of this latter fort of introduction we have an admirable fpecimen in Cicero's fecond oration againft Rullus.

Exordiums are of two kinds; either juft and formal, or vehement and abrupt. In the firft, the audience is prepared and conducted by due and eafy fteps; in the fecond, the orator, as if feized with fome fudden paffion, breaks out upon his audience at once. Such is that exordium of Ifaiah; "Hear, Oh heavens! and give ear, Oh earth!" Or that of Cicero againft Catiline; "Quoufque tandem abutere patientia noftra, Catilina?" Abrupt exordiums are moft fuitable on occafions of extraordinary joy, indignation, or the like; though we have inftances of panegyrics of the greateft orators, begun abruptly, without any fuch occafions. Such is that of Gorgias, who began his eloge of the city and people of Elis with Ἦλις, πόλις εὐδαίμων, *Elis, beata civitas.* Abrupt, hafty, exordiums, were more to the tafte and manner of the Greeks than of the Latins.

Agreeably to the objects which the orator fhould have in view in this part of his difcourfe, as we have already ftated them, the requifites in an exordium are, 1. *Propriety*, whereby the exordium appears eafy and natural, becomes of a piece with the whole difcourfe, and matches it as a part does the whole; fo that it could not be accommodated to any other, or, perhaps, a contrary occafion. The ancient orators were very defective in this point; their exordiums had frequently nothing in common with the fubject.

In order to render introductions natural and eafy, Dr. Blair fuggefts that they fhould not be planned, till the fubftance of the difcourfe has been thoroughly digefted in the mind. This mode of forming an introduction is conformable to the rule given by Cicero, though not always to his practice. "Omnibus rebus confideratis," fays he, "tum denique id quod primum eft dicendum, poftremum foleo cogitare, quo utor exordio. Nam fi quando id primum invenire volui nullum mihi occurrit, nifi aut exile, aut nugatorium, aut vulgare;" *i. e.* "when I have planned and digefted all the materials of my difcourfe, it is my cuftom to think, in the laft place, of the introduction with which I am to begin. For if at any time I have endeavoured to invent an introduction firft, nothing has ever occurred to me for that purpofe, but what was trifling, nugatory, and vulgar."

2. *Modefty*, or an ingenuous bafhfulnefs, which recommends the orator exceedingly to the favour of his audience. This is what Cicero extols fo much in L. Craffus, "Fuit enim in L. Craffo pudor quidnam, qui non modo non obeffet ejus orationi, fed etiam probitatis commendatione prodeffet." The fame Tully owns of himfelf, that at the beginning of his oration every limb trembled, and his whole mind was in a flutter. The vain-glory of that author fhould be carefully avoided, of whom Horace fpeaks, and who began his poem "Fortunam Priami cantabo et nobile bellum."

The modefty of the orator fhould difcover itfelf not only in his expreffions at the beginning, but in his whole manner; in his looks, in his geftures, and in the tone of his voice. However, the modefty of an introduction fhould never betray any thing mean or abject. The orator, whilft he exhibits to his hearers modefty and diffidence, real and not affected, fhould manifeft a becoming fenfe of dignity, arifing from a perfuafion of the juftice or importance of the fubject of which he is to fpeak. The modefty of an introduction requires that it fhould not promife too much. "Non fumum ex fulgore, fed ex fumo dare lucem." Horace.

> "He does not lavifh at a blaze his fire.
> Sudden to glare, and then in fmoke expire;
> But rifes from a cloud of fmoke to light,
> And pours his fpecious miracles to fight."—Francis.

Although, in general, the orator fhould not put forth his whole ftrength in the beginning, but gradually rife as his difcourfe advances; yet there are cafes in which he may be allowed to fet out in a high and bold tone; *e. g.* when he rifes to defend fome caufe which has been much decried by the public. In fubjects too of a declamatory nature, and in fermons, where the fubject is ftriking, a magnificent introduction has fometimes a good effect, if it be properly fupported in the fequel. Boffuet, Flechier, and the other celebrated French preachers, very often begin their difcourfes with laboured and fublime introductions; thefe raife attention, and throw a luftre on the fubject; but every fpeaker fhould be on his guard againft ftriking a higher note at at the beginning than he is able to keep up in his progrefs, and thus difappointing the expectations which he has excited. Among Englifh preachers, attempts of this kind are not always fo fuccefsful. Variety fhould be ftudied in introductions as much as poffible. Explanatory introductions from the context are the moft fimple of any, and frequently the beft that can be ufed; but they fhould never be long. An hiftorical introduction has generally a happy effect in roufing attention; when one can lay hold upon fome noted fact that is connected with the text or difcourfe, and by a proper illuftration of it, open the way to the fubject that is to be treated of.

3. *Brevity*, not amplified or fwelled with a detail of circumftances, or a long circuit of words; and in this refpect it fhould be accommodated to the length of the difcourfe; nor fhould the introduction anticipate any material part of the fubject.

4. The *ftyle* of the exordium fhould be juft, eafy, and pleafant. Quinctilian facetioufly compares a faulty exordium to a fcarred face, which is prefently difcerned, and very difagreeable. Thus, Cicero, "Veftibula, aditufque ad caufam facias illuftres."

Correctnefs of expreffion is peculiarly requifite on account of the fituation of the hearers, who are then more difpofed to criticize than in any other ftage of the oration or difcourfe; becaufe they are as yet unoccupied with the fubject or the arguments, and their attention is chiefly, if not wholly, directed to the fpeaker's ftyle and manner. A correct plainnefs, an elegant fimplicity, is the proper character of an introduction, ; "ut videamur," fays Quinctilian, "accuraté non callidé dicere."

5. *Calmnefs* of manner is peculiarly fuitable to the exordium. This is feldom the place for vehemence and paffion. Emotions muft rife as the difcourfe advances. The minds of the hearers muft be prepared, before the fpeaker can venture on ftrong and paffionate fentiments. To this rule there are fome exceptions, as, for inftance, when the fubject is fuch that the mere mention of it naturally awakens fome paffionate emotion, or when the unexpected prefence of fome perfon or object, in a popular affembly, inflames the fpeaker, and makes him break forth with unufual warmth. Either of thefe will juftify what is called the exordium *ab abrupto.* An inftance of this kind we have already referred to in Cicero's firft oration againft Catiline. However, introductions of this kind fhould rarely occur. In the introduction the fpeaker fhould prepare the way for thofe warm emotions, which he defigns to raife in the fubfequent parts of his difcourfe.

The exordium appears an effential part of an oration; though anciently in the Areopagus, Julius Pollux tells us they fpoke without any exordium, and paffions, and any peroration or epilogue. The like is faid to have been done by Xenophon, who began thus: "Darius et Parifatis duos habuere filios."

EXORMISTOS, in *Ichthyology*, a name given by fome of the old writers to that fpecies of the petromyzon which other authors call the lampetra fluviatilis, and we in Englifh the lampern. This is diftinguifhed by Artedi by the name of the petromyzon, with only one feries of fmall teeth in the verge of the mouth, and fome large ones, below. See MUSTELA, LAMPETRA, and PETROMYZON.

EXOS, the name by which Rondeletius diftinguifhes the acipenfer hufo. See STURGEON.

EXOSTOSIS, from ἐξ, *out of*, and ὀστέον, *a bone*. This term, in *Surgery*, fignifies an offeous tumour growing on a bone. Alfo, a fwelling of the bone itfelf.

Boyer remarks, that a fwelling may take place in bones as well as other parts of the body. The particular kind of tumour which occafionally forms on the furface of the bones, is that to which this writer affigns the appellation of *exoftofis.* He notices, however, that this name comprehends different fpecies, which fhould be confidered in a diftinct manner. Thus, *ofteo-farcoma* is one peculiar affection; and there is another fpecies of exoftofis, different from all others, and which confifts principally in a thickening of the periofteum. Boyer is of opinion, that the difeafe might be very properly named *periofiofis.*

In cafes of exoftofis, the bony fwelling acquires, on fome occafions, fuch a degree of hardnefs, that no veftiges of a fibrous texture can be difcerned, and it abfolutely refembles ivory. In fome inftances, the ftructure of the tumour is fpongy; and in others the fwelling is compofed of a mafs of flefhy and bony matter blended together.

According to Boyer, the bones moft frequently affected with exoftofis are the broad bones of the head, the lower jaw, fternum, humerus, radius, cubitus, the bones of the carpus, and the femur, and tibia. However, he remarks, that there is bone, which may not become the feat of the difeafe, and the affection may extend to a fmall, or a confiderable portion of it. It is not uncommon to find the bones of the cranium affected with exoftofis over their whole extent; and Boyer inftances the offa parietalia, as fometimes acquiring an inch in thicknefs, in confequence of the affection.

In the majority of cafes, an exoftofis rifes from the furface of a bone, and appears in the form of a hard round tumour. It fometimes occurs near the extremities of the long bones, and, at other times, near the middle portion. It is remarked, that exoftofes, originating from a venereal caufe, and commonly called *nodes*, are found, for the moft part, on compact bones, and fuch of thefe as are not thickly covered with foft parts, as, for inftance, the bones of the cranium and face, the internal fide of the tibia, &c.

Mr. John Bell has treated of tumours of the bones in the third volume of his Principles of Surgery. The following extract will ferve to fhew fome of this gentleman's opinions upon the fubject: "Many things confpire (fays this author) to give the tumour proceeding from a bone a peculiar afpect; it is always irregular and anomalous, never fimple. I have rarely feen a fingle bony protuberance arifing from the head, or fhaft, of a fingle bone. When a bone falls into difeafe, a large proportion of tendinous and mufcular parts of burfæ, and of cellular fubftance partake of the morbid action. The bone lies in the centre of the limb, connected by its larger head with a joint, and by its periofteum with the tendons, burfæ, and mufcles; and all this mafs of parts is, fooner or later, affected; and fince every depofition from veffels appointed for the fecretions of bone is folid, and every increafe of fuch a tumour permanent, it foon atttains a great fize; it is ponderous and maffive from the proportion of bony fecretion, and from the various ftructure of thefe feveral parts, it has every irregularity of form and fubftance.

"When the tumour of a bone has attained a confiderable fize, much of the original ftructure is deftroyed, and a new irregular mafs of gelatinous and bony matter is fubftituted for it. The bony tumour is firm, bulky, and ponderous, but not folid; feeling it from without, we can conjecture of what fubftance it is compofed within; we are fenfible that the tumour is covered by a fhell, bony in moft parts of its circumference, cartilaginous in fome parts, and, throughout the whole, yielding and elaftic; we are fenfible, alfo, that within there are irregular points, or fpiculæ traverfing the cavities, or cells, of the hollow tumour; that thefe are mixed with the cartilaginous fubftance, and with irregular collections of of matter, partly purulent, but chiefly gelatinous; we are fenfible of fuch foft cartilaginous and gelatinous parts being fucceffively added, in the progrefs of its growth to the tumour, which was, at the firft, folid and firm; and we find at laft, by pain and partial ulcerations, and by the increafe of fluctuation and rednefs at particular points, that ulceration, the laft ftage of the difeafe, approaches. Then the limb is effectually ruined, and the patient muft fubmit to amputation, or die of hectic.

"When fuch tumour is diffected, we find our fufpicions of its internal ftructure confirmed; we fee that foul matter flow out, when we open into the centre of the tumour, which we felt but indiftinctly through its walls; the parts which appeared the moft folid are hollowed out by ulceration, and full of foul and putrid fanies; while the bone has been declining into difeafe, the cancelli and marrow have been degenerating into a fort of fatty mafs, with which much of the cavity of the tumour is filled, and thence fuch difeafe has been very generally defcribed under the name of *ofteo-fteatoma*. This fatty excretion, occupying the difeafed cavity, is the part which, when the tumour burfts into an open ulcer, throws out fuch prolific fungus, growing apparently from the fubftance of the bone, and fprouting up, when amputated, in the courfe of a few hours. The folid bone, whether radius, or thigh-bone, is annihilated, and a mere fhell of offeous matter fubftituted in its place, and that in a manner fo peculiar, that it muft feem to the unintelligent obferver as if the fmall and folid bone had been expanded into an extenfive and flat plate of offeous fubftance, whereas the procefs is in truth very fimple and very intelligible. The bone dies piecemeal of ulceration, what, in technical language, is termed caries, and is conveyed away by abforption; but the bone being dead, the furrounding membranes, *viz.* the periofteum and tendinous expanfions, which once formed a part of its fyftem of circulation, continue ftill alive and ready to fecrete new bone; and thus it happens, that while a carious abfcefs preferves a large cavity full of foul matter, the furrounding membranes continue fecreting bone, which, like a fhell, thin and expanded, covers this cavity, and forms the walls of the tumour, of which fome part is compofed of thin expanded bone, refembling a cranium, fome of cartilage, fome of thickened membrane; and this fhell is formed in proportion as the original fabric of the bone is deftroyed.

"Bone is deftroyed by this internal ulceration, juft as it is by open caries, piecemeal; the procefs would not be ulceration, if, while one part were perifhing, the other were not active and fecreting new matter; fo vigorous ftill is the general life of the bone, while the internal parts are thus fuffering, that while one fide is wafting with ulcer, the other fide is often fecreting bone irregularly and profufely, and fhooting out into fantaftic forms among the membranes and furrounding foft parts, whence the centre of the tumour is cavernous and cellular, and the walls often rough with fpinous and projecting points. So merely local is the action of arteries in a tumour, whether offeous or foft, that one fide, or part, or bump of a tumour, grows vifibly and protrudes; the features and external form of the tumour gradually changing, without any fenfible caufe; and fo peculiar is the fecretion of each fpecies of vafcular ftructure, according to the original deftination of the part, that in one part of the tumour is generated bone, in another griftle, in another gelatinous effufion; while in another part, the vafcular action is violent and deftructive, and the folid bone, marrow, and furrounding membranes, are all refolved into a foul and fetid fuppuration. From the periofteum is fecreted bone: from the marrow, this fteatomatous and folid fat, with which much of the tumour is filled; to the tendinous and aponeurotic parts we can diftinctly trace the cartilaginous fecretion; and the gelatinous effufions, we can perceive, even during life, have their walls thicker, or thinner, according to the degree of inflammation.

"Thefe are the external characters and internal conditions of a tumour occupying any of the bones. Such tumour arifes often from a bruife, or fracture; fometimes from a lefs obvious caufe, or from internal difeafe. The radius, for example, is fractured at the wrift, re-unites and heals; but heals clumfily, the thickening never fubfides, the pain never ceafes, and, though not great, is greater than what is natural to a fracture. At length, a fenfible tumour arifes; at firft it is firm, but in proportion as it increafes in fize, it becomes fomewhat foft and elaftic, the thin plate of bone, of which it is compofed, yielding to the diftention from within. From time to time the tumour changes its form, ftill increafing in bulk. On the fide of the radius, it is firm and folid; it bends and yields at the parts moft diftant from it; it is plainly bony at its bafis, and as obvioufly cartilaginous in the extreme part of its circle; it plainly contains matter in thofe fofter parts, where it yields to the impreffion of the finger. Cartilaginous knobs arife, and fometimes are reddened on the furface; and, at certain points, the fluctuation is of fuch a kind, as to imply that the effufion is in part of a gelatinous nature. Thus the tumour grows and extends, with various irregularities in form and confiftence; it overhangs the dwindled hand, the ufe of the joint is loft, and the patient, who might gladly have been delivered of it at an earlier period, has, in the end, no choice left; for, when once it burfts into carious ulceration, it never heals, the fetor is inconceivably overcoming, attended with hectic. You are alfo to remark, that, when fuch difeafe takes place in the hand itfelf, the joints of each of the fingers grow out into tumours, at firft of a heart-like form, correfponding with the articulations of the finger bones; but, in procefs of time, they grow to globular, irregular, and almoft tranfparent tumours, ftill firm, or, at leaft, of a cartilaginous firmnefs. The whole hand degenerates into a deformed mafs, difcoloured, ulcerated, and fetid; from the individual knobs of which deformed mafs, the points of the refpective fingers project like griffin's claws, with crooked nails of enormous length." Page 58—60.

The foregoing paffage makes us tolerably well acquainted with Mr. John Bell's fentiments relative to the pathology of exoftofes, and though we do not ourfelves adopt fome of his conclufions, nor think that all bony tumours coincide with his account, yet many cafes certainly anfwer the defcription which he has given.

Some exoftofes cannot be difcovered before the patient's death. Such was the cafe referred to by Boyer, of a perfon whofe parietal bone was found after death to be three times thicker than natural. A fimilar cafe is alfo related in the memoirs of the academy of Dijon. In the latter example, the patient died from an exoftofis on the internal fide of the os pubis. The tumour, by preffing on the neck of the bladder, prevented the paffage of the urine, and the introduction of the catheter.

Boyer notices the poffibility of miftaking the head of a luxated bone for an exoftofis. He informs us, that this happened with a young man, whofe clavicle was diflocated at the end, which is articulated with the fternum. The tumour, formed by the end of the difplaced bone, was miftaken for an exoftofis, and was treated as fuch, of courfe, with no benefit.

Boyer alfo adverts to the liability of miftaking the en-

largements

largements of the ends of ricketty bones for exoftofes. Fungous excrefcences of the dura mater might likewife (as the fame author explains) be erroneoufly conceived to be exoftofes; for, after they have deftroyed a part of the bones of the cranium, they form an external protrufion. Their real nature, however, may be eafily difcriminated by attending to their confiftence and progrefs, and particularly their pulfatory motion, which correfponds with the action of the arteries in general. We need not here fay more concerning thefe fwellings, as they are already defcribed in another part of this Cyclopædia. See DURA MATER, *Tumours of.*

There are certain fymptoms which may be faid to be common to all exoftofes; fuch are, a fwelling; a fenfe of weight; pain, or at leaft a degree of uneafinefs arifing from the morbid action; and deformity.

Another clafs of fymptoms may be called *particular*, becaufe they are entirely dependent on the fituation of the tumour. Thus, as Boyer obferves, and as we have related in the article EXOPHTHALMIA, if an exoftofis were to take place in the orbit, the eye would neceffarily be expelled from that cavity. An exoftofis arifing from the inner furface of the clavicle, or fternum, might occafion preffure of confiderable blood-veffels, and on the thoracic vifcera, fo as to induce a train of very dangerous and even fatal confequences

An exoftofis, arifing from the internal fide of the os pubis, may give rife to a fatal retention of urine, as, indeed, we have already detailed. A fimilar tumour, fimilarly fituated, might alfo render parturition, in the natural way, impoffible.

The generality of furgical writers reprefent fcrofula as being a caufe of exoftofes. This ftatement, however, feems to reft on no foundation whatever. The fwelling of the joints, when they are affected with fcrofulous difeafe, is not produced by an expanfion of the bones themfelves, but altogether by a thickening of the foft parts, fometimes conjoined with a collection of a fluid refembling glair, or of purulent matter in the capfular ligament. The head of a bone, really enlarged from fcrofula, has never yet been demonftrated, and cannot be found in any of the collections of morbid preparations in the various mufeums. The particular form of difeafe, with which fcrofula affects the bones, we fhall defcribe in fpeaking of the *White Swelling.*

A fcorbutic diathefis is alfo fet down by authors as fometimes exciting the growth of exoftofes: on this point, we can only profefs our ignorance of any rational evidence in favour of the opinion.

The venereal difeafe does undoubtedly occafion one fort of exoftofes, denominated *nodes;* but, thefe we fhall difmifs from prefent confideration.

It is painful for us to be obliged to acknowledge, that we are almoft in total ignorance, in regard to the caufes of exoftofes; for, excepting contufions and fractures, which fometimes unqueftionably lead to the production of bony tumours, we have no certain knowledge of any others.

Mr. John Bell informs us, that he has feen a woman's ankle fall into this difeafe, in confequence of a very trivial accident; the tibia and fibula grew into a common tumour, the bones feemed annihilated, and a large offeous fhell appeared to be fubftituted in their place. In the courfe of the difeafe, the leg became twifted round in a fingular manner, and enlarged to the fize of a pillow of a fettee. The woman died of hectic from the open caries of the tumour. The fame author remarks, that the wrift, which is more expofed to fprains and fractures, is moft liable to be thus deformed and ruined. He reprefents the hand itfelf as being alfo particularly fubject to fimilar diforder. The original injury is fome flight blow, or fprain; one finger is firft deformed; joint after joint enlarges; one finger after another becomes crooked; the nails project like talons, and force their way into the very flefh of the fwelled and ulcerated hand, which, according to Mr. John Bell, they fometimes penetrate through and through. At length, the hand degenerates into an unwieldy and irregular mafs, ftudded with knobs and bony tumours. This furgeon tells us, alfo, that in confequence of a neglected fracture of the collar-bone, in a ftout young man, he once faw a tumour produced; partly confifting of bone, and partly of cartilage, rifing to the height of fix inches, of round figure, and infulated, moving when the arm was moved, too large and too critically fituated over the axillary artery, to admit of extirpation, and which Mr. John Bell doubts not has by this time become carious, and occafioned death.

When exoftofes originate from external violence, the exciting caufe is involved in no obfcurity; but the caufes in moft other inftances feem to baffle all human refearch. Frequently, a conftitutional difpofition to the formation of bony tumours, in various parts of the body, feems to prevail. Mr. Samuel Cooper, in his "Dictionary of Practical Surgery," quotes an example of a boy, who came out of Cornwall, fo exceffively afflicted with an apparent propenfity to exoftofes, or an exuberant depofition of bony matter, that a very trifling blow would occafion a bony fwelling on any bone of his body. The ligamentum nuchæ was offified, and prevented the motion of his neck; the margins of the axillæ were alfo converted into bone, fo that the poor lad was, as it were, completely pinioned.

There is one fpecies of exoftofis remaining to be noticed, which is of a very peculiar kind, as it is in its appearance exceedingly like a bony fungus.

A ftriking inftance of fuch a difeafe has been recorded by Mr. Abernethy. The cafe being highly interefting, we fhall take the liberty of quoting it. The patient, who was 34 years of age when the account was written, perceived, when about ten years old, a fmall tumour on his left cheek, which gradually attained the fize of a walnut, and then remained for fome time ftationary. About a year afterwards, the tumour having again enlarged, a cauftic was applied to the integuments, fo as to expofe the bone. The actual cautery was next applied, and an opening thus made into the antrum. After the exfoliation, the antrum became filled with a fungus, which rofe out upon the cheek, and could not be reftrained by any applications. Part of the fungus alfo made its way into the mouth, through the focket of the fecond tricufpid tooth, the other teeth remaining natural. The difeafe continued in this ftate nine years, occafionally bleeding in an alarming way. When the patient was in his 20th year, the whole fungus floughed away during a fever, and did not return. After this, the fides of the aperture in the bone began to grow outwards, forming an exoftofis, which grew to a great magnitude. A fmall exoftofis took place in the mouth, but became no larger than a horfe-bean. The exoftofis of the maxillary bone was of an irregular figure, and projected from the whole circumference of the aperture a great way directly forward. Mr. Abernethy compares its appearance, when he was writing, with that of a large tea-cup faftened upon the face, the bottom of which may be fuppofed to communicate with the antrum. The diameter of the cup, formed by the circular edge of the bone, was three inches and a half: the depth two inches and feven-eighths. The general height of the fides of the exoftofis, from the bafis of the face, was two inches; its walls were not thick, and terminated in a thin circular edge. The integuments, as they approached this edge, became extenuated, and they extended over the edge into the cavity. The exoftofis reached to the nofe in front, and to the mafleter mufcle behind; above it included the very ridge of the orbit, and below it grew from the edge of the alveolary procefs. A line that would have feparated the difeafed from the found bone, would have included the orbit and nofe, and indeed one half of the face. Mr. Abernethy faw no means of affording the man relief. Med. Chirg. Tranf. vol. 2.

In regard to the treatment of exoftofes, it is exceedingly difficult to lay down any determinate rules. With the exception of venereal nodes, we cannot fay that we are acquainted with any remedy which has the power of diminifhing bony tumours. Perhaps blifters kept for a long while open, by means of the favin cerate, and applied to the neareft furface of the integuments, might have the effect of exciting the action of the abforbents, fo that the depofited bony matter would be at leaft in part removed. That blifters would operate in this manner, we may conclude from their having been known to diminifh the fwelling of venereal nodes, after mercury has ceafed to be productive of any benefit. However, we do not mean to reprefent this plan as likely to anfwer fully in practice; for, even were it to prove fuccefsful, it could only be after fuch time and perfeverance as few patients would allot.

The chief method of getting rid of an exoftofis is by attacking the tumour with a cutting inftrument, and it is obvious that this mode of proceeding cannot be adopted, except when no anatomical confiderations forbid it. Hopes of its fuccefs, alfo, fhould never be fanguine; becaufe, though you may fucceed in removing every particle of the bony fwelling, ftill the depofition of bone may continue, and the difeafe recur, and this even in a more malignant form.

When an exoftofis has acquired much magnitude, it feldom admits of being cut, or fawn away. But there are exceptions to this remark; for Heifter records an example of an exoftofis, fituated on the middle of the fternum, and as large as a child's head, being fuccefsfully extirpated. If an exoftofis were to be met with, growing on the middle part of one of the long cylindrical bones, with rather a narrow bafe, an attempt might be prudently made to remove the tumour, notwithftanding its fize might be very great. When the attachment of the fwelling is on the head of a bone, near a large joint, an endeavour to extirpate the difeafe is much more dangerous.

It would be in vain to pretend to detail particularly how the operator is to conduct himfelf in extirpating exoftofes. His firft object fhould be, if poffible, to make fuch incifions through the foft parts as will expofe the bafe of the tumour, fo as to allow the faw to be applied to it. When this can be effected, it is manifeft that the whole of the fwelling may be removed by one fection made with the faw. In the majority of cafes, fmall fhort faws with long handles, in a word, the inftruments defcribed in Mr. Hey's "Practical Obfervations in Surgery," will be found much more proper and convenient than larger ones.

Sometimes, when owing to depth of fituation, or fome other anatomical reafon, no direct attempt to cut through the bafe of an exoftofis can be made, the furgeon may venture to remove the tumour by attacking its furface with trephines, the faws defcribed by Hey, or with a gouge and mallet, as the French furgeons are fo much in the habit of doing. When the confiftence of the exoftofis is not too hard, a ftrong knife may be occafionally employed for removing portions of the fwelling, which purpofe it will accomplifh better than any faw.

The ancients, indeed, we might fay feveral of the moderns, have attempted to deftroy exoftofes with the actual and potential cautery. Sometimes thefe violent means have fulfilled the object in view; but, frequently, inftead of affording relief, they have killed a large portion of the bone, and converted the difeafe into the more afflicting one of necrofis, attended with large fores and abfceffes, and often with fuch debility and hectical fymptoms, as have ended in death.

Few good practitioners of the prefent day, in England, ever have recourfe to this plan for the extirpation of exoftofes.

When prudence prohibits an endeavour to cut away an exoftofis, the difeafe fhould never be fuffered to expand itfelf in fo great a degree as to deprive the patient of the choice of parting with his limb for the prefervation of his life. Amputation fhould always be performed ere the diforder attains this deplorable ftate.

We fhall conclude the prefent article with this general obfervation, that if an attempt is to be made to extirpate an exoftofis, let it be done at an early period of the difeafe, before its fize is very confiderable.

EXOSTRA, in the *Ancient Theatre*, a place where fuch parts of the play were recited as were fuppofed to be acted privately in the houfe.

Exostra was likewife the name of a warlike engine ufed in the fieges of towns.

EXOTERIC and Esoteric, are terms denoting *external* and *internal*, and applied to the double doctrine of the ancient philofophers: the one was public or exoteric, the other fecret, acroamatic, or efoteric. The firft was that which they openly profeffed and taught to the world; the latter was confined to a fmall number of chofen difciples. This method was derived originally from the Egyptians, who, according to the united teftimony of Herodotus, Diodorus Siculus, Strabo, Plutarch, &c. had a two-fold philofophy, one fecret and facred, another public and common. The fame practice alfo obtained among the Perfian Magi, the Druids of the Gauls, and the Brachmans of India. The Egyptian priefts, with whom it originated, fuftained the character of judges and magiftrates, and probably introduced this diftinction with a view to the public welfare, and to ferve the purpofes of legiflation and government. Clement of Alexandria informs us, that they communicated their myfteries principally to thofe who were concerned in the adminiftration of the ftate; and Plutarch confirms the fame declaration. However, others have fuppofed that they invented the fables of their gods and heroes, and the other external ceremonies of their religion, to difguife and conceal natural and moral truths; but whatever was the motive of their practice, it was certainly applied to political purpofes. See Aristotle.

EXOTIC, Ἐξωτικος, a term properly fignifying *foreign*, or *extraneous*, *i. e.* brought from a remote or ftrange country. In which fenfe we fometimes fay, *exotic*, or *barbarous terms* or *words*, &c.

The word is derived from the Greek, ἐξω, ἐξωθεν, *extra*, *without*, *on the outfide*.

Exotic is chiefly applied to plants which are natives of foreign countries, particularly thofe brought from the Eaft and Weft Indies, and which do not naturally grow in Europe.

The generality of exotics, or exotic plants, do not thrive in England without fome peculiar care and culture; they require the warmth of their own climates, whence the ufe of hot-beds, glafs-frames, green-houfes, &c. See Green-*houfe* and Stove.

In

In fending plants from one country to another, particular cautions are neceffary. The plants fent from a hotter country to a colder, fhould be always put on board in the fpring of the year, that the heat of the feafon may be advancing as they approach the colder climates; and on the contrary, thofe which are fent from a colder country to a hotter, fhould be fent in the beginning of winter.

The beft way of packing up plants for a voyage, if they be fuch as will not bear keeping out of the earth, is to have boxes with handles, filling them with earth, and planting the roots as clofe together as may be; the plants fhould be fet in thefe boxes three weeks before they are to be put on board; and in good weather they fhould be fet upon the deck, and in bad removed, or covered with a tarpaulin.

If they are going from a hotter country to a cold one, they muft have very little moifture; if, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being fhaded from the heat of the fun, they will come fafe.

Many plants, however, will live out of the earth a great while; as the fedums, euphorbiums, ficoides, and other fucculent ones. Thefe need no other care than the packing of them up with mofs in a clofe box, and there fhould be a little hay put between them, to prevent them from wounding or bruifing one another, and holes bored in the boxes to keep them from heating and putrefying. In this manner they will come fafe from a voyage of two or three, or even four or five months.

Several trees alfo will come fafely in the fame manner, taking them up at a feafon when they have done growing, and packing them up with mofs. Of this fort are oranges, olives, capers, jafmines, and pomegranate-trees. Thefe, and many others, are annually brought over thus from Italy; and though they are three or four months in the paffage, feldom mifcarry. And the beft way of fending over feeds is in their natural hufks, in a bag, or packed up in a gourd-fhell, keeping them dry, and out of the way of vermin. Miller.

Dr. Lifter has a difcourfe in the Philofoph. Tranf. on Exotic Difeafes, *i. e.* fuch difeafes as are never bred among us, but brought, from time to time, by infection from other countries. Such, according to this author, are, 1. The plague, which is properly a difeafe of Afia, where it is epidemic. 2. The fmall-pox, which is an Oriental difeafe, and not known to Europe, or even Afia Minor or Africa, till a fpice-trade was opened to the remoteft part of the Indies, whence it originally came, and where it ftill rages more cruelly than among us. 3. The griping of the guts, which he takes for a difeafe peculiar to the Weft Indies, and yearly received from thence: for this, he adds, is a quite different difeafe from the tormina ventris of the ancients, and is fcarce ever known in the midland counties, or far in the north of England.

EXOUCONTII, in *Church Hiftory*, a kind of Arian heretics, who maintained that the Son of God was made out of nothing: *i. e.* Ἐκ τῶν ἐκ ὄντων, fuppofed by Gothofred to be the fame with the Exocionitæ; but this opinion is contradicted by the authority of Theodoret.

EXPAND, in a *Military Senfe*, relates to the exterior of a line or front, either for the purpofe of occupying a greater fpace, or in order to outflank the enemy, thereby to beat in his wings upon his centre.

It is often of the greateft importance to prefent a more extended line of fire, efpecially if it can be directed towards any particular fpot; for inftance, when a column is iffuing from a defile, a detroit, or pafs, the enemy will certainly endeavour to pour upon its front as heavy a fire as the fpace may allow.

Thus, he will probably oppofe a formidable cannonade thereto, fo that the fhots may range along the column, doing great havoc therein, not only among the foldiery, but deftroying the cattle, and difabling the artillery. The reft of the field he will generally occupy in an inflected form, prefenting a crefcent; much the fame as that oppofed to the immortal Nelfon in his laft victory! By this means every mufket becomes obnoxious, each being levelled at the head of the column.

If we imagine 3000 men to be drawn up in fuch a manner as may produce this effect, and that five or fix guns are brought to bear as above defcribed, with perhaps a body of cavalry ready to charge in flank, when the column may have proceeded to contend with the centre of the oppofing force, we fhall then fee how neceffary it is for the column to expand with all poffible celerity, and not to attempt fuch an attack before a fufficient front can be formed to make it with effect.

The mode of expanding may be feen under the article DEPLOY, where this particular operation will be found more fully defcribed. We fhall in this place remark, that expanfion is by no means proper where the enemy can bring a large body of cavalry to act in an open country, unlefs an equal number of fuch troops may be at hand to oppofe them.

Where a line of intrenchments is to be carried, expanfion is not eligible; yet the concentration muft be managed with peculiar care whenever the enemy may be able to line their works with artillery, efpecially howitzers of large calibre, which, by pouring grape among clofe bodies of men, would foon thin their ranks, and probably occafion, what is delicately called, "a precipitate retreat." The beft authorities inftruct us to fay, that nine battles in ten are loft by allowing the troops to be too expanded: in fuch a condition they are every where weak; whereas, when properly concentrated, they are every where formidable.

We may from this collect, that allowing an army to cover too great an expanfe, is, generally fpeaking, expofing it to ruin; it enables the enemy to force a line in whichever quarter they may judge proper, and, after forcing it, to cut up the feveral parts in detail. Hence, blockades are, with few exceptions, extremely dangerous, as may be better underftood by reference to *environ*, which fee.

When a column is to expand or deploy, or when an augmentation of front is to be made, fuch ought to be done with great promptnefs, and under a heavy fire from each divifion, fo faft as it can arrive at its ftation in the line. By this means, efpecially if the wind be favourable, the whole may be done under cover of the fmoke, and the enemy may be fo rapidly gained upon, as in turn to render it neceffary for him to change pofition; but without great coolnefs and firmnefs, nothing will be effected.

EXPANDING RIGGER, or *Drum*, in *Mechanics*, is a wheel, or rigger, to receive an endlefs rope, which can be enlarged or diminifhed in its diameter, to give a greater or lefs velocity to the rope.

The common expanding rigger is a caft-iron wheel with twelve arms, in each of which a groove is formed, extending nearly from the centre to the circumference, as A A, *fig.* 5. *Plate* XXVI. *Mechanics*. Againft each arm a piece of wood is placed, which has a rebate fitting into the groove, and a fcrew-bolt paffing through both wood and the arm of the wheel; a nut fcrewed upon the bolt faftens the bolt and wood at any place in the groove: each piece of wood has a groove in it to receive the rope which paffes round the wheel. The diameter of this rigger can be altered by loofening the nuts, then placing the pieces of wood all in one circle of the propofed diameter, and faftening them there by the nuts. To facilitate the placing of the pieces of wood in one circle, each arm is divided into inches, and numbered from the centre.

Mr. Andrew Flint, of London, lately received a premium of fifty guineas from the Society of Ats, for two expanding band wheels, or riggers. *Figs.* 5, 6, and 7, are different views of the firft of thefe; A A is a caft metal wheel with twelve arms, each divided by a groove from near the centre to the circumference: thefe grooves receive rebates on the backs of twelve racks *a a*, *figs.* 6 and 7, which have projecting pieces *b*, *b*, with grooves to contain the endlefs rope *d d*. In *fig.* 5. which is a back view of the wheel *e e*, are nuts, which draw up the racks to flide in the grooves without fhake, yet freely to and from the centre: the racks are moved all together by means of a circular plate *d d*, which has a fpiral rib upon it entering between the teeth of each rack, fo that when the plate is turned round, all the racks move to or from the centre at once: the fpiral plate *d d* is fcrewed to an iron crofs, which fits upon the axis *f f*, and is turned round by a pinion *g* of fix teeth, working into a ring of teeth made in the infide of the fpiral plate *d*.

Another method of accomplifhing the fame object is by means of twelve fcrews *h* (*figs.* 8. and 9) pointing to the centre of the wheel; they are are all moved together by means of equal bevelled wheels fixed on them; by this means the fcrews are turned about contrary ways alternately: they muft, therefore, be alternately cut right handed and left handed, that they may produce the fame effect. The fcrews are turned, when the diameter of the rigger is to be altered, by a winch put upon any of the three fquares *h*, *h*, *h*, on the ends of the fcrews. In this machine the number of fcrews muft be even.

Figs. 10, 11, and 12, are drawings of an expanding rigger contrived by the writer of this article: it confifts of two wheels of caft-iron A, A, (*figs.* 10, 11, and 12.) which have fixteen fectorial apertures marked *a*, which leave fixteen arms between them; the arms and the fpaces are exactly equal, and each arm has a triangular piece of wood *b d e*, (*fig.* 12.) fcrewed upon it, by four fcrews going through the arm into the wood, which is alfo kept firm and perpendicular to the face of the wheel, by a rib *f*, (*fig.* 11.) which projects from each arm, and is let into a groove cut in the wood. The wheels have fockets *g*, *g*, (*figs.* 10 and 12.) which are bored out with a very true cylindrical hole to receive the fhaft or fpindle B B of the rigger, which is turned in the lathe to fit the fockets without fhake, yet at the fame time allowing them to move backwards and forwards upon the axis B B. The wheels are put together upon the fpindle facing each other, the wooden triangles of one wheel entering the fpace between the arms of the other, as is fhewn in *figs.* 10 and 12; in this manner it is plain that the points, or rather plane, of interfection of the triangles *b d e* of each wheel, will form a circular groove to receive a rope, which groove can be increafed in its diameter by advancing the wheels towards each other, or diminifhed by fetting them farther apart, as in *fig.* 10. The wheels are prevented from turning on the fpindle by means of a fillet, which is inferted partly into a groove cut in the axis, and partly in another groove made in the focket of the wheel. The wheels may be brought nearer together, or thrown farther apart, by two fcrews *h*, *h*, (*fig.* 12.) which have fockets in one wheel, and are tapped into the other: two equal cog-wheels *i*, *i*, are keyed faft upon the fcrews, and an intermediate cog-wheel *k*, placed loofely upon the main axis between them, caufes both fcrews to turn at the fame time. A more fimple method of altering the diameter is by pufhing the wheels together by hand, and faftening them to the axis by fcrews *e*, *e*, *fig.* 10.

EXPANSION, in *Metaphyfics*, expreffes the idea we have of lafting or preferving diftance, *i. e.* of diftance, all the parts whereof exift together.

Expansion, from the Latin *expando*, in *Philofophy*, denotes the increment of furface or of bulk, of which natural bodies are fufceptible. With refpect to the expanfion of furface, fee the articles Ductility and Gold *Beating*.

Bodies of every kind, as far as we are acquainted with them, are expanded in bulk by heat, and are contracted by cold; and to this law there are very few exceptions, which will be noticed in due time. The expanfions, or the increments of bulk, are not exactly proportional to the increments of heat in the fame body; nor are different bodies expanded alike by the like elevation of temperature. Thus, if a quantity of water be increafed one inch in bulk, by the communication of ten degrees of heat, the communication of twice or thrice as much more heat will not caufe it to expand two or three inches more. Alfo, if a rod of gold, and another fimilar rod of glafs, be heated to the fame degree, their increments of bulk, arifing thereby, will not be equal, the gold expanding more than the glafs.

Of the three principal ftates of natural bodies, *viz.* folids, liquids, and elaftic fluids, the folids are expanded leaft; the liquids are expanded more than the folids, but the elaftic fluids are expanded a vaft deal more than the liquids. The knowledge of the precife quantities of thefe expanfions of bodies is of great ufe in philofophy, in mechanics, and in other fcientific fubjects; hence no pains have been fpared by philofophers to inveftigate and afcertain them; various inftruments have been contrived for that purpofe; innumerable experiments have been inftituted; and a great many ufeful refults have been obtained. Of thefe refults we fhall now endeavour to give a regular and diftinct account.

The inftruments which have been contrived for the purpofe of meafuring the expanfions of folids arifing from an elevation of temperature, are called *pyrometers*. The objects which muft be had in view in the conftruction of pyrometers, are to form a fteady frame, wherein folids of a certain length may be applied either fucceffively, or feveral of them at the fame time, fome contrivance by which thofe metallic bodies may be heated to any required degree, and a mechanifm capable of meafuring the increafe of bulk which is caufed by the heat; and this may be accomplifhed by means of multiplying wheels, by levers, by fcrews, by a microfcopical micrometer, or otherwife. See Pyrometer.

Some of the firft determinations of the expanfion of bodies, that may be confidered as being fufficiently accurate, were made by Mr. Ellicot with a pyrometer of his contrivance. Mr. Ellicot determined the proportional expanfions of feven metallic bodies by the fame elevation of temperature. They are as follows:

Gold.	Silver.	Brafs.	Copper.	Iron.	Steel.	and Lead.
73.	103.	95.	89.	60.	56.	149.

Mr. Smeaton contrived a much better pyrometer, and with it he determined the expanfions of feveral folids. Mr. De Luc alfo contrived a pyrometer of a peculiar conftruction; but Mr. Ramfden's pyrometer is fuperior to any other contrivance of the kind.

The following table fhews, in parts of an inch, how much one foot length of different fubftances is expanded by 180° of heat, Fahrenheit's fcale, between the freezing and the boiling

boiling points of water. To the firſt ſeven ſubſtances, (which were examined in Mr. Ramſden's moſt accurate pyrometer,) there are added the expanſions for a ſingle degree of heat. The others were determined by Mr. Smeaton with his pyrometer.

Iron, inſtead of being condenſed into a ſmaller bulk, expands in its tranſition from a fluid into a ſolid ſtate; ſo that a quantity of iron occupies more room in the ſolid form than it does in a fuſed ſtate.

Dr. Wollaſton, in order to form ſome eſtimate of the comparative rate of expanſion of platina and palladium, ſays, "I rivetted together two thin plates of platina and palladium, and obſerving that the compound plate, when heated, became concave on the ſide of the platina; I aſcertained that the expanſion of palladium is in ſome degrees the greater of the two. By a ſimilar mode of compariſon I found that palladium expands conſiderably leſs than ſteel by heat." Phil. Tranſ. for 1805.

It muſt be remarked with reſpect to the expanſion of glaſs, that ſometimes glaſs tubes are extended more than ſolid glaſs rods: their dilatation, however, is not conſtant; for tubes of different diameters, or of different ſorts of glaſs, are expanded differently by the like degrees of heat.

Wood is not expanded much longitudinally; that is, in the direction of its fibres, by heat, and this is particularly the caſe with deal and other ſtraight-grained wood. Probably, upon the whole, the longitudinal expanſion of wood is leſs than that of glaſs. It has been obſerved, (eſpecially by Dr. Rittenhouſe, Tranſ. of the American Phil. Society) that very dry and ſeaſoned wood, if not expoſed to a very high or to a very low temperature, will expand in length pretty regularly: otherwiſe its expanſion by heat, and its contraction by cold, are very irregular: for they ſeem to depend partly upon the heat, and partly upon the moiſture, which the wood acquires in certain circumſtances, and is deprived of in others.

It is hardly neceſſary to mention, that the ſolids of the preceding table contract their dimenſions by cooling as much as they are expanded by heating; thus, for inſtance, if a yard length of any particular metallic body, by being heated 100° above the actual temperature of the atmoſphere, be lengthened one fiftieth part of an inch; afterwards, when cooled down to the temperature of the atmoſphere, it will be found to have loſt exactly that fiftieth part of an inch which it had acquired by heating.

From the experiments hitherto made on the expanſions of ſolids by heat, no correſpondence has been obſerved between the expanſions and the quantities of caloric they are capable of abſorbing. The fuſibility of metals ſeems to coincide with the dilatations; platina, the leaſt fuſible of the metals, dilates the leaſt; lead dilates moſt; and the moſt fuſible glaſs is alſo the moſt dilatable. We may therefore conclude with Mr. Berthollet, that bodies are ſo much the more expanſible, the leſs caloric they require to change their conſtitution from ſolid to liquid, and from liquid to gaſes or vapours.

There is a ſubſtance which expands when heated; but does not contract when cooled; and of this ſingular property Mr. Wedgwood availed himſelf for the conſtruction of his ingenious thermometer for meaſuring the higheſt degrees of heat; *viz.* thoſe degrees which exceed the ſcale of the mercurial thermometer. (See Thermometer.) The ſubſtance alluded to is the argillaceous earth or clay, and it appears that the above-mentioned property belongs, more or leſs, to argillaceous bodies of every kind. This property may at firſt ſight appear to be an unaccountable exception from the general law: the difficulty, however, will vaniſh, if it be conſidered that bodies of the argillaceous genus contain a conſiderable quantity of water, and that the contraction of theſe bodies, when expoſed to the action of a ſtrong fire, is in great meaſure due to the eſcape of the water, and hence they do not contract by ſubſequent cooling.

The method of meaſuring the expanſions of fluids is to incloſe them in a certain veſſel, and to meaſure that part of the cavity of the veſſel, which is occupied by the fluid under trial, in different temperatures. It is evident that the ſubſtance of the veſſel is likewiſe expanded by the heat, and of courſe the cavity of the veſſel is enlarged. Therefore, when we find that the bulk of the fluid is increaſed, that increment is only the difference between the enlarged capacity of the veſſel and the increaſed bulk of the fluid. This ſhews the neceſſity of forming thoſe veſſels of ſuch ſubſtances as are leaſt expanſible by heat. Indeed glaſs is the ſubſtance which is univerſally uſed for ſuch purpoſes, both on account of its little expanſibility, and of its tranſparency; beſides its having other uſeful properties. A glaſs veſſel, filled to a certain degree with a liquid, for the purpoſe of ſhewing the expanſions of that liquid in different temperatures, or for the purpoſe of ſhewing the temperature of the correſponding expanſion of that liquid, is called a thermometer; *viz.* a meaſure of the temperature. See Thermometer.

The propereſt ſhape for a thermometer is that of a long

 tube

tube with a narrow bore, having a globular cavity at one end; which, familiarly speaking, may be called a globular glass bottle with a long and narrow neck. The globular cavity, and part of the tube of one of these vessels, is filled with the liquor whose expansion is to be examined, and the vessel is then heated, in consequence of which the liquor, which is contained in it, is expanded, and not being able to extend itself any other way, all the increment of bulk must be manifested in the tube; *viz.* the surface of the fluid will rise in the tube; or, if cooled, it will descend in it. If the same vessel of the above-mentioned shape be successively filled with different fluids, and with each fluid it be exposed to certain degrees of temperature, (which must be determined by an accurate thermometer,) the proportional expansions of the different fluids may thereby be ascertained. The same object may be obtained by filling several such vessels with the different fluids, that are to be examined, and heating or cooling them all at the same time; but in this case the corresponding capacities of the different vessels must be previously ascertained; which may be done by filling all the vessels with the same kind of fluid, and exposing them all to different degrees of temperature; so that the corresponding elevations of the fluid in the different vessels may be marked on the tubes. These vessels are afterwards emptied and filled again with the fluids, &c. Thus the proportional expansions of liquids may be determined; but when the actual or absolute increase of bulk is required, then the capacity of the vessel must be accurately gauged. This measurement of the capacity may be accomplished in the following manner. In the first place weigh the empty glass tube; secondly, fill part of the tube with a convenient fluid, (mercury, for instance, which is the fittest for such purposes); thirdly, measure the length of the tube which is occupied by the mercury, and weigh the instrument a second time; then, by subtracting this second weight from the former, you will have the weight of mercury which fills up a certain length of the cavity of the tube; fourthly, fill the bulb of the vessel entirely with mercury, and weigh the vessel a third time. This weight being subtracted from the first, *viz.* from that of the empty vessel, will leave the weight of the mercury in the bulb. Now, having the weight of the mercury in the bulb, as well as of that which fills a certain length of the tube, the ratio of the former to the latter may be easily determined by simple division. Also the absolute quantity in bulk of the former is obtained from the well known specific gravity of mercury, and from the weight of a cubic inch of distilled water, which (when the barometer is at 29.74 inches, and Fahrenheit's thermometer at 66°) is equal to 252.42 grains Troy; one pound Troy being equal to 5760 of those grains. An English cubic inch of mercury of the specific gravity 13.6 weighs 3443.2 English grains. Instead of mercury, some other fluid may be employed for this purpose; but not so conveniently as mercury. The expansions of a fluid, which are caused by different degrees of heat, may likewise be determined by ascertaining the specific gravity of that fluid in different temperatures; for the specific gravity decreases in proportion as the fluid is expanded, and *vice versâ;* but this method is not capable of as much accuracy as the former.

Liquids differ from each other in regard to their expansibility; some expanding more than others. Also the expansions of the same liquid by equal degrees of heat are not quite regular; and it has been observed that this irregularity is greater when they approach the state of vapour. Upon the whole, mercury has been found to be expanded by heat more regularly that any other fluid; yet its increments of bulk are not perfectly regular. Mr. De Luc, with great care and patience, has endeavoured to ascertain the real expansibility of mercury, or rather the real quantities of heat that are required for expanding mercury arithmetically, *viz.* by equal augmentations. These are expressed in the following table, the first column of which contains the degrees of Reaumur's scale, from five to five, which are equal parts; the second shews the real quantities of heat which are required to raise the mercury to the corresponding degrees, where z is a fixt but unknown quantity; and the third column shews the differences of those quantities. De Luc's Recher. sur les Modif. de la Atmosph. 1772, p. 309.

	Mercurial Thermom.	Real quantities of heat.	Real differences of heat corresponding to the variations of the Mercury in the thermom. from 5 to 5 degrees.
Point of boil. water	80°	$z+80.00$	
	75	$z+75.28$	-4.72
	70	$z+70.56$	-4.72
	65	$z+65.77$	-4.79
	60	$z+60.96$	-4.81
	55	$z+56.15$	-4.81
	50	$z+51.26$	-4.89

	10	$z+10.74$	-5.20
	5	$z+5.43$	-5.31
Point of melt. ice	0	z	-5.43

From the third column it appears, that the differences of heat requisite to make equal and progressive additions to the bulk of the mercury, though not exactly equal, yet are not very far from the ratio of equality. If the bulk of a quantity of mercury, at the temperature of 32° Fahrenheit's scale, be conceived to be divided into 100,000 equal parts, and then be heated as high as the temperature of boiling water; (*viz.* 212°) its bulk will thereby be increased by 1836 of those parts.

The expansion of water is attended with a singular deviation from the general law; *viz.* this fluid is expanded by heat from about the 40th degree of Fahrenheit's thermometer upwards; but below 40° its bulk is expanded by a farther decrease of heat, or increase of cold; and in fact ice is lighter than water, so as to float upon it; the specific gravity of ice being to that of water nearly as 7 to 8. The bulk of ice is to that of the water, when the ice is melted, as 9 to 8 very nearly. The bulk of water, from its most contracted state at the temperature of 40°, increases continually; but that increase is not very regular; for instance, the increase of bulk from 180° to 212°, is considerably greater than from 40° to 72°. If the bulk of water at 40° be called 1, its bulk at 212° will be 1.04785. Beyond that degree of heat water becomes vapour; *viz.* an elastic fluid; and the formation of this elastic fluid on the sides of the vessel within the water, forms the bubbles, the escape of of which conftitutes the boiling. The bulk of fteam at the boiling point is fomewhat lefs than 1800 times the bulk of the water from which it originated.

The expanfion of freezing water is not owing to the extrication of air; for water deprived of air expands like other water in freezing. Mr. Mairan attributes it to a ftrong tendency the particles of water have to arrange themfelves into ranks and lines, which crofs one another at angles of 60° and 120°. This tendency feems to begin at the temperature of 40°. The expanfion of freezing water has a prodigious force. It is owing to this that in hard frofts timber is burft, plaifter is removed from walls, and even iron mortar fhells filled with water, and accurately ftopped, have been burft by the freezing of the water.

This fingular property of water, *viz.* its expanding from the temperature of 40° downwards, fo as to become lighter and lighter in proportion as it becomes colder and colder, is a moft ftriking inftance of the wifdom of the Creator, and is a property of immenfe confequence to the very exiftence of animals and vegetables. A quantity of water is indifpenfably neceffary to animals and to vegetables at all times of the year. In winter, when the cold air freezes the furface of the water, that effect feldom penetrates lower than two or three feet. Below that depth the water continues fluid, and the cruft of ice itfelf contributes to preferve its fluidity. The heat of the earth, which has been acquired during the fummer, undoubtedly prevents the formation of ice below a certain depth. But if water in cooling had continued to increafe in fpecific gravity, and had ice been actually heavier than water, the heat of the earth would not have been fufficient to prevent the total freezing of all the waters of lakes, feas, rivers, &c. "For," fays count Rumford, "as the particles of water on being cooled at the furface would, in confequence of the increafe of their fpecific gravity, on parting with a portion of their heat, immediately defcend to the bottom, the greateft part of the heat accumulated during the fummer in the earth, on which the water repofes, would be carried off and loft before the water began to freeze; and when ice was once formed, its thicknefs would increafe with great rapidity, and would continue increafing during the whole winter; and it feems very probable that in climates which are now temperate, the water in the large lakes would be frozen to fuch a depth in the courfe of a fevere winter, that the heat of the enfuing fummer would not be fufficient to thaw them; and fhould this once happen, the following winter would hardly fail to change the whole mafs of its waters to one folid body of ice, which never more could recover its liquid form, but muft remain immoveable till the end of time." (7th Effay.)

The following table fhews the expanfions of the principal liquids that have been fubmitted to fuch experiments, according to Mr. De Luc's obfervations. With refpect to this table it muft be underftood that different thermometers (each being filled with a particular fluid, fuch as is mentioned at the top of each column, and each being divided into 80 equal parts between the freezing and the boiling points of water) are placed with their bulbs in the fame veffel full of water, and that the water is gradually heated. Then when the mercurial thermometer ftands at 5°, 10°, 15°, &c. the furfaces of the fluids in the other thermometers will be found at the degrees which ftand on the fame levels; for inftance, when the mercurial thermometer ftands at 40°, the water thermometer will be found to ftand at 20°.5, the fpirit thermometer will be found to ftand at 35°, the oil thermometer at 39°.2, &c.

The expanfions of elaftic fluids, fuch as common air, the gafes, and vapours, are more difficultly afcertained; for the expanfions of thofe fluids are occafioned by a diminution of preffure, as well as by an increafe of temperature; and it is difficult to fubject any of thofe fluids to the action of one of thefe caufes only at a time, in order that the effect of each may be duly eftimated.

When common air is acted upon by preffure only, independent of any alteration of temperature, its bulk is found to increafe and to decreafe in the inverfe proportion of the preffure; thus, the air clofe to the furface of the earth is compreffed into the bulk which we experience, by the fuperincumbent atmofphere. If that preffure be increafed, the bulk of the lower air will be contracted, which is manifefted by an augmentation of its weight; if that preffure be diminifhed, the bulk of the lower air will be increafed, as is manifefted by a diminution of its weight. And this expanfion and contraction of the air is exactly but inverfely proportional to the preffure; fo that a double preffure will comprefs it into half the fpace, a treble preffure into one third of the original fpace, &c. The fame thing, *mutatis mutandis*, may be faid of the removal of preffure, and of the expanfion thereby arifing. This elafticity of the air has not been found to be impaired by a long continuance of the preffure; for air has been left during feveral years very much compreffed in proper veffels, wherein there was nothing that could have a chemical action upon it; and afterwards on removing the unufual preffure, and replacing it in the fame temperature, the air has been found to recover its original bulk. It is not known how far a quantity of air may be expanded by removing the preffure, nor how much it may be compreffed by increafing the preffure; for no experiments have as yet been able to afcertain either limit.

The inftrument, in which the expanfion of air is tried, has been called *manometer*, (which fee,) It is a fort of large air thermometer, confifting of a tube five or fix feet long, having a bulb at one end, and being open at the other end. The bore of the tube is about a 20th of an inch in diameter. A fmall quantity of quickfilver is placed in fome

part

part of the cavity of the tube, and the expanfion of the air in the bulb, when heated, forces the quickfilver to move towards the open end of the tube. The degree of heat to which the manometer is expofed is meafured by means of a thermometer; the quantity of expanfion of the air is meafured by gauging the manometer, and making marks on the tube, which may indicate parts of the cavity of the tube that are proportional to the capacity of the manometer; as for inftance 100dths, 1000dths, &c. By placing the manometer horizontal or vertical, either with the bulb downwards or upwards, the air in it may either be left of the natural denfity, or it may be condenfed, or, laftly, it may be rarefied; for when the manometer ftands horizontal, the quickfilver in the tube does not prefs upon the air in the bulb, nor on that of the atmofphere; when the bulb is downwards, the quickfilver preffes upon the air of the manometer, and when the bulb is upwards, the quickfilver preffes againft, and counteracts, in fome meafure, the gravity of the atmofphere. Hence this preffure, and this expanfion of the air within the manometer, may be increafed to any required degree by increafing the quantity of quickfilver within the tube: and thus the expanfibility of common, or of condenfed, or of rarefied air, may be tried. The expanfion of air, by the fame degrees of heat, differs according to its denfity, and to the quantity of moifture it contains; nor are the increments of its bulk proportional to the degrees of temperature.

It appears from Col. Roy's very numerous experiments (Phil. Tranf. vol. 67th) that 1000 parts of air, of the denfity of the common atmofphere, at 0° of heat, become 1484.21 at 212°; *viz.* are expanded 484.21, by 212° of heat.

1000 parts of air loaded with $2\frac{1}{2}$ atmofpheres, are expanded 434 of thofe parts, by 212° of heat.

1000 parts of air preffed only with $\frac{1}{6}$ths of an atmofphere, are expanded nearly 484 of thofe parts by 212° of heat.

1000 parts of air preffed with $\frac{1}{5}$th of an atmofphere, are expanded about 141 parts by 180° of heat; *viz.* from the freezing to the boiling point of water.

"From thefe laft experiments," Col. Roy fays, "it would feem that the particles of air may be fo far removed from each other, by the diminution of preffure, as to lofe a very great part of their elaftic force."

The above-mentioned expanfions of air are by no means regular: *viz.* they are not proportional to the number of the degrees of heat. The maximum of expanfion takes place between 52° and 72: and the minimum is conftantly at the boiling point of water. Moift air expands a great deal more than dry air, efpecially when it approaches the boiling point of water; fo that between 192, and 212°, moift air expands about eight, or nine, times as much as dry air in fimilar circumftances.

The expanfions of gafes may be tried and determined in the fame manner as the expanfion of common air. From a long feries of experiments, Meffrs. Guyton and Prieur deduced a dilatation peculiar to each gas; but Mr. Guy-Luffac has fhewn, that all gafes, without exception, poffefs the fame expanfibility at the fame degree of temperature, and that the prefence of water in gafes occafioned the errors into which his predeceffors had fallen. He is led to conclude from his experiments made on gafes reduced to the utmoft degree of drynefs, that 100 parts of each of the permanent gafes acquire an increafe of $\frac{1}{213}$ by every degree of the thermometer from 0° to 80° Reaumur's fcale. Vapours, he alfo thinks, follow the fame laws of dilatation as gafes, provided the temperature be fufficiently elevated to keep them in the elaftic ftate. Therefore, Mr. Chaptal fays, it may be laid down as a principle, that gafes and vapours are equally dilatable, and equally compreffible; but it will be neceffary to be more particular with refpect to the expanfibility of the vapour of water, upon the elafticity of which numerous natural phenomena, and the action of feveral important machines, depend.

Mr. Schmidt alfo made a feries of experiments upon the expanfibility of air, made as dry as poffible by expofure to hot potafh. He found the expanfion of a quantity of air which meafured one inch at the freezing point, *viz.* at the temperature of 0° Reaumur's thermometer, to expand as below.

Degrees of Reaumur.	Expanfion of one inch.
1	0.0044675
4	0.0178700
8	0.035740
12	0 0536100
16	0.0714800
20	0.0893500

40	0.1787000

This table alfo fhews, by its differing from the refults of D'Amontons, De Lue, Lambert, Schuckburgh, Berthollet, and others, that thofe gentlemen operated upon air more or lefs charged with moifture. They alfo took the barometers at different altitudes. In Mr. Schmidt's experiments the barometer was taken at 29,841 Englifh inches. Thefe variations of the rates of expanfibility of moift air, faturated at different temperatures, Schmidt attributes to the variations of the degrees of affinity between air and vapour.

Water heated to the 212th degree of Fahrenheit's thermometer (or thereabout, for the different gravity of the atmofphere occafions a confiderable difference) overcomes the ordinary preffure of the atmofphere and becomes fteam, an elaftic fubftance, the bulk of which at that point is fomewhat lefs than 1800 times the bulk of the water from which it originated. Beyond that point vapour is expanfible in a moft aftonifhing degree; for 30° more of heat (*viz.* the temperature of 242°) will double the elaftic force of fteam; 30° more added to that (*viz.* the temperature of 272°) will render the elaftic force of fteam nearly equal to four atmofpheres; and fo forth. This immenfe expanfibility of fteam, when the heat which produces it is quickly fupplied, is capable of producing prodigious effects. When water is caufed to boil in a veffel upon a common fire, the heat which is communicated cannot convert all the water at once into fteam; but if the quantity of water be fmall in proportion to the heat which can be communicated in a given time, then the converfion of water into fteam is quickened to any degree, and it may be rendered inftantaneous; in which cafe it produces a fudden and violent expanfion, or an explofion. A drop of rain in boiling linfeed oil, falls to the bottom, is inftantly converted into vapour, and occafions dangerous confequences. "It has fometimes," Dr. Black fays in his Chemical Lectures, "happened that a perfon, by carelefsly fpitting into a copper foundery, has occafioned an explofion that deftroyed the whole building." Count Rumford attributes the vaft force of gun-powder to the fudden converfion into vapour of that quantity of water which naturally enters into the compofition of that powder; it being a component of the nitre. Phil. Tranf. for 1797.

Water

Water at the temperature of 212° is converted entirely into fteam, or rather, under the ordinary preffure of the atmofphere, water cannot be heated higher than 212°; but water is gradually converted into fteam or vapour at a much lower temperature. Mr. Pictet inftituted a feries of experiments on the clafticity of pure vapour in low temperatures. He found that a grain of warm water in vacuo evaporates in forty minutes in the temperature of 38° Fahr. under a receiver containing 1452 Englifh cubic inches, but that it did not diffufe itfelf equally in lefs than fix hours and then raifed the hygrometer from 17° to 60°, that is, 43°; and during this whole time the cold under the receiver was conftantly decreafing, though flowly: which decreafe undoubtedly contributed to the diffufion of the vapour. Effais de Phyfique, p. 157.

The beft, or moft extenfive experiments upon the expanfive force of the fteam of water, and of the fteam of alcohol, were made by the Chev. de Bettancourt; and are related by Prony in the fecond volume of his "Architecture Hydraulique;" from which the following compendious fketch is derived.

The fluid with which the experiments were made was confined in a very ftrong copper boiler, being eight inches at its greateft diameter, and fourteen inches in height. The upper part of it was clofed by a cover made of copper, through which paffed three tubes. The firft ferved to introduce the fluid into the boiler, and could be clofed by means of a fcrew. The fecond was occupied by a thermometer, having its ball about two inches above the bottom of the boiler, and the fcale, which was on the outfide, contained from 0° to 110° of Reaumur. To the third was adapted a bent barometer tube, having two lines of internal diameter; the afcending branch of which was 110 inches in length. By means of a lateral cock a communication was eftablifhed between the boiler and an air pump, which ferved to make a vacuum before the fire was kindled in the furnace below the apparatus. This circumftance of evaporation in a vacuum forms an effential difference between the experiments of Bettancourt and thofe made before by Ziegler, and renders them applicable to the theory of the fteam-engine, where the vapour acts in a fpace freed from air.

A vacuum having been made in the boiler, the mercury brought as nearly as poffible to a level in the two branches of the barometric tube, and the thermometer reduced to zero by means of ice, the ice was removed, and a fire was kindled, which was excited gently and with much equality, that the thermometer paffed over about a degree per minute. One perfon then ftood by to obferve the barometer, and another to obferve the thermometer, and each kept a regifter from degree to degree of the preffure and correfponding temperatures; the preffure being expreffed by the height, in French inches, of the columns of mercury, which rofe above the level in the long branch of the barometer.

Thefe obfervations of the expanfive force of the fteam of water furnifh 110 refults, proceeding from degree to degree of the thermometer, and beginning at zero. Thefe refults are contained in the following table, where the degrees of preffure are expreffed in French inches of perpendicular height of mercury, and the temperature is denoted according to Reaumur's fcale. The experiments on the expanfive force of the fteam of alcohol were made by the like procefs, and with the fame apparatus.

Table of the Expanfive Force of the fteam of Water and of Alcohol.

The expanfive force of the fteam of water has alfo been determined by Mr. Schmidt, with all the accuracy that the experiments feem to admit of: but the refults which he has not ftated for every degree of the thermometer, do not agree exactly with thofe of Bettancourt. We deem it therefore neceffary to fubjoin thofe refults in the following fhort table, wherein the temperature is expreffed in degrees of Reaumur's thermometer, as in the preceding table, and the expanfive force in French inches of perpendicular altitude of mercury.

Table

TABLE of the Expanſive Force of the pure vapour of Water, according to Mr. Schmidt.

Temperature.	Expanſive Force.	Temperature.	Expanſive Force.
0	0.0	22	1.01
5	0.11	25	1.30
6	0.15	27	1.42
10	0.28	30	1.93

13	0.44	35	2.68
15	0.55	37	3.20
16	0.61	39	3.40
18	0.76	40	3.64
20	0.90	80	28.00

Mr. Dalton has likewiſe endeavoured to determine the expanſive force of the vapour of water; but the reſults of his experiments nearly coincide with thoſe of the preceding tables, which ſuperſedes the neceſſity of ſtating them in the preſent article. See EVAPORATION.

From a careful examination of all the experiments made on this ſubject, Dr. Young has deduced a formula by which the expanſive force of ſteam may be determined for any degree of the thermometer, pretty near the real reſults of the experiments. The formula is as follows:

Let f denote the temperature according to Fahrenheit's thermometer, and e the number of inches in perpendicular height of mercury, which the ſteam is capable of ſupporting; then the formula is $e = .1781\ (1 + .006 f)^7$.

The reader might perhaps expect to find in the preſent article the particulars relative to the expanſions of heat, and of electricity; but the uncertain natures of the fluids, to which the effects of heat and of electricity are attributed, beſides other conſiderations, oblige us to refer him to other parts of this Cyclopædia. See HEAT, CALORIC, and the articles belonging to electricity.

Dr. Gregory, in his Aſtron. p. 407, proves, that a globe of our air, of an inch diameter, if it were removed to the diſtance of a ſemidiameter of the earth, would expand itſelf ſo as to fill all the planetary region as far as, nay, far beyond the ſphere of Saturn. See AIR.

EXPANSUM FOLIACEUM. See FOLIACEUM.

EX PARTE, i. e. *partly*, or of *one part*, in *Law*. A commiſſion ex parte, is that taken out and executed by one part only; where both parties join it is called a joint commiſſion. See COMMISSION.

EX PARTE TALIS, a writ that lies for a bailiff or receiver, who, having auditors aſſigned to take his account, cannot obtain of them reaſonable allowance, but is caſt into priſon. The courſe in this caſe is to ſue this writ out of chancery, directed to the ſheriff, to take four mainpernors to bring his body before the barons of the exchequer at a certain day, and to warn the lord to appear at the ſame time. F. N. B. 129.

EXPECTANT FEE, where lands are given to a man and his wife, and the heirs of their bodies; in which ſenſe it differs from fee-ſimple, where lands are given to a man and his wife in frank marriage, to hold to them and their heirs.

EXPECTANCY, ESTATES IN, are of two ſorts; one created by act of the parties, called a *remainder*; the other by act of law, called a *reverſion*. See theſe articles; and alſo ESTATE and EXECUTORY *Deviſe*.

EXPECTATION, in the *Doctrine of Chances*, is applied to any contingent event, and is capable of being reduced to the rules of computation. Thus, a ſum of money in expectation, when a particular event happens, has a determinate value before that event happens; ſo that if a perſon is to receive any ſum, *e. gr.* 10*l.* when an event takes place which has an equal probability of happening and failing, the value of the expectation is half that ſum or 5*l.* and in all caſes, the expectation of obtaining any ſum is eſtimated by multiplying the value of the ſum expected by the fraction, which repreſents the probability of obtaining it. The expectation of a perſon who has three chances in five of obtaining 100*l.* is equal to $\frac{3}{5} \times 100$ or 60*l.* and the probability of obtaining 100*l.* in this caſe is equal to $\frac{60}{100} = \frac{3}{5}$.

If the obtaining of any ſum requires the happening of ſeveral events that are independent on each other, the value of the expectation of that ſum is found by multiplying together the ſeveral probabilities of happening, and by multiplying the product by the value of the ſum expected. *E. gr.* Suppoſe, that in order to obtain 90*l.* two events muſt happen, one of which has three chances to happen and two to fail, and the other has four chances to happen, and five to fail; the value of the expectation is $= \frac{3}{5} \times \frac{4}{9} \times 90 = \frac{12}{45} \times 90 = \frac{4}{15} \times 90 = \frac{360}{15} = 24$*l.* for if the firſt event had actually happened, the value of the expectation depending ſolely on the ſecond event, would be $\frac{4}{9} \times 90 = 40$*l.* and therefore the happening of the firſt event is the condition of obtaining an expectation worth 40*l.* but the probability of the firſt happening is $\frac{3}{5}$, and the expectation ſought for is evidently worth $\frac{3}{5} \times 40 = \frac{3}{5} \times \frac{4}{9} \times 90 = 24$*l.* The rule will be the ſame if an expectation depends on the happening of one event and the failing of another; and alſo on the failing of two events; and on the happening or failing of any number of events that may be aſſigned. It is here ſuppoſed that the events are independent, or that the happening of one, neither forwards nor obſtructs the happening of the other. But if two events are dependent, *i. e.* if they are ſo connected together as that the probability of either's happening is altered by the happening of the other, the probability of their happening is the product of the probability of the happening of one of them by the probability which the other will have of happening, when the firſt is conſidered as having happened; and the ſame rule will extend to the happening of any aſſigned number of events: thus, in a heap of thirteen cards of the ſame colour, the probability of taking out the ace is $\frac{1}{13}$; and the probability of taking the ace out of another heap of the ſame number is $\frac{1}{13}$; and the probability of both theſe independent events happening will be $\frac{1}{13} \times \frac{1}{13} = \frac{1}{169}$: but the probability of taking the ace firſt out of a ſingle heap of thirteen cards is $\frac{1}{13}$; and that of taking the deuce afterwards is $\frac{1}{12}$; and therefore the probability of both happening is $\frac{1}{13} \times \frac{1}{12} = \frac{1}{156}$. If a perſon has ſeveral expectations on ſeveral ſums, the value of his expectation on the whole is the ſum of his expectations on the particulars: thus, let one event be ſuch, that the probability of obtaining any ſum, *e. gr.* 90*l.* in caſe it happens, may be $\frac{3}{5}$; in which caſe the value of the expectation is $\frac{3}{5} \times 90 = 54$*l.* Let the probability of another event, on which depends a ſecond ſum of 90*l.* be $\frac{4}{9}$, and the value of the expectation in this caſe be $\frac{4}{9} \times 90 = 40$*l.* and the value of the expectation on the whole $54 + 40 = 94$*l.* But if a perſon is to receive 90*l.* once for all for the happening of one or other of the two forementioned events, then the expectation of the firſt event being worth 54*l.* as before, yet the expectation of the ſecond will be different; becauſe this depends on the happening of the firſt, and takes place only in caſe the firſt happens to fail, the probability of which is $\frac{2}{5}$; and on the ſuppoſition of its having failed, the expectation of the ſecond will be 40*l.*; therefore $\frac{2}{5}$ is the meaſure of the probability of obtaining an expectation worth 40*l.*; and conſequently the expectation will be worth $\frac{2}{5} \times 40 = 16$*l.* and the value of the expectation on the whole will be $54 + 16 = 70$*l.* See the farther illuſtration and application of theſe principles and rules in De Moivre's Doctrine of Chances, edit. 3. 1776. See CHANCES and GAMING.

EXPECTATION *of Life*, in the *Doctrine of Life Annuities*, donotes, according to the moſt obvious ſenſe of the term, that particular number of years which a life of a given age has an equal chance of enjoying, or the time which a perſon of a given age may juſtly expect to continue in being. But Mr. Simpſon has ſhewn, that this period does not coincide with what the writers on annuities call the expectation of life, except on the ſuppoſition of an uniform decreaſe in the probabilities of life; and Dr. Price adds, that even on this ſuppoſition, it does not coincide with what is called the expectation of life, in any caſe of joint lives: for two lives of 40 have an even chance, according to Mr. De Moivre's hypotheſis (ſee COMPLEMENT *of life*) of continuing together only $13\frac{1}{2}$ years. According to that hypotheſis, the *probability* that a life aged 40 will continue $13\frac{1}{2}$ years will be expreſſed by $\frac{32.5}{46}$; and this fraction multiplied by itſelf is the probability that two lives of this age ſhall both continue $13\frac{1}{2}$ years; *i.e.* $\frac{32.5}{46} \times \frac{32.5}{46} = \frac{1056.25}{2116}$, equal nearly $\frac{1}{2}$, which repreſents an even chance; but the expectation of two joint lives being (according to the ſame hypotheſis) always a third of the common complement, will be in this caſe $15\frac{1}{3}$ years. Therefore, the expectation of life may ſignify the mean continuance of any given ſingle, joint, or ſurviving lives, according to any given table of obſervations, or the number of years which, taking them one with another, they actually enjoy; ſo that if 46 perſons are alive, all 40 years of age, and one be ſuppoſed to die every year, according to Mr. De Moivre's hypotheſis, till they are all dead in 46 years, half 46 or 23 will be their expectation of life; *i.e.* the number of years enjoyed by them all will be the ſame as if every one of them had lived 23 years, and then died; and ſuppoſing no intereſt of money, the value of an annuity payable for life to every ſingle perſon in ſuch a ſet, would juſt be equal to 23 years purchaſe.

The expectation of life coincides with the ſums of the preſent probabilities, that any given ſingle or joint lives ſhall attain to the end of the firſt, ſecond, third, &c. moments, from this time to the end of their poſſible exiſtence; or (in the caſe of ſurvivorſhips) with the ſum of the probabilities, that there ſhall be a ſurvivor at the end of the firſt, ſecond, third, &c. moments, from the preſent time to the end of the poſſible exiſtence of ſurvivorſhip. From theſe principles Dr. Price has ſhewn how to deduce the demonſtrations of Mr. De Moivre's rules for finding the expectations of lives, which he has omitted; we ſhall here ſubjoin them for the information and amuſement of our mathematical readers. Let $\dot{x}$ ſtand for a moment of time, and n be the *complement* of any aſſigned life; then $\frac{n - \dot{x}}{n}, \frac{n - 2\dot{x}}{n}, \frac{n - 3\dot{x}}{n}$, &c. will be the preſent probabilities of its continuing to the end of the firſt, ſecond, third, &c. moments; and $\frac{n - x}{n}$ the *probability* of its continuing to the end of x time: therefore, $\frac{n - x}{n} \times \dot{x}$ will be the fluxion of the ſum of the probabilities, or of an area repreſenting this ſum, whoſe ordinates are $\frac{n - x}{n}$, and axis x. The fluent of this expreſſion, or $x - \frac{x^2}{2n}$, is the ſum itſelf for the time x; and this, when $x = n$, becomes $\frac{1}{2}n$, the expectation of the aſſigned life, or the ſum of all the probabilities juſt mentioned for its whole poſſible duration. In like manner $\frac{n - x}{n} \times \frac{n - x}{n}$ or $\frac{\overline{n - x}|^2}{n^2}$ is the probability that two equal joint lives will continue x time, and $\frac{\overline{n - x}|^2}{n^2} \times \dot{x}$ will be the fluxion of the ſum of the probabilities; the fluent of which, or $x - \frac{x^2}{n} + \frac{x^3}{3n^2}$, becomes, when $n = x$, $\frac{n}{3}$, or the expectation of two equal joint lives. Again, ſince $\frac{n - x}{n} \times \frac{2x}{n}$ is the probability that there will be a ſurvivor of two equal joint lives at the end of x time, $\frac{n - x}{n} \times \frac{2x}{n} \times \dot{x}$ will be the fluxion of the ſum of the probabilities; and the fluent, or $\frac{x^2}{n} - \frac{2x^3}{3n^2}$ is, when $x = n$, $\frac{1}{3}n$, or the expectation of ſurvivorſhip between two equal lives, which appears to be equal to the expectation of their joint continuance. The expectation of two unequal joint lives found in the ſame way is $\frac{m}{2} - \frac{m^2}{6n}$, m being the complement of the oldeſt life, and n the complement of the youngeſt. The whole expectation of ſurvivorſhip is $\frac{n}{2} - \frac{m}{2} + \frac{m^2}{3n}$; and the expectation of ſurvivorſhip of the oldeſt will be to that of the youngeſt as $\frac{m^2}{6n}$ to $\frac{n}{2} - \frac{m}{2} + \frac{m^2}{6n}$.

From the definition already given of the expectation of life, it follows, that if in a ſociety limited to a fixed number of members, a 28th part of its members dies annually, 28 would appear to be their common expectation of life at the time they entered; and if it were found in any town or diſtrict, where the number of births and burials are equal, that a 20th or 30th part of the inhabitants die annually, it would appear that 20 or 30 was the expectation of a child juſt born in that town or diſtrict.

Having a table of obſervations, ſhewing the number that die annually at all ages out of a given number alive at thoſe ages, it is eaſy to find the expectation for all ſingle lives by the following rule: divide the ſum of all the living in the table at the age whoſe expectation is required, and at all greater ages, by the number in the table of the living at that age, and ſubtract half unity from the quotient, the remainder will be the expectation required.

The reaſon of this ſubtraction may be underſtood by conceiving the recruit neceſſary to ſupply the waſte of every year to be made always at the end of the year, ſo that the dividend ought to be the medium between the number living at the beginning and the end of the year; that is, it ſhould be taken leſs than the ſum of the living in the table at and above the given age by half the number that die in the year; the effect of which diminution will be the ſame with the ſubtraction here directed. This rule may be illuſtrated by taking the ſum of all the living at 20 and upwards in Tab. I. and dividing it by 360, the number living at that age, and the quotient leſs half unity, will be nearly 28.9 the expectation of 20 in Tab. II.

Table I.—Shewing the Probability of the Duration of Life in London, deduced by Mr. Simpſon from Obſervations on the Bills of Mortality in London for 10 Years, from 1728 to 1737.

Dr. Price has applied his reaſoning on this ſubject to the ſolution of a curious queſtion in political arithmetic, or to determine the number of inhabitants in any place from a table of obſervations, or the bills of mortality for that place, on the ſuppoſition that the yearly births and burials are equal. For this purpoſe find by the table the expectation of an infant juſt born; and this, multiplied by the number of yearly births, will be the number of inhabitants.

Were the bills of mortality conſtructed with the leaſt regard to truth, and were a regular account kept of all the perſons who annually migrate from the country, this rule of Dr. Price might be ſafely applied towards aſcertaining the number of inhabitants in London, but in their preſent form the London tables are ſo very incorrect that it can hardly be ſafe to derive any concluſions from them.

It appears from Tab. I. that though an infant juſt born in London has not an equal chance (the probability being $\frac{496}{1000}$) of living three years, his expectation is twenty years, and by Tab. III. that though the expectation of ſuch a child in Northampton is twenty-five, it has only an equal chance of living eight years. This difference proceeds from the greater probability of life in the more mature ages, than in the firſt moments of exiſtence. Were the decrements of life, however, the ſame through every period of it, theſe quantities would always be equal; but as this is not the caſe, neither in the earlier nor the latter ages, the computations founded on ſuch an hypotheſis can in general be of very little uſe. De Moivre's Doctrine of Chances, applied to the Valuation of Annuities, p. 288, &c. Simpſon's Select Exerciſes, p. 253, &c. and particularly Dr. Price's Obſervations on Reverſionary Payments, eſſ. i. vol. ii. or Phil. Tranſ. vol. lix. p. 89. See COMPLEMENT *of Life*, LIFE *Annuities*, MORTALITY, SURVIVORSHIP.

EXPECTATIVE, in the *Canon Law*, a hope founded on a promiſe of obtaining the next benefice that ſhall become vacant, or a right to the reverſion of the next. See BENEFICE.

EXPECTATIVE *Canons*. See CANON.

EXPECTATIVE *Graces*, *Gratiæ Expectativæ*, called alſo *preventions*, were bulls frequently given by the popes or kings for future benefices. The biſhops were exceedingly mortified with them, becauſe they encroached on their privileges; beſides, that ſuch expectatives are odious, as they induce people to wiſh for the death of others.

The uſe of expectatives is very ancient, though it was not near ſo frequent in the firſt ages as afterwards. Originally they were no more than ſimple requeſts made on the part of kings or popes, which the biſhops conſented to with the more willingneſs, as they only preſented to them perſons fit to ſerve the church: but the frequent exerciſe of this privilege made it at length be deemed a matter of obligation and neceſſity.

The council of Trent annulled all expectatives; but the canons relating thereto were never admitted in France, where the right of conferring expectative graces is looked on as one of the regalia.

EXPECTORANT MEDICINES, are thoſe which facilitate the excretion of the mucous diſcharges from the cells and paſſages of the lungs; or *ex pectore*, from the breaſt.

This evacuation muſt be accompliſhed by more or leſs of coughing, which the irritation of the collecting mucus, &c. naturally occaſions. It were, therefore, obviouſly uſeleſs and ſuperfluous to give medicines with a view to excite coughing, (if indeed we were acquainted with any ſubſtance poſſeſſed of ſuch quality,) or to uſe any external means, as the ancient Cnidians are ſaid to have done, for that purpoſe. The principal object, in attempting to facilitate the diſcharge of the contents of the bronchial veſſels and cells, muſt conſiſt in changing the nature of thoſe contents, ſo as to render them thinner, leſs tenacious, and more moveable than before. Whether we are poſſeſſed of any medicines, however, capable of producing ſuch a direct effect, may admit

mit of a queftion. The generality of writers on the materia medica, and of phyficians, fpeak of the utility of fuch medicines as they have termed *attenuantia* and *incidentia*, for this purpofe: but we believe, with Dr. Cullen, that their hypothefis on this fubject is altogether erroneous, and that no fuch medicines exift. The only probable explanation of the action of an expectorant medicine appears to be, that by increafing the fecretion from the exhalent arteries in the lungs, the mucus may be diluted and rendered lefs vifcid and the paffages from the cells may be more fully moiftened with a lefs tenacious fluid. We know that there is a conftant and confiderable exhalation of moifture from the cavity of the lungs: and there are many reafons for believing that this is an excrementitious fecretion, connected with the other excrementitious fecretions, particularly with the perfpiration from the furface of the body. If, therefore, there are medicines difpofed to pafs by perfpiration, it may be prefumed that the fame are difpofed to pafs by the exhalation from the lungs: and this exhalation may not only be increafed, but the mucus, produced by the follicles, may alfo be poured out in a lefs vifcid form, and confequently in a ftate to be more eafily brought up by expectoration.

It would appear, that fome fuch increafe of the thinner fecretion of lungs is produced, by fympathy with the ftomach, when a condition approaching to naufea is induced, and that, therefore, medicines which poffefs an emetic quality, when ufed in fmall dofes, operate in fome degree as expectorants; fuch as the fquill, ipecacuanha, nicotiana, antimony, &c. A full dofe of an emetic feems to produce this effect more completely, and, affords confiderable relief to thofe afthmatic complaints, as they are called, in which the lungs are loaded with a quantity of vifcid phlegm. Many expectorant medicines are mentioned by different writers, fuch as the tuffilago, or colt's foot, enula campana, iris florentina, petafites, &c. which recent experience feems to have rejected, from their failure to anfwer the expectation which thofe writers had excited.

Many other medicines which give relief to coughs have been employed under the appellation of expectorants; but their operation is to be explained upon principles altogether different from that of facilitating expectoration. Among thefe are fpermaceti, liquorice, oil of almonds, and other vegetable and animal oils, various mucilaginous vegetables, fuch as mallow, horehound, &c. all of which give a temporary alleviation to the irritation about the glottis, and thus appeafe the cough, but do not in the fmalleft degree aid the expectoration. See CATARRH.

In the chronic coughs of old people, expectoration appears to be facilitated by the ufe of the ftimulant gums, and of volatile alkali. But perhaps thefe medicines operate indirectly, by fupporting the ftrength of the patients, and thus enabling them to ufe greater mufcular exertion in the act of coughing.

EXPECTORATION, the act of bringing up the mucous and other excretions from the lungs, by coughing, hawking, &c. The word has the fame derivation as the preceding.

EXPEDITATION, in the *Foreft-Laws*, fignifies a cutting out the balls of a dog's fore-feet for the prefervation of the king's game.

Every one that keeps any great dog, not expeditated, forfeits three fhillings and four-pence to the king. In maftiffs, not the ball of the feet, but the three claws, are to be cut to the fkin. Inftit. part. iv. p. 308. "Nullos Dominicos canes abbatis & monachorum expeditari cogat." Chart. Hen. III. "Et fin quieti de efpeditamentis canum." Ex. Mag. Rot. Pip. de ann. 9 Ed. II.

The expeditation was to be performed once in every three years, and was done to every man's dog who lived near the foreft, and even the dogs of the forefters themfelves.

EXPEDITION, the march of an army to fome diftant place, with a view of hoftilities.

Such were the expeditions of Cyrus againft Xerxes, and of Bacchus and Alexander to the Indies.

Expeditions for the recovery of the Holy Land were called croifades.

The fuccefs of an expedition depends on rapid and unexpected movements. An expedition is planned and governed by the following principal maxims, *viz.* fecrecy, if poffible, of preparation, and a concealment of defign, &c.; a juft proportion of the means to the end; a knowledge of the ftate and fituation of the country, which is intended to be the fcene of action, and of the place or object that is to be attacked; the appointment of a commander, poffeffed of thofe abilities, and of that difpofition, which are adapted to the warfare propofed; and the arrangement of the plan of the expedition before it is undertaken or carried into effect. The French ufe the word expedition to exprefs any particular military quality, which an officer or foldier may poffefs. Thus, "cet officier eft un homme d'expedition," that is, this officer is a man of enterprife, or courageous and daring.

EXPENCES, in *Book-keeping*. See BOOK *of Expences*.

EXPENDITORS, in *Law*, are the perfons appointed by commiffioners of fewers, to pay, difburfe, or expend the money collected by the tax for the repairs of fewers, &c. when paid into their hands by the collectors on the reparations, amendments, and reformations ordered by the commiffioners; for which they are to render accounts when required for that purpofe.

Thefe officers are mentioned in the ftatute 37 H. VIII. cap. 11. and other ftatutes. The fteward who fupervifes the repair of the banks and water-courfes in Romney Marfh is likewife called the expenditor.

EXPENSE MAGAZINE, is a fmall receptacle for fuch quantities of ammunition as may be required on emergency, or for the fupply of powder, &c. in that ordinary courfe which enables the proper officers to eftimate with correctnefs what quantity fhould be kept at hand for the purpofe of annual exercife, or for the furnifhing the neighbouring camps, pofts, or batteries, with fuch ftores as may be neceffary for their ufe. Thus we fee, in almoft every fortrefs, various expenfe-magazines built in commodious and fafe fituations, for the exprefs purpofes of enabling the commiffaries, and the ordnance officers, to prevent the defenders of the feveral works in their vicinity from being at a ftand for want of ammunition. Some of thefe little ftores are occafionally built even upon the terre-pleine of the batteries they are to fupply; but we have heard this practice cenfured; for, though it may be true, that owing to their very folid conftruction they may fuccefsfully refift the enemies' fhot, ftill, as they are liable to explode from other accidents, we cannot join an unqualified approval of fuch pofitions. We avail ourfelves of a fuggeftion offered to us, in which we think the foregoing objection is greatly diminifhed, if not totally removed. The fuggeftion is, that in lieu of allowing any expenfe-magazines to be built on a terre-pleine, a ramp fhould be thrown up at the back of every fixth or feventh piece of ordnance on the defences, the interior of which fhould be a magazine of this defcription. The ramp would ferve as a paffage for the perfons employed in conveying the powder to the gunners, and fhould have a door at that fide leaft expofed to enfilades, or to accidental fhots. The entrance might, indeed, be either above or below the ramp; though we are difpofed to recommend the latter; as the delay occafioned by afcending would not be of any confequence in ordinary defences, and would be fully counter-balanced by the fafety with which all the expenfe-magazines might be worked. Poffibly, the fuggeftion might be rather improved if the expenfe-magazines were to be built partly under the refpective ramparts; thereby becoming mines on occafion. (See *Plate* I. *Tactics*, *fig*. 4.)

Againft works of mafonry built upon the terre-pleine, we cannot too powerfully inveigh: the immenfe numbers of fplinters which are generally created by fuch being fufficient grounds for their condemnation. If, however, it is deemed proper to have fmall magazines in fuch fituations, (for there may be localities which afford no alternative,) fuch ought to be funk fo far as to allow the fummits of their arches to be little more than level with the terre-pleine. Being then covered with foil, and well gazoned, (*i. e.* turfed,) they would become ufeful, by caufing fuch fhots as might be fent over the epaulement to throw up, inftead of allowing them to trundle along the terre-pleine. (See ENFILADE.)

The entrances of all magazines of this defcription ought to be towards the back of the battery, and certainly might be rendered fafer by making a few fteps down upon the inner revetement; fo as completely to cover not only the magazine itfelf; but the perfons who might be employed to hand up the cartridges. (See *fig*. 5.)

EXPENSIS *Militum Levandis*, in *Law*, was a writ anciently directed to the fheriff, for levying allowance for the knights of parliament. See PARLIAMENT, and REPRESENTATIVE.

EXPENSIS *militum non levandis*, &c. an ancient writ to prohibit the fheriff from levying any allowance for knights of the fhire upon thofe that hold lands in ancient demefne. Reg. Orig. 261.

EXPERIENCE, a kind of knowledge acquired by long ufe without any teacher.

Experience confifts in the ideas of things we have feen or read, which the judgment has reflected on, to form for itfelf a rule or method.

Authors make three kinds of experience: the firft is the fimple ufes of the external fenfes, whereby we perceive the phenomena of natural things, without any direct attention thereto, or making any application thereof.

The fecond is, when we premeditatedly and defignedly make trials of various things, or obferve thofe done by others, attending clofely to all effects and circumftances.

The third is that preceded by a fore-knowledge, or at leaft an apprehenfion of the event, and determines whether the apprehenfion were true or falfe; which two latter kinds, efpecially the third, are of great fervice in philofophy.

Dr. Campbell, in his "Philofophy of Rhetoric," (vol. i. p. 129, &c.) inveftigates the nature and origin of experience; and obferves, that thofe fources in our natures which give being to it, and confequently to all thofe attainments, moral and intellectual, that are derived from it, are fenfe and memory. The fenfes, both external and internal, are the original inlets of perception; and the articles of information exhibited by them are devolved on the memory. As remembrance inftantly fucceeds fenfation, the memory becomes the fole repofitory of the knowledge received from fenfe; and hence it is the only original voucher extant of thofe paft realities for which we had once the evidence of fenfe. In order to render the knowledge thus acquired and preferved ufeful to us, in difcovering the nature of things and regulating our conduct, a further procefs of the mind is neceffary, and this is affociation. This retention and affociation are called experience. We may here obferve, that though memory gives birth to experience, which refults from the comparifon of facts remembered, the experience, or habitual affociation, remains, when the individual facts on which it is founded are all forgotten. We cannot purfue the reafoning of this ingenious writer in his illuftration of the evidence of experience, which he confiders as one fpecies of moral evidence, (analogy and teftimony being the two others,) and which, in his opinion, is the criterion, if not the foundation, of all moral reafoning whatever, and the principal organ of truth in all the branches of phyfiology, in the largeft acceptation of the term. See TESTIMONY.

EXPERIMENT, from the Latin *experimentum*, is a trial, or practical proof of fomething. In philofophy it means the refult of certain applications, difpofitions, or combinations, of natural bodies, made with fome particular view. Experiments are faid to be mechanical, or chemical, or electrical, or magnetical, &c. according to the fubject to which they more immediately belong. The object of making experiments is to afcertain either certain caufes or certain phenomena; and for the proper attainment of thefe objects care muft be had to inftitute experiments that admit of no equivocal refult, and fo as to anfwer the purpofe in the quickeft and moft direct way. The main object, however, of the inquiry can feldom be determined by a fingle decifive experiment; hence, in moft cafes, it becomes neceffary to divide the queftion into parts, and to afcertain each part feparately by one or more appropriate experiments. When the experiment is fo prefcribed as to decide the queftion without any poffible doubt or equivocation, it has in that cafe frequently been called *experimentum crucis*; meaning a capital or decifive experiment; fuch as fuperfedes the neceffity of inftituting more experiments for the fame purpofe. The origin of the expreffion *experimentum crucis* has probably been derived from its being a kind of torture, whereby the nature of the queftion is, as it were, extorted by force. It has been alfo attributed, though with lefs apparent probability, to the guide or inftruction which it affords, like that of a direction poft, which is fhaped fomewhat like a crofs.

It is not practicable to give any inftructions for the right performance of experiments in general; for not only every fubject, but every particular queftion belonging to any fubject, muft be determined by a peculiar mode of inveftigation. The experimenter can only be inftructed by practice. The nature of the fubject, a ftrict attention to every apparent circumftance, an accurate ftatement of particulars, and an unprejudiced mode of reafoning, will eafily fuggeft a proper train of experiments which the fubject in queftion may admit of. It deferves to be remarked, that though in the inveftigation of any fubject, the philofopher propofes a certain order of inveftigation, (and it is always proper to propofe to onefelf fome fuch plan or train of experiments;) yet it is but feldom that the propofed plan can, or deferves to be ftrictly executed; for the refult of the firft or fecond experiment frequently points out a new track or a more promifing road; in confequence of which, new and different trials muft be inftituted; and it is in the ready adoption of fuch plans as may be more fuited to the laft indications, that the genius of the philofopher is rendered confpicuous.

Such mode may fuffice for the determination of any doubtful point; but when a difcovery has been made and is to be explained

explained to other perfons ; then it is of ufe to fhew the fame refult by different experiments ; for it is not only a fatisfaction to have feveral concurring proofs of the fame propofition ; but it is alfo rendered intelligible to a greater number of readers or hearers ; it being feldom the cafe, that the fame experiment conveys an equal degree of conviction and fatisfaction to the mind of every body.

EXPERIMENTAL Farm, in *Agriculture*, that fort of farm eftablifhment which is chiefly applied to, or calculated for, the purpofe of making experiments, with the view of afcertaining unknown caufes, effects, or refults in the various departments of hufbandry. This is a plan which has often been attempted, both individually and collectively, by numbers of perfons warmly interefted in promoting the improvement of agricultural knowledge ; but hitherto, we believe, without that fort of fuccefs which might naturally be expected. The caufe of which has probably been the want of a due combination of real practical agricultural information with that of the fcientific kind, as without a full comprehenfion of both thefe, in perfons who have the direction and management of fuch eftablifhments, it muft be utterly impoffible that they can be fo highly advantageous as they ought to be. But a writer, who has beftowed much attention on the fubject, feems to fuppofe that there is much doubt of any real benefit being at all produced in this way ; as he confiders both experience and experiment the two means by which facts concerning the art may be afcertained as equally liable to objection. The term *experience* he conceives to denote thofe deductions which a perfon draws as the average refult of practice continued for a confiderable length of time, and which is unqueftionably the fureft guide that can be followed, where the obfervations are fufficiently correct, and the circumftances difcriminated in fo clear a manner as to create no fort of confufion ; ftill where thefe peculiarities are wanting, the conclufions thus drawn may be extremely fallacious. And what increafes the evil in this cafe is, that when conclufions have been once drawn in confequence of an imperfect difcrimination of circumftances, there is fcarcely any chance of eradicating the error ; as the mind, when once accuftomed to think in a certain way, is apt to proceed in the fame ever afterwards ; and that the fame indifcrimination which caufed the firft error will induce a fucceffion of others of the fame fort *ad infinitum*. Unfortunately, too, it happens that in agriculture, things which are capable of affecting the refult of a procefs or operation, are fo jumbled and thrown together into one chaotic mafs, that it is a matter of extreme difficulty even for the moft nice obferver to diftinguifh fuch as are effential, from thofe which are merely accidental, confequently extremely eafy to miftake one for the other. The inaccuracy likewife, which too much prevails in the operations of the farmer, concerning the actual expence of different proceffes, as affecting any particular object ; and all the difficulty of keeping the different produce of different fields feparate, render it, in moft cafes, almoft impoffible for the actual farmer to afcertain, with any fort of precifion, either the expence or the value of the produce of any one of his fields ; confequently the profit or lofs of any operation or procefs is merely gueffed at, not afcertained by the teft of his experience ; in confequence of which he is at liberty, and will of courfe draw the conclufion, which feems moft to confirm his own pre-conceived notion on the head, whatever it may be. Under fuch circumftances experience muft, he conceives, be a very fallacious and imperfect guide. It may, indeed, it is fuppofed, furnifh hints or indications of what ought to be purfued or laid afide and avoided ; but that unlefs facts be afcertained with much greater precifion than it admits of, they muft, it is conceived, afford a very unftable foundation for promoting the fcientific improvement of agriculture.

In confequence of which, experiment, he thinks, has been introduced and adapted, in order to fupply the deficiencies which are thus produced ; but which, though, at the firft fight, it may promife fair to accomplifh fuch purpofes, upon a nearer view has not been found adequate in any material degree. An experiment in this art is, it is conceived, a particular operation, undertaken with the defign of elucidating and explaining fome fact which is involved in doubt or difficulty ; of courfe extreme accuracy, in order to guard againft every circumftance that may unintentionally affect or influence the refult, is an indifpenfable requifite in the conducting of it ; as, unlefs this be the cafe, the fame experiment, under different circumftances, may lead to a variety of conclufions. In general, however, farmers, from their having been but little accuftomed to the nice difcriminations of fcientific inveftigation, are but indifferently qualified to guard againft the fecret influence of caufes, which they have never even fo much as fufpected of having any power upon the refult of their experiment. It is, therefore, contended, that from thefe caufes the experiments made by actual farmers frequently prove extremely defective ; and when amateurs of a higher rank project experiments, the detail of them muft be left to fervants and dependants, who commonly put down at random all the circumftances which their careleffnefs prevented them from noticing ; fo that thefe experiments, though they may affume a more engaging appearance of accuracy, are, in fact, for the moft part, more inaccurate and erroneous than the former. Confequently, with the view of remedying thefe evils, the notion of an experimental farm has prefented itfelf to many perfons as the only means of forwarding the progrefs of fcientific agriculture, and upon a flight view, the benefits that might refult from it have indeed feemed fo obvious, that in feveral diftricts of this country funds have been provided, as has been already hinted, for the fupport of fuch eftablifhments, but on trial they have all found fuch difficulties in the way, as have not hitherto been capable of being furmounted. The chief reafon of which, it is conceived, is, as has been fuggefted before, that of the difficulty of procuring a perfon in every way properly qualified for conducting fuch an undertaking. On thefe grounds, the expectations of the benefits that are to be derived from the eftablifhment of an experimental farm are not by any means fo great as may be fuppofed. It is, indeed, contended, that there are many experiments of the very firft importance in fcientific agriculture, which are totally out of, or beyond the fphere of a farm of this kind. Of this defcription, it is conceived, are all thofe facts which have a relation to the original conftitution of foils, and the infinitely diverfified, though little obvious qualities thefe poffefs in confequence of peculiar impregnations, which they may have derived from the operations of nature or of art. It is fuppofed that an experimental farm, in fo far as this particular is concerned, is precifely the fame as another farm, in which the experimenter, like the farmer, may in time acquire a knowledge of what will fuit his own foil. But if thefe experiments were prefented to the public under the idea that the refults which they afforded fhould be deemed generally conclufive in all diftricts, fuch a decifion would turn out fallacious, as it would foon be found, that, in many other cafes, the refults would be extremely different. Nor is it believed that the practical farmer could derive much advantage from the experimental farm, in what refpects the economical

economical diſtribution or arrangement of the neceſſary buſineſs which is to be purſued in the conducting of the work, which is a branch of the art that is of the greateſt conſequence to be well underſtood by the real farmer, but that is totally incompatible with the complex arrangements and continually varying operations of the experimental farm.

But however true many of theſe remarks may be, there can be little doubt, but that the eſtabliſhment of experimental farms in different parts of the country muſt, under proper management, be attended with great advantage in throwing additional light on different branches and modes of cultivation, as well as in bringing agriculturiſts acquainted with a variety of new and intereſting facts.

When conducted under a proper ſyſtem of management, farms of this kind might readily aſcertain the following important queſtions.

1ſt. What is the beſt mode of cultivating arable land?

2d. What is the beſt ſyſtem for the management of graſs land?

3d. What are the moſt uſeful implements of huſbandry?

4th. What are the moſt profitable breed of animals, and the beſt, and cheapeſt modes of feeding and fattening them? and,

5th. What is the beſt plan for rendering waſte or barren land productive?

All theſe queſtions are evidently to be conſidered in relation to the differences of ſoils, circumſtances and ſituations.

Mr. Arthur Young, in ſpeaking of the eſtabliſhment of a farm of this nature, as being properly an undertaking only fit for a ſovereign, in the fourth volume of his "Annals of Agriculture," remarks, that it would have great effects in promoting agriculture in this country, but in others, where that art is ſtill leſs underſtood, it is abſolutely eſſential to the progreſs of it. And that if, in ſome future age, this art, ſo neceſſary to the welfare of mankind, ſhould receive an attention that has hitherto been denied it, and a farm of this ſort ſhould be eſtabliſhed, the following hints may be found of uſe. It is conceived, that a divided attention to complex queſtions ſhould be avoided; and thoſe great leading objects moſt nearly connected with the deficiencies of the national agriculture demand the firſt exertions to aſcertain. With this view the ſoil of the farm ſhould regulate the plan of it. If it were a ſand one in this country, it ſhould, it is ſuppoſed, be thrown into the Norfolk huſbandry, and the object of theſe experiments would be to examine how far that ſyſtem, by means of carrots, turnip-cabbage, and other new plants, equi-diſtant drilling, manuring for the roots and graſſes inſtead of the wheat, &c. could be improved. And connected with this inquiry would be the collateral one of the breed of ſheep, proper for this ſoil; with other objects too numerous to recite, which are at preſent unaſcertained.

If the ſoil were of the clayey or loamy kind, too wet for turnips, the great objects would, it is ſuppoſed, be, the means of baniſhing ſummer fallows, an inquiry of great inportance; the culture and uſe of cabbages; the modes of draining by hollow cuts and arched lands; the beſt means of converting ſuch lands to meadows, and the proper breed of cattle.

And on a loamy ſoil, ſtrongly inclining neither to clay nor ſand, very intereſting inquiries are to be purſued. Every plant, common on all other ſoils, is to be cultivated on this. The rotations of crops; the culture of potatoes and carrots, and their application to all ſorts of cattle; lucerne, and its uſe in ſummer feeding a dairy of cows, that are ſupported in the winter on the roots, &c. are among the numerous inquiries to be proſecuted on this ſort of ſoil. On chalky ſoils the principal object is, it is ſuppoſed, the culture of ſaintfoin, and the beſt means of converting it to corn and turnips preparatory to a renewal.

But on a peat-moor many dubious points are to be aſcertained; the beſt means of reclaiming, whether by paring and burning, fallow, or mere manuring. The graſſes proper to lay down with; and the means by roots or cabbages of ſupporting the greateſt poſſible ſtock of that breed of cattle and ſheep, which are found by experiment moſt proper for the ſoil; the method of draining, manuring, and giving ſolidity to bogs, &c. Upon all, or either of theſe ſoils, collateral inquiries would ariſe in relation to manures, tillage, inſtruments, &c. and a great variety of doubtful points to be decided in the culture and management of all the plants uſually raiſed on any of them.

A ſmall botanical garden of two or three acres, under a botaniſt, for ſmall experiments upon plants not cultivated but promiſing; and a laboratory for chemical trials on ſoils, manures, and vegetables, would, it is ſuggeſted, be two neceſſary additions to ſuch an eſtabliſhment; and with a ſmith's and wheelwright's work-ſhop would render the whole complete.

The great features of ſuch a plan would, it is ſuppoſed, be of utility; it would, however, be ſuſceptible of no inconſiderable ornament. The lines of the incloſures might be decorated in any imaginable way, provided the contents of the field applicable to uſeful graſs or corn were traced by right lines. Every tract of land, of a conſiderable extent, has ſome broken ground, ſteep ſlopes, water-courſes in glens, or pieces where the plough cannot move with convenience, and where graſs is not an equal object with more level ſpaces; theſe, by a judicious diſpoſition of the ground, might be connected with the margins of the fields, and, by walks being traced through them, might be made highly ornamental and pleaſing. It is ſuggeſted that one of Brown's winding walks, with its uſual accompaniment of ſhrubs and velvet lawn, ſurrounding thirty, forty, or more acres of graſs, is never ſeen, but it brings to the mind the variety ſuch a ſpace is capable of, by being thrown into experiments that yield a food for the mind as well as the eye. Some delicious ſpots, it is true, unite ſo happily in all their parts, melting by an eaſy gradation into ſo rich a harmony of diſtribution, that any change would offend as much as diſſonance in a piece of pleaſing muſic. But ſuch ſpots are rare: in general, the variety of neat and elegant experiments would not injure the effect at all. The Leaſſowes was, it is ſtated, in all its parts, a farm, and much more agreeable to the eye, than if the whole had been lawn. But in the preſent ſyſtem of decorating ground, variety of effect is wanting; ſomething to bring variations to the ſcene, in which the owner ſhall be intereſted. The lawn that was ſmooth yeſterday is ſmooth to day, and the revolution of the ſeaſons that bids the roſe breathe its perfume in June, and wither in November, brings to the eye a ſucceſſion of the ſame images which pleaſe this year, as they pleaſed the laſt, without novelty in the cauſe, or increaſe of pleaſure in the effect. The higheſt decoration of landſcape will not give it the power of variety; it will be the ſame this Auguſt as it was the laſt; it will be gay in ſummer; and dreary in December; its forcible effect is for others not yourſelf; for at every repetition of viewing the colours fade, and what once excited rapture, now brings no other emotion than cold approbation. The beauty of a mere garden-ſcene is like that of a fine face; it moves admiration at firſt, and we feel ourſelves under the enchantment of a ſpell that chains all our ſenſes; but let the enchantreſs ſpeak, and prove herſelf a pretty

pretty fool, the inanity of her converfation breaks the fpell, and fhe is from that moment lefs than a pretty picture, fince no one claims a merit in making her. The beauty of a garden-fcene is much of the fame kind; it holds little converfation with you; it fuggefts no new ideas; it furnifhes no food to an inquifitive mind. If a perfon be told that he may contemplate the works and wifdom of God; and hold converfe with the vegetable and animal creation, he replies, not becaufe he is in a garden, for a nettle is as wonderful a production of divine power as a lily, and the ftructure of a toad an object to philofophize on, as much as a nightingale. Hence the contemplative pleafures of a decorated fcene are not appropriated; they arife from the parts and not the combination; and therefore, in this refpect, might as well not be combined at all. But when the ornamented walks lead you to fomething that offers novel information with evey feafon, when you are in the purfuit of unknown facts, to afcertain which is to promote not your own folitary pleafures and contemplations only, but a fcience intimately connected with the profperity of a nation; when every inclofure is pregnant with inftruction, the field of a purfuit, and confequently of a pleafure; in fuch a cafe, it is not a queftion of an arrangement of a lawn, and water, and fhade, that fhall pleafe the eye for a time; it is not the bloom of a flower, or the bend of a walk, but a fubject where the renovation of the year brings perennial employment for the mind: your landfcape becomes the fource of thought; the eye may be pleafed, but the underftanding is fatisfied; and inftead of modes of duration that have been repeated to fatiety, a novel fcene is created, at once the theatre of private pleafure and public inftruction; where ufeful knowledge is fought, not in vain theories, and indolent fpeculation, but in the vigour and activity of experimental exertion. Compared with fuch an application of a tract of land, what are parks and gardens, fhrubberies and decorated grounds, but fo many baubles to pleafe children; frivolous efforts to fill the eye, but leave the mind vacant. The prince that raifes palaces, and embellifhes the gardens that furround them, may be commended for his tafte, and praifed for his magnificence. Verfailles was called a creation; but had Lewis XVI. eftablifhed fuch a farm as has been defcribed; had the experiments been regiftered and publifhed for the benefit of France; how little would the reputation of that creation now be found, compared with the genuine and never dying fame that would have fprung from a different application of the fame ground. The prince that rears a palace, does what princes have done before him; but he who founds an eftablifhment for the inftruction of his people in the moft neceffary of all arts, does that which none have done before him, and deferves a title more truly valuable than that of *Great*, fo often ill applied to the deftroyers, not the protectors, of humanity; he will enjoy the title of the " Friend of Mankind."

A late writer on modern hufbandry, however, feems to think more favourably of this method of bettering the ftate of agriculture than the author mentioned above, as he confiders it as a mean by which a general fpirit for fuch improvements may be the moft effectually introduced. It is a meafure, he fuppofes, which there is every reafon to believe would be attended with good confequences, in regard to the determining with exactnefs the proper quantities of the different forts of manures that ought to be applied to the different kinds of foils; the forts beft adapted to each; and the effects they produce when applied fingly or in their compound ftate. But the utility of public experimental farms in every county, if put under the direction and management of perfons of extenfive knowledge and experience, fhould not, it is contended, be eftimated by a reference to any particular branch: hufbandry, in all its departments, would be greatly improved in this way; and fhould the period ever arrive when the obftacles that ftand in its way fhall be removed, and proper means be had recourfe to, for diffufing a general knowledge of the beft methods of conducting the various operations connected with that fcience, that which has been fuggefted muft not be overlooked. It is fuppofed that fuch forts of farms would become fo many feminaries, at which youth might be inftructed in the nature, principles, and practice of agriculture, and to which the common farmer might occafionally refort for information, in refpect to the fuccefs of experiments made as it were under his own eye, and on foils, in fituations fimilar to thofe of his own.

And the author of " Rural Economy of the Midland Counties," in fpeaking of the advantages of thefe forts of farms, afks, " what man, whether of the fuperior clafs of yeomanry or tenants, or of a fuperior clafs of tradefmen or others, who are now bringing up their fons to hufbandry, would not, after his fon had gone through a courfe of private tuition, and received the rudiments of inftruction from himfelf or fome profeffional friend, wifh to perfect his education in a public feminary; where he would have not only an opportunity of feeing practice in its higheft ftate of improvement, and of converfing with profeffional men of the moft enlightened underftandings; but where he would be duly initiated in the theory of rural knowledge, in the method of making, regiftering, and obferving the refult of experiments; of afcertaining the inherent qualities, and improving the various breeds of live ftock; where he would fee order and fubordination, and learn the proper treatment of fervants; and among a variety of other branches of ufeful knowledge, the form and method of keeping farm-accounts, and of afcertaining with accuracy the profit or lofs upon the whole, and every part of his bufinefs; confequently of bringing it, as nearly as in its nature it is capable of being brought, to a degree of certainty."

But whatever may be the opinion of fome concerning the utility of public eftablifhments of this nature, we are inclined to believe that they will be found more beneficial when under the direction and management of private individuals who are fufficiently qualified for fuch undertakings, for though they may be far lefs extenfive, they will be much more ufefully conducted from their being lefs fubject to thofe improper checks and controuls, which are continually taking place when a number of perfons are concerned.

EXPERIMENTAL *philofophy*. Pythagoras is faid to have been the firft perfon who called himfelf philofopher, *viz.* a lover of knowledge or wifdom, from the Greek words φιλος, *a friend*, or *lover*, and σοφιας, *knowledge* or *wifdom*; from which appellation the word philofophy was derived, meaning the love of general knowledge; and according as this knowledge relates to the manners, the duties, and the conduct of human beings, confidered in a rational and focial light, or to the phenomena of natural bodies, fo it has been called either *moral philofophy* (from the Latin *mos* or *mores* its plural, which means *behaviour* or *manners*) or *natural philofophy*.

The philofophers of the primitive ages, among the Greeks, Romans, &c. in explanation of the phenomena of nature, fuch as the motions of the celeftial bodies, the rain, fnow, froft, thunder and lightning, the rainbow, the combuftion of fuel, the production of animals and vegetables, and fo forth, generally offered the inadequate fuggeftions of their imaginations, which, though moftly unintelligible, and frequently abfurd in the greateft degree, were neverthelefs received with deference by their fcholars, and were propagated

with

with fidelity or diligence from one generation to another. Their acquiefcence refted merely on the authority of the teacher. That thefe explanations were generally inadequate and abfurd, is eafily evinced by obferving that different contemporary philofophers entertained and taught opinions diametrically oppofite to each other, though they related to the very fame queftion; and that fubfequent philofophers have by actual obfervations, and unerring demonftrations, fhewn their fallacy. It may amufe an inquifitive mind to obferve, that whilft the exertions of the early mathematicians, whofe productions have obtained the admiration of fubfequent generations, were ftrictly rational and correct, the inveftigations of their contemporary philofophers were conducted in a manner altogether flovenly and fuperficial. This method of philofophifing prevailed for a very long period, and in confequence of it feveral centuries elapfed, during which the knowledge of nature made no progrefs deferving of notice, excepting a few rare and accidental difcoveries.

The 15th century, which was productive of the greateft events and the moft confequential difcoveries that hiftory can record, feems to have given a new turn to the fubject of natural philofophy. The old tenets began to be doubted, and the energies of the human mind began to manifeft their unfettered powers. In the next century, the incoherent dogmas of the preceding ages were freely combated; the authority of names and fects was difregarded, and in lieu of opinions, the explanation of natural phenomena was referred to the evidence of actual experiments; and this introduced the appellation of *experimental philofophy*, meaning the knowledge of natural powers and natural effects, acquired by means of experiments or trials. The leaft reflection readily fhewed the fuperiority of this new method of philofophifing; but, independent of any other confideration, its eftablifhment is principally due to the fuccefs with which it was attended, and which exceeded even the moft fanguine expectations of its firft promoters; for it was no fooner adopted, than difcoveries of importance were made, old-eftablifhed errors were detected, and the fubject of philofophy affumed an entirely new afpect.

It is undoubtedly true, that in this mode of inveftigation the experiments muft be preceded by hypothefis, or fuppofition; for a man cannot begin to make experiments without the previous formation of a certain plan; but then the plan, the fuppofition, or the hypothefis goes no farther than to propofe fomething, the confirmation or refutation of which is referred to the refult of experiments, affifted by mathematical calculation.

In the 13th century, the neceffary preliminaries for the improvement of natural knowledge began to be made; *viz.* collections of what then prevailed under the denomination of fcientific knowledge, natural knowledge, fecrets of nature, and the like; and the farrago of truths, errors, inconfiftencies, doubts, and perplexities, which thefe works contain, is ftrange indeed. Among the few who effectually began to work in the experimental mode of inveftigation, during that century, friar Bacon held the moft diftinguifhed place. His defire of information was great; his views extenfive; his mind clear and capacious; and he is faid to have fpent about 2000*l.* (a fum very confiderable at that time) in the performance of his numerous philofophical experiments. Baptifta Porta alfo diftinguifhed himfelf for fimilar purfuits in Italy. This inquifitive perfon lived at Naples, and about the year 1560 formed a fociety of fcientific perfons, who met in his own houfe. The great Galileo, who was born in Italy in the year 1564, became famous as a philofopher and a mathematician towards the latter end of that century and the beginning of the next. His genius, fuperior to the prejudices of the times, inveftigated and eftablifhed feveral leading propofitions in natural philofophy; and his fuccefs, his example, and his precepts diffeminated an univerfal ardour for the true mode of inveftigating the powers and the effects of natural bodies. His fucceffor, Torricelli, was not unworthy of a moft diftinguifhed rank amongft the philofophers of the age; and the Torricellian tube, or the barometer, is a magnificent monument of his experimental inquiries.

In England, as we have already mentioned, friar Bacon was the firft promoter of true knowledge; but a great part of the work of philofophical reformation was accomplifhed by another inquifitive genius of the fame name. Francis Bacon, lord chancellor of England, gave a frefh and vigorous impulfe to the progrefs of experimental enquiry. He recorded a vaft number of facts, propofed and executed a great many experiments, and nothing that related to nature feemed to be below his notice.

Thefe early reformers of philofophy, befides other obvious difficulties, were obliged to ftruggle againft, and the fuccefs of their labours was much impeded by, the wrong notions which then prevailed, and which had been long rooted in the minds even of the moft able perfons then living. Galileo was nearly oppreffed by the ignorance and prejudices of the clergy. Crichton, who flourifhed about the latter end of the 16th century, wrote an able book exprefsly againft the vain philofophy of Ariftotle, which had long been read in the fchools. The two Bacons, and other able writers, frequently allude to, and ftrenuoufly endeavour to remove, the wrong notions of their contemporaries, and, in fhort, the demolition of the old defective fabric, proved nearly as laborious as the erection of the new ftructure.

The reform which had been begun by the above-mentioned and other worthy perfons was foon after completed by the extraordinary genius of Newton. This truly great man, like a luminary of the firft magnitude, illuftrated whatever came within the limits of his notice, and his notice was employed in the greateft and moft admired works of the creation. His method was to inftitute experiments, to examine the phenomena with accuracy, and to ground upon them the ftricteft mathematical reafoning. The conviction which fuch rational method conveyed, and the numerous difcoveries with which it was attended, completely exploded the old tenets, and eftablifhed the only true method of inveftigating nature.

The progrefs of experimental philofophy might have been interrupted by the death of a fingle individual; for it does but feldom occur that genius, health, opulence, and other opportunities concur in the qualification of an experimental philofopher; but the danger was in great meafure averted by the inftitution of philofophical focieties, which, by uniting the efforts of feveral ingenious labourers, by furnifhing in great meafure the means of inveftigation, by encouraging improvements, and by recording and propagating the refults, have eftablifhed the progrefs of knowledge in a regular and permanent channel.

The firft fociety of the kind which we find recorded, is that which we have already mentioned at the houfe of Baptifta Porta in Naples, towards the latter end of the 16th century. It was called "Academia Secretorum Naturæ." Next to this, and before the end of the fame century, the Academy, called of the Lyncei, was founded at Rome, and was rendered famous throughout the world principally by the renown of one of its members, the great Galileo. The Academy del Cimento, and feveral other affociations of fcientific perfons, were eftablifhed in the fucceeding, *viz.* the

the 17th century. And amongft thofe affociations the firft rank muft be affigned to the Royal Society of London. This moft learned and diftinguifhed fociety had its origin foon after the middle of the 17th century. A few men of learning began to meet at ftated times in Wadham college, Oxford; and among thofe perfons there were the following confpicuous characters; *viz.* Dr. Ward, Robert Boyle, Dr. Wilkins, fir William Petty, Mr. Matthew Wren, Dr. Wallis, Dr. Goddard, Dr. Willis, Dr. Bathurft, Dr. Chriftopher Wren, and Mr. Rooke. From Oxford this affociation transferred its meetings to Grefham college in London, which took place in the year 1658. There they increafed their number, and foon after the reftoration of Charles II. that fociety received a royal charter, which eftablifhed it into the form that has been continued ever fince; but we muft refer the reader to other articles of this Cyclopædia for the particular account of the Royal Society of London, as well as of other fcientific affociations in this and other countries; and at the fame time we muft proceed to explain the new mode of philofophifing in a manner fomewhat more particular.

The objects of the univerfe, or the natural bodies, which affect our fenfes, become known and ufeful to us by their properties, fome of which affect one of our fenfes, whilft others affect fome other fenfe. Thus we perceive luminous bodies through our eyes, found through our ears, heat or cold by the touch or feel, &c. Some of thefe properties are called general, like gravity and extenfion, becaufe they belong to all bodies; and others, like tranfparency and fluidity, are called particular, becaufe they belong to certain bodies only. The better we become acquainted with the properties of natural bodies, the more extended the fphere of our powers and of our advantages becomes; and it is for the difcovery of thefe properties, either in fimple or in compound bodies, that experimental inquiries are inftituted.

In the acquirement of knowledge, the human being has no other affiftance befides that of his fenfes, and of his reafoning faculty. By the firft he obferves and acquires ideas of felf evident propofitions, or properties of natural bodies; fuch as the human mind cannot diffent from without manifeft violence; by the fecond he is led from one of thefe evident fimple propofitions, to another ftrictly depending upon the firft, then to a third ftrictly depending upon the fecond, and fo on, to the acquifition of fome idea more complex, and lefs apparent at the firft annunciation.

The conftant obfervations of philofophers, with fir Ifaac Newton at their head, and the dictates of plain reafoning, have furnifhed certain axioms and certain rules of philofophizing, the propriety of which is too evident to be objected to.

The axioms of philofophy, or the axioms which have been deduced from common and conftant experience, are fo evident, and fo generally known, that it will be fufficient to mention a few of them only.

1. Nothing has no property; hence

2. No fubftance, or nothing can be produced from nothing.

3. Matter cannot be annihilated, or reduced to nothing.

The propriety of the laft axiom may perhaps be not readily admitted by certain perfons; obferving that a great many things appear to be utterly deftroyed by the action of fire; alfo that water may be caufed to difappear by means of evaporation, and fo forth. But it muft be obferved, that in thefe cafes the fubftances are not annihilated; they are only difperfed, or removed from one place to another, and by being divided into particles very minute, they elude our fenfes, and efcape our immediate notice. Thus, when a piece of wood is placed upon the fire, the greateft part of it difappears, and a few afhes only remain, the weight and bulk of which do not amount to the hundredth part of the weight and bulk of the original piece of wood. In this cafe the piece of wood is divided into its conftituent principles, which the action of the fire drives different ways. The fluid part, for inftance, becomes fteam, the light coaly part either adheres to the chimney, or is difperfed through the air, &c. fo that if, after the combuftion, the fcattered materials were collected, (which may in great meafure be accomplifhed,) the fum of their weights would equal the weight of the original piece of wood.

4. Every effect has, or is produced by, an adequate caufe, and is proportionate to it.

It may in general be obferved, with refpect to thefe axioms, that we only mean to affert what has been conftantly fhewn, and confirmed by experience, and is not contradicted either by reafoning or by any known experiment. But we do not mean to affert that they are as evident as the axioms of geometry; nor do we in the leaft prefume to prefcribe limits to the agency of the Almighty Creator of every thing, whofe power and whofe ends are too far removed from the reach of our underftandings.

Having thus ftated the principal axioms of philofophy, it is in the next place neceffary to mention the rules of philofophizing, which have been formed, after mature confideration, for the purpofe of preventing errors as much as poffible, and of leading the ftudent of nature along the fhorteft and fafeft path to the attainment of true and ufeful knowledge. Thefe rules are not more than four; *viz.*

1. We are to admit no more caufes of natural things, than fuch as are both true and fufficient to explain the appearances.

2. Therefore to the fame natural effects we muft, as far as poffible, affign the fame caufes.

3. Such qualities of bodies as are not capable of increafe or of decreafe, and which are found to belong to all bodies within the reach of our experience, are to be efteemed the univerfal qualities of all bodies whatfoever.

4. In experimental philofophy we are to look upon propofitions collected by general induction from phenomena, as accurately or very nearly true, notwithftanding any contrary hypothefes that may be imagined, till fuch time as other phenomena occur, by which they may either be corrected, or may be fhewn to be liable to exceptions.

With refpect to the degree of evidence which ought to be expected in natural philofophy, it is but proper to remark that phyfical matters are not in general capable of fuch abfolute certainty as the branches of mathematics. The propofitions of the latter fcience are clearly deduced from a fet of axioms fo very fimple and evident, as to convey perfect conviction to the mind; nor can any of them be denied without a manifeft abfurdity. But in natural philofophy we can only fay, that becaufe certain particular effects have been conftantly produced under certain circumftances, therefore they will moft probably continue to be produced as long as the fame circumftances exift; and likewife that they do, in all probability, depend upon thofe circumftances. And this is what we mean by *laws of Nature; viz.* certain effects which are or have been uniformly produced by certain caufes, as far as our obfervations reach.

We may, indeed, affume various phyfical principles, and by reafoning upon them, we may ftrictly demonftrate the deduction of certain confequences. But as the demonftration goes no farther than to prove that fuch confequences muft neceffarily follow the principles which have been affumed;

the

the confequences themfelves can have no greater degree of certainty than the principles are poffeffed of; fo that they are true, or falfe, or probable, according as the principles upon which they depend are true, or falfe, or probable.

The foundations of experimental philofophy, as we have already obferved, are the properties of natural bodies, *viz.* of all thofe bodies, either folid or fluid, which in any way affect any of our fenfes: and fince our fenfes are affected by the properties of thefe bodies, *viz.* by their extenfion, colour, hardnefs, tranfparency, &c. we cannot know any more of thefe bodies than what is manifefted to us by fuch properties only as we are able to perceive. Were we furnifhed with other fenfes, we might difcover other properties which would make us more intimately acquainted with the nature of fuch bodies.

Human art has not been able to difcover more fenfes than thofe which every body knows; but it has, in great meafure, improved fome of thofe which we poffefs, and this alone is fufficient to point out the limited nature of our perceptions. Thus, for inftance, the difcovery of the microfcope, and the telefcope, have fhewn us wonders of which our forefathers were utterly ignorant; and the number and variety of thefe wonders have increafed in proportion as the above-mentioned inftruments have been improved. The improvements of thefe inftruments have been fuggefted by the difcoveries that have been made refpecting the refrangibility of light, and the properties of tranfparent bodies, and thefe have been made in confequence of the innumerable experiments that have been inftituted by various intelligent perfons. Thus it appears, that by means of trials and obfervations new facts are afcertained, which, befides their being immediately ufeful to the human fpecies, furnifh, at the fame time, the means of making farther difcoveries; and the treafures of the natural world are far, indeed, from a ftate of exhauftion. Hence the improvements and the difcoveries of experimental philofophy proceed in a kind of increafing geometrical progreffion; unlefs they be impeded by fome extraordinary occurrence.

In contemplating the intimate nature of natural bodies, when our mind goes beyond the bounds of our fenfes, (and our fenfes, even with the affiftance of inftruments and reafoning, are only capable of perceiving a few properties of thofe bodies;) we wander in the boundlefs field of probability and conjecture. Two principal hypothefes have been entertained with refpect to the primitive component particles of bodies. One is, that the particles of each peculiar fpecies of bodies are different from the particles of another fpecies of bodies. Thus the primitive particles of gold are fuppofed to be different from the particles of calcareous earth, different from the particles of water, &c. The other hypothefis is, that there is one kind of primitive or original particles of matter, and that from the different arrangement of thofe ultimate particles, the various bodies arife. Experience fhews that certain bodies, which, at firft fight, appear to be abfolutely different from each other, are, upon further examination, exactly of the fame nature. On the other hand, a vaft number of bodies are fo diftinct from each other, that no art has been able to form one of them from the particles of another; thus gold cannot be converted into a diamond, iron cannot be converted into lead, &c. The former of thefe obfervations feems to favour the fecond hypothefis; the latter feems to favour the firft hypothefis; but it is not in our power to determine the real ftate of the matter.

With refpect to the number of bodies, which, by our not being able to change one of them into the other, are called elementary, or primitive and diftinct, the reader will find fufficient information under the article Element; but it may be remarked in this place, that new bodies are frequently difcovered in proportion as new inftruments, and the improvements of fcience in general, furnifh us with the means of difcriminating them from others; hence we are naturally led to conclude, that moft probably there may exift a vaft number of other bodies, of which we at prefent have not the leaft fufpicion. Some of thefe may perhaps be difcovered hereafter, whilft others may remain utterly unknown to the human fpecies.

The properties of natural bodies, which are the objects of refearch to the experimental philofopher, are either general, or particular. The general properties, which belong to all kinds of bodies, are, as far as we know, not more than fix; *viz.* extenfion, divifibility, impenetrability, mobility, vis inertiæ, or paffivenefs, and gravitation. We have faid that thefe are the general properties as far as we know, becaufe matter in general may poffefs other properties that are not yet come to our notice. And the fame obfervation may be made with refpect to the univerfality of thefe properties: for they are faid to be general, becaufe no body was ever found which wanted any one of them. But mankind are not acquainted with all the bodies of the univerfe, and even feveral of thofe which are known to exift, cannot be fubjected to experiments.

The peculiar properties, *viz.* thofe which belong to certain bodies only, and not to others, are denfity, rarity, hardnefs, foftnefs, fluidity, rigidity, flexibility, elafticity, opacity, tranfparency, the properties of light, the properties of heat, the properties of electricity, the properties of magnetifm, and three other kinds of attraction, (independent of gravitation, of electricity, and of magnetifm,) *viz.* the attraction of aggregation, which the homogeneous parts of matter have towards each other, or by which they adhere together; and fuch is the power by which two fmall drops of mercury, when placed contiguous to each other, rufh, as it were, into each other, and form a fingle drop; the attraction of cohefion, or that power by which the heterogeneous particles of bodies adhere to each other without any change of their natural properties, fuch as the adhefion of water to glafs, of oil to iron, &c.; and the attraction of compofition, or of affinity, which is the tendency that the parts of heterogeneous bodies have towards each other, by which they combine, and form a body, differing more or lefs from any of its components.

It is to be remarked, that of all thefe properties we know their exiftence only, and fome of the laws under which they act; but we are otherwife utterly ignorant of their nature and dependence.

The inveftigation of fome of the above-mentioned properties, whether general or particular, has been carried much farther than the inveftigation of other properties. The refults of thefe inveftigations have likewife been various, both in point of extent and of application. Some of them are fo very extenfive and fo ufeful, as to form the foundations of very important branches of fcience or of art, under peculiar appellations. Thus, upon the mobility and the vis inertiæ of bodies, the doctrine of motion, or dynamics, is grounded, which comprehends mechanics, hydroftatics, or the mechanical properties of fluids, pneumatics, &c. Tranfparency and the properties of light form the important foundation of optics. The attraction of affinity is the foundation of chemiftry, as well as of various arts, and fo forth. Whatever belongs to thefe properties, or to the extenfive fubjects that are grounded upon the fame, will be found under the various articles of their peculiar denominations.

The

The phenomena of the univerſe, are the appearances which take place in conſequence of the above-mentioned properties of natural bodies, together (reſpecting ſome of them at leaſt) with ſome original impulſe. The phenomena which take place amongſt the luminous celeſtial bodies, properly ſo called, ſuch as the ſtars, the planets, &c. are examined by a particular ſcience called aſtronomy; the meteors, or the phenomena, which take place within the limits of the terreſtrial atmoſphere, ſuch as ſhooting ſtars, northern lights, halos, rain, fogs, hail, winds, &c. form the ſubject of meteorology. The phenomena that take place upon the ſurface of, or within, the earth, are treated of under the comprehenſive denominations of *vegetation, earthquakes, volcanoes, combuſtion*, &c. all which will be found explained under their appropriate articles.

EXPERIMENTUM Crucis, denotes a capital, leading, or deciſive experiment; thus called, either, becauſe like a croſs or direction poſt, placed in the meeting of ſeveral roads, it guides and directs men to the true knowledge of the nature of the thing they are enquiring after; or as it is a kind of torture, whereby the nature of the thing is, as it were, extorted by violence.

EXPIATION, the act of ſuffering the puniſhments adjudged to a man's crimes, and thus paying off, or diſcharging the debt or guilt; and it is figuratively applied to the pardon procured for the ſins of the penitent by the interpoſition and death of Chriſt.

The Romaniſts hold, that ſouls after death are ſent to purgatory to expiate or atone for their ſins. See Purgatory.

Expiation is alſo applied to ſacrifices offered to the Deity, to implore his mercy and forgiveneſs.

Expiation, *the Feaſt of*, among the Jews, called by our tranſlators the *day of atonement*, was held on the tenth day of Tiſri, or the ſeventh month of the Jewiſh year, anſwering to part of our September and October. It was inſtituted by God himſelf, Levit. xxiii. 27, &c. On that day the high-prieſt, the figure or type of Jeſus Chriſt, entered into the moſt holy place, and confeſſed his ſins; and, after ſeveral ceremonies, made an atonement for all the people to waſh them from their ſins. Lev. chap. xvi. See Scape-*Goat*.

Expiation, among the *Heathens*, denoted a purification uſed for effacing or aboliſhing a crime, averting any calamity; and on a thouſand other occaſions, as purifying towns, temples, and ſacred places, and armies, before and after battle.

It was practiſed with divers ceremonies; the moſt uſual was ablution.

Expiations were performed for whole cities as well as particular perſons. After the young Horatius had been abſolved by the people for the murder of his ſiſter, he was farther purified by ſeveral expiations preſcribed by the laws of the pontiſices for involuntary murders. Dion. Halicarnaſſ.

EXPILATION, from *expilo, I rob*, in the *Civil Law*, the act of withdrawing or diverting ſomething belonging to an inheritance, before any body had declared himſelf heir thereof.

This made a peculiar ſpecies of theft; for there could not properly be a theft in taking a thing not poſſeſſed by any body, or before the inheritance was accepted.

For this reaſon the Roman legiſlature introduced the action of expilation for the puniſhment of this crime.

Beſide this meaning, it was uſed in a more ſpecial manner to ſignify a robbery committed by night; whence an expilator was looked upon as a greater criminal than a common thief.

The expilators were ſo called from their robbing and ſtripping people of their cloaths.

EXPIRATION, in *Phyſiology*, is the act of expelling air from the lungs, produced by a diminution of the cavity of the cheſt. It is oppoſed to inſpiration, in which air is drawn into the cheſt. See Respiration.

Expiration is alſo uſed figuratively, for the end of a term of time granted, or agreed on, or adjudged.

EXPLEES, in *Law*, the rents or profits of an eſtate, &c. See Esplees.

EXPLICATION *of the Subject of a Diſcourſe*, in *Pulpit Oratory*, and in the compoſition of ſermons, comes in the place of narration at the bar, and ſhould be conducted in a ſimilar manner. It ſhould be conciſe, clear, and diſtinct, and in a ſtyle correct and elegant, rather than highly adorned. To explain the doctrine of the text with propriety, to give a full and perſpicuous account of the nature of that virtue or duty which forms the ſubject of the diſcourſe, is properly the didactic part of preaching; on the right execution of which much depends for all that comes afterward in the way of perſuaſion. The great art in ſucceeding in it is, to meditate profoundly on the ſubject, ſo as to place it in a clear and ſtrong point of view. Conſider what light other paſſages of ſcripture throw upon it; conſider whether it be a ſubject nearly related to ſome other from which it is proper to diſtinguiſh it, conſider whether it can be illuſtrated to advantage by comparing it with, or oppoſing it to, ſome other thing; by enquiring into cauſes, or tracing effects; by pointing out examples, or appealing to the feelings of the hearers; that thus a definite, preciſe, circumſtantial view may be afforded of the doctrine to be inculcated. Let the preacher be perſuaded, that by ſuch diſtinct and apt illuſtrations of the known truths of religion, it may both diſplay great merit in the way of compoſition, and, what he ought to conſider as far more valuable, render his diſcourſes weighty, inſtructive, and uſeful. Blair's Lectures, vol. ii. p. 297.

EXPLICATIVE Proposition, in *Logic*. See Complex *Propoſition*.

EXPLICITE, in the *Schools*, ſomething clear, diſtinct, formal, and unfolded.

The will or intention is ſaid to be explicite when it is fully explained in proper terms; and implicite, when it is only to be learnt by deductions and conſequences.

The Jews had not all an explicite knowledge of Jeſus Chriſt, but they had at leaſt an implicite one.

Such a teſtator has declared his will explicitely, *i e.* in formal terms; there is no need to have recourſe to explications.

EXPLOITS, Bay *of*, in *Geography*, a bay of the Atlantic, on the eaſt coaſt of Newfoundland. N. lat. 49° 45′. W. long. 55° 20′.

EXPLOSION. It is a matter of great moment, in military engineering, ſo to load, and indeed to conſtruct, a mine, that it may explode with the greateſt preciſion, and with the maximum effect. A variety of theories has been given upon this ſubject, but it would be out of place to notice the whole of what appertains thereto in this place; therefore we ſhall refer our readers to the word Mine for the particular detail of what relates to this ſubject, contenting ourſelves with now offering a few remarks on the manner in which the exploſion is uſually effected.

It is of the firſt importance to aſcertain, ſo nearly as may be practicable, what depth, and what weight of ſoil is to be removed by an exploſion. This being done, the mine is formed,

formed, by a gallery leading to the chamber in which the powder is to be depofited in a very ftrong cheft, let into a recefs, and firmly fecured in every part. Now, it being the nature of the rarefied air to efcape by that part which may be the weakeft, it is evident, that if a mine is made under a rampart, fo as to be within fix feet of the furface, while all the fides are thicker by far than that meafurement, the explofion will be directed towards that part which is thinneft, and which from that circumftance is called " the line of leaft refiftance."

But, in order to direct the explofion to that part, it will be neceffary to confider whether the foil be every where alike; for if the fuperincumbent portion fhould be part of a large ftratified rock, while the fides are of a loofe, inadhefive fubftance, the latter, though meafuring more in diameter, will give the line of leaft refiftance, which, in fuch cafe, would follow the intenacity, and create a falfe explofion. Hence explofions may be lateral as well as vertical.

It was formerly fuppofed, that the diameter of the entonnoir, or explofion, was equal to double the line of leaft refiftance; but we find that *fix times* that line may be exploded, by allowing a load of 300lbs. of gun-powder, duly concentrated, and fired in the middle of the mafs, for every foot of the line of leaft refiftance. We are not to infer from this, that 300lbs. will be requifite to lift one foot of foil; far from it; for as a cubic foot of excavation will contain only 75lbs. of powder, the above quantity (300lbs.) would require a fpace of exactly four cubic feet; the proportion would therefore be prepofterous. But when we calculate upon large maffes of foil, fuch as thofe prodigious cones thrown out from entonnoirs of great extent, we then find, that, to produce the completeft explofion, an immenfe quantity of powder muft be fupplied.

It is felf evident, that the power of the powder, according to the above fcale, is only computed to that extent which may be neceffary towards the ordinary purpofes of military devaftation; for if we were to contribute, *ad infinitum*, 300lbs. of gunpowder for every foot in the line of leaft refiftance, we fhould be accumulating power only in arithmetical proportion, while the refiftance would be increafing in a geometric ratio: of courfe the power muft be in a regular ftate of comparative diminution, in proportion as the line of leaft refiftance is increafed; and this muft, after a while, occafion the powder to be inert; or, if there fhould be any explofion, it could only follow the track of the train; its ignition to be fure might be felt partially, like that of a flight earthquake, but no fuperficial effects would be obfervable.

It has been already ftated, that the powder muft be lodged in bulk; and that it fhould be ignited at the centre. This may, perhaps, appear fuperfluous; but all military men know, that much powder is blown out of the muzzles of pieces without ever being ignited; and we have a moft remarkable fact, a very recent one indeed, which fhews that, unlefs in bulk, powder is not always fure to be fired *in toto*. The incident alluded to is as follows.

In the month of March of this year, (1809,) a barge was proceeding along the new cut, from Paddington, laden with cafks of fpirits and barrels of gunpowder. One of the crew, it is fuppofed, allured by the former, bored a hole for the purpofe of drawing off a little wherewith to tipple. Unhappily the action of the gimblet fet fire to the contents of that barrel, which the difhoneft navigator had miftaken for one of fpirits. The barrel exploded, and drove eleven other barrels, filled with gunpowder alfo, to the diftance of near a hundred and fifty yards. It is curious, that although the whole of the powder-barrels were together, indeed in contact, only that in queftion exploded.

Vauban gives us the following fcale for exploding foils of various defcriptions. He calculates, or perhaps found from experience, that for a cubic fathom (fix feet) of foil, meafuring in all 216 folid feet, the following proportions of gunpowder were needful.

1. Light earth, mixed with fand,	11lb.
2. Common earth	12
3. Strong fand	15
4. Clay, or fat earth,	16
5. Old, and good mafonry	18
6. Rock	20

In following this calculation, we are to confider the entonnoir to be in diameter equal to only double the line of leaft refiftance; and not according to a maximum explofion.

Explosion, from the Latin *explodo*, is the act of driving out fomething with noife and violence. The caufes, the report or noife, and the other effects of explofions, however infignificant they may appear at firft fight, are neverthelefs, when duly confidered, of great confequence to the human fpecies, and as fuch they have been carefully inquired into by divers philofophers. A variety of experiments have been inftituted for determining the particulars that relate to them, and numerous conjectures have been offered in explanation of thefe concomitant circumftances, which have not as yet been thoroughly inveftigated.

Explofions may be diftinguifhed into natural and artificial. The principal natural explofions are thofe of the atmofpherical thunder, of volcanoes, of earthquakes, and to thefe there may be added the inferior explofions arifing from hard frofts. The artificial explofions are fuch as are produced by the force of fired gunpowder in the various engines in which it is ufed, the explofions produced by other chemical compounds, and the pneumatic explofions; meaning thofe which are produced by the air rufhing into a partial vacuum, by the difcharge of air-guns and the like.

Of all thefe kinds of explofions we fhall now briefly treat, not in the order in which they have been enumerated, as this would prove a ufelefs formality; but in a manner which may be more likely to elucidate the moft interefting part of the fubject; and this undoubtedly is the ftupendous force with which effects, in great variety, are produced in certain explofions.

The firft thing that ftrikes the obferver is the fudden and violent noife of an explofion. It is hardly neceffary to obferve that this noife or report is owing to the intermediation of the air between our ears and the caufe, whatever that may be, of the percuffion which is given to the air. Without that intermediation, or without air, the report could not be heard. But it muft be farther obferved, that the mere introduction of fomething into the ambient air is not the principal caufe of the report. That effect principally depends upon the fudden replacing or collapfing of the air, after its having been removed or rarefied in any particular place. So that in order to account for the immediate caufe of the noife in an explofion, we muft look out for fomething which after having been introduced into the atmofphere, whether flowly or quickly, is afterwards *fuddenly* withdrawn or contracted. A few examples will eafily illuftrate this obfervation.

Take a common fyringe, ftop the aperture of it, then draw the pifton entirely out of its other extremity, and at that moment a report is heard, which is occafioned by the replacing of the air within the fyringe; for in drawing the pifton out of it, the air within the cavity of the fyringe is rarefied,

rarefied, *viz.* a partial vacuum is formed, but as soon as the piston is quite out, the air of the atmosphere suddenly rushes in to supply that deficiency, and produces the noise or the report.

There is an experiment commonly shewn with the air-pump, and a glass vessel open at both ends. To one of the apertures of the glass vessel a wet piece of bladder is tied, and is suffered to become dry. The other aperture of the glass vessel is then placed upon the plate of the air-pump. This done, the air is extracted by working the pump, by which means the glass vessel covered over with the bladder is partially exhausted, and of course the pressure of the atmosphere is in great measure removed from the under surface of the piece of bladder. The atmosphere, then pressing on the upper part of the bladder, and not being counteracted from below, distends the bladder towards the cavity of the vessel, and at last breaks it with a considerable explosion. The reason of which noise is the sudden rushing in of the air.

An air-gun, when discharged, produces a trifling noise, the reason of which is, that after the expulsion of the condensed air from the inside of the instrument, which is impelled against the ambient air, there is no collapsion of the latter; for the condensed air, on coming out of its confinement, expands itself to the tension of the ambient air, and remains in that state; *viz.* without any subsequent contraction.

There are little glass balls, containing a small quantity of water, which are made and sold for diverting experiments, under the name of *glass granades*. A ball of this kind is nothing more than a diminutive glass bottle partially filled with water, and having a longish neck or tail, hermetically sealed. One of these little bottles is stuck with its tail into the tallow or wax of a burning candle, and so that the little ball may be in the flame of the candle. In this situation the heat of the flame converts part of the fluid within the ball into vapour, and when the elasticity of this vapour is sufficient to overcome the resistance of the glass the ball breaks, and produces a smart explosion. The reason of which is, that the condensed vapour, on coming out of the glass, displaces a considerable quantity of air, but being instantly cooled, it contracts, and the air collapses.

A musket loaded with gunpowder, on being fired off, produces a strong explosion. Now the difference between the discharge of such a musket and that of an air-gun is, that though in both an elastic fluid is discharged; yet in the musket the elastic fluid contracts immediately after its coming into contact with the external air: but with the air-gun, the elastic fluid which issues out of it does not contract after its expulsion; hence the report is incomparably louder with the former than with the latter.

An electric spark, especially in the discharge of a Leyden phial or battery, is accompanied with a smart report, in consequence of its suddenly displacing the air from the spot in which it explodes; and of the subsequent collapsing of the air. And that the electric spark really displaces the air, is easily shewn by means of an electrical instrument, called "Kinnersley's electrical air thermometer." In this instrument the spark is taken into a close glass vessel, which by an annexed narrow tube, partially filled with a liquor, indicates the rarefaction or displacing of the air within the vessel. With this apparatus, whenever a spark or discharge of an electric jar is taken within the close vessel, the rising and falling of the liquor within the annexed tube shews that the air is suddenly displaced, and is likewise heated in some degree; for the liquor rises suddenly to a certain degree; and as suddenly descends, not quite to its former station, but to a place a little above it, from which afterwards it descends gently to its original station.

From these facts, and from a vast many more which might here be described, it clearly appears that the sudden introduction of something into the ambient air produces little noise; but that the noise of an explosion is mostly due to the collapsing of the air, which takes place in consequence of the instantaneous contraction of that which has been introduced in it. The noise, *cæteris paribus*, is more or less loud in proportion as a greater or lesser quantity of air is displaced and replaced, and likewise in proportion to the quickness of that operation.

When more reports than one are heard; these are produced either by an equal number of explosions, or by a reverberation, *viz.* by an echo.

The air thus agitated conveys the sound of an explosion, or propagates its own vibrations, to immense distances. The firing of heavy ordnance has been sometimes heard at the distance of 50 or 60, and even more miles. The explosions of volcanoes, or those which accompany earthquakes, have often been perceived at distances much more considerable; but with respect to the extent of this kind of communication, rate of moving, &c. the reader is referred to the article Sound, *propagation of*, and Hearing. We shall, however, in this place, briefly mention an effect of this kind of violent aerial vibration; which it might be wished that such persons as are opportunely situated, would examine with particular attention. The phenomenon is, that the explosion of cannons, and especially of powder magazines, or powder mills, renders the air considerably electrified, and that it electrifies the glasses of windows.

After the noise, or the report, the next step is to inquire into the cause or causes which produce it: *viz.* into the nature of the elastic fluid which, in coming out of any confinement, displaces the circumambient air, and then suddenly gives way to it. Until very lately the immediate cause of most explosions was principally attributed to the generation or extrication of permanently elastic fluids, *viz.* gases; and this is undoubtedly true in a great many cases; but upon a closer examination of the concomitant particulars, the expulsion of these elastic fluids, even in a state of incandescence, was found inadequate to the effects that were experienced in a variety of cases; hence philosophers began to look out for some other agent more active; and though the force of steam was known to be concerned in some kinds of explosions; yet it must be acknowledged, that we are indebted to count Rumford for a masterly examination of this particular point; for which purpose he instituted a long and laborious series of well contrived experiments. His account at large under the title of "Experiments to determine the Force of fired Gunpowder," is contained in the Phil. Trans. for the year 1797, and from that account we shall extract such particulars as may seem sufficiently to illustrate this important part of the subject of explosions. We call it important, because it is the particular from which the causes of natural explosions, such as of volcanoes, earthquakes, &c. may be obviously manifested.

Count Rumford justly says, "The explosion of gunpowder is certainly one of the most surprising phenomena we are acquainted with, and I am persuaded it would much oftener have been the subject of the investigations of speculative philosophers, as well as of professional men, in this age of inquiry, were it not for the danger attending the experiments; but the force of gunpowder is so great, and its effects so sudden and so terrible, that, notwithstanding all the precautions possible, there is ever a considerable degree of danger attending the management of it."

Several able philosophers had, at different times, endeavoured to determine the force of it. "But," count Rumford

ford fays, " the great defideratum, the real meafure of the initial expanfive force of inflamed gunpowder, fo far from being known, has hitherto been rather gueffed at than determined ; and no argument can be more convincing to fhew our total ignorance upon that fubject, than the difference in the opinions of the greateft mathematicians of the age, who have undertaken its inveftigation."

The ingenious Mr. Robins thought, that the force of the elaftic fluid, which is generated in the combuftion of gunpowder, is 1000 times greater than the mean preffure of the atmofphere. Mr. D. Bernouilli reckoned it equal to 10,000 times that preffure.

Count Rumford, in one of his firft experiments, confined gunpowder in a ftrong iron tube, and fired it by heating part of the tube, or rather of an appendage that had been fixed to it. This was done with a view of confining the elaftic fluid, that was generated in the combuftion. " The refult," he fays, " of this experiment fully anfwered my expectations. The generated elaftic fluid was fo completely confined, that no part of it could make its efcape. The report of the explofion was fo very feeble, as hardly to be audible: indeed it did not by any means deferve the name of a report, and certainly could not have been heard at the diftance of twenty paces ; it refembled the noife which is occafioned by the breaking of a very fmall glafs tube."

And farther on, he fays, " It has generally been believed, after Mr. Robins, that the force of fired gunpowder confifts in the action of a permanently elaftic fluid, fimilar in many refpects to common atmofpheric air : which being generated from the powder in combuftion, in great abundance, and being, moreover, in a very compreffed ftate, and its elafticity being much augmented by the heat, (which is likewife generated in the combuftion,) it efcapes with great violence, by every avenue ; and produces that loud report, and all thofe terrible effects which attend the explofion of gunpowder.

" But though this theory is very plaufible, and feems upon a curfory view of the fubject to account in a fatisfactory manner for all the phenomena, yet a more careful examination will fhew it to be defective. There is no doubt but the permanently elaftic fluid generated in the combuftion of gunpowder, *affifts* in producing thofe effects which refult from its explofion ; but it will be found, I believe, upon afcertaining the real expanfive force of fired gunpowder, that this caufe, alone, is quite inadequate to the effects actually produced : and that, therefore, the agency of fome other power muft neceffarily be called in to its affiftance."

This author then proceeds to defcribe a variety of experiments and calculations which prove, beyond a doubt, that the above-mentioned theory is infufficient to account for the effects which are produced by the inflammation of gunpowder ; for he computes, in the ampleft manner poffible, the force of the gas which is generated even in the heat of red-hot iron, by which elevation of temperature air is known to be expanded not much above four times its ordinary bulk. He endeavoured to meafure the force in queftion by the lifting up of a very great weight, and his ingenious experiments were attended with refults fufficiently fatisfactory ; but we muft refer the reader to the above-mentioned paper itfelf for the detail of thefe interefting particulars ; and we muft here only add an abridgment of the latter part of the account, which more immediately relates to the principal object of our prefent enquiry.

" I will finifh," the Count fays, " this paper by a computation, which will fhew that the force of the elaftic fluid generated in the combuftion of gunpowder, enormous as it is, may be fatisfactorily accounted for upon the fuppofition that its force depends *folely* on the elafticity of watery vapour or fteam.

" It has been fhewn by a variety of experiments made in England, and in other countries, that the elafticity of fteam is redoubled by every addition of temperature equal to 30 degrees of Fahrenheit's thermometer.

" Suppofing now a cavity of any dimenfions (equal in capacity to one cubic inch for inftance) to be filled with gunpowder, and that on the combuftion of the powder, and in confequence of it, this fpace is filled with fteam (and I fhall prefently fhew that the water exifting in the powder *as water* is abundantly fufficient for generating this fteam) ; if we know the heat communicated to this fteam in the combuftion of powder, we can compute the elafticity it acquires by being fo heated.

" Now it is certain that the heat generated in the combuftion of gunpowder cannot poffibly be lefs than that of red-hot iron. It is probably much greater, but we will fuppofe it to be only equal to 1000 degrees of Fahrenheit's fcale, or fomething lefs than iron vifibly red-hot in day light."

" As the elaftic force of fteam is juft equal to the mean preffure of the atmofphere, when its temperature is equal to that of boiling water, or 212° of Fahrenheit's thermometer, and as its elafticity is doubled by every addition of temperature equal to 30 degrees of the fame fcale, with the heat of $212° + 30° = 242°$ its elafticity will be equal to the preffure of two atmofpheres ; at the temperature of $242° + 30° = 272°$ it will be equal to four atmofpheres, &c.

" Following up our computations on the principles affumed, (and they are founded on the moft incontrovertible experiments,) we fhall find that at $692° + 30° = 722°$, the elafticity will be equal to the preffure of 131,072 atmofpheres, which is 130 times greater than the elaftic force affigned by Mr. Robins to the fluid generated in the combuftion of gunpowder ; and about *one-fixth* part greater than my experiments indicated it to be.

" But even here the heat is ftill much below that which is moft undoubtedly generated in the combuftion of gunpowder. That the elafticity of fteam would actually be increafed by heat in the ratio here affumed, can hardly be doubted ; it has abfolutely been found to increafe in this ratio in all the changes of temperature between the point of boiling water, (I may even fay of freezing water,) and that of 280° of Fahrenheit's fcale, and there does not appear to be any reafon why the fame law fhould not hold in higher temperatures.

" A doubt might poffibly arife with refpect to the exiftence of a fufficient quantity of water in gunpowder, to fill the fpace in which the powder is fired, with fteam, at the moment of the explofion, but this doubt may eafily be removed.

" The beft gunpowder, fuch as was ufed in my experiments, is compofed of 70 parts (in weight) of nitre, 18 parts of fulphur, and 16 parts of charcoal ; hence 100 parts of this powder contain $67\frac{1}{10}$ parts of nitre, $17\frac{3}{10}$ parts of fulphur, and of charcoal $15\frac{4}{10}$ parts.

" Mr. Kirwan has fhewn that in 100 parts of nitre there are feven parts of water of cryftallization ; confequently in 100 parts of gunpowder, as it contains $67\frac{3}{10}$ parts of nitre, there muft be $4\frac{711}{1000}$ parts of water.

" Now as one cubic inch of gunpowder, when the powder is well fhaken together, weighs exactly as much as one cubic inch of water at the temperature of 55° F. namely 253,175 grains troy ; a cubic inch of gunpowder in its drieft ftate muft contain at leaft $10\frac{927}{1000}$ grains of water ;

for

for it is 100 to 4,711, as 253,175 to 10,927. But besides the water of cryſtallization which exiſts in the nitre, there is always a conſiderable quantity of water in gunpowder, in that ſtate in which it makes bodies damp or moiſt. Charcoal expoſed to the air has been found to abſorb nearly $\frac{1}{8}$th of its weight of water, and by experiments I have made on gunpowder, by aſcertaining its loſs of weight on being much dried, and its acquiring this loſt weight again on being expoſed to the air, I have reaſon to think that the power of the charcoal, which enters into the compoſition of gunpowder, to abſorb water, remains unimpaired, and that it actually retains as much water in that ſtate as it would retain were it not mixed with the nitre and the ſulphur.

"As there are $15\frac{4}{10}$ parts of charcoal in 100 parts of gunpowder, in one cubic inch of gunpowder, (= 253,175 grains troy,) there muſt be 38,989 grains of charcoal; and if we ſuppoſe $\frac{1}{8}$th of the apparent weight of this charcoal to be water, this will give 4,873 grains in weight for the water, which exiſts in the form of moiſture in one cubic inch of gunpowder.

"If now we compute the quantity of water which would be ſufficient, when reduced to ſteam under the mean preſſure of the atmoſphere, to fill a ſpace equal in capacity to one cubic inch, we ſhall find that either that contained in the nitre which enters into the compoſition of one cubic inch of gunpowder, as water of cryſtallization, or even that ſmall quantity which exiſts in the powder in the ſtate of moiſture, will be much more than ſufficient for that purpoſe.

"Though the denſity of ſteam has not been determined with that degree of preciſion that could be wiſhed, yet it is quite certain that it cannot be leſs than 2000 times rarer than water, when both are at the temperature of 212°. Some have ſuppoſed it to be more than 10,000 times rarer than water, and experiments have been made which ſeem to render this opinion not improbable; but we will take its denſity at the higheſt poſſible eſtimation, and ſuppoſe it to be only 2000 times rarer than water. As one cubic inch of water weighs 253,175 grains, the water contained in one cubic inch of ſteam at the temperature of 212° will be $\frac{1}{2000}$dth part of 253,175 grains, or 0.12659 of a grain.

"But we have ſeen that one cubic inch of gunpowder contains 10,927 grains of water of cryſtallization, and 4,873 grains in a ſtate of moiſture; conſequently the quantity of water of cryſtallization in gunpowder is 86 times greater, and the quantity which exiſts in it in a ſtate of moiſture, is 38 times greater than that which would be required to form a quantity of ſteam ſufficient to fill completely the ſpace occupied by the powder.

"Hence we may venture to conclude, that the quantity of water actually exiſting in gunpowder is much more than ſufficient to generate all the ſteam that would be neceſſary to account for the force diſplayed in the combuſtion of gunpowder, (ſuppoſing that force to depend ſolely on the action of ſteam,) even though no water ſhould be generated in the combuſtion of gunpowder. It is even very probable that there is more of it than is wanted, and that the force of gunpowder would be ſtill greater, could the quantity of water it contains be diminiſhed.

"From this computation it would appear that the difficulty is not to account for the force actually exerted by fired gunpowder, but to explain the reaſon why it does not exert a much greater force."

Beſides the common gunpowder, there are ſeveral other chemical compoſitions which are capable of exploding with greater or leſs violence; and the moſt remarkable of theſe compoſitions are, the gunpowder formed with the ſuperoxygenated muriate of ſoda, inſtead of nitre; that preparation of gold which, from its remarkable property, is called fulminating gold; the fulminating ſilver, Howard's mercurial powder, the common fulminating powder, which conſiſts of nitre, potaſh, and ſulphur, &c. The exploſions of almoſt every one of theſe chemical compoſitions is louder than the exploſion of an equal quantity of the common gunpowder; yet when confined in a barrel or other fit inſtrument, few of theſe compoſitions exert a force, or produce an effect equal to that of gunpowder. This, which at firſt ſight may appear to be an inexplicable paradox, will be eaſily underſtood by conſidering, that the ſmartneſs of the report depends in great meaſure on the quickneſs of the inflammation or exploſion; whereas the force of the exploſion is moſtly proportional to the quantity of elaſtic fluid, be it gas or vapour, which is generated, and that the abovementioned chemical mixtures explode quicker than common gunpowder, may be eaſily proved. Let, for inſtance, two trains of equal length be formed upon a ſtone pavement; *viz.* one with the common gunpowder, and another with Howard's mercurial powder, and let one extremity of each train come into mutual contact; ſo that by applying a red-hot iron to that point, both trains may be fired at the ſame time. It will be found that the train of mercurial powder goes off viſibly much quicker than that of gunpowder; for when the former is entirely conſumed, the fire of the latter will hardly have proceeded half way of the whole train.

The exploſion of the gunpowder made with the ſuperoxygenated muriate of ſoda, and Howard's mercurial powder, exert an immenſe force when fired in barrels or other like veſſels. Fulminating gold aud fulminating ſilver explode very readily, eſpecially the latter, which, when once prepared, can no longer be touched; for it will explode, not only when heated a few degrees above the temperature of the atmoſphere, but even when touched with any ſolid body. Yet when either of theſe preparations is confined in a barrel or other like inſtrument, and is inflamed, the force which it exerts is by no means equal to that which one who has heard the noiſe of their exploſions would be led to expect. It is worthy of remark, that, upon the whole, no other compoſition hitherto diſcovered has been found preferable to the common gunpowder, for muſkets, cannons, and other inſtruments of the like nature. Moſt of theſe preparations are conſiderably more expenſive than the common gunpowder; ſome of them are not nearly ſo manageable as the gunpowder, for they will explode by the leaſt touch or grinding, even by the friction of the ſtopple into the neck of the veſſel that contains them; but the principal fault is that very property by which they might be expected to have a ſuperior power; namely, the quickneſs of their exploſion.

There is a certain time requiſite for the motion of the wadding and bullet from the lower part to the muzzle of a gun, and the gradual inflammation of the gunpowder, when uſed in proportionate quantity, ſeems to correſpond with that gradual movement of the bullet, wadding, &c. When the exploding compoſition goes off much quicker than the common gunpowder, that force which is exerted ſpherically all round, and quicker than the time during which the wadding, &c. can get along the cavity of the barrel, frequently breaks the barrel, and endangers the by-ſtanders. We cannot illuſtrate this effect better than by mentioning the common and well-known obſervation, that though an open door may be ſhut by a gentle application of a child's a child's hand, yet if you point a gun, and fire a bullet at it, the latter will make a hole through it without ſhutting, or cloſing it in the leaſt.

Speaking of the force of exploſions, it may naturally be required that we ſhould treat of the force and effects of electrical exploſions. But as the nature of ſuch exploſious cannot be properly underſtood without other particulars relative to the ſubject of electricity, their force and effects will be found deſcribed under the articles which belong to that extenſive ſubject; ſuch as ELECTRIC *Sparks*, LEYDEN PHIAL, FIRE *Balls*, LIGHTNING, &c.

It is in a manner ſimilar to the effects of gunpowder, that water projected upon red-hot or fuſed metal, occaſions a moſt powerful, and moſt dangerous exploſion. In both caſes the water is inſtantly reduced into ſteam, at a high temperature, conſequently of very high elaſticity; hence the force which is exerted is often prodigiouſly great; and there are inſtances recorded of whole founderies having been inſtantly demoliſhed, in conſequence of ſome perſons having inadvertently ſpit upon the liquid metal. If a ſmall quantity of water be poured upon red-hot charcoal, or red-hot glaſs, a hiſſing noiſe is heard; the part which is touched by the water loſes its redneſs, and nothing elſe remarkable takes place, becauſe the above-mentioned ſubſtances are bad conductors of heat, and it is only that part which is touched by the water that communicates its heat to the water, and this is not ſufficient to convert the water ſuddenly into ſteam of very great elaſticity. But metallic bodies are the beſt conductors of heat, and fuſed copper is particularly ſo; hence, when a ſmall quantity of water happens to fall upon a large quantity of that metal, in a ſtate of fuſion, the heat from a great part of the metal ruſhes to the ſpot where the water is fallen, and inſtantly converts it into ſteam of high elaſticity.

The exploſion of a mixture of hydrogen and oxygen gaſes, or of hydrogen gas and common air, does likewiſe exert a conſiderable force, but not to be compared with that of gunpowder. Theſe gaſes, when inflamed, expand conſiderably, but inſtantly after, they contract into an exceedingly narrow compaſs, which occaſions the report; for, by the combuſtion, they are converted principally into water, the bulk of which is leſs than the ten or twenty thouſandth part of the original bulk of the gaſes.

The laſt kind of exploſion we ſhall take notice of, is produced not by the generation or contraction of an elaſtic fluid, but by a ſort of mechanical derangement. Thoſe lumps of glaſs with a long tail, or prolongation, which are well known by the name of Glaſs Tears, or Prince Rupert's Drops, are an inſtance of this kind. If one of theſe drops be held in the hand, and part of the tail is broke, a ſmart kind of exploſion is heard, and the whole is inſtantly converted into powder. In order to underſtand the cauſe of this phenomenon, it is in the firſt place neceſſary to conſider how theſe drops are formed. For this purpoſe the glaſs manufacturers take a quantity of the fuſed glaſs, (about half an ounce of it, and green bottle glaſs is the fitteſt for it,) and drop it in that ſtate of incandeſcence into cold water; the conſequence of which is, that the external part of the lump of glaſs is cooled and rendered ſolid long before the internal part of it. Then when the internal part is cooled, and of courſe contracts its dimenſions, the external part being already cooled and ſettled, cannot follow it, ſo that it remains in a ſtate of ſuſpenſion ſomewhat like an arch; hence, when part of the lump is broken, the key-ſtone, as it were, of the arch, is removed, and the whole aſſemblage of particles is deranged. See GLASS *Tears*, for a more detailed explanation of theſe their properties.

Several other ſubſtances explode and are broken upon analogous principles. Such are glaſs veſſels made for different purpoſes, and eſpecially for electrical machines; alſo large caſt-metal veſſels ſometimes ſpontaneouſly explode and break in the act of cooling. Sir William Hamilton mentions certain volcanic bodies, which he calls *volcanic bombs*, that explode probably on the ſame principle. They were large pieces of lava, which burſt in pieces like bombs as they fell to the ground. Theſe were obſerved in the great eruption of mount Veſuvius, which took place in the year 1779. The cauſe of volcanic exploſions, as well as of thoſe which accompany or precede earthquakes, is moſtly attributed to the action of ſteam; but theſe kinds of exploſions will be found particularly examined under the articles EARTHQUAKE and VOLCANO.

The uſe to which certain exploſions are applied is ſo well known as not to require any particular deſcription. Every body knows the various uſes of ſhooting with gunpowder, eſpecially in military affairs. The blaſting or breaking of rocks, by means of the exploſion of gunpowder, is likewiſe well known. But theſe uſes, together with all the particulars that relate to them, are often mentioned in various other articles of this Cyclopædia; ſuch as GUNNERY, MINING, SHOOTING, &c.

EXPOLITION, in *Rhetoric*, a figure whereby we explain the ſame thing in different phraſes and expreſſions, in order to ſhew it more fully.

Expolition was the favourite figure of Balzac.

EXPONAS VENDITIONI. See VENDITIONI.

EXPONENT, from *expono*, *I expreſs*, in *Arithmetic*. Exponent of a power denotes the number which expreſſes the degree of the power, or which ſhews how often a given power is to be divided by its root before it be brought down to unity.

Thus, the exponent or index of a ſquare number is 2; of a cube, 3; the ſquare being a power of the ſecond degree; the cube of a third, &c.

Exponents are commonly written above, and ſomewhat towards the right-hand of the number or quantity whoſe power they expreſs. Thus, 3^5, a^5, ſignify the fifth power of 3, and of a. See POWER.

EXPONENT is alſo uſed in the ſame ſenſe with index or logarithm.

Thus a ſeries of numbers in arithmetical progreſſion being placed under another ſeries in geometrical progreſſion, are called the exponents, indices, or logarithms thereof. *E. gr.* in the two progreſſions,

Geom.	1,	2,	4,	8,	16,	32,	64,	128,	256,	512
Arith.	0,	1,	2,	3,	4,	5,	6,	7,	8,	9

0 is the exponent, index, or logarithm of the firſt term 1; 5 that of the ſixth, 32, &c.

Hence, unity is to the exponent of a power as the logarithm of the root to the logarithm of its power; conſequently, the logarithm of the power is had by multiplying the logarithm of the root by its exponent; and the logarithm of the root is had by dividing the logarithm of the power by its exponent.

EXPONENT *of a ratio*, is the quotient ariſing upon dividing the antecedent by the conſequent.

Thus, in the ratio 3 to 2 the exponent is $1\frac{1}{2}$, and the exponent of the ratio 2 to 3 is $\frac{2}{3}$. See RATIO.

Hence, 1. If the conſequent be unity, the antecedent is the exponent of the ratio. Thus, *e. gr.* the exponent of the ratio 4 to 1 is 4; and again, the exponent of a ratio is to unity as the antecedent to the consequent.

2. Since in a rational ratio the exponent of a ratio is had by dividing a rational number by another rational, the exponent of a rational ratio is a rational number.

EXPONENTIAL Calculus, *Calculus exponentialis*, is a method of differencing exponential quantities, and of summing up the differences of exponentials. See Calculus.

Exponential *curve* is that which is defined by an exponential equation.

Exponential curves partake both of the nature of algebraic and transcendental ones; of the former, because they consist of a finite number of terms, though those terms themselves are indeterminate; and of the latter, because they cannot be algebraically constructed, or represented by an algebraic equation. Thus $a y = x^2$ is the equation of an algebraic curve; $y = a^x$ is the equation of an exponential curve: this equation $y = a^x$ denotes that any ordinate y is to a constant ordinate assumed equal to 1, as a constant quantity a raised to a power whose exponent expresses the ratio of the abscis x to the line equal to 1 is to the line taken for unit or 1, raised to the same exponent. Let b represent the line $= 1$, and the equation $y = a^x$ (since $y : b :: a^{\frac{x}{b}} : b^{\frac{x}{b}}$), will become $\frac{y}{b} = \frac{a^{\frac{x}{b}}}{b^{\frac{x}{b}}}$. Note, $y = a^x$ is the equation of the logarithmic curve. See Logarithmic. See also Curve.

Exponential *equation*, is that wherein there is an exponential quantity. See Equation, &c.

Exponential *quantity*, is a power whose exponent is an indeterminate or variable quantity.

Exponential quantities are of several degrees and orders: when the exponent is a simple indeterminate quantity, it is called an exponential of the first or lowest degree.

When the exponent itself is an exponential of the first degree, then the quantity is an exponential of the second degree. Thus, z^y is an exponential of the first degree, because the quantity y is a simple flowing quantity; but z^{y^x} is an exponential quantity of the second degree; because y^x is an exponential of the first degree; so also, $z^{y^{x^y}}$ is an exponential of the third degree, the exponent y^{x^y} being one of the second; and universally, the exponential quantity of any degree has for its exponent, the exponential quantity of the degree next preceding it. See Bernouilli Oper. tom. i. p. 182, &c.

EXPORTATION, in *Commerce*, the act of sending commodities out of one country into another.

Exportation is a part of foreign commerce (see Commerce), distinguished by the appellation *active*, or *selling part*, in opposition to *importation*, which is called the *passive*, or *buying part*. It is observed, as a general maxim, that commerce, when active, must produce a flow of riches, the balance being received in money; whereas, if it be passive, treasures will be exhausted, as the balance of trade must continually be made good out of the remaining coin. Hence, plenty of money in any place implies, that the quantity of goods exported far exceeds that of goods imported; and wherever money is scarce, it may be concluded that greater quantities of goods have been imported than exported. See Exchange.

It has been a principal object of commercial policy in almost every country, to encourage exportation, with the exception of a few articles; that of manufactured goods has been promoted with a view of encouraging the internal industry of the country, and that of foreign produce, as a means of drawing wealth from other countries by the profits of the carrying trade. The excess of the value of goods exported beyond that of the imports has usually been considered as a criterion of the profits which a country derives from foreign trade; but this is a fallacious mode of determining this important point, because advantageous foreign trade might long exist, even if the imports constantly exceeded the value of the exports. The laws in force relating to exportation consist principally of prohibitory or restrictive regulations concerning bullion, corn, wool, machinery, and tools used in various branches of the manufactures, the exportation of which, it is thought, might diminish the necessary supply of provisions for the consumption of the country, or enable foreigners to rival valuable branches of its manufactures. The acts relative to the exportation of wool, prohibit the exportation, not only of the commodity itself, but also of live sheep, rams, or lambs, from Great Britain, Ireland, Jersey, Guernsey, Alderney, Sark, or Man, on penalty of the forfeiture thereof, and of the ships conveying them; also 3*l.* for every sheep, &c. and three months' solitary imprisonment of the offender; for a second offence, 5*l.* for every sheep, &c. and six months' imprisonment; except wether sheep for ships' use, put on board by licence of the port-officer of the customs. A limited quantity of wool, however, is allowed to be exported from the port of Southampton to Jersey, Guernsey, Alderney, and Sark.

The duties on exportation, payable in Great Britain and Ireland, were formerly the principal branch of the revenue derived from foreign trade; but they are now of small amount compared with the duties payable on goods brought into the country.

The *official* value of all exports from Great Britain, for three years ending the 5th of January 1809, was as follows:

	British produce and manufactures.	Foreign merchandize.
Year ending 5th Jan. 1807	£.27,402,685	£. 9,124,499
- - - 1808	25,171,422	9,395,149
- - - 1809	26,692,288	7,863,207

The *actual* value of British produce and manufactures exported from Great Britain, agreeably to the prices current, and to the declarations of the exporters, was, in the year ending the 5th of January 1809, £. 40,881,871.

The official value of imports into Great Britain from Europe, Africa, and America, during the same periods, is as follows:

Year ending 5th January	1807	- - £. 25,089,136
- - - - -	1808	- - 25,453,149
- - - - -	1809	- - 23,784,516

The official value of imports into Great Britain from East India and China is as follows:

Year ending 5th January	1807	- - £. 3,746,771
- - - - -	1808	- - 3,401,509
- - - - -	1809	- - not ascertained.

The real value of Irish produce and manufactures exported from Ireland in the year ending the 5th of January 1809, computed at the average prices current, was £. 12,577,517 10*s.* 11*d.*

10*s.* 11*d.* See Customs, and Duty. See alfo Commerce.

Dr. Smith, in his "Nature and Caufes of the Wealth of Nations," ftates and explains the principles upon which the exportation trade is founded. When the produce of any particular branch of induftry exceeds what the demand of the country requires, the furplus muft be fent abroad, and exchanged for fomething for which there is a demand at home. Without fuch exportation, a part of the productive labour of the country muft ceafe, and the value of its annual produce diminifh. The land and labour of Great Britain produce generally more corn, woollens, and hard ware, befides fome other manufactures, than the demand of the home market requires. The furplus part of them muft, therefore, be fent abroad, and exchanged in the manner already mentioned. It is only by means of fuch exportation, that this furplus can acquire a value fufficient to compenfate the labour and expence of producing it. The neighbourhood of the fea-coaft, and the banks of all navigable rivers, are advantageous fituations for induftry, only becaufe they facilitate the exportation and exchange of fuch furplus produce for fomething elfe, which is more in demand there.

When the foreign goods, which are thus purchafed with the furplus produce of domeftic induftry, exceed the demand of the home market, the furplus part of them muft be fent abroad again, and exchanged for fomething more in demand at home. When the capital ftock of any country is increafed to fuch a degree that it cannot be wholly employed in fupplying the confumption, and fupporting the productive labour of that particular country, the furplus part of it naturally difgorges into the carrying trade, and is employed in performing the fame office to other countries. The carrying trade is the natural effect, and fymptom of great national wealth; but it does not feem, fays Dr. Smith, to be the natural caufe of it. Holland had formerly the greateft fhare of the carrying trade of Europe, and in proportion to the extent of its land, and the number of its inhabitants, it was the richeft country in Europe. England, now the richeft country of Europe, has appropriated to itfelf the greateft fhare of this trade. This ingenious writer fuggefts, that, whether the capital, which carries this furplus produce abroad, be a foreign or a domeftic one, is of very little importance. If the fociety has not acquired fufficient capital both to cultivate all its lands, and to manufacture in the completeft manner the whole of its rude produce, there is even a confiderable advantage derived from the exporting of that rude produce by a foreign capital, in order that the whole ftock of the fociety may be employed to more ufeful purpofes.

Dr. Smith farther obferves, in reference to this fubject, that with a view of multiplying gold and filver, in which, it has been commonly fuppofed, the wealth of a country confifts, it neceffarily became the great object of political economy to diminifh, as much as poffible, the importation of foreign goods for home confumption, and to increafe, as much as poffible, the exportation of the produce of domeftic induftry: and, therefore, its two great engines for enriching the country have been reftraints upon importation, and encouragement to exportation. The former were of two kinds, *viz.* reftraints upon the importation of fuch foreign goods for home confumption as could be produced at home, from whatever country they were imported; and reftraints upon the importations of goods of almoft all kinds, from thofe particular countries, with which the balance of trade was fuppofed to be difadvantageous. Thefe different reftraints confifted fometimes in high duties, and fometimes in abfolute prohibitions. Exportation was encouraged fometimes by drawbacks, fometimes by bounties, fometimes by advantageous treaties of commerce, and fometimes by the eftablifhment of colonies in diftant countries. Thus it has been intended to increafe the quantity of gold and filver in any country by turning the balance of trade in its favour. Our author has particularly examined what are likely to be the effects of thefe reftraints and encouragements upon the annual produce of the induftry of a country. According as they tend either to increafe or diminifh the value of this annual produce, they muft evidently tend either to increafe or diminifh the real wealth and revenue of the country. See Exchange, Monopoly, and *Balance of* Trade. Of the encouragements to exportation above enumerated, thofe which are called *Drawbacks* (fee the article) feem to Dr. Smith to be the moft reafonable. Concerning the grant of bounties; fee Bounty,

EXPOSING, the act of fetting a thing to public view.

In the Romifh church, the facrament is faid to be expofed when it is fhewn in public, uncovered, on feftival days, and during the time of plenary indulgences.

Exposing is alfo ufed with a farther latitude; thus, we fay it is prohibited to expofe falfe and clipped money.

Such a houfe ftands very high, and has a delicious profpect; but it is expofed to all the four winds. Such a city being on the frontiers, and not fortified, is expofed to the infults of every party of forces.

Exposing *of Children*, a barbarous cuftom practifed by moft of the ancients excepting the Thebans, who had an exprefs law to the contrary, whereby it was made capital to expofe children, ordaining at the fame time that fuch as were not in a condition to educate them, fhould bring them to the magiftrates, in order to be brought up at the public expence. (Ælian Hift. Var. l. ii. c. 7.) Among the other Greeks, when a child was born, it was laid on the ground; and if the father defigned to educate his child, he immediately took it up; but if he forebore to do this, the child was carried away, and expofed. Pitifc. Lex. Ant. in voc. Expofitio.

The Lacedæmonians, indeed, had a different cuftom; for with them all new-born children were brought before certain tryers, who were fome of the graveft men in their own tribe, by whom the infants were carefully viewed; and if they were found lufty and well-favoured, they gave orders for their education, and allotted a certain proportion of land for their maintenance: but if weakly, or deformed, they ordered them to be caft into a deep cavern in the earth, near the mountain Taygetus, as thinking it neither for the good of the children themfelves, nor for the public intereft, that defective children fhould be brought up. Plutarch takes notice of this law of Lycurgus, and paffes no cenfure upon it.

Many perfons expofed their children only becaufe they were not in a condition to educate them, having no intention that they fhould perifh. It was the unhappy fate of daughters efpecially to be thus treated, as requiring more charges to educate and fettle them in the world than fons.

The parents frequently tied jewels and rings to the children they expofed, or any other thing whereby they might afterwards difcover them, if Providence took care of their fafety. Another defign, in adorning thefe infants, was either to encourage fuch as found them to nourifh and educate them, if alive; or to give them human burial, if dead.

The places where it was ufual to expofe children were fuch as people frequented moft. This was done in order that they might be found, and taken up by compaffionate perfons who were in circumftances to be at the expence of their education. With this intention the Egyptians and

Romans chofe the banks of rivers, and the Greeks the highways.

Dionyfius Halicarn. (Antiq. Rom. l. ii.) informs us, that Romulus obliged the citizens to bring up all their male children, and the eldeft of the females. They were allowed therefore to deftroy all their female children but the eldeft. And even with regard to their male children, if they were deformed or monftrous, he permitted the parents to expofe them, after having fhewn them to five of their neareft neighbours. In Cicero's third book of laws, (cap. 8.) there is a paffage, from which it has been concluded, that the law of Romulus, with regard to the expofing and deftroying of male children that were remarkably deformed, was confirmed by a conftitution of the twelve tables. It appears, from a paffage in Terence, that this inhuman cuftom of expofing and deftroying children, efpecially females, was not uncommon even among parents of the beft character. Sentiments of this kind were publifhed with applaufe on the Roman theatre: and we learn from Seneca (de Ira, l. i. c. 15.) that fo late as in his time, it was ufual among the Romans to deftroy weak and deformed children. "Portentofos fœtus extinguimus: liberos quoque, fi debiles monftrofique editi funt, mergimus."

This unnatural practice was prefcribed and approved even by the more eminent philofophers. Plato (Republ. l. v.) recommends it to be ordered by law that men or women, who are paft the age of having ftrong children, fhould take care that their offspring, if they fhould have any, fhould not come to the birth, or fee the light; or if that fhould happen, that they fhould expofe them without nourifhment. Ariftotle (Politic. l. vii. c. 16.) exprefsly fays, that it fhould be a law not to bring up or nourifh any child that is weak or maimed; and that when the law of the country forbids to expofe infants, it is neceffary to limit the number of thofe who fhould be begotten; and if any one begets children above the number limited by the laws, he advifes to procure abortion before the fœtus has life and fenfe. The practice that has long prevailed among the Chinefe, and that fubfifts among them even to this day, is well known.

EXPOSITION, the act of expofing. See Exposing.

Exposition is likewife applied to the interpretation or explication of an author, or paffage therein. See Exegesis.

Exposition *of deeds*, in *Law*, fhall be favourable, according to the apparent intent; and be reafonable, and equal, &c. Co. Litt. 313.

Exposition, *expofitio*, in *Rhetoric*, is fometimes ufed for divifion. See Division; and fee alfo Exergasia.

Exposition, in *Gardening*. See Exposure.

EXPOSITOR, or Expository, a title which fome writers have given to a leffer kind of dictionaries or vocabularies, ferving to expound or explain the meaning of the obfcure or difficult words of a language.

It is alfo ufed in the fame fenfe with commentary and paraphrafe.

EX POST FACTO, in *Law*, denotes fomething done after another thing that was committed before. An eftate granted may be made good by matter ex poft facto, that was not fo at firft, by election, &c.

EXPOSTULATION, Expostulatio, in *Rhetoric*, a complaint addreffed to a perfon from whom we have received fome injury. It varies according to circumftances.

EXPOSURE, or Exposition, in *Gardening*, the afpect or fituation of a garden wall, building, or the like, with refpect to the fun, wind, &c.

There are four regular kinds of expofures, *viz*, eaft, weft, north, and fouth; but it muft be obferved that among gardeners thefe terms fignify juft the contrary to what they do among geographers.

The gardeners, in effect, do not give the names eaft, weft, &c. to the places where the fun is, but to thofe whereon he fhines; and they confider the manner wherein he fhines, whether as to the whole garden, or fome of its fides.

If they find, that the fun at his rifing, and during the firft half of the day, continues to fhine on one fide of a garden or wall, they call that an eaftern expofure, or eaft wall, &c. and if the fun begin to fhine later, or end fooner, it is not a proper eaftern expofure.

For the fame reafon, they call the weft the fide the fun fhines on the latter half of the day; *i. e.* from noon to night; and accordingly, the fouth, or fouthern expofure, is the place whereon he fhines from about nine o'clock in the morning till night; or which, in the general, he fhines longeft on in the whole day; and the part he fhines leaft on is the north, or fouthern expofure, at what hour foever it begin or end, being ufually from eleven o'clock to one.

The eaftern and fouthern expofures are, by common confent of all gardeners, the two principal, and have a confiderable advantage above the reft. A weft expofure is not much amifs; at leaft, it is better than a northern one, which is the worft of all: each has its inconveniences.

The eaftern, commencing differently at different feafons of the year, and ending about noon, fubjects the trees, &c. to the N.E. winds, which wither the leaves and new fhoots, blow down the fruit, &c. befide that it has little benefit of rains, which come moftly from the weft. Yet does the reverend Mr. Laurence judge the eaft better than the weft-wall for all kinds of fruit; not that it has more hours of fun, or that there are any peculiar virtues in the eaftern rays, but becaufe the early rays of the fun do fooner take off the cold chilly dews of the night.

M. Gentil recommends the eaftern expofure as beft for all kinds of peaches; adding, that they ripen fooneft, grow bigger, are better coloured, and of a finer tafte, than in any other; but Mr. Carpenter reftrains the rule to the early and middle forts; for the backward, he rather choofes a fouthern, or fouth-eaft expofure, which is beft for all late fruits, becaufe the influence of the fun is ftrongeft, and continues longeft.

The weftern, accounted from half an hour paft eleven till fun-fet, is backwarder than an eaftern one by eight or ten days; but it has this advantage, that it receives little damage from the frofts, which melt before the fun comes to fhine upon the fruit, and fall off like dew, without doing any prejudice; fo that it may bear apricots, peaches, pears, and plums; but it is incommoded with north-weft winds in the fpring, as alfo with the autumnal winds, which blow down a great quantity of fruit.

According to Mr. Miller, the beft afpect or expofure for walls in England is the point to the eaftward of the fouth; becaufe thofe will enjoy the benefit of the morning fun, and be lefs expofed to the weft and fouth-weft winds, which are very injurious to fruits in England, than thofe walls which are erected due fouth; the next beft expofure is due fouth, and the next to that fouth-eaft, which is preferable to the fouth-weft. Other walls, however, may be planted with fruit-trees that fuit their feveral expofures.

The northern expofure is the leaft favourable of any in England, as having very little benefit from the fun even in the height of fummer, therefore can be but of little ufe, whatever may have been advanced to the contrary. For although many forts of fruit-trees will thrive and produce fruit in ſuch poſitions, yet ſuch fruit can be of little worth, ſince they are deprived of the kindly warmth of the ſun to correct their crude juices, and render them well taſted and wholeſome. It is therefore to little purpoſe to plant fruit-trees againſt ſuch walls, except it be for fruit intended for baking, &c. in which caſe the fire will ripen and render thoſe juices wholeſome which could not be performed while growing.

In ſuch ſituations, morelli cherries for preſerving may be planted, and white and red currants to come late, after thoſe which were more expoſed to the ſun are gone; and if the ſoil be warm and dry, ſome ſorts of ſummer pears will do tolerably well on ſuch an expoſure, and will continue longer in eating than if they were expoſed to the ſun. But winter pears ſhould by no means be planted in ſuch an aſpect, as has been practiſed by many ignorant perſons, if we find that the beſt ſouth walls in ſome bad years are barely warm enough to ripen them. Duke cherries planted againſt walls expoſed to the north will ripen much later in the ſeaſon; and if the ſoil be warm, will be well flavoured, and continue a month later than others. Miller.

The ſouthern expoſure, accounted from about nine till four, is recommended for peaches, pears, grapes, and plums.

EXPRESS, ſomething that is preciſe in formal terms, or for ſome particular deſign. I told him as much in expreſs terms; he gave me a commiſſion expreſs; he had expreſs orders; a courier was diſpatched expreſs.

We alſo ſay, ſomewhat abuſively, to ſend an expreſs, meaning a courier.

Express *Condition*, *Contract*, *Malice*, and *Warranty*. See the ſubſtantives.

EXPRESSED Oils, are ſuch as are procured from bodies only by preſſing; as the oils of olives, almonds, and the like. See Oil.

Expressed *ſpecies*. See Species.

EXPRESSION, in *Algebra*, denotes the value of a quantity expreſſed or repreſented under an algebraic form: thus, if $x = \sqrt{a^2 + b^2}$, and a and b are known, the value of x is known. See Equation.

Expression, in *Chemiſtry*, *Pharmacy*, &c. the act of expreſſing out, or extracting the juices of oils or plants, fruits, or other matters, by ſqueezing, wringing, or preſſing them in a preſs. This is one of the three modes of obtaining them; the other two being *infuſion* and *decoction*, which ſee. The hard fruits ſhould be well bruiſed, and herbs moderately bruiſed, before expreſſion. They are then to be incloſed in a hair or other bag, and preſſed between wooden plates in the common ſcrew preſs, till the juice ceaſes to run. The expreſſion of oils is performed nearly in the ſame manner as that of juices, by means of iron plates, or the apparatus of an oil-mill, adapted to this purpoſe. The inſipid oils of all unctuous ſeeds are obtained uninjured by this operation, if performed without the aid of heat, which, though it may promote the extraction of the oil, gives it an ungrateful flavour. The oils expreſſed from aromatic ſubſtances generally carry with them a portion of their eſſential oil.

Expression, in *Muſic*, is a quality by which a muſician manifeſts his feeling, and executes with energy all the ideas with which he ought to impreſs the hearer, and all the ſentiments which the compoſer intended to expreſs. There is an expreſſion in compoſition as well as in its execution, and it is by their concurrence that the moſt pleaſing and agreeable effect reſults.

To give an expreſſion to his works, a compoſer ought to ſeize and compare all the relations which can be found between the features of his object, and the productions of his art; in a muſical drama, he ought to know and feel the peculiar caſt of all the characters, in order ſeverally to exhibit them exactly as delineated by the poet; for as a good painter does not throw the ſame light on every figure, neither will the able muſician give the ſame energy to all the ſentiments, nor the ſame force to every figure, but will put each part in its true place, leſs to give it weight, individually, than to contribute to the effect of the whole.

After having well conſidered what a character has to ſay, he meditates how he ſhall ſay it; and here begins the application of the precepts of his art, which is to find the particular language in which the actor would wiſh to make himſelf underſtood.

Melody, harmony, movement, choice of inſtruments and voices, are the elements of the muſical language; and melody, by its immediate connection with the grammatical and oratorical accent, is that which gives a character to all the reſt. So that it is conſtantly from melody that the principal expreſſion ſhould be derived, as well in inſtrumental as vocal muſic.

What a compoſer therefore has to expreſs by melody is tone of voice, with which the ſentiments can beſt be rendered; and care ſhould be taken not to mimic that of theatrical declamation, which is in itſelf only an imitation, but the voice of nature ſpeaking without affectation and without art.

The compoſer will therefore at firſt ſeek a kind of melody which ſhall furniſh muſical inflections the moſt conſonant to the ſenſe of the words, always lowering their expreſſion to the thought, and the thought to the interlocutor's ſtate of mind; for when we are ſtrongly affected, all that we ſay in a manner favours of the general ſentiments which govern us; and we never chide what we love in the ſame tones as we ſhould an indifferent perſon. Our ſpeech is differently accented according to the different paſſions by which we are agitated; ſometimes acute and vehement, ſometimes languid and monotonous, ſometimes varied and imperious, ſometimes ſmooth and tranquil in its inflections. Thence the muſician regulates the choice of keys which he uſes in his melody, and the different places in which he employs voice, keeping it down with ſmall intervals to expreſs the languor of ſorrow and dejection; and ſtraining it with acute ſounds in paſſion and grief; driving it rapidly through all the intervals of the diapaſon in the agitation of deſpair, or the turbulence of diſtracted paſſions. Above all it muſt be remembered, that the charms of muſic conſiſt not only in imitation, but in an agreeable imitation; and that the declamation (or recitative) itſelf to have its full effect, ſhould be ſubordinate to melody; ſo that there is no painting ſentiment without giving it this ſecret charm inſeparable from it, nor touch the heart without pleaſing the ear. And this is ſtill very conformable to nature, which gives to the tone of voice of perſons of ſenſibility, certain touching and delicious inflections, which thoſe who feel nothing never poſſeſſed. Never, therefore, miſtake rough and coarſe for expreſſive, nor harſhneſs for energy. Give not a hideous picture of the paſſion which you wiſh to paint, nor imitate the performers at the French opera, where the voice of paſſion reſembles a complaint of the colic, more than tranſports of love.

The natural pleaſure which reſults from harmony, augments in its turn the moral pleaſure of imitation, in uniting the agreeable ſenſations of chords to the expreſſion of the melody, upon the ſame principle as that juſt mentioned. But harmony does ſtill more; it enforces even the expreſſion in giving more truth and preciſion to melodious intervals; it animates their character, and exactly marks their place in the order of the modulation; it calls back the preceding, announces

announces that which ought to follow, and thus connects the phrafes in the melody, as ideas are linked together by grammar in a difcourfe. Harmony, regarded in this light, furnifhes the compofer with powerful means of expreffion, which efcape him when he feeks expreffion in harmony alone; for then, inftead of animating the accent, he extinguifhes it by his chords, and all the intervals, confounded in a continued crowd of combined founds, offer to the ear only a feries of fundamental chords, which have nothing touching or agreeable in their effect, and often not only fuffocates the melody, but the fenfe of the words. What then muft the harmonift do to fortify the expreffion of the melody, and give it more effect? He will carefully avoid covering the principal found in the combination of chords; he will render all the notes of the accompaniment fubordinate to the vocal part; he will give relief and energy to it by the concurrence of other parts; he will enforce the effect of certain paffages, by the chord of the fharp 7th; he will difguife others by fuppofition or fufpenfion, in making no provifion for them in the bafe; he will gain ftrong expreffions by major difcords, he will referve the minor, for tender fentiments; fometimes he will unite all his parts by fmooth and flowing notes; fometimes he will contraft them with the melody by pointed notes; fometimes he will fill the ear with full harmony, and fometimes enforce the accent by the choice of a fingle interval. He will render prefent and fenfible the chain of modulation throughout, and will make the bafe and its harmony ferve to determine the place of each paffage in the key, in order that no interval or trait of melody fhall be heard, without feeling at the fame time its relation with the whole.

With refpect to rhythm, formerly fo powerful as to give force, variety, and ornament to poetical harmony; if modern languages lefs accentuated and lefs profodic have loft this charm, our mufic can fubftitute another more independent of fpeech in the precifion of meafure, and in the combination of its proportions, whether moving together or feparately in each part.

Quantity in language is almoft wholly loft in notes of mufic; and the mufic, inftead of fpeaking with words, borrows, in fome fort, from the meafure a language apart.

The force of the expreffion confifts in this particular, in the uniting thefe two languages as much as poffible together, in fuch fort, that if the meafure and the rhythm fpeak not in the fame manner, they will at leaft fay the fame things.

Chearfulnefs, which gives vivacity to all our movements, ought to do the fame in mufical meafures. Melancholy locks up the heart, relaxes all our motions, and the fame languor is felt in the melodies which it dictates; but when grief is poignant, or great conflicts are paffing in the mind, fpeech is unequal; it moves alternately with the flownefs of the fpondee and the rapidity of the Pyrrhic, and fometimes fuddenly ftops fhort, as in accompanied recitative; it is on this account, that the moft expreffive mufic, or at leaft the moft paffionate, is commonly that in which the times or portions of each bar, though equal in themfelves, are the moft unequally divided; whereas the image of fleep, of repofe, of peace of mind, require fmall exertion of voice, and are naturally painted with notes of equal length, which move neither quick nor flow.

There is one obfervation which the compofer ought not to neglect, and which is, that the more ftudied and extraneous is the harmony, the flower fhould be the movement, in order that the mind may have leifure to difentangle the difcords, and follow the rapid chain of modulation. Nothing but the laft degree of fury can permit the union of rapid meafures and harfh chords. When the head is diftracted, and the actor, by violent agitation, feems not to know what he fays, this energetic and terrible confufion may be communicated to the mind of the fpectator, and, in like manner, make him lofe his reafon. But if the compofer is not inflamed and fublime, he will only be coarfe and cold; if he does not throw the audience into a delirium, he runs a great rifk of a failure: for he who lofes his reafon is only mad in the eyes of thofe who preferve it, and infanity is no longer interefting.

Though the greateft force of expreffion is derived from the combination of founds, the quality of their tone is not indifferent in the effect. There are voices fo ftrong and fonorous as to impofe by their force; others thin, flexible, and fit for execution; others again fo touching and delicate as to penetrate the heart by foothing and pathetic ftrains. In general, treble voices and acute are fitteft to exprefs tendernefs and affection; bafes and baritones for intemperate paffion and choler; but the Italians have banifhed bafes from their ferious operas, as a part, of which the melody is too rude and boifterous for the heroic ftyle, and have fubftituted in their ftead tenors, of which the melody has the fame character, with a more agreeable effect. They employ bafe voices in the grotefque and ridiculous parts of their comic operas with more propriety.

Inftruments have alfo their peculiar expreffions, proportioned to their quality of tone, force, and compafs. The flute is tender, the hautbois cheerful, the trumpet military, the horn fonorous, majeftic, and proper for grand expreffions. But there is no inftrument of more varied expreffion, and more univerfally ufeful, than the violin. This admirable inftrument is the foundation of every orcheftra, and can furnifh a great compofer with all the effects which mean muficians vainly feek in a multitude of different inftruments. The compofer ought to be acquainted with the fingerboard of the violin, to confider the fhifts, and know how to write arpeggios, by diftinguifhing the open from the ftopped ftrings, and to choofe and make ufe of keys according to the different characters they have upon that inftrument.

It is in vain for the compofer to attempt to animate his orcheftra, if the ardour which ought to reign in it does not inflame the performers. The finger who only fees notes in his part, is not qualified to feize the expreffion of the compofer, nor to give one of his own to what he fings, if he has not well comprehended the fenfe. He muft underftand what he reads before he can make it comprehended by others; and it is not enough to be poffeffed of general fenfibility, if not particularly energetic in the language we fpeak. Let him begin therefore by thoroughly underftanding the character of the melody which he has to execute, its expreffion of the words, the diftinction of its phrafes, the accent which it has in itfelf, that which it requires in the voice of the finger, the energy which the compofer has given to the poet, and that which in his turn he can give to the compofer. Let him refign his whole powers, then, to all the enthufiafm which thefe confiderations fhall have infpired; he fhould exprefs every thing as completely as if he were at once the poet, compofer, actor, and finger, and he will then have all the animation which it is poffible for him to give to the work which he has to execute.

In this manner he will naturally embellifh with tafte and delicacy airs that are only elegant and graceful; with fpirit and fire, fuch as are animated and gay; with fighs, the tender and pathetic; and with all the agitation of forte and piano, fuch as are expreffive of rage and fury. Whenever the mufical and oratorical accents are united (as in arie parlanti), wherever the time fhall be ftrongly marked, and ferve as a guide to the accents of the melody; wherever the ac-

companiment

companiment and the voice ſhall ſo agree in their effects as to form only one melody, and the hearer, deceived, wholly attributes to the voice the paſſages which the orcheſtra embelliſhes; and, finally, wherever ſober ornaments, judiciouſly applied, manifeſt the abilities and facility of the finger, without diſguiſing and injuring the melody, the expreſſion will be ſweet, agreeable, and animated; the ear will be delighted, and the heart affected; nature and art will at once concur in pleaſing the hearer, and there will reign ſuch a coincidence between the words and the muſic, that the whole will ſeem to proceed from one delicious language, which can ſay every thing, and always pleaſe.

This is more a diſſertation than an article of a dictionary, but theſe are the ſentiments of the citizen of Geneva, to moſt of which in muſic we readily ſubſcribe, as he is ever more reaſonable and conſiſtent in ſpeaking of that art than on any other ſubject. His views concerning dramatic muſic are always ſo ingenious, elevated, and refined, that we cannot reſiſt tranſlating him. Though we fear that the French, with all their preſent rage for Italian muſic and Italian expreſſion, will not adopt them; and the Italians themſelves, in their moſt happy moments of conception, have been ſucceſsful from inſtinct and enthuſiaſm, more than precepts or reflection.

Expression, in *Oratory*, denotes the manner of delivering or conveying one man's ideas to another. Accordingly it denotes that felicity of diſcriminative energy in the reader, ſpeaker, or reciter, by which the characteriſtic beauties or peculiarities, whether of language, ſentiment, or paſſion, in a compoſition or oration, are forcibly and happily illuſtrated, and the various ſhades and tranſitions of ſtyle, ſignification, feeling, and alluſion, in ſuch compoſition or oration, are diſtinctly and intereſtingly marked. Expreſſion in this, as in every other art, is one of the chief conſtituents of excellence; and contradiſtinguiſhes the elocutioniſt of taſte and genius, from the mere mechanical reader or declaimer. It depends chiefly upon that quickneſs and vitality of perception which may be regarded, in ſome degree, as an original gift of nature, and on that prompt and perfect ſympathy between the perceptive faculty and the executive organs, which it is the higheſt glory of art and practical exerciſe to produce.

Expression is more particularly uſed for the elocution, diction, and choice of words in a diſcourſe. See Elocution.

It is not enough that a poet or orator have fine thoughts, he muſt likewiſe have a happy expreſſion. Defects in the expreſſion ordinarily ariſe from defects in the imagination: abundance of the beauties of the ancient writers are annexed either to expreſſions which are peculiar to their language, or to relations, which, not being ſo familiar to us as to them, do not give us the ſame pleaſure.

Expression, *diverſifying of*, in *Rhetoric*. See Diversifying.

Expression, in *Painting*, principally conſiſts in the repreſentation of thoſe attitudes of the body, and variations of the countenance of men, which always accompany and denote the immediate influence of the paſſions of their minds. Beſides this more important uſe of the word, it is uſed in painting to ſignify the repreſentation of any object by a mode of execution agreeable to its nature, its character, and the ſituation it holds in the work. When wrought with juſt ſenſe and propriety in theſe reſpects, it is ſaid to be *well expreſſed*. We will firſt conſider it in the former and more uſeful ſenſe.

The paſſions which influence the conduct of men have each a general character of expreſſion, by look or geſture, attached to them in the whole race of mankind; and they are alſo marked in individuals by peculiarities, ariſing from the temperament and conſtitutional habits with which each of them is endowed by nature.

To ſeize and repreſent with energy theſe characteriſtics of the paſſions of the mind, and accompany their repreſentation without diminiſhing its force, with the varieties appropriate to the individual perſonages introduced into a picture, is the eſſence, the ſoul of art. The ſlighteſt ſketch poſſeſſing this quality, acquires an intereſt uninſpired by, and far above, that excited by the moſt highly and excellently wrought pictures which are void of it.

Very few painters, amongſt the immenſe numbers of thoſe who lay claim to the name, have been happy enough to obtain a ſuper-eminent degree of expreſſion in their works; indeed it is a taſk of extreme difficulty to overcome, requiring the ſoundeſt ſenſe to ſelect the knowledge of it, and the greateſt ability in art to repreſent it when underſtood. The man who aims at it, beſides being an ever active obſerver, ſhould poſſeſs great ſuſceptibility of mind to enter into the feelings of others, and thus draw, as it were, from himſelf: yet that ſuſceptibility ſhould be under the regulation of ſound diſcernment, and cool diſpaſſionate judgment, to enable him to diſcriminate the fictitious repreſentations of paſſion, from thoſe natural unartificial actions, and looks, dictated by, and ariſing from, genuine feeling: and in his continued obſervations upon the actions and aſpects of men under their influence, he ſhould be careful to ſeparate thoſe points which identify a peculiar paſſion, and diſtinguiſh it from others that are nearly allied to it.

Artiſts endowed with very conſiderable talents have failed in two different ways in their endeavours to embelliſh their works with this valuable quality. Some, by an over-anxious deſire to give ſtrength and energy to their expreſſions, have carried them into artifice and bombaſt: others, on the contrary, wiſhing to unite the beautiful with the pathetic, have only rendered their works inſipid and unintereſting in expreſſion; and it appears that he who is obliged to labour to produce it, who does not work from a clear comprehenſion of the characteriſtic lines of an expreſſion in its ſimpleſt and moſt undiſguiſed ſhape, can never effect the repreſentation of it to any degree of perfection, and the beholder of his works will ſtill leave them unimpreſſed with any portion of the ſenſation the real paſſion is calculated to produce; the only true teſt of the value of works of art, as far as relates to expreſſion.

"By tedious toil no paſſions are expreſt,
He who conceives them ſtrongeſt paints them beſt."

The power of rendering, or producing expreſſion in painting, is, next to grace and elegance, the leaſt communicable talent of thoſe requiſite to form a perfect painter. He who attempts to obtain it, if not originally gifted by the great Author of nature with a peculiar propenſity to obſerve and imbibe the leading features which conſtitute its excellencies, follows a phantom that will for ever elude his graſp. If, however, he happily poſſeſſes that inclination, he may obtain ſome aſſiſtance in his purſuit of it from the works of others, which will ſhorten his labour, but will not lead him to the ultimate point of his deſire; to that, the ſtudy of nature can alone effectively induce.

We allude to ſome general rules given by artiſts who have communicated the reſult of obſervations made in their endeavours to obtain an underſtanding of the expreſſion of the paſſions of the mind, in the countenances and actions of men; and they are by ſome, whoſe names authorize reliance upon their obſervations, particularly Lionardo da Vinci, Trattata de la Pittura, and Le Brun's Paffions. They have pointed out and illuftrated thofe actions of the countenance and figure which moft ftrongly defignate the reigning influence of particular paffions.

Thefe rules, however, go only a fhort way in a general view of the fubject; much lefs do they comprize what is requifite, when the multitudinous varieties of expreffion in the almoft infinitely varying countenances and habits of men of all degrees are taken into confideration. How, indeed, can it be poffible to direct the means of obtaining with certainty that which is in itfelf fo infinitely divifible, as the courfe of the feelings and dictates of the ungovernable heart of man, and his correfponding actions and turns of feature?

It is in having afcertained and eftablifhed the features of the more ftrong and leading paffions, that thefe general rules are found ufeful. We learn from them, that the influence of exceffive joy or laughter draws all the features of the face upwards; that grief reverfes that order, and draws them downwards. Violent anger diftorts them, and enlarges their appearance, particularly the eyes and noftrils; and the action of the body is violent, with quick and fhort motions. Defire enforces an eager advancing action towards its object, and the eyes and mouth are fomewhat expanded. Acute pain is generally expreffed by a mouth fomewhat opened and drawn back, the eyes raifed, and partly covered by the upper eye-lid; and the eye-brows drawn clofely together, wrinkling the forehead. Fear is denoted by expanded eyes and mouth, the eye fixed upon the exciting caufe, the hair elevated and thickened, the colour livid, and the figure drawn back as if attempting to retire from the object which caufes the alarm. The effects of the fenfation of fcorn or hatred on the figure and countenance are marked by the mouth being clofed firmly, and the lips drawn down at the corners; whilft the elevation of the noftril caufes the middle of the upper lip to rife; the forehead is ftrongly preffed, and the brow falls over the eyes, which exprefs the paffion beft when they are turned fideways, towards the object, with the body inverted from it. Awe, or veneration, produces a general inclination of the body, and the head ftill more fo, towards the object exciting it.

Under one or other of thefe paffions and expreffions all the feelings of our minds are more or lefs ranged; and of courfe will participate more or lefs of the indications of them, according to the excitation they meet with: therefore, fo far the general rules will be of ufe in their reprefentation. But mankind, from their various modes of education, their habits, and manners, accompany thefe fenfations, when excited in them, by peculiarities which it is of the utmoft importance to the painter juftly to difcriminate, and be careful not to give that action to one, which, in propriety, belongs to another; not to attach the vulgar action of an uncultivated clown, to the dignified character of a man of rank and liberal education.

Befides remarking the expreffive characters of the ftronger paffions, great attention is requifite to be paid to the phyfiognomical expreffion of the countenance, and of the figure (if one may fo fpeak); the influence of which is daily felt and acknowledged. Though our information upon that fubject is much thwarted by the effect of education and reflection, yet its bafis is juft and firmly fixed, as every day's experience proves. Perfons whofe features and general forms correfpond, are found to be correfpondent alfo in character; that is, in their natural propenfities: one of two, thus fimilarly formed, may have cultivated his mind more than the other, and education and fociety may have taught him to mafk or difguife his inclinations; but nature is ftill true to herfelf, and the fame general difpofition remains. Nay, it goes ftill further; young perfons not naturally addicted to vice, being drawn by accident or early affociation to continue in the practice of indulgence, acquire, in procefs of time, a change of feature and expreffion, in great meafure fimilar to that form ufually indicative of the vice or paffion indulged in, where it is implanted by nature.

In this, therefore, we have a ground of expreffion which is well worthy, indeed very neceffary, to be carefully attended to by thofe who aim at perfection in the art of painting. They ought to make themfelves acquainted with the forms that belong to the peculiar inclinations and different degrees of capacity of mind in the perfons they chufe to bring forward in their works, of whatever clafs they may be. They fhould not put into the face of a man of mild character any of the features indicative of warm paffions; in fuch an one the eye fhould not have an eager look; the noftrils fhould not be large, or inflated; all the lines fhould be fmooth, and have little variation of form. And, on the contrary, when the figure of one whofe difpofition is naturally hot and impetuous is introduced, he fhould not have a fmooth ftraight forehead; which is indicative of mildnefs and fuavity; his nofe fhould not be ftraight; nor his mouth gently undulating, of a mild pleafing character: though he may not be in the act of exerting his natural impetuofity of character, yet he fhould have the appearance of one who would be eafily roufed to that feeling and expreffion. A man of great fenfe and intellect fhould not be reprefented with the features that characterize imbecility; nor the weak, and undecided character, have the forms denoting fenfe and intellectual power; and it fhould be conftantly remembered, that though every paffion, every fentiment of the mind, has its peculiar expreffion; every particular perfon has his peculiar mode of expreffing it.

In reprefentations of the paffions, 'tis not form alone which is required to perfect the work: though that indeed yields a very ftrong impreffion of it, yet its effect is greatly heightened when a proper tone of colour is fuperadded. By colour we judge of health or ficknefs, of youth and age, as well as by form. The fallow hue of melancholy is proverbial. It is well known how anger affects the hue of the countenance; in fome it produces a violent flufh of blood, and confequent rednefs of colour, even almoft to blacknefs: in others a pallid hue denotes it, or a change from one to the other rapidly fucceeding. The malignant paffions are generally accompanied in their expreffions by a pallid tone of colour: and the more noble fentiments by the reverfe. A man performing a benevolent action feels a degree of fatisfaction which affects his countenance; his eyes exhibit his fentiments by their livelinefs, and his mouth by its gentle curves at the corners, whilft his cheeks bear (what is perfectly underftood fo as to be admitted a common phrafe) the cheerful glow of humanity ftampt on them. Clearnefs of complexion, and colour in the cheeks, indicate youth and health; fallownefs, and the lofs of the ruddy hue of colour, ficknefs and age. The inhabitants of the town, and of the country, exhibit the fame diftinctions; as alfo the ftudious man and the fportfman. Independent of the individual hue of the character reprefented, one general tone over the whole picture fhould prevail, correfpondent to the fubject. Thus, if it be one of a grave caft, the tone of colours fhould be low, yet rich; and though harmonious not monotonous. If, on the contrary, the fubject is gay, the hues of the colouring fhould be bright and cheerful, and greatly diverfified; and every part of the picture fhould affift in expreffing the nature of the fubject chofen for reprefentation.

It is attention to this point which gives to painting its real value, its intrinfic worth; and feparates it from the more

more vulgar or merely mechanical arts. Hence it becomes of moral utility, and its power is not furpaffed by the poetic, or other effufions of the pen, in the force and vivacity of the impreffions it is calculated to produce. Of this there are many notices given to us in hiftory. Alexander is faid to have trembled and grown pale on feeing a picture of Palamedes betrayed to death by his friends: it bringing to mind the remembrance of his treachery to Ariftonicus. It is alfo related of an Athenian courtezan, that in the midft of a riotous banquet, cafting her eye on the portrait of a philofopher marked with the happy character of virtue and temperance; fhe was ftruck with fo lively an image of her own unworthinefs, that fhe inftantly went home and became an example of temperance. In both thefe cafes, to the truth of the expreffion muft be afcribed the force with which the pictures wrought upon the obfervers; and produced the powerful impulfe related.

It appears, indeed, to have been the principal object of attention with the ancient Greeks, and very naturally fo; for in the beginning of an art, before any rules for regulating its efforts were adopted. the artift's attention muft of courfe have been folely directed to relating his ftory; and whatever affifted in effecting that, was preffed into the fervice. Firft of all, we are told, the efforts were fo rude it was neceffary to explain them: afterwards labels were placed as iffuing from the mouths of figures; and other means of giving the ideas, fuppofed to occupy their minds, were adopted, till at laft the artifts arrived at the perfection of imitations of nature; and by giving their figures the actions and expreffions appropriate to their fituations, caufed them to tell their own ftory, and imprefs all its intereft on the beholders, without any extraneous aid. Unhappily, excepting the few pictures found at Herculaneum, and thofe are of a trivial kind, we have none of their works in this art to judge of the degree of perfection they arrived at in this moft important point of it; but we have the teftimony of many authors, fome of whom fpeak as eye-witneffes, by whom we are led to believe, on convincing grounds, that their beft pictures were full fraught with this beft of good qualities; and there is no reafon to doubt the truth of the report, when we fee the fculpture of the fame period which remains to us, fo rich in poffeffion of it.

In their ftatues, which were principally of gods, a great degree of minutiæ of expreffion does not appear to have been the object of their attention, as far as relates to the paffions, the reprefentation of which they feem properly to have regarded as degrading to the dignity of a divinity. A calm unruffled ftate of mind appears in their countenances, and governs their looks and actions, but each has its appropriate character. What can be more dignified and majeftic than the countenance of the Jupiter? Yet the line which its air, partaking fomewhat of feverity, infpires, is fo blended with mildnefs, that it produces implicit confidence and veneration. The Apollo Belvedere has alfo the dignity of the godhead fhining in it; but lefs impofing and overpowering, of a milder character, and the expreffion of his figure and action is perfect; no one doubts the intent of it for an inftant; and this juft difcernment, and imprefs of character, run through the whole clafs of ftatues of the primary deities of the Greeks. The Venus, the Bacchus, the Hercules, &c. have each their diftinctive line of character without paffion, whofe influence they are fuppofed to be exalted above, whilft in the lower orders, the fauns and nymphs, and rural deities, are no lefs properly marked with characteriftic features and actions. In the figure of Laocoon deftroyed with his fons by ferpents, the authors (who were three) have exhibited a moft powerful extent of feeling and power in expreffion, remaining almoft unrivalled in fubfequent productions; the agony of pain and diftrefs of mind are fpread over the whole work which chills the beholder with horror.

Correfpondent with this powerful effect is that related of and attributed to their pictures. Pliny fays of Ariftides, "that he infufed into his pictures all the paffions of the foul." It is faid, "that Parrhafius, in his picture of Philoctetes, had renewed the pains of the hero, as feen in his parched deep funk eyes, and the tears which flowed from them;" (Anthol. lib. 4.) and the epigrammatift concludes with a handfome compliment to the painter, blaming him "for not allowing the fufferings of Philoctetes to end with his life." Philoftratus, Vita Apollonii. cap. 10. fays, fpeaking of the Ajax of Timotheus, "we cannot do juftice to the picture where Ajax is reprefented diftracted, unlefs we previoufly form in our minds the image of his condition. The picture of "Medea contemplating the Murder of her Children," by the fame painter, was the fubject of numerous epigrams (Anthologia); fo that it muft have been very powerful to excite fo much emulation among the wits to celebrate it. It was faid to reprefent in her face, fury mixed with pity of the innocence of her children, who were reprefented fmiling at the dagger in her hand. Ovid fays, "her crime was confeffed in her eyes." Plutarch fays of Lyfippus the painter, that he was ingenious as well as fublime; that from the flight inclination of the neck natural to Alexander, he invented a fublime expreffion; making him look up to the heavens with manly boldnefs, and commanding majefty. The fame author (in Timoleon) praifes the paintings of Nicomachus "for their juft expreffion," comparing them "to the poetry of Homer in grace and facility:" and Apelles in this point affirmed himfelf fuperior to other painters, though inferior in fome others of lefs importance. It is needlefs to repeat the well known ftory of Timanthe's picture of the Sacrifice of Iphigenia, and of his artifice in hiding the face of the father, having exhaufted the force of expreffion in the beholders; commendations and imitations of it are met with every where; and of his ingenious contrivance to convey an idea of the immenfe fize of a Cyclops, by drawing fome Satyrs meafuring his figure with a thyrfus; and Pliny remarks of him on this occafion, that "in all his works there is more underftood than is marked, and though his execution be mafterly, yet his ideas exceed it."

Whatever allowance be made for the zeal and ftrength of terms with which perfons at all times defcribe thofe things, than which they are unacquainted with any thing better, and which muft have been the cafe in the early periods of art, the writers not being fo learned in it as the painters who made it their continual ftudy; yet we cannot refufe belief to a wonderful extent of power in rendering expreffion among the Greek painters, accompanied, as (it has been before obferved) thefe defcriptions of it are, by the actual effect in fculpture. It is more aftonifhing that it fhould ever have been loft fight of; yet that was the cafe, and on the revival of the art of painting the old original futile means of labels, &c. were had recourfe to, till the gradual advance of learning and propriety of fentiment again reftored it in the 15th century to the juft imitation of the impreffions of nature. Maffaccio was among the firft who thus advanced it, but it was Lionardo da Vinci who firft perfected its claim to intereft over the mind, though, perhaps, in none of his works fo completely as in his reprefentation of the Laft Supper, painted on the walls of the refectory of the Dominican convent at Milan, where it fhone for a period, unrivalled in truth and vigour of expreffion.

 It

It repreſents the moment wherein our Saviour has juſt ſaid to his diſciples "One of you ſhall betray me." Each figure has intelligence beaming from it; each individual exhibits a full report of what paſſes within his boſom. How tranquilly, yet how fully does our Lord diſcloſe this forerunner of his approaching miſeries, that one of thoſe whom he had loved and cheriſhed ſhould become treacherous, and turn his bounty to his ruin; and with what propriety is he thus repreſented tranquil, yet dignified! ſo conſiſtent with his high character and office! With what eagerneſs does the impetuous Peter apply to the well deſignated meek and humble John, to learn the name of the culprit that would betray ſo good a maſter! while that conſcious culprit, hearing the requeſt, ſtarts backward with alarm, fearing the conſequences of ſuch a diſcloſure. Theſe are repreſentations ſo powerful, that it needs but the regard of a moment to comprehend all ſaid, and to be ſaid, to complete the whole intereſt of the ſtory. The timid heſitating Thomas, at a ſmall diſtance from Peter, preſſes his hand on the other's ſhoulder, to urge him to make the requeſt his own timidity prevents him from doing himſelf. The next of the apoſtles, whoſe peculiarities hiſtory hath not ſo fully recorded, are repreſented in great variety of actions and expreſſions correſponding with, and juſtly originating in, the incredible circumſtance juſt announced to them. One, with his hands preſſed on his boſom, riſing, aſſerts his innocence; another ſtarts with ſurpriſe, and, in the pious conſciouſneſs of ſinful weakneſs, ſeems to demand "Lord, is it I?" One calmly, yet earneſtly, liſtens to the reſult of the queſtion urged by Peter: others, in contraſt with him, ſeem to argue together if it be poſſible ſuch iniquity could dwell with man, and in ſo doing declare their own innocence. Anxiety is depicted as diſturbing every breaſt, yet the peculiarities of each are preſerved with the moſt juſt diſcrimination; and all appear ſo impreſſed with nature, that while it is recognized as the offspring of that great man's genius, the mere imagination of his mind, it has the appearance of a portrait of the actual ſcene. It is now unfortunately much injured by time and cleaning, being painted in oil, and not, therefore, adhering to the wall ſo perfectly as freſco.

To become able to produce a work of this ſurpriſing power in expreſſion, Lionardo ſays of himſelf, that he loſt no opportunity which the occaſions of life afforded him, of ſtoring up remarks upon the nature of its action in men. He paid much attention to anatomy, and is ſaid to have attended executions, not only to watch the looks and actions of the ſufferers, but alſo to obſerve how the different perſons compoſing the crouds of ſpectators were affected. The common occurrences of life are every day affording the attentive and ingenious artiſt leſſons on this head; and he will ſucceed, accordingly as he is intelligent and active in obſervation of them; or if he neglects to improve his mind by them, is inattentive and unfeeling to them, he can never become equal to the taſk of repreſenting them.

Michael Angelo was alſo a powerful promoter of this high quality in works of art, but his expreſſion is of a grand and more myſtic nature than Lionardo's, and it is Raffaelle alone that has approached in his own way the ſuperior excellencies of the work we have above deſcribed. "We ſtand in awe of Michael Angelo," ſays M. Fuſeli, "while we embrace Raffaelle, and follow him wherever he leads us." He has not ſucceeded well where he has attempted the ſublime. His gods are not even heroes, and his heroes are common vulgar men, except in a few inſtances; but where tenderneſs, and the amiable qualities of human nature have been his ſubject, he is not behind his great forerunner. Nor in the relation of his ſtory is he ever deficient; ſometimes, indeed, as has been obſerved on the Cartoon of Ananias ſtruck dead, under the word Energy, in *Painting*, he combines the paſt events on which it depends, and the future, to which it leads. His Cartoons of "St. Paul preaching at Athens;" the "Healing the Lame Man at Lyſtra;" "Elymas ſtruck blind," are inſtinct with feeling and expreſſion: they are but ſlightly finiſhed, and lack the extreme perfection of Lionardo's work; however, from the high degree of character to which Raffaelle has carried ſome of his heads, in his picture of the "Transfiguration," 'tis fair to ſuppoſe he could have perfected theſe, if the nature of the works (being only examples for tapeſtry) had required it. In comparing the reputation of Raffaelle to Lionardo da Vinci in this reſpect, it ſhould not be forgot that he was only 36 years old when he died, and the latter was 49 or 50 when he painted the aſtoniſhing work of the "Laſt Supper." Had Raffaelle lived to an advanced age, it is probable he would have ſurpaſſed even him. The ſimplicity and fullneſs with which he deſcribes, or effects, the relation of his ſubject, is beautifully inſtanced in the Cartoons of "St. Paul and Barnabas healing the lame Man at Lyſtra," and the conſequent adoration paid to them. The apoſtles are raiſed upon ſome ſteps above the croud, and thus diſtinguiſhed, as well as by the attention of all being directed to them. The reſtored cripple is known from the reſt, by his eager demonſtrations of gratitude and adoration; by his united and uplifted hands and animated looks, addreſſed to his reſtorers, and by the crutches now become uſeleſs, and fallen at his feet to the ground. An aged man bending forwards, lifts with one hand the garments of the healed man, to view the limb now become perfect, and ſimply by the uplifting of the other, expreſſes his admiration of the cure ſo miraculouſly effected. It is the ſimplicity of the means Raffaelle uſes, which gives ſo much the appearance of nature to his expreſſions: no one, on ſeeing the works, doubts but that he ſhould have employed the ſame means; the art is loſt ſight of. The effect of the pictures of Raffaelle, in point of expreſſion, on the artiſt who obſerves them, is much the ſame as Garrick's acting the character of a clown is ſaid to have had upon a countryman, who completely loſt ſight of the actor, and criticiſed only the ſentiments, in which, by the by, he complimented the author alſo, by ſtating that he ſhould have done the ſame himſelf. Yet it is a fact, that no point in art is ſo difficult to attain as this true ſimplicity of character with effect. Perhaps the moſt beautiful piece of expreſſion in painting known to the world, is Raffaelle's head of the Madonna della Sedia, now in Paris. The ſweetneſs of ſentiment conveyed by the mouth is completely undeſcribable: no picture has been ſo frequently copied, none ſo rarely imitated.

Titian has frequently ſucceeded in rendering expreſſion in his works, though it is not his general characteriſtic. His picture of St. Peter Martyr, before alluded to, (ſee Execution, in *Painting*,) is almoſt perfect in this, as well as in moſt other points. Indeed, when taken in the whole, we cannot help conſidering this as the moſt perfect picture in the world; poſſeſſing more of every good quality than any other we are acquainted with. It has ſtrongly the character of expreſſion, both in form, and correſpondent tone of colour. No man of feeling regards it, but with an inſtantaneous ſentiment of ſeriouſneſs; ſomewhat, indeed, of horror is inſpired by the firſt view of it; particularly by the figure of the monk who is running away, and who eyes the proffered palm of martyrdom itſelf with horror. In direct oppoſition to him is the figure of the ſaint; who, ſuffering under the power of the

the aſſaſſin, (in whoſe perſon nought but the ſentiment of brutality prevails,) turns his eyes towards the angels deſcending with the palm and crown, and hails the viſion of future glory. The hue of the picture, we have ſaid, is ſerious, and it is alſo rich and deep in colour; 'tis the effect of that hue which prevails at twilight, and is moſt judiciouſly choſen as ſuitable to the affecting nature of the ſubject. Raffaelle has employed it in his portrait of Leo X. with the cardinals Roſſi and Medici attending him. Here the ſubject was grand, and its effect is increaſed by the deep and ſerious tone of the colouring.

Pouſſin has, in ſeveral inſtances, been very happy in the expreſſion of his ſubject. One of his pictures we will mention as a very excellent model of it; 'tis the Judgment of Solomon, a picture bad in its colour, in its compoſition, and execution, but fraught with the quality we are now conſidering. The king is ſeated upon his throne, ſurrounded by his attendants, and has juſt given the command to divide the living child. A ſoldier is proceeding to execute the order, and this gives occaſion to the admirable diſplay of diverſity of feeling in the by-ſtanders. An old man ſeems coolly to reaſon with himſelf if the king can intend the performance of ſo cruel a ſentence. Another looks earneſtly forward with the vacuity of aſpect ſo commonly produced by ſurpriſe. A woman turns away her head to avoid the ſight, and her child clings to her ſide alarmed. A ſoldier regards the ſcene with a countenance fraught with pity, another turns from it with diſguſt. Whilſt the wicked, abandoned woman, who had ſlain her own child, ſeeks the deſtruction of her neighbour's alſo; the real mother implores, with an earneſtneſs never to be too much admired, the preſervation of her child; rather willing to diſown, than to ſee it deſtroyed. The expreſſion of the action of the king is completely that of conviction to whom the child belongs; he almoſt ſeems to exclaim, now I ſee the right, now I know to whom to give the award. Pouſſin has alſo in this inſtance added another uſeful indication of character in the attire of the woman, no leſs different in mind, than in habit. He has given to the vicious creature that negligence in dreſs which is too often indicative of a general habit of idleneſs and neglect; whilſt he has dreſſed the other with decent care, and propriety.

This great painter has in another picture exhibited the force of colour in rendering expreſſion, almoſt independent of form: 'tis in his picture of the deluge; one of a ſeries of four pictures meant to repreſent the four ſeaſons of the year. It is almoſt entirely of one hue. The compoſition conſiſts of little more than a large portion of ſky and water; the latter in the lower part of the picture falling in a cataract. In the diſtance is the ark, ſcarcely diſcernible through the thickneſs or dullneſs of vapour, through which the ſun is with difficulty alſo ſeen, of a reddiſh hue. In the loweſt corner of the picture is a family, conſiſting of a man, his wife, and child, endeavouring to climb from a boat upon a rock, on which a ſerpent glides along; and a little farther towards the centre are ſeen the heads of a man and horſe juſt ſinking in the water. With theſe ſlight materials has Pouſſin wrought a picture which is completely overpowering in its melancholy effect. It is ſaid that Rouſſeau would ſit enwrapt in ſilence over it for hours, gratified with the ſenſations it inſpired.

Another maſter, whoſe attempts to render expreſſions have been ſometimes very ſucceſsful, is Guido Rheni; but he ſeldom goes farther than the characters of ſaints in pious ejaculations, Magdalens in the moment of contrition, and Ecce Homos. Of the latter, there is one of ſuper-excellent perfection, in the poſſeſſion of B. Weſt, eſq. a head only, but full of feeling; ſurely "never was ſorrow like unto his ſorrow," may be as juſtly applied to the painting, as to the ſufferings of the divine original. There is an ancient painting of a Satyr's head, now in the Barberini palace at Rome, which is eminently diſtinguiſhed by expreſſion of character.

There are but few among the large maſs of the Italian and French painters who have ſucceeded in their efforts (to any pre-eminent degree) in giving expreſſion to their works in its more exalted ſenſe. Ludovico Carrache, and Domenichino have ſometimes effected it, but rarely, and Annibal Carrache ſtill leſs frequently, notwithſtanding his immenſe power in execution. Among the Flemings, Jan Stein, and Oſtade, hold the principal places. The former particularly is exceedingly happy in characterizing the aſpects and manners of that claſs of men he undertook to paint, and he does it with great freedom and eaſe. Oſtade is more laboured in his manner, but perfect in his finiſh in the confined ſcale in which he exerted himſelf. Rubens has ſometimes ſucceeded to a high degree in this quality, but, in general, the expreſſions of his figures in ſerious ſubjects are too violent, and outſtep the modeſty of nature. In the gayer ſcenes, where nymphs and fawns are fancifully indulging their humours, his power is complete; they live and breathe with all their native gaiety and animation; and in expreſſing the characters of beaſts, either calm or enraged, not even Snyder has ſurpaſſed him. Vandyke rarely appears to have felt it in his hiſtorical pictures; but in ſome of his portraits he is extremely happy. His Cardinal Bentivoglio is a perfect inſtance of expreſſion in this branch of art. His picture of lord Strafford and his ſecretary at Wentworth-houſe, Yorkſhire, is another; but the idea is taken from Titian; whoſe portraits are maſter-pieces of identical character and expreſſion, and the prototype of Vandyke's excellence. In this reſpect, ſir Joſhua Reynolds is no leſs happy than either of them: prints from whoſe pictures are in ſo many hands, and ſo generally known, that it is needleſs to exemplify the aſſertion by further remark, yet we cannot decline mentioning the picture of Mrs. Siddons in the character of the Tragic Muſe, as a very happy inſtance of his power.

Rembrandt, though ſeldom happy in repreſenting the purity of expreſſion in his figures, yet ſometimes effects it; but his great characteriſtic is the truth with which he gives expreſſion in the ſecondary ſenſe we have affixed to it, as regarding painting. To imitate the peculiarities of nature was his delight. He ſeized and expreſſed, with the greateſt truth, the moſt extraordinary effects of the illumination of objects, and gave it its greateſt poſſible brilliancy and force. In a different line, Netſcher and Metzu were highly ſkilful in the exact expreſſion of the nature of the objects they choſe to repreſent. Silks, furs, carpets, metals, &c. all are expreſſed by them with the greateſt truth, and in a free, broad ſtyle of execution, particularly by the former. Teniers, and in ſhort almoſt all the painters of the Dutch and Flemiſh ſchools, have exhibited great ability in expreſſing the character of natural objects. But to this ſtudy they ſacrificed attention to expreſſion in its more elevated and uſeful province.

Not ſo our inimitable Hogarth. Though he took the common ſcenes of nature as his field of action; and was not unſkilful in imitating the natural effect of objects; yet with him this meaner talent was of ſecondary conſideration. By his pencil he inculcates leſſons of morality, and no lectures from the pulpit are more effectually ſtrong and convincing, than thoſe conveyed by his pictures. Witneſs the Rake's, and the Harlot's Progreſs; where the evils attendant on vice, and the bleſſings which a courſe of virtue is calculated to produce, are ſo powerfully exemplified. With what force has he ſatirized pride and luxury in his Marriage-a-la-Mode; bigotry, ſuperſtition, and folly, in many of his other works!

 and

and no one has ever expreffed identical character more ftrongly than he has. The figure of the exhaufted rake in the breakfaft-fcene of the Marriage a-la-Mode, has never been furpaffed in truth and force. We could enlarge with pleafure upon his value in this point of view, but content ourfelves with recommending his works with the excellent comments upon them by Mr. J. Ireland, to the perufal and obfervation of our readers; and are proud to have fo excellent an exemplar of the value of expreffion in painting as Hogarth, whofe talents were native, unindebted to foreign fchools, in praife of whom to conclude our obfervations on this very important point.

EXPROBATION, Exprobatio, in *Rhetoric*, is the reproaching a perfon with ingratitude, and unmindfulnefs of fome particular benefit conferred upon him.

EXPUGNATION, in *Military Language*, the taking of any place by affault.

EXPULSION, the act of driving a man by force out of a city, community, or the like.

Expulsion is alfo ufed for the act of driving out a foreign body with violence from the place it was in.

The uterus has the chief office in the expulfion of the fœtus: if the expulfion of the fœtus happen very foon after conception, it is called a *falfe birth*. See Delivery, Foetus, and Labour.

EXPURGATION, in *Aftronomy*, is ufed by fome authors for that ftate or action of the fun, wherein, after having been eclipfed and hid by the interpofition of the moon, it begins to appear again.

Later aftronomers call this emerfion, not expurgation.

EXQUIMA, in *Zoology*, the name of a fpecies of monkey common on the coaft of Guinea, of which Ray enumerates two or three varieties. See Simia.

EXSIBIDANTES, in *Antiquity*, a kind of hiffers, who, in the theatre, and other public auditories, ufed to make a noife with their feet, and even fometimes beat the feats with battons.

EXSICCATION, formed of *ex* and *ficcus*, *dry*, in *Chemiftry*, *Pharmacy*, &c. the act of drying up or evaporating the moifture of a thing. For this purpofe two methods are ufually employed: in one of which the humidity is evaporated by heat, and in the other it is imbibed or abforbed by fubftances adapted to the purpofe. Bodies combined with, or diffolved in a fluid, require the firft mode, and to fuch as are only fuperficially blended with it, the fecond mode is applicable. Vegetables are commonly exficcated by the natural warmth of the air, though the affiftance of artificial heat is often very ufeful. By a moderate fire the more tender flowers may be foon dried without any confiderable lofs, either of their odour or lively colour, which would be injured, if not deftroyed, by a more flow exficcation in the air. Some plants, particularly thofe of the more acrid kind, lofe their virtues by this procefs.

EXSORS Particula. See Particula.

EXSUCCATIO, a word ufed by fome *Chirurgical Writers*, to exprefs an enchymofis, or fuggillation.

EXSUFFLATION, a ceremony obferved in baptifm, by which the candidate was fuppofed to renounce the devil. See Baptism.

EXTACY, Εξςασις, a rapture, or removal of the mind out of its natural ftate and fituation; or a tranfport, whereby a perfon is hurried out of himfelf, and the office of his fenfes is fufpended. See Enthusiasm.

Extacy, in *Medicine*. See Ecstasis.

EXTANT, fomething that ftill fubfifts, or is in being. It is but part of the hiftory of Livy, of the writings of Cicero, Cæfar, &c. that are extant, the reft are loft. We have nothing extant of Socrates, though he wrote a great deal.

EXTEMPORANEOUS Prescription. See Prescription.

Extemporaneous *Playing*, flights in *Mufic*, on a harpfichord, or piano forte, have many appellations; as toccata, toccatina, *Ital.* prelude, capriccio. On the organ it is called a voluntary.

There have been organifts, whofe abilities in unftudied effufions on their inftruments have almoft amounted to infpiration, fuch as Sebaftian Bach, Handel, Marchand, Couperin, Kelway, Stanley, Worgan, and Keeble, feveral of whom played better mufic extempore, than they could write with meditation.

EXTEND, in the *Manege*. To extend a horfe, is an expreffion ufed by fome to import the fame with making a horfe go large. See Large.

Extend, in *Military Language*. When the files of a line, or the divifions of a column, are to occupy a greater fpace of ground, they are faid to extend their front or line.

Extend, in *Law*. See Extending.

EXTENDENDA Terra. See Terra.

EXTENDI Facias, in *Law*, a writ of extent, whereby the value of lands is commanded to be made and levied, &c. Reg. Orig. See Extent.

EXTENDING, in a *Legal Senfe*, fignifies the valuing of lands and tenements of one bound by ftatute, &c. and who hath forfeited his bond at fuch an indifferent rate, as that by the yearly rent the obligator may in time be fully paid his debt. See Extent.

EXTENSION, in *Philofophy*, is one of the general and effential properties of matter; the extenfion of a body being the quantity of fpace which the body occupies, the extremities of which limit, or circumfcribe, the matter of that body. It is otherwife called the *magnitude*, or *fize*, or *bulk* of a body.

A quantity of matter may be very fmall, or fo as to elude the perception of our fenfes, fuch as a particle of air, a particle of water, &c.; yet fome extenfion it muft have, and it is by the comparifon of this extenfion, that one body is faid to be larger than, equal to, or fmaller than, another body. The meafurement of a body confifts in the comparifon of the extenfion of that body with fome determinate extenfion, which is affumed as a ftandard, fuch as an inch, a foot, a yard, a mile; hence it is faid, that a body is a foot long, or three inches long, &c.

The extenfion of a body is meafured three different ways; or a body is faid to have length, breadth, and thicknefs. Thus an ordinary fheet of writing paper is about 16 inches long, about 14 inches broad, and nearly one hundredth part of an inch thick. Either of thefe dimenfions might be called the length, or the breadth, or the thicknefs; but, by general cuftom, the greateft extenfion is called the length, the next is called the breadth, and the fhorteft is called the thicknefs. The outfide of a body, its boundary, or that which lies contiguous to other bodies that are next to it, is called the *furface* of that body, and this furface has two dimenfions only, *viz.* length and breadth; but it has no thicknefs, for if it had, it would not be the outfide of the body; yet a furface by itfelf cannot exift. In mathematics, however, furfaces are mentioned, and are reafoned upon, abftractly from matter. But in thefe cafes the furfaces exift in the imagination only, and even then our ideas have a reference to body, for our fenfes cannot perceive a furface without a body.

As a furface is the outfide or boundary of a body, fo a line

line is the boundary of a finite furface. Suppofe, for inftance, that a furface is divided into two parts, the common boundary of the two parts is called a line; and this has one extenfion only, *viz.* it has length.

The beginning, or the end of a line, or the interfection of two lines which crofs each other, is called a *point*, and this has no dimenfions; or, according to the mathematical definition, a point is that which has no parts or magnitude. Thus, if you divide a line into two parts, the divifion or boundary between the two parts is a point.

Our fenfes are only capable of perceiving bodies which have three dimenfions; or rather the furfaces of bodies, which furfaces have two dimenfions, but a furface cannot be reprefented nor perceived without a body, and of courfe neither a line nor a point can be perceived without a body. In the ftudy of geometry, and in a variety of other branches, furfaces, lines, and points are reprefented upon paper, or upon fomething elfe; but in thofe cafes, the paper or that fomething elfe is the body whofe furface we perceive, and the furface of a particular figure is circumfcribed, not by real lines, but by a narrow flip of furface, which is fufficient to direct our reafoning with refpect to the geometrical properties of lines and furfaces. Thus alfo when points are reprefented by themfelves, the marks are not real points, but very fmall portions of the furface of a body.

There is a cafe in which extenfion is often faid to be perceived without the exiftence of a body, and this is the extenfion between two bodies. But, upon confideration, it will eafily be comprehended, that we may perceive the two bodies, and that they are feparate from each other; but we cannot perceive any thing pofitive between them. So that in this cafe the word extenfion is ufed in a figurative manner, as if fome other body exifted between the two bodies.

The particular extenfion, whether under the name of inch, foot, yard, metre, league, &c. with which other extenfions are compared, or by which they are meafured, are eftablifhed only by the common confent or agreement of perfons of a certain nation, or profeffion, and are ufed as ftandard meafures by them only. Hence, the meafures of different nations, though fometimes they have the fame name, do, however, differ confiderably from each other. Great endeavours have been made by divers ingenious perfons, at different times, for the purpofe of determining an unalterable univerfal ftandard of meafures; but thofe endeavours, and the fucceffes with which they have been attended, will be found defcribed under the article STANDARD *of Meafures.*

Extenfion is ufually defcribed as confifting in the fituation of parts beyond parts, with which fome authors cavil, maintaining, that we can conceive abfolute extenfion without any relation to parts.

If a man confider the diftance between two bodies abftractedly, and without any regard to bodies which may fill that interval, it is called fpace; and when he confiders the diftance between the extremes of a folid body, it is called extenfion.

Extenfion is frequently confounded with quantity and magnitude; and, for what we can perceive, without much harm, the thing fignified by them all appearing to be the fame; unlefs we admit a diftinction made by fome authors, that the extenfion of a body is fomething more abfolute, and its quantity and magnitude more refpective, or implying a nearer relation to much and little. See QUANTITY, MAGNITUDE, MASS, and MATTER.

The infinite divifibility of extenfion has been a famous queftion in all ages. It is not eafy to reconcile the doctrine of mathematicians on this head with the tenets of fome philofophers. They who hold that all extenfion and magnitude are compounded of certain *minima fenfibilia;* and that a line, for inftance, cannot increafe or decreafe, but by certain indivifible increments or decrements only, muft, confiftently with themfelves, affirm, that all lines are commenfurable to each other, contrary to the tenth book of Euclid, who demonftrates that the diagonal of a fquare is incommenfurable to its fide. But if all lines were compofed of certain indivifible elements, it is plain one of thofe elements muft be the common meafure of the diagonal and the fide. This is a gordian knot which none of the philofophers have yet thought fit to untie.

Bifhop Berkeley obferves, that the infinite divifibility of finite extenfion, though it is not exprefsly laid down either as an axiom or theorem in the elements of geometry, yet is throughout the fame every where fuppofed, and thought to have fo infeparable and effential a connection with the principles and demonftrations in geometry, that mathematicians never admit it into doubt, or make the leaft queftion of it. (See DIVISIBILITY.) And as this notion is the fource from whence do fpring all thofe amufing geometrical paradoxes, which have fuch a direct repugnancy to the plain common fenfe of mankind, and are admitted with fo much reluctance into a mind not yet debauched by learning; fo is it the principal occafion of all that nice and extreme fubtility which renders the ftudy of mathematics fo difficult and tedious. Hence, fays he, if we can make it appear, that no finite extenfion contains innumerable parts, or is infinitely divifible, it follows, that we fhall at once clear the fcience of geometry from a great number of difficulties and contradictions which have ever been efteemed a reproach to human reafon, and withal make the attainment thereof a bufinefs of much lefs time and pains than it hitherto hath been.

Every particular finite extenfion, which may poffibly be the object of our thought, is an idea exifting only in the mind, and confequently each part thereof muft be perceived. If therefore, fays this author, I cannot perceive innumerable parts in any infinite extenfion that I confider, it is certain they are not contained in it; but it is evident, that I cannot diftinguifh innumerable parts in any particular line, furface or folid, which I either perceive by fenfe, or figure to myfelf in my mind; wherefore, I conclude they are not contained in it. Nothing can be plainer to me than that the extenfions I have in view are no other than my own ideas; and it is no lefs plain, that I cannot refolve any one of my ideas into an infinite number of other ideas; that is, that they are not infinitely divifible. If by an infinite extenfion be meant fomething diftinct from a finite idea, I declare I do not know what that is, and fo cannot affirm or deny any thing of it. But if the terms extenfion, parts, and the like, are taken in any fenfe conceivable; that is, for ideas; then to fay a finite quantity or extenfion confifts of parts infinite in number, is fo manifeft a contradiction, that every one at firft fight acknowledges it to be fo. New Theory of Vifion, § 54, 55. Analyft. § 31.

On the other hand, it is obferved by an eminent mathematician, that geometricians are under no neceffity of fuppofing that a finite quantity or extenfion confifts of parts infinite in number, or that there are any more parts in a given magnitude than they can conceive or exprefs: it is fufficient that it may be conceived to be divided into a number of parts equal to any given or propofed number; and this is all that is fuppofed in ftrict geometry concerning the divifibility of magnitude. It is true, that the number of parts into which a given magnitude may be conceived

to

to be divided, is not to be fixed or limited, becaufe no given number is fo great but a greater than it may be conceived and affigned: but there is not therefore any neceffity for fuppofing that number infinite; and if fome may have drawn very abftrufe confequences from fuch fuppofitions, they are not to be imputed to geometry. Geometricians are under no neceffity of fuppofing a given magnitude to be divided into an infinite number of parts, or to be made up of infinitefimals; neverthelefs, they cannot fo well avoid fuppofing it to be divided into a greater number of parts than may be diftinguifhed in it by fenfe in any particular determinate circumftance. But they find no difficulty in conceiving this; and fuch a fuppofition does not appear to be repugnant to the common fenfe of mankind, but on the contrary to be moft agreeable to it, and to be illuftrated by common obfervation. It would feem very unaccountable not to allow them to conceive a given line, of an inch in length for example, viewed at the diftance of 10 feet, to be divided into more parts than are difcerned in it at that diftance; fince by bringing it nearer, a greater number of parts is actually perceived in it. Nor is it eafy to limit the number of parts that may be perceived in it when it is brought near to the eye, and is feen through a little hole in a thin plate? or, when by any other contrivance it is rendered diftinct at fmall diftances from the eye. If we conceive a given line that is the object of fight to be divided into more parts than we perceive in it, it would feem that no good reafon can be affigned why we may not conceive tangible magnitude to be divided into more parts than are perceived in it by the touch; or a line of any kind to be divided into any given number of parts, whether fo many parts be actually diftinguifhed by fenfe, or not. In applying the reafonings and demonftrations of geometricians on this fubject, it ought to be remembered, that a furface is not confidered by them as a body of the leaft fenfible magnitude, but as the termination or boundary of a body; a line is not confidered as a furface of the leaft fenfible breadth, but as the termination or limit of a furface; nor is a point confidered as the leaft fenfible line, or a moment as the leaft perceptible time; but a point as a termination of a line, and a moment as a termination of a limit of time. In this fenfe they conceive clearly what a furface, line, point, and a moment of time is; and the poftulata of Euclid being allowed and applied in this fenfe, the proofs by which it is fhewn, that a given magnitude may be conceived to be divided into any given number of parts, appear fatisfactory; and if we avoid fuppofing the parts of a given magnitude to be infinitely fmall, or to be infinite in number, this feems to be all that the moft fcrupulous can require. See Maclaurin's Treatife of Fluxions, art, 290, 291.

Dr. Reid, in his "Inquiry into the Human Mind, on the Principles of Common Senfe," endeavours to obviate the difficulties fuggefted by Berkeley, by overturning the fyftem of ideas eftablifhed by Mr. Locke. According to his theory, it is abfurd to deduce from fenfation the firft origin of our notions of external exiftence, of fpace, motion, and extenfion, and all the primary qualities of bodies; they have, he fays, no refemblance to any fenfation, or to any operation of our minds, and therefore they cannot be ideas either of fenfation or reflection; nor can he conceive how extenfion, or any image of extenfion, can be in an unextended and indivifible fubject like the human mind.

Extension, in the *Ancient Mufic*, according to Ariftoxenus, was one of the four parts of the melopœia, which confifted in fuftaining certain founds longer than their quantity ftrictly required. We call thefe binding-notes, and fometimes perhaps tempo rubato. See Compass.

Extension *of Fractured Limbs*. See Fracture.

EXTENSOR, in *Anatomy*, a name given to thofe mufcles which have the ufe of extending or making ftraight thofe parts to which they are attached.

Extensor *brevis digitorum pedis*; calcaneo-fus-phalangettien commun, is a thin and flat mufcle, placed on the fuperior or convex furface of the foot. Poffeffing a fomewhat quadrilateral figure behind, it divides into four flat tendons in front. It arifes from the upper and front part of the os calcis, and from the ligament which connects that bone to the aftragalus. Thence its fibres are continued obliquely forwards and inwards, and divide into four fecondary fafciculi, (of which the two innermoft are the largeft,) giving origin to the fame number of tendons; which, in paffing over the metatarfus, crofs thofe of the extenfor longus, and terminate in the toes. The firft, on the infide, is attached to the upper furface of the metatarfal extremity of the firft phalanx of the great toe: the three fucceeding tendons become intimately attached to the external edge of the correfponding tendons of the extenfor longus, and are connected at the firft joints of the toes, as well as thofe of the latter mufcle, with the tendons of the lumbricales and interoffei. They extend over the fecond phalanges, and are inferted in the third.

Covered on its external furface by the tendons of the extenfor longus and peroneus tertius, and by the aponeurofis of the back of the foot, this mufcle lies upon the anterior phalanx of the tarfus, upon the metatarfus, and the phalanges.

It extends and elevates all the phalanges of the toes, at the fame time turning them rather outwards.

Extensores *carpi radiales*. See Carpi.

Extensor *carpi ulnaris*. See Carpi.

Extensor *communis digitorum manus*; epicondylo-fus-phalangettien commun; extenfive digital; a mufcle belonging to the fingers, fituated on the pofterior or dorfal furface of the fore-arm, hand, and fingers; elongated, fomewhat rounded and flefhy above, and divided into four tendons below.

It arifes above, by means of a tendon common to it with the furrounding mufcles, from the external condyle of the humerus; is connected internally to a tendinous partition, which feparates it from the extenfor of the little finger, externally to a fhorter feptum placed between it and the extenfor carpi radialis brevior, and pofteriorly to the fafcia of the fore-arm. The fibres, uniting together obliquely from thefe origins, form a mufcle, at firft thin, and afterwards more confiderable, which is divided, towards the middle of the fore-arm, into four portions, united at firft by cellular fubftance, then feparating, and giving origin to the fame number of tendons. Thefe at firft are connected by a loofe cellular fubftance, pafs together with the tendon of the indicator under the annular ligament at the back of the wrift, and in a fuperficial groove of the radius, furrounded by a burfa mucofa, then diverge towards the fore fingers, and become completely flattened. They are often fplit longitudinally, and are united to each other, at the back of the hand, by crofs flips of tendon and their aponeurofes. At the firft joints of the fingers the broad thin tendons of the extenfor communis are joined, on either fide by the tendinous expanfions of the lumbricales and interoffei, and completely cover the articulation. They divide, at their extremities, into three portions, the middle of which are inferted in the fecond phalanges of the fore-fingers; while the lateral divifions, running along the fides of thefe phalanges, are inferted clofe together into the third.

This mufcle is covered by the aponeurofis of the fore-arm, the annular ligament and ſkin. It covers the ſupinator radii brevis, the extenſors of the thumb and fore-finger, the carpus, metacarpus, interoſſei muſcles, and poſterior ſurface of the phalanges.

The annular ligament at the back of the fore-arm conſiſts of a broad, thin, and flat, but ſtrong fibrous expanſion, extended from the outer part of the carpal extremity of the radius, over all the extenſor tendons at the back of the wriſt, and connected to the end of the ulna, and to the os piſiforme. It confines the tendons to the ſurface of the bones. Thoſe of the common extenſor are ſurrounded, as they paſs under it, by a ſynovial membrane, in which we may diſtinguiſh a cavity containing the membranes completely iſolated, and a ſuperior and inferior cul de ſac, where the membrane is reflected over the tendons. The ſynovial membranes of the firſt joints of the fingers are cloſely connected to the tendons of the extenſor communis, where they paſs over thoſe joints.

This muſcle extends the different joints of the fingers; and afterwards, or if the fingers are bent by their flexors, it extends the wriſt upon the fore-arm.

Extensor *indicis*. See Indicator.

Extensor *longus digitorum pedis*; peroneo-tibi-ſus-phalangettien commun; grand extenſeur; is a long, thin muſcle, flattened laterally, and placed at the outer and anterior part of the leg, and upper part of the foot. It ariſes above from the external tuberoſity of the tibia, from a ſmall aponeurotic ſeptum which ſeparates it from the tibialis anticus, and from the anterior ligaments of the peroneo-tibial articulation; behind from five or ſix inches of the upper and anterior part of the fibula; before, at its upper part, from the aponeuroſis of the leg; and externally, from a broad aponeurotic ſeptum, which ſeparates it from the two peronei. The ſuperior fibres deſcend perpendicularly, the inferior ones more and more obliquely, to end in a common tendon at firſt concealed in the ſubſtance, but, from the middle of the leg, occupying the anterior edge of the muſcle. It divides into three or four portions, which paſs together behind the annular ligament: below which part we always ſee four ſeparate tendons diverging over the convexity of the foot, aſſuming a broad and flattened form, and croſſing the direction of the tendons of the extenſor brevis, in their paſſage to the four ſmaller toes. At the firſt joints of the toes theſe tendons are connected to thoſe of the extenſor brevis, and of the lumbricales and interoſſei, as in the hand, and they have ſimilar inſertions to thoſe of the extenſor communis digitorum, which ſee.

In the leg, this muſcle, on its inner ſurface, is ſeparated above by the anterior tibial veſſels from the tibialis anticus; lower down it is contiguous, on the ſame aſpect, with the extenſor proprius hallucis: externally it is in contact with the peronei; and the aponeuroſis of the leg covers it on the front. At the ankle it runs in a peculiar cavity of the ſtrong tranſverſe annular ligament, which binds it firmly down in its place. Here the tendons are ſurrounded by a ſynovial membrane. In the foot it is covered by the ſkin, and covers the extenſor brevis and phalanges.

This muſcle extends the toes, and afterwards bends the ankle joint. If the foot be fixed to the ground, it may either maintain the leg erect upon the foot, or carry it forwards.

Extensor *longus pollicis pedis*; or *proprius*; peroneo-ſus-phalanginien du pouce; thin, elongated and flattened in its form, it lies on the inſide of the preceding muſcle. It ariſes from the inner and anterior part of the fibula, and neighbouring portion of the interoſſeous ligament, for a ſpace of five or ſix inches, beginning about two inches below the upper end of the fibula. Its fibres paſs obliquely downwards and forwards, parallel to each other, and joining a tendon which runs along their anterior edge, conſtitute a ſingle penniform muſcle. The tendon goes behind the annular ligament, in a peculiar burſa mucoſa, runs along the inner edge of the metatarſus, and paſſing over the firſt, terminates in the ſecond phalanx of the great toe. Sometimes a ſmall portion of its tendon is inſerted in the firſt phalanx.

This muſcle is placed between the tibialis anticus, the anterior tibial veſſels and nerves being however interpoſed, and the extenſor longus digitorum. On the front it is covered by the aponeuroſis of the leg, the annular ligament, and the integuments. Its tendons lie on the lower end of the tibia, the tarſus, metatarſus, and phalanges of the great toe, and is cloſely connected to the ſynovial membrane of the firſt joint of that toe.

It extends the two joints of the great toe, and acts upon the foot in the ſame manner as the preceding muſcle.

Extensor *major pollicis*. See Extensores *pollicis*.

Extensor *minor pollicis*. See Extensores *pollicis*.

Extensor *oſſis metacarpi pollicis*. See Extensores *pollicis*.

Extensores *pollicis*; are three muſcles belonging to the three bones of the thumb.

Extensor *primi internodii*; extenſor oſſis metacarpi pollicis; abductor pollicis longus of Albinus; cubito-radi-ſus-metacarpien du pouce; grand abducteur du pouce; is a muſcle of an elongated, thin, and flattened form, ſituated obliquely on the back of the fore-arm. It ariſes above from the ulna, below the ſupinator radii brevis; from the interoſſeous ligament; and from the radius juſt below the inſertion of the ſupinator brevis. The fleſhy fibres unite together from theſe origins to form a flattened faſciculus at firſt ſmall, but afterwards larger, which croſſes the fore-arm obliquely from above downwards, and from the radial towards the ulnar ſide. Towards the lower extremity of the radius it terminates in a tendon, which runs in a ſmall groove on the outer ſide of the carpal extremity of the bone. Here it is ſurrounded by a hollow burſa, common to it with the tendon of the next muſcle. It is inſerted, generally by means of ſeveral more or leſs diſtinct portions, into the radial ſide of the carpal end of the firſt phalanx of the thumb. One of theſe portions is often connected with the abductor pollicis.

It is covered, in its fleſhy portion, by the extenſor carpi ulnaris, extenſor ſecundi internodii, extenſor proprius auricularis, and communis digitorum; and it covers the radius, ulna and interoſſeous ligament. Its tendon is covered by the aponeuroſis of the fore-arm, and covers the extenſores carpi, the radius, radial artery, and joint of the wriſt.

It extends the firſt bone of the thumb, when that has been bent towards the palm of the hand. It carries the thumb away from the other fingers; and it may move the whole hand towards the radius.

Extensor *ſecundi internodii*; extenſor minor pollicis; cubito-ſus-phalangien du pouce; is an elongated and ſlender muſcle, ſituated cloſe to the former, and lying on its ulnar edge. Ariſing from the interoſſeous ligament and radius, it croſſes the direction of the fore-arm, like the former, and forms a ſlender tendon, which cloſely accompanies that of the preceding muſcle. It paſſes along the firſt, and is inſerted in the ſecond phalanx of the thumb. It is covered by the extenſor tertii internodii, proprius auricularis, and digitorum communis, by the aponeuroſis of the fore-arm, and the integuments. It lies upon the bones of the fore-arm and the interoſſeous ligaments, the extenſores carpi radiales, the

joint

joint of the wrift, and the firft bone of the thumb. It extends the firft and fecond joints of the thumb, and carries it into the ftate of abduction. It may draw the whole hand towards the radius.

Extensor *tertii internodii*; extenfor major pollicis; cubito-fus-phalangettien du pouce; is an elongated and flender mufcle, placed clofe on the ulnar edge of the former, and following the fame general direction. It arifes from the middle third of the pofterior furface of the ulna, and a very little from the interoffeous ligament; and croffes the fore-arm obliquely towards the thumb. Surrounded by a hollow burfa, it runs along a peculiar groove of the radius, being placed about an inch on the ulnar fide of the preceding tendons. It paffes along the ulnar fide of the firft phalanx of the thumb; is connected with the infertion of the preceding tendon in the fecond phalanx, and terminates in the third. Situated at its origin between the bones of the fore-arm and interoffeous ligament, and the extenfor communis, proprius auricularis, and carpi ulnaris, it afterwards runs in its peculiar groove: it is then fub-cutaneous, and lies on the extenfores carpi, joint of the wrift, and bones of the thumb. It extends all the joints of the thumb, and at the fame time rather carries it towards the fingers. It will alfo act as an extenfor of the wrift.

Extensor *proprius auricularis*, or digiti minimi; epicondylo-fus-phalangettien du petit doigt; is a thin, flender, and elongated mufcle, fituated in the firft or fuperficial layer of the back of the fore-arm, and placed clofe along the ulnar fide of the extenfor digitorum communis. It arifes above by means of the common tendon, from the external condyle of the humerus; on the outfide, from a feptum, which feparates it from the extenfor communis; on the infide, from one interpofed between it and the flexor carpi ulnaris; and behind, from the aponeurofis of the fore-arm. It gives origin to a flender tendon, which paffes in a feparate canal of the annular ligament, and forming the tendon which the little finger receives from the extenfor communis, is inferted together with it into that finger. On the fore-arm, this mufcle is covered by the fafcia, and covers the fupinator brevis, the extenfors of the thumb, and the indicator. The extenfor communis lies on its outfide, and the extenfor carpi ulnaris on the infide. Its tendon is furrounded by a tendinous fheath, lined with a fynovial membrane, at the wrift; and afterwards is covered by the integuments lying on the laft metacarpal bone, and on the phalanges of the little finger. It extends the little finger, and afterwards moves the wrift in the fame direction; it will carry the little finger rather in the direction of abduction.

Extensor *proprius pollicis pedis*. See Extensor *longus pollicis pedis*.

Extensor *tarfi minor*, a name given by Douglas to the plantaris, which fee.

Extensor *tarfi furalis*, or magnus; a name under which Douglas claffes the gaftrocnemius and foleus. See thofe words.

EXTENT, or Extendi Facias, in *Law*, fometimes denotes a writ or commiffion to the fheriff for the valuing of lands and tenements; fometimes the act of the fheriff or other commiffioner upon this writ; and fometimes the eftimate or valuation of lands, *per proprios viros;* which, when taken at the utmoft value or extent, furnifh our extended, or rack-rents. Fleta. lib. ii.

This is a fpecies of *execution* (which fee) upon fome profecutions given by ftatute; as in the cafe of recognizances or debts acknowledged on ftatutes-merchant, or ftatutes-ftaple; upon forfeiture of which, the body, lands, and goods may be all taken at once, to compel the payment of the debt. And by ftatute 33 Hen. VIII. c. 39. all obligations made to the king fhall have the fame force, and of confequence the fame remedy to recover them, as a ftatute-ftaple; though, indeed, before this ftatute, the king was entitled to fue out execution againft the body, lands, and goods of his accountant or debtor. (3 Rep. 12.) And his debt fhall, in fuing out execution, be preferred to that of every other creditor, who hath not obtained judgment before the king commenced his fuit. The king's judgment alfo affects all lands, which the king's debtor hath at or after the time of contracting his debt, or which any of his officers, mentioned in the ftatute 13 Eliz. c. 4. hath at or after the time of his entering on the office; fo that, if fuch officer of the crown alienes for a valuable confideration, the land fhall be liable to the king's debt, even in the hands of a *boná fide* purchafer; though the debt due to the king was contracted by the vendor many years after the alienation. (10 Rep. 55, 56.) Whereas judgments between fubject and fubject reverted, even at common law, no farther back than the firft day of the term in which they were recovered, in refpect of the lands of the debtor; and did not bind his goods and chattels, but from the date of the writ of the execution: and now, by the ftatute of frauds, 29 Car. II. c. 3. the judgment fhall not bind the land in the hands of a *boná fide* purchafer, but only from the day of actually figning the fame; which is directed by the ftatute to be punctually entered on the record; nor fhall the writ of execution bind the goods in the hand of a ftranger, or a purchafer (Skin. 257.); but only from the actual delivery of the writ to the fheriff or other officer, who is therefore ordered to endorfe on the back of it the day of his receiving the fame. Blackft. Comm. book iii.

EXTENUATION, the act of diminifhing or leffening the bulk or fubftance of a thing, efpecially of the human body. Fevers, agues, long abftinences, &c. occafion great extenuations or emaciations.

Extenuation is alfo a figure in *Rhetoric*, oppofite to the hyperbole. The Greeks call it λιτότης.

EXTERIOR *Polygon, Talus*. See the fubftantives.

EXTERMINATION, formed of *ex* and *terminus*, *boundary*, the act of extirpating, or totally deftroying a people, race, family, &c.

The Jews have been exterminated out of Portugal, the Moors out of Spain, the Albigenfes out of France, &c. Philip the Fair of France, to be revenged on the Knights Templars, took a refolution, in 1307, to exterminate them.

Extermination, or *Exterminating*, in *Algebra*, is ufed for taking away. Thus algebraifts fpeak of exterminating furds, fractions, and unknown quantities out of equations. See Maclaur. Algebr. part i. chap. 12, where we have fome general theorems for the exterminating unknown quantities in given equations. See Equation.

EXTERNAL, or Exterior, a term of relation, applied to the furface or outfide of a body; or that part which appears or prefents itfelf to the eye, touch, &c. In which fenfe it is oppofed to *internal* or *interior*.

The fenfes are divided into external, which are thofe whereby we perceive ideas, or have the perception of external objects; as feeing, hearing, &c. and internal. See Sense.

External is alfo ufed to exprefs any thing that is with-outfide a man, or that is not within him, and particularly in his mind. In which fenfe we fay external objects, &c.

The exiftence of an external world, *i. e.* of bodies and objects out of the mind, is a thing which has been greatly called

called in queftion by Dr. Berkeley and others. See Existence, Body, and Quality.

External *Angles*. See Angles, *external.*

External *Denomination, Ear, Modes, Place.* See the fubftantives.

EXTERNUS Auris, in *Anatomy*. See Ear.

Externus *Cubitæus*. See Cubitæus.

Externus *Duvèrni*, a name given by Douglas to one of the mufcles of the ear, called by Cowper and others obliquus auris, and by Albinus externus mallei. See Ear.

Externus *Gaftrocnemius, Iliacus.* See the fubftantives.

Externus *Mallei.* See Ear.

Externus *Orbiter, Pterigoideus, Vaftus, Rectus Capitis,* See the feveral articles.

EXTINCTION, the act of extinguifhing, that is, of putting out, or deftroying, fire, flame, or light.

The Ariftotelians account for the extinction of fire from the principle of contrariety; thus, fay they, water puts out fire, becaufe the qualities of water are contrary to thofe of fire, the one being cold and moift, and the other hot and dry. But how far this will go, may appear hence, that fire is extinguifhed by hot water as readily as cold; nay, even by oil, earth, &c.

Some of the moderns offer two more plaufible caufes of extinction; *viz.* diffipation, as when the next immediate fuel of the flame is difperfed and blown off by too forcible a wind; and fuffocation, when it is fo compreffed, that its free motion cannot be maintained; as happens upon throwing water, &c. thereon. Various preparations and engines have been contrived for extinguifhing accidental fires. See Fire.

Boerhaave denies that there is properly any fuch thing as extinguifhing of fire; it is a body *fui generis*, of an immutable nature, and we can no more extinguifh or deftroy it than we can create it.

Extinction, in *Chemiftry* and *Pharmacy*, is when a metal, mineral, or the like body, after having been heated red-hot in the fire, is plunged in fome fluid, either to foften or temper its acrimony, as tutty in rofe-water; or to communicate its virtue to the liquor, as iron or fteel to common water; or, laftly, to give it a temper, as in the extinction of fteel in water, or fome other preparation.

EXTINGUISHER, Self-acting, is a contrivance whereby a candle can be extinguifhed at any given time after being lighted. There are feveral ways by which this can be effected. The moft fimple is placing the candle in a veffel of water, with fuch a length above the furface as will burn as long as a light is wanted; of courfe when the candle burns down to the water it will be extinguifhed.

Figs. 10 and 11, *Plate* XII. *Mifcellany*, reprefent two neat mechanical contrivances for the above purpofe; in *fig.* 10, *a a* is a brafs clip, formed of two pieces, and jointed together by the pin, *b*, by means of a fliding ring, *d*; this clip can be clofed round the candle fo as to fix firmly thereto; the pin, *b*, has a joint in the upper end to receive a crooked lever, *e*, which has a conical extinguifher faftened at the other end of it. This extinguifher is held up from falling upon the candle, by means of a fmall wire, *f*, which is bent fideways at the end, and thruft into the candle, at the place where it is intended to be put out; as the tallow is confumed, it becomes fo foft as to be unable to fuftain the preffure of the wire, *f*, which therefore flies forward, and the extinguifher falls upon the candle. It muft be obferved that the wire, *f*, muft only be put into the tallow, but not in the wick, as it might not then fall down quickly.

Fig. 11 is another extinguifher, invented by Mr. J. J. Hawkins, and placed in his mufeum of mechanical inventions: *a a* is a pair of nippers, made of tinned iron plate, and jointed in the middle; between the outer ends a piece of watch-fpring is fixed, which caufes the ends, *b*, to clofe upon the candle, and thus hold the extinguifher on the candle. The centre-pin of the joint is long enough to ferve for the centre of another clip, *b b*, which is exactly fimilar to the lower one, except that inftead of the bow to embrace the candle, two wires, *e*, *e*, are fixed to the ends, to fhut the extinguifher, which is compofed of two flat plates, *f*, *f*, which open and fhut upon the joint, *g*. The fpring between the ends of the nippers, *b*, *b*, has a conftant tendency to clofe the extinguifher, but is prevented from fhutting by the candle. When the candle burns away, it becomes foft at the place where the extinguifher bites the fpring, then fhuts it up, and puts out the light.

EXTINGUISHMENT, in *Law*, is ufed for a confolidation. Thus, if a man, having a yearly rent due to him out of my lands, afterwards purchafe the fame lands; both the property and rent, becoming confolidated, or united in one poffeffor, the rent is faid to be extinguifhed.

So, where a man has a leafe for years, and afterwards buys the property, there is a confolidation of the property, and an extinguifhment of the leafe.

But if a man have an eftate in land merely for life or years, and hath a higher eftate in a fee-fimple, in the rent, this rent is not extinguifhed, but in fufpence for a time; for, after the term, the rent fhall revive. (Terms de Ley.) See Release.

So alfo, if there be lord mefne and tenant, and the lord purchafe the tenancy, the mefnalty is extinct.

Likewife by purchafing of lands wherein a perfon hath common appendant, the common is extinguifhed. (Cro. El. 594.) A releafe of common in one acre, is an extinguifhment of the whole common. Shower's Rep. 350.

And where a perfon hath common of vicinage, if he inclofes any part of the land, all the common is extinct. (1 Brownl. 174.) If a man hath a highway appendant to land, and afterwards purchafeth the land wherein the highway is, the way is extinct: though it is held, that a way of neceffity to a market or church, or to arable land, is not fo extinguifhed. 11 Hen. VII. 25 Co. Litt. 155.

Extinguishment *of a copyhold* takes place on any act of the copyholder's, which denotes his intention to hold no longer of his lord, and amounts to a determination of his will. (Hutt. 81. Cro. Eliz. 21. 1 Jon. 41.) As if a copyholder in fee accepts a leafe for years of the fame land from the lord, or accepts an affignment of a leafe made to another from the leffee, his copyhold is extinct. (Moor. 184. 2 Co. 166. Godb. 11. 101.) A copyhold eftate is extinct whenever it becomes not demifeable by copy. Coke's Copyholder, 62. See Copy-hold.

Extinguishment *of debt* happens in a variety of cafes. Thus, if a creditor accepts a higher fecurity than he had before, or accepts a bond for a legacy, the firft debt or legacy is hereby extinguifhed.

Extinguishment *of liberties.* If liberties and franchifes granted by the king, fuch as felon's goods, waifs, ftrays, wrecks, &c. (9 Rep. 25.) come again to the crown, they are extinct in the crown, and the king is feifed of them *jure coronæ*: but if liberties of fairs, markets, or other franchifes, and jurifdictions, be erected, and created by the king, they will not be extinguifhed, nor their appendances fevered from the poffeffion. 9 Rep. 25.

Extinguishment *of fervices.* If the lord purchafes or, accepts any part of the tenancy, out of which an entire fervice is to be paid or done, the fervice becomes thereby extinct; unlefs it be for the public good, or homage and fealty, ſealty, which are not ſubject to extinguiſhment. (6 Rep. i. 105. Co. Litt. 149.) If the lord and another perſon do purchaſe the lands out of which he is to have ſervices, they are extinct; alſo by ſeverance of the ſervices a manor may be extinguiſhed. Co. Litt. 147. 1 And. 257. See Tenure.

Extinguishment *of ways.* See Extinguishment.

EXTIRPATION, formed of *ex* and *ſtirps, root,* the act of pulling up, or deſtroying, a thing to the very roots.

Among the prayers of the Romiſh Jubilee, there is one for the extirpation of hereſy.

Extirpation. This word, in *Surgery,* ſignifies the eradication of any diſeaſe, tumour, &c. by ſome manual operation, whether done with a cutting inſtrument, with cauſtic, with a ligature, or any other means.

Thus, the generality of tumours are extirpated with a knife; but ſome, which claſs as excreſcences, or warts, are frequently extirpated with cauſtic, or with the ligature. The extirpation of polypi in the noſe is, for the moſt part, accompliſhed with forceps, by which ſuch tumours are pulled, or rather twiſted off.

The art of extirpating encyſted tumours with adroitneſs conſiſts in diſſecting the parts, ſurrounding the tumour, without wounding the cyſt. If the latter accident occur, the contents frequently flow out, the cyſt collapſes, and the continuance of the diſſection is attended with more difficulty. It is a great point to remove every particle of the cyſt, and, hence, it is ſatisfactory to take it out entire, that is, without wounding it. When any portion remains behind, the wound will frequently not heal, in conſequence of fungous granulations, ariſing from the diſeaſed part. Unleſs the ſwelling be large, a ſingle inciſion through the ſkin is ſufficient; but, in other inſtances, it is advantageous to make two cuts in this manner ( ); firſt, becauſe it facilitates the removal of the tumour; ſecondly, becauſe it prevents a redundance of ſkin, which would take place, if none were removed, and would greatly retard the cicatrization of the wound.

After the operation, the edges of the wound are to be brought together with ſticking plaſter, and a compreſs and bandage are to be applied.

When the breaſt is affected with any diſeaſe of an incurable nature, the ſurgeon can ſometimes extirpate the malady by cutting away the whole of the diſeaſed parts.

If the diſeaſe be of a ſcirrhous or malignant nature, ſome particularity in the mode of operating is requiſite. The ſurgeon ought, in this caſe, not to be content with merely removing parts, which are palpably and viſibly diſeaſed, but he ſhould alſo endeavour to remove a certain quantity of the ſubſtance, which is in the immediate circumference of the diſeaſe. In ſcirrhus, every ſurgeon knows the propenſity of the ſkin to be affected, and the frequent extenſion of white morbid bands into the ſurrounding adipoſe ſubſtance. Theſe facts greatly confirm the propriety of making a free removal of the ſkin, whenever it is in the leaſt diſcoloured, puckered, adherent to the ſwelling beneath, or in any way altered; and of taking away a good deal of the fat, in which ſcirrhous tumours are ſometimes involved. When there are no reaſons for ſuppoſing the diſeaſe of the breaſt to be any thing elſe than a mere ſarcomatous enlargement, the removal of the ſkin muſt certainly be conſidered unneceſſary. When cancer recurs, the ſkin is the firſt part in which it uſually makes its appearance, and the ſkin of the nipple in particular. Hence, many ſurgeons always make it a rule to remove the latter part, when it is judged proper to take away any of the integuments.

The operation is uſually performed as the patient is in a ſitting poſture, well ſupported by pillows and aſſiſtants.

The pectoral muſcle is to be made tenſe by keeping the arm back, by means of a ſtick, placed tranſverſely behind the back, in front of the two arms.

If none of the integuments are to be removed, a ſtraight inciſion is to be made through them; the tumour is to be regularly diſſected all round from the circumjacent parts; and, laſtly, its baſe is to be detached from its connections, from above downward, till the whole is ſeparated.

This is the mode of removing all ſimple tumours, which are not of a malignant nature, and which are not of an immenſe ſize.

When the tumour is of a malignant nature, and adherent to the ſkin and pectoral muſcle beneath, the operator is to remove, at leaſt, an inch or two of the fat on every ſide of the diſeaſe. The portion of the ſkin intended to be taken away muſt be included in two ſemi-circular inciſions, which meet thus ( ) at their extremities; and when the baſe of the tumour is to be detached, the ſurface of the pectoral muſcle, wherever it is adherent to the tumour, is alſo to be removed.

It is ſufficiently obvious, that the advantage of making the inciſion in the above manner conſiſts in enabling the ſurgeon to bring the edges of the wound together after the operation, ſo as to form a ſtraight line, and unite by the firſt intention.

The mere magnitude of a tumour frequently renders it highly judicious to take away a portion of the ſkin in the above method. If ſome were not removed, the diſſection of the tumour would be exceedingly tedious; and, after the operation, the looſe undiſtended ſkin would lie in folds, and form, as it were, a large pouch for the lodgment of matter.

The tumour being removed, the ſurgeon ſhould examine the interior of the wound, in order to aſcertain that no indurated part is left behind. If any hardneſs ſhould be felt, it is proper to remove it. The ſurgeon ſhould alſo examine the ſurface of every ſcirrhous tumour, immediately after it is taken out, for the purpoſe of knowing whether any of the white bands, ſhooting into the ſurrounding fat, have been divided; for, in this caſe, ſome portions have been left behind, and ought to be taken away. Their ſituation may eaſily be known, by conſidering the poſition of the tumour before the operation.

When the diſſection of a ſwelling will occupy a conſiderable time, it is always judicious practice to tie every large artery as ſoon as it is divided. This remark is not meant to comprehend veſſels of ſuch a diameter, that though they bleed when firſt cut, they do not emit blood afterwards, ſo as to require a ligature. It was Deſault's invariable method, in cutting out tumours, to tie every large artery before he continued the diſſection.

When a tumour of the breaſt has been entirely detached, and the hemorrhage ſuppreſſed, the ſtick confining the arm backward is to be removed. Then if there are any diſeaſed glands in the axilla, it is a very excellent plan to tie the pedicles, by which they are attached on the ſide towards the axilla, before attempting to cut the tumours completely away. It would be extremely difficult, after taking off the gland, to tie the little ſhort artery which enters the ſwelling, almoſt immediately after it has quitted one of the thoracic arteries. The bleeding alſo, in conſequence of the ſhortneſs of the veſſel, and vicinity of its orifice to the thoracic arteries, would be exceedingly profuſe, ſeeming rather to arife from a wound of the latter veffels than of a fmall branch.

The celebrated Default ufed to purfue the practice above recommended; and fir Charles Blicke has long been in the habit of obferving the fame rule, in the numerous operations which he has performed with the utmoft benefit to the afflicted, and well deferved honour to himfelf.

When the operation is finifhed, the fkin of the wound is to be relaxed, and the edges of the incifion brought together with ftrips of adhefive plafter. Proper compreffes and bandages are next to be applied. Should the operation have been the removal of a difeafed breaft, the neareft arm fhould be kept completely at reft in a fling, as whenever it moves, it occafions a difturbance of the pectoral mufcle, and, of courfe, of the wound. (Firft lines of the "Practice of Surgery," by Samuel Cooper.)

For the mode of extirpating a difeafed teftis, fee CASTRATION.

The method of effecting the extirpation of polypi is to be defcribed in the article POLYPUS.

Some obfervations are offered, under the head EXOSTOSIS, on the fubject of extirpating tumours of the bones. The way in which a difeafed eye ought to be cut out, will be hereafter explained. See EYE, *Extirpation of*.

For an account of the plan of extirpating certain excrefcences, fee EXCRESCENCE.

EXTIRPATIONE, in *Law*, a judicial writ, either before or after judgment, that lies againft a perfon, who when a verdict is found againft him for land, &c. doth malicioufly overthrow any houfe, or extirpate any trees upon it. Reg. Jud. 13. 56.

EXTISPEX, formed of *exta*, and *fpicere*, of *fpicio*, or *infpicere*, *I view*, *confider*, in *Antiquity*, an officer who viewed and examined the intrails of victims; in order to draw prefages from them as to futurity.

This kind of divination, called extifpicium, was much in vogue throughout Greece, where there were two families, the Jamidæ and Clytidæ, confecrated, or fet apart, peculiarly for it.

It appears to have been very ancient, and was probably derived from the ancients. Vitruvius, cap. 4. lib. i. gives the following plaufible account of its origin. He fays that the ancients infpected the livers of thofe animals which frequented the places where they intended to build or encamp; and if they commonly found that the liver, to which they attributed fanguification, was injured, they concluded that the waters and nourifhment collected near fuch places were not wholefome.

In Italy, the firft extifpices were the Etrurians or Tufcans; among whom, likewife, the art was in great repute. Lucan gives us a fine defcription of one of thefe operations in his firft book.

EXTORTION, in *Law*, denotes generally any oppreffion under colour of right; and it is ufually applied to fignify an illegal manner of wrefting any thing from a man, either by force, menace, or authority: *e. g.* if an officer, by terrifying another on pretence of his office, or "by colour of his office," takes more than his ordinary fees or dues, he commits, and is indictable for, extortion.

So the exacting of unlawful ufury, winning by unlawful game, and, in fine, all taking of more than is juftly due, by colour or pretence of right, as exceffive tolls in millers, exceffive prices of ale, bread, victuals, wares, &c. come under extortion.

Crompton fays, that wrong done by any man is properly a trefpafs, but exceffive wrong is extortion; which is moft properly applicable to fheriffs, mayors, bailiffs, and other officers, who, by colour of their office, greatly opprefs and wrong the king's fubjects, by taking exceffive reward, or fees, for executing their office: and extortion has been deemed more odious than robbery, becaufe it carries an appearance of truth; and is often accompanied with perjury in officers, &c. by violating their oaths of office. The diftinction between bribery and extortion feems to be this: the former offence confifts in the *offering* a prefent, or receiving one if offered; the latter, in *demanding* a fee, or prefent, by colour of office. Extortion by the common law is feverely punifhed, on indictment, by fine and imprifonment, and removal of officers from the offices in which the crime was committed. By the ftat. 3 Edw. I. inferior officers of juftice, &c. guilty of extortion, are to render by c. 26. double, and by c. 30. treble, value; and there are divers other ftatutes for punifhing extortions of fheriffs, bailiffs, gaolers, clerks of the affife, and of the peace, attornies and folicitors, &c. ftats. 23 H. VI. c. 7 & 9. 33 H. VIII. c. 24. 29 Eliz. c. 4. 1 Jac. I. c. 10. 9 & 10 W. III. c. 41. 10 & 11 W. III. c. 23. 3 Geo. I. c. 15. 17 Geo. III. c. 26. § 6. In cafes of extortion, there muft be a pofitive charge, that the charged perfon did it *extorfivé*, or *colore officii*. The place where it was committed muft be fet down in the declaration; the fum extorted particularly fpecified, and the indictment or information muft ftate the full particulars by fpecifying the time, &c. Againft attornies for extortion, action may be brought, and the party aggrieved fhall have treble damages and cofts; but information will not lie on the ftat. 3 Jac. I. c. 7. Sid. 434. 4 Nelf. 822.

EXTRA-*Conftellary Stars*. See SPORADES.

EXTRA-*judicial*, fomething done out of the proper court, or the ordinary courfe of law. As when judgment is given in a caufe, or cafe, not depending in that court where fuch judgment is given, or wherein the judge has no jurifdiction.

EXTRA-*mundane fpace*, is the infinite empty void fpace, which is by fome fuppofed to be extended beyond the bounds of the univerfe, and confequently in which there is really nothing at all.

EXTRA-*parochial*, a place out of the bounds of any parifh; or privileged and freed from the duties of a parifh.

EXTRACT, in *Chemiftry*. The term extract, as ufed in chemical nomenclature, has been borrowed from the pharmaceutical difpenfatories, where it has long been applied to a great variety of fubftances which have little other agreement than in the mode of preparation, which confifts in extracting by water, or any other menftruum, the foluble part of certain parts of vegetables, and infpiffating this folution by heat to a thick confiftence, or fometimes to entire folidity.

The term extract, therefore, in its original and pharmaceutical fenfe, only refers to the mode of preparation, and not to the nature of the fubftance prepared; and hence much confufion and uncertainty have prevailed in the attempts of chemifts to define the nature of the fubftance to which this term fhould in ftrictnefs be limited.

All the pharmaceutical extracts are extremely compounded, for being prepared either by water or alcohol, of courfe every thing foluble in thefe liquids would be confounded in the general mafs. Hence we find in one or other, and fometimes in a fingle extract, mucilage, fugar, tannin, gallic acid, refin, gluten, feveral neutral falts, and other ingredients. But along with thefe there always is found a confiderable quantity of a brown tenacious fubftance, often with a bitter tafte, and poffeffing a number of chemical properties, which entitle it to be confidered as a peculiar fubftance, ſtance, and to which the term extract, or extractive principle, has been given.

The diſtinguiſhing properties of this ſubſtance have been laid down with much ability by Vauquelin, in his memoir on the extractive principle (Journal de Pharmacie, p. 132.) and in his reſearches on the ſap and native juices of trees (An. Chem. tom. 31.) and alſo by Fourcroy in an elaborate and excellent analyſis of the cinchona of St. Domingo. An. Chem. tom. 8 & 9.

We ſhall firſt notice the experiments of Vauquelin, which being made on the native juices of plants, the extract already in ſolution, and unaltered by the heat requiſite in artificial decoction, is probably in a purer ſtate.

When the ſap of any tree is firſt drawn it is always colourleſs, or nearly ſo, but when inſpiſſated by heat, however moderate, it always aſſumes a brown colour, and in the proceſs of evaporation a certain though ſmall quantity of pulverulent brown inſoluble matter falls down. If this is collected ſeparately before the juice is entirely inſpiſſated, and treated with muriatic acid, one portion diſſolves with effervеſcence, and is found to be chiefly carbonat of lime, and an inſoluble part remains, which is conſidered by this excellent chemiſt as extract altered and oxygenated during the evaporation. If the concentrated ſap is now ſlowly evaporated to dryneſs, it yields a brown extract, ſtrongly deliqueſcent, and of a pungent ſaline taſte. This entire extract is always extremely compounded, containing in fact all the ſoluble ingredients of the original juice. Gallic acid, when preſent, is detected by a ſolution of iron; tannin, by a ſolution of iſinglaſs; ſalts of lime, by oxalic acid; ſugar, by the taſte, and by its ſoon acquiring the vinous fermentation. The entire extract alſo always contains acetous acid, partly in exceſs and partly united both to lime, potaſh, and ammonia, and hence when a few drops of ſtrong ſulphuric acid are poured upon any extract, copious vapours of pungent acetic acid are given out; and if this is done with large quantities, and in cloſe veſſels, acetic acid may be obtained pure. It is probably owing to the preſence of theſe neutral acetites, that all the inſpiſſated native juices attract moiſture ſtrongly from the air, and hence too their great diſpoſition, to mould and change by keeping.

Ammonia alſo is detected in moſt inſpiſſated juices of plants by the pungent vapours of this alkali, that are perceived on the addition of quick-lime, but in the natural ſtate the ammonia is more than neutralized by the acetous acid, as all the ſoft extracts redden betimes.

Extractive matter (meaning by this term the pure extract) appears to form a great portion of the colouring matter of vegetables. If to any liquid containing extract a ſolution of alum be added, a copious coloured inſoluble precipitate is produced, conſiſting chiefly of alumine in intimate combination with extractive matter, and the ſupernatant liquor remains clear and nearly colourleſs. The ſame proceſs takes place in dyeing, the alum being firſt fixed on the cloth as a *mordant*, as it is called. The ſolutions of tin poſſeſs this power of precipitating coloured extract as an inſoluble powder in a ſtill more ſtriking manner. That of the other metallic ſalts produce a ſimilar precipitate of extract, combined with the metallic oxyd.

The experiments of Fourcroy on the cinchona have been detailed at length under that article, to which we refer our readers. It may be obſerved in this place, that the facts relative to the ſubject of extract were, ſhortly, that the decoction of cinchona during evaporation depoſited a quantity of black matter, inſoluble in cold water, but which moſtly was diſſolved in alcohol, leaving however a portion of a red powder of a peculiar nature, which the author of the experiments conſiders as extractive matter, changed by union with oxygen, and thereby rendered inſoluble in water or alcohol. The appearance of this powder, and its inſolubility in water, might at firſt lead to the ſuppoſition that it was reſin, but its equal inſolubility in alcohol refutes this idea.

The preciſe nature of this inſoluble matter, which is depoſited on the evaporation of all vegetable infuſions or decoctions, is hitherto not known, and ſeveral objections to the opinion of its being merely *oxygenated extract* may be adduced, which we have already detailed under the article Cinchona.

On the whole, however, we may ſafely admit, that there is a peculiar ſubſtance found in almoſt all ſoluble matter of vegetables, and particularly in the common circulating juices, to which the term extract, or pure extractive principle, has been given, and which has the following diſtinguiſhing properties.

In its natural ſtate in the ſap of trees it is colourleſs, or nearly ſo; but when the ſolution is heated and inſpiſſated, it always acquires a deep colour, which is generally brown or fawn, with various ſhades, and by the ſame proceſs its ſolubility in cold water is diminiſhed.

It is in its natural ſtate equally ſoluble in alcohol as in water, by which circumſtance it is diſtinguiſhed both from pure mucilage and reſin.

It is inſoluble in ether.

It has a very ſtrong affinity with alumine, and with metallic oxyds, and when combined with ether it becomes inſoluble in water, alcohol, and many other menſtrua. By deſtructive diſtillation it is reſolvable into carbon, oxygen, and hydrogen, and a ſmall proportion of azot.

Much variety is found in the properties of ſmell, taſte, and colour, in the various extracts, and we are ſtill totally ignorant how far theſe varieties may depend on other admixtures, or whether there are different ſpecies of extract; and in general we may add that this ſubſtance appears to be one which moſt eaſily enters into intimate combination with all the other ſoluble vegetable principles, and, conſequently, can hardly by any known means be obtained pure, as it exiſts in the vegetable itſelf, and unchanged by the proceſſes of analyſis.

Extract, in *Pharmacy*. The greater number of pharmaceutical extracts are made by boiling the ſubſtance (in coarſe powder) in water, ſtraining the decoction, boiling it down till it is conſiderably concentrated, then gently drying the reſidue in a ſtove, or ſlow oven, to the requiſite conſiſtence.

A few of the extracts are made with alcohol inſtead of water, or with a mixture of the two; the ſubſtance being firſt digeſted with the alcohol, and the tincture, thus prepared, ſtrained off; the reſidue then boiled with water, and the decoction poured off, and both the decoction and tincture mixed, and evaporated ſlowly.

The purely ſpirituous extracts are alſo called reſins, and are always evaporated to dryneſs, when they remain hard brittle maſſes, with a vitreous fracture, reſoluble in alcohol, and in all eſſential characters reſembling the natural reſins.

In preparing the extracts by water the decoctions are uſually directed to be ſet aſide for ſome hours, that any ſediment may be depoſited, which laſt is to be rejected. But this is obviouſly a bad practice, as in many caſes much of the medicinal property of the plant reſides in this reſidue which ſubſides from the hot decoction on cooling.

Another ſpecies of extracts is the inſpiſſated juices of plants. Several powerfully medicinal plants, ſuch as the hemlock, are ſucculent vegetables, which, when ſtrongly

expreſſed,

expreſſed, yield a large quantity of a green turbid juice, which (after ſeparating the mere fragments of the plant) only requires to be inſpiſſated by a very gentle heat, to form the extract in the form in which it is uſed.

All the extracts, except thoſe made by alcohol, are liable to ſpoil by keeping. This is particularly the caſe with the inſpiſſated juice of the ſucculent plants, being compoſed of materials all extremely liable to fermentation, and being kept in a conſtant tendency to deliqueſcence by the neutral acetites which they contain. Therefore they muſt be kept in cloſe veſſels, but with every care the moſt important of them loſe their medicinal quality in no great length of time.

Extract, in *Matters of Literature*, denotes a ſhort abridgment of a book or paper, or of ſome of the matters thereof. The journals, nouvelles, bibliotheques, memoires, and other monthly reviews, or quarterly accounts of the affairs of learning, conſiſt principally of extracts of the moſt material paſſages, doctrines, &c. found in the ſeveral books publiſhed in that time.

Extract *ab Eccleſia*. See Restitutione *Extracti*.

EXTRACTA Curiæ, in our *Old Writers*, the iſſues or profits of holding a court, ariſing from the cuſtomary fees, &c.

EXTRACTION, in *Pharmacy* and *Chemiſtry*, an operation, whereby eſſences, tinctures, &c. are drawn from natural bodies. See Extract.

Extraction, in *Surgery*, is the drawing from, or out of the body, any thing fixed in it, as a thorn, or bullet, in the fleſh, a tooth from the jaw, &c. Surgeons ſpeak alſo of the extraction of a ſtone from the bladder, a cataract from the eye, foreign bodies from the œſophagus, extraneous ſubſtances from wounds, &c. For a deſcription of the methods of extracting a ſtone from the bladder, ſee Lithotomy.

The operation of extracting the cataract is explained in the article Cataract.

Extraction, or *Deſcent*, in *Genealogy*, denotes the ſtock, or family, which a perſon is deſcended from.

In ſome military orders, chapters, &c. a candidate muſt make proof of the nobility of his extraction before he is admitted.

Extraction *of Roots*, the method of finding the roots of given numbers, or quantities. See Root.

The ſquare, cube, and other powers of a number, or root, are formed by multiplying the given number into itſelf a greater or leſs number of times, as the power required is higher or lower. See Power.

This multiplication compounds the powers; and the extraction of the roots decompounds them again, or reduces them to their principles or roots. So that the extraction of the root is to the multiplication of the power, what the analyſis is to the ſyntheſis.

Thus, 4, multiplied by 4, produces 16; which is the ſquare of 4, or the factum of 4, by itſelf; and 16 multiplied by 4, makes 64, which is the cube of 4, or the factum of 4 by its ſquare. Such is the compoſition of powers.

Again, the ſquare root of 16 is 4, becauſe 4 is the quotient of 16 divided by 4; and the cube root of 64 is likewiſe 4, as 4 is the quotient of 64 divided by the ſquare of 4. Such is the extraction of roots.

Hence to extract the root out of a given power, is the ſame thing as to find a number, *e.gr.* 4, which being multiplied a certain number of times into itſelf, produces the given power, *e.gr.* 16 or 64.

For the extraction of ſquare and cube roots, it is neceſſary to have the ſquares and cubes of all the digits in readineſs; as exhibited in the following table.

Roots	1	2	3	4	5	6	7	8	9
Square	1	4	9	16	25	36	49	64	81
Cube	1	8	27	64	125	216	343	512	729

To extract the ſquare root out of a given number.—1. Divide the given number into claſſes, of two figures a-piece; and include each claſs between two dots, commencing with the place of units, and proceeding to the left in integers, and to the right in decimals; the root will conſiſt of ſo many parts or figures as you have claſſes. By the way obſerve, it may happen, that for the laſt claſs on the left hand there ſhall be only one figure left.

2. Then the left-hand claſs being the ſquare of the firſt figure of the root ſought, look in the table of roots for the ſquare root anſwering to that number; or, if that ſquare number be not preciſely there, to the next leſſer number: this root write down for the firſt figure of the quotient; and ſubtract its ſquare from the left-hand claſs. To the remainder bring down the next claſs toward the right.

3. Write down the double of the quotient figure under the left-hand figure of the ſecond claſs; and ſeek how oft this duple is contained in the figure over it: the quotient gives the ſecond figure of the root.

4. Write the ſame quotient under the right-hand figure of the ſame claſs, and ſubtract the product of the whole number underwritten, multiplied by the ſecond figure of the root, from the number over it, as in diviſion.

5. The operation being repeated according to the third and fourth ſteps, *i. e.* the remainder being ſtill divided by the double of the root as far as extracted; and from the remainder ſubtract the product of the laſt diviſor, having the laſt found figure of the quotient added to it, multiplied by this figure, you will have the root required.

E. gr. To extract the root of 99856, point it after the following manner, 99856: then ſeek a number, whoſe ſquare ſhall equal the firſt figure 9, *viz.* 3, and write it in the quotient; then having ſubtracted from 9, 3 × 3, or 9, there will remain 0; to which ſet down the figures as far as the next point, *viz.* 98, for the following operation. Then, taking no notice of the laſt figure 8, ſay, How many times is the double of 3, or 6, contained in the firſt figure 9? Anſwer, 1. Wherefore, having written 1 in the quotient, ſubtract the product, of 1 × 61, or 61 from 98, and there will remain 37, to which connect the laſt figures 56, and you will have the number 3756, in which the work is next to be carried on. Wherefore, alſo neglecting the laſt figure of this, *viz.* 6, ſay, How many times is the double of 31, or 62, contained in 375 (which may be gueſſed at from the initial figure 6 and 37, by taking notice how many times 6 is contained in 37)? Anſwer 6; and writing 6 in the quotient, ſubtract 6 × 626, or 3756, and there will remain 0; whence it appears, that the buſineſs is done, the root coming out 316.

```
 .  .  .
99856 ( 316
9
-----
098
 61
-----
3756
3756
-----
   0
```

Otherwiſe,

Otherwiſe, with the diviſors ſet down, it will ſtand thus :

```
    . . .
    99856 (316
    9
6)  98
    61
62)  3756
     3756
        0
```

And ſo in others.

Again, if you were to extract the ſquare root out of 22178791 :

```
22178791 ( 4709, 43637, &c.
16
 617
 609
  88791
  84681
   411000
   376736
    3426400
    2825649
     60075100
     56513196
      356190400
      282566169
       73624231
```

Firſt having pointed it, ſeek a number, whoſe ſquare (if it cannot be exactly equalled) ſhall be the next leſs ſquare (or neareſt) to 22, the figures to the firſt point, and you will find it to be 4. For 5×5, or 25, is greater than 22 ; and 4×4, or 16, is leſs ; wherefore 4 will be the firſt figure of the root. This, therefore, being writ in the quotient, from 22 take the ſquare 4×4, or 16 ; and to the remainder 6, adjoin the next figures 17, and you will have 617 ; from whoſe diviſion, by the double of 4, you are to obtain the ſecond figure of the root, *viz.* neglecting the laſt figure 7, ſay, how many times is 8 contained in 61 ? Anſwer, 7 ; wherefore write 7 in the quotient, and from 617 take the product of 7 into 87, or 609, and there will remain 8, to which join the two next figures 87, and you will have 887 ; by the diviſion whereof by the double of 47, or 94, you are to obtain the third figure ; in order to which ſay, how many times is 94 contained in 88 ? Anſwer, 0 ; wherefore write 0 in the quotient, and adjoin the two laſt figures 91, and you will have 88791, by whoſe diviſion by the double of 470, or 940, you are to obtain the laſt figure ; *viz.* ſay, how many times 940 in 8879 ? Anſwer, 9 ; wherefore write 9 in the quotient, and you will have the root 4709. But ſince the product 9×9409, or 84681, ſubtracted from 88791, leaves 4110, the number 4709 is not the root of the number 22178791 preciſely, but a little leſs.

If then it be required to have the root approach nearer, carry on the operation in decimals, by adding to the remainder two cyphers in each operation. Thus, the remainder 4110, having two cyphers added to it, becomes 411000 ; the diviſion whereof, by the double of 4709, or 9418, will give the firſt decimal figure 4. Then having writ 4 in the quotient, ſubtract 4×94184, or 376736, from 411000, and there will remain 34264. And ſo having added two more cyphers, the work may be carried on at pleaſure, the root at length coming out 4709, 43637, &c.

But when the root is carried on half way or above, the reſt of the figures may be obtained by diviſion alone : as in this example, if you have a mind to extract the root to nine figures, after the five former 4709,4 are extracted, the four latter may be had, by dividing the remainder by the double of 4709,4.

Thus if the root of 32976 were to be extracted to five places, in numbers ; after the figures are pointed, write 1 in the quotient, as being the figure of whoſe ſquare 1×1, or 1, is the greateſt that is contained in 3, the figure to the firſt point ; and having taken the ſquare of 1 from 3, there will remain 2 ; then having ſet the two next figures, *viz.* 29, to it (*viz.* to 2,) ſeek how many times the double of 1, *viz.* 2, is contained in 22, and you will find indeed that it is contained more than ten times ; but you are never to take your diviſor 10 times, nor even 9 times in this caſe ; becauſe the product of 9×29, or 261, is greater than 229, from which it would be to be taken, or ſubtracted ; wherefore write only 8. And then having written 8 in the quotient, and ſubtracted 8×28, or 224, there will remain 5 ; and having ſet down to this the figures 76, ſeek how many times the double of 18, or 36, is contained in 57, and you will find one, and ſo write 1 in the quotient ; and having ſubtracted 1×361, or 361, from 576, there will remain 215. Laſtly, to obtain the remaining figures, divide this number 215, by the double of 181, *viz.* 362, and you will have the figures, 59 which, being writ in the quotient, give the root 181,59.

```
      . . .
      32976 (  181,59
      1
    2)229
      224
36)   576
      361
362)  215(59, &c.
```

After the ſame manner are roots extracted out of decimal numbers. Thus the root of 329,76 is 18,159 ; and the root of 3,2976 is 1,8159, and the root of 0,032976, is 0,18159, and ſo on. But the root of 3297,6 is 57,4247 ; and the root of 32,976 is 5,74247. And thus the root of 9,9856 is 3,16.

To extract the other, or higher root, out of a given number.—The extraction of the cubic root, and all other roots, may be comprehended under one general rule ; *viz.* every third figure, beginning from unity, is firſt to be pointed, if the root to be extracted be a cubic one ; or every fifth, if it be a quadrato-cubic (or of the fifth power ;) and then ſuch a figure is to be writ in the quotient, whoſe greateſt power (that is, whoſe cube, if it be a cubic power, or whoſe quadrato-cube, if it be the fifth power, &c.) ſhall either be equal to the figure, or figures, before the firſt point, or next leſs under them ; and then having ſubtracted that power, the next figure will be found by dividing the remainder augmented by the next figure of the reſolvend, by the next leaſt power of the quotient multiplied by the index of the power to be extracted, that is, by the triple ſquare, if the root be a cubic one ; or by the quintuple biquadrate, (that is, five times the biquadrate,) if the root be of the fifth power, &c. And having again ſubtracted the power of the whole quotient from the firſt reſolvend, the third figure will be found by dividing that remainder, augmented by the next figure of the reſolvend, by the next leſſer power of the whole quotient, multiplied by the index of the power to be extracted.

Thus, to extract the cube root of 13312053, the number is firſt to be pointed after this manner, *viz.* 13312053 then you are to write the figure 2, whoſe cube is 8, in the firſt place of the quotient, as that which is the next leſſer leffer cube to the figure 13, (which is not a perfect cube number) or as far as the firft point; and having fubtracted that cube, there will remain 5; which being augmented by the next figure of the refolvend 3, and divided by the triple fquare of the quotient 2, by feeking how many times 3×4, or 12, is contained in 53, gives 4, or the fecond figure of the quotient. But fince the

$$\begin{array}{rl} & 13312053\ (237 \\ \text{Sub. the cube} & 8 \\ \hline 12)\ \text{rem.} : & 53\ 4 \text{ or } 3 \\ \hline \text{Subtract cube} & 12167 \\ 1587)\ \text{rem.} : & 11450\ (\ 7 \\ \hline & 13312053 \\ \text{Remains} & 0 \\ \hline \end{array}$$

cube of the quotient 24, *viz.* 13824, would come out too great to be fubtracted from the figures 13312, that precede the fecond point, there muft only 3 be writ in the quotient; then the quotient 23 being in a feparate place multiplied by 23, gives the fquare 529, which again multiplied by 23, gives the cube 12167; and this taken from 13312, will leave 1145, which augmented by the next figure of the refolvend 0, and divided by the triple fquare of the quotient 23, *viz.* by feeking how many times 3×529, or 1587, is contained in 11450, gives 7, for the third figure of the quotient. Then the quotient 237, multiplied by 237, gives the fquare 56169, which again multiplied by 237, gives the cube 13312053; and this taken from the refolvend, leaves 0. Whence it is evident, that the root fought is 237.

So alfo, to extract the quadrato-cubical root of 36430820, it muft be pointed over every fifth figure; and the figure 3, whofe quadrato-cube, or fifth power 243, is the next leffer to 364, *viz.* to the firft point, muft be writ in the quotient. Then the quadrato-cube 243 being fubtracted from 364, there remains 121, which augmented by the next figure of the refolvend, *viz.* 3, and divided by five times the biquadrate of the quotient, *viz.* by feeking how many times 5×81, or 405, is contained in 1213, gives two for the fecond figure. That quotient 32 being thrice multiplied by itfelf, makes the bi-

$$\begin{array}{rl} & 36430820(32{,}5, \\ \hline & 243 \\ 405) & 1213(2 \\ \hline & 33554432 \\ 5242880) & 2876388{,}0(5 \end{array}$$

quadrate 1048576; and this again, multiplied by 32, makes the quadrato-cube 33554432, which, being fubtracted from the refolvend, leaves 2876388. Therefore 32 is the integral part of the root but not the true root; wherefore, if you have a mind to profecute the work in decimals, the remainder, augmented by a cypher, muft be divided by five times the aforefaid biquadrate of the quotient, by feeking how many times 5×1048576, or 5242880, is contained in 2876388,0, and there will come out the third figure, or the firft decimal 5. And fo by fubtracting the quadrato-cube of the quotient 32,5, from the refolvend, and dividing the remainder by five times its biquadrate, the fourth figure may be obtained. And fo on *in infinitum.*

In fome cafes it is convenient only to indicate the extraction of a root, efpecially where it cannot be had exactly. Now, the fign or character whereby roots are denoted, is $\surd$; to which is added, the exponent of the power, if it be above a fquare, and even fometimes if it be not. *E. gr.* $\sqrt[2]{}$ denotes the fquare root; $\sqrt[3]{}$ the cube root, &c. See ROOT.

When a biquadratic root is to be extracted, you may extract twice the fquare root, becaufe $\sqrt[4]{}$ is as much as $\surd \times \surd$. And when the cubo-cubic root is to be extracted, you may firft extract the cube root, and then the fquare root of that cube root, becaufe the $\sqrt[6]{}$ is the fame as $\sqrt[2]{} \times \sqrt[3]{}$; whence fome have called thefe roots, not cubo-cubic ones but quadrato-cubes. And the fame is to be obferved in other roots, whofe indices are not prime numbers.

To prove the extraction of roots.—1. For a *fquare root;* multiply the root found by itfelf, and to the product add the remainder, if there were any: if the fum be equal to the number given, the operation is juft.

2. For a *cube root.* Multiply the root found by itfelf, and the product, again, by the fame root. To the laft product, add the remainder, if there were any. If the fum come out the number firft given, the work is juft.

After the like manner may the extraction of the other roots be proved.

To extract the roots of equations, or algebraic quantities.—The extraction of roots out of fimple algebraic quantities, is evident, even from the nature, or marks of notation itfelf; as that $\sqrt{aa}$ is a, and that $\sqrt{aacc}$ is ac, and that $\sqrt{9aacc}$ is 3ac; and that $\sqrt{49a^4xx}$ is 7aax. And alfo that $\sqrt{\frac{a^4}{cc}}$, or $\frac{\sqrt{a^4}}{\sqrt{cc}}$ is $\frac{aa}{c}$, and that $\sqrt{\frac{a^4bb}{cc}}$ is $\frac{aab}{c}$, and that $\sqrt{\frac{9aazz}{25bb}}$ is $\frac{3az}{5b}$, and that $\sqrt{\frac{4}{9}}$ is $\frac{2}{3}$, and that $\sqrt[3]{\frac{8b^6}{27a^3}}$ is $\frac{2bb}{3a}$, and that $\sqrt[4]{aabb}$ is $\sqrt{ab}$; moreover, that $b\sqrt{aacc}$, or b into $\sqrt{aacc}$, is equivalent to b into ac, or abc: and that $3c\sqrt{\frac{9aazz}{25bb}}$ is equivalent to $3c \times \frac{3az}{5b}$, or $\frac{9acz}{5b}$. And that $\frac{a+3x}{c}\sqrt{\frac{4bbx^4}{81aa}}$. is equivalent to $\frac{a+3x}{c} \times \frac{2bxx}{9a}$, or to $\frac{2abxx+6bx^3}{9ac}$. I fay all thefe are evident, becaufe it will appear at firft fight, that the propofed quantities are produced, by multiplying the roots into themfelves (as aa from a into a; aacc from ac into ac; 9aacc from 3ac into 3ac, &c.) The rule is to extract the required root of the numeral coefficient, if there be any, and to divide the exponents of the literal or algebraic quantities by the number that denominates the root required. It is evident from the application of this rule, that any power which has a pofitive fign may have either a pofitive or negative root, if the root is denominated by an even number, becaufe + or −, multiplied into themfelves an even number of times will give +. Alfo, that if a power have a negative fign, no root of it denominated by an even number can be affigned. But if the root to be extracted is denominated by an odd number, the fign of the root will be the fame as the fign of the given quantity whofe root is required. However, it will often happen, that the number, denominating the required root, will not exactly divide the exponent of the given power, in which cafe the required root will have a fractional exponent, thus, $\sqrt[3]{8a}$ is $= 2a^{\frac{1}{3}}$. But when quantities confift of feveral terms, the bufinefs is performed as in numbers.

Thus, to extract the fquare root out of aa + 2ab + bb; in the firft place, write the root of the firft term aa, *viz.* a, in the quotient, and having fubtracted its fquare $a \times a$, there will remain 2ab + bb to find the remainder of the root by. Say, therefore, how many times is the double of the quotient, or 2a, contained in the firft term of the remainder 2ab? I anfwer, b [times]: therefore write b in the quotient, and having fubtracted the product of b into 2a + b, or 2ab + bb,

$$\begin{array}{l} aa + 2ab + bb\ (a + b \\ aa \\ \hline 0 + 2ab + bb \\ \quad + 2ab + bb \\ \hline \quad 0 \qquad 0 \end{array}$$

there

there will remain nothing; which ſhews that the work is finiſhed, the root coming out a + b.

And thus to extract the ſquare root out of $a^4 + 6a^3b + 5aabb - 12ab^3 + 4b^4$, firſt ſet in the quotient the root of the firſt term a^4, *viz.* aa, and having ſubtracted its ſquare aa × aa, or a^4, there will remain $6a^3b + 5aabb - 12ab^3 + 4b^4$ to find the remainder of the root. Say, therefore, how many times is 2aa contained in $6a^3b$? Anſwer, 3ab; wherefore write 3ab in the quotient; and having ſubtracted the product of 3ab, into 2aa + 3ab, or $6a^3b + 9aabb$, there will yet remain $-4aabb - 12ab^3 + 4b^4$, to carry on the work. Therefore, ſay again, how many times is the double of the quotient, *viz.* 2aa + 6ab, contained in $-4aabb - 12ab^3$? or, which is the ſame thing, ſay, how many times is the double of the firſt term of the quotient, or 2aa, contained in the firſt term of the remainder $-4aabb$? Anſwer, $-2bb$. Therefore having writ $-2bb$ in the quotient, and ſubtracted the product $-2bb$ into $2aa + 6ab - 2bb$, or $-4aabb - 12ab^3 + 4b^4$, there will remain nothing.

Whence it follows, that the root is $aa + 3ab - 2bb$.

$$\begin{array}{l}
a^4 + 6a^3b + 5aabb - 12ab^3 + 4b^4\ (aa + 3ab - 2bb \\
a^4 \\
\overline{\quad} 6a^3b + 5aabb - 12ab^3 + 4b^4 \\
o + 6a^3b + 9aabb \\
\hline
\quad o - 4aabb - 12ab^3 + 4b^4 \\
\quad\ \ - 4aabb - 12ab^3 + 4b^4 \\
\hline
\quad\ o \quad o \quad o
\end{array}$$

And thus the ſquare root of the quantity $xx - ax + \frac{1}{4}aa$ is $x - \frac{1}{2}a$, and the ſquare root of the quantity $16a^4 - 24aaxx + 9x^4 + 12bbxx - 16aabb + 4b^4$ is $3xx - 4aa + 2bb$, and the ſquare root of the quantity $y^4 + 4y^3 + 8y^2 + 8y + 4$ is $yy + 2y + 2$; as may appear underneath.

1.
$$\begin{array}{l}
xx - ax + \frac{1}{4}aa\ (x - \frac{1}{2}a \\
xx \\
\hline
o - ax + \frac{1}{4}aa \\
\hline
\quad o \quad o
\end{array}$$

2.
$$\begin{array}{l}
9x^4 \begin{array}{l} \quad\qquad\qquad + 16a^4 \\ - 24aa \\ + 12bb \end{array} x^2 \begin{array}{l} \\ - 16aabb \\ + 4b^4 \end{array} \left(3x^2 \begin{array}{l} - 4aa \\ + 2bb \end{array} \right. \\
9x^4 \\
\hline
o \qquad\quad + 16a^4 \\
\begin{array}{l} - 24aa \\ + 12bb \end{array} x^2 \begin{array}{l} - 16a^2b^2 \\ + 4b^4 \end{array} \\
\hline
\quad o \quad o
\end{array}$$

3
$$\begin{array}{l}
y^4 + 4y^3 + 8y^2 + 8y + 4\ (yy + 2y + 2 \\
y^4 \\
\hline
o \\
4y^3 + 8yy \\
\hline
\quad o + 4yy + 8y + 4 \\
\quad\ \ + 4yy + 8y + 4 \\
\hline
\quad o \quad o \quad o
\end{array}$$

If you would extract the cube root out of $a^3 + 3aab + 3bb + b^3$, the operation is performed thus:

$$\begin{array}{l}
a^3 + 3aab + 3abb + b^3\ (a + b \\
a^3 \\
\overline{\quad} \\
3aa)\ o + 3aab\ (b \\
\hline
\quad a^3 + 3aab + 3abb + b^3 \\
\hline
\qquad o \quad o \quad o
\end{array}$$

Extract firſt the cube root of the firſt term a^3, *viz.* a, and ſet it down in the quotient; then ſubtracting its cube a^3; ſay, how many times is its treble ſquare, or 3aa, contained in the next term of the remainder 3aab; and there comes out b; wherefore write b in the quotient, and ſubtracting the cube of the quotient a + b, there will remain o; therefore a + b is the root. After the ſame manner, if the cube root is to be extracted out of $z^6 + 6z^5 - 40z^3 + 96z - 64$, it will come out $zz + 2z - 4$. And ſo likewiſe in higher roots.

The general rule for extracting any root out of any given quantity, is as follows. Having ranged the quantity according to the dimenſions of its letters, extract the ſaid root out of the firſt term, and that ſhall be the firſt member of the root required; then raiſe this root to a dimenſion lower by unit than the number that denominates the root required; and multiply the power that ariſes by that number itſelf; divide the ſecond term of the given quantity by the product, and the quotient ſhall give the ſecond member of the root required. The other members of the root, if there be more than two, are found after the ſame manner. In ſome caſes the exact root cannot be found in finite terms: thus, the ſquare root of $a^2 + x^2$ is found to be $a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5} - \frac{5x^8}{128a^7}$, &c.

The operation is thus:

$$\begin{array}{l}
\qquad\qquad a^2 + x^2\ (a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5}, \&c. \\
\qquad\qquad a^2 \overline{\qquad\quad} \\
2a + \frac{x^2}{2a}) * + x^2 \\
\quad \times \frac{x^2}{2a}) \ = x^2 + \frac{x^4}{4a^2} \\
\hline
2a + \frac{x^2}{a} - \frac{x^4}{8a^3}) \ - \frac{x^4}{4a^2} \\
\quad \times - \frac{x^4}{8a^3}) = - \frac{x^4}{4a^2} - \frac{x^6}{8a^4} + \frac{x^8}{64a^6} \\
\hline
\qquad\qquad + \frac{x^6}{8a^4} - \frac{x^8}{64a^6}, \&c.
\end{array}$$

In the ſame manner the cube root of $a^3 + x^3$ will be found to be $a + \frac{x^3}{3a^2} - \frac{x^6}{9a^5} + \frac{5x^9}{81a^7} - \frac{10x^{12}}{243a^{11}}$, &c. Thus,

$$\begin{array}{l}
\quad a^3 + x^3 \left(a + \frac{x^3}{3a^2} \right. \\
\quad a^3 \\
3a^2)\ * x^3.
\end{array}$$

Then cube $a + \frac{x^3}{3a^2}$, and we ſhall have $a^3 + x^3 + \frac{x^6}{3a^3} + \frac{x^9}{27a^3}$, which ſubtracted from the given quantity $a^3 + x^3$, leaves $- \frac{x^6}{3a^3} - \frac{x^9}{27a}$ for the next reſolvend; and this

this divided by $3a^2$ will give $-\frac{x^6}{9a^5}$ for the next term of the quotient, &c. But the roots of quantities of this kind are much more expeditioufly obtained by means of the binomial theorem. For the fquare root of $a^2 + x^2 = \overline{a^2 + x^2}|^{\frac{1}{2}}$; and $\overline{a^2 + x^2}|^{\frac{1}{2}} = \overline{a^2}|^{\frac{1}{2}} + \frac{1}{2} \times \overline{a^2}|^{\frac{1}{2} - 1} \times x^2 + \frac{1}{2} \times \frac{\frac{1}{2} - 1}{2} \times \overline{a^2}|^{\frac{1}{2} - 2} \times \overline{x^2}|^2 + \frac{1}{2} \times \frac{\frac{1}{2} - 1}{2} \times \frac{\frac{1}{2} - 2}{3} \times \overline{a^2}|^{\frac{1}{2} - 3} \times \overline{x^2}|^3$, &c. $= \overline{a^2}|^{\frac{1}{2}} + \frac{1}{2} \times \overline{a^2}|^{-\frac{1}{2}} x^2 + \frac{1}{2} \times -\frac{1}{4} \times \overline{a^2}|^{-\frac{3}{2}} x^4 + \frac{1}{2} \times -\frac{1}{4} \times -\frac{1}{2} \times \overline{a^2}|^{-\frac{5}{2}} x^6$, &c. $= a + \frac{1}{2} \times a^{-1} x^2 - \frac{1}{8} \times a^{-3} x^4 + \frac{1}{16} \times a^{-5} x^6$, &c. = (bringing the powers of a from the numerators to the denominators, by changing the figns of their exponents) $a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5}$, &c.

Thus alfo the cube root of $a^3 + x^3 = \overline{a^3 + x^3}|^{\frac{1}{3}}$; and $\overline{a^3 + x^3}|^{\frac{1}{3}} = \overline{a^3}|^{\frac{1}{3}} + \frac{1}{3} \times \overline{a^3}|^{\frac{1}{3} - 1} \times x^3 + \frac{1}{3} \times \frac{\frac{1}{3} - 1}{2} \times \overline{a^3}|^{\frac{1}{3} - 2} \times \overline{x^3}|^2 + \frac{1}{3} \times \frac{\frac{1}{3} - 1}{2} \times \frac{\frac{1}{3} - 2}{3} \times \overline{a^3}|^{\frac{1}{3} - 3} \times \overline{x^3}|^3$, &c. $= \overline{a^3}|^{\frac{1}{3}} + \frac{1}{3} \times \overline{a^3}|^{-\frac{2}{3}} x^3 + \frac{1}{3} \times -\frac{1}{3} \times \overline{a^3}|^{-\frac{5}{3}} x^6 + \frac{1}{3} \times -\frac{1}{3} \times -\frac{5}{9} \times \overline{a^3}|^{-\frac{8}{3}} x^8$, &c. $= a + \frac{1}{3} \times a^{-2} x^3 - \frac{1}{9} \times a^5 \times x^6 + \frac{5}{81} a^{-8} x^9$, &c. $= a + \frac{x^3}{3a^2} - \frac{x^6}{9a^5} + \frac{5x^9}{81a^8}$, &c. See Maclaurin's Algebra, part i. ch. viii. p. 50, 51. See ROOT.

EXTRACTOR, in *Midwifery*, an inftrument contrived to extract children in cafes of difficult births. We have the defcription of a forceps for extracting children by the head when lodged low in the pelvis of the mother, in the Medic. Eff. Edinb. vol. iii. art. 20. See alfo the abridgment of this book, vol. ii. p. 438, where fome alteration is mentioned of this inftrument from Giffard's Midwifery, and an improvement of it by Mr. Freke. See FORCEPS.

EXTRACTUM CATHARTICUM, a form of medicine in the London Difpenfatory, intended as an equivalent for the *extractum Rudii*, commonly called Rudius's pill, and which is for many reafons a better compofition than that pill. It is now called "extractum colocynthidis compofitum." See COLOCYNTHIS.

EXTRADOS, the outfide of a vault.

EXTRANEOUS FOSSILS, in *Geology*. Adventitious, fecondary, or figured foffils, have among them (fee FOSSILS, *Extraneous*) thofe remains and exuvia of organized beings, which are found imbedded in the ftrata of the earth. Since the difcovery of Mr. William Smith, that each particular fhell, and other organic remain, has its proper and appropriate place in the lamina of fome particular ftratum, and of which it is often a perfect, and, perhaps, the moft unerring teft of identity, in moft inftances, the knowledge and exact difcrimination of thefe numerous animal and vegetable remains has appeared a matter of the firft importance to geologifts, efpecially fince it has been further afcertained, as it now is, that moft, if not every one, of the organic remains, differ effentially from any recent fpecies of the animals and plants, to which former, and too curfory, obfervations had referred them; while many of them differ altogether and entirely from any thing now living or growing: which two points afcertained, have tended irrefiftibly to fhew that thefe organic remains were not entombed by the Mofaic deluge, as moft writers had fuppofed, becaufe they differ entirely from the antediluvian race, of which the prefent living ones are the defcendants and exact reprefentatives, as the Mofaic account informs us, and are not of fubfequent creation. Another refult of the former of thefe facts has been to fhew, that the feveral animals and plants whofe foffil remains we meet with in the ftrata, lived and died on the ftratum in which we find them, prior to the depofition, and, perhaps, prior alfo to the creation of the matter of the lamina which covers them; and that the period of the exiftence of particular fpecies was in moft, if not every inftance, limited to that took up in the depofition of the particular ftratum in which they are found imbedded, feeming to fuggeft, that they were *created* at the period of the ftratification, which anfwers to the loweft lamina in which they are found, and ceafed to exift altogether at the period anfwering to the higheft lamina in which they are found; a fuppofition in no ways inconfiftent with the Mofaic account of creation, if the whole of the foffil race be different from the prefent race of organized beings, and of a period of time antecedent to the events defcribed by the facred hiftorian, except in his introductory words, "In the beginning God created the heavens and the earth." It may, poffibly, be urged, againft the idea of a temporary duration of the primitive animals and plants, and their becoming after that *extinct*, that the fame kind of organic remains are found again, after large fucceffions of depofitions with remains of different beings, in afcending the feries of ftrata, or in very diftant parts of the globe; to which it may be anfwered, that where fufficient difcrimination has been made in the fpecific differences of organic remains refembling each other, but found imbedded in a ftrata feparated by thofe of a different kind, and with different kinds of organic beings in them, it has generally, if not always, turned out, that the remains refembling each other, and hitherto fuppofed identic, are in reality not fo, but of perfectly diftinct fpecies; their *varieties*, as fome might be difpofed to call them, in conformity to the language of the naturalifts refpecting accidental deviations in fome recent fpecies, being *conftant*, and fuch as properly conftituted diftinct fpecies in the great families of the primitive creation. Refpecting organic fubftances found at very diftant places on the globe, which, on being brought together and thoroughly examined, appear to be identic; before any argument is drawn therefrom, againft the temporary exiftence and extinction of their originals in the primitive race which inhabited the waters of this globe, it fhould be diftinctly afcertained that the feries of ftrata and organic remains above and below the two places in the feries whence the fpecimens were brought are really different; or, in other words, that the identic fpecies really do belong to different parts of the feries of ftrata: for if, on the contrary, they belong to the *fame ftratum*, however its obvious mineralogical character may appear changed, it is to be expected that the organic remains will be identic, fince Mr. Smith has, on tracing the ending or actual out-crop of a ftratum for feveral hundred miles, always found the organic remains the fame; as the numerous fpecimens in his collection, marked and brought from the extreme and intermediate points of fuch examination, do teftify.

It is alfo to be taken into confideration, that the difcoveries of Mr. Farey, relative to denudated tracts on our globe, fhew the poffibility, and, perhaps, the frequent occurrence of fuch deep excavations being left in the ftrata of the earth, as to exhibit the edges, and indeed confiderable tracts of the planes of ftrata, at immenfe depths in the feries, below thofe proper to the general ftrata on the fur-

 faces

face, and having their regular baffet, or ending, on the furface, at great diftances from fuch denudated expofurcs of them. The immenfe denudation, for inftance, which has laid bare the fourth or loweft limeftone rock of Derbyfhire and Staffordfhire, and the excavation of Dove-dale and other vallies therein, appears to have expofed ftrata to view, which are from $1\frac{1}{2}$ to 2 miles in perpendicular depth beneath the red earth, or gypfeous tract, which furrounds them on all fides! (except, perhaps, a narrow ftrip on the north, along the grand ridge, or waterfhead of the ifland,) which lower expofed parts of the fourth lime rock do not, perhaps, anywhere baffet, or come regularly to the furface, within 90 or 100 miles of Dove-dale and other vallies, where the denudation has expofed them. The continents feem, from the relations of travellers, likely to furnifh numerous inftances of denudations in the mountain chains, which will be found to expofe ftrata that lie very low indeed in the general feries, and at very great diftances from the regular or continued line of ending or outcrop of thofe particular ftrata; and, without adverting to which circumftances, the exact identity of organic remains from diftant places fo circumftanced, might feem to contradict our ideas of their being peculiar to peculiar ftrata. But after all, fhould identically the fame fpecies of organic remains be found in diftant parts of the feries of terreftrial ftrata, what have we to limit the architect of "heaven and earth," from having re-created fimilar animals or plants during the countlefs periods of the primitive creation and exiftence? Analogy furely cannot be faid to do this, when the animals and plants created fince he faid "Let the waters be gathered together, and let the *dry land* appear," and which ftill continue to exift, have fo many points of refemblance to fome of the primitive and extinct ones, both in forms and habits, that they have for ages paffed as identic therewith. Mr. James Parkinfon and Mr. W. Martin, having engaged in works intended to collect information on, and more accurately to difcriminate, extraneous or organic foffil remains, which works are ftill in progrefs, and the refults of Mr. W. Smith's labours and thofe of his pupils being yet in a great meafure unpublifhed, we fhall defer what we have further to add on thefe highly interefting and curious relics to the article Reliquia, which feems, indeed, their more appropriate title. In the mean time, as the ufual names of the feveral foffil animals and plants, &c. occur, we fhall not fail to lay before our readers fuch facts and particulars as we can collect, and with propriety communicate, concerning the objects of the unpublifhed refearches of the meritorious individuals alluded to; to whofe credit it ought to be known, that extended and undifguifed communications have all along been made among the circle of their friends, and in confequence of which a fpirit of enquiry on the fubject has been excited, in various diftricts of the kingdom, from which the happieft confequences to fcience may be expected fhortly to arife.

Extraneons, *Extraneus*, Lat. belonging to nothing, forcing. This word, during the laft century, was admitted into the mufical technica, in fpeaking of an unufual and irregular change of key, which is called extraneous modulation, or modulating into an unrelative key, as in the key of C natural, D with a fharp 3d, D ♭, B ♮, and B ♭, which are unrelative keys, having no found in common with the chord of C natural. With refpect to extraneous modulation, Rouffeau fays that no compofers have frequent recourfe to fudden and unufual modulation, but thofe who are fteril in fancy and invention: and we fhould believe the affertion well founded, if Eman. Bach, Haydn, and Mozart, were excepted, who cannot be accufed of want of invention. It is to the clumfy imitators of thefe great mafters, who, in total want of melody, have recourfe to unexpected harmony, that Rouffeau's accufation feems to attach.

EXTRAORDINARII, in *Roman Antiquity*, a body of forces, confifting of a third part of the horfe, and a fifth part of the foot, which was feparated from the reft, to prevent any defign that might be formed againft the natural forces. See Ablecti.

EXTRAORDINARY, fomething out of the common courfe.

Extraordinary *couriers*, are thofe fent exprefs on fome urgent occafion.

Extraordinary *embaffador*, or *envoy*, is fuch a one as is fent to treat or negociate fome fpecial and important affair, as a marriage, a treaty, confederacy, &c. or even on occafion of fome ceremony, as condolence, congratulation, &c. See Embassador.

A gazette, journal, or other news-paper extraordinary, is that publifhed after fome great and notable event, containing the detail or particulars thereof, which are not found in the ordinary papers. Our news-writers generally ufe poftfcripts, or fupplements, inftead of extraordinaries.

Extraordinary *culverin*. See Culverin.

EXTRAVAGANTES, a part of the canon law, containing divers conftitutions of the popes, not included in the body of the canon-law; whence the denomination extravagantes: "quafi extra corpus juris vagantes."

The extravagantes are divided into two parts: the firft contains twenty conftitutions of John XXII. and the fecond other later conftitutions of the faid John, and his fucceffors. See Canon-*Law*, and Decretals.

EXTRAVASATION, a term in *Surgery*, derived from *extra*, *out of*, and *vafa*, *the veffels*; it fignifies an effufion of any fluid from the veffels, vifcus, or receptacle, in which fuch fluid is naturally contained, and the paffage of the fame into another fituation, which is very frequently the interftices of the cellular membrane. In the head, blood is often extravafated, under the cranium, upon the furface of the dura mater, in confequence of the rupture of one of the arteries of this membrane from external violence. The fame fluid is alfo frequently extravafated on the pia mater, and in the convolutions of the cerebrum, or, more deeply in the ventricles, and very fubftance of the brain.

In cafes of wounds of the abdomen, large quantities of blood are occafionally extravafated in the cavity of the peritonæum, or the contents of the ftomach, bowels, gall-bladder, or fome other injured vifcus, may become effufed. When the urinary bladder is wounded, or when a flough takes place in a certain part of it, from the diftenfion occafioned by a long protracted, and unrelieved retention of urine, the latter fluid may become extravafated in the abdomen. In the example of ftrictures, the urethra occafionally ulcerates between the obftruction, and the neck of the bladder, and the urine is confequently extravafated in the cellular membrane of the perinæum and fcrotum. Sometimes, when a portion of the bowels mortifies, after being returned into the belly, in cafes of hernia, the inteftinal matter efcapes from the alimentary canal, through the breach occafioned by the floughing.

In the thorax, furgeons fometimes have opportunities of feeing cafes, in which confiderable extravafations of blood arife, in confequence of ftabs and gun-fhot wounds.

In the limbs, and indeed, we might fay, in every fituation, practitioners frequently meet with extravafations of blood, in cafes of wounded arteries, aneurifms, and violent contufions

contufions and blows, which rupture veffels of important fize. Bloody fwellings, produced in the laft-mentioned manner, are technically named ecchymofes, and have already been treated of elfewhere. See Ecchymosis.

Our defign, in the prefent place, is to confider extravafations in a furgical point of view, as they occur in the head, the cheft, and the belly; taking occafion, however, to refer the reader for certain parts of the fubject to other places in this work.

Extravafation of blood in the head, from external violence.—After explaining with equal perfpicuity and elegance, how the dura mater ferves as a periofteum to the internal furface of the bones of the cranium, in the fame manner as the pericranium does to the external table, Mr. Pott notices, that by blows, falls, and other fhocks, fome of the larger of the veffels, which carry on the communication between the dura mater and the fkull, may be broken, and a quantity of blood fhed upon the furface of that membrane. This, he obferves, is one fpecies of bloody extravafation, and, indeed, the only one which can be formed between the fkull and dura mater. If the broken veffels be few, and the quantity of blood which is fhed, be fmall, the fymptoms are generally flight, and, by proper treatment, difappear: when they are large, or numerous, or the quantity of extravafated fluid confiderable, the fymptoms are generally urgent in proportion; but, continues Mr. Pott, whether they be flight, or confiderable, whether immediately alarming, or not, they are always, and uniformly, fuch as indicate preffure made on the brain and nerves, *viz.* ftupidity, drowfinefs, diminution, or lofs of fenfe, fpeech, and voluntary motion.

The fhock which the head fometimes receives by falls from on high, or by ftrokes from ponderous bodies, may likewife occafion a breach in fome of the veffels, either of the pia mater, or brain, and thus produce an extravafation of the fluid which fhould circulate through them.

Mr. Pott remarks, that an extravafation may be the only complaint caufed by the accident; or it may be joined with, or added to, a fracture of the fkull. But, this is not all; for it may be produced not only when the cranium is unhurt by the blow, but, even when no violence of any kind has been offered to, or received by the head.

Vertigo, vomiting, ftupidity, hemorrhage, lofs of fenfe and motion, either partial or total, are fet down by this celebrated furgical author as the fymptoms of an extravafation within the cranium; fometimes one or more occur in the fame fubject; fometimes all of them. Thefe fymptoms, which are all eafily accountable for from extravafation of fluid, and unnatural preffure made on the brain and nerves, are, fays Pott, frequently miftaken as indications of a difeafe, which, confidered abftractedly, can never caufe them; he means a fimple undepreffed fracture of the cranium, which may be accompanied by them, but cannot caufe them.

The fame writer repeats, that when a fluid is extravafated in any confiderable quantity within the cavity of the cranium, if any bad fymptoms are produced by it at all, they are, and muft be, fuch as indicate preffure made on the brain, and origin of the nerves, occafioning thereby either difturbance, or abolition of the offices of fenfe and motion; and this in a different degree, according to the quantity, kind, and fituation of the preffing fluid.

Mr. Pott feems to have entertained the common notion of hemorrhage from the ears and nofe being alfo fymptoms of an extravafation. However, the leaft reflection muft foon make any body perceive, that a bleeding from thofe parts is only indicative of their having fuftained a violent fhock in common with the reft of the head. Even the degree of violence is not at all denoted with any certainty by thefe circumftances; for, with refpect to the nofe, we know, that, in many perfons, the flighteft caufe will make it bleed.

When the above-mentioned fymptoms exift, Mr. Pott was of opinion, that we might pronounce, in a pofitive manner, our judgment, that the brain fuffers compreffion; but, fays he, to our very frequent mortification, we find thefe are the only circumftances which, in fuch cafe, we can depend upon; every thing elfe which relates, or belongs to them, being involved in a moft perplexing obfcurity. We not only have no certain infallible rule whereby to diftinguifh what the preffing fluid is, or where it is fituated; but we are, in many inftances, abfolutely incapable of knowing whether the fymptoms be occafioned by any fluid at all; for, a fragment of bone broken off from the internal table of the cranium, and making an equal degree of preffure, will produce exactly the fame complaints.

When a cafe, attended with the preceding fymptoms, occurred, the old furgeons ufed in general to conclude, that the brain had fuffered a concuffion, to which all the confequences were imputed.

Mr. Pott obferves, that a concuffion and an extravafation are very diftinct caufes of mifchief, though not always very diftinguifhable. M. Le Dran, and others of the modern French writers, have made a very fenfible and juft diftinction between that kind and degree of lofs of fenfe, which arifes from a mere commotion of the brain, and that which is caufed by a mere extravafation, in thofe inftances, in which the time of the attack or appearance of fuch fymptoms, is different, or diftinct. The lofs of fenfe, which immediately follows the violence, fay they, is moft probably owing to a commotion; but, that which comes on after an interval of time is paft, is moft probably caufed by extravafation.

Mr. Pott remarks, that this diftinction is certainly juft and good, as far as it will go. That degree of abolition, or diminution of fenfe, which immediately attends, or follows the blow or fall, and goes off again, without the affiftance of art, is in all probability occafioned by the fudden fhake or temporary derangement of the contents of the head; and the fame kind of fymptoms recurring again fome time after they had ceafed, or not coming on until fome time has paffed from the receipt of the violence, do moft probably proceed from the breach of a veffel within, or upon the brain. But, unluckily, we have it not very often in our power to make this exact diftinction. An extravafation is often made fo immediately, and fo largely, at the inftant of the accident, that all fenfe and motion are inftantaneoufly loft, and never again return. And it alfo fometimes happens (continues Mr. Pott), that, although an extravafation may poffibly not have been made at the moment of the accident, and the firft complaints may have been owing to commotion merely, yet a quantity of fluid having been fhed from its proper veffels very foon after the accident, and producing its proper fymptoms, before thofe caufed by the commotion have had time to go off, the fimilarity of the effects of each of thefe different caufes is fuch, as to deprive us of all power of diftinguifhing between the one and the other, or of determining, with any tolerable precifion, to which of them fuch fymptoms as remain are really owing.

Mr. Pott next obferves, that the nature and degree of the fymptoms, produced by the preffure of an extravafation, are various and different in different perfons, according to the kind, quantity, and fituation of the preffing fluid. Sometimes it is mere fluid blood; fometimes blood in a ſtate of coagulation; ſometimes it is a clear lymph; and, at others, blood and water are found mixed together; each of theſe is found either ſimple or mixed in different ſituations; that is, between the ſkull and dura mater, between the dura and pia mater, or in the natural cavities of the brain, called its ventricles, and ſometimes, in caſes of great violence, they are found at the ſame time in all theſe different parts. Sometimes, a conſiderable quantity is ſhed inſtantly at the time of the accident; and ſometimes the breach, by which the effuſion is made, is ſo circumſtanced, both as to nature and ſituation, that it is at firſt very ſmall, and increaſes by faſter or ſlower degrees. In the former (ſays Pott), the ſymptoms are generally immediate and urgent, and the extravaſation is of the bloody kind. In the latter, they are frequently ſlight at firſt, appear after ſome little interval of time, increaſe gradually, till they become urgent, or fatal, and are, in ſuch caſe, generally occaſioned by extravaſated lymph. So that although the immediate appearance of bad ſymptoms does moſt certainly imply miſchief of ſome kind or other, yet, on the other hand, no man ought to ſuppoſe his patient free from hazard, either becauſe ſuch ſymptoms do not ſhew themſelves at firſt, or becauſe they appear to be but ſlight; thoſe which come on late, or, appearing ſlight at firſt, increaſe gradually, being full as much to be dreaded as to conſequence as the more immediately alarming ones; with this material difference between them, that the one *may* be the conſequence of a mere concuſſion of the brain, and may by means of quietude and evacuation go quite off; whereas, the other being moſt frequently owing to an extravaſation of lymph, (though ſometimes of blood alſo,) within the ſubſtance of the brain, are very ſeldom removed by art. (Pott's Works, vol. i.) It appears from ſome excellent obſervations publiſhed by Mr. Abernethy on the ſubject of injuries of the head, that a fracture of the ſkull is not likely to be followed by an equal degree of extravaſation in every part, as the veſſels, connecting the dura mater to the cranium, are in moſt parts of that membrane of a ſmall ſize. If theſe are accidentally ruptured, a ſlight hemorrhage enſues, which ſoon ſtops, and only a thin ſtratum of coagulated blood is found, if the bone be removed. But, ſays Mr. Abernethy, if the fracture happens in the track of the principal artery of the dura mater; if the trunk, or even a conſiderable branch of that veſſel be torn, the hemorrhage will be profuſe, and the operation of the trephine becomes immediately neceſſary to preſerve the life of the patient.

When an interval of ſenſe occurs between the blow and the ſtupor occaſioned by the effuſed blood, the diſcrimination of the nature of the caſe is greatly facilitated by that circumſtance, as we have already related, becauſe it becomes manifeſt, that the bad ſymptoms, which now come on, are not owing to the firſt mere ſhock of the external violence on the brain. The patient was moſt probably ſtunned by the blow, at the very inſtant of its occurrence; but he gradually regained his ſenſes, in proportion as the firſt effects of the ſhock on the brain ſubſided. However, as ſome veſſel was wounded by the ſame blow, an hemorrhage continues under the cranium, on, or within, the brain, and as ſoon as a certain quantity of blood is extravaſated, its preſſure produces a recurrence of ſtupefaction.

Unfortunately, great obſcurity attends numerous caſes, in conſequence of patients having no interval of ſenſe, and remaining in a ſtate of complete ſtupefaction ever after the accident. We know not, whether the brain is labouring under concuſſion, or compreſſion, or both; and even when we do know that the bad ſymptoms ariſe from an extravaſation, we are frequently unable to ſay where the effuſed blood is ſituated. Now, ſince the operation of trepanning is not likely to afford aſſiſtance, unleſs the blood be upon the dura mater, ſo as to allow of being taken away, and ſince the operation itſelf is by no means free from danger, we ſhould be very reluctant to put it in practice, without having good foundation for believing that there will be found immediately under the perforation, which we are about to make in the bone, the extravaſated blood, which gives riſe to the urgent complaints. Practitioners are highly indebted to Mr. Abernethy for a ſuggeſtion, which promiſes to be of exceedingly great aſſiſtance in directing whether the trephine ought to be uſed, or not, on a particular part of the head. "Unleſs one of the large arteries of the dura mater be wounded, (ſays this gentleman,) the quantity of blood poured out will be inconſiderable; and the ſlight compreſſion of the brain, which this occaſions, may not be attended with any peculiar ſymptoms; or, perhaps, it may occaſion ſome ſtupor, or excite an irritation diſpoſing the ſubjacent parts to become inflamed; but both theſe effects will gradually abate, nor will any inflammation enſue, if proper means are taken to prevent it. It is indeed highly probable that in many caſes, which have done well without an operation, ſuch an extravaſation has exiſted. But, if there be ſo much blood on the dura mater as materially to derange the functions of the brain, the bone, to a certain extent, will no longer receive blood from within; and by the operation performed for its expoſure, the pericranium muſt have been ſeparated from its outſide. I believe, that a bone ſo circumſtanced will not be found to bleed; and I am certain it cannot with the ſame freedom and celerity, as it does when the dura mater remains connected with it internally."

In ſome caſes, related by Mr. Abernethy, there was not the leaſt hemorrhage, and this gentleman mentions his having twice been able, by attending to the want of hemorrhage from the outſide of the cranium, to aſcertain the extent to which the dura mater was detached within. Alſo, when ſymptoms ſeemed to require the perforation of the ſkull, Mr. Abernethy has frequently ſeen the operation contra-indicated by the hemorrhage from the bone, and rightly, as the event proved.

When the bone has been for ſome time bare, this criterion may not be ſo clear; but Mr. Abernethy ſcraped the ſurface of a portion of the ſkull, which had remained ſome time in a denuded ſtate, and he found that it bled freely enough to denote that the dura mater was adherent to the inner-table, and, conſequently, that making a perforation there could be of no ſervice. See Eſſay on Injuries of the Head, p. 32—34.

We ſhall next enumerate the ſymptoms of preſſure on the brain, and contraſt them with thoſe of concuſſion. It is to be underſtood, that the complaints produced are nearly the ſame, whether the preſſure is made by an extravaſation, or a fracture of the cranium with depreſſion.

Symptoms of Preſſure.

1. Patient at firſt ſtunned, with cold extremities.
2. Revives, and has an interval of ſenſe, in caſes of extravaſation, but not in thoſe of a depreſſed fracture.
3. The quantity of effuſed blood increaſing, he becomes drowſy and ſtupid.
4. Pulſe regular and ſlow.
5. Patient quite inſenſible.
6. Pupil dilated.
7. Stertorous reſpiration.

N.B. When the bleeding is very copious in the firſt inſtance,

ſtance, or when a violent concuſſion of the brain has alſo happened, the patient has no interval of ſenſe.

Symptoms of Concuſſion.

First ſtage.

1. Patient at firſt ſtunned.
2. Extremities cold; pulſe hardly perceptible.
3. When the violence has not exceeded a certain degree, the ſenſes return gradually.
4. The ſtomach rejects its contents; ſickneſs betrays irritability in the œſophagus and ſtomach, and cannot be expected, when the brain is labouring under much compreſſion, the great effect of which is to produce an univerſal inſenſibility, or palſy, throughout the body.
5. The pulſe is now ſlow, and intermits.

Second ſtage.

6. In proportion as the immediate effects of the ſhock of the brain ſubſide, ſymptoms of irritation and inflammation of that organ come on.
7. Symptomatic inflammatory fever begins.
8. Pupil of the eye contracted.
9. The veſſels of the eye become red and turgid.
10. Delirium.
11. Pulſe very frequent and ſmall.

We ſhall not expatiate on this ſubject; but refer to Compression, Concussion, Injuries *of the* Head, and Trepanning, for further information.

Extravaſation of blood in the thorax.—In caſes of wounds which penetrate the cavity of the cheſt, the intercoſtal arteries are liable to be injured, and if the blood cannot readily flow outward through the wound, it is apt to inſinuate itſelf between the pleura and lungs. An extravaſation of blood may alſo occur in the thorax, when ſome of the veſſels of the lungs, one of the coronary arteries of the heart, or the internal mammary artery, have been wounded. An effuſion of blood in the cheſt may likely obviouſly originate from a wound of the auricles, or ventricles of the heart, or of the thoracic aorta, and vena cava; but we need hardly obſerve, that in theſe and other inſtances, in which the bleeding would be in a moment exceſſively profuſe, the extravaſation proves inſtantly fatal. Smaller veſſels are frequently injured, and pour out a conſiderable quantity of blood in the cheſt; yet the records of ſurgery evince, that theſe accidents do not always have a fatal termination.

The ſymptoms commonly enumerated by ſurgical writers, as indicative of an extravaſation of blood in the thorax, are the following: the patient is greatly oppreſſed, and experiences a kind of uneaſineſs which will not let him remain for any length of time in the ſame poſture. He feels conſiderable difficulty in ſitting up in bed, except his body be bent a good way forward, in which poſition the diaphragm is relaxed, and not ſo much dragged by the weight of the extravaſated fluid. When the thighs are bent, the patient can lie with tolerable eaſe on his back, he is alſo not averſe to lying on the ſide on which the wound is ſituated; but he cannot place himſelf on the oppoſite one, without feeling very acute pain in the ſituation of the mediaſtinum.

His reſpiration is ſhort, frequent, and interrupted by ſighs; his veins become empty, a mortal paleneſs ſpreads over his countenance; his extremities become cold; a viſcid perſpiration covers his neck and temples; his teeth chatter, his pulſe grows weak, and if (as moſt frequently happens) the lungs are wounded, he coughs up frothy blood, and air iſſues from the wound.

The preceding claſs of ſymptoms, however, are not always attendant on every conſiderable effuſion of blood in the thorax. Wounded perſons have been known to die of ſuch an extravaſation, whoſe reſpiration was tolerably free, and who did not complain of ſuffering more inconvenience in one poſture than another. Sabatier ſtates, that ſeveral facts of this kind have fallen under his own obſervation. Other wounded perſons alſo, who have had moſt of the complaints, uſually imputed to extravaſations of blood in the thorax, have been cured by ordinary means.

The ſymptoms of an extravaſation of blood in the thorax are upon the whole very equivocal. Hence, ſeveral attentive practitioners have taken extraordinary pains to diſcover additional circumſtances, by which the nature of the caſe might be more infallibly aſcertained. Theſe endeavours, however, ſeem to have been attended with little ſucceſs. A ſurgeon of the name of Valentine aſſerted, that a ſort of ecchymoſis of the integuments, over the angles of the ribs, was an invariable ſymptom; but ſucceeding obſervers have not found the remark correct.

When there is no doubt in the practitioner's mind that blood is extravaſated in the cavity of the thorax, and that it is the occaſion of a dangerous oppreſſion of the lungs and diaphragm, the obvious indication is to endeavour to promote the eſcape of the effuſed fluid. However, before undertaking any operation, the revived ſtate of the pulſe, the return of warmth in the extremities, and the ceſſation of convulſions ought to denote, that the hemorrhage no longer continues from the wounded veſſels. If vent were given to the extravaſation before the bleeding had ceaſed, a freſh quantity of blood would ſoon be poured out in the cheſt, and the patient die exhauſted.

For another reaſon, alſo, prudence requires that the practitioner ſhould not precipitately have recourſe to an operation: *viz.* allowing a little while gives nature an opportunity of employing her own reſources, and any one who will be at the trouble of referring to books of ſurgical caſes, will ſoon meet with examples in which there is every reaſon to believe that there was more or leſs blood extravaſated in the cheſt, though the patients completely recovered without any operation.

There are five principal methods of diſcharging blood from the cavity of the cheſt. 1. By placing the patient in a poſture which favours the eſcape of the blood. 2. By introducing a ſyringe for the purpoſe of ſucking it out, or a mere cannula, through which it is to flow. 3. By enlarging the wound. 4. By employing injections, with which the clots of blood are to be waſhed away. 5. By making an opening into the thorax in a depending ſituation.

Having thus curſorily treated of extravaſations in the cheſt, we ſhall quit the ſubject for the preſent, intending to reſume the conſideration of it in ſpeaking of wounds of the thorax. See Wounds.

For an explanation of the method of making a depending opening into the cheſt, ſee Paracentesis.

Extravaſations in the Abdomen.—Various kinds of fluids may be extravaſated in the abdomen in caſes of wounds, ſloughing of the inteſtines, &c. Bile, chyle, urine, blood, feces, &c. are all apt to be effuſed under particular circumſtances. Surgeons uſed formerly to ſuppoſe, that whenever any fluid eſcaped from a veſſel, or bowel, into the general cavity of the peritonæum, it always became extenſively diffuſed among the convolutions of the inteſtines. The erroneous ſuppoſition ſeemed to be confirmed by facts, the most open to obfervation, and completely exempt from the poffibility of miftake. Practitioners faw that the water of dropfies, the pus of abfceffes, which had burft into the abdomen, as well as the chyle and feces, which had efcaped through a wound, or other fort of breach of an inteftine, were invariably and univerfally diffufed among the folds of the mefentery and bowels after death.

M. Petit (the fon) firft queftioned the accuracy of the foregoing opinion, in relation to the patient while alive. He fuggefted that as in the living body the inteftines were diftended with feces, alimentary matter and air, while they were alfo mutually acting againft each other, and in a continual ftate of compreffion from the alternate contraction of the diaphragm and abdominal mufcles, there might be a fuperior refiftance made to the weight of the extravafated fluid tending to feparate the vifcera to which we allude. On the contrary, fays Petit, is it not poffible that, as foon as the patient is dead, and the above kind of refiftance is taken away, the extravafated fluid may infinuate itfelf any where without difficulty? M. Petit remarks, that the truth of the preceding fuggeftion cannot be doubted, when we confider, that certain cafes of hernia get well, notwithftanding the burfting of the gangrenous part of the inteftine, after its reduction into the abdomen. In fuch inftances, in fact, the contents of the bowels appear to efcape outward through the wound entirely in confequence of the refiftance made to their diffufion among the convolutions of the inteftines. However it might be objected, that, in cafes of hernia, fince the bowel is almoft always adherent to the edge of the abdominal ring, the iffue of the inteftinal matter through the wound is rather to be afcribed to the eafe with which this event may happen, than to any refiftance made internally by the furrounding vifcera. But M. Petit cites feveral cafes, which fully confirm, that there is a vaft refiftance made to the lodgment of extravafated fluids among the convolutions of the bowels, and folds of the mefentery.

After death, any fluid, extravafated in the abdomen, may by its mere gravity infinuate itfelf any where, and become difperfed among the various parts, becaufe thefe parts being without action make no oppofition. But in the living ftate, all the abdominal vifcera reciprocally act upon each other, and forming, as it were, only one body, by reafon of fuch mutual fupport, the refiftance which is made to any extravafated matter will always keep it from becoming widely diffufed, in the manner which many have imagined.

Let us next, with M. Petit, reflect upon the inferences to be drawn from fuch reciprocal action of the abdominal vifcera.

The firft confequence is, that an extravafated fluid can only infinuate itfelf into the cavity of the abdomen, in the fame way that a fluid becomes effufed in an external part; that is to fay, the extravafation can only fpread by degrees, and fucceffively, into fuch places as offer the leaft refiftance. Blood, when it infinuates itfelf into the interftices of the mufcles, can only get from one membranous cell into another, by the firft one being fo diftended, that the fluid can more readily get into a fecond cell, and from this into a third, than increafe the diftended ftate of its firft fituation. Juft fo in the abdomen, the blood which efcapes from a wounded veffel, is firft effufed into a fituation near the opening in the veffel, either between the peritonæum and furface formed by the inteftines, or more deeply among the convolutions of the bowels, or fome of the folds of the mefentery. In the proportion as the bleeding continues, the blood forces its original boundary, and dilates the place which it occupies, in every direction, until it meets with lefs refiftance in making its way, either upward or downward, or to the right or left. The extravafation continues to dilate the new fpace, which it fills in the fame way, until either the firft limits are forced, or the effufed fluid fpreads in fome other direction. The extravafation will expand in this manner, till the refiftance, made by the vifcera, becomes equal to the impetus, with which the blood iffues from the veffel. M. Petit was of opinion, that it was this kind of refiftance which put a ftop to the hemorrhage, even before any coagulum had been formed in the opening of the veffel. That the blood, while flowing from the veffel and in a fluid ftate, fhould only make one mafs and be contained in one cavity, till coagulation takes place, is a circumftance which cannot rationally be imputed to any thing elfe, than the refiftance depending upon the mutual action of the vifcera in the living ftate. It is alfo equally certain, that it is in confequence of the fudden ceffation of fuch refiftance, that extravafated blood, which is fluid after death, becomes difperfed among the different convolutions of the bowels, and forms numerous fcattered collections.

The fecond inference which M. Petit mentions, as deducible from the refiftance arifing from the reciprocal preffure of the abdominal vifcera, is that an extravafation in the cavity of the abdomen cannot fo eafily happen, as fome have fancied. It was once not an uncommon idea, that a breach in a very moderate veffel could occafion a confiderable extravafation, becaufe the orifice could not be compreffed, like that of a veffel in a more external fituation. It is indeed true, that no compreffion can be directly applied to the opening in an internal veffel; but the refiftance which the furrounding vifcera make to the extravafation, operates as a fubftitute. It is even probable, according to Petit, that when blood is effufed in the abdomen, it has a greater refiftance to overcome, than when extravafated in an external part. This author ftates, that the refiftance of the cellular membrane, the common bond of connection between the mufcles, is undoubtedly lefs than that which depends on the reciprocal action of the inteftines, and reft of the vifcera. The inceffant alternate motion of the abdomen and thorax is in favour of the preceding opinion. The facility alfo, with which abfceffes fituated in the abdomen are difcharged, through a fmall, and very frequently not a depending opening, is an additional fact, proving that the abdominal vifcera, by the manner in which they mutually prefs upon each other, make a greater refiftance to an extravafation, than can be made by the cellular fubftance in other parts of the body.

Swords have often been thruft completely through the body, without giving rife to any dangerous fymptoms, or only to fuch as frequently attend wounds, which do reach into the cavity of the belly. We cannot imagine, contrary to all probability, that, in this cafe, the weapon has flipped over the inteftines, through their interftices, and by good luck has wounded none of the blood-veffels. We muft rather conclude, that an extravafation does not always enfue from a wound of the vifcera or blood-veffels, or at leaft, that the extravafation is not invariably attended with fuch confequences as former practitioners ufed to fuppofe.

For the purpofe of rendering the foregoing remarks more intelligible, let us follow M. Petit in his obfervations, and take notice of the principle which he has laid down in his excellent memoir, *viz.* that without a particular action in the mufcular fibres of the inteftine or artery, no extravafation would occur in the abdomen, even were there a breach in fuch bowel or veffel. Suppofing the blood veffels deftitute of action, and the place of the opening preffed upon by a force equal to that, which operates upon the reft of their extent, the fluid, which they contain, would never be be effufed in the abdomen, fo as to form an extravafation. Befides its being evident, that this muft be the fact, M. Petit mentions his having actually obferved it in the body of a man, who died of gangrene in the abdomen, in confequence of a hernia, which was attended for upwards of a fortnight with the moft violent fymptoms of ftrangulation. Nearly the whole of the inteftinal canal was equally affected with gangrenous mifchief, fo that it was fcarcely poffible to handle any of the bowels without occafioning a breach in them. However, although the inteftines were filled with very fluid excrement, none of it was extravafated in the abdomen. In feveral places, indeed, Petit difcovered numerous little breaches of continuity, which had allowed a little of the excrement to efcape, but only juft enough to tinge the adjacent parts. Petit acknowledges, at the fame time, that round where thefe holes were fituated, fome flight adhefions had taken place between the bowels, and thefe and other parts ; but they were fo weak, and eafily broken, as to be quite incapable of hindering an extravafation. Petit concludes, that in this inftance no extravafation happened, becaufe the inteftinal canal was every where affected with gangrene in nearly the fame degree, and the difeafe had deftroyed the tone and action of the mufcular fibres of the inteftines.

It is contended by Petit, that the foregoing cafe affords fufficient proof, that, without a contractile power in the blood veffels and inteftines, no extravafation of their contents could be produced in the abdomen, and that fuch an event would certainly be oppofed by the action of the abdominal mufcles and diaphragm, which make uniform and equal preffure upon all the vifcera. If this ftatement be correct, it is obvious, firft, that the greater the action of the wounded veffels is, in relation to the quantity of fluid which they have to propel, the greater will be an extravafation from them : fecondly, that no extravafation can arife unlefs the action of the veffels themfelves be capable of overcoming the refiftance depending upon the mutual action of the parts. Hence, only wounds of veffels above a certain fize can give rife to extravafations, at leaft, to any of importance. The veins cannot occafion fo much extravafation as the arteries : nor are wounds of the inteftines fo apt to be followed by an effufion of the chyle and feces, as the fame injuries of the blood veffels are liable to be attended with an extravafation of blood. Petit was alfo of opinion, that wounds of the ftomach were not fo often as thofe of the bowels the caufe of this kind of accident.

The feces cannot be fo eafily extravafated as blood, not only becaufe the action of the inteftines, particularly that of the fmall ones, upon their contents, is weaker than that of the blood veffels upon the blood, but, principally, becaufe, when there is a breach in one of the bowels, the contents will continue their courfe through the inteftinal canal, without any need of there being a confiderable obftacle to the occurrence of an effufion. However, Petit admonifhes us not to conclude, from what has been faid, that the chyle and feces can never be extravafated in the abdomen. There is no doubt whatever, he obferves, that an extravafation may take place, when the wound in the bowel is of ample fize, the gut filled with chyle or excrement, and care is not taken to empty the large inteftines very often with glyfters. The event may alfo happen, when pain and irritation render the mufcular action of the inteftines violent, irregular, and convulfive, and when unequal preffure is made upon the abdomen. Under fuch circumftances, the refiftance made to an extravafation, by the reciprocal action of the vifcera, is overcome, and the contents of the bowels will continue to be effufed, until the impulfe arifing from the contractile power of thefe organs returns to a ftate of equilibrium with the refiftance depending on the mutual action of all the vifcera.

The extravafation of chyle and feces does not take place differently from that of blood ; but in wounds of the bowels there is this advantage, that the fame opening which has given paffage to the extravafated fluid, may alfo allow it to return and pafs off. Petit remarks that we need no further proof of what has been ftated, than the great evacuations of blood, which fome wounded perfons have had with their ftools, without being afflicted with any of the fymptoms of extravafation. It is highly improbable, that fuch bleeding could depend upon the injury of any of the veffels ramifying upon the inteftinal canal, fince their fize is too inconfiderable. We rather believe that, in thefe cafes, fome veffels, either of the mefentery, or fome other part, have been wounded at the fame time as the inteftine, and that the blood has infinuated itfelf into, and taken its courfe through the bowels, in confequence of the refiftance made to its extravafation among the vifcera.

The foregoing remarks, made by Petit (the fon), clearly prove not only that an extravafation of feces cannot fo eafily happen in the abdomen as has been imagined ; but, alfo, that it is lefs dangerous than an effufion of blood ufually is, and that it is accompanied by lefs violent fymptoms. When the contents of the bowels are extravafated, adhefions are likewife obferved to form more readily, and to limit the effufed matter fooner, than when the extravafation confifts of blood. After fuch adhefions have once formed, it is probable that the extravafated matter may be got rid of in the fame favourable way, as certain abfceffes, which have difcharged themfelves into the inteftinal canal. Blood, however, cannot infinuate itfelf again into the canal of the veffel, out of which it has efcaped, becaufe a clot blocks up the opening. But a wound in an inteftine remains continually open, till it is clofed by the adhefions which the bowel contracts to the adjacent parts : adhefion, indeed, is the only means by which a wound of this defcription can be healed.

M. Petit remarks, that among the numerous facts which might be adduced in proof of the difficulty with which a wound of the ftomach permits the aliment to be extravafated, the operation of an emetic in this cafe is a ftriking one. Petit expreffes his belief, that vomiting does not depend upon the action of the mufcular fibres of the ftomach, but entirely upon the fudden and violent contraction of the abdominal mufcles. This author conceives, that, if the particular action of the ftomach itfelf had much concern in the production of vomiting, an extravafation of the alimentary matter would neceffarily happen in the abdomen when that vifcus is wounded. However, in the inftances referred to by Petit, the occurrence did not take place, becaufe, notwithftanding the violence with which the abdominal mufcles and diaphragm contracted, they made equal and uniform preffure on all fides of the ftomach. The danger of an extravafation is alfo lefs, inafmuch as a wound of the ftomach is always much fmaller in relation to its cavity, than that of a bowel, in regard to the inteftinal canal.

Circumftances are very different, in refpect to wounds of the gall and urinary bladders, efpecially when thefe receptacles are full. An extravafation is then an inevitable confequence, both on account of the great fluidity of the bile and urine, and of the contractile power with which the parts are endued, and againft which the action of the abdominal mufcles makes no fort of refiftance. An extravafation of thefe fluids is extremely dangerous, by reafon of their irritating quality with refpect to the vifcera. The co-

lics,

lies and irregular contractions which fuch ftimulating fluids excite, caufe the extravafation to become more widely diffufed. The eafe alfo, with which the bile and urine mix with the ferum, that naturally moiftens the furfaces of all the vifcera, leads us to fufpect, that whenever thofe fluids are extravafated, they very foon become univerfally difperfed among all the convolutions of the inteftines.

Againft thefe latter extravafations little can be done, and unlefs they are in fmall quantity, and their increafe can be prevented, the patient's life hardly admits of being faved. Leaving a catheter in the bladder, indeed, is a fure means of hindering the extravafation of urine from augmenting; but not much confidence can be placed in the kind of outlet afforded by the duct of the gall-bladder.

When the extravafated matter is completely encyfted and circumfcribed, it happens, that as fuch matter had to overcome the refiftance of the parts before it could be effufed, no fooner is a paffage afforded for its efcape, than the reaction of the feparated parts neceffarily forces out whatever fluid has infinuated itfelf between them. This is a third confequence, which is pointed out by Petit as refulting from the refiftance, made by the reciprocal action of the abdominal vifcera, to extravafations.

The foregoing obfervations tend to fhew, that an extravafation in the abdomen, and efpecially one of blood, may be as completely difcharged as a collection of fluid in the thorax. The evacuation, at leaft, may always be eafily effected, when the extravafation is bounded at any part by the parietes of the abdomen: a circumftance, which muft invariably occur, whenever the extravafation is confiderable. Indeed Petit informs us, that it was always the cafe, as far as his experience went even when the effufion was not very copious.

It is not enough to make furgeons underftand, that fluids, extravafated in the abdomen, admit of being difcharged by an operation; we deem it alfo neceffary to explain the fymptoms denoting the cafes in which fuch a proceeding is proper.

In order to underftand this interefting part of the fubject, Petit, and moft furgical writers after him, have advifed us to draw a diftinction between the confecutive fymptoms and the primary ones, or thofe which attend the wound from the firft, and are, ftrictly fpeaking, proper to it, becaufe they depend effentially upon the divifion of the injured parts. Such breach of continuity occafions, from the firft, pain, irritation, tenfion, convulfions, and fwelling and inflammation of the abdomen, affections naturally leading to other confecutive fymptoms, which vary according to the injured parts, and the degree of inflammation. Of the latter clafs are, hiccough, vomiting, conftipation, fuppreffion, or retention of the bile and urine, a great deal of fever generally at firft, and, after the inflammation has attained a certain pitch, a concentration and finking of the pulfe, confiderable proftration of ftrength, and cold fweats.

If when the firft train of fymptoms has been relieved, and after an interval of from four to eight days or more, the fymptoms recur, or become exafperated, without any apparent caufe, we may infer that fuch confecutive complaints depend upon an extravafation.

It may at firft feem extraordinary, that the fymptoms of an extravafation of blood fhould be confecutive; for, as the effufion takes place at the moment, when the wound firft happens, why do not the fymptoms commence at the fame time?

Petit has referred the reafon to the following circumftances: blood, extravafated in the abdomen, does not give rife to any complaints, either by the preffure which it makes, or by its quality; and whenever any fymptoms are occafioned on the firft occurrence of the effufion, they are thofe of weaknefs, depending on the lofs of blood to the circulation. The extravafation afterwards becomes entirely circumfcribed by the adhefions, which are produced by the inflammation around. An additional quantity of fluid continues to be fecreted from the veffels into the encyfted cavity of the effufed blood, and confequently pain, inflammation, &c. are occafioned by the increafing diftention, now produced.

We fhall not ftop to enquire into the accuracy of the latter part of the foregoing ftatement, as the fact, that the fymptoms of an extravafation are confecutive, is a piece of information highly important to the practitioner, while the theory of the fubject is a fubordinate confideration.

The remainder of the remarks, refpecting extravafations in the abdomen, and their treatment, will be found in the article WOUNDS. Some obfervations will alfo be offered, when we fpeak of HERNIA.

EXTRAVASATION is a term fometimes likewife ufed by the gardeners in fpeaking of gums, juices, &c. which oufe out of their trees either fpontaneoufly, or at incifions.

EXTREAM, or EXTREME, is applied to the laft and outermoft part of any thing; or that which finifhes and terminates it on that fide.

The extreams of a line are points. There is no paffing out of one extream into the other, without going through the middle. Extream remedies muft only be had recourfe to in extream neceffity.

Some anatomifts apply the denomination extremes, or extremities, to the arms and legs. See EXTREMITIES.

EXTREAMS, in *Logic*, denote the two extream terms of the conclufion of a fyllogifm, *viz.* the predicate and fubject.

They are called extreams, from their relation to another term, which is a medium or mean between them.

The predicate, as being likewife had in the firft propofition, is called the *majus extremum*, greater extream; and the fubject, as being put in the fecond, or minor propofition, is called the *minus extremum*, leffer extream.

Thus, in the fyllogifm, man is an animal: Peter is a man, therefore Peter is an animal; the word animal is the greater extream, Peter the lefs extream, and the man the medium. See SYLLOGISM.

EXTREAM *and Mean Proportion*, in *Geometry*, is when a line is fo divided, that the whole line is to the greater fegment, as that fegment is to the other.

Or, as Euclid expreffeth it, when the line is fo divided, that the rectangle under the whole line, and the leffer fegment, is equal to the fquare of the greater fegment.

The invention of this divifion is thus: let the given line be $AB = a$ (*Plate* VII. *Geometry. fig.* 87.) and for the greater fegment put x, the leffer will be $a - x$. Then, by the hypothefis, $a : x :: x : a - x$. Therefore, $aa - ax = xx$, confequently $aa = ax + xx$. And, by adding $\frac{1}{4}aa$ on each fide, to make $xx + ax + \frac{1}{4}aa$, a complete fquare, the equation will ftand thus, $\frac{5}{4}aa = xx + xa + \frac{1}{4}aa$.

Now, fince the latter is exactly a fquare, its root $x + \frac{1}{2}a = \sqrt{\frac{5}{4}aa}$, and by tranfpofition it will be $\sqrt{\frac{5}{4}aa} - \frac{1}{2}a = x$; which laft equation is a canon for finding x.

For at the foot of $AB = a$, fet at right angles $CB = \frac{1}{2}a$; then draw CA, the fquare of which is equal $ABq + CBq = \frac{5}{4}aa$. And therefore $AC = \sqrt{\frac{5}{4}aa}$; make $CD = CA$. From whence $CB = \frac{1}{2}a$ being taken as the

cafe

case requires, there remains B D = x; which transferred into A B, shall give the point E, where A B is cut according to extream and mean proportion.

This cannot be exactly done in numbers; but if you would have it tolerably near, add together the square of any number, and the square of its half, and extract, as near as you can, the square root of the sum; from whence taking half, the remainder is the greater part.

Extreams, in right-angled spherical trigonometry. When one of the five circular parts of a right-angled spherical triangle, *viz.* the three sides and two oblique angles, (for the right-angle is neglected) is pitched upon for the middle term, then the two circular parts lying immediately next to it are called extreams conjunct; and the two parts remote from the assumed middle part, or not immediately next it, extreams disjunct. See Circular *Parts*, Triangle, and Trigonometry.

Extream *Unction*, one of the sacraments of the Romish church, the fifth in order, administered to people dangerously sick, by anointing them with holy oils, and pronouncing several prayers over them.

It is called extream unction, as being only given to persons in extremity. In the thirteenth century, it was called the "unction of the sick," and not extream unction: for, in the earlier ages, it was given before the viaticum; which practice, according to F. Mabillon, was not changed till the thirteenth century.

The reasons he assigns for the change are, that in that age there arose divers mistaken opinions, several of which we find mentioned and condemned in the English councils; among the rest, it was held, that such as had received this sacrament, in case they recovered, might not make use of their wives, nor eat meat, nor go barefooted; whence they chose to forbear it till the last extremity, which practice prevailed. See the Councils of Worcester and Exeter, in the year 1287; that of Winchester, in 1308; and F. Mabillon, Acta Sanct. Benedict. Sæc. iii. p. 1.

The form of extream unction is now deprecative, as the divines call it; formerly it was absolute and indicative. This sacrament is not only in use in the Latin, but also in the Greek church, and throughout the East, though under another name, and with some difference in the circumstances; in that the orientals do not wait till their sick are come to extremity, in order to anoint them; but the sick generally go to church themselves; and it is administered to them as often as they are indisposed: the Greeks taking that direction of St. James, chap. v. ver. 14. which is the foundation of the practice, in a general sense: "Is any sick among you? let him call for the elders of the church, and let them pray over him, anointing him with oil." F. Dandini distinguishes two kinds of unction among the Maronites: the one called unction with the oil of the lamp; but this, he suggests, is not the sacramental unction ordinarily administered to such as are in extreme sickness; because the oil is only consecrated by a priest, and it is given to all who are present; not to the sick only, but also to the healthy; even the priest who officiates partakes of it. The other kind of unction, according to that father, is only for the sick; this is performed with oil consecrated by the bishop alone, on Holy Thursday; and this, it seems, is the sacramental unction.

The unction with lamp-oil is in use, not only among the Maronites, but throughout all the Eastern church, who use it very religiously. The truth is, they do not seem to have any other sacrament of extream unction beside this. Yet F. Goar observes, though it be only a ceremony, with regard to those in health, it is a real sacrament to those that are sick.

In their great churches they have a lamp, wherein this oil for the sick is preserved; this lamp they call κανδηλα του ευχελαιου, that is, *the lamp of oil joined with prayer;* for what the Latins call extream unction, the Greeks call ευχελαιον, or αγιον ελαιον, that is, *oil with prayer*, or *holy oil.*

Extreme, in *Music*, is applied to such intervals as deviate as much as possible from the true chord of the same name, without changing their names; generally when the term extreme is added to the prefix diminished or superfluous (which denote a minor semitone), its effect is to double that diminishing or superfluous effect, or to make it $\frac{576}{625} = 72\,\Sigma + 2f + 6m$; but sometimes we find Mr. Orwend applying a major comma and a minor semitone as the effect of his term extreme, or $\frac{128}{135} = 47\,\Sigma + f + 4m$, = the medius semitone: at other times we find extreme, when added to other prefixes, to have different effects, as extreme sharp intervals, for instance, are sometimes found a minor semitone above the intervals respectively, or $\frac{24}{25} = 36\,\Sigma + f + 3m$: but in other instances the same prefix signifies a major comma more, or $\frac{128}{135} = 47\,\Sigma + f + 4m =$ the medius semitone. It were much to be wished that these various applications of terms, so perplexing to a reader, could be got rid of, and a consistent nomenclature in harmonies adopted.

EXTREMITIES, in *Anatomy*, is a term applied to the limbs, as distinguishing them from the other divisions of the animal body, the head, and trunk. They are immediately connected with the latter by one end, and totally free in all other parts. The numerous varieties of their form depend partly on the bones, which enter into their composition; but, in a material degree also, on the soft parts which surround these, and which give to the limbs that roundness and elegance of figure, in which beauty is united with activity and strength. The extremities, being essentially concerned in all the functions of animal life, and constituting the great agents of locomotion, are composed of organs especially destined for these purposes. Their volume is formed by bones and muscles, supplied by numerous vessels, and communicating with the common centre of sensation, the brain, by nerves distributed most extensively; producing, in one part, the most important sense of touch, and giving the spring in all to rapid and varied motions.

The extremities are four in number, divided in man into upper and lower; in other animals into anterior and posterior. Each extremity is divided into four parts; the upper into the shoulder, the arm, the fore-arm, and the hand; the lower into the hip, the thigh, the leg, and the foot. In treating of these, both separately and generally, we shall consider only the bones, and the connections between them. On these depend all the motions of the limbs, the direction and extent of action of the muscles being wholly dependent on the bony points to which they are attached, and on the form and mode of junction of the bones on which they exert their power. The influence of any muscle will be considered in the detailed description of each, and may be easily applied to the subject immediately before us.

Our present plan is to offer, first, some general observations on the external figure of the bones of the extremities, as far as it relates to their uses; on their modes of articulation and their motions. We shall next examine separately and in detail each division of the bones of the upper extremity, the ligaments connecting them, the mechanism of their articulations, and their individual motions; afterwards the combined movements of the several parts, and the powers of the member, as resulting from this construction, both in the passive paffive and active ftate. A fimilar mode will be purfued in confidering the lower extremity. We fhall conclude with a comparifon between the upper and lower limbs as to fize, figure, direction, motions, and growth.

The bones determine effentially the fize, figure, and direction of the extremities, forming, by their affemblage, folid and flexible columns, capable of motion in very varied directions. Some of thefe in each column differ very widely in form; while others partake of the figure of both oppofite varieties. We defcribe them under the different names of long, of broad or flat, and of fhort bones.

In the limbs the bones diminifh fucceffively in length and fize, and increafe in number, as we defcend from the trunk to the oppofite extremity, from the arm, or thigh, to the fingers or toes. In confequence of this arrangement the upper part of the limb enjoys extenfive motions, whilft the lower is characterized by multiplied, but confined movements. Thefe bones have every where an analogous ftructure, being broad and voluminous at their *extremities*, contracted, and frequently rounded in their middle part, or *body*. The increafed volume of the extremities poffeffes the double advantage of enlarging the articular furface, and thereby diminifhing the chances of difplacement, and of preferving the fymmetry of the limb. We perceive, for inftance, that the bellies of the mufcles correfpond to the middle or fmalleft part of the bone, while the flat and contracted tendons are fixed near the protuberant extremities. The augmentation of fize, in the ends of the long bones, is by no means fudden; it commences infenfibly from the body. We remark, on thefe extremities, various eminences, fubfervient to the purpofes of articulation, or giving an advantageous attachment to tendons. The middle part, or body, is generally fmooth, offering prominent lines for mufcular or tendinous attachments. Thefe, where ftrongly marked, deftroy the cylindrical form of the bone: they are ufually three in number, longitudinal, feparated by plane furfaces, and give the bone a prifmatic figure, as may be obferved in the arm, fore-arm, and leg. In thefe inftances a fection of the bone is manifeftly triangular; yet its internal canal preferves a circular form. We may obferve alfo, that the body, in nearly all the long bones, appears as if twifted on itfelf; fo that the direction of the upper end differs more or lefs from that of the lower. This is rendered evident, by tracing the oblique courfe of the prominent lines between the two extremities; for example, in the bone of the arm.

The long bones are formed from three points of offification. The firft of thefe is obferved in the centre of the body, extending on each fide to the extremities, at which the bony cylinder is arrived at the period of birth. Soon after this time, a point of bone is perceived in the centre of each cartilaginous extremity, which increafes gradually, advancing towards the body, with which it at laft unites. From this confideration of the figure and formation of the long bones, we may naturally derive the arbitrary divifion into a *body* and two *extremities*; which divifion we fhall adopt throughout. The body of the bone is the *diaphyfis* of fome Latin writers; and the two ends being at firft united to the body only by cartilage, are called *epiphyfes*.

The broad bones are not found fo generally in the extremities as thofe of the long form; we obferve them only at the part immediately united with the trunk, where they offer an ample fpace for the attachment of the powerful mufcles concerned in moving the limb. In our defcription we obferve two *furfaces* and a *circumference*. The former, if they give attachment to mufcles, are ufually unequal and rough; the latter is thicker than the middle of the bone, offering more points of origin to mufcular fibres, as we may obferve in the margin of the hip bone.

The fhort bones of the extremities are found in fituations where it was requifite to unite a certain degree of mobility with firmnefs, as, for inftance, in the foot. They are collected in confiderable number in the regions which they occupy; and have numerous eminences and depreffions on their external furfaces, neceffary for their reciprocal articulations and for the infertion of the connecting ligaments. Nothing can be more irregular than their figure, which, in addition to their comparative fmallnefs and number, has given rife to much ambiguity of defcription. By confidering them under the fame afpects as the other bones, and by carefully noticing their relations to thefe, all confufion may be avoided. The fhort bones, in general, continue longer in a cartilaginous ftate than the others, refembling, in the phenomena of their offification, the epiphyfes, or extremities of the long bones.

There ftill remain fome fmall bones, found only in the extremities, which can hardly be included in either of the above claffes, and are diftinguifhed by the epithet of fefamoid. They poffefs this peculiarity, that they are formed, not in common cartilage, but in the middle of a tendon, or ligament, and that no trace of them can be obferved in early life. Of their ufe we fhall fpeak hereafter.

There are fome general characters belonging to all the above-mentioned claffes of bones. We obferve in all eminences and hollows, either giving attachment to mufcles, or ligaments, or forming furfaces for articulation. The eminences defigned for the former purpofe are very numerous in the bones of the extremities, and vary greatly in figure. They fometimes appear only as afperities impreffed in the midft of a fmooth furface, giving origin to a number of diftinct aponeurotic fibres; fometimes as prominences or tubercles more or lefs elevated and rough, giving infertion to one or more tendons; or, laftly, as a continued raifed line. In general thefe eminences are proportioned to the mufcles which are fixed to them; fo that under which-ever form they appear, there is an equality of fpace allowed for the tendinous infertions of mufcles of equal bulk. They are in general lefs ftrongly marked in the female than in the male; in the infant than in the adult; in feeble animals than in the carnivorous tribes, which live by preying on others. Their prominence is indicative of vigour and activity of motion; being more developed as the mufcles are more powerful. This is ftrikingly exemplified by a comparifon of the bones of a well made and mufcular man, where the outline of each mufcle might be traced with energy and precifion through the fkin, with thofe of a weak and ill proportioned male, whofe rounded and faintly marked limbs, refembling thofe of the female, betray a total want of vigour or addrefs. The ufes of thefe eminences may be clearly traced to their removing the infertions of mufcles farther from the centre, or axis of the bone, and confequently increafing their power of moving it. The eminences, which give attachment to ligaments, poffefs the advantage of removing the ligament farther from the joint, and thereby facilitating, and giving greater extent to its motions. Thefe eminences have received different names, according to their fituation, their direction, or figure, as we fhall fee more particularly hereafter.

The hollows obferved on the external furfaces of the bones, (with the exception of articular cavities, of which we fhall fpeak below,) are defigned either for the attachments of mufcles, or for giving paffage to their tendons. The firft of thefe have the evident advantage of increafing the furface, without augmenting the bulk of the bone; the

the latter appear as gutters, or grooves more or lefs deep, lined by cartilage, and completed by very ftrong ligamentous bands, through which the tendons glide in their way to their final attachments.

The connections between the bones of the extremities, whatever be their mode, are known by the general term of articulations. Their varieties have given rife to numerous technical, and in fome meafure obfolete, names, for which we refer to the articles JOINT and DIARTHROSIS. Some joints allow of motion in every direction; and we may trace a gradual decreafe of mobility, through many intermediate fteps, till we arrive at articulations which admit only of a gliding of the bones on each other. We have examples of the firft in the joints of the fhoulder and hip; where the extent of motion requires rounded articular furfaces, concave and convex in the oppofite contiguous bones; conftituting what is commonly termed the ball and focket joint. In man the moveable bone has the rounded head, the fupporting bone the correfponding hollow. In fome animals we have inftances of a contrary difpofition, in which a concavity in the moveable bone moves in all directions on an oppofite convex furface. This mode of connection is found only in the fhoulder and hip; and one advantage refulting from this ftructure being found at the upper part of the limbs, is, that the whole member neceffarily partakes of the fame extenfive motions; while it allows of a greater firmnefs and folidity in the inferior articulations. The joints we have juft mentioned are, in this fenfe, the joints, not only of the bones of the arm and thigh, but of all the limb, the motions of which, confidered as a whole, they effentially and principally influence. Hence, if their mobility is deftroyed, either by accident or difeafe, the limb becomes ufelefs: whilft a fimilar occurrence in the inferior joints produces a partial inconvenience only. By this arrangement alfo, the joint, which, from its want of firmnefs, is moft liable to injury, is the furtheft removed from the immediate action of external bodies.

The extent of motion decreafes as we proceed towards the extremities of the limbs. We find no rounded head, whofe axis makes an angle with that of the cylinder of the bone, but an articular furface placed directly at the top or bottom. Of this we have examples in the connection of the collar bone with the breaft, of the fore-arm with the wrift, &c. In thefe, all power of rolling the bone, which is enjoyed in a high degree by the thigh, and by the arm, is deficient. In the next ftep, the motions are confined to flexion and extenfion, as in the elbow, the knee, and the middle of the fingers. In this divifion the articular furfaces confift of eminences and hollows adapted reciprocally to each other, allowing of motion in one direction only. They are remarkable alfo for their large extent, which imparts to them folidity; and for admitting a greater degree of motion in the direction of flexion, than in the oppofite one of extenfion, as may be obferved in the knee, elbow, and fingers. The degree of extenfion is always effectually limited, either by a projection of bone, as in the elbow; or by ftrong ligaments, as in the knee, &c. In other inftances, the articulation allows of rotation only; a convex furface turning in a concave, or a hollow furface rolling over a convex one; both of which may be feen in the motions of the bones of the fore-arm. In the laft kind we obferve only a gliding of plane articular furfaces on each other, more or lefs obfcure, limited on all fides by ligaments binding the bones clofely together. To make up for this very confined motion, we ufually find many fuch joints united, producing in this ftate a more fenfible degree of motion than could poffibly occur in any of them fingly. This may be feen in the wrift.

In all thefe articulations we find a fmooth and polifhed cruft, of an elaftic fubftance, called cartilage, on the furface of the correfponding bones, the immediate means of their motions on each other. It is fuppofed to obviate by its elafticity the dangers refulting from fudden and violent fhocks. The two correfponding cartilages of oppofite bones are fo difpofed as to touch at all points in fome pofitions of the limb, whilft in others they quit each other more or lefs, and are found oppofite the foft parts furrounding the articulation. They are moulded into the form of the bone to which they adhere, preferving its general figure. But in fome cafes the cartilage is thicker in its middle than at the edges, thereby increafing the convexity; in others the converfe may be obferved, and the hollow of the articular furface is proportionably increafed. Both occur in the hip and fhoulder: the firft in the heads of the thigh and arm bones, the laft in the cavities which receive them, and in this manner the uniformity of contact is preferved. In the other articulations the cartilaginous crufts are nearly of equal thicknefs throughout.

The contact of the articular furfaces is fecured by ligaments deftined immediately for this purpofe, and by the mufcles which pafs from one bone to another, fupporting the joint either by the mufcular fibres, or their tendons. The ligaments are formed by very ftrong fibres, a little elaftic, difpofed in parallel lines, or interlaced in various directions. Their great refiftance infures, at all times, more particularly when the limb is at reft, the relations between the oppofite bones; their fituation limits in a great degree their inordinate motions. We obferve them under many forms, and named either from thefe, or from their fituation. Among the firft are capfular ligaments, which are found furrounding fome of the joints like cylindrical bags, embracing the oppofite bones by the circumference of the two ends. Of this we have examples in the hip and fhoulder, and nowhere elfe perhaps in the extremities. The ligamentous fibres are here interwoven and ftrengthened by the adherence of the furrounding tendons, loft at either extremity in the periofteum, to which they are firmly united. The reafon why capfular ligaments are found only in thefe articulations will be readily underftood. They enjoy motion in every way nearly alike, and require on all fides an equal degree of refiftance. Where, from the form of the articular furfaces, the motions are confined to narrower bounds, ligaments are neceffary only in particular fituations in order to regulate them. We find them in the other joints generally on the fides, from which the name of lateral ligaments. Thefe are fometimes rounded, fometimes flat, interwoven with the periofteum at each extremity, formed of fibres lying in parallel lines, or diverging at either end. There are other ligaments, not directly concerned in the joint, which ftill ftrengthen and regulate its motions, as may be remarked particularly in the fhoulder. Befides thefe we obferve many irregular flips, or bands of ligaments, difperfed here and there over the joint feparated by fat and cellular tiffue from the neighbouring parts. The ligaments, of whatever defcription, unite the oppofite furfaces of bones, prevent their difplacement, and yet allow of eafy and rapid motions; a double advantage arifing from their firmnefs on one part, from their flexibility on the other. They fometimes give attachment to mufcles.

The mufcles furrounding the joints of the extremities are very powerful agents in fecuring their contact, and the more fo as their power increafes in proportion as the chance of difplacement is greater. The moft vigorous efforts at difplacement are made during violent and extended motions; at fuch times the mufcles paffing from bone to bone, and croffing the articulation, are ftrongly contracted, are firm in their contractions, and powerfully oppofe the tendency which the extremities of the bones may have to abandon each other. In repofe, when the mufcles are relaxed, and offer but little refiftance, the chances of luxation are few, but if they occur, the probability of its taking place is exceedingly increafed.

In fome joints of the extremities we find a fubftance of a fomewhat cartilaginous ftructure, occupying the interval between the cartilaginous furfaces, and called for this reafon inter-articular cartilage. Such bodies are fometimes moveable, as in the knee, correfponding to the varying want of uniformity in the articular extremities, or fixed more firmly to the end of the bone, or the neighbouring ligaments. They are elaftic and highly flexible, refembling cartilage in the firft quality, the fibrous ligaments in the fecond. This peculiarity of ftructure has given rife to the name of articular fibro-cartilages, a term beftowed on them in recent times by the French anatomift Bichat.

Thefe furfaces are all moiftened by a fluid, called fynovia, on the compofition of which we fhall not dwell here. It is fecreted by a delicate membrane which completes the ftructure of the joint, by lining every part of its furface : whatever be the figure of the cartilages, or the ligaments, from both of which it is diftinct, it adheres clofely to them. It forms a bag without an opening fpread over the whole organ, reflected from the cartilages to the ligaments or tendons ; fo that whatever it embraces is, in reality, without the articular cavity as it is termed, though projecting into it. To the whole it gives that fmooth, polifhed furface fo neceffary for the eafy and rapid movements the articulations enjoy, at the fame time fecreting the fluid which facilitates them ; it gives to the joint alfo its peculiar fhining character.

The moft fimple motion of articular furfaces, common to them all, is gliding on each other in oppofite directions ; it is often fo obfcure as to be fcarcely perceptible. As we afcend we find it multiplied in a variety of ways. The limb can be confiderably bent, or extended ; it can be removed from, or brought nearer to the axis of the trunk : the firft of thefe motions is called abduction, the latter adduction ; in fome cafes, as in the fhoulder, they are termed elevation, or depreffion. The motions of fome joints are confined to any two of thefe, as in the knee ; others enjoy the whole, and all the intermediate degrees, as in the thigh. The union of thefe different movements, as exhibited in the arm or thigh, has been called circumduction. In this cafe the bone, inftead of being moved in one direction, and back again to the oppofite, is carried fucceffively through all, defcribing by its extremity a circle, or the bafe of a cone, the apex of which is in the articulation above. Rotation, or rolling, is very different from this. In circumduction the bone is moved from its prior fituation to a more diftant one ; in rotation it remains in the fame place, it turns only on its axis, as may be obferved in fimply rolling the arm.

From this curfory review of the external characters of the bones of the extremities, of their modes of connection and motions, we proceed to the detailed defcription of each. It will be neceffary to premife, that in our terms of pofition and afpect, we fhall always fuppofe the body erect, the arms depending, and the hands fupine, fo that the little finger is in contact, or at leaft next to the external fide of the thigh. In this fituation we fhall fuppofe a vertical plane dividing the body into two halves, from before backward. With a clear impreffion of this idea we fhall find no difficulty or confufion in the terms anterior and pofterior, fuperior and inferior, external and internal, as applied to the different afpects or furfaces of bones ; by the latter, internal, we always mean the furface next the imaginary middle plane above-mentioned. Thefe arbitrary terms, though applicable only to one determined pofition of the body, are yet neceffary to give tolerable precifion to anatomical defcription : when by their affiftance we have made ourfelves familiar with the objects they are defigned to illuftrate, they may be difmiffed as eafily as they have been adopted ; our ideas of the relative fituation of parts will be diftinct, and may be applied readily to every poffible variety of pofture. In order to obviate all ambiguity, we fhall introduce alfo the nomenclature of Chauffier, as conveying exact and precife notions of the relations of oppofite bones to each other. The terms are generally fimple, and always perfpicuous as applied to the prefent fubject.

The upper extremity—is divided into four parts ; the fhoulder, the arm, the fore-arm, and the hand, each of which will be feparately confidered.

The fhoulder is the divifion of the upper extremity attached immediately to the fuperior and lateral parts of the trunk ; it is formed by two bones, one broad, placed vertically behind, called the *fcapula*, or fhoulder blade, the other long, fituated horizontally before, called the *clavicle*, or collar bone. The difpofition of thefe bones gives the broad form and character to the upper part of the cheft, which is in itfelf very confiderably contracted at this part, its apparent breadth and magnitude being derived from the lateral appofition of the fhoulders. Generally, alfo, there is a proportion between thefe and the dimenfions of the cheft : they are large, and ftrongly developed, when the latter is well formed ; contracted and narrow when it is fmall or badly fhaped. The height of the fhoulder depends on the fituation of the fcapula ; it is lower proportionably in the female, and in males of a feeble body, than in individuals of the oppofite character. In the latter cafe, though the bones form the outline, it is the brawny mufcles which fill it up, conftituting, by their well-defined and maffy forms, the diftinguifhing character of the fex in man, and other animals.

The *fcapula*, fhoulder blade, or omo-plate, is a bone of an irregularly triangular figure, feated on the upper and back part of the trunk. It is connected by mufcles to the head, the vertebræ, and the ribs, by articulation to the clavicle and humerus. The fcapula has fuch a latitude of motion as to make it difficult to affign precifely its fituation on the trunk. But when the arm is at reft, it covers the fpace between the firft and eighth ribs, with its bafe or pofterior margin at a fmall diftance from the vertebral column, to which it approaches nearer above than it does below. At this line the fcapula lies pretty clofe on the ribs ; forwards, we find it receding confiderably from the oppofite furface of the trunk, in which fituation it is conftantly preferved by its connection with the clavicle.

For convenience of defcription, we divide the fcapula into two furfaces, the dorfal or exterior, and the coftal or interior ; into three margins or coftæ, the fuperior, the pofterior, or bafe, and the inferior, or external cofta. The rounded points at which thefe edges meet are ufually called angles, and are named, from their feveral fituations, the fuperior, the inferior, and the anterior angles of the fcapula.

The dorfal furface, the dorfum, or back of the fcapula, is divided into two very unequal portions by a ftrong and folid procefs of bone projecting from it tranfverfely, called, the fpine of the fcapula. It commences at the pofterior margin, about one-fourth part of the whole length below the fuperior angle, increafes gradually in depth as it advances

vances obliquely forward towards the anterior angle, beyond which it projects in the form of a broad, flat procefs, called the acromion. The fpine is connected with the whole breadth of the dorfum, with the exception of that portion of it called the neck; its anterior edge is fmooth, rounded, and concave, and is gradually loft in the under furface of the arch of the acromion. The pofterior, or projecting ridge of the fpine, is broad and flattened, varying however in breadth in different parts. At its commencement is a fmooth, triangular fpace, over which paffes a part of the tendon of the trapezius. Further on it is rough, the upper margin of the crifta giving attachment to this mufcle, the lower to the pofterior half of the deltoid. The acromion is flattened in a direction contrary to that of the fpine of which it is a continuation, is of confiderable breadth, rough and fomewhat convex above, concave and fmooth below. On the internal edge, which is continuous with the fuperior crifta of the fpine, is a fmooth oval furface for articulation with the clavicle. The external edge is rough and irregular, giving attachment to the middle part of the deltoid. The fummit of the acromion is rounded, and marked by the attachment of a ligament which connects it with the coracoid procefs. Towards the anterior part of the bafis of the fpine, near the neck, we obferve holes for the admiffion of the nutrient veffels. The upper furface of the fpine is hollow, forming a portion of the fupra-fpinal foffa, the name given to that portion of the dorfum fituated above the fpine, and which gives lodgment to the fupra-fpinatus mufcle. The lower furface is alfo concave, though irregularly fo, and contributes to the formation of the infra-fpinal foffa, the part of the dorfum lying below the fpine, which is occupied by the infra-fpinatus mufcle; the latter portion fcarcely deferves the name of foffa, being convex in its centre. Towards the inferior part of the dorfal furface is a ridge running in the direction of the inferior cofta, for nearly its whole length; it gives attachment to an aponeurofis, which feparates the infra-fpinatus from the teres major, and teres minor. Towards the inferior angle this ridge is met at a very acute angle by another, originating in the inferior cofta. The latter forms the line of divifion between the two laft mentioned mufcles, the upper and fmaller part giving attachment to the teres minor, the lower and broader to the teres major.

The under or coftal furface of the fcapula is concave, marked by feveral converging ridges running from the bafe towards the anterior angle. They give attachment to the aponeurotic divifions of the fub-fcapularis, its flefhy bundles lying in the intervening fhallow depreffions. Towards the fuperior and inferior angles we mark fome projecting points, which give attachment to the ferratus major anticus, as alfo more or lefs evidently a rifing line between, defigned for the fame purpofe.

The fuperior margin, or cofta of the fcapula, is the fhorteft of the three borders. It is thin towards the fuperior angle, becomes broader as we trace it forwards to its termination in a ftrong curved procefs, called, from its fimilarity to a crow's beak, the coracoid procefs. At the root of this procefs we obferve a deep notch, croffed by a ligament, fo as to form a circular hole; in many inftances the circle is completed by bone. It gives paffage to the fupra-fcapulary nerve, and ufually to a branch of the fupra-fcapulary artery and veins. Juft behind this notch the omohyoideus mufcle has its origin. The coracoid procefs is rather flattened, convex and rough above, where it gives attachment to ligaments connecting it with the under furface of the clavicle, concave and fmooth below. Its internal edge gives attachment to the pectoralis minor, its external to a ftrong ligament, croffing from it to the acromion, its fummit to the united heads of the biceps, and the coraco-brachialis.

The bafe of the fcapula is the longeft of the three margins, offering a waving line with an obtufe projection in it, oppofite the commencement of the fpine; to this, and to the margin below it, the rhomboidei are attached. From its junction with the fuperior cofta refults the fuperior angle, to which the levator fcapulæ is partly attached.

The inferior cofta is much broader than the other, dividing at its anterior part into two projecting lines, with a hollow between them. Towards the inferior angle, where it joins the bafe, the edge is thinner, and convex, giving attachment to the teres major, and occafionally to fome fibres of the latiffimus dorfi. The outer of the prominent lines gives origin above to the long head of the triceps; below to the teres minor. The inner line, and intervening hollow, is occupied by the fub-fcapularis. The inferior cofta terminates above, at the anterior angle, towards the coracoid procefs, in an ovate, flightly hollowed furface, called the glenoid cavity. This furface is at right angles with the plane of the bone, its long diameter perpendicular, and its broader part below. It is covered by cartilage, the edges raifed a little by a fibrous ring, which adds fomewhat to its depth. At the upper end of the brim is attached the long head of the biceps. The glenoid cavity is articulated with the head of the humerus; it ftands off a little from the body of the bone, fupported by a fhort procefs, more contracted than the brim of the cavity, called the neck of the fcapula. This narrowing is more particularly obfervable on the back, under the fpine.

The fcapula is, in its ftructure, compact; thin and diaphanous every where but at its edges and proceffes, where the bone is thick and cellular. Its offification commences at an early period in the fœtus, and advances confiderably before birth. At the latter period, however, the acromion, the coracoid procefs, and the bafe, ftill exift in the ftate of cartilaginous epiphyfes.

The clavicle, or collar bone, is placed nearly tranfverfely at the fuperior and anterior part of the cheft, between it and the top of the fhoulder. In figure it fomewhat refembles the italic *f*; the two thirds next the fternum being of an irregularly cylindrical, or nearly prifmatic form, and gently convex anteriorly; the third next the fcapula flattened horizontally, broad, and with a more confiderable convexity directed backwards. It is more flender, and lefs curved in the female than in the male.

The extremities of the bone are diftinguifhed from their fituation by the names of the external or pectoral, and the fcapular, or humeral ends of the clavicle. The firft of thefe is triangular, prefents an irregular articular furface of confiderable extent for connection with the fternum; its plane is nearly at right angles to the body of the bone. The fcapular extremity prefents alfo a flat, articular furface, oblong horizontally, accommodated to the oppofite one in the acromion. The upper furface is rounded towards the fternum, where the fterno-cleidomaftoideus is attached, fmooth in its middle portion, flat and broader next the fcapula. The under fide, to which thefe characters are equally applicable, is marked near the fternal end, by a roughened furface, for the attachment of a ligament connecting the clavicle to the firft rib. Towards the middle is a confiderable longitudinal hollow for the lodgment of the fub-clavius mufcle. Near the fcapular end the face of the bone is unequal, with a rough eminence in it for the infertion of ligaments which bind it to the coracoid procefs of the fcapula. Towards the fternum the anterior edge is broad, and

and bends gently forwards, for about one-half of its length, where it gives origin to a portion of the pectoralis major; it then becomes thinner, flopes backwards, and terminates by fuddenly turning forwards again towards its junction with the acromion. It gives attachment to the anterior half of the deltoid. The curvatures of the pofterior edge are the inverfe of the preceding. The bone is rounded, fmooth and concave for the two-thirds next the fternum; unequal and convex towards the fcapula, where the trapezius is attached.

The clavicle is in ftructure like the other long bones; the medullary cavity is very confined. At the time of birth its form is already ftrongly marked, and its offification nearly complete.

The articulations of the fhoulder.—The fcapula is connected with the trunk by a great number of mufcles, which partly fupport it, and allow of all thofe varied motions of which it is capable. It is clofely bound alfo to the clavicle, which latter bone is immediately articulated with the fternum. We have here only to examine the two laft connections, beginning with that between the clavicle and fternum, as forming the union between the fhoulder and the trunk.

The fternal end of the clavicle is covered by a cartilaginous cruft of confiderable thicknefs, prefenting an irregular convex furface. At the upper part of the fternum is an articular cavity, flightly hollowed, of lefs extent than the oppofite articular furface of the clavicle, fo that the latter rifes confiderably above it; a circumftance particularly ftriking in lean perfons.

The ligaments which connect thefe furfaces are four, an anterior and a pofterior, an inter-clavicular, and a cofto-clavicular ligament. To complete the joint, we find alfo an inter-articular cartilage, dividing it into two feparate cavities, and a diftinct capfular membrane lining each of thefe.

The anterior ligament covers the front of the joint, lying between the fkin and the fterno-maftoideus without, and the capfules immediately within. It is compofed of fibres, which defcend obliquely from the upper and anterior edge of the clavicle, diverging as they proceed to be fixed into the upper edge of the articular cavity in the fternum. Thefe ligamentous fibres leave feveral intervals between them, which are occupied by cellular tiffue and veffels.

The pofterior ligament is fmaller and not fo ftrong as the anterior. It feparates the fterno-hyoideus and fterno-thyroideus from the capfules to which it firmly adheres. It extends from the pofterior edge of the clavicle to the oppofite part of the fternum. The fibres defcend a little in their paffage, diverging as they approach the latter bone.

The inter-clavicular ligament is placed between the two clavicles, immediately above the hollow at the upper edge of the fternum, with the integuments only in front, and the fterno-hyoidei and fterno-thyroidei behind. It is attached to the upper edge of the fternal extremity of each clavicle, the fibres croffing in a flattened form from one to the other, and longer above than below; they are often feparated by intervals filled up with cellular tiffue.

The cofto-clavicular, or rhomboid ligament, paffes obliquely upward from the cartilage of the firft rib to the internal edge of the under furface of the clavicle, clofe to its fternal end. It is flat and fhort, the fibres becoming longer as they recede from the fternum. In front of it lies the fubclavian mufcle, and immediately behind it the fubclavian vein. It has no immediate connection with the articulation, but ferves to ftrengthen it and regulate its motions.

Between the clavicle and fternum we find an intermediate round, flattened piece of fibro-cartilage, its furfaces accommodated to the ends of thefe two bones. Its circumference lying immediately under the ligaments of the joint, is united to the furface of the anterior and pofterior. It is united alfo above and below, by means of a ftrong and thick fibrous fubftance, to the circumference of the articular furface of both the clavicle and fternum. The fibro-cartilage is thicker above, and much thinner next the cartilage of the rib. The fibres which compofe it are lefs apparent in its middle than nearer its edges. From its clofe connection with the furrounding parts, it cannot be moved in any of the actions of this joint.

The capfular membranes adhere to the ligaments which furround the articulation, between the fibres of which they are often apparent. They both adhere alfo to the fibro-cartilage, one of them lining the cavity between it and the fternum, the other the correfponding cavity between it and the end of the clavicle. The membrane is every where delicate, its inner furface moiftened by fynovia, which is fecreted but in a very fmall quantity.

From the difpofition of the ligaments belonging to this articulation, there remain but few intervals not covered and fupported by them; fo that it nearly approaches in ftructure thofe joints which we find furrounded by a fibrous capfule, as in the cafes of the fhoulder and the hip, which it fomewhat refembles, alfo in the extent of its motions.

Articulation of the clavicle with the fcapula.—At the fcapular extremity of the clavicle we find a fmall oval facet, covered by cartilage, correfponding to a fimilar one in the internal edge of the acromion. We often meet alfo with a delicate inter-articular cartilage, its fuperficies fometimes equalling the articular furfaces of the bones, at others lefs; it is thickeft above, and adheres by its circumference to the ligaments. To fecure this joint, we find ligaments above and below it; and the clavicle is further bound to the coracoid procefs of the fcapula by ftrong ligaments, without being any where in contact with it.

The upper ligament forms a broad and flat band, which covers the whole length of the articulation, croffing from the upper edge of one articular furface to the other, the fibres being longer as they are feated more fuperficially. It lies immediately under the tendinous aponeurofes of the trapezius and deltoid, which form a ftrong, diftinct layer of fibres, not eafily feparable from the ligament.

Underneath the joint lies another ligament, the fibres following the direction of the preceding, which it approaches in front, being feparated behind by an interval filled with cellular tiffue. Above, it is in contact with the capfular membrane; below, with the fupra-fpinatus. The fynovial membrane is found lining the articular furfaces, reflected from one to the other, and containing but little fynovia. It is fometimes double, where the inter-articular cartilage is perfect.

The ligaments which further connect the clavicle with the fcapula are attached to the coracoid procefs, from which they purfue different directions to be inferted into the clavicle. The moft delicate of thefe has been called the ligamentum bicorne. It arifes from the inner edge of the coracoid procefs, near its point, and, as it advances upwards and inwards, fplits into two layers, which envelope the fubclavian mufcle. The upper band is attached to the clavicle, near the end of the rhomboid ligament; the under layer paffes to the rib immediately below it. It is not ftrong enough to add much to the fecurity of the connection between the bones. The other ligamentous bands, placed between the coracoid procefs and the clavicle, have been divided by many authors into two diftinct ligaments: one, the pofterior bundle, has been called, from its figure, conoides; the other,

 for

for a fimilar reafon, trapezoides. Though fcarcely diftinct in their origin, they differ fo much in figure, and in the direction of their fibres, that we fhall confider them as feparate ligaments. The pofterior ligamentum fcapulæ commune conoides is attached below, by the fummit of the cone, to the root of the coracoid procefs; above, to the rough tubercle fituated on the under fide of the humeral end of the clavicle. It is compofed of fhort thick fibres, radiating as they afcend, parallel to, and continuous with thofe of the anterior ligament, as they approach nearer the acromion. Below, its fibres are often united with thofe forming the ligament croffing the notch of the fcapula. The anterior ligament, ligamentum commune trapezoides, croffes obliquely from the coracoid procefs to the clavicle, as a broad flattened band, exceeding the preceding in length. It is fixed below to the pofterior part of the upper furface of the coracoid procefs, above, to an oblique line proceeding from the tubercle towards the end of the clavicle. The anterior fibres are longer than the pofterior; the latter, at the union with the fibres of the pofterior ligament, form an angle pointing towards the acromion, and leaving in front an angular cavity which is filled by fat. Thefe ligaments are covered by the fubclavius in front, by the trapezius behind, leaving an interval of an inch or more towards the fcapulo-clavicular articulation.

The fcapula has two other ligaments proper to itfelf, which we fhall defcribe here, although they have no immediate relation with the articulation of the clavicle and fcapula. One clofes the notch in the laft-named bone, the other is extended between the coracoid procefs and the fcapula. The firft, confifting of a flat, compact band of filvery fhining fibres, croffes from the pofterior angle of the notch to the bafe of the coracoid procefs, converting it into an hole, through which the fupra fcapulary nerve, and frequently alfo the fupra fcapulary veffels pafs.

The ligament placed between the coracoid procefs and the acromion is of a triangular form, of confiderable furface, thin, and flattened. Its bafe is attached along the external edge of the coracoid procefs, from which it proceeds in two diftinct bands, feparated by cellular tiffue, and converging, as they approach the acromion, into one common fheet. The pofterior fibres pafs obliquely outwards, the anterior are directly tranfverfe; the interval between them is croffed by fome fcattered flips of ligament. Its upper furface is covered by the deltoid and clavicle, its lower fide is in contact with the fupra-fpinatus. Its anterior edge is not defined, but continuous with a thick and denfe layer of cellular membrane, lying between the deltoid and the tendons of the infra and fupra-fpinatus. This ligament completes the arch formed by the coracoid procefs and acromion over the fhoulder-joint.

The mechanifm and motions of the fhoulder.—The fcapula, by its mufcular connection with the trunk, is capable of powerful and varied motion; the clavicle, on the contrary, can only follow the impulfe communicated by the fcapula, whofe motions it regulates and limits under certain circumftances. The fcapula forms the effential part of the fhoulder, the clavicle can be confidered only as acceffory in man, and fome animals who ufe their anterior extremities for other purpofes befides progreffion. The fcapula may in fome meafure be confidered as defending that part of the thorax over which it moves; but its more evident ufe is to ferve as the bafe of all the motions of the arm, which at the fame time it increafes moft extenfively. In this refpect it differs from the hip, which is in itfelf motionlefs, although affording a point from which the thigh directs all its movements. We fhall recur to this difference hereafter: in this place it will be fufficient to notice, that notwithftanding the apparent want of firmnefs in the fhoulder, it is enabled, by means of its numerous and powerful mufcles, to offer a folid refiftance to the impulfe communicated from the arm in any of the violent actions of the upper extremity. The fcapula plainly accompanies the motions of the arm, forwards and backwards, but in the fimple elevation outwards, and in depreffion of that bone, its movement is fcarcely obfervable. In the former cafes it rotates on an imaginary axis, perpendicular to its plane, placed fomewhat about the middle of the bone.

In the inftance where the arm paffes forward from the ftate of adduction, the fuperior angle of the fcapula is lowered a little, and approaches the vertebral column, whilft the inferior recedes from it, and is at the fame time fomewhat elevated. Where the arm is carried backwards the converfe of this occurs. In thefe rolling motions the clavicle is concerned but little if at all; the fcapula turning on it at the joint which unites them, the articular furfaces gliding on each other, and the ligaments above and below becoming alternately ftretched or relaxed, as the motions are fucceffively continued. They, however, are not capable of refifting alone any violent effort tending to difplace the bones in this rotatory motion; it is the ftrong ligaments croffing from the coracoid procefs, to the tubercle of the clavicle which, by their alternate tenfion, fecure their relations under thefe circumftances. This articulation is further defended from injury by the mobility of both bones, which would recede before any violent fhock.

The clavicle acts as a prop, preventing the fhoulder and arm from falling forwards and approaching the breaft, either by their weight or by the action of the mufcles which move them. It is partly preferved in its fituation by mufcles which are fixed to it above. Its exiftence is neceffary for many of the motions of the upper extremity, particularly thofe in which it is carried forward; it favours alfo the circumduction of the arm, by keeping it at a diftance from the trunk, and allows the whole limb to defcribe arcs of a fphere, the centre of which is found at its fternal end. We find confequently that animals without clavicles enjoy thefe motions but imperfectly, in many inftances in no degree. Their abolition in the cafe of fractured clavicle is another proof of the utility of the latter in directing the actions of the fhoulder.

The combined motions of the fcapula and clavicle are thofe of depreffion, elevation, thofe in which the fhoulder is carried forward, or backward, and the combination of thefe or circumduction.

When we raife the fhoulder, the fcapula paffes during its elevation a little obliquely forward. The inferior angle advances, whilft the upper edge or cofta recedes from the trunk. The fcapular end of the clavicle is neceffarily alfo raifed, fo as to increafe the fpace between it and the firft rib, and to diminifh fomewhat the angle it forms with the acromion, its fternal end preffing more and more on the articular cavity in the fternum; the rhomboid ligament is ftretched, limiting the elevation, and the inter-clavicular ligament relaxed.

In depreffing the fhoulder the exact inverfe of thefe effects is produced, and requires not therefore a minute detail. We fhall obferve only that the lower furface of the clavicle may be brought fo near to the firft rib, as to comprefs the intervening veffels very confiderably, and produce a painful fwelling of the arm. The depreffion is much limited by this contiguity of the rib, which lies pretty clofe to the clavicle in the moft common and eafy pofition of the fhoulder.

When the fcapula advances forwards its, anterior angle recedes from the trunk, being kept off by the clavicle, the bafe at the fame time approaching nearer the breaft. The clavicle becomes more diftant from the firft rib in the horizontal

horizontal direction, the inter-clavicular, and the pofterior ligaments are rendered tenfe, the fternal end preffing inwards and backwards. In this fituation luxations have occurred, but the accident is rare, as the fhoulder is feldom expofed to any violence under thefe circumftances, that by its direction would probably effect it.

In carrying the fhoulder backward, the anterior angle of the fcapula is brought nearer to the cheft, and the bafe approaches the fpine. As the fcapula has a confiderable extent of motion in this direction, and is accompanied by the fcapular end of the clavicle, it will readily be conceived, that if the movement is fudden and violent, the fternal end will diftend its anterior ligament, may rupture it and become luxated forwards on the fternum. In fact this is the moft common mode of difplacement.

The fhoulder may be moved in any of the intermediate directions to thofe we have defcribed; and in all we are to confider it as a lever compofed of two parts, one horizontal, the other vertical, the fternal end of the clavicle being the refting point, or the centre of the movements of the lever. The continued fucceffion of all thefe motions produces the circumduction of the fhoulder, a motion in which the clavicle defcribes a cone, the fummit of which will be at its fternal, and the bafe traced by its fcapular extremity. We are not to confound this motion of the fhoulder with that of rotation, defcribed above.

The direction of the fhoulder is fubject to variations from the flighteft motion; in general it is fo inclined that the glenoid cavity points outwards, proving moft evidently, if any argument were wanting, that the upper extremities are not defigned to fupport the body in the attitude of a quadruped. In fact, in that pofition, the head of the arm bone would prefs, not againft the glenoid cavity, but on the capfular ligament which furrounds it, and which is utterly incapable of long refifting the effort.

The Arm.—The humerus, the only bone in the arm, the largeft and ftrongeft of thofe of the upper extremity, is placed between the fhoulder and the fore-arm. It is nearly ftraight, bending gently forwards below, "tanquam ad meliorem amplexem," fays Albinus. Of an irregular prifmatic form, fomewhat rounded at its upper and middle portions, flattened and gradually widening below, fo as to be broadeft at its lower end where it fupports the fore-arm. It has the appearance of having been twifted in the middle, as if at an early period the upper end had been carried round forcibly outwards, and the lower end in the oppofite direction. We divide it into two extremities, a fuperior or fcapular, and an inferior, or cubital; and into a middle portion or body.

At the upper end, the moft bulky part of the bone, are three eminences; the head, and the great and fmall tubercle of the humerus. The head of the humerus is rounded, forming nearly the half of a fphere, fmooth, covered by cartilage, articulated with the glenoid cavity of the fcapula. It ftands on a very fhort procefs, fomewhat more contracted than the articular circumference, called improperly, perhaps, the neck of the humerus. The head and neck are directed obliquely upwards, fo that a line drawn in their axes would form an obtufe angle with the body of the bone; they are alfo inclined backwards with refpect to the plane of the condyles at the lower extremity. From this oblique pofition of the head with regard to the body of the humerus, the neck is longer, and the contraction more ftrongly marked below than it is above, where we remark only a fhallow groove dividing the head from the tubercles.

The great tubercle is placed externally, oppofite to the head. It is rough, broad, and flattened; marked by three diftinct furfaces for the attachment of tendons. One, anterior, for the tendon of the fupra-fpinatus mufcle; a middle fpot, for that of the infra-fpinatus, and one below for the teres minor. The leffer tubercle, placed in front of the bone, is rough, much fmaller but more elevated than the laft. It gives attachment to the fub-fcapularis. Dividing the tubercles is a deep longitudinal groove, of which we fhall fpeak below.

The body of the humerus, though of a very irregular form, is fufficiently marked for us to divide it into three differently inclined furfaces, and as many projecting lines between them. Owing to the twifted figure of the bone thefe angular lines purfue rather a fpiral than a ftraight courfe.

The anterior ridge or fpine commences at the inner edge of the great tubercle, and is continued through the middle of the bone to the lower end. It is rough in its upper half, giving attachment above to the pectoralis major, and lower down to a portion of the deltoid: below it is rounded and fmooth, giving attachment to and covered by the brachialis internus. The internal line defcending from the fmall tubercle, gives attachment above to the latiffimus dorfi, and lower down to the coraco-brachialis and triceps. Towards the anti-brachial extremity it becomes much more prominent, affording attachment to a ftrong inter-mufcular aponeurofis. The external edge begins at the under fide of the neck, running obliquely forwards as it defcends. It is but faintly marked above where it gives attachment to a portion of the triceps; is interrupted towards the middle, leaving a fmooth flat furface, over which the radial nerve and accompanying veffels turn; below it rifes again into a more acute, and elevated ridge, which gives attachment to an inter-mufcular ligament, and fome mufcles belonging to the fore-arm. In the internal furface, bounded by the anterior and inner lines, we obferve above the bicipital groove, continued between the tubercles and the fpines, proceeding from them for fome way down the bone, increafing in breadth, and gradually becoming obliterated. It is lined by cartilage, and provided with a fynovial membrane, where it lodges the tendon of the long head of the biceps. Towards the lower end of the groove, at its outer fide, is a rough line for the infertion of the tendon of the teres major. About the middle of the internal furface the coraco-brachialis has an attachment, and below this the brachialis internus. The external face is larger than the preceding: covered above by the deltoid, ftrongly marked by a rough prominence interfecting it obliquely for the infertion of this mufcle. Immediately below this ridge is a broad fhallow oblique depreffion, along which the radial nerve and fome veffels pafs. Towards the lower extremity the bone is flightly concave, and gives attachment to the brachialis internus. The pofterior furface is fmooth and rounded, altering its direction in a confiderable degree as we trace it downwards: it gives origin to and is covered by the triceps.

The lower, or anti-brachial extremity of the humerus, is broad and flattened tranfverfely, and advances a little forwards from the axis of the body of bone. In the middle is an articular furface for connection with the fore-arm, and on either fide a projecting point, called tuberofity, or condyle. Of thefe the internal (pofterior of Albinus) is the moft projecting. It is fomewhat flattened, continuous above with the internal fpine, marked irregularly below by the attachments of mufcles, and the internal lateral ligament of the elbow joint. The external condyle (prior Albini) is much lefs prominent, and gives attachment to the external lateral ligament, as well as to feveral mufcles which lie on the radial and dorfal fides of the fore-arm.

The

The articular furface, placed between thefe two points, defcends a little way beyond them. It is marked by feveral eminences and hollows. Next to the external condyle is a rounded eminence (capitulum of Albinus) adapted to the hollow in the head of the radius, and at its inner fide is a groove for the internal projecting edge of that hollow. The remaining divifion forms the pulley or trochlea (rotula of Albinus) for articulation with the ulna. We obferve two prominent edges and a depreffion between them. The edge next the radius is not fo prominent in front as behind, neither does it rife fo high as the edge next the internal condyle, which defcends a confiderable way below the reft of the articular furface, floping gradually into the hollow of the pulley on one fide, and terminating abruptly by an acute margin on the other. The hollowed part, forming nearly three-fourths of a circle in extent from before backwards, is much broader behind, directed from thence obliquely inwards as we follow it to the front of the bone. Above the middle of the pulley, at its back part, is a deep cavity, oblong tranfverfely, which receives the olecranon, or extremity of the ulna, during the extenfion of the fore-arm. Oppofite to this, at the termination of the pulley in front, is a fmaller hollow for the reception of the coronoid procefs of the ulna, when the fore-arm is bent. Between thefe correfponding hollows there remains but a thin plate of bone, in many inftances diaphanous.

The humerus refembles in ftructure the other long bones. Its offification commences at three points; at the middle and at each end. At the time of birth the fcapular extremity of the humerus is entirely cartilaginous, and of greater proportionate bulk. At the lower extremity the capitulum is much larger in comparifon with the trochlea than in the adult bone.

The articulation of the humerus with the fcapula, forming the fhoulder joint.—The head of the humerus is covered by a layer of cartilage, much thicker in the middle than at the circumference. The glenoid cavity of the fcapula is lined by cartilage, thinner in the middle than round its edges. The margin of the cavity is further provided with a fibrous elevated border, proceeding above from the tendon of biceps which gives off a bundle on either fide; below, from the circumference of the articular cavity. Over the joint is the bridge formed by the acromion, the coracoid procefs, and the ligament ftretched acrofs between them. The head of the humerus moves on the glenoid cavity; but from the fmall relative fize of the latter, the furface of the head of the humerus in contact with it forms but a fmall part of its articular fuperficies, the remainder of which is thus out of the cavity, and correfponds to the capfular ligament.

The capfular or orbicular ligament enclofes the whole of the joint in the form of an oblong fac, contracting a little at each extremity. The upper edge is fixed round the glenoid cavity of the fcapula, beyond the fibrous ring we have juft mentioned. In fome inftances there is an interval left on the inner fide, which is then fupplied by the tendon of the fub-fcapularis. The lower edge is attached round the neck of the humerus; clofe to the margin of the articular cartilage above, at a greater diftance from it below. The attachment is interrupted between the two tubercles, the ligament croffing from one to the other over the bicipital groove. The deficiency occafionally obferved on the inner fide is fupplied as above by the tendon of the fub-fcapularis, which may be feen from within the joint covered only by the reflected fynovial membrane. The capfular ligament is remarkable for its length, which allows the articular furfaces of the two bones to be feparated from each other, by the diftance of an inch, on the admiffion of air into the cavity. It is covered above by a denfe ligamentous band paffing from the outer edge of the coracoid procefs, to the anterior part of the larger tubercle, where it unites with the tendon of the fupra-fpinatus; and fo clofely joined by its under furface to the capfular ligament, that, but for its attachment to the coracoid procefs, it would be difficult to make any diftinction between them. It is this acceffary band which makes the capfular ligament thicker above than in any other part. The fhoulder joint is further ftrengthened by the tendons of the fupra-fpinatus, infra-fpinatus, teres minor, and fub-fcapularis, which furround it, and which are firmly united to different parts of the capfular ligament. The latter is in contact alfo with the deltoid above, and the origin of the long head of the triceps below. It is formed by fibres running in various directions, and croffing each other, is thinneft where covered by the infra-fpinatus, and teres minor, ftronger on the inner and under fides; apparently infufficient to fecure the firmnefs of the articulation, if not fupported by the mufcles proceeding from the fcapula. The fynovial membrane is fpread over its internal furface, and reflected over the articular cartilages. At the edge of the bicipital groove a procefs goes from it, which defcends along the groove, lining it for the fpace of about an inch. It is then reflected on all fides over the tendon of the long head of the biceps, and continues to give it a covering in its paffage through the joint to its attachment above the glenoid cavity. By the reflection of the fheath below, the efcape of fynovia is prevented, and the tendon may ftill be faid to be exterior to the cavity of the joint.

The mechanifm of the fhoulder joint as to mobility and refiftance.—Although motion be the principal office of the upper extremity, there are many accidental circumftances in which firmnefs of oppofition is as neceffary as in the lower, and the means nearly as complete.

The motions of the arm are very extenfive, generally combined in different degrees with thofe of the fhoulder. Indeed fo great is its mobility, that it efcapes on that account many injuries it would otherwife be liable to, from the loofenefs of its articulation with the fhoulder. Add to this that the point of fupport, the glenoid cavity of the fcapula, is in itfelf fo moveable, as further to modify and leffen the effects of external impulfes. We have before obferved that the fcapula more particularly accompanies the arm in its motions backwards and forwards, lefs fo in its elevation outward and depreffion; the clavicle neceffarily partakes of the movement, and from this difpofition two advantages are derived that the circuit of motion is enlarged, whilft tendency to difplacement is diminifhed by the diftribution of the effort over three points inftead of one.

The arm, and confequently the whole limb, may be elevated, depreffed, carried forward, backward, and in all the intermediate directions; it may be rolled alfo on its axis in any of thefe conditions.

When the arm is raifed, the head of the humerus glides from above downwards in the glenoid cavity, in fome meafure abandons it, and refts againft the lower fide of the capfular ligament, which it diftends more or lefs according as the fcapula has accompanied it in its movement. If the arm be elevated outwards or abducted, it cannot be much affifted by the fcapula; the great tubercle is buried under the arch formed by the acromion, the coracoid procefs, and the ligament between them, and in this fituation the capfule is particularly ftretched, is liable to be torn, and the arm luxated downwards. When the arm is thus raifed above the horizontal line, at a diftance from the trunk, the weight of the body brought to bear with force on the head of the bone, as in the cafe of falling, tends to deprefs it; and at the fame time the actions of the pectoralis major, latiffimus dorfi, and teres major, concur in producing the fame effect; fince they have their fixed points in the trunk, and their moveable point in the humerus. Luxation, under thefe circumftances, is by no means rare. The action of mufcles alone is fcarcely adequate to the effect, which is generally the confequence of fome violent impulfe.

In depreffion or adduction, the arm returns to its natural pofition, in which difplacement is almoft impoffible. Where the limb is perpendicular, any external impulfe acting on its lower end, would only prefs the head of the bone firmly againft the arch of the acromion. The only mode in which it could be made to pafs beyond the arch, would be by carrying the lower end inwards; but this is oppofed by the trunk, fo that in this pofition of the arm luxation upwards is effectually prevented.

When the arm is carried forward to a confiderable height, it is accompanied in its motion by the rotation of the fcapula, and the head of the bone fcarcely quits the glenoid cavity. It is on thefe accounts that when in falling forward the arm is projected confiderably beyond the head, luxation is rarely the confequence, though the fhock be fevere. In the motion backwards the head of the humerus quits in fome degree the articular cavity, and bears againft the capfular ligament and the tendon of the fub-fcapularis. The extent of this motion is alfo increafed by the coincident movement of the fcapula, and at the fame time the probability of luxation diminifhed; it is not, however, fo free as the motion forwards.

Circumduction, or the fucceffion of thefe motions, is enjoyed extenfively in the joint of the fhoulder; the execution of it in the anterior half of the circle is more eafy, becaufe more unconfined than in the pofterior. And we may obferve as a general axiom, applicable to all the motions of the arm, that the movements forwards are far more extenfive than thofe in the contrary directions, whatever be the point from which they commence, in whatever direction the limb may be; examples of thefe are too familiar for us to particularize them, the caufe will be readily underftood from our account of the mechanifm of this part of the upper extremity.

The rotation of the arm takes place exclufively in the fhoulder joint, not accompanied as the others by any correfponding motion of the fcapula and clavicle. In this motion the head of the humerus merely glides backwards or forwards in the glenoid cavity, according as it is rolled inwards or outwards; it is not extenfive, and cannot give occafion to difplacement of the bones. In cafes where the functions of the elbow joint have been fo far deftroyed, as to prevent the rolling of the bones of the fore-arm one over the other, the rotation of the humerus has been obferved to be more marked, to compenfate the deficiency.

The fore arm, placed between the arm and the hand, is compofed of two bones, the ulna and radius.

The ulna, the largeft of the two, is on the inner fide. Irregular in fhape, ftrong, and larger above, leffening gradually in fize to its lower end. We divide it into two extremities, an upper or humeral, a lower or carpal; and into a middle portion or body.

The humeral extremity comprifes two ftrongly marked eminences, the olecranon and coronoid proceffes, and two lunated cavities, the largeft articulated with the pulley in the lower end of the humerus, the leffer with the head of the radius. The olecranon projects beyond the coronoid procefs in a line with the body of the bone; it is ftrong, fomewhat curved, rough above, where it affords attachment to the triceps; fmooth behind, where it lies immediately under the fkin; concave before, where it forms the upper part of the great figmoid cavity. The coronoid procefs ftands oppofite to the olecranon in front of the bone. Its upper furface forms the lower part of the laft named cavity, the under is marked by the attachment of the brachiæus internus. The edge next the radius is hollowed by the leffer figmoid cavity, the oppofite margin is acute, and gives attachment to the pronator teres, the flexor fublimis, and the internal lateral ligament of the elbow joint. The great figmoid cavity (finus lunatus of Albinus) lies between thefe proceffes. It is deeply concave longitudinally, adapted to the figure of the trochlea of the humerus; divided tranfverfely in the middle by a contraction of the articular furface, and a faintly marked line between the narrowed points. The upper divifion made by the olecranon is the largeft. The cavity is divided alfo into two unequal portions, by a convex line traverfing its whole length, the internal divifion is the largeft, and moft hollowed, for the reception of the inner border of the trochlea. The leffer figmoid cavity is oval tranfverfely, flightly hollow, continuous above with the larger cavity.

The body of the ulna is of an irregular prifmatic form, largeft above, curved gently forward, and turning towards the radius below. We diftinguifh in it three furfaces, and a like number of angular ridges between them. The anterior edge or fpine paffes from the leffer figmoid cavity in a curved line to the carpal extremity; it is acute above, and gradually foftened below, till it becomes fcarcely vifible. It gives attachment to the interoffeous ligament. The internal edge (pofterior, Alb.) is rounded, giving attachment to the flexor profundus above, to the pronator quadratus below. It follows a curved line from the infide of the coronoid procefs, and is fomewhat more prominent below, for the attachment of the latter mufcle. The pofterior edge (exterior, Alb.) beginning from behind the olecranon, is ftrongly marked in its upper two thirds, and infenfibly loft below. It gives attachment to an aponeurofis. The anterior furface (latus interius, Alb.) is broader above than below, gibbous in the middle, and concave at each end: the hollow part below is occupied by the pronator quadratus, the remainder gives attachment to flexor profundus. Towards the upper end is a fmall hole directed upwards for the admiffion of the nutrient veffels. The pofterior furface (prius, Alb.) is divided through its whole length by a prominent line; at the upper end of the internal divifion is a triangular fpace for the attachment of the anconæus; below it is covered by the extenfor carpi ulnaris. The external divifion, that neareft the radius, gives attachment above to the fupinator brevis, below to the extenfors of the thumb and fore-finger. The internal furface is broad, and a little concave above, giving attachment to the flexor profundus, convex and much narrower below, lying immediately under the fkin.

The carpal extremity is fmall, marked by two eminences; one placed externally, called the head or capitulum, the other, from its fhape, the ftyloid procefs. The head prefents a rounded articular furface, correfponding below to a triangular inter-articular cartilage placed between it and the carpus; externally to an articular cavity in the inner fide of the carpal extremity of the radius. The ftyloid procefs projects beyond the head; it is fmall, of a conical fhape, the point giving attachment to the internal lateral ligament of the wrift. Between thefe proceffes is a tranfverfe groove, which gives attachment to the fibro-cartilage juft mentioned. Behind they are feparated by another longitudinal groove, which lodges the tendon of the extenfor carpi ulnaris.

The ulna is formed from three points of offification, as the

 other

other long bones. At the time of birth the form of the olecranon is fully determined, whilſt the coronoid proceſs projects but little. The conſequence is, that the great ſigmoid cavity is leſs concave in compariſon than in the adult, and the leſſer ſigmoid cavity is proportionably ſmall and ſhallow.

The radius is ſituated on the outer ſide of the fore-arm. It is ſhorter than the ulna; ſmaller above than below, and gently curved in the middle. The upper or humeral extremity, called alſo the head of the radius, preſents a circular articular ſurface; ſlightly hollowed in the middle, correſponding to the rounded eminence on the cubital end of the humerus. The ſmooth articular ſurface is continued a ſhort way down the bone, and is broadeſt on the inſide, where it lies in the leſſer ſigmoid cavity. This diviſion is ſupported by a narrower portion of bone, cylindrical, and of an inch in length, called the neck of the radius. Immediately below, on the inner ſide, is an oval protuberance, ſmooth on its anterior half, over which the tendon of the biceps paſſes, ſeparated from it by a burſa mucoſa; rough poſteriorly where this tendon is inſerted.

The body of the radius is of an irregular priſmatic form, which makes a natural diviſion of it into three faces, and as many angular lines. The anterior edge is more prominent above than below. The upper part gives attachment to the long flexor of the thumb, to the flexor ſublimis, and to the ſupinator brevis; its lower to the pronator quadratus. The internal edge or ſpine, acute in the middle, rounded at each end, gives attachment to the interoſſeous ligament. The poſterior, prominent alſo in the middle, and diſappearing inſenſibly above and below, gives no muſcular attachments. The anterior ſurface is concave above, where it gives origin to the flexor longus pollicis; a little convex below, where the pronator quadratus is fixed. About its middle is the hole for the nutrient veſſels of the bone. The poſterior ſurface, like the former, increaſes gradually in breadth from above downwards, is irregular, gives attachment above to the ſupinator brevis, and lower down to the extenſors of the thumb; its inferior part, covered by the extenſor communis, the extenſor tertii internodii pollicis, and the indicator. The external ſurface is convex throughout. Its upper third gives attachment to the ſupinator brevis: about its middle is a rough eminence, into which the pronator teres is implanted; below it is covered by the radial extenſors of the carpus.

The carpal extremity is larger than the ſuperior, irregularly quadrilateral, the longeſt ſide anterior. We obſerve in it an articular cavity, oblique, ſlightly hollowed, croſſed by a riſing line from before backwards, adapted to two of the bones of the carpus; the outer diviſion to the os ſcaphoides, the internal to the ſemi-lunare. The anterior edge of the cavity is rough for the inſertion of ligaments. The poſterior offers two grooves; the internal, broad and ſuperficial, gives paſſage to the extenſor communis and indicator, the outer, narrow and deeper, follows an oblique courſe from within outwards and downwards: through it paſſes the extenſor tertii internodii pollicis. On the inner margin is a lunated articular ſurface, correſponding to the capitulum of the ulna. The outer ſide, divided from the poſterior by a riſing ſpine, is marked in a ſimilar manner by two hollows. The anterior offers two grooves for the extenſores primi and ſecundi internodii pollicis; the poſterior is marked by the tendons of the radial extenſors. At the ſharp ridge, between this ſide and the anterior, the ſupinator longus is implanted. The prominence between the hollows is continued downwards into a blunt proceſs, paſſing beyond the articular ſurface, called the ſtyloid proceſs of the radius. It gives attachment to the external lateral ligament of the wriſt. The radius reſembles, both in its formation and ſtructure, the other long bones. At the time of birth its extremities are yet cartilaginous; the lower end is ſooneſt completely oſſified.

The elbow joint; the articulation of the ulna and radius with the humerus.—The lower end of the humerus preſents an articular ſurface compoſed of alternate eminences and depreſſions, covered by a continued cruſt of ſmooth cartilage. The great ſigmoid cavity of the ulna is lined by cartilage, interrupted in the middle by a tranſverſe contraction and groove; continued into the leſſer ſigmoid cavity. The head of the radius is alſo covered by cartilage, continued over its circular margin for a ſhort way down its cylinder. The humeral end of the ulna correſponds to the pulley, that of the radius to the capitulum at the lower extremity of the humerus. Theſe ſurfaces are bound together by ligaments, and covered by a ſynovial membrane reflected from one to another.

The ligaments which more particularly ſecure the joint are called lateral, one being placed on its outer, the other on its inner ſide. The internal lateral ligament is fixed above to the internal condyle of the humerus. It radiates as it deſcends, dividing into two portions; the anterior is fixed to the inner ſide of the coronoid proceſs of the ulna, the poſterior, the ſmalleſt of the two, to the olecranon. The anterior diviſion is covered by the tendon common to the muſcles proceeding from the internal condyle, and is partially united to it. Immediately under the ligament is the capſular membrane. The external lateral ligament can with difficulty be diſtinguiſhed from the common tendon of the muſcles attached to the external condyle. It is fixed above to this condyle, below it is united to a large portion of the circle of the annular ligament of the radius. It is not ſo ſtrong, ſo large, nor ſo clearly defined as the internal lateral ligament, its fibres diverge conſiderably, and are in contact with the ſynovial membrane. In addition to theſe ligaments we find ſcattered bands of fibres traverſing in different directions, both before and behind the articulation; their irregularity ſcarcely admits of deſcription. Between them and the ſynovial membrane lie ſome cellular tiſſue and fat. This ſynovial membrane is reflected from the humerus cloſe at the margin of the articular cartilage, and is continued under the ligaments to the oppoſite ſurfaces of the ulna and radius, lining the ſigmoid cavities of the firſt, and ſpread over the head of the latter. It is common therefore to the articulations of the fore-arm with the arm, and of the bones of the fore-arm between themſelves. This joint is ſtrengthened alſo in a remarkable degree by the numerous muſcles which are attached round it, and which cover it on every ſide.

The motions of the fore-arm on the arm—are confined to flexion and extenſion, the ulna executing the principal part, the radius neceſſarily following the ſame direction. In a ſtate of complete flexion the coronoid proceſs of the ulna and the prominent margin of the head of the radius are found correſponding to the oppoſite hollows in front of the humerus, the olecranon below the condyles, having moved a conſiderable diſtance from the internal one. At this time the lateral ligaments are relaxed; the poſterior half of the trochlea of the humerus in contact with the capſular membrane, reflected from it to the olecranon, and protected by the triceps. Under theſe relations the joint is ſecure; diſplacement in any direction would be almoſt impoſſible, without ſome fracture of bone. In the intermediate ſtates between flexion and extenſion the articulation has not the ſame appearance of ſecurity; but from the great mobility of the lower end of the humerus; from its receding eaſily

before

before every ſhock when the fore-arm is in ſuch ſituation, we ſeldom meet with a diſlocation of the latter under theſe circumſtances. In the extenſion of the fore-arm on the arm, the radius and ulna glide backwards over the articular ſurface of the humerus, until ſtopped by the olecranon becoming locked in the cavity adapted for its reception in the latter bone. At this time the lateral ligaments are tightened as well as the capſule in front of the joint. It is in the ſtate of complete extenſion that luxations moſt uſually occur, the humerus paſſing down in front of the bones of the fore-arm. This frequently happens in a violent fall on the hands. The whole weight of the body is carried forwards with conſiderable impetus on the arms which are ſtretched out to ſave the head from coming to the ground. In this caſe the fore-arm is fixed, and the humerus, following the impulſe of the body, ruptures the ligaments, and is thruſt forwards, the olecranon oppoſing itſelf to all diſplacement backwards. It would appear alſo, that a diſlocation might occur from lifting a heavy weight with the arm fully extended; but here the effort is voluntary, and the pain felt in the bend of the elbow is a ſufficient warning to deſiſt. When the fore-arm is extended it forms an obtuſe angle with the arm, and when bent it is not found in the ſame line with the humerus, but ſlants a little inwards towards the breaſt. Both theſe circumſtances depend on the obliquity of the pulley at the lower end of the humerus. This direction of the fore-arm, and conſequently of the hand in the ſtate of flexion, is particularly obſervable in man, and neceſſarily requires the exiſtence of a clavicle, without which the fore-arm, when bent, would be carried to the oppoſite ſhoulder. Thus in the different ranks of animals the exiſtence of a clavicle, and the motion of pronation, are found generally connected with this obliquity in the flexion of the fore-arm. In the ſtate of demi-flexion we may obſerve a ſlight lateral motion of the fore-arm on the arm, which cannot take place in the ſtates either of complete flexion, or extenſion.

The articulations of the radius with the ulna.—Theſe bones are in immediate contact at their humeral and carpal extremities; between theſe points there is a vacancy occupied by a flat interoſſeous ligament. Above, the head of the radius is received into the leſſer ſigmoid cavity of the ulna; below, it offers a ſhallow articular ſurface, which revolves on the capitulum at the carpal end of that bone. Firſt we ſhall examine the articulation at the humeral ends. It is lined by the ſynovial membrane common to it, and to the articulation of the fore-arm with the arm, and ſecured by a ſtrong flat circular band of fibres, called the annular or orbicular ligament of the radius. This ligament forms three-fourths of a circle, which is completed by the leſſer ſigmoid cavity, and in which the head of the radius turns. It is about three lines in breadth, fixed before and behind to the ends of the leſſer ſigmoid cavity, loſt inſenſibly above over the ſurface of the ſynovial capſule, to which it is firmly united, terminating by a more defined edge below. It is compoſed of parallel circular fibres, into which the external lateral ligament is fixed from above, as alſo ſome oblique fibres proceeding from the olecranon, the ligamentum adceſſorium poſticum of Weitbrecht. The annular ligament is of a denſe compact texture, frequently cartilaginous in advanced age. It lies immediately over the ſynovial membrane, but is no where connected in any degree with the radius. It is covered by muſcles.

The ſpace between the upper and lower articulations is filled by the intervention of ligamentous fibres, which further ſecure the relations between the radius and ulna. A portion of theſe has obtained the name of the oblique ligament, or chorda tranſverſalis; the remainder is included under the general term of interoſſeous ligament. The oblique ligament, a ſmall and flat band of fibres, paſſes obliquely from the inner edge of the coronoid proceſs below the leſſer ſigmoid cavity to be inſerted into the radius at a point which lies juſt below its tubercle. In this courſe it accompanies the inner edge of the tendon of the biceps, its direction being oppoſite to the fibres of the interoſſeous ligament, and in a plane anterior to them. Between this ligament and the head of the radius there is left a triangular ſpace filled by cellular tiſſue, in which the tubercle of that bone revolves. The interoſſeous ligament commences below the tubercle attached to the inner ridge or ſpine of the radius, from which the fibres paſs obliquely downwards and inwards to be attached to the oppoſite ſpine of the ulna. It is compoſed of flat parallel fibres, leaving various intervals for the paſſage of veſſels. It is covered on both its ſurfaces by the deep ſeated muſcles of the fore-arm, to which it affords attachments. It is more delicate above, inſenſibly loſing its ſhining appearance, and interrupted by a large vacancy, which gives paſſage to the poſterior interoſſeous veſſels; ſtronger below, where we find another opening for the paſſage of the anterior interoſſeous veſſels. On the poſterior ſurface of this ligament, and more eſpecially at the upper end, we often find flat bands of fibres decuſſating it: they have been deſcribed under the name of the poſterior tranſverſal chord.

The inferior articulation between the radius and ulna, or that at the carpal ends of theſe bones, is provided with a ſynovial capſule, and a triangular fibro-cartilage interpoſed between the ulna and the bones of the carpus, and filling the vacancy obſerved between them in the ſkeleton.

This triangular cartilage is fixed by its baſe to the prominent edge which divides the articular cavity at the bottom of the radius, from that which receives the capitulum of the ulna. It is attached by its ſummit to the groove between the capitulum and the ſtyloid proceſs. Its edges are united to the ſynovial membranes of both articulations, the radio-carpal and the radio-cubital. Its upper and lower ſurfaces are concave and ſmooth, the ſuperior correſponding to the lower ſurface of the ulna. It is occaſionally incomplete at the baſe, allowing of the contact of the two capſular membranes juſt mentioned.

The capſular membrane is looſe, ſo as not to impede the extended rotation of the radius. It is continued from the upper ſurface of the inter-articular cartilage over the articular ſurfaces of the radius and ulna. It is ſometimes covered here and there by a few ſcattered ligamentous fibres, which are in many inſtances ſcarcely obſervable.

The motions of the bones of the fore-arm, between themſelves and their powers of reſiſtance.—We have hitherto conſidered the fore-arm only in its relation to the arm, in which the ulna was more eſſentially concerned; the movements in the preſent caſe depend chiefly, and almoſt excluſively, on the radius, and are neceſſarily communicated to the hand with which it is articulated below, the ulna concurring but little in the conſtruction of the joint of the wriſt. Theſe bones are thus diſpoſed inverſely as to importance in the joints of the elbow and wriſt: above, the ulna plays the principal part, the radius being acceſſary only; whereas below, the ulna is of comparatively little importance, the radius of the greateſt. Their form is accommodated to the different uſe of each: the ulna large above and ſmall below; the radius of little volume at its upper extremity, broad and ſolid at its lower, where it ſupports the hand. This double oppoſition in the form of the bones is not only accommodated to their functions, but renders the ſolidity of the fore-arm nearly equal throughout.

out. The radius, however, from its more direct connection with the hand, more immediately fuftains any effort impreffed on the latter, as in pufhing violently, or falling, and is often fractured under fuch circumftances. Still the refult of the general mechanifm will be, that the fame bone, not having to fupport the motions of the two joints, the elbow and wrift, motions which are often fimultaneous, fractures and diflocations are the lefs likely to occur.

The radius may be rolled on the ulna inwards and outwards. In the former cafe, fuppofing the radius to be horizontal, the palm of the hand is turned downwards, and the motion called on that account pronation; in the latter it is turned upwards, and the motion called fupination. In pronation, which is the moft common pofition, the humeral end of the radius turns on its axis in the hoop formed for it by the leffer figmoid cavity dna the annular ligament, while the carpal extremity rolls over the lower end of the ulna, tracing an arc of a circle. In this ftate the relative fituations of the bones are changed, the radius croffing the ulna, and diminifhing the fpace between them. If pronation be carried forcibly too far, a diflocation may take place in either articulation; more readily in the lower, on account of the greater extent of motion, and lefs ftrength of reftraining ligaments; in the upper, the radius does not quit its fituation, and is fecured by a very ftrong ligament, befides the powerful fupport of the mufcles attached round it. In fupination the radius moves in the contrary direction, until it becomes parallel to the ulna, beyond which it cannot go. If it is forced beyond thefe limits a diflocation of one of the articulations muft enfue, moft probably of the lower. A great obftacle to luxations of this joint, either in pronation or fupination, is found in the triangular fibro-cartilage at the lower end of the bones, which is very ftrong, and which muft neceffarily be torn.

Although at firft fight one might be difpofed to imagine the ulna an immoveable fulcrum, round which the radius rolls, it is certain that in pronation the carpal end of the ulna paffes outwards, in fupination in the contrary direction, fo that it traces arcs of a circle in a contrary way to the carpal end of the radius. Of this any one will be effectually convinced by obfervation or experiment. But as the ulna cannot roll on the lower end of the humerus, it neceffarily involves the latter bone in the execution of thefe motions, which it thus affifts by its powers of rotation. Pronation and fupination then depend not only on the rotation of the radius, but on the oppofite motion of the ulna, and the rotation of the arm. The latter of thefe is very much more fenfible if the motions take place when the fore-arm is extended on the arm, than when it is bent: in the former cafe, from the difpofition of the bones and ligaments, any rotatory motion of the ulna is impoffible, in the latter it may exift in a flight degree.

We have obferved that the difpofition of the bones of the fore-arm is fuch as to offer the beft poffible refiftance to external efforts: nor is their pofition as to thefe motions lefs favourable, the head of the radius lying a little before the ulna, and the breadth of its carpal extremity removing its axis from the lower end of the ulna, fo as to increafe and facilitate the pronation and fupination of the hand, offering at the fame time a broad bafis for its fupport.

The hand—forms the fourth and laft divifion of the fuperior extremity; it is articulated with the lower end of the fore-arm. It varies confiderably in fize and form in different individuals: moft commonly is comparatively fmaller in females. We diftinguifh in it two furfaces, a dorfal and a palmar; two edges, a radial and ulnar; and alfo an upper or anti-brachial, and a lower or digital end. It is compofed of twenty-feven bones, which have been arranged under the different titles of carpus, metacarpus, and fingers.

The Carpus.—The carpus, or wrift, is oval tranfverfely, convex on its dorfal, hollowed on its palmar furface, where it gives paffage to the flexor tendons. This hollow is bounded laterally by four eminences refulting from different bones of the carpus, which give attachment to a ftrong ligament confining the tendons in their fituation. It is convex at the edge next the fore-arm, offering a number of irregular articular furfaces at the border next the metacarpus. It is formed by two rows of fmall irregularly fhaped bones, the upper range called anti-brachial, the lower metacarpal. Each of thefe ranges is compofed of four bones: thofe in the anti-brachial row, commencing from the radial edge, are the fcaphoides, lunare, cuneiforme and pififorme; in the metacarpal row the trapezium, trapezoides, magnum and unciforme. Although varying much in figure, they have fome characters in common, which allow of our defcribing them with tolerable precifion, without rendering confufed or obfcure our ideas of their mutual relations. We diftinguifh in each bone fix furfaces, or fides; an upper or anti-brachial, a lower or metacarpal, an anterior or palmar, a pofterior or dorfal, an outer or radial, and an inner or ulnar.

The fcaphoides, fo called from a fuppofed refemblance to a boat, is the largeft bone of the firft row. It is fomewhat oval in figure, the long axis being directed obliquely from above outwards and downwards. The upper furface is convex, triangular, articulated with the radius; the lower is alfo convex, correfponding to the oppofite furfaces of the trapezium and trapezoides. The pofterior narrow, and grooved by the infertion of ligaments; the anterior long and contracted, concave towards the fore-arm, convex and projecting below, forming one of the eminences before mentioned. The outer, or radial fide, is rough for the attachment of the external lateral ligament of the wrift; the internal prefenting a double articular furface, the upper narrow and convex, connected with the os lunare; the lower broad and concave, forming part of the articular cavity for the reception of the os magnum of the fecond row.

The lunare, or femi-lunare, has obtained its name from the figure of one of its articular furfaces, which refembles a crefcent. It is not fo elongated in form as the laft bone; convex and triangular above when articulated with the radius; concave below, narroweft in its tranfverfe diameter, articulated with the os magnum, and in a fmall degree with the unciforme; rough and unequal on the anterior and pofterior furfaces for the attachment of ligaments, the anterior fide the fmalleft; the outer face narrow, fmooth, in the form of a crefcent, with the convexity upwards in contact with the fcaphoides; the inner alfo fmooth, plane, articulated with the cuneiforme.

The os cuneiforme (triquetrum of Albinus) lefs in volume than the preceding, oblong and fomewhat pyramidal in fhape, its bafe next the os lunare, its apex directed obliquely inwards and downwards. The upper furface is convex, articulated with the bottom of the ulna by the intervention of the triangular fibro-cartilage before mentioned; the lower oblique, concave, articulated with the unciforme; the anterior prefents on its inner fide a flat circular articular facet articulated with the pififorme, on its outer it is rough for the attachment of ligaments; the pofterior and internal are alfo unequal and rough for fimilar purpofes; the external or radial furface is plane and fmooth, articulated with the lunare.

The os pififorme (fubrotundum of Albinus) has obtained its

its name from its rounded figure. It is the ſmalleſt of the bones of the carpus. On its poſterior ſurface we obſerve a ſlightly hollowed articular ſurface, where it reſts on the laſt deſcribed bone, "aſſidens patellæ in modum, aut ſeſamoidei," (Alb.) With this exception the bone is convex on all ſides, projecting beyond the plane of the other carpal bones, rough, and unequal, giving attachment above to the flexor carpi ulnaris, below to the abductor of the little finger, and before to the annular ligament of the wriſt. It conſtitutes one of the four prominent points of the palmar ſide of the carpus.

The trapezium (multangulum majus, Alb.) is the firſt bone on the radial ſide of the ſecond range of carpal bones, and lies ſomewhat anterior to them. Above it offers a concave articular ſurface, ſemi-circular, oppoſed to the ſcaphoides; below another, convex antero-poſteriorly, concave tranſverſely, articulated with the metacarpal bone of the thumb; on the front rough, with a deep groove at the upper end for the paſſage of the flexor carpi radialis; the outer edge of the groove giving attachment to the annular or tranſverſe ligament, and forming one of the eminences already mentioned; on the back and outer ſides rough and unequal for attachment of ligaments; on the inner ſide are two articular ſurfaces; the upper, large and concave, connected with the trapezoides; the lower, narrow and plane, for the metacarpal bone of the fore-finger.

The trapezoides (multangulum minus, Alb.) is very irregular in figure, placed like a wedge between the laſt and the following bones, the baſe of it being poſterior, the point towards the palm. The upper ſurface is concave, quadrilateral, and articulated with the ſcaphoides; the lower divided by a convex line croſſing from before backwards, adapted to the hollow of the metacarpal bone of the fore-finger; the dorſal or poſterior, convex, rough and broad; the anterior poſſeſſing the former characters, but much ſmaller; the external, convex articulated with the trapezium; the internal or ulnar, ſmaller and concave, ſmooth anteriorly where articulated with the following bone, rough behind for ligamentous attachments.

The os magnum (capitatum, Alb.) is the largeſt of the eight; longeſt in its vertical axis, rounded into an articular head above, (from whence it derives its name,) of a quadrilateral form below. The upper articular ſurface is convex, divided by a prominent line into two portions, one for the ſcaphoides, the other for the lunare; the lower is divided into three facets, the external articulated with the ſecond bone of the metacarpus, the middle the largeſt of the three, concave, ſupporting the third, the internal or poſterior very ſmall, plane, oppoſed to the inner edge of the fourth; the palmar and dorſal ſurfaces, rough and unequal for ligaments, the latter the largeſt of the two, the external narrow, articulated with the trapezoides; the internal of greater extent than any of the preceding, ſmooth above where contiguous to the unciforme, rough below, giving attachments to ligaments.

The unciforme (os hamatum; cuneiforme Alb.) completes the ſecond row of carpal bones, being the laſt on the ulnar ſide. Above is a rounded angle oppoſed to the lunare; below a ſmooth ſurface, convex tranſverſely, the outer ſurface ſupporting the fourth, the inner the fifth metacarpal bone; on the anterior ſide we obſerve, below, a curved proceſs projecting forward, to which the annular ligament is attached, as alſo ſome muſcles of the little finger; it forms the laſt of the four eminences referred to before; the ſuperior part of this ſurface is narrow, unequal, but ſmooth, giving attachment to ligaments; the poſterior ſurface is broad, triangular, and rough; the external offers an articular ſurface above, in contact with the os magnum, is rough below for ligamentary connections; the internal is directed obliquely, preſenting a curved, oblong, articular facet, and a rough line below it; the former oppoſed to the cuneiforme, the latter ſerving for attachments to ligaments.

The bones of the carpus reſemble each other in ſtructure; compoſed of a cellular or ſpongy ſubſtance, externally covered by a thin layer of compact bone. They are developed from ſingle points of oſſification, which do not commence till after birth. At that period they are entirely cartilaginous, diſtinct, well marked, and not at all proportionably larger than when fully oſſified, and on this account differing from the cartilaginous extremities of the long bones.

The articulation of the fore-arm with the carpus, or joint of the wriſt.—The ſuperior ſurfaces of the ſcaphoides, lunare, and cuneiforme, form by their union a common convex ſurface, oblong tranſverſely; each bone is covered by its proper cartilage, firmly united to the next by an intervening band of a fibro-cartilaginous ſtructure, which ſeparates this joint from the articulations of the carpal bones between themſelves. The lower extremity of the radius, and the triangular cartilage at the bottom of the ulna, form an elliptical concave ſurface, which receives the oppoſite convexity of the carpus, ſo that the ſcaphoides and lunare are oppoſed to the radius, and the cuneiforme to the inter-articular cartilage which ſeparates it from the ulna. The joint is ſtrengthened by ligaments on each ſide, and alſo before and behind, and lined by a ſynovial membrane.

The external lateral ligament is attached above to the ſtyloid proceſs of the radius; it advances forward a little as it deſcends, and is fixed on the outer ſide of the ſcaphoides. The fibres of which it is compoſed diverge below, and become continuous with the anterior ligament: we can often trace them on to the trapezium. Its form is irregular, and by no means defined, the edges being variouſly connected with the parts around it. The internal lateral ligament proceeds from the ſtyloid proceſs of the ulna, and is attached below to the inner ſide of the os cuneiforme. it is implanted alſo by ſome of its anterior fibres into the annular ligament, and piſiforme bone.

The anterior ligament is broad, and flat; fixed above to the anterior part of the ſtyloid proceſs of the radius, and the whole anterior edge of the articular cavity; from hence the fibres deſcend obliquely inwards, and are fixed below in an irregular line to the ſcaphoides, lunare, and cuneiforme; ſome fibres go to the piſiforme, the greateſt number are attached to the lunare. The flexor tendons lie in front, the ſynovial membrane immediately behind it. The poſterior ligament is not ſo broad as the preceding, and more evidently fibrous; its direction is nearly the ſame, being fixed above to the poſterior border of the articular hollow of the radius, below the lunare, and cuneiforme; it is covered by the extenſor tendons. Theſe ligaments are in nowiſe connected with the ulna, ſo that they cannot in any ſituation impede the rotation of the radius on that bone. The ſynovial membrane is ſpread over the articular ſurfaces of the radius, and triangular cartilage above, and the three bones of the carpus below; it is reflected between them under the ligaments, appearing in the intervals between their fibres in ſeveral ſpots. The joint of the wriſt is ſtrengthened on every ſide by ſtrong and numerous tendons, ſome of which are inſerted in its vicinity, others cloſely bound to its ſurface by ſtrong tranſverſe ligaments as they paſs from the fore-arm to the hand and fingers. The ſecurity derived from this conſtruction muſt be very great, without it the joint would preſently yield to the many violent impulſes it has to

ſuſtain

fuftain, to which the ligaments alone would offer a very inadequate refiftance.

The motions of the carpus on the fore-arm—are thofe of flexion, extenfion, lateral inclinations or abduction, and adduction, and circumduction. From the clofe connection of the carpal bones between themfelves, and with the reft of the hand, thefe motions of the carpus may be confidered at the fame time as general motions of the hand. Thofe of pronation and fupination depend on the motions of the bones of the fore-arm, and are in nowife dependant on this joint.

In flexion the articular convexity of the carpus glides from before backwards in the correfponding cavity of the fore-arm, and the pofterior ligament and extenfor tendons are ftretched; it may be carried to nearly a right angle without violence; an effort preffing beyond this point would ftrain, and might certainly diflocate the bones.

In extenfion an oppofite fucceffion of phenomena occurs, it is the anterior part of the joint which has the effort to fuftain. This motion is not confined to the bringing the carpus and hand into the fame ftraight line with the fore-arm, but may be continued in the oppofite direction to fome extent, fo as to make them form a confiderable angle with it on the dorfal afpect. The freedom of motion enjoyed by the carpus in this fenfe is fubfervient to many of the important ufes of the hand, and is not to be found in other analogous joints, where the power of flexion is greater, and that of extenfion limited to bringing the oppofite bones into the fame axis, as in the elbow, knee, &c. The lateral motions, thofe of abduction and adduction, are more confined, efpecially the laft. The lateral ligaments are alternately ftretched and relaxed, preventing their too great extent. Circumduction is alfo confined to narrow bounds, more particularly fo when pronation and fupination are not concerned in producing it.

The articulations between the carpal bones—all communicate together, being lined by a continuous fynovial membrane. The bones lie in clofe appofition, and are bound firmly by ligaments on the palmar and dorfal furfaces, fome by ligaments paffing deeply between them. The three firft bones of the upper row are in contact by nearly plane furfaces covered by cartilage, the fcaphoides connected with the lunare, the latter with the cuneiforme. The palmar ligaments uniting them lie deep under the anterior ligament of the wrift, the fibres of each paffing tranfverfely from bone to bone. The dorfal ligaments are more diftinct, the fibres longer as they are more fuperficial, they have the fame direction as the former. The fuperior, or interoffeous ligaments, have been already mentioned in fpeaking of the joint of the wrift, as feparating it from the articulations of the carpus. They are of clofe condenfed texture, paffing between the bones from before backwards, one joining the fcaphoides to the lunare, the other this laft bone to the cuneiforme. They are very narrow, the upper fide fmooth, covered by fynovial membrane forming a polifhed furface with the convexity of thefe bones, with the edges of whofe cartilages they are continuous. The os pififorme is placed without the ranks of the carpal bones, and has no communication with the common joint between them. It refts by a flightly concave articular furface on a correfponding convexity of the cuneiforme; the joint is lined by a fynovial membrane reflected from one to the other, ftrengthened by fcattered ligamentous fibres. Two bands of thefe, of confiderable fize and ftrength, pafs from the lower fide of the bone, one to the root of the metacarpal bone of the little finger; the other to the os unciforme. The pifiform bone is retained in its fituation by thefe, and, in fome meafure, alfo by the abductor mufcle of the little finger, to which it gives attachment. Above we obferve fome ligamentous fibres paffing from it to the ulna, and the infertion of the flexor carpi ulnaris. It performs the office of a patella, or fefamoid bone, for this latter mufcle "pofitum porrectumque inter ejus tendinem, ligamentumque ad os metacarpi digiti auricularis pertinens." Its motions are very limited; it forms, together with its connections above and below, a large portion of the channel through which the flexor tendons glide.

To form the articulation between the firft and fecond row we find the fcaphoides touching the trapezium and trapezoides, forming, in conjunction with the lunare, a cavity for the reception of the head of the os magnum, and the cuneiform bone fupporting the unciforme. The refpective articular furfaces are covered by a thin cruft of cartilage, and preferved in their fituations by palmar, dorfal, and lateral ligaments. The palmar ligaments are fhort and ftrong, formed by fibrous bands, paffing from one row to the other in different directions; the moft fuperficial are confounded with the anterior ligament of the wrift. The dorfal ligaments refemble them in their paffing from the upper row to the lower, but are too irregular in fize and direction to allow of fpecific defcriptions. Indeed they are both fo mixed with the furrounding ligamentous fibres as fcarcely to admit of diftinction. Of the lateral ligaments, the external is the fhorteft and ftrongeft, paffing from the fcaphoides to the trapezium; the internal ftretched between the cuneiforme and unciforme.

The bones of the fecond row are in contact by cartilaginous furfaces, and connected by ligaments, as thofe of the firft. The dorfal tranfverfe ligaments, are very diftinct, one between every two correfponding bones; the palmar are not fo well defined, the fibres of each being fhorter and more numerous, as they are more deeply feated. We can obferve one band, paffing from the trapezium to the os magnum in front of the trapezoides, independent of thofe between the contiguous bones. Between the unciforme and os magnum is a ftrong collection of fibres paffing from fide to fide through the depth of the carpus, adhering firmly to fuch parts of the correfponding bones as are not covered by cartilage. A fimilar connection exifts alfo between the os magnum and unciforme.

The fynovial membrane is continued from one articular facet to another, lining the ligaments we have defcribed, appearing in many places between their fibres. Nor does it form a continued furface only between the carpal bones, it is extended below into the joints, between the carpus and metacarpus; not always, however, into thofe formed above by the os magnum and unciforme. Owing to this general communication, difeafe of one articular furface is prefently propagated to the whole; in this refpect it muft be confidered only as a fingle joint.

The pifiform bone is in nowife concerned in the mechanifm of the carpus; its ufes have been mentioned above. So clofely are the bones of each row bound one to another, that they allow of fcarcely any perceptible gliding motion. The articulations between the two rows allow of a more fenfible movement; though this is confined to narrow limits. It refembles fomewhat that obferved in the joint of the wrift; they can be bent, and extended a little on each other, as well as inclined laterally; the firft of thefe is the moft evident. The little motion they poffefs is produced principally by the articulation of the head of the os magnum, which has the greateft effort to fuftain, and has been fometimes luxated backwards. Notwithftanding the obfcurity of movement in the carpal bones, it co-operates in increafing the mobility of the hand, whilft at the fame time, by the number

ber of articulating furfaces, impulfes may be to a certain degree weakened.

Before we enter on the latter point, it will be proper to take fome notice of another ligament, materially affecting the folidity of the carpus, though deftined but in a fecondary way for this purpofe, its firft office being to confine the flexor tendons in their paffage to the fingers. The annular ligament in front of the wrift, (ligamentum armillare, ligamentum carpi proprium,) paffes from the eminences formed by the pifiform and unciform bones to the oppofite ones of the fcaphoides and trapezium, completing the canal for the flexor tendons. It is compofed of very ftrong and thick fibres, becoming gradually thinner above and below; rough fuperficially, lined behind by a fynovial burfa. It gives attachment to feveral mufcles of the thumb and little finger. The fibres are all tranfverfe, numerous and compact, fecuring, in addition to its other ufes, the arch formed by the carpal bones. The carpus then derives its firmnefs from the large furface of the articulating facets in comparifon with the fmallnefs of the bones, from their number, from the numerous ligaments, and from the arched form refulting from the connection of the whole. It is further ftrengthened by numerous tendons, the flexors in front, the extenfors on its dorfal furface. Another caufe of the folidity of the carpus is, that the articulations between the two ranks are not in the fame tranfverfe line, the unciforme, and more efpecially the head of the os magnum, mounting far beyond the level of the trapezium and trapezoides, fo that any impulfe would not act on all at once, and caufe a general difplacement, the effort and the injury muft be partial, confined to the articulations between one or two of the bones.

The metacarpus (die mittelhand, Germ.) - is compofed of five bones, refting on the carpus above, giving fupport to the thumb and four fingers below. They are ftrong, thofe fupporting the fingers parallel to each other, the other a little anterior, and capable of altering its pofition. The intervals between them are filled by mufcles fo as to form a broad and folid body. The anterior face of the metacarpus is concave, conftituting the palm of the hand, the pofterior convex, and forms the back. The bones are diftinguifhed, from the connections below, into the metacarpal bones of the thumb, the fore, the middle, the ring, and the little fingers, or we clafs them numerically, beginning on the radial fide with the metacarpal bone fupporting the thumb. Of thefe divifions we fhall adopt the latter. The firft metacarpal is the largeft, and fhorteft of the whole; the fecond and third are nearly of the fame length; the fourth and fifth are fucceffively fhorter and fmaller. They are all fomewhat concave before, and flat behind, prefenting feveral more or lefs acute angles; larger at each extremity, the upper angular and unequal, the lower forming a convex head, compreffed laterally, with an articular furface terminating on the palmar fide in two prominent points; fmalleft in the middle of the body of the bone, increafing gradually in fize above and below. In confidering the diftinguifhing characters of each metacarpal bone, we fhall obferve them as feen on the carpal extremities, the bodies, and the digital extremities of each fucceffively, and not tire the reader by a feparate defcription of the feveral bones, in which it would be impoffible to avoid repetition, and which muft neceffarily be of greater length.

At the upper or carpal end of the firft metacarpal bone we obferve an articular furface convex tranfverfely, flightly concave in the oppofite direction, oppofed to the trapezium. It is furrounded by ligaments, and gives attachment on the outer fide to the extenfor offis metacarpi pollicis.

In the fecond are three articular furfaces, the middle concave, correfponding to the prominence of the trapezoides; the external fmall and flat, articulated with the trapezium; the internal divided into two portions, the upper articulated with the os magnum, the lower with the following bone. The circumference of this extremity is rough, and gives attachment to ligaments. On the palmar fide is a rough fpot, which gives attachment to the flexor carpi radialis; on the dorfal a tubercle, into which the extenfor carpi radialis longior is inferted.

In the third a quadrilateral articular furface oppofite to the os magnum, bounded before and behind by inequalities, giving attachments to ligaments; on the outfide by a fmooth facet articulated with the preceding bone; on the infide by two fmall round articular furfaces, feparated by a hollow contiguous to the following bone. At the external dorfal angle is a pyramidal eminence (proceffus ftyliformis), and clofe on the inner fide the infertion of the extenfor carpi radialis brevior.

In the fourth, at the top, a double articular furface, accommodated to thofe of the os magnum and unciforme, furrounded before and behind by rough points for ligamentous attachments, on the outfide by two prominent articular facets, correfponding to thofe of the laft bone; on the infide by a flightly concave furface articulated with the following.

In the fifth, a broad articular furface, convex from before backwards, concave tranverfely; flanting outwards and upwards, oppofed to the unciforme, bounded before and behind by rough furfaces for ligaments, on the outfide by a fmall articular facet connected with the laft bone on the infide by a tubercle which gives attachment to the tendon of the extenfor carpi ulnaris.

The bodies of the metacarpal bones are all concave anteriorly, and flightly convex on their dorfal furface. Although rather irregular in figure we can diftinguifh in them four fides, an anterior, a pofterior, an internal, and external. In the firft the pofterior furface is broad; in the three next we obferve above a prominent line running lengthwife, which foon bifurcates, forming the lateral boundaries of a flat triangular furface, the breadth of which increafes as it approaches the digital extremity; in the laft an angular line, running diagonally from the inner fide of its carpal end to the outfide of its lower extremity. In all of them the pofterior furface is covered by the extenfor tendons.

The anterior or palmar furface prefents alfo a longitudinal rifing line, generally more prominent towards the lower end. It feparates the attachments of the interoffei mufcles, and has fomewhat different directions in the feveral bones. In the firft rounded, covered by the opponens, and flexor brevis pollicis; in the third giving attachment above to the latter mufcle, below to the adductor pollicis. The lateral furfaces of thefe bones are broad, inclined obliquely in various directions, giving attachment to mufcles. In the firft they are compreffed and rounded, the outer fide giving attachment to the opponens, the inner to the firft external interoffeus (the abductor indicis of Albinus). In the laft the inner or ulnar fide gives attachment to the adductor offis metacarpi minimi digiti; the outer fide, as well both fides of the other metacarpal bones, give attachment to and are covered by the external and internal interoffeous mufcles.

The digital extremities are in all convex, and nearly alike in figure. On the palmar fide of the firft we obferve two flight depreffions correfponding to the fefamoid bones in front of the joint; on the fides of the articular furfaces of each deep hollows for ligaments, which fecure the articulations between thefe bones and the fingers.

The metacarpal bones refemble in ftructure and formation the other long bones. At the period of birth the extremities are cartilaginous, offification commencing in the body of the bone in the embryo of three months.

In the preceding defcription we have reckoned five metacarpal bones, according to the plan followed by the moft eminent anatomifts. By many the firft metacarpal bone has been omitted, and defcribed as the firft bone of the thumb, which they confider as compofed of three bones, like the fingers. By Albinus the metacarpus is divided into two portions, one, comprifing the four laft bones, he calls the metacarpus manus; the other, the metacarpus pollicis.

The articulations between the bones of the carpus and metacarpus are nearly fimilar in all but the firft. The articular furface at the upper end of the metacarpal bone of the thumb is convex and concave in oppofite directions, adapted to the correfponding furface of the trapezium. The joint is furrounded by ligamentous fibres paffing from one bone to another, amongft which the external and dorfal are the moft ftrongly marked, and the moft in number, the internal and anterior are continued on to the annular ligament. It is lined by a diftinct fynovial membrane. The difpofition of the ligamentous fibres is fuch as to form a capfule round the articulation, like that obferved in the fhoulder joint, but not fo loofe. The whole is fupported by the mufcles and tendons of the thumb. The fecond metacarpal bone is articulated with the trapezium, the trapezoides, and the os magnum; the third with the latter only; the fourth with it and the unciforme; the fifth with the laft alone. The furfaces are covered by cartilages continuous with thofe forming the joints between the metacarpal bones themfelves, and lined by a common fynovial membrane with occafional exceptions, as mentioned when fpeaking of the carpus. The ligaments on the dorfal furface pafs in different directions from the lower row of carpal bones, to the upper end of thofe of the metacarpus. There are two for the fecond of thefe, one from the trapezium, the other from the trapezoides; the third has but one from the os magnum; the fourth two, paffing from this bone and the unciforme; the fifth a fingle band from the latter. They are all fhort, flat, and compact. The palmar ligaments are lefs diftinct, being confounded with thofe around them. The moft evident are, a band paffing from the trapezium to the third and fourth metacarpals, confining in its paffage the tendon of the flexor carpi radialis; and a band between the trapezium and firft metacarpal.

The articulations of the metacarpal bones between themfelves.—The metacarpal bones, with the exception of the firft, touch at both ends by lateral articular facets, which have been already defcribed. The fynovial membrane lining thofe at the carpal extremity is open above, forming a free communication with the carpus. They are fecured in their relations by tranfverfe ligaments at both ends. At the carpal end thefe are found on the palmar and dorfal furfaces; on the firft of thefe the fuperficial ligaments form a continued layer, paffing from the fecond to the laft, the more deeply feated paffing from bone to bone. The dorfal ligaments pafs acrofs between each bone. Befides thefe, we find immediately below the articulations ftrong ligaments paffing deeply between the bones, uniting them moft firmly together. At the digital end is a ftrong tranfverfe ligament on the palmar fide, the fuperficial fibres paffing from the firft bone to the laft, thofe more deeply feated between each individual bone. It is covered in front by tendons and veffels, behind it fupports the interoffei mufcles, and is united to the ligaments connecting the metacarpus with the fingers.

Among the bones of the metacarpus, the firft enjoys very extenfive motions in every direction. The moft important motion is that which brings the thumb in oppofition to the fingers, and enables us to grafp the object before us; an office which made Albinus beftow on it the emphatic name of "manus parva majori adjutrix." The freedom of this motion depends on the extent and obliquity of the articular furfaces, between it and the trapezium, and is favoured alfo by their being on a plane anterior to the reft of the hand.

Circumduction of the thumb is very free towards the palm, very much lefs fo in the oppofite direction. The interval between this and the other metacarpal bones is highly advantageous in allowing of all its motions. The four laft bones of the metacarpus are bound fo clofely together, as to allow of much individual motion. They can be brought clofer together below, and bent a little forwards, fo as to increafe the hollow of the hand; this motion is moft evident in the two laft, thofe of the ring, and little fingers. The four laft bones of the metacarpus hold a middle rank, as to motion and folidity, between the carpus and fingers; above they partake of the firmnefs of the carpus, below approach nearer the mobility of the fingers.

The fingers, including the thumb,—are five in number. They are either reckoned numerically from the radial to the ulnar fide, or diftinguifhed by proper names. The latter are in common acceptation. We count, therefore, the thumb as the firft; the fore-finger or index as the fecond; the middle finger as the third; the ring finger as the fourth; and the little finger as the fifth. By this arrangement we can immediately compare their relations to the metacarpal bones, which have been defcribed alfo in a fimilar numerical order. The fingers are compofed of rows of long bones, placed vertically one beyond another, called *phalanges*; of thefe we find three in the fingers, properly fo called, and two only in the thumb, the middle phalanx being wanting. They are diftinguifhed by the names of the firft or metacarpal phalanx, the fecond or middle, and the third or unguinal. As the correfponding bones of the feveral rows are effentially alike in all, we fhall include them in one defcription, noticing the peculiarities of each. We divide them into two extremities, and a body.

The firft, or metacarpal phalanges,—are the largeft, and longeft of the three; of different lengths and fize, the third being the longeft, and all diminifhing fucceffively in volume from the firft to the laft. They are convex on the dorfal furface, the tranfverfe convexity forming nearly half a circle; concave anteriorily, with fharp angular edges laterally. At the fuperior extremity we obferve an articular furface, oblong tranfverfely, flightly hollowed, articulated with the correfponding bone of the metacarpus; a broad tubercle on each fide giving attachment to lateral ligaments, divided anteriorly by a depreffion, in which the flexor tendons pafs. In the thumb this extremity gives attachment to the abductor, the flexor brevis, and the adductor. The bodies of the phalanges are convex pofteriorly, covered by the extenfor tendons; concave on the palmar fide with projecting edges, fo as to form a kind of gutter, in which the flexor tendons are partly lodged; the edges give attachment to ligamentous fheaths confining the tendons in their fituation. The lower extremity offers an articular pulley, extended further and much broader on the palmar fide than on the oppofite, and the edges diverging confiderably from behind forwards. On each fide are depreffions, which give attachment to lateral ligaments.

The fecond, or middle phalanges,—are fmaller and fhorter than the firft, which they refemble much in general figure. The thumb poffeffes none. As to individual comparifon, they differ but little, that of the middle finger is the longeft, the laft belonging to the little finger the fhorteft and fmalleft.

fmalleft. The upper extremity offers an articular furface croffed antero-pofteriorly by a rifing line, correfponding to the oppofite pulley of the firft phalanx; on each fide are tubercles giving attachment to ligaments. The body refembles that of the metacarpal phalanx. About the middle of the anterior furface are two rough prominences, giving attachment to the divided tendon of the flexor fublimis, and to a fibrous fheath, which croffes over it from fide to fide, confining alfo the tendon of the flexor profundus. Its pofterior furface gives attachment to a portion of the tendon of the extenfor communis. The lower extremity refembles that of the firft.

The third, or unguinal phalanges—are found, in all, five, diminifhing in fize from the thumb to the little finger, that of the former being by far the largeft of the whole. The upper extremity or bafe (from a comparifon of the bone to a pyramid with its apex downwards), forms an articular furface, oval tranfverfely, with a convex line croffing from before backwards, accommodated to the pulley of the middle phalanx; is tuberculated for ligaments on each fide, giving attachment behind to extenfor tendons. The body is contracted; on its anterior furface the flexor profundus is fixed in the fingers, and flexor longus in the thumb. The lower extremity, or point, is flat, rounded, broader than the body, fcabrous at the edges and on the anterior fide, fmoother behind, where it fupports the nail.

The bones of the fingers have nothing peculiar in ftructure or formation: the firft and fecond phalanges are formed from three offifying points, the third from only two. At the time of birth, their figure is well marked, and their formation very confiderably advanced.

The articulations of the thumb and fingers with the metacarpus.—The convex heads of the metacarpal bones are covered by articular cartilages, in contact with thofe lining the concave furfaces of the firft digital phalanx. They are bound together by lateral ligaments, and ftrengthened in front by the fheaths of the flexor tendons, behind by the expanfion of the extenfors, on each fide by the interoffei mufcles. The lateral ligaments are attached above to the fides of the lower end of the metacarpal bones, and divide as they defcend into two diftinct bands, which are fixed to the fides of the correfponding bones of the firft phalanx. They are ftrong, formed of parallel fibres, lined on the inner furface by the fynovial membrane. In front of the joint we find the tranfverfe ligament of the lower end of the metacarpus, which has been already defcribed. The fynovial membrane is loofe, particularly before lining the extenfor tendon in its paffage behind over the joint, and appearing between the ligaments, which it alfo covers in front and on the fides. In front of the joint of the thumb we find two fefamoid bones developed in the tendons of the flexor brevis, leaving a furrow between them, in which the tendon of the flexor longus paffes. They reft on the head of the metacarpal bone, gliding up or down, as the joint is bent or extended. They are fometimes found in the articulations between the metacarpus and fingers. The motions enjoyed by this joint are thofe of flexion, extenfion, abduction, and adduction; of thefe the firft is by far the moft confiderable, the thumb poffeffing it in the leaft, the little finger in the moft extenfive degree.

The articulations between the phalanges are alike in all; the condyles, at the lower extremities of the firft and fecond phalanx, are covered by cartilage, and correfpond to the little hollows at the upper ends of the fecond and third. They are covered by a fynovial membrane, and connected by lateral ligaments, which pafs from bone to bone, refembling thofe of the preceding articulation. The fynovial membrane is fupported by thefe, as alfo by the extenfor and flexor tendons. It is fo clofely united to the extenfor tendon, at the upper end of the fecond and third phalanx, that it is almoft impoffible to feparate them. It is continued much further down on the bone on the palmar, than on the dorfal furface, forming a little bag in front of the joint. The thumb has but one of thefe articulations, which is in every refpect fimilar to the joints between the phalanges of the fingers.

In this laft part of the hand we obferve an evident decreafe of firmnefs, when compared with the metacarpus and carpus, and a proportionate increafe of facility and extent of motion. The fhortnefs of the bones, however, fcarcely offering a refifting point to external impulfes, fecures their relations, and leffens the chance of fracture, though the fingers are more immediately within the action of furrounding bodies, and more expofed to injuries than any other part of the limb. The joints of the phalanxes of the thumb and fingers allow only of flexion and extenfion; the latter cannot be carried beyond the ftraight line, the former is very free; an effect which depends on the continuation of the articular furfaces in front, far beyond their extent on the dorfal furface, and which is provided for by a correfponding laxity of the fynovial membrane. The advantages of this difpofition, for the important functions of the fingers, is fo confpicuous as to require no comment. In opening the hand, the fingers cannot be extended beyond the plane of the hand; from this fituation they may be bent in various degrees, until their points touch the lower end of the metacarpus. This general flexibility, derived from the fucceffive rows of firm bones, and their peculiar modes of articulation, allows of the fingers being applied accurately to any body whofe qualities we wifh to examine, whatever be its figure. The decreafing length and fize of the feveral phalanxes permit us to feize objects conveniently and firmly, to retain them, however fmall. The power we poffefs of moving them fingly, or in different degrees, of touching the palm of the hand at any point of its furface, of fpreading them laterally, of feparating one from another, &c. enables us to adapt their pofition to every poffible ufe. In all the actions of the hand, the thumb holds a confpicuous rank. Alone, it oppofes the efforts of the other fingers, which are much longer, and bend, as it were, to meet the thumb, whenever we clofe them on the object. With regard to the different lengths of the thumb, and feveral fingers, we may obferve, that when feparated moft widely from each other, by gently bending the points they may be brought to defcribe nearly a circle on a plane furface, forming with the hollow of the palm a concave hemifphere; from which fituation they may be further contracted, till the feveral points meet: from this conftruction they are fuited to grafp equably and firmly bodies of a rounded form. The fenfe of touch owes, in a great meafure, its delicacy and perfection to the readinefs and precifion with which the fingers can be applied to the object whofe qualities we wifh to examine. It would be almoft endlefs to defcribe the different motions of which they are fufceptible; they are fo rapid in fucceffion, fo varied in direction, extent, and power, fo exquifitely adapted to the innumerable offices they have to perform, as to conftitute an inexhauftible, not to fay an inexplicable fubject for difcuffion.

We conclude our hiftory of the upper extremity, by fome remarks on its powers of refiftance and fufceptibility of motion, as a complete member, enjoying the affemblage of all the properties we have defcribed as refulting from the mechanifm of each divifion.

The cafes in which the upper extremities are required to fupport ſupport great efforts, or to oppoſe a powerful impulſe, are by no means ſo numerous or ſo frequent as in the lower limbs, where conſiderable exertion and reſiſtance are neceſſary, to ſupport the body in the ordinary attitudes. In the action of puſhing, the hand is applied to an object, the fore-arm and arm extended between it and the trunk forming a ſtraight lever, which conveys the weight of the latter on the body to be puſhed. In this motion the hand being inflected backwards on the fore-arm, the joint of the wriſt is ſoon fatigued by the diſtenſion and preſſure in front; the ſigmoid cavity of the ulna bears directly againſt the lower end of the humerus, the latter reſts on the glenoid cavity of the ſcapula, which is fixed firmly by its muſcles and the clavicle.

It is only, however, when the arm is directed outwards, that it bears directly on the glenoid cavity; if it be turned forwards or backwards, the capſular ligament and the ſurrounding muſcles ſuſtain the effort. The firſt circumſtance is moſt favourable to firmneſs and continued reſiſtance; and we may obſerve, that when at liberty to chooſe our attitude in puſhing with one arm, we always place it in ſuch a direction as to bring it to bear directly on that cavity. For inſtance, if the object be in front, we turn ourſelves ſo as to bring the ſide of the body correſponding to the limb we are about to exert oppoſite to the object. In preſſing downwards, in reſting on the arm, &c. the mechaniſm is nearly the ſame, as far as regards the hand, which is ſo much extended on the fore-arm as to form an angle with it behind, while the fore-arm is placed in the ſame line with the arm, the joint of the elbow being fixed and immoveable. The difference depends only on the change of ſituation which takes place in the joint of the ſhoulder, the head of the humerus preſſing more or leſs advantageouſly, as the direction of the preſſure varies from the relative poſition of the object on which the limb reſts.

The beſt poſſible direction is where the arm is extended laterally, ſo as to bear on the glenoid cavity, the ſcapula being at the ſame time ſupported directly by the clavicle. It is underſtood that in every caſe the poſition of the limb is preſerved by muſcles, which are called on to act more or leſs, as that poſition is more or leſs favourable for ſuſtaining the effort, and become tired in the ſame proportion. This obſervation is more particularly applicable to the caſe in which the upper extremities have to ſuſtain the whole weight of the body, as in the inſtance of tumblers, when the hands are placed on the ground, and the body raiſed into the air, the upper exerting for a time the functions of the lower extremities. This attitude is both difficult and painful, from the want of ſufficient muſcles to maintain it, and from the ſmall extent of the articular ſurfaces. The wriſt ſuffers more particularly, as in marching on all-fours, becauſe theſe ſurfaces do not bear on each other, but on the front of the joint; the elbow is not ſo much diſtended from the conſtruction of the articulation; the ſhoulder-joint ſuffers almoſt equally with the wriſt, from the preſſure on its capſule. The upper extremities are articulated with the trunk in a plane poſterior to the lower; the line of gravity in the attitude above-deſcribed is anterior to the ſupport, and we find, conſequently, that to preſerve the balance, to counteract the tendency to fall forwards, the lower extremities are thrown conſiderably backwards.

The motions of the upper extremity are ſo numerous and varied, as ſcarcely to admit of claſſification; they are ſo familiar as not to require deſcription. The mechaniſm by which they are performed has been conſidered in treating of the ſeveral articulations, and may readily be applied to any caſe; we ſhall now only briefly recapitulate the more material points. The ſhoulder is the centre of motion of the whole limb; the arm gives the general movement, the parts below thoſe which are more partial. The motions of the ſhoulder affect the whole limb; as we deſcend, the actions are more and more confined. A finger may be employed while the arm is motionleſs; if the latter is moved, all below muſt partake of the motion. It is from the combination of the ſeveral partial motions that the increaſe and variety of the whole are derived, and theſe are multiplied the lower we go. The hand enjoys the individual motions of its component parts; a general motion from the joint of the wriſt; a more general ſtill from the connection of the bones of the fore-arm and the elbow, which is increaſed to a ſtill greater extent by the ſhoulder joint and ſhoulder. The motions then may be more compound as we deſcend, as well as more partial, becauſe each part enjoys the motion reſulting from its proper articulation, in conjunction with all thoſe above it. This general action of the parts of the upper extremity is obſervable in ſeizing or graſping any body, or in embracing, where all the articulations are *bent*, or in the oppoſite actions of ſpreading the arms, or *extending* the whole limb in different directions, &c. It is more commonly ſeen under caſes where the different joints are inflected variouſly at the ſame time, ſome extended, and others bent, theſe motions being often alternate. All theſe modifications of action may be obſerved in puſhing, pulling, climbing, graſping a diſtant object, ſwimming, ſtriking, &c. &c. In ſhort, in all the familiar exerciſes of the upper extremity we are conſtantly in the habit of performing. We cannot conclude without hinting at thoſe impreſſive actions of the upper extremity, which form a mute language employed moſt emphatically in aiding the expreſſions of our paſſions, or our will; it is enough to ſay, they are as numerous and varied as the feelings which bring them into play.

The lower extremity—is divided, as the upper, into four parts, *viz.* the hip, the thigh, the leg, and the foot, each of which has a more or leſs ſtriking analogy with the correſponding diviſions of the upper extremity. We ſhall examine their points of reſemblance and difference more minutely hereafter; at preſent, we would obſerve only, that the bones, which form the baſis of the lower extremity, are more maſſy and ſolid in their forms, and are hence adapted to their functions, as organs by which the reſt of the body is ſupported and moved. Their prominent character is ſolidity and firmneſs; in the upper extremity every thing is conſtructed for variety and quickneſs of motion.

The lower extremity is connected with the trunk by the articulation of the hip bone with the baſis of the vertebral column, the ſacrum; through which the whole weight of the body is tranſmitted to the bones of the hip. The connections of the two hip bones with the ſacrum behind, and with each other in front, form a bony cavity called the *pelvis*, the principal uſes of which are, to contain ſome important viſcera, to offer a baſis of ſupport to the trunk above, and two fixed points for the motions of the limbs below. It is in the laſt functions only that we ſhall have occaſion to notice the pelvis here; we ſhall not, therefore, enter into a deſcription of it as a whole, but attend to thoſe of its parts which bear on the preſent ſubject, and correſpond to analogous portions of the upper extremity.

The os coxæ, os innominatum, hip, or haunch bone, is the largeſt of the broad bones, placed laterally at the lower end of the trunk, connected with its fellow in front, by means of cartilage, and ſeparated from the oppoſite bone behind by the intervention of the ſacrum. The hip-bone is very irregular in figure, broad and flattened above, con-

 tracted

tracted and maſſy in the middle, and apparently more ſlender in the anterior and lower portions: it is curved ſo as to have its flat ſurfaces in almoſt oppoſite directions; the upper diviſion is flattened from ſide to ſide, the lower from back to front, the change of direction taking place in the middle portion. In young ſubjects this bone is formed of three ſeparate pieces; a ſuperior, called the *ilium*, an anterior, the *pubes*, and an inferior, the *iſchium*. In the adult they are ſo intimately united, that we can with difficulty trace their former line of ſeparation. We can ſee therefore no reaſon for deſcribing as diſtinct, what in its perfect ſtate forms but one ſolid bone. We ſhall conſider it as ſuch; but, not to deviate too much from common uſage, ſhall notice the different diviſions as we proceed, and afterwards particularly deſcribe their lines of union. We diſtinguiſh in the os innominatum two ſurfaces; an internal or pelvic, an external or femoral, and a circumference or border, which is again ſubdivided into ſeveral parts.

The external ſurface looks outward above, and forwards below; it is covered by ſtrong and numerous muſcles. The outſide of the broad upper diviſion, the dorſum of the ilium, is convex and concave in different parts; at the poſterior and ſuperior part is a rough eminence, which gives attachment to the gluteus maximus; below this a ſurface, concave and broad behind, convex and gradually narrowing in front, gives attachment to the fibres of the gluteus medius; it is bounded by the eminence juſt mentioned, by the upper edge or criſta of the ilium, and below by a ſemi-circular line, with the convexity upwards, paſſing forwards from a deep notch behind, (the great ſacroſciatic,) and terminating in the criſta of the ilium in front. The ſpace compriſed between this curved line and the deep articular cavity below, gives origin to the gluteus minimus; it is concave behind, and gibbous in front. At the anterior part, immediately above this cavity, is a rough impreſſion, where the curved tendon of the rectus cruris is fixed. The portion of the external ſurface, which is directed downwards and forwards, is very irregular in figure. Above is a deep and large cavity, called the acetabulum or cotyloid cavity; it forms nearly the half of a ſphere, lined by cartilage in its upper two thirds, the lower part a little deeper, lodging ſome cellular tiſſue, and the ſtrong ligament paſſing to the head of the thigh-bone. The margin of the cavity is irregular and waving, more prominent above than below, ſurmounted by a ligamentous ring, which makes the acetabulum ſtill deeper, interrupted towards the inner ſide by a notch, completed by a ligament which leaves only a ſmall opening for the paſſage of the articular veſſels; it gives attachment to the capſular ligament of the hip joint. The bone ſurrounding the cotyloid cavity is thick and maſſy, eſpecially at the upper and outer ſides; the cavity itſelf is directed obliquely outwards, downwards, and forwards. Below, and on the inner ſide of this cavity, is a large hole, of an oval ſhape, the foramen ovale, obturatorium, or thyroideum. Its long diameter is from above downwards, its edges are acute and rough, except at the upper part, where there is a ſmooth gutter directed obliquely from above inwards and downwards, in which the obturator nerve and veſſels are lodged. The groove is formed by the internal and external edges of the circumference croſſing each other at the top of the oval, the latter paſſing in front to a point called the ſpine of the pubes, leaving the oblique hollow between itſelf and the internal margin which paſſes up in the oppoſite direction. The foramen ovale is cloſed by a ligament attached to its edges every where but at the groove juſt mentioned, where it leaves a vacancy for the paſſage of the obturator veſſels, &c. In the female this foramen is ſmaller than in the male, and of a triangular figure. On the inner ſide of the foramen is a rough and unequal ſurface, broader above and below than in the middle, giving attachment to portions of the triceps, and the external obturator muſcle.

The internal or pelvic ſurface is concave, correſponding in its direction to the external or femoral, covered by muſcles which ariſe from it. The anterior part of the upper diviſion, the foſſa iliaca, is occupied by the iliacus internus muſcle; the poſterior is very ſcabrous and unequal, divided into two portions, of which the anterior is covered by cartilage, and articulated with the ſacrum, forming the ſacro-iliac ſymphiſis, reſembling ſomewhat in outline the human ear, the poſterior is convex and very rough, giving attachment to the ſtrong and numerous ligamentous fibres which connect this bone with the ſacrum above. Below the iliac foſſa, croſſing from the articular ſurface to the anterior angle of the bone, is a prominent angular line, forming a part of the ſuperior aperture of the pelvis, ſeparating the upper diviſion from the lower. The latter preſents a plane ſurface behind, broader above than below, giving attachment to the obturator internus and levator ani; in front of this is the obturator foramen, and in the inſide of the latter a narrower ſurface correſponding to the bladder above, giving origin to a part of the obturator internus below.

The circumference of the os innominatum is exceedingly irregular, with alternate prominences and hollows, and is divided into four portions, *viz.* a ſuperior, an inferior, a poſterior, and an anterior. The ſuperior margin bears the name of the criſta of the ilium; is convex, narrower in the middle than at the ends, and inclined outwards. The inner edge, or labium, gives attachment to the tranſverſalis abdominis, and quadratus lumborum; the external to the obliquus externus, the latiſſimus dorſi, and the faſcia of the thigh; the middle convex portion to the obliquus internus. The anterior margin is concave, and its lower half nearly horizontal. Its union with the criſta forms the anterior ſuperior ſpine of the ilium, which gives attachment to the tenſor vaginæ femoris, the ſartorius, and the upper end of that part of the tendon of the external oblique, called Poupart's ligament. Below this point is a ſlight notch, riſing again into another eminence, the anterior inferior ſpine of the ilium, from which the rectus crucis ariſes. This is ſucceeded by a ſmooth hollow, over which paſs the pſoas magnus, and iliacus, bounded by a protuberance called eminentia ileo-pectinea, into which the tendon of the pſoas parvus is implanted, when it exiſts. On the inſide of this there is an oblique ſurface, concave, triangular, with the baſe outwards, and the point inwards, bounded in front by a line which is continued from the external margin of the obturator foramen, behind by a ſharp ridge, the criſta of the pubes, which is continued from the tranſverſe line deſcribed as croſſing the pelvic ſurface. Over this concave ſpace paſs the crural veſſels. The anterior margin terminates by uniting with the inferior, at a right angle, called the angle of the pubes. A little before its end we obſerve on it a projecting point, the ſpine of the pubes, giving attachment to the pyramidalis, and the external pillar of the abdominal ring, formed by the tendon of the external oblique. The inferior margin is the ſhorteſt, preſenting above a perpendicular oblong ſurface, forming with the oppoſite bone, by the intervention of cartilage, the ſymphyſis pubis; below this the edge is thinner, forming with the oppoſite one the arch of the pubis, affording attachment to the gracilis, to portions of the triceps, to the corpus cavernoſum, the tranſverſalis perinei, and the erector penis, or clitoridis. The upper half of this bony plate is called the deſcending ramus of the pubis, the lower the aſcending ra-

 mus

mus of the iſchium. The poſterior margin is the moſt irregular in its outline. Beginning from above we obſerve the angle formed by its junction with the ſuperior margin, the ſuperior poſterior ſpine of the ilium, an hollow ſeparating it from the eminence below, the inferior poſterior ſpine; a very deep notch forming part of the ſacro-ſciatic notch; a ſharp prominence, the ſpine of the iſchium, giving attachment to the ſuperior gemellus, the coccygeus, and the leſſer ſacro-ſciatic ligament; a ſmooth concave ſurface, over which the tendon of the obturator internus plays; and a broad eminence where it joins the inferior margin, the tuberoſity of the iſchium giving attachment, externally, to the quadratus femoris, and the great head of the triceps; within to the great ſacro-ſciatic ligament, and the inferior gemellus, in the interſpace to the biceps, the ſemi-tendinoſus, and ſemi-membranoſus.

The os innominatum is in ſtructure like the other flat bones; the two compact tables, encloſing the more cellular parts, touch each other in the middle of the iliac foſſa, and again at the depreſſion in the acetabulum. It is developed from three points of oſſification, at the angle of the pubis, the tuberoſity of the iſchium, and the middle of the upper diviſion, or ilium. The union of the bony plates proceeding from theſe points takes place between the ilium and pubes at the eminentia ileo-pectinea; between the latter and the iſchium, in the middle of the branch which forms the inner ſide of the foramen ovale, and the half of the arch of the pubes; between the iſchium and the ilium at the great ſacro-ſciatic notch. The junction of the three takes place in the acetabulum, which forms the principal point of union; the ilium makes the upper part of the cavity, the pubes the anterior, the iſchium contributing the principal ſhare, and completing it at the inferior and poſterior portions. The part which either bone takes in forming any of the principal features of the os innominatum will be immediately ſeen, by obſerving their lines of union with each other. At the time of birth the acetabulum, being far removed from the centres of oſſification, is wholly cartilaginous, as are alſo the different eminences, the ſpines, and the criſtæ. It is not till the time of puberty that all traces of cartilage are obliterated. The os innominatum is articulated with the ſacrum, by the ſacro-iliac ſymphyſis; with its fellow, by the ſymphyſis pubis; and with the thigh-bone by means of the cotyloid cavity. We ſhall ſay nothing of the two former of theſe connections, but that they are exceedingly ſtrong, and the bones bound ſo cloſely together, as not to allow of any perceptible motion; we ſhall deſcribe the laſt after having gone through the hiſtory of the thigh bone.

In commenting on the mechaniſm of the ſhoulder, we had to notice its articulation with the trunk, and the motions reſulting from its peculiar mode of connection; in the preſent inſtance we find an immoveable adherence of ſurfaces, which allows of no deviation from one determined poſition. In conſequence of this total want of motion, we ſhall not enter on the detail of the connections of the hip bone with the trunk, or with its fellow; they can influence the functions of the lower extremity no farther than by tranſmitting to it the weight of the body.

The oblique direction of the articular ſurfaces of the ſacrum, which gives it the form of a wedge driven between the two oſſa innominata, is well adapted to the purpoſe of tranſmitting ſecurely the weight of the trunk to the latter bones: the ſtronger the depreſſing impulſe, the more cloſely the ſurfaces are brought together; the ſhock muſt be violent indeed, which can in anywiſe looſen their connection. It is then through the medium of the ſacrum that every effort is propagated to the two hip bones, which in ſome poſitions are the immediate baſe of ſupport, while in others they continue the impulſe to the limb below. In the common attitude of ſitting, the trunk is ſupported on the tuberoſities of the iſchia; in progreſſion, or in ſtanding, on the cotyloid cavities. Theſe being at a diſtance from each other, facilitate the motions of the thighs, and increaſe their extent, the pubes executing one of the offices of the clavicle, in keeping the hip joints far aſunder, as the clavicle does thoſe of the ſhoulder. It will be ſeen, from the deſcription of the hip bone, that its ſurfaces and circumference give attachment to numerous and powerful muſcles, by far the greater number of which are deſtined to regulate, or to give vigour and effect to the motions of the thigh and leg, and to balance the varying weight above them.

The thigh—is the diviſion of the lower extremity between the hip and the leg. It is formed by a ſingle bone, called the *femur*, or *thigh bone*.

The femur is the longeſt bone of the body, the largeſt in volume, and the ſtrongeſt. It has a conſiderable curve forwards, is contracted in the middle, wider and more bulky at each extremity, one of which is called the upper, or *iliac*, the other the lower, or *tibial*.

The upper extremity includes three remarkable eminences; the head, ſupported by a long neck, and the great and little trochanters. The rounded head of the femur is received into the cotyloid cavity of the os innominatum; it forms more than half of a ſphere, directed upwards, inwards, and a little forwards; ſo that the greateſt part of its convexity is above, and its axis the ſame as that of the neck, which ſuſtains it. The convex ſurface is ſmooth, except juſt below the centre, where we find an hollow, which gives attachment to an inter-articular ligament; it extends further in front than behind, above than below, and terminates in a waving line at the neck. The latter contracts immediately below the head, and becomes a little flattened vertically, the upper edge remaining the wideſt; it is longer below and behind, on which aſpects it is alſo hollowed, than above and in front; joined by a broad baſis to the body of the bone, from which it ſtands off in a direction ſlanting upwards and inwards, advancing at the ſame time a little forwards, forming with it an angle more or leſs obtuſe. The length and obliquity of the neck vary conſiderably in different ſubjects, being in ſome nearly horizontal. The great trochanter is on the outer ſide, directed a little backwards, below the level of the head, riſing above the hollow of the neck, quadrilateral, convex on the outſide, and exceſſively rough for the attachment of ſtrong tendons, the tendon of the gluteus maximus paſſing over the ſmooth ſurface at the poſterior part; hollow, and of much leſs extent on the inſide, giving attachment above to the tendons of the gemelli, the obturator internus, and the pyramidalis below, and towards the back part to the obturator internus. It has rough and irregular borders; to the anterior is fixed the tendon of the gluteus minimus; to the lower part of the poſterior the quadratus; to the upper the gluteus medius; to the lower the vaſtus externus. The attachments of theſe muſcles are hardly, however, confined to the edges of the trochanter; their tendons are implanted alſo to a greater or leſs extent over the outer ſurface, for which purpoſe its roughneſs, as mentioned above, ſeems particularly deſigned. The little trochanter is placed at the internal and poſterior part of the baſe of the neck, oblong and ſomewhat pyramidal in ſhape, its rough ſummit giving attachment to the united tendon of the pſoas magnus and iliacus. From its baſe we trace two prominent lines proceeding obliquely upwards to the great trochanter, one uniting them

them in front, the other behind. Thefe, in conjunction with the two trochanters, mark the circumference of the bafis of the neck, and give attachment, more efpecially the anterior, to the capfular ligament of the hip joint. The body of the thigh bone is convex forwards, and hollowed behind, appearing nearly cylindrical when viewed in front, but almoft triangular above, and flattened tranfverfely towards the lower end. It has been divided in defcriptions into three furfaces and as many angular lines; thefe characters, however, are not ftrongly marked; the furfaces are univerfally fmooth, the dividing lines blunt and rounded, if we except the pofterior ridge formed by the union of the internal and external furfaces, called with great propriety the linea afpera, or fpina femoris. This is formed by two converging rough lines, commencing from each trochanter above; that which proceeds from the trochanter major is the moft prominent and rough, giving attachment to the gluteus maximus; the pectineus is affixed to the other; and the interfpace is occupied by the quadratus and a portion of the triceps. The double ridge, formed by the approach of the two rough lines, is continued down the bone, when it again divides into two lefs remarkable lines, which terminate in the condyles at the lower extremity. The whole middle of the linea afpera gives attachment to the triceps; a portion of the biceps has its origin at the lower part, which is continued along the line diverging towards the external condyle; the line going to the internal condyle is fcarcely obfervable for a little way below the point of bifurcation. Thefe two branches of the linea afpera leave a triangular interval between them, fmooth and fomewhat concave, correfponding to the popliteal veffels. Befides the mufcles fixed to different parts of the linea afpera, the vaftus externus is attached to almoft the whole extent of the line, proceeding from the great trochanter to the external condyle; and the vaftus internus is connected in a fimilar manner to the line from the little trochanter to the internal condyle. The furfaces of the body of the femur are covered by thefe mufcles, and by the crurcus, which cover the bone at every point, excepting towards the lower end, and the fpace intercepted between the bifurcation of the linea afpera. The nutrient arteries of the body of the bone are found in the courfe of the linea afpera; the principal one about the point of convergence above.

The lower extremity much exceeds the upper in volume, and prefents two eminences called condyles, the internal and external. They are both convex, project more behind than in front, are fmooth below for articulation with the tibia, this furface being terminated behind by two hollows, which give origin to the heads of the gaftrocnemius. They diverge behind, leaving a deep notch between them, where the crucial ligaments of the knee joint are fixed; on the front they are joined by a continued articular furface, which is hollowed to receive the knee-pan or patella; the edge of the pulley formed by the outer condyle being more elevated than the oppofite one. The articular furface terminates abruptly in the lateral direction, in the perpendicular rough fides of the condyles; in front it is continued a little way up the bone, ending in a flightly prominent edge. The internal condyle gives attachment on the inner fide to a lateral ligament, and to the tendon of the triceps. The external furface of the outer condyle is marked by a depreffion to which the popliteus is affixed, and by an eminence for the external lateral ligament of the knee. The articular furface of this condyle is broader than that of the internal, and not fo convex, the anterior part being nearly plane; and it is continued much higher up in the front than on the oppofite fide. The internal condyle, when the thigh bone is placed perpendicularly, appears to defcend much lower than the external; but in the natural oblique direction of the femur, the bottom of the two condyles will be found nearly in the fame horizontal plane, the internal ftill exceeding a little.

The femur is compact in its ftructure in the middle part, reticular and fpongy at the extremities, which are yet cartilaginous at the time of birth. Offification commences in the middle of the bone, and it is not till after this has reached the extremities that we obferve three centres of offification above, in the great, the little trochanter, and the middle of the head, and two below, one for each condyle. The cartilages between them and the body of the bone gradually decreafe in thicknefs, and they become united, the two trochanters the firft, then the head, and laft of all the conjoined condyle. It is not till the bone has nearly arrived at its complete and adult form that the line of feparation is entirely obliterated. In infancy the neck of the bone is nearer at right angles to the body than at any after period; as the age advances the angle becomes more and more obtufe in the majority of fubjects; in fome few it fcarcely alters its direction. This alteration, from an horizontal to an oblique line, is a proof among many others how little the functions or growth of the animal body are fubject to phyfical laws; we fee the neck of the thigh bone rifing, as it were, in direct oppofition to the weight of the fuper-incumbent body. This portion of the femur is alfo proportionally fhorter than in the adult, and wholly cartilaginous. The body of the bone is ftraight, inftead of being curved forwards, as in the adult; and the inferior extremity is comparatively of larger dimenfions. Thefe characters of the infantile bone are loft as it gradually becomes developed, and acquires its remarkable denfity and firmnefs. The thigh bone is articulated above with the os innominatum, below with the tibia and patella.

The articulation of the femur with the os innominatum, the hip joint.—The furface of the cotyloid cavity of the hip bone is lined by an articular cartilage, of which the central parts are thinner than the circumference. It terminates at the edge of the depreffion obferved at the inner and lower parts of the cavity, which is filled up by a fatty cellular tiffue, fupplied by numerous veffels. The bony margin of the cavity is completed by a ligament croffing the notch, and the whole rim of the acetabulum is furmounted by a circular ligament, called the cotyloid ligament, which much increafes its depth. In this round articular cup, or acetabulum, the head of the thigh bone is lodged. The latter is covered by cartilage thinner at the circumference than towards the centre, where it is partially interrupted by the infertion of a ligament, and accommodated exactly to the oppofite furface of the acetabulum; the cartilaginous head, however, is fo deep as not to be wholly embraced by this cavity in any pofition; and hence fome part of its margin always appears expofed on turning back the enveloping ligament. The contiguous furfaces are fecured in their relations by a very ftrong capfular ligament, fupported by fibres from the neighbouring parts, and furrounded on all fides by mufcles; and by an inter-articular ligament. The oppofed furfaces are covered by a fynovial membrane.

The cotyloid ligament adheres firmly to the edge of the acetabulum at every point, excepting the great notch which it croffes. It is thick at the border next the bone, thin at the oppofite prominent margin, broader above, and externally thin in the contrary directions, and partially broader wherever there is any depreffion in the offeous rim, fo that the unconnected margin of the ligament is exactly plane throughout. It is formed by ligamentous fibres arifing from

from the edges of the cavity without, inclining gently towards it in their progrefs, and inferted again into the fides of the margin within at a greater or lefs diftance from their point of origin. Thefe fibres receive an addition above from the curved tendon of the rectus cruris; below they are confounded with the fibres of another ligament, completing the great notch. The latter is formed by two crofs planes of fibres paffing from one edge to the other; they decuffate each other in their courfe, one band correfponding to the furface of the joint, the other to the edge of the obturator foramen, from the ligament occupying which it partly takes its origin. They leave a vacancy below for the paffage of veffels into the joint; towards the brim of the cavity they are continuous with the cotyloid ligament in the manner above-mentioned; they give a partial attachment alfo to the ligamentous capfule. The cotyloid ligament, in conjunction with thefe bands, completes the figure of the acetabulum, and by increafing its depth fecures the joint without in any degree diminifhing the motions of the head of the femur, to the preffure of which it readily yields. They are both lined towards the joint by the fynovial membrane, which is continued over the edge of the cotyloid ligament a little way down the oppofite furface, before it is reflected to the capfular ligament. Thefe two laft are oppofed to each other in part by its intervention; towards their mutual attachment to the brim of the cavity they are intimately united. Into the articular hollow thus conftituted, the head of the femur is received, and fecured by an orbicular and internal ligament.

The capfular ligament of the hip joint, (l. orbiculare, membrana capfularis femoris, Soemm.) extends from the circumference of the acetabulum to the bafe of the neck of the femur. It is fixed to the bony margin of the former from the line of infertion of the cotyloid ligament, to a fhort fpace beyond it, fo as to furround the latter, which projects freely into the joint. Its infertion extends further beyond the cotyloid ligament in front and on the outer fide than it does internally, where it may be almoft faid to arife from its very edge. From this circular attachment the capfule defcends, enveloping in its courfe the chief part of the neck of the femur, to the circumference of whofe bafe it is finally fixed. In front it reaches the oblique line between the trochanters, the linea inter-trochanterica; behind, fome of its fibres only reach fo far, the greater number are implanted into the neck between the pofterior oblique line and its middle; above, it is fixed to the root of the great trochanter; below, it extends nearly to the little. The capfular ligament is in general very thick, and of a clofe and condenfed texture; it is thinneft internally and behind, thicker externally, and moft decidedly fo in front, where it is ftrengthened by a layer of longitudinal fibres arifing from the anterior margin of the os innominatum, and from the anterior inferior fpine, and fixed below to the anterior linea inter-trochanterica. In other parts of the ligament the courfe of the fibres is lefs diftinctly marked; from the margin of the acetabulum they follow different directions, decuffating each other, and leaving occafional intervals, more efpecially below, through which veffels pafs to the fynovial membrane. This laft is occafionally expofed and bare on the fide next the obturator foramen. The capfular ligament is covered in front by the rectus cruris, pfoas magnus, and iliacus internus, a fynovial burfa lying between them; on the internal fide, by the obturator externus and pectineus; behind, by the quadratus femoris, the gemelli, the tendon of the obturator internus, and the pyramidalis; above and without, by the gluteus minimus, which is more clofely connected with it than any other of thefe mufcles.

The interior, or round ligament, (ligamentum teres, internum) is entitled to almoft any name rather than round; it is flattened, and of a triangular figure, the bafe towards the acetabulum, the fummit next the head of the femur. It is fixed at one end to the extremities or corners of the great notch of the colytoid cavity, and to the pofterior edge of the tranfverfe ligament occupying the vacancy; from thence it mounts obliquely backwards, and is attached to the depreffion noticed towards the centre of the head of the thigh bone. It appears as if compofed of two bands of fibres, one arifing from the fuperior, the other from the inferior extremity of the great cotyloid notch, which approach each other towards their oppofite infertion. The upper of thefe is by far the weakeft; in many cafes it appears only as a duplicature of the fynovial membrane, enclofing only a fmall number of ligamentous fibres. It muft reftrain the head of the femur from quitting the cavity upwards and outwards, and muft be partially, if not entirely, ruptured in the luxations in thofe directions; in the difplacement towards the obturator foramen it would not apparently fuffer much injury.

The fynovial membrane lines the cotyloid cavity, is fpread over the fatty cellular tiffue, occupying the finus at its bottom, is reflected from thence over the internal ligament, which it wholly encafes, adhering to it more or lefs intimately in different parts: it covers the articular cartilage of the head of the femur, is continued over the periofteum of the neck, which appears through it as if formed of parallel fibres; at the bafe of the neck it turns back over the inner furface of the capfular ligament, lines it to its attachment round the brim of the acetabulum, and from thence paffes over the cotyloid ligament. The hip joint is very much ftrengthened by the furrounding mufcles, efpecially by thofe which immediately cover it.

The motions which take place in the hip joint refemble thofe in the fhoulder; they are, however, with the exception of rotation, lefs extenfive, owing to the immobility of the cotyloid cavity, its great depth, and the comparative tightnefs of its capfular ligament. The femur can be bent on the hip bone, extended, brought nearer to, or removed further from, the mefial plane, moved between thefe directions, or carried round in a circular direction (*circumduction*), and rolled inwards and outwards. In the moft common pofition, with the thigh in the fame line as the body, the fummit of the great trochanter, which can be always felt externally under the integuments, is in the fame horizontal line with the fpine of the pubis, and about the middle of an oblique line extended between the fuperior anterior fpine of the ilium, and the tuberofity of the ifchium. By a previous knowledge of the relative pofition of this eminence to points which can be eafily felt, we fhall be competent to decide on any accidental difplacement, as well as to follow the alteration of pofition in the different motions of the femur.

When the thigh is bent, the head rolls in the acetabulum in the axis of the neck, the fummit of the trochanter recedes from the fpine of the ilium, and approaches the tuber of the ifchium, and the lower end of the bone is advanced. In moderate flexion there is but little alteration in the relations of the articular furfaces; when carried to its greateft degree, a portion of the head of the femur quits the acetabulum, and refts on the pofterior part of the capfular ligament, which undergoes confiderable diftenfion. Extenfion of the thigh is the replacement of the limb in its former ftate, from the pofition of flexion. The very clofe manner in which the head of the bone is covered in front by the ftrong ligamentous fibres, which proceed from the anterior and inferior fpine

 of

of the ilium, and the neighbouring anterior portion of the cotyloid line, entirely prevent us from carrying the limb backwards beyond a perpendicular line drawn from the pelvis downwards, if the latter part be preserved immoveable. The degree of motion in this direction, if it exist at all, is very trifling, supposing the trunk to be erect, and the pelvis fixed; the apparent freedom of motion in the direction of extension arises from the pelvis being ordinarily moved in the opposite direction.

In abduction, or removing the thigh from its fellow, the great trochanter rises towards the fossa of the ilium, which it touches, if the motion be continued as far as possible, and thereby limits the extent of that motion. The internal surface of the head abandons the acetabulum, while the external sinks deeper into it; the capsular ligament is made very tense on the inner side, where it supports the head and opposes its tendency to any displacement in that direction. In adduction nothing remarkable occurs; it is merely the return of the thigh from the last position to its natural one; the limb may, however, be carried, in this direction, across the opposite one. Besides these four motions in opposite lines, it will be readily understood that the femur can be moved through all of the intermediate points. Circumduction is not so free as in the shoulder joint, as may be gathered from the preceding observations: rotation is, on the contrary, less confined, on account of the length and obliquity of the neck of the femur, so strikingly different from that of the humerus. In the latter rotation is nearly in the axis of the bone, on account of the extreme shortness of the neck; in the femur, where the axis of the bone is so far removed from the centre of motion, this motion passes round a line extended from the upper part of the head to the middle point or interval between the condyles. In rotation inwards, which is more confined than that outwards, the great trochanter describes the arc of a circle from behind forwards, and the head of the bone is buried deeper in the cavity; the motion of the trochanter is more sensible and more extensive as the neck is proportionally longer. In rolling the thigh outwards the great trochanter sinks under the muscles, and the head of the bone distends the capsule somewhat in front. In its most natural position the thigh is turned a little outwards, which contributes, with the direction given to the foot by the construction of the ankle joint, to point the toes moderately outwards. As the leg and foot necessarily follow the rolling motions of the thigh, and more perfectly so when the leg is extended on the latter, it will be seen that the rotation of this bone inwards and outwards will imply a corresponding alteration in the position of the foot; and the great power we enjoy of turning the toes outwards, and the narrow limits to which we are confined in directing them inwards, will be found to result from the difference observed in the powers of rotation of the thigh.

The motions of the hip bone on the thigh, when the latter is the fixed point, will require no particular detail after the preceding remarks. It is sufficient to say they may be made in every direction, and with tolerable facility, particularly lateral inclination, in which one hip bone is lowered, and the opposite one elevated, and rotation; motions executed with promptness and to a great extent in the *pirouettes* of our stage dancers. We shall have occasion to speak at length of the flexion and extension of the hip bones on the thigh, when we examine the mechanism of the whole in the attitude of standing.

The leg—is the part of the lower extremity placed between the thigh and the foot; the bones which it contains are the tibia, the fibula, and the patella.

The tibia, the largest of the three, alone supports the weight placed on the leg from above; it comes next to the femur in size, is larger above than below, nearly triangular throughout, divided into an upper, femoral extremity, or head, a middle part or body, and a lower or tarsal extremity.

The upper extremity is nearly oval, with the long diameter transverse, large, and spreading.

The vertex or top presents two articular hollows or sinuses; of which the internal is oblong from before backwards, and deeper than the external, which is nearly circular. They correspond to the condyles of the femur by the intervention of moveable cartilages; and are divided from each other by a middle eminence, terminating in a rough depression before and behind, which completes the separation. This protuberance, placed nearest to the posterior edge of the head, is not much elevated; it slopes into the articular surfaces at the base, and is bifid at the summit, with a rough groove in the interval. The rough depression in front is larger than that behind; they both give attachment to the semi-lunar inter-articular cartilages of the knee, and to the crucial ligaments of the joint. In front of the upper extremity is a broad, flat, triangular surface, with the base upwards, corresponding to the ligament of the patella. The lateral parts have been called the tuberosities; they project considerably by a convex edge, separated in front by the flat space just mentioned, behind by a notch varying much in depth. The internal protuberance is the largest, and is marked by the attachment of the semi-membranosus behind, the external presents in the same aspect a rounded articular surface inclined downwards, for connection with the fibula.

The body of the tibia is slightly curved outwards above, and inwards below, diminishing in bulk as we trace it from the upper extremity till about one-third from its lower end, from which point its size gradually increases again downwards. It is of a prismatic form, with strongly marked edges. The anterior of these, the crista or spine, commences above at a rough eminence, called the anterior tuberosity of the tibia, into which the inferior ligament of the patella is fixed in front, and the tendons of the sartorius, gracilis, and semi-tendinosus internally; it is sharp above and in the middle, in the latter of which portions it projects a little, and becomes insensibly lost below; it forms by its course a waving line, which gives attachment to the aponeurosis enveloping the muscles of the leg. The internal edge is flattened above, and more angular below; in the first portion it gives attachment to the popliteus, for the lower two-thirds to the long flexor of the toes. To the external ridge, the least prominent of the three, the interosseous ligament is fixed; below it bifurcates and is continued into the edges of the articular cavity, which receives the lower end of the fibula. Of the surfaces between these edges, the internal or the shin is the largest; smooth, slightly convex above, and covered by the tendons of the sartorius, gracilis, and semi-tendinosus; throughout the rest of its extent it lies immediately under the skin. The outer surface is hollowed longitudinally above, and convex below, where it turns a little forward; its upper half is covered by the tibialis anticus, to which it gives attachment, and lower down the tendon of this muscle, with those of the extensor of the great toe, and the common long extensor of the toes, pass over it. The posterior surface is crossed obliquely by a line passing downwards and inwards from the articular surface, at the back of the external tuberosity; above this the popliteus is attached; below, the tibialis posticus, and long flexor of the toes; to the line itself these muscles are fixed, as also the soleus. It is is towards the upper end of the posterior surface that we find the hole which gives passage to the nutrient vessels.

The lower extremity is much less in volume than the femoral or upper; it is nearly quadrilateral with an articular cavity of the same form at the bottom, which rests on the foot. Of the four sides, the anterior and posterior are straight, transversely and nearly parallel, giving attachment at their edges to ligamentous fibres; the latter presents also a groove for the passage of the long flexor of the great toe. The internal is prolonged downwards below the level of the others, forming a broad and strong process, called the malleolus internus. This eminence does not correspond exactly to the inner tuberosity of the femoral end, but is situated a little more forwards from the slightly twisted form of the bone. The circumference of its anterior and lowest parts gives attachment to ligaments; the posterior has a broad and superficial hollow, over which pass the tendons of the tibialis anticus, and the long flexor of the toes; the inner surface is convex, and covered by the skin, the external is smooth, presenting a vertical articular surface, joining above the large articular cavity, the depth of which it considerably increases. On the outer side of the tarsal extremity is a triangular hollow with the summit upwards, smooth below, and covered by cartilage, where it receives the fibula, rough above for the attachment of strong and short ligamentous fibres, which secure the connection: the edges of the cavity are continued above into the external spine of the body of the bone, and give attachment to ligaments which pass to the fibula. The articular surface at the bottom is a little concave, quadrilateral, narrowest and deepest towards the inner side, crossed antero posteriorly by a broad gently rising eminence; it corresponds to the upper surface of the astragalus, the highest of the bones of the tarsus.

The structure and formation of the tibia resemble those of the other long bones. At birth the extremities are cartilaginous, and are not completely ossified and united to the body till a late period; the bony spines in the latter are already very prominent, and better marked than in any other bone. The tibia is articulated with the femur, the fibula, and astragalus.

The patella, rotula, or knee-pan (kniescheibe, Germ.) is situated in front of the knee-joint, or articulation between the femur and tibia, varying as the leg is bent or extended, in its relative position with regard to the femur. It is flattened, of a triangular form, with the base upwards, the upper angles rounded, the lower more acute. The anterior surface is convex, pierced by numerous longitudinal openings, covered by a tendinous expansion from the extensors of the leg, which is partially attached to it, and by the skin. The posterior articular surface is oblong, transversely divided by a blunt elevated line, passing rather obliquely from the upper edge to the lower angle, into two differently inclined concave faces, of which the external is the largest and deepest; they both correspond to the condyles of the femur on which they play. It is terminated below by a rough depression, into which a portion of the ligament of this bone is fixed. Of its circumference, the upper edge is thick, and gives attachment to the tendon of the extensors, the lateral borders slightly convex, to the common aponeurosis of these muscles. In the lower angle the strong anterior ligament which connects the patella to the tuber in front of the tibia is firmly implanted.

The substance of the patella is spongy in the middle, covered by a thin crust of compact bone. It is formed in the thickness of the tendon of the extensors, and always preserves the appearance of longitudinal fibres. It is not till some years after birth that bony matter is deposited in room of the cartilaginous substance at first observable, and it is a later period still before it is fully developed. The patella is articulated with the femur, and connected with the tibia by means of a ligament, of which we shall speak below.

The knee joint, or articulation of the femur with the tibia and patella.—This joint, one of the most complicated in the body, results from the contact of the condyles of the thigh bone with the head of the tibia and the posterior surface of the patella. The first of these, as well as the articular pulley formed by their union in front, are covered by cartilage, which is thicker in the middle of the condyles than at their circumference; the cartilage covering the patella is particularly thick, it is thinner on the hollows of the tibia, particularly in their centres. The forms of the articular surfaces of the femur are accommodated to those of the patella and tibia; but in the latter case the correspondence is further maintained by means of two inter-articular semilunar fibro-cartilages, interposed between the femur and tibia in such a manner, that a small portion only of the latter bone comes into actual contact with the condyles of the former. The relations between these parts are secured by muscles, and their tendons, by the ligament of the patella, two lateral, and the same number of crucial or oblique ligaments, a posterior ligament, and by a synovial membrane spread over the whole.

The ligament of the patella, which may be regarded as the termination of the tendons of the extensor muscles, consists of a very strong flat band of fibres attached above to the lower angle of that bone, and to the depression on its posterior surface, from which points it extends about two inches in length, and half as much in breadth to the anterior tuberosity of the tibia. It is covered in front by the skin and an aponeurotic expansion. The posterior surface corresponds above to some fat and cellular tissue lying betwixt it and the synovial membrane, below to a small synovial capsule placed between it and the tibia, a smooth portion of which it covers, just above the insertion of the ligament. The edges are continuous, with an aponeurosis proceeding laterally to the tibia. It is composed of parallel, shining, tendinous fibres, of which the anterior or most superficial are continued in front of the patella to be identified with those of the immediate tendons of the extensors. It is exceedingly strong, and capable of resisting the strongest efforts of these muscles.

The internal lateral ligament is flat and thin, attached above to the internal condyle of the femur, it becomes broader as it descends, part of its fibres is inserted into the edge of the internal semi-lunar cartilage, and into the edge of the head of the tibia, the greater portion contracted in breadth is continued further down, and becomes fixed at the commencement of the body of the bone to the internal edge, where it joins the aponeurotic insertion of the popliteus. It is covered by an aponeurosis descending from the fascia lata of the thigh, and below by the tendons of the sartorius, the gracilis, and semi-tendinosus: it lies over the synovial membrane, the internal semi-lunar cartilage, and a small part of the tibia. The external lateral ligament is placed between the external condyle of the femur, and the fibula, in the form of a long, round, shining cord, covered nearly throughout by the tendons of the biceps. Immediately under it are the inferior articular vessels. It is fixed to the condyle above the attachment of the tendon of the popliteus, and rather behind it; to the fibula on the outside of its upper extremity, adhering to the outer semilunar cartilage in its passage. The posterior ligament is nothing but a tendinous expansion given off from the tendon of the semi-membranosus, which mounts obliquely upwards and outwards behind the crucial ligaments, from which it is feparated by cellular tiffue and the middle articular veffels. It is attached above to the external condyle, and is confounded with the tendon of the outer head of the gaftrocnemius. Independent of this band, which is very irregular in its form and fize, we find other fibrous parcels croffing in different directions above it.

The crucial ligaments are more deeply feated, but may ftill be confidered as external to the joint as they are covered only in front, and on the fides by the fynovial membrane, and are really without the fac which it forms. They are ftrong fibrous bands croffing each other in their courfe, from which they derive their name. The anterior paffes from the pofterior and upper part of the hollow between the condyles, and from the interior fide of the external condyle; obliquely downwards and forwards, narrowing as it defcends, to be fixed in the rough furface, in front of the fpine at the head of the tibia, behind the attachment of the internal femi-lunar cartilage, and on the infide of the external, being partially united to both. The pofterior crucial ligament is attached above to the anterior part of the finus between the condyles, and the outer-fide of the internal condyle. It defcends backwards and inwards, becomes broader, and divides into two pretty diftinct bands, of which the largeft is inferted into the depreffion behind the fpine, the other joins the external femi-lunar cartilage. Thefe two ligaments are feparated from each other by cellular tiffue, and by the fame means from the pofterior ligament behind; they adhere firmly to the fynovial membrane, invefting them on the anterior and lateral furfaces.

The femi-lunar cartilages, as they are termed, lie on the articular furfaces of the tibia, between them and the correfponding condyles, occupying only the circumference, the femur and tibia touching in the centre of each. They are thick at the convex margin, and become gradually thinner, terminating in a delicate concave edge, increafing thereby the depth of the cavities which receive the gibbous condyles of the femur. The internal is broadeft behind, the external in front; the firft reprefents a portion of an oval, of which the fhort diameter is tranfverfe; the latter forms nearly a circle, correfponding, in this refpect, to the figure of the two articular furfaces of the tibia. The upper furface of each cartilage is concave, accommodated to the convexity of the condyles, the lower is nearly flat. The convex margins are united to the ligaments which crofs them in their courfe, efpecially to the lateral; that of the external has an oblique depreffion in it behind, where it is contiguous but not adherent to the tendon of the popliteus. The concave edges are free, thin, and fharp. The anterior extremity of the internal cartilage paffes in front of the anterior crucial ligament, and is inferted on the outer fide of the depreffion which gives attachment to it; the pofterior is attached behind the fpine, before the infertion of the pofterior crucial ligament. The anterior extremity of the external femi-lunar cartilage is faftened to the depreffion in front of the fpine, but much behind the attachment of the internal, and united in part with the anterior crucial ligament; behind it is implanted into the pofterior depreffion, and is connected with a portion of the pofterior crucial ligament. We have called thefe cartilages, not to depart too much from eftablifhed language, though they are of a fibrous texture. They are formed of curved concentric fibres, which are particularly evident at their extremities and convex margins, lefs fo in the middle, where they are more analogous in their appearance to cartilage. They are fometimes immediately joined by a fhort tranfverfe ligament, continued from the convex borders in front. The internal appears more fixed in its fituation than the external, which has a gliding motion backwards and forwards on the tibia.

The fynovial membrane, if we trace it from above, is reflected from the condyles of the femur, fome way above the termination of the cartilage to the circumference of the patella. In this part it is loofe, covered above by loofe fat and by the cruræus, to the tendon of which it adheres moft firmly, and laterally by an aponeurotic expanfion, from the extenfors paffing from the edges of the patella to the tibia and femur. After lining the pofterior furface of the patella, it paffes on to the upper edge of the tibia in front, lying under the ligament of the former bone, and a large quantity of fat and cellular tiffue placed underneath it, and keeping them at a confiderable diftance. From this part a duplicature of it paffes backwards through the joint, and is attached to the anterior and external part of the finus between the condyles. It has been called the ligamentum alare by Weitbrecht, or l. mucofum, feu adipofum; all names equally unapplicable to it. Laterally, alfo, it defcends towards the tibia, invefting the upper furfaces, and concave edge, and the under furfaces of the femi-lunar cartilages; after which it is continued downwards, covers the articular cartilages at the head of the bone, and is reflected upwards over the crucial ligaments in the middle, lining behind the tendons of the gaftrocnemius on their anterior furface, and enveloping the tendon of the popliteus. It thus reaches the condyles behind, to the edges of which it is attached, leaving the finus between them without the bag, and paffes over the cartilages to the point from which we fet out. It is covered in front by the extenfors and their tendon; by their aponeurofis laterally, as alfo on the infide by the tendons of the fartorius, gracilis, and femi-tendinofus, and by the internal lateral ligament with which it is in contact; on the outfide by the tendon of the biceps and the external lateral ligament, behind by the femi-membranofus and its lateral tendon, by the gaftrocnemius and popliteus. After all, we fhould have a very imperfect idea of the knee joint, if we confidered it in this abftract ftate. It is moft ftrongly fupported by the mufcular powers attached to the tendons we have mentioned, the latter being numerous, and of great ftrength, and the mufcles maffy and exceedingly powerful, fecuring moft effectually, when in action, the relations of the oppofite bones.

The motions of the leg on the thigh—are thofe of flexion, extenfion, and under particular circumftances of rotation. In flexion, the tibia and femi-lunar cartilages glide backwards on the condyles of the femur; the patella quits the articular pulley, and defcends in front of the joint, fo as to be oppofite to the finus between the condyles: the tendon of the extenfors occupies its place, and is much diftended if the flexion be carried far back, as is alfo the ligament of the patella; and the crucial and oblique ligaments, as well as the pofterior, are relaxed. In extenfion, the tibia glides forwards again, and the femi-lunar cartilages are brought oppofite to the inferior inftead of the pofterior furfaces of the condyles, which, in this pofition, reft againft the heads of the gaftrocnemius; the patella mounts again, and, in complete extenfion, if the mufcles are in action, paffes up a little way above the articular pulley; if the mufcles are quiefcent, the tendon of the patella is relaxed; this bone is loofe and may be moved in all directions; the pofterior crucial and lateral ligaments are ftretched, and prevent this motion from being carried beyond the point which brings the femur and tibia in the fame line. The great ftrength of the crucial ligaments, which are effentially diftended at this time, is a powerful obftacle to the luxation, which would throw the head of the tibia backward. When the leg is near the middle ftate,

between

between complete flexion and extenfion, it can be rotated flightly inwards and outwards ; a motion, of which the foot neceffarily partakes, and which carries the toes in correfponding directions. In rotation the articular furfaces of the tibia glide in oppofite curves in the rounded furfaces of the condyles ; not, however, in equal degrees, the moft evident motion occurring on the outer condyle. In rotation inwards the pofterior crucial ligament is brought to crofs the anterior more directly, and is much tightened, fo as effectually to limit it. In rotation outwards, which, on account of the difpofition of thefe ligaments, is more extenfive, we find them fcarcely affected. In both cafes the lateral ligaments are rendered tenfe ; the femi-lunar cartilages undergo little change of pofition, excepting that in rotation inwards, the external one, from its connection with the pofterior crucial ligament, is drawn a little afide. When the leg is bent, the motions by which the toes are carried alternately inwards or outwards take place in the knee joint ; when it is extended, they are effected in the hip, and depend on the rotation of the femur. The patella favours extenfion, by removing the power further from the centre of motion, befides which it glides more readily over the pulley of the femur, than a flexible tendon could have done, and protects materially the front of the joint in flexion, for inftance in kneeling. It fcarcely moves in rotation inwards or outwards.

The fibula—is placed on the external fide of the leg, obliquely with regard to the tibia, being behind it above, and immediately on the outfide below. It is a flender bone, nearly equal in length to the tibia, but very much fmaller, divided into an upper or tibial, or lower or tarfal extremity, and a middle portion or body.

The upper extremity is very irregular ; we remark in it above, and a little on the infide, an oblique, flightly hollowed, articular furface, correfponding to one on the outer tuberofity of the head of the tibia. In every other afpect the furface is rough and unequal, giving attachment to ligaments which connect it with the tibia, to the external lateral ligament of the knee, and to the tendon of the biceps.

The body of the fibula is of an irregular prifmatic figure, fomewhat twifted, and curved a little, fo as to approach nearer the tibia in the middle of the three angles, the anterior rifes gradually from above, is fharp and prominent in the middle, and bifurcates below, where it is covered only by the fkin. It gives origin, in the greateft part of its extent, to an aponeurofis, which feparates the peronei mufcles from the extenfor communis of the toes. The external edge is fpiral in its courfe, running backwards as it defcends. It gives attachment to an aponeurofis, which divides the peronei from the long flexor of the great toe and the foleus. The internal edge becomes anterior as it defcends ; it is very prominent in the middle, and gradually loft above and below. The upper two-thirds give origin to the flexor of the great toe, and the tibialis pofticus, the lower third to the interoffeous ligament. Of the furfaces between thefe borders, the external alters its afpect, becoming pofterior below ; it is covered by the peronei, which are fixed to the two upper thirds. The internal furface looks rather backwards above, and forwards below ; it is divided into two unequal portions by a fpine extending from the upper part of the anterior angle to the lower part of the internal angle, and which gives attachment to the interoffeous ligament. Of thefe two planes the anterior is covered by, and gives origin to, the extenfors of the great and of the other toes, and to the peroneus tertius ; the pofterior, which is hollowed longitudinally, to the tibialis pofticus. The direction of this fpine varies very confiderably, as alfo its length. The pofterior face is inclined outwards above, where the foleus has its attachment ; below it turns inwards, giving attachment by nearly its lower two-thirds to the long flexor of the great toe. About the middle is the opening for the nutrient artery directed longitudinally downwards. It widens towards the lower extremity, where it terminates in a rough convex furface, connected with the tibia.

The lower or tarfal end of the fibula is oblong, flattened tranfverfely, thicker behind than in front ; it forms the outer malleolus, which defcends rather lower, and is more pointed than the inner. The external furface is convex, and covered only by fkin ; the internal prefents, at its anterior part, a fmooth articular furface convex from above downwards, articulated with the external fide of the aftragalus, and behind this a rough depreffion for ligamentous attachments. The pofterior border has in it a fuperficial groove for the paffage of the peronei ; the anterior, as well as the angle below, give attachment to ligaments.

The fibula is in ftructure like the other long bones. It is formed from three points of offification, one for the body and one for each extremity. The latter are ftill cartilaginous at birth.

The articulation between the tibia and fibula—is by actual contact at the two extremities, and by means of an interoffeous ligament in the intervening fpace. The fuperior articulation refults from the contact of two flat cartilaginous furfaces, fecured by ligaments in front and behind, and covered by fynovial membrane. The anterior ligament paffes from the fore part of the upper end of the fibula to the anterior part of the external tuberofity of the tibia. The fibres are tranfverfe, the fuperior ones the longeft, and divided into feveral parcels, with intervening cellular tiffue. It is ftrengthened by a portion of the tendon of the biceps, which embraces the external lateral ligament of the knee, and paffes over this anterior ligament before it is fixed to the tibia. The pofterior ligament is alfo tranfverfe, but not fo ftrong, or fo well marked as the preceding ; it is continued above with fome ligamentous fibres found in the back of the knee-joint ; it is covered by the popliteus. Befides thefe two ligaments, we find a few other fcattered bands below, which help to fecure the articulation. The fynovial membrane lines thefe ligaments, and the cartilaginous furfaces ; it is feparated from the tendon of the biceps by cellular tiffue, and is contiguous behind to the fynovial membrane of the knee. The middle connection is preferved by means of an interoffeous ligament, analogous to the one we have defcribed in the fore-arm. It is thin, compofed of parallel fibres defcending obliquely from the external edge of the tibia to the ridge dividing the internal furface of the fibula, and below to the internal edge of this bone. It is broadeft at the upper part, and terminates in a point beneath, where the bones begin to touch each other. It is pierced by many openings for the paffage of veffels ; of thefe the moft remarkable are, one above, near the edge of the fibula, for the paffage of the anterior tibial veffels ; and another below for a branch from the peroneal artery. The anterior furface ferves for attachment to the tibialis anticus, the extenfors of the great and other toes, and to the peroneus tertius, and fupports the anterior tibial veffels. To the pofterior furface the tibialis pofticus and long flexor of the great toe are fixed. The inferior articulation is compofed of the contact of two cartilaginous furfaces below, a convex for the fibula, and a correfponding concave one for the tibia, lined by a continuation of the fynovial membrane from the ankle joint. The relations are fecured by ligaments before, behind, and between the bones. The anterior ligament is broad, attached to the anterior edge of the tarfal end of the fibula; in crofsing to the tibia it mounts a little upwards, widening in its progrefs, its fibres divided by intervals filled with cellular tiffue, the fuperior the longeft, and is fixed to the neighbouring parts of the tibia. It is covered by the peroneus tertius, aponeurofis of the leg and the fhin; its lower end is confounded with ligamentous fibres paffing from the fibula to the aftragalus. The pofterior ligament refembles it in direction, but it is not fo large, and the lowermoft fibres are the longeft. It paffes immediately from the pofterior part of this end of the fibula to be fixed to the tibia behind the cavity which lodges that bone, is confounded with the furrounding ligaments below, covered behind by the two lateral peronei mufcles. In addition to thefe ligaments we obferve, between the oppofite furfaces of the two bones, juft above their cartilaginous contact, a fibrous fubftance paffing from one to the other, occupying a confiderable fpace, interrupted here and there by cellular tiffue, and continuous above with the interoffeous ligament. It materially fecures the articulation.

The motions of the fibula on the tibia are exceffively limited, very different in this refpect from thofe between the bones of the fore-arm. The upper end of the fibula may glide a little backwards and forwards; the lower is nearly motionlefs from the difpofition of the ligaments, a ftructure neceffary for the ftability of the articulation of the leg with the foot, as refifting the tendency to lateral difplacement.

The foot—forms the laft divifion of the lower extremity; it has fome characters in common with the hand, but is diftinguifhed from it in a remarkable manner by its great depth and firmnefs, by the preponderance of its folid over its moveable parts, the reverfe of which is fo ftrikingly feen in the hand. It varies much in fize, in general is proportionably fmaller in the female than in the male, is elongated in form, broad and flat anteriorly, thick and narrower behind. It is convex on the upper furface, which is called the back of the foot, concave on the lower, called the fole, thin on the outer edge, deeper and longer internally, with a projection behind, named the heel, and terminated by the points of the toes in front. We divide it, as we did the hand, into three portions; the tarfus behind, the metatarfus in the middle, and the toes before.

The tarfus (oberfufs, Germ.) forms about the pofterior half of the foot; it is compofed of feven bones, *viz.* the aftragalus, the os calcis, naviculare, cuboides, and three cuneiform bones.

The aftragalus, (talus of Albinus,) occupies the upper part of the tarfus, rifing far above the level of the other bones; it is of a very irregular form, convex above, hollowed below, flattened at the fides, and running out into a ftrong procefs before, termed the cervix or neck of the bone. It is placed faft between the two bones of the leg, the heel bone, and the os naviculare. On the upper furface, anteriorly, is a rough, tranfverfe depreffion, forming part of what has been called the neck of the bone, for infertion of ligaments; behind this is a large articular furface, broader before than behind, convex in thofe directions, rather concave from fide to fide, fo as to form a fuperficial pulley, fuited to the oppofite furface of the tibia. Below we have two articular furfaces, which reft on the os calcis, feparated by a deep groove, running obliquely from within outwards, widening much in its courfe, and rough for ligamentous attachments. The pofterior articular furface, which is external, is the largeft, concave, and oblong obliquely; the anterior is fmall, oval, and nearly flat. The pofterior fide is narrowed horizontally, and prefents the commencement of an oblique groove, in which the tendon of the long flexor of the great toe glides. In front is a convex rounded articular furface, which has been called the head of the bone; it refts againft the os naviculare, and by a fmall furface on the os calcis. On the outfide a triangular articular furface, concave vertically, correfponding to the lower end of the fibula. On the infide another articular furface, flat, elongated horizontally, adapted to the defcending malleolus internus; below this a rough irregular furface for ligaments. Thefe two articular furfaces are continuous with that on the upper furface, and form part of the ankle joint. It is developed from two points of offification, which are juft appearing at birth.

The os calcis (calcaneus of Albinus,) is fituated at the pofterior part of the tarfus, where it forms the heel. It is the largeft of the feven bones; its greateft extent is from behind forwards, its next is in the depth, and it is narroweft tranfverfely. On the fuperior furface we obferve pofteriorly a concave part occupied by the fat and cellular tiffue in front of the tendo Achillis; next we have a large, convex, oblique articular face, adapted to one in the aftragalus; on the infide of this a groove, which divides it from another fmaller oval, flat, articular facet, correfponding alfo to the aftragalus. This laft is placed on a lateral procefs of the bone, ("fuftentaculum cervicis tali, Alb.") and is rather anterior to the firft. It is fometimes continuous with another fmall articular furface in front of it, though generally feparated by a narrow groove. The reft of the upper furface is flat and rough for ligaments. The under furface is long, much contracted tranfverfely, terminated behind by two tubercles which give attachment to fome mufcles of the toes; the internal is the largeft. There are alfo other eminences further in front to which ligaments are fixed. The pofterior furface is bulging and convex, and forms properly the heel; at the upper part it is fmooth, where it is feparated from the tendo Achillis by a fynovial burfa, and rough below for its infertion. The anterior furface is the fmalleft of the whole; it is articulated with the os cuboides, and is flightly concave. The outfide is flat, much broader behind than before, and marked by two fuperficial grooves for the long and fhort peronei mufcles. The infide is large and hollowed deeply, to lodge the nerves and veffels going to the fole of the foot, and alfo the tendons of the tibialis pofticus, the long extenfor of the toes, and the long extenfor of the great toe, which plays in a peculiar groove obferved at its upper part. The mufculus acceflorius has its origin from this furface, towards the back part. The os calcis is formed from two points of offification, which are vifible at birth. The two bones we have been defcribing have been confidered as the firft row of tarfal bones; the remaining five as the fecond.

The os naviculare is fituated in the middle of the tarfus, of an oval figure, with its longeft diameter tranfverfe; its circumference is rough for ligamentous attachments; broad and convex above, concave below, pointed and projecting internally where the tibialis pofticus is inferted, and narrowed on the outer fide, on which we generally find a flat articular facet oppofed to the cuboides. The anterior furface is convex, divided into three articular planes for the three cuneiform bones; of thefe the internal is broadeft below, and the two external above. The pofterior furface is concave, articulated with the aftragalus.

The os cuboides, (cubiforme, Alb.) is placed at the external and anterior part of the tarfus, and refembles fomewhat a cube in figure. Above is a rough, flightly convex furface, with four unequal fides; below pofteriorly an eminence for ligaments, a fuperficial hollow, and a more marked protuberance for the fame purpofe, in front of which is a deep groove, which gives paffage to the tendon of the peroneus longus, as it croffes the foot. Anteriorly an oblique articular furface nearly plane, fupporting the two outer metatarfal bones. Behind a concave fmooth furface, ftill more oblique, articulated with the os calcis. Externally, a narrow border, in which we obferve the commencement of the groove for the tendon of the peroneus longus. Internally, a fmall articular facet behind, in contact with the os naviculare ; a larger one in the middle for the third cuneiform bone ; the reft of the furface is rough for ligaments.

The firft cuneiform bone (majus five internum) lies at the inner and anterior part of the tarfus, and is the largeft of the three ; it is deeper than it is broad, with the bafe of the wedge below, and the narrower border upwards, of a rhomboid figure viewed laterally. The upper fide is oblique, and gives attachment to ligaments ; the inferior is convex, and gives attachment before to the tibialis anticus, behind to a part of the tibialis pofticus, as well as to ligaments. The pofterior furface, articulated with the naviculare, is concave and pointed above ; the anterior, by which it refts on the firft metatarfal bone, is longer, and of an oblong, or rather femi-lunar figure. Internally, it is convex, rough, and fub-cutaneous ; externally concave, with a fmall articular facet near the upper edge, in contact with the fecond bone of the metatarfus, and another near the pofterior edge, which touches the following bone.

The fecond cuneiform bone (minus five medium) is the fmalleft of the three, and of all the bones of the tarfus ; it well deferves its name both from its figure and fituation. The bafe of the wedge forms the upper furface which is quadrilateral, with the fhort diameter tranfverfe, and rough for ligaments. The edge of the wedge below is fharp, and ferves the fame purpofes ; behind it is articulated by a concave furface, with the middle plane in the front of the os naviculare ; before, by a convex one, with the fecond metatarfal bone. Of the two four-cornered fides the internal is nearly plane, with an articular facet near the upper edge, and another at the pofterior, joined to the laft bone ; the external has a concave articular facet for connection with the third cuneiform bone towards the upper and pofterior angle : they are both rough on the remainder of their furfaces for fibrous attachments.

The third cuneiform bone (externum, or medium, Alb.) is rather larger than the preceding, and longer from before backwards ; it refembles it much in figure and pofition. The bafe, which is above, and the edge below, give attachment to ligaments. Behind is a triangular articular furface, correfponding to one of the planes in front of the naviculare ; before an oblong flat one in contact with the third metatarfal bone. The internal furface is marked by two articular facets, feparated by a rough depreffion for ligaments, of which the anterior correfponds to the fecond metatarfal bone, the pofterior to the fecond cuneiform. The external fide is rough anteriorly, and has a plane articular facet towards the upper and pofterior angle, in contact with a correfponding one on the inner fide of the cuboides.

The laft five bones of the tarfus are wholly cartilaginous at birth, and are gradually and folely developed from fingle points of offification. They are not proportionably larger in this ftate than when in their perfect offeous forms, in which refpect they refemble the carpus.

The articulation of the leg with the foot, the ankle joint.— To form this joint, the upper articular furface of the aftragalus, nearly all the outer fide, and the narrow cartilaginous facet on the infide, are received into the cavity formed by the lower end of the tibia and fibula, and embraced clofely by the two ankles. The correfponding furfaces are covered by cartilage, and united by feveral ligaments, the moft efficient of which are placed at the fides ; the connection is much ftrengthened by the numerous tendons which pafs over or near it to be attached to different bones of the foot.

The internal ligament (l. deltoides) is of confiderable breadth ; attached above to a part of the circumference of the internal malleolus, more efpecially to its point, it defcends a little obliquely backwards, and is fixed to the inner furface of the aftragalus, and the neighbouring parts of the os calcis. It is compofed of a confiderable quantity of longitudinal fibres, of which the anterior and the moft fuperficial are the longeft. On the infide, the tendon of the tibialis pofticus paffes over it, and is connected with it by its fibrous fheath ; it is contiguous alfo to the long flexor of the toes. On the outfide is a ftraight rounded and thick ligament (l. medium perpendiculare) which defcends from the lower extremity of the fibula a little obliquely backwards, paffing under the tendon of the peroneus longus, and is attached to the outer fide of the os calcis ; it is formed of compact, longitudinal fibres. In front of this is another ligament (l. anterius malleoli externi), which paffes from the anterior part of the point of the outer malleolus, forming a ftrong flat band of fibres, frequently divided into two or more portions of confiderable ftrength, and is fixed to the aftragalus in a depreffion before the external articular furface. The front of the joint is ftrengthened alfo by a collection of irregular fibrous bands, which defcends from the anterior part of the lower extremity of the tibia, amidft much cellular tiffue and fat, and are inferted partly into the aftragalus clofe to the termination of the articular pulley, and are partly continuous with the ligaments paffing from this bone to the naviculare. Towards the back of the joint, we have arifing from the fibula a ftrong ligament (l. pofterius malleoli externi) paffing nearly tranfverfely inwards, and fixed to the edge of the articular pulley at the back of the aftragalus, clofe to the outer margin of the groove for the tendon of the long flexor of the great toe. It is ftronger than any of the preceding ligaments, and compofed of numerous diftinct packets of fibres. Immediately above this, and connected intimately with it, at its origin from the back of the external malleolus, is a tranfverfe band of fibres paffing directly acrofs, or mounting a little obliquely, to be attached to the pofterior border of the articular furface of the tibia, and to the inner ankle. It increafes a little the depth of the articular cavity behind, and might be regarded properly as one of the pofterior ligaments connecting the tibia and fibula. The fynovial membrane is diftributed as ufual, lining all the cartilaginous furfaces and the ligaments ; lining alfo the narrow articular facets between the tibia and fibula, making this little joint communicate with that between thefe bones and the aftragalus. It is loofe in front, where we find a confiderable quantity of cellular tiffue and fat ; covered in this afpect by the tendons of the tibialis anticus, the long extenfors of the great, and other toes, and the peroneus tertius ; behind by the tendons of the tibialis pofticus, the flexors of the toes, and the peronei ; partly in thefe fituations, and on the fides by the ligaments juft defcribed. In addition to the many tendons enumerated, this articulation is further ftrengthened by the tendo Achillis behind, a powerful agent in preferving its relations.

The motions which take place between the leg and foot are chiefly thofe of flexion and extenfion ; the lateral inflexions

flexions are extremely limited. In flexion, which is more confined than the oppofite motion, on account of the difpofition of the articular pulley of the aftragalus, this bone glides backwards on the lower end of the tibia, regulated by the two malleoli lying clofe on either fide ; the pofterior ligament is ftretched, the others undergo but little change ; and luxation rarely occurs. In extenfion the motion may be continued, fo as to make the foot form a very obtufe angle with the leg ; the external anterior ligament is diftended confiderably, the others lefs fo, the pofterior is relaxed. In ftanding on the toes this pofition is maintained by mufcular efforts, particularly by means of the tendo Achillis ; the tibia refts on the pofterior part of the pulley of the aftragalus, and tranfmits the principal weight to the naviculare, inftead of the os calcis, as in ordinary ftation. The lateral inclinations of the foot on the leg, as far as this joint only is concerned, are extremely confined, owing to the lateral defcent of the malleoli ; in which refpect they differ much from the lateral motions of the carpus on the fore-arm. The lateral ligaments are here reciprocally ftretched or relaxed, as the foot is turned inwards or outwards. Diflocations to either fide occur more frequently than we might at firft imagine from the apparent fecurity afforded by the malleoli. Luxation outwards is the moft frequent, the fibula breaking two or three inches above its lower end, fo as to allow of the everfion of the foot ; it is generally the confequence of fudden violence, as in jumping, or in falling on the foot from any height.

The articulations between the bones of the tarfus.—The aftragalus is articulated by two, fometimes three cartilaginous planes on its inferior furface, with correfponding ones on the upper furface of the os calcis. Thefe furfaces are preferved in contact by a ftrong collection of ligamentous fibres, paffing directly upwards from the whole length of the oblique groove, between the articular facets on the upper furface of the os calcis to a fimilar depreffion on the under fide of the aftragalus, where it is attached to every point not occupied by articulating cartilage. The internal fibres lie deep between the bones, and are fhort ; the external ones are longer, and more in quantity, buried in the cellular tiffue and fat which contribute to fill the vacancy obferved in this part. Behind there are fome parallel fibres paffing down from the back of the aftragalus to the os calcis, which concur in forming the fheath for the tendon of the long flexor of the great toe ; they are not numerous. This articulation is alfo ftrengthened by the lateral ligaments of the ankle joint, efpecially by the external, which paffes immediately from the fibula to the os calcis. The fynovial membranes offer nothing remarkable. The motions which have place here are always combined with others, and will be confidered farther on.

The anterior convex articular furface of the aftragalus is received into a cavity formed by the concave furface of the os naviculare, a fmall fpot of the os calcis, and completed below by ligaments paffing between thefe two bones. We obferve above a dorfal ligament, thin and flat, compofed of fibres paffing from the depreffion called the neck of the aftragalus to the upper rough furface of the naviculare ; they fometimes reach to the cuneiform bones. It is covered by the extenfors of the toes. Below is a very ftrong ligament, paffing from the anterior and internal parts of the os calcis obliquely forwards and inwards to be attached to the hollow in the lower furface of the naviculare. It is covered on the infide by the tendon of the tibialis pofticus : above it is lined by fynovial membrane, and forms the lower part of the cavity which lodges the head of the aftragalus, to the fupport of which it eminently contributes. It is very denfe in its ftructure. There is alfo a fhort and very firm band paffing from the anterior part of the os calcis to the outfide of the naviculare, completing the cavity externally. This joint is lined by a fynovial membrane, which communicates with the anterior articulation between the aftragalus and os calcis, as before mentioned. It is fpread over the correfponding furfaces and ligaments we have been defcribing.

From what we have faid, it appears that the os calcis is firmly connected with the naviculare, though in contact only by a very narrow fpot ; the ligaments crofs the head of the aftragalus in their courfe, and their apparent ufe is to fupport the latter at a point which appears fo deficient, when examining the mechanifm in the dry fkeleton. The os calcis is more extenfively articulated with the cuboides by cartilaginous furfaces flightly concave and convex in oppofite fenfes. The joint is fecured by two ligaments, a fuperior or dorfal, an inferior or plantar. The firft is broad and thin, compofed of fhort parallel fibres paffing rather obliquely forwards from the upper and external parts of the os calcis, to the fuperior rough furface of the cuboides. It is often formed into two feparate longitudinal bands. It lies under the peroneus tertius. The inferior ligament is the longeft, and ftrongeft of all the ligaments of the tarfus. It is attached behind to the middle of the inferior furface of the calcis, paffes horizontally forwards, and is fixed principally into the oblique protuberance obferved on the lower furface of the cuboides. It is formed of a great number of fibres, divided into feveral bundles, which diverge rather as they approach the cuboides. The inferior ones, or the moft fuperficial, are much longer than thofe more deeply feated, and are continued under the tendon of the peroneous longus, part of whofe fheath they form, to the pofterior extremities of the firft and fecond metatarfal bones. The upper plane is fhorter in its courfe, and fixed behind the groove for the peroneus longus. The ligament is covered below by feveral mufcles of the foot, which have partly their origin from it. It fhould be remembered that this joint is in the fame tranfverfe line with the one between the aftragalus and naviculare.

For the articulation between the naviculare and cuneiform bones we have in the firft a cartilaginous furface divided into three planes, in the latter correfponding furfaces covered by articular cartilages continued laterally into their mutual articulations. It is fecured by three dorfal ligaments, attached to the upper and lateral portions of the circumference of the naviculare, paffing one internally to the firft cuneiform, another in the middle to the fecond, and a third more externally to the outer cuneiform bone. They leave intervals filled by cellular tiffue : the internal is the largeft ; and thicker at its inferior edge. The plantar ligaments have been defcribed as three alfo, but they are too irregular for diftinction, appearing as fibrous bundles paffing between the oppofite bones, confounded at their attachment to the naviculare. This joint is ftrengthened internally by an elongation of the tendon of the tibialis pofticus, which is attached to the bafe of the firft cuneiform bone, and continuous with the more internal of the ligaments we have been defcribing.

The articulation of the naviculare with the cuboides is formed by the contact of two fmall plane cartilaginous furfaces, lined by their proper fynovial membrane, and fecured by numerous fhort ligamentous fibres paffing from bone to bone, occupying the remaining fpace ; they are very clofe and compact. There is alfo a plantar ligament rounded in form, paffing obliquely from the inferior and external part of the naviculare to the oppofite point of the cuboides ; and a dorfal tranfverfe band, croffing from one to the other, covered by the extenfors.

The

The cuneiform bones are articulated with each other by cartilaginous facets connected by ligaments paffing from bone to bone, deeply as well as fuperficially. The dorfal ligaments are tranfverfe, and form really but a fingle band, continued over the three, and attached in its courfe to each. The plantar ligaments are alfo tranfverfe, but not fo marked; the one which goes from the firft to the fecond is the ftrongeft: they are covered by an extenfion of the tendon of the tibialis pofticus, one part of which is fixed to the fecond cuneiform, another to the fecond metatarfal bone; thefe are diftinguifhed from the ligaments by the oppofite direction of their fibres. We find alfo many fhort ligamentous fibres paffing between thefe bones, as between many others of the tarfus, attached to the parts not occupied by cartilage; they add much to the ftrength of union.

We have here a fynovial membrane common to thefe joints, and that with the os naviculare above defcribed. It is fpread over the anterior furface of the latter, over the connecting ligaments, and dips between the cuneiform bones, lining their articulation throughout.

The articulation of the third cuneiform with the cuboides is by means of plane cartilaginous furfaces, provided with their diftinct fynovial capfule, and fecured by ligaments. Of thefe the dorfal is oblique, fmall and thin, uniting the oppofite edges of bone; the plantar is confiderably thicker, and more directly tranfverfe. Here alfo are many interoffeous ligamentous fibres, fixed to the parts not covered by cartilage, or where the bones are not in immediate contact.

Motions of the tarfal bones on each other.—The motions which take place between the tarfal bones are very limited, if we except thofe between the aftragalus, and the os calcis and fcaphoides. By this chiefly the foot is turned inwards and outwards; the lateral inflexions of the ankle joint affifting the motion but little. In the movement which carries the point of the foot a little outwards, which depreffes its internal and elevates its external edge, the naviculare glides on the head of the aftragalus, and the os calcis on its lower articulating furfaces: the latter bones approach each other more clofely, the interoffeous ligament, and the external lateral one of the ankle joint are relaxed, the internal lateral ligament is ftretched, efpecially thofe fibres which pafs to the calcaneum. In the oppofite motion of twifting the foot inwards, and bringing the fole to face the other, the bones move in the contrary direction, the inner border of the foot is raifed, and the external becomes inferior; the interoffeous, and external lateral ligaments are diftended. Thefe motions, which are very fenfible, may be accidentally forced beyond their natural limits, and give rife to injuries which are too generally referred to the joint of the ankle. The naviculare and cuboides may be moved up and down on the aftragalus and os calcis, and the cuneiform bones have gliding motions on the naviculare, the cuboides, and between themfelves, by which the concavity of the foot may be a little increafed or diminifhed. The utility of thefe numerous articulations in enabling the foot to refift the fhocks it muft often neceffarily fuffer, and in giving grace and eafe to the motions of the lower extremity in progreffion needs fcarcely be infifted on: their great relative fize and the very powerful ligaments fubfervient to them make difplacement of more rare occurrence than we might at firft imagine, on confidering the efforts they have to fuftain.

The metatarfus (mittelfufs, Germ.)—is compofed of five long bones placed horizontally and nearly parallel to each other, fo as to form a gently convex furface above, and a concavity below. It is fituated between the tarfus and the toes, and is analogous in many points to the metacarpus. The individual bones are diftinguifhed numerically, beginning from the infide. The firft metatarfal bone, that of the great toe, is by much the largeft in volume, though rather fhorter than the reft; the fecond is of the greateft length; the third comes next to it, the two laft differ but little: the four latter differ very little in fize. They all contract a little in the middle, and fwell at each end, particularly towards the tarfus, and are divided into two extremities and a body.

The tarfal, or pofterior extremity of the firft, is oblong vertically, with a femi-circular articular cavity behind, refting on the firft cuneiform bone. The inner edge of the circumference, which is convex, gives attachment about its middle to a part of the tendon of the tibialis anticus; below is a blunt projecting procefs, to which the tendon of the peroneus longus is fixed; and on the outer concave edge a fmall fmooth fpot, which is in contact with the fecond metatarfal bone.

The tarfal are much larger than the digital extremities of the other four, angular, and in clofe oppofition with each other. That of the fecond is placed farther back than the firft, is triangular, with the bafe upwards; it is wedged between the cuneiform bones, refting on the fecond by a concave triangular articular furface behind; on the firft by a fmall fpot on the infide, and on the third by one on its outer fide. In the laft afpect there are two other articular facets in front of the laft joined to the third metatarfal bone, furrounded by afperities for ligaments: the edge above, and the point below are alfo rough, for the fame purpofes. The tarfal end of the third is triangular in the fame direction as the preceding, articulated by a plane furface behind, with the third cuneiform bone. On the infide are two fmall facets contiguous to correfponding ones in the fecond metatarfal; on the outfide a fmooth fpot above, articulated with the following bone, and a rough depreffion beneath for ligaments. It is rough alfo above and below. In the fourth, the tarfal extremity is more quadrilateral: behind it is articulated with the front of the cuboides; on the infide with the fame bone, and with the third; on the outfide with the laft metatarfal. Below, and in front of thefe articular fpots, the bone is rough for ligamentous attachments. The tarfal end of the fifth or laft metacarpal bone is larger than thofe of the preceding, It prefents behind an oblique triangular articular furface for the cuboides; above and below rough and unequal borders, the former giving attachment to the peroneus tertius, and both to ligaments; on the infide a fmall articular facet in contact with the fourth; and on the outfide a rough eminence projecting backwards, to which the peroneus brevis is fixed, and a portion of the abductor of the little toe.

The bodies of the metatarfal bones are concave from before backwards below, and gibbous above, very irregular in form, and fcarcely admitting of regular divifions into furfaces. That of the firft is of a triangular prifmatic form, with the upper furface convex, and inclined a little inwards; the inferior concave, covered by the flexor brevis of the great toe; the external flat and large, correfponding to the mufcles which lie between thefe bones. The bodies of the reft may be regarded in four afpects; the dorfal prefents in each a blunt rifing line, which divides the attachment of the interoffei; the plantar offers a fmooth furface for mufcular attachments; the internal and external exhibit varioufly inclined furfaces, of different breadths, continuous with the two former, fmooth, and covered by the mufcles which arife from them, and fill the interfpaces. In the fifth the body is curved a little from within outwards, and its external fide, or rather edge, gives origin in part to

the

the abductor of the little toe; the dorfal furface is inclined confiderably outwards, and terminates on the infide by a prominent line; the plantar furface is coverd partly by the flexor brevis of the fame toe. In all the dorfal furface is covered by the tendons of the long and fhort extenfors, by veffels and nerves, and the plantar by the deep-feated mufcles and tendons in the fole of the foot, by ligaments, and by larger blood veffels and nerves.

The digital, or anterior extremity, is very fimilar in all. It prefents a rounded articular furface, called the head, fupporting the firft phalanx of the toes: this extends further from above below than tranfverfely, in which direction it is compreffed. The circumference is rough, offering above a fenfible groove for ligaments, and on each fide a hollow, in which the lateral ligaments are fixed. The articular furface is prolonged further below than on the dorfal afpect, and terminates on each fide by projecting tubercles. In the firft this lower furface is divided by a prominent line into two pulleys, on which the fefamoid bones glide, which are placed below this joint of the great toe. In this bone alfo the articular furface has a much greater proportional breadth.

The metatarfal bones refemble in ftructure and formation the other long bones, with this exception only, that the fmaller ones are fometimes developed from two points of offification, one for the tarfal extremity, and body, another for the digital: in the firft there are always three.

The articulations of the metatarfus with the tarfus.—The firft bone of the metatarfus is articulated with the anterior furface of the firft cuneiform; the fecond with the three cuneiform bones; the third with the correfponding cuneiform; the fourth and fifth with the cuboides. The oppofite articular furfaces are covered by thin cartilage, and their relations preferved by ligaments above and below; they are all lined by fynovial membranes common in general to thefe joints, and to the articulations of the metatarfal bones between themfelves.

The dorfal ligaments pafs from each metatarfal bone to thofe bones of the tarfus with which they are articulated. From the firft there paffes a broad and thin band to the firft cuneiform, attached to the fuperior furface of each. From the fecond, which is let in between the three cuneiform bones, we find three ligaments croffing, one internally to the firft, another in the middle to the fecond, a third externally to the third cuneiform: the firft and laft are oblique in their courfe, the fecond paffes directly from before backwards. The dorfal ligament of the third is fhort, and goes ftraight to the third cuneiform; thofe of the third and fourth are attached to the upper furface of the cuboides; they are more or lefs oblique, and by no means conftant in their forms or fituation, the dorfal ligament of the fourth being often attached to the third cuneiform. They are all covered by the extenfor tendons.

Of the plantar ligaments, which are analogous in direction and attachment to the dorfal, that paffing from the firft metatarfal is very ftrong, and the joint is ftrengthened alfo by an extenfion of the tendon of the tibialis anticus, which is fixed to the infide of the tarfal end of that bone. The plantar ligaments of the fecond are fimilar to thofe above. That which paffes from the firft cuneiform is thicker, and larger than the other, reaching to the bafe of the third metatarfal; the other two are covered and ftrengthened by a portion from the tendon of the tibialis pofticus. The inferior ligaments of the others are fmall, yet diftinct, and of various lengths. The plantar ligaments are much ftrengthened by the numerous tendinous fheaths which are found in the fole of the foot, and particularly by that of the peroneus longus, which croffes moft of them as it paffes along to reach the firft metatarfal bone. The ligaments, both above and below, are compofed of fhort and clofe parallel fibres, following longitudinal, oblique, or tranfverfe directions, according to the relations between the points to which they are fixed. They are feparated by intervals filled with cellular tiffue, and giving paffage to veffels. The fynovial membrane, lining the joint between the firft metatarfal and cuneiform bones, is diftinct, and offers nothing remarkable in its diftribution. That lining the triple articulation, formed by the fecond with the three cuneiform bones, is continuous with the fynovial membrane, lining the articulation between the two firft of thefe bones. A feparate one is found fpread over the joint of the third metatarfal and cuneiform, and fending off two fmall lateral elongations, which dip between the articulations of the third with the fecond, and fourth metatarfals. It often communicates with the former at the point where they are in contact. Another fynovial membrane belongs to the articulation of the two laft metatarfals with the cuboides, common alfo to that between the two former of thefe bones.

The articulations between the metatarfal bones,—are formed behind by the contact of lateral articular facets, with the exception only of the firft, which touches the fecond without being articulated with it. Thefe two bones are united by fhort ligamentous fibres paffing from one to the other, of confiderable ftrength; the others are connected by dorfal, plantar, and interoffeous ligaments. The dorfal are tranfverfe, and three in number, paffing from one bone to the next, irregular in form, and attachment, appearing in fome fubjects as a fingle tranfverfe band. The plantar are fimilar in number and direction, but in addition we find feveral fmall flips paffing from the fifth to the three next metatarfals, feparated by cellular tiffue. The interoffeous ligaments between the pofterior ends of thefe bones are formed by numerous fhort fibres, occupying the parts not covered by cartilage, and tending very materially to fecure their relations. The anterior extremities of the metatarfal bones are not in abfolute contact, but they are firmly connected together by a tranfverfe ligament paffing below them, and attached to each bone, refembling the ligament defcribed as paffing between the digital ends of the metacarpal bones in its form and direction.

The metatarfal bones have but an obfcure motion on the tarfus, on which they may be flightly elevated and depreffed. They may be moved alfo fo as to approach each other in front, and augment the depth of the concavity of the fole; this effect is produced chiefly by the motion of the firft and laft towards the long axis of the foot, and is in confequence of mufcular action: when the foot is flattened by preffure they are forced farther apart mechanically.

The toes, forming the laft divifion of the foot, are five in number, placed horizontally fide by fide, compofed of rows of fmall bones extending longitudinally one beyond another. We reckon them numerically, beginning from within. The firft and laft are known alfo by the names of the great and little toe. The fecond is rather longer than the firft, the other three diminifh fucceffively in length. We find three bones, named phalanges, in all, excepting the firft, which has only two; thefe are termed, from their fituation, the firft or metatarfal phalanx, the fecond or middle, and the third or unguinal; in the great toe the bone of the middle phalanx is deficient. The two bones of this laft are very ftrong, and exceed very much in volume the different rows of the other toes which are flender in form, and comparatively weak. The bones of the firft phalanx are the longeft; thofe of the fecond are very fhort, as alfo the third. They all

all ſwell conſiderably at the extremities, and are contracted in the middle part or body. They reſemble the fingers very nearly in the material points of their formation, differing from them chiefly in ſize and mobility.

The firſt phalanges are by much the longeſt, and the bones are more rounded than the correſponding ones in the fingers. They are hollowed below, particularly near the extremities, where the flexor tendons lie, the edges giving attachment to the ſheaths which confine them. The poſterior extremities are concave for the heads of the metatarſal bones, the anterior have condyles, and a middle depreſſion for the ſecond phalanx. The two oppoſite articulating ſurfaces between theſe bones and the correſponding ones of the metatarſus, are cruſted by cartilage, and ſecured by lateral ligaments, as in the fingers. Theſe are thick and ſtrong, paſſing from the end of one bone to the oppoſite. The joint is ſtrengthened below by a tranſverſe ligament, covering it from ſide to ſide, contributing to the ſheath of the flexor tendons; and is further ſupported by theſe laſt, by the extenſors, and the ſmaller muſcles which ſurround them. The ſynovial membrane is looſe and extenſive; in the joint of the great toe it lines the two ſeſamoid bones. Theſe ſmall bones are unequal in ſize; the internal is the largeſt, oblong, gibbous below, concave longitudinally above, and a little convex tranſverſely, covered in the laſt aſpect by cartilage, and reſting on the head of the metacarpal bone in the two hollows already mentioned, ſo as to be ſeparated by a ſmall interſpace. They are connected by ligaments to the firſt bone of the great toe, as the patella is to the tibia, and glide backwards and forwards in the different motions of the joint, defending it effectually below, giving an advantageous purchaſe to the muſcles which are fixed to them, and preſerving from preſſure the tendon of the long flexor, which runs between them. Theſe bones are rarely met with in the other articulations. The motions between theſe bones and the metatarſus may be effected in every direction, except rotation, and are in general more limited than in the fingers. The toes, however, can be inflected backwards, or extended on the metatarſus to a greater degree than they can be bent. The advantages of this mechaniſm, ſo widely different from what we noticed in the hand, may be particularly noticed in ſtanding on the toes, and in progreſſion, and will be examined hereafter.

The ſecond phalanges of the four leſſer toes are ſo ſhort and compreſſed longitudinally, as to have ſcarcely the uſual characters of the long bones. This is a diſtinguiſhing point, in comparing them with the ſecond phalanges of the fingers, which they otherwiſe reſemble in miniature, giving attachments in a ſimilar manner to flexor and extenſor tendons, and to the fibrous ſheaths of the former. The articulations are alſo analogous; the motions, which are thoſe only of flexion and extenſion, are more limited.

The laſt, or unguinal phalanges, five in number, reſemble thoſe of the fingers both in ſtructure and formation. That of the great toe is ſtrong and broad; the others are more than proportionably ſmall. This laſt difference is the principal one between them and the fingers; the articulations and motions are very nearly the ſame; the latter may be a little more limited. In children they are very moveable: this mobility diminiſhes as we grow up, and is often completely deſtroyed in advanced age, owing moſt probably to the confinement of our ſhoes. The metatarſal rows have three points of oſſification, the others have two, and very frequently only one.

From the aſſemblage of the bones we have been deſcribing, there reſults a long, broad, and partly vaulted baſis, for the ſupport of the weight above, ſecured by numerous and ſtrong ligaments binding the arch beneath. The principal points of bearing are on the lower part of the heel bone; the outſide of the foot in nearly its whole length, eſpecially the poſterior end of the metatarſal bone of the little toe; the anterior ends of all the metatarſal bones, and moſt conſpicuouſly that of the great toe, which is proportionably ſtrong. When the heel is elevated from the ground, the whole preſſure is on theſe laſt mentioned points, and on the toes, which compenſate, by their augmented breadth, their comparative want of ſolidity. The vaulted form gives a ſpace in which the veſſels and nerves can paſs free from compreſſion; and the number of the articulations, by diſtributing the ſhock over numerous ſlightly yielding ſurfaces, prevents the injurious effects which might otherwiſe ariſe from leaps, or falls on the feet.

Mechaniſm of the lower extremities.—In ſupporting the trunk, the hip bones are placed between two oppoſite efforts; *viz.* the weight of the body tranſmitted by the ſacrum; and the reſiſtance oppoſed by the limb below in the direction of the cotyloid cavity. The depreſſing impulſe acts in a plane poſterior to that of ſupport, tending to make the hip bones move backwards on the thighs, if they were not counterbalanced by muſcular efforts. The baſe of ſupport, as far as regards the oſſa innominata, is contained between the plane of the vertebral column behind, and that of the thigh bones in front; a ſpace which varies in different individuals, and which is comparatively narrow in infancy, from the more oblique direction of the hip-bones, which brings the thighs more immediately under the vertebral column. As the oſſa innominata become more horizontal, the baſe of ſupport is rendered wider, and the muſcles being at the ſame time more fully developed, give it additional ſecurity. This is one ſource of the difference in gait in manhood and infancy. Another is found in the diſpoſition of the cotyloid cavities. As they are at a diſtance from the points of oſſification, they are almoſt wholly cartilaginous for ſome time after birth, and therefore can offer but a feeble reſiſtance to the thighs, quite inſufficient for ſtanding or progreſſion, until the place of cartilage is ſupplied by bone. Add to this, that the two joints are comparatively nearer to each other; which circumſtance, though it give facility, muſt neceſſarily diminiſh firmneſs. The greater proportional diſtance in the adult throws the thighs further apart above. In females this diſtance is greater than in the male, which gives a peculiarity to their walk, a more obſervable rolling of the hip in the ſucceſſive advancement of each limb. This is not to be ſeen in the infant female, where the poſition and form of the hip bones differ but very little from thoſe of the male of the ſame age.

The femur, which is the only bone in the thigh, is curved conſiderably forwards in the middle; hence a larger ſpace is left behind for muſcles; and the baſe of ſupport, afforded by this bone to the trunk, is directed forwards, ſo that the latter is ſuſtained in the direction, in which it has the greateſt tendency to fall. The neck of the bone, beſides increaſing the extent of rotation, enlarges tranſverſely the baſe of ſupport; gives the body a greater firmneſs in ſtanding, without impeding progreſſion, ſince the head of the bone, and not the body, is the centre of motion. If the thigh bones poſſeſſed no neck, but were kept equally far apart, by increaſing the diſtance between the cotyloid cavities, the attitude of ſtanding would be equally ſecure, the tranſverſe baſe of ſupport being ſtill the ſame; but progreſſion would be impeded, as it actually is in the female, from the greater tranſverſe diameter of the pelvis. The head of the femur, ſunk into a deep cavity, is forced, in ſupporting

ſupporting the trunk, againſt the moſt reſiſting part of this cavity, *viz.* under the anterior ſpines. The ſtrong ligamentous bands which ſtrengthen the capſule in front and above, are ſo diſpoſed as to augment the reſiſtance to any effort of the thigh-bone in that direction, and to reſtrain any part of the head which may not be contained in the acetabulum. The interior ligament alſo adds to the firmneſs of the joint; preventing, by its tenſion, the diſplacement of the articular ſurfaces in every effort which forces the head upwards; an effort which, from the preſſure of the trunk, is almoſt conſtantly operating. In the infant, the body of the bone is nearly ſtraight, a conformation unfavourable to ſtanding, according to the reaſons above alledged: the neck is ſhorter, and conſequently the baſe of ſupport diminiſhed; it is cartilaginous, and therefore leſs able to endure, for any time, an attitude which demands ſolidity in the ſuſtaining parts. Theſe are other reaſons for the inſecurity of the ſtation and progreſſion of young children, and ſhew by contraſt the advantages of the form of the adult bone.

In the knee, we are ſtruck with the extent of the articular ſurfaces, and the number and ſtrength of the ligaments which connect them, ſo well adapted to ſuſtain the weight tranſmitted by the thighs; the crucial ligaments limiting and maintaining the extenſion of the leg, preventing it from paſſing in this direction beyond the axis of the thigh; the patella in ſome meaſure reſtraining its flexion, protecting the joint, and more particularly favouring the action of the extenſor muſcles, which play ſo important a part in the functions of the lower extremity. The perpendicular direction of the leg is very advantageous in giving firmneſs; to this end alſo the immobility of the two bones which compoſe it ſeems directed. The tibia, ſolid and broad at either end, alone receives the preſſure and continues it to the foot; the fibula ſerves principally to afford attachments to muſcles. This diſpoſition, ſo different from that obſerved in the analogous part of the upper extremity, bears an obvious relation to its different function. In infancy the patella is ſcarcely perceptible; its abſence muſt be unfavourable to the power of the extenſors, and may be one cauſe of the feebleneſs obſervable at that period; and further, its want is felt in kneeling.

The foot is admirably adapted to its office of ſuſtaining every effort continued from above. It is articulated at right angles with the leg, through which it receives the weight of the body in a perpendicular direction, bearing directly on the upper ſurface of the aſtragalus, the whole length of the foot reſting on the ground. The articulation is ſituated nearer to the poſterior than to the anterior part of the feet, which gives to the baſe of ſupport a greater extent forwards, a direction towards which the line of gravity naturally inclines. The lateral deſcent of the malleoli materially ſecures the firmneſs of the ankle joint The breadth of the foot, increaſing gradually towards the front, the length of the metatarſal bones, the direction of that which ſuſtains the great toe, its ſituation and want of mobility, are other circumſtances marking the diſtinction between the hand and foot, and adapted to increaſe the ſolidity and extent of baſe afforded by the latter. The functions of the foot are aſſiſted alſo by its concave form, which enables it to gain a kind of hold of the bodies on which it reſts, and to accommodate itſelf to unequal ſurfaces, an advantage almoſt deſtroyed by the uſe of ſhoes, but eminently conſpicuous in thoſe people whoſe feet are not cramped by artificial means of defence. In its poſterior half nearly it reſts on the ground by its outer ſide, compoſed of the ſolid bone of the heel, and the os cuboides, the inner ſide repreſenting an arch, and placed at a diſtance from the plane below; in the anterior half the weight is principally ſupported by the inner ſide, where we find the ſolid bones of the great toe very little aſſiſted by the external edge.

Every thing in the ſtructure of man evinces that he is deſigned by nature for the erect poſture: we ſhall notice here thoſe proofs only which are deducible from the framing of the extremities. One of the moſt obvious is the great diſproportion in the reſpective lengths of the upper and lower limbs, and the greater comparative ſtrength of the lower. Other marks are found in the width and direction of the hip bones, in that of the neck of the femur, in the articulation of the leg at right angles with the foot, in the ſize and length of the latter, and the predominance of its ſolid over its moveable parts. We may remark alſo the flattened cheſt, and the ſhoulders ſet off by long clavicles, ſo very different from the conſtruction of theſe parts in quadrupeds, where the cheſt is compreſſed laterally, and the anterior extremities approach each other in front for the better ſupport of the body. The form of the hand, and the modes of articulation between the ſeveral bones of the upper extremity, are among the numerous and evident arguments that the erect poſture is natural to man, and we believe we may add, peculiar to him. In all the poſitions, produced by different motions, this poſture is more or leſs preſerved; ſo that, before we enter on progreſſive movements, it will be well to conſider ſeparately the ſimple act of ſupporting the body, which they neceſſarily include.

Station—or the act of ſtanding, in man, as far as the lower extremities are concerned, will be the firſt point for our obſervation. In this attitude it is neceſſary that the perpendicular line, which paſſes through the centre of gravity of the whole body, ſhould fall ſomewhere in the ſpace intercepted between the two feet, or on the ſole of the foot itſelf, if we are ſupporting ourſelves on one only. This centre of gravity, when the body is erect, has been proved by Borelli to be placed between the hip bones, "inter nates et pubem," in the human ſubject. To favour this diſpoſition, we find a vertebral column curved alternately in oppoſite directions, and placed obliquely with regard to the direction of the oſſa innominata, by which means the diſtribution of the ſoft parts is more eaſily managed, the balance preſerved, and permanent ſtation much facilitated. If this obliquity did not exiſt, and the vertebral column had been ſtraight, it would approach too nearly the line of direction of the leg and thigh, a diſproportionate quantity of the maſs of the body would be placed in front of the line paſſing through the centre of gravity, which would continually tend to make the body fall forwards in prolonged ſtation or progreſſion. In the orang outang the angle, which the vertebral column raiſed perpendicularly makes with the hip bones, is much more obtuſe than in man, and the equilibrium is preſerved by the length of the arms; the ſame may be obſerved of the gibbon, the ſimia lar of Linnæus. In quadrupeds this angle, under ſimilar circumſtances, is ſtill more obtuſe, and the efforts they make to remain upright on the hinder feet are continued with difficulty, more eſpecially if not aſſiſted by ſome other peculiar advantages of conſtruction, as in the bear, for inſtance, by the length of the heel. In man, the hip bones united to the ſacrum form a circular ſupport, by means of which the columns below are not inclined to the trunk, but ſuſtain it in perpendicular lines. If they had converged above, they would have formed an angular ſupport, not ſo capable of reſiſting the preſſure, and requiring a conſtant and powerful exertion on the part of the adductor muſcles. As it is, the columns are preſſed on perpendicularly by the tranſverſe width of the hip bones,

ſo

ſo that the preſſure may be ſaid to render them more firm and ſteady. The long bones of the lower extremity in man are placed nearly vertically on each other, and on the foot. And we may juſt remark, that even in ſtation a ſucceſſion of columns of the ſame ſize is probably more advantageous than a ſingle one, equal in bulk and length to the whole: this has been demonſtrated in the caſe where the weight is upheld by columns ſuppoſed to be flexible. The direction of the head and neck of the femur has been already mentioned as increaſing the baſe of ſupport, and we may add that the oblique poſition of the latter decompoſes, in ſome meaſure, the preſſure of the trunk from above, and renders it leſs ſenſible than if it had been vertical; avoiding at the ſame time the diſadvantages ariſing from an inclined poſition of the whole columns, as mentioned above. By the arch of the necks alſo the thigh bones are projected from under the hips, and ſuſtain the trunk with greater conſtancy and freedom than if they had been placed vertically beneath it during its different inclinations. The thighs, charged with the whole weight above, tranſmit it to the leg at the knee joint; ſomewhat differently, however, in the adult, and in the aged. In the latter the ſpine is bent forwards, and to preſerve the balance the thighs are neceſſarily alſo bent, and preſs obliquely on the leg, a diſadvantageous bearing, as requiring greater muſcular efforts, and ſoon becoming on this account weariſome. It is through the tibia alone that the preſſure is communicated to the foot, which finally ſupports the whole weight. The arch of the latter is favourable to ſtation only inaſmuch as it favours the adaptation of the ſole to inequalities of ſurface. In progreſſion it may give eaſe and grace, but the long and ſomewhat flattened foot is probably beſt ſuited to firmneſs of ſtation. The concavity is leſſened by the preſſure, which acts moſt ſenſibly on the anterior and more moveable part: it is very evident, when the foot comes with force to the ground, and it may be proved alſo by the aching and uneaſineſs produced by wearing ſhort ſhoes, which impede the elongation of the foot. A queſtion has ariſen concerning the moſt advantageous baſe of ſupport, or what opening between the two feet is beſt ſuited to ſecurity of ſtation. An anſwer equally applicable to every caſe cannot readily be found; the nearer it approaches a ſquare, including the feet, the better. Still different individuals muſt require different baſes as ſuited to their own form. In every caſe, if the ſeparation be too wide, the limbs loſe their perpendicular bearing, and become inclined to the trunk. The ſmaller the angle made by two lines produced backwards in the direction of the feet, the better: it ſeems, indeed, that a parallel direction of the two feet is the moſt natural, as we ſee it in children and in the greateſt number of adults, eſpecially of thoſe who have not been inſtructed by art. The body has a tendency to fall forwards, which is partly counteracted by the length of the foot; increaſing the baſe of ſupport in the anterior direction. Now if the foot be turned much outwards, the baſe is neceſſarily ſhortened towards the front; and, as in ſtation, the trunk has no diſpoſition to fall laterally, what the baſe gains in that direction is in no degree equivalent to what is taken away from the other. The ſame obſervation applies to turning the toes inwards; but as this never takes place to any conſiderable degree, an abuſe of it is leſs to be apprehended. The unnatural poſition, in which education teaches us to place our feet, with the heels forming an obtuſe angle behind, is contrary to the whole mechaniſm of the limbs, is uneaſy, and inſecure. In different gymnaſtic exerciſes the feet are placed ſo as to offer the greateſt poſſible reſiſtance to the probable direction of the effort they will have to withſtand. In wreſtling, where the force in the firſt inſtance is generally applied laterally, we obſerve the feet parallel, and at a conſiderable diſtance from each other. Conſtant attention, however, is abſolutely neceſſary to change this baſe, if any unexpected impulſe be made in a contrary line. A deficiency in this reſpect is the reaſon why inexperienced wreſtlers are ſo readily pulled down forwards, or thrown on their backs, their exertions being uniformly directed to oppoſe the expected ones of their adverſaries; if theſe be ſuddenly altered, there is no adequate power of reſiſtance. In boxing, the baſe is increaſed from before backwards, the feet are placed nearly at right angles and far apart, the knees are bent a little, and the trunk lowered. Here the impulſe is expected in front, and the attention is particularly directed to oppoſe it in that point. This, in ſhort, is one of the great principles obſerved not only in theſe exerciſes, but in every laborious exertion, as in puſhing or pulling, where the line of oppoſition does not vary. Whatever be the direction or diſtance of the feet from each other, no muſcular effort can prevent the fall of the body, whenever the perpendicular line from the centre of gravity falls without the quadrilateral ſpace intercepted between the feet. And a man can ſupport a weight much heavier than himſelf, provided that the line from the centre of gravity of ſuch body fall within the baſe of ſupport.

Our obſervations hitherto are principally applicable to ſtation, with the trunk erect. Let us now ſuppoſe the feet fixed ſecurely on the ground, and the trunk moving in different directions by means of the articulations of the hip with the thigh-bones. In bending forwards, if the motion be prolonged conſiderably, the centre of gravity is no longer ſupported, and a fall is the immediate and neceſſary conſequence. We have before remarked, that the articulation of the ſacrum with the oſſa innominata is in a plane poſterior to that of the feet. Now, if in bending forwards, the hip-bones move on the thighs, ſo as to bring the two baſes into the ſame plane, the centre of gravity is eaſily thrown forwards beyond them, and a fall is the reſult. To counteract this, when the trunk is bent much forwards, we at the ſame time carry the upper part of the lower extremities backwards, the feet remain advanced, the leg and thigh are inclined backwards, ſo as to form an angle with the body. In extending the body on the thighs, and carrying it back beyond the perpendicular, as there is no extended baſe of ſupport behind, analogous to that formed by the feet in front, we are obliged to bend the knees, in order to bring the centre of gravity within the ſpace occupied by the feet. If the lower extremities are maintained in an upright poſition, while the trunk paſſes behind the perpendicular line, a fall is inevitable. Lateral inclinations of the trunk on the thighs are neceſſarily confined; ſince, in order to lower it on one ſide, the oppoſite limb muſt be proportionably raiſed; when both feet touch the ground, it is almoſt completely prevented, ſo that the lateral balance is ſeldom loſt, eſpecially as we can at pleaſure widen the baſe of ſupport.

The power of ſtanding on the toes reſults from the mode of their articulation with the metatarſus, which allows of extenſion or inflection upwards, beyond the axis of the latter. By this mechaniſm we reſt on the whole length of the toes, not merely on their points, which would be utterly incapable of ſupporting the weight; here too the ſeſamoid bones are eſſentially uſeful, the preſſure bearing directly on them, as it does on the patella in kneeling. In this attitude the feet are extended on the leg, and form an obtuſe angle with the toes, which conſtitute the baſis of ſupport; the legs and thighs are in the ſame ſtraight line, and the trunk is projected a little forwards by the elevation, ſo that the centre of gravity is brought over the contracted plane, which now forms the base of support, lessened very much in length posteriorly by the loss of the tarsus and metatarsus. The same difficulties occur if we stand on any pointed, or narrow body, and for the same reason, *viz.* the diminution of the space in which the vertical line from the centre of gravity must fall, in order to preserve the equilibrium. This applies also, and more forcibly, to the cases in which we stand on the toes, or heel of one foot only. In the last instance the foot is bent, the sole elevated, the rounded heel alone touches the ground by a very limited surface, great muscular exertion is required to keep the line of gravity vertical, the body vibrates on every side, and the attitude is necessarily soon lost or discontinued. We have not so much difficulty in standing on the heels of both feet, though this is far less easy than on the toes, on account of the points on which the weight rests. Standing on a single foot, with the whole sole on the ground, is an attitude more easily maintained, on account of the greater length of contact, and the less muscular exertion necessary to inflect or erect the trunk so as to bring the line of gravity within it. In this position the body is more or less inclined on the limb which supports it, and may be moved with facility in every direction by means of the joint at the hip. The long neck of the thigh-bone is here eminently useful, by widening the base of support afforded above to the trunk; and the position cannot for an instant be maintained by animals, who, besides other obstacles, have a very short neck to the femur. It is obvious that station on one foot must be more difficult than on two, as in the last case it is not only the feet, but the plane intercepted by them, which form the base, and much less exertion is required to keep the line from the centre of gravity within it. We must have observed also, that when in station on one foot, the trunk is much inclined in any direction, we throw out the other limb in the opposite one, in order to keep the centre of gravity vertical to the base: and if we stand on the toes or heel of one foot, not only the other leg, but the arms also, are called into action to preserve the equilibrium, which is perpetually lost and regained by the tottering trunk, and shuffling base. A fixed stability is utterly prevented by the difficulty of keeping the balance even under the greatest muscular exertions.

In sitting, the support is afforded by the tuberosities of the ischia, the thighs and the interval between them, and by the legs also, if we sit on the ground with them extended. This is a firm position, easily continued, especially if the body is inclined a little forwards over the base; if it is inflected backwards a fall may easily take place. On this account we have generally backs to our seats, to allow the trunk to recline, when the muscles are fatigued by supporting it in its position of inclination forwards. The legs and thighs are concerned only in a secondary way in this posture, as the principal support is afforded by the tuberosities of the ischia resting immediately on the surface below.

Kneeling is another attitude in which the lower extremities are employed, but the base of support is extended posteriorly, consisting of the space included by the legs, which are projected backwards under the trunk. Hence the body, if erect, is disposed to fall forwards; we require a resting place in front, as we throw the hips backwards, to bring the line of gravity over the legs. This posture is far from an easy one, since it requires a constant and unfavourable exertion of muscular force. The use of the patella has been already explained.

The importance of the general law, by which it is necessary that a vertical line passing through the centre of gravity should fall on some point within the base of support, is strikingly exemplified by the following observations. If we stand with our back and feet touching a wall, and then make a profound bow forwards, we inevitably fall, as the vertical line from the centre of gravity soon over-reaches the base of support. Again, when sitting with the trunk and legs perpendicular to an horizontal plane, we cannot rise from our seat; because the centre of gravity of the trunk falls far behind the feet: we are obliged consequently either to incline the trunk very much forwards, or draw the feet backwards under it, in the first case changing the centre of gravity, in the latter the base of support; and then by muscular efforts the thighs are easily extended on the legs, the trunk suspended, and the whole body erected; operations extremely difficult, if not impossible, supposing the original position had been preserved. Our notions of station would be very imperfect if we did not take muscular exertions into the account; it is in vain that we place a dead body so as to bring the centre of gravity over the base of support; the bony columns are no longer regulated by the varied efforts of numerous muscles, as in the living subject; the machine is incomplete, and instantly gives way to the pressure. The same phenomena occur if fainting comes on in the erect posture; the head and neck incline forwards, as also the trunk; the bones bend on the thighs, the latter on the legs, and these again on the feet. We must not therefore confine our attention to the idea of bony columns pressing vertically on each other, but recollect that they have highly moveable articulations, which require some strong external efforts to give them positive stability. These exertions are more or less powerful as the bones depart more or less from a vertical bearing on each other. Hence the anterior extremities of quadrupeds possess fewer and less powerful muscles than the posterior: as, in the first instance, the bones are directly extended on each other, and press vertically on the ground; in the last, they form angles more or less open, which can be preserved only by a constant exertion of muscular force. The elephant is an illustrative exception to this observation; his hind limbs are nearly vertical columns; a mechanism which diminishes the quantity of muscle otherwise necessary to support his enormous bulk. In insects, on the other hand, the joints are bent at very acute angles; a structure less inconvenient than we might at first suppose, as on account of the smallness of their body, the weight is diminished in a sub-duplicate ratio to their size. In birds who sleep perched on trees there is a peculiar construction, by which the mere cessation of muscular action, the allowing the body to sink, and the knees to bend, induces a mechanical contraction of the toes, which grasp firmly the body on which they rest, and secure their position when at roost. In the grallæ tribe, in the stork for instance, who stands motionless for hours waiting for his prey, there is a particular construction in the articulation of the knee, which enables him to stand without much muscular exertion.

Progression—may be effected in many different ways, of which we shall examine only the most ordinary and simple. In walking, the action, which carries the body forwards, backwards, or to either side, consists in alternate motions of the lower extremities, in which each of them becomes, in its turn, the fixed point on which the whole weight of the body is supported; the limb which moves, giving in its elevation an impulse to the trunk by means of the hip bone. Each of these motions is called a step, and a sustained succession of them constitutes progression: and in order to understand the latter, we shall examine the mechanism of the step under different conditions. In walking, if we suppose both

both feet to be on the fame tranfverfe line, the limb (fay the left) which makes the firft ftep, is raifed from the ground and advanced, by bending the hip joint; it is then extended, and laftly, the foot preferving its advanced pofition, is fixed on a different fpot; fo that the centre of gravity of the body which, during the advance of the left leg, was fuftained by the right, is moved forwards by a fimultaneous movement of the trunk; and the line of gravity falls between the two feet. If the ftep is fhort, the hip and trunk move but little; if it be long, and the left leg carried far beyond the right, there is an evident rotation of the right hip, and confequently of the trunk on the correfponding thigh. By this horizontal rotation, which carries the left fide of the body obliquely onwards, the extent of the ftep is greater than it would have been by the fimple bending the thigh; and we fee it in fact moft evidently in long ftrides, where the rotation is fo great, as to bring the fhoulder of the advanced fide immediately in front, the hip moving through the quarter of a circle, giving thereby an additional impulfe to the limb below. As the ftep is fhorter, this lateral rotation is lefs obfervable, till in fome cafes it can be no longer noticed. It is more evident in the female, from the greater tranfverfe diameter of the pelvis; and is particularly ftriking in individuals who have a ftiff, or anchylofed hip joint, where the limb cannot be advanced by bending the thigh. The fhort ftep is effected, on the contrary, chiefly by the alternate flexions and extenfions of the joints of one extremity, uninfluenced by any movement of the trunk on the other.

If the feet are not in the fame tranfverfe line at the commencement, the limb, which is behind, and inclined to the trunk, is the one to be moved forwards. Here the foot rifes, each part quitting the ground fucceffively, from the heel to the toes, by a kind of circular motion. The limb is thus elevated and advanced, and the centre of gravity is carried in the fame direction, which latter is effected with greater facility, as the body at the fame time leans a little forwards. When this impulfe is carried to its full extent, the toes are detached from the ground by the thigh being fuddenly bent on the hip, which has been moved forwards, and the limb is carried on as in the former cafe, the other remaining fixed as the temporary fupport. The hip and knee joints are then extended, and the foot bent on the leg. The foot touches the ground firft by the heel: this is fucceeded by a circular motion of the anterior part of the foot round this fixed point, and a correfponding motion of the leg in the fame direction, which brings it to a vertical line at the time that the toes begin to bear on the plane below. In thefe circular motions the foot is fenfibly elongated, and its concavity leffened by the preffure, its vaulted form, and the number and mode of its articulations imparting a degree of eafe and grace to the whole motion which we look for in vain, where the foot is flat and ftiff, and the whole fole quits, or reaches the ground at the fame inftant. There is, in this cafe, an awkwardnefs of gait, and a real inability of walking with promptitude and vigour. This ftep we have been defcribing takes place fucceffively in each limb in progreffion; and differs from the preceding in being more extenfive, and depending more importantly on the foot. The impulfe which its elevation communicates to the trunk will be influenced however materially by the knee: if this is bent in proportion as the foot rifes, the limb lofes in one action what it gains by another; the impulfe will be ftronger as the knee is kept more extended. And when the foot is detached at once, without this rotation, no impulfe will be given to the hip by the limb in motion: if the pelvis roll on the thigh which is fixed, it muft be by an independent mufcular action, as in the former cafe. In every cafe, as foon as the foot has left the ground, the trunk fupports the limbs; and carries it forwards. The mechanifm of the ftep backwards will be eafily underftood from what has been faid: we obferve only that the foot is raifed more immediately by bending the knee; and that when the ftep is prolonged, there is an evident horizontal rotation of the trunk in the fame direction. The fide ftep is produced by gently bending the knee to detach the foot from the ground, and then abducting the thigh; or by lifting the whole limb by a lateral inclination of the trunk on the oppofite one, and then feparating them, the knee being all the while extended.

Walking is a fucceffion of thefe motions, and requires for its regularity an equal length of both limbs; a fhortnefs of either limb induces a finking and relative inclination of the whole trunk to the correfponding fide, every time that the deficient extremity touches the ground. In the moft natural mode of walking, one foot does not quit the ground entirely, until the other touches it wholly, or in a great part of its length: the latter begins to fix itfelf while the former ftill refts on its point; the vertical line from the centre of gravity, which fell on one foot during the tranfportation of the other, being carried forward, and dropping at this time between the two. When the advanced foot is firmly fixed, we throw on it the centre of gravity; the fame motion neceffarily projects the whole body forwards, and a fucceffion of fimilar phenomena takes place. At each ftep the impulfe given to the trunk by the limb which has juft quitted the ground produces an undulatory motion up and down, and at the fame time an horizontal rotation alternating from one fide to the other. It is the latter which, from not being fuftained equally, produces the deviation from the ftraight line in walking forwards, fo conftantly obferved if we walk blind folded, where confequently we cannot correct incidental errors by the fight. The beft chance of walking ftraight in this cafe is by taking very fhort fteps, and for the reafons infifted on above. In fact, the centre of gravity is not, when we carefully endeavour to attain it, moved forward in the fame ftraight line, but varies more or lefs between the lines defcribed by the feet at every ftep, in a degree proportionate to the extent of each. This is fcarcely noticed, but is evident from this fimple experiment. If we ftand at any diftance from a fmall perpendicular rod, and fix our eyes on any point fome way behind it, and in the fame ftraight line, we fhall, as we advance to the rod, find this point alternately to the right and left of it, as we move each limb. A proof that the trunk is not carried as in a ftraight line, but defcribes a tortuous one, winding from one fide to the other. Another confequence of this rolling of the trunk on the oppofite limbs in fucceffion, is a fwinging motion communicated to the upper extremities: thefe move, moft commonly, in an oppofite way to the feet; that is, the right arm moves on at the fame inftant that the left leg propels the trunk. The ufe of this crofs motion of the arms is fuppofed to be that of correcting the lateral impulfe given to the trunk by the leg in its elevation. In every cafe of progreffion there muft be a regulated degree of flexions and extenfions, which is in fome inftances provided for by the mechanifm of the bones, and their ligaments, but in all depends principally on an uniform fucceffion of fuftained mufcular actions. The greater difficulty and fatigue experienced in walking up an afcending plane depends upon the greater degree of flexion neceffary to raife the limb from the ground; this muft be increafed as the plane becomes more vertical; the heel is at the fame time lower than the toes, and muft pafs through more

more ſpace in each elevation than in the ordinary caſe of walking on plain ground. Walking down hill is for the ſame reaſons leſs difficult; there is leſs occaſion for extenſive muſcular action. The object is to regulate the impulſe which the trunk eaſily acquires, and to keep the centre of gravity over the feet, by throwing the trunk a little backwards, inſtead of leaning forwards, as in the preceding caſe. In aſcending alſo we have each time to elevate the weight of the body by muſcular powers; in deſcending we have only to prevent it from ſinking too faſt. Mounting ſteps, or a ladder, or deſcending either, are ſtill more difficult, as the reaſons above given apply more ſtrongly.

Running differs from walking chiefly in the rapidity and force with which the motions of the lower extremities are executed. The mechaniſm by which they are produced is nearly ſimilar; the remarkable differences are, that the toes only touch the ground, and the whole trunk is inclined very conſiderably forwards. In conſequence of the firſt circumſtance, a ſmall ſurface only is in contact with the ground; and this can be more rapidly applied and detached, while the extenſion of the foot upon the leg adds to the length of the limb. From this ſmall extent of the baſe of ſupport ariſe the frequent falls in running from trifling obſtacles, or ſlight lateral impulſes; and hence, in this mode of progreſſion, we ſhould conſtantly endeavour to preſerve the balance, by preventing the centre of gravity from being removed too quickly from the leg behind, or from being thrown too ſoon on the one in advance. Running is alſo inſecure from the ſhort time allowed for fixing the point of ſupport; and hence poſitive ſtability is leſſened inverſely as the neceſſity for it is increaſed by the quick tranſition of the centre of gravity from point to point. At each ſtep the trunk is ſuddenly and violently carried forwards by the limb which has juſt left the ground, and which muſt be immediately and conſiderably advanced to ſupport the centre of gravity. In running very faſt, eſpecially on a declivity, ſo powerful an impulſe is communicated to the trunk, that it is almoſt impoſſible to ſtop ſuddenly; we gradually ſlacken our pace, ſtill projecting the limbs to ſupport the trunk till the impulſe is weakened. In running up an acclivity we always bend forwards, to aſſiſt the propulſion of the centre of gravity, which is effected under many diſadvantages; we generally do ſo in running on plain ground, though, when we run carefully, the head and ſhoulders are thrown back to counterbalance the impulſe below. When from fear, or inability to continue the muſcular exertions neceſſary to maintain this poſture, the trunk is neither thrown back, nor even kept vertical to the horizon, the runner appears to yield entirely to the impulſe, to commit himſelf almoſt to chance; his only endeavours being to throw his legs out rapidly and to the greateſt extent, to ſuſtain the increaſing velocity with which the centre of gravity is carried onward: the ground covered at each ſtep is really immenſe, the power of balancing is totally loſt, and the ſlighteſt inequality of ſurface is ſufficient to overturn him with the rougheſt violence. If he is ſteady enough to reach the bottom in ſafety, he continues his courſe a very conſiderable way before the impulſe is deſtroyed, and the power of regulating his movements recovered. In running, the lateral rotation of the hip and trunk on the thigh is extenſive, from the length of the ſteps; and the ſame cauſe produces an equally great and rapid motion of the oppoſite arm to preſerve the equilibrium, which is more eaſily loſt than in walking.

In leaping, the body may be raiſed vertically, or with any degree of obliquity. The joints of the lower extremities are firſt cloſely bent, and then ſuddenly extended, ſo as to propel the trunk: for the ground effectually reſiſts the impulſe, which muſt be entirely ſpent on the moveable parts above. The alternate angles, formed by the ankles, knees, and hips, depreſs the centre of gravity, without altering its bearing on the feet; and the ſame mechaniſm enables us to elevate the trunk nearly in a vertical line, the circular motions in oppoſite directions executed with almoſt inſtantaneous velocity, acting in a ſtraight line intermediate to them all. If the flexions were all made in the ſame direction, ſubſequent extenſion would be more laborious, and a perpendicular impulſe, ſuch as produces the vertical leap, would be impoſſible. The mechaniſm of leaping may be illuſtrated by comparing it with other motions. The muſcular powers being the ſame, the leap will be more conſiderable as the levers are longer, and more inclined on each other. Hence animals, whoſe hind limbs appear diſproportionately long, can make the moſt extenſive bounds; we need ſcarcely inſtance the kangaroo, hare, ſquirrel, or graſshopper.

The elevation of the body in a vertical leap is continued ſo long as the communicated impulſe exceeds the power of gravitation; as the former diminiſhes, the latter again begins to operate, and the body deſcends in the ſame line with that in which it had been elevated. It is incapable, while in the air, of altering the general direction derived from the firſt impulſe; although many motions of the extremities may be produced, as we obſerve in dancing. The ground, from its want of elaſticity, communicates no impulſe to the body at the moment of elevation. A certain reſiſtance to the action of the muſcles on the moveable levers is required. If the ground be ſoft or ſandy, it yields too readily to the impulſe of the feet, and leaping is impeded: on the contrary, if the point from which the jumper ſprings be elaſtic, as in the caſe of a flexible board, or a tight rope, there is an evident re-action, conſiderably increaſing the impulſe communicated by the exertion of the lower limbs. In jumping forwards the trunk is inclined, and projected in the ſame direction by the extenſion of the thigh on the leg. This latter motion is counterpoiſed or varied, according to circumſtances; but it is ſo eſſential in every caſe, that we cannot leap if the knees are kept extended, no muſcular action or exertion could then raiſe the body from the ground. The chief effort is to turn the thigh and trunk balanced on it forwards on the tibia; and the impulſe thus given predominates over the others; in leaping backwards, the tibia is the more moveable diviſion of the lever by a variation in the combined action of the muſcles employed, determinable by the will. In the vertical leap the body moves up and down in the ſame line: but if the impulſe is given in a line inclined to the horizon at oblique angles, the line deſcribed by the centre of gravity will be a parabolic curve, compounded of the uniform ſtraight motion of projection, and the force of gravity, as in other projectiles. While the firſt predominates over the laſt, the body aſcends; when they are in equal power, the elevation is the greateſt; from this point, it deſcends, the force of gravity acting with increaſing effect as the impulſe is weakened. The impulſe, in this caſe, may be conſiderably increaſed by a previous motion given to the body by running: the impetus is ſomewhat altered in direction by the violent extenſion of the extremities, but it acts with almoſt undiminiſhed force in projecting the body: there are here two cauſes acting in oppoſition to gravitation. This kind of leap is facilitated by inclining the body forwards; and, in order to afford a point of ſupport to the centre of gravity, we always find, before the body is elevated from the ground, that one of the legs, generally the right, is much before the other; this poſition is preſerved throughout, for the ſame reaſon, or the two legs are brought into parallel obliquely inclined lines, before we reach the

I ground

ground at the end of the leap. If we jump with the feet together, we cannot incl ne the body much forwards, without lofing the balance. In this cafe, to affift the impulfe, we fwing the arms backwards and forwards before we make the fpring, endeavouring to give fome degree of horizontal impetus to the trunk, which muft however always be inferior to that obtained by even a fhort run. The body comes in contact with the ground, at the end of the leap, impreffed by a double force, *viz.*; the projectile impetus, and that acquired by gravitation in the defcent. We extend the feet on the legs, fo as to touch the ground firft by the toes; we then yield fomewhat to the force, and allow the joints to be bent gradually, fo as to weaken and finally deftroy the fhock. In order to deftroy the impulfe given to the centre of gravity, we throw back the head and fhoulders, and flacken our pace by degrees, till the power of balancing is reftored.

The action of dancing, which confifts in a rapid change, in various manners and directions, of the lower extremities, principally refembles, in fome refpects, the *run*, in many others the *leap*. We omit the detail of thofe extraordinary and amazing feats of agility, which aftonifh us in the ftage dancer, or the tumbler; as they depend, not on any peculiarity of mechanifm, but on the powerful, long fuftained, or rapid actions of mufcles, educated to the tafk, and preferved by conftant exercife in the higheft poffible ftate of energy. Hopping is a fucceffion of leaps on one leg only; the actions are otherwife analogous. Skaiting is a fimple motion; the mechanifm of which may be readily conceived after the obfervations we have made: the centre of gravity is brought alternately over the oppofite feet, as each glides on the plane beneath, and the balance is preferved by mufcular action. Swimming is a more compound action of both upper and lower extremities, involving in its difcuffion many interefting queftions, independent of their functions, and which confequently cannot properly be confidered here.

For more detailed information on the fubject of animal mechanics, we refer the reader to Borelli, de Motu Animalium; Haller, Element. Phyfiol. tom. iv.; Barthéz, Nouvelle Mécanique de l'Homme: fee Jour. des Scavans 1782-1783. Bichat, Anatomie Defcriptive, tom. i. Cuvier, Leçons d'Anatomie comparée; tom. i. fur la fin. There is a catalogue of authors on this fubject in Dr. Young's Natural Philofophy v. ii. p. 164.

Comparifon of the upper and lower extremities.—A review of the differences in the conftruction of the upper and lower limbs will illuftrate the mechanifm of their component parts. There is a general refemblance of form throughout; and the effential varieties may be all referred to the principle of mobility in the upper, and to that of firmnefs in the lower. In man, the extremities are nearly parallel to the long diameter of the trunk; and confequently they muft be parallel to each other; but they are not in the fame vertical plane. A line drawn from the glenoid cavity of the fcapula to the acetabulum, will be very oblique from above downwards and forwards, becaufe the plane in which the former lies is pofterior to that in which the latter is found. Hence the arm drops neceffarily behind the thigh. The advantage of fuch a difpofition in the upper extremities is, that the principal motions, which are thofe in the anterior direction, have a greater range than if the glenoid cavity had been feated nearer to the front of the trunk. The extremities differ alfo in the fpace, by which they are feparated from each other. If we judged only by the intervals between the right and left glenoid and cotyloid cavities refpectively, we fhould fuppofe the difference to be great; the long clavicles keeping the firft at a greater diftance than the pubal portions of the hip bones do the fecond. This, however, is compenfated by the length and obliquity of the necks of the thigh bones, which throw the axes of thefe bones far without the cotyloid cavities. We have here fuppofed the legs to be extended, and the arms lying in their natural direction by the fides of the trunk; if the knee and elbow be bent in this pofition, we fhall find the angles are open in nearly oppofite directions, that of the knee backwards, and the elbow forwards. Thefe are the only joints in which the articulations are directly inverfe in their modes of action; in quadrupeds, this condition prevails from the fhoulder and hip to the feet in a very ftriking manner. The lower extremities are nearer together below than above; while the upper are kept afunder by the intervening body. The lower extremities are rather longer than the upper, in confequence of the great length of the thigh and leg, when compared with the arm and fore arm. For the latter, by the long axis of the hand being in the fame line with their length, gain much more than the lower extremity does by the mere thicknefs of the foot. When the arm hangs eafily extended by the fide, the points of the fingers reach to about the middle of the thigh; yet there are many varieties in this refpect. The folid form, and the broad articular furfaces of the lower, are ftrikingly contrafted with the flender make and narrow articulations of the upper; the firft bearing a marked relation to their principal function of fuftaining the body, the latter to their diftinguifhing character of mobility. At the time of birth the upper extremities are more advanced in formation than the lower. This feature is, however, more remarkable, the nearer we mount to the firft developement of the embryo; it is gradually loft after birth, and the ftructure of both is completed nearly about the fame period. The different nature of their functions, thofe of the upper commencing almoft immediately, and thofe of the lower not until a confiderable interval after the birth of the child, explains eafily the reafon of this difpofition.

The bones of the hip and fhoulder differ more in their form and connections than any other parts of the extremities. The fcapulæ are fuftained by mufcles, allowing a great variety of motion, and are kept apart by the two moveable clavicles in front; the hip bones are bound firmly to the fpine, and the articular cavities feparated from each other by an immoveable medium. The fpace between the cotyloid cavities is proportionably greater in the female than in the male. The fame excefs may be obferved in the fhoulders, where it arifes from the greater comparative length of the clavicle. The breadth of the fcapulæ increafes in the male the tranfverfe diameter of the fhoulders, which on this account is particularly ftriking from behind; in front they are not proportionably fo wide as in the female. It is therefore the proportional excefs of width in the hips, and not any decreafe in the breadth of the fhoulders, which gives to the female figure one of its moft prominent features; this diftinguifhes it from the male, in whom the ftrong, though narrow, hips are oppofed to the comparatively fpreading fhoulders. Thefe circumftances are fufficiently evident in examining the difpofition of the bones; but they become ftill more ftriking, by the addition of the foft parts, in the complete fubject, where the ftrongly marked and mufcular form of the fhoulders, and the contracted outline of the hips in the male, is finely contrafted with the delicacy of the firft, and the fwelling roundnefs of the laft in the female. The hip bone exceeds the fcapula and clavicle in volume, as well as in the firmnefs of its articulation; it further gives a fixed point of motion to the thigh, by a deep

deep articular cavity, whereas the ſcapula offers a ſhallow and eaſily moveable one, yielding to a ſlight impulſe.

The femur exceeds the humerus very much in ſize, and length, (this laſt being nearly in the ratio of 46 to 33,) and in the extent of its articular ſurfaces. Although their motions are for the moſt part analogous, ſome differences may be pointed out. The movements of circumduction and rotation exiſt in an inverſe ratio to each other. In the thigh bone, the length of the neck, which is the lever of rotation, gives great extent to this motion, and thus ſupplies the want in the leg of the motions correſponding to the pronation and ſupination of the fore-arm, ſo that all rolling of the foot out and in, when the limb is extended, ariſes from a motion of the whole limb. The ſhort neck of the humerus, on the contrary, by bringing the axis of the bone nearer the centre of motion, limits rotation; which is leſs eſſential, inaſmuch as the hand is moved by the pronation and ſupination of the fore-arm. Circumduction is more confined in the thigh by this very length of the neck, which makes an angular lever of this bone, differing much from the nearly rectilineal one of the humerus. In the firſt caſe the axis of motion is not in the long axis of the bone; in the laſt, it is nearly ſo; and the difficulty of this motion is proportional to the difference between the two axes, while its facility is greater as they approach each other more nearly. The advantages of this diſpoſition, in giving mobility to the upper, and firmneſs to the lower extremities, may be readily perceived.

The leg exceeds the fore-arm in the ſize and length of the bones, the proportions being as 39 to 26. In the orang-outang the ratio of the thigh to the arm is as 9 to 10, and that of the fore-arm to the leg as 9 to 11; which proportions are very different from thoſe of the human ſubject. The exceſs of length in the lower extremity of man is ſeen moſt evidently when he attempts to move on all fours, as we expreſs it. To correct this diſproportion he is obliged to bend the joints of the lower extremities, or to throw them out very obliquely behind the trunk, whilſt the upper are perpendicular to it. The leg and fore-arm reſemble each other leſs than the thigh and arm; in the fore-arm the parts are arranged favourably to mobility; in the leg the object is to procure a firm and ſolid ſupport, which can tranſport the centre of gravity with eaſe and ſafety from one point to another. Of the two bones of the fore-arm, which are nearly equal in every reſpect, one rolls eaſily over the other, and the hand is articulated with the moveable bone. In the lower extremity theſe rolling motions would have been dangerous; to give it firmneſs, the foot is articulated with the tibia, which correſponds to the ulna, and not with the fibula; the latter poſſeſſes no perceptible power of motion.

The hand and foot reſemble each other moſt cloſely in the ſtructure and number of the phalanxes, and of the bones which ſupport them; the principal differences occur in the carpus and tarſus, which are the moſt ſolid portions. That part of the hand in which its ſtrength reſides is leſs developed, and has far leſs volume than the analogous parts of the foot, on which the whole weight of the body in ſtation finally reſts. The moveable phalanges, which are the principal agents in executing the functions of the hand, are much longer, and larger than thoſe of the toes, which are not ſo eſſential to ſtation or progreſſion. The foot and hand are diſpoſed inverſely as to form; the poſterior part of the former, and the anterior part of the latter, is the moſt important, the longeſt, and poſſeſſes the moſt ſtriking characters. The functions of the hand render it neceſſary that its plane ſhould be nearly continuous with that of the fore-arm; otherwiſe the radius could not guide it ſo preciſely over the objects in view. In the foot, the articulation is ſo diſpoſed that its poſterior part offers a powerful lever for muſcular agents, and a ſolid ſupport for the maſs above; it is formed by a ſingle bone of the foot, which neceſſarily adds to its ſolidity. The metacarpus and metatarſus have a much greater ſimilarity to each other; the latter is the more ſolid, and offers this principal difference. The metatarſal bone of the great toe, by far the ſtrongeſt of the whole, has ſcarcely any motion on the tarſus, and is on the ſame plane with the others; while that which ſupports the thumb has a very conſiderable extent of motion, and is anterior to the reſt. This ariſes from the obliquity in the articulating facet of the trapezium, which is directly tranſverſe in the firſt cuneiform bone of the tarſus. Further, this bone in the foot is not ſeparated from the other metatarſal bones, by an interoſſeous ſpace larger than that between all the reſt, as is the caſe with the metacarpal bone of the thumb. Theſe remarkable differences depend wholly on the ſolidity neceſſary for ſtation, and the great mobility required for the important offices executed by the thumb in the human ſubject. In the ape tribe, the great toe on the contrary may be properly regarded as another thumb in its ſtructure and uſes. The toes can be inflected further on the back of the foot than the fingers can be on the hand, a diſpoſition which is accommodated to progreſſion, eſpecially to running ſwiftly; an analogous effect is produced in the hand by the inflection of the carpus backwards on the fore-arm. At the time of birth the important parts of the hand are already well developed; the metacarpus, and more eſpecially the fingers, are ſufficiently formed for the infant to ſeize objects within its reach, and to diſtinguiſh ſome of their qualities. This early developement of the organs of touch would ſeem to bear a marked relation to the correſponding advancement in the formation of two other organs of ſenſe, the eye and ear, they being all aſſociated cloſely in confirming, or correcting external ſenſations. The important part of the foot, the tarſus, is far behind in formation, as it is not called into uſe till ſome time after birth, till the organs of ſenſe have long been exerciſed in common, and can now mutually aſſiſt each other.

Reſpecting this compariſon between the upper and lower limbs, ſee Vicq D'azyr ſur la comparaiſon des extremités entr'elles dans l'homme, et dans les quadrupedes, in the Hiſtoire de l'Acad. des Sciences 1774.
