ARTS and SCIENCES.

ELOCUTION.

ELOCUTION is a term which, according to the ftrictnefs of etymological definition, might be applied to fignify every thing that is included in the faculty and utterance of thought, by the means of language, whether oral or written; and fome writers, even in modern times, have applied it, with more attention apparently to derivation than to authorized precifion and neceffary contradiftinction, to written compofition as well as to actual fpeech. At the fame time, two other terms, oratory and eloquence, (which etymological refinement might undoubtedly reduce to the fame original fignification,) have admittance and current ufage in our language, and are occafionally ufed as fynonyms of elocution in our loofer converfation. But every copious fubject, when it comes to be treated in a didactic way, requires more terms of fettled diftinction than the fimplicity of rigid etymology can be expected to furnifh; and "many terms which, in the laxity of general converfation, are indifferently and indiftinctly ufed, in the precifion of fcientific difcuffion muft be carefully feparated and placed in contradiftinction: the very admiffion of fynonyms being perfectly inconfiftent with the progrefs and comprehenfion of fcientific truth."

Thefe three terms, therefore, in the very outfet of the prefent fubject, fhould be clearly and diftinctly defined, and the boundaries of fignification affignable to each, as terms of contradiftinction, be precifely marked. This has accordingly been done by a popular lecturer of the prefent day. "Eloquence," fays he, "may be defined, "the art of expreffing our thoughts and feelings with precifion, force, and elegance; and of heightening the impreffions of reafon by the colourings of imagination." It is applicable, therefore, to the whole faculty of verbal difcourfe, whether oral or written. It addreffes itfelf by the pen, to the eye, as well as by the living organs to the ear. Thus we fpeak (with admitted accuracy) of an eloquent book, as freely as of an eloquent oration; of the eloquent Buffon (alluding to his celebrated work upon natural hiftory); and of the eloquent writings, as well as the eloquent fpeeches of Edmund Burke. The Apoftrophe to the queen of France, is as genuine a piece of eloquence as if it had been fpoken in the houfe of commons.

Oratory, on the contrary, is precife and limited in its application: and, in this refpect, indeed, even popular ufage is pretty generally correct. It may be defined, "oral eloquence; or the art of communicating, by the immediate action of the vocal and expreffive organs, to popular, or to felect affemblies, the dictates of our reafon, or our will, and the workings of our paffions, our feelings, and our imaginations." Oratory, therefore, includes the idea of eloquence: for no man can be an orator who hath not an affluence of thought and language. But eloquence does not neceffarily include the idea of oratory; fince a man may be rich in all the ftores of language and of thought, without poffeffing the advantages of a graceful and impreffive delivery. It is, therefore, the name of a more complex idea; and includes, befides the general notion of eloquence, the practical part of elocution: which being our immediate object, muft be fpoken of more at large. "Elocution may be regarded either as a fcience, or as an act. In the former cafe it may be defined, "the fcience by which the rules for the juft delivery of eloquence are taught;" in the latter, "the happy combination and coincidence of vocal, enunciative, and gefticulative expreffion, by which oratorical excitement is fuperadded to the eloquence of thought and language." In other words: "Elocution is the art, or the act of fo delivering our own thoughts and fentiments, or the thoughts and fentiments of others, as not only to convey to thofe around us (with precifion, force, and harmony) the full

Strahan and Prefton,
New-ftreet Square, London,

purport and meaning of the words and fentences in which thofe thoughts are clothed; but, alfo, to excite and imprefs upon their minds, the feelings, the imaginations, and the paffions, by which thofe thoughts are dictated, or with which they fhould naturally be accompanied."

"Elocution, therefore, in its more ample and liberal fignification, is not confined to the mere exercife of the organs of fpeech. It embraces the whole theory and practice of the exterior demonftration of the inward workings of the mind." In fhort, "eloquence may be confidered as the foul, or animating principle of difcourfe; and is dependent on intellectual energy and intellectual attainments. Elocution is the embodying form, or reprefentative power; dependent on exterior accomplifhment, and cultivation of the organs. Oratory is the complicated and vital exiftence refulting from the perfect harmony and combination of the two."

The object, then, of the fcience of elocution is the improvement of oral language, as contradiftinguifhed from mere graphic compofition; and the cultivation of every external grace and accomplifhment with which the delivery of language fhould be accompanied, whether in reading, in recitation, or in fpontaneous utterance: an object, to the attainment of which the ancients devoted a very confiderable portion of attention; and for the due comprehenfion of which, it appears to be neceffary to go fomewhat deeper in our refearches into the phyfical and moral powers of man, than has been fufpected by the generality of modern profeffors; and inftead of calling in queftion, as fome recent cavillers have done, whether elocution is even to be regarded as an art, to eftablifh its doctrines on the fettled principles of fcience, and demonftrate the effential elements of that fcience as a branch of natural philofophy. To the want of this due confideration of the fubject, and to the incongruous maxims relative to it, are perhaps to be attributed not only the frequency of every fpecies of difgufting impediment in modern fpeech, but the lame and impotent ftate of public fpeaking among us, when compared in its effects with the fplendid and impreffive oratory of ancient times. "In thofe parts of oratory, indeed, which relate to the arrangements of thought, and the energies of expreffive language, there is no deficiency of exifting models; and, certainly, no paucity whatever of pedantic rules and treatifes. Cicero and Demofthenes ftill continue to fpeak to the eye, in all the eloquence of graphic words; and Quintilian and Blair (like two confpicuous luminaries, in the ancient and modern hemifpheres of oratorical criticifm) illumine the tracks of written language, and may help to inform us how orations fhould be compofed. In this part of oratory, the prefent and the preceding generation have, accordingly, fomething to boaft. But for the theory and practice of thofe impreffive exterior demonftrations with which the delivery of fuch orations fhould be accompanied, to what fyftems, or to what models can the Englifh ftudent appeal? In fhort, eloquence has been cultivated among us with confiderable diligence; but elocution has been fo much neglected, that the very nature of the fcience feems to be entirely forgotten; and the few fragments of antiquity that have defcended to us upon the fubject, are evidently mifunderftood by thofe who have pretended to comment upon them; and many of our moft learned critics have either ingenuoufly acknowledged, or unwarily betrayed, their total inability to comprehend fome of thofe very diftinctions moft indifpenfable to the expreffion and harmony of oratorical delivery: fuch, for example, as the mufical accents of fpeech, or inflections of the voice in the harmonic fcale; the proportions of refpondent founds and cadences, and the effential contradiftinctions of percuffion, accent, and quantity."

Such is the language of the lecturer already quoted; who, to refcue the elements of elocution from this ftate of neglect and chaos, and to facilitate the general attainment of an accomplifhment fo generally defirable, proceeds, in his "Introductory Difcourfe," thus curforily to ftate the extent and nature of the fubject.

"Elocution," fays he, "is, 1. Partly a fcience, founded on afcertainable principles, and fufceptible of palpable demonftrations; 2. Partly an art, attainable by imitative application and obfervance; and fubject to fuch laws as refult from comparifon of general principles with practical experience; and, 3. Partly an object of tafte and fentiment, dependent on acutenefs of perception, and delicacy and refinement of feeling.

1. "As a fcience its foundations are to be fought, 1ft. In phyfiology; that is to fay, in the anatomical ftructure of the elocutionary organs, and the laws of phyfical neceffity, by which their actions and reactions are directed and circumfcribed: fome knowledge of which feems to be indifpenfably requifite to the complete developement and exertion of their refpective powers; to the fupply of accidental and occafional deficiencies; and to the correction of thofe erroneous and defective modes of utterance, which, originating in negligent or vicious imitation, have ripened into habitual impediments. 2d. In mufic, the effential laws and accidents of which, with only one confpicuous exception;" the progrefs of the tune, in one inftance, being by flides or accentual inflections, "lifting the voice up and down in the mufical fcale;" and in the other, by afcertainable intervals and perceptible gradations; "are as applicable to elocution as to fong: all fluent and harmonious fpeech (even that of the moft eafy and familiar converfation) as neceffarily and as abfolutely falling into the rythmical divifion of mufical bars, and into the two generic meafures of common and of triple time, as the warblings of the moft fcientific finger on the ftage; while feveral of the impediments which moft ferioufly obftruct and deform the elocution of injudicious fpeakers, may be proved to originate in no other caufe than the violation of thefe mufical principles, and the confequent refiftance of thofe phyfical neceffities which limit the facilities of organic action, and with which the elementary principles of harmonic proportion fo admirably and fo myfterioufly conform. 3d. In philology, alfo, elocution hath a bafis, inafmuch as to the philofophy of the ftructure and compofition of language, and to the acute refearches of the etymologift, many of thofe difputed queftions of pronunciation, quantity, and percuffive accent, which have hitherto been furrendered to the arbitrary and fluctuating decifions of fafhion, ought, in reality, to be referred."

To which might have been added that the time of fpeech itfelf, is, or ought to be, a refult of philological perception: the quantities, emphafes, and inflections of fyllables, in all perfect fpeech, being dictated by the fenfe and import of fuch fyllables; either inherent in their original ftructure and individual fignification, or derivable from fentiment and affociation.

2. As an art, the laws of elocution are partly grammatical, as arifing out of the ftructure and arrangement of fentences, and the confequent degrees of connection and relationfhip between the different words and members and portions of the difcourfe to be pronounced; partly harmonic, as connected with the practical regulation of the variations and proportions of harmonic found, with which fuch difcourfe fhould be accompanied; and partly mechanical, or experimental,

mental, as relating to the motions and pofitions of the refpective organs, by which the varieties of vocal and enunciative expreffion are produced.

3. As a matter of tafte, elocution embraces the confideration of fuch peculiar habits of ftudy, deportment, and affociation, as are favourable to acutenefs and delicacy of fufceptibility, both in the intellectual and the organic fyftem, and give them their peculiar bias and direction. In this point of view, all the finer arts, and all the more intellectual accomplifhments conftitute effential parts of the ftudies of the finifhed elocutionift. He fhould have an *eye* for the glowing tints and flowing lines of picture, the proportions of architecture and the fymmetries of ftatuary; an *ear* for the ravifhing delights of mufic; a *perception* of the vital graces of look and attitude and motion, far beyond all that the dancing fchool and the opera houfe can teach; and a *foul* tremblingly alive to all the enthufiafm of poetry, and all the poignancy of fentiment and pathos.

In vindication of the claim of this fcience to fuch an ample field of illuftration and accomplifhment, an appeal may be made from modern maxims to the example of claffical antiquity, to the facts that ftand upon record, and the relics of ancient criticifm that yet remain: for although much in the outfet of the inquiry appeared to the lecturer in the light of original difcovery, further inveftigation, we are informed, "convinced him, that many of thofe doctrines, which he imagined to be new, are only "reftitutions of decayed intelligence:" and what has, in reality, been added to the treafures that well-directed labours might have redeemed from the overwhelmed ruins of claffical criticifm, is probably confined to the phyfiological parts of the fubject, and the connection attempted to be traced between the primary laws of phyfical action and re-action, and the elements of mufical proportion."

Thefe, however, conftitute a very effential portion of the fcience of elocution; and the ftudent of that fcience muft begin, in the firft inftance, by inveftigating the ftructure and offices of thofe organs upon which the functions of fpeech depend, which will be found to confift of two diftinct claffes, the feparate actions and attributes of which, it is highly important that the profeffor at leaft fhould accurately comprehend, left by miftaking the fource of the defects to be removed, he fhould neceffarily fail in the application of the remedy. Thefe are, 1, the vocal organs, or thofe portions of the organic fyftem employed by the human (or other animated) being in the production and variation of expreffive founds; and, 2, the enunciative organs, which, in the complication and perfection of their ftructure, are peculiar to man, and are employed in fuperadding to the founds of voice, certain other fpecific impulfes, conftituting thereby the elements and fyllables out of which are compofed the whole mechanifm of human language.

When, however, thefe two claffes of organs are faid to be diftinct, that word is not to be underftood in fo abfolute a fenfe, as to preclude the fuppofition of fome of them difcharging the two-fold office of modifying the tune and fuperadding the fpecific quality of literal element. The noftrils, for example, which conftitute a very effential part of the complicated organization that gives character to individual voices, are the chief implement employed in forming the elementary founds of *n*, *ng*, &c. while the teeth, and fome other parts of the mouth, principally employed in the formation of the characteriftic elements, have, alfo, a material operation in modifying the tone of the voice. The practical diftinction is, however, fufficiently evinced, by the feparate manifeftation of their effects: the tones and inflexions of voice being exhibited in the moft exquifite perfection by feveral fpecies of finging birds, who are deftitute of the organization requifite for fpeech, and fpeech itfelf being capable of proceeding, in the human fubject, in forcible whifpers, that is to fay, by the action of the enunciative organs on a mere ftream of breath, without accompaniment of any tone, or found of voice. Of this, however, more hereafter. See VOICE, ENUNCIATION, ORGANS of SPEECH, &c.

From the ftructure of the organs, the phyfiological enquirer is next conducted to a confideration of the laws of phyfical neceffity, under which the functions of thefe refpective organs are performed; and the mode of operation by which volition accommodates itfelf to the reftrictions inevitably impofed: an inveftigation which involves feveral topics of confiderable curiofity. From the fimple principle of pendulation (the primary and indifpenfible law of all reiterated action) are explained many of the effential phenomena of enunciative and vocal expreffion, as the trill of the R; the impracticability of *reiterating* identical elements, or pronouncing, in immediate fucceffion, certain elements clofely approximating in organic formation, without intervening paufes; the facilities of certain combinations of element, the difficulty of others, and, confequently, the phyfical caufes of euphony and cacophony; (fee EUPHONY, &c.) and, above all, the nature and caufes of thofe radical differences in the qualities of fucceffive fyllables fo well underftood (in practice, and effence at leaft, if not in caufe,) by the grammarians of Greece, and defignated by them under the terms *thefis* and *arfis*, but the total inapprehenfion of which has been the caufe of fo much confufion in the theories and embarraffment in the practical inftructions of modern profeffors. The leading dogmas of this fyftem are fo felf-evident, their application to organic as well as mechanic motion, and to the actions of the organs of fpeech in particular, fo demonftrable, and the coincidence of thefe actions with the phenomena of a certain alternate energy and remiffion in the procefs of verbal utterance fo apparent, that it is only aftonifhing how the principle itfelf fhould have remained fo long obfcured. But there is ftill room enough in the world of fcientific difcovery for other Columbufes to crack the heavy end of other eggs. But our bufinefs is an abftract, not a declamation. Thus then, it is contended, that action is of two kinds, continuous, or proceeding for a certain fpace of time, in a certain direction, from one original impulfe, as the flight of a dart by the impulfe of the bow, or of a ball from the explofion of a cannon, &c.; or reiterated and capable of unlimited continuity, from fucceffive impulfe, as in the pendulum of a clock, the motion of the legs in walking, &c. But fpeech is not a continuous action proceeding for a certain fpace in a certain direction from one original impulfe, like the flight of a dart, &c. but a feries of reiterated actions like thofe of the pendulum, or of walking, &c. though much more complicated and diverfified by variety of phenomena, and, for that end, by neceffary modification of impulfe. Still, however, fpeech is action, reiterated action, refulting from reiterated impulfe, and confequently fubject to the indifpenfible law of reiteration, namely, re-action, or alternation; for as the pendulum when it has made its full fwing in one direction muft re-act in the oppofite direction, before the primary action can be repeated; and as when one of the lower extremities has been advanced at full ftride before the body it muft either be drawn back again towards its former pofition, or, by a more complicated pendulation, the body muft advance upon the limb, and thus reftore the original poife to give the other extremity an opportunity of fimilar action, before the leg firft advanced can advance again; fo when the tongue, lip, or uvula have acted in any given direction for the formation of any given element, it muſt re-act ſilently or expreſſively either upon the primary, or in ſome new direction, before the ſame element can be repeated, or any other element, requiring a ſimilar line of action can be formed. And ſo, alſo, when the primary organ of cadential or ſyllabic impulſe (the cartilage that ſurrounds the larynx) has been once contracted for the impulſion of the more energetic note, a re-action of that organ, either ſilent or accompanied by another note of leſs energy, muſt take place before the contractile energy can be renewed. Hence are derivable all the phenomena that belong to, or are to be deſcribed under the denominations of *cadence*, *meaſure*, *rythmus*, *metrical feet*, and other diſtinctions ariſing out of thoſe radical and eſſential differences in the qualities of ſyllables, ſometimes deſcribed by the terms *accented* and *unaccented*, and ſometimes by the very ſame writers, in the very ſame page, denied the diſtinction of accentuation; and ſometimes, alſo, confounded with the *quantities*, and by the denominations, of *long* and *ſhort*, but with which moſt certainly, neither accent nor quantity have any thing whatever to do. (See ACCENT, MEASURE, RYTHMUS, PROSODY, METRICAL FEET, QUANTITY, &c. See, alſo, POISE, THESIS, and ARSIS, PULSATION, and REMISSION, &c.) Hence, alſo, will be found derivable (not from caprice, or taſte, or arbitrary invention, but from phyſical principles) the diſtribution of all vocal melodies (and thence by imitation of all other melodies) into the proportions and cadences of common and of triple time; (ſee TIME,) and hence ſome light perhaps may be thrown upon that curious and hitherto unfathomable queſtion, the cauſe of the excluſive ſatisfaction received by the human ear from ſounds that follow each other in thoſe definite and ſimple proportions.

Having laid theſe foundations of theory on the ſolid baſis of experiment, the elocutionary phyſiologiſt may proceed to practice, and the crown and pinnacle of his labours conſiſt in the expoſition of the nature and cauſes of the various impediments and imperfections of ſpeech; and in the application of the proper remedies applicable to thoſe defects, whether originating in organic deficiencies, or malconformations; or adopted from imitation, confirmed by the inveteracy of erroneous habit. (See IMPEDIMENT.) The practical part of elocution alſo neceſſarily includes all that relates to the education and management of the organs of ſpeech; the improvement of the expreſſive powers of voice and enunciation; the laws of inflection, proportion and harmony; and the graces and accompliſhments with which the delivery of ſpeech (whether original or imitative) ſhould naturally be accompanied; and by which its effects upon the heart, the judgment and the imagination may be heightened and confirmed. See PHYSIOGNOMICAL EXPRESSION, GESTICULATION, &c.

Such is the general outline of the ſcience of elocution, according to the only profeſſor of modern times, by whom the ſubject has ever been treated in a ſcientific point of view, and from the notes of whoſe public lectures this abſtract is principally furniſhed; a ſcience which, however neglected, deſerves (for its practical application at once to the nobleſt purpoſes of public exertion, and the moſt familiar gratifications of private life,) a conſiderable portion of the attention of thoſe who are entruſted with the education of youth. For if oratorical excellence be an object only to the few, yet that thoſe few ſhould have the means of cultivating thoſe parts of ſuch excellence which appear to be within reach of ſyſtematic tuition, is certainly highly deſirable; and (not to dwell upon the conſideration that it is not always practicable to foreſee, during the ſeaſon of early tuition, who ſhall, or who ſhall not, be among the number of that few to whom ſuch accompliſhment might be of primary importance) "ſome degree, at leaſt, of elocutionary accompliſhment is certainly deſirable by all. There are few, indeed, to whom it would not be advantageous (at leaſt in point of mental gratification) to be able to read, with emphaſis and harmony, the fine paſſages of our poets, or the inſtructive and elegant compoſitions of our hiſtorians, moraliſts, and amuſive writers:— There is, perhaps, ſcarcely any individual who has not, occaſionally, experienced the advantage of delivering what he had to ſay with correctneſs, eaſe, and impreſſiveneſs; or (lacking this accompliſhment) who has not felt the diſadvantages reſulting from ſuch defect. Even in the ſocial intercourſes of private life, how great are the benefits of this attainment! How does it multiply the ſources of innocent pleaſure! What a zeſt does it impart to the higheſt, though moſt familiar, of our intellectual gratifications!"

"Fortunately for mankind," continues Mr. Thelwall, "this accompliſhment, ſo univerſally to be deſired, needs never to be deſired in vain. With thoſe exceptions only, which reſult from deafneſs, or from mental imbecility, I ſhall, I think, demonſtrate, that (by no greater ſacrifice of time and effort than is uſually devoted to leſs important ſciences and much more frivolous accompliſhments) correct and impreſſive elocution is attainable by all." He admits, however, "that hitherto, at leaſt, the inſtances of ſuch attainment have been exceedingly rare; that few are the Engliſhmen who converſe with fluency and impreſſive grace; and fewer ſtill who can read with tolerable harmony and propriety. Even in our churches, the ſublimeſt paſſages loſe their impreſſiveneſs from the imperfect manner in which they are delivered; and thoſe very preachers who are moſt accompliſhed in every other particular, too frequently obſcure, by the wretchedneſs of their elocution, the eloquent diſcourſes they compoſe.

"But the cauſes of this it is not difficult to diſcover. We trace them, at once, in the almoſt univerſal neglect of this important branch of education. Even of the profeſſed teachers, in this department, where is the individual who has properly explored the extent, or the principles of the ſcience, or who has even ſuſpected that ſcience had any thing to do with the ſubject? It has almoſt been queſtioned whether elocution were even an art? Excellence has been regarded as the mere myſterious gift of nature or of fortune —as the original and unſolicited diſpenſation of a partial providence; which no education could ſecure, and which ſtudy and application were ſcarcely neceſſary to improve. With reſpect to the conſtituents of that excellence, mere taſte and preſentiment have been regarded as the only arbiters; the very laws of inflection and poportion have been denied all foundation and exiſtence in the utterance of modern ſpeech; and pronunciation, tone, and melody, and even the conſtituent requiſite of percuſſive accent, (upon which the individuality, the character and the force of ſpoken words eſſentially depend,) have been abandoned to the lawleſs rule of faſhion and caprice." Introductory Diſcourſe on the Nature and Objects of Elocutionary Science.

Elocution has by many been conſidered as contradiſtinguiſhable into three ſeveral kinds, reading, recitation, and ſpontaneous ſpeech; and ſome profeſſors have marked theſe diſtinctions ſo abſolutely, as to preſcribe different ſtyles of utterance, both in vocal and enunciative expreſſion, to the reader and the reciter, from thoſe which they regard as belonging to the unpremeditative ſpeaker. Mr. Cockin, in particular, in an ingenious diſſertation (publiſhed without his name, 1775) on "The Art of Delivering written Language," has maintained this hypotheſis; and has diſcuſſed the ſubject of theſe ſuppoſed differences under the reſpective five heads of accent, emphasis, modulation, expression, (of voice as well as gesture,) and pauses; for the latter four of which, see hereafter under their respective titles. This work, we are informed in the dedication, was altogether approved by Mr. Garrick, who assured the author "that the doctrine laid down in that essay agreed exactly with his own sentiments." The popular axiom, however, "read exactly as you would speak," (supposing it addressed to a good speaker,) seems, in its principle, to be a rule much more rational than any thing that even the ingenuity of Mr. Cockin, though applauded by Mr. Garrick, has been able to adduce. It is objectionable, indeed, on account of its impracticability; pointing out a degree of perfection that was never yet attained, nor ever will be, till perfection in other arts and accomplishments shall be attained also. But the principle is not, therefore, the less valuable; the models of perfection must not be discarded from our minds, because art could never yet completely realize them: and although there are impediments, perhaps insurmountable, in the way of giving either to reading or recitation all the ease, the grace, and the vitality of spontaneous speech, yet, in principle, they should assuredly be the same; for reading and recitation are only two different modes of imitating that nature, which spontaneous speaking exhibits in her original reality; and the imitation ought to be so much the more perfect and exact, as, in this instance, the artist has the exclusive advantage of operating not only on the model, but with the very materials which nature herself employs in her creations. Mr. C., however, contends, "that reading does not receive any of its beauties from the principles of imitation, being no copy, but only another kind of speech." That, generally speaking, it is so, cannot be denied: but it is so far from unquestionable that it ought to be so, that this may be perhaps assigned as the genuine reason why the *reading* even of those very persons produces only sleep, whose unpremeditated *speaking*, is the delight of all ears; and why lectures never interest the auditors, like spontaneous harangues.

There are, however, certain particulars of essential distinction in the practical facilities; and even capabilities of excellence, in reading, recitation, and original speech, which the student of elocution ought to understand, as thereby each may perhaps be brought somewhat nearer to perfection than can be expected without the due consideration of these circumstances. Thus, for example, spontaneous speech, springing immediately from the inspiration of feeling, with all the freshness and glow of original conception, is capable of a degree of warmth, ease, and flowing energy, which can belong only to first impressions and unpremeditated language. From this very circumstance, however, it is incapable of all the smoothness, proportion, and harmony, which a minute attention to euphony, construction, rythmus, and quantity, may enable the reader and reciter to accomplish. The reader, on the contrary, who finds the language ready polished to his hands, and sees it spread out before him, has leisure for full attention to all the minutiæ of rythmical cadence; and if his ear be good, his perceptions acute, and his notions of the principles of elocutionary harmony correct, he may certainly attain a degree of perfection of utterance, in what relates to mere proportion and melody, which none but the reader must expect. But then, on the other hand, the reader (especially he who reads at sight; and if he has previously studied, he becomes, in a certain degree, a *reciter*,) pronounces what he reads, not with the feelings of an originator, or imparter, but with the feelings of a recipient; his mind is passive while his organs only are active: hence, inevitably, a certain degree of coldness and unnatural restraint. The reciter partakes of the advantages and disadvantages of both; and he has both advantages and disadvantages peculiar to himself. If what he should repeat be completely in his memory, he makes it, to a certain degree, his own, and may *approximate* to the ease of the spontaneous speaker, and the smooth melody of the accomplished reader, though he can never completely attain the unsophisticated warmth and vitality of the former, or the complete rythmus and nicely measured pauses of the latter. At the same time, by repeated experiment, he may have adjusted his tones and attitudes, and the expressions of his countenance, more completely to the sentiment and passion of the passages he is to deliver than the reader could possibly have done, and have accommodated them more completely to the rules and principles of grace, than is practicable to the spontaneous speaker: but what he gains in force and propriety he is in danger of losing in simplicity; and the mere reciter, however excellent, is more likely to extort applause than to awaken the genuine sympathies of the soul. From this view of the subject, the lecturer already cited concludes, that though the principles of English elocution, fundamentally considered, are the same, to which soever of these three modes of utterance they may be applied, yet the practical excellencies and obvious difficulties of each being peculiar, the student of elocution, whatever department be his ultimate object, should practise in all three, since reader, reciter, and spontaneous speaker, have each something to learn, from the other two, for the full accomplishment of his own particular branch of the art.

Another and more rational division of the art of elocution may be made from a consideration of the subjects to which it is applied, or the circumstances under which it is exercised. According to this principle, elocution may be considered as distinguishable into the following kinds, 1. The conversational; 2. The narrative; 3. The didactic; 4. The authoritative or judicial; 5. The argumentative; 6. The persuasive; 7. The declamatory and impassioned; relative to each of which some general rules may be laid down both with respect to voice and enunciation: as that in the first, the enunciation should be easy and familiar the tone simple, the inflection limited, and the pitch of the voice but just so far beyond a whisper as to render it tuneable. In the second, the enunciation, though exceedingly simple, should be somewhat more precise and emphatic; the tone clear, unostentatious, and impressive; level, but not monotonous. In the third, both tone and enunciation should be strong, firm, and emphatic; which in the authoritative and judicial should swell to something like pomp, mingled with a degree of firmness that in effect should border on austerity, and with respect to modulation, almost on monotony. In the argumentative, clearness of voice and perspicuity of enunciation are the principal objects. In the persuasive, the tones should be mild, insinuative, and pathetic, the pronunciation remote alike from the affectation of sonorousness and of precision. In this, indeed, as in the seventh and last description of elocution, the enunciation should rather be subservient to the tone, (that is to say, to the feelings,) than the tone to the enunciation, as the object of the speaker is rather to be understood by the heart than by the understanding. In subjects and passages of strong passion and emotion, the enunciation should be occasionally accelerated and retarded; apparently wild and irregular, but obedient always to the changes of passion and sentiment; the modulation extensively varied, and the voice ranging through great varieties of softness, force, and vehemence, of acuteness and gravity, and the whole compass of expressive or reflective intonation.

The four great schools of elocution, or rather the four great

great theatres for the exhibition of that talent, are, the bar, the pulpit, the fenate, and the ftage; and before we take leave of the fubject, fomething ought to be faid on each of thefe. We fhall confider them, therefore, in their alphabetic order.

Elocution of the Bar.—The ftyle of elocution adapted to this profeffion, will beft be underftood by confidering the objects to which the eloquence of the bar is principally to be directed. Thefe are, 1. To demonftrate, by the elucidation of evidence, difputed facts; 2. To convince, by arguments, the doubtful judgment; 3. To influence by perfuafion, or controul by declamation, the paffions, the fympathies and moral feelings of thofe upon whom the decifion of a caufe may depend. For the firft of thefe, we require an elocution diftinguifhed by impreffive diftinctnefs, an unaffected deliberation, and collected coolnefs; an enunciation precife without formality, at once terfe and familiar; a deportment candid, firm, and unaffuming. For the fecond, we demand an emphatic perfpicuity; an air of decifive, but modeft confidence; an ardour not impetuous, but chaftened and reftrained, by all the decorums of circumftance and fituation. For the laft, the nobleft, and moft arduous of all the exertions of forenfic eloquence, are required, a range of elocutionary expreffion, as various as the paffions and emotions to be commanded; an infinuating mildnefs, a melting or a kindling pathos; the tone, the look, the whole manner, gefticulation and deportment, fhould occafionally affume the entire range of expreffive variety, from the moft conciliating fympathy to the deepeft folemnity, and even, perhaps, on fome occafions to intimidating boldnefs. The occafions, indeed, on which all that is here demanded can with propriety be exerted by the forenfic orator, may but rarely occur; but when they do occur, the opportunities are decifive, and the reputation of the pleader, who is fully qualified to avail himfelf of them, is ftamped for ever.

Elocution of the Pulpit.—The objects of clerical eloquence have been oratorically thus enumerated, "to inform the underftanding even of the inapprehenfive; to aroufe the flumbering confcience; to regulate the moral feelings; to reftore the focial fympathies, which the difparities of fortune have but too much tendency to fufpend; to reftrain the fury of ambition, and check the mad career of voluptuous prodigality; to unlock the iron grafp of avarice, and expand the liberal palm to deeds of charity; to humble the towering infolence of pride, and difarm the uplifted hand of oppreffion and revenge; to infufe the fpirit of benevolence into the heart of unfeeling obduracy; to breathe the facred love of peace into the bofoms of the turbulent, and the mild fpirit of forbearance and toleration into the foul of perfecuting bigotry and prejudice." How far all thefe objects are, practically, in the contemplation of every orator of the pulpit, this is no place to difcufs; but if fuch be, in reality, among the proper objects of pulpit eloquence, it is obvious that all, and more than all, that we have demanded for the elocution of the bar, is requifite in this fpecies of elocution alfo. Among the indifpenfible requifites of fuch elocution, are a familiar fimplicity, infinuative and endearing; an impreffive energy, ftimulative and aroufing; a pathos varied, characteriftic, and defcriptive; and a fublimity awful, elevating, and commanding. A mingled folemnity and enthufiafm fhould occafionally give an air of infpiration to the preacher, and his pronunciation, and all the particulars of utterance properly included in the term enunciation, fhould be full, fonorous, and oratorical, rather than loofe and colloquial. At the fame time, nothing is more to be avoided than any overmarked peculiarity or affectation, or than the vulgar vehemence, the bawling and vociferation, which are fometimes miftaken for energy and oratorical animation.

The modes of elocution in this profeffion, are thofe of reading, as applied to portions of the fcriptures, or to fet forms of worfhip; of fermon, which may be either read, (according to the general cuftom of the church of England,) recited, (as is ufual among the preachers of the church of Scotland,) or delivered fpontaneoufly, (that is to fay, from notes or reflections previoufly digefted, without actual compofition,) as has been recommended by bifhop Burnet, and as is practifed by fome of our feparatifts, and even by a very fmall number of our regular clergy; and of prayer. Of the firft of thefe, it is only neceffary to fay, that the only circumftance in which it fhould differ from any other fpecies of reading, feems to be, that it fhould be rather more folemn, and deliberate, from refpect to the place and the occafion to which it is accommodated. In all kinds of reading, the ftyle of elocution fhould accord with the fubject, the tone and manner fhould harmonize with the language and fentiment; and as the fubjects of fcriptural and devotional reading are fo exceedingly diverfified, it follows as a confequence, that the ftyle of the reader fhould be diverfified as widely; and that nothing can be more inconfiftent with the objects of clerical elocution than monotony. With refpect to the three modes of delivering a fermon, this is not the place for difcuffing their refpective claims of preference; and what has been already faid of the application of the fame common principles to reading, recitation, and fpontaneous fpeech, and the different kinds of excellence moft attainable in each, precludes the neceffity of particular rules for them refpectively. In prayer, a folemn proftration of manner, with a confiderable mixture of enthufiafm, feems particularly required; and an efpecial avoidance of all thofe odd tricks and peculiarities, into which minifters are fo apt to fall. But the further confideration of this fubject belongs, properly, to the title Gesture.

Elocution of the Senate.—As the eloquence of the fenate is partly deliberative, partly controverfial, and partly declamatory, it requires an elocution uniting almoft all the principal requifites enumerated under the two preceding heads; and it admits, and even occafionally demands, a more impetuous warmth, a more rapid and vehement emotion, than in either of the former inftances could be at all decorous. The fermons of Maffillon might require, or, at leaft, their effect might be heightened by a denunciative feverity, an awful aufterity of manner, that fhould imprefs his audience with all the ideas and feelings of a fupernatural agency; and under fuch circumftances the oratory of the pulpit might feem to have been carried, even above the heights, and beyond the force of fenatorial and popular oratory; but it is in the fenate alone, and the popular affemblies of the nation, that the orator is to hurry away the impetuous paffions, and tranfport the hearer into abfolute action; and there only are, of courfe, required the full thunders of elocutionary energy. But it is not only in the fervid tones of an impetuous declamation, that the fenatorial elocutionift fhould excel; in the calm dignity of a well modulated cadence, and the polifhed grace and propriety of enunciation, he fhould alfo furpafs; and in the eafy urbanity of tone and euphony (when the ftronger exertions of eloquence are not required) he fhould manifeft, at once, the dignity of the ftatefman, and the elegance and refinement of the polite fcholar. How little thefe circumftances, (almoft all of them within the reach of a well directed education,) are attended to, is but too generally known; and in the humble ftate of modern oratory (as judged by its effects) the confequences may but too well be difcovered.

Elocution of the Stage.—The critical object of theatrical reprefentation is *imitation.* Its excellence is *verifimilitude.* It is a moving picture, that exhibits founds as well as objects,

jects, and a part of whose pigments are the tones of the human voice. Its elocution, therefore, should be that of Nature—Nature in her highest perfection. Ideal nature, if you please; superior, in perfection, to any thing that individual nature ever exhibited, but in principle nothing deviating from unsophisticated reality. The harmony may be more perfect, the intonation something more diversified, the inflection and range of the voice rather more extensive, the utterance a little more emphatic, and some other graces and observances may be carried a degree further than ever was observable (or perhaps practicable) in spontaneous speech and real life; but still that spontaneity and reality must be the models; and the elocution, in all essential particulars, that would be unfit for the bar, the pulpit, or the popular assembly (so far as the difference does not arise out of the different sentiments to be expressed and passions to be indulged or excited) is unfit for the stage also. It should be remembered, however, that the drama deals in the *extremes* of passion and emotion; that its moral requires that it should exhibit those passions bursting all bonds of decorum, and triumphing over the restraints of reason. The player has frequently to exhibit the judgment under the domination of passions; and is even to represent the full malignity of the worst, as well as the imprudent excesses of the best passions of our nature; while the passions of the orator are always, in reality, (though not always in appearance,) to be under the controul of his judgment; and all the malignant and evil passions are to be suppressed, or kept out of sight, any otherwise than as they may be *mentioned*, or alluded to, in moral reprehension. Hence even the simplicity and truth of principle may, and must produce, occasionally, much apparent difference of effect; and the same exercise of judgment (for the judgment of the player must, in reality, still be paramount over his passion, though he be exhibiting the very reverse) that leads the orator, to temper and qualify, may induce the actor, to exaggerate the passion. It is in these exaggerations, however, that the art and mastery of the performer are most severely tried, and taste and judgment are alike imperiously requisite. They are necessary undoubtedly to the perfection of his art; yet the instant the exaggeration is apparent, disgust begins;—the instant the vulgar feeling of wonder is excited, the tragedian sinks to a level with the rope dancer; and many a time ought he to be overwhelmed with confusion, by those very plaudits to the attainment of which he has sacrificed all the finer touches of nature that might have secured the genuine applause of sympathy and emotion. But fully to attain, or even distinctly to comprehend, the higher excellencies of theatrical elocution, requires a very different course of preparation and study from what generally falls to the destiny, or enters into the apprehensions of the professors of this art. It is not in the science of the green room, the library of the prompter, and the technical knowledge of stage trick, to make a finished actor. To deliver language well, it is necessary fully to comprehend it, not loosely and colloquially merely, but grammatically, etymologically, and sympathetically; to detect the nicest shades of allusion and discrimination, and enter into the sentiment of the author; to realize the passion, where passion is, and the character, where the composition is characteristic. To excel in any species of elocution, therefore, demands some knowledge of general literature; to be a master of that elocution that should illustrate the fine passages of Shakespeare, will require a knowledge of our language which, fully possessed, would entitle the elocutionist to the rare and valuable character of an *English scholar*. But the sources of human passion must be studied also; human nature must be known, in the general, and in the particular, in all ranks and conditions, and under all circumstances and associations. The perceptions must be diligently cultivated; the discriminative powers must be well exercised; feeling, keen, vigorous, varied feeling, must be cherished; and the imagination must be perpetually at work. For the developement of the flexible powers of the voice, no pains well directed can be too elaborate, and the mind should comprehend, and the ear should perceive the delicacies and varieties of rythmus, with all the subtile nicety of a poet. The actor so qualified will discard from his elocution all the pedantries alike of the convent and of the green room; all professional affections and prescriptive peculiarities; he will copy nature in such a style, that nature in her turn will copy him; and like the great actors of Greece and Rome, he will be worthy to give, while he receives, instructions to another Cicero or Demosthenes.

ELODES, in *Botany*, Adanson 444. (Elodea; Juss. 255.) A genus formed by Adanson of the *Hypericum Ægyptiacum* of Linnæus, on account of an oblong scale or appendage to the claw of each petal, considered by Linnæus as a sort of nectary, to which opinion he was probably led by the analogy of the nectariferous glands in his own *Hypericum Elodes*. We see no reason to separate the above plant from *Hypericum*, nor does Jussieu more than hint at the measure. See HYPERICUM.

ELODES is also used among the ancient writers in *Medicine*, for a species of fever, attended with profuse sweats.

ELOGIUM, ELOGE, a praise, or panegyric, bestowed on any person or thing, in consideration of its merit.

The word is Latin, but formed of the Greek ευλογια, *commendation;* which is compounded of ευ, *well*, and λεγω, *to say*, or *speak*.

The secretary of the Royal Academy of Sciences at Paris formerly composed the eloges of such members as died; and delivered them at the next public meeting of the company. Funeral orations are eloges of eminent persons deceased.

Extravagant and improbable eloges are of the greatest dis-service to their own design; and do, in effect, diminish the person whom they pretend to magnify, and degrade him whom they profess to exalt. Any worthy man may pass through the world, unquestioned and safe, with a moderate recommendation: but when he is set off and bedaubed with rhetoric, and embroidered so thick, that you cannot discern the ground, it awakens naturally (and not altogether unjustly) interest, curiosity, and envy; for all men pretend a share in reputation, and love not to see it engrossed, or monopolized; and are therefore apt to enquire (as of great estates suddenly got) whether the person so commended, came honestly by it, and of what credit the person is that tells the story.

ELOHA, in *Scripture*, the singular of Elohi, one of the names of God. See ELOHI.

ELOHI, ELOI, or ELOHIM, one of the names of God. But it is to be observed, that angels, princes, great men, judges, and even false gods, are sometimes called by this name. The connection of the discourse assists us in judging rightly concerning the true meaning of this word. It is the same as Eloha; one is the singular, the other the plural. Nevertheless, Elohim is often construed in the singular number, particularly when the true God is spoken of; but when false gods are spoken of, it is construed rather in the plural. Calmet, Diction. Bibl. See JEHOVAH.

ELOI. See ELOHI.

ELOIGNED, in *Law*. See ELONGATA and ELONGATUS.

ELOINE, signifies to remove, or send a great way off. Thus it is said, if such as be within age be eloined, so that they cannot come to sue personally, their next friends shall be admitted to sue for them. Stat. 13 Ed. I. cap. 15.

ELOME, a name given by ſome authors to orpiment.

ELON, in *Ancient Geography*, a town of Paleſtine, in the tribe of Dan. Joſh. xix. 43.

ELONGATA, in *Law*, is a return of the ſheriff, that cattle are not to be found, or removed, ſo that he cannot make deliverance in replevin. 2 Lil.-Abr. 454. 458.

ELONGATION, in *Aſtronomy*, The angle, under which we ſee the diſtance of a planet from the ſun, reduced to the ecliptic.

Let S T (*Plate* XII. *Aſtronomy, fig.* 104.) be the diſtance of the ſun from the earth, S L the curtate diſtance of the planet from the ſun, the angle T S L equal to the difference of longitude of the planet P and earth T ſeen from the ſun, called the commutation; the reſolution of the triangle T S L, in which the two ſides and contained angle are given, will give the angle at the earth S T L, called the elongation, and this being taken from the longitude of the ſun, if the planet is to the eaſt, or right of the ſun, will give the geocentric longitude of the planet.

The triangle S L T may be reſolved by the following rule: the leaſt ſide is to the greateſt as radius is to the tangent of an angle, from which 45° muſt be taken. The tangent of the remainder, multiplied by the tangent of half the ſum of the unknown angles, gives the tangent of half their difference, which muſt be added to or ſubtracted from the half ſum to trace the angle of elongation. This angle is the leaſt of the unknown angles in the caſe of an inferior planet when the half difference muſt be ſubtracted; it is the greateſt for a ſuperior planet when it muſt be added.

It is ſometimes uſeful to recollect the following proportions.

The ſine of the commutation is to the ſine of the elongation as the tangent of the heliocentric latitude is to the tangent of the geocentric latitude.

The ſine of the elongation is to the ſine of the commutation as the curtate diſtance of the planet from the ſun is to the curtate diſtance of the planet from the earth.

It is at the time of the greateſt elongations of the inferior planets Mercury and Venus, that they are uſually ſeen to the greateſt advantage. The greateſt elongation of Venus was, according to Ptolemy, from 45° 25″ to 47° 35′, and that of Mercury between 16° 8′ and 28° 37′. According to our modern tables theſe numbers are, for Venus 44° 57′ to 47° 48′, and for Mercury 17° 36′ to 28° 20′.

Elongation is alſo uſed, by ſome authors, for the difference in motion, between the ſwifteſt and the sloweſt of two planets; or the quantity of ſpace, whereby the one has overgone the other; called alſo *ſuperation*.

The ſwifteſt motion of the moon, with regard to the ſun, is called the elongation of the moon from the ſun. We alſo ſay diurnal elongation, horary elongation, &c.

Elongation, as it relates to *Fortification*, is a term uſed to expreſs that deviation from the immediately regular conſtruction, which is derived from a polygon formed upon a circle, to one formed upon an ellipſis, or oval: when this happens, only two of the faces retain that conſtruction and proportion which would appertain to the reſpective circles of which they would each form a part. In this we conſider the ellipſis in queſtion to be drawn upon two circles, and having a line paſſing through both their centres, as well as through the centres of the two retained faces; which neceſſarily are parallel. The two ſides, or *elongated* arcs of the ellipſis, may be divided into any number of faces, according to the extent of the area incloſed; they are uſually on the ſcale of the *greater* ſyſtem, while the ends are on the ſcale of the mean ſyſtem. Sometimes the elongation muſt be made ſo as to occupy a great extent of front; in which caſe it may become expedient to throw forth a crown-work from the centre of the *elongated* arc, or line, in order to prevent the enemy from occupying any part of the eſplanade ſufficiently near to batter thoſe works which may be rather weak for want of a flanking fire ſufficiently powerful to impede the beſiegers. Theſe crown-works anſwer much the ſame purpoſe as advanced redoubts in front of a line of entrenchments, and ſcour the whole advance ſo completely, enfilading the aſſailants, as to render it peremptorily neceſſary to become maſters of them before the lines can be carried. This will ſhew not only their ability, but the abſolute neceſſity for conſtructing all ſuch advanced defences, in that ſcientific manner which may render them untenable by the enemy, after being poſſeſſed by them, as well as perfectly incompetent to make any impreſſion on the intrenchments, which would command them *in reverſe*, that is, in their rear, and compel the enemy to quit. Crown-works being on a more important ſcale, require that every attention ſhould be paid that their batteries ſhould not bear upon any of the main defences.

The foregoing relates to regular works: for the irregular we have ſcarcely any thing like a defined rule; but it muſt always be held in mind, that the more the defences are elongated, the more they will require additional ſupport, either from various lines of fortification one within the other, or from detached works, ſo ſituated as to defend the weaker parts. This neceſſity ariſes chiefly from the ſaliant angles being rarely allowed to fall within 90°, leſt they ſhould plonge upon ſome other parts of the defences; whereas in all works formed upon a pentagon, hexagon, heptagon, or even an octagon, the angles of the baſtions may be conſiderably reduced, and the ravelines equally ſo; it is owing to this that fortreſſes, on a large ſcale, not only admit, but require, numerous additional defences to fill up the ſeveral intervals between the exterior ſaliant angles, or extremes of the defences, but to prevent the enemy from occupying poſitions favourable to their views.

We do not term works conſtructed in an irregular manner along the ſhores of a bay, or around a peninſula, *elongated*; they may be carried for miles without coming under that deſignation; it is only when a line of defence, and particularly fortifications, forming a figure either perfectly regular, or nearly ſo, are in every particular part extended, for the purpoſe of embracing more ſpace, or conforming to any particular local circumſtance, that we conſider the term *elongation* to be applicable.

In *Tactics*, the term implies ſuch an extenſion of the front as is produced artificially, without the aid of reinforcements. Thus, we draw up troops only two, inſtead of three, deep, for the purpoſe of elongating our front; which conſequently thus becomes extended to half as much more as it formerly occupied in length. This is often neceſſary, but it certainly weakens the fire and the reſiſtance throughout; beſides, it prevents the caſualties in the front from being ſo readily filled up, and is apt to leave gaps, or openings, through which the enemy's cavalry may make a charge.

Where it is abſolutely neceſſary to retain a very firm front, yet to extend it ſo far as local means may allow, eſpecially where it is principally intended to repel the enemy's horſe, thoſe parts of the line which may be moſt expoſed by the evenneſs of the ground, &c. ought to be blocked by *abbatis*, that is, timber felled and laid in ſuch a manner as ſhould obſtruct the paſſage of cavalry; behind theſe a few men ſhould be diſperſed to prick off any of the aſſailants who ſhould attempt to cut an opening, or to drag away the trees, ſo as to obtain admiſſion. Frequently trees can be cut down, but cannot be drawn away to any chofen fpot: in fuch cafe, their trunks and principal branches may be left, while their leffer boughs may be cut into ftakes and palifades for the defence of other parts. The line will of courfe be elongated by fuch devices, while the more expofed parts may retain their effective ftrength. Where a convoy is in queftion, and that the attack upon it can be made only upon one long front, which cannot be entirely covered by the waggons, &c. then, placing the artillery in the moft commanding fituations, the infantry muft be ranged in fuch manner as may *elongate* the defences, and keep the enemy in check. This will be peculiarly neceffary where a neighbouring height muft be cut off from the enemy's poffeffion, though it could not be occupied by the defenders of the convoy without weakening and dividing them.

The elongation of an attack, is where only a fmall front is fhewn at firft, but is gradually extended fo as to embrace a greater portion of the defences: thus, when after opening a battery upon a baftion only, other batteries are made to bear upon the curtain almoft parallel thereto; in fuch cafe, we fuppofe only a bridge-head, or a *fleche* to exift, but no raveline. Likewife, when a column of infantry bearing down upon, and menacing only one particular point, fuddenly deploys, and acts upon a greater extent of line, the attack is faid to be *elongated*. But, in either cafe, the term does not apply to any additional force brought to act on the fame point; it relates to extenfion merely.

Elongation, in *Surgery*, is an imperfect luxation; when the ligament of any joint is fo extended, or relaxed, as to lengthen the limb, but yet not to let the bone go quite out of its place. See Luxation.

ELONGATUS, Eloigned, a return of the fheriff that a perfon is conveyed out of his jurifdiction. See writ *de* Homine Replegiando.

ELOPEMENT, in *Law*, is when a married woman, of her own accord, departs from her hufband, and dwells with an adulterer; for which, without voluntary reconcilement to the hufband, fhe fhall lofe her dowry; nor fhall the hufband, in fuch cafe, be compelled to allow her any alimony. Stat. Weftm. 2. 13 Edw. I. c. 34. See Divorce and Dower.

"Sponte virum mulier fugiens, & adultera facta,
Dote fua careat, nifi fponfo fponte retracta."

The word is formed from the Belgic, *Ee*, matrimony, and *loopen*, to run away.

However, mere advertifing a wife in the Gazette, or other public papers, is not a legal notice to perfons in general not to truft her; though a perfonal notice given by the hufband to particular perfons is faid to be good. An action lies, and large damages are ufually given, againft a perfon for carrying away, and detaining another man's wife. See Forcible *Abduction* and Ravishment.

ELOPS, in *Ichthyology*, a genus of abdominal fifhes, the character of which, according to the Linnæan fyftem, confifts in having the head fmooth; edges of the jaws and palate rough with teeth; gill-membrane with thirty rays, and armed on the outfide in the middle with five teeth.

The genus elops is defined by Bloch as having the gill-membrane furnifhed with more than thirty rays, (fpecimens he examined exhibiting thirty-four,) and Bofc admits there fhould not be lefs than thirty to conftitute the genus. Bloch confiders the bony fhield or plate beneath the chin, and the dorfal fin being placed oppofite the ventral, as effential characters of the genus.

The only fpecies of this genus at prefent known is the Linnæan elops faurus; le lézard of the French writers. Perhaps the earlieft defcriber of this fifh is fir Hans Sloane, who, in the fecond volume of his hiftory of Jamaica, gives a figure and detailed defcription. He fpeaks of it under the name of faurus maximus, and acquaints us that it is called in Jamaica the fein-fifh, or fea gally-wafp. "This fifh (he obferves) was about fourteen inches long, in the middle five inches round, and tapering to both ends; the mouth in both jaws had one row of fmall fharp teeth, and on the upper two more within, parallel to them, and a row of the fame on the upper part of the cartilaginous tongue; three quarters of an inch from the end of the fnout were the eyes, round, and grey; there were two *pinnæ poft branchias*, two under the belly, one on the middle of the back, *poft anum* another, and a forked tail; it was all over fcaly, the back of a dark brown, and the belly of a white colour." The fpecies is found in various parts of the American feas; it was met with by Dr. Garden about Carolina, and communicated by him to Linnæus. The ftrong fpine at each fide of the tail is confidered as a fpecifical diftinction of elops faurus by Linnæus, Gmelin, and others, but this muft obvioufly remain a very doubtful character till another fpecies at leaft of the fame genus be difcovered in order to afcertain whether fuch fpines be not characteriftic of the genus inftead of the fpecies.

It has been obferved by writers that elops faurus bears fome refemblance to a pike, or rather to a falmon; with the former it has no kind of affinity whatever, but on the contrary it is fo clofely allied to the falmo tribe that were it not from being deftitute of the flefhy raylefs fin, fo uniformly obfervable on the lower part of the back in the falmon kind, we fhould be almoft induced to refer it to that genus.

The head of elops faurus is without fcales. The lower jaw rather longer than the upper. Both jaws, together with the tongue and palate, are armed with a vaft number of fmall teeth. The eyes nearly vertical; the irides double, the inner one yellow, exterior red, and the pupil black; and the eyes partly covered with the fkin of the head. The body of this fifh is flender, and the fcales large; the head yellowifh, back blueifh, fides filvery. The lateral line is ftraight. All the fins brownifh; the exterior half of the pectoral fin, anterior part of the dorfal fin, and extremity of the tail blueifh. The tail is much furcated, and divided in the middle by a diftinct longitudinal ftripe of black.

Elops, Ελοψ, in *Zoology*, the name of a ferpent, otherwife called elaps.

ELOQUENCE, the art of fpeaking or writing well, fo as to move and perfuade. The term, however, in its greateft latitude, denotes that art or talent, by which the difcourfe is adapted to its end; "Dicere fecundum virtutem orationis. Scientia bene dicendi." Quintilian. In common converfation, however, the word eloquence is feldom ufed in fuch a comprehenfive fenfe. But this definition exactly correfponds to Tully's idea of a perfect orator; "Optimus eft orator qui dicendo animos audientium et docet, et delectat, et permovet." Accordingly all the ends of fpeaking are reducible to four; every difcourfe or fpeech being intended to enlighten the underftanding, to pleafe the imagination, to move the paffions, or to influence the will. When a fpeaker addreffes himfelf to the underftanding his aim is to inform, and to convince, for the former of which purpofes the predominant quality is perfpicuity, and for the attainment of the latter, argument. By the firft we are made to know, and by the fecond to believe. The imagination is addreffed, by exhibiting to it a lively and beautiful reprefentation of a fuitable object. As in this exhibition, the tafk of the orator may be faid to refemble that of the painter, which confifts in imitation, the merit of the performance refults entirely from the two following fources, *viz.* dignity, as well in the fubject, or thing imitated, as in the manner of imitation, and refemblance, in the portrait or performance. This addrefs attains the fummit of perfection in the *fublime*, (which fee,) or thofe great and noble images, which, prefented to the mind in fuitable colouring, expand, as it were, the imagination with fome vaft conception, and quite ravifh the foul. The characteriftic of the third fpecies of difcourfe, or that which is addreffed to the paffions, is the *pathetic.* (See Passions and Pathos.) But the moft complex and moft important of all the kinds of eloquence is that which is calculated to influence the will and to perfuade to a certain courfe of conduct. This is an artful mixture, of that which propofes to convince the judgment, and of that which interefts the paffions; and its diftinguifhing excellence refults from thefe two, the argumentative and the pathetic duly blended. Thefe, combining their force and acting in concert, conftitute that *vehemence* of addrefs, which is admirably fitted for perfuafion, and has always been regarded as the fupreme qualification in an orator. This animated reafoning was by the Greek rhetoricians termed δεινότης, and from fignifying the principal excellency in an orator was ufed at length to denote oratory itfelf. Hence, as vehemence and eloquence became fynonymous, the latter, in conformity to this mode of thinking, was fometimes defined "the art of perfuafion." In order to perfuade, which, though not the only object of eloquence, is the moft important and for many reafons the moft difficult, the moft effential requifites are folid argument, clear method, a character of probity appearing in the fpeaker, joined with fuch graces of ftyle and utterance as fhall command attention to what he fays. Hearers who exercife their underftanding cannot be perfuaded, without being convinced; but conviction and perfuafion, though they are fometimes confounded, ought to be diftinguifhed from each other. Conviction affects the underftanding only; perfuafion, the will and the practice. It is the bufinefs of the philofopher to convince a perfon of the truth; but it is the bufinefs of the orator to perfuade him to act agreeably to it, by engaging the affections of the hearer. Conviction and perfuafion ought always to accompany each other, but this is not univerfally the cafe; becaufe the inclinations do not regularly follow the dictates of the underftanding. The inclination may revolt, though the underftanding be fatisfied; the paffions may prevail againft the judgment. Conviction, however, is one avenue to the inclination, or heart; and it is that which an orator fhould firft endeavour by his utmoft efforts to gain; for no perfuafion is likely to be ftable, which is not founded on conviction. But in order to perfuade, the orator muft do more than produce mere conviction; he muft duly confider the nature of man, and endeavour to act upon the different fprings by which he is moved. He muft addrefs himfelf to the paffions; he muft paint to the fancy, and touch the heart; and hence, befides folid argument and clear method, all the conciliating and interefting arts, both of compofition and pronunciation, enter into the idea of eloquence.

"We may diftinguifh," fays Dr. Blair, (Lectures, vol. ii.) "three kinds, or degrees, of eloquence. The firft, and loweft, is that which aims only at pleafing the hearer. Such, generally, is the eloquence of panegyrics, inaugural orations, addreffes to great men, and other harangues of this fort. This ornamental fort of compofition is not altogether to be rejected. It may innocently amufe and entertain the mind; and it may be mixed, at the fame time, with very ufeful fentiments. But it muft be confeffed, that where the fpeaker has no farther aim than merely to fhine and to pleafe, there is great danger of art being ftrained into oftentation, and of the compofition becoming tirefome and languid.

"A fecond and a higher degree of eloquence is when the fpeaker aims not merely to pleafe, but alfo to inform, to inftruct, to convince; when his art is exerted in removing prejudices againft himfelf and his caufe, in chufing the moft proper arguments, ftating them with the greateft force, arranging them in the beft order, expreffing and delivering them with propriety and beauty, and thereby difpofing us to pafs that judgment, or embrace that fide of the caufe, to which he feeks to bring us. Within this compafs, chiefly, is employed the eloquence of the bar.

"But there is a third and ftill higher degree of eloquence, wherein a greater power is exerted over the human mind; by which we are not only convinced, but are interefted, agitated, and carried along with the fpeaker; our paffions are made to rife together with his; we enter into all his emotions, we love, we deteft, we refent, according as he infpires us; and are prompted to refolve or to act, with vigour and warmth. Debate, in popular affemblies, opens the moft illuftrious field to this fpecies of eloquence; and the pulpit alfo admits it." See farther on the different fpecies of eloquence under the article Elocution. For the hiftory of eloquence, and an account of the moft diftinguifhed orators; fee Oratory and Orator. Thofe who diftinguifh between eloquence and rhetoric reprefent the latter as propofing and explaining the theory, and the former as the practice of the art; but they are generally ufed indifcriminately for each other. See Elocution and Rhetoric. On the fubject of this article, fee Campbell's Philofophy of Rhetoric, Blair's Lectures, vol.ii. and Cambray's Dialogues on Eloquence.

ELORA, or Ellora, in *Geography*, a town of Hindooftan, in the vicinity of Dowlatabad, famous for its numerous pagodas, moft of which are cut out of the natural rock. M. Thevenot, who has particularly defcribed them, fays, that for two leagues together nothing is to be feen but pagodas, in which are fome thoufands of figures. The fculpture of them he does not much commend; and we may apprehend, fays major Rennell, that they are of early Hindoo origin. It fhould be recollected, that Deoghire, which ftood in this neighbourhood, was the greateft and richeft principality in the Deccan; and that the fame of its riches incited Alla to attack it in 1293; and thefe elaborate monuments of fuperftition were probably, as Rennell fuggefts, the offspring of that abundant wealth, under a government purely Hindoo. Sir C. W. Malet has given a particular account of thefe wonderful excavations, illuftrated with drawings, in the fixth volume of the "Afiatic Refearches." As to their origin or date no inquiry which he had been able to make afforded him fatisfaction. He has no doubt, however, that they are the works of people, whofe religion and mythology were purely Hindoo; and he adds, that moft of the excavations carry ftrong marks of dedication to "Mahdew," as the prefiding deity. Neverthelefs he fuggefts, that the moft northerly caves of Ellora, occupied by naked fitting and ftanding figures, are the works of the "Sewras" or "Juttees," who by the Brahmens are efteemed fchifmatics, and whofe fect, called "Srawuk," is very numerous in Guzerat. The tenets, obfervances, and habits of the "Sewras" are peculiar, and in many points very different from other Hindus. Their adoration of the deity is conveyed through the mediation of "Adnaut" and "Parifnaut," the vifible objects of their worfhip, perfonified as a naked man fitting or ftanding. This fect is fuppofed to be of a comparatively modern origin; and if this be the cafe, and the hypothefis of the dedication of the temples to their idol be

 admitted,

admitted, the limit of their poffible antiquity will be affigned; but without afcertaining, or affecting, that of the others. As to the antiquity of thefe aftonifhing works, this writer has detailed two different accounts; one given by an intelligent Mahometan and another by a Hindu. The account of the firft is faid to have been derived from a perfon of acknowledged erudition. The fecond was deduced from a book, entitled "Sewa Lye Mahat," or the grandeur of the manfion of Sewa, *i. e.* Mahdew. The Mahometan reported, that "the town of Ellora was built by rajah Eel, who alfo excavated the temples, and being pleafed with them, formed the fortrefs of Deoghire (Dowlatabad,) which is a curious compound of excavation, fcarping, and building, by which the mountains were converted into a fort, refembling, as fome fay, the infulated temple in the area of the "Indur Subba" (one of the pagodas.) Eel rajah was contemporary with Shah Momin Araf, who lived 900 years ago." The Brahmen, on the other hand, faid, "that the excavations of Ellora are 7894 years old, formed by Eeloo rajah, the fon of Pefhpout of Elichpore, when 3000 years of the Dwarpa Youg were unaccomplifhed, which, added to 4894 of the prefent Kal Youg, makes 7894." Our author inclines to the former opinion. He farther informs us, that the "Koond," or ciftern, mentioned by the Brahmens, is ftill in excellent prefervation, juft without the town of Ellora; and the holinefs of its water is even now in fuch high eftimation as to render it a "Teerut" (pilgrimage) of great reputation and refort, under the appellation of "Sewalla Teerut," or "Kond." There are many other excavations in a femicircular mountain, that commands a view of the fine valley of Ellora. In order to account for thefe extraordinary works, and the fituation in which they were conftructed, it fhould be confidered, that the ancient Brahmens avoided the contamination of cities, and affected the purity and fimplicity of rural retirement. In fituations remote from obfervation, the imagination of their difciples probably enhanced the merits of their fanctity. Accordingly, to alleviate aufterities, and to gratify the devout propenfities of thefe holy men, became objects of pious emulation. Under the influence of this principle, the munificence of princes may have engaged to provide them retreats, which, fanctified by the fymbols of their adoration, were at once fuited, in fimplicity and feclufion, to thofe for whom they were intended, and in grandeur to the magnificence of their founders. Thus power and wealth may have been combined, under the guidance of enthufiafm, to produce monuments, fcarcely lefs extraordinary or lefs permanent, though lefs confpicuous and lefs known, than the pyramids of Egypt. Although fome of thefe excavations are of very ancient origin, there are others, and particularly two, in a hill near a garden in the neighbourhood of Aurungabad, formed, as it is confidently afferted, by rajah Paur Sing, one of the Rajpoot Ameers of Aurungzebe's court, as a place of retirement, during his attendance on that monarch in his excurfions to the neighbouring garden.

ELOTZ, a town of Ruffia, in the diftrict of Orlof; 112 miles E.N.E. of Orel. N. lat. 53° 20′. E. long. 39° 14′.

ELOVKA, a town of Ruffia, in the government of Tobolfk; 16 miles W. N. W. of Tomfk.

ELOY, Nicholas Francis Joseph, in *Biography*, was born at Mons, in the province of Hainault, on the 20th of September 1714, and died on the 10th of March 1788, having exercifed his profeffion as a phyfician with great ability and difinterefted humanity. He was a man of extenfive learning, and great modefty, and much addicted to ftudy; whence, notwithftanding his profeffional avocations, he was enabled to write upon a variety of topics, and his publications are numerous. His firft work, which was publifhed in 1750, was a fmall treatife, entitled "Reflexions fur l'Ufage du Thé." His next publication was an attempt at a hiftory of medicine, arranged in the form of a dictionary, and entitled "Effai du Dictionnaire Hiftorique de la Medicine Ancienne et Moderne," in two volumes octavo, which appeared in the year 1755; this work was afterwards greatly enlarged, by extending the different articles which it contained, and was publifhed in 1778, in four volumes quarto, with the title of "Dictionnaire Hiftorique de la Medicine Ancienne et Moderne;" to which, as our readers will have obferved, we have been much indebted for information relative to the different medical characters, of whom we have already given a biographical account. Eloy likewife publifhed, in 1755, a fmall volume, entitled "Cours Elementaire des Accouchemens;" and, a few years previous to his death, *viz.* in the years 1780 and 1781, he committed to the prefs two other effays, the firft of which was entitled "Memoire fur la Marche, la Nature, les Caufes, et le Traitement de la Dyfenterie;" and the other, "Queftion Medico-politique; fi l'Ufage du café eft avantageux à la fanté, et s'il peut fe concilier avec le bien de l'état dans les Provinces Belgiques?" As a flight reward for the patriotic zeal manifefted in this tract, the eftates of Hainault prefented him with a fuperb fnuff-box, with this infcription, "Ex Dono Patriæ;" *the Gift of his Country.* He held the honourable office of phyfician to prince Charles of Lorraine. Nouveau Dict. Hiftor. &c. Lyon, 1804.

ELPHIN, in *Geography*, a poft town of the county of Rofcommon, province of Munfter, Ireland, 75 Irifh miles W. by N. from Dublin, and 7 miles S. from Carrick, on Shannon.

Elphin, a bifhopric in Ireland, in the archi-epifcopal province of Tuam. It dates its origin from St. Patrick, in the middle of the 5th century. It comprizes the greater part of the county of Rofcommon, a large fcope in Sligo and Galway, and a very little in Mayo; and is reckoned one of the moft valuable of the Irifh bifhoprics. There are 75 parifhes, which are formed into 29 benefices, and of thefe 26 have churches, which are the only ones in a tract of 420,150 Irifh acres! The cathedral is a poor parifh church, but the bifhop's palace is a very good modern houfe, in the midft of an excellent demefne, and adjoining the fmall town of Elphin. Beaufort.

ELPHINSTON, William, in *Biography*, a Scotch prelate and ftatefman, was born at Glafgow about the year 1431. He was educated at the Univerfity of his native place, and became diftinguifhed for his proficiency in the learning of the times. He afterwards went to Paris, where he ftudied the civil and canon law, and likewife delivered lectures with great reputation for feveral years. Upon his return to Scotland he was promoted to church livings, and admitted a member of the king's council. He was, foon after this, appointed a joint commiffioner with the bifhop of Dunkeld and the earl of Buchan, in fettling fome difputes between the courts of Scotland and France. As a reward for the prudence and eloquence which Mr. Elphinfton difplayed on this occafion, he was, on his return, nominated to the bifhopric of Rofs; whence, about the year 1484, he was tranflated to the fee of Aberdeen, and appointed, at the fame time, to the chancellorfhip of the kingdom, an office which he held fome time with the higheft reputation; but when the troubles which took place between the king, James III., and his difcontented nobility, had involved the kingdom in a civil war, he abandoned public ftate affairs, and confined himfelf wholly to the duties of his bifhopric. But, on the acceffion of James IV. his talents as a ftatefman were again called into exercife, and from this time his fovereign undertook no affairs of moment without his advice and concurrence. He died in 1514, at the advanced age of eighty-three, leaving behind him an excellent character; he was the patron of learning and learned men, and it is fuppofed, that by his influence the bull was obtained from the pope, for eftablifhing a univerfity at Aberdeen, with as ample privileges as were enjoyed by the moft favoured feats of learning; and to his perfonal exertions and fuperintendence, it was chiefly owing that the building of King's college was undertaken and completed. To that foundation he proved himfelf a munificent benefactor during the remainder of his life; and, at his death, when he bequeathed large fums of money for its fupport. Gen. Biog.

ELPISTICI, Ελπιστικοι, among the Greeks, a fect of philofophers, who made hope the ruling paffion of mankind.

ELRICH, in *Geography*, a town of Germany, in the circle of Upper Saxony, and county of Klettenburg; formerly the capital of the county; in which are fome confiderable manufactures; 6 miles N. W. of Nordhaufen.

ELRICK, or EGELRIC ROAD, in *Antiquity*, was an ancient artificial road, made with great labour and expence through the fens, ten miles from Spalding to Deeping, by Egelric, abbot of Crowland, in the county of Lincoln, and afterwards bifhop of Durham; who, as Ingulphus relates in his hiftory of that monaftery, raifed, by means of wood and gravel, a caufeway, or caufey, for travellers, through the centre of a wild foreft and deep marfhes, called, after him, Egelric; or, by abbreviation, Elric-road. A part of it is ftill vifible, lined with willows, between the river Welland, and the marfhes north of Crowland. Gough's Tranflation of Ingulphus's Hiftory of Crowland.

ELS, in *Geography*, a town of Moravia, in the circle of Brunn, 32 miles W. of Olmutz, and 24 N. N. W. of Brunn.

ELSA, a river of Tufcany, which runs into the Arno, about a mile W. from Empoli.

ELSE, a river of Silefia, which runs into the Oder, near Oderburg.

ELSEN, a fmall town of France, in the department of the Roer, chief place of a canton in the diftrict of Cologne, with a population of 304 individuals. But the canton contains 36 communes, and 12,239 inhabitants.

ELSEN, a town of Germany, in the kingdom of Weftphalia, and bifhopric of Paderborn; 2 miles W. N. W. of Paderborn.

ELSFLETH, a fmall town of Germany, in the duchy of Oldenburg, fituated on the river Wefer, where the duke of Oldenburg exacts a confiderable toll from all veffels failing up the river towards Bremen. At the peace of Luneville, the duke was offered an indemnity for this toll, with the view to favour the commerce of Bremen; but its produce is fo important, that the duke would not confent to its abolition.

ELSGAU, a bailliage of Switzerland, being part of the bifhopric of Bafle, lying between the mountains and the Larg, and comprehending the town and bailiwick of Porentru, and 20 parifhes.

ELSHEIMER, ADAM, in *Biography*, a painter of very extraordinary talents, ftanding quite alone in the peculiar province of the lift he adopted, *viz.* fmall pictures of landfcapes with figures, and of fmall figures with landfcape back-grounds. The figures being in fome the principal object, and occupying the largeft portion of the fpace of the picture; and, in others, the landfcapes being the moft important. He was born at Franckfort; at what period, thofe who have written his life, differ much in ftating; but the beft authorities determine it to have been in 1574, and his death to have happened in 1620, fo that he lived only 46 years.

He was at firft a difciple of Philip Uffenbach, whom he foon excelled, and then determined to go to Rome, where alone he could acquire that high tafte to which he afpired.

After fome time fpent in ftudy of the fine works there expofed to his view, and an intimacy with many eminent painters, he fixed upon that ftyle of art which has been mentioned as decidedly his own; in which no one had ever before exerted himfelf; and in which no one has ever fince fo highly excelled as Elfheimer.

That which renders his pictures fo interefting is, the grandeur of ftyle in which they are executed. Many of his figures partake fo much of Raphael's beft manner of character, of action, and difpofition of the draperies, that if they were magnified, they would appear to be of that great mafter's own hand; and they have fuperadded a colour which is of a fuperior clafs; in the production of which, indeed, the fmallnefs of their fize was of confiderable affiftance to him; for it is by no means fo eafy to extend a full body of colour over a large furface, with equally pleafing variety of tone, and freedom of execution; and in it to feparate and form the diftinct parts as in a fmaller one; and though it requires more neatnefs in the execution of the latter, it does not demand fo free and fo ready a hand to unite, to blend, and foften the various parts, and to give expreffion its full force, as in the former.

His pictures exhibit great attention to nature; particularly his perfpective is very perfect, in lines, at leaft; and he not unfrequently chofe very difficult things to manage: fuch as working with a fhort perfpective diftance, and fometimes placing his figures on the top of a hill, and fuddenly lofing the ground, till it is recovered again in a deep valley. His landfcapes have, in general, the air of real views, and are finifhed with wonderful attention to general form, and beautiful fcenery. Their colour is not always exactly that of nature, but as feen under a peculiar illumination, like the tone which Titian has adopted in his St. Peter Martyr; giving it an air of grandeur not to be obtained, perhaps, by the brighter hues of nature.

From the extreme care and excellence with which his works are finifhed, they were not, of courfe, in his fhort life, very numerous; and are rarely to be met with. The richeft collection of them in this country is at the earl of Egremont's, at Petworth, in Suffex. There are ten pictures by him, eight of which are of one fize, *viz.* about four inches high, by two and a half wide, or perhaps a little more. The fubjects are, a St. Peter, St. Paul, St. John Baptift, Tobit and the Angel with a Fifh, an old Woman and a Girl, an old Man with a Boy, and a Capuchin Friar, with a model of a convent in his hand. The figures in all thefe are about three inches high, yet their characters and expreffions are juft and excellent; and the drawing of their figures, and the draperies, in the beft ftyle of art. Another picture reprefents the interior of a brothel by fire and candle light, in which there are ten or more figures gaming, and indulging in the licentioufnefs of fuch a place, all exquifitely wrought; with fome expreffions that have never been furpaffed, although the figures are not more than two inches and a half high. The laft is Nicodemus's vifit to Chrift; but it is not of fo good a quality as the others.

The

The subjects he chose were generally moon light or candle light pieces, which he painted with great lightness, spirit, and delicacy of touch, and with great knowledge of the chiaro-scuro, and excellent colour; and with such finish, that every part will bear the minutest inspection.

While he lived his pictures bore high prices, and they of course were greatly enhanced on his death; one of them is mentioned by Houbraken, representing Pomona, as having sold for 800 German florins. There are engravings from many of Elsheimer's pictures by his friend and benefactor, count Gaud; but they are in general too heavy and black, and have a flatness of effect, particularly in the trees, very unlike the originals; among them is one from his most famed picture, the Flight into Egypt, a moonlight. It is now, with two others of different subjects, in the National Museum at Paris.

Elsheimer, though thus endowed with taste and skill, was not the favourite of fortune. Notwithstanding he obtained great prices for what he did, yet his care in the execution of them, and the time they cost him to finish, were not so recompensed as to enable him to live and maintain a large family with comfort. As what he earned by his paintings would not find sustenance for himself and them, he fell into debt, and was cast into prison; the disgrace of which, though he was not suffered to remain long confined, is said to have preyed on his spirits, and hastened his dissolution. He was greatly regretted, and his works eagerly bought up, even by the Italians. The grand duke of Tuscany had several of them, and the world justly lamented the severe fortune of so extraordinary a genius, who deserved far more felicity than he was permitted to enjoy.

Elsheimer is highly celebrated, says another writer, for his careful pencil and extraordinary effects of light. Most of his landscapes are illumined by fire, or by moon, or torch light; and in them he has introduced small historical figures, which are highly appropriate to the scenes, and most exquisitely painted: yet his Aurora, of which there is an excellent print by count Gaudt, shews that bright and sudden light was not absolutely necessary to the display of his powers, and that he dipped his pencil in early dawn, with equal felicity.

The accuracy of his observation, and the retention of his memory were great, and the skill was scarcely less with which he introduced into his compositions, such picturesque incidents as he had once seen. Pilkington says that "it is impossible to conceive any thing more exquisite in painting than the productions of the pencil of Elsheimer; for whether we consider the fine taste of his design; the neatness and correctness of the drawing of his figures; the admirable management and distribution of his lights and shades; the lightness, the spirit, and the delicacy of his touch; or the excellence of colouring; we are astonished to observe such combined perfections in one artist; in whose works even the minutest parts will bear the most critical inspection, and the whole together is inexpressibly beautiful. He understood the principles of chiaro-scuro to the utmost perfection; and shewed the solidity of his judgment in the management of his subjects, which for the most part were night-pieces, by candle, or torch light," &c.

With these high claims to contemporary patronage, it was the fate of Elsheimer to fall a martyr to his own merits. Not affluence, nor even comfort, attended him in his professional pursuits. His family was numerous, and the great care with which his sensibility to the minuter beauties of nature prompted him to finish his pictures, occupied so much time, that he was gradually overwhelmed with debts, and cast into prison. Being much respected, he was soon released; probably by his friend Gaudt, the engraver: but returned, spirit-broken, to his art, and survived not long. Posterity will reverence his professional merits, and regret his misfortunes.

Of artists of transcendant talent, it has been the frequent lot to receive from their contemporaries but a trifling earnest, either of the value of their works, or the extent of their fame: so blind is taste, with all its lofty pretensions, or so reluctant is human nature to recognise the claims of living excellence.

Among the most celebrated of his works, which are known through Europe, by the diffusion of count Gaudt's excellent engravings after them, may be mentioned his "Flight into Egypt," wherein he has contrasted the effects of fire and moonlight; two landscapes, in each of which he has introduced "Tobit and the Angel;" a "Cottage Door by Candle-light, with Ceres drinking from a Pitcher;" the story of "Baucis and Philemon;" the "Decollation of John the Baptist;" "Latona and her Sons, with the Lycian Peasants metamorphosed into Frogs;" and the "Death of Procris:" the two latter subjects were engraven in England by Magdalen Pass. Some of his most valued performances were late in the gallery of the grand duke of Tuscany. L.

ELSHOLTZIA, in *Botany*, so named by professor Willdenow in memory of a Prussian botanist, John Sigismund Elsholtz, who lived in the middle of the 17th century, and published a *Flora Marchica*, or catalogue of plants cultivated in the principal gardens of Brandenburg, printed at Berlin in 1663, in small 8vo. Willdenow mentions also a manuscript work on Horticulture by the same writer in his native tongue, preserved in the royal library of Berlin.—Willden. in Römer Usteris Magazine, fasc. 11. 1. t. 1. Sp. Pl. v. 3. 59. Class and order, *Didynamia Gymnospermia*. Nat. Ord. *Labiatæ*, *sect.* 3. Juss.

Gen. Ch. *Cal.* Perianth of one leaf, bell-shaped, with ten furrows, and five oblong acute teeth; the orifice closed with hairs. *Cor.* of one petal, ringent: tube cylindrical, short, the length of the calyx: upper lip shortest, obtuse, concave, four-toothed, clothed externally with long white hairs; lower obtuse, straight, sharply crenate, externally clothed with hairs. *Stam.* Filaments four; the two uppermost shortest, lodged in the upper lip; the two lowermost in the under one: anthers roundish. *Pist.* Germens four, roundish, superior: style thread-shaped: stigma cloven. *Peric.* none. *Seeds* four, naked, brownish, in the bottom of the calyx. Willdenow.

Ess. Ch. Calyx tubular, five-cleft. Corolla ringent: upper lip four-toothed; lower longest, undivided, finely crenate. Stamens distant.

1. E. *cristata*. Willd. as above. (Hyssopus ocymifolius; Lamarck Encycl. v. 3. 187.) "Spikes solitary, erect." Native of Siberia, about the lake Baikal. *Root* annual, fibrous. *Herb* with the habit of an *ocymum*, and a very fragrant scent, especially when rubbed after drying, compared by some to roses, but in our opinion more resembling the muscat grape. *Stem* a foot or more in height, square, leafy, with opposite branches. *Leaves* stalked, opposite, ovate, acute, serrated, light green, smooth. *Spikes* terminal, solitary, stalked, unilateral, consisting on one side of a double row of obovate, pointed, imbricated bracteas, and on the other of three or four dense rows of pale lilac-coloured flowers. This plant is propagated by seed, with little trouble, in our gardens, but has more singularity than beauty in its aspect. The scent indeed renders it desirable.

2. E.

2. E. *paniculata.* Willd. Sp. Pl. v. 3. 59. (Hyſſopus criſtatus; Lamarck Encycl. v. 3. 187. Manám-podám; Rheede Hort. Mal. v. 10. 129. t. 65.) "Spikes panicled, reflexed." Native of moiſt places on the coaſt of Malabar. Lamarck, who had in his poſſeſſion fine ſpecimens of this plant from Sonnerat, aſſures us that the leaves are not alternate, as drawn in the *Hortus Malabaricus*, but oppoſite as in the preceding ſpecies, with which he rightly perceived its generic affinity. The chief ſpecific difference ſeems to be in the inflorefcence, which in the plant we are deſcribing is panicled, each branch of the panicle conſiſting of a numerous ſeries of reflexed ſpikes, ſhorter than in the former, with more oblique, unequally cordate, bracteas. Every part of this herb is ſaid to exhale an agreeable aromatic odour. The root ſeems to be annual.

ELSIMBURG, in *Geography.* See HELSINBURG.

ELSINEUR, in Daniſh *Helſingoer*, a handſome town of Denmark, in the iſland of Zealand, at the entrance of the Baltic, oppoſite the Swediſh coaſt, 20 miles N. of Copenhagen. E. long. 12° 34′. N. lat. 55° 58′. The population amounts to between 6 and 7000 individuals. It derives its name from the Helſingers, an ancient Gothic colony, and is ſituated on the declivity of a hill, almoſt directly over-againſt Helſinburg, in the Swediſh province of Scania. The paſſage is not above 4 Engliſh miles. The narrow arm of the ſea, which joins the North ſea and the Baltic, is called the Oereſund, or *Sound*, and is protected by the caſtle of *Cronenburg*, which ſee.

Till the year 1425, when king Erick of Pomerania beſtowed on it the privileges of a city, Elſineur was but a ſmall inſignificant place. It has two churches, a grammar-ſchool, ſeveral handſome private buildings, and a ſugar-houſe. In 1753, a harbour was attempted, but the execution of the project was found impracticable. The road-ſtead, however, is excellent.

The principal trade of Elſineur is in wine and ſpirituous liquors; but it derives all its importance from the Sound dues, which, in times of peace, are paid at Elſineur by all veſſels paſſing through the Sound from either the Baltic or the North ſea. The cuſtom-houſe, where theſe duties are paid, is a very fine building, and it is on account of this toll, that all nations trading in the Baltic keep a conſul at Elſineur. The Sound dues are in proportion to the ſize of the ſhip and to the value of the cargo. They were originally a mere contribution to the expence of keeping light-houſes on the coaſt.

The number of veſſels of different nations that ſailed through the Sound and paid the dues at Elſineur, was in

1768 - - - -	6930 veſſels.
1778 - - - - -	8476
1788 - - - - -	9224
1792 - - - - -	12,114
1798 - - - - -	9508
1802 - - - - -	12,130
1803 - - - - -	11,631
1804 - - - - -	10,579
1805 - - - - -	11,587
1806 - - - - -	7140
And in the firſt three months of	
1807 - - - - -	342

From which ſtatement it appears, that the Baltic trade has been moſt conſiderable in the years 1792 and 1802, which both preceded the two late ruptures between England and France. See SOUND.

ELSNABBAN, a ſea-port town of Sweden, in the province of Sudermania, on the coaſt of the Baltic; 32 miles E.N.E. of Nikioping.

ELSNER, JAMES, in *Biography*, a doctor of theology, was born, in 1692, at Saalfield, in Pruſſia, and was deſtined by his father for trade, to which, however, he felt ſo ſtrong a diſinclination, that nothing could overcome it. He was accordingly ſent to the univerſity of Konigſberg, where he became private tutor to ſome young noblemen, and was afterwards appointed chaplain in the garriſon to field-marſhal count Alexander Von Dohm. He next went to Utrecht and Leyden, where he formed an intimacy with the moſt eminent literary characters of thoſe cities. In the year 1719, he publiſhed a work on the delivery of the law on Mount Sinai, and ſhortly after the firſt volume of his "Sacred Obſervations on the New Teſtament." In the following year he left Holland, at the invitation of his Pruſſian majeſty, by whom he was appointed profeſſor of theology and the oriental languages at Lingen, having firſt taken his degree of doctor at Utrecht. From this place he was called to Berlin to reſtore the reputation of Joachim's ſchool, which had fallen into much diſrepute for want of proper diſcipline. Elſner performed all that was required of him, and attained a high degree of reſpect, by the dignity and firmneſs of his manners In the autumn of 1722, he pronounced an inaugural diſcourſe on the obligation of uniting piety to learning; and immediately after this, he was choſen a member of the Royal Academy of Sciences. Other preferments were conferred upon him, and he was always very fully employed either as a preacher or an author; and, in 1742, he was appointed director of the claſs of the belles-lettres in the Royal Academy; and when the ſociety was renewed in 1744, he retained the ſame office, and maintained the character which he had heretofore ſupported, as well by his attention to his academical duties, as by the learned diſſertations with which he enriched the memoirs of the inſtitution. He died of a fever on the eighth of October, 1750. His works are very numerous, and on various topics, but chiefly in theology. He publiſhed alſo, "A new deſcription of the ſtate of the Greek Chriſtians in Turkey," in which he received very important aſſiſtance from Athanaſius Doroſtamos, who came to Berlin to collect money for the Chriſtian ſlaves in England.

ELSTER, originally *Halſtrow*, in *Geography*, a ſmall town of the kingdom of Saxony, in Upper Luſatia, on a river called the *Black Elſter*, remarkable for its manufacture of knitted ſtockings.

ELSTERBERG, a ſmall town of the kingdom of Saxony, in the circle of Voigtland, between ſome high hills on the river Elſter, with an old ruined caſtle. It has a grammar-ſchool, about 2000 inhabitants, and a flouriſhing manufacture of ſtuffs and woollen cloth.

ELSTERWERDA, a ſmall town of the kingdom of Saxony, in the circle of Meiſſen, on the river Elſter, with a fine hunting caſtle and a beautiful park. It has only 700 inhabitants; but is remarkable for a canal which was dug here in 1740, and by means of which it has a conſiderable timber trade to Meiſſen and Dreſden.

ELSTOB, WILLIAM, in *Biography*, was born at Newcaſtle-upon-Tyne, in the year 1673. He was educated at Eton and Cambridge, but the latter place not being congenial to his health, he removed to Queen's college Oxford, where he was choſen fellow and tutor. In the year 1697, he took his degree of M. A., and in 1702 was appointed rector of the united pariſhes of St. Swithin and St. Mary Bothaw in London. He died in 1714, when he was only forty-one years of age. He publiſhed ſeveral works, and had collected materials for a hiſtory of Newcaſtle. He had likewiſe projected many literary deſigns, of which the moſt important,

important, was an edition of the Saxon laws, with great additions, together with notes of various learned men, and a prefatory hiftory of the origin and progrefs of the Englifh laws, down to the Conqueror and to Magna Charta. This great work was completed in 1721 by Dr. Wilkins, who deplores the lofs which the literary world had fuftained in the early death of Mr. Elftob. He intended alfo a tranflation, with notes, of Alfred's Paraphraftic Verfion of Orofius, of which his collections came into the poffeffion of the late Dr. Tegge. This work was afterwards publifhed by the Hon. Daines Barrington, with an Englifh tranflation, who made ufe of Mr. Elftob's tranfcript. Biog. Brit.

Elstob, Elizabeth, fifter of the preceding, was attached to the fame kind of purfuits, and was born at Newcaftle in 1683. From a very early period fhe fhewed a ftrong predilection for literary purfuits. She refided at Oxford during her brother's continuance at that univerfity, and is defcribed as having been the *indefeffa comes* of his ftudies. She probably accompanied him to London, and affifted him in his antiquarian purfuits. To one of his publications, *viz.* the Homily on St. Gregory's day, fhe gave an Englifh tranflation, and a preface in vindication of female learning. By the encouragement of Dr. Hickes, fhe undertook a Saxon Homiliarium with an Englifh tranflation, notes, and various readings, but only a few of the homilies were printed at Oxford in folio. In the year 1715, fhe publifhed a "Saxon Grammar," the types for which had been cut at the expence of lord chief juftice Parker, afterwards earl of Macclesfield. After the death of her brother, her circumftances were fo very low, that fhe was reduced to the neceffity of keeping a fchool at Evefham, in Worcefterfhire. By the interceffion of fome friends, queen Caroline allowed her a penfion of twenty guineas, which was paid very regularly till the death of that princefs, when fhe was again reduced to great difficulties, and had recourfe to education as a refuge from poverty. In 1739, fhe was received into the family of the duchefs of Portland, where fhe continued till her death in the year 1756. Biog. Brit.

ELSYNGE, Henry, was born at Batterfea in 1598, and received his education at Weftminfter-fchool, and Chrift-church college, Oxford. From the univerfity he went to the continent, and fpent feven years in foreign travel. Upon his return he was, through the intereft of archbifhop Laud, elected clerk of the houfe of commons, the duties of which office he performed with fingular ability, and much credit. He acquired the efteem of all parties in the midft of much difcord and faction, and kept his poft under the long parliament till December 1648, when he chofe to retire rather than take a part in the trial of the king. After this, he declined public bufinefs till his death in 1654. As an author his chief publication was entitled "The ancient Method and Manner of holding Parliaments in England." This was firft printed in 1663. Anthony Wood fuppofed that it was chiefly tranfcribed from a MS. of the author's father, who was clerk of the houfe of lords, but there is no doubt it received many valuable additions from our author's own parliamentary experience. Mr. Elfynge left a tract concerning proceedings in parliament, never publifhed; and alfo other tracts and memorials. Biog. Brit.

ELTEN, in *Geography*, a fmall town of Germany, in the new kingdom of Weftphalia, formerly a free imperial abbey, which was fecularized at the peace of Luneville, and given as an indemnity to the king of Pruffia, who loft it again at the peace of Tilfit in July, 1807.

ELTERLEIN, a fmall town of the kingdom of Saxony, in the circle of the Ertzgebirge, fituated between Annaberg and Grunhayn, with about 1000 inhabitants. It is chiefly remarkable for the adjacent mines, which yield excellent magnefia and a very fine potters' clay for china. There is likewife a good manufacture of thread lace at Elterlein.

ELTHAM, a large village in the hundred of Blackheath and lathe of Sutton, in the county of Kent, England, confifts of 256 houfes, which are occupied by 1627 inhabitants. Its ancient name was Eald-ham, the old manfion or dwelling. John de Vefei, lord of Eltham, procured a grant of a market for this manor; and two other grants relating to it are extant among the records in the Tower. The market appears to have been difcontinued in the time of James I., when the royal palace, the remains of which ftand about two furlongs fouthward from the village, ceafed to be vifited by our kings.

Eltham palace was for feveral centuries a favourite retreat of the Englifh fovereigns, to which, probably, its vicinity to the metropolis contributed, as well as the pleafantnefs of its fituation. When it was originally built is unknown, yet it muft have been prior to the year 1270, when Henry III. kept a grand public chriftmas here, accompanied by his queen and all the great men of the realm. In the next reign, Anthony Bec, the warlike bifhop of Durham, obtained poffeffion of it, and confiderably improved it: he died here in 1311. Edward II. frequently refided here; and in the year 1315, his queen was delivered of a fon in the palace, who was called John of Eltham, from the place of his birth. Edward III. held a parliament here in 1329, and another in 1375, when the Commons petitioned him to make his grandfon, Richard de Bourdeaux, prince of Wales. Edward IV. was at a great expence in repairing the palace, where, in 1482, he kept his chriftmas in a very magnificent and coftly manner, two thoufand perfons being daily fed at his charge. Moft of the fucceeding monarchs, to the time of Henry VIII., refided much in this palace; but on the rife of Greenwich it was gradually deferted. The change which it has undergone is exceedingly ftriking: formerly the abode of fovereigns, and the birth-place of princes, it is now a farm; and the beautiful great hall, where parliaments were held, and entertainments given in all the pomp of feudal grandeur, is now ufed as a barn for the houfing and threfhing of corn. The area, in which the buildings ftand, is furrounded by a high ftone wall, that has been partially repaired and ftrengthened by arches, &c. of brick, and a broad and deep moat, over which are two bridges, nearly oppofite to each other, on the north and fouth fides. The hall is a moft noble remain, meafuring 100 feet in length, by 56 broad, and about 60 high. The windows have been extremely elegant, but are now bricked up. The roof is of timber, curioufly wrought in the manner of that of Weftminfter-hall, and richly ornamented with finely carved pendants. Three parks, well provided with deer, were formerly connected with this palace: in the largeft, which includes an area of two miles in circumference, ftands a refpectable manfion, called Eltham lodge. Hafted's Hiftory of Kent.

ELTMAN, a town of Germany, in the circle of Franconia, and bifhopric of Wurzburg; 8 miles W.N.W. of Bamberg, and 40 E.N.E. of Wurzburg.

ELVAS, formerly *Jelves*, a town and bifhop's fee of Portugal, in the province of Alentejo, containing three parifh churches, feven convents, two hofpitals, and 12,500 inhabitants, including the diftrict, in an open and fruitful territory, 18 leagues N.E. of Evora, and fix W. of Badajoz, in Spain. It has a caftle on an eminence, and is commanded by Fort la Lippe, a new and ftrong fortification on the top of a hill. Here is a remarkable aqueduct, fupported

ported in fome places by three arches one over the other; the ftreets are narrow, irregular, and dirty; and the houfes are indifferently built. At fome diftance from the town the country is bleak and barren. N. lat. 38° 44′. W. long. 7°.

ELVÆ. See ELFS.

ELUDING, the act of evading, or rendering a thing vain, and of no effect: a dextrous getting clear, or efcaping out of an affair, difficulty, embarraffment, or the like.

We fay, to elude a propofition, &c. The defign of chicanery is, to elude the force of the laws; this doctor has not refolved the difficulty, but eluded it. Alexander, fays the hiftorian, in cutting the Gordian knot, either eluded the oracle, or fulfilled it: "Ille nequicquam luctatus cum latentibus nodis, Nihil, inquit, intereft, quomodo folvatur; gladioque ruptis omnibus loris, oraculi fortem, vel eludit vel implevit." Q. Curt. 13.

ELVEN, in *Geography*, a fmall town of France, in the department of Morbihan, chief place of a canton in the diftrict of Vannes, with a population of 3829 individuals. The canton contains five communes and 9136 inhabitants, upon a territorial extent of 220 kiliometres.

ELVERDINGHE, a fmall town of France, in the department of the Lys, chief place of a canton in the diftrict of Ypres, with 2729 inhabitants. Its canton has a population of 9057 individuals difperfed in 9 communes, on a territorial extent of 112½ kiliometres.

ELVERS, in *Ichthyology*, an Englifh name for a fmall fort of eels, caught in fome parts of the kingdom, particularly about Gloucefter and Tewkfbury. Thefe are, in reality, young congers, or fea-eels. They get up into rivers while very fmall, and as they precede the fhads, it is conjectured that they fupply them with food. They are taken in prodigious numbers in the rivers, in dark nights, by a kind of fieve made of hair-cloth, fixed to a long pole, and are efteemed a very delicate food. Willughby.

EL-VISO, in *Geography*, a well built town of Spain, in the province of New-Caftile, and diftrict of La Manche, containing a parifh church, a convent, a palace of the marquis D'El-Vifo, and 3500 inhabitants, about 20 leagues S.W. of Alcaraz; and 13 S.S.E. of Ciudad Real, fituated in a fertile plain, producing corn, wine, and fruits.

ELVIUS, PETER, in *Biography*, was born at Upfal in 1710, and applied himfelf in early life to the ftudy of mechanics, under able mafters. In the year 1738, the royal college of Mines entrufted him with the care of its collection of machines. His own knowledge enabled him to conftruct a fulling mill on new principles. In 1743 he undertook, with M. O. Hamren, a tour through the kingdom of Sweden, to examine where the beft fituations could be obtained for works to be driven by water; and on this occafion he drew plans of thofe places which feemed moft convenient for the purpofe. For this fervice he obtained a place in the academy of Upfal, and applied himfelf to the calculation of chances and probabilities, which led him to confider the exifting bills of mortality, and the means for rendering them more accurate and ufeful. He was a diligent obferver of the heavens, and on the ifland of Huen fearched out the ruins of the refidence of Tycho Brahe, and made fome celeftial obfervations amidft the remains of Uranienburg. He died at the early age of 38, on the 27th of Sept. 1749, and the Academy of Sciences, to which he had been the fecretary, caufed a medal to be ftruck in honour of his memory. Gen. Biog.

ELUL, in *Chronology*, one of the Hebrew months, anfwering partly to our Auguft and September. There are but nine and twenty days in it. It is the twelfth month of the civil year, and the fixth of the ecclefiaftical. Upon the feventh or ninth day of this month the Jews faft, in memory of what happened after the return of thofe who went to view the promifed land. Numbers, xiii. xiv.

Upon the twenty-fecond of this month, the feftival of the xylophori was obferved, when wood was carried to the temple. Selden fays, that it was celebrated on the eighteenth day of the month Ab. On the twenty-fixth of the fame month, the dedication of the walls of Jerufalem by Nehemiah was commemorated. Jofeph. lib. ii. cap. 17. p. 811. Nehem. xii. 27, &c. Calmet, Diction. Bibl.

ELVO, in *Geography*, a river of Italy, which runs into the Sefia, 2 miles N. of Vercelle.

ELUSA, in *Ancient Geography*, a town of Paleftine, in Idumæa, W. of Jordan, according to Ptolemy. This town was once an epifcopal city, and it is placed by P. Hardouin in the third Paleftine.

ELUSA, called alfo *Elufæ*, and *Civitas Elufatium*, a town of Gaul, was formerly the metropolis of Novempopulania, and maintained that rank till the eighth century. But upon its deftruction by the Normans, the fee of Auch was advanced to the rank of Metropolitan. Some remains of this place retain the name of Ciutat near Eufe.

ELUSATES, the inhabitants of Elufa, who occupied the N.W. diftrict of Armagnac. Cæfar mentions them, and places them between the Tarufates and the Garites.

ELUTRIATION, or *wafhing over*, is a method of feparating fubftances of different fpecific gravities from each other by means of water. For this purpofe the mixture is ftirred about brifkly in a veffel full of water, and when the heavier particles have again fallen to the bottom, the water, ftill turbid with the lighter ones that are as yet fufpended, is poured off into another veffel, to the bottom of which they, in a fhort time, fubfide. By this fimple method a fkilful perfon will feparate from each other three or four fubftances with great exactnefs.

ELUVIES, in *Geology*, is a term ufed by Mr. Parkinfon, (Organic Remains, i. 275.) and fome other writers, to exprefs the fuppofed ruins of the antediluvian earth, effected by the Noachic deluge, but which it is prefumed by others, from the Mofaic account of that miracle, did not deftroy the exifting vegetable productions or the fifh, and much lefs therefore could it have effected the univerfal difintegration of mineral fubftances, on which Dr. Woodward's and fome other theories are built. Befides, the animal and vegetable fubftances, which are found imbedded in the fuppofed poft-diluvian ftrata, are none of them of the fpecies, which, by the eftablifhed modes of generation, have been handed down to us, immediately from thofe individuals of each fpecies which Noah preferved in the ark, when the reft were drowned by the flood.

ELUXATIO, (from *eluxo*, to put out of joint,) a diflocation.

ELWAD-AD, in *Geography*, a town of Arabia, in the country of Yemen; about 40 miles nearly W. of Chamir. N. lat. 16° 16′. E. long. 42° 30′.

ELWALL, EDWARD, in *Biography*, was born at Sedgley, near Wolverhampton, in Staffordfhire. At Wolverhampton he fettled in bufinefs, and acquired the reputation of honefty and great integrity in his dealings. As a politician, he was diftinguifhed as the zealous affertor of the civil and religious rights of the people, and as a vigorous fupporter of the Hanoverian fucceffion. He was of a ferious and inquifitive turn of mind, and never hefitated to proclaim his fentiments on any fubject that he deemed important. He confidered the fourth commandment as binding on all generations, and not only wrote in defence of the opinion, but while in businefs, conftantly fhut up his fhop on the feventh day, and opened it on the firft day of the week; hence he was ftigmatized as a Jew. About the year 1714 he became diftinguifhed as an Unitarian, and publifhed "A true Teftimony for God and his facred Law, being a Defence of the firft Commandment of God, againft all Trinitarians under Heaven." This drew on him the refentment of the neighbouring clergy, who ceafed not to purfue him with their enmity, till they procured an indictment againft him for herefy and blafphemy; on which he was tried, without having had a copy of his indictment, before judge Denton about the year 1726, at Stafford affizes. He pleaded his own caufe, and vindicated the principles which he had embraced with a firmnefs and prefence of mind, faid to have been rarely equalled in modern times, and with complete fuccefs, for a refpectable and honeft jury, under the direction of an upright judge, acquitted him. Mr. Elwall was not daunted by the obloquy and profecution which his firft piece had drawn on him from defending with freedom the fentiments for which he had fuffered, but publifhed feveral other tracts, having the fame tendency. After his trial he removed to London, and became a member of the feventh-day Baptift church at Mill-yard, Goodman's fields. In the latter part of his life he frequently attended the religious affemblies of the quakers, and was fometimes admitted to fpeak among them. He died in London at an advanced age, with an unfullied reputation, about the year 1745. He had not enjoyed the advantages of a learned education; but his natural abilities, and good judgment, were fuch as rendered his converfation agreeable to perfons in the higher ranks of fociety, by whom he was known, and refpected, on account of his ardent attachment to the houfe of Hanover. Speaking of himfelf, his principles, and conduct, he fays, "I have been a fturdy and ftrenuous friend to my royal friend George thefe forty years and upwards, ever fince the nation happily fettled the crown in his illuftrious family; and many a ftately Jacobite and Tory have I filenced by dint of argument, and brought to the ground by dint of fift, yet generally in felf-defence, and not to convince his judgment." He was a man of inflexible integrity and of extenfive charity, as well as of fervent piety.

ELWANGEN, in *Geography*, a fmall town of the kingdom of Wurtemberg, 18 miles S.E. of Halle, in Suabia, and 30 S.W. of Anfpach. It was formerly a rich abbey of the German empire, whofe prelate ranked as a prince, and voted in the college of princes. At the peace of Luneville it was given to Wurtemberg as an indemnity for the territory which its fovereign was forced to cede to France on the weftern fhore of the Rhine.

ELWY, Britain, the name of two rivers in Wales, one rifing near Gwythrin, in the weft part of Denbighfhire, in North Wales, runs eaftward for fome miles, then fuddenly turning northward above St. Afaph, paffes by that city, and falls into the Clwyd, about three miles below it. Another river of the fame name rifes in the mountains to the northward of Capelton Ybedyddier, in Glamorganfhire, South Wales; and running in a fouth-eafterly direction paffes Henfall park, St. Fagan's, &c. and meeting the Taf, at the Embochure, near Penarth-point, forms Penarth harbour.

ELXAI, in *Biography*. See Elcesaites.

ELY, Isle *of*, in *Geography*, a tract of land fo called, is fituated in the northern part of Cambridgefhire, England, and was formerly furrounded by waters; but, in confequence of the vaft improvements made by draining the fens, &c. it is now merely known by the name of an ifland. The whole diftrict, called the ifle of Ely, extends from the bridge at Tyd on the north, to Upwere on the fouth, 28 miles in length; and from Abbot's or Bifhop's Delf on the eaft, to the river Nene, near Peterborough, on the weft, 25 miles in breadth: and includes feveral confiderable towns and villages, of thefe the principal place is

Ely, which, though far from populous, claims, as being the fee of a bifhop, the appellation of a city. It is fituated on a fmall eminence near the river Oufe, and owes its origin to the eftablifhment of a monaftery here, A.D. 673, by Etheldreda, daughter of Anna, king of Eaft-Anglia. After her death, in 679, the government of the abbey fucceffively devolved on her fifter Sexburga, queen of Kent; Ermenilda, queen of Mercia, daughter of Sexburga, and the princefs Werburga, her grand-daughter, all of whom were, with the foundrefs, for many centuries confidered as faints. A town gradually arofe about the monaftery; and both remained in peace and fecurity till the year 870, when this place of monaftic retirement was difcovered by the Danes, who invaded the ifle, and, though at firft repulfed by the bravery of the inhabitants, returned in greater numbers, and overcame every defenfive effort. They put the religious to the fword, fet fire to the church and other buildings, and departed, loaded with the fpoil, not only of the town and monaftery, but alfo of all the neighbouring places, whofe inhabitants had depofited their valuables here for better fecurity. Some of the inmates of the monaftery, who had efcaped the maffacre by flight, returned a few years afterwards, and commenced a college for fecular clergy, which continued till 970, when the monaftery was reftored to its former eftablifhment by Ethelwold, bifhop of Winchefter, under the patronage of king Edgar, who, in confideration of a large fum paid by the bifhop, gave up to the convent the jurifdiction of the ifle, which after the Danifh maffacre had been annexed to the crown. Bifhop Ethelwold beftowed large benefactions on the abbey, which now confifted of regular monks of the order of St. Auguftine. Brithnoth, the firft abbot, exerted himfelf to complete the repairs of the church. The abbey continued to profper till the conqueft: its privileges being previoufly augmented and confirmed by Canute, and again by Edward the Confeffor, the latter of whom had received his education within its walls. During the confufion which enfued on the Norman invafion, the abbey was deprived of many eftates; and Thurftan the abbot, fearing that its whole poffeffions would be feized by the Conqueror, refolved to fupport the intereft of Edgar Atheling, in which he was joined by feveral Englifh nobles, who were determined to defend their country from the dominion of William, whom they regarded as an ufurper. A vigorous, and, for fome time, effectual refiftance was made; but at length, the abbot having feceded from the confederacy, the fuperior prowefs of the Norman foldiers prevailed. Great numbers of the Englifh were flain in battle; and many of thofe, who were made prifoners, were cruelly mutilated; fome having their eyes put out, and others their hands and feet cut off, that they might remain living monuments of the Conqueror's vengeance, and become a terror to fuch as difputed his authority.

A bifhop's fee was eftablifhed here in 1107, and Henry, bifhop of Bangor, was appointed the firft diocefan. This prelate procured many gifts and privileges for his bifhopric, and a grant of a fair for the city, to continue for feven days. The king granted a mandate to make an equal divifion of the abbey eftates, between the prelate and the abbot, but the former contrived to retain a full third of the poffeffions more than he was entitled to. On the furrender of the monaftery to Henry VIII. that monarch granted his letter-patent, dated September 10, 1541, to convert the conventual

tual church into a cathedral, by the title of the Cathedral Church of the Undivided Trinity; the eftablifhment for the performance of divine fervice to confift of a dean, a prieft, and eight prebendaries, with other minifters; the dean and prebendaries to form a body corporate. The bifhop of Ely poffeffes the rights of a lord of a county palatine, and is fovereign within the ifle, where all caufes are heard and determined by a judge of his appointing, who holds affizes, gaol delivery, and quarter feffions.

The cathedral is the workmanfhip of very different periods, and difplays a fingular admixture of the Saxon, Norman, and Englifh ftyles of architecture; yet, notwithftanding the diffimilarity of its parts, it muft, when confidered as a whole, be regarded as a very magnificent ftructure. The north and fouth tranfepts, which are the oldeft parts, were erected in the reigns of William Rufus and Henry I. Here the arches are femi-circular, as well as in the nave, which was begun in the reign of the latter monarch, and completed before 1174. Between this period and the year 1189, bifhop Rydel erected the great tower at the weft end, which was anciently flanked on the north fide by a building of the fame kind as that on the fouth: but this either fell or was taken down, and another building begun in its place. This was never carried higher than 12 or 14 feet. The interior view of this tower is particularly beautiful, it being decorated with fmall columns and arches running round in feveral ftories, and lighted by 27 windows. The lower part was repaired, and new cafed with ftone, in the middle of the 15th century. The handfome veftibule at the entrance, formerly called the Galilee, was built about the year 1200, by bifhop Euftachius. The foundation of the elegant ftructure which was originally the prefbytery, but now forms the choir, was laid by Hugh Northwold, the eighth bifhop, in the year 1234, and finifhed in 1250. The three moft weftern arches were deftroyed by the fall of the lofty central tower, in the night of the 12th of February, 1322. To prevent the recurrence of a like accident, Alan de Walfingham, fub-prior of the convent, and facrift of the church, a perfon eminently fkilled in architecture, defigned and erected the prefent magnificent octagon, which is fupported on eight pillars, and terminated by a lantern. The capitals of the pillars are ornamented with hiftorical carvings, reprefenting the principal events in the life of Etheldreda. This octagon is probably unequalled by any of the kind: the ftone work was completed in fix years, and the wood work raifed thereon, and covered with lead, in about 15 years. The whole was perfected in the year 1342, at the expence of 2406*l.* 4*s.* 11*d.* The three arches eaftward of the octagon were rebuilt about the fame period, by bifhop Hotham, and are very much embellifhed. At the eaft end of the north aifle is a fumptuous chapel, erected by bifhop Alcock, who died at his caftle at Wifbech, in 1500. His tomb, with his effigy lying thereon, but much defaced, is placed under an arch of ftone on the north fide. In the fouth aifle, and in fome refpects correfponding with the former, but much fuperior in its embellifhments, is another chapel, which was erected by bifhop Weft, about the year 1530, and is highly enriched with ornaments and elegant tracery, &c. Both thefe chapels were greatly dilapidated by the enthufiaftic reformers who fprung up during the civil wars, and feem to have had an invincible antipathy to every religious edifice that difplayed tafte and elegance.

The extreme extent of the cathedral, from eaft to weft, is 535 feet; but the interior length is only 517. The length of the tranfept is 190 feet, the height of the lantern over, 170. The extreme height of the weftern tower 270, and the tower on the fouth wing of the latter 120. The length of the nave is 203 feet, and the height of the roof over it 104. The height of the eaftern front to the top of the crofs is 112 feet. Near the eaft end of the cathedral, on the north fide, is St. Mary's chapel, now Trinity church; it having been affigned to the ufe of the inhabitants of that parifh foon after the Reftoration, by the dean and chapter. This elegant ftructure was commenced in the reign of Edward II. and is one of the moft perfect buildings of that age. The fhape is an oblong fquare; the interior length being 200 feet, the breadth 46, and the height of the vaulted roof 60. This building has neither pillars nor fide aifles, but is fupported by ftrong buttreffes, furmounted with pinnacles. The fpaces over the eaft and weft windows were formerly decorated with ftatues, and a variety of well-executed fculpture: and the interior was embellifhed with niches highly carved, and enriched with ftatues, ornamental foliage, and flower-work. This edifice was built at the charge of the convent by John de Wifbech, one of the monks, and Alan de Walfingham, who erected the octagon. The firft ftone was laid by the latter on Lady-day, 1321. The cloifters, and other buildings belonging to the monaftery, have been long fince demolifhed, with the exception of the refectory, which has been converted into the deanery; and an elegant little chapel built by prior Crauden, now ufed as a granary, adjoining to it.

The principal charitable benefaction for the ufe of the poor of Ely is vefted in the churchwardens, and arifes from eftates in the neighbourhood, bequeathed by —— Parfon, about the year 1425. Here is alfo a free-fchool, fupported by the dean and chapter; and a charity-fchool for twenty-four boys, who are educated and cloathed by the income of an eftate bequeathed by Mrs. Needham about 1740. The police of Ely is regulated by the magiftrates, who are appointed by the bifhop, and are juftices of the peace within the ifle. Thefe meet for the difpatch of bufinefs every market-day, which was altered in 1802 from Saturday to Thurfday. This city is the only one in England not reprefented in parliament. Many of the houfes are of ftone, and fome of them have an ancient appearance. The ftreets are irregular, and, with the exception of the principal one, neither lighted nor paved. The population, as afcertained under the late act, was 3713; the number of houfes about 700. The chief employment of the inhabitants is gardening, which is carried on in this neighbourhood to a great extent. Cambridge, St. Ives, and even London, receive confiderable fupplies of vegetables from this place. Great quantities of ftrawberries are alfo reared here, and fome other fruits; but thefe are chiefly conveyed in barges to Lynn, and carried thence by the veffels employed in the coal trade to Newcaftle-upon-Tyne, and other places in the north of England.

The Rev. James Bentham, author of "The Hiftory and Antiquities of the conventual and cathedral church of Ely," was a native of this city. Some account of this gentleman has already appeared in this work. (See Bentham.) An interefting and well written account of Ely cathedral has recently been publifhed by the Rev. Mr. Miller, of this place. See alfo Lyfons's Magna Britannia, vol. ii.

About one mile from Ely is Tatterfall-hall, which derived its name from the late Mr. Tatterfall, of fporting memory, and is now poffeffed by his fon.

Ely, *Elie*, or *Ellie*, a parifh of Fifefhire, in Scotland, within which is an ancient royal borough of the fame name. This is fituated clofe to the fea, on the fouthern fhore of the Frith of Forth, where there is an excellent harbour, much reforted to by "wind-bound veffels." Seven

fquare-ſquare-rigged veſſels, carrying 1000 or 1100 tons, belong to it, and are employed in foreign trade. Veſſels of large ſize are built here; and in the town are ſome manufactories for checks, bed-ticks, and ropes. Near the ſhore rubies have been diſcovered. Contiguous to the town, in the face of Kincraig rocks, is the cave of Mac-Duff, in which it is related that Mac-Duff retreated from Macbeth and his followers. Malcolm granted many privileges to this town. Sinclair's ſtatiſtical Account of Scotland.

ELYMAIS, in *Ancient Geography*, or, as it is called by Strabo, *Elymatis*, a province of Perſia, lying between the rivers Eulæus and Oroates, and extending from the confines of Media to the Erythræan ſea, or Perſian gulf. It was formerly divided into three great diſtricts, *viz.* Meſabatene, Gabene or Gabiene, and Carbiana, and containing the following cities, *viz.* Seleucia or Soluce, on the banks of the Hedypos or Hedypnus, which Strabo calls a great city, Safirate, at a ſmall diſtance from mount Caſyrus, Badaca, on the Eulæus, and Elymais, the metropolis of the province, famous for a rich temple conſecrated to Diana, which Antiochus Epiphanes attempted to plunder, but he was obliged by the inhabitants to retire in diſgrace to Media. This temple was afterwards plundered by one of the Parthian kings, who found in it, as we are informed by Strabo, 10,000 talents. In this country there was alſo a very rich temple conſecrated to Jupiter Belus, which Antiochus the Great attempted to plunder, but loſt his life in the attempt. The country of Elymais was inhabited, according to Pliny, by the following nations, *viz.* the Oxii, or Uxii, Mizæi, Parthuſi, Mardi, Saitæ, Hyi, Coſſæi, Parætaceni, and Meſſabatæ. The Elymæans were a powerful people, inured to the toils of war, ſkilful bowmen, and never ſubdued either by the Syro-Macedonian, or Parthian kings, but governed by their own princes. If we may depend upon the authority of Strabo, the riſe of this kingdom may be dated from the downfall of the Perſian monarchy, for the ancients are agreed that the Elymæans were ſubject to the kings of Perſia; and if they never ſubmitted to the Syrian yoke, they muſt have been firſt governed by their own princes, either in Alexander's life-time, or ſoon after his death. Nothing is known of their kings, but that they aſſiſted Antiochus the Great in his wars with Rome, but afterwards cut him off in defence of their temple. They afterwards engaged, under the conduct of their king, in a war againſt the Babylonians and Suſians, in which they were aſſiſted by the Coſſæans with 13,000 archers.

Elymais is alſo a name given by ſome writers to the city of Perſepolis.

ELYMI, or Helymi, a people who inhabited the N.W. part of Sicily, about the river Crimiſa, where were ſituated the towns of Ægeſta or Aceſta, Erice and Entella.

ELYMIA, a town of Greece, in the Peloponneſus, placed by Xenophon towards the towns of Mantinæa and Orchémene.

ELYMIOTÆ, a people of Macedonia, who occupied a plain almoſt ſurrounded by mountains, towards the ſource of the river Aliacmen, according to Ptolemy. They had to the N.W. the country of the Lynceſtes, to the N.E. Emathia, to the S.E. the Pelaſgiotide, and to the S.W. Pelagonia.

ELYMNIUM, one of the names of the iſland of Eubœa.—Alſo, a town of Macedonia, on mount Athos.

ELYMUS, in *Agriculture*, a term ſignifying lime-graſs, a genus of graſſes which are of but little uſe to the farmer, except in protecting the looſe ſandy banks on the ſea-ſhores, in different parts of the iſland; and for which purpoſe the following ſort is the moſt uſeful.

Elymus *Arenarius*, ſea lime-graſs, which is a kind of graſs that, with the ſea-reed, helps very much, according to the opinion of Mr. Sole, to ſuſtain and keep up the looſe ſand-banks on the borders of the ſea, from the deſtructive effects of the tides.

Elymus, in *Botany*, ελυμος of Dioſcorides, from ελυω, *to fold up*, alluding to the ſheath which incloſes the ſpike or ear of ſome ſpecies. This etymology applies at leaſt to the Millet or Panick, ſuppoſed to be the ancient ελυμος, but Linnæus has adopted the name for a new genus of his own, akin to *Hordeum* and *Triticum*, to which it is leſs ſuitable. Linn. Gen. 39. Schreb. 54. Willd. Sp. Pl. v. 1. 467. Juſſ. 31. Sm. Fl. Brit. 152. Mart. Mill. Dict. v. 2. Claſs and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Common receptacle elongated into a ſpike. Perianth lateral, aggregate, conſiſting of two lanceolate glumes to each ſpikelet. *Cor.* of two valves; the outer one largeſt, pointed, awned; the inner concave, emarginate, finely fringed. Nectary a pair of oblong, acute, fringed ſcales. *Stam.* Filaments three, capillary, very ſhort; anthers oblong, cloven at the baſe. *Piſt.* Germen turbinate; ſtyles two, divaricated, ſhort; ſtigmas feathery. *Peric.* none, except the permanent corolla. *Seed* ſolitary, linear, convex at the back, concealed by the glumes.

Eſſ. Ch. Calyx lateral, aggregate, of two valves, containining many florets.

A genus of large coarſe rigid graſſes, for the moſt part perennial, with long creeping roots. This laſt quality renders the *E. arenarius*, Linn. Sp. Pl. 122. Sm. Engl. Bot. t. 1672. Knapp. t. 108, particularly valuable, as forming a natural barrier, in the looſe blowing ſand of many ſea ſhores, to the encroachments of the ocean, being indeed one of the principal means by which the induſtrious Hollanders have gained a part of their territories from the ſea. It is in England comprehended with *Arundo arenaria* and *Carex arenaria*, (ſee thoſe articles,) under the name of Marram, and acts of parliament have been made for their preſervation. The roots and leaves of ſuch graſſes being very durable, retain the blowing ſand, of which they accumulate more and more as they extend in growth upward, and thus gradually form a natural and very firm bank. In a clay ſoil they are of no avail. Of the economy of the American or Siberian ſpecies of *Elymus*, we have no information. Two annual European ſpecies, *E. Caput-Meduſæ* and *E. Hyſtrix*, are furniſhed with very long rough capillary awns, by which their ſeeds are not only wafted to a diſtance, but detained by the accumulation of blowing ſand, when they have once alighted, till they can fix themſelves by roots.

ELYOT, *Sir* Thomas, in *Biography*, a gentleman eminent in various branches of learning, and a patron and friend of moſt of the learned men in the reign of Henry VIII., was deſcended of a good family in the county of Suffolk, and ſon of ſir Richard Elyot. He was educated at St. Mary's Hall, in Oxford, where he made a great progreſs in logic and philoſophy; but the year in which he entered (like the year of his birth) is not certainly known; it is, however, ſuppoſed to have been about the year 1514. After he had ſpent ſome years at the univerſity, he travelled into foreign countries, and, on his return, was introduced at court. His uncommon genius and extenſive learning recommending him to the favour of Henry VIII. who was a great patron of men of letters, his majeſty conferred upon him the honour of knighthood, and employed him in ſeveral embaſſies. He ſent him, particularly, to Rome in the year 1532, on the ſubject of the divorce of queen Catharine, and afterwards to the emperor Charles V. in the year 1536. Elyot was, as Wood obferves (fee his Athen. Oxon.) an excellent grammarian, poet, rhetorician, philofopher, phyfician, cofmographer, and hiftorian; and was diftinguifhed as much for his candour, and for the innocence and integrity of his life, as for his accomplifhments. He was admired and beloved by all the men of learning who were his contemporaries, and his memory is celebrated by them in their refpective works, particularly by Leland, in his "Encomia Eruditorum Virorum." He was buried on the 25th of March 1546, in the church of Carleton, in Cambridgefhire, of which county he had been fheriff; and a monument was foon after erected over his grave. He poffeffed feveral manors in Cambridgefhire, and one or more in Hampfhire.

He wrote and tranflated feveral works. 1. "The Caftell of Health," which is faid to have been firft publifhed in 1541; but Dr. Aikin obferves, that his edition of that year is afferted to be "corrected, and in fome places augmented, by the firft author thereof." It was reprinted in 1572, 1580, and 1595. The reading of the author, as it appears from his *proheme*, or preface, was unufually great, confidering that he did not follow the profeffion of phyfic, having extended to the works of all the Greek, Arabian, and Roman writers of credit. This book was greatly efteemed, not only by the public in general, but by fome of the faculty in his time, and is, indeed, fully as worthy of notice as moft of the medical pieces of that age. His rules for diet and regimen, when not drawn from Galenical theory, are on the whole founded upon plain good fenfe; and he uniformly inculcates temperance of every kind. This he carries to a degree, with regard to certain enjoyments, that would no doubt be generally thought fomewhat too rigorous, except by fuch a bridegroom as the old gentleman in La Fontaine, who would be pleafed with our knight's authority to add all the months, from April to October, to the red letter days of his calendar.

We learn from the work in queftion, that the difeafe now called *a cold*, began to be common in England in the time of Elyot. "At this prefent time," he fays, "in this realme of England, there is not any one more annoyance to the health of man's body, than diftillations from the head, called rheums." The caufe of their being fo much more frequent than they ufed to be forty years before, he fuppofes to be "banquettings after fupper, and drinking much, efpecially wine, a little after fleep;" and alfo covering up the head too hot, a practice which prevailed to fuch a degree, that he tells us, "now a days, if a boy of feven years of age, or a young man of twenty years, have not two caps on his head, he and his friends will think that he may not continue in health; and yet if the inner cap be not of velvet or fatin, a ferving man feareth to lofe his credence."

The other works publifhed by fir Thomas Elyot, were, 2. "The Governor," in three books, 1544, 8vo.; 3. "Of the Education of Children;" 4. "Banquet of Sapience;" 5. "Prefervative againft the Fear of Death;" 6. "De rebus memorabilibus Angliæ;" 7. "An Apology for Good Women;" 8. "Bibliotheca Eliotæ, or Elyot's Library or Dictionary," 1541, folio; which work was afterwards augmented and improved by Cooper. He tranflated alfo from the Greek into Englifh, "The Image of Governance, compiled of the Arts and Sciences, by the Emperor Alexander Severus," 1556, 8vo.; and from the Latin into Englifh, "St. Cyprian's Sermons of the Mortality of Man," 1534, 8vo.; and, "The Rule of a Chriftian Life," written by Picus, earl of Mirandula, printed in the fame year. (Gen. Biog. Dict. Aikin's Biog. Memoirs of Med. in Great Britain.)

ELYRUS, in *Ancient Geography*, a town of the ifland of Crete, which, according to Paufanias, was fituated in the mountains.

ELYS BAY, in *Geography*, a bay of the ifland of Antigua, on the N. coaft, a little to the fouth of Beggar's Point.

ELYSII, in *Ancient Geography*, a people who inhabited the eaftern part of Germany.

ELYSIUM, Ελυσιος, in the *Ancient Theology*, or rather *Mythology*, a place in the inferi, *i. e.* in the lower world, or, as we fometimes render it, in hell; furnifhed with fields, meads, agreeable woods, groves, fhades, rivers, &c. whither the fouls of good people were fuppofed to go after this life.

Orpheus, Hercules, and Æneas, are fuppofed to have defcended into elyfium, in their life-time, and to have returned again. Virgil. lib. vi. ver. 638, &c. Tibullus, lib. i. eleg. 3. gives us fine defcriptions of the elyfian fields.

Virgil oppofes elyfium to tartara; which was the place where the wicked underwent their punifhment.

"Heic locus eft, partes ubi fe via findit in ambas:
Dextera, quæ Ditis magni fub mœnia tendit:
Hac iter elyfium nobis: at læva malorum
Exercet pœnas, et ad impia tartara mittit."

He affigns elyfium to thofe who died for their country, to thofe of pure lives, to truly infpired poets, to the inventors of arts, and to all who have done good to mankind.

Some authors take the fable of elyfium to have been borrowed from the Phœnicians; as imagining the name elyfium formed from the Phœnician עלז, *alaz*, or עלצ, *alats*, or עלס, *alas*, *to rejoice*, or *to be in joy*; the letter *a* being only changed into *e*, as we find done in many other names; as in *Enakim*, for *Anakim*, &c. On which footing, elyfian fields fhould fignify the fame thing as a place of pleafure; or,

"—— Locos lætos, & amœna vireta
Fortunatorum nemorum, fedefque beatas." Virg.

Others derive the word from the Greek λυω, *folvo*, *I deliver*, *I let loofe*, or *difengage*, becaufe here men's fouls are freed, or difencumbered from the fetters of the body. Beroaldus and Hornius, Hift. Philofoph. lib. iii. cap. 2. take the place to have derived its name from Eliza, one of the firft perfons who came into Greece after the deluge, and the author and father of the Ætolians. According to Diodorus Siculus (l. 1. c. 36.) the whole fable of the infernal regions was borrowed from the funeral rites of the Egyptians, and introduced into Greece by Orpheus. Hence Homer is faid to have borrowed his ideas and defcriptions, which occur in various parts of the Odyffey. Accordingly in the fourth book he gives the following account of elyfium in the addrefs of Proteus to Menelaus:

"Elyfium fhall be thine; the blifsful plains
Of utmoft earth, where Rhadamanthus reigns.
Joys ever young, unmix'd with pain or fear,
Fill the whole circle of th' eternal year:
Stern winter fmiles on that aufpicious clime:
The fields are florid with unfading prime:
From the bleak pole no winds inclement blow,
Mold the round hail, or flake the fleecy fnow.
But from the breezy deep, the bleft inhale,
The fragrant murmurs of the weftern gale."
Pope's Od. b. iv. v. 765, &c.

The other poets as well as the philoſophers ſeem to have copied their notions of hell and of the elyſian fields from Homer. Plato, in his account of the ſtate of departed ſpirits, repreſents the ſoul of the deceaſed as paſſing into a place, which he calls divine, and as being there judged. If his life was conformable to the right of reaſon, he is advanced to a higher apartment, where he enjoys pleaſure and proſperity in the ſociety of the gods; whilſt the ſouls of bad men ſink into a noiſome abyſs, there to dwell in thick darkneſs, and to endure every kind of miſery. Socrates alſo adopted ſimilar ideas. This philoſopher diſtinguiſhed a threefold ſtate of ſouls departed. Thoſe who had neither ſingular merit nor enormous vices, inhabited the confines of Acheruſia, where, being purified by the waters of the lake, they received the rewards of the few virtues they had practiſed. The ſouls of the wicked wandered about their tombs, where they were tormented in different ways. After which, having drank the water of Lethe, they entered into new bodies, more or leſs honourable, according to their merit. The ſouls of the good went immediately into the elyſian fields. Pythagoras maintained, that the ſoul, upon its immediate ſeparation from the body, was conducted by Mercury into a place of the pureſt air, in which were the elyſian fields, called by Virgil the "aerial regions," *aerios campos*. The ſouls of the philoſophers, which were the beſt of all, became like to the gods, while thoſe of the wicked were tormented by the furies without intermiſſion. Both the one and the other, after a certain period of purification, returned to the earth to animate new bodies. Thus did this philoſopher inculcate, firſt in Europe, the doctrine of the metempſychoſis, or tranſmigration of ſouls, which he is ſaid to have borrowed from the Egyptians, and which had been taught before by Orpheus and Homer, who had borrowed it from the ſame people. Accordingly we learn from Herodotus, that the Egyptian prieſts maintained, that the ſoul does not die with the body, but is received into Amenthes, which was a place under ground, reſembling the hell of the Greek poets. Plutarch ſays, that this word denotes "that which gives, and that which receives," and adds, that it was a place in the centre of the earth, the common receptacle of departed ſouls. Hence, after a certain period, they were releaſed, and united to new bodies. The poets have delivered ſentiments ſimilar to thoſe of the philoſophers concerning the ſtate of ſouls after death, and whilſt each had his peculiar notions, all agreed, that the ſoul goes either to Elyſium or Tartarus; though they are far from being unanimous as to the ſituation of theſe two manſions. Some place the elyſian fields in the middle region of the air; ſome in the moon; others in the ſun; and others again in the centre of the earth adjoining to Tartarus. The moſt common opinion is, that they lay in one of the iſles of the ocean, called the "Fortunate iſlands," which are reckoned to be the Canaries. According to Ol. Rudbecks the elyſian fields were ſituated in Sweden. In the opinion of many of the ancients, the manſion of the bleſſed was in the charming country of Betica (the preſent Andaluſia in the extremity of Spain towards Cadiz,) whither the Phœnicians had travelled from the earlieſt times, and which was repreſented as a delicious country, poſſeſſing a fertile ſoil, abounding with enchanted groves, enriched by mines of gold and ſilver, and watered with rivers, ſtreams, and fountains. According to Homer, the infernal regions were in the country of the Cimmerians, who are ſaid to have inhabited the weſtern coaſts of Italy, near Baiæ and Puteoli, where Ulyſſes arrives on the ſame day that he takes his leave of Circe. Virgil has adopted Homer's notion, and places the mouth of hell upon the ſame coaſt, near the lake Avernus. Others, however, of the poets, place the entrance of hell at the promontory of Tenarus, where was the cave from which Hercules dragged Cerberus when he went down to hell. Others ſeek for it in Theſprotia, and Lucan refers it to the banks of the Euphrates. The ancients differ in opinion with reſpect to the time, during which departed ſouls continued in the infernal regions. Some ſuppoſe that ſouls doomed to Tartarus continued there a thouſand years, before the period of their tranſmigration commenced. Pindar fixed the reſidence of the bleſſed in the elyſian fields for ever; whence, according to Virgil and the other poets, they were to depart after a certain period of time, having drank the water of oblivion; and this period was uſually limited to a thouſand years. (See Tartarus.) The poets, Homer, Virgil, Pindar, Claudian, Catullus, &c. deſcribe the regions of bliſs under a variety of pleaſing images, ſuch as green bowers, gliding ſtreams, murmuring ſprings, charming meadows, ſerene air, perpetual ſprings, warbling birds, &c. Tibullus, whoſe imagination was voluptuous, repreſents it as abounding with mirth and all ſenſual pleaſures. Virgil admits merely chaſte and innocent enjoyments, and in this reſpect he has copied Homer.

ELYTROCELE, (from ἐλυτρον, the *vagina*, and κηλη, a *tumour*,) in *Surgery*, a hernia in the vagina.

ELYTROID, in *Anatomy*, from ἐλυτρον, a *ſheath*, and ειδος, *form*, is a name applied to one of the coverings of the teſticle. See Generation, *Organs of*.

ELYTRON, properly a covering of any ſort, and for any ſubſtance. Hippocrates has appropriated the word to ſignify the membranes which involve the ſpinal marrow.

ELZEVIRS, in *Biography*, celebrated printers at Amſterdam and Leyden, lay claim to a ſhort notice in this work, on account of the many valuable books which were printed at their preſſes, and of the perfection to which they carried their art at a comparatively early period. The firſt of the family was Lewis, who was diſtinguiſhed for his editions from the year 1595. He was ſucceeded by Bonaventure, Abraham, and Daniel, of whom the laſt died about the year 1680. The ſmall types of theſe famous printers have a clearneſs and elegance which have rarely been equalled. Virgil, Terence, and the Greek Teſtament, printed in 1633, diſtinguiſhed by characters in red ink, are reckoned maſter-pieces; and the beſt of their claſſics ſtill maintain a high value. Moreri.

ELZT, or Eltz, in *Geography*, a town of Germany, in the country of Lower Saxony, and biſhopric of Hildeſheim on the Saale; 9 miles S.W. of Hildeſheim.

EM, or Embak, a river of Ruſſia, in the government of Riga or Livonia, which iſſues from the lake Wyrtz, and falls into the Peipus.

EMANATION, formed of the Latin *e*, out of, and *manare*, to flow or ſtream, the act of flowing, or proceeding, from ſome ſource or origin. Such is the emanation of light from the ſun; or that of effluvia from odorous, &c. bodies; of wiſdom from God, &c.

The principle of emanation was adopted from the moſt remote times by the oriental philoſophers, and by means of emanation from an eternal fountain of being, they endeavoured to explain the nature and origin of things. Zoroaſter, at an early period, maintained this ſyſtem, alleging, that various orders of ſpiritual beings, gods or dæmons, have proceeded from the deity, which are more or leſs perfect, as they are at a greater or leſs diſtance, in the courſe of emanation, from the eternal fountain of intelligence; among which, the human ſoul is a particle of divine light which will return to its ſource, and partake of its immortality; and matter is the laſt or moſt diſtant emanation from

the

the firſt ſource of being, which, on account of its diſtance from the fountain of light, becomes opake and inert, and whilſt it remains in this ſtate is the cauſe of evil: but, being gradually refined, it will at length return to the fountain whence it flowed. This doctrine of emanation afterwards produced many fanciful opinions in theology. It was adopted by the ancient Indians, and taught under various modifications by the Brachmans. The ſame ſyſtem was likewiſe received among the Egyptians, taught by Orpheus and Pythagoras, and communicated to the Greeks either from Egypt or from the Eaſt. Wherever it originated, it was taught for many ſucceſſive ages in the more civilized regions of Aſia and Africa, and both before and after the commencement of the Chriſtian era, it gradually ſpread through the Alexandrian, Jewiſh, and Chriſtian ſchools. It was a diſtinguiſhing tenet of the Jewiſh Cabbala, of Simon Magus, and of the Gnoſtics and modern Platoniſts. This ſyſtem, as it was taught by the oriental, Alexandrian, and Cabbaliſtic philoſophers, comprehended the following tenets. All things are derived, by emanation, from one principle; which principle is God. From him a ſubſtantial power immediately proceeds, which is the image of God, and the ſource of all ſubſequent emanations. This ſecond principle ſends forth, by the energy of emanation, other natures, which are more or leſs perfect, according to their different degrees of diſtance, in the ſcale of emanation, from the firſt ſource of exiſtence, and which conſtitute different worlds, or orders of being, all united to the eternal power from which they proceed. Matter is nothing more than the moſt remote effect of the emanative energy of the Deity. The material world receives its form from the immediate agency of powers far beneath the firſt ſource of being, and is the neceſſary effect of the imperfections of matter. Human ſouls are diſtant emanations from Deity; and, after they are liberated from their material vehicles, will return, through various ſtages of purification, to the fountain whence they firſt proceeded. Nothing can be more fanciful than the numerous fictions which are blended in this ſyſtem, and which have been grafted upon it by enthuſiaſts of different deſcriptions, both philoſophical and theological; inſomuch that it has been the ſoul of enthuſiaſm and fanaticiſm. (See THEOSOPHISTS.) Some of the modern Eclectic philoſophers attempted to unite the atomic and emanative ſyſtems; and Jordano Bruno, in particular, founded his doctrine on the ancient ſyſtem of emanation. See BRUNO.

EMANATION is alſo uſed for the thing that proceeds, as well as the act of proceeding. The power given a judge is an emanation from the regal power; the reaſonable ſoul is an emanation from the divinity.

EMANATION is alſo uſed among the ſchoolmen, for the production of a leſſer thing, in order to the production of a greater, by virtue of ſome natural connection, or dependence between them.

Hence that is called an emanative cauſe (in contradiſtinction to an efficient cauſe) which produces an effect by its mere preſence, without the intervention of any action; as a roſe doth a ſmell, &c. Others, and with good reaſon, deny that there is any ſuch thing as an emanative cauſe, to produce an effect without any action. See CAUSE.

EMANCIPATION, formed from the Latin *ex*, of, and *mancipium*, a ſlave, in the *Roman Law*, was the act of ſetting a ſon free from the power and ſubjection of his father.

Emancipation differs from manumiſſion, as the latter was the act of a maſter in favour of a ſlave, the former that of a father in favour of his ſon.

The effect of emancipation was, that the goods, and moveable effects, which the ſon ſhould thenceforth acquire, ſhould be his ſole property, and not the property of his father, as they were before emancipation. Beſides, emancipation put the ſon in a capacity of managing his own affairs, and of marrying without his father's conſent, though a minor, or pupil, and under twenty-five years of age.

There were two kinds of emancipation; the one *tacit*, which was by the ſon's being promoted to ſome dignity, or by his coming of age, or by marriage; in all which caſes, the ſon became his own maſter of courſe.

The other *expreſs*, where the father declared before the judge, that he emancipated his ſon. This was not performed without ſome formality: the father was firſt to ſell his ſon imaginarily to another man, whom the lawyers call *pater fiduciarius*, *father in truſt*; of whom being bought back again by the natural father, he manumitted, or ſet him free, by a declaration before the judge. This imaginary ſale was called mancipatio; and the manumiſſion conſequent thereon, emancipatio.

Emancipation obtained in France, chiefly with regard to minors, or pupils, who were hereby ſet at liberty to manage their effects, without the advice, or direction, of their fathers or tutors. It muſt be obſerved, however, that emancipation only extended to the ſelling of moveables, and letting of leaſes, &c. of immoveables; not to the ſelling or mortgaging of immoveables; which were only done with the conſent of a curator, ordinarily a perſon appointed, when emancipated.

Formerly emancipation was performed in the ordinary courts of juſtice, when deſired by the child; but if he were a minor, the king's letter was alſo required. Though there were other ways of emancipation, as by marriage; arriving at the age of twenty years; and in ſome provinces by the death of the mother, becauſe the children were there under the power of the father and mother conjointly; ſo that the death of either of them emancipated the child.

Emancipation by marriage, in France, gave a power of marrying again, without the father's conſent though under age; but among the Romans, Cujas tells us, a widow, under twenty-five years of age, though emancipated by her former marriage, returned into the power of the father, and might not marry a ſecond time, without his conſent.

Du-Cange obſerves, that the word emancipation was alſo uſed in the monaſteries, in ſpeaking of monks promoted to any dignity, or removed from under the power of their ſuperiors; as alſo in ſpeaking of monaſteries, chapels, &c. themſelves, when exempted by the pope, from the juriſdiction of the ordinary.

EMANUEL, in *Biography*, king of Portugal, ſon of the infant Don Ferdinand, duke of Viſco, ſucceeded his couſin John II. in 1495. He was then in his twenty-ſixth year, and highly eſteemed for the excellent qualities of his mind. He began his reign by reſtoring the nobility to that conſequence in the ſtate of which it had been the policy of his predeceſſor to deprive them. He ſhewed an inclination to favour the Jews, who had been enſlaved in the former reign; but by the violence of his adviſers, he did not dare to follow the bent of his own mind, and demanded of theſe unhappy people, as the terms of their liberty, that they ſhould inſtantly profeſs themſelves Chriſtians, in name, though a period of twenty years ſhould be allowed them for their converſion. Moſt of them complied with the required condition; but others, and thoſe not a few, voluntarily put an end to their lives, rather than ſubmit to a dereliction of principle. Some of them were ſo indignant at the requiſition that they firſt murdered their own children, and then

then committed the raſh deed upon themſelves; thinking death in any form better than an abandonment of the religion of their fathers. In 1496 he married Donna Iſabella, daughter of Ferdinand and Iſabella of Spain, who died the next year, having firſt given him a ſon and heir. This was the period in which the new paſſage to the Indies was diſcovered by Vaſco de Gama, a circumſtance which proved the ſource of great riches to Portugal., and contributed to fix the epithet of *fortunate* upon this prince. In 1499 he married the younger ſiſter of his late wife; and in 1501, under his auſpices, the Brazils were diſcovered, which have proved a more laſting benefit to Portugal than her Indian poſſeſſions, and which has at length become an aſylum to the exiſting monarch, driven by Bonaparte from his European poſſeſſions. Emanuel, in gratitude for the important diſcoveries made in his reign, founded the famous monaſtery of Bethlehem, near Liſbon. He now adopted the plan of making conqueſts in Africa, in which he was not very ſucceſsful, but by the talents of Albuquerque he formed a very uſeful alliance with the king of Congo. Although proſperous in a high degree, he met with mortifications ſufficient to lead him to declare his purpoſe of reſigning his crown into the hands of his ſon. The eagerneſs which the young man ſhewed for power, and the marked attention which the courtiers paid him, cauſed the monarch to change his purpoſe. He died in 1521, in the 53d year of his age, at a time when he was regarded as one of the moſt powerful and ſplendid princes in Europe. Emanuel, when religion was out of the queſtion, was capable of liberal and generous conduct. He treated with great favour Don George, natural ſon of the late king, for whom his father had endeavoured to procure the ſucceſſion to the crown; and he reſtored to their titles and eſtates the Braganza family, who had ſuffered attainder and confiſcation in the late reign. In the hiſtory of his country, Emanuel ſtands very high for piety, humanity, munificence, and thoſe other good qualities that do honour to an enlightened ſovereign. Univer. Hiſt.

Emanuel-Philibert, duke of Savoy, ſon of duke Charles III., was born in 1528, and though deſtined for the church, yet by the early death of two elder brothers, he was brought up as heir to the ſovereignty. He viſited the court of the emperor Charles V., by whom he was created knight of the Golden Fleece. He accompanied Philip II. into England, and was afterwards entruſted by him with the command of his armies. He was general at the ſiege of Metz, and at the battle of St. Quintin, in 1557, in which the French ſuſtained a ſignal defeat. He married Margaret, daughter of Francis I. of France, and by that alliance regained all the dominions which his father had loſt. At the perſuaſion of ſome bigots he attempted the extirpation of the Vaudois, proteſtants of Savoy, but was defeated in his projects, and by the influence of the ducheſs, who was well diſpoſed towards the reformation, he willingly allowed them the exerciſe of their religion. He died reſpected and beloved in 1580, after a reign of 27 years. Univer. Hiſt. Moreri.

EMARGINATUM Folium, in *Botany*. (See Leaf.) The term applies only to the extremity or apex of a leaf, and expreſſes a notch in that part, apparently cauſed by a greater tightneſs or contraction in the nerve, than in the ſofter more dilatable parts adjacent, which are therefore extended beyond it. The petals of flowers, however, are very often emarginate in their original conformation, as in many ſpecies of Chickweed or Sandwort.

EMASCULATION, the act of taking from a male thoſe parts which are characteriſtic of his ſex. See Castration.

EMAUX *de l'Eſcu*, in *Heraldry*, the metals and colours of a ſhield, or ſcutcheon.

EMBA, or Yemba, in *Geography*, a river of Ruſſia, which takes its riſe in the ſouthernmoſt part of the Ural mountains, and conſtitutes the border between the Uſimſkoi government and the country of the Kirchiſtzi, though the forts are much more to the weſt, namely, on the river Ural. The Emba takes up only one river of note, the Sagiſs, has a ſtrong current, but is at the ſame time very ſhallow. It is the moſt eaſterly of all the rivers that fall into the Caſpian.

EMBABE', a village of Egypt, oppoſite to Boulac, near Cairo, upon the weſt bank of the Nile, famous for the excellent quality of its butter, and for a variety of lupins, which grow in its vicinity, and called embaben. Theſe are ſold ready dreſſed in the ſtreets and markets, and they ſupply Lower Egypt. Their general appellation in the country is "termeſs." The Chriſtians of the Eaſt eat lupins as a ſtimulus for drinking brandy. Flour is made of them, which is uſed for cleaning the hands and ſoftening the ſkin. The ſtalk, reduced to aſhes, is preferred to other charcoal in the compoſition of gun-powder.

EMBALMING, the opening of a dead body, taking out the inteſtines, and filling their place with odoriferous and deſiccative drugs and ſpices, to prevent its putrefying.

The word is formed from *balm*, which was a principal ingredient in the embalmings of the ancient Egyptians.

Dr. Grew, in his Muſeum Regalis Societatis, is of opinion, that the Egyptians boiled their bodies in a large cauldron, with a certain kind of liquid balſam. His reaſon is, that in the mummies preſerved in the collection of the Royal Society, the balm has penetrated not only the fleſhy and ſoft parts, but even the very bones; ſo that they are all as black as if they had been burnt.

The Peruvians had an effectual method of preſerving the bodies of their incas, or kings, embalmed.

The mode of embalming dead bodies among the Egyptians was as follows: when a man died, his body was carried to the artificers, whoſe trade it was to make coffins; they took the meaſure of the body, and made a coffin for it, proportioned to its ſtature, the dead perſon's quality, and the price that people were willing to give. The upper part of the coffin repreſented the perſon who was to be ſhut up in it, whether man or woman. If it was a man of condition, this was diſtinguiſhed by the figure which was repreſented on the cover of the coffin; there were generally added paintings and embelliſhments, ſuitable to the quality of the perſon. Vide Caſſian Collat. 15. cap. 3. & Cicero, Tuſc. Quæſt. lib. i. Herodot. lib. ii. cap. 86. Diodor. lib. ii. cap. 5.

When the body was brought home again, they agreed with the embalmers at what rate particularly they would have it embalmed, for the prices were different; the higheſt was a talent of ſilver, eſtimated at about 258*l.* 6*s.* 8*d.* or, as others ſay, about 300*l.*: twenty minæ was a moderate one, and the loweſt price was a very ſmall ſum. They immediately ſent for a deſigner, who marked the body, as it lay extended, at the place where it ſhould be opened, on the left ſide, and the length of the inciſion. A diſſector, with a very ſharp Ethiopian ſtone, made the inciſion, and hurried away as faſt as he could, becauſe the relations of the perſon deceaſed, who were preſent, took up ſtones, and purſued him as a wicked wretch, with an intention to ſtone him.

This operation being finiſhed, the embalmers, who were looked upon as ſacred perſons, entered to perform their office,

office. They drew all the brains of the dead perſon through his noſtrils, with a hooked piece of iron, provided particularly for this purpoſe, and filled the ſkull with aſtringent drugs; they likewiſe drew all the bowels, except the heart and kidneys, through the aperture which they had made in the ſide. The inteſtines were waſhed in wine from the palm-tree, and in other ſtrong and binding drugs. The whole body was anointed with oil of cedar, after having been filled with myrrh, cinnamon, and other ſpices, for about thirty days, ſo that it was preſerved entire, not only without putrefaction, but had a good ſcent with it. Αιγυπτιοι δε τα εντερα εξελοντες ταριχευσιν αυτους. And the Perſians, as the ſame author, Sextus Empiricus, obſerves, were uſed νιτρω ταριχευειν. Sext. Empir. Pyrrhon. Hypoth. lib. ii. cap. 24.

Bodies thus preſerved are called *mummies*, from the Arabic word *mam*, which ſignifies wax, this being an ingredient in the preparation.

After this the body was put into ſalt for about forty days; wherefore when Moſes ſays, that forty days were employed in embalming Jacob, we are to underſtand him as meaning the forty days of his continuing in the ſalt of nitre, without including the thirty days paſt in performing the other ceremonies above-mentioned, ſo that, in the whole, they mourned ſeventy days in Egypt, as Moſes likewiſe obſerves.

Afterwards the body was taken out of the ſalt, waſhed, wrapt up in linen ſwaddling-bands, dipped in myrrh, and rubbed with a certain gum, which the Egyptians uſed inſtead of glue. Then the body was reſtored to the relations, who put it in a coffin, and kept it in their houſes, or in tombs made particularly for this purpoſe. There are ſome found, at this day, in Egypt, in chambers, or ſubterraneous vaults, which fully juſtify the truth of what is here ſaid.

They who were not rich enough to bear this expence, contented themſelves with infuſing, by a ſyringe, through the fundament, a certain liquor extracted from the cedar, and leaving it there, wrapt up the body in ſalt of nitre. This oil preyed upon the inteſtines, ſo that when they took it out, the inteſtines came along with it dried, and not in the leaſt putrefied. The body being incloſed in nitre, grew dry, and nothing remained beſides the ſkin glued upon the bones. They who were too poor to be at any conſiderable expence, did no more than cleanſe the inſide, by ſyringing a liquor into it; this done, they put the body, without farther ceremony, into nitre for ſeventy days, in order to dry it. Calmet, Diction. Bibl. Pococke's Deſcription of the Eaſt, vol. i. p. 230, &c.

The preſent method of embalming in Egypt differs very much from the ancient. Mallet informs us, that it is now the cuſtom to waſh the body ſeveral times in roſe-water; then to perfume it with incenſe, aloes, and other odours, in great abundance; the body is afterwards wrapped up in a winding-ſheet, made partly of ſilk, and partly of cotton, moiſtened probably with ſome liquid perfume; this is again covered with another cloth of unmixed cotton, to which is added one of the richeſt ſuits of clothes of the deceaſed. Letter X. p. 88.

The art of embalming, ſays Sonnini, is now unknown to the Egyptians. As ſoon as a perſon is dead, they preſs the different parts of the body, in order to make it diſcharge all its impurities; they repeatedly waſh it, ſhave it, pluck out all the hair, and ſtop all the apertures cloſely with cotton; they then pour upon them odoriferous waters, and the perfumes of Arabia penetrate into all their pores. The inanimate remains are then committed to the earth; and upon the ſpot where the head of the deceaſed lies, they erect a ſmall ſtone pillar, crowned with a turban. Every Friday they reſort to the foot of this ſepulchral monument, and renew their mournful adieus.

Dr. Ward, in his Diſſertations on this ſubject, ſuppoſes that the Jewiſh method of embalming was very different from the Egyptian, and that this appears from ſeveral paſſages in the New Teſtament. Both, as he conceives, ſwathed up their dead; but inſtead of the Egyptian *embowelling*, he ſuppoſes the Jews contented themſelves with an *external unction*; and that inſtead of myrrh and caſſia, they uſed myrrh and aloes. To this account he alſo adds the ſuppoſition, that St. John might mention the circumſtance of our Lord's embalming, in order the better to obviate the falſe report which then prevailed among the Jews, that the body of our Lord had been ſtolen away in the night by his diſciples; for the linen, he ſuppoſes, could not have been taken from the body and head, in the manner in which it was found in the ſepulchre, on account of its clinging ſo faſt from the viſcous nature of theſe drugs, if they had been ſo fooliſh as to attempt it. It is certain that the modern Egyptian mode of embalming, if it may be ſo called, differs very much from the ancient; but it is not eaſy to determine how far the Jewiſh method, in the time of our Lord, differed from that of the Egyptians. It does not appear indeed to be certain, that the Jews were not accuſtomed to embowel their dead in embalming. As all other nations ſeem to have embalmed exactly according to the Egyptian manner, the ſame cauſes that induced them to do ſo, probably occaſioned the Jews not to vary from them in this reſpect. It does not, however, follow from hence, that our Lord was embowelled, though St. John ſays (ch. xix. 40.), that he was buried with ſpices, "as the manner of the Jews was to bury;" for theſe words do not neceſſarily ſignify, that all was done that was wont to be done in thoſe caſes among the Jews. Indeed, the contrary appears to have been the fact, from the farther preparations made by the women, who probably were not acquainted with what had been done, though Dr. Ward ſuppoſes the contrary; ſince St. Luke expreſsly tells us (ch. xxiii. 55.), that "the women, which came with him from Galilee, followed after, and beheld the ſepulchre, and how his body was laid." Admitting this ſtatement, Ward's thought concerning the difficulty of taking off the bandages, beſmeared with very glutinous drugs, muſt appear to be unfounded; for in that caſe, the women could have done nothing more as to the embalming of him. Beſides, aloes and myrrh do not appear to poſſeſs that very glutinous quality which Dr. Ward aſcribes to them; and it is more reaſonable to ſuppoſe that St. John mentions this circumſtance, concerning which the other evangeliſts are ſilent, becauſe he publiſhed his hiſtory for the uſe of perſons leſs acquainted with the cuſtoms of the Eaſt, than thoſe for whoſe information the others wrote. This reaſon induced him to ſay to thoſe who were wont to *burn* their dead, that our Lord was *buried with ſpices*, which was *in general* the Jewiſh method of diſpoſing of their dead; and this he might very well do, though the ſhortneſs of the time occaſioned ſome deviation from what they commonly practiſed. This ſhortneſs of time prevented them alſo from ſwathing him with that accuracy and length of bandage, which they would otherwiſe have uſed; in conformity to the cuſtom obſerved among the Egyptians, and probably alſo among the Jews: for we are informed, that the Egyptians have uſed above a thouſand ells of filletting about a body, beſides what

what was wrapped about the head. Such, indeed, was the hurry of the difciples, that our Lord's head was fimply bound about with a napkin; a practice ufed by the Mahometans at this time. What was done by Jofeph and Nicodemus with the mixture of myrrh and aloes, which they provided, doth not appear. Dr. Lardner fuppofes, they might have formed a bed of fpices. A modern Jew, cited by bifhop Kidder, objects to the hiftory of the New Teftament; alleging that the quantity was fufficient for 200 dead bodies, that is, allowing half-a-pound for each body. But this quantity falls far fhort of that which modern furgeons ufe in embalming. It appears from what Jofephus (Antiq. lib. 15.) fays of the funeral of Ariftobulus, the laft of the high priefts of the family of the Maccabees, that the larger the quantity of fpices ufed in their interments, the greater honour was thought to be done to the dead; and therefore we may eafily account for the quantity brought by Nicodemus, though we may not be able to tell precifely how he difpofed of it. Might not large quantities of precious perfumes be ftrewed, or defigned to be ftrewed, about the body of our Lord? Harmer's Obf. vol. ii.

It is no wonder that we find human bodies preferved without corrupting for many ages, by means of fpices, and other ingredients, proper to refift putrefaction, applied with the niceft care; but it is ftrange that there fhould be a fort of embalming performed by nature, in fome places, where bodies are preferved merely by the virtues of the foil in which they lie; yet this is evidently the cafe in fome inftances. We have, in the Philofophical Tranfactions, an account of a man and a woman who were loft in the great fnows on the moors of Hope, near the woodlands in Derbyfhire, on the 14th of January, 1674. Thefe perfons were not found till the 3d of the May following, at which time they fmelt fo ftrong, that the coroner prudently ordered them to be buried on the fpot. Thefe bodies lay buried in the peat-mofs 28 years before they were looked at again; when fome people of the country, who had heard of the ftrange virtues of the foil thereabouts in preferving dead bodies, opened the ground, and found them no way altered, the colour of the fkin being fair and natural, and the flefh as foft as that of perfons newly dead. Phil. Tranf. N° 434, p. 415.

After this the place was remarked where they lay, and they were fhewn for a fight for 20 years, though they were much changed by having been fo often uncovered in that time.

EMBANKMENT, in *Rural Economy*, a large body, mound, or bank of earth, conftructed and thrown up in different ways, according to circumftances, with the view of guarding, protecting, and defending lands on the borders of the fea, rivers, and lakes, from being inundated and injured by them.

They are of different kinds and forms, according to the nature of the fituations and the materials of which they are conftituted. In embanking againft the fea and large rivers, where the flopes next them are naturally gentle and eafy, they are moftly of the earthy defcription, being well put together, and covered on the furface with turf cut from the tough fward of the land in the neighbourhood; but, in cafes where the banks, borders, and fhores, are more fteep and bold, they are ufually of a more hard and folid nature: being often made with ftone, brick, gravel, fand, fhells, and other fimilar fubftances, laid clofely in fome fort of tenacious material, fuch as clay, mortar, and other matters of the fame quality. Wood is likewife, in fome inftances, employed in their conftruction.

In works of this fort, very much depends upon the form in which they are conftructed, and the nature and management of the materials which are made ufe of in the bufinefs. In refpect to the firft, it may be remarked, that banks of thefe kinds are commonly conftructed with too narrow bafes for the heights which are given them: from which circumftance, the fides which are oppofed to the effects of the water become too fteep and upright; confequently, in cafes of high tides or floods, they are utterly incapable of refifting their weight, which has equally a lateral and downright preffure. Befides this, there is another difadvantage attending this method of forming them, which is, that the floods, as well as the tides, in ebbing and flowing, have a more continued action on one part than would be the cafe, if the flopes were more gentle and gradual; confequently, they have a much greater tendency to break down and deftroy the fuperficial parts of the banks. With fome variations in the forms, moft of the embankments in this country are, however, made in this way. They may fucceed in fome particular inftances; but in general it is found, that breaches are frequently taking place in them, from the effects of the fea or floods, which are not capable of being filled up or repaired, without confiderable difficulty and trouble; and which, if fuffered to continue even for a fhort fpace of time, endanger the whole embankment.

The common form of embankment is fhewn at *fig.* 1, *Plate* X. *Agriculture*, and the improved form pointed out at *fig.* 2, in the fame plate.

The angles or flopes of thefe forts of works are made very different in different cafes; but that fhewn in the above figure feems in general well calculated for the purpofe of refifting the impreffion of heavy tides, or the waters of floods. The greater breadth they have in proportion to their height, the more effectual they muft be in refifting the power of the waters which come upon them.

In regulating the heights of embankments, it is neceffary to afcertain the greateft depth of water at the higheft tides or floods; making the fummits of them about two feet higher than the points to which they rife at fuch times. By fome, a lefs height than this above the higheft mark of the tides or floods has, however, been confidered fufficient; but it is always proper to be on the fafe fide, as the confequences of an overflow are very ferious.

In forming embankments with ftones, or other fimilar materials, which, as has been feen, is effential in bold fteep banks or fhores, it is neceffary that they be laid in proper materials, and be clofely jointed next the fea, or the rivers, fo as to be fully capable of refifting the entrance of water; as, unlefs this be the cafe, they will by no means be complete: for the water, infinuating itfelf between the openings, finks down among the ftones, foftens and loofens the clayey or earthy matters underneath, by which portions of them are continually forced out and wafhed away; hollows being formed in that way below, and the ftones naturally finking down; in confequence of which, the waters rufh into the cavities with confiderable impetuofity, and quickly difplace others, and the whole embankment is foon deftroyed. This very frequently takes place with the heads thrown acrofs rivers, and fuch paved or caufewayed banks as are formed with the view of protecting and preferving thofe bold and open fhores, which are liable to be undermined and carried away by the wafhing operation of the waters which come againft them. In order to render the embankments perfectly fecure in fuch cafes, they fhould be laid with good mortar, and be pointed with a ftrong cement. A good coat of gravel, in fome cafes of this kind, is even found far fuperior to paving with ftones.

In conſtructing embankments of the quay, or other ſimilar kinds, a mortar formed from powdered unburnt lime-ſtone and coarſe ſharp ſand is employed; the whole being pointed with puzzolana earth, by which they become as ſolid as rock, and fully reſiſt the effects of water. The lime of particular ſorts of lime-ſtone is found more proper for forming this ſort of mortar cements than that of others: thus, that found at Dorking in Surrey is ſuppoſed to conſtitute the moſt durable ſubſtance of this kind of any in the kingdom; and has been employed in forming the new docks in the river, near London. And an excellent ſort of lime-ſtone for the ſame purpoſe has likewiſe been diſcovered near Worſley, in Lancaſhire, which is there termed Sutton lime.

It has been ſuggeſted by a late writer, that an excellent mortar cement for this uſe, which hardens under water, may be compoſed by having four parts of blue clay, ſix of the black oxyd of mangáneſe, and nine of carbonate of lime, ſubmitted to a white heat, and then well incorporated with ſixty parts of ſand, and as much water as may be neceſſary to form it into a mortar.

It is invariably found, in examining the ſhores of the ſea, and the banks of rivers, that ſuch as have eaſy and gently declining ſlopes from their beds to their borders or banks; and thoſe which are formed in a ſteep upright manner, of rocky materials, ſuch as are ſhewn at *figs*. 3, and 4, are the leaſt expoſed to injury from the effects of their waters: the two former being the moſt ſecure, when ſpread over or coated with good coverings of ſand or gravel, or uniformly turfed over quite down to the water-ſide with the ſward of a tough old paſture. The ſtrength and firmneſs of their banks are in proportion to the extent of the ſlope; and their durability depends on that of their being made uniform on their ſurfaces, both in reſpect to hardneſs and ſmoothneſs: as, in the former caſe, from the great length of ſlope, the flows and decreaſes of the waters act more momentarily on their different parts, and their greater weight renders their banks more firm; while, in the latter caſe, by the equality of their ſurfaces, the power of the waters is rendered the ſame on one part as another, and no obſtacles are left for the producing of eddies, or other means of forming holes or breaks in them.

In the latter, or thoſe of the bold, upright, rocky kind of banks, their ſtrength chiefly depends on the reſiſtance of the large quantity of materials by which they are backed, and not on the manner in which they are diſpoſed, as in the former caſe; and their durability, on that of the uniform compactneſs of texture in the parts oppoſed to the effects of the waters: as, where theſe have fiſſures in them, or are ſofter in ſome parts than others, the waters are liable to enter and break down the banks in time, according to the particular nature of the caſes. A ſtriking example of this kind lately occurred in the Iſle of Wight.

It is, therefore, of importance that the modes and forms of embankment, which are thus naturally preſented, ſhould be improved upon by art. It is evident, that if a cut was formed behind the embankment, as in *fig*. 5, at the letter *x*, the ſhores or banks, though, in this caſe, as it were, detached from the land, would be found equally ſtrong and capable of reſiſting the preſſure of the waters, as in their original ſtate. Hence, if a mound or bank was formed, and placed out at the diſtance of one, two, or three miles from the ſhore or other embankment, within the bed of the ſea or other waters, as at *y* in the ſame figure, it would be equally capable of reſiſting them as in the former inſtance, and not more liable to be broken down by their preſſure than in its former ſtation; and would alſo defend them as completely from the intermediate ſpace of land, as it did before from the narrow trench. Conſequently, on this principle, vaſt tracts of land may, in different parts of the kingdom, be obtained by judicious embankments.

Though the ſhores of bold ſteep coaſts may not afford examples equally capable of being followed with advantage as the above, they nevertheleſs ſuggeſt uſeful hints for the purpoſe of defence, in caſes of bold, abrupt, broken ſhores, conſtituted of earth, or of that material and rocky ſubſtances intermixed. It readily preſents itſelf to the mind, that the raiſing a good perpendicular ſtone-wall againſt ſuch banks, renders them nearly as ſtrong and laſting as thoſe formed by nature of ſteep, ſolid, rocky bodies. This ſort of walled bank is exhibited at *fig*. 6. But though this method may be practiſed, in caſes of the above kind, with great advantage, it is not by any means applicable in general to rivers; as, with them, the water, during the periods of floods, ſtands in need of room to ſpread, which is the great uſe of giving their banks a ſloping form; while, in this way, by being confined, it would have the effect of doing more injury than was the caſe before. Inſtances may, however, happen in which it may be had recourſe to with propriety, in defending a part of the bank of a river, without giving it a ſloping direction, or for protecting one part of a bank at the riſk of that which is oppoſite to it; but well-conſtructed piers, in ſuch caſes, are frequently more perfect, and conſtantly attended with leſs expence. But inſtead of theſe, art may ſuggeſt one that may anſwer in ſome reſpects more perfectly; as in place of bringing together ſuch a maſs of earthy or other ſubſtances, as may be proper for conſtructing ſuch banks as are ſhewn at *figs*. 1, and 7, it may be more advantageous to have one formed, ſuch as is ſhewn at *fig*. 8, the ſide of which next the water forms with the baſe an angle of about 45 degrees. This will be capable of bearing all the weight or preſſure of water that can poſſibly be brought upon it, equally well with that of *fig*. 1, except that the operation of the tides would break the ſuperficial part of the ſide next the ſea, unleſs prevented by coating it with ſome durable ſubſtance, ſuch as paving ſtones, bricks, or other ſimilar materials.

But various different ones may be invented between this and the firſt natural kind, which differ only in the degree of inclination which they have towards the ſea; that which ſlopes in the higheſt degree, as *fig*. 1, having the ſurface covered over with ſand or gravel; and that which has the leaſt ſlope, as *fig*. 8, may be covered with pavement; the different intermediate ſlopes being protected by materials which have a quality between the two, ſuch as coarſe gravel, chalk-ſtones, brick, and ſand, as ſhewn in *fig*. 9. This embankment is wholly conſtructed of a ſandy loam, being depoſited upon a ſoil of the ſame quality; but as it would not, for ſome time after being formed, be ſufficiently impervious to water, a column of clay is carried upright in the middle, from the clayey ſubſtratum of the ſoil underneath, as ſhewn at *x x* in the ſection.

In caſes where the ſhores are of a very ſandy nature, it is frequently neceſſary to form the embankments wholly of a ſort of wicker-work. In ſuch circumſtances, three or four rows of pailing may be put down, of different heights; and the vacant ſpaces between them be well filled, by forcing in furze, bruſh-wood, or even ſtraw, as repreſented at *fig*. 10. Theſe ſubſtances, by detaining the mud and ſand, as the tide paſſes through them, or during high floods, ſoon form a ſort of embankment, ſuch as that ſhewn in the above repreſentation. It ſhould afterwards be covered with ſome plant, which is capable of binding and giving it ſolidity, ſuch as the *elymus arenarius*. This embankment would continue,

continue, during extraordinary tides, to retain ftill larger quantities of the fandy materials, until ultimately raifed higher than they could reach, by which a fafe bank would be formed. It is fuggefted by Mr. Loudon, in his ufeful "Treatife on forming Country Refidences," from which many of the above hints have been drawn, that from twenty to thirty thoufand acres of land might be gained in this way, in a very few years, in different parts of the rivers Severn, Humber, Frith, &c.

In all cafes of embankment, however they may be formed, tunnels and fluices of a proper kind, with valves towards the fea or rivers, muft be occafionally placed, according to circumftances, fo as to permit the water that may be collected within to pafs away, and that of the fea or rivers to flow up, with different intentions in the view of improving the land.

The utility of projecting points is very confiderable, in different cafes, on the fea-coafts and rivers, in defending the bays and inlets of the former, as well as guarding the banks of the latter, by diverting their ftreams or currents to the oppofite fides. Hence arifes the formation of piers, which become highly beneficial in defending embankments, as well as the borders of rivers and brooks. In the firft of thefe cafes, they may generally be conftituted and coated over with the fame fort of material as that of which the embankment is formed; while, in the latter, they fhould be formed of fome fort of ftony matter, being conftructed in fuch a way as to decreafe in every direction as they advance outwards, as reprefented in *fig.* 11. In each of thefe cafes, they are, however, capable of being conftituted of brufhwood, fecured by means of ftakes, often with more perfect fuccefs. And it frequently happens that a fimple rude wicker-work fence, of not more than three or four yards in length, may be fully fufficient for the purpofe. Embankments formed of ftone, unlefs conftructed in the manner reprefented at the above figure, are apt to caufe eddies below them; while thofe formed of brufh-wood cannot have this effect.

It is obvious that confiderable attention muft be required in deciding the moft proper fituations for conftructing thefe forts of projections in, and the diftances to which they fhould extend into the rivers: as a too extended projection may be highly dangerous to the oppofite bank, and of courfe do harm inftead of being beneficial; while not carrying them out fufficiently may prevent the effect which is wanted. In cafes where piers are to be formed of ftone, as in rivers where the bottoms are of a rocky nature, the plan reprefented at *fig.* 11. is probably the moft proper, as it will fcarcely caufe any eddy, and be nearly equally mild with that of wicker-work in the effect which it produces. Different works of thefe feveral kinds have been conftructed in the northern parts of the ifland with much fuccefs.

Proper Materials for Embankments.—There cannot be any doubt, but that different forts of materials may be made ufe of in different fituations and kinds of works of this nature, with more advantage than others, both in fo far as duration and expence are concerned.

Thofe fteep upright embankments which are conftructed with the view of protecting bold fhores, or coafts, and the banks of particular rivers, may probably be beft formed of good brick, rubble, or afhler work in the manner of a wall, as feen at *fig.* 6. in the plate, the materials being laid in the ftrongeft fort of mortar that can be made. But where this is not the cafe, they may be built in the common way, and pointed with puzzolana earth, or what is termed the Roman cement, prepared by Meffrs. Parker and Co. London.

The different kinds of floped embankments may be formed either with common earthy materials, clay, mud, or a mixture of thefe feveral different fubftances: and any other matters which are capable of uniting into a folid, firm, compact mafs, may be had recourfe to for the fame purpofe. Where the fides next the fea or other waters form angles of from twenty to thirty or even thirty-five degrees, with their bafes, they may be coated with fand, the fhells from the fea, or coarfe gravel from the borders of the fhores. And ftones, broken down to uniform fizes of a few pounds in weight, may be employed in a fimilar manner. But where none of thefe fubftances are capable of being procured in fufficient abundance, a method practifed in Holland, of covering them with fuch perifhable materials as mats, reeds, ftraw, bark, and others of the fame nature, may be had recourfe to; but thefe are obvioufly difadvantageous, as requiring very frequent renewal. They might likewife be protected by a low fence of brufh-wood, fixed in an erect manner all along at the bottom of the bank, of an equal height, as tending to break off the violence of the waves. Another method might alfo be employed, which is, that of covering the whole front of the bank with brufh-wood, either made into bundles or in the manner of wicker-work, or fixed down in a neat manner by means of long poles and ftrong hooked ftakes. And further, they may be laid in the form of caufeway with ftones in mofs, or covered with wicker-work applied upon the moffy material when fpread out over the bank. And there are ftill many other modes which may be adopted under particular circumftances.

In all cafes where the fides and flopes towards the fea conftitute angles of from thirty-five to forty-five degrees, with their bafes, as in *fig.* 8, recourfe may be had to ftones of the flag kind as coverings, which fhould be jointed with cement mortars formed in fome of the manners mentioned above. And where thefe forts of ftones cannot be provided, if clay can be found, proper kinds of bricks may be made, and ufed in the fame way as the ftones. But where the flopes or inclined planes are from forty to forty-five degrees, it is frequently more cheap and economical to have them covered with ftones of about fix or eight pounds in weight, applied to the thicknefs of a foot and a half or nearly two feet; or thefe may be ufed on a bed of common mofs of three inches, or of peat-mofs of the flow kind, of fix inches in thicknefs, fpread upon the banks, only to the thicknefs of fix or eight inches. Stones of thefe kinds may likewife be formed into a fort of caufeway, or be laid in ftrong clay, and their furfaces be jointed with lime or a ftrong cement mortar, which has the property of quickly hardening, and of enduring the operation of the air and tides, which alternately act upon it.

There may likewife be cafes in which it may be the moft advantageous practice to have the fides next the fea or rivers protected by coverings of wood only, in which cafes, larch may be the moft proper, or fuch others as are durable, having their furfaces covered over with pitch and fome fort of fharp fand. And old fail cloth, or oil cloth pitched and coated over with fand in the fame manner; or even thin plates of metals have been fuggefted as ufeful in particular inftances.

Expence of forming Embankments.—This muft obvioufly be very different in different fituations and circumftances, according to materials and the price of labour, but though in general pretty confiderable, it is feldom fo high as is commonly fuppofed. It is probable that in cheap diftricts, and where the materials are plentiful, the expence of forming an earth bank covered with fand or gravel, fuch as that fhewn at *fig.* 1, could not be lefs than from four-pence or fix-pence, to ten-pence or a fhilling the cubic yard. And fuch as have more fteep and bold flopes, as from thirty-five to forty degrees,

grees, and are formed with pavement on the furfaces, cannot coft lefs than from nine-pence to one fhilling and fixpence the cubic yard. One made on the plan of that fhewn at *fig.* 6. could not be conftructed for lefs than from twelve or fifteen to thirty pounds for every thirty-two yards. And one conftituted of brufh-wood, in the fame method, for foft ground which will not admit of a wall, would not be lower than from fix-pence or eight-pence to fix or feven fhillings for each foot forward in a lineal manner. In many fituations the expences would, however, in all forts of embankments, ftand a great deal higher than thefe.

In fome diftricts embankments are formed by the rod and the floor, the former being from four to five pounds, and the latter about four fhillings and fix-pence, the workmen finding all forts of neceffary things for the bufinefs.

Extent of Land capable of being gained by Embankments.—It is evident, that great quantities of land might in many fituations be obtained from the fea and large rivers by the forming of proper embankments. Some notion of this may indeed be formed by a careful examination of fuch lands, as lie along their fhores and banks, by afcertaining the diftances to which the waters ebb out at common tides, as it is found by experience, that one half of the extent of land, thus uncovered in any particular fituation, may at leaft be gained; hence throughout the whole kingdom it could hardly be eftimated at a lefs quantity than from two to three millions of acres, but it is probably much more than even the laft quantity, if it were capable of being afcertained with any degree of accuracy or correctnefs.

Importance of Embankments.—When the extent and value of the lands which are capable of being gained by thefe means are fully confidered, there can be no doubt of their being of the greateft confequence to the interefts of the country. It has been well remarked by a late writer on this fubject, that there are numerous places in the kingdom where vaft improvements may be effected by the judicious application of thefe means. Vaft tracts of land of the beft kind may not only be gained from the fea, but likewife from the large rivers and lakes, befides the beneficial confequences which muft neceffarily arife from the prevention of fuch rivers from overflowing their banks, and injuring the level grounds in their vicinity by fuch inundations. In fome cafes, it is fuppofed, that by raifing a bank of only three or four feet in height, at very fmall expence, fome thoufands of acres might be prevented from being overflown, the crops from being carried away, and much other mifchief from being produced. In other inftances the forming of very trifling banks might be the means of obtaining much extent of country, which in its prefent ftate is of but very little value; yet fo indifferent are people in general about improvements of this defcription, that though immenfe tracts are year after year overflown, and the moft dreadful devaftations committed, they have recourfe to no means of prevention; nay, even though the fea itfelf, fays the writer, as if to roufe them from their inaction, prefents to their view twice every four and twenty hours large tracts that might by proper means be made of very great value, yet thefe repeated invitations are difregarded, and no attempts are made to poffefs what might, in many cafes, be fo eafily and fo advantageoufly acquired. This is confidered altogether as extraordinary and unaccountable, while the acquifition of diftant poffeffions is conceived by them of fuch great importance, as there can be no doubt but that the addition of portions of ground at home, when brought into proper cultivation, is of far greater national advantage than double the quantities gained in other diftant countries.

The acquifition of additional territory at home fhould, therefore, be more attended to, and have more expence beftowed upon it than has hitherto been the cafe. In particular fituations, indeed, a few active and enterprifing perfons have taken advantage of the opportunities which have been prefented; as in the counties of York, Lincoln, Cambridge, and others, many hundred thoufands of acres have been gained by embankments. In Norfolk, too, a confiderable extent of land has been gained in this way. In the neighbourhood of Chefter, the river Dee company have likewife gained feveral thoufands of acres from the fea, which have been fince divided into different beautiful farms, the whole of which pay in rent more than two thoufand pounds *per* annum. And in Holland the whole country has, in a great degree, been obtained by thefe means.

It is ftated by Mr. Beatfon, in the fecond volume of Communications to the Board of Agriculture, that large fums have been expended in fome places by individuals, with a view of guarding againft inundations; but owing to the embankments they have made being injudicioufly placed, and as badly conftructed, the defired effect has not always been produced, particularly in the northern parts of Chefhire, on the banks of the river Merfey, where works of this kind have been thrown up at a great expence, which, from the manner of their being placed, may, in fome cafes, by confining the courfe of the river, do more harm than good. By the appearance of that part of the country, fo far as he could judge from the curfory view he had of it, it feemed to him that the inundations from that river might have been effectually prevented at a much eafier rate, if a proper method had been taken at firft; but from a certain ill-judged and miftaken tenacioufnefs of property, the embankments are reared fo clofe upon the fides of the river, that, in many places, it is confined to a fpace not more than twenty yards over. Owing to this, and to an aqueduct acrofs the river, with only one arch inftead of two, which it ought at leaft to have had, the water fometimes, in great floods, rifes, he was informed, to the height of about twenty feet above its ordinary level, and overflows the embankments, although now, by frequent additions, they are about that height. Inftead of twenty yards, had thefe embankments been eighty or a hundred yards diftant from each other, and the river widened in the narroweft places, one-third or one-fourth of their prefent height would have been quite fufficient. They would have been much eafier conftructed, and lefs liable to damage by the floods, and a great deal of money would have been faved, not only in the firft conftruction, but in keeping the banks afterwards in repair. Neither would that fpace of ground between the embankments and the river be altogether ufelefs; on the contrary, it would have produced the richeft pafture, or meadow-hay, by its frequent manurings with the fertilizing particles left upon it, when flooded by the fwelling of the river; and in thofe places, if any, that are unfit for pafture or hay, willows or other aquatics might have been planted to great advantage; and thus it might have been of more value perhaps than at prefent, and the interior grounds more effectually fecured from the ravages occafioned by a fudden flood. Notwithftanding the general indolence fhewn in moft parts of the country refpecting the acquifition of land by embanking, and the feeming averfion that moft people have to engage in fuch undertakings, there have been, however, fome ingenious and enterprifing projectors, whofe ideas upon that fubject have foared far beyond the bounds allotted to common underftandings. From the fpeculations of fuch people, the moft important advantages are fometimes produced; and furely the man who is poffeffed of a fpeculative turn of mind, and who confiders no obftacles infurmountable, is a much more ufeful member of fociety than he who is perpetually ftarting difficulties againft every new project, and is for all things remaining *in ftatu quo*, that is, for leaving the world as he found it. The idea of embanking Lancafter fands, for example, never would have occurred to a torpid genius of this kind. A thoufand difficulties and impoffibilities would have immediately ftarted up at fuch a propofal, which, to a more expanded mind, appear perfectly practicable to overcome. What then, fays he, muft thofe anti-projectors think, when they are told it is propofed to exclude the fea entirely from thefe extenfive fands, which form a bay, expofed to a fouth-wefterly wind, more than ten miles acrofs, containing a furface of near forty thoufand acres, and where the tide rifes about fourteen to eighteen feet perpendicular height. Some propofals and eftimates have already been made for carrying this project into execution. One very public-fpirited and enterprifing gentleman; the late Mr. John Wilkinfon, offered to begin a fubfcription for that purpofe, by leading off with the princely fum of 50,000*l.*; but fo many unexpected obftacles have come in the way, by the claims of lords of the manors, and in proportioning the tythes, in the event of acquiring fo large a tract of country, that few people have on that account chofe to embark their fortunes in this immenfe undertaking, feeing that their profits may be liable to fo many deductions; confequently nothing conclufive has yet been done in it. Ulverftone and Duddon fands, on the fame coaft, have alfo been propofed to be embanked. The latter, over which the writer went with major Gilpin, a gentleman who has paid great attention to that bufinefs, appears to be the moft practicable. According to his opinion, there might be about nine hundred acres of very good land gained there, by laying out a fum not much exceeding 20,000*l.* If, on a correct furvey being made by perfons properly fkilled in fuch undertakings, fo valuable an acquifition is proved to be attainable at fo fmall an expence, can there be the leaft hefitation about immediately commencing a project fo highly advantageous to that part of the country, and to every individual concerned in it.

That there are many large tracts of land in different parts of the kingdom, both on the fea-coafts and on the fides of lakes and rivers, much more eafily attainable than Lancafter-fands, or any of the fands here noticed, there cannot be the fmalleft doubt. It is, therefore, an object worthy of the attention of thofe who are fo fortunate as to poffefs property in fuch fituations, to have it afcertained by perfons of experience in fuch matters, how far the acquifition of additional portions of land may be adequate to the expence which it may be neceffary to incur in procuring it.

But embankments are important in other views than thofe of gaining ground by them. When rivers are concerned, one material advantage is the deepening of their courfes, by which veffels of greater burthen than they admitted formerly may be permitted to trade in them.

And further, as embankments become more frequent on the borders of rivers and fea fhores, the intervening diftances may become a fort of bays, in which accumulations of fhells, mud, fand, gravel, and other matters, may take place by the influx of the tides; and thefe, however difficult they may be at firft to embank, will in time be as eafy to perform the work on, as the natural bays and creeks are at this period. In this way many rivers, which in their prefent ftate are eight or ten miles in width at their junction or influx with the fea, may in the courfe of years be reduced to lefs than half thefe diftances. Confequently fuch embankments would be equally beneficial to the proprietors of land, and the merchant or manufacturer, as many rivers would become more eafily navigable, and thofe obftacles which interrupt their mouths be wholly removed.

Embanking againft the Sea.—When encroachments of this nature are to be guarded againft by embankments, the methods of afcertaining their proper heights have been fhewn above. But as new works of this fort, efpecially where the banks are large, are liable to fubfide too much, it may be a proper precaution to take the levels frequently for fome time after they are completed, in order to guard againft any mifchief which might arife in this way. Where the banks are low this is not, however, fo neceffary, as the fettling is always more or lefs according to their height; in low banks it will of courfe be very little. In the making of fuch embankments, it is fcarcely poffible to lay down any general rule in regard to their fize or dimenfions, as thefe muft be directed by fituation and circumftances, under the management of an expert engineer. In cafes where the embankment to be formed is to exclude the fea from a piece of low marfhy ground, over which it only flows at fpring tides, the work is eafy and capable of being accomplifhed at no great expence. But where it is intended to reclaim a portion of land which is covered every tide, in fome bay or creek, or on the fides or windings of fome large river in which the tide ebbs and flows, the bufinefs will be in fome degree more difficult, according to the depth and rapidity of the current of the water. And where it is propofed to exclude the fea from fome expofed fituation at the mouth of a river, or in a bay or inlet, which is uncovered every tide, the operation will be the moft difficult and expenfive of all, according as it is expofed to prevalent winds, and the depth of the water to be refifted. Each of thefe fituations, therefore, requires a different method of management. The bufinefs of embanking againft the fea, when at any confiderable diftance within high-water mark, is not only the moft tedious, but at the fame time the moft difficult of any; as when the materials are not very good and the work not well performed, the force of the water at every flowing of the tide will quickly undo all that has been effected, efpecially if the foil be of a fandy nature, as is often the cafe in fuch fituations. If it be a ftrong clay, as is fometimes the cafe in marfhy places, there will be the lefs rifk of its being wafhed away. In fandy fituations it has been advifed by fome to lay bundles of ftraw or reeds well-faftened down, or any other impediment, to hinder the foil from being carried away by the ebbing tide. Where a fufficient fupply of good ftrong turf cannot be had, expedients may be tried: but where fuch turf can be provided, as is the cafe in moft marfhy fituations, and where the embankment required is not to exceed the height of four or five feet, it is beft to finifh the flope with good turf as expeditioufly as poffible, as the work proceeds; that is, fuppofing the length of thirty, forty, or fifty feet or yards of it can be completed in a tide; it is better to finifh that length to its intended height, than to trace out or begin a greater extent than can be finifhed before the tide returns, by which a great deal of the foil might be carried away, and much of the work be demolifhed, which is not fo likely to be the cafe when the flope is finifhed. Turf which contains the roots of bent or rufhes is very good for this ufe. The firft thing, however, to be done in an embankment of this kind, is to ftrike out the intended line of it, fetting out the breadth at the bafe, alfo the width of the excavation or trench to be made in the infide, from which moft of the materials that compofe the bank are to be taken: this trench alfo ferves as a drain to keep the grounds within dry. There fhould alfo be trunks or fluices at different parts of it, to fhut of themfelves againft any external water, and to open when the tide ebbs,

ebbs, to let out any water from within. The width of it ſhould be proportioned to the quantity of materials required from it for the raiſing of the embankment, as eight, ten, or fifteen feet wide, and three or four feet deep, leaving a *berme*, or ſpace, between the edge of the trench and the inner bottom of the embankment. If the ſoil be ſtrong, one foot or eighteen inches will be ſufficient for this purpoſe; but if looſe or ſandy, three or four feet at leaſt will be required. The more eaſy and gradual the external ſlope is made, and the leſs ſudden the reſiſtance againſt the ſea will be, as has been ſeen above, and of courſe the embankment be leſs liable to injury; this ſlope ſhould therefore be formed according to the expoſure of it to the winds and tides; nothing, however, can be a greater error than the making it too bold or upright. *Fig.* 1. in the plate, is ſuppoſed to be a ſection of an embankment of this nature, in which the baſe or horizontal line *g h* ſhould at leaſt be three times the perpendicular height *h i*, but *l m*, the inſide ſlope, need not be more than three-fourths of the perpendicular height, that is, nine inches for every foot of riſe. The inſide ſlope ſhould be faced with turf likewiſe, laid greenſide downwards, as in building common ſod walls. Some expert ſodders can finiſh this ſort of work extremely neat by ſetting the ſod on edge, according to the ſlope intended to be given, and with proper mallets and beetles ramming the earth hard behind, which conſolidates the work as it advances, and tends to render it durable. As ſoon as the firſt or lower courſe is finiſhed, the upper edge of the ſods is pared with a ſharp knife quite even, by laying a rule to them, and then they go on with the ſecond courſe, which they finiſh in the ſame manner, and thus proceed until the whole height is completed, which, when properly finiſhed, has a ſmooth beautiful appearance, not a joint between the turfs being ſeen. Where turf is uſed in covering the outſide ſlope, it ſhould all be laid with the graſs uppermoſt, as already noticed, and be well beaten down with a flat ſod-beetle for the purpoſe, and in order the better to ſecure them, it may be proper to drive ſmall ſtakes, about eighteen inches in length, through every ſod. In cutting ſods for this uſe, they ſhould be taken up in a careful manner, and be all traced by a line of the ſame breadth; their edges being cut as even as poſſible, that they may make the cloſer joints, which will tend very much to their ſecurity, until they are grown properly together. In laying the different courſes of ſuch ſods, care ſhould alſo be taken that the joints of the one be covered by the other, in the manner that good brick work is made.

Where it is propoſed to reclaim a piece of land, upon which the ſea ebbs and flows every tide, to a greater depth than in the foregoing caſe, as in a creek, or on the ſide of a large river, a different mode of proceeding muſt be purſued, according to the ſoil, and the nature of the materials to be employed. Where plenty of ſtones can be readily procured, a bank may be formed of them, with a mixture of clay, either by means of land carriage, or which, in ſome inſtances, is better, by conveying them in flat bottomed boats, or punts, and throwing them over-board until the bank is formed. Where ſtones cannot be eaſily had, clay, or other materials proper for the buſineſs, may be thrown in, in ſufficient quantity, in the ſame manner, with perhaps nearly equal ſucceſs. It is ſuppoſed that moſt of the embankments in Holland were formed in this way, the clay dug from the canals being made uſe of for the purpoſe. In either caſe it is requiſite to fix up ſtrong poles before the work is begun, as guides for laying down the materials. Proper ſluices muſt likewiſe be laid in ſuitable directions for taking off the back water when the tide ebbs, under the inſpection of the engineer. Much, in all caſes of this ſort, depends on a ſkilful engineer, who is capable of ſuggeſting and contriving various means of facilitating the buſineſs, and of obviating the difficulties that may ariſe in its execution. A perſon of real genius is often capable, by his different contrivances, of rendering the accompliſhment of a great undertaking comparatively eaſy, which to others would be almoſt impracticable, or carried on at ſuch a heavy expence as to counterbalance the advantages to be drawn from it. In caſes of the kind juſt noticed, he might ſuggeſt the erection of ſtages or platforms, in ſuch a manner as to carry on the work at all times of the tide, which would be an immenſe ſaving, as the delays cauſed by the tides in this ſort of buſineſs are both tedious and expenſive. Waggons might likewiſe be contrived in ſuch a way as to carry on ſuch platforms large quantities of materials at once, which could be eaſily emptied and filled; and at the ſame time be drawn by machinery, in ſuch a manner as to ſave much labour and expence, both in carriage and tide work.

There is another ſpecies of ſea-embankment which is, perhaps, the moſt important of any; as there are few eſtuaries or mouths of rivers in which large tracts of land may not be gained by it. The ſhoals, or flats formed at the entrance of ſuch rivers, are moſtly compoſed of the richeſt materials and moſt fertiliſing particles, brought down from the towns and circumjacent country through which they paſs. Such ſhoals and flats may, therefore, under proper management, be in moſt caſes readily converted into the moſt fertile plains. In ſuch ſituations the firſt object is that of collecting the whole river into one ſtream, and preventing its overſpreading a wider extent than is merely ſufficient for its diſcharge, or it may be better, perhaps, to alter its courſe altogether, and cauſe it to be diſcharged at ſome other outlet. It is in this latter method that it has been propoſed to reclaim the extenſive tract covered by the tides, known by the names of the Lancaſter and Milthrop ſands, as well as thoſe of Ulverſton and Duddon. And the principle on which it is founded is this: it has been found by experience that where the courſe of a river is changed in ſuch a manner as to make it diſcharge itſelf into the ſea at a different place to that where it did before, the former place will, in a few years, by the continued accumulation of ſand and mud brought in every tide, be ſo choaked up and raiſed above its former level, as to form of itſelf, in the courſe of time, a bank that, with a very little aſſiſtance, will quite exclude the ſea; for as the current of the river before carried away all that ſediment which the motion of the waves naturally ſtirred up, from its being now removed, it is obvious that all or moſt of the muddineſs will not only be carried further up the old channel of the river, but a great part of it be depoſited there as the tide recedes. It has been found that in ſpring-tides and particular winds, this ſediment is depoſited in larger quantities than at other times, and the writer has been informed that a gentleman in Lancaſhire, who has gained ſome land in this way, has found, on making a perpendicular cut in the ground ſo recovered, that the different layers were ſo diſtinct, he could readily diſtinguiſh thoſe made at ſpring-tides from the reſt. This curious fact is well deſerving of the attention of all thoſe who have lands ſituated at the mouths of rivers, as there may in many ſuch ſituations be conſiderable tracts gained in this manner at a very light expence. But though this fact may exiſt in ſome places, as has been proved by experience, nevertheleſs it is ſuppoſed that the effect cannot be the ſame in all ſituations. Where there is a great extent of flat or muddy ſhores, the motion of the waves will no doubt ſtir up the mud or ſand, and carry great quantities of them along with the current on the flowing of the tide, and when the tide ebbs, though

ſome

fome of the lighter particles will be carried away again, yet it is reafonable to fuppofe the heavier ones will be left behind. If the fhores are bold and rocky, except juft near the entrance of the river, there will be the lefs of this mud; but on fuch fhores there can, indeed, be little or no occafion for embanking, unlefs perhaps in fome creeks, narrow at the entrance and fpreading out wide above. If the fea were excluded from fuch creeks, a great deal of land might probably be gained.

It was found, on having a furvey made of the Lancafter fands, and of the propofed alteration of the courfe of the river Kent, that the length of the cut, neceffary to be made from a little below Dalham Tower to the river Lune, was 21,340 yards, or twelve miles and one furlong. This cut was propofed to be about thirty-four yards wide, and four yards of average depth, making in the whole an excavation of 2,902,240 cubic yards: the expence of excavating which, at 4½*d.* per yard, would amount to 54,417*l.* But perhaps this eftimate is rather under-rated at 4½*d.* the cubic yard; but on the contrary the average depth of the excavation is prefumed to be confiderably over-rated at four yards, as a great part of the depth neceffary may be made up by the foil thrown out; confequently whatever is made up cannot be confidered as a part of the excavation; befides if the river Kent, Lindale pool, and the other ftreams propofed to be taken into this new cut, require, when united, a fpace or channel to contain them whofe tranfverfe fection is 136 yards fuperficial, it would be much lefs expenfive, it is fuppofed, to add eleven yards to the breadth, and to take one from the depth propofed, unlefs it be neceffary, from the level of the bottom of the river, to make the bottom of the new cut of a certain ftated depth. The whole expence of completing this great undertaking has been eftimated at only 150,000*l.*, and in the opinion of fome perfons fifty, or perhaps fixty thoufand lefs might be fufficient. It is, however, apprehended, that in this eftimate there has been no allowance made for the neceffary buildings on fo extenfive a tract, or for inclofing and draining; all which, as well as the intereft of money laid out before any return can be expected, fhould be confidered in calculating the expence of bringing into improvement fuch lands as thefe. And further, there are other eftimates to be made for neceffary buildings in its cultivation; befides in the eftimates which have been made, it is taken for granted, that if the frefh water be conducted another way, as propofed, in a few years the fea will completely exclude itfelf from this extenfive tract of land, and confequently no allowance whatever is made for any fort of embankment acrofs thofe fands. Experience has not, however, fo fufficiently fhewn the certainty of this method of gaining land from the fea, as to place that fort of confidence in it that is requifite. If, indeed, it could be fully depended on, the fpeculation would be admirable, as well as the advantage and profits arifing from fuch an acquifition immenfe; but if after laying out nearly perhaps 200,000*l.* in altering the courfe of the rivers, &c. it fhould be found that the fea left little or nothing behind, or if it did leave fome at one time, but carried it all away at another, in what predicament muft thofe perfons concerned find themfelves? They muft either lofe the whole of the money laid out, or they muft expend at leaft 200,000*l.* more, perhaps, in performing what they had fo implicitly trufted to the operation of the fea. If, however, it were certain that even a fiftieth part of an inch was depofited every tide, the fuccefs of the undertaking would be unqueftionable, and a concern in it highly profitable, as in very little more than eight years ten feet of perpendicular height would be raifed, and it would be an eafy tafk to accomplifh the reft of the bufinefs.

The Duddon fands are another tract, it is fuppofed, where great improvement is capable of being effected at a very eafy rate, when compared with that juft noticed. In the prefent ftate a great deal of land, that is capable of producing the beft crops, is often overflown and rendered fo wet and marfhy as to be of little or no value. While, by altering the courfe of that river, and bringing it farther north on the low marfhy ground, it would feem from viewing it, without actually taking the levels, that not only the whole of the ground might be completely drained, but a confiderable tract of lands be reclaimed. The making of the new channel for the river feems perfectly eafy and practicable, the ground being nearly level, with the exception of a fmall rife at one place, all the way from where the new cut would begin, which is about two hundred yards above Duddon bridge to Havering pool; where it would empty itfelf into the fea. The length of this cut would therefore be about fix miles, which ought to be made navigable all the way, with a lock near the fea, and a bafin with proper landing places for delivering goods. The quantity of land that might be thus gained, including the fands and marfhy ground on each fide, would, it is fuppofed, on the authority of major Gilpin, be about 2000 acres, and the whole expence under 20,000*l.* The land, too, has every appearance of becoming one of the moft fertile kind: in proof of which a farmer, who fome years ago gained a few acres of it by embanking them againft the fea, found that it produced the beft crops of all kinds, even with little or no manure. So large a tract of valuable land, capable of being gained at fo very trifling an expence, is therefore an object highly worthy of attention, not only as a profitable concern, but on account of many other advantages that would arife from it. It is, therefore, furprifing, that the proprietors in the vicinity or other enterprifing individuals have not long ago taken the neceffary fteps to reclaim thefe fands. The execution of thefe projects would, it is conceived, be attended with the moft beneficial effects to a very extenfive tract of country, and be ultimately felt in fome meafure by the nation at large. There would not merely be an addition of territory larger than either of the iflands of Guernfey or Jerfey, but it would tend to improve at leaft four times that extent of the interior country. A fafe and fpeedy communication would be opened between the towns of Lancafter, Whitehaven, Ulverfton, Ravenglafs, Dalton, Bootle, Egremont, &c. and all the intermediate country, inftead of a mountainous and very circuitous route, or a precarious and dangerous paffage over Lancafter fands, in croffing which accidents are not unfrequent. Independently of the advantage arifing from the produce of the lands to be acquired, the produce of the interior part of the country, which in many places is extremely fertile and well cultivated, would be eafily brought to market; whereas it is at prefent, with the utmoft difficulty and inconvenience, that any commodity whatever can be tranfported over thefe dangerous fands and almoft inacceffible mountains. By diverting the river Duddon into the navigable cut propofed, it would yield the moft important advantages to the town of Broughton and all the back country, by facilitating the importation of coal, lime, and other produce of every kind, and the exportation of flate, iron, and other productions of the country. But though different public-fpirited individuals have been active in forwarding thefe highly laudable and important undertakings, the oppofition which has been given by the proprietors of fome trifling fifheries, who were offered a full indemnification, and from fome lords of manors, who would neither contribute towards fuch improvements, nor relinquifh any part of their claims to the ground when improved, they have been for ſome time in a great meaſure in a dormant ſtate. It is hoped, however, that in theſe enlightened times, when the ſpirit for improvements of this kind ſhould be particularly arouſed, theſe important and neceſſary projects may be again taken up in a ſerious and effectual manner, and that every obſtacle which may ſtand in the way of their completion may be ſpeedily removed. And that if the attempt of re-claiming Lancaſter ſands ſhould be conſidered as a too expenſive and too mighty undertaking to begin with, an experiment may be made on Duddon ſands, where the money propoſed to be expended is comparatively trifling, and where, if the ſcheme ſhould ſucceed, there could not be the ſmalleſt reaſon for doubting the ſucceſs of the other.

In the marſhland diſtrict of the county of Norfolk, lying between the rivers Wyn and Ouze, immenſe tracts of the moſt rich land, ſuch as is compoſed of the muddy depoſitions left by the tides and floods, which is there called filting, have been obtained by means of embanking. In this important buſineſs, the late count Bentinck, and his ſon, the preſent poſſeſſor, have been largely concerned. This kind of work has ſometimes been undertaken by the tenants on a new piece of marſh, in conſideration of having the land free for twenty-one years. But in theſe caſes the banks have often been very imperfectly made, not having coſt more than forty ſhillings a rod. And thoſe which were conſtructed by the landlords were indeed frequently but little better, being moſtly deficient in not having ſlope enough given them towards the water. Count Bentinck therefore laid his out upon a ſcale never practiſed in that part of the iſland before, and his ſucceſſor has ſtill far exceeded it. That planned by the former extends about four miles, and has added to the old eſtates not leſs than a thouſand acres. The baſe of the embankment, in this caſe, is about fifty feet, the ſlope to the ſea thirty-ſix feet, forming an angle, it is ſuppoſed, of about twenty-five or thirty degrees. The crown is four feet in width, and the ſlope to the fields ſeventeen feet, in an angle ſuppoſed of about fifty degrees; the ſlope towards the ſea being very neatly turfed over. The firſt expence incurred in forming this bank was four pounds per rod, but a very high tide coming before it was finiſhed, not only made ſeveral breaches, but occaſioned an additional height and ſlope to be given to ſeveral different parts, in order to bring it to the dimenſions mentioned above, all of which made the groſs expence to amount to about five pounds the rod. The whole coſt was ſomething more than 5000 *l.* The expence of the houſes, farm buildings, and other things, was about as much more, for five new farms, which was a greater expence than was neceſſary, as the land would have let as well in two or three as five farms. Suppoſing, therefore, the expence at 10,000 *l.* and the new rental as 1000 *l.* a-year, it is juſt ten *per cent.* for the capital laid out. The expence here, however, ſeems to have run too high, when the neceſſary repairs of the bank are taken into the account. The repreſentation, given at *fig.* 11. in the plate, fully explains the nature of the embankment formed in this caſe.

In another new embankment, in which two hundred and ſeventy-three acres of marſh land, and eighteen of bank were gained, the men were paid four ſhillings and ſix-pence a floor of four hundred cubical feet, finding wheeling planks, barrows, truſſels, &c. When it is thus formed, the front ſlope is ſodded, for which they are paid in addition four ſhillings a floor of four hundred ſquare feet, earning from five ſhillings and ſix-pence to ſeven ſhillings a day, and there is ſome little further expence neceſſary for beating it down in a firm manner. The whole of the expence of the bank, ſluice, and every thing elſe, was about 3300 *l.* The land was immediately offered to be rented at four pounds an acre for four years, or three pounds an acre for ſix years; which, in the former caſe, would amount to 4368 *l.* in that length of time, or one thouſand guineas more than the whole of the capital laid out in the undertaking.

On this coaſt the operation of *filting* up, or raiſing the ſurface of the marſh land by the repeated depoſitions of muddy matters from the ſea, is performed in a more rapid manner than in many others; and the little hollows and creeks are found from experience to filt up much faſter where the tide waters are ſpeedily taken off by proper cuts and channels formed for the purpoſe, than where the contrary is the caſe.

Embanking againſt Rivers.—The embankments againſt rivers may be divided into two kinds; namely, ſuch as are for preventing their encroaching on the adjacent lands, and for protecting thoſe lands and the neighbouring level country from being overflown, when the water riſes above its ordinary level. It may be remarked, that where the courſe of a river is a ſtraight line, or nearly ſo, it hardly ever makes any encroachment upon its banks, unleſs, perhaps, in very large rivers when they riſe above their common level, either owing to an increaſe in the waters, or to their being, in ſome degree, affected by the tides. In either caſe, the waves occaſioned by a ſtrong wind, where the river is wide, will moulder away the banks on that ſide upon which it blows, unleſs prevented in proper time. This may be done either by ſecuring the bank properly with ſtones, or by driving a row of long piles pretty cloſe together at a little diſtance from the ſhore, the piles being of ſuch a length, and ſo driven, that their tops may be always above the higheſt riſe of the water. It is ſurpriſing the effect that piles driven in this manner have in reſiſting the power of the waves in ſuch ſituations.

Some years ago, when Mr. Beatſon was on duty as an engineer at a fort near Portſmouth, built on a point of land much expoſed to the ſea, the waves made ſuch havock, that the walls on that ſide were conſtantly giving way, although built in the moſt ſubſtantial manner, and having bulwarks of large heavy ſtone beſides to protect the foundation: however, all would not do; thoſe bulwarks were ſoon knocked to pieces, and ſeveral times the wall itſelf. At length it was propoſed to drive a number of piles at about forty to fifty yards from the fort. Theſe piles were twelve or fifteen inches in diameter, and driven about one diameter from each other nearly in a ſtraight line, parallel to the wall where the waves did ſo much damage. They were driven into the ground with a pile engine till perfectly firm, perhaps eight or nine feet deep, and about two feet of the top of them left above the level of high-water mark. After this was done the wall received no farther injury, the ſpace between the piles and the fort being always perfectly ſmooth, however tempeſtuous the waves might be without. The ſame ſimple method might, it is ſuppoſed, ſometimes, perhaps, protect the banks of large rivers, if expoſed to the waves, when other methods might fail.

But it is ſuggeſted, that the moſt common courſe of rivers encroaching on their banks, is the reſiſtance occaſioned by a ſudden bend. In flat countries, apt ſometimes to be overflown, where there are any ſuch bends or windings in the rivers, it would be of great advantage to ſtraighten the courſe as much as poſſible, for, as every impediment or obſtruction will naturally cauſe the water to riſe higher than it otherwiſe would do, and as ſuch bends have that effect, conſequently, in the time of a flood the waters will overflow a greater extent of country, and to a greater depth than if the river had a free and uninterrupted courſe ſtraight forward.

If

If the windings of the river cannot be altered, and encroachments are making on fome part of the banks, it muft firft be confidered, whether the force of the water can be driven to another place where no injury can be done. If, for example, a river is encroaching on its banks, at *x*, *fig.* 2. a jutty of ftone, a little way up the river in the direction *y z*, would throw off the current towards *w*, and might totally prevent any further encroachment. On the river Nith, in Dumfriesfhire, it is ftated that a good deal has been done in this way by Mr. Millar of Dalfwinton, a gentleman of the moft enterprifing genius and moft liberal mind, who has paid more attention, and laid out more money in making important and ufeful experiments, than almoft any other private individual. The courfe of the river, where Mr. Millar has been carrying on his operations, is faid to be nearly as fhewn at *fig.* 3. by *r s t u*; at *t*, it was encroaching moft rapidly, and feemed inclined to take a new courfe towards *v*, which would have deftroyed fome very fine land, and done a great deal of mifchief in that part of the country. To prevent this, Mr. Millar made a large cut about 400 yards in length from *w* to *r*, and threw in a great quantity of ftones quite acrofs the river at *s*, to direct its courfe in a ftraight line from *r* to *w*. This had, in a great meafure, the defired effect, by totally preventing its progrefs at *t*, but now it began to encroach on its banks at *u*. He at firft endeavoured to prevent this by driving in at a confiderable expence a number of piles at a little diftance from the bank, and wattled them with willow branches, &c. thinking thereby to protect the bank. The piles were drove in with heavy mallets, apparently firm into the ground; they continued fo for fome months, till a heavy fall of rain came on, which fwelled the river, undermined the piles, and carried them all away. But, indeed, it is in vain to think of piles doing any good in fuch a fituation, unlefs firmly driven in by a pile engine; for it is not poffible to drive them in properly with mallets; this muft have been the caufe of their giving way fo foon. The piles not fucceeding, Mr. Millar was refolved to try another plan; feveral of his adjacent fields being covered with an immenfe quantity of ftones, he ordered them to be gathered and thrown into the river, fo as to form a jutty at *x*, a little way above the injured bank. Being obliged to go from home about that time, and to leave the execution of the work to fome country people, they carried out this jutty too much at right angles to the ftream. It had not, therefore, the defired effect, but rather made the matter worfe than before; for, if a jutty is carried out at right angles, as at *a* in *fig.* 4, the current will be forced from *a* to the oppofite fide of the river at *b*, and from thence it will rebound towards *c*, more violently than it did before. But if a jutty be placed obliquely, as at *d*, it will force the current gradually towards *e*, in which pofition one jutty may do more good than feveral placed improperly at right angles. Mr. Millar was, therefore, under the neceffity of making other jutties in this way, and has now the fatisfaction to find that they anfwered the purpofe intended. Thefe he made laterally formed a fort of convex flope, the convexity being parallel to the current. Strong planks were alfo firmly fet on edge among the ftones, their ends pointing towards the river, fo that if ever any current came fo rapidly as to move any of the ftones, it muft move them all in a body the whole length of the plank. Perhaps this precaution was unneceffary; for although ftones are thrown into a river loofe in this manner, the flufh fand, &c. that come down the river will foon fill up all the cavities, and render it as firm and folid as a regular built wall. Mr. Beatfon has been the more particular in this defcription, he fays, in order to fhew the errors that Mr. Millar at firft fell into, and the great expence they occafioned, whereas, had he been on the fpot himfelf, and got the work executed as he intended, it would have faved a great deal of unneceffary labour as well as money.

It is ftated by the fame writer, that the next fort of embankments againft rivers, are thofe to prevent them overflowing their banks, and inundating large tracts of country. This may be confidered as the fimpleft and eafieft of all forts of embanking, if judicioufly executed. It is, therefore, the more inexcufable to fee, in fome places, extenfive tracts of the richeft meadows completely overflown by every flood for want of them.

Two ordinary fized rivers rife no more even in the greateft flood than five or fix feet above their common level, unlefs when they meet with fome confiderable interruption or confinement in their courfe. But if interrupted or confined, they will rife twenty feet or more, as is the cafe with fome parts of the river Merfey already mentioned. If, for example, a given quantity of water is fix feet deep, when running over a fpace twenty feet wide, it is clear, if that fpace was only made ten feet wide, the water would rife to twelve feet, and if it were made forty feet wide, the fame quantity of water would only rife to the height of three feet.

It is, therefore, of great confequence, in preventing inundations, to give the river as much width as poffible, by widening every narrow place. All kinds of obftructions fhould alfo be removed, whether occafioned by windings, fhoals, ftones, trees, bufhes, or any thing elfe. In fome cafes this may even preclude the neceffity of embanking; but where embanking is neceffary, let the banks by all means be at a fufficient diftance from each other, to contain with eafe, between them, the largeft contents of the river in great floods. The diftance and height of the banks may eafily be afcertained by meafuring a fection of the river when at its higheft, or when the flood mark is vifible. By not attending to this, a great deal of money has been thrown away on the embankments on the river Merfey, and after all they do not effectually anfwer the intended purpofe; a great part of the country being ftill overflown every time the river rifes to any confiderable height.

Where a fufficient diftance is allowed between the embankments their height need not exceed from four to fix feet. If irremovable obftacles are in the way, which caufe the river to rife higher, the banks muft be higher in proportion. In either cafe, however, the flope of thefe kinds of banks on each fide may be equal to its perpendicular height, and the breadth on the top about one-third of that height, which, fuppofing the bank fix feet high, the bafe would be fourteen feet, and the breadth of the top two feet, as fhewn at *fig.* 5. in the plate.

The materials for making thefe banks fhould be taken as much as poffible from the fides of the river, which will have the double effect of widening the river and forming the embankments; and there fhould be a trench on the infide (from which materials may alfo be got) with fome fluices, as formerly directed, to drain off any water from within; alfo fluices to let in water from the river, if required, which would very much fertilize the meadows if properly laid out for that purpofe.

Such farms as are fituated on the borders of rivers are frequently, it was obferved by a late writer, liable to much injury and inconvenience from them: 1ft. From part of the foil being carried away in times of flood. 2d. From their overflowing their banks. 3d. From their flowing back in times of flood into the channels of the rivulets and ftreams that conduct the water from the more elevated and diftant grounds

grounds to the rivers, whereby thefe rivulets and ftreams are made alfo to overflow their banks.

In refpect to the firft, the danger of the foil being carried away in time of floods, it is inercafed or decreafed according to circumftances, as the form of the banks, the nature of the foil, the rapidity of the river, and the quantity of water that lodges on the margins of the banks, or falls over them into the river. Where the banks of a river are perpendicular, efpecially if the foil be of a rich mouldering nature, the danger of part of them being carried away by floods is much greater than where they flope gently from the furface of the field to the bed of the river, as has been already fully feen.

Where that is not the cafe naturally, they ought to be moulded into that form by art; as when a river, in place of being confined in its progrefs, has a power of efflux and reflux, the damage to be apprehended is inconfiderable, compared with what is likely to happen when, being reftrained within too narrow limits, it is conftantly ftruggling for an extenfion of fpace. Where the foil is rich free mould, and the under ftratum oppofite to the greateft force of the water, fand, or gravel, this ftruggle never fails to be attended with bad confequences. If the foil and fubfoil be one entire mafs of clay or ftrong loam, and the current of the river does not prefs more upon one part than another, a moft fubftantial improvement may be effected by floping the bank, fo that the declivity may be one foot in three or four from the furface of the field to the bed of the river. This fome may object to, as facrificing a certain portion of valuable land; but it fhould rather, it is thought, be confidered as a premium paid for the infurance of the remainder, than as a total lofs. If gravel, mixed with fmall ftones, can be conveniently procured, fpreading thefe materials on the floping bank to the depth of eight or ten inches, and till beyond the flowings of the river, will prove a good fecurity againft further damage; and if the bank be planted thick with any fort of willow, efpecially the Dutch willow, it will in a fhort time become an impenetrable fence, while the annual cuttings of wood will foon be equal to the heritable value of the land thus apparently facrificed. Where no gravel can be procured, the new floped bank fhould be immediately covered with well fwarded turf, which fhould be preffed down as hard as poffible, either with the back of a fpade, or with wooden mallets. If this be done in the beginning of fummer, and willows be planted the following autumn, the improvement, it is fuppofed, will be both effectual and permanent. In cafe the river run with extraordinary violence againft any one particular part of the bank, it may be neceffary to make a fence or bulwark of ftone in the front of that place; the beft way of doing which, is, in place of building a wall, to drop the ftones in a carelefs manner, but fo as they may lie clofe together on the floped bank, as already fuggefted.

This is a much more fecure mode of fencing, if the bank be made with fufficient declivity, than any ftone wall that ever was built for the purpofe, and while it is the moft fecure, it is alfo the leaft expenfive; but care fhould be taken to lay the ftones all the way from the bed of the river, till confiderably beyond where the river flows in common. Where the foil is of a ftrong adhefive nature, and the under ftratum is fand or a pebbly gravel, it becomes in a much greater degree neceffary to flope the banks. The water, when rufhing violently along, has a powerful effect in undermining the bank, and carrying off thofe incoherent fubftances; fo that the foil, having nothing to fupport it, naturally gives way, and frequently in fuch quantities as to occafion very ferious loffes both to proprietors and tenants. In all fuch cafes, the flope fhould be made much more gradual than where the foil and fubfoil is of the fame quality, and fuch as will nourifh aquatic plants. The banks, having been floped according as circumftances require, a thick coat of gravel, mixed with fmall ftones, where fuch can be procured, fhould be laid on fo as to form a kind of natural beach, over which the river, when in flood, may have power to extend itfelf at pleafure. Should it be difficult or impoffible to procure fuch materials as are proper for forming this beft of all defences, ftrong thick fods fhould be placed on the furface in the manner before directed, which, if laid on in fpring, or early in fummer, will have time to unite, and to become one compact body before the autumnal floods (which are thofe whence the greateft danger is to be expected) begin to flow. If the fubfoil be of fuch a nature as that willows will not grow, fuch fods as are full of the roots of rufhes fhould be made choice of in preference to all others; as where thefe plants thrive and fpread over the furface, it becomes in a great degree impenetrable by water, even in great floods, and when the river runs with confiderable violence and rapidity.

The directions above given will, it is fuppofed, be found more or lefs practicable and ufeful according as the river on ordinary occafions runs with greater or lefs rapidity. In level, or nearly level diftricts, all that is neceffary is to fecure full fcope for the rivers to overflow their ufual bounds without interruption; when that is fecured by either of the methods before mentioned, floods, unlefs very violent, feldom do any material damage to the banks of rivers in fuch fituations. It becomes in many cafes extremely difficult to fence rapid running rivers in fuch a manner as to prevent part of the banks from being carried away by inundation. Sloping the banks would be attended with no good confequences. Even ftrong bulwarks made of ftone are often fwept away by the overpowering flood. A method has, however, been fuggefted, of fencing the fides of a rapid running river, which has been practifed with fuccefs, after feveral other attempts had failed; it is by means of a fort of large bafkets, provincially termed creels, formed of hazle, willow, &c. into a kind of open net work, which being placed along the bottom of the banks, were filled with ftones. This is a very fimple, and by no means an expenfive expedient; and as thefe bafkets may be made to contain two or three tons of ftone, it can only be on few occafions, and in very particular fituations, that a bafket, containing fuch a weight, can be difplaced or carried away. Such a mode of fencing as this, it is imagined, would prove effectual in many parts of Scotland and Wales, where the rivers run with uncommon rapidity. Owing to inattention, or rather to not being aware of the confequences, much damage is often done to the banks of rivers in level diftricts, efpecially if the banks be perpendicular, and of a confiderable height, by allowing the land floods to fall over them into the river. As the water from the furrows approaches the bank, it is frequently ftopped in the furrow of the head ridge, which becomes for a time a kind of refervoir; the confequence of which is, that a confiderable proportion of water finks and filters through the earth, which being thus foftened and fwelled, is more eafily undermined and carried off by the river. Sometimes little cuts or openings are made for the furrows acrofs the head ridge, for the purpofe of conducting the rain water into the river; here, again, the confequences are equally bad. Whoever will examine the bank of a river where this mode of management is adopted, and it is very common, will obferve, that at every one of thefe cuts or openings a little creek is formed, in confequence of the bank having been more foftened, and by that means having

ing become a more eafy prey to the river when in flood. To prevent thefe evils, it is neceffary, befides floping the banks, to devote a part of the lands adjoining to the breadth of twenty or thirty yards, for inftance, either to pafturage or the growth of trees, and to form a drain at a proper diftance from, and parallel to the bank, for the purpofe of collecting and carrying off the water from the furrows. Were this done, and were the water from this drain conducted into the river by conduits formed a little above its ordinary level; much land, which is annually loft by neglecting this fimple precaution, would be faved, and preferved in a proper ftate.

In the fecond cafe it is evident that injuries, although of another nature, are often fuftained by farmers, from rivers overflowing their banks. Sometimes the farmer is prevented from fowing his field; at other times the crops of grain and grafs are greatly injured, by being covered for a confiderable time with water; and at others again, the whole produce of the year, the hay and corn crops are fwept away. To prevent evils fo complicated, and fo ferious in their nature, is certainly the bufinefs of every man, who, from the fituation of his farm, has reafon to apprehend, that without ufing proper precautions, he may be fubjected to fuch vifitations. Thefe damages can only happen in level tracts, where the banks of the rivers are low, and where the courfe is not of fufficient breadth to contain the water in time of flood. Some people, although very improperly, raife mounds of earth clofe to the top of the bank, and of a height exceeding that to which the river can be expected at any time to rife. Thefe mounds, from being placed fo near the river, are unable to refift the preffure of the water, and by giving way, frequently admit a current into the fields, which proves much more injurious in its courfe than if no mound whatever had been erected. Were a mound of earth, formed on the fide of the drain, propofed to be made for carrying off the land water, and were that mound well floped on the fide towards the river, it would be the moft fecure and effectual guard againft rivers doing injury to the adjoining lands, of any that could be adopted. By thefe mounds being placed at a diftance from the river, the force of the ftream would be much leffened, and the natural boundaries of the rivers greatly enlarged, as in proportion as the mounds are removed from the centre of the current of the river, in like proportion will they become more fecure, as being lefs liable to violent preffure. The propriety of erecting thefe mounds at a proper diftance muft, therefore, be fufficiently evident, as when mounds are erected near the top of the bank, which can only be owing to ill-judged parfimony, they form as it were a part of the bank, and are liable to be undermined and fwept away. Whereas, when they are placed at the diftance of twenty, thirty, or forty yards, they ferve rather as a boundary to confine the overflowing waters which glides along the bottom, than as a barrier to prevent the encroachments of an impetuous river during the time of floods.

In regard to the third cafe it is obferved, that farmers who poffefs lands in low fituations often fuftain damage from rivers, in time of flood, by their flowing back into the channels of the rivulets and ftreams that conduct the water from the more diftant and elevated grounds to the rivers, whereby thefe rivulets and ftreams are made alfo to overflow their banks.

The only precaution that can be adopted, in fuch a cafe, or at leaft the one which appears to have the greateft probablity of anfwering the purpofe, is to erect mounds at a diftance from the banks, and of a fize proportioned to the quantity of water which, from the caufe now mentioned, may be fuppofed at any time to ftagnate in thefe channels. This may be done at a very trifling expence either in money or land. If the proprietors do not choofe to ornament the county and improve their own eftates, by planting trees on the borders of the rivulets and ftreams, the farmers may fo conftruct thefe mounds, as that they may become fences to their arable fields, while that portion of the farm, neceffarily and properly cut off for the protection of the remainder, may be devoted to pafturage.

Several different embankments of a fuccefsful kind have been lately effected in the northern parts of the kingdom. An important work of this nature has been executed on the eftate of lord Galloway, fituated on the mouth of the river Cree, near Cree town, by his lordfhip's tenant, Mr. Thomas Hannay, who ftates in the third volume of the "Farmer's Magazine," that he "entered to the farm about four years ago, on a leafe of twenty-one years, and his life; at which time upwards of 100 Scottifh ftatute acres were regularly flooded by the higheft fpring-tides, excepting about three months in fummer, when the tides were lower. They were feldom, however, covered above the deepnefs of one or two feet, and never above four or five. Eighty acres of the above confifted of a rich fea marfh, or *ings*, as they call them there, almoft a true level, excepting where hollows were formed by the egrefs and regrefs of the tides, and the paffage of frefh water from the higher grounds; and about four or five acres, which were about fixteen inches lower, being a younger marfh, and nothing but what they call ink-grafs growing upon it (as he is no botanift he can give it no other name); other graffes, fuch as clover, rib-grafs, &c. grew on the reft of the marfh, forming a very beautiful clofe cover in the fummer. The other twenty acres were at an average about eighteen inches higher; confequently, the fea did not cover them fo often. It had formerly been ploughed, but not for about twenty years paft. Laft time it was in corn, it was flooded immediately after being fown, which rendered the crop almoft entirely ufelefs, and deterred former tenants from ploughing it again. He began to bank this field in the autumn of the year 1798, by making a dike along the fide oppofite to the river, in a direct line facing the eaft. This dike was made, at an average, about three feet and a half high, and fix feet broad at bottom, and twenty inches at top, built after the fame manner with that mentioned below. "He inclofed, along with the faid fields," he fays, "four acres of the marfh adjoining, by making a dike five feet high, and five feet in bottom almoft wholly of folid feals or fods, with a very little ftuff, properly beat, in the heart of it, which makes an excellent fence, and promifes to be a very durable one. This dike, together with two fmall drains, one on each fide of it, about two feet deep, coft 3*d.* per yard. He has been more particular in mentioning this dike here, he fays, as the divifion dikes of the whole marfh, which is now divided into four parts, are all built after the fame manner, only that there is no loofe ftuff in the heart of fome of them, but all of folid feal, jointed like brick, as may be feen at *fig.* 6, which reprefents an end-view, or fection of it. This dike, meant as a permanent fence, anfwered as a temporary bank, and enabled him to plough that field in fpring 1799, although the bank round the whole marfh was not finifhed till the winter following." He "fowed oats on this field, and, confidering the badnefs of the feafon, had a very good crop; particularly fo on that part which had not been ploughed formerly. On further confideration, he altered the plan of the bank round the marfh, (which extends in a circular direction facing the north,) by making it, at an average, about four feet and a half high, and allowing about two feet in the base for one in height, as at *fig.* 7, where *a b c* represent an end-view, or section of it, every small span representing the section of a feal or sod; *ab* shews the inside of the bank, with the green side of the feal down; *bc* the base; *a c* the side next the water, with the green side of the feal out, (which adds greatly both to the strength and beauty of the bank); and *d* the heart of the dike, made up with stuff properly compressed with a rammer. The stuff was taken from a ditch in the inside of the bank, leaving a casement of a foot, which ought to have been three at least; and, where the ground is of a sandy nature, more; as the fresh water, running in the inside, was likely to undermine the bank, had he not prevented it, by cutting a new drain, and filling the old one with the stuff cast from it. The only creek worth noticing, through which the bank passed, was was one about forty feet wide, and nine feet deep, in the bottom of which a wooden pipe, with a stopper, was laid through the bank. No tide offered the smallest injury to the bank till January last, when there was one of the highest ever remembered by the oldest inhabitant, which broke it at this creek. This, he thinks, was owing to the wooden pipe not being made strong enough, as the weight of the stuff and water pressed in the sides of it, and thereby admitted the water below. The tide made also three small breaches in that part of the bank, which was built after the first manner; but in the part made after the manner represented in the figure, no breach took place, though it was rather lower than the other part. There are now about fifty acres of the same kind of marsh land adjoining his; and also about 100 acres on the other side of the river, banked in, all neraly in the same manner as represented in the figure. The bank on the farm adjoining his, suffered little from the high tide; but the one on the other side of the river was made almost a complete wreck, owing to its lying quite opposite to the south-west winds, which always send up the highest tides; but this is not the case on this side, these winds blowing right over their bank. In his opinion, the bank on the other side of the river, in order to be durable, would require to be thirty feet broad, and eight feet high, covered with feals, with the green side out; and that no stuff should be lifted within six or seven feet of it, the ground being of a sandy nature. It might be made after the form shewn at *fig.* 8. He has now got the breaches in his bank made up, and has begun to give the whole a complete repair, by adding, at an average, fifteen inches to its height, and two feet of base for each foot in height. The whole bank is about 1500 yards in length, and, when the repairs are completed, will altogether cost him betwixt 80 and 90*l.*

"In the year 1800, he ploughed another field, he says, of about twenty-six acres of the marsh, besides the one formerly mentioned, on which he had an excellent crop of oats, thought by many to be the best they had ever seen. Last year, he had the same field, part in oats, and part in wheat: the wheat was a very good crop; and the oats, which were of the Polish kind, far exceeded the crop of the former year. Last summer, he levelled the old ridges of the first-mentioned field, all by the spade; gave it a complete summer-fallow; shelled and dunged it well; had part sown with wheat, part with potatoe-oats, and all with grass-seeds. The other field is sown, part with wheat, and part with beans drilled; and, what is very surprising, he says, although the wheat was covered several times by the salt water, when the bank was broke, some of it to the depth of three feet, yet it is all looking well. The whole marsh is, he says, this year, under the plough. It may be worthy of observation, that the four or five acres, which he mentioned as being a younger marsh, harrowed easier than the rest, and produced as good, if not better, crops."

Another improvement of the same nature has been accomplished, on what in Scotland is termed Carse land, on the farm of Netherton of Grange, belonging to James Peterkin, esq. by Mr. John Hoyes, his tenant; the estate having been let to him on a nineteen years lease. The work was undertaken under an agreement with the proprietor, to allow one year's rent of 195*l.* sterling, with the further allowance of ameliorating the farm-houses to the extent of 150*l.* more. It is stated in the work already mentioned, that, "under these circumstances, the embankment was begun about the 1st of June, 1802; and, in November, it was brought to its full height over the whole; so that the Carse has been completely defended from the sea ever since the spring tides in October. He cannot positively ascertain, he says, the extent of ground gained, as it has not been measured since the dike was erected; but, from the last survey of that part of the estate, it would appear, fifty acres were improveable; from which is to be deducted the quantity occupied by the base of the dike, the border on the outside, with a few detached spots, probably included in the measure." The method adopted for carrying on the operations was this: "After looking over the Carse, and marking out the line or dike, the length of which is 1400 yards, mostly in a right line, except an angle at the distance of 300 yards from the west end, and a segment of a circle at about 250 from the south-east end, it was resolved to make the embankment six feet of height in the highest part of the ground, and to allow two feet of breadth in the bottom of every foot of height, as seen by the draught of the mould at *fig.* 9. After taking the level of the Carse, it was found, he says, that where the ground was low, and a good deal of it broken by runs of the sea and outlets for the water, the dike would require to be eight and ten feet high, to have it on a level at the top; so that the average will be nine feet high. The embankment was built in the following manner: It was begun on the highest ground, near the west end, and two moulds set up at the distance of seventy or eighty yards; the height six feet by twelve broad in the base; the slope on the outside six feet, on the inside four feet, and the breadth at the top two feet; the sides made up with feal from the broken ground on the outside of the dike, which were laid with the grass-side down, two feal deep on each side of the dike; the outside feal of the first course with the ends out and in, and the other running along; the next course, the outside feal running along, and the inside out and in, and so on alternately, each course consisting of a head and runner; the body of the dike being made up of the Carse ground from which the feal had been cut, and packed down by men with beaters. When this was brought to the height of four or five feet, another piece was begun, leaving an intermediate space, where there were any water-runs, for the egress of the tide: this was found necessary, to draw off the water from the low parts of the Carse, which would have been filled up in spring-tides; and, by coming in at the end and over the high ground, would have been prevented from getting out by the dike, if it had not been done in that way; so that the embankment was all in detached pieces, till it was brought near the height. These intermediate spaces were then filled up, betwixt the fall of one and rise of next spring-tide, after laying down wooden pipes wih stoppers in the dike, to carry off the sink-water." He adds, that "it was a great labour to get the work carried on; in some places having to cross over lakes and runs made by the tides, which required vast quantities of materials, the dike being in some places upwards of ten feet high, and twenty-two broad in the base: the greatest part of the dike is sixteen to eighteen feet broad. There was one lake, of 150 feet in length, and fifty feet in breadth, filled up with earth, clay, and sand, to the height of five feet; on which the dike was then built. This forms a mound, on the outside of the dike, of fifteen or sixteen feet broad; and through this there are pipes laid, to carry off the sink-water." He further adds, that "a stream of water formerly ran this way; but it was turned by the west end of the farm, by cutting a canal, which conveys the water through the embankment there, by means of an outlet built of stone, with a sluice on the inside, raised to the level of the running water, and a folding-door on the outside, to be shut by the spring-tides. At this place, a road, that formerly led to Findhorn at low water through the Carse, is carried over the top of the dike, by making a mound of earth at each side, with a gradual approach and descent." It is stated further, that "since the Carse has been enclosed, the tides have been so high, that the water, during a severe storm, was from six to seven feet deep at the back of the dike: the wind, being from the north, occasioned a heavy swell and surge, but no water came over the top of it." He suggests, that "it is in contemplation, as soon as the ensuing season permits, to cover the outside with seals, the green side uppermost; and he has no doubt, when finished, it will effectually secure the lands from any further visitation of the sea. The expences of the embankment cannot be well ascertained at present; but it will be a good deal more than is allowed by the proprietors." He says, that "a great part of the land is already ploughed; but, the winter setting in so severe, prevented the whole from being done. It is intended to fallow it, in preparation for a crop of oats in the succeeding spring; but this intention may not be unalterably adhered to. There are various sorts of soil in it: some of it clay, sand, gravel, black rich earth, and parts of it of a mossy nature; in some places below the gravel, which may, he thinks, have been forced on by the tides, a thin stratum of clay, upon sand; and some parts, clay and sand alternately. There are other parts not so rich as might be expected, the surface having been carried off by former tenants, for mixing in their dunghills or compost heaps. In *fig.* 9, *a* is the breadth of the dike at the top, when finished; *b*, the breadth of dike at bottom, being twelve feet, when it is six feet high; *c*, the breadth when eight feet high; *d*, the breadth when ten feet high; *f*, the slope on the sea-side of the dike, which is always equal to the half of the breadth of the bottom: the inside slope, and breadth of the dike at top, is equal to the other half; and *e* is a plumb-rule in a frame, made to apply to the mould or dike: the intention of it was, to find if the dike was kept on the proper slope, where a line could not be applied from one mould to another, as in a round or turn, or when the moulds were obliged to be taken down; but this one only answered for the sea-side, another being used for the inside, to fit its slope." *Fig.* 10. is a scale of the mould one-eighth of an inch to a foot.

Various other improvements of this nature have been accomplished, in particular circumstances and situations; and large tracts of land thereby rendered more than doubly beneficial to their occupiers. The methods which have been had recourse to, in such cases, will be fully detailed in speaking of *Hough-land* and *Rivers*.

A curious, useful, and highly ingenious method of embanking, and preventing the waters of the tides from soaking through the porous banks, formed in fenny and moorish situations, has been described by Mr. John Smith, in the fourth volume of "Communications to the Board of Agriculture," who begins by "concisely observing, that the great land of the fens is divided into three large levels; and that each of these levels is subdivided into numerous districts by banks: but as these banks are made of fen moor, and other light materials, whenever the rivers are swelled with water, or any one district is deluged either by rain, a breach of banks, or any other cause, the waters speedily pass through these light, moory, porous banks, and drown all the circumjacent districts. The fens have sometimes sustained 20,000*l.* or 3-,000*l.* damage by a breach of the banks; but these accidents seldom happen in the same district twice in twenty years; the water, however, soaks through all fen-banks every year, in every district; and when the water-mills have lifted the waters up out of the fens into the rivers in a windy day, a great part of the water soaks back through the porous banks, in the night, upon the same land again." And he adds, that "this water that soaks through the bank drowns the wheat in the winter, washes the manure into the dikes, destroys the best natural and artificial grasses, and prevents the fens from being sown till too late in the season. This stagnant water lying on the surface, causes also fen agues, &c. Thus, says he, the waters that have soaked through the porous fen-banks have done the fertile fens more real injury than all the other floods that have ever come upon them."

Having been much concerned in fen-banking from his youth, he had some time since devised the plan which he now finds to answer so well; but found it difficult to prevail with any gentleman, who had a proper extent of this sort of land, to give it a fair trial. However, during the last autumn, he prevailed with a person in the parish where he lives to try it, which shewed it to be equal to his highest expectations.

This improved method of embanking chiefly consists in this: that "a gutter is cut eighteen inches wide, through the old bank down to the clay, (the fen sub-stratum being generally clay,) the gutter is made near the centre, but a little on the land-side of the centre of the old bank. This gutter is afterwards filled up in a very solid manner with tempered clay; and to make the clay resist the water, a man in boots always treads the clay as the gutter is filled up. As the fen-moor lies on clay, the whole expence of this cheap, improved, and durable mode of water-proof banking costs in the fens only sixpence *per* yard. This plan was tried last autumn on a convenient farm, and a hundred acres of wheat were sown on the land. The wheat and grass lands on this farm are now all dry, whilst the fens around are covered with water. This practice answers so well on this farm, that all the farmers in this parish are, he says, improving their banks in the same manner, and some have begun in adjacent parishes."

It is unquestionably a mode of practice that requires to be fully known and understood, in all those districts which have lands of this description; as by it great advantages may probably be derived.

Embanking against Lakes.—The business of forming embankments, in cases of what are termed lakes, or mires, in this part of the country, and loughs in Scotland and Ireland, is much more simple and easy than in the preceding cases. It has been remarked by Mr. Beatson, that the waters in these situations generally subside during the summer months, rising considerably in winter, and whenever the season is very wet. In particular cases, the extent of surface, which is overflown in the winter season, so far exceeds

exceeds that which it covers during the summer, that it would be an object, and sometimes a considerable acquisition, to confine the water within its summer boundaries, or to cut off some of its parts. Where these are intended, the principal outlet must be first carefully examined, and be considerably widened and enlarged; which, on the principle already noticed, in speaking of rivers, will prevent the water from rising so high as was formerly the case. Where the levels will not admit of much depth being had, or where the ground is of a rocky nature, and would of course be difficult and expensive to deepen, the breadth should be increased as much as possible, and all obstacles cleared away, that the water may run freely in a shallow stream. Where it is required to ascertain with exactness, or to fix with certainty, the future limits of the water, a section of the greatest quantity running out during a flood should be taken. Suppose this section, for example, be ten feet in width and four feet in depth; by making it forty feet in width, the same quantity of water will not rise above one foot: consequently, by this means alone, three feet in height will be gained all round the lake, which, in case of embanking it, would be a great object. During the summer season, when the water is lowest, is the most proper time for carrying on these, as well as other embankments. When, however, any materials are to be brought from a distance, they may be laid down or be prepared at other seasons, with the exception of turf, which should always be used as soon as possible after it is cut. The manner of constructing embankments of this kind may be sufficiently understood, from what has been already said in the other descriptions of embankments: observing, however, as a general rule, that when the materials on the spot will answer the purpose, they should invariably be made use of, although at the expence of digging a trench larger and deeper than would otherwise be necessary. It should constantly be attended to, in executing all sorts of embankments, that the greatest care be taken to make them perfectly firm and solid, by continually beating them, and examining them carefully, during the whole of the time they are in the state of being formed.

The various methods and plans of management, which are necessary to be adopted in the improvement of such lands as have been gained from the sea, will hereafter be more fully considered and explained. See MARSH-*Land*.

EMBANKMENT, in *Canal-making*, is a term for any large mound of earth, either for confining the water of a canal or reservoir, or upon which a canal or aqueduct is formed across a valley or low piece of ground. It may have arches under it, for the passage of a road, a river, or brook: such are called *aqueduct-arches*, and ought by all means to be constructed on the true curve of equilibration, for avoiding the great expence and disgrace which attends the failure of less scientific arches, as at Wolverton on the Grand Junction Canal. See CANAL.

EMBAR, in *Geography*, a town of Africa, in the country of Senegal.

EMBARCADERO, in *Commerce*, a Spanish term, much used along the coasts of America, particularly those on the side of the South sea.

It signifies a place which serves some other considerable city farther within land, for a port, or place of shipping, *i. e.* of embarking and disembarking commodities.

Thus Calao is the embarcadero of Lima, the capital of Peru; and Arica the embarcadero of Potosi. There are some embarcaderos forty, fifty, and even sixty leagues off the city which they serve in that capacity.

EMBARGO, a restraint or prohibition, laid by a sovereign on merchant-vessels, to prevent their going out of port; sometimes to prevent their coming in; and sometimes both, for a limited time. See PROCLAMATION.

Embargoes are usually in time of war; in apprehensions of invasions, &c. One great occasion of embargoes is, that the government may make use of the merchant-vessels, with their equipage, &c. in armaments, expeditions, transporting of soldiers, &c.; another is, to stop the communication of intelligence at such critical seasons. Embargoes are of very mischievous consequence to commerce.

EMBARKATION *of Ordnance and Stores.* The first thing necessary is to prepare a list of all the articles to be embarked, with the weight of each. This list must have an ample column for remarks; and the reputed tonnage must have an allowance of one-third added, for all articles whose weights and measures are not always the same, but receive, or lose, in consequence of damp, dirt, &c.; such as tents, &c.: but the tonnage of ordnance, shells, shot, &c. should be set down at their actual weight, according to their natures, calibres, &c. respectively. If vessels are paid for according to the tonnage they carry, the master will, of course, stow away to the best advantage, and load with as much as the vessel can possibly contain; whereas when freighted for a voyage, upon the estimated tonnage of the hold, they will stow so very loosely, as both to carry less, and to subject the cargo to considerable injury. It is, therefore, proper that a naval officer should be appointed to superintend every embarkation, and to see that every thing is stowed to the best advantage. It may be useful, in this place, to shew how tonnage is estimated. The usual method of finding the tonnage of any ship is,—Multiply the length of the keel by the length of the beam, and half that product by the breadth of the beam; divide the last product by 94, and the quotient will be the ship's tonnage. Thus, say a ship's keel measures 90 feet, and that her beam, *i. e.* her extreme breadth, be 30:

$$90 \times 30 = 2700 \times 15 = \frac{40500}{94} = \overset{\text{Tons.}}{430.8}$$

The tonnage of goods and stores is taken sometimes by weight, and sometimes by measurement; and that method is allowed to the vessel which yields the most tonnage: were it otherwise, the owners would be considerably losers in the freight of bulky, light articles, on which the calculation by weight would give them but little claim to charge; and, *vice versâ*, if ordnance, shot, &c. were to be carried by measurement, they would be under a similar disadvantage. In tonnage by weight, 20 cwt. make a ton; and in tonnage by measurement, 40 cubic feet make a ton, the same as in timber computations. All carriages, or other stores to be measured for tonnage, should be reduced to their smallest dimensions, by taking to pieces, and packing into as little space as possible. All ordnance is shipped according to actual weight; as are also musket cartridges in boxes or barrels, and other such ponderous articles. The following table will exhibit the rates of tonnage allowed for the embarkation of the most material stores in the ordnance department.

EMBARKATION.

When ordnance and ftores are embarked, all appertaining to the fame fpecies fhould be claffed and divided into the feveral veffels, in fuch manner as may infure the fafe arrival of a certain portion; thereby avoiding that great inconvenience which could not fail to arife, were any one veffel, containing the whole of any particular ftores, to be loft, taken, or unable to make the place of deftination. With each piece of ordnance fhould be embarked every thing neceffary for its fervice; fo as to be inftantly come at, when required to be landed. This principle fhould be carried to the fulleft extent: even the platforms for the battering cannon fhould be in the fame veffel with them; and, in fhort, every precaution ought to be taken to obviate delay, or omiffion, or imperfection. In general, all the heavy ftores fhould be put in firft; both to prevent their crufhing lefs fubftantial articles, and to ferve as ballaft: the lighter ftores, being generally moft perifhable, fhould be ftowed uppermoft, and be all numbered according to their feveral natures, and to their feveral intentions. Thus, every piece of ordnance, its carriage, and even all the parts of that carriage, together with its fponges, rammers, limbers, and boxes, ought to bear the fame number; fo that, when about to be landed, the whole may be difcharged at one time from the fhip, and be fent on fhore in that regular manner, which may enable the artillery men and artificers to mount every one in fucceffion with promptnefs and exactitude. All the chefts, barrels, &c. muft be lettered and numbered diftinctly, in fuch manner as may indicate their refpective contents. The numbers, &c. ought to be painted in clear white on a black ground, thereby to be legible at night: for the fame purpofe, it would perhaps be found ufeful to have the letters marked with white-headed tacks; fo that, when not legible, for want of light, as often happens, they may be traced with the finger. In fhipping gun-carriages, it is eligible to fend them down into the hold, &c. without taking off the axle-trees from the cheeks; as they cannot be replaced without proper workmen, and a tedious operation. When a carriage is difmounted, all the fmall articles, fuch as elevating-fcrews, linch-pins, drag-wafhers, &c. fhould be carefully collected, and fecured either in a fmall box, or in a bag of leather, tarpaulin, &c. duly marked.

In order to give more room, all articles, of the fame defcription in particular, fhould be placed fo as to lock into each other, or to fit in fuch manner as may leave the leaft poffible intervals. A perfon fhould attend to regifter, not only the feveral articles as they fhould be fhipped, but to note the exact part of the hold, &c. where each might be ftowed. Thefe precautions, added to the affixment of particular marks, fuch as numbers, in white paint, on each bow, and each quarter of every tranfport, fo as to be diftinguifhable at feveral miles diftance, will tend confiderably to facilitate the debarkations, and enable the feveral commanders and public officers to afcertain with perfect precifion the amounts of loffes, and the fituations of the feveral ftores, according as veffels may lie to windward, or to leeward, &c. It is a matter of confiderable importance in embarking ftores, to have them ready at hand which would be the firft wanted in cafe of emergency: as well as to arrange them in fuch manner as fhould anfwer the purpofes of the expedition in the moft efficacious manner. Thus, if it is expected that troops will have to difembark in the prefence of an enemy, the light field-pieces, and howitzers, in lieu of being fent below, ought to be kept, together with all their implements, and a certain portion of their ammunition in fome fecure part, whence they could be lowered into the boats at a fhort notice. Entrenching tools fhould alfo be held in equal readinefs, together with abundance of fand-bags. When troops are to be embarked, every precaution muft be taken to prevent confufion, and to obviate danger. Certain corps fhould be appointed to be in readinefs on given days at particular ports; taking with them only fuch baggage as fhould be allowed on the occafion. The ftores of every defcription and the difpofable lumber fhould be previoufly fent on board, under charge of the quarter-mafter, who fhould be particular in feeing that every thing neceffary to the comfort and efficiency of the troops were duly arranged. The tranfports being in readinefs, they fhould, if poffible, be brought up to a pier, fo that, by the aid of gang-boards, the files might march on board at once; otherwife recourfe muft be had to boats and fmall craft, in which the troops muft proceed from the fhore to the fhipping. The lee-fide is generally preferred for embarking; it being the fmootheft water, and often the afcent up the gang-ladder lefs difficult. The fafeft mode is for the arms to be handed up into the main chains, and from thence into the veffel. The bayonets ought to be well fecured to their fcabbards, and the pouches fhould be buttoned down. The men neareft the gang-ladder fhould be the firft to afcend; the others taking care to balance the boat, &c. as fhe becomes lighter, and requiring equipoife in confequence of being quitted by the troops. It fhould be obferved as a ftanding regulation never to let one boat lie abreaft of another that is difcharging her crew into a veffel: otherwife there will not only be danger of broken-legs, but of being upfet: each boat fhould range up under the lee-quarter, in fucceffion, and when evacuated by the troops fhould pull a-head, by means of a painter, or a boat-hook, fo as not to impede its fucceffor. When the troops are on board boats, they fhould fit as low as poffible, keeping their mufkets perpendicular, and refted on the bottom, or on their own feet. In going on board the men fhould proceed very leifurely and filently to their places, fpreading fo as to preferve the due time of the boat, and fitting down fo foon as duly arranged. In cafe of accident, or running foul of any other veffel, they fhould be particularly enjoined to remain feated, and not to obftruct the boat's crew in their endeavours to remedy the mifhap. Where troops are to embark in the face of an enemy, the greateft order and coolnefs will be requifite; efpecially when within the reach of their cannon. If the embarkation in boats is to be made from a fhip, they muft all be manned from that fide leaft expofed to the enemy's fire; the fhip covering them as they fucceffively put off, and reft on their oars, until the whole may be ready to ftart together by fignal; after which no time fhould be loft in gaining the fhore, and in forming on the beach. It fometimes occurs, that a river is to be croffed in boats for the attack of an enemy pofted on the oppofite bank: in fuch cafe, the number of boats being previoufly afcertained, the troops muft be told off into as many divifions as there may be veffels to convey them, the ftrength of each divifion correfponding with the tonnage of that it is to occupy. Each divifion then proceeds on board with rapidity, but with perfect regularity, and the whole put off without delay. Where the water is rather fhallow, the boats muft lie out fo far as to be afloat after the men have, by wading, got on board. All debarkations from boats and fhipping fhould be conducted with as much order as circumftances may admit; and even when troops are driven back to their boats, as much fhould be preferved as the preffure of purfuit may allow. It is a well-known fact, that many re-embarkations have taken place in the prefence of a fuperior force without diforders, or allowing the enemy to make a fingle prifoner. The greateft danger generally

arifes

arifes from allowing the boats to lie in fo clofe, as to touch the ground, whereby, when the troops have got on board, they have been unable to pufh off, and thus remained fubject to a galling fire. When re-embarking after a repulfe, it fhould be ftudied to man fome of the craft, (efpecially a few of the lighteft conftruction, and any gun-boats whofe draught of water may allow them to lie near the beach,) for the purpofe of covering the retreat, and to take in flank fuch of the enemy as fhould follow the fugitives into the water. When fuch a precaution is obferved, the embarkation will proceed quickly, and the enemy will content themfelves with a diftant fire on the retreating force; in lieu of mixing pell-mell, as they would do if there exifted no pre-eftablifhed check. Troops embarked on board tranfports, or fhips of war, are only allowed three-fourths of a feamen's ration of provifions; unlefs when acting as marines, when they are on a footing. The meffes are formed of fix men in each, for each of which a fpace of fix feet fquare is allowed, that is, 36 fquare feet; but only four are ever there at the fame time, it being a rule that one-third of each mefs fhould always remain on deck. When embarked for foreign fervice, fix women are allowed provifions for every hundred men; and when on home fervice, ten women are allowed with the fame number. That part of the charter-party which relates to the provifion, firing, candles, utenfils, &c. intended for the ufe of the troops, is always fubject to the infpection of their commanding officer on board; and is fometimes copied out, and hung up in the cabin, open to the perufal of all. The regulations regarding fmoking, extinction of lights, &c. are alfo pofted up in various parts, together with the whole allotment in regard to births, meffes, and particularly the accommodations for the officers of the veffel, and thofe attached to the troops. It being neceffary to eftablifh fome limit for the quantities of baggage taken on board, the following proportions were fixed for that purpofe.

For a field-officer - -	five tons.
For a captain - -	three tons.
For a fubaltern - -	a ton and a half.

General officers are rarely limited, but it is ufually intimated to all embarking, that the quantity of baggage fhould be reduced as much within bounds as might be practicable.

The embarkation of horfes is ufually effected by means of flings of canvas, which paffing under their bellies, and being duly fecured with cords, enable the crew to hoift them in, and to lower them down between decks without doing the fmalleft injury to the animals; which, however fpirited they may be while on terra firma, generally become perfectly paffive under fuch circumftances. On arriving at the place of deftination they are debarked in the fame manner. It certainly is among the moft important improvements in this branch of fervice, that the horfes can be flung, during bad weather, to the beams in fuch manner as to prevent their fuffering in confequence of the fhip's motion. Yet we cannot but judge, from the crippled ftate in which cavalry are fometimes debarked, that much room remains for improvement.

EMBARRAS, Embarrasment, a French term, though now naturalized; denoting a difficulty, or obftacle, which perplexes or confounds a perfon, &c.

EMBASIS, in the writings of the *Ancient Phyficians*, the name of a large veffel, in which they prepared their medicated baths, and which was capable of holding the perfon to be bathed at his full length.

EMBASSADOR, or Ambassador, is a public minifter fent from one fovereign prince or independent ftate to another, as a reprefentative of that prince or ftate, and furnifhed with credentials which verify his miffion as an embaffador.

Such a public minifter is called in Latin *legatus*, or *orator*, but the meaning of the word embaffador is much more extenfive. The only circumftance in which the modern embaffador and the ancient legatus agree is the protection of the law of nations. See Legation.

The Englifh word embaffador is probably derived from the Spanifh *embaxador*, the fame as the French *ambaffadeur*, which comes from *ambafciator*, a Latin word of the middle age, formed of *ambactus*, or *ambact*, an agent, domeftic, or client among the Gauls. The term *ambafcia* is found in the Salic law, Tit. xix. and in the law of Burgundy.

The cuftom of fending embaffadors dates from the origin of civil focieties. As foon as mankind were divided into diftinct nations, differences would arife which muft be amicably fettled by the interference of neighbours, guarded againft by the protection of the more powerful, or decided by wars ending in reconciliations. The negociating of thefe mediations, alliances and treaties of peace is entrufted to public minifters; and fovereign princes having, like private perfons, interefts to difcufs with other princes regarding their own concerns as individuals, fuch as the contracting of matrimonial alliances; the management of thefe tranfactions is likewife confided to public minifters, or negociators. See Negociation.

Among the public minifters fent as negociators, from one independent ftate or fovereign prince to another, embaffadors hold the firft rank. Envoys, minifters plenipotentiary, and refidents, are negociators of lefs eminence. (See Envoy, Plenipotentiary, and Resident.) Their functions are the fame; they are equally under the protection of the law of nations, and they enjoy nearly the fame privileges.

The pre-eminence of embaffadors manifefts itfelf chiefly in the particular ceremonial of their reception in the country where they are appointed to refide. They are entitled to be faluted with the firing of guns; to be complimented by deputies of the prince or ftate to which they are fent; to make a folemn public entry; to fpeak at the audiences they obtain with their heads covered; to have places of honour affigned to them at all public ceremonies; to keep a canopy or throne in their dwelling; and, fince the year 1593, when this title was firft given them at Rome, to be ftyled excellencies. The name of embaffador, Cicero obferves, is facred and inviolable: "non modo inter fociorum jura, fed etiam inter hoftium tela incoluma verfatur:" (In Verr. orat. 6.)

The privileges which embaffadors fhare with other public minifters, fent as negociators, are.

1. The right of being received by the prince or ftate to which they are deputed, unlefs there be a juft caufe for refufing to receive them. The duke of Buckingham, fays Hume, had Englifh familiarity, and French levity, two of the moft offenfive qualities in an embaffador. When, in 1626, he was defirous of being once more embaffador at the French court, it was fignified by the French embaffador to the court of St. James's that for reafons well known to the duke his perfon would not be agreeable to his moft Chriftian majefty. His prefumption to talk of love to the queen in a former embaffy had given offence, and would have been a juft caufe for his non-admiffion.

The correfponding obligation of receiving foreign embaffadors has its foundation in the deareft interefts of fociety and of humanity. As nations are in continual need of mutual affiftance, they could never freely communicate, if the law

law of nations had not made it an imperious duty to all ftates to admit the embaffadors who are fent to them. Even the embaffadors of an enemy have a right to be received and to be heard, fince it is the duty of nations at war with each other to endeavour by all poffible means to re-eftablifh the accuftomed relations of peace and amity.

2. The inviolability of their perfons. Embaffadors reprefent the fovereign or chief magiftrate of an independent ftate; their miffions are frequently of the moft delicate nature, and could not be accomplifhed if the fecurity of their perfons were not exprefsly provided for. Thofe who infult an embaffador infringe not only the civil law, which forbids the doing of injuries in general, but more particularly the public law of nations, which extends its fpecial protection to public minifters, that the harmony of nations may not be difturbed, or if unfortunately the ties of friendfhip have been broken, that the effecting of a reconciliation may labour under no reftraint. The fmalleft infult offered to an embaffador ought to be punifhed with the greateft feverity; the neglect to punifh the offender is a juft caufe of war.

If an embaffador grofsly offends, or makes an ill ufe of his character, he may be fent home, and accufed before his mafter: who is bound either to do juftice upon him, or avow himfelf the accomplice of his crimes. (Mont. Sp. of L. 26. 22.) But writers on the law of nations are not agreed, whether this exemption of embaffadors extends to all crimes, as well natural as pofitive: or whether it only extends to fuch as are *mala prohibita*, as coining, and not to thofe that are *mala in fe*, as murder. Our law feems formerly to have taken in the reftriction, as well as the general exemption. For it has been held, both by our common lawyers and civilians (1 Roll. Rep. 175. 3 Bulftr. 27.) that an embaffador is privileged by the law of nature and nations; and yet if he commits any offence againft the law of reafon and nature, he fhall lofe his privilege (4 Inft. 153.); and therefore, if an embaffador confpires the death of the king in whofe land he is, he may be condemned and executed for treafon; but if he commits any other fpecies of treafon, it is otherwife, and he muft be fent to his own kingdom. However, the general practice of this country, as well as of the reft of Europe, feems now to purfue the fentiments of the learned Grotius, that the fecurity of embaffadors is of more importance than the punifhment of a particular crime. And therefore few, if any, examples have occurred within a century paft, where an embaffador has been punifhed for any offence, however atrocious in its nature.

Even the domeftics and the perfons in the retinue of an embaffador are inviolable. If any one of them were infulted, the punifhment ought to be as fevere as if the infult had been offered to the embaffador himfelf. The domeftics of the duke of Créqui, French embaffador at Rome, having been infulted by the Corfican guards of Pope Alexander VII. Louis XIV. infifted upon their being feverely punifhed.

But this inviolability extends only to the perfons who compofe the embaffador's family, as his wife and children, and who being actually in his retinue are regiftered as fuch by the police of the country where he refides. Should, however, any of them be guilty of a great crime, as a forgery, theft, or murder, it would be no violation of the law of nations to claim the offender, and to punifh him according to the laws of the country. When Sully refided in England as embaffador of Henry IV of France, he was informed that one of his gentlemen had killed an Englifhman in a houfe of ill fame. He immediately got him arrefted, and fent word to the magiftrates of London that they might feize the murderer. The latter having been tried, the king of England granted him his pardon and his liberty.

In confequence of this inviolability the actions of an embaffador or of any perfon in his retinue are not fubject to the controul of the private law of the country in which he is appointed to refide; and with regard to civil fuits they cannot be profecuted for any debt contracted in that country as long as the embaffador continues in it in his public capacity. This privilege is allowed in the Englifh courts of law, and, the more effectually to enforce the law of nations in this refpect, when violated through wantonnefs or infolence, it is declared by the ftatute 7 Ann. c. 12. (an act paffed in 1708, in confequence of the arreft of an embaffador from Peter the Great, czar of Mufcovy, for a debt of 50*l.*) that all procefs whereby the perfon of any embaffador, or of his domeftic or domeftic fervant, may be arrefted, or his goods diftrained or feized, fhall be utterly null and void; and that all perfons profecuting, foliciting, or executing fuch procefs, being convicted by confeffion on the oath of one witnefs, before the lord chancellor and the chief juftices, or any two of them, fhall be deemed violators of the laws of nations, and difturbers of the public repofe; and fhall fuffer fuch penalties and corporal punifhment as the faid judges, or any two of them, fhall think fit. But it is exprefsly provided, that no trader, within the defcription of the bankrupt laws, who fhall be in the fervice of any embaffador, fhall be privileged or protected by this act; nor fhall any one be punifhed for arrefting an embaffador's fervant, unlefs his name be regiftered with the fecretary of ftate, and by him tranfmitted to the fheriffs of London and Middlefex. Thefe exceptions are ftrictly conformable to the rights of embaffadors, as obferved in the moft civilized countries. In confequence of this ftatute, thus declaring and enforcing the law of nations, thefe privileges are now held to be part of the law of the land, and are conftantly allowed in the courts of common law. (Fitz. 200. Stra. 797.) Blackftone's Commentaries, vol. i. and iv.

3. The moft perfect freedom and independence in the difcharge of their official duties. This is a further confequence of their inviolability. If an embaffador fhould even excite difturbances, or enter into any confpiracy againft the prince, or the ftate to which he is fent, the general practice of Europe is in favour of the opinion of the learned Grotius, in his book "De Jure Belli et Pacis," that the inviolability of an embaffador is of greater importance than the punifhment of a particular crime. His public character ought to be conftantly and invariably refpected; but he may be difmiffed, and fent back to the prince or ftate whofe reprefentative he is. The bifhop of Rofs, embaffador of the queen of Scotland at the court of Weftminfter, having engaged in a confpiracy with the duke of Norfolk againft the queen, he was arrefted, confronted with his accomplices, and fent back to Scotland. In the reign of Henry IV. of France, the Spanifh embaffador took a part in the confpiracy of the count d'Auvergne and duke d'Angoulême, who were both tried; but no mention was made of the embaffador. A certain Mérargues had agreed, with the fecretary of the fame embaffador, to deliver Marfeilles into the hands of the Spanifh monarch. The French parliament condemned Mérargues to death; but the Spanifh fecretary was delivered to the king of France, who gave him up to the Spanifh embaffador, and obliged the latter to fend the fecretary out of the kingdom.

If an embaffador be difmiffed and efcorted to the frontiers, he is entitled to the privileges and immunities of his dignity, as long as he is on the territory of the ftate that fends him back. He ought alfo to be allowed a convenient time to prepare for his departure. This indulgence muſt even be granted to the embaſſador of a power againſt which a declaration of war has been iſſued, and he muſt be furniſhed with paſſports to return home unmoleſted. The cuſtom of the Turks, who, in the caſe of war being declared, confine the embaſſador of the power againſt which it is declared in the caſtle of the Seven Towers, is in direct violation of the law of nature, and of the public law of nations. The enlightened ſovereigns of Europe ſhould join in remonſtrating againſt ſo unjuſt a practice, and inſiſt upon its abolition.

4. The inviolability of the houſe in which they reſide. An embaſſador's dwelling is a ſacred aſylum, where no perſon can be arreſted without the embaſſador's conſent. Any felon, however, that might have taken refuge in an embaſſador's houſe, ought to be given up to the criminal juſtice of the country.

Neither have embaſſadors the right of trying or puniſhing, within the walls of their manſion, perſons of their retinue who have been guilty of any crime. Though independendent of the criminal and civil laws of the country in which they reſide, they cannot exerciſe any judicial functions, becauſe the judicial power of the ſovereign they repreſent does not extend to that country.

5. The right of having divine ſervice performed in their houſes, at a chapel of their own, according to the rites of the worſhip of their country: but embaſſadors cannot claim the free acceſs of others to their chapel than the ſubjects of the country they repreſent, who are under their ſpecial protection in this reſpect. At the time when the Proteſtants were cruelly oppreſſed and perſecuted in France, the French Proteſtants reſiding at Paris have frequently been moleſted in going to and coming from the chapel of the Dutch embaſſador; but he had no right to remonſtrate againſt this cruelty, becauſe it was exerciſed on the ſubjects of the king of France.

6. The right of being exempt of all duties, charges, taxes, impoſts, exciſe and cuſtom dues. This right has ſometimes been reſtricted in countries where it had been abuſed by embaſſadors, who, forgetful of their dignity, had not ſcrupled to make it a cover to an illicit trade.

7. The privilege, that in caſe of death, the houſehold furniture, moveables, and perſonal property of embaſſadors, or of any individual in their retinue, devolve to their heirs, though aliens, without being liable to any deduction, tax, or alien duty, commonly called "Droit d'Aubaine." But this right does not extend to immoveables, or landed property.

8. The right of legalizing or certifying the authenticity of documents or writings which are to be tranſmitted to the ſtate or country which they repreſent, and that of granting paſſports to the natives of that country.

9. The right of following the court at which they are appointed to reſide, to whatever place that court is removed to, unleſs the prince ſhould declare his abſence to be merely temporary, and requeſt the embaſſador's non-attendance. During the ſeven years' war in Germany, from 1756 to 1763, the Engliſh embaſſador at the court of Berlin attended the great Frederick of Pruſſia at all his head-quarters.

10. Laſtly, embaſſadors conſider themſelves as entitled, and indeed cuſtom appears to have ſanctioned it as a right, to receive ſome valuable trinkets as preſents at their laſt audience, when they take leave of the prince at whoſe court they have reſided.

Embaſſadors ought to be very attentive not to ſuffer any of their privileges or immunities to be infringed upon; neither ought they to paſs over any attack on the perſon or dignity of the prince, or on the character of the ſtate they repreſent. Whenever they have a complaint of a breach of privilege to prefer at the court where they are appointed to reſide, they are ſupported in their demands of redreſs by the whole diplomatic body, or corps diplomatique, that is to ſay, by the aggregate of all the foreign miniſters reſiding at the ſame court.

But embaſſadors cannot claim their privileges and immunities, unleſs they have proved their miſſion as embaſſadors by the delivery of their credentials; nor can they diſplay their character of public miniſters in any other country than that to which they are ſent in that quality. When they are under the neceſſity of traverſing the dominions of any other ſovereign prince, they muſt provide themſelves with the permiſſion to travel through that country by means of regular paſſports, for the law of nations does not oblige a prince or nation to reſpect an ambaſſador on his journey through their country, if he ſhould attempt to traverſe that country without having previouſly obtained their permiſſion.

At Athens the embaſſadors from foreign princes and ſtates always mounted the tribunal, or pulpit, of the public orators, and there opened their commiſſion, and acquainted the people with their buſineſs. At Rome they were introduced to the ſenate, and delivered their commiſſion to them. Among us they make their addreſs immediately and ſolely to the king.

Athens and Sparta, ſays M. Tourreil, when in all their glory, were never ſo much delighted as to ſee and hear a number of embaſſadors in their aſſemblies, ſuing for their protection or alliance. It ſeemed to them the nobleſt homage that could be paid them; and that ſtate which received the moſt embaſſies, was judged to have the advantage over the other.

There are ſome uſages to which embaſſadors ought to conform. They ſhould never attend at any marriage, chriſtening, funerals, or other private ſolemnity; nor muſt they even go into mourning on any occaſions of their own, becauſe they are no longer private individuals; they are the repreſentatives of a ſovereign prince or independent ſtate.

Embaſſadors, in modern times, are either *ordinary* or *extraordinary*.

An *embaſſador ordinary* is he who conſtantly reſides at the court of a ſovereign prince or independent ſtate, to maintain a mutual good underſtanding between the two ſtates, to watch over the permanent intereſts of his country, to tranſact ſuch affairs as may occur, and to give a regular account of his proceedings and obſervations to the prince or ſtate which he repreſents. The practice of keeping embaſſadors ordinary in foreign courts is but of modern invention. It is generally aſcribed to the cardinal de Richelieu. Raymond de Beccaria, baron de Forquevaux de Pavie, knight of the order of St. Miehael, was one of the firſt public miniſters who reſided permanently at a foreign court. He was ſent to Spain in 1565, as embaſſador ordinary of Charles IX. of France at the court of Philip II. probably on account of the miſunderſtanding which prevailed between the Spaniſh monarch and his conſort Elizabeth, who was a French princeſs.

The frequent intercourſe which takes place between modern nations; the many relations in which they ſtand to each other; their mutual intereſts; their political and commercial jealouſies; the wiſh of being rapidly and confidently informed of their reſpective projects, enterpriſes, connections and partialities, of the ſprings by which their governments are ſet in motion, and of the general adminiſtration of their concerns abroad and at home; and laftly, the want of a powerful protection for individuals trading in foreign countries, are indeed circumftances which confer on the permanent refidence of public minifters in foreign courts a high degree of public convenience and utility. Every independent European ftate has adopted the practice, except the Helvetian Republic, and the fublime Ottoman Porte. Thefe two ftates have hitherto at leaft employed only embaffadors extraordinary.

An *embaffador extraordinary* is he who is fent from one fovereign prince or independent ftate to another on fome particular occafion or emergency, and who retires as foon as the bufinefs of his miffion is terminated Hence it follows that an embaffador extraordinary may be difpatched to a court or country where an embaffador ordinary of the fame prince or ftate is permanently refiding. Thus the king of Great Britain appointed Mr. Rofe embaffador extraordinary to the United States of America in 1808, for one particular purpofe, whilft the honourable Mr. Erfkine continued as Britifh embaffador ordinary at Wafhington.

In ancient times, all embaffies were extraordinary. They were generally undertaken from motives of neceffity, policy, or adulation, fometimes even from the mere love of magnificence, and commonly compofed of a great number of embaffadors. This ufed alfo to be the cafe with the extraordinary embaffies of the Swifs, becaufe every canton appointed its embaffadors. The embaffy which Switzerland fent to the king of France in 1663, confifted of forty-two embaffadors.

In our days, extraordinary embaffies of more than one embaffador, are very rare; at leaft they never confift of more than three embaffadors. Their number, however, is noways limited by the public law of Europe; neither is the retinue or train of an embaffador extraordinary reftricted to any particular number of perfons. It ought only not to be fo numerous as to create any uneafinefs in the country where the embaffador extraordinary is appointed to fojourn for a fhort time. The duke of Feria, who went to France as embaffador extraordinary of the king of Spain, to compliment Louis XIII. on his acceffion to the throne, after the death of Henry IV. had fo numerous a retinue, that the governor of Bordeaux refufed to admit him in that city. He affigned him his quarters in one of the fuburbs, and wrote to inform him, that he could not admit him in the place, becaufe his train formed a fmall army, which might eafily affail the governor with a thoufand firelocks. This cautious conduct of the governor was fully approved of at the French court.

Extraordinary embaffies are generally very brilliant. The earl of Manchefter's public entries into Venice as extraordinary Englifh embaffador in 1698 and 170-, are defcribed as uncommonly magnificent. His excellency was attended by fixteen footmen, and fix pages, dreffed in velvet and gold brocade, befides his fecretary, and a confiderable number of Englifh gentlemen.

The embaffador extraordinary has the precedency before the embaffador ordinary of the fame power. When it happens that an embaffador extraordinary is fent to the fame court after another embaffador extraordinary, he who is laft arrived has the precedency, unlefs the prince or ftate by which they are appointed determines their rank differently. When embaffadors ordinary are relieved, he who is going to quit the court or country where he has refided walks at the right of his fucceffor in proceeding to the audience: but, in returning, he gives the right to the new embaffador, becaufe his functions are terminated by the farewell audience.

With refpect to the rank of foreign embaffadors refiding at the fame court among themfelves, the nuncio of the pope was always confidered as holding the firft rank at the French court before the eftablifhment of the French republic in 1792. He ufed to compliment the king on particular occafions in the name of the whole diplomatic body. In other courts the French embaffador had the precedency before the embaffadors of any other kingdom. The Spaniards alone difputed his pre-eminence for a time: but it was folemnly recognized by Spain in 1662, and no other power did ever difpute it. The French embaffador claimed even the precedency before the Ruffian imperial embaffador. M. D'Efterno, the French embaffador at the court of Berlin in 1786, found himfelf highly offended, that the queen of Pruffia, confort of the late Frederick William II. fat down to cards with the Ruffian embaffador, whilft he was only invited to take a hand with the princefs Friderika, eldeft daughter of the king of Pruffia, at prefent duchefs of York.

The right of fending embaffadors is generally vefted in the prince or chief magiftrate, to whom the exercife of the executive power is entrufted in independent ftates. It is an effential attribute of fovereign power. Yet it is not abfolutely neceffary that a prince be in the actual poffeffion of this power to appoint embaffadors; provided he have not abdicated the crown, his embaffadors ought to be received at other courts, unlefs there be fome political motives for refufing their admiffion: but even in that cafe they are like other public minifters, under the fpecial protection of the public law of nations.

The actual poffeffion of the fovereign power, whatever may have been the means by which it has been acquired, is confidered as a fufficient title to the right of fending embaffadors, and the embaffadors of an ufurper have often been admitted in courts where thofe of the lawful prince have been refufed. The embaffadors of Cromwell were received in France, when Charles II. himfelf could not obtain an audience.

To admit an embaffador, is to acknowledge the fovereignty of the prince, or the independency of the ftate which he reprefents. France acknowledged the independence of the United States of America, by admitting Franklin as their embaffador before they were declared independent by Great Britain.

During the minority of a monarch the regent may appoint embaffadors, but always in the name of the king. They reprefent him in whom the executive power is vefted by the conftitution and not his fubftitute. It is this reprefentative dignity which fubjects the proceedings and motions of embaffadors to formalities and ceremonies that frequently impede and obftruct their negociations. Hence it is not unufual to appoint a fimple minifter plenipotentiary to carry on an important and difficult negociation, but to furnifh him at the fame time with the credentials of an embaffador extraordinary, with the ftrict injunction not to make any ufe of them unlefs he fhould be fuccefsful in his miffion. In that cafe he delivers them only at the clofe of the negociation, juft before the figning of the treaty, which derives a certain additional folemnity for being figned by an embaffador extraordinary.

As the functions of an embaffador confift in watching in the country where he is appointed to refide over the interefts of the ftate which he reprefents, in making regular reports of his proceedings, and in communicating every circumftance, the knowledge of which is deemed of importance to the minifter at the head of the department for foreign affairs in his own country, it follows that an embaffador ought to be well acquainted with the political ftate and the language of the country in which he refides, with the temper and difpofition of the prince or chief magiftrate by whom it is governed, with the particular character of the minifter who manages its foreign affairs, with the relations of that country with the other powers of Europe, and with the particular policy which influences them towards that country. To this indifpenfible political information an embaffador ought to join a confummate knowledge of mankind in general, an incorruptible integrity, an enlightened prudence, a fagacious judgment, mild and refined manners, an infinuating addrefs, a generous difpofition, found difcretion, and dignified firmnefs, and above all a great command over himfelf. This catalogue of qualities, which are rarely combined, fhews how difficult it muft be to find fit fubjects for embaffies. There is in France a fort of diplomatic gradation through which all individuals employed in miffions to foreign courts are generally obliged to pafs. The firft ftep is that of fecretary of legation of the fecond clafs, then follows that of fecretary of legation of the firft clafs; the third ftep is that of minifter plenipotentiary, and the fourth that of embaffador. Frequent exceptions, however, take place with regard to the appointment of embaffadors, who are fometimes taken from the army. (Wicquefort. l'embaffadeur et fes fonctions. Pecquet. difcours fur l'art de négocier. L'efprit de Leibnitz, tome ii. Chefterfield's letters ccii. ccxix. clii. cclxxxviii.)

EMBASSADRESS, in French *Ambaffadrice*, is, in the common acceptation of the word, the wife of an embaffador, who as fuch fhares his rank and privileges. But there have been embaffadreffes in their own right, or female embaffadors. The famous league of Cambray was figned, in 1508, on the part of the emperor, by Margaret of Auftria his daughter, to whom he had given full powers for that purpofe. The peace concluded at Cambray, in 1529, in confirmation of that of Madrid, was alfo figned by the fame Margaret of Auftria, duchefs of Parma, in the name of Charles V. and by Louifa duchefs of Savoy, mother of Francis I. by virtue of full powers given to thefe two illuftrious ladies by the emperor and the king of France. In the year 1645, Louis XIV. expreffedly appointed Madame la Maréchale de Guébriant his embaffadrefs extraordinary, to confign Mary de Gonzagues, daughter of the duke of Nevers, to the arms of her royal hufband, the king of Poland, who had married the princefs by procuration. Circumftances might indeed arife in which a lady might with great propriety be appointed embaffadrefs at the court of a fovereign princefs, into whofe confidence fhe might more eafily infinuate herfelf than an embaffador. In fuch cafes fhe would be under the fpecial protection of the law of nations, and enjoy all the rights and immunities of an embaffador.

EMBASSY, formerly *Embaffage*, in French *Ambaffade*, *legatio*, is the charge or office of an embaffador, or any other public minifter fent to reprefent one fovereign prince or independent ftate at the court of another. It alfo denotes the folemn meffage, miffion, or errand, on which fuch a public minifter is fent.

F. Daniel obferves, that under the ancient French kings, their embaffies confifted of a body, or number of perfons, joined together in commiffion, and who compofed a kind of council; fomething like which is ftill retained at treaties of peace. Thus the French embaffy at Nimeguen, for the peace confifted of three plenipotentiaries; that of Utrecht, of two, &c. See Embassador.

EMBATTLED, a term in *Heraldry*, when the outline of any ordinary is notched fo as to reprefent the battlements of a wall, or caftle. See Battlement.

None were fuffered, in ancient times, to embattle their houfes, but thofe who had great dignities, as the barons, and the like. Camden proves this in his account of Tunftal's feat in England, in which he expreffes it as a fignal mark of the royal favour, that he had liberty given to embattle it. The heralds exprefs this embattled line by the term *crenelle*; and when it has the embattling on both fides, which is the more rare, they call it *bréteffe*; which fee.

EMBAUL, in *Geography*, a town of Africa, in the kingdom of Damel. N. lat. 15° 15'. W. long. 15° 37'.

EMBDEN. See Emden.

EMBELIA, in *Botany*, corrupted from the Ceylon name Aembilla. Burm. Ind. 62. t. 23. Juff. 427. (Ribefioides; Linn. Fl. Zeyl. 190.) Clafs and order, *Pentandria Monogynia*. Nat. Ord. uncertain. *Juff.*

Gen. Ch. *Cal.* Perianth fmall, five-cleft, inferior. *Cor.* Petals five, regular, undivided. *Stam.* Filaments five, equal; anthers . . . . *Pift.* Germen fimple, fuperior; ftyle one; ftigma . . . . *Peric.* Berry . . . .

A fmooth fhrub, without thorns. *Leaves* alternate, oblong, entire. *Flowers* in terminal panicled clufters. *Fruit* white, acid, ufed for making rob or jelly. Native of Ceylon. Schreber, by his index, feems to refer this plant to *Antidefma*, but their characters do not accord.

EMBER-Goose, in *Ornithology*, the *colymbus immer* of Linnæus; which fee.

Ember-*weeks*, are thofe wherein the ember or embering days fall.

In the laws of king Alfred, and thofe of Canute, thefe days are called *ymbren*, that is, *circular days*, from whence the word was probably corrupted into ember days. By the canonifts, they are called "quatuor anni tempora," the four cardinal feafons, on which the circle of the year turns; and hence Henfhaw takes the word to have been formed, *viz.* by corruption, from *temper*, or *tempora*. The ancient fathers called them "quatuor tempora jejunii."

Mr. Somner thinks they were originally fafts, inftituted to beg God's bleffings on the fruits of the earth. Agreeably to which, Skinner fuppofes the word ember taken from the afhes, embers, then ftrewed on the head.

The ember days are the Wednefday, Friday, and Saturday, next after Quadragefima Sunday, or the firft Sunday in Lent, after Whitfunday, after Holyrood day in September, and after St. Lucy's day in December; which four times anfwer well enough to the four quarters of the year, fpring, fummer, autumn, and winter. Thefe days are mentioned by Britton, c. 53, and other writers; and particularly in the ftat. 2 and 3 Edw. VI. c. 19.

Thefe ember weeks are now chiefly taken notice of on account of the ordination of priefts and deacons; becaufe the canon appoints the fundays next fucceeding the emberweeks for the folemn times of ordination; though the bifhops, if they pleafe, may ordain on any funday or holiday.

EMBERIZA, in *Ornithology*, a genus of the Pafferine order, the character of which confifts in the bill being conic; mandibles receding from each other from the bafe downwards, the lower with the fides narrowed in, and a hard knob within the upper mandible. This laft-mentioned procefs in the mouth is adapted in a very peculiar degree to the manners of the emberiza tribe; all the fpecies feed on feeds, and by the aid of this knob they are able to break and comminute the fhells of the harder kinds with facility. The genus is extenfive, and includes fome very beautiful birds.

Species.

Species.

Nivalis. Quill-feathers white, primaries black on the outer edge; tail-feathers black, the three lateral ones white. Linn. *Hortulanus nivalis*, Briff. *Ortolan de niege*, Buff. *Pied mountain finch*, Albin. *Snow bunting*, Lath. Donov. Brit. Birds.

Inhabits the northern parts of Europe, Afia, and America, during fummer, and migrates to warmer climates in the winter. Its fize rather exceeds that of the chaffinch; it builds in cavities of rocks and lays five eggs, which are of a white colour, fpotted with brown. The fpecies varies confiderably in its plumage at different feafons of the year, and three diftinct kinds are defcribed as permanent varieties. One variety is white, with the feathers dafhed with yellow, and the chin and throat marked with very fmall brown fpots. This is called by Frifch Weifs Fleckige Ammer. Another (hortulanus nivalis pectore nigro of Briffon), is yellowifh-white above, beneath with the breaft black; wings and tail black and white intermixed. The pied chaffinch of Albin is the third; the body of this is reddifh-brown; head and neck white, breaft with a blueifh fpot; wings and tail varied with black and white.

Mustelina. Quill-feathers dufky, white at the bafe, the laft entirely black; tail-feathers black; middle ones at the edge, and three lateral ones each fide, white with a dufky fpot without. Gmel. *Emberiza nivalis*, Linn. *Emberiza glacialis*, Lath. *Tawny bunting*, Brit. Zool.

About the fame fize as the former, and is by fome writers erroneoufly confounded as a variety of it. The fpecies occurs rarely in the northern parts of Britain.

Montana. Five firft quill-feathers blackifh-brown, the reft white, fpotted with brown at the tip; tail-feathers brown; three lateral ones each fide entirely white. Gmel. *Leffer mountain brambling*, Willughby. *Mountain bunting*, Lath. Donov. Brit. Birds.

Found in Yorkfhire and Lincolnfhire.

Hyemalis. Black, belly white. Gmel. *Fringilla hyemalis*, Linn. *Paffer nivalis niger*, Kalm. *Ortolan jacobin*, Buff. *Snow bird*, Catefby. *Black bunting*, Lath.

The length of this bird is about fix inches and a half. During winter, and more efpecially in fnowy weather, it is feen in Virginia and Carolina; its fummer place of refidence is unknown. By fome it is called the chuck-bird. The flefh is held in efteem as an article of food.

Miliaria. Brown, beneath fpotted with black; orbits rufous. Linn. *Alaudæ congener*, Aldr. *Strilozzo*, Olin. *Cynchramus*, Briff. *Gerft-ammer*, Gunth. *Le Proyer*, Buff. *Common bunting*, Lath. Donov. Brit. Birds, &c.

Common during the fummer and autumn in moft parts of Europe; in England they remain throughout the winter, but in the more fouthern climates migrate at the approach of that feafon. They affociate in flocks. The females build their neft in a low hedge, or on a ftump near the ground, and lay from five to fix eggs. Thefe birds are rather larger than the yellow-hammer, and in the appearance of their plumage fo clofely refemble the lark, that they are commonly fold under the name of bunting larks in the London markets. They are caught in vaft numbers for fale during the winter feafon; the flefh is bitter, and inferior to that of the true lark.

Hortulana. Quill-feathers brown, the firft three whitifh at the edges; tail-feathers brown, the two lateral ones black on the outer fide. Linn. *Hortulanus*, Gefn. *Ortolano*, Olin. *Ortolan*, Lath.

The varieties of this fpecies are numerous; the principal are β (ortolan jaune of Buff.); the plumage of which is yellowifh, with the quill-feathers edged with white; γ (ortolan blanc) fnowy white; δ (hortolanus quintus of Ray) which has the tail white; and ε (ortolan noiratre of Buff.) the colour of which is blackifh, head and neck greenifh, bill red, and legs cinereous.

Thefe birds are found chiefly in the fouth of Europe, from whence they migrate northwards as far as Sweden, but have not been known to vifit England. The fize is that of our yellow-hammer, and its fong is not very diffimilar to the notes of that common bird, but more melodious; its neft is ufually built in a low hedge, or on the ground, and contains five eggs of a greyifh colour. The celebrity of the ortolan for the tables of epicures is perfectly well known: they are caught for this purpofe in vaft number at the times of their periodical migrations in fpring and autumn, and fattened in a peculiar manner. Their feeders place them in a dark room, with an abundance of oats and millet, upon which they feed with avidity, and become in a very fhort time extremely fat, in which ftate they weigh fometimes three ounces each. When thus fed they are confidered exquifitely delicious, and fetch a high price. Ortolans are taken in great numbers in the fouth of France and Italy, fome parts of Germany, and the fouthern provinces of Ruffia and Siberia; and are potted or otherwife preferved, and form an article of exportation to thofe countries where thefe delicious birds are lefs commonly found.

Sinensis. Reddifh brown, beneath pale yellow; leffer wing-coverts yellowifh; quill and tail-feathers with the longitudinal ftreak on the belly brown. Lath. Ind. Orn. *Ortolan de la Chine*, Sonner. *Chinefe bunting*, Lath.

Inhabits the fouthern provinces of China during the months of October, November, and December. Size not mentioned.

Citrinella. Tail-feathers blackifh, the two outer ones on the inner edge with a pointed white fpot. Linn. *Emberiza flava*, Gefn. *Zivolo*, Olin. *Braunt*, Buff. *Yellow-hammer*, Ray. Donov. Brit. Birds.

A general inhabitant of Europe, in every part of which it appears to be common. The male differs from the female in having the colours of the plumage more obfcure, and the head only tinged with yellow; in the male the head is of a very vivid yellow, whence its name. The neft of this common bird, as is well known, confifts of hay, and other dry fubftances, flightly put together, and placed either on the ground or in a bufh clofe to it: the eggs from four to five in number, and of a grey colour with ftreaks, and a few blotches of brown. Thefe birds are eaten in Italy.

Olivacea. Olive, beneath whiter; chin orange; pectoral band blackifh. Gmel. *Emberiza dominicenfis*, Briff. *Olive*, Buff. *Olive bunting*, Lath.

Inhabits St. Domingo, and is about the fize of the common wren.

Passerina. Above grey-ferruginous; middle of the feathers black beneath, whitifh-afh fpotted on the fides; tail-feathers black, the middle ones edged with ferruginous; the outer one each fide nearly to the bafe, the next as far as the middle obliquely white. Pallas. *Pafferine bunting*, Lath.

Size of the reed fparrow. The head and chin in the male black; behind the eyes a pale ftreak; tail rather forked; legs brownifh flefh colour. Inhabits Ruffia near the Ural, and Jaick.

Pusilla. Above grey-ferruginous; beneath whitifh; throat fpotted; head with alternate longitudinal teftaceous and black bands. Pallas.

A fmall

A ſmall ſpecies, found among the ſnowy mountains of Dauuria.

Rustica. Head black, with three longitudinal white bands, chin, body beneath, and two outmoſt tail-feathers each ſide obliquely white. Pallas.

Inhabits Dauuria, chiefly in woody ſituations.

Fucata. Grey-ferruginous; ears with a round rufous ſpot; eye-brows, line beneath the eyes and throat white; chin ſurrounded with a brown ſpotted circle. Pallas.

Frequent in rocky parts of Siberia.

Spodocephala. Grey-ferruginous, beneath pale ſtraw colour; frontlet black; head and neck hoary-aſh. Pallas.

Inhabits near the waterfalls in the Alpine regions of Dauuria. Size of the reed bunting.

Chrysophrys. Grey-ferruginous; crown black; eye-brows citron, from the middle of the crown to the nape a white band. Pallas.

Found with the latter; ſize of the common yellow-hammer.

Maelbyensis. Head and neck lead-cinereous; chin whitiſh; belly ferruginous. Sparrman, Muſ. Carl.

Deſcribed from a ſpecimen taken at Maelby, in Sweden, a ſeat of count Carlſon, in the dukedom of Sudermania. Some writers ſuggeſt that the bird mentioned might be either the female or young of the pine bunting.

Rutila. Sanguineous rufous; beneath ſulphur; wings grey ruſty. Pallas.

Inhabits Siberia, and is the ſize of the yellow-hammer.

Ferruginea. Ferruginous; belly, and two ſpots on the primary quill-feathers, white. Arct. Zool. *Ruſty bunting*, Lath.

Native of North America.

Americana. Above cinereous, ſtreaked with brown; beneath yellow; chin white; quill and tail-feathers black, with pale edges. Gmel. *Black throated bunting*, Arct. Zool.

Found in New York. Size of the yellow-hammer. The female is like the male, but has no black ſpot on the throat, nor ſtreak of yellow above the eye. Dr. Latham deſcribes a variety met with in Hudſon's bay, the colour of which is aſhy brown, beneath whitiſh, front and eyebrows yellow; band under the eyes, and the creſcent on the front, black; chin, as in the male of the other, with a triangular black ſpot in the middle.

Brasiliensis. Crown, neck, and body beneath, yellow; back, wings, and tail greeniſh, varied with yellow and brown. Gmel. *Guiram heemgata*, Ray. *Guirnegat*, Buff. *Braſilian bunting*, Lath.

Size of a ſparrow. The ſpecies inhabits Brazil.

Mexicana. Above browniſh, beneath whitiſh, ſpotted with brown; head and throat yellow. Gmel. *Thereſe jaune*, Buff. *Mexican bunting*.

Length ſix inches and a half; the legs and bill pale; wings and tail browniſh. Native of New Spain.

Militaris. Head, wings, tail, and back brown; lower part of the back and breaſt yellow; ſhoulders greeniſh; belly white. Haſſelq. *Military bunting*, Lath.

Inhabits Malta.

Melanocephala. Yellow, head black; back rufous. Scop. *Black-headed bunting*, Lath.

Size of the yellow-hammer, and inhabits Europe.

Brumalis. Body beneath; front and region of the eyes citron; hind head and neck cinereous. Scop.

Native of the Tyroleſe country. This and the two following are ſmall ſpecies.

Coccinea. Body above ſilvery, beneath crimſon; vent white; bill, head, and quill-feathers black; hind head and tail black-blue. Sander.

Found in the woods about Baden.

Badensis. Olive, ſtriated with blackiſh, beneath paler; throat orange; breaſt with black ſtreaks. Sander.

Inhabits Baden. The bill is black above, beneath yellowiſh, with a ſingle obtuſe tooth in the middle.

Erythrophthalma. Black, with a red gloſs; belly reddiſh; wings with a white ſpot. Gmel. *Fringilla Carolinenſis*, Briſſ. *Towhee bird*, Cateſby.

This ſpecies inhabits Carolina, frequents ſhady woods, and is generally ſeen in pairs. Called by ſome the American bulfinch. Length eight inches.

Leucophrys. Ruſty brown, beneath white; vent yellow; crown black, with a white fillet in the middle; eye-brows white. Forſt. *White crowned bunting*, Arct. Zool.

Inhabits Canada, feeds on graſs, ſeeds, and worms, ſings melodiouſly, and lays three or four chocolate-coloured eggs. Length rather exceeding ſeven inches.

Luctuosa. Black; beard on the cheſt, front, breaſt, belly, rump, and vent white. Scop. *Wreathed bunting*, Lath.

Size of the greater titmouſe.

Aureola. Rufous, beneath yellow; tranſverſe pectoral band ferruginous; crown, cheeks, and chin black. Pallas. *Emberiza Sibirica*. Lepechin. *Yellow breaſted bunting*. Lath.

Size of the reed ſparrow, and inhabits the pine groves of Siberia

Sandwichensis. Brown, beneath whitiſh, ſpotted with brown; eye-brows yellow; temples duſky. Gmel. *Unalaſha bunting*, Arct. Zool. *Sandwich bunting*, Lath.

Length ſix inches; bill and legs black; under the eyes a duſky line; middle of the belly whitiſh and immaculate. Native of Sandwich bay.

Aoonalaschkensis. Reddiſh brown; beneath whitiſh, ſtreaked with brown; middle of the belly white. Gmel.

Length ſeven inches, inhabits Aoonalaſchka, and reſembles the former.

Atricapilla. Cheſnut, beneath cinereous; chin white; crown pale yellow, front and ſtreak through the eyes to the nape black. Gmel. *Black crowned bunting*, Lath.

Native of the Sandwich iſlands; its neck is ſeven inches, the bill black, and legs brown. A variety is deſcribed in Cook's laſt voyage, which has the breaſt waved with black; the female without the yellow ſpot on the crown.

Pithyornus. Middle of the crown with an oval white ſpot; nape varied with white; chin red-teſtaceous; two exterior tail-feathers, each ſide with an oblique white band. Pallas. *Emberiza leucocephala*, S. G. Gmelin. *Emberiza alia ſpecies*, Lepechin. *Pine bunting*, Lath.

Inhabits the pine foreſts of Siberia, from the Uralian chain of mountains to the Lena; it lives among reeds on the ſhores of rivers, and paſſes the winter ſometimes on the borders of the Caſpian ſea. The ſize is that of the yellow-hammer, and it has the note of the reed ſparrow.

Cinerea. Bay, beneath whitiſh, ſpotted with bay; tail and quill-feathers brown, edged with grey; rump grey; tail-coverts reddiſh white. Gmel. *Emberiza canadenſis*, Briſſ. *Cul-rouſſet*, Buff. *Cinereous bunting*, Arct. Zool.

Length five inches and a half, and inhabits the juniper woods in Canada.

Cærulea. Rufous and blue varied; crown rufous;

greater

greater wing-coverts, quill-feathers, and tail-feathers, brown, with the outer edge rufous. Gmel. *Emberiza canadenſis cærulea*, Briff. *Azuroux*, Buff. *Blue bunting*.

Inhabits Canada, and rarely New England. Its length is four inches and a half.

Cyanea. Blue; crown deeper; quill, and tail-feathers brown edged with blue. Lath. Ind. Orn. *Emberiza cyanea, rectricibus fuſcis*, Gmel. *Tanagra cyanea*, Linn. *Miniſtre*, Buff. *Blue linnet*, Cateſby. *Indigo bunting*, Lath.

Size of the ſiſkin. The male, when in full plumage, is blue, at other times reſembles the female, which is nearly throughout of a browniſh colour; in the latter, however, the edge of the wing is tinged with green, and by this peculiarity the female may be diſtinguiſhed from the male, the edge of his wing being blue. In Carolina, the inland parts of which this ſpecies inhabits, it is called the parſon, and by ſome the biſhop; and the Spaniards at Mexico, which country it inhabits, alſo name it azul lexos, or "far-fetched blue bird." It feeds on ſeeds, and is ſaid to have the note of the common linnet.

Cyanella. Shining blue-interſcapulars and ſhoulders varied with blue and rufous; quill and tail-feathers edged with blueiſh. Sparrm. Muſ. Carlſ. *Emberiza cyanella*, Gmel. *E. cyanea*, β Lath.

Deſcribed by Sparrman as a ſpecies. Gmelin admits it with doubt, and Latham conſiders it as a variety only of cyanea; it is a native of North America.

Quelea. Grey; front black; bill ſcarlet. Gmel. *Moineau à bec rouge du Sénégal*, Buff. *Black faced bunting*, Lath.

The bill of this bird is thick; cheeks and chin black; reſt of the head, ſhoulders, and back varied with black and grey; breaſt and belly reddiſh white; quill and tail-feathers blackiſh, edged with cinereous. The ſpecies inhabits Senegal, and is four inches and a half in length. The female reſembles the male, but wants the black about the head. The bird deſcribed by Buffon, under the name of Moineau du Senegal, is conſidered as a variety.

Tetrix. Cheſnut, beneath yellow; eye-brows and rump yellow; middle of the head and breaſt with a broad black band. Gmel. *Weaver bunting*, Lath.

Size of the houſe ſparrow, which bird it reſembles in the browniſh colour of the plumage during winter. The name of weaver bunting was given to this bird from its propenſity to interweave ſilk between the wires of its cage, like the weaver oriole, and, it is conjectured, the neſt of the weaver bunting is compoſed in a manner ſomewhat ſimilar to that of the above-mentioned oriole, which conſiſts of leaves curiouſly ſewed together with the filaments of plants. This bird inhabits Africa.

Rubra. Crimſon; neck and back varied with olive and black, and a few crimſon marks; belly and vent cinereous; quill and tail feathers black, edged with grey-green. Gmel. *Moineau de l'iſle de France*, Buff. *Crimſon bunting*, Lath.

Size of the laſt, and inhabits the iſle of France. The bill is black; legs pale fleſh colour; female olive and paler beneath.

Capensis. Grey; throat whitiſh; ocular band and another beneath blackiſh. *Hortulanus capitis bonæ ſpei*, Briff. *Ortolan du Cap de Bonne Eſperance*, Buff. *Cape bunting*, Lath.

Native of the Cape, and in ſize reſembles the ſparrow. Three varieties of this ſpecies are deſcribed in Buffon's "Planches Enluminees," namely, β, the body of which is yellow beneath, and the ſides of the head and neck marked with three black ſtripes; γ, having the body beneath whitiſh; and δ, which is whitiſh beneath, and has the throat varied with cinereous. The two firſt of theſe are conceived to be merely varieties of the Cape kind, the laſt is a native of Cayenne, where, according to Buffon, it is called *Bonjour-commandeur*, from being accuſtomed to commence its ſong at the break of day.

Fusca. Browniſh; wings and tail brown with duſky bands; belly white; noſtrils, cheeks, and chin with feathered tufts. Gmel. *Barred-tailed bunting*, Lath.

Deſcribed by Dr. Lathan from a figure met with among ſome Chineſe drawings. The ſize is ſaid to be that of the common bunting. The beak is fleſh-coloured; legs roſy.

Ludovicia. Rufous ſpotted with black; beneath pale; breaſt rufous; head with a black creſcent. Gmel. *Hortulanus ludovicianus*, Briff. *Ortolan de la Louiſiane*, Buff.

Length five inches and a quarter. The bill rufous ſpotted with black, head and throat reddiſh; rump and cuneated tail black; breaſt rufous; legs cinereous. Native of Louiſiana.

Cia. Reddiſh; head with a few blackiſh lines; eye-brows white. *Emberiza barbata*, Scop. *Emberiza pratenſis*, Geſn. *Bruant fou*, Buff. *Bruant de ſprés*, Buff. *Fooliſh bunting*, Lath.

Native of the warmer parts of Europe, and delights moſt in mountainous ſituations; it is a ſilly bird, and eaſily caught in any ſnare, whence its name; its note is only a repetition of ſounds, like the pronunciation of the words zi-zi-zi-zip-zip. The Genoeſe call it Cia montanina.

Cirlus. Fuſcous; breaſt ſpotted; eye brows pale yellow; two outmoſt tail-feathers with a white cuneated ſpot. Gmel. *Emberiza ſepiaria*, Briff. *Cirlus*, Aldr. *Cirl bunting*.

Size of the yellow-hammer, and inhabits Italy and France; the ſpecies has been lately found in Britain.

Familiaris. Cinereous ſpotted with brown; tail-feathers white at the tip; hind part of the back yellow. Gmel. *Bruant familier*, Buff. *Familiar bunting*.

Oſbeck deſcribes this ſpecies under the name of Motacilla familiaris. This writer ſpeaks of it as a docile bird, and ſays, if the cage-door was opened it would jump out upon the perſon's hand who releaſed it, and if any one whiſtled in its hearing, it ſang ſweetly in return. If a diſh of water was placed before it, the bird inſtantly plunged into it, and bathed itſelf. It was fed with rice.

Flaveola. Grey; face yellow. Gmel. *Flaveole*, Buff. *Yellow-faced bunting*.

Native of warm climates, and very ſmall.

Amazonia. Brown; crown fulvous; vent whitiſh. Gmel. *Amazone*, Buff. *Amazon bunting*.

Size of the titmouſe, and inhabits Surinam.

Oryzivora. Black; crown reddiſh; belly black; tail-feather daggered. Gmel. *Agripenne ou Ortolan de riz*, Buff. *Rice bird*, Cateſby. *Rice bunting*, Arct. Zool.

About the ſize of the ſparrow. The ſpecies is confined to the continent of America, and is of the migratory kind, paſſing in flocks at particular ſeaſons from one part to another. The Americans call it Bob Lincoln and Conquedle. Its food conſiſts of grain and inſects, and the maize eſpecially; they are remarkably fond of this plant, and prove highly deſtructive to the crops, by unneceſſarily perforating the huſks after ſatisfying their appetites, and thus leaving openings

openings through which the rain penetrates, and effectually deftroys the plants. Some, for this reafon, call it the maize thief, or white backed maize thief. Its note is much admired. There is a variety of this bird of an olive-brown colour, beneath y llowifh; rump yellow, tranfverfely lined with brown; greater wing-coverts and quill-feathers edged with white.

SCHOENICULUS. Head black; body grey and black; outmoft tail-feathers with a white wedged fpot. Linn. Fn. Suec. *Junco turneri*, Gefn. Buff. *Reed bunting*, Lath.

Native of Europe and the fouthern parts of Siberia. The female differs from the male in having the head brownifh inftead of black.

LESBIA. Beneath white; face white with three black bands; breaft and rump brownifh; tail-feathers white, the two middle ones dufky, edged with rufous. Gmel. *Mitilene de Provence*, Buff. *Lefbian bunting*, Buff.

Length about four inches and a half; it inhabits Provence, where it is called Chic de Mitilene, being rare in that part, and known to be common in the Greek ifle Mitylene, or Lefbos. They are faid to exert a peculiar kind of fcream on the approach of any bird of prey, a circumftance which the Greeks turn to fome advantage, for they place one or more of thefe birds inclofed in ftrong iron cages in their poultry yards, and the approach of the hawk, or any other bird of prey, is loudly announced by thefe little centinels the moment it appears in fight; and by this means the poultry are allowed fufficient time to effect their efcape.

PROVINCIALIS. Beneath white; band acrofs the eyes and on the wing and chin white; fpot under the eyes, ftreak each fide the chin, and breaft brownifh fpotted with black; quill and tail-feathers dufky, edged with rufous. Gmel. *Gavoué de Provence*, Buff. *Muftachoe bunting*, Lath.

Size of the laft, and inhabits Provence.

LOTHARINGICA. Spotted with black; above rufous, beneath cinereous, abdomen rufous; ftreak acrofs the eyes and on the mandibles black; tail-feathers black and white, middle ones rufous; exterior ones nearly all white. Gmel. *Ortolan de Lorraine*, Buff. *Lorrain bunting*.

Inhabits Lorrain; the female is white beneath, and has a whitifh fpot above and a rufous one beneath the eyes. Length fix inches and a half.

PSITTACEA. Brownifh-afh; wings tawny; two tail-feathers very long. Gmel. *Fringilla brafilienfis*, Seba. *Veuve éteinte*, Buff. *Pfittaceous bunting*, Lath.

Size of a fparrow, and inhabits Brafil.

PARADISEA. Black; breaft red; four middle tail-feathers long, and pointed; two very long, bill black. Scop. *Vidua*, Briff. *Indian long-tailed fparrow*, Will. *Red-breafted long-tailed finch*, Edw. *Whidah bird*, Lath.

Native of Angola in Africa.

SERENA. Head black; crown red; tail cuneated; two middle tail-feathers very long; legs grey. Gmel. *Vidua minor*, Briff. *Veuve dominicaine*, Buff. *Dominican bunting*, Lath.

Like the reft of the long-tailed buntings, this bird is deftitute of the two long tail-feathers during winter, and changes its plumage twice in the year.

VIDUA. Blackifh; beneath whitifh; four middle tail-feathers long and pointed, two of them very long; bill red. Gmel. *Vidua major*, Briff. *Grande veuve*, Buff. *Long-tailed fparrow with a fcarlet bill*, Will.

The body of this fpecies is lefs than that of the fparrow; the fpecies inhabits Angola in Africa and India.

PRINCIPALIS. Variegated; breaft rufous; four middle tail-feathers very long; bill and legs red. Gmel. *Vidua angolenfis*, Briff. *Variegated bunting*, Lath.

Inhabits Angola.

REGIA. Middle tail-feathers very long, equal, feathered only at the tip; bill red. Gmel. *Veuve à quatre brins*, Buff. *Shaft-tailed bunting*, Lath.

Inhabits the maritime parts of Africa. Length four inches and a half. The body above and vent black; throat, temples, orbits, and body beneath rufous; legs red.

LONGICAUDA. Black; fhoulders orange, edged with white; tail-feathers long, the fix middle ones very long. Gmel. *Veuve à épaulettes*, Buff. *Yellow-fhouldered oriole*, Brown.

Native of the Cape of Good Hope.

PANAYENSIS. Black; breaft with a large fcarlet fpot; four middle tail-feathers very long, pendulous, pointed and equal. Gmel. *Veuve en feu*, Buff. *Veuve de l'ifle de Panay*, Sonnerat. *Panayan bunting*.

Inhabits the ifle of Panay.

ANGOLENSIS. Black; crown and collar yellow; tail long. Gmel. *Gros-bec à poitrine couleur de feu*, Salerne. *Angola bunting*.

Size of a finch, and inhabits Angola.

CIRIS. Head bule; abdomen fulvous; back green; feathers green brown. Gmel. *Painted finch*, Catefby. *China bulfinch*, Albin. *Painted bunting*, Arct. Zool.

Length five inches and a half, varies in colour, and inhabits South America; they build in the orange trees, and feed on plants of various kinds. In Holland, and fome other parts of Europe to which they have been tranfported, they are reared in cages like the Canary with us, and are faid to live eight or ten years in this ftate of captivity.

QUADRICOLOR. Head and neck blue; back, wings, and tail at the tip green; tail and abdomen in the middle red; breaft and remainder of the belly brownifh. Gmel. *Grofbeak de Java*, Buff. *Red rump bunting*, Lath.

Native of Java. Length five inches.

CYANOPIS. Green; rump and abdomen rufous; front, cheeks and chin blue; quill-feathers brown, edged with green; tail-feathers edged with red; middle ones green, the reft brown. Gmel. *Chloris javenfis*, Briff. *Toupet bleu*, Buff. *Blue faced bunting*, Lath.

Length four inches; inhabits fame country as the laft.

VIRIDIS. Above green; beneath white; wings and tail blue. Gmel. *Chloris indica minor*, Briff. *Parement bleu*, Buff. *Green bunting*, Lath.

Size of a fparrow; the bill greenifh brown; fhafts of the quill and tail-feathers white; and legs black. Native of India.

PLATENSIS. Above greenifh-brown; beneath whitifh-afh; back varied with black; quill, and lateral tail-feathers edged with yellow. Gmel. *Emberife à cinq couleurs*, Buff. *Plata bunting*, Lath.

Length eight inches. This fpecies inhabits near the river Plata in South America.

BORBONICA. Rufous red; wings, tail, and legs chefnut. Gmel. *Mordoré*, Buff. *Bruant de l'ifle de Bourbon*, Buff. *Bourbon bunting*.

Inhabits the ifle of Bourbon.

CALFAT. Hoary; beneath vinaceous; head, chin, and edge of the tail black; bill and orbits rofy. Gmel. *Calfat*, Buff. *Red-eyed bunting*, Lath.

Lefs than the common fparrow, and inhabits the ifle of France.

CHLOROCEPHALA. Fufcous; head and neck olive; back and wing-coverts varied with brown and black; tail forked. Gmel. *Green-headed bunting*. Brown's illuftr.

A very ambiguous kind; probably an accidental variety of fome European bunting. The bird defcribed was caught in Mary-le-bone fields, and preferved in the Tunftal Collection.

Grisea. Grey; wing-coverts and breaft varied with red; quill and tail-feathers within white, without varied with grey and red. Gmel. *Emberiza Surinamenfis*, Briff. *Gonambouch*, Seba. *Grey bunting*, Lath.

Inhabits Surinam, where it is common, and its note is faid to be equal to that of the nightingale. Its food is chiefly maize. The natives call it gonambucho.

Surinamensis. Grey, beneath pale-yellow; breaft with oblong black fpots. Gmel. *Prayer*, Fermin. *Surinam bunting*. Lath.

Rather larger than the lark. Inhabits Surinam.

Ruficapilla. Body above fufcous, beneath cinereous; chin ferruginous; frontlet white; above reddifh; tail black. Sparm. Muf. Carlf.

Asiatica. Cinereous; wings and tail brown. Lath. Ind. Orn. *Gaur bunting*.

Inhabits the Eaft Indies, where it is known by the name of gaur.

EMBLEM, Εμϐλημα, a kind of painted ænigma, which, reprefenting fome obvious hiftory, with reflections underneath, inftructs us in fome moral truth, or other matter of knowledge.

The word is pure Greek, formed of the verb εμβαλλειν, *to caft in, to infert*. Suetonius relates, that Tiberius caufed the word to be erafed out of a decree of the Roman fenate, becaufe it was borrowed from another language.

Such is that very fignificant image of Scævola, holding his hand in the fire; with the words, "agere & pati fortia, Romanum eft;" "to do and fuffer courageoufly is Roman."

The emblem is fomewhat plainer, and more obvious, than the *ænigma;* which fee. Gale defines emblem an ingenious picture, reprefenting one thing to the eye, and another to the underftanding.

The Greeks alfo frequently gave the name emblems, εμβληματα, to inlaid or mofaic works, and even to all kinds of ornaments of vafes, moveables, garments, &c. And the Latins ufed emblema in the fame fenfe. Accordingly, Cicero, reproaching Verres with the ftatues and fine wrought works he had plundered from the Sicilians, calls the ornaments fixed thereto (and which, on occafion, might be feparated from them) emblemata. Add, that Latin authors frequently compare the figures and ornaments of difcourfe to thefe emblemata: thus, an ancient Latin poet, praifing an orator, fays, that all his words were ranged like the pieces in mofaics,

"Ut tefferulæ omnes,
Arte pavimenti, atque emblemate vermiculata."

We do not ufe the Englifh word emblem in this fenfe; though the ancient jurifconfulti always retain the Latin emblema to exprefs fuch ornaments; becaufe the Greek εμϐλημα literally denotes any thing applied, or added to a body by way of enrichment.

With us, emblem ordinarily fignifies no more than a painting, baffo relievo, or other reprefentation, intended to hold forth fome moral or political inftruction.

What diftinguifhes an emblem from a device is, that the words of an emblem have a full, complete fenfe of themfelves; nay, all the fenfe and fignification which they have together with the figure. But there is yet a farther difference between emblem and device; for a device is a fymbol appropriated to fome particular perfon, or that expreffes fomething which concerns him particularly; whereas an emblem is a fymbol that regards all the world alike.

Thefe differences will be more apparent from comparing the emblem above quoted with the device of a candle lighted; and the words, "juvando confumor," "I wafte myfelf in doing good." See Device.

According to lord Bacon, emblems are of ufe in the art of memory, as fenfible objects ftrike the mind ftronger than what is intellectual. Thus, it is eafier to retain the image of a fportfman hunting a hare, of an apothecary ranging his boxes, an orator making a fpeech, a boy repeating verfes, or a player acting his part, than the correfponding notions of invention, difpofition, elocution, memory, and action. Works abr. vol. i. p. 136. vol. ii. p. 475. and vol. iii. p. 106.

Emblems, *Hagiographical*. The ftatues and pictures of the apoftles, martyrs, and other ancient faints, are diftinguifhed by their refpective emblems. Thefe appear to have been fixed upon by the artifts of the 12th and 13th centuries. Sometimes they reprefent the inftruments of their death or torments, as the Burgundy crofs of St. Andrew, the gridiron of St. Laurence, the cardine comb of St. Blafe, the wheel of St. Catharine; at other times they relate to fome circumftances in the life or legend of the faint, as the organ of St. Cecily, the dove of St. Gregory the Great; frequently they bear allufion to the name of the holy perfonage, as the lamb of St. Agnes, the gigantic ftature of St. Chriftopher, bearing the infant Chrift upon his fhoulders.

EMBLEMATICAL Characters. See Character.

EMBLEMENTS, *Fr.* from *emblaver*, q. d. *femer en blè*, to fow with wheat, a term ftrictly fignifying the profits of lands fown; though fometimes ufed more largely for any profits arifing, and growing naturally from the ground; as grafs, fruit, &c.

If a tenant for life fow the land, and die before harveft, his reprefentatives fhall have the emblements to compenfate for the labour and expence of tilling, manuring, and fowing the lands, and alfo for the encouragement of hufbandry; and not he in reverfion. But if the tenant for years fow the land, and before feverance the term expires, or the eftate for life be determined by the tenant's own act, as by forfeiture for wafte committed, or if a tenant during widowhood thinks proper to marry, there the leffor, or he in reverfion, fhall have the emblements, and not the leffee.

The advantages of emblements are particularly extended to the parochial clergy by 28 Hen. VIII. cap. 1.

All the cafes of emblements turn upon the point of uncertainty; fince the tenant could not poffibly know when his landlord would determine his will, and therefore could make no provifion againft it; and having fown the land, which is for the good of the public, upon a reafonable prefumption, the law will not fuffer him to be a lofer by it. But it is otherwife, and upon reafon equally good, where the tenant himfelf determines the will; for in this cafe, the landlord fhall have the profits of the land. (Co. Litt. 55, 56.) Thefe emblements are diftinct from the real eftate in the land, and are fubject to many, though not all, the incidents attending perfonal chattels. They were devifable by teftament before the ftatute of wills (Perk. § 412.); and at the death of the owner, fhall veft in his executor, and not his heir; they are forfeitable by outlawry in a perfonal action (Bro. Abr. tit. emblements, 21. 5 Rep. 116.); and by the ftatute 11 Geo. II. c. 19. though not by common law (1 Roll. Abr. 666.), they may be diftrained for rent arrear. Although the emblements are affets in the hands of the executor, are forfeitable upon outlawry, and diftrainable for rent, they are not in other refpects confidered ſidered as perſonal chattels; and particularly, they are not the object of larciny, before they are ſevered from the ground. (3 Inſt. 109.)

EMBLICA, in *Botany*, Gærtn. t. 108. f. 2. See Phyllanthus and Myrobalanus.

EMBODY, in the *Military Art*. To *diſembody*, relates to the ſeparation of thoſe individuals forming a regiment, &c. when its ſervices are no longer required. This term is totally diveſted of that diſgrace which is conveyed under the terms *diſmiſſed*, or *broken*. Thus we find, that, during times of danger, the militia are called out; and on the return of peace, that orders are iſſued for their being "diſembodied." Hence, in that admirable ſatire, "the Mayor of Garrat," major Sturgeon ſays, "Our corps is diſembodied, ſo the French may ſleep in ſecurity."

When a regiment is diſembodied, or, in other words, diſbanded, (though the latter term is often, but erroneouſly, intended to convey reproach,) the arms are lodged in the proper ſtore-rooms; and every thing is numbered or ticketted, in order that when the regiment may again be called out, all may be in readineſs for its equipment.

EMBOLE, in *Surgery*, the reduction or ſetting of a diſlocated bone. The term is derived from the Greek εμβαλλω, *to put in*.

EMBOLI, in *Geography*, a town of European Turkey, in the province of Romania, a colony from Athens. It is called by the Chriſtians "Chriſtopolis," but is little better than a heap of ruins; 48 miles E. of Saloniki.

EMBOLIMA, in *Ancient Geography*, a town of India, on this ſide of the Ganges. It was ſituated S.W. of Petra Aornos, upon the right of the Indus, and N. of Taxila.

EMBOLIMÆAN and Embolismic, *Intercalary*, is chiefly uſed in ſpeaking of the additional months which chronologiſts inſert to form the lunar cycle of 19 years.

The 19 ſolar years, conſiſting of 6939 days, and 18 hours; and the 19 lunar years only making 6726 days; it was found neceſſary, in order to render the 19 lunar years equal to the 19 ſolar, which make the lunar cycle of 19 years, to intercalate or inſert 7 lunar months, containing 209 days; which, with the 4 biſſextile days happening in that interval, make 213 days, and the whole, 6939 days. See Cycle.

By means of theſe ſeven emboliſmic, or additional months, the whole 6939 days and 18 hours of the ſolar years are employed in the calendar.

In the courſe of 19 years there are 228 common moons, and 7 emboliſmic moons. Their diſtribution is thus: every 3d, 6th, 9th, 11th, 14th, 17th, and 19th, years, are emboliſmic, and conſequently contain 384 days a-piece. And this was the method of computing time among the Greeks, when they uſed the enneadecæterides, or cycle of 19 years. But they did not keep regularly to it, as the Jews ſeem to have done. The Greeks were followed by the Romans till the time of Julius Cæſar.

The emboliſmic months, like other lunar months, are ſometimes 30 days, and ſometimes only 29. See Year.

The emboliſmic epacts are thoſe between XIX and XXIX; which are thus called, becauſe, with the addition of the epact XI, they exceed the number XXX: or rather, becauſe the years, which have theſe epacts, are emboliſmic; having 13 moons a-piece, whereof the 13th is the emboliſmic.

EMBOLISMUS, Εμβολισμος, in *Chronology*, ſignifies intercalation.

The word is formed of εμβαλλειν, *to inſert*. See Embolismic.

As the Greeks made uſe of the lunar year, which is only 354 days, in order to bring it to the ſolar, which is 365 days, they had every two or three years an emboliſm, *i. e.* they added a thirteenth lunar month every two or three years; which additional month they called embolimæus, εμβολιμαιος, becauſe inſerted, or intercalated.

EMBOLUS, the immoveable part of a pump, or ſyringe; called alſo the *piſton*, and popularly the *ſucker*. See Piston, Pump, and Syringe.

The pipe, or barrel of a ſyringe, &c. being cloſe ſhut, the embolus cannot be drawn up without a very conſiderable force; which force being removed, the embolus returns again with violence. This phenomenon the Ariſtotelians attribute to nature's abhorrence of a vacuum.

But the modern philoſophers finding, that in an exhauſted receiver the embolus is eaſily drawn up, though the orifice be ſtopped, prove that it is the preſſure of the atmoſphere on the external parts of the embolus, that makes the difficulty of drawing it up. See Air, Atmosphere, and Suction.

EMBORDERED, in *Heraldry*, a term applied to a border, when it is of the ſame metal, colour, or fur, with the arms.

EMBORISMA, an aneuriſm.

EMBOSSING, or Imbossing, the act of forming, or faſhioning works in relievo, whether they be caſt, or moulded, or cut with the chiſſel, &c.

Emboſſing is one great part of ſculpture; being that which has to do with figures raiſed, or prominent from the plain, or ground; the other part, which makes figures, &c. that are indented, or cut in below the ground, is called engraving. See Enchasing.

Embossing, or *Imboſſing*, in *Architecture*, is that kind of ſculpture wherein the figure is made to ſtand in relief beyond a plane or naked from which it ſeems to riſe. It has three denominations, according to the degree with which it riſes from the ſurface, as baſſo-relievo, mezo-relievo, alto-relievo; or low-relief, mean-relief, high-relief.

EMBOTHRIUM, in *Botany*, ſo named by Forſter from εν, *in*, and Βοθριον, a *little pit*, or *hollow*, alluding to a ſmall cavity towards the point of each petal, in which the almoſt ſeſſile anthers are ſeverally placed. Forſt. Gen. 8. t. 8. Linn. fil. Suppl. 16. Schreb. 62. Willd. Sp. Pl. v. 1. 537. Juſſ. 79. Mart. Mill. Dict. v. 2. Sm. Bot. of N. Holl. 19—29. t. 7—10. Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*.

Gen. Ch. *Cal.* none. *Cor.* Petals four, cohering by their lower part into a tube, linear, oblique, at length revolute; their ſummits dilated, concave, bearing the ſtamens. *Stam.* Filaments four, very ſhort, inſerted into the hollow in the tip of each petal; anthers rather large, kidney, or heart-ſhaped. *Piſt.* Germen ſuperior, ſtalked, linear, aſcending, inflexed; ſtyle incurved; ſtigma large, obtuſe, lateral. *Per.* Follicle ſtalked, ſomewhat cylindrical. *Seeds* in two rows, imbricated, compreſſed, each with a membranous wing, generally numerous.

Eſſ. Ch. Petals four. Stamens inſerted into the limb. Follicle containing ſeveral winged ſeeds.

This is a fine genus of the Proteaceous order, chiefly found in New Holland. One of the two original ſpecies, indeed, E. *coccineum*, Linn. Suppl. 128, Cav. Ic. v. 1. 47. t. 65, grows on the cold hills bordering the ſtraits of Magellan, even in Terra del Fuego. Yet this appears by Commerſon's and Forſter's ſpecimens to be a very handſome ſhrub, with all the air of a North American *Kalmia* or *Rhododendron*. The *leaves* are elliptical and entire, ſmooth, pale beneath. *Flowers* ſcarlet, in a denſe terminal cluſter, with

with small linear *bracteas*. *Follicle* short, and rather semi-ovate.

E. *speciosissimum*, Sm. Bot. of New Holland 19, t. 7, is a still finer species, a native of New South Wales, where the natives call it Waratah. Living plants were sent many years ago to the dowager lady de Clifford. This is remarkable for the numerous large scarlet *bracteas*, which envelop its dense spike of the same colour. The *leaves* are obovate and serrated, remarkably obtuse.

E. *silaifolium*, Sm. Bot. of N. Holland, 23. t. 8. flowered at Mr. Grimwood's nursery, Kensington, in 1792, being forced in the stove. It comes also from New South Wales, and has finely divided rigid *leaves*, with loose spikes of white *flowers*.

E. *sericeum*, ibid. 25. t. 9, and some of its varieties are now not rare in the greenhouses about London. See Curt. Mag. t. 862, and Andr. Repos. t. 100 and t. 272.

Mr. R. Brown, in paper on *Proteaceæ*, read last winter before the Linnæan Society, has new-modelled and greatly subdivided the genus *Embothrium*, he having had opportunities of studying its species alive in their native situations, which no other botanist has so fully enjoyed.

EMBOUCHURE, a French term in *Music*, literally the hole in the upper joint of a German flute, in which the performer breathes; but when it is said that a flute player has a good embouchure, it means that his tone is good.

EMBOUL, in *Geography*, a town of Africa, in the country of Senegal.

EMBOWELLING Alive, in *Law*, is part of the punishment of high treason.

EMBRACE *a* Volt, in the *Manege*, is used when a horse, in working upon volts, makes a good way every time with his fore legs. The opposite term to embracing a volt, is beating the dust, which is putting his fore-feet near the place from whence he lifted them.

Embracing the ground is used in the same sense with embracing the volt. A horse cannot take in too much ground provided his croupe does not throw out; that is, does not go out of the volt. See Beat.

EMBRACEOR, in *Law*, a person who, when a matter is in trial between party and party, comes to the bar with one of the parties (having received some reward so to do), and speaks in the cause, or privately labours the jury, or stands there to overlook, awe, or put them in fear; or, who makes any attempt to influence a jury corruptly to one side by promises, persuasions, intreaties, money, entertainments, and the like. (1 Hawk. P. C. 259.) The punishment for the person embracing is by fine and imprisonment; and for the juror so embraced, if it be by taking money, the punishment is (by divers statutes of the reign of Edward III.) perpetual infamy, imprisonment for a year, and forfeiture of the tenfold value.

EMBACERY, the act or offence of embraceors. See Embraceor.

EMBRASURE, in *Architecture*, an enlargement of the gap or aperture of a door, or window, within-side the wall. See Door.

Its use is to give the greater play, for the opening of the door, wicket, casement, &c. or to take in the more light.

The embrasure coming sloping inwards, makes the inner angles obtuse. When the wall is very thick, they sometimes make embrasures on the outside.

Embrasure, in *Fortification*, is an opening made through the upper part of the defences, called the *parapet*, for the purpose of pointing the cannon, so as to be as little as possible exposed to the fire of the enemy. The embrasure must vary in dimensions with the several sizes, or, as they are technically termed, the "natures" of the cannon to be employed in them respectively. It is, however, generally found, that about $2\frac{1}{2}$ diameters of the muzzle of the cannon intended to be mounted give space enough for traversing, and at the same time afford but little opening for the shot from opposing batteries. The embrasure must be cut down in that proportion which may suit the height of the carriages on which the cannon may be mounted: thus, for all under 24 pounders, the height, between the front of the platform, and the crest, *i. e.* the interior, or highest part of the slope, over which the cannon is levelled, ought not to exceed 28 inches, unless the trucks on which the carriages run are unusually high; for all cannon of 24 pounds calibre, and upward, the space above described, and which is called the *genouillere*, ought to be from 34 to 40 inches. The best rule is, to allow eight inches between the crest of the slope and the under part of the cannon, when horizontally laid, thereby to command freedom of action, even when the depression of the line of fire may be considerable: were this not attended to, the cannon might, at such times, be levelled after each discharge, before it could be run up to the *genouillere*; whereby considerable delay would be created. The slope, by which we mean that part under the muzzle of the cannon, is ordinarily made with a descent of about ten or twelve degrees from the crest outwards, to allow of depression, so as to fire either into the ditch, or over the glacis; this slope must necessarily vary according to the situation, and intention of the battery. Thus, in some situations it is found necessary even to invert the slope, the cannon being always pointed above the horizon: this occasionally happens in erecting batteries while besieging a place, where it would be both useless and disadvantageous to cut the embrasures any lower than the lowest direction to which the cannon should be pointed. On the other hand, we sometimes see the slopes made at full forty degrees of depression, in consequence of the battery being intended to command some work, of approach, far below its own level. But, as before observed, when works are constructed upon an ordinary *defilement*, (or branching out,) originating from a level at the exterior of the *glacis*, and proceeding without any increase of elevation to the centre of the place, then from 10 to 12 degrees of depression in the slope will be fully adequate to all the purposes of depression of the cannon. The expansion of an embrasure, that is, its becoming wider exteriorly, than it is interiorly, must depend on circumstances; but we generally find their sides to diverge at an angle of about 12 or 15 degrees from a line passing through the centre of the slope, in a direction with the chace of the cannon when brought up square to the *genouillere*. It should, perhaps, seem proper to make the embrasure spread as widely as possible, for the purpose of including a greater extent of direction; but were such to be practised, the *merlon*, *i. e.* the body of parapet left between any two embrasures, would be so considerably diminished as to afford little protection from the enemy's shot, which would, at the same time, gain admission, obliquely, into the battery, and dismount the cannon by a plunging fire. On the other hand, it is absolutely necessary to give such an expansion as may not only allow the reasonable traversing of the cannon, thereby to cover a greater extent of the approaches, but to prevent the *merlons* from being destroyed by the fire of their own cannon, of which the explosion would speedily bring down the revetements, whether of masonry or of turf, unless ample space were allowed for the concussion of the air created by the discharge to be sufficiently weakened. We have heard of defences that were destroyed rather by the want

want of this confideration, than from the enemy's fire. Where the *merlons* are of folid mafonry, and confequently the thicknefs of the parapet inconfiderable, when compared with that attendant upon *merlons* made of foil, there may be allowed rather more contraction than in the latter cafe, becaufe the explofion is not confined for fuch a diftance. Few cafes, however, can occur, in which the divergence of the fides can come under ten, or exceed fifteen degrees. Where it is not adviseable to keep all the intended embrafures open, or where deception is an object, they are either left unfinifhed, the parapet being left entire, or their fronts are filled up with the fame materials as the front of the parapet. The former is common in fituations where the foil is loofe, and the difficulty of fuftaining the merlons confiderable. When embrafures are cut through fuch parapets, their fides muft be fuftained by *fafcines*, as in the cafe of field batteries, and approaches during a fiege. The latter defcription, *i.e.* the concealed embrafures, form what is called a mafked battery, which generally opens by furprife; the firft difcharge generally ferving to clear away the flight work built up for the purpofe of concealing the fituations of the cannon. Where it is abfolutely neceffary that cannon fhould be allowed to traverfe freely in various directions, fuch, for inftance, as fea-lines, where every gun fhould be made to follow a fhip paffing with a rapid tide, and likewife in block-houfes mounting heavy ordnance on their roofs, no embrafures fhould be made; but the cannon fhould be mounted on carriages traverfing on pivots, and elevated above the body of the ramparts, which may neverthelefs be made high enough to cover the defenders very completely. Cannon mounted in this manner command a great range of direction, and, though not fo well fecured from being difmounted as when placed in embrafures, are pre-eminently ferviceable in fome fituations. Batteries of this defcription are called *barbet batteries*, and fhould, with little exception, be invariably preferred, wherever they are not liable to be oppofed by cannon, or where the force to be acted upon is expected to pafs with velocity, without being able to take a fettled aim at the *barbet*. Mortar batteries have no embrafures, they requiring only a given line of direction, aided by due elevation, to effect their object; and, as both may be given without feeing it, the parapets of fuch batteries are left entire. What are called embrafures on board bomb-ketches, are nothing more than temporary openings made by unfhipping hatches, and by fitting ftout planks at the fides to confine the fparks from fpreading within the veffel. In cafemates, efpecially thofe in the *curtain*, &c. the embrafures are made like the portholes in a fhip; that is, nearly fquare, and allowing the muzzles of the cannon to pafs completely through.

EMBREGMA, an embrocation. The term is derived from εμβρεχω, *to make wet.*

EMBROCATION, or rather EMBROCHATION, *Embrocha*, Εμβροχη, formed from βρεχω, *irrigo*, *I fprinkle*, or *moiften*, in *Pharmacy*, denotes the application of remedies, as oils, fpirits, decoctions, and other liquids, by fprinkling, or even rubbing them on the part affected: this is alfo called irrigation.

Embrocations are only a kind of lotions; they are ufed to remove obftructions, and to relieve pains, numbnefs, and palfies. The pumping ufed in natural baths is properly an embrocation.

EMBROCATION, *gall.* See GALL.

EMBROIDERY, the enriching of a cloth, ftuff, or muflin, by working diverfe figures thereon with the needle, and thread of gold or filver.

The word embroidery is derived from the French *broiderie*, of *broider*, *to embroider*; which fome deduce, by tranfpofition, from *bordeur*, becaufe they formerly embroidered only the borders of ftuffs, whence the Latins alfo call the embroiderers *limbularii*. Du-Cange obferves, that they anciently wrote *aurobruftus* for embroidered with gold, or *bruftus brudatus*, and *brodatus*; whence *broderie.*

That done with filk, flax, or the like, is not now called embroidery; though anciently, and properly, the word denoted all kind of figuring or flourifhing.

The chief ufe of embroidery is in church veftments, cloaths, houfings, guidons, ftandards, &c. The invention of embroidery is attributed to the Phrygians; whence the Latins call embroidered garments "veftes Phrygioniæ," and embroiderers *Phrygiones*. In the "Menæchmi" of Plautus, (act ii. fcene 3), a young woman, defirous of fending her mantle to be embroidered, fays: "Pallam illam ad phrygionem ut deferas, ut reconcinnatur atque ut opera addantur, quæ volo." The Greeks feem to have ufed the words κεντειν and καταποικιλλειν, as we ufe the word embroider.

The embroidery of ftuffs is performed in a kind of loom; that of muflin is done by ftretching it on a pattern already defigned; the former kind is the moft eafy, but the latter admits of the greateft richnefs and variety. The thinneft muflins are the beft for this purpofe; and they are embroidered to great perfection in Saxony.

There are diverfe kinds of embroidery; as *embroidery on both fides*, that which appears on both fides. *Guimped embroidery*, performed either in gold or filver. In this work, a fketch is firft made on the cloth, then they put on a cut vellum, and afterwards few on the gold and filver with filk thread, interfperfing filver and gold cord, tinfel, and fpangles. *Embroidery on the ftamp*, where the figures are very high and prominent, being fupported on wool, cotton, hair, &c. *Low and plain embroidery*, where the figures are low and flat, and without any enrichment between them. It is probable that the covering of the fword of Goliath, which was laid up in the tabernacle as a confecrated memorial of the victory gained by David over that vain-glorious idolater, or the wrapper that enveloped it, was fome beautiful piece of embroidered work. (1 Sam. xxi. 9.) By ftatute 22 Geo. II. c. 36. no foreign embroidery, or gold or filver brocade, fhall be imported, upon pain of being forfeited and burnt, and penalty of 100*l.* for each piece. No perfon fhall fell or expofe to fale any foreign embroidery, gold or filver thread, lace, fringe, brocade, or make up the fame into any garment, upon pain of having it forfeited and burnt, and penalty of 100*l.* All fuch embroidery, &c. found, may be feized and burnt, and the mercer, &c. in whofe cuftody it was found fhall forfeit 100*l.*

EMBRUN, or AMBRUN, in *Geography*, a town of France, in the department of the Upper Alps; chief place of a diftrict of the fame name, fituated upon a high rock on the right fhore of the river Durance, 66 miles S.W. of Grenoble, and 480 miles S. by E. of Paris, is chiefly remarkable for its cathedral, and has a population of 3138 individuals. The canton contains 8 communes and 9667 inhabitants, on a territorial extent of 285 kiliometres.

As chief place of a diftrict Embrun has a fub-prefect, two courts of juftice, and a regifter office. The whole diftrict is extremely mountainous, but the vallies and the declivities of the mountains are uncommonly fertile. It contains five cantons, 36 communes, and 26,968 inhabitants, on a territorial extent of $1472\frac{1}{2}$ kiliometres.

EMBRYO, or EMBRYON, in *Anatomy* and *Phyfiology*, is the child, with its coverings, as contained in the uterus previoufly to the time of birth. It is fuppofed at firft to be in an imperfect ftate, but to contain rudiments of all the parts.

parts, which, when fully developed, make up a perfect animal. The term is derived from the Greek word ἔμβρυον, which has the ſame ſignification, and is formed from ἐν, *in*, and βρύω, *I ſhoot out;* conveying a notion, that the living germ buds forth and expands in the uterus of the mother, as a ſeed is developed in the earth. The term embryo is employed, in its moſt ſtrict acceptation, during the firſt ſix weeks only after conception, but it is often uſed more generally during the whole time of utero geſtation. The young animal, after the firſt ſix weeks, is called a *fœtus;* but we uſe this word alſo to denote the ſame object as ſoon as it can be diſtinctly perceived. By the *ovum*, we underſtand the fœtus, together with its ſurrounding membranes; but that term is ſometimes applied to the latter only, in contradiſtinction to the former. We ſhall conſider, under the preſent article, the progreſs of the uterine contents, until the time of utero-geſtation is completed; the changes, which they paſs through, in the different ſtages of this period; the peculiarities of ſtructure belonging to the fœtus; and the mode of its nutrition and exiſtence.

A ſketch of the progreſs of the germ, after impregnation, from the ovarium into the uterus, and of its developement in the latter cavity, will be found in the article CONCEPTION; a more detailed hiſtory of the anatomy of the ovary and uterus, together with a ſtatement of all the facts that can be aſcertained concerning the mode of impregnation, and its immediate conſequences, will be contained under the head of GENERATION.

When the germ is detached from the ovarium, the mode of its exiſtence differs in the different claſſes of the animal kingdom. In the greateſt number of inſtances it is accompanied by an organized maſs, to which it adheres by means of veſſels, and the abſorption of which is ſufficient to nouriſh and develope it, until it is brought forth into the world. It requires no ſupply therefore from the body of the mother; and is even ſeparated from her by more or leſs numerous and ſolid coverings. The germ, together with the nutritious ſubſtance, and the common envelopes, conſtitute an *egg*, and the animals which propagate their ſpecies in this way, are called *oviparous*. In many of theſe, the germ contained in the egg is not developed and hatched, until the egg has quitted the body of the mother, or has been *laid;* in which caſe fecundation may be performed afterwards, as in many fiſhes, or external heat only may be required, as in the incubation of birds: or, laſtly, the natural temperature of the climate may ſuffice, as in reptiles and inſects. All theſe are *oviparous* animals, properly ſo called. In ſome others, the egg, after having been fecundated, and detached from the ovary, remains in the mother's body, until the young one is developed and hatched, as in the viper, and in ſeveral fiſhes: ſuch are falſely viviparous, or *ovo-viviparous* animals. Mammalia only are truly *viviparous;* their germ is provided with no ſupply of aliment, but derives the materials of its growth from the juices of the mother. For this purpoſe it is attached to the internal ſurface of the uterus, and occaſionally, by accident, to ſome other part, by a kind of root; by an infinite ramification of blood-veſſels, conſtituting the *placenta*. Inſtead, therefore, of being ſeparated by its coverings from the body of the mother, theſe are the medium of a moſt intimate connection between them, eſſentially neceſſary to the life of the germ. Through them there is a conſtant influx of nutritious juices until the embryo is completely developed. At that time the membranes are torn, and the young animal comes into the world, capable of enjoying an independent organic exiſtence, and free from all external covering. The very rare occurrence, of the child being born with its membranes entire, cannot be regarded as an exception to this aſſertion; Wriſberg only ſaw it three times in 2000 births; (ſee his Obſervat. de Structurâ ovi, p. 76.) and it is probably ſtill leſs common on the average. In the mammalia then there is no *egg*, in the ſenſe already explained: the membranes of their *ovum* being an intimate connection between the mother and the germ, by which the former ſupplies the latter with nouriſhment; while the *egg* is entirely detached, and contains, with the germ, the nouriſhment neceſſary for its growth. Hence we ſee that the old and much-conteſted maxim of "omnia ab ovo," cannot be received without great limitation, and is more likely to perplex, by confounding together things eſſentially different, than to impart any additional light to a ſubject already very obſcure.

The following parts, which are of courſe contained in the cavity of the pregnant uterus, make up the human ovum; *viz.* the *placenta*, *membranes*, *navel-ſtring*, *liquor amnii*, and *fœtus*. The three firſt are called alſo the ſecundines or after-birth; as they are expelled, in the act of parturition, after the child. The placenta and membranes every where line the cavity of the uterus, and the former muſt undoubtedly have ſome communication with the veſſels of the mother, although anatomiſts have not yet ſucceeded in demonſtrating the preciſe mode of that connection. In the membranous bag formed by the ſecundines, there is found, beſides the fœtus, a greater or ſmaller quantity of clear fluid, called the liquor amnii. The umbilical chord contains blood-veſſels, by which the circulating organs of the fœtus communicate with the arteries and veins of the placenta.

The ſecundines are all more or leſs gelatinous and tranſparent, and contain no manifeſt fibrous ſtructure. Being deſtroyed after every pregnancy, their exiſtence is temporary; and their organization correſponds to this limited term of duration. They never contain any fat, either in the ſound, or in the morbid ſtate of parts, at any period of utero-geſtation, however the mother or child may be circumſtanced in this reſpect.

The cavity of the uterus, examined immediately after conception, exhibits nothing which can be regarded as the fruits of that proceſs. In a few days, we perceive a tranſparent membranous veſicle, filled with a gelatinous liquor, but offering no appearance of organization or life. Some writers have aſſerted that ova may be found in the uterus of the human ſubject, or of animals, immediately after conception; and have even publiſhed delineations of them in the firſt days of pregnancy. Such ſtatements deſerve no credit. Thoſe modern phyſiologiſts, in whom we can place the greateſt confidence, have found, during the firſt ſeventeen days, nothing but a fluid like white of egg, in which there was no trace of any more conſiſtent body. Mr. Cruikſhank, however, has met with ova in the tubes and uteri of rabbits, at a much earlier period. He found them in the former ſituation on the third day after coition: they were mere points, but the diſtinction of the chorion and amnios could be diſcerned by the aid of magnifying powers. The fœtus was rendered viſible on the eighth day, by pouring vinegar on the ovum. We may regard all obſervations in which an ovum is ſaid to have been diſcovered in the human ſubject, earlier than the twentieth day, as extremely ſuſpicious: indeed, we know of no inſtance, in which it has been obſerved, before this time, by any perſon whoſe teſtimony has ſufficient authority. A round little body is gradually developed in the cavity of the uterus, and may be recognized at the end of the third week. This is the covering of the future, but not yet diſcernible fœtus. The ſurface of ſuch an ovum is probably flocculent from the firſt; this at leaſt is the caſe in the ſmalleſt hitherto delineated,

delineated, and in well preferved fpecimens of very fmall and early abortions. The flocculi are very fine vafcular ramifications, connecting the ovum to the decidua, which refembles in appearance a layer of coagulable lymph produced by inflammation. The refemblance of thefe villi to the roots of a plant, the mode of their infertion in the decidua, and the analogy of their function, in draining from the uterus and conveying to the child, the materials of its fupport, to the office which roots perform, in extracting nourifhment from the foil, has led almoft every writer to compare the rudiment of the future animal to a feed, and to confider its connection with the mother's body as fimilar to that between a plant and the earth. The vafcular proceffes are fmall in very young ova, but enlarge afterwards rapidly till the fecond month: they gradually difappear from two-thirds of the furface of the ovum, and are collected together on the remainder, to be united into a mafs, and form the placenta.

It has not been hitherto determined at what period the ovum becomes connected to the uterus; indeed it is fo fmall, at its firft arrival in the cavity, that the inveftigation is difficult. Cruikfhank fays, that the ovum increafes in the rabbit, to one hundred times its original fize, before it becomes fixed to the uterus. The fize of the ovum, at different periods of pregnancy, cannot be determined with much accuracy, becaufe many abortions are not well formed, and their exact age cannot be well afcertained. Hence different writers contradict each other confiderably in this point. Within the firft month it is not larger than a hazel nut; in the fecond and third it may equal a pigeon's or hen's egg. At the latter period its developement is complete, and the future changes are chiefly in fize. It increafes in proportion to the augmentation of the uterus.

Particular defcription of the component parts of the ovum.— The membranous covering including the fœtus, within the uterus, confifts of feveral diftinct parts, which admit eafily of artificial feparation. The number of thefe has been very varioufly reprefented. The older anatomifts only defcribe two; *viz.*, the chorion and amnios; and divide the former into two laminæ. Moft moderns defcribe three coverings, adding the decidua of Hunter to the two former. Haller mentions four;—the membrana exterior ovi, chorion, membrana media, and amnios. Blumenbach's divifion into the proper, and adventitious coverings is a good one: the latter are the chorion and amnios; the former, the decidua, which covers the ovum and lines the uterus.

The *decidua*, or *membrana caduca*, is the medium of connection between the embryo and the mother. In its appearance, as well as in its mode of formation, it refembles the lamina of coagulating lymph, which is formed by inflamed furfaces. Both membranes are of a yellowifh white colour; both are tender, pulpy, and vafcular. The lamina of lymph is formed by an inflamed membrane; the uterus, before the appearance of the decidua, becomes much more vafcular, and is probably in a ftate of increafed action analogous to inflammation. The developement of this membrane is probably anterior to the arrival of the germ in the uterus, and may be regarded as a meafure of preparation for its reception. It is not neceffary for the formation of the decidua, that the ovum fhould reach the uterus. For when it grows in the ovarium, or in the Fallopian tube, the decidua is formed in the uterus, and that organ is confiderably enlarged; fo that it undergoes, to a certain degree, changes exactly fimilar to thofe which take place in natural pregnancy. It lines the whole internal furface of the uterus, being perforated at the Fallopian tubes, and cervix uteri. Numerous fmall arteries and veins, often feen containing red blood, ramify from its outer furface inwards through its fubftance, and are derived from the veffels of the uterus. It is very thin, and has no perceptible veffels near the cervix uteri; but grows thicker and more vafcular towards the placenta, at the very edge of which it acquires a confiderable thicknefs, and fplitting into two ftrata, is continued over both furfaces of the placenta, but efpecially the inner fmooth furface, blending itfelf there infeparably with the umbilical portion of the placenta. The layer of the decidua, which lies between the chorion and placenta, is in one cafe much thicker than in another. It fometimes forms a fmooth, tender, opaque membrane; but is more frequently reticulated, efpecially towards the edge of the placenta, looking fomewhat like lace. Occafionally there are portions of it a good deal thicker than the reft; which, fhining through the tranfparent chorion, bear fome refemblance to pieces of fat. This layer is generally thicker than that which adheres to the rough, external, lobulated furface of the placenta. It communicates with that other, by means of the proceffes of the decidua, which pafs between the lobules of the placenta, and along the external furface of the umbilical veffels.

We have already obferved, that the decidua adheres clofely, on its external furface, to the uterus, and that this adhefion is effected by means of blood-veffels paffing to the former from the latter. By its means the whole external furface of the ovum grows to the uterus. Its internal furface is very clofely attached to the chorion, fo that their feparation is difficult in recent fecundines. Gentle putrefaction makes them part eafily; and we obferve, on the feparation, numerous white flender threads, emerging from the fubftance of the chorion, and ramifying into fmaller filaments upon the decidua. Thefe appear like veffels by the aid of a magnifying glafs.

As this membrane is an adventitious production of the internal furface of the uterus, formed for the temporary purpofe of a connecting medium between the mother and the child; its office ceafes as foon as the fœtus has quitted its original fituation; and it is confequently fhed whenever a woman bears a child, or fuffers a mifcarriage. Hence its names of *decidua* and *caduca*. As it may be partially feparated into two ftrata, one of thefe is left on the uterus after delivery, and afterwards diffolves, and comes away with the lochia. Frequently a thicker ftratum feparates from the uterus in one part, and a thinner in another. The adhefion of the decidua to the uterus and chorion is ftronger than that of the two layers of the membrane to each other; and hence, probably, we may explain the circumftance of a ftratum being left upon the uterus after parturition. The beft method of feeing the decidua after labour, is to wafh the fecundines well in warm water, to remove the loofe coagulated blood, and then put them into cold water, that the blood, which remains in the veffels, may congeal. The decidua will then be very diftinguifhable by its yellowifh appearance and pulpy confiftence; and numerous veffels may be clearly difcerned in its fubftance. The number and fize of the veffels, paffing from the uterus to the decidua, fufficiently account for the bleeding which always takes place on the feparation. Thefe veffels are reprefented as filled with blood in Hunter's 29th plate, fig. 4: and in their injected ftate in feveral other figures of the fame work; *viz.* the arteries in fig. 3, tab. 24; the veins in tab. 24, fig. 4: and both kinds of veffels coming from the uterus, in tab. 31. The fecond fig. of tab. 29. of the fame work, exhibits the reticulated lace-like appearance of the membrane, when viewed with magnifying powers: in this refpect it much refembles the adventitious productions of coagulating lymph.

The preceding defcription applies to the decidua, as it is found

found in ova of feven, eight, or nine months. The membrane is very different in the earlier periods; and as the defcriptions of anatomifts have been derived chiefly from abortions, in which more or lefs of the decidua may come away with the ovum, and as the appearance of the membrane differs very much in the different periods, the accounts of it are very perplexed, and difficult to underftand. The thicknefs of the membrane is in an inverfe ratio to the age of the embryo. In an early ftate, too, its external furface is covered with numerous loofe and floating flocculi, by which it adheres to the furface of the uterus; thefe are not feen at more advanced periods: they are excellently reprefented in an abortion of the feventh week, in two beautiful figures, forming the vignette of the title page of Soemmerring's Icones Embryonum Humanorum: alfo in Hunter, figs. 1, and 2. pl. 33.

From the time that the ovum has acquired fome fize, until about the fourth month, the decidua not only lines the whole cavity of the uterus, but alfo gives another covering to that part of the chorion, which is not occupied by the placenta. This fecond inveftment is continuous with the former at the edge of the placenta; and, as it appears at this part as if reflected from the exterior layer over the ovum, Dr. Hunter, to whom we are indebted for the moft accurate obfervations on the whole fubject, called it *decidua reflexa;* the addition of Hunteri is often made by foreign anatomifts. He compares, in the explanation of pl. 33, fig. 1, the reflection of the decidua over the ovum, to that of the pericardium over the heart; and the comparifon might be correct, if the exterior portion of the pericardium covered the whole of the heart, as the outer layer of decidua does the whole ovum. According, then, to the preceding defcription, we may diftinguifh three portions of decidua, all, however, completely connected together; 1ft. The exterior portion, covering the whole ovum, and lining the whole uterus, excepting the apertures correfponding to the Fallopian tubes and cervix; *decidua uteri, d. vera, membrana ovi exterior* of Haller, membrana caduca *craffa* of Mayer (Befchreib. des menfchlichen Körpers, v. 5. f. 272.) becaufe it is thicker than the reflected portion, firft membrane of the ovum of Mekel, decidua externa of Sandifort, and external lamella of the Hunterian decidua of fome authors. 2dly. A production over the concave furface of the placenta. 3dly. D. *reflexa*, covering the chorion, and continuous at the margin of the placenta, with the D. uteri. This is Blumenbach's acquired membrane, Mekel's fecond membrane, villofa membrana placentæ, involucrum membranaceum of Albinus, membrana filamentofa of Wrifberg and Roderer, chorion of Haller, chorion fungofum, flocculentum, &c., fpongy chorion, reflected vafcular membrane, &c. Denman calls it connecting membrane, and Baillie decidua chorii. A cavity muft neceffarily be intercepted between this and the d. uteri. The diftinction of thefe two parts, and their relative pofition, are beft feen in the plates of Hunter; as in fig. 1, of tab. 28: alfo in a perpendicular fection of the uterus, containing an ovum of three months, reprefented in tab: 32, where the letters *k*, *l*, *m*, *n*, *o*, reprefent the two deciduæ, the angle of reflection, and the cavity left between them. The fame facts are alfo reprefented in two abortions, figs. 1, 2, 3, and 4, of tab. 33. The d. reflexa covers the fhaggy veffels of the chorion, which feem to be implanted in it. In proportion as pregnancy advances, it becomes gradually thinner and thinner, fo that at the fourth month it forms an extremely fine layer covering the chorion. It comes at the fame time into more clofe contact with the d. uteri, and, at length, the two adhere together. Yet the membrane diminifhes in thicknefs, and continues to decreafe until parturition. How it comes to pafs, that the decidua fhould envelope the ovum in the way already defcribed, is mere matter of fuppofition, and does not admit of being fhewn by direct demonftration. In two examinations, mentioned by Dr. Baillie as having been performed with great care at an early period of pregnancy, the decidua was already formed, but no ovum could be difcovered.

In the 18th fig. of his work already quoted, Soemmerring has given an excellent view of the external furface of an ovum of five months. It appears on clofe infpection covered with fine and thinly fcattered flocculi, which are the moft numerous and long in the fituation of the placenta. The firft, or external coat, (the decidua,) is continued into the placenta, or the placenta is extenuated into this membrane, in fuch a way, that we might, with equal propriety, either regard the placenta as the thickeft portion of the decidua, or the decidua as an extenuated production from the placenta. The decidua grows gradually thinner as we recede from the placenta, fo that its thinneft portion is precifely oppofite to the placenta.

The *chorion* is that covering of the ovum which is placed next in order to the decidua. It is the firft proper membrane of Blumenbach, the third membrame of Mekel, and the fecond of many anatomifts; the membrana media of Haller, chorion pellucidum or læve.

It is a firm and ftrong membrane, forming a complete bag, which includes the amnios and child. It adheres firmly to the concave furface of the placenta, and in that fituation is thicker, and covers the great divifions of the umbilical veffels; being clofely attached to the amnios at the infertion of the umbilical chord. At firft it is nearly tranfparent, and tender in its texture: as the ovum increafes, it becomes more opaque, ftronger, and of a yellowifh colour. We have mentioned already how its external furface adheres to the decidua, and the threads connecting them together, which feem to be veffels. Thefe are the only veffels which the membrane poffeffes.

The external furface of the chorion is covered completely with flocculi in the firft month of pregnancy. A great abundance of thin tender threads of different thicknefs arife from it. Thefe divide and fubdivide in a very minute manner, and the neighbouring ramifications join each other. They are extremely fmall on very young ova; but they cover the whole furface at the end of the firft, and in the fecond month. They difappear from fome parts in the third month; and collect clofer together towards the upper part of the ovum, in order to form the placenta.

The decidua reflexa, covering this external furface of the chorion, unites the flocculi together; which penetrate it, and are implanted in the decidua uteri. Many erroneous names and reprefentations have arifen from this ftructure, becaufe the proceffes of the chorion have been regarded as belonging to the d. reflexa; and hence many of the names applied to that membrane have arifen.

In the fourth, fifth, and fixth months the chorion is fmooth on the greateft part of its external furface. The d. reflexa, which is now thin and fcarcely recognizable, is clofe upon it. When the placenta is formed, the external furface of the chorion is firmly attached to its concavity.

The internal furface of the chorion is fmooth, and united to the amnios. In the firft month there is a confiderable interval between the two membranes, filled with a clear aqueous fluid, probably produced by the veffels of the chorion: this fpace is foon diminifhed; the amnios growing fafter than the chorion, the two membranes foon come in contact;

contact. In the third month they lie near together, and are loofely connected by a tender gelatinous medium.

Twins have a double chorion, as well as amnios; but are covered by a common decidua reflexa.

Amnios; the fecond proper membrane of Blumenbach; and fourth membrane of Haller and Mekel; is found univerfally in animals. In man it forms an oval-bag, including a certain portion of fluid, and the fœtus. It is a thin tranfparent membrane, of tolerably firm confiftence. Its external furface is connected, in the way already defcribed, with the chorion, from which it is eafily feparable. It lines the concave furface of the placenta, and terminates, apparently, by a clofe adhefion at the infertion of the navel-ftring, where the chorion alfo feems to end. The gelatinous fubftance connecting the two membranes adheres more clofely to the amnios than to the chorion, and hence the former membrane has a rough appearance, when feparated. The internal furface is every where perfectly fmooth. In birds and quadrupeds it poffeffes manifeft veffels; but none in the human fubject.

The allantois, which was formerly enumerated among the membranes of the human ovum, is now known to be peculiar to quadrupeds.

There is, however, a fmall membranous bag, named *veficula umbilicalis,* found in the early months of pregnancy between the amnios and chorion. This poffeffes an elliptical figure, and contains a clear fluid. It contracts into a thin and round thread, which runs along the navel-ftring, and divides into two at the infertion of the umbilical chord in the child's body. They are afterwards loft upon the vifcera. This veficula can only be feen until the third month, and in very frefh abortions; for it is fo delicate that it decays very quickly; and it is extremely difficult to trace the thread from it through the umbilical chord. Its fize is in an inverfe ratio to the age of the embryo.

Liquor amnii is the name given to the fluid which fills the cavity of that membrane. This is perceivable as foon as the ovum can be difcerned; it diftends the membranes, and preferves their rounded form. Its quantity is the largeft, in proportion to the fize of the embryo, in the firft month of pregnancy; fo that in the firft and fecond it confiderably exceeds the weight of the fœtus, which muft confequently be loofely fufpended in the fluid. The fœtus weighs more in the third month than the liquor amnii; and, as it touches the membranes in the fifth, the proportional quantity of the water has very greatly decreafed; fo that it merely filled up the intervals caufed by the inequalities of the child's body. Stein, an experienced German writer, ftates that the weight of the fœtus and the amniotic fluid fhould be equal about the middle of pregnancy; and that it muft be regarded as an unnatural appearance, if the latter exceeds the former in the fixth month. It continues afterwards conftantly decreafing relatively to the increafe of the child. The quantity varies greatly in different fubjects; from one to two pounds is the ordinary proportion at the period of nine months; but it may be much more or lefs. It is a clear yellowifh fluid; but fometimes differently coloured and obfcure. In its pure ftate it poffeffes no fmell, and a mild faltifh tafte. Heat and alcohol coagulate it in the recent ftate; but the chief bulk of it is aqueous. The fources of the fecretion are unknown. The abfurd opinions, by which it has been fuppofed to proceed from the fkin or various other parts of the fœtus, are fufficiently refuted by the fact of its exiftence when there is no fœtus. The amnios poffeffes no apparent veffels. For an account of the chemical properties of this fluid, fee the article Amnios.

The old opinion of the ufe of the amniotic fluid in nourifhing the fœtus cannot be fuftained; for deglutition could not be performed without the prefence of air; many fœtufes are born with the mouth clofely fhut, and others have grown to the full fize without any mouth at all. The great ufe of the fluid feems to be that of protecting the fœtus from external violence; and hence we find it moft copious when the child is youngeft and moft delicate in texture, to prevent its different parts from adhering together, or to the furrounding membranes. The bufinefs of parturition, as far at leaft as the dilatation of the os uteri is concerned, is alfo facilitated by the liquor amnii.

The *umbilical chord, funis* or *funiculus umbilicalis,* or navel-ftring, made up of three large veffels twifted together, united by more or lefs gelatinous fubftance, and conftituting, in confequence of certain convolutions of the veffels, an irregular rope, rather lefs in general than the fize of the little finger, is fixed at one end to the child's navel, and at the other to the placenta. This being the organ of communication, through which the materials of growth and nourifhment are derived to the fœtus from the mother, conftitutes a moft effential part of the fecundines, and can never be deficient. It paffes through the liquor amnii, from the child to the reft of the fecundines; is commonly about two feet long, but may be no more than one foot, or on the contrary exceed four feet. Wrifberg once faw it only feven inches long; and it was neceffary to cut it in the courfe of the delivery. Its moft frequent length is between 18 and 22 inches. The younger the fœtus, the fhorter is the chord proportionally. It is alfo thicker relatively to the fize of the fœtus, as that is younger. It is ufually turned round fome part of the child's body; very commonly round the neck, which it has been feen to encircle four times and a half.

From the important function performed by the navel-ftring, we fhall expect to find it as foon as the embryo itfelf is perceptible; and confequently it is feen as foon as the fœtus itfelf is vifible.

The veffels of the chord are two umbilical arteries, and one umbilical vein. The two arteries are of equal fize, and poffefs ftrong coats, fo that their fection prefents a circular area. In rare inftances there is only one. The umbilical arteries are a continuation of the internal iliacs; which, inftead of defcending into the pelvis afcend along the fide of the bladder to the umbilicus. When there is only one umbilical artery, the internal iliac of one fide only is reflected along the bladder. The internal iliac which in the adult is no larger, but rather fmaller than the external, is confiderably the largeft of the two in the fœtus. It paffes obliquely from the fide of the pelvis to that of the bladder, and takes the name of umbilical or hypogaftric; croffing the ureter in fuch a manner that that tube lies internally, and the artery externally. It afcends along the fide to the fundus of the bladder, and proceeds over the furface of the peritoneum, to the umbilicus. Thefe veffels make very numerous convolutions and turnings which differ confiderably in different fubjects: and hence they are much longer than the length of the chord. In the fituation of thefe turns, the diameter of the veffels will appear contracted, and thefe contractions are the *quafi-valvulæ* of Hoboken.

The third veffel of the chord is the umbilical vein, which arifes from the placenta, forms numerous convolutions, in company with the arteries, and enters the child's body at the umbilicus. Paffing over the furface of the peritoneum, it arrives at the fufpenfory ligament of the liver; defcends along its anterior margin to the foffa, dividing the two lobes; and there enters the fubftance of the liver. It diftributes feveral branches to this vifcus, particularly to its left

left lobe, and ends by an anaſtomoſis of its trunk, with the left branch of the vena portarum. From the veſſel formed by this union a ſmall canal, about three quarters of an inch in length, is continued into the inferior vena cava, under the name of *ductus venoſus*.

The umbilical vein is much larger than the artery, and its ſides collapſe when divided. It is ſaid that two veins have been ſeen; but Dr. Hunter never met with a caſe; quadrupeds have two. The umbilical veſſels give off no viſible branches till they come to the placenta; then the two arteries anaſtomoſe, commonly by a croſs canal, nearly of the ſize of one of the arteries.

" There is a great variety," ſays Dr. Hunter, " in the twiſting of the veſſels of the navel-ſtring. Sometimes they are uniformly and cloſely twiſted like a rope, in their whole courſe; and ſometimes they run almoſt ſtraight and parallel, eſpecially in that part of the ſtring which is towards the placenta; for near the fœtus it is almoſt always more or leſs twiſted. In ſome navel-ſtrings there is a great irregularity, from ſolitary turnings of particular veſſels, commonly called knots, as we ſee in twiſting a cord, where ſome of the conſtituent threads are longer and therefore looſer than others. The end of the navel-ſtring which is next the placenta, is always leſs twiſted, and more uniform than the end which is next the fœtus.

" Whatever be the cauſe, in moſt which I have attended to, the twiſting of the navel-ſtring has been in the ſame direction, *viz*. ſuch as would be produced in turning the child round upon the navel, as a centre, by puſhing its head towards the right ſide, and its feet to the left. In two and thirty preparations now before me, four only are twiſted the contrary way; and of the twenty-eight which are twiſted in the common way, three have the contrary twiſt for ſome inches, at the extremity, which was towards the fœtus." The veſſels appear to be ſtraight in young embryos. When the chord is very long, *true* knots are formed in it; as diſtinguiſhed from thoſe which ariſe merely from projections of particular veſſels. Theſe are not ſuppoſed in general to affect the communication between the mother and child, but Dr. Hunter thinks he has ſeen two caſes in which it was obſtructed from this cauſe. The true knots are ſometimes double, as if twice tied; and in very rare caſes treble.

The *urachus* is another part belonging to the umbilical chord; it is a ſmall fibrous ſtring aſcending from the fundus of the bladder to the navel, between the umbilical arteries, and growing more ſlender as it proceeds. In the navel-ſtring it is hardly perceptible, except near the fœtus; it is like a fine thread, a little more white and opaque than the reſt. When once found near the fœtus, it may be traced, with a little trouble, nearly the whole length of the ſtring. This part is a canal in the embryo of animals, leading from the bladder to the allantois; but the latter membrane not exiſting in the human ſubject, the urachus is ſolid. Portal, who has inveſtigated the matter very attentively, found the urachus to conſiſt of four threads in embryos of five and ſix months. Theſe paſs together from the navel to the bladder; then ſeparate and expand over the latter organ. In the eighth and ninth month, theſe threads can hardly be ſeparated. The urachus altogether is largeſt in the youngeſt embryos.

The covering of the navel-ſtring, which is ſmooth and poliſhed, is conſidered to ariſe from a reflection of the amnios. Both that membrane and the chorion are firmly adherent to the chord, at its connection with the placenta; and the covering of the chord itſelf is moſt firmly connected with the ſubjacent ſubſtance, ſo that it cannot be ſeparated like a diſtinct membrane. The integuments of the abdomen are continued for a ſhort ſpace over the chord, and there is an abrupt line obſerved at their termination, beyond which not even the cuticle is continued. The ſeparation is much more ſtrongly marked, when the integuments are minutely injected, by the ſudden ending of the injection, no veſſel extending into the chord. The tying of the chord without the leaſt pain is a ſufficient proof that it has nothing to do with the ſkin.

The ſtrong connection between the abdomen of the child, and the chord, is produced by the three umbilical veſſels, penetrating the tendinous opening of the linea alba. They run externally to the peritoneum, which lies behind them entire and unperforated. The oppoſite end of the funis is connected with equal ſtrength to the placenta, both by the continuation of the veſſels into that body, and by the cloſe adheſion of the chorion and amnios.

Beſides the veſſels, the urachus, and the coat of the navel-ſtring, it contains nothing but a fine cellular ſubſtance, loaded with a tranſparent ropy fluid, giving the part both firmneſs and bulk. By touching the cut ſurface of the freſh funis, and removing the finger ſlowly, we ſee the fluid ſo tenacious and ductile, as to be drawn out into fine threads ſome inches in length. When it has been kept ſome days, the fluid loſes entirely that glutinous quality, and tranſudes like water; by which means the ſtring loſes much of its bulk. In this ſtate, if a ſmall blowpipe be puſhed into the interſtices of the veſſels, and proper ligatures be made, the whole interſtitial ſubſtance may be rendered emphyſematous and white. In this condition it may be dried, and then cut up to ſhew the cellular ſubſtance more diſtinctly. The great variety that is obſerved in the thickneſs or ſize of the navel-ſtring in different parts, and in different caſes, depends principally on the quantity of the cellular ſubſtance, and not on the bulk of the child.

Dr. Hunter thinks that " the winding courſe of the veſſels in the navel-ſtring prevents their being much affected by any ſtretching force, and the firmneſs of the interſtitial ſubſtance, protects them againſt dangerous compreſſion. Theſe accidents might otherwiſe perhaps have occaſioned frequent miſchief, eſpecially where there is a large child, and a ſmall quantity of the liquor amnii. In ſuch a caſe the navel-ſtring paſſing under the arm or ham, or in the groin, might have been compreſſed, ſo as to prevent the return of the venous blood at leaſt. The ſame thing might have eaſily happened, where a knot is formed upon the navel-ſtring."

The umbilical arteries divide in the placenta into ſmaller and ſmaller ramifications; and their ultimate branches communicate with the umbilical veins; injected fluids at leaſt return very readily by this courſe. The vein is made up by the union of the minute branches into larger and larger trunks. In the early periods of pregnancy, the umbilical veſſels branching out very minutely, conſtitute the flocculi of the chorion.

Placenta.—This, together with the membranes, makes a complete bag lining the uterus, and containing the child. As Dr. Hunter has done much in elucidating its ſtructure, and has given a very good account of the ſubject, we ſhall avail ourſelves chiefly of his labours.

Its figure is commonly round and flat; it is about an inch in thickneſs and a ſpan in breadth. It grows gradually thinner towards the edge, ſo as to render the change from the placenta to the membranes more imperceptible. When the cellular part is well filled with wax, or any fluid, it is at leaſt two inches thick. Its ſhape is often oblong or triangular, or irregular; and ſometimes there is a ſmall lobe or two entirely diſtinct from the reſt. The outer ſurface, which adheres to the womb, and is therefore naturally convex, is rough, tender in its fubftance, commonly covered with blood, lightly fubdivided into fmaller conftituent lobes, and, to a common obferver, apparently poffeffing no blood-veffels, or at leaft none of any confiderable fize. The internal furface, naturally more or lefs concave, is gloffy, hard or compact in its texture, and beautifully marked with the ramifications of the umbilical veffels. The navel-ftring, which produces thefe branching veffels, is inferted fometimes into the very centre, but more commonly a little nearer the edge, and often into the very edge of the placenta. In four different inftances, Dr. Hunter faw the navel-ftring terminate on the infide of the membranes, at the diftance of five or fix inches from the placenta. In all thefe cafes the umbilical veffels parted from one another even to confiderable diftances in their courfe upon the membranes, and came to the edge and inner furface of the placenta at different places, even at the oppofite parts. The termination or infertion of the navel-ftring, wherever it happens to be, makes the centre of ramification for the large veffels on the internal furface of the placenta.

The human placenta, like that of quadrupeds, is a compofition of two parts intimately blended, *viz.* an umbilical or infantile, and an uterine portion. The former is made up by the ramification of the umbilical veffels of the fœtus; the other is a certain portion of the decidua, produced, as we have already defcribed, from the furface of the uterus. The umbilical portion of the placenta is made by a regular ramification of the arteries and veins of the navel-ftring into fmaller and fmaller branches, without any lateral anaftomofis, fo that when unravelled by gentle putrefaction, motion, and wafhing, this part takes on the appearance of a tree whofe branches divide to almoft infinite minutenefs, not only towards its outer furface, but every where through its fubftance.

The two umbilical arteries anaftomofe freely by a canal of communication juft where they are going to branch out upon the placenta, fo that by injecting one of them, the other is readily filled alfo. Every branch of an artery is attended with a branch of a vein; thefe cling to one another, and frequently, in the fubftance of the placenta, entwine round one another as in the navel-ftring.

Injections prove, both in the human fubjects and in quadrupeds, that the umbilical arteries terminate in the veins of the fame name, and not in the veffels of the uterus; and that the blood paffes from the arteries into the veins, as in other parts, and fo back to the child again. If the placenta be whole in all its fubftance, which is feldom the cafe, and its blood-veffels be pretty well emptied of their blood, any fubtile injection thrown into an artery will fill the arterial fyftem through the whole fubftance of the part to an amazing degree of minutenefs, and return fo freely by the veins as to fill them very generally and equally. In the fame manner the whole umbilical fyftem may be filled by injecting the vein, the fluid returning from the veins into the arteries. In both thefe experiments the injected fluid is confined to the umbilical vafcular fyftem, none efcaping at the external furface of the placenta, neither by large nor fmall orifices, whether of veins or arteries.

When a placenta is finely injected, and then fteeped, and frequently wafhed in clear water, it is evident that the umbilical veffels do not reach even the outer furface of the placenta, but are only feen through a membrane (decidua,) which covers all that furface. It is rough or ragged, like the inner furface of the uterus, to which it adheres, and by its whitenefs becomes very diftinct from the vafcular injected part of the placenta, over which it is fpread. It becomes ftill more diftinguifhable when the part is put into fpirits, which render it more opaque and whiter. This membrane is an efflorefcence or production of the inner membrane of the uterus, and is analogous to the uterine fungi of quadrupeds. It receives no veffels, demonftrable by the fineft injections, from thofe of the navel-ftring, yet it is full of both large and fmall arteries and veins. Thefe are all branches of the uterine veffels, and are readily filled by injecting the arteries and veins of the uterus; and they all break through in feparating the placenta from the uterus, leaving correfponding orifices on the two parted furfaces.

This decidua, or uterine portion of the placenta, is not a fimple thin membrane expanded over the furface of the part, it produces a thoufand irregular proceffes which pervade the fubftance of the placenta, as deep as the chorion or inner furface; and are every where fo blended and entangled with the ramifications of the umbilical fyftem, that no anatomift will perhaps be able to difcover the nature of their union. While thefe two parts are combined, the placenta makes a pretty firm mafs; no part of it is loofe or floating. But when they are carefully feparated, the umbilical fyftem is evidently nothing but loofe floating ramifications of the umbilical veffels, like that vafcular portion of the chorion which makes part of the placenta in a calf; and the uterine part is feen fhooting out into innumerable floating proceffes and rugæ, with the moft irregular and moft minutely fubdivided cavities between them that can be conceived. This part anfwers to the uterine fungus of the quadrupeds. In a placenta at nine months the two conftituent parts can only be feparated by fome degree of putrefaction, and gentle rubbing and wafhing; but this operation always deftroys the uterine portion, which is more tender, and yields to putrefaction fooner than the other. In the placenta of an earlier age, the union of the two conftituent portions is lefs intimate, and they may both be preferved very entire, like the vafcular chorion and fungus of the quadruped. Dr. Hunter feparated them in a conception of four months, and left the uterine portion attached to the infide of the uterus.

The two portions of the placenta are fo interwoven with each other as to leave innumerable fmall vacuities, with free communications, through the whole fubftance. If this cellular ftructure be inflated or injected, the placenta, like the corpora cavernofa penis, acquires a very confiderable increafe of thicknefs, and fubfides again when the fluid efcapes. This cellular receptacle in the placenta cannot be completely filled after it has been parted from the uterus, becaufe then the fluid, which we may by any contrivance throw in, will be difcharged at innumerable orifices on the outer furface of the placenta; but while it remains attached to the uterus, all the cells may be eafily and completely filled by injecting any fluid into the arteries or veins of the uterus. Thefe veffels, and thefe only, have a demonftrable communication with the fpongy cells of the placenta, which receive the maternal blood from the arteries of the uterus, and give it back into the veins of that part. Both thefe veffels pafs in the decidua, and the larger branches of both, with little or no ramification, terminate abruptly in the cells. The arteries are all much convoluted and ferpentine; the larger, when injected, are almoft of the fize of crow-quills. The veins have frequent anaftomofes, pafs in a very flanting direction, and generally appear flattened; fome of them are at leaft as big as a goofe-quill, and many of them are very fmall. They are very numerous round the edge of the placenta, and many run for a little way, in the direction of tangents to the circle, in the very angle between the membranes and the placenta.

In feparating the latter part from the uterus, which can be effected with very flight force, all thefe veffels are neceffarily torn through; and then each broken veffel has an open mouth on the inner furface of the uterus, and a correfponding orifice on the outer furface of the placenta. They may be readily obferved on a frefh placenta, as foon as it has come away in a common labour. Air blown into the cellular part by thrufting in the end of a blow-pipe, rufhes out readily by the open mouths both of the arteries and veins.

While the placenta remains adhering to the uterus, injection will pafs either from the uterine arteries or veins into the cells of that organ; and, after filling thefe cells, it returns by the oppofite order of veffels to that by which it was thrown in. Hence, if we wifh to inject both fyftems in the gravid uterus, we fhould fill the firft only moderately, and then the other.

The venous fyftem of the decidua and uterus may be filled with air from the cells of the placenta. Introduce a blunt probe through a flit in the coat of the navel-ftring, and force it into the cells of the adjacent part of the placenta; then, withdrawing the probe, infinuate an injecting pipe, and tie it firmly with a broad thread round the navel-ftring. By that pipe you may fill the whole placenta uniformly in its cellular part, and likewife all the venous fyftem of the uterus and decidua, as readily and fully as if you had fixed the pipe in the fpermatic or hypogaftric vein; fo ready a paffage is there reciprocally between the cells of the placenta, and the uterine veffels. It is as much reciprocal, and more largely open, than between the corpus fpongiofum and the veins of the penis.

From all his experiments, repeatedly and diligently made, Dr. Hunter concludes, that the human placenta, like that of the quadruped, is compofed of two diftinct parts, though blended together, *viz.* an umbilical, which may be confidered as a part of the fœtus, and an uterine, which belongs to the mother; that each of thofe parts has its peculiar fyftem of arteries and veins, and its peculiar circulation, receiving blood by its arteries, and returning it by its veins; that the circulation through thefe two parts of the placenta differs in the following manner; in the umbilical portion the arteries terminate in the veins by a continuity of canal, whereas in the uterine portion there are intermediate cells, into which the arteries terminate, and from which the veins begin. Though the placenta be completely filled with any injection thrown into the uterine veffels, none of the wax finds its way into any of the umbilical veffels; and in the fame manner fluids injected into the umbilical veffels can never be pufhed into the uterine, except by rupture or tranfudation.

Several views of the arteries and veins, which pafs from the uterus to the placenta, are exhibited in Dr. Hunter's plates; fee Tab. 15. fig. 1. Tab. 19. Tab. 29. fig. 1. and Tab. 30. and the fame veffels on the furface of the uterus in fig. 3. Tab. 10. and fig. 2. Tab. 28.

It has been ftated already, that the human placenta is made of a fingle mafs; but fome varieties have been obferved in this refpect. It poffeffes fometimes a fmall appendix; or it may be made up of three or more fmall pieces, united by means of the chorion. Wrifberg faw a placenta compofed of feven pieces. Where there are twins, or three children, the placenta is ufually fingle; but there may be two or three feparate ones united by the amnios, which forms the partition of the bags containing the children.

The Fœtus.—The proportions of parts, and confequently the whole figure of the fœtus, differ very much before birth, from that which they poffefs afterwards; and they differ alfo very confiderably at different periods of utero-geftation. Influenced by their opinions of the beauty and due proportions belonging to the human frame in later ftages of exiftence, many have called the fœtus, in its early periods, fhapelefs and deftitute of fymmetry; not reflecting that a different figure and relation of parts belongs, in the order of nature, to the age we are fpeaking of, and that this may ftill be beautiful and fymmetrical according to the ftandard of that age. While the rofe is ftill inclofed in the calyx, its appearance is very different from that which it exhibits when the petals burft forth from their confinement, and the whole flower is difplayed in its mature and perfect ftate: yet we do not deem the rofe bud inelegant or imperfect in its form. We may affirm, on the fame principles, that every age in the human fubject is diftinguifhed by its peculiar kind of beauty; that the embryo, the fœtus, the infant, the youth, &c. poffefs their refpective proportions, thofe of each differing from the others; and confequently, that an embryo may, with propriety, be termed beautiful, if its formation correfpond to the ftandard of its age. It is true, indeed, that the fœtus in abortions is often ill-formed, being fmaller than it fhould be, deviating from the ufual proportions, or monftrous; and, very probably, this mal-formation may be one of the caufes why fuch embryos die, and are feparated with the ovum from the uterus; juft as we fee that mif-fhapen or worm-eaten fruits feldom arrive at maturity, but have their further growth impeded by that very caufe. To the fame purport it is obferved by Autenrieth, § 8, "that he found three monftrous fœtufes, out of nineteen, whofe parts could be diftinguifhed; that Wrifberg met with two among five, which he examined; and Ruyfch two in twelve; the proportion of the whole being feven in twenty-nine. This large number, (if we confider, at the fame time, that all the collections of anatomical preparations abound with monftrous fœtufes, which have died immediately after birth, while adult monfters are extremely rare,) renders it very probable that nature employs the fhort, but effectual means of extirpation, in order to preferve the genuine figure of the human frame, and that one model only, of all thofe into which the human frame may pafs, is endued with permanent vital powers." This author obferves alfo, that a greater number of abortive embryos are of the male than of the female fex; and this obfervation is confirmed by Soemmering, who extends it likewife to monfters.

It is extremely difficult to afcertain at what exact time the fœtus of an ovum becomes vifible; becaufe it is almoft always impoffible, in the human fubject, to afcertain the date of the impregnation. Dr. Baillie ftates, that he faw a preparation in the poffeffion of Dr. Combe, where, from peculiar circumftances, it had been afcertained that the conception was twenty-two days old, and where the fœtus was vifible, although extremely fmall. In an abortion, which came away after the firft ceffation of the catamenia, diffected by Blumenbach, and exhibited in the 4th table of his "Inftitutiones Phyfiologicæ," the amnios was about the fize of a large pea, but no veftige of the fœtus could be difcerned.

The following account of the fucceffive developement of the embryo is derived chiefly from Soemmering's work, "Icones Embryonum Humanorum," which is chiefly devoted to this fubject, and exhibits a moft beautiful feries of embryos from the earlieft period to the fifth month.

Generally fpeaking, the embryo grows the moft rapidly in the firft weeks after conception; the rate of its progrefs afterwards diminifhes to the ninth month: this growth, however, does not proceed uniformly at all times. It is gradually retarded in the fecond month, accelerated in the third; ftopped again in the beginning of the fourth, and continued

continued more rapidly from the middle of that month to the fixth; from which time it is again retarded till the period of maturity. A fimilar obfervation has been made concerning the chief vifcus of the embryo, by Walter, the fon. (Annot. Acad. de hepate, § 8.) He found that the rapid and prodigious growth of the liver did not continue beyond the end of the fourth month. It appears, moreover, that different parts of the body of the embryo grow very differently; and that fome arrive at a certain degree of perfection fooner than others.

The younger the embryo, the larger is the containing ovum. That part, therefore, in proportion to the fœtus, is the largeft, moft capacious, thickeft, and firmeft, in the earlieft periods after conception; and the fmalleft, thinneft, and moft tender, at the complete term of utero-geftation. At the middle of pregnancy it exhibits an intermediate ftate between thefe extremes.

In the firft and fecond months the embryo is completely bent; a little ftraightened in the following month, and afterwards, as the limbs increafe, convoluted into a kind of oval fhape. The head is brought forwards on the cheft during the whole period of utero-geftation. The younger the embryo, the greater is the bulk of the head, compared to that of the trunk; or, what is equivalent, the trunk is fmalleft at that time. The head muft confequently be the largeft when it can be firft diftinguifhed. In the firft month the head confiderably exceeds the fize of the reft of the body. Its growth goes on lefs rapidly after this time, and does not exceed that of the trunk; fo that at the age of five months, it bears a moderate proportion to the body. The younger the embryo, the fmaller is the face, in comparifon to the cranium. The pyramidal proportions of the temporal bones are particularly large in the firft month.

The neck, correfponding in fome degree to the fize of the head, is large and fhort; fo fhort, indeed, that it can hardly be recognized at all in the firft and fecond months, being marked by the flighteft conftriction. It is fcarcely diftinguifhable before the third month, on account of the head being bent forwards.

The extremities are fmalleft, in proportion to the trunk, in the youngeft embryo. They firft fhoot out from the trunk in the form of hemifpherical tubercles, like buds from a tree; are protruded a little further, and elongated in the fecond month; at which time, the upper limbs may be diftinguifhed into arms and hands, and the lower into legs and feet. Then the fingers arife, like little papillæ from the hands; the arms and fore-arms being more developed; at the fame time thighs, legs, and feet, may be diftinguifhed in the lower limbs, but the latter are ftill without toes. Thefe, however, fhoot out at the end of the fecond month, the fingers being at the fame time elongated. In the three firft months the upper limbs exceed the fize of the lower ones; they become nearly equal in the fourth; and in the fifth the lower ones have acquired that fuperiority which they afterwards retain.

The lower part of the fpine is at firft curved round towards the belly, fo as to refemble fomewhat the tail of a quadruped, when thrown between the hind legs. This prominence, fometimes called *tuber coccygeum*, is largeft in the two firft months, projecting beyond the lower limb, fo as to give the fpine a keel-like form. It gradually difappears in the third month, as the lower limbs are elongated.

The eyes are firft obferved, of the organs of fenfe, and are larger and more prominent as the embryo is younger. They are feen very diftinctly in a beautiful and, as it fhould feem, perfectly formed fœtus of the firft month, not larger than a middle fized pea, reprefented by Soemmerring. They may always be recognized, in the very youngeft embryos, by a deep black circle. Before the fecond month either the eye-lids are open, or fo thin, that the black pigment of the bulb is difcerned through them. Soemmerring thinks that the eye-lids are really open until about the tenth week, when they are clofed. After that time he has always found them firmly fhut, and the flit between them fhorter than the diameter of the globe. The circle of the iris, which is of the deepeft black, is completed fooner on the outer than the inner fide.

Very fmall pores are feen in the fituation of the external ears about the feventh or eighth week; the middle of the helix then rifes from the head, and is followed fucceffively by the tragus, antihelix, antitragus, lobulus, and upper part of the helix. The ears are completed by the formation of the concha and fcapha in the fifth month. Their proportions are ftill very different from thofe of the adult. Two fmall holes at firft occupy the fituation of the nofe, which itfelf gradually fhoots out about the feventh week; the dorfum, alæ and feptum are diftinguifhable in the eleventh week. The mouth is largeft in the firft months; and is open, without any lips. The latter parts are diftinctly formed about the eleventh week, and are firmly approximated, fo as to clofe the mouth, from the third month.

The genital organs, fcarcely diftinguifhable in the firft weeks, have acquired a confiderable fize at the commencement of the third month. The penis is large and prominent about the twelfth week, and the glans uncovered; the fcrotum is fmall and empty until the 9th month. Sometimes it is loofe, and diftended with water; fometimes corrugated. A fmall flit is fometimes difcerned in the female in the fecond month. The clitoris is large and prominent in the third month, like the correfponding organ of the male; fo that a female embryo, viewed laterally, might be miftaken for one of the other fex. About the fourth month the clitoris hangs more downwards, but is ftill large even in the fifth.

The umbilical chord at firft is fhort, but large; it fometimes equals the trunk in very fmall embryos. Afterwards its length increafes, but the relative breadth diminifhes. Its furface is always unequal and knotted.

Soemmerring has remarked that the fex of the youngeft embryos can be diftinguifhed, independently of the genital organs, if they are well proportioned. The moft ftriking difference is found in the ftructure of the thorax. That of the male is longer, more conical, formed of thicker ribs, and more prominent, with refpect to the abdomen and pelvis, than that of the female. In the latter, not only is the whole thorax fhorter, but alfo rather larger above, as far as the fourth rib, and therefore lefs conical. It is more diftant from the pelvis, on account of the greater interval between the laft rib and os innominatum, and lefs prominent, fo that where the body is either erect or fupine, the fymphyfis pubis is the moft prominent part in the female, and the thorax in the male fubject.

The abdomen begins higher in the female, and is large and prominent, expanding towards the genitals: we might fay that the female thorax is compreffed, and the abdomen tumid.

The diftinction is fo obvious, in refpect to the points now mentioned, that it will not only be readily obferved in the well formed embryos carefully compared; but it may even be thought ftrange that it fhould have hitherto efcaped obfervation. It will often be noticed, according to Soemmerring, in very fmall embryos; and if we can afcertain the fex by the organs of generation, we fhall readily perceive the diftinction in the form of the cheft.

The

The form of the head exhibits another ſexual diſtinction. It is on the whole larger in proportion to the body, but leſs rounded in the male than in the female: the occiput too is convex, ſo that the neck is hollowed in appearance, and the vortex is flattened. In the female the form is more globular, the occiput not prominent, and the neck conſequently not hollowed, and the vortex ſpherical.

Soms points of diſtinction may be ſeen alſo in the extremities; of which males have the ſuperior rather larger, the ſcapulæ ſtronger and more prominent, and therefore ſuitable to the ſtronger thorax of this ſex, the arms rather conical, the fore-arms more muſcular, the carpi broader, and the ends of the fingers more obtuſe. The lower limbs, adapted to the narrow male pelvis, are contracted above; the thighs are more ſlender, but the feet very ſtrong, with prominent malleoli and heels. The great toe exceeds the others in ſize very remarkably. The characters of the female are juſt the reverſe of theſe. The upper limbs are ſhorter, with the ſcapulæ more ſloping, the arms cylindrical, fore-arms ſlender, wriſts narrow, and ends of the fingers acuminated. The lower limbs, from the ſuperior breadth of the pelvis, are largeſt above, and diminiſh conically towards the knees; the heels and ancles are not prominent, and the great toe exceeds the others but ſlightly.

The ſpinous proceſſes of the inferior dorſal, and ſuperior lumbar vertebræ form a kind of projecting ridge in the back of the male, where the female preſents a depreſſion. The ſame difference is ſeen not only in the mature fœtus, but alſo in infants, and in the beſt proportioned boys and girls.

After deſcribing the progreſs of the embryo, and the differences of the male and female at this early period, Soemmering alludes to the much diſputed queſtion, whether the ſame powers of body and mind are beſtowed on all men, or whether there be not natural diverſity in theſe in different individuals, ariſing from original differences in the ſtructure of the frame. Attentive examination will ſhew that the bodies of embryos are marked by native traits of diſtinction, clearly recogniſable at a time, when neither food, education, habits, clothing, nor the operations of diſeaſe can have exerted any influence on them. Not to mention that fœtuſes are born, who, from too delicate an organization of the eyes, ſhun as the greateſt evil, that light, which is our firſt bleſſing; that imperfection in the ſtructure of the ears incapacitates ſome from the ordinary buſineſs of life; that others are almoſt cut off from human ſociety by deficient formation of the organs of voice; that mal-formation of the heart devotes ſome to an exiſtence of conſtant ſuffering, incapable of all exertion of body and mind, while deformity of the limbs circumſcribes the powers of others; that many are born without brain, and therefore utterly deſtitute of all mental faculties; putting all theſe circumſtances out of the queſtion, we notice great differences in the form and proportions of well made embryos. Wide differences exiſt in the ſhape, capacity, and firmneſs of that part of the head which lodges the brain; the countenance varies infinitely in the diſtance, ſize, and form of the organs of the external ſenſes; and there are marked diverſities in the volume of the cheſt, and in the ſtrength and form of the limbs.

To our account of the progreſſive developement of the different parts of the body, we ſhall ſubjoin a ſhort deſcription of the fœtus in its different periods. In the firſt month it conſiſts of a mere jelly; which is eaſily deſtroyed by very little touching, and evaporates almoſt entirely by heat. Authors have delineated embryos at the end of the firſt month of the ſize of a barley corn, or a pea. Soemmering gives a repreſentation of one very elegantly formed, no larger than a very ſmall pea. At this time the head is fully developed, and much exceeds the reſt of the body. The cranium is particularly large. The eyes and mouth are diſcernible. The figure of the whole is globular, the head and ſpine being ſtrongly bent towards each other. The poſition of the bodies of the vertebræ is diſcernible. The arms are two very ſmall tubercles; the lower extremities are the ſame; and the coccygeal tubercle is a larger prominence between the right and left of the latter limbs.

In the ſecond months the body becomes more firm and opaque, and its parts are more developed. The mouth and noſe are diſcernible; the eyes diſtinguiſhed by their blackneſs; and the ears can hardly be ſeen without the aid of the microſcope. The whole figure is ſtrongly incurvated, ſo that the coccygeal tubercle, which is larger than the rudiments of the lower limbs, nearly touches the head. At the end of this month the fingers and toes are diſcernible. Oſſification alſo commences; firſt in the clavicles, the large cylindrical bones, the lower jaw, frontal and occipital bone, &c. The body may now be half an inch long. The umbilical chord, very ſhort and thick, connects the child cloſely to the ovum. In the end of the third month the features are well formed. The forehead is very prominent. The general figure ſtill incurvated. The coccygeal tubercle diminiſhes and diſappears. The extremities are fully developed, and the fingers and toes perfectly diſtinct. The organs of generation are clearly ſeen; the penis and clitoris being very large, the nymphæ prominent, and the labia thick. The abdomen projects towards the umbilicus. Soemmerring has given a moſt exquiſite figure of a male embryo of about 12 weeks. The eye-balls are clearly diſtinguiſhable, larger than the opening of the lids. The noſe is well formed; and even the philtrum is clearly diſcerned in the upper lip. There is ſcarcely a veſtige of the coccygeal arch. The ſize and form of the ſcapula is evident, and the parts of the extremities in general diſtinctly ſeen; even the prominence of ſeveral muſcles, as the deltoid and biceps, gluteus major, vaſtus externus, &c.

In the fourth and fifth months the form and proportions approach conſtantly more nearly to thoſe which the body poſſeſſes in future. All the external parts are clearly diſtinguiſhable in the 14th and 15th weeks; except the hair and nails. Hitherto the fœtus was ſurrounded on all ſides by a large quantity of the water of the amnios; but as it grows now more rapidly than the ovum, it occupies the cavity of that part more completely. The head, in the fourth month, on account of its conſiderable ſize when compared to the body, ſinks conſtantly lower in the uterus. The fœtus comes completely in contact with its coverings in the fifth and beginning of the ſixth months, and conſequently the mother uſually begins now to feel its motions. On a very rare occaſion, Wriſberg ſaw clearly, for a few minutes, a ſlight motion of the arms and feet in a fœtus of 130 days. He could not diſcern any beating of the heart or arteries; neither did the muſcles of reſpiration act, when he inflated the lungs. In the ſixth month the membrana pupillaris of the eye is very viſible. The ſcrotum is ſtill empty and corrugated. Hair and nails are formed. The integuments ſtill hang rather looſely on the body, ſo that it has a lean and wrinkled appearance. In a fœtus of between 5 and 6 months, the length of the body was $10\frac{1}{2}$ inches; and that of the head, from the vertex to the lower jaw, $3\frac{1}{4}$ inches.

The length of three fœtuſes, whoſe ages were 158, 162, and 170 days, varied from 16 to 19 inches; and their weight from 1lb. 10oz. to 1lb. 13oz. All three came into the world alive; the pulſation of the arteries could be clearly felt,

felt, they refpired, but cried feebly. They moved their limbs freely, could not fuck, but fwallowed milk which was poured into their mouths; and they lived feveral hours.

The fize of the fœtus is confiderably increafed in the laft three months. The greater comparative growth of the limbs makes it appear as if the head became fmaller; the latter part is about one-third of the body in a newly born child. More fat is accumulated under the fkin, fo as to make the outline of parts more rounded.

The increafe at this time is rather in breadth and thicknefs than in length. The hair grows longer, and the nails more firm. The membrana pupillaris difappears, and the teftes defcend into the fcrotum. A child of feven months can live a few hours only out of the uterus, and thofe of eight months feldom live a fortnight.

The fœtus is fully developed and mature, fo that it can live out of the uterus at the end of the ninth calendar month. Experience has fhewn that children may live, when born a fortnight or three weeks before this time, if well taken care of; and it feems probable that a longer interval may elapfe before birth: but the neceffary uncertainty of the mode of reckoning renders the point dubious. The proportions of parts are very different in the fully grown fœtus from thofe of the adult. The head is extremely large; and the upper part of the trunk, and upper extremities, are very confiderable when compared with the lower parts.

"The fize and weight of a child's body at birth, fays Dr. Hunter, are generally over-rated in this country; infomuch that we are often told, even by thofe who ought to know, of children weighing from 15 to 20 pounds. So far is this from being true, that I never knew an inftance of a child which weighed 12 pounds, and the greateft number a little above half that weight. Dr. Macaulay was at pains, at our hofpital, to afcertain the ordinary bulk of new-born children, by firft weighing a great number indifcriminately as they were born; and then by giving an order to our matron to weigh occafionally all fuch as were of a remarkable fize in either extreme. Of feveral thoufands born in the Britifh hofpital at their full time, while the doctor's order was attended to, the fmalleft weighed about four pounds, the largeft 11 pounds two ounces, and by far the greater number weighed from five to eight pounds, avoirdupois. In cafes of twins, it feldom happens that each attains the weight of a fingle child. It has been remarked that the firft is ufually the ftrongeft."

The meafure and weight of the fœtus cannot be much depended on as criteria of its being mature or otherwife: yet if a child is much under between fix and five pounds, and fhorter than eighteen inches, it may be deemed immature. The following are alfo characters from which we draw the fame conclufion. Thinnefs of the body, and mobility of the fkin; a reddifh livid colour of the furface, particularly in the palms and foles, probably from the blood fhining through the thin integuments: and a fine woolly covering of the body. Mobility of the parietal bones, and great fize of the fontanell. Thinnefs and fhortnefs of the nails. The eyes being much clofed, and the child not looking about at furrounding objects. Coldnefs of the hands and feet.

The growth of the child, during its refidence in the uterus, is very confiderable compared to its fubfequent increafe. According to Haller, (Element. Phyfiol. lib. 29. fect. 4. § 17.) it increafes in the firft month to a bulk 300,000 times greater than its original fize. In the fecond month its increafe is to 48 times the fize it poffeffed at the end of the firft. From this time to the full period it will only average an increafe of 15 times for each month. At the end of the three firft years, the proportion to the mature fœtus is as 14 to 5: and at the end of the 22 following years, the proportion to an infant of three years, as 8 to 1. The increafe in the firft month of exiftence is to that of the laft month of growth as 4,885,717 to 1, and the whole increafe is from 1 to 108,000,000,000.

The number of twin-cafes to fingle births, according to Süffmilch, is as 1 to 65 or 70: by the fame calculator, one inftance of three children occurs in 6500 births; but probably it does not happen fo often. Four children are extremely rare, and the cafes of five are ftill more extraordinary. Twins live often enough; three children but feldom; and four, perhaps, never.

As a general obfervation, it may be ftated that male children are larger than females. Dr. Clarke of Dublin has given us fome interefting facts on this fubject from a regifter of 20,000 births, in a paper contained in the 76th vol. of the Philofophical Tranfactions. The weights of fixty males and fixty females were as follows, leaving out fractions:

Males.

℔s. - - -	4.	5.	6.	7.	8.	9.	10.
Number of children	0.	3.	6.	32.	16.	2.	1.

Females.

℔s. - - -	4.	5.	6.	7.	8.	9.	10.
Number of children	2.	9.	14.	25.	8.	2.	0.

He found the dimenfions of the head in the male to exceed thofe of the female: thus, of 120 children, fix only meafured more than 14½ inches round the head; and all thefe were males. This greater fize of males expofes them to greater difficulty in the birth, and confequently a greater number dies in that procefs; one half more than of females. The proportion of males born to females was nine to eight: but, in confequence of the greater mortality of the former in parturition, and the firft days of exiftence, the balance in favour of the male fex, out of 20,177 children, was only 483 at the end of a fortnight, although originally 1177. In countries where polygamy is allowed, more females are faid to be born than males.

Pofition of the Child.—"The fœtus in utero," fays Dr. Hunter, "is naturally contracted into an oval form, adapted to the figure and circumftances of its habitation. The vertex of the head makes one end of the oval, and the nates the other, one fide or edge of the oval is formed by the occiput, the back part of the neck, and the incurvated trunk; the other is made by the forehead, and the mafs of contracted and conglomerated limbs. The chin is clofe to the breaft, the trunk is bended forwards, the knees are clofe to the fore parts of the hypochondria, the legs drawn to the back parts of the thighs, the feet or lower parts of the legs decuffating each other; and the upper extremities contracted into the vacant fpace betwixt the forehead and knees. The moft common fituation of the extremities is not to be determined, as they are found to be a little different in different diffections; and in the living body they vary almoft every moment: thence the hands are feen indifcriminately on the head or face, or acrofs one another, or round the knees, or legs; and the legs are fometimes extended, and the feet are placed by the face; or one is in that pofition, and the other contracted, and the foot downwards.

"The navel-ftring, in paffing from the child to the placenta, is often varioufly entangled with the extremities, and frequently winds once or oftener round the neck.

"When there is a confiderable quantity of liquor amnii, the child takes the advantage of room, and the compofition of its parts is not fo clofe or globular. In proportion as there

there is lefs room, its figure is more compacted and moulded to the fhape of the cavity of the uterus. In two different cafes which I examined, there was fo little fluid furrounding the child, though the waters had not been difcharged, that the uterus had preffed and moulded all parts of the child into a very ugly form, as if it had been made of dough: and in fuch cafes the hands and more particularly the feet are liable to be compreffed and twifted into deformity, on account of their being projecting or pliant parts.

"With regard to the mother, the moft common fituation of the child, by far is, with its head downwards, and its nates at the upper part of the uterus. Once, perhaps, in twenty or thirty cafes, it is the contrary, and prefents, as they term it in midwifery, with its pofteriors. All the obfervations that I have been able to make in diffections, and in the practice of midwifery, would perfuade me that the child's head is naturally downwards through all the later months of utero-geftation."

By the pofition of the fœtus, as we have now defcribed it, rolled up and compacted into an oval figure, it takes up the fmalleft poffible room in proportion to its fize. It diftends the uterus too equably: and, in order to fulfil this object more completely, the intervals left by the inequalities of the child's body are filled with a fluid (the liquor amnii), and the whole is contained in membranes, fo as to form a perfectly oval mafs, diftending the uterus in all directions. Hence the fluid is more copious in younger embryos, becaufe they cannot be compacted into an oval mafs, and are too tender to diftend the uterus.

The peculiarities of ftructure, in various parts of the body, which diftinguifh the fœtus, will come under confideration, moft properly, when we defcribe the different parts in which they are found. We fhall, therefore, merely enumerate them on the prefent occafion.

The furface of the body is covered every where with a firm febaceous and white fubftance, called by fome vernix cafeofa. This covering, which renders the whole body greafy, cannot be wafhed off with plain water. It is infoluble in alcohol, oils, or pure water; but fome alkalies diffolve part of it, and form a kind of foap. It has often been fuppofed that this is a fediment from the liquor amnii; but that is very improbable, as the liquor amnii contains nothing unctuous, and there is none of it on the amnios or navel-ftring. It muft, no doubt, be a fecretion from the fkin.

The cutis, at firft thin and gelatinous, is covered by a cuticle in the earlieft ftages. Proper fat is not formed under the fkin before the fourth month; its place is occupied by a kind of jelly-like fubftance. Afterwards a pretty thick layer of fat is formed over the whole body, next to the fkin; but there is very little about the vifcera or internal parts: little among the mufcles, or in the bony ftructure. The fkin has a very red and vafcular appearance; and is faid to have this appearance, even in negroes, who are affirmed to change to the black colour a few days after birth. A foft woolly covering, feen particularly about the fides of the face, the back, fhoulders and ilia, in young embryos, difappears in the mature fœtus.

The ftate of the bones in the fœtus has been already alluded to in the article Bones. The jelly, of which the embryo is firft compofed, becomes more firm and confiftent in the fourth and fifth weeks. The materials of the parts which will afterwards be bones, are firft changed from the gelatinous confiftence, common to all the organs, into cartilage, at firft foft and tender, and affuming gradually firmnefs and elafticity. Its figure reprefents that of the future bone. It lofes its tranfparency, and white opaque fpots are difcerned in it (*puncta offificationis*) about the feventh or eighth week after conception. Thefe are firft obferved in the clavicles, ribs, vertebræ, large cylindrical bones, lower jaw and other bones of the face, os frontis, and occipitis. Large veffels are feen ramifying through the cartilage, and diftributed on the offifying points; thefe fecrete the offeous matter, which is there depofited. In fimple flat and fmall bones there is a fingle point, from which the offeous depofit extends into the reft of the bone. In moft others, particularly fuch as have an irregular figure, there are two, three, or more points, beginning at the fame time, and extending in their circumference until they meet. Such bones confift of certain pieces in the fœtus and young child, united by plates of cartilage. In other bones, particularly of the long kind, a principal point is obferved at firft, forming the body of the bone, or diaphyfis. Afterwards, fmaller points arife, efpecially at the ends, which had hitherto remained cartilaginous. Thefe are called epiphyfes, and, after their offification has proceeded confiderably, they are ftill connected to the body of the bone by a plate of cartilage. The offific points generally commence in the very middle of the cartilage, and extend thence into the cirumference. They differ in appearance in the different bones. In the flat ones, particularly of the head, they are thin reticulated fcales, perforated with innumerable fmall holes. The bony fibres, as they are called, extend, in thefe fcales, in a radiated manner, from the centre to their circumference: in the long bones they are fhort cylinders, with a fmall depreffion at each end, and poffeffing, apparently, parallel fibres: in the round bones they are globular granules; and in thofe of irregular figure, irregular in their outline, and generally poffeffing feveral points.

At the time of birth the officula auditus, labyrinth, and tympanum, are completely formed; all the other bones of the body are in a more or lefs incomplete ftate.

Phyfiologifts in all ages have attempted to explain how offification is effected, in what manner the cartilage is removed, and bony fubftance put in its place: which points we fhall probably underftand, when the hitherto unveiled myfteries of fecretion and nutrition are completely laid open to our infpection. In the mean time, inftead of bringing forwards a feries of old hypothefes, we fhall juft quote a paffage from Albinus, (Annot. Acad. lib. 7. p. 76). "We may conjecture that there exifts, from the firft origin of the embryo, rudiments of the cartilages, however fmall, foft, tender, and approaching to the nature of fluid: or at leaft that fomething is generated at that time, which is afterwards cartilage. But of the effential nature of cartilage or bone; of the manner in which cartilage is fubftituted in the place of bone; how either cartilage or bone is formed from our aliments; and what particular part of the fluids furnifhes the materials of this growth; we muft confefs ourfelves ignorant, and fhall probably remain fo."

The bones of the fœtus contain much more animal matter, and lefs earth than thofe of the adult; they are confequently of a greyifh colour, and acquire more of a white or yellow hue, as they advance towards their perfect confiftence. The extremities of the long bones, on account of their numerous blood-veffels, are dark coloured. The periofteum is ftrong and thick, and feparates eafily. The place of marrow is fupplied, in the embryo, by a mere gelatine, which acquires fomewhat of a fatty or oily nature towards birth.

The younger the embryo, fo much larger is the head in proportion to the trunk and extremities; fo much fmaller are the bones of the face compared to the cranium; fo much larger the organs of hearing; and fo much lower and flatter is the lower part of the face. The internal furface of the

fkull

skull has no marks arising from the convolution of the brain, nor any grooves for the blood-vessels. The cranium is at first merely membranous; the mode in which it is ossified has been already considered under the article Cranium. We may just enumerate here, as peculiarities of the fœtal cranium, the want of the frontal, sphenoidal, and maxillary sinuses, of the mastoid processes, and of the meatus auditorii externi, and the imperfect state of the ethmoid sinuses. The condition of the jaws, with their contained teeth, has been considered at large in the article Cranium.

The os hyoides has scarcely began to ossify at the time of birth.

The cavity of the thorax is proportionally larger than in the adult, and more conical. Blumenbach attempts to account for this size by the peculiarities in the circulation, and the consequently greater bulk of the liver. The pelvis is very small, so that there is no room in it for the urinary bladder. The individual bones of the chest and pelvis, as indeed of the rest of the body, will be more particularly described in other articles.

In the upper extremities, the clavicles begin to be formed very early, and attain to a very large size, when the rest of these limbs is extremely small. Thus in the tenth week they are three times the size of the femora. The scapula is also considerable at an early period, and has a piece of ossification double the size of that in the os innominatum. The carpus is completely cartilaginous, as is the tarsus in the lower limbs, excepting the astragalus and os calcis, each of which possesses a small ossific point. The ossification proceeds afterwards more rapidly in the tarsus than in the carpus, probably on account of the erect stature of the human subject, and the share which the tarsus has in supporting the body in that position.

All the bones of the embryo are uniform on their surfaces, where, in the adult, elevations and impressions are found.

The muscles can hardly be distinguished in the three first months, like the rest of the soft parts they seem composed of a mere jelly. The fibrous texture becomes discernible in the following months; when we are able to distinguish tendons also. Such, at least, is the observation of Wrisberg, in an embryo of $5\frac{1}{2}$ months. The tendons, which are fixed to the bones of the adult, terminate in the periosteum and perichondrium of the fœtus, and come away entirely with these membranes.

It is observed, by Soemmerring, that the tendons of the recti abdominis are proportionally broader and stronger than in the adult. The pyramidales are considerably larger. There is a round opening in the linea alba for the passage of the umbilical vessels. The muscles of the internal ear are nearly complete at the time of birth; the intercostals and diaphragm are considerably developed at the same period, and the muscles of the upper more than those of the lower extremities.

The eyes are developed at a very early period, being distinctly visible in the youngest embryos hitherto observed. They appear as black points at the end of the first month. The pigmentum is visible from the first, and is particularly thick and black. It has been correctly observed by Hogarth, that no part of the body grows so quickly, and is so perfect in the fœtus, requiring no additional growth after birth, as the iris. The cornea, crystalline lens, and vitreous humor, have a reddish tint. The lens is spherical in its figure. That great peculiarity of the fœtal eye, the membrana pupillaris, will be described in the article Eye.

The external ears are developed rather late, as there is not the slightest trace of them at the end of the first month. The meatus externus is often filled up with the vernix caseosa. The membranous texture of the whole meatus; the covering of the membrana tympani by the membrana mucosa; the attachment of that membrane to the annulus auditorius; the want of mastoid cells are all further explained in the article Ear.

The formation of the nose commences late; and the cavity is small and very incomplete in the fœtus, as a necessary consequence of the state of the bones of the head at that time.

The thyroid gland is large and vascular in the fœtus.

The thymus, which is of very considerable size before birth, and gradually disappears afterwards, will be considered under that article.

The lungs are small, collapsed, of a red colour, and sink in water.

The mammæ are large in proportion to the size of the body. The papilla is small, and not yet surrounded by an areola. The breasts of the male and female fœtus do not differ: they contain a whitish fluid, which can be forced out by gentle pressure, and sometimes flows spontaneously in children.

The abdomen is very large in the fœtus, and is drawn into a conical form towards the navel in young embryos. The great size of the abdomen may be accounted for by considering, that this cavity holds the bladder, and that the liver and renal capsules are very large. The distance from the end of the sternum to the pelvis, in a newly born child, is one-third of the length of the body; in the adult it is not one-fifth.

In the alimentary canal of the fœtus, we observe an almost entire want of valvulæ conniventes in the small intestine; and of appendices epiploicæ in the large. The appendix vermiformis is a gradual conical contraction of the cæcum. The intestines are more or less filled with a soft matter, of a yellowish green colour in the small, and of a dark green, approaching to black, in the large, called meconium. There is very little of this near the stomach; it increases in quantity lower down, and is the most abundant in the large intestines. But in the early months, the latter part of the canal contains no meconium. It is not distinguished by any peculiar taste or smell.

The pancreas is large, and the liver of immense size in the embryo. The kidneys are also considerable, and lobulated on the surface. The renal capsules equal the size of the kidneys. The urinary bladder is very large, equalling the dimensions of the stomach.

The situation of the testis in the abdomen, and its passage from that cavity into the scrotum, will be considered when the testis itself is described.

The heart is proportionally large in the fœtus, and occupies a considerable part of the thorax. Hence, on exposing that cavity, this viscus comes immediately into view, and seems in a manner to cover the lungs. The foramen ovale, by which the two auricles communicate; and the equal strength of the two ventricles, will be considered when the heart itself is described. The pulmonary artery of the fœtus divides into three branches, of which the middle is the largest. This is termed the *ductus arteriosus*, and it runs directly to join the aorta, immediately below the arch of that vessel. It is often named after Botal, although Galen and others knew it. Its length is about equal to a finger's breadth. It conveys into the aorta a large part of that blood which passed from the right auricle into the right ventricle; more than half of it, according to Haller. This canal is closed very soon after birth, often within a few days.

days. The umbilical veffels have been already defcribed in a former part of this article. The arteries are found obliterated from the navel to the bladder, very foon after birth, often within a very few days; near the bladder they are very much contracted, but not clofed, and give origin to the arteries of the bladder. The umbilical vein, and ductus venofus are clofed in the fame way. The mode in which the circulation is carried on through the parts now defcribed, is reprefented in the article CIRCULATION.

The coverings of the brain are at firft fo thin and tranfparent, that this organ can be feen through them. It is almoft fluid until the 5th or 6th month, and remains very foft even to the time of birth, fo that its diffection is difficult. It is always larger in proportion to the body, the younger the fœtus. The nerves are larger in proportion to the body.

Phyfiology of fœtal exiftence.—Some remarks on this fubject will be found in the article CIRCULATION. We have only to obferve, further, on the fubject of the connection between the mother and child, that the *mode* by which this is effected, notwithftanding it has been a favourite fubject of refearch with the greateft phyfiologifts of all ages, remains ftill a problem. The account which we have given of the ftructure of the placenta, fhews that the arteries and veins of the uterus have communications with the fubftance of the former organ; we are, however, entirely unable to ftate *how* the blood of the mother, or any nutritive fluid, is admitted into the umbilical veffels; although the obvious impoffibility of the fœtus deriving the materials of its growth from any other fource, leads us to conclude, without hefitation, that fuch admiffion muft take place. The reader will probably think that the following quotation, containing Mr. Hunter's opinion, does not tend to elucidate materially this obfcure queftion.

"The blood, detached from the common circulation of the mother, moves through the placenta of the fœtus, and is then returned back into the courfe of the circulation of the mother, to pafs on to the heart.

"This ftructure of the placenta, and its communication with the uterus, leads us a ftep further in our knowledge of the connection between the mother and fœtus; the blood of the mother muft pafs freely into the fubftance of the placenta, and the placenta moft probably will be conftantly filled; the turgidity of which will affift to fqueeze the blood into the mouths of the veins of the uterus, that it may again pafs into the common circulation of the mother; and as the interftices of the placenta are of much greater extent than the arteries, which convey the blood, the motion of the blood in that part muft be fo much diminifhed, as almoft to approach ftagnation." (Obf. on certain parts of the Animal Economy, p. 135.)

The exiftence of the fœtus is purely vegetative. Conftantly receiving the materials of its nourifhment and growth from the juices brought to the placenta by the veffels of the mother, it may be regarded as a new organ produced by conception, participating in the general life, but having its own peculiar life, which is, to a certain degree, independent of that of the mother.

The animal life, or that clafs of functions by which the animal is connected to the external world, has not yet commenced in the fœtus. Its ftate therefore cannot, with any juftice, be compared to that of a perfon afleep, in whom thefe functions are only fufpended: but in the fœtus they have not begun.

The fœtus can have no fenfations from the furrounding medium; its temperature being invariable, it can have no object of comparifon, which is effential to fenfation. The fenfes cannot act, becaufe none of the caufes, which excite them, have hitherto operated. That of touch, being dependent on the others, and ferving to rectify the conclufions which they tend to, muft of courfe be inactive. This inaction of the fenfes fuppofes a fimilar ftate of their nerves, and of the brain. Tranfmiffion of impreffions is the function of the former; perception of the latter: but neither of thofe acts can take place when there are no objects to be tranfmitted or perceived. Memory and imagination flow immediately from perception: judgment arifes from one of thefe three, and gives origin to the will. This connected feries of faculties has not begun in the fœtus, becaufe of the want of fenfations. The brain is capable of acting, and poffeffes all the requifites for action; it is not *excitability* but *excitation* that is wanted. The fœtus moves while contained as the uterus; and thefe motions are confidered as fymptoms of pregnancy. As all motion arifes from fome foregoing impreffion, and as the fenfes of the fœtus are completely inactive, it is difficult to affign a fatisfactory caufe for thefe movements of the child.

The functions of organic life, or thofe by which the nutrition and growth of the body are effected, muft commence almoft as foon as the fœtus is conceived. The matter of nutrition arifes in its body in an affimilated ftate, having been prepared by the mother: it enters immediately into the circulating fyftem, without traverfing the digeftive organs, then nearly inactive. The organs of excretion, which decompofe the body, as the lungs, fkin and kidnies, are alfo almoft inert. The fecretions have hardly commenced.

To the great fimplicity of the affimilative procefs in the fœtus, let us add the remarkable activity of the organs employed in it; an activity which depends on the greater proportion of their vital powers. The whole force of the animal economy feems to be concentrated on the two fyftems of circulation and nutrition; the proceffes of digeftion, refpiration, fecretion, and exhalation being exercifed, at moft, but feebly: the diminifhed energy of the latter being made up by the increafed power of the former. If we confider, moreover, that the organs of the animal life, condemned to a neceffary inaction, are gifted with a very fmall fhare of vital powers; we fhall fee, that nearly the whole of that living energy, which is deftined, in the fequel, to animate all the fyftems of the body, is, in the fœtal ftate, concentrated upon thofe which are concerned in building up the various parts; and confequently that the functions of nutrition and growth poffefs, at this age, an energy vaftly fuperior to that of any others.

We may refer the reader to a great number of works on the fubjects of the preceding article. In the eighth volume of the Elementa Phyfiologiæ, Haller has difplayed his ufual erudition and judgment in a complete collection of all the facts afcertained previoufly to his time. Dr. Hunter's Anatomia uteri humani gravidi, folio, and Soemmerring's Icones embryonum humanorum, folio, 1799, contain a perfect feries of reprefentations of the human ovum, and its contents from the earlieft time to its maturity. Dr. Hunter's Anatomical defcription of the human gravid uterus and its contents, publifhed after his death by Dr. Baillie, 4to. 1794, is a clear and plain defcription of the fubject. We may mention further, Wrifberg defcript. anat. embryonis, obfervationibus illuftr. 4to. Gött. 1764, or, in the third volume of Sandifort's Thefaurus; alfo, his remarks on the ftructure of the ovum in the Göttingen Commentaries for 1773 and 1783. Roderer De pondere & longitudine infantum recens natorum in the Göttingen Commentaries for 1753; and Wrifberg de vita fœtuum humanorum dijudicanda;

canda, in the fame work for 1773. Autenrieth fupplementa ad hiftoriam embryonis humani, Tubingen, 1797, 4to.

On the comparifon of the ftructure of the fœtus and adult, fee C. I. Trew de differentiis hominis nati et non nati, Altdorf, 1736. I. G. Roderer de fœtu perfecto, Strafburg, 1750. Portal in the Mem. de l'Acad. des Sciences de Paris 1770. A. and F. Roefslein de differentiis inter fœtum et adultum, 4to. Strafburg, 1783. On the nutrition of the fœtus, fee Leveillé fur la nutrition du fœtus confideré dans les mammiferes & les oifeaux. Paris an. 7. & Lobftein differtation fur la nutrition du fœtus, Strafburg, 4to. 1802. The moft complete book on the whole of the fubject, that is, the ftructure and developement of the ovum, and the anatomical peculiarities of the fœtus, is F. G. Danz Grundrifs der Zergliederungs kunde des ungebohrnen kindes in den verfchiedenen Zeiten der Schwangerfchaft, 2 vols. 8vo. 1793, which contains moft abundant references to all the fources of information on every part of the fubject.

Embryo, in *Vegetable Phyfiology*, εμβρυον, a *fœtus*, or *infant*, the Corculum of Linnæus, under which term we have already mentioned it, is the moft effential part of a perfect feed. When fexual impregnation has not taken place, this organ is defective, however perfect all the other parts of a feed may be, as in the *Cycas revoluta* which bore fruit at the bifhop of Winchefter's, and is defcribed and figured in the Tranfactions of the Linnæan Society, v. 6. 312. t. 29, 30. Here every part of the fruit and feed was apparently in the higheft perfection, except that a fmall cavity was only found in the place of the embryo, a defect doubtlefs to be attributed to the abfence of a male plant of the fame fpecies. The fame has been obferved in cucumbers and melons, whofe fruits are not the worfe in flavour on account of fuch a deficiency, though dates, when unimpregnated, are known to be much inferior in quality. The embryo or corculum is very confpicuous in the walnut, the garden bean, pea, lupine, &c. In a very poifonous plant, the *Jatropha Curcas*, figured in Gærtner, t. 108. f. 1. this author mentions as a remark of Mr. Boyle, that the nucleus or albuminous part of the feed may be eaten with impunity, if the embryo and cotyledons, or rather perhaps *plumula*, be taken away. This fame circumftance was pointed out by the natives of Sierra Leone to Dr. Afzelius and his companion Borone. The internal ftructure of the embryo, before it begins to vegetate, is obferved by Gærtner to be remarkably fimple, confifting of an uniform medullary fubftance, enclofed in its appropriate bark or fkin. When the vital principle is excited to action, veffels are formed, and parts developed, which feemed not previoufly to exift, as in the egg of a bird. The embryo is generally fituated within the fubftance of the feed, but not always, being entirely external to the body of the feed, though within the fkin, in the natural family of graffes or corn. In umbelliferous plants it occupies the very centre of the feed, and in that family its pofition is reverfed; whereas in compound or fyngenefious flowers, though equally central, it is erect with regard to the bafe or infertion of the feed. In the date and fome other palms the embryo is lateral and horizontal; while in the cocoa-nut and others it is erect, in the centre of the bafe of a large *albumen*. Its direction is either ftraight, curved, or even fpiral. Its form is moft fimple in plants that have only one cotyledon, or rather no proper cotyledon at all. S.

Embryo-*worms*. It is a matter of no fmall curiofity, to obferve the arrangement of the multitudes of the embryo-worms, as they are lodged in the bodies of the viviparous two-winged flies.

An accurate diffection of one thefe little animals, fhews very plainly the parts where the embryo-worms are inclofed. This diffection is eafily made with a pair of fine pointed fciffars, taking off the whole upper fhell of the body from the lower; and that part which covers the belly may be turned back upon the corcelet, without difturbing the internal parts by the operation; and the form and arrangement of the parts which contain the embryo-worms in thefe, will be found very different from that of thofe which contain the eggs in the common flies. Baker on the Microfcope, p. 115. 416. 417. 428. 430.

EMBRYOPTERIS, in *Botany*, from εμβρυον, an *embryo*, and πτερον, a *wing*, as appears from an examination of Gærtner's figure; though, from the conftruction of the word, it feems to be derived from πτερις, a *fern*, or *brake*. Hence this name, as it at prefent ftands, is liable to a double objection, as being compounded of one previoufly eftablifhed, *Pteris*, and ftill more as conveying a falfe idea of its own application. *Embryopterum* would have been correct and unexceptionable, and we fhould without fcruple have adopted fuch an alteration; but the name is altogether fuperfluous, the plant in queftion being a *Diofpyros*; under which head its generic character may be feen. We have, therefore, here only to add to that lift of fpecies the following.

Diofpyros glutinifera, Roxb. MSS, (Embryopteris peregrina; Gærtn. v. 1. 145. t. 29. f. 2. E. glutinifera; Roxb. Coromand. v. 1. 50. t. 70.) Stamens numerous. Leaves oblong, palifh beneath. Seeds eight or ten. This is a middle-fized evergreen tree, growing in the moift cool valleys among the mountains of the northern Circars, flowering in March and April. The natives call it Tumika, and eat the fruit, which Dr. Roxburgh defcribes as ftrongly aftringent, and not palatable. The Malays name it Mangoftan-utan, and the Dutch Lym-appel. The wood is of an indifferent quality, and not much ufed. The *branches* are fmooth. *Leaves* alternate, ftalked, oblong, fometimes inclining to elliptic, and occafionally a little heart-fhaped at the bafe; entire, fmooth, palifh beneath. *Flowers* white; the males in fmall axillary clufters; females on a feparate tree, folitary and larger. *Berry* globular, about two inches in diameter, of a rufty yellow, and covered with a rufty farina when ripe. Gærtner miftook the top of the fruit for the bafe, and hence erroneoufly defcribes the calyx as fuperior. He alfo miftook the radicle of the embryo for a fimple cotyledon, but his profound knowledge led him to fufpect that a cavity in the other extremity might be the real feat of the embryo, and that the circumambient fubftance was confequently a vitellus. We prefume this cavity to have arifen in the plumula, from a fhrinking of the parts, after the vital principle was extinct, his fpecimen being an old one, and therefore his fufpicion was, fo far, well founded. He defcribes the *albumen* as gelatinous in its centre, and diffolving in water, to which Dr. Roxburgh's fpecific name, and the Dutch appellation, both feem to allude. S.

EMBRYOTHLASTES, Εμβρυοθλαστες, in *Surgery*, an inftrument wherewith to crufh the bones of an embryo, or dead child; fo as to make it eafier of extraction, and prepare it for the embryulcus, to draw it out of the womb.

EMBRYOTO'MIA, from εμβρυον, *a fœtus*, and τεμνω, *to cut*, the operation of cutting into the womb, in order to extract the fœtus. See Cæsarian *Section*.

EMBRYULCUS, from εμβρυον, and ελκω, *to draw*, an inftrument ufed in extracting dead children. See Crotchet.

EMBS, or Ems, in *Geography*, a fmall town of Germany, which, till the peace of Luneville, belonged in part to the landgrave of Heffe Darmftadt, and in part to the prince of Naffau Dietz, to whom it has been ceded; is chiefly remarkable for five fulphureous baths in its neighbourhood.

Embs, or *Hohenembs*, a fmall diftrict of Germany, in the circle of Swabia, fouth of the county of Bregentz and the lake of Conftance, about 10 miles long and 5 broad, erected into a county by Charles V.

EMDEN, or Embden, a town of the kingdom of Holland, capital of the department or province of Eaft Friefland, which, till the year 1807, belonged to Pruffia, to the fovereign of which it had been fold by the United Provinces of the Netherlands, in 1744. It is fituated on the Ems, not far from the fea, and near the lake Dollart; 30 miles N.E. of Groningen. N. lat. 53° 20′. The harbour is commodious; it holds 400 veffels.

Emden had gained confiderable commercial importance, from having been declared a free-port by the king of Pruffia, in 1751. Its fituation was extremely convenient for the Dutch, to carry on their commerce with the greateft fecurity in time of war; particularly during the late wars between England and France, when the Texel was blockaded by the Englifh. Goods ufed to be forwarded, on the river Ems, to within a fhort diftance of Munfter in Weftphalia; from which city they were conveyed by land-carriage to the interior of the continent, to Switzerland, and Italy. In the year 1781, the number of fhips cleared outwards was 1025, inwards 1004; but in 1799, there entered at Emden inwards 3402 veffels, and 2151 failed outwards. In 1784, Emden had 273 veffels of the tonnage of 38,578 tons, befides 43 veffels for the herring fifhery; in 1804, the number of fhips employed in the carrying trade only, belonging to Emden, exceeded 500.

The population of Emden, in the year 1785, amounted to 7968 individuals, without the garrifon: in 1802, Emden counted 10,400 inhabitants. The herring fifhery produced annually near 1000 tons of herrings. It employed 60 boats, and a great many hands among the lower orders of the people.

EMEGIAGEN, a town and fortrefs of Africa, in the empire of Morocco.

EMENDALS, an old term ftill ufed in the accounts of the Inner Temple; where, fo much in emendals at the foot of an account, on its balance, fignifies fo much in the bank, or ftock of the houfe, for reparation of loffes, and other occafions.

EMENDATIO *Panis & Cerevifia*, the affize of bread and beer; or the power of fupervifing and correcting the weights and meafures belonging to them. See Assize.

EMERALD. Of this mineral there are two diftinct varieties: the true emerald, and the beryl or aquamarine, both of which we fhall proceed to defcribe.

True Emerald.—Emeraude Verte, *Fr.* Schmaragd, *Germ.*

The colour of emerald is pure prifmatic green, of various degrees of intenfity; but the deep-coloured varieties pafs occafionally into grafs and verdegris-green, and the lighter ones into greenifh-white. The only natural ftate in which it has been hitherto met with is cryftallized. Its primitive form is a regular hexahedral prifm; fometimes the lateral edges are replaced by fecondary planes, forming a dodecahedral prifm; or, the folid angles are replaced by fmall triangular facets; or, the terminal edges are bevelled, fometimes very flightly, and fometimes fo deeply as to prefent the appearance of terminal truncated pyramids. The length of the prifms feldom greatly exceeds their diameter. The cryftals are middle-fized and fmall, rarely large: they are generally implanted, and fometimes imbedded, and always occur in clufters. The internal luftre is vitreous and fhining; the fracture is fmall and imperfectly conchoidal, paffing into obfcurely foliated. It is tranfparent or tranflucent, and exhibits a double refraction. Its hardnefs is fomewhat fuperior to that of quartz. Sp. gr. 2.72 to 2.77.

It is fufible *per fe* before the blow-pipe, but with difficulty, into a femi-opake whitifh glafs. With borax it melts eafily, and without effervefcence. Its conftituent parts, according to Vauquelin and Klaproth, are as follows:

	Vauq.		Klapr.
Silex -	64.50	—	69.
Alumine -	16.	—	15.
Glucine -	13.	—	12.5
Lime -	1.6	—	0.25
Oxyd of chrome	3.25	—	0.25
Oxyd of iron	0.	—	1.
Water -	2.	—	0.
	100.35		98.

It is at prefent found only in Peru, in the valley of Tunia or Tomana, between the mountains of New Granada and Popayan; and near Puerto Viejo, in the diftrict of Manta, in the fame province. It is faid to occur in veins, paffing through argillaceous fchiftus, and other primitive rocks, and is accompanied by quartz, felfpar, black fchorl, mica, calcareous fpar, and iron pyrites.

Emerald is reckoned among the gems, and when of a fine colour, and without flaws, is highly efteemed. The moft magnificent fpecimen known of this mineral was prefented to the church of Loretto, by one of the Spanifh kings: it confifted of a mafs of white quartz, thickly implanted with emeralds, more than an inch in diameter.

The emerald is fuppofed by Dutens and others to have been unknown to the ancients; and it is certain, that feveral of their defcriptions of the fmaragdus are not at all correfpondent, except in colour, to the modern emerald. But among the twelve kinds of fmaragdus, or rather pfeudofmaragdus, enumerated by Pliny, one of them, and that the moft valued, appears to be the real emerald. With regard to its colour, this naturalift fays, "Nihil omnino viridius comparatum illis viret." He ranks it, in eftimation, immediately after the diamond and pearl; and adds, that fo pleafing was its tone of colour, that by common confent the engraver was ordered to fpare it; "Quapropter decreto hominum iis parcitur, fcalpi vetitis." The emeralds of the ancients were procured from Ethiopia; but thefe mines have now been for many ages forgotten and neglected; nor is it certain that any except the Peruvian emeralds are now extant. The only one that may with any probability be referred to an African origin, is that with which pope Julius II. adorned the papal tiara: for as this fovereign died in 1513, and the enterprize of Pizarro againft Peru did not take place till 1545, it is not unreafonable to conclude that the emerald in queftion is not an American one. There are two fpecimens, which formerly obtained great eftimation as invaluable Ethiopian emeralds, which the fuperior accuracy of modern knowledge has ftripped of their value, both in the eyes of the naturalift and of the jeweller. The one is a tabular mafs, of the weight of 28 *lbs.* now in the abbey of Reichenau, and which formerly belonged to Charlemagne: this Mr. Coxe has afcertained to be green fluor. The other is the "Sacro cattino de Smeraldo orientale," which was depofited in the treafury of Genoa, and was not allowed to be feen except in confequence of an order from the fenate: in this the acute eye of M. Condamine

mine detected fome air-bubbles, which induced him to confider it as only green glafs; and fubfequent examination has fully confirmed his fufpicion.

Beryl, or *Aquamarine*.—Emeraude verte bleuatre, Hauy. Edler beril, Wern. Its colour is mountain-green, paffing into whitifh-green, yellowifh-green, wine-yellow, and honey-yellow, or blueifh-green, paffing into fmall and fky-blue. Its colours are almoft always pale; and when two exift in the fame cryftal, they are generally arranged in alternate layers. The primitive form and varieties of cryftallization are the fame as thofe belonging to the true emerald; but the actual and proportional length of the prifms is much greater. The lateral planes of the cryftal are ftriated longitudinally, fo as fometimes to give the prifm a cylindrical appearance. The joints perpendicular to the axis are generally very diftinct, and moft commonly are plane furfaces; but fometimes, like thofe of articulated bafalt, they are formed by a convex protuberance let into a cup-fhaped concavity. Another fingular accident to which this mineral is fubject is, that a prifm, which at its lower end is folid, terminates occafionally in a brufh-like extremity, compofed of numerous fmall prifms. Sometimes a joint is fo difpofed, that it is no longer perpendicular to the axis of the prifm; in confequence of which, an elbow is produced, as if the prifm had been broken acrofs, and the pieces ill cemented together again. Sometimes, again, the axis of the prifm is perforated. The fize of the cryftals varies from capillary to 18 inches long by 2 or 3 in diameter. Its external luftre is fhining and gliftening; internally, it is brilliant and vitreous. The crofs fracture is fmall, and imperfectly conchoidal; the longitudinal fracture is foliated. It is commonly tranfparent, paffing into tranflucent; its hardnefs is nearly the fame as that of the emerald. It is electric by friction, and often phofphorefcent. Sp. gr. 2.68 to 2.72.

According to the analyfes of Vauquelin and Rofe, it is compofed of,

	Vauq.		Rofe.
Silex -	68.	—	69.
Alumine -	15.	—	14.
Glycine -	14.	—	14.
Lime -	2.	—	0.
Oxyd of iron	1.	—	1.
	100.		98.

Beryl occurs imbedded in primitive rocks, alfo in veins accompanied by quartz, felfpar, fluor fpar, garnet, mica, and topaz. It is found in Brazil, in Saxony, in the fouth of France, near the village of Barat, whence very large but ill-coloured cryftals have been procured, and occafionally in the higheft mountains of Aberdeenfhire. But the fineft fpecimens of all come from Siberia, and are found chiefly in three places of this vaft country.

Firft, in the Uralian mountains, about 25 leagues to the north of Ekaterinbourg. The fpecimens that come from this mine are of a fmall fize, but a very good colour.

Secondly, in the Altaic mountains, between the Ob and the Irtifch. The cryftals from this mine are large, and of a greenifh-blue colour, but coarfe, and mixed with quartz.

Thirdly, in the granitic mountain of Odon Tchelon, in Daouria. This is by far the moft interefting and the richeft mine. There are in fact three different mines at different heights on this mountain, from which beryls are procured: that fituated the loweft is in a mafs of femi-decompofed granite, mixed with ferruginous clay and nodules of Wolfram; in this there are irregularly diffeminated minute prifms of beryl, rarely exceeding an inch in length, and of a greenifh-yellow colour. About 800 yards above this mine is an irregular vein of micaceous clay, from which are procured the moft valuable cryftals; their colour is a pure pale green, and their dimenfions not very unfrequently amount to feven or eight inches in length by two in diameter. At the very fummit of the mountain is fituated the third mine, in a vein of white indurated clay, mixed with arfenical pyrites: the beryls that it yields are generally of a greenifh blue colour, but fometimes of a pure but pale fky-blue, and very tranfparent.

Beryl is ranked by courtefy among the gems, but its value is greatly inferior to that of the emerald.

Emerald, *Oriental*, is a greenifh variety of fapphire.

Emerald, *Counterfeit*. The manner of making counterfeit emeralds in pafte is this: take cryftal prepared, two ounces; common minium, or red lead, four ounces; mix thefe well together, then add of good verdegris two pennyweights, and crocus martis made with vinegar, eight grains. Mix all thefe well together, and fet the whole in the hotteft part of a potter's furnace, as long as the fire lafts. It muft be put in a ftrong crucible, and covered with a lute. When it is cold take off the lute, and, if it is baked enough, it will be clear to the bottom; otherwife relute the pot, and put it into the furnace again. Twenty-four hours commonly are fufficient for making this; fometimes it requires a little more. The pafte, thus made, is harder than ordinary, and is of a fine colour, and capable of a good polifh. Neri's Art of Glafs, p. 128.

If the pafte be defired of a very deep emerald colour, take prepared cryftal one ounce; red-lead, fix ounces and a half; of verdegris, three penny-weights and thirteen grains; and of crocus martis, made with vinegar, ten grains. This requires a longer baking than the other, and is lefs hard, though of a deeper colour.

The proportions of thefe ingredients may be varied at pleafure, and the colour be made of all degrees of deepnefs; but the more lead is added, the more baking is required, and, after all, the pafte will be fo much the fofter.

Emerald *Colour*, in the *Glafs Trade*. The way of giving this beautiful dye to glafs is this: in the pots of melted metal, made of polverine, and without manganefe, when the matter is well purified, put a little crocus martis calcined with vinegar. About three ounces of this crocus is enough for a hundred weight of glafs; let it ftand till thoroughly mixed, then put into every hundred weight of metal two pounds of calcined brafs; this muft be added at fix different times, letting the metal ftand two hours every time. When this is all in, make a proof of the metal; and if it has any blueifhnefs, add more crocus martis, a fmall quantity at a time. When the whole is of a fine leek-green, let it ftand twenty-four hours to mix thoroughly, and then work it. Neri's Art of Glafs, p. 51.

Emerald, or *Emeraud*, in *Heraldry*, is ufed in lieu of vert, or green, in blazoning the arms of dukes, earls, &c.

EMERGENT Year, in *Chronology*, is the epocha, or date, whence we begin to account our time.

Our emergent year is fometimes the year of the creation; the Jews ufe that of the deluge, or the Exodus, &c. The emergent year of the Greeks was the eftablifhment, or at leaft reftoration, of the Olympic games by Iphitus. The Romans accounted their years from the building of the city, ab u. c. that is, ab urbe condita. See Epocha.

EMERITA Augusta, in *Ancient Geography*. See Augusta, and Merida.

EMERSA, Folia, in *Botany*, applies to fuch leaves of aquatic plants as are raifed above the furface of the water, and

and which are ufually of a different figure from thofe that are *immerfa*, or funk under water. See LEAF.

EMERSION, in *Phyfics*, the rifing of any folid above the furface of a fluid fpecifically heavier than itfelf, into which it had been violently immerged, or thruft.

It is one of the known laws of hydroftatics, that a lighter folid, being forced down into a heavier fluid, immediately endeavours to emerge; and that with a force, or moment, equal to the excefs of a weight of a quantity of the fluid above that of an equal bulk of the folid.

Thus, if a folid be immerged in a fluid of double its fpecific gravity, it will emerge again, till half its bulk, or body, be above the furface of the fluid.

EMERSION, in *Aftronomy*, is when the fun, moon, or other planet, begins to re-appear, after its having been eclipfed, or hid by the interpofition of the moon, earth, or other body.

The difference of longitude is fometimes found by obferving the immerfions and emerfions of the firft of Jupiter's fatellites.

The immerfions are obferved from the time of Jupiter's being in conjunction with the fun, to his oppofition; and the emerfions, from the oppofition to the conjunction; which two intervals are ufually fix months a-piece, and divide the year between them.

But when Jupiter is in conjunction with the fun, and fifteen days before and afterwards, there is nothing to be obferved; the planet, with his fatellites, being then loft in the light of the fun.

EMERSION is alfo ufed when a ftar, before hid by the fun, as being too near him, begins to re-appear, and to get out of his rays.

EMERSION, *Scruples*, or *Minutes of*, an arch of the moon's orbit, which the moon's centre paffes over, from the time fhe begins to emerge out of the fhadow of the earth to the end of the eclipfe. See ECLIPSE.

EMERSON, WILLIAM, in *Biography*, an eminent Englifh mathematician, was born in 1701, at Hurworth, a village near Darlington, in the county of Durham. His father kept a fchool, and was a good mathematical fcholar: to him, and to a young clergyman, the fubject of this article was chiefly indebted for his early inftruction in the different branches of the mathematics. He attempted to keep a fchool himfelf, but foon found his temper unfitted for the tafk; and, on the death of his parents, having come into the poffeffion of a moderate competence, he devoted himfelf to a life of ftudious retirement, where he compofed a great number of treatifes, by which his name has been long known to all lovers of fcience; and from the profits of which he redeemed his little patrimony from fome incumbrances which he found on it. He enjoyed a good ftate of health till nearly the clofe of his life, when he had frequent and very fevere attacks of the ftone; a difeafe to which, in the year 1782, he fell a victim, when he had attained to the 81ft year of his age. Mr. Emerfon was fingular in his behaviour, drefs, and converfation. His manners were rough, coarfe, and often very difagreeable. In converfation, he was pofitive, dogmatical, and impatient of contradiction. His relaxation from ftudy was fometimes working in the fields, and fometimes the amufement of fifhing, to which he was much attached. When he had any treatife for publication, he always went to London, to attend to the printing himfelf. He was an able mathematician; but his ftyle as a writer is not adapted to fmooth the path of fcience for beginners. His works, which are very numerous, are now chiefly fuperfeded by other and more popular writers, who have had the better art of facilitating the ftudies of young perfons, by a more agreeable ftyle, and an eafier method of demonftration. His "Treatife on Mechanics" is that which is now beft known, and to which reference is more frequently made than to any of his other works.

EMERSTORFF, in *Geography*, a town of Germany, in the archduchy of Auftria, feated on the Danube; 6 miles above Crems.

EMERUS, in *Botany*. See CORONILLA, fpecies 1.

EMERY, *Schmiergel*, Wern. in *Mineralogy*. Its colour is greyifh-black or blueifh-grey. It occurs maffive and diffeminated: when in mafs, it is generally encrufted with magnetic iron ore, pyrites, and mica; the latter fubftance frequently penetrates the whole mafs, giving it, when broken, a filvery appearance. It poffeffes a gliftening or glimmering luftre. Its fracture is fine-grained uneven, paffing into fplintery. In hardnefs it is about equal to Adamantine fpar, cutting flint and rock-cryftal with great eafe. It is heavy, and not very eafily frangible. When moft free from iron, it confifts, according to Tennant, of

Silex	- -	3.4
Alumine	- -	92.
Iron	- -	4.6
		100.

When highly impregnated with iron, this ingredient amounts to about 36 *per cent.*

Emery is procured from the iflands of the Archipelago, efpecially from Naxos; alfo from the neighbourhood of Alocer, in Eftremadura, in Spain. Much of the emery ufed in France is imported from the iflands of Guernfey and Jerfey, in the Britifh channel. It is alfo found at Ochfenkopf, in Saxony, in beds of talc and fteatite.

This mineral is largely ufed for cutting and polifhing, by lapidaries and workers in glafs and metal. The mode of its preparation is very fimple. Being pulverized in an iron mortar, it is carefully wafhed over, and thus feparated into five or fix different degrees of finenefs, according to the work in which it is to be employed.

EMER-YAPAR, in *Geography*, a town of Afia, in Thibet; 17 miles from Cha-tcheou.

EMESA, EMISA, *Emiffa*, or *Emefus*, in *Ancient Geography*, an ancient city of Syria, fituated on the eaftern bank of the Orontes, between Apamea and Laodicea Cabiofa. During the troubles which agitated Syria, this city was feized by an Arabian, named Sampficeramus, who, affuming the title of king, held Emefa and its fmall territory, undifturbed by the Seleucidæ, engaged in more important concerns. He left two fons, Jamblichus and Alexander; the former of whom fucceeded his father, and was much attached to the Romans. In the civil wars of Rome, he took part firft with Cæfar againft Pompey, and afterwards with Antony againft Octavianus. After the victory gained by the latter at Actium, Antony, dreading his concurrence with other princes in favour of the conqueror, and upon this fufpicion, having got him into his power, caufed him to be put to a moft cruel death. Upon his death, Antony beftowed the kingdom on his brother Alexander, who, continuing faithful to his benefactor in his greateft diftrefs, was taken prifoner by Octavianus, and not only deprived of his kingdom, but carried in triumph to Rome, and afterwards put to death. His fon, Jamblichus II., was favoured by Octavianus, and reftored by him to his father's kingdom, after he had remained for fome time in a ftate of exile. He had fome fucceffors, who fupported the dignity of this fmall kingdom; but the laft of its kings, whofe name is recorded

corded in hiftory, was Azizus, who, falling in love with Drufilla, the fifter of Agrippa Minor, embraced the Jewifh religion, in order to marry that princefs. This fmall kingdom was afterwards, as we may prefume, feized by the Arabians; for we find that, fome years after, it was poffeffed by the Ituræans. Emefa was the birth-place of the emperor Heliogabalus; and it was one of the cities in which the Romans planted colonies. It is now called *Homs;* and though formerly a ftrong and populous city, it is at prefent only a large ruinous town in the pachalic of Damafcus, containing not more than 2000 inhabitants, partly Greeks and partly Mahometans. An aga refides here, who holds, as a fub-renter of the pacha of Damafcus, the whole country as far as Palmyra. The pacha himfelf holds this farm, as an appanage deriving immediately from the fultan. Hama and Marra are held in the fame manner; and thefe three farms pay 400 purfes, or 500,000 livres (about 20,000*l.*), but they produce nearly four times that fum. Volney's Travels in Egypt and Syria, vol. ii.

EMETICS, in *Medicine,* from ἐμέω, *I vomit,* thofe fubftances which excite vomiting, or caufe the ftomach to reject its contents upwards.

Medicines of this clafs have been employed, for the purpofe of clearing the ftomach, from the earlieft ages to which any authentic records of practice extend. In the time of Hippocrates, indeed, the ufe of emetics feems to have been very general, not only as a remedy in difeafes of fome feverity; but as a popular expedient for relieving flight indifpofition, efpecially the occafional derangements of the organs of digeftion, brought on by indulgence in eating and drinking. Hippocrates even recommends them to the healthy as a prefervative; and he has ftated many precepts with refpect to the proper times for adminiftering them, in conjunction or alternation with fafting, bathing, exercife, &c. under various circumftances of health and difeafe. See his treatife on Diet, book iii. and elfewhere. Yet it muft be remarked, that the catalogue of emetic fubftances in the poffeffion of the ancients was very imperfect, in comparifon with our own; and confifted either of uncertain and almoft inert articles, on the one hand, or of fevere and rather unmanageable fubftances on the other. Hippocrates prefcribed powdered hyffop in about a gallon of water, as a vomit for corpulent men, with the addition of a little vinegar and falt; it was to be drank at firft gradually, and afterwards more quickly.

Celfus has likewife detailed a fet of rules, relative to the ufe of emetics, among the means of reducing the habit, if too plethoric. He fays, " emetics are more ufeful in the winter than in the fummer, becaufe in that feafon there is more phlegm, and a greater heavinefs in the head. They are of no advantage to thofe who are flender, or who have a weak ftomach; but are ufeful to plethoric, and bilious people, whether they have fuffered from repletion, or have their digeftion impaired. For if they have taken more than the digeftive power is able to concoct, they ought not to rifk the danger of its corrupting; and if it is already corrupted, it is proper to expel it in the moft expeditious way poffible. Hence, when any perfon is attacked with bitter eructations, together with pain and weight in the region of the ftomach, let him immediately refort to a vomit. It is alfo proper for thofe, who have a fenfe of heat in the breaft, a frequent fpitting or naufea, or a noife in the ears, or humour in the eyes, or a bitternefs in the mouth," &c. " I grant," he obferves farther, " that emetics fhould not be taken for the fake of indulging a luxurious appetite; but that they are advantageous in fome forms of difeafe, I know from experience: I admonifh thofe, however, who wifh to enjoy good health and attain old age, not to make a daily ufe of them. If any one wifhes to vomit after taking food, he fhould firft drink warm water only, if he vomits eafily; if with fome difficulty, he fhould add a little falt or honey to the water: but he that intends to vomit in the morning, fhould drink *mulfe* (a mixture of wine and honey,) or eat hyffop, or radifh, and then drink warm water, as has been already directed. All the other fubftances, which the ancient phyficians prefcribed, are injurious to the ftomach. If that organ is weak after the vomit, a little food fhould be taken, of a proper kind; and if the fauces have been much irritated, three cups of cold water may be drunk. He who has ufed a vomit, if it were in the morning, ought to take a walk, then anoint, and afterwards fup; but if after fupper, he fhould bathe on the following day, and fweat in the bagnio: he will do well to make the next meal flight, and that of roafted meat, with auftere and unmixed wine, ftale bread, and food of the drieft kind." He concludes with this obfervation: " he that chufes to vomit twice in the month, will find it more advantageous to do it for two days fucceffively, than if he were to repeat it on the fifteenth day; unlefs this intermiffion fhould occafion a weight at his breaft." De Medicinâ, lib. i. cap. 3.

Thefe ftatements fhew, that the ufe of emetics conftituted a part of that regimen, among the ancients, in which more of their time was occupied, and more attention beftowed, than the moderns in this country are accuftomed to give to the fubject. They alfo reforted to vomiting, as a remedy in fevers, and other difeafes. See Celfus, lib. iii. cap. 7. And emetics, as well as purgatives, were employed after the termination of fevers, upon theoretical principles, to evacuate the remainder of the morbid matter, after its virulence was fuppofed to be fubdued by concoction. In the ufe of purgatives, we find fome remains of this theory among the people, as well as among the ignorant part of the profeffion, even at the prefent day. Hippocrates feems to have believed, that this remnant of the morbid matter, like a piece of leaven, if retained after the crifis, was the occafion of the return of the difeafe. " Quæ per morbos poft judicationem intus relinquuntur, morborum reverfiones faciunt." Aphor. 12. fect. ii.

The direct effect of an emetic is the evacuation of the contents of the ftomach. Hence the principal purpofe, for which it may be ufed, would feem to be the removal of morbid or noxious matters from that organ; whether confifting of its own fecreted juices, in a difeafed condition of indigeftible food, either from quantity or quality, of poifons, or of other noxious fubftances, which may have been fwallowed. Hence the vulgar refort to emetics on every occafion of what is popularly called a " foul ftomach," or of " bile on the ftomach." Thefe conditions are prefumed to exift, when fuch fymptoms as the following are prefent: when there is a want of the ufual appetite, or, in addition to that, a loathing of food; or, when, after food, or during the time of its digeftion, an uneafy fenfation of fullnefs, weight, and diftenfion is felt in the ftomach, efpecially if accompanied with heartburn, flatulency, and acid or bitter eructations; and to thefe may be added frequent head-achs, particularly in the morning.

Now, although it cannot be queftioned, that the removal of the prefent contents of the ftomach, in fuch cafes, generally affords more or lefs relief; it is not the lefs certain, that this relief is feldom very durable; for the noxious matters are more frequently to be confidered as the effects, than as the caufes of the morbid condition of the ftomach: they depend moft commonly on the weaknefs and lofs of tone in the mufcular fibres of the ftomach, and the imperfect fecretion of the gaftric juice; and thefe, it is obvious, are not to be cured by by vomiting, though their consequences may be relieved by this for a longer or shorter time. On the contrary, there can be no doubt, that frequent vomiting renders the stomach less able to retain, what is thrown into it, and to weaken its powers of digestion. " They are unhappy," says Dr. Cullen, " who trust to this mode of relief, and have therefore frequent recourse to it; for I am certain, from much experience, that frequent vomiting hurts the tone of the stomach, and often makes the symptoms of indigestion recur more frequently and sooner than they otherwise would have done." Treatise on the Materia Medica, vol. ii. p. 465.

The same author remarks, that the effects of vomiting, and the degree of disease that required it, are commonly judged of by the vulgar, and often by physicians, though not always fairly, by the appearance of the matter thrown up. For example, there is commonly thrown up a considerable quantity of viscid mucus; and to this the symptoms of the disease are frequently imputed. " It is, indeed, possible," he adds, " that an unusual accumulation of mucus in the stomach may be the cause of want of appetite, and other symptoms of indigestion, but not always so justly as might be imagined. The mucous follicles of the stomach constantly pour out a considerable quantity of this matter; a considerable quantity is to be found in the stomachs of the most healthy persons: and the experiments of M. Senac shew, that there is always a considerable quantity of it in the mucous follicles, which may very readily be squeezed out very copiously in vomiting. It is not, therefore, to be judged that the quantity, and even a large quantity, thrown up by vomiting, had either previously existed in the cavity of the stomach, or that such a mucus had been the cause of the morbid symptoms, indicating therefore the repetition of vomiting. It has been upon occasions of this practice, that I have known repeated vomiting, not only to give no durable relief, but rather to increase the supposed cause."

The evacuation, however, occasioned by an emetic, is not confined exclusively to the stomach; the upper part of the intestines, namely, the *duodenum*, and even part of the *ilium*, is commonly evacuated at the same time. The peristaltic motion of the alimentary canal may proceed either downwards or upwards; and when the action of any part of it is directed in one way, the next adjoining portion follows in some degree the same direction. Whence, in vomiting, as the peristaltic motion of the stomach is directed upwards, so the motion of the duodenum, is directed in the same way, and it pours its contents into the stomach; from which it will appear that a considerable portion of the upper part of the intestines may be evacuated. The most clear proof of this inverted motion of the duodenum, in vomiting, is, that, especially after repeated vomiting, a quantity of bile is poured into the stomach, and is in consequence thrown out by the mouth. This frequent appearance may depend entirely upon the quantity of bile for the time present in the duodenum; but it probably extends farther. In the action of vomiting, as the contraction of the diaphragm and of the abdominal muscles concurs at the same time, the whole viscera of the abdomen are strongly pressed: this pressure must affect the gall bladder and the biliary ducts, and occasion them to pour out their contents very largely, which, being thrown into the stomach from the *duodenum*, may be ejected by vomiting. It is commonly supposed, indeed, by the vulgar, that the bile thus thrown up existed previously in the stomach, and in some instances it may have been so: but it is more probable that it had been brought from the *duodenum*, and even from the gall-bladder and biliary ducts in the way just explained. For had the bile been previously lodged in the stomach itself, it might have appeared in the first vomitings, as well as in the last; but it happens, in almost all instances, that the bile is thrown out by the mouth only after repeated vomitings, and often after repeated strainings in the organs employed in that act.

Dr. Cullen attributes some good effect to the pressure on the liver and abdominal viscera, just alluded to, in obviating the stagnations which are liable to occur in the system of the *vena portarum*, and which lay the foundation of obstinate diseases. He affirms, that he knows no means of expediting the circulation in the liver so powerful as that of vomiting. Other writers have expressed an opinion of the advantages derived from this mechanical pressure and conquassation of the viscera of the abdomen, in exciting the mesenteric circulation, as well as that of all the glands, and consequently in favouring and aiding all their secretions. (See Dr. Fothergill, De emeticorum usu, &c. Cullen, loc. cit. p. 468.) Dr. Cullen, however, considers the effects of this mechanical compression and motion as most evident in the viscera of the thorax, especially in promoting expectoration: hence the utility of vomiting in catarrhal affections, more particularly the chronic catarrh of old people. He also allows that it may be useful in many cases of pulmonary consumption; but justly adds, that we cannot, either from theory or experience, find any reason to believe that frequent vomiting is adequate to cure that disease.

There is also another indirect action of vomiting, which is beneficial to the system, arising from the sympathy between the stomach and the skin. This sympathetic consent between the vessels of the skin and of the stomach is very great, insomuch that the several states of each may be communicated to those of the other. Thus, wetting the skin relieves thirst, as was proved by Capt. Bligh and his party; and in the same way the action of an emetic excites particularly the action of the vessels on the surface of the body; and this action is excited by doses of these medicines, which are not sufficient to excite vomiting. Hence most of the substances employed as emetics are capable of exciting perspiration. We are disposed to believe that a similar sympathy, between the stomach and the vessels in the cells of the lungs, is the cause of the utility of vomiting in producing expectoration, rather than the mere mechanical pressure of the lungs.

The action of vomiting, when excited rather briskly, by the general shock or conquassation of the whole frame, affects the nervous system at large as a stimulant. In this way the utility of an emetic, in the commencement of a continued fever, is partly to be accounted for. Dr. Cullen, indeed, attributes the advantages of vomiting in that case to the relaxation of the spasm of the extreme vessels in the skin, according to his theory of fever; and partly, perhaps, the operation may be accounted for in this way: but it is to be remarked, that other expedients, which have nothing in common but the general shock which they occasion to the nervous system, also contribute to cut short or to alleviate fever, under the same circumstances; a brisk purgative, for example, cold affusion, or the shower-bath, &c.

It is also observed by Dr. Fothergill, who ascribes considerable effects to the *stimulant* operation of emetics, that, in spasmodic disorders, and several others of the nervous kind, which seem to arise principally from the torpor and languor of the digestive organs, emetics are often of essential benefit. He mentions Chorea, or St. Vitus's Dance, certainly not the least obstinate of nervous complaints, as often relieved by emetics.

The same celebrated physician cautions us particularly respecting the administration of emetics to those who are of plethoric habit, or who labour under difeafes, in which general or local plethora is prefent. If the fymptoms, in fuch cafes, indicate the propriety of employing emetics, blood-letting ought, in his opinion, to precede their ufe; for there is danger, left in the temporary convulfion of ftraining to vomit, the diftended veffels fhould be ruptured, or the blood be carried with too great force, or in too great quantity, to parts where the refiftance of the veffels is too weak to withftand it. Thus, if the veffels of the head fhould give way, a fudden and fatal apoplexy may be brought on; if thofe of the lungs fhould be ruptured, a fpitting of blood, followed by a flow, but not lefs fatal confumption, may be induced, or fimilar mifchief may be occafioned in other vifcera. (Loc. citat.) In cafes, however, in which thefe plethoric difeafes are to be fufpected, the prudent practitioner will, even after blood-letting, confider emetics as inadmiffible, unlefs the neceffity of immediately emptying the ftomach of its contents be great and preffing.

The occafion, on which fuch a neceffity is the moft obvioufly paramount to all other confiderations, is when poifon has been recently fwallowed. In this cafe, the greateft rifk is from the operation of this fubftance on the ftomach, and therefore the moft expeditious means of inducing vomiting are to be adopted. If the poifon be of the vegetable narcotic fpecies, fuch as opium, it often fo completely paralyzes the mufcular fibres of the ftomach, as that ordinary emetics have no power to excite its action. The white vitriol, or fulphate of zinc, operates in general almoft inftantaneoufly, efpecially if fwallowed with a large quantity of water. When this has failed, we have known a few grains of the blue vitriol, or fulphat of copper, diffolved in warm water, given with fuccefs, where opium had been fwallowed. A ftrong infufion of ipecacuanha, drank copioufly, has fometimes effectually emptied the ftomach under fimilar circumftances.

In a fit of inebriety, when vinous or fermented liquors have been drunk to the extent of inducing a ftate approximating to apoplexy, the fafeft, perhaps, and beft mode of emptying the poifon from the ftomach, confifts in pouring in warm water as copioufly as it can be fwallowed; fince it at once dilutes the inebriating liquor in the ftomach, and therefore diminifhes its effects, and urges the ftomach to expel it. See Drunkenness.

Although emetics have been found to be beneficial in the early ftages of all fevers, as already mentioned, yet we muft not here omit to notice their peculiar good effects in the fcarlet fever, as obferved by Dr. Withering. (See his Treatife on the Scarlet Fever.) This fact, indeed, had been pointed out by Tournefort (in his voyage to the Levant, tom. i.), and other writers; but Dr. Withering recommends vomiting, repeated according to circumftances, as the moft effential remedy for this difeafe. "In the very firft attack," he fays, "a vomit feldom fails to remove the difeafe at once. If the poifon has begun to exert its effects upon the nervous fyftem, emetics ftop its further progrefs, and the patients quickly recover. If it has proceeded ftill further, and occafioned that amazing action in the capillaries, which exifts when the fcarlet colour of the fkin takes place, vomiting never fails to procure a refpite to the anxiety, the faintnefs, and delirium." Dr. Willan alfo fpeaks highly of the utility of emetics in fcarlet fever, with fore throat, but has not found it neceffary to repeat them fo often as Dr. Withering advifed. Treatife on Cutaneous Difeafes, ord. 3.

Emetics are fometimes ufeful in afthma, and in hooping-cough, probably upon the fame principle as in chronic catarrh, before noticed. They have been faid alfo to affift in forwarding a gall-ftone through the ducts into the inteftines as well as an urinary calculus from the kidney to the bladder, through the ureter, by the mechanical agitation of the body, which they occafion. But their operation in this way muft be very feeble and uncertain, and may do injury, when the calculi are large or angular. Sydenham employed ftrong emetics as remedies for dropfy; but they generally purged alfo, to which operation their good effects, when they did prove beneficial, muft be the rather attributed.

The catalogue of medicines poffeffing an emetic power, which were in ufe among the ancients, although fufficiently ample, contained, as we have already faid, fubftances either of feeble and uncertain action, or of acrid and violent qualities. The hellebore was fometimes fatal. Even Sydenham complained in his time, that an emetic fubftance, which was "fafe, and at the fame time effectual," was a defideratum in the Materia Medica. His active emetic confifted of the *crocus metallorum*, as it was then termed, or *crocus antimonii*, (a preparation made by deflagrating the fulphurated antimony with an equal weight of nitre,) which being foluble in any acid, was moft uncertain in its operation, as it depended upon the quantity of acid with which it met in the ftomach. The ipecacuanha root appears to afford that fubftance to us, which was a defideratum in the time of Sydenham.

We may, with Dr. Fothergill, confider emetics under three heads, the very mild, the moderate, and the ftrong or draftic; not to mention the irritation of the throat with a feather; the exercife of fwinging, failing, or whirling round certain objects of fight, &c. which are not reforted to as remedies. Among the mildeft means of exciting vomiting, is filling the ftomach fuddenly with a large quantity of liquid; fimple warm water is generally fufficient for the purpofe; but its operation is aided, when other fubftances of little power are combined with it: thus, infufions of green tea, of chamomile flowers, the carduus benedictus, broths, &c. may be employed for this purpofe. Again, when it might not be proper to give an emetic fubftance, in fuch a dofe as might of itfelf excite vomiting, by the affiftance of copious draughts of warm water, fmall dofes may ferve the purpofe of evacuating the ftomach, and even of obtaining the other effects to be derived from vomiting.

The moderately active emetic fubftances are thofe which are at prefent in general ufe; namely, the ipecacuanha, and the tartar emetic, or tartrite of antimony, in fmall dofes; and alfo fome other fubftances, when much diluted with warm water, which might be of too inflammatory a nature if given alone, in fuch quantity as to produce vomiting; fuch are, an infufion of the root of horfe-radifh, or a tea-fpoonful of muftard as prepared for the table, fome preparations of the fquill, the afarum, &c. The ipecacuanha was firft introduced as a remedy for dyfentery; but it is now afcertained that its utility in that difeafe depends upon its purgative quality.

The metallic falts formed with fulphuric acid are active emetics, and may be arranged in the ftrongeft or draftic clafs. The leaft violent of thefe is the white vitriol, or fulphate of zinc, which has been chiefly employed on account of the fuddennefs of its operation, when poifonous matters have been taken into the ftomach: but, in order to render its effects certain, the dofe muft generally be large, and if it is not thrown out again immediately, it is apt to continue a difagreeable naufea, or even a vomiting, longer than is neceffary. Dr. Cullen fays, "I find that the purpofe of this medicine (that is, a fudden vomiting,) may commonly be obtained by employing a large dofe of ipecacuanha, either in powder or in the wine; and by following this foon after with a large draught

draught of warm water impregnated with chamomile, or rather with what is more at hand, a tea-ſpoonful of table-muſtard; the buſineſs may be commonly very effectually executed."

The preparations of mercury are ſeldom employed as emetics. The ſulphat, or turpeth mineral, has been chiefly uſed, but its operation is violent.

Dr. Darwin obſerves, that "the quantity of the doſe of an emetic is not of ſo great conſequence as of other medicines, as the greateſt part of it is rejected with the firſt effort. All emetics are ſaid to act with greater certainty when given in a morning, if an opiate had been given the night before. For the ſenſorial power of irritation of the ſtomach had thus been in ſome meaſure previouſly exhauſted by the ſtimulus of the opium, which thus facilitates the action of the emetic; and which, when the doſe of opium has been large, is frequently followed on the next day by ſpontaneous ſickneſs and vomitings, as after violent intoxication." Zoonomia, part 3. art. v. 2. 1.

Emetic *Powder*, called alſo *powder of Algaroth*, from the name of its author, is a precipitate of antimony; or butter of antimony ſweetened and ſoftened by repeated lotions. See Antimony.

Emetic *Tartar*, is now called *Antimonium Tartariſatum*. See Antimony.

Emetic *Wine*, *vinum antimonii*, is only white wine, wherein is infuſed ſome glaſs of antimony. See Antimony.

Small doſes of emetic wine have been recommended as deobſtruent and ſudorific in ſlow fevers, in many chronical diſeaſes, and eſpecially in an obſtinate rheumatiſm. See Medic. Eſſ. Edinb. abr. vol. i. p. 170. and Huxham, Obſ. de Aere & Morb. epidem.

EMETZ, in *Geography*, a town of Ruſſian Siberia, in the government of Tobolſk; 28 miles W. of Iſchim.

EMEU, in *Ornithology*, the common name of the Caſſowary, a large bird of the oſtrich kind.

EMILE, in *Geography*, a ſmall town of France, in the department of the Seine and Oiſe, chief place of a canton in the diſtrict of Pontoiſe, with a population of 1800 individuals. The canton contains 20 communes and 13,843 inhabitants, on a territorial extent of $127\frac{1}{2}$ kiliometres.

EMILI, Paul, in *Biography*, a modern hiſtorian, was born at Verona. In Italy he obtained a great character, and was brought into France by the cardinal de Bourbon, in 1487, who patronized him till his death. After this he was obliged to teach the languages for a ſubſiſtence. He undertook to write the hiſtory of France, for which he was rewarded with a canonry in the cathedral of Notre Dame. This hiſtory he brought down, in ten books, from Pharamond to the 5th year of Charles VIII.; it was publiſhed at different times; and likewiſe altogether at Paris in the year 1539, and has been ſeveral times re printed and tranſlated into foreign languages. His ſtyle is pure, but ſometimes too conciſe, and even bordering on the obſcure; he is nevertheleſs to be regarded as the firſt writer who gave to French hiſtory a juſt form and method. He died at Paris in the year 1529, leaving behind him a very excellent character: his morals were as pure, as the language adopted in his works was chaſte and elegant. Bayle.

EMILION, Saint, in *Geography*, a ſmall town of France, in the department of the Gironde, near the river Dordogne; ſix miles E. of Libourne, remarkable for the excellent wine which grows in its neighbourhood.

EMILIUS, Anthony, in *Biography*, profeſſor of hiſtory in the univerſity of Utrecht; was born Dec. 20th, 1589, at Aix la Chapelle, where his father had retired for the ſake of his religion. He received the early parts of his education in his native country, and finiſhed his claſſical ſtudies at Dort, under the famous Gerard John Voſſius: he then went to Leyden and other univerſities, and ſpent ſome years in foreign travel. On his return to his native country he ſucceeded Voſſius as rector of the college of Dort, and ſome time after he went to Utrecht to exerciſe the ſame office, where he was afterwards elected to the profeſſorſhip of hiſtory, an office in which he continued till his death, November 10th, 1660. His lectures, for more than twenty-ſix years, were taken from the annals of Tacitus. He publiſhed, about the year 1651, a collection of Latin ſpeeches and poems. Bayle.

EMILLAGUE, in *Geography*, one of the Pelew iſlands.

EMINENCE, a little hillock, or aſcent, above the level of the adjoining champain.

Eminence is alſo a title of honour given to cardinals.

The decree of the pope, whereby it is appointed, that the cardinals ſhould be addreſſed under the quality of eminence, bears date the 10th of January, 1630. They then laid aſide the titles of *illuſtriſſimi*, and *reverendiſſimi*, which they had before.

The grand maſter of Malta is likewiſe addreſſed under the quality of eminence.

The popes John VIII. and Gregory VII. gave the ſame title to the kings of France. The emperors have likewiſe borne it.

Eminentiſſimus, the ſuperlative of eminent, hath of late been attributed to the cardinals.

EMINENTIAL Equation is uſed by ſome algebraiſts in the inveſtigation of the areas of curvilinear figures; for a ſort of artificial equation, containing another equation eminently. Hayes Flux. p. 97.

EMINENTLY, Eminenter, in the *Schools*, is uſed in contradiſtinction to *formally*, and in the ſame ſenſe with *virtually*, *viz.* to denote that a thing poſſeſſes, or contains, any other in a more perfect or higher manner than is required to a formal poſſeſſion thereof.

Thus an angel is ſaid to have prudence eminently; as he has it in a higher and more perfect degree than it is in man, in whom it is formally.

For one thing to contain another eminently, there are uſually required two conditions. 1. That the containing be of a more excellent nature than the contained. 2. That the leſs excellent be ſome way contained in the more excellent; *viz.* either as in its productive cauſe, or by ſome ſimilitude, or as to the manner and order of acting, &c.

EMIR, a title of dignity, or quality, among the Turks, and Saracens, attributed to ſuch as are relations or deſcendants of their great prophet Mahomet.

The word is Arabic, and literally ſignifies *prince*. It is formed of the verb אָמַר, *amar*, which is originally Hebrew; and in both theſe languages ſignifies *to ſay*, and *to command*. This is a title given to all the nobility of the firſt rank in the empire of the Mogul and in Tartary. The plural of this term is "Omra."

The emirs are held in high veneration, and have alone the privilege of wearing a green turban. On the borders of the Holy Land there are ſeveral emirs ſovereign princes; as the emir of Gaza, and the emir of Terabea, over whom the grand ſignior has but little authority. The title emir, at firſt, was only given to the caliphs: in Perſia they were alſo called *emir zadeh*, *q. d.* prince's ſon; whence by abbreviation of emir, they formed *mir;* and of *emir zadeh*, *mirza*. In after times, when the caliphs had aſſumed the title of ſultans, that of emir remained to their children, as that of Cæſar did among the Romans.

At length, the ſame title of emir came to be attributed to all who were judged to defcend from Mahomet by his daughter Fatimah, and who wear the green turban.

EMIR is alfo a title, which being joined to fome other word, frequently denotes an office or employ; as the *emir al omera*, commander of commanders, who, in the time of the caliphs, was chief of the councils and armies.

The appellation emir is alfo applied by the Turks to all viziers and bafhaws, or governors of provinces. (See BASHAW, &c.) Add, that *emir akhor*, vulgarly *imrahor*, is mafter of the horfe to the grand feignior.

Emir alem, vulgarly *miralem*, ftandard-bearer and director of all the ftandards of the empire.

Emir bazar, the provoft, or fuperintendant of the markets, who regulates the prices of provifions.

The *emir hagge*, or *hadj*, denoting pilgrimage, or prince conductor of the pilgrims of Egypt to Mecca, is bafhaw, or pacha of Damafcus. See CARAVAN and DAMASCUS.

Emir al mofleim, or *emir al moumenin*, *i. e.* commander of the faithful, or the believers, was a title affumed by the Almoravides and Almohades, who reigned in Africa and Spain.

EMIR-*Bacha*, in *Geography*, a town of Afiatic Turkey, in the province of Natolia; 80 miles W. of Tocat.

EMISSARIA, in *Anatomy*, are the veins which pafs into the fkull from the external parts of the head, and terminate in the finufes of the dura mater. Thefe openings are defcribed in the article CRANIUM. The veins are fometimes called after Santorini, an Italian anatomift. See VEINS.

EMISSARIUM, in *Antiquity*, a fluice, or drain, to draw off the water ufed in watering gardens, fields, &c.

EMISSARY, formed of *e* and *mitto*, *q. d.* I fend out, a trufty, dextrous, able perfon, fent fecretly, to found the fentiments and views of another, to make him fome propofal or overture; or to fpread reports, watch the actions, motions, and countenance of a contrary party or perfon, in order to make advantage of them all. See SPY.

The leaders of parties have abundance of emiffaries employed in their fervice, who inform them of what paffes every where, that they may take their meafures accordingly.

EMISSION, the act of throwing, or driving a thing, particularly a fluid, from within, outwards. The ancients took vifion to be performed by the emiffion of vifual rays from the eye.

But the term emiffion is chiefly applied among us to the expulfion or ejaculation of the feed.

EMISSION *of Heat*.—All the heat we experience in the world is derived from three fources; *viz.* from the fun; from compreffion, which comprehends collifion and friction; and laftly, from the decompofition and compofition of bodies.

It is hardly to be doubted, that the emanation of heat from the fun, like the emanation of light from the fame fource, is not conftantly the fame; and it is recorded in hiftory, that at certain times the light of the fun has been obferved to be pale, or lefs bright than ufual; and had the thermometer been in ufe amongft the ancients, it would probably have been obferved that the dimnefs of light was accompanied with a proportionate diminution of the ufual heat; for thefe alterations, as far as we can conjecture, feem to depend upon the fize of the fpots which cover the furface of the fun at different and uncertain times.

The direct rays of the fun on the fame part of the furface of the earth, are more or lefs hot according to the time of the year, the clearnefs of the atmofphere, the ftate of the wind, and the colour or other quality of the fpot upon which they fall. On this ifland, in the fummer feafon, the direct rays of the fun feldom raife the thermometer to 110° But in other climates, efpecially within the tropics, they raife it much higher; fometimes as high as 150°. We muft not, however, believe the ftrange accounts of their melting lead or firing gun-powder; for thofe rays cannot produce any fuch effect, provided they are not concentrated, or affifted, by artificial means.

It is not on account of the fun's being nearer or farther from us, that we receive much more heat at one time of the year than at another; for the difference of its diftance is too fmall to produce any fenfible effect; nor is it owing to the fun's emitting more calorific rays at one time of the year than at another. But we receive more heat in fummer than in winter, 1ft, becaufe the fun being nearer to our vertex, or to the zenith, in the former, than in the latter feafon, its rays have a fhorter way to pafs through the atmofphere, and are of courfe lefs obftructed by it. And the fame caufe renders the fun's rays hotter about the middle, than at the commencement or the clofe of the fame day: 2dly, we receive more heat when the fun is higher, becaufe in that cafe a greater quantity of its rays fall upon any given portion of the furface of the earth; than when it is lower, and its rays come in a direction more oblique; and, 3dly, becaufe in the fummer feafon the fun remains longer above the horizon than in winter.

With refpect to the caufe of the emiffion of heat from the body of the fun, we cannot pretend to have the leaft knowledge. It is generally fuppofed that the fun is a body of fire; but it is impoffible to fay, whether it is an aggregate of caloric, independent of other matter, or a compound body undergoing a gradual decompofition. It was, fome time ago, alfo fuppofed, that the fun emitted only rays of light, and that the action of thofe rays upon terreftrial bodies, extricated the heat from the latter. But the recent difcovery (made by Dr. Herfchell,) of the calorific rays of the fun fuffering a different refraction from that of its luminous rays, befides other confiderations, renders this fuppofition vain. Excepting from the fun, no fenfible degree of heat is derived from the moon or from any other celeftial object.

The immediate production of heat by the other means that have been mentioned above, *viz.* by compreffion, collifion, friction, compofition and decompofition of bodies, arifes either from the caloric being fqueezed out of a body, like water out of a fpunge; or from an alteration of the capacities of bodies for containing heat. We fhall endeavour to illuftrate thefe proceffes.

I. Experiments fhew, that when a certain fubftance is compreffed into a narrower fpace, a quantity of heat comes out of it, and is communicated to the furrounding bodies. On the contrary, when a certain fubftance is expanded into a larger fpace, it abforbs a quantity of heat from the furrounding bodies; for thefe bodies are cooled in confequence of it. Thus, if you wet your hand, and then expofe it to the ambient air, the water, in the act of expanding itfelf into the form of vapour, abforbs a quantity of heat from the hand, which is thereby fenfibly cooled. If, by means of a condenfing engine, air is compreffed in a proper veffel, heat is extricated from it; and if the operation be performed quickly, a quantity of heat will be emitted, which is fufficient to fet fire to tinder, and other light combuftible bodies. When the fteam of water is condenfed, heat is depofited by it upon thofe bodies which are in contact with it.

Wood rubbed againft wood, or againft any hard body; metal rubbed againft metal, or againft any other hard body; in fhort, folid bodies rubbed or knocked againft each other, are thereby heated, often fo far as to become red-hot.

By this means, heat may be produced where there is no oxygen, fo that in thofe cafes it cannot be derived from the decompofition of that air. This has made fome perfons fufpect that heat is not the effect of a peculiar fubftance called *caloric*; but that it is only a peculiar movement of the particles of bodies. The moft ftriking experiments relative to this fubject were made by count Rumford (Phil. Tranf. for 1798. p. 1.) He took a cannon, not yet bored, having a projection of two feet beyond its muzzle, a part which is ufually caft with the piece, in order to infure the folidity of the metal throughout, by the preffure which its weight occafions. This piece was reduced to the form of a cylinder, joined to the cannon by a fmaller neck, and a large hole was bored in it: the whole cannon was then made to revolve on its axis by means of the force of horfes, while a blunt fteel borer was preffed againft the bottom of the hollow cylinder, by a force equal to about 10,000lb. avoirdupoife; the furface of contact of the borer with the bottom of the cylinder being about two fquare inches. This apparatus was wrapped up in flannel, when its temperature was about 60°. In half an hour, when the cylinder had made 960 turns, the horfes being ftopped, a mercurial thermometer was introduced into a perforation in the bottom of the cylinder, extending from the fide to the axis, and it ftood at 130°, which count Rumford confiders as expreffing very nearly the mean temperature of the cylinder. The duft or fcales, abraded by the borer, weighed only 837 grains, or about $\frac{1}{948}$th of the whole weight of the cylinder. In another experiment, the cylinder was furrounded by a tight deal box, fitted with collars of leather, fo as to allow it to revolve freely, and the interval between the cylinder and the box was filled with 19 pounds of cold water, which was excluded from the bore of the cylinder, by oiled leathers fixed on the borer; and after two hours and a half the water was made to boil. Hence count Rumford calculates that the heat produced in this manner, by the operation of friction, was equal to that of nine wax candles, each three quarters of an inch in diameter, continuing to burn for the fame time.

Reafoning upon thefe refults, count Rumford thinks, that the heat, thus produced, cannot be extricated from the bodies concerned; and he is led to afk "What is heat?—Is there any fuch thing as an *igneous fluid?*—Is there any thing that can with propriety be called *caloric?*"

He then fays, "We muft not forget to confider that moft remarkable circumftance, that the fource of the heat generated by friction, in thefe experiments, appeared evidently to be *inexhauftible*.

"It is hardly neceffary to add, that any thing which any *infulated* body, or fyftem of bodies, can continue to furnifh *without limitation*, cannot poffibly be a *material fubftance*: and it appears to me to be extremely difficult, if not quite impoffible, to form any diftinct idea of any thing, capable of being excited, and communicated in thefe experiments, except it be *motion*.

"I am very far from pretending to know how, or by what means, or mechanical contrivance, that particular kind of motion in bodies, which has been fuppofed to conftitute heat, is excited, continued, and propagated, and I fhall not prefume to trouble the Royal Society with mere conjectures."

It muft, however, be confidered, that there is no friction which does not produce compreffion; *viz.* a contraction of the bulk of the bodies concerned, at leaft for a time; and therefore that the caloric is forced out of the bodies themfelves; and, being communicated to the furrounding bodies, produces the ufual figns of heat. It is a ftrong corroboration of this affertion, that fubftances, which are not compreffible, are not heated by mechanical force; thus, a flint will only be broken, but a piece of foft metal will be heated, by the ftrokes of a hammer. Thus, alfo, you may place any weight upon a quantity of water, without altering its temperature, becaufe the compreffibility of water is next to nothing; but if you place an additional weight upon a quantity of air; the bulk of the air will be contracted, and its temperature will be raifed.

By about 15 or 20 fmart and quick ftrokes of a hammer on the end of a foft iron rod of about a quarter of an inch in diameter, placed upon an anvil, an expert blackfmith will render that end of the rod vifibly red-hot; and the fofter the iron is, the quicker the effect will take place. But the production of vivid red fparks from a piece of fteel, when ftruck againft the edge of a flint, is a phenomenon not lefs curious. Thefe particles are fcraped off by the flint, and are of courfe compreffed fo as to become red-hot.

"One of the moft remarkable circumftances, attending the production of heat by friction," fays Dr. Young, "is the difcovery of profeffor Pictet, that it is often much more powerfully excited by foft fubftances than by harder ones. In making fome experiments in a vacuum, in order to examine how far the prefence of air might be concerned in the effects of friction, he accidentally interpofed fome cotton between the bulb of his thermometer and the cup, which was fubjected to the friction of various fubftances as it revolved; and he found that the foft filaments of the cotton excited much more heat, than any other of the fubftances employed."

II. When a body heated above the actual temperature of the atmofphere, is placed amongft other bodies, the fuperfluous heat of the former is communicated to the latter; for there is no known body that can effectually intercept the tranfition of heat from one fubftance to another. But there is a remarkable phenomenon attending the communication of heat, which is neither very obvious, nor eafily obferved. This is, that in the diftribution of heat amongft a variety of fubftances, fome bodies abforb more of it than others, though they be all placed exactly in the fame fituation; hence different bodies are faid to have different *capacities* for abforbing heat. (See HEAT, SPECIFIC HEAT, or SPECIFIC CALORIC.) So that if a certain quantity of heat is communicated to a mixture of equal weights of water and of mercury; the water will imbibe a much greater fhare of that heat than the mercury, and yet both will appear of the fame temperature.

Now it has been found that by mixing certain bodies together, their capacities for abforbing heat is diminifhed; therefore they part with a portion of their heat, which is of courfe communicated to the furrounding bodies. Thus, when a pint of fpirit of wine is mixed with a pint of water, the mixture grows fenfibly hot, becaufe their capacities for containing heat are diminifhed in confequence of their action upon each other. And it is to be remarked that whenever heat is emitted in the act of mixing fluids, as in the above-mentioned example of water and fpirit, or of water and fulphuric acid, &c. a concentration of bulk takes place; thus the above mixture of a pint of water with a pint of fpirit will be found to meafure lefs than two pints.

In combuftions, the heat which is firft communicated by the contact of an ignited body, or otherwife, decompofes part of the combuftible body, and of the furrounding oxygen air, which produces more heat, and this decompofes more of thofe bodies, and fo the combuftion proceeds and continues as long as there are combuftibles and oxygen air ready for the procefs. See EXCITATION *of heat*.

EMISSION *of Light*. The perception of objects, which we receive through our fight, is obtained by the intermediation of fomething, which we call *light*. Hence the blind muft judge of the prefence of particular objects, by means of the found, or the fmell, or the touch, &c. but not by the means of light. In fhort, light does not fenfibly affect any other part of our bodies, befides the eyes. It follows then, that fomething muft pafs between any object we fee and our eyes, but concerning this fomething we have no certain knowledge. A variety of conjectures and hypothefes have been offered; but of thefe hypothefes two only may deferve our attention. Defcartes, Huyghens, and others, thought that a fubtile fluid was difperfed throughout the univerfe; that the luminous bodies, fuch as the fun, the ftars, a lighted candle, &c. put that fluid, not in a progreffive, but in a certain vibratory motion; (fomewhat like the motion which is communicated to the air by fonorous bodies;) and that this motion, being communicated to the nerves of our eyes, rendered the luminous objects perceptible to us. Newton and his followers fuppofe that light is a real emanation from luminous objects; *viz.* that a fubtile fluid, confifting of certain peculiar particles of matter, proceeds from the luminous bodies; and by entering our eyes, excites in us the fenfation of light, or the perception of luminous objects. A variety of facts and confiderations feems to render this Newtonian hypothefis of light by far the moft probable of the two. See the article LIGHT.

Admitting then Newton's hypothefis, feveral confequences, which naturally depend upon it, demand a particular illuftration; *viz.* this emiffion of light muft confift of particles; thofe particles muft have a very minute, but determinate, fize;—they muft be at certain diftances from each other; muft move with a certain velocity, and muft have a certain momentum. Several remarkable difcoveries that have been made in aftronomy, and in other branches of natural philofophy, enable us to determine the above-mentioned particulars, not with abfolute precifion, but within certain limits of probabilty. The facts upon which this probability refts, are as follows.

If a fmall hole be made in a fcreen, and the fcreen be placed before our eyes, as about the diftance of five or fix feet; and if a luminous body, as a red-hot coal, be repeatedly paffed before that hole, on the other fide of the fcreen, we muft naturally perceive the hole luminous at intervals of time. But if the interval of time, during which the coal is not before the hole, be lefs than the tenth part of a fecond, then the hole will appear conftantly luminous, exactly as if the red-hot coal were held fteadily before it. This fhews that the impreffion of light upon our eyes continues a certain time after the removal of the luminous objects. This is alfo the reafon why, when a ftick with a lighted extremity is quickly turned round in a circle before our eyes, we perceive an uninterrupted luminous circle.

The duration of the impreffion of light upon our eyes is longer or fhorter, according as the object is more or lefs luminous; fo that the impreffion is proportionally ftrong. See the article VISION.

Aftronomers have obferved, that the eclipfes of the fatellites of Jupiter appear to take place fooner than the time which is determined by the tables of their motions, when the planet is nearer to us; and later when that planet is farther from us. Hence it is naturally conjectured, that light moves progreffively, and equally; *viz.* that it employs a certain time in going through a certain fpace; and this conjecture is corroborated by other aftronomical obfervations. The calculations, which have been made upon thefe appearances, fhew that light moves at the aftonifhing rate of, at leaft, 170,000 miles per fecond; fo that in its motion from the fun to us, light employs about $8\frac{1}{4}$ minutes.

If a fmall hole be made in a fcreen, and feveral perfons are fituated on one fide of the fcreen; every one of them looking through that hole at a different object placed on the other fide of the fcreen; it is evident that the various ftreams of light from thofe objects to the eyes of the obfervers, muft pafs through the fame fmall hole in different directions, and without difturbing each other, at leaft in an obfervable degree. This fhews, that the particles of light muft be fo very fmall, and fo diftant from each other, as not fenfibly to obftruct each other's paffage through a very narrow aperture.

In fome experiments (rather imperfect) which were made by throwing the focus of a concave mirror upon the extremity of a very delicate beam, which was nicely fufpended, a flight motion was thereby communicated to the beam; whence it was deduced, that the light thus collected had a fenfible momentum. From the weight of the beam, and from the motion which it had received from the impulfe of the light (upon the fuppofition that its motion was occafioned by it); alfo from the above-mentioned velocity of light; it was calculated, that the quantity of matter, which was contained in the light which was thrown upon the end of that beam, during one fecond of time, and which was collected from a reflecting furface of about four fquare feet; amounted to no more than one twelve hundred millionth part of a grain. (Prieftley's Hift. of Light, Vifion, &c. per. vi. fect. i. chap. 3.) Thefe facts, joined to our daily experience, feem to authorize the following conclufions.

1. Since every phyfical point of a luminous object may be feen from every point of an immenfe fpherical fpace which furrounds it, when no opaque body is interpofed, it follows, that the ftreams of light, which proceed from all the points of vifible objects, and move in all manner of directions, are paft all conception. If this be alleged as an objection to Newton's theory, the leaft reflection will fhew, that it offers an objection equally great, if not greater, to the other hypothefis that has been mentioned above; but the following reafoning will, in great meafure, clear the difficulty with refpect to Newton's hypothefis.

2. It has been mentioned above, that the impreffion of light remains a certain time upon our eyes, and (in the experiment with the red-hot charcoal) it has been fhewn to remain about one-tenth part of a fecond; but fuppofe it to remain only during the 100dth part of a fecond. Then it is evident, that if 150 particles of light be emitted in a fecond from a fingle point of a luminous object, as from a point on the furface of the fun; thefe particles will be more than fufficient to give our eyes an uninterrupted vifion of that point; yet ftill thefe particles, on account of their immenfe velocity, may be more than 1000 miles diftant from one another, and, of courfe, may leave room enough for millions of other particles to pafs in all directions. Canton's Calcul. Ph. Tr. vol. 58.

3. The wafte of the fubftance of a luminous body, arifing from the emiffion of light, confidering the minute nature of its particles, is very trifling, even with refpect to the fun, which has been the great fountain of light during fo many centuries. Dr. Prieftley, alluding to the above-mentioned experiment, where an impulfe was communicated to a beam by concentrated light, fays, "Now the light in that experiment was collected from a furface of about four fquare feet, which reflecting only about half what falls upon it, the quantity of matter contained in the rays of the fun, incident upon a fquare foot and half of furface, in one fecond of time, ought to be no more than the twelve hundred millionth part of a grain. But the denfity of light at the

furface of the fun is greater than at the earth in the proportion of 45,000 to 1; there ought, therefore, to iffue from one fquare foot of the fun's furface in one fecond of time, in order to fupply the wafte by light, one-forty thoufandth part of a grain of matter; that is, a little more than two grains in a day, or about 4,752,000 grains, which is about 670 pounds avoirdupois, in 6000 years." Hift. of Light, &c. p. 390.

4. In confequence of the motion of light, it is evident, that if a luminous body were fuddenly placed in the heavens, at the fame diftance that the fun is from us, we could not poffibly fee it before the lapfe of $8\frac{1}{4}$ minutes. Alfo, when we behold a celeftial object, we do not fee it exactly in the place where it actually ftands; but we fee it in the place where it ftood fome time before.

5. Light moves in ftraight lines, as long as it goes through the fame uniform medium, or through a vacuum.

6. When we direct our eyes towards certain polifhed furfaces, we frequently fee in them the appearances of objects, which are fituated in places quite different from thofe in which we fee them. In this cafe the rays of light coming from thofe objects fall upon the polifhed furfaces, and from them they are *reflected* (that is, *fent back*) to our eyes. Thofe objects then are faid to be feen by reflected light, and the furfaces in which their appearances are feen are called the *reflecting furfaces*. Indeed, every body which does not itfelf emit any light, (as is the cafe with all thofe which cannot be difcerned in a dark room,) are feen by reflected light; for the light which is emitted from the fun, from a candle, from a fire, &c. falls upon thofe bodies, and is from them reflected to our eyes; but that light is reflected irregularly on account of the inequalities on the furfaces of moft bodies; fo that though all bodies which do not fhine of themfelves, are feen by reflected light; yet they are called reflectors, or are faid to have reflecting furfaces, only when thofe furfaces are fmooth and polifhed, in which cafe they reflect the light regularly, fo as to reprefent the images of other objects, that are placed before them. See REFLECTION *of* LIGHT.

7. In its paffage from one body into another, or from a vacuum into any fubftance, and *vice verfâ*, light is often bent in its direction; and that bending is called the *refraction of light*. See REFRACTION *of* LIGHT.

8. Light is likewife bent in its direction, when it paffes clofe by the furfaces of bodies; and this bending is called the *inflection of light*, which fee.

The fources of light are various, but they may be comprifed under the following enumeration.

1. The celeftial bodies, which fhine either by their own light, as the fun and the ftars; or by reflected light, like the moon and the fatellites.

2. The *aurora borealis*, and other meteors, whofe nature is not as yet diftinctly known.

3. Bodies that are in a ftate of *combuftion*, and emit heat as well as light.

4. The *electrical light*; and,

5. The *phofphorefcent bodies*, of which there are feveral fpecies, *viz*. 1. The *phofphorus* properly fo called, which is confidered as an elementary fubftance. 2. The living animals which have the property of fhining in the dark, fuch as glow-worms, lantern-flies, &c. 3. Thofe bodies which abforb light when expofed to it, and then emit it in the dark; fuch are feveral precious ftones, calcareous bodies, Canton's phofphorus, the Bolonian ftone after due preparation, &c. 4. The bodies which emit light when they are heated to a certain degree; fluoric ftones, feveral marbles, calcareous earth, &c. have this property. 5. The fubftances which emit a light either quite white, or tinged with different fhades of red or blue, by attrition; *viz*. by being rubbed or ftruck againft each other. Moft ftones of the filicious kind poffefs this property. 6. And laftly; thofe bodies which emit light without any fenfible heat, whilft they actually are under a ftate of decompofition; and of this fort are moft animal matters, and fome vegetable fubftances, efpecially rotten wood.

The doubtful nature of the *ignis fatuus*, or *jack-a-lantern*, may perhaps alfo be reckoned amongft the phofphori. See AURORA BOREALIS, ELECTRIC *light*, METEORS, PHOSPHORUS, PHOSPHORESCENT BODIES, and IGNIS FATUUS.

EMITES, in *Natural Hiftory*, a name ufed by fome authors for the chermites, a beautiful fpecies of white marble, of which the tomb of Darius, and many other of the great works of antiquity, were made. It was valued for its fine polifh.

EMLY, in *Geography*, a village of the county of Tipperary, province of Munfter, Ireland, the fee of a bifhop; which was united to Cafhel in 1568. It is 15 miles W. from Cafhel.

EMLYN, THOMAS, in *Biography*, an eminent nonconformift divine, was born at Stamford, in the county of Lincoln, in the year 1663. His parents, though accuftomed to attend the religious fervice of the eftablifhed church, thought fo favourably of the principles of the Proteftant diffenters, that they determined to educate their fon for the miniftry among perfons of this defcription. Accordingly he was placed for academical inftruction in the year 1678, under the care of Mr. Shuttleworth, who refided at Sulby, near Welford, in Northamptonfhire. In the following year he was admitted at Emanuel college, in the univerfity of Cambridge; but afterwards returned to Mr. Shuttleworth, under whofe tuition he remained for four years. With a view to the enjoyment of fuperior advantages, he removed, in 1682, to the academy of Mr. Doolittle in the vicinity of London, and in this fituation he diligently availed himfelf of the collateral means and opportunities of improvement, afforded him by an accefs to books, and intercourfe with literary perfons; and made fuch improvement in the knowledge, connected with his profeffion, that he was encouraged to commence the exercife of his profeffion in December, 1682. His mind, at this early period, difdained the fhackles of eftablifhed fyftems of theology; and he determined to inquire freely, and to exercife, independently of the controul of authority, the right of private judgment. It was favourable to his future improvement, that he was not under a neceffity of immediately connecting himfelf with a congregation, and of devoting his whole time to neceffary preparation for the public fervices of his profeffion. In the year 1683, he became chaplain to the countefs of Donegal, and accompanied her to Belfaft in Ireland, where he had a liberal appointment, and was treated with refpect and kindnefs. The countefs married fir William Franklin, a gentleman of confiderable property in the weft of England, who offered our young divine a valuable living in that country; but not approving the terms of minifterial conformity, he declined the acceptance of it. His fentiments, however, were fo liberal, that he regularly attended the public fervices of the eftablifhed church, and was himfelf attended in the evening, when he officiated in the countefs's hall, by the minifter of the parifh, with whom he cultivated an intimate acquaintance. He likewife occafionally officiated in the parifh church, having obtained, without fubfcription, a licence to preach from the bifhop of the diocefe. At this time he vifited Dublin, and

and his services were so acceptable to the congregation, of which Mr. Daniel Williams and Mr. Joseph Boyce were pastors, that he was afterwards induced to settle among them. In the mean while a variety of circumstances occurred in the agitated state of the north of Ireland, and the domestic disunion of the family of his patroness, which rendered it expedient for Mr. Emlyn to remove to England. Accordingly in the year 1688, he came to London, where he renewed his acquaintance with Mr. (afterwards Dr.) Daniel Williams, who had relinquished his pastoral connection with the congregation at Dublin. As he passed to and fro from Ireland to London, he was accustomed to preach in several parish churches; and at Liverpool in particular, where he had accidentally officiated, his preaching was so much approved, that upon the decease of the parish minister, whose place he had supplied, several of the inhabitants expressed their wishes, that they might be allowed to procure for him the living. But this offer, however respectful on their part, his principles would not permit him to accept. In 1689, Mr. Emlyn, being altogether unemployed, was invited by sir Robert Rich, one of the lords of the admiralty, to his residence near Beccles in Suffolk; and he was induced to officiate to a dissenting congregation at Lowestoff, where he continued about a year and a half; though he declined complying with their invitation to undertake the pastoral office. The liberality of his sentiments and conduct, during his abode in this place, served to promote a perfect harmony between the members of the established church and the dissenters. Here he became acquainted with Mr. William Manning, a respectable non-conformist minister in the neighbourhood; and their mutual intercourse led them both to adopt sentiments, with regard to the doctrine of the Trinity, in vindication of which Dr. Sherlock's treatise had just appeared, very different from those which they had hitherto entertained. Mr. Manning became a Socinian; but Mr. Emlyn adopted what has been generally called the Arian opinion, believing the pre-existence of our Saviour, as the Logos, and that by him God had created the material world. To this opinion he adhered through life. Upon the abdication of king James II., the turbulence of Ireland in some degree subsided; and Mr. Boyce urged Mr. Emlyn, to join him in the pastoral care of the dissenting congregation in Wood street, Dublin. After much previous deliberation, he accepted the proposal, and, in 1691, removed to Dublin. Here he soon acquired distinguished reputation as a preacher. His discourses were rational, persuasive, and pathetic; his voice was clear and strong, and his delivery dignified and graceful; the devotional services were conducted with great propriety; controversial subjects were avoided; and all the private duties of a Christian pastor were discharged in an exemplary manner. In 1694, Mr. Emlyn married Mrs. Esther Bury, a widow lady, with a handsome jointure; and he was thus enabled to maintain a respectable appearance. After considerable hesitation and suspence, he determined, when a proper occasion offered, to avow his opinion concerning the doctrine of the Trinity. But before the formal execution of his purpose, he met with various domestic troubles. In 1701, he lost both his son and his wife; the latter affliction deeply wounded his feeling, and led him to that admirable train of meditation, which is pursued in the funeral sermon preached on the occasion, and which was printed under the title of "Funeral Consolations." Soon after he was bereaved of his wife, and whilst his mind was in an unfit state to encounter new conflicts, his opinion concerning the Trinity became the subject of investigation. Dr. Cummins, a physician of Dublin, and a member of his congregation, communicated his suspicions to Mr. Boyce; and they determined to apply to Mr. Emlyn for a declaration of his real sentiments. Having explicitly avowed his opinion, that the God and father of Jesus Christ is alone the Supreme Being, and that the son derives his excellence and authority from him, he offered to withdraw quietly from the congregation, and thus to prevent the disturbance that was likely to ensue. But this pacific measure was unsatisfactory. Mr. Boyce, in a manner that reflects disgrace on his memory, brought the matter before the Dublin ministers, who, after a candid declaration of his sentiments on the part of Mr. Emlyn, immediately forbade him to preach any more. His congregation, during this precipitate course of proceedings, was never consulted on the occasion. Mr. Emlyn avowed his sentiments to the deacons and principal managers of the church; and after respectfully acknowledging their kindness to him, requested his dismission. The conduct of his accusers was the cause of much surprise and concern to the congregation, and Dr. Cummins himself regretted the part which he had acted. However, it was at length determined that Mr. Emlyn should retire for an interval to England; and such was the violence of the Dublin ministers, that, notwithstanding the great inconvenience and expence, to which he was constrained to submit, two of their number were deputed to "charge him not to preach any where when he went thither." These persecutors followed him with their letters of accusation to London, and endeavoured to deprive him of the benefits of that candour and charity which he experienced on his arrival. Whilst he remained in London, he published a short account of his case; and after an absence of 10 weeks, he resolved to return to his family in Dublin. In order to obviate the prejudices that were entertained against his person and doctrine, he wrote his "Humble Inquiry into the Scripture account of Jesus Christ, or a short Argument concerning his Deity and Glory, according to the Gospel." He then determined to return to England; but his purpose was prevented by the persecuting spirit of his enemies, who obtained a special warrant from the lord chief justice to seize our author and his books. At first the chief justice refused bail; but afterwards allowed it, when two sufficient persons became bound in a recognizance of 800*l.* for Mr. Emlyn's personal appearance. In the next term the grand jury found a bill against him, in which he was indicted of blasphemy. The trial came on in June 1703; and it was conducted in a manner no less disgraceful and tyrannical than the proceedings of a board of popish inquisitors. The jury were intimidated to deliver their verdict, and to bring in the defendant guilty, for which some of them afterwards expressed their concern. After the verdict was pronounced, the attorney-general moved, that the author might have the honour of the pillory; but sentence was deferred till the last day of the term. In the mean time Mr. Emlyn was committed to the common gaol. Mr. Boyce now began to relent, and used all his interest to prevent the passing of the cruel sentence threatened by the attorney-general. Mr. Emlyn also, in deference to the advice of his friends, wrote a letter to the lord chief justice, which was indited with a spirit, and in a style which ought to have influenced his mind. When he appeared to receive judgment, one of the queen's council moved that he should retract; but Mr. Emlyn would not consent. The lord chief justice, therefore, sentenced him to suffer a year's imprisonment; to pay a fine of 1000*l.* to the queen, and to lie in prison till it should be paid; and to find security for his good behaviour during life. He was given to understand, that though the pillory was due to his crime, this punishment was not inflicted, as he was a man of letters. After sentence was pronounced, he he was led round the four courts with a paper on his breaſt, to be expoſed. For more than a quarter of a year, he was kept a cloſe priſoner in the under-ſheriff's houſe; and after the expiration of this term he was hurried away to the common gaol, where he lay among the priſoners in a cloſe room, filled with ſix beds, for about five or ſix weeks; and then he was removed upon his petition, by *habeas corpus*, to the Marſhalſea, on account of his health. In this priſon he wrote, in 1704, a treatiſe, entitled "General Remarks on Mr. Boyce's Vindication of the true Deity of our Bleſſed Saviour." In this ſtate of impriſonment, he remained until the month of July 1705, viſited by few of his former friends, and altogether neglected by his ſavage brethren, the Dublin miniſters. Mr. Boyce, indeed, ſhould be excepted; and to his zealous and repeated ſolicitations, to the generous interference of Thomas Medlicote, eſq., the humane interpoſition of the duke of Ormond, and the favourable report of the lord chancellor, that the exorbitant fine paſſed upon him was illegal, his releaſe from confinement was owing. By their exertions the fine was reduced to 70*l.*, which was actually paid into her majeſty's exchequer; but the archbiſhop of Armagh, the queen's almoner, who had a claim of 1 *s.* in the pound upon the whole fine, inſiſted on the whole ſum, nor would he extend his charity to a conſcientious ſufferer till he received 20*l.* by way of compoſition for the 50*l.* to which the ſentence entitled him. During Mr. Emlyn's confinement in the Marſhalſea, he conſtantly preached on ſundays to ſome of the impriſoned debtors, and ſeveral of the lower claſs of his former hearers. Soon after his releaſe Mr. Emlyn removed to London, where he preached once every ſunday to a ſmall congregation of perſons of ſentiments ſimilar to his own, but without receiving any ſalary. Attempts were made to reſtrain him by Charles Leſlie, the famous non-juror, and alſo by the lower houſe of convocation, but by the moderation of archbiſhop Teniſon, and the interference of government, they were unſucceſsful. Mr. Emlyn's congregation gradually declined by the death of his hearers, and was at length diſſolved; upon which he retired to obſcurity, and employed himſelf in vindicating, by various publications, the principles he had adopted, and the cauſe to which he was devoted. One of his moſt elaborate productions was entitled, "A Vindication of the Worſhip of the Lord Jeſus Chriſt, on Unitarian principles," and publiſhed in the year 1706. One of his moſt curious works was publiſhed in 1710, and was entitled "The Previous Queſtion to the ſeveral Queſtions about valid and invalid Baptiſm, lay Baptiſm, &c. conſidered, *viz.* whether there be any neceſſity, (upon the principles of Mr. Wall's Hiſtory of Infant Baptiſm) for the continual uſe of Baptiſm among the poſterity of baptiſed Chriſtians." In 1715, he publiſhed his "Full Enquiry into the original Authority of the Text, 1 John, v. 7, &c. containing an account of Dr. Mill's evidence from antiquity, for and againſt its being genuine, &c." In this controverſy there appeared, pro & con, ſeveral tracts, the titles of which we cannot recite in this place, nor can we mention the various publications of Mr. Emlyn on the ſubject of the Trinity. In 1719, he publiſhed "A true Narrative of the proceedings of the Diſſenting Miniſters of Dublin, againſt Mr. Thomas Emlyn, and of his Proſecution, (at ſome of the Diſſenters' Inſtigation,) in the ſecular court, &c." Mr. Emlyn, though himſelf unpopular, had the ſatisfaction to obſerve, that the opinion for which he ſuffered excited attention, and gained advocates, both in England and Ireland. Although none of the diſſenting miniſters in London could dare to aſk him to preach for them, except Mr. Burroughs, and Dr. James Foſter, he was honoured with the eſteem and friendſhip of many perſons, diſtinguiſhed by their ſtation and learning; and particularly by Dr. Samuel Clarke, and Mr. Whiſton. Upon the death of Mr. James Pierce of Exeter, about the year 1726, it was propoſed to invite Mr. Emlyn to be his ſucceſſor; but he wiſhed them to decline all thoughts of him, as his advanced age, and increaſing infirmities would not permit him to accept the office. The gout had much impaired Mr. Emlyn's conſtitution, and he at length fell a martyr to it, on the 30th of July, 1743, in the 79th year of his age. A complete collection of his works was made in 1746, and is compriſed in two vols. 8vo.; to which are added memoirs of his life, written by his ſon Sollom Emlyn. His ſermons are ſeparately publiſhed in one volume.

EMMA, in *Biography*, daughter of Richard II. duke of Normandy, wife of Ethelred king of England, and mother of Edward the Confeſſor, had a conſiderable ſhare of power during her ſon's reign. The duke of Kent, who was jealous of her great aſcendancy, and deſirous of getting rid of her as a rival, cauſed her to be accuſed of ſeveral high crimes, to which the king her ſon too readily liſtened, and not only deprived her of all thoſe immenſe treaſures which ſhe had amaſſed, but confined her for life in the monaſtery of Wincheſter. Some hiſtorians go much farther, and contend that ſhe was accuſed of murder, and of incontinence with the biſhop of Wincheſter, but Mr. Hume conſiders ſuch reports, and the ſtory of her being obliged to juſtify herſelf by walking over the nine red-hot plough-ſhares, as the inventions of Monks, and propagated for the ſake of exciting the ſilly wonder of poſterity. Bayle, however, gives full credit to the facts, and adds that the king, now ſenſible of the complete innocence of his mother, and penitent for the ſufferings he had inflicted on her, ſubmitted his back to the ſcourge. Hume. Bayle.

EMMAUS, in *Ancient Geography*, a village of Paleſtine, 60 furlongs N. of Jeruſalem; mentioned, Luke xxiv. 13, as the place whither two of our Lord's diſciples retired on the day of his reſurrection, and where he joined them in the form of a traveller, and demonſtrated to them, that the Meſſiah was to ſuffer death and to riſe again; and where he diſcovered himſelf to them at ſupper, while he was breaking bread. At this place were hot baths; and a church was erected on the ſpot where Cleopas, one of the fore-mentioned diſciples, ſtood. Joſephus informs us, that Veſpaſian left 800 ſoldiers in Judea, to whom he gave this village.

EMMAUS, a city of Judea, 22 miles from Lydda, afterwards called *Nicopolis*, and different from the village of Emmaus, though often confounded with it. Mr. Reland proves theſe to be different places from the teſtimonies of Joſephus, St. Jerom, the Maccabees, and the Talmudiſts. In this Emmaus, or Nicopolis, there were hot baths, in which, as the tradition of the inhabitants reports, our Lord waſhed his feet, and communicated a healing virtue to them. Julian, the apoſtate, from enmity to Chriſt, gave orders for ſtopping up this fountain.—Alſo, a town near Tiberias, in which were hot waters. Joſeph. de Bell. l. iv. c. 1.

EMME, in *Geography*. See EMMENTHAL.

EMMELIA, Εμμελεια, in *Antiquity*, a dance peculiar to tragedy, which had all the gravity and dignity that were ſuitable to the action then repreſenting, and was deſigned to inſpire the audience with ſentiments of compaſſion and benevolence for the unfortunate and oppreſſed, with indignation againſt the guilty, and with the love of virtue, and abhorrence of vice. The happy mixture of noble and elegant concords, together with an exquiſite modulation in the action of the perſonages, denoted by emmelia, is ſtrikingly exemplified in that piece of Æſchylus, in which king Priam offers a ranſom a ranfom for the body of his fon. The chorus of Trojans, proftrate with him at the feet of the conqueror of Hector, and like him uttering, amid their dignified emotions, expreffions of grief, fear, and hope, communicate to the foul of Achilles, and thofe of the fpectators, the fentiments with which they are penetrated.

The movements of fuch a dance as this muft have been very folemn and majeftic, and have bore a great affinity to the action of an orator; it was the only one, excepting the military dances, that had the approbation of Plato. Mem. Acad. Infcript. vol. ii. p. 160. See DANCE.

EMMELIA, in *Mufic*, tuneful founds among the Greeks, fuch as were fit for melody.

EMMELOORT, in *Geography*, a town in the north part of the ifland of Schockland, in the Zuyder fea; 10 miles E. of Vollenhove.

EMMENAGOGUES, MENAGOGA, in *Medicine*, are fuch fubftances as are underftood to poffefs the power of exciting the menftrual difcharge in the female fex.

Both the ancient and modern writers on the Materia Medica, but efpecially the former, mention a great number of medicines, to which they attribute this power, and fpeak of it with confiderable confidence. But the articles, to which an emmenagogue quality has been thus afcribed, have not fucceeded in the hands of the phyficians of cautious obfervation in our own times; fo that it is now generally admitted, that we are not in poffeffion of a medicine, which has any fpecific power in ftimulating the veffels of the uterus. Dr. Gregory afks, in his Lectures, "What effect a medicine, poffeffed of fuch a power, could have upon men?" which he feems to confider as an unanfwerable refutation of the notion of emmenagogues. But may we not equally difprove the exiftence of a diuretic medicine, by inquiring what effect fuch a medicine would produce in animals which have no kidney? Experience, however, amply corroborates the opinion; and the operation of thofe fubftances, which have occafioned the catamenia to flow, is explicable on other principles than that of a fpecific ftimulus to the uterine veffels. But it is alfo to be remarked, that there is great room for deception with refpect to the operation of medicines, in reftoring or exciting the menftrual difcharge; and that the fallacious conclufion of "poft hoc, ergo propter hoc," has given a character of efficacy to many medicines, (in all departments of practice, but in this moft eminently,) which in truth poffefs no fuch power. The catamenia frequently appear fpontaneoufly, after long retention or fuppreffion; and whatever medicine happens to be under adminiftration at that time gains the credit of the cure.

There is an error almoft univerfally prevalent among the women themfelves, and fanctioned by goffiping medicafters, that the fuppreffion of the menfes is the *caufe* of almoft every diforder which the female conftitution can fuffer; and confequently, that its reftoration, in thefe cafes, is the moft important point to be attended to in their treatment. Now the converfe of this pofition is much nearer the truth. The fuppreffion of the catamenia is moft commonly the *effect* of a previoufly difordered ftate of the conftitution, and will be removed, as a matter of courfe, when the health in general is reftored. Hence, fuch a fuppreffion is one of the fymptoms of almoft all chronic difeafes, and debilitated conditions of the body: it is fometimes the confequence of the oppofite ftate, of a plethoric or inflammatory diathefis. The remedies, therefore, which poffefs an emmenagogue power, operate indirectly upon the uterine fyftem, through their effects upon the fyftem at large; and are confequently of oppofite qualities, as they apply to two oppofite conditions of the conftitution: or, they operate locally upon the adjoining parts, and affect the uterus from its contiguity.

The retention of the catamenia in young women, about the age of puberty, is generally connected with extreme debility of the fyftem, often with that morbid change of complexion which defignates the green-ficknefs, or CHLOROSIS, which fee. It is in fuch cafes, that preparations of iron, bark, and other tonic medicines, may be deemed emmenagogues, by reftoring the general tone of the habit: the chalybeates have been particularly extolled for their emmenagogue powers. But in full florid habits, when the catamenia are fuddenly fuppreffed, laxatives, diaphoretics, and even blood-letting, moft effectually contribute to reftore the difcharge. Many other reputed emmenagogues operate as local ftimuli to the contiguous parts: hence aloes, and other warm purgatives, which irritate the lower portion of the inteftines, have been celebrated for their emmenagogue powers. Electricity, applied through the pelvis to the hips and back, has fometimes been an efficacious emmenagogue. Savine, caftor, the fœtid gums, the warm-bath, and pediluvium, may be deemed ftimulants to the uterus, as a part of the general fyftem: the efficacy of the warm-bath, or flipper-bath, when employed about the expected period of menftruation, is often very great. Dr. Mead highly extolled the tincture of black hellebore, which, he fays, feldom failed in his practice; and he attributed to it fuch a ftimulative power over the blood-veffels, that when it did not produce the menfes, he affirms, the blood was driven through other outlets, as from the nofe, bowels, &c. But Dr. Home, and many other phyficians, have ufed it largely in vain. Dr. Home attributes fome powers to the favine, and much to madder (rubia tinctorum); which, however, has appeared to others to be altogether inert. Cullen Mater. Medica, vol. ii. Home Clinical Exper. p. 377. See AMENORRHOEA.

EMMENDINGEN, in *Geography*, a fmall town of Germany, in the grand duchy of Baden Durlach, fituated on the river Eltz, in the diftrict of Hochberg, the neighbourhood of which produces excellent wine; but it is chiefly remarkable for a fruitlefs conference, which was held here in the year 1590, between the Roman Catholic and Lutheran divines of Germany. Emmendingen is on the high road from Switzerland to Francfort, on the Mayn.

EMMENTHAL, one of the fineft and richeft valleys of Switzerland, in the canton of Aarau, deriving its name from the river Emme, by which it is irrigated. The principal towns are Signau, Trachelwald, Soumifwald, and Brandis. Its cheefe is known all over Europe under the name of "fromage de Gruyères."

EMMERAN, SAINT, formerly a rich imperial abbey of Germany, in the town of Ratifbon. Its poffeffions form now a part of the territory of the prince primate of the Confederation of the Rhine.

EMMERICH, or EMMERICK, a fmall town of Germany, in the grand duchy of Berg, fituated on the Rhine, in the former duchy of Cleves; 9 miles E. of the town of Cleves, and 24 miles S.E. of Nimeguen. N. lat. 51° 39'. It has a confiderable trade with Holland, and was anciently one of the Hanfeatic towns. Its origin dates from the year 1247, when it was firft furrounded with walls.

EMMIELLURE, in the *Manege*, a kind of compofition of honey, and other ingredients, ufed for fprains and fhoulder-fplaits of horfes. See CHARGE.

The word is French, derived from *miel*, honey, which is a part of the compofition.

EMMIUS, UBBO, in *Biography*, a learned philologift and hiftorian, was born in 1547, at Gretha, a village in

Eaſt Frieſland, of which his father was the paſtor. In his ſtudies he was diligent and remarkably ſucceſsful. His natural timidity and baſhfulneſs prevented him from undertaking the office of miniſter; and in 1579, he engaged as maſter of the ſchool of Norden, in Eaſt Frieſland, which he conducted with great reputation, till he was haraſſed by bigots for refuſing to ſubſcribe the confeſſion of Augſburg; and at length not only deprived of his ſalary, but prohibited from teaching. From Norden he went to Leer, where he undertook the ſame office, to the great injury of his late ſchool. When Groningen aſſociated itſelf with the United Provinces, and planned the re-eſtabliſhment of its college, Emmius was choſen its director, with the full power of forming ſuch ſtatutes for its government as he ſhould think proper. In this office he continued 20 years, when the college was erected into an univerſity; and Emmius was appointed profeſſor of hiſtory and Greek, in which he gave lectures to a very advanced period of life. He died at Groningen, in 1625, in the 79th year of his age, highly reſpected by all with whom he was connected; and his memory was ſo much honoured, that the magiſtrates, to whom he had been an able counſellor on all important occaſions, placed his portrait in the town-houſe. He publiſhed many valuable works on hiſtory, chronology, and antiquities: among theſe are, "Decades Rerum Friſicarum;" "Vetus Grecia illuſtrata," in three volumes, which is highly eſteemed as a valuable ſummary of the geography, hiſtory, polity, &c. of ancient Greece. It is recorded of him in his life, that he was ſo thoroughly verſed in the hiſtories of all kingdoms and countries, that, at the requeſt of his friends, he could at any time, and without previous conſideration, ſpeak upon the hiſtory of all kingdoms and countries, beginning with any period that might be fixed on, and give a complete detail of all the places, times, and circumſtances of perſons, as if he had come prepared expreſsly to explain thoſe hiſtories. Eulogies were pronounced on his memory by Thuanus, Scaliger, Douza, Heinſius, David Chytræus, and others. By Scaliger his hiſtory of Frieſland is called "divine." Bayle.

EMO, or Emo *Inn*, in *Geography*, in the Queen's county, province of Leinſter, Ireland, has been made a poſt-town, and is much frequented by travellers, as a convenient ſtage. Adjoining it is Emo-park, the ſeat of the earl of Portarlington. Emo is 35 miles S.W. from Dublin, and 5 E. from Maryborough.

EMODI Montes, or *Emodi Mons*, in *Ancient Geography*, part of a chain of mountains in Aſia. Pliny ſays, that the Emodus, the Imaus, the Paropamiſus, and the Caucaſus, were connected together; and that the Serres inhabited the country beyond theſe mountains. Dionyſius Periegetes places the ſprings of the Oxus in the Emodian mountains, and extends this chain as far as the Eaſtern ocean. The mountains Emodus and Imaus, according to major Rennell, are the mountains which extend from the Ganges, above Sirinagur, to Caſhmere: ſeparating the dependencies of Hindooſtan from thoſe of Great Thibet. This ingenious geographer ſuſpects Emodus and Imaus to be different readings of the ſame name; and Emaus or Himaus are, without doubt, derived from the Sanſcrit word *Himmaleh*, ſignifying ſnowy. That vaſt ridge bears the ſame name at preſent; and Pliny (l. vi.) well knew the circumſtance. The mountains of Rimola, ſo called in the Lama's map, to which the territories of Napaul extended, were anciently denominated Emodus; and they are a continuation of the chain between Taſſudon and Paridrong.

EMODIA, Αιμωδια, of *αιμα*, *blood*, and *οδους*, *tooth*, in *Medicine*, a word uſed by ſome authors to expreſs a ſtupor of the teeth.

EMOLLIENTS, are medicines which, when externally applied, have the power of relaxing or ſoftening the fibres, when too rigid. They have all been ſuppoſed to act mechanically, but this may be doubted. The commoneſt form of emollient is a cataplaſm or poultice of bread and milk, or other mucilaginous vegetable matter, applied to the ſkin as warm as can be borne without pain. The relaxation and conſequent eaſe which warm cataplaſms produce is very great; but as none of the materials can be readily abſorbed through the cuticle, when unbroken, the emollient effect has with great probability been attributed chiefly, if not entirely, to the relaxing effect of warmth and moiſture upon the extreme veſſels of the living ſurface, unconnected with any ſuppoſed interpoſition of moiſture between the moving fibres.

The other claſs of emollients comprehends unctuous bodies of all kinds, when aſſiſted by friction; and as there is no doubt of a conſiderable abſorption taking place in this method, it is not improbable that the fibres may be actually ſoftened, and rendered more flexible by mechanical operation. No comparative experiments have yet been fairly made to decide whether one unctuous body is more penetrating, that is to ſay, more readily abſorbed by the ſkin, than another; ſo that, as mere emollients, they all have equal claim to uſe.

EMOLUMENT, is properly applied to the profits ariſing daily from an office or employ.

The word is formed of the Latin *emolumentum*, which, according to ſome, primarily ſignifies the profits redounding to the miller from his mill; of *molo*, *molere*, *to grind*.

The patent, or other inſtrument, whereby a perſon is preferred to an office, gives him a right to enjoy all the dues, honours, profits, and emoluments, belonging thereto.

In our law-books, emolument is uſed in a ſomewhat greater latitude, for profit, or advantage, in the general.

EMOTION, in *Elocution*, a mode of utterance applied to appropriate paſſages and on proper occaſions, expreſſive of diſturbance and agitation in the mind of the ſpeaker, reader, or reciter, and calculated to produce the like diſturbance and agitation in the minds of the auditors. Under proper regulation of the judgment, this is one of the higheſt graces of elocutionary expreſſion; nay, ſo eminently is it calculated to produce the effects at which the higheſt ſpecies of elocution principally aim, that it may ſometimes be ſaid moſt completely to attain its end, when the judgment of the ſpeaker becomes for a while ſuſpended, or is at leaſt ſurrendered to its influence and domination. By ſome, however, it is diſputed whether the elocutioniſt (eſpecially the actor) ought really, (for the moſt perfect production of the effect deſired,) to be under the poſitive influence of the emotion exhibited, or ought only to imitate, by the ſtrong operation of judgment and recollection, ſo much of the actual emotion of real life, as appears calculated to excite the general or particular ſympathy deſired; and the writer of this article remembers an inſtance in which a public lecturer was much cenſured by a critical auditor, for having ſuffered himſelf to be overpowered by his own emotions, in deſcribing the tragical fate of Virginia, under the tyranny of the Roman decemviri, that the laſt ſyllable of the ſentence "he ſaved his honour, but he loſt his child," expired in an almoſt inarticulate ſob, and the orator, choaked with tears, was unable to proceed any farther. The effect produced was, however, the beſt anſwer to this hypercriticiſm. The orator had already proceeded far enough; for although one perſon remained cold enough to criticiſe, a ſhriek of horror had run through the audience, one half of whom had burft into tears of fympathy, and fome of whom had actually fwooned away, overpowered by contagious agitation. So fuperior is nature and reality, to the boafted mechanifm of fophiftication and art. Art, however, and the fevereft exercife of judgment, are neceffary both to the actor and the orator, (efpecially to the latter,) in the direction and regulation of thefe emotions; that it may be known when, and how far they are to be indulged; the cafes being very rare in which it can be fafe and proper to throw the reins on the neck of feeling, and leave it to make its way to the goal, by its own independent energies. Emotion is partly expreffed by change of time or momentum, in the action of the organs of enunciation, and by different degrees of irregularity in the fucceffion and proportions of the cadences; and partly by the modulations of the voice; the intonations of which become modified by the different character of the paffion to be expreffed; while, in fome inftances, a tremulous expreffion, and in others frequent interruptions and abrupt tranfitions in the tune, confiderably heighten the effect. Two things are principally to be avoided in the purfuit or cultivation of this excellence;—the unreftricted indulgence of fuch feelings as might hurry into coarfenefs, indecorous vehemence, or bombaft; and that frigid affectation which aims at impreffion by unnatural or unappropriate tones; extremes, which though they may extort *applaufe* from "the unfkilful," always difguft "the judicious," and difappoint completely the legitimate end which genuine emotion muft have in view,—the excitement of a correfpondent fympathy.

Phyfiognomical expreffion, or the play and fympathy of the features, and the language of gefticulation, muft not be overlooked: for, as Mr. Sheridan has obferved, it is a palpable "delufion," to fuppofe, "that by the help of words, alone, we can communicate all that paffes in the mind of man. The paffions and the fancy have a language of their own, utterly independent of words, by which only their exertions can be manifefted and communicated." Lect. on Eloc.

In the recommendation of thefe accompaniments of elocution to any but the profeffed actor, the profeffor, however, muft be aware that he has many and obftinate prejudices to encounter. The dullnefs and indolence of modern elocutionifts having confpired, with other caufes, to reduce almoft all public fpeaking, but that of the ftage, to one fympathetic monotony of tone, and look, and attitude, the fuperftition of criticifm (miftaking fanction for propriety, and eftablifhed ufage for the law of nature) has raifed a fort of hue and cry, againft all expreffion of attitude and feature; as if thefe were mere theatrical affectations and meritricious artifices.

But this fubject will be further purfued under the proper heads Gesticulation and Oratory; for the prefent it is only neceffary to obferve, that as effential to the perfection of that particular branch of the art, accompaniments of gefticulative and phyfiognomical emotion are univerfally admitted to be legitimate portions of the art of theatrical recitation, to the judicious application of which the elocution of the ftage is indebted for a confiderable part of its effect.

Emotion, in the *Theory of the Mind*, is applied by Dr. Cogan (Treatife on the Paffions) to the external marks, or vifible changes produced by the impetus of paffion upon the corporeal fyftem. Thus he diftinguifhes it from paffion, which denotes the violent impreffion made upon our minds by the perception of fomething very ftriking and apparently interefting, and from affections, which are applicable to the lefs violent, more deliberate, and more permanent impreffions, by caufes which appear fufficiently interefting. The ftrong impreffion, fays this writer, of vivid fenfation, immediately produces a re-action, correfpondent to its nature; either to appropriate and enjoy, or to avoid and repel the exciting caufe. This re-action he diftinguifhes by the term *emotion*. The fenfible effect produced at the firft inftant by the caufe of the paffion greatly agitates the frame; its influence is immediately communicated to the whole nervous fyftem, and the commotions excited in that, indicate themfelves both by attitudes and motions of the body, and particular expreffions of the countenance. It is alone by thefe vifible effects, that the fubject is difcovered to be under the influence of any paffion; and it is merely by the particular changes produced, or kind of emotion, that we are enabled to judge of the nature of the paffion. Thus, although the paffion exifts prior to the emotions, yet as thefe are its external figns, they muft indicate its continued influence as long as they continue to agitate the fyftem.

Sheridan, in his "Art of Reading," difcriminates between ideas and emotions. The former, he fays, denote all thoughts which rife and pafs in fucceffion in the mind. Emotions fignify all exertions of the mind in arranging, combining, and feparating its ideas, as well as all the effects produced on the mind itfelf by thofe ideas, from the more violent agitation of the paffions to the calmer feelings produced by the emotion of the intellect and the fancy. Thought is the object of the one, internal feeling of the other. That which ferves to exprefs the former Sheridan calls the language of ideas; and the latter the language of emotions. Words are the figns of the one, tones of the other. Without the ufe of thefe two forts of language, it is impoffible to communicate through the ear all that paffes in the mind of man.

EMOY, or Hia-men, in *Geography*, an ifland near the S.E. coaft of China, within the jurifdiction of the province of Fo-ken, about 15 miles in circumference. The port of Emoy is properly an anchoring-place for fhips, inclofed on one fide by the ifland from which it takes its name, and on the other by the main land; but it is fo extenfive, as to be capable of containing feveral thoufand veffels; and its water is fo deep, that the largeft fhips may lie clofe to the fhore without danger. About a century ago it was much frequented by European veffels; but few vifit it at prefent, as all the trade is carried on at Canton. The emperor keeps here a garrifon of fix or feven thoufand men, commanded by a Chinefe general. At the mouth of the road is a large rock, vifible feveral feet above the furface of the water; and three leagues from it is a fmall ifland, with a natural arch in the middle which admits light from the oppofite fide; and hence it obtained the name of the "Perforated ifland." The ifland of Emoy is particularly celebrated on account of the magnificence of its principal pagoda confecrated to the deity "Fo." This temple is fituated on a plain, terminated by the fea on one fide, and on the other by a lofty mountain. The front of the edifice is 180 feet in length, and its gate is adorned with figures in relief, the ufual ornaments of the Chinefe architecture. At the entrance is a large portico, with an altar in the middle, on which is placed a gigantic ftatue of gilt brafs, reprefenting the god "Fo," fitting crofs-legged. Four other ftatues, 18 feet high, though reprefenting perfons fitting, occupy the four corners of the portico. Each of them is formed from a fingle block of ftone, and bears in its hands appropriate fymbols; *e. g.* one bears a ferpent in its arms, twifted round its body in feveral folds; another has a bent bow and quiver; the two others prefent, one a kind of battle-axe, and the other a guitar, or fome fimilar inftrument. Beyond this portico is an outer

 court,

court, having at its four fides four pavilions, terminating in domes, and communicating with one another by a gallery. In one is a bell ten feet in diameter: in another a drum of enormous fize, ufed by the bonzes for proclaiming the days of new and full moons. The two other pavilions contain the ornaments of the temple, and often ferve to lodge travellers, whom the bonzes are obliged to receive. In the middle of the court is a large tower, terminating in a dome, with a beautiful ftone ftair-cafe winding round it. The dome contains a neat temple, the cieling of which is ornamented with mofaic work, and the walls covered with figures in relief, reprefenting animals and monfters. The pillars that fupport the roof are framed of wood, varnifhed, and on feftivals are ornamented with differently coloured flags. The pavement of the temple is formed of fmall fhells, prefenting in different compartments birds, butterflies, flowers, &c. The bonzes continually burn incenfe upon the altar, and keep the lamps fufpended from the cieling always lighted. At the extremity of the altar is a brazen urn, which, when ftruck, emits a mournful found, and on the oppofite fide is a hollow machine of wood, ufed for the fame purpofe, which is to accompany with its found their voices, when they fing in praife of the tutelary idol of the pagoda. The god "Pouffa" is placed on the middle of this altar, on a flower of gilt brafs, which ferves as a bafe, and holds a young child in his arms; feveral idols, which are without doubt fubaltern deities, are ranged around him, and by their attitudes fhew their refpect and veneration. Behind the altar is a kind of library, containing books which treat of the worfhip of idols. Acrofs the court is a kind of gallery, containing 24 ftatues of gilt brafs, reprefenting philofophers, who were the ancient difciples of Confucius. At the end of the gallery is a hall, which is the refectory of the bonzes; and beyond a fpacious apartment is the temple of "Fo," to which there is an afcent by a large ftone ftair-cafe. This temple is ornamented with vafes, full of artificial flowers, and in it are mufical inftruments, fuch as we have already mentioned. The ftatue of this god is feen through a piece of black gauze, which forms a fort of veil or curtain before the altar. The reft of the pagoda confifts of feveral large chambers; the gardens and pleafure-grounds are on the declivity of the mountain, and a number of delightful grottos are cut out in the rock, and afford an agreeable fhelter from the exceffive heat of the fun. There are feveral other pagodas in the ifland of Emoy; one of which is called the "Pagoda of 10,000 ftones," which is built on the brow of a mountain, in which there is a like number of little rocks, under which the bonzes have formed grottos and pleafant covered feats. Grofier's China, vol. i.

EMPALEMENT, or IMPALEMENT, a cruel kind of punifhment, whereby a fharp pale or ftake, is thruft up the fundament and through the body.

The word comes from the French, *empaler*, or the Italian, *impalare;* or rather, they are all alike derived from the Latin, *palus*, *a ftake*, and the prepofition *in*, *in*, *into*.

We find mention of empaling in Juvenal. It was frequently practifed in the time of Nero, and continues to be fo in Turkey.

EMPALEMENT, or *Calyx*, in *Botany*, denotes the termination of the cortex, or outer bark of a plant; which, after accompanying the trunk or ftem through all its branches, breaks out with the flower, and is prefent in the fructification in this new form. Its chief ufe is to enclofe and protect the other parts. It has received different appellations, according to the circumftances that attend it; as *Perianthium*, or flower-cup, *Involucrum*, or cover, *Amentum*, or catkin, *Spatha*, or fheath, *Glume*, or hufk, *Calyptra*, or veil, and *Volva*, which fee refpectively. See CALYX.

EMPANELLING, or IMPANELLING, in *Law*, fignifies the writing and entering into a parchment fchedule, or roll of paper, by the fheriff, the names of a jury fummoned by him to appear for the performance of fuch public fervice as juries are employed in. See JURY.

EMPARLANCE, or IMPARLANCE, *Interlocutio*, or *licentia loquendi*, in *Law*, a defire, or petition, in court, of a day to confider, or advife, what anfwer the defendant fhall make to the action of the plaintiff.

The civilians call it *petitio induciarum*. Kitchen mentions emparlance *general*, and *fpecial;* the firft feems to be only that made in one word, or in general terms without any fpecial claufe. This is of courfe where the defendant is not bound to plead the fame term; and it is without faving to the defendant any exception, which is always to another term. It is granted to the defendant before he pleads by confent of the court; to fee if he can end the matter amicably without farther fuit, by talking with the plaintiff:—a practice, which is fuppofed (Gilb. Hift. Com. Pl. 55.) to have arifen from a principle of religion in obedience to that precept of the gofpel "agree with thine adverfary quickly, whilft thou art *in the way* with him." (Matt. v. 25.) It may be obferved, that this gofpel precept has a plain reference to the Roman law of the twelve tables, which exprefsly directed the plaintiff and defendant to make up the matter while they were *in the way*, or going to the prætor;—*in via, rem uti pacant orato.* Emparlance *fpecial*, is where the party requires a day to deliberate, adding thefe words, "Salvis omnibus advantagiis tam ad jurifdictionem curiæ, quam ad breve et narrationem."

This emparlance is had on the declaration of the plaintiff; and it is of ufe where the defendant is to plead fome matters, which cannot be pleaded after a general emparlance. (5 Rep. 75.) This fpecial emparlance is with a faving of all exceptions to the writ or count which may be granted by the prothonotary; or they may be ftill *more fpecial*, with a faving of all exceptions whatfoever, which are granted at the difcretion of the court. (12 Mod. 529.)

Imparlance is generally to the next term; and if the plaintiff amend his declaration after delivered or filed, the defendant may imparl to the next term, if the plaintiff do not pay cofts, but if he pay cofts, which are accepted, the defendant cannot imparl. Alfo, if the plaintiff declares againft the defendant, but doth not proceed in three terms after, the defendant may imparl to the next term. (2 Lill. Abr. 35.) If the writ be returnable on the laft day of term, the defendant is of courfe entitled to an imparlance, but muft plead in four days of the next term, provided a rule be given either in a town or country caufe. On a declaration delivered of *Hilary*, there may be an imparlance to *Trinity* term, if the defendant has not pleaded before; for it is the courfe of the court to give imparlance or declaration till the day of pleading. If a writ be returnable in one term, and the declaration is not delivered *before* the effoign day of the *fecond* term, the defendant is not obliged to plead in the *fame* term, but is entitled to an imparlance. (Impey, K. B.) The caufes of imparlance are as follow. The not delivering a declaration in time is fometimes the caufe of imparlance of courfe, and where the defendant's cafe requires a fpecial plea, and the matter which is to be pleaded is difficult, the court will, upon motion, grant the defendant an imparlance, and longer time to put in his plea, than otherwife by the rules of the court he ought to have: if the plaintiff keeps any deed or other thing from the defendant, whereby he is to make his defence, imparlance may be granted till the plaintiff delivers

delivers it to him, or brings it into court, and a convenient time after to plead. (Hil. 22 Car. I. B. R.) There are many cafes in which imparlances are not allowed. No imparlance is granted in an *homine replegiando;* or in an affife, unlefs on good caufe fhewn; nor fhall there be an imparlance in an action of fpecial *claufum fregit*, though it is allowed in general actions of trefpafs. (Hil. 9 W. III. 3 Salk. 186.) Where an attorney, or other privileged perfon of the court fues another, the defendant cannot imparl, but muft plead prefently: if the plaintiff fues out a fpecial original, wherein the caufe of action is expreffed, and the defendant is taken on a fpecial capias, he fhall not have imparlance, but fhall plead as foon as the rules are out. (2 Lil. 35, 36.) In cafe of pleadings afterwards, a plea to the jurifdiction may not be pleaded after general imparlance. (Raym. 34.) Dilatory pleas cannot be pleaded after a general imparlance, which is an acknowledgment of the propriety of the action. After imparlance the defendant cannot plead in *abatement;* however, if it appear by the record that the plaintiff hath brought his action before he had any caufe, the court *ex officio* will abate the writ. (2 Lev. 197.) Although a fpecial imparlance fhall not be allowed the defendant without leave of the court firft obtained (R. E. 5 Ann.); yet if the writ be returnable *before the laft return of any term*, and the declaration not filed, and notice given four days exclufive before the end of fuch term, the defendant is entitled to an imparlance. (R. Trin. 22 Geo. III.) Blackft. Com. vol. iii. Jacob's Law Dict. by Tomlins. Art. *Emparlance*.

Britton alfo ufes emparlance for the conference of a jury upon a caufe committed to them.

EMPASMA, Εμπασμα, from εμπασσο, *I fprinkle*, in *Pharmacy*, a powder thrown or fprinkled over the body, to correct fome ill fmell thereof, or to prevent unneceffary fweats.

EMPASTING, or IMPASTING, a term ufed in *Painting*, for the laying on of colours thick and bold, or applying feveral lays of colours, fo that they may appear thick. See COLOURING.

It is formed of the French, *empafter*, which has the fame fignification of *pafte*, or *pâte*, *pafte*.

A painting is faid to be well empafted with colours, when the colours are beftowed plentifully, or it is well foaked, and faturated with colours.

The term is alfo ufed when the colours are laid diftinct, and afunder, and not foftened and loft in each other: *e. g.* this head is not painted, it is only empafted.

EMPATTEMENT, French, from *empater*, *to thicken*, in *Fortification*, a term ufed by fome to denote the fame with talus.

EMPEDOCLES, in *Biography*, a native of Agrigentum, in Sicily, was a difciple of Telauges, a fcholar of Pythagoras, and diftinguifhed for his knowledge in every department of fcience and philofophy, as a poet, an orator, an hiftorian, and a phyfician. He adopted the Pythagorean doctrine of the tranfmigration of fouls, and wrote a poem on the fubject, which the ancients have highly praifed. He ftated the hiftory of the different changes which his own foul had undergone during its tranfmigrations, as follows; it commenced its career in the perfon of a girl, next appeared in that of a boy, afterwards it animated a fhrub, then a bird, a fifh, and laftly Empedocles. In the fame poem, the title of which was, "On the Nature of Things," he explained his doctrine refpecting the elements. He contended that "there were four of thefe elements, which are at continual war with each other, without the power of deftroying each other; and that all bodies were produced by this conflict." The fragments of his verfes, which are difperfed through various ancient writers, have been, in part, collected by Henry Stephens. (In Poefi Phil. 1574, 8vo.) This circumftance affords fome ground for the opinion of Fabricius, (Bib. Græc. v. i. p. 466.) that Empedocles was the real author of that ancient fragment, which bears the title of "The golden Verfes of Pythagoras." From thefe fragments his philofophical opinions have been collected. Befides his hypothefis of four elements, the firft material principles of which were indefinitely fmall, round, and fimilar atoms, he maintained, that it is impoffible to judge of truth by the fenfes without the affiftance of reafon; which is led, by the intervention of the fenfes, to the contemplation of the real nature, and immutable effences, of things. The firft principles of nature are of two kinds, active and paffive; the active is unity, or God; the paffive, matter. The active principle is a fubtle, ethereal fire, intelligent and divine, which gives being to all things, and animates all things, and into which all things will be at laft refolved. Many dæmons, portions of the divine nature, wander through the region of the air, and adminifter human affairs. Man, and alfo all brute animals, are allied to the divinity; and it is therefore unlawful to kill or eat animals. The world is one whole, circumfcribed by the revolution of the fun, and furrounded, not by a vacuum, but by a mafs of inactive matter. In the formation of the world, ether was firft fecreted from chaos, then fire, then earth; by the agitation of which were produced water and air. The heavens are a folid body of air, cryftallized by fire. The ftars are bodies compofed of fire, they are fixed in the cryftal of heaven; but the planets wander freely beneath it. The fun is a fiery mafs, larger than the moon, which is in the form of a hollow plate, and twice as far from the fun as from the earth. The foul of man confifts of two parts, the fenfitive, produced from the fame principles with the elements; and the rational, which is a dæmon fprung from the divine foul of the world, and fent down into the body as a punifhment for its crimes in a former ftate, where it tranfmigrates till it is fufficiently purified to return to God.

The ftyle of Empedocles, if we may believe the account of Ariftotle, as quoted by Diogenes Laertius, very much refembled that of Homer; it was extremely energetic and enriched with metaphor, and every variety of poetical figure. His talents drew upon him the eyes of all Greece: his verfes were fung at the Olympic games, with thofe of Homer, Hefiod, and the moft famous poets; and at the games, and on all other public occafions, he is faid to have been himfelf the moft attractive part of the fpectacle, fo anxious were the people to behold him. He was greatly diftinguifhed too as an orator, and is faid to have been the firft of the philofophers who gave leffons on rhetoric in Sicily. He ufefully employed this talent of oratory in reforming the licentious manners of the Agrigentines, whom he reproached "for purfuing pleafures, with as much eagernefs as if they were to die before to-morrow; and for building houfes as if they believed that they fhould live for ever."

Empedocles was likewife celebrated as a phyfician, and wrote a poem "On Medicine," confifting of fix hundred verfes. In this work he is faid to have boafted, that he was able not only to cure difeafes, but alfo to drive away old age, and even to reftore the dead to life; and to have intimated that the fick would hereafter inveft him with divine honours. Pliny affirms that he fucceeded in reftoring a female, who had lain thirty days, without any figns of refpiration: and

Paufanias,

Paufanias, one of his difciples, and a phyfician, wrote a treatife refpecting the difeafe and recovery of this woman, whom he termed ἄπνους. He was greatly fkilled in mufic, which, after the example of Pythagoras, he employed as a remedy, not only againft the difeafes of the mind, but even againft thofe of the body. Being lodged in the town of Gela, with his friend Auchitus, he was informed that a young man in a great rage was determined to kill this friend, who had fentenced his father to capital punifhment. Empedocles endeavoured to calm his mind by perfuafive difcourfe; but his eloquence producing no effect, he took his lyre, and combined its melodious founds with the flowing numbers of poetry; and fo employed the modulations, which made the greateft impreffion on the heart of the young man, that by degrees he was entirely foftened, and afterwards became his conftant difciple. As a phyfician, he is related to have been eminently ferviceable to his country on many occafions. He paid great attention to meteorology, and not only predicted ftorms, but propofed remedies againft their effects. He counteracted the blighting influence of the Etefian winds, by conftructing walls in the narrow paffages of the mountains, through which they blew, and occafioned fterility in the neighbouring land: hence, according to Jamblichus and Diogenes Laertius, he was called *Alexanemos* and *Colyfanemos*, or repeller of the winds. Pliny relates that he allayed a peftilence at Agrigentum, by means of fumigation (ignium fuffitu); and Plutarch mentions another inftance, in which he fuppreffed a plague, which raged with extreme violence and fatality, by clofing an aperture or chafm of the earth, in the vicinity of the mountains, from which he alone obferved that peftilential effluvia iffued.

For thefe various fervices to his country, the Agrigentines offered him the government; which he refufed, preferring a philofophical tranquillity to regal honours. He is faid, by fome of his hiftorians, to have been ever generous, humane, and moderate, and ready at all times to ftand forth as the declared enemy of tyrants; and to have vigoroufly purfued all thofe who feemed to afpire at the fovereign power. An anecdote is handed down to us in confirmation of this fact. A citizen of Agrigentum having invited him home to fupper, and the hour of the repaft being arrived, he inquired why it was not ferved up; "becaufe," faid the hoft, "we wait for the minifter of the council." At length this officer appeared, and he was made mafter of the feaft; during which he gave himfelf fo many infolent airs, that Empedocles began to fufpect that fome fecret project was concerted between the mafter of the feaft and his inviter, with a view to re-eftablifh the tyranny. The fufpicion was but too well founded. The philofopher next day citing the two perfons before the council, they were condemned to death.

A very different character, however, is afcribed to Empedocles by many other writers. He is faid to have conducted himfelf with the utmoft pride and haughtinefs towards his fellow-citizens, and to have afpired to divine honours; walking pompoufly about the country, and through the cities, habited like the gods, and feeking the plaudits of the people. He wore a golden crown on his head, with Delphic chaplets in his hands, and brazen fandals on his feet, and was clothed in a robe of purple and gold, his hair being long and flowing.

The accounts of his death are not lefs various and contradictory. Some authors affirm, that thinking to pafs himfelf for a deity, and to perfuade the people that he had been taken directly up into heaven, he afcended Ætna in the night, and threw himfelf head-long into the burning crater of the mountain, imagining that his death would remain for ever concealed from mortals; but that the treacherous mountain threw up one of his brazen fandals, and thus expofed the folly of the vifionary, who difdained to be thought man.

> " —— Deus immortalis haberi
> Dum cupit Empedocles ardentem frigidus Ætnam
> Infiliit." Hor. Ars Poet. v. 465.

Others, however, admitting that he perifhed in mount Ætna, affert that, impelled by his paffion for the ftudy of nature, he refolved to examine the crater of that volcano, and that having ventured too far, he accidentally fell into the burning gulf. Some authors, again, have affirmed, that he broke his leg, by falling from a chariot, which brought on a difeafe that proved fatal. Others pretend that he terminated his own exiftence, fome fay by throwing himfelf into the fea, and fome by ftrangulation with a rope: while others maintain that he died a natural death, at the age of 77 years. But the moft commonly received opinion, notwithftanding thefe contradictions, is, that this philofopher, being extremely advanced in years, accidentally fell into the fea, and was drowned, about 440 years before Chrift, or in the 84th Olympiad. Timæus relates, that, towards the clofe of his life, Empedocles went into Greece, and never returned, and on this account, the exact time and manner of his death remain unknown. According to Ariftotle, he died at the age of 60 years. Some writers make a diftinction between Empedocles the philofopher, and another who was a poet. Caftellani, upon what authority we know not, ftates that Empedocles, the philofopher and poet, was the fon of Meto, and grandfon of Empedocles, who was an excellent poet.

A ftatue was erected to the memory of Empedocles at Agrigentum. See Caftellani Vit. Medicor. Illuft. Mangeti Bibliotheca Scriptor. Med. Haller. Bibl. Med. Pract. Dict. Hiftorique. Brucker's Hift. Philof. by Enf. vol. i.

EMPERESS, Empress, *Imperatrix*, the feminine of emperor; the wife or widow of an emperor; or a princefs who is the fupreme ruler of an empire in her own right.

Emperess, is alfo ufed in the *Ancient French Poetry*, for a particular kind of rhime, thus denominated by way of excellence.

The "rhime emperiere" was a fort of crowned rhime, wherein the fyllable that made the rhime was immediately preceded by two other like fyllables of the fame termination; which made a kind of echo, called the *triple crown*; and which, to the fhame of the nation, (as fome of their late authors exprefs it,) their beft ancient poets took for a wonderful beauty and excellence.

Fa. Mourgues, in his treatife on French poetry, gives us an inftance very proper to raife contempt of the miferable tafte of that age, which knew no way of expreffing that the world is impure, and fubject to change, fo excellent, as by faying,

> "Qu'es tu qu'un imonde, monde, onde."

EMPEREUR, Constantine, L', in *Biography*, a learned divine, was a native of Holland, where he took the degree of doctor of theology, and became diftinguifhed in oriental literature and Jewifh antiquities. He was profeffor of theology and Hebrew at Harderwyck during eight years, and then was appointed profeffor of Hebrew at Leyden in 1627. He died in 1648, a fhort time after he had been appointed theological profeffor at Leyden. He obtained the character of a zealous defender of the Chriftian religion,

religion, againſt the objections of the Jews. He was the friend of the moſt learned men of his age, *viz.* of Heinſius, Buxtorf, &c. and offered to ſuperintend an impreſſion of their Talmudical dictionary in Holland. His works were chiefly theological, and highly eſteemed by his contemporaries. Moreri.

EMPERICHORESIS. See CIRCUMINCESSION.

EMPEROR, as far as this word denoted formerly the head of the German empire. See GERMANY.

EMPEROR, *Imperator*, among the *Ancient Romans*, ſignified a general of an army, who, for ſome extraordinary ſucceſs, had been complimented with this appellation. It was emphatically beſtowed by the ſoldiers, when, on the field of battle, they proclaimed their victorious leader worthy of that title. When the Roman emperors aſſumed it in that ſenſe, they placed it after their name, and marked how often they had taken it. Thus Auguſtus having obtained no leſs than twenty famous victories, was as often ſaluted with the title emperor; and Titus was denominated emperor by his army, after the reduction of Jeruſalem. See AUGUSTUS and TITUS.

Afterwards it came to denominate an abſolute monarch, or a ſupreme commander of an empire; a Roman emperor, &c. In this ſenſe Julius Cæſar was called emperor, and the title deſcended with the dignity to Octavius Auguſtus, and the ſucceeding emperors.

In ſtrictneſs, the title emperor does not, and cannot add any thing to the rights of ſovereignty; its effect is only to give precedence and pre-eminence above other ſovereigns; and as ſuch, it raiſes thoſe inveſted with it to the ſummit of all human greatneſs.

The emperors, however, pretend, that the imperial dignity is more eminent than the regal; but the foundation of ſuch prerogative does not appear: it is certain, the greateſt, moſt ancient, and abſolute monarchs, as thoſe of Babylon, Perſia, Aſſyria, Egypt, Macedonia, &c. were called by the name of *kings*, in all languages, both ancient and modern. See KING.

It is diſputed, whether or not emperors have the power of diſpoſing of the regal title. It is true, they have ſometimes taken upon them to erect kingdoms; and thus it is that Bohemia and Poland are ſaid to have been raiſed to the dignity; thus alſo, the emperor Charles the Bald, in the year 877, gave Provence to Boſon, putting the diadem on his head, and decreeing him to be called *king*, "Ut more priſcorum imperatorum regibus videretur dominari." Add, that the emperor Leopold erected the ducal Pruſſia into a kingdom, in favour of the elector of Brandenburg; and though ſeveral of the kings of Europe refuſed for ſome time to acknowledge him in that capacity, yet by the treaty of Utrecht, in 1712, they all concurred.

In the Eaſt, the title and quality of emperor are more frequent than they are among us; thus, the ſovereign princes of China, Japan, Mogul, Perſia, &c. are all emperors of China, Japan, &c.

In the year 1723, the czar of Muſcovy aſſumed the title of emperor of all Ruſſia, and procured himſelf to be recognized as ſuch by moſt of the princes and ſtates of Europe. See RUSSIA.

In the Weſt, the title has been a long time reſtrained to the emperors of Germany. The firſt who bore it was CHARLEMAGNE, who had the title emperor conferred on him by pope Leo III. though he had all the power before. His empire, however, was of no long duration. When the German branch of his family became extinct, the Germans exerciſed the right inherent in a free people, and, in a general aſſembly of the nation, elected Conrad count of Franconia emperor. After him Henry of Saxony, and his deſcendants, the three Othos, were placed, in ſucceſſion, on the imperial throne, by the ſuffrages of their countrymen: the extenſive territories of the Saxon emperors, their eminent abilities, and enterpriſing genius, not only added new vigour to the imperial dignity, but raiſed it to higher honour and pre-eminence. (See OTHO.) But while the emperors, by means of new titles and new dominions, gradually acquired additional authority and ſplendour, the nobility of Germany went on at the ſame time extending their privileges and juriſdiction. Upon the whole, the imperial prerogatives were formerly much more extenſive than they are at preſent. At the cloſe of the Saxon race, A.D. 1024, they exerciſed the right of conferring all the great eccleſiaſtical benefices in Germany; of receiving the revenues of them during a vacancy; of ſucceeding to the effects of inteſtate eccleſiaſtics; of confirming or annulling the elections of the popes; of aſſembling councils, and of appointing them to decide concerning the affairs of the church; of conferring the title of king on their vaſſals; of granting vacant fiefs; of receiving the revenue of the empire; of governing Italy as its proper ſovereigns; of erecting free cities, and eſtabliſhing fairs in them; of aſſembling the diets of the empire, and fixing the time of their duration; of coining money, and conferring the ſame privilege on the ſtates of the empire; and of adminiſtering both high and low juſtice within the territories of the different ſtates. But in the year 1437, at the period of the extinction of the emperors of the families of Luxemburgh and Bavaria, they were reduced to the right of conferring all dignities and titles, except the privilege of being a ſtate of the empire; of *preces primariæ*, or of appointing once during their reign a dignitary in each chapter, or religious houſe; of granting diſpenſations with reſpect to the age of majority; of erecting cities, and conferring the privilege of coining money; of calling the meetings of the diet, and preſiding in them.

In the one period, the emperors appear as mighty ſovereigns, with extenſive prerogatives; in the other, as the heads of a confederacy, with very limited powers. The revenues of the emperors decreaſed ſtill more than their authority. The early emperors, particularly thoſe of the Saxon line, beſides their vaſt patrimonial or hereditary territories, poſſeſſed an extenſive domain both in Italy and Germany, which belonged to them as emperors. Italy belonged to the emperors as their proper kingdom; and the revenues which they drew from it were very conſiderable. But the firſt alienations of the imperial revenue were made in this country. The Italian cities, having acquired wealth, and aſpiring at independence, purchaſed their liberty from different emperors. Many diſtricts, poſſeſſed by the emperors, which were intermixed with the eſtates of the dukes and barons, were ſeized by the nobles, during the conteſts that took place between the emperors and the court of Rome. The emperors were alſo almoſt entirely robbed of their caſual revenues; the princes and barons appropriating to themſelves taxes and duties of every kind, which had been uſually paid to them. From the reign of Charles IV., whom Maximilian called the peſt of the empire, the emperors were reduced to the neceſſity of depending entirely on their hereditary dominions, as the only ſource of their power, and even of their ſubſiſtence. Pfeffel Abregé de l'Hiſt. d'Allem.

One principal cauſe of the degradation of the emperors was the aggrandizement of the clergy. The popes, before the firſt period above mentioned, A.D. 1024, had been dependent on the emperors, and indebted for their power as well as dignity to their beneficence and protection. But they afterwards began to claim a superior jurisdiction; and in virtue of authority, which they pretended to derive from heaven, tried, condemned, excommunicated, and deposed their former masters. Pope Gregory VII. combined political discernment and sagacity with his presumption and violence; and commenced his rupture with Henry IV. upon a pretext that was popular and plausible. He complained of the venality and corruption with which the emperor had granted the investiture of benefices to ecclesiastics. All the censures of the church were denounced against Henry; and the most considerable of the German princes and ecclesiastics were excited to take arms against him. So successful was the court of Rome in inflaming the superstitious zeal, and conducting the factious spirit of the Germans and Italians, that an emperor, distinguished not only for many virtues, but possessed of considerable talents, was at length obliged to appear as a supplicant at the gates of the castle in which the pope resided, and to stand there three days, bare-footed, in the depth of winter, imploring a pardon, which was at length obtained with difficulty. This act of humiliation degraded the imperial dignity. Nor was the depression momentary. The contest between Gregory and Henry gave rise to the two powerful factions of the Guelfs and Ghibellines; the former of which supporting the pretensions of the popes, and the latter defending the rights of the emperor, kept Germany and Italy in perpetual agitation during three centuries. A regular system for humbling the emperors, and circumscribing their power, was formed and uniformly adhered to during that period. The decline of the imperial authority may partly be ascribed to the change which took place with regard to the mode of their election. During a long period, all the members of the Germanic body assembled, and chose the person whom they appointed to be their head; but amidst the violence and anarchy which prevailed for several centuries in the empire, seven princes, who possessed the most extensive territories, and who had obtained an hereditary title to the great offices of the state, acquired the exclusive privilege of nominating the emperor. This right was confirmed to them by the golden bull; the mode of exercising it was ascertained; and they were dignified with the appellation of *Electors*. These electors, by their extensive power, and the distinguishing privileges which they possessed, became formidable to the emperors, with whom they were placed almost on a level in several acts of jurisdiction. See ELECTOR, and DIET.

To the privileges and powers formerly belonging to the emperors, and which have been above enumerated, some have added, 1. That all the princes and states of Germany are obliged to do them homage, and swear fidelity to them. 2. That they, or their generals, have a right to command the forces of all the princes of the empire, when united together. 3. That they receive a kind of tribute from all the princes and states of the empire, for carrying on a war which concerns the whole empire, which is called the *Roman month*. As to the present mutilated state of the German empire, see ELECTOR and GERMANY.

The kings of France were anciently also called emperors, at the time when they reigned with their sons, whom they associated to the crown: thus, Hugh Capet having associated his son Robert, took the title of emperor, and Robert that of king; under which titles they are mentioned in the history of the council of Rheims, by Gerbert, &c. King Robert is also called emperor of the French, by Helgau of Fleury. Lewis le Gros, upon associating his son, did the same. In the first register of the King's Charters, fol. 166, are found letters of Louis le Gros, dated in 1116, in favour of Raymond, bishop of Maguelonne, wherein he styles himself "Ludovicus, Dei ordinante providentia, Francorum imperator Augustus." The kings of England had likewise anciently the title of emperors, as appears from a charter of king Edgar: "Ego Edgarus Anglorum basileus, omniumque regum insularum oceani quæ Britanniam circumjacent, &c. imperator & dominus."

We also say the king of England, "Omnem habet potestatem in regno suo quam imperator vindicat in imperio:" whence the crown of England has been long ago declared in parliament to be an imperial crown.

EMPEROR, among *Hebrew Grammarians*, is an appellation given to a species of accents serving to terminate a sense completely, and answers to our point. See ACCENT.

EMPEROR *Elect*. See ELECT.

EMPETRON, in *Botany*, a name by which some authors, as Dodonæus, &c. have called the kali or glass wort. Ger. Emac. Ind. 2. See KALI.

EMPETRUM, from εν, *in* or *upon*, and πετρος, *a rock*, or *stone*, expressing its stony barren places of growth. Linn. Gen. 515. Schreb. 676. Sm. Fl. Brit. 1072. Mart. Mill. Dict. v. 2. Juss. 162. Gærtn. t. 106. Class and order, *Dioecia Triandria*. Nat. Ord. *Ericis affine*, Juss.

Gen. Ch. Male. *Cal.* Perianth in three deep, ovate, permanent divisions. *Cor.* Petals three, sometimes more, ovate-oblong, contracted at their base, larger than the calyx, withering. *Stam.* Filaments three, sometimes nine, capillary, very long, pendulous; anthers erect, short, deeply cloven.—Female. *Cal.* and *Cor.* as in the male. *Pist.* Germen superior, depressed; style short, simple; stigmas nine, spreading, a little reflexed. *Peric.* Berry orbicular, depressed, of one cell, larger than the calyx. *Seeds* three or nine, ranged circularly, gibbous at the outer edge, angular at the other. The flowers are commonly dioecious, but sometimes the two sexes are found on the same plant, and even both organs united in one flower.

Eff. Ch. Male, Calyx deeply three-cleft. Petals three. Stamens capillary, from three to nine. Female, Calyx deeply three-cleft. Petals three. Stigmas nine. Berry superior, with three to nine seeds.

The species are two.

1. E. *album*. Linn. Sp. Pl. 1450. (Erica coris folio decima; Clus. Hist. v. 1. 45. E. baccifera tenuifolia; Ger. em. 1381.) "Stem erect." Observed by Clusius on sandy heaths near Lisbon, bearing fruit early in November. He compares the berries, which are white, acid, and transparent, to pearls of an inferior kind. He generally found but three seeds in each, which accords with Gærtner's account of this species. The *stems* are shrubby, a foot and half high, erect, branched in a determinate order. *Leaves* ternate, evergreen, linear, obtuse, revolute, smooth above, resembling those of many heaths. *Flowers* not observed. *Berries* lateral, solitary, the size of a moderate pea, resembling those of Misseltoe.

2. E. *nigrum*. Linn. Sp. Pl. 1450. Sm. Fl. Brit. 1072. Engl. Bot. v. 8. t. 526. (E. montanum, fructu nigro; Raii Syn. 444. Erica baccifera procumbens; Ger. em. 1383.) "Stems procumbent." Black Crow-berry, or Crake-berry. Plentiful on mountainous heaths in the north of England, as well as in Sweden, Lapland, Denmark, &c. blossoming in May, and ripening fruit in August. It differs from the former in its more humble and procumbent growth, and in having black berries, with nine seeds. *Flowers* reddish, axillary, plentiful about the tops of the last-year's branches. The fruit has a mild flavour of elder-

berries,

berries, and "affords fuftenance to ptarmigans, groufe, partridges, and even to the hardy highlander himfelf."

EMPHASIS, in *Elocution*, a term generally, but abfurdly, ufed by modern writers, exclufively in the *fingular* number. "Emphafis," fays Mr. Sheridan (Lecture iv.), "difcharges in fentences the fame kind of office that accent does in words. As accent is the link which ties fyllables together, and forms them into words; fo emphafis unites words together, and forms them into fentences, or members of fentences. As accent dignifies the fyllable on which it is laid, and makes it more diftinguifhed by the ear than the reft; fo emphafis ennobles the word to which it belongs, and prefents it in a ftronger light to the underftanding. Accent is the mark which diftinguifhes words from each other, as fimple types of our ideas, without reference to their agreement or difagreement. "Emphafis is the mark which points out their feveral degrees of relationfhip," and the rank which they hold in the mind. Accent addreffes itfelf to the ear only; emphafis, through the ear, to the underftanding. Were there no accents, words would be refolved into their original fyllables: were there no emphafis, fentences would be refolved into their original words. And in this cafe, the hearer muft be at the pains himfelf, firft, of making out the words, and afterwards their meaning: and as this could not be done, without fuch length of paufes at the end of fentences, and their feveral members, as would allow him time to revolve in his memory the founds which have been uttered, it would make the action of liftening to difcourfe laborious and difguftingly tedious. Whereas, by the ufe of accent and emphafis, words, and their meaning, being pointed out by certain marks, at the fame time that they are uttered, the hearer has all trouble faved, but that of liftening; and can accompany the fpeaker at the fame pace that he goes, with as clear a comprehenfion of the matter offered to his confideration as the fpeaker himfelf has if the fpeaker delivers himfelf well."

It is not very eafy to difcover what Mr. S. means, (even with his interpretation of the word accent,) when he fays, that "were there *no accent*, words would be refolved into their *original fyllables*;" fince monofyllables, though denied the property of what is here called accent, are neverthelefs admitted by Mr. S. and the grammarians in general to be words; and fince, as will be fhewn hereafter, the ear alone (unaffifted by the memory of impreffions received through the eye) has even yet (with all the affiftance derived from that *poife* and that *percuffion* of particular fyllables, fo abfurdly confounded in the popular abufe of the term accent) no poffible means of diftinguifhing polyfyllabic words from fucceffive monofyllables, when properly pronounced. Certainly he is not at all more intelligible, when he adds, "were there *no emphafis*, fentences would be refolved into their *original words*;" or again, when he informs us, that "by the ufe of accent and emphafis, *words, and their meaning*, are pointed out by certain marks, *at the fame time* that they are uttered." That fhifting the percuffion, or varying the poife of fimilar affociations of fyllables, will effentially change the meaning even of words in their feparate capacity, (as *díffer, defér; défert, defért; préfent, prefént; réfufe, refúfe; óbject, objéct; íncenfe, incénfe*, &c. fee B. Jonfon's Gram.) and ftill more of fuch affociated fyllables as may occafionally be brought together in the compofition of fentences, muft be readily allowed; and that the fenfe of *all fentences* would be much obfcured by the omiffion, and of *many* entirely inverted by a tranfpofition of the emphafes: but ftill the words, as words, and their meanings as words, (though not their fpecific relations to the other words of the fentence,) would be recognized "*at the fame time* they were uttered," whether they were accompanied with emphafes or not: and as for what is here mifcalled the accent, the *poife* at leaft muft of phyfical neceffity be fomewhere placed; and *fpeech* without it could not be conducted at all. But Mr. S. never feems to have dreamed of fubmitting either the procefs or the nomenclature of elocution to phyfiological or critical analyfis. He ufed the terms of his art as he found them in the works of the grammarians and rhetoricians of modern times; and as their phrafeology was all confufion and contradiction, his elucidations were not likely to be very fatisfactory. The Lecture on Emphafis, however, is by far the moft valuable portion of this work.

"The neceffity of obferving propriety of emphafis," fays he, "is fo great, that the true meaning of words cannot be conveyed without it. For the fame individual words, ranged in the fame order, may have feveral different meanings, according to the placing of the emphafis. Thus, to ufe a trite inftance, the following fentence may have as many different meanings as there are words in it, by varying the emphafis: "Shall you ride to town to-morrow?" If the emphafis is on fhall, as, *Shall* you ride to town tomorrow? it implies, that the perfon fpoken to had expreffed before fuch an intention, but that there is fome doubt in the queftioner whether he be determined on it or not; and the anfwer may be, Certainly, or, I am not fure. If it be on you, as, Shall *you* ride to town to-morrow? the queftion implies that fome one is to go, and do you mean to go yourfelf, or fend fome one in your ftead? and the anfwer may be, No, but my fervant fhall. If on ride, as, Shall you *ride*, &c.? the anfwer may be, No, I fhall walk, or go in a coach. If on town, as, Shall you ride to *town* to-morrow? the anfwer may be, No, but I fhall ride to the foreft. If on to-morrow, as, Shall you ride to town *to-morrow?* the anfwer may be, No, not to-morrow, but the next day."

Thefe obfervations and illuftrations may ferve to fhew the importance of emphafes in general; but they do nothing towards illuftrating the fpecific characteriftics of fuch emphafes. Indeed, in all that Mr. S. has faid upon this fubject, it fhould feem as if he had no clear conception of any other fpecies of emphafis, than the emphafis of force; and it is evident, indeed, that the conceptions of the generality of readers and reciters, practically, go no farther. Mr. S. does indeed fay, in another place, "that emphafis is of two kinds," (furely, then it fhould have been that emphafes are of two kinds,) "fimple or complex. Simple, when it ferves only to point out the plain meaning of any propofition; complex, when, befides the meaning, it marks alfo fome affection or emotion of the mind; or gives a meaning to words, which they would not have in their ufual acceptation, without fuch emphafis. In the former cafe, emphafis is little more than a ftronger accent, with but little change of tone; when it is complex, befides force, there is always fuperadded a manifeft change of tone. Simple emphafis belongs to the calm and compofed underftanding; complex, to the fancy and the paffions." But the concluding remark fufficiently evinces how little the nature of thefe varieties was underftood by this author, and how imperfectly the terms of his art were defined in his own mind; for it will prefently be fhewn, that even without any neceffity of appeal to the fancy and the paffions, a much more complex fyftem of emphafes is neceffary fully to elicit, and agreeably to illuftrate, the fenfe of many paffages. Mr. Cockin, in his "Art of delivering written Language," animadverts upon the want of clearnefs in this diftinction, and upon the

the apparent confufion between the fignificant power of emphafis and the various "tones, fimply confidered, of all the emotions of the mind;" and feems to imagine he has remedied the confufion by contradiftinguifhing emphafes into "emphafis of fenfe, and emphafis of force;" and Mr. Walker, (Elements of Elocution, p. 190.) confiders this diftinction as having "thrown great light upon this abftrufe fubject." But as the emphafis of force is moft affuredly as indifpenfable to the full expreffion of the fenfe, as any of the other *feveral* fpecies of emphafes, it is very queftionable whether this pretended diftinction does any thing more than render confufion worfe confounded. Mr. Cockin proceeds; "now from the above account of thefe two fpecies of emphafis it will appear, that in reading, as in fpeaking, the firft of them muft be determined entirely by the fenfe of the paffage, and always made alike: but as to the other, tafte alone feems to have a right of fixing its fituation and quantity." Farther, "fince the more effential of thefe two energies is folely the work of nature, (as appears by its being conftantly found in the common converfation of people of all kinds of capacities and degrees of knowledge,) and the moft ignorant perfon never fails of ufing it rightly in the effufions of his own heart, it happens very luckily, and ought always to be remembered, that provided we underftand what we read, and give way to the dictates of our own feeling, the emphafis of fenfe can fcarce ever avoid falling fpontaneoufly upon its proper place." That mere tafte has any thing to do with fixing the *fituation* of the emphafis of force (whatever it may have to do with its *quantity* or *degree*) we utterly deny; or that, in juft reading or recitation, it can be determined by any thing but the *fenfe* alone. And as for what is faid of even the moft ignorant perfon never failing, in common converfation and the effufions of his own heart, in the right application of the *emphafis of fenfe*, it is true of all the kinds of emphafes; for, in fpontaneous fpeaking, all emphafes are emphafes of fenfe; and in all other kinds of fpeaking (reading or reciting) whatever emphafes are not fo, muft be emphafes of nonfenfe. Mr. Walker, indeed, has himfelf fuggefted a much more rational fpecies of diftinction, and has made fome confiderable advances towards a juft fyftem or theory upon this fubject, by drawing a clear line of demarcation between what, perhaps, might very properly have been called the inherent or *grammatical powers* of particular claffes of words, and the arbitrary or *fignificant emphafes* of fpecific words in a fentence. Perhaps had Mr. W. fo denominated them, not only his diftinctions, fo far as they go, might have been rendered more obvious, but the denomination itfelf would have led him to difcover that there are ftill diftinct fpecies of actual emphafes, properly fo called, which have efcaped his obfervation. He would not then, perhaps, have told us, that "emphafis, in the moft ufual fenfe of the word, is that ftrefs with which certain words are pronounced, fo as to be diftinguifhed from the reft of the fentence." He would have perceived that fuch a definition was much too vague to meet even the full fignification of the term in popular ufage: for no one does in reality apply the term emphafis to the mere grammatical or inherent force that diftinguifhes, in all diftinct and intelligible fpontaneous fpeech, the nouns and verbs above the articles, conjunctions, and prepofitions. The term, on the contrary, always fuppofes fome fuperadded diftinction given to a word or words of what defcription foever, and conferring upon fuch words a degree of importance in the fentence, beyond what is inherent in their mere grammatical quality. Mr. W. proceeds, "among the number of words we make ufe of in difcourfe, there will always be fome which are more neceffary to be underftood than others: thofe things with which we fuppofe our hearers to be pre-acquainted (he might have added, 'or which are neceffary only for the mere grammatical connection of the more important words,') we exprefs by fuch a fubordination of ftrefs as is fuitable to the fmall importance of things already underftood; while thofe of which our hearers are either not fully informed, or which they might poffibly mifconceive, are enforced with fuch an increafe of ftrefs, as makes it impoffible for the hearer to overlook or miftake them. Thus, as in a picture, the more effential parts of a fentence are raifed, as it were, from the level of fpeaking; and the lefs neceffary are, by this means, funk into a comparative obfcurity." This is both juft and pertinent, and the fimile at the conclufion is even more appofite, than Mr. Walker feems himfelf to have been aware; for, to purfue the metaphor in elocution as in picture, it is not merely by the force of a line or the depth of a fhadow, that all the varieties of emphatic effect are to be expected to be produced. "From this general idea of emphafis," continues Mr. W., "it will readily appear of how much confequence it is to readers and fpeakers not to be miftaken in it; the neceffity of diftinguifhing the emphatical words from the reft, has made writers on this fubject extremely folicitous to give fuch rules for placing the emphafis as may, in fome meafure, facilitate this difficult part of elocution; but few have gone farther than to tell us that we muft place the emphafis on that word in reading which we fhould make emphatical in fpeaking; and though the importance of emphafis is infifted on with the utmoft force and elegance of language, no affiftance is given us to determine which is the emphatic word, where feveral appear equally emphatical, nor have we any rule to diftinguifh between thofe words which have greater, and thofe which have a leffer degree of ftrefs; the fenfe of the author is the fole direction we are referred to, and all is left to the tafte and underftanding of the reader."

He then proceeds to ftate with high commendation the above-mentioned diftinction of Mr. Cockin, whofe definition he quotes as follows: "Emphafis of force," he tells us, "is that ftrefs we lay on almoft every fignificant word: emphafis of fenfe is that ftrefs we lay on one or two particular words, which diftinguifhes them from all the reft of the fentence. The former ftrefs," he obferves, "is variable, according to the conception and tafte of the reader, and cannot be reduced to any certain rule: the latter," he fays, "is determined by the fenfe of the author, and is always fixed and invariable. This diftinction, it muft be owned," continues Mr. Walker, "is, in general, a very juft one, and a want of attending to it has occafioned great confufion in this fubject, even in our beft writers. Thus, when the emphatical words were to be marked, by being printed in a different character, we find in feveral of the modern productions on the art of reading, that fometimes more than half of the words are printed in italics, and confidered as equally emphatical. The wrong tendency of fuch a practice," continues Mr. W., "was never pointed out till the publication of the effay above-mentioned;" by the affiftance of which Mr. W. profeffes to endeavour to pufh his inquiries ftill farther; "not only to eftablifh the diftinction he has laid down, but to draw the line between thofe two kinds of emphafis, fo as to mark more precifely the boundaries of each. To this diftinction of emphafis he accordingly adds another, making a diftinction of each into two kinds, according to the inflexion of voice they adopt; which, though of the utmoft importance in conveying a juft idea of emphafis, had never been noticed by any of our writers on the fubject." The diftinction thus added is that

that which relates to the application of the rifing and falling inflexion, and which, though in reality fuch inflexions apply not only to emphatic words, but in a fmaller or greater degree to all the words and fyllables of which language, properly delivered, is compofed, (every fyllable not delivered in a *monotone*, *i.e.* not fung, having of neceffity either an acute, a grave, or a circumflex accent,) is affuredly a diftinction of much importance, in what relates to the practical adjuftment of the emphafis, and for the comprehenfion of Mr. Walker's theory, relative to which (imperfect as that theory, perhaps, may be) the ftudent will do well to refer both to the "Elements" and to the "Rhetorical Grammar" of that elaborate profeffor. "This," fays Mr. W., "brings us to a threefold diftinction of words, with regard to the force with which they are pronounced; namely, the conjunctions, particles, and words underftood, which are obfcurely and feebly pronounced; the fubftantives, verbs, and more fignificant words, which are firmly and diftinctly pronounced; and the emphatical word, which is forcibly pronounced: it is the laft of thefe only which can be properly ftyled emphafis; and it is to a difcovery of the nature and caufe of this emphafis that all our attention ought to be directed. And firft, we may obferve, that if thefe diftinctions are juft, the common definition of emphafis is very faulty. Emphafis is faid to be a ftrefs laid on one or more words to diftinguifh them from others: but this definition, as we have juft feen, makes almoft every word in a fentence emphatical."

Mr. W. then adds, "the principal circumftance that diftinguifhes emphatical words from others, feems to be a meaning which points out, or diftinguifhes, fomething as diftinct or oppofite to fome other thing. When this oppofition is expreffed in words it forms an antithefis, the oppofite parts of which are always emphatical. Thus, in the following couplet from Pope:

> 'Tis hard to fay, if greater want of fkill
> Appear in writing or in judging ill.

The words *writing* and *judging* are oppofed to each other, and are therefore the emphatical words.

But this defcribes only the emphafis of antithefis, which is certainly not the only fpecies of emphafis, properly fo called, that is requifite to well delivered fpeech; for words are rendered important by appofition, as well as by oppofition; by their relative, and their abfolute confideration in the fentence, and by their reflective, as well as their antagonift meaning, and to afcertain and exemplify all the varieties and circumftances of emphafes, were almoft to illuftrate the whole theory of the actual and practicable melody of fpeech. The threefold diftinction above quoted does, however, furnifh a clue to a part of this mazy labyrinth; and Mr. W.'s concluding definition, though imperfect, as excluding fome effential claffes of emphafes, is ftrictly applicable to the full extent of his view, which was certainly the moft comprehenfive that had then been taken of the fubject. "Emphafis," fays he, "when applied to particular words, is that ftrefs we lay on words, which are, in contradiftinction to other words, either expreffed or underftood. And hence will follow this general rule; wherever there is contradiftinction in the fenfe of the words, there ought to be emphafis in the pronunciation of them; the converfe of this being equally true, wherever we place emphafis we fuggeft the idea of contradiftinction." Now though it is not true, that all emphafis has an antithefis, either expreffed or underftood, yet as the emphafes of antithefis conftitute a very large and material clafs of thefe rhetorical diftinctions, the following rules may be regarded as highly important. "If the emphafis excludes the antithefis, the emphatic word has the falling inflexion; if the emphafis does not exclude the antithefis, the emphatic word has the rifing inflexion. The grand diftinction, therefore, between the two emphatic inflexions is this; the falling inflexion affirms fomething in the emphafis, and denies what is oppofed to it in the antithefis; while the emphafis with the rifing inflexion, affirms fomething in the emphafis without denying what is oppofed to it in the antithefis; the former, therefore, from its affirming and denying abfolutely, may be called the ftrong emphafis; and the latter from its affirming only, and not denying, may be called the weak emphafis."

They who purfue Mr. W. through all his diftinctions of fimple, double, and triple emphafis, will undoubtedly, upon the whole, be much edified, though even with refpect to the application of the inflexions they may not agree with him in every inftance. But if Sheridan attempted nothing more than a practical elucidation of the application and mifapplication of emphafis, without laying down any general principles, or rules of extenfive and perfpicuous application, or difcriminations of the characteriftic varieties of emphafes; and if Cockin only fuggefted without properly defining the differences between the grammatical import, and the emphatic diftinction of words; Mr. W. while he has in fome inftances well defined the principle of the application of the rifing, and the falling inflexions to emphatic words, has left it to more recent difcovery to define, and to claffify the feveral fpecies of emphafes, (properly fo called,) and to point out the diftinct properties, or actions both of the voice and the enunciation by which thofe fpecies are to be contradiftinguifhed. "All emphafes," it is maintained by the lecturer on the fcience and practice of elocution, "affect the words upon which they fall in the three predicaments, of time, of tune, and of force, but as fome fpecies of emphafes require a preponderancy of one, and other fpecies of another of thefe properties, emphafes may properly be contradiftinguifhed into three kinds; emphafis of time, or the condition of words rendered emphatical, by the encreafed quantity affigned to the refpective fyllables; emphafis of tune, or the condition of words rendered emphatical, by the diftinction of a fuperior degree of inflexion, or by a higher or lower pitch in the mufical fcale; and emphafis of force, or the condition of words rendered emphatical by the fuperior energy with which they are uttered. And the adjuftment of thefe refpective varieties of emphafes, to their refpective occafions, it is contended, is of equal importance with the felection of the proper fituations for placing an emphafis at all; fince the fenfe may be as completely perverted, or at leaft the ear may be as much fhocked by inferting the emphafis of force (a very common error in theatrical recitation,) where that of tune, or of quantity was required, as by placing it altogether on a wrong word. To elucidate this fyftem fatisfactorily, would require more fpace than can conveniently be fpared, in a general dictionary of the circle of fciences; but as there at prefent exifts no printed copy of the lectures in queftion, nor any book upon the fubject to which the ftudent can be referred, part of a column will not perhaps be mifapplied, by being devoted to the fubject. The kinds of emphafes enumerated are principally as follows. 1. The objective emphafis, or emphafis of import, *i.e.* the ftrefs of voice by which proportionate importance is given to the word or words, conveying the fubftantive matter, or leading object of the fentence, as "I am defirous of being acquainted with *the nature of Man.*" That is to fay, "the nature of man is a fubject to which I am defirous of directing fome enquiry;" an idea which may be expreffed either with or without any

 reference

reference to any other subject, either as associated or rejected. In which latter case, no antithesis is either expressed or implied, and the simple emphasis of import is expressed, by an increased stress of the voice, thrown upon the whole of the syllables, composing the amalgamated substantive, or compound name of that object, to wit, "the nature of man." 2. Emphasis of antithesis, or that characteristic stress and inflexion of the voice by which the opposition between two ideas, or parts of a compound idea, is pointed out, and emphatically impressed upon the mind. The antithesis may be either expressed or understood. Thus, if the preceding passage be requoted with an emphasis upon the word nature only, and that emphasis be principally specified by a strong circumflective accent (that is to say, by a partial increase of quantity and a specific peculiarity of time) I am desirous of becoming acquainted with the *nature* of Man;—the words have changed to a certain degree their signification; an antithesis is understood; and the interpretation becomes "It is not the *history*—it is not the outward *form* and *complexion*, or any other particular incident relative to man, but his general nature, his physical and moral attributes that I am desirous of knowing." Again, if the single word Man be rendered emphatic by superadding to the customary energy of the closing poise or final heavy syllable a certain portion of the same species of time, "I am desirous of becoming acquainted with the nature of *man*," will then by another implied antithesis come to signify, "It is not with the nature of stones, and earths, and shrubs, and herbs, and brute animals, that I am desirous of becoming acquainted, but with that of man." Of the direct or expressed antithesis we have an illustration in the following sentence. "It is not with the nature of *Màn*, but with the nature of *Gód*, that I am desirous of being acquainted." Upon this species of emphasis little need be added to what has already been said by Mr. Walker. 3. The emphasis of coincidence, or the level and equal stress of the voice upon two or more words either in the same or different members of a sentence; by which the relationship, agreement, and equal importance of the annexed ideas are indicated: as—"The *stature*, the *form*, and the *complexion* of man, as well as his *moral* and *physical attributes* are parts of his nature; and his *history* must be studied that his nature may be understood." In this instance all the words distinguished by italics demand the emphasis of coincidence: a species of emphasis which is expressed more by its time, or quantity, than either by its inflexion or its force. As this is the species of emphasis that is least obtrusive, it is that which may be used with the greatest frequency and freedom. 4. Complicated emphases. Sometimes all the different kinds of emphases are mingled in one sentence; so that several different words, or pairs of words, require to be discriminated in all the varieties and degrees of time, tune, and force. "It is not the NATURE of **Man** that I am *desirous* of STUDYING; but the LAWS of **God** that I am *anxious* to COMPREHEND." Here NATURE, LAWS; **Man**, **God**; *desirous*, *anxious*; STUDYING, COMPREHEND, require to be respectively balanced and coupled in the mind by appropriate responses of quantity, tune, and force; which if the sentence flowed spontaneously would as spontaneously be adjusted in all propriety, but the due application and apportioning of which to written language constitutes one of the most difficult parts of the art of reading.

There is one thing more which it is necessary to observe on the subject of emphasis, and then we have done with this long article. It has been mistakenly supposed, that the distinction of emphasis necessarily belongs to single words; nay some there are, who, confounding emphasis with mere percussion, would confine it to single syllables; but the fact is, that emphasis (properly so called) belongs not either to the syllabic separation, or grammatical structure of words, but to the idea; and whether the substantive idea be expressed by a simple or by a compound name, the *whole* name of that idea, not a part only of that name, must bear the equal impress of that emphasis:—thus, for example, in the famous reply of the first William Pitt to Mr. Walpole,—"But youth it seems is not my only crime; I have been accused of acting a theatrical part." Here neither the word *acting*, nor the word *theatrical*, nor the word *part*, taken separately, designates the jut of the accusation, or constitutes the name of the idea included in the accusation: for if we read, "I have been accused of *acting* a theatrical part," placing the emphasis only on the word acting; may it not properly be asked—Why, what would you do with a theatrical part but *act it?* If the emphasis be placed on theatrical, "I have been accused of acting *a theatrical* part:"—what part should be *acted*, but one that is theatrical?—if upon the word part alone—I have been accused of acting a theatrical *part?*—what that is theatrical can be acted but a *part?* The whole latter member of the sentence constitutes therefore the jut or object of the accusation.—"I have been accused"—(of what?)—*of acting a theatrical part!*" These words therefore constitute, accordingly, the amalgamated substantive, or compound name of the indivisible, accusatory idea, and must receive throughout an equal portion of *objective emphasis*. Not that the syllables are thereby to be rendered equally forcible, or to be otherwise reduced to one monotonous level. They are only to receive one common superaddition of emphatic force; and as independently of such superaddition, they would have differed among themselves in pause, quantity, accent, and grammatical, or inherent force; in all those particulars they will still continue to differ.

Such is the present state of discovery and ascertainment to which enquiries had been conducted upon the subject of emphasis: by which it should seem, that it constitutes an essential part of the theory and practice of the melody of speech; to which we refer the reader; concluding the present article with the following definition. "Emphases consist in the superadditional importance given to particular words or parts of a sentence, by an increased stress, tune, quantity, or force in the pronunciation of such words or parts of a sentence; and by which their relative importance is pointed out, and the contrasts and assimilations of different members of a description, argument, or position, are discriminated to oral perception." Whether it be possible, or even desirable that a system of notation (the want of which is lamented by Sheridan and others) should be invented and applied to the indication of these varieties, is a question that may belong to the article NOTATION; but which shall not be here discussed.

EMPHATICAL, is used by the *Ancient Philosophers*, to express those apparent colours which are often seen in clouds before the rising or after the setting of the sun; or those in the rainbow, &c.

These, because they are not permanent and lasting, they will not allow to be true colours; but, since these emphatical colours are light modified chiefly by refractions and with a concurrence of reflections, and some other accidental variations; and since they are the proper objects of sight, and capable as truly to affect it as other permanent colours are, there is no reason for excluding them from the number of true and genuine colours, since all other colours are only modifications of light, as these are.

EMPHEREPYRA, in *Natural Hiſtory*, a genus of ſiderochita, compoſed of various cruſts or coats, ſurrounding a nucleus of the ſame matter and ſtructure with themſelves. See Siderochita.

Of this genus we have five ſpecies. Hill's Hiſt. Foſſils, p. 532.

EMPHRACTIC, in *Pharmacy*, the ſame with *emplaſtic*. The word is formed from the Greek εμφρακτικ, *I ſtop.*

EMPHRAXIS, in *Medicine*, an obſtruction in any part.

EMPHRUE, in *Botany*, the name given by the people of Guinea to a ſpecies of tree, the leaves of which they boil in wine, and give as a great reſtorative in caſes of weakneſs and decay. Its leaves are exactly of the ſhape of thoſe of the common mulberry but they are not indented at the edge. Petiver has thence called it "arbor Guineenſis mori folio non crenato." Phil. Tranſ. N° 232.

EMPHYSEMA. The common meaning of this word, in *Surgery*, is an inflation of the texture parts, in conſequence of air getting out of a breach in the lungs, and paſſing into the communicating cavities of the cellular ſubſtance on the outſide of the cheſt, through another breach exiſting at the ſame time in the pleura coſtalis, or membrane lining the thorax. However, there are ſome leſs frequent caſes of emphyſema, which are not comprehended in the preceding definition, as will be explained in the courſe of the preſent article. The term is derived from the Greek εμφυσαω, *to inflate*. Dr. Halliday, in a late ingenious eſſay on the ſubject under conſideration, deſcribes the following as the ſymptoms of an emphyſema, when the affection proceeds from an injury of the thorax. A conſtant pain takes place in the ſide, that has been hurt. At firſt, the ſuffering is not increaſed even by a very full inſpiration; but, no great length of time elapſes, before a very conſiderable difficulty of breathing occurs, and the patient complains of a ſenſation, as if cords were drawn acroſs the cheſt, and of a peculiar tightneſs at the ſcrobiculus cordis. If the part, where the pain and uneaſineſs were firſt felt, is now examined, a ſoft puffy tumour may be noticed, which is ſo very prominent as to prevent the ribs immediately under it from being felt. This tumour increaſes very rapidly, and is ſoon diffuſed over all the cheſt; but is particularly conſpicuous on the neck, breaſt, and face. The rapidity, with which it now ſpreads over the whole ſurface of the body, is amazing, and, in many places, the ſkin is elevated ſeveral inches from the ſubjacent bones and muſcles. When the ſwelling has become general, the patient finds it extremely difficult both to expire and inſpire; the motion of the extremities is very much impeded, and, indeed, when the ſkin is conſiderably elevated, ſuch motion is almoſt entirely prevented. The integuments crackle under the hand; the ſkin is much paler than natural, feels cold, and when ſtruck, ſounds like a wet drum. The air may, in general, be eaſily preſſed from any part; but it returns to the ſame place again as ſoon as the preſſure is removed. The reſpiration is exceedingly laborious, and quick. The patient inſpires with a ſudden effort, and the air, in paſſing the epiglottis, makes a peculiar noiſe. Expiration follows inſpiration almoſt inſtantaneouſly, and is performed with a deep ſigh, or rather groan. The patient is incapable of lying with comfort on either ſide of his body, and feels moſt eaſe, and breathes beſt, when ſitting half erect in bed. The ſkin and extremities feel very cold. The pulſe is ſometimes quick and hard; at other times, it is hard and full; but it can only be felt with ſome difficulty. The eye-lids are frequently ſo puffed up that the patient cannot ſee; the features are very much deformed; and the lips aſſume a purple, or rather a livid hue. At the beginning of the caſe there is generally a ſhort tickling cough, which increaſes with the other ſymptoms, ſo as to become almoſt inceſſant. What the patient ſpits up is generally very frothy and mixed with blood. The tongue is dry, and the patient complains of a conſtant thirſt. The voice becomes very weak, and unleſs the effuſed air is ſpeedily let out, ſo as to reduce the ſwelling and preſſure, the patient dies ſuffocated. (See obſervations on Emphyſema, 1807.) It is utterly impoſſible for any one to underſtand the ſubject of emphyſema, without previouſly having ſome idea of the manner in which the function of reſpiration is naturally carried on. He muſt at leaſt know, that, in the perfect ſtate, the ſurface of the lungs always lies in cloſe contact with the membrane lining the ribs, both in inſpiration and expiration. The lungs themſelves are only paſſive organs, and are quite incapable, by any action of their own, of expanding and contracting, ſo as to maintain their external ſurface conſtantly in contact with the inſide of the thorax, which is continually undergoing an alternate change of dimenſions. Every muſcle that has any concern in producing an enlargement, or diminution, of the cheſt, muſt contribute to the effect of adapting the volume of the lungs to the ſize of the cavity in which thoſe organs are contained. This muſt happen while there is no communication between the cavity of the pleura and the external air, and while there is no breach of continuity in the ſurface of the lungs themſelves. In the act of inſpiration, the thorax becomes enlarged in every direction, the lungs are proportionally expanded, and the air entering through the windpipe, into the air-cells of theſe organs, prevents the occurrence of a vacuum. On the other hand, in the act of expiration, certain muſcles diminiſh the capacity of the thorax, and the lungs being of courſe compreſſed, a large portion of the air, which had juſt before been inhaled in the preceding inſpiration, is again expelled from the trachea.

The few obſervations, already made, muſt render it obvious to every reader, that by the conſtant continuance of the ſurface of the lungs in cloſe contact with the inſide of the cheſt, both in its enlarged and diminiſhed ſtate, the air is regularly drawn into, and expelled out of the air-cells of thoſe important viſcera. It muſt alſo be manifeſt, that immediately a free and direct opening is made through the ſkin and muſcles into the cavity of the cheſt, ſome air muſt enter through the wound, and inſinuate itſelf into this laſt ſituation, on the dimenſions of the thorax being enlarged by the action of the muſcles of inſpiration. The lungs on the wounded ſide, of courſe, remain collapſed, and leſs air is drawn into the trachea, in proportion as a larger quantity accumulates between the inſide of the cheſt and the outſide of the lungs. In this manner, the expanſion of theſe latter organs on one ſide becomes gradually more and more obſtructed. A certain part of the accumulated air, it is true, is forced out of the wound again in each expiration; but a larger quantity enters at every inſpiration, and the lungs on the injured ſide become at laſt quite collapſed.

Caſes of this kind, by which we imply wounds, attended with a free and direct opening into the cavity of the cheſt, can never be attended with any ſerious degree of emphyſema. If the wound be not quite ample and ſtraight, a certain quantity of air, expelled at each expiration, inſtead of getting out of the external orifice, may undoubtedly inſinuate itſelf into the adjoining cellular ſubſtance, and occaſion ſome emphyſematous ſwelling. However, this never ſpreads, under ſuch circumſtances, to any conſiderable extent.

The emphyſema alſo, abſtractedly conſidered, is never productive of much danger, when there is a free and direct opening into the cheſt; for it will be preſently underſtood that

that the danger, in emphyſematous caſes, depends on the manner in which the air is confined in the cavity of the cheſt, ſo as to produce ſuch a degree of preſſure on the mediaſtinum and diaphragm, as obſtructs the function of the oppoſite lung, and occaſions a fatal ſuffocation. Now the very exiſtence of a free opening removes the poſſibility of the air accumulating in ſuch a manner in the cheſt, as to cauſe any dangerous degree of preſſure on the diaphragm and other lung. This latter ſupports life, while the lung on the wounded ſide lies quietly collapſed, till the wound in the parietes of the cheſt has healed, and the air has been abſorbed.

The foregoing remarks muſt make us percieve what wiſdom there is in the arrangement, of having the cheſt divided into two cavities, which have no communication with each other. If things were not ſo ordained, ſuffocation would be a common conſequence of every large wound, that extended into the cheſt. Bertrandi informs us, that whenever a free opening is made into each ſide of an animal's thorax, the lungs collapſe, and ſuffocation is always the conſequence.

However, wounds which merely penetrate the cheſt, without wounding the lungs, are never attended with any conſiderable degree of emphyſema. Whatever emphyſematous ſwelling does ariſe is alſo produced by the external air, which paſſes into the thorax through the wound, in the act of inſpiration, and out of the orifice of the injury again, when the patient diminiſhes the capacity of the cheſt in expiration.

The caſes of emphyſema, moſt apt to be attended with alarming ſymptoms, interrupted reſpiration, and an extenſive diffuſion of air in the cellular ſubſtance of the body, are commonly produced by narrow oblique ſtabs, which penetrate the parietes of the cheſt, the pleura coſtalis, and pleura pulmonalis, ſo as to make an opening into the air-cells of the lungs. Emphyſema alſo frequently aſſumes the ſame urgent and dangerous form, in caſes of fractured ribs, the ſharp ſpiculæ of which, being driven inward, tear the pleura coſtalis, pleura pulmonalis, and ſurface of the lungs themſelves. The latter inſtances differ from wounds in the circumſtance of there being no breach of continuity in the integuments. We have already explained, that whatever air inſinuates itſelf into the cellular ſubſtance, in wounds, which ſimply enter the cheſt without injuring the lungs, muſt be derived from without; that is, it firſt paſſes into the thorax through the wound. But when emphyſema ariſes from narrow oblique ſtabs, which enter the cheſt and injure the lungs; or when the affection originates from the pleura coſtalis, pleura pulmonalis, and part of the ſubſtance of the lungs being torn by the ſharp points of a broken rib; whatever air becomes diffuſed in the cellular ſubſtance, firſt eſcapes from the breach in the air-cells of the lungs into the cavity of the thorax, and thence is expelled through the wound, or laceration in the pleura coſtalis, into the common cellular ſubſtance, ſituated on the outſide of this latter membrane. In wounds, which ſimply enter the thorax, without injuring the lungs, the air paſſes through the opening, into the cavity of the pleura in inſpiration, at the ſame time, and from the ſame cauſes, that the air alſo enters the lungs through the trachea. Circumſtances, however, are exceedingly different, when emphyſema ariſes from narrow oblique ſtabs, or fractures of the ribs, attended with an injury of the lungs. In the firſt of theſe caſes the air cannot enter the cavity of the cheſt in the ſame manner as it does when there is a free and direct opening made in the parietes of the thorax. In the ſecond inſtance, (namely, fractured ribs,) there is no external orifice at all. Both theſe latter kinds of caſes, being alſo accompanied by a wound of the lungs, are eſſentially different, in many reſpects, from ſuch examples of emphyſema as proceed from a wound, which only enters the cheſt without doing any miſchief to the lungs. When the ſurface of theſe organs is wounded, no ſooner does the cheſt become expanded in the act of inſpiration, than ſome of the air eſcapes from the breach in the ſubſtance of the lungs, gets into the cavity of the pleura, and afterwards inſinuates itſelf, through the opening in the pleura coſtalis, into the common cellular ſubſtance.

We ſhall next endeavour to make the reader underſtand more clearly the cauſe of the air collecting in the cheſt, and becoming effuſed in ſuch caſes of emphyſema as proceed from wounds, or injuries, which cauſe a breach either in the pleura pulmonalis alone, the pleura pulmonalis and pleura coſtalis together, or in the integuments, muſcles, and pleura coſtalis, without the pleura pulmonalis being at all concerned. We ſhall enter into this part of the ſubject rather fully, becauſe it is by no means well underſtood by the generality of ſurgeons, and, without a clear comprehenſion of it, the practitioner muſt feel completely in the dark, in regard to the right mode of treating the affection.

Dr. Halliday notices, that the lungs in the thorax have often, and not unaptly, been compared to a bladder in a cloſe pair of bellows; but, if we ſuppoſe the bellows to be divided into two compartments, and each of theſe to contain a bladder, which mutually communicate with each other, and with the external air by means of a tube, which is exactly adapted to the nozzle of the bellows, and which admits the air only into the cavity of the bladders, and not into the ſpace betwixt the bladders and bellows, we ſhall then have a perfect repreſentation of the mechanical ſtructure of the thorax. The bellows will repreſent the thorax divided in the middle by the mediaſtinum; the bladders will repreſent the lungs of the right and left ſides; and the tube, which communicates with the bladders and the external air, will repreſent the trachea. The only thing which is wanting to render this mechanical repreſentation perfect is, that the bladders ſhould exactly fill the bellows, ſo as to leave no air betwixt them and the bellows.

It is evident, ſays Dr. Halliday, that when we lift up the handle of the bellows, the bladders will be filled by the external air ruſhing in through the tube, which communicates with both, and that, when we depreſs the handle, the air will be again expelled. Dr. Halliday conceives that this is exactly the way in which the lungs are filled and emptied in reſpiration. The cavity of the thorax being enlarged, by the contraction of the diaphragm and intercoſtal muſcles, &c. a vacuum is formed, into which the air ruſhes through the trachea, and we perform what is called *inſpiration;* whereas, by the contraction of the abdominal muſcles, and relaxation of others, the cavity of the thorax is diminiſhed, and the air is expelled, or we *expire.*

The bellows and bladders, continues Dr. Halliday, will alſo ſerve to illuſtrate the caſes of injury mentioned as giving riſe to emphyſema, and firſt as occaſioned by the pleura pulmonalis of one ſide being wounded, or ulcerated. This caſe is, in many reſpects, the ſame as if an opening were made in one of the bladders, and which opening would form a communication with the ſpace betwixt the bellows and bladder on one ſide. Now, ſuppoſe that this takes place while the handle of the bellows is depreſſed, as ſoon as the handle is raiſed, air will ruſh into the ſpace betwixt the bladder and bellows, and, if you keep the handle up for a little time, the bladder will collapſe altogether, and the place which it naturally occupied, when diſtended, will

now

now be occupied by the air. If we attempt to force out the air by depreffing the handle of the bellows, we fhall find that this cannot be done; for there is no direct communication betwixt the bellows and external air; and, as the effufed air preffes equally on all parts of the collapfed bladder, it cannot efcape through it. Dr. Halliday next explains, that by the action of the mufcles of infpiration, the preffure is removed from the furface of the wounded lung, and the air, which fhould have rufhed in and diftended the lung, now paffes through the wound, into the fpace betwixt the pleura pulmonalis and pleura coftalis. In the living body the whole of the air infpired will not be thus effufed; but, as it muft pafs through the lung, it will alfo at firft diftend it, more or lefs, according to the fize of the opening in the pleura pulmonalis, and this partial dilatation of the wounded lung will always happen while air continues to be infpired on that fide. As foon as expiration begins, the general cavity of the thorax being thereby diminifhed, the effufed air will be compreffed againft the wounded lung; but none of the air which has efcaped can re-enter the lung again, becaufe the whole of the air contained in the lung muft be forced out, and the preffure againft every part of the collapfed lung being equal, will prevent the effufed air from feparating any part, fo as to make a paffage for itfelf into the trachea. In this manner frefh air is accumulated in the fpace betwixt the pleura at every infpiration, while none is allowed to efcape during expiration, and the quantity accumulated at laft will be equal to that which was received into the other lung, during the moft powerful infpiration after the accident. Dr. Halliday next notices, that this kind of accumulation of air in the cheft has been denominated *thoracic emphyfema*, and has been fuppofed to have fometimes proved fatal, without any more extenfive diffufion of the air.

Dr. Halliday afterwards informs us, that when an opening exifts both in the pleura pulmonalis and pleura coftalis, the fame circumftances happen as in the foregoing cafe, till the lung has collapfed; but, that if the patient now attempt to expire, the injured fide of the thorax muft continue diftended, notwithftanding every effort. However, in general the air makes a way for itfelf through the cellular membrane, and as the paffage of air into the cavity of the thorax, during infpiration, is eafier than the return of that which has been already effufed into the cellular membrane, this effufion continues to go on with great rapidity, while the patient lives, fo as to occafion what has been termed *fubcutaneous emphyfema*.

The above writer alfo obferves, that in the cafe of a wound which fimply penetrates the cheft, without hurting the lungs, if the accefs of air be more free by the wound than by the trachea, more air will enter during infpiration into the cavity of the thorax than into the lungs; and that if the accefs of air be, on the contrary, lefs free, then alfo lefs air will enter the thorax than the lungs. However, Dr. Halliday remarks, that in the fame proportion as air enters into the lungs, or into the cavity of the thorax, it will likewife be expelled from thefe cavities during expiration. Hence, air would not accumulate in the thorax, did not the lungs always tend to collapfe from their natural gravitation. Perhaps no author has offered a more accurate and fpirited defcription of an emphyfema arifing from a fractured rib than Mr. John Bell, of Edinburgh. This gentleman remarks, that when a rib is broken, the point of the broken bone is preffed down upon the furface of the lungs, fo as to lacerate them. It is often from the flighteft and moft fuperficial wound of this kind, that the emphyfematous tumour proceeds, the laceration of the lungs extending to fo inconfiderable a depth in the lungs, that it does not even occafion the leaft fpitting of blood, or any other fymptom of a deep wound; and Mr. John Bell obferves, that if the patient die, the wound cannot be feen even after diffection; but can only be difcovered by inflating the lungs. Yet, fays this gentleman, the furface of the lungs being touched even in this flight way, the air efcapes from them at every infpiration; the air which is then within the cavity of the thorax is of courfe compreffed, fo that at the next expiration this compreffion muft force the air either back again into the lungs, or elfe out of the wound in the parietes of the thorax, and thence among the cellular fubftance furrounding the broken rib. Thus, obferves Mr. John Bell, in every infpiration there is a fuction of fome air, which is drawn through the wounded lungs, the air expands in the cavity of the thorax, the lung which gave out that air fubfides again, and lies almoft entirely quiefcent, partly from the wound in it, which, like a rent in a bladder, prevents it from being inflated, and partly from the preffure of the air in the cavity, in which there ought to be a vacuum to make the lung expand. Every new infpiration draws more air from the wounded lung, and every new expiration drives more air out into the cellular fubftance. There is no further outlet for the air, which makes its way forwards, and (to ufe Mr. John Bell's expreffion) undermines the common fkin with wonderful rapidity. Thus, the emphyfematous crackling tumour appears firft over the broken rib, or over the wounded point of the thorax; then extends over the whole cheft, attended with great oppreffion of the breathing; then over the neck and face, and filling the eye-lids particularly, fo that the eyes are abfolutely clofed. Next it fpreads over the belly, and down the thighs. At laft, the private parts become enormoufly fwollen, and no part efcapes this tumour, except the palms of the hands and foles of the feet. More air, fays Mr. John Bell, is every moment drawn out from the wound of the lungs, and driven under the fkin; the patient is every moment more and more oppreffed; till, at laft, the breathing is quite interrupted, the pulfe flags, the extremities grow cold, and the patient, if he be not relieved by fome operation, muft die.

According to the fame writer, the wounded lungs collapfe, and continue in this ftate until the breach in them has healed, which happens in a very few days. From the moment when the lungs are wounded, the ufe of the wounded lobe is loft, fo that if the right lung be the one injured, the breathing is entirely carried on by the left, only half the quantity of air is infpired, and the refpiration is attended with difficulty. Mr. John Bell confiders this collapfe of the injured lung, which muft inevitably continue for at leaft a few days, a chief means of fafety, at the fame time that it is a caufe of diftrefs. He obferves, that when the lungs are unfolded their veffels have their full diameter, they hold their full proportion of blood, and, if they were not collapfed, their wounded veffels would be in a condition to emit a confiderable quantity of blood. But, the fact is, when one of thefe organs is wounded, it collapfes towards the fpine, and can no more be filled than a torn bladder can be inflated. The lung is alfo oppreffed by whatever air or blood may be effufed in the cavity of the thorax. The collapfe of the lung caufes lefs blood to be extravafated in the cheft, and lefs to be thrown into the bronchiæ, which latter kind of hemorrhage is even more dangerous than that which takes place in the cavity of the pleura, becaufe it may not only affect the wounded lung, but obftruct the entrance of air into the other one, fo as to produce a fatal fuffocation.

Mr.

Mr. John Bell very judiciously remarks, that, if the injured lung were not to collapse, it would be difficult to conceive, how the breach could ever be healed; for, the air would be continually streaming through the wound, which becoming alternately dilated and contracted, like that of an artery, could never close. However, since the wounded lung lies in a collapsed state, the edges of the wound are in contact with each other. We find by dissection, that a slight effusion of blood, a degree of livor, a swelling, thickening, and inflammation, take place round the wound, and thus, in two days, the breach is closed. The lung becomes again entire, and capable of resuming its functions.

Mr. John Bell also takes notice, that the blast of air, from a wound in the thorax, is often so strong, that at every breath it is capable of extinguishing a candle, and rushes out with a considerable noise. This stream of air, so far from being a sign of wounded lungs, is often most remarkable, when the lungs are absolutely entire. It is a sign of a free and open wound in the chest; but, by no means of wounded lungs; for whether these organs be wounded or not, the air enters so freely by the outward wound, when ample and direct, that there is no vacuum formed to give the lung play, and it must collapse, till the external wound has healed. Wounds of the thorax, therefore, are totally different cases from wounds of the lungs. When the chest has a large free opening made into it, it is (as Mr. John Bell describes) like a pair of bellows, having a large air-hole, which admits the air every time the breast rises; and expels it again as often as the breast falls down. The air is alternately drawn in, and thrown out at every respiration, with a strong blast; but, whatever air issues through the wound, had been drawn in by the wound, and had never passed through the lungs. Hence, when there is a free opening made in the thorax, no vacuum can form so as to lead to the expansion of the lung, and whether entire, or injured, it must be in a collapsed state.

We may be convinced, that the lung, on the side opposite the wound, is adequate to the temporary support of life, by the recollection of several kinds of cases. When a large free opening has been made into the chest by some accident, or by the surgeon's knife, the lungs on the injured side of course collapse; yet, the patient has often been known to live with tolerable ease in this condition, until a perfect recovery has followed. When the right or left lung has been utterly prevented from becoming expanded, in consequence of the pressure of air in emphysema, water in hydrops pectoris, or pus in empyema, the patient has often lived a considerable while in this state, and ultimately got well. Persons have lived so long with disease in the chest, that when they have died, and their bodies have been opened, only a small knob, or tubercle of the lungs on one side, has been found remaining. See Koelpen de Empyemate Observatio, p. 135, 136.

When the lungs are wounded by the point of a broken rib, or when they are injured by a narrow stab in the thorax, the air cannot readily escape from the cavity of the chest, while at every inspiration more and more is drawn out from the lungs, till at last such a quantity accumulates, that it not only oppresses the lung, which is on that side, but by hindering the free action of the diaphragm, and loading the mediastinum, it oppresses the other lung also. In this manner, the breathing becomes gradually more and more interrupted; the pulse sinks; the extremities grow cold; and after great tossing, and undescribable anxieties, the patient dies. All this may happen, even when a part of the air escapes through the breach in the pleura costalis, so as to inflate a great part of the common cellular membrane of the body. See Discourses on the Nature and Cure of Wounds by John Bell, vol. ii.

From what has been stated, it must be evident, that the emphysematous swelling itself, or, in other words, the diffusion of air in the cellular substance, is a matter of secondary consequence, and, that the great peril of an emphysema depends on the manner in which one side of the chest may become so distended with air, that the pressure produced on the diaphragm, mediastinum, and opposite lung, occasions a fatal interruption of respiration.

However, in cases in which there is a free and open wound in the parietes of the chest, or when the surgeon has made an ample and direct incision into the thorax, the opening, in fact, does not relieve the lung on the same side, but the opposite one, by obviating the pressure of any confined air on it. In the mean while, the lung on the wounded side lies in a collapsed state, till the wound in it has healed.

It is curious to observe, how few of our best modern surgical writers have had accurate notions concerning emphysema. Hewson, Benjamin Bell, and Bromfield, have all fallen into the mistake of supposing it possible to make the wounded and collapsed lung immediately expand again by exhausting the air from the cavity of the pleura. Mr. Bromfield writes, "in case an opening is made between the ribs, and a cannula introduced, whose diameter is larger than the wound of the lungs, the air will be forced out as fast as it escapes from the lungs, therefore the lungs will have room for their *expansion*," &c. See Chirurgical Cases and Observations.

Mr. Hewson observes, "it is natural to suppose, that the wound of the pleura and intercostals may sometimes be too small to suffer the air to get readily out into the cellular membrane, and to inflate it, but may confine a part of it in the cavity of the thorax, so as to compress the lungs, *prevent their expansion*, and cause the same symptoms of tightness of the chest, quick-breathing, and sense of suffocation, which water does." Mr. Hewson seems to have no idea of the danger of suffocation proceeding from the pressure on the opposite lung, and though he wrote professedly to recommend paracentesis thoracis in these cases, he advises making a small incision, rather than a large one, *lest the air should enter, and hinder the expansion of the lungs*. Med. Obs. and Inq. vol. iii.

Mr. Benjamin Bell has undoubtedly run into most strange absurdities in the description in his System of Surgery, of plans for expelling the air from the surface of the lungs. "While the wound yet remains open," says he, "let the patient, in a slow gradual manner, make a full *inspiration*, by which a considerable quantity of the collected air will be discharged. This being done, the skin must be instantly drawn over the *sore*, so as to cover it completely during *expiration*; and if the wound be moderately opened during *inspiration*, the whole quantity will be soon expelled."

In this passage, the author has obviously confounded the words expiration and inspiration, besides displaying ignorance in thinking it practicable to make the collapsed wounded lung rise up again by such proceedings.

The same author remarks: "the other means which we wish to propose for drawing off air from the thorax, is suction; an exhausting syringe may be fitted with such a mouth of ivory or metal, as will allow it to be closely applied over the orifice in the pleura:" He adds, that "as much distress has, on some occasions, ensued from both cavities of the chest being at the same time laid open, it ought never to be attempted." He afterwards imputes the danger, not to the collapse of both the lungs, but to the inflammation likely

likely to arife from the admiffion of air into the two cavities of the cheft at once. The fact is, a free opening made into each fide of the cheft at the fame time would be inftantly followed by a collapfe of both lungs, and immediate fuffocation. There would neither be time for any inflammation to arife, nor for relieving the patient with exhaufting fyringes.

There is certainly a poffibility of making the lungs expand again, by fyringes, &c. as foon as the breach in them has healed, or the injured air-cells have been clofed with coagulating lymph; but, the propriety and utility of the plan may be juftly called in queftion. The introduction of pipes into the cheft cannot be done without irritation; no more air can efcape from the lung now the air-cells are clofed; what is already effufed in the cheft will be abforbed, and the lung expand again, in proportion as this is effected; and fhould the diaphragm and oppofite lung fuffer dangerous preffure from the large quantity of accumulated air, relief may be derived from making an opening in the diftended fide of the cheft, fufficient for letting out a certain quantity of the confined air. In this inftance, a fmall puncture in the pleura would fuffice: the cafe is not like fome others, in which the breach in the lung is not clofed, and a very free and direct opening is required, in order to let the air efcape from the thorax, as faft as it paffes out of the wound in the lung itfelf. By this ftep, and no other, can we prevent the fpreading of the emphyfematous fwelling over the whole body, and what is of ftill higher moment, a perilous degree of preffure on the diaphragm and oppofite lung.

Some of the moft remarkable cafes of emphyfema, on record, are related by M. Littre, M. Mery, Dr. Hunter, and Mr. Chefton, in the Mem. de l'Acad. Royale des Sciences for 1713, Medical Obfervations and Enquiries, vol. ii, and Pathological Enquiries.

With refpect to the treatment of emphyfema, when the air becomes effufed in the cellular fubftance round a wound, which merely injures the parietes of the cheft, the beft plan muft be to direct the patient to expel as much of the air from the thorax as he can, by making long expirations, the opening being regularly clofed when the patient enlarges his cheft in infpiration. After getting as much air as poffible out of the thorax in this manner, the edges of the external wound may be carefully brought together, and well covered with adhefive plaifter, compreffes, &c. fo as to prevent the ingrefs of any more air into the cheft. The emphyfematous fwelling can now no longer increafe, or, at all events, can only do fo as long as whatever air is ftill in the cheft continues unexhaufted; and in proportion as it becomes effufed, or is abforbed, the lung muft expand and refume its function again. In this particular inftance, as there is no breach in the lung, the practitioner, if he thinks proper, may endeavour to make the vifcus expand again at once, by drawing the air out of the cavity of the pleura with a fyringe. However, fince all examples of emphyfema, which are attended with urgent fymptoms of fuffocation, are accompanied by a wound or laceration of the air-cells of the lung, we cannot rationally attempt to make this organ immediately expand again by means of fuction. The thing is not practicable, becaufe how can we exhauft the air from the cheft, as long as more is capable of paffing out of the opening in the lung itfelf. We have likewife already explained, that the collapfed ftate of the injured lung is the moft favourable for the clofure of the wound in it, and for the prevention of hemorrhage from its veffels.

In all confiderable cafes of emphyfema, the air, effufed in the cavity of the thorax, and common cellular membrane, is derived from a rent, or wound in the fubftance of the lungs. The worft fymptoms in thefe inftances, as we have already repeatedly infifted upon, depend on the preffure of the air confined in the injured fide of the thorax, on the diaphragm, and oppofite lung. Both this accumulation of air, and the diffufion of another portion of it in the cellular texture of the body, are entirely owing to one circumftance, *viz.* there being no free and direct paffage through which the air can efcape outward, as faft as it paffes out of the breach in the lung.

The inflation of the external parts with air, a thing which often takes place in an enormous degree, is not itfelf a cafe of urgent danger, and, indeed, it is fo far a favourable event, as it proves, that the air effufed from the lung can efcape from the cavity of the pleura in a certain meafure. If it could do fo with fufficient celerity, no oppreffion of the diaphragm and oppofite lung would be occafioned.

In cafes of emphyfema, Mr. John Bell recommended the following treatment to be adopted. 1ft. Upon obferving the crackling tumour begin to form over a fractured rib, fmall punctures fhould be made with the point of a lancet, and, if the inftrument be carried deeply enough, the air will rufh out in an audible manner. As this air was in the thorax before it came into the cellular fubftance, it is plain, that the thorax is ftill full, and that the lung of that fide is already collapfed and ufelefs, and muft continue fo for a certain time; that is until the breach in it is clofed. The purpofe, therefore, of making thefe fcarifications, and efpecially of making them fo near the fractured part, is not to relieve the lungs, but merely to keep the air from fpreading more widely beneath the fkin.

When the emphyfema proceeds from a narrow ftab in the cheft, the practice fhould of courfe be the fame, in the fame ftage of the cafe, or, in other words, at the period when the external emphyfematous fwelling is in an incipient ftate. The two examples refemble each other, inafmuch as the lungs and pleura coftalis are wounded in both cafes, and the air, which paffes through the breach in the pleura, cannot make its way completely outward; but becomes diffufed in the cellular membrane.

2dly. If, before the furgeon arrives, the air fhould have fpread to very remote parts of the body, as to the fcrotum and down the thighs, it will be eafier, fays Mr. John Bell, to make fmall punctures in thofe parts, in order to let out the air directly, than to prefs it along the whole body, till it arrives at the punctures, made on the cheft, over the wounded part.

3dly. If, notwithftanding free punctures, and preffing out the air in this way, it fhould be found by the oppreffion, that either air or blood is accumulating within the cavity of the thorax, fo as to oppress not the wounded lung only, which, from the firft, is of courfe collapfed and ufelefs, but, alfo, fo as to opprefs the diaphragm and other lung; then a freer incifion muft be made through the fkin and mufcles, and a fmall one in the pleura coftalis, in order to let the confined air out of the thorax.

In the courfe of a few days the wound in the collapfed lung becomes clofed by the adhefive inflammation, in which procefs the breach in the air-cells is fhut up with coagulating lymph, and the air can no longer get out of them into the cavity of the cheft. The air, which is already there, is alternately abforbed, and the lung, expanding in proportion, refumes its original functions.

Emphyfema has been known to arife from the burfting of a vomica, and ulceration of the furface of the lungs; but the air, which efcapes in this inftance, cannot find its way into the cavity of the thorax, becaufe the inflammation, which precedes the abfcefs and ulceration of the air-cells, clofes closes those which are adjacent, and produces an adhesion of the edges of the vomica, or ulcer, to the inner surface of the chest, so as entirely to separate the cavity of the abscess from that of the thorax. We do not know of any example, in which the symptoms imputed to the confinement of air in the chest, originated in consequence of suppuration and ulceration of the surface of the lungs. However, Palfyn, Dr. Hunter, and the author of the article "Emphysema" in the French Encyclopædia, have seen cases, in which emphysema has arisen from abscesses of the lungs, attended with adhesion to the pleura, and ulcerations in the situation of such adhesion. In these cases, the pus having made its way through the pleura, and intercostal muscles, the air escapes also through the same tract, so as to get into the cellular membrane on the outside of the chest.

A certain degree of emphysema has been observed to be occasionally produced by a violent effort of respiration. In the instances referred to, the air is said first to make its appearance about the clavicles, and afterwards to spread over the neck and adjacent parts. The violent efforts of parturition have also been remarked to occasion a similar symptom; but without being followed by any bad consequences. See Medical Communications, p. 176.

In the fourth volume of the Mémoires de l'Academie de Chirurgie, 4to. M. Louis has described an emphysema of this latter sort, which, on account of its cause, and the indication which it affords the practitioner, is highly important. M. Louis had occasion to remark the occurrence in a young girl, who died suffocated, from a bean falling into her wind-pipe, and he considers the kind of emphysema in question as a pathognomonic symptom of such an accident. If this opinion be correct, a knowledge of the circumstance must be of great importance to the practical surgeon; for, if making an opening into the trachea, and attempting to extract the foreign body be delayed, from any doubt concerning the nature of the case, the patient will inevitably die of suffocation. In the case which first attracted the attention of M. Louis to the subject, the emphysema made its appearance on both sides of the neck above the clavicles, and came on suddenly, on the third day after the foreign substance had fallen into the trachea. On examining the body, after death, the lungs and mediastinum were also found to be in an emphysematous state. The retention of air by the extraneous substance produced, according to M. Louis, at every attempt to expire, and, particularly, during the violent fits of coughing, a strong propulsion of this fluid towards the surface of the lungs into the spongy substance of these viscera. The air next insinuated itself into the cellular texture, which unites the surface of the lung to the pleura pulmonalis; and, by communications from cells to cells, it occasioned a prodigious swelling of the cellular substance, between the two layers of the mediastinum. The emphysema increasing, at length made its appearance above the clavicles. This tumefaction of the lungs and surrounding parts, in consequence of air getting into their spongy and cellular texture, is an evident cause of suffocation, and M. Louis observes, that the swelling seems to be so natural an effect of the presence of a foreign body in the trachea, that one can hardly fail to think it an essential symptom, though no author has made mention of it.

An emphysema of the head, neck, and chest, has also been noticed in some typhoid fevers. Dr. Huxham relates an instance of this sort, which took place in a sailor of a scorbutic habit. Medical Observations and Inquiries, vol. iii. art. 4.

Surgical practitioners have frequent occasion to remark the occurrence of a partial emphysema in cases of gangrene. Emphysema, arising from wounds in the thorax, is very often a case, complicated with large extravasations of blood in the chest, and inflammation of the pleura and lungs; circumstances which must greatly increase the danger, and ought materially to influence the mode of treatment.

The adhesions, so frequently met with between the pleura costalis and pleura pulmonalis, must obviously have the effect of preventing the collapse of the lung, in circumstances under which it would otherwise happen. Were a wound to enter through the middle of any adherent parts, it is plain that no air could find its way out of the lung into the cavity of the thorax.

EMPHYTEUSIS, in the *Civil and Canon Law*, the letting out of poor barren lands for ever, or at least for a long term of years, on condition of the tenants cultivating, meliorating, or mending them, and paying a certain yearly consideration.

The word is formed of the Greek, εμφυτευσις, which signifies *an engraftment*, and by metaphor, a *melioration* or *amendment;* for as we only graft trees to mend them, so a man only alienates his land by emphyteusis, on condition of having it amended.

Emphyteuses are a kind of alienations, differing from sales, in that they only transfer the *dominium utile*, the benefits of the ground, not the property, or fee-simple. Among the Romans they were at first temporary, afterwards perpetual.

The twentieth canon of the council of Carthage prohibits the bishops seizing the church's emphyteusis out of the hands of private persons, unless they have been three years without paying rent.

EMPIRE, the territory or extent of land under the command and jurisdiction of an emperor. See Emperor.

We say the Roman empire, the empire of the East, the empire of the West, or the western empire, the empire of the Great Mogul, &c.

Antiquaries distinguish between the medals of the *upper* and *lower*, or *bas empire:* the curious only value those of the upper empire, which commences with Cæsar or Augustus, and ends in the year of Christ 270.

The lower empire comprehends nearly 1200 years, reckoning as low as the destruction of Constantinople, in 1453.

They usually distinguish two ages, or periods of the lower empire; the first beginning where the upper ends, *viz.* with Aurelian, and ending with Anastasius, including about 200 years; the second beginning with Anastasius, and ending with the Palæologi, which includes about 1000 years. See Medal.

In ancient history we read of four great monarchies or empires, *viz.* that of the Babylonians, Chaldeans, and Assyrians; that of the Medes and Persians; that of the Greeks; and that of the Romans. The first subsisted from the time of Nimrod, the same with Belus, or, as others say, from the time of Ninus, the son of Belus, who founded it in the year B.C. 2059, according to Blair's tables, to Sardanapalus their last king, B.C. 820, and consequently lasted about 1239 years. But chronologers differ much concerning both the commencement and duration of the Assyrian empire. (See Assyria.) The empire of the Medes commenced under Arbaces in the year B.C. 821, and was united to that of the Babylonians and Persians under Cyrus, in the year B.C. 538, and it closed in the 5th year of Darius Codomannus, who was conquered by Alexander B.C. 331. The dominion of Persia, after the death of Darius, was transferred to the Greeks. The Grecian empire lasted only during the reign of Alexander the Great, beginning in the year B.C. 336, and terminating with the death of this conqueror B.C. 323, his conquests being divided

vided among his captains. The Roman empire commenced with Julius Cæfar, when he was made perpetual dictator, after the battle of Pharfalia, in the year of the city 706, 48 years B.C. Some, however, date the commencement of the Roman empire after the battle of Actium, with the firft year of Auguftus, A.U C. 723, B.C. 31. The decline of the Roman empire may be confidered as principally owing to the defpotifm of Severus, and the paffive obedience of the people. From this period we behold a train of emperors vicious, or impotent, either wilfully guilty, or unable to affert the dignity of their ftation. The empire itfelf gradually decayed, harraffed on all fides by powerful invaders, and convulfed by the furious contefts of domeftic foes. During the reign of Gallienus, 30 pretenders contended for the fupreme power, and added all the calamities of civil war to the misfortunes of this devoted empire. The power and influence of the emperors were likewife diminifhed by the adoption of feveral colleagues, and by the divifion of the empire between the two fons of Theodofius the Great, A.D. 295. Arcadius was proclaimed emperor of the Eaft, and Honorius emperor of the Weft. The weftern empire contained all Italy, Spain, France, Britain, Germany, Pannonia, and Africa. The eaftern empire comprehended Afia the Lefs, Arabia, Syria, Egypt, Lybia, and the feveral regions on the Danube. The feat of the empire was removed to Byzantium by Conftantine, in the year of our Lord 328: the Eaft and Weft were then united under the title of the Roman empire, till the Romans proclaimed Charlemagne emperor, A.D. 800. From this epocha the Eaft and Weft formed two feparate empires; that of the Eaft, governed by Greek emperors, commenced under Nicephorus, A.D. 802, or, rather, was continued; but being gradually weakened, terminated under Conftantine Palæologus, in 1453, when the Saracens, having fubdued Syria, Paleftine, Egypt, Cilicia, and other neighbouring countries, and having ravaged the reft of the Roman territories in the Eaft, befieged Conftantinople under Mahomet II. and became mafters of it. From this period the city has been the imperial feat of the Turkifh or Ottoman emperors. The weftern empire, properly fo called, terminated with Auguftulus, fon of Nepos, A.D. 476, but being revived under Charlemagne, it ended with Charles Le Gros, who poffeffed all the dominions of Charlemagne, A.D. 887, and it was afterwards known by the appellation of the *empire* or German empire.

Empire, or *the* Empire, ufed abfolutely, and without any addition, long fignified the empire of Germany, called alfo in juridical acts and laws, the *holy Roman empire*, *S. R. I.* q. d. *facrum imperium Romanum*, which conftituted what was otherwife called the *Germanic body*.

The empire had its beginning with the ninth century; Charlemagne being created firft emperor by pope Leo III. who put the crown on his head in St. Peter's church on Chriftmas day, in the year 800.

Authors are at a lofs under what form of government to range the empire; fome fuppofe it to have been a monarchical ftate, becaufe all the members thereof are obliged to afk the inveftiture of their ftates of the emperor, and to take an oath of fidelity to him.

Others maintain that it was a republic, or ariftocratic ftate, becaufe the emperor could not refolve or determine any thing without the concurring fuffrages of the princes. It is added, that if they required inveftiture from, and fwore fealty to him, it was only as head of the republic, and in the name of the republic, and not in his own; juft as at Venice, every thing is tranfacted in the name of the doge. See Doge.

Laftly, others will have the empire to have been a monarcho-ariftocratic ftate, *i. e.* a mixture of monarchy and ariftocracy; becaufe, though the emperor in many cafes feemed to act fovereignly, yet his decrees and refolves had no force, in cafe the ftate refufed to confirm them.

In fine, we fhould rather choofe to call it an arifto-democratic ftate, becaufe the diet, wherein the fovereignty is lodged, was compofed of princes, and the deputies of the cities, and was divided into three orders, or bodies, called *colleges*, *viz.* the college of electors, the college of princes, and the college of cities.

We fay, diet of the empire, circles of the empire, fiefs of the empire, princes of the empire, eftates of the empire, members of the empire, capitulations of the empire, receffus of the empire, &c. See College, Diet, Circle, Prince, Capitulation, and Recessus.

The ftates or eftates of the empire were of two kinds, *mediate* and *immediate*. The *immediate* ftates were thofe who held immediately of the empire, whereof, again, there were two kinds; the firft, fuch as had feats and voices in the imperial diet; the fecond, fuch as had none. The *mediate* ftates were thofe who held of the *immediate*.

The ftates which afterwards compofed the empire were the princes of the empire, the counts of the empire, the free barons of the empire, the prelates of the empire, the princeffes or abbeffes of the empire, the nobles of the empire, and the imperial cities. For an account of the fubfequent changes which this empire has undergone, fee Electors, Emperor, and Germany.

EMPIRIC, in *Medical Hiftory*, from the Greek word ἐμπειρία, *experience*, an appellation affumed by a fect of phyficians, who contended that all hypothetical reafoning refpecting the operations of the animal economy was ufelefs, and that obfervation and *experience* alone were the foundation of the art of medicine.

The origin of this fect is varioufly ftated by different writers of antiquity, who have attributed it to three different perfons. The empiric phyficians themfelves feem to have confidered Acron of Agrigentum, who was a contemporary and rival of Empedocles, (a pupil of Pythagoras,) in the 70th olympiad, as their founder; and Pliny has afferted the fame opinion, in his fketch of the hiftory of medicine. (Nat. Hift. lib. xxix. cap. 1.) "Alia factio, ab experimentis fe cognominans *Empiricen* cæpit in Sicilia, Acrone Agrigentino, Empedoclis phyfici auctoritate, commendato." This account of the rife of their fect was maintained by the empirics, in order to obtain the advantage over the rational or dogmatic phyficians, who could only date their origin from the time of Hippocrates. But it has been juftly remarked, that the phyficians, who lived between the time of Æfculapius, and the period, when philofophy and reafoning were applied to medicine, were empirics in fact, though not in name, in confequence of the rude and imperfect ftate of the art, and cannot be regarded as fectaries, fince all were at that time equally empirical.

The beft hiftorians refer the eftablifhment of this fect to a much later period; namely, to about the 123d olympiad (A. C. 260); but they are not agreed as to the individual, who firft promulgated the doctrine of empiricifm. Galen and others have afcribed the origin of the fect to Philinus of Cos, who was a difciple of Herophilus, to whom he was faid to be indebted for the firft hints of his fyftem. Herophilus was doubtlefs more attentive to the ufe of drugs than any of his predeceffors, and the empirics directed their views particularly to the difcovery of medicines: his numerous difcoveries in anatomy likewife led him, and ftill more his difciples, to queftion the value of the reafoning of their predeceffors, in whofe ftatements of fact they found fo much error,

error, particularly in regard to the ſtructure of the human body. Little, however, is known with certainty reſpecting this Philinus. Galen quotes him, when writing on the ſubject of the compoſition of medicines; and he is ſaid to have written on the nature of plants, and to have commented on the writings of Hippocrates.

Celſus, however, aſſerts, that Serapion was the firſt who maintained the doctrine, that the application of reaſoning and philoſophy to the art of medicine was of no avail, and confined the ſtudy of it to practice and experience. (De Medicina, Præf.) Serapion was born, and practiſed medicine at Alexandria, and appears to have been contemporary with Philinus, and the diſciples of Herophilus. Galen accuſes him of having ſhewn a contempt for Hippocrates and all his predeceſſors, in his writings, and of praiſing himſelf on all occaſions. (Galen. de ſubfigurat. Empir. Cap. ult.) Apollonius, Glaucias, Heraclides of Tarentum, and others of no ſmall note ("non mediocres viri") followed in the ſteps of Serapion, according to Celſus. Heraclides was one of the moſt famous of the empirics, and appears to have been the firſt to employ that valuable ſubſtance, opium, in the practice of medicine. Many other names are on record, as belonging to this ſect, antecedent and poſterior to Heraclides: one of the lateſt was Marcellus, who lived in the time of Theodoſius, and appears to have held ſome office in the court of that emperor, and was probably therefore a Chriſtian. He has left a treatiſe on medicines, compiled from various writers, and adapted to the cure of all diſeaſes. The art of medicine, indeed, is indebted to the empirical phyſicians for many important additions to the Materia Medica. With reſpect to the doctrines of the ſect, however, and the principles on which they defended themſelves againſt the dogmatics, we have no other accounts, than thoſe which their adverſaries have given, in quoting them with a view to their refutation; all their works upon theſe topics have periſhed. Celſus and Galen have ſtated probably the greater part of the leading points of their tenets.

The *empiric* ſyſtem, as the term imports, was founded altogether upon *experience:* and thoſe, who belonged to this ſect have remarked, that there are three modes by which we learn, from experience, to diſtinguiſh what is advantageous and what is prejudicial, in regard to our health. The firſt of theſe, and the moſt ſimple, ariſes from *accident*. A perſon, for example, having a violent pain in the head, happens to fall, and divides a veſſel in the forehead; and it is obſerved that, having loſt blood, his pain is relieved. Under the ſame mode, they include the experience which is acquired by obſerving the ſpontaneous operations of the conſtitution, where no remedy has been applied, as in the following caſe: a perſon labouring under a fever, finds his diſeaſe mitigated, after a hemorrhagy from the noſe, a profuſe perſpiration, or a diarrhœa. The ſecond mode of gaining experience, is, that, in which ſomething is done by *deſign*, with a view to aſcertain what will be the ſucceſs of it: as, for inſtance, when a perſon, having been bitten by a ſerpent, or other venomous creature, applies to the bite the firſt herb that he finds; or when a man attempts to alleviate the ſymptoms of an acute and burning fever, by drinking as copiouſly as he is able of cold water; or when a perſon tries a remedy, ſuggeſted to him by a dream, as was frequently done in heatheniſh times. The third mode of experimenting, is that which the empirics termed *imitative;* which is purſued in caſes, when, after having remarked the effects reſulting from *accident*, or the ſpontaneous actions of the ſyſtem, on the one hand, or from *deſign* on the other, we make an attempt to accompliſh a ſimilar reſult, by imitating that which was done on thoſe occaſions.

This laſt ſort of experience, they contend, is that which peculiarly conſtitutes the art of medicine, when it has been frequently repeated. They call that *obſervation*, (τήρησις,) or *autopſia* (αὐτοπσια,) which each individual ſees himſelf; and uſe the term *hiſtory*, or *record*, (ἱστορία) for ſuch obſervation when committed to writing; that is, the autopſia, or perſonal experience, conſiſts of the obſervations which each perſon has made, by his attention to the progreſs of a diſeaſe, whether in regard to its ſymptoms and changes, or to the remedies employed; while the record is a ſort of narration or regiſter of all that was obſerved by thoſe individuals; which regiſter being completed, (*i. e.* including all the diſeaſes, incident to mankind, and the remedies adminiſtered for their alleviation,) the art of medicine would be eſtabliſhed with a conſiderable degree of certainty. But as new diſeaſes ſometimes occur, in regard to which neither our perſonal experience, nor the obſervations of others, can furniſh us with any aſſiſtance; and we meet with diſorders in particular ſituations, where the means of relief, ſanctioned by experience elſewhere, are not within our reach; we muſt neceſſarily have recourſe to ſome other expedient in order to alleviate the ſufferings of the patient. The empirics were provided againſt this particular difficulty, in what they termed *a ſubſtitution* of ſimilar means, (*tranſitus ad ſimile*, as the Latins have tranſlated it.) This was a new experiment, which they inſtituted, after having compared one diſeaſe with another; or one part of the body with another, of ſimilar ſtructure; or, laſtly, one remedy, the nature of which was aſcertained by experiment, with another which reſembled it. "They tried, for example, in *herpetic* eruptions the remedies which had relieved *eryſipelas;* in the diſeaſes of the *arms*, they employed the expedients which had been practiſed in thoſe of the *legs;* and if they could not procure *quinces*, which are an auſtere fruit, they uſed *medlars*, which are not ſo."

Obſervation, then, *record*, and the *ſubſtitution* of ſimilar means, were the three fundamental reſources of the art of medicine; according to the empirics; and theſe were denominated by Glaucias, and others, the *tripod of medicine* (τρίπες της ἰατρικῆς.)

There is obviouſly a great deal of good ſenſe and ſound philoſophy in this doctrine of empiriciſm. It points out the true mode of inveſtigating the phenomena of nature, by unwearied experiment; the mode which Bacon laboured to inculcate on the dogmatiſts, and hypotheſis-mongers of his age, which Newton ſucceſsfully purſued, and which has led the philoſophers of later times to the developement of that fund of natural knowledge in the ſciences of electricity, chemiſtry, mechanical, and every branch of natural philoſophy, by which modern inquiry is diſtinguiſhed. Compared with this ſpecies of inveſtigation, how futile are the ſpeculations, miſnamed philoſophy in the ſchools, relative to elements, and eſſences, which had no exiſtence, except in the imagination of the diſputants. For it muſt be obſerved, that the ancient empirics did not diſregard the dictates of reaſon and reflection; they only deprecated the application of them to circumſtances out of the reach of the ſenſes, and beyond the ſcope of experiment. Thoſe miſchievous principles and practices, which their ſucceſſors or at leaſt thoſe who have ſubſequently aſſumed the title, have made the refuge of ignorance and craft, cannot be alleged againſt them. This is evident, from the clear and explicit ſtatement of their tenets, which Celſus has tranſmitted to us: in order to underſtand which, it will be neceſſary to attend to the tenets of their opponents, the rationaliſts or dogmatics, as ſtated by the ſame elegant writer.

The

The dogmatic phyficians maintained the neceffity of a knowledge of the four following fubjects, in order to be able to cure difeafes; namely, 1, of the occult and effential caufes of difeafe; 2, of the evident caufes; 3, of the natural actions of the conftitution, (or phyfiology;) and, laftly, of the internal parts, or anatomy. 1. By the *occult* caufes, they meant the effential principles of the conftitution, or of animal life, under its various conditions of health and difeafe. And they held, that it was impoffible to cure difeafe, if we are ignorant of the circumftances in which it confifts; for that different methods of cure muft neceffarily be requifite, if a redundancy or deficiency of the *four elements* were the effential caufe of difeafe, according to the hypothefis of fome philofophers; or if all difeafe confift in depravations of the fluids, as was the opinion of Herophilus; or, in difordered refpiration, as Hippocrates imagined; or in the paffage of the blood into thofe veffels, which naturally convey air, caufing inflammation, and that inflammation exciting the commotion obferved in fever, according to the fuppofition of Erafiftratus; or in the obftruction of the invifible pores, by the corpufcles, or atoms, as Afclepiades contended. Againft this fyftem of reafoning by hypothefis, beyond the bounds of experimental inquiry, the empirics objected upon the moft irrefragable principles. "The attempt," fay they, "to fcrutinize the occult principles of animal life is fruitlefs; for 'nature is incomprehenfible:' we may afcertain *what* fhe performs; but *how* fhe performs it, is to us infcrutable. And the very diffenfions among the theorifts, and the difference of their accounts of thofe operations, evince the infcrutability of the fubject. They cannot all be right; and why fhould we believe the ftatement of one, rather than that of another? Why is Hippocrates more entitled to credit than Herophilus, or Herophilus than Afclepiades? It is obvious that we cannot decide in favour of the opinion of any of them, either from their arguments, or their practical authority; for the arguments of each may be fufficiently plaufible and confiftent with probability; and their practice may have been equally fuccefsful. Indeed this very fact, that phyficians of the moft oppofite theoretical opinions have equally fucceeded in reftoring health to the fick, proves the independence of the art of medicine upon fuch difquifitions, and that their fuccefs is to be afcribed to their principles of cure having been deduced, not from their fpeculations about occult effential caufes, nor even about the natural actions, but from experiment, from what actual practice had taught them. And fuch is the cafe in all other arts. The hufbandman and the pilot are not qualified for their refpective occupations by theory and difcuffion, but by practice and experiment. Indeed if reafoning could enable a perfon to cure difeafes, the philofophers would neceffarily be the beft phyficians; whereas, we obferve that they are gifted with an abundance of words, but poffefs very little fkill in the art of healing."

2. With refpect to the *evident* caufes, the dogmatifts underftood, by that term, the obvious exciting caufes of difeafes, fuch as heat and cold, fafting and excefs in eating, &c., to the operation of which difeafes are often obferved immediately to fucceed. The empirics admit the utility and importance of attending to thefe caufes; but they contend that, however obvious they may be in many inftances, the method of cure is neverthelefs not apparent from them, as in ophthalmia, or in a wound; but is afcertained only from experience.

3. The *natural actions* of the body, a knowledge of which the dogmatifts maintain to be abfolutely neceffary to the phyfician, are thofe operations of the conftitution, which the moderns comprehend under the term phyfiology; namely, the nature of refpiration; of the concoction or digeftion of our food and drink, and its diftribution to the different parts of the body, which it nourifhes; of the "rife and fall" of the arteries; of fleeping and waking, &c. "Without an acquaintance with the caufes of thefe actions," fay the rationalifts, "it muft be impoffible for any one either to fupprefs incipient difeafes, or to cure them when they are completely eftablifhed." But of all thefe actions, they deem the digeftion of the food the moft important, and infift more particularly upon the neceffity of its being underftood. But in this point again there is great diffenfion among them: fome of them, following the hypothefis of Erafiftratus, maintain that the food is concocted by mechanical attrition; others, after Pliftonicus, the difciple of Praxagoras, affert that digeftion is produced by the putrefaction of the food; while others prefer the opinion of Hippocrates, and contend that it is effected by heat. The difciples of Afclepiades, again, affirm that all thefe hypothefes are idle and futile, for that there is no fuch thing as concoction, but that the alimentary matter, crude as it is received, is diftributed through the whole body. Various as thefe opinions are, however, they do not difpute the neceffity of accommodating the food of the fick to the nature of the function; that is, if the concoction be the refult of attrition, then fuch food fhould be felected as is moft eafily broken down; if it be effected by putrefaction, then fuch food is to be chofen as is moft readily putrefcent; if by heat, fuch as moft effectually cherifhes heat: but if there be no fuch procefs as that of concoction, then all thefe kinds of aliment are improper, and fuch only fhould be taken as moft completely refifts all change. In the fame manner, they contend, when a difficulty of breathing occurs, or a morbid degree of fleep or watchfulnefs, that phyfician will be the moft capable of curing them, who is acquainted with the nature of thefe functions.

Againft this doctrine of the dogmatifts, it is evident that the arguments of the empirics were equally conclufive, as againft their preceding hypothefes, refpecting the occult caufes. Their ftatements, that the very difference of the theories of the dogmatifts implies their want of foundation, and that the mode in which nature operates being incomprehenfible, we muft be content with learning what fhe operates, are obvious refutations of the futility of thefe, and indeed of all other hypothefes. "It is of no importance," fay the empirics, "to inquire in what manner the diftribution of the aliment through the body is accomplifhed; our only ufeful inquiry is, what fort of aliment is moft eafily diftributed; and whether digeftion is performed by heat or putrefaction, or whether it is not a digeftion, but a diftribution only, is altogether immaterial, provided we know, from experience, what is moft eafy of digeftion, or the contrary. For," they continue, "the art of medicine, even in its infancy, was not deduced from fuch hypothetical reafoning, but from experiments. Whence it was obferved, among thofe who were fick, and without phyficians, that fome, prompted by appetite, had immediately taken food at the beginning of their illnefs; while others, loathing victuals, had fafted altogether; and that the difeafe in thofe who had abftained from food had been alleviated. It would be remarked, too, that fome took food in the paroxyfm of a fever, others a little before it came on, and others again after its remiffion; and that it would agree the beft with thofe who ate after the removal of the fever. In like manner, it would be feen, that thofe who took food freely in acute difeafes, fuffered an aggravation of their fymptoms, while the abftemious would not thus fuffer. Thefe and fimilar circumftances, occurring daily, would be noted

by

by diligent obfervers; and what had been feen to fucceed moft generally, that they afterwards prefcribed to the fick. Such was the origin of the art of medicine, which, in confequence of the recovery of fome, and the death of others, taught us to difcriminate the ufeful expedients from thofe that were pernicious: and when remedies were difcovered by fuch experiments, then men began to reafon about their operation; for the art of employing remedies was obvioufly not the refult of reafoning, but explanatory hypothefes were fought for after the remedies were afcertained.

4. The dogmatifts contend, in the laft place, that as pains and various diforders attack the *internal parts*, no perfon, in their opinion, can apply proper remedies to them, when difeafed, if he is ignorant of their fituation and appearance. Hence, they affirm, that it is neceffary to diffect the bodies of the dead, and to examine the vifcera and inteftines: and they extol the method of Herophilus and Erafiftratus, who procured criminals out of prifon, by royal permiffion, and, having diffected them alive, contemplated, even while they were breathing, the parts which nature had before concealed; and remarked their pofition, colour, figure, fize, arrangement, foftnefs, hardnefs, fmoothnefs, and connection, as well as their proceffes and depreffions, or what is inferted into and received by each part. "For," fay they, "when any internal pain occurs, the feat of that pain cannot be afcertained by one who is ignorant of the fituation of the vifcera and inteftines; nor can he cure any part difeafed, who does not know what the part is. Befides, if the vifcera happen to be expofed in confequence of a wound, if the obferver be unacquainted with the natural appearance of each part, he cannot difcover what is found, and what injured or corrupted, and therefore is not qualified to cure that part which is difeafed. Even external remedies are applied with much more judgment by one who knows the fituation, figure, and fize of the internal parts. Nor can it be juftly deemed cruel (although it is generally fo reprefented) to put a few guilty individuals to torture, with a view to afcertain means of relief for all the innocent among mankind in all fucceeding ages.

To thefe arguments the empirics reply, that "the preceding doctrines of the dogmatifts were only idle and frivolous, but in this there is the addition of exceffive cruelty: for what can be more cruel than to cut open the abdomen and cheft of living men, and thus to render that benign art, which is the guardian of the health of mankind, the inftrument of torture, and that of the moft atrocious kind? more particularly when it is confidered, that fome of the information, which is fought after with fo much barbarity, cannot be thus acquired at all, and that the reft may be afcertained without committing murder. For the colour, fmoothnefs, foftnefs, hardnefs, and other fuch qualities, are not the fame in the body, when diffected, as when it was found: even in bodies that have fuffered no violence, thefe qualities externally are often changed by fear, grief, hunger, indigeftion, fatigue, and a thoufand other inconfiderable affections. Whence it is ftill more probable, that the internal organs, which are ftill more delicate than the external, and to which even expofure to the light is new, muft be changed by the fevereft wounds, or rather by fuch fatal mangling. Nothing can be more abfurd than to fuppofe that appearances are the fame in a dying man, nay, in one already dead, as during life. The abdomen, indeed, may be opened, while a man yet breathes; but no fooner does the knife reach the thorax, and divide the tranfverfe feptum, which feparates the upper cavity from the lower, (which the Greeks call the *diaphragm*, διαφραγμα,) than he immediately expires: it is, therefore, the præcordia and vifcera of a dead man which alone the butchering phyfician brings to his view; and which neceffarily have the appearance of the organs of the dead, and not of thofe of the living. Thus all that is gained by the phyfician is the opportunity of committing a barbarous murder, and not that of witneffing the condition of the vifcera in a living man. If, however, any information can be obtained, as to the appearances of the internal parts while the individual yet breathes, accident often gives the practitioner opportunities for fuch obfervation: for it frequently happens that a gladiator in the *arena*, a foldier in battle, or a traveller attacked by robbers, is wounded in fuch a manner as to expofe fome internal organ to view; whence a fagacious phyfician will learn the fituation, pofition, connection, figure, and other circumftances belonging to each, while he is endeavouring to relieve, and not to murder the patient; and thus will acquire, through compaffion, that knowledge which others have obtained by the moft horrid cruelty. Moreover, it is clear, from the arguments already ftated, that it is not neceffary to mangle even dead bodies; which, though not cruel, is loathfome to the fight, as are moft of the circumftances connected with the dead; and whatever can be learned, refpecting the living, may be acquired during the treatment of their difeafes and wounds." See Celfus, De Medicina, in Præf.

The concluding obfervations, which deny the neceffity of anatomical knowledge, acquired by the diffection of dead bodies, appear to be the only point in the tenets of the empiric phyficians which is liable to difpute. But even in this point, we are fatisfied, there is a great portion of truth, fo far as relates to the knowledge and treatment of thofe internal difeafes, to which the knife of the furgeon cannot reach; for the knowledge of the appearances and connection of the vifcera does not enable us to fuggeft the practical means of relief, when they become difeafed: experience and obfervation alone, as the empirics contend, have taught us to apply the remedies. See an Effay on the Importance of Anatomical Knowledge to Medicine, in the Edinburgh Med. and Surg. Journal for Jan. 1809.

After having thus ftated the doctrines of the empiric phyficians, in oppofition to thofe of their opponents, Celfus has fubjoined a fenfible and judicious criticifm refpecting the merits of both. But this is not the place to enter more fully into the fubject; we muft therefore refer thofe, who wifh for the opinion of that claffical phyfician, to his work already quoted.

There is one point, which could not be well introduced under any of the preceding heads, which the dogmatifts conftantly threw out againft the empirics, namely, that *new* difeafes occafionally occur, for the cure of which, confequently, practice and experience have afforded no rules or information; whence, they fay, it is neceffary to inveftigate their caufes, both evident and occult, without a knowledge of which no mortal can find out why one curative expedient ought to be adopted rather than another. But the reply of the empirics to this point is not lefs accurate and fatisfactory than in the preceding parts of the difpute. "New difeafes," they fay, "requiring new remedies, feldom if ever occur; but if any unknown diforder fhould appear, the phyfician would not require the hypothetical doctrines about occult caufes to direct him in his method of treatment: he would immediately obferve to what known difeafe it was moft nearly allied in its nature and fymptoms, and employ the remedies which experience had fhewn to be fuccefsful in the fimilar malady; and by fuch refemblance he would be able to difcover a proper remedy." Celfus.

It

It is evident, then, that both the dogmatic and empiric phyficians appealed to experience, and that neither excluded altogether the dictates of reafon and reflection. The principal difference in their tenets appears to have confifted chiefly in this: that the empirics reafoned only from the facts afcertained by obfervation, without attempting to explain their effential and infcrutable nature by hypothefes; and that the latter fpeculated upon the mode and nature of every action and phenomenon in the animal body, and took thefe fpeculations as the bafis of their reafoning:—an error in the inveftigation of nature, which, as we have before faid, was fo well expofed by lord Bacon, in modern times; and which was practically illuftrated in the triumph of Newton's *empiric* doctrines, over the hypothefes of Des Cartes.

No longer engaged in ftudying fyftems, and averfe to fpeculation, even in regard to the fymptoms of difeafes, the empirics exerted their whole faculties in inveftigating the power of medicinal fubftances, which laid the foundation of their pre-eminence in pharmaceutical fkill, and gradually effected thofe changes in the art of medicine which fubfequently occurred. The properties of the productions of nature, efpecially of the vegetable world, were extenfively examined; and the inftruments of the phyfician, by which he could influence the functions of the living body, were greatly multiplied. It is chiefly to the induftry of the ancient empirics that we are indebted for the introduction, or rather for the full knowledge, of fedative and narcotic remedies; on the liberal ufe of which probably depended the fuperior reputation acquired by fome of them over their more cautious antagonifts. Of this fuperiority, a fingular inftance occurs in the many exifting teftimonies to the fame of Heraclides of Tarentum, before mentioned, who is recorded as the moft fuccefsful phyfician in any age or country of the world.

It is eafy to fee, however, that this direction of medical inquiry, given by the empiric phyficians, to the difcovery of the qualities of medicinal fubftances, or drugs, would in all probability lead to many abufes and evils. Experiment of this fort being much eafier, at leaft when carelefsly made, than that unremitting and accurate obfervation of the phenomena of difeafes, which alone can conftitute the fcientific phyfician, the ignorant and idle would content themfelves with pharmaceutic experiments, and neglect the tafk of pathological inveftigation; and felfifh craft and difhonefty would foon learn to impofe on the credulity of the people, in the adminiftration of fecret remedies, when the ufe of a particular drug, and not the general treatment of a difeafe, was fuppofed to be the effence of medicine. Hence it actually happened, even in the early ages of phyfic, that thefe ignorant and illiberal pretenders to *panaceas*, and infallible remedies, who did not know one difeafe from another by its fymptoms, appeared in Egypt, Greece, and Arabia, and were much complained of by their more rational contemporaries. In all fucceeding ages, the race of thefe illiterate pretenders has been multiplied, under the abufed name of *empirics*. In our own time, indeed, while a college of phyficians, conftituted by royal and parliamentary authority, exifts in the metropolis, for the regulation of the practice of medicine, and the prevention of the mifchiefs occafioned by noftrum-mongers, and pretenders of all kinds, *quackery* thrives, unmolefted by the college, and fanctioned, licenfed, and protected by patent, on the part of government, to an extent heretofore unexampled. Le Clerc Hift. de la Med. Schulzii Hift. Med. Celf. in Præf. Galen, Loc. Cit. Walker's Mem. of Medicine.

Empiric, in *Modern Medicine*, is applied to a perfon, who fells or adminifters a particular drug, or compound, as a remedy for a given diforder, without any confideration as to the variations of that diforder, in its different ftages, or degrees of violence, or as it occurs in different conftitutions, climates, or feafons, or in perfons of different age, fex, ftrength, &c. Such a practice implies a total ignorance of the nature of the human conftitution, both in health and difeafe; and therefore is generally found to be the refort of the illiterate and felfifh, not to fay difhoneft, part of mankind. See the preceding article. See alfo Quack.

EMPIS, in *Entomology*, a genus of dipterous infects. The mouth is furnifhed with an inflected fucker and probofcis; fucker with a fingle-valved fheath and three briftles; feelers fhort and filiform; antennæ fetaceous. Thefe are carnivorous, and fubfift on flies and other fmall infects, which they feize with their feet, and pierce with their roftrum, to fuck the blood and juices of their body. Some of the fpecies are found on flowers, in the winged ftate. None of the larvæ are known.

Species.

Borealis. Black; wings fubrotund and ferruginous-brown. Linn.

Inhabits Sweden, Britain, and various other parts of Europe, and is often feen in fwarms in the air, like the gnat, on a ftill evening, about fun-fet.

Pennipes. Black, with the pofterior legs long and feathered. Fabr. *Afilus pennipes*, Scop. Ent. Carn. 994.

Found in Europe, on the geranium fylvaticum and cardamine pratenfis. A fuppofed variety is defcribed by Linnæus, which has the four pofterior thighs feathered, and the wings brown, with a black rib.

Marginata. Black; wings white, with black margin. Fabr.

A fmall fpecies, found in Saxony.

Maura. Black; fhanks of the fore-legs thick and ovate. Fabr.

Inhabits environs of Hamburgh, about ftagnant waters.

Livida. Livid; thorax pale-green, with three black lines; bafe of the wings and legs ferruginous. Fabr.

Frequent on the flowers of the cow-parfnip (heracleum fphondylium) in Europe. The wings are oblong, and veined with fufcous.

Ciliata. Blackifh; wings with fufcous rib; legs black, four pofterior ones feathered. Fabr.

Inhabits Europe, and in fize refembles the laft. The head is black, with a teftaceous probofcis; thorax hairy.

Cinerea. Cinereous; thorax immaculate; legs pale; wings at the tip brownifh. Fabr.

Inhabits Sweden, on umbellate flowers.

Maculata. Cinereous; fnout, fides of the abdomen, and legs teftaceous; wings fpotted. Fabr.

Native of Italy. The thorax is cinereous, with faint lines; legs teftaceous, with black claws; abdomen with a teftaceous line on each fide.

Stercorea. Teftaceous, with a dorfal black line; wings reticulated. Linn. Fn. Suec.

On umbellate flowers, in Europe.

Minuta. Black; legs teftaceous; wings white. Fabr.

Inhabits Denmark, on fungi. Small.

Crassipes. Black; all the fhanks with a long thick joint; wings white, lower half of the outer margin black. Schranck.

Very fmall, and inhabits Auftria.

Rufipes. Black, and fomewhat cinereous, legs ferruginous. Linn.

Native of Europe.

Quadrilineata. Black, and fomewhat greyifh; thorax

thorax with four lines; abdomen cylindrical, with the tip inflected. Linn.

Inhabits Europe.

Trilineata. Cinereous; thorax with three black impressed lines; wings white; legs pale-yellow. Linn.

Abdomen sometimes yellow, sometimes fuscous. This and the three following species inhabit Europe.

Nigricus. Cinereous; thighs black; shanks and wings ferruginous. Linn.

Gibbosa. Fuscous; thorax gibbous; abdomen thin; wings spotted; shanks and ends of the legs white. Linn.

Fuscipes. Brown-cinereous; wings white; legs livid; feet fuscous. Linn.

Leucoptera. Thorax cinereous; abdomen black; wings white; legs livid. Linn.

EMPLASTICS, in *Pharmacy*, are salves, or medicines, which stop up and constipate the pores of the parts they are applied on; otherwise called *emphractics*.

The word is formed from the Greek, εμπλασσειν, *to stop up*.

Such are fats, mucilages, wax, the whites of eggs, &c.

EMPLASTRA Amyntica. See Amyntica.

EMPLASTRUM, popularly called *plaster*, a medicine of a stiff, glutinous consistence, composed of divers simple ingredients, spread on leather, or linen, and applied externally.

The word is formed from the Greek, εμπλαττω or εμπλασσω, *to put in a mass*, or *to smeer over*, because the emplaster is made of divers kinds of simple drugs, worked up into a thick tenacious mass; or because it covers over the piece of leather or linen to be applied on the part affected.

Emplasters are made up in a strong solid body, that by remaining a long time on the part, the medicinal ingredients they are chiefly composed of, may have time enough to produce their effect.

The drugs used to give a body and consistence to emplasters, are usually wax, pitch, gums, fats, litharge, and other preparations of lead.

There are emplasters of divers kinds, and used with divers intentions; stomachic emplasters; cephalic, styptic, hepatic, diaphoretic, resolutive, detersive, emollient, incarnative, astringent, conglutinative, &c. emplasters.

In the prescription of extemporaneous plasters, the greatest regard is to be had to that particular consistence which the part can most conveniently bear, whereupon the application is to be made. Thus, plasters to the breast and stomach, especially in the intention of emollients or discutients, should be yielding and soft, as in the officinal emplastrum stomachicum; but to the loins, or any of the limbs, where warm discutients and strengtheners are to be applied, an higher and more adhesive consistence is to be sought for. The emollient plasters likewise should be laid on thick, and frequently repeated, if the symptoms continue, because their better parts are soon spent. Discutients also applied to hard tumours, require repetition; but the strengtheners, which are purposely contrived of a strong adhesive consistence, are permitted to lie on till they grow dry, and come off spontaneously. In some flatulent tumours, where a plaster alone will not prevail, they are at intervals taken off, and discutient fomentations or lotions made use of; such as are composed of bitters, carminatives, comprehending also lixivial salts or alkaline spirits.

Emplastrum *Adhæsivum*, *Adhesive Plaster*, now called "Emplastrum lithargyri cum resinâ," or "litharge-plaster with resin," is composed of three pounds of litharge or common plaster, with the proportion of half a pound of yellow resin; and is prepared by melting the litharge plaster with a slow fire, and mixing the powered resin. The black sticking-plaster, called the lady's court-plaster, is formed by dissolving twelve ounces of the gum benjamin in twelve ounces of rectified spirit of wine, and straining the solution. In a separate vessel, dissolve a pound of the best isinglass in five pints of pure water; and after straining this solution, mix it with the former, and let them stand in a narrow vessel, that the grosser parts may subside: when the liquor is cold, it will become a jelly, which will melt near the fire when it is to be spread. This quantity will be sufficient for spreading on ten yards of half-yard wide silk; in order to which, the silk must be stretched in a frame, and the mixture may be spread upon it with a spunge or brush, which should be done near a fire. As each spreading dries, it must be repeated to the tenth or twelfth time, and then touched lightly with a brush to give it a gloss. The following more simple preparation may be substituted for the former; dissolve a pound and a quarter of fine isinglass in five pints of water, and before it cools spread it on silk in the manner above directed.

Emplastrum *ex Ammoniaco cum Mercurio*, now called "Emplastrum ammoniaci cum hydrargyro," a form of medicine, ordered to be prepared in the following manner.

Take gum ammoniacum, strained, a pound; purified quicksilver, three ounces by weight; sulphurated oil, one dram by weight, or q. s. Rub the quicksilver with the sulphurated oil till the globules no longer appear; then add by degrees the gum ammoniac melted, and almost cooled again, and make the whole into a plaster.

This plaster is recommended in pains of the limbs, arising from a venereal cause. Indurations of the glands, and other violent tumours, are likewise found sometimes to yield to it.

Emplastrum *Anodynum*, *Anodyne Plaster*, is prepared by melting an ounce of the adhesive plaster; and, whilst it is cooling, mixing with it a dram of powdered opium, and the same quantity of camphor previously rubbed up with a little oil. This plaster gives relief in acute pains, especially of the nervous kind.

Emplastrum *Attrahens*, *the Drawing Plaster*, now "Emplastrum ceræ compositum," a plaster ordered to be now made in this manner: take yellow wax and prepared mutton suet, of each three pounds; and yellow resin, one pound: melt all together, and strain the mixture while it is hot.

Emplastrum *Cephalicum*, or "Emplastrum picis Burgundicæ compositum," is composed of Burgundy pitch, two pounds; ladanum, one pound; yellow resin and yellow wax, of each four ounces by weight; and expressed oil of nutmeg, one once by weight: to the pitch, resin, and wax, melted together, add first the ladanum, and then the oil of nutmeg.

Emplastrum *Commune*, or "Emplastrum lithargyri," litharge plaster, a name given to what has been long called *diachylon-plaster*. It is ordered to be made of a gallon of oil of olives, and five pounds of litharge in very fine powder, boiled together on a slow fire, with about a quart of water, to keep them from burning, till they are perfectly mixed, and have the consistence of a plaster.

This plaster is generally applied to slight wounds and excoriations of the skin; it keeps the part soft and warm, and defends it from the air, which is all that is necessary in such cases.

Emplastrum *Commune cum Mercurio*, or "Emplastrum lithargyri cum hydrargyro," is made in the same manner

manner as the ammoniacum-plaſter with quickſilver, of litharge-plaſter, one pound; purified quickſilver, three ounces by weight; and ſulphurated oil, one dram by weight, or q. ſ.

Emplastrum *è Cymino*, or "Emplaſtrum cumini," is compoſed of cummin, caraway, and bay-berries, of each three ounces by weight; Burgundy pitch, three pounds; and yellow wax, three ounces by weight. Let the pitch be melted with the wax; powder the reſt, and mix all together.

Emplastrum *Gummi*, *Gum Plaſter*, now called "Emplaſtrum lithargyri compoſitum." Take of the common or litharge plaſter, three pounds; ſtrained galbanum, eight ounces by weight; common turpentine, ten drams by weight; and frankincenſe, three ounces by weight. Melt the galbanum with the turpentine, and mix with them, firſt, the powdered frankincenſe, and then the litharge plaſter, previouſly melted with a ſlow fire. This is uſed as a digeſtive, and for diſcuſſing indolent tumours.

Emplastrum *Roborans*, the *Strengthening-Plaſter*, now called "Emplaſtrum thuris compoſitum," or compound frankincenſe plaſter, is ordered to be made thus: take of the common or litharge-plaſter, two pounds; of frankincenſe, half a pound; and dragon's blood, three ounces by weight: melt the plaſter, and then add to it the other ingredients in powder.

Emplastrum *Saponis*, *Soap-Plaſter*, is made by mixing half a pound of ſoap with three pounds of melted litharge-plaſter; and boiling them to the conſiſtence of a plaſter.

Emplastrum *Stomachicum*, *Stomach-Plaſter*, or "Emplaſtrum ladani compoſitum," is compoſed of ladanum, three ounces by weight; frankincenſe, one ounce by weight; cinnamon, powdered, expreſſed oil of nutmeg, of each half an ounce by weight; and oil of ſpearmint, one dram by weight. To the melted frankincenſe add, firſt, the ladanum ſoftened by heat, and then the expreſſed oil of nutmeg. Mix theſe and the cinnamon with the oil of mint, and beat them together in a warm mortar. Let it be kept in a cloſe veſſel. An ounce or two of this plaſter, ſpread on ſoft leather, and applied to the region of the ſtomach, will be of ſervice in flatulencies, ariſing from hyſteric and hypochondriac affections.

Emplastrum, *Veſicatorium*, *Bliſtering-Plaſter*, or "Emplaſtrum cantharidis," is formed by melting two pounds of plaſter of wax, and half a pound of prepared hog's lard; and a little before they coagulate, ſprinkling one pound of cantharides, finely powdered. In order to render bliſtering-plaſters efficacious, care ſhould be taken that the flies be good, freſh powdered, and the powder fine; and that the plaſter ſhould neither be made in too great quantity at once, nor ſpread with a ſpatula too much heated. See Blister.

EMPLEURUM, in *Botany*, from εν, *in* or *upon*, and πλευρα, the *ſide*, alluding to the lateral inſertion of the ſtigma upon the germen. Soland. in Ait. Hort. Kew. v. 3. 513. Schreb. 812. Willd. Sp. Pl. v. 4. 333. Mart. Mill. Dict. v. 2. Juſſ. 298. Claſs and order, *Monoecia Tetrandria*. Nat. Ord. *Rutaceæ*, Juſſ.

Gen. Ch. Male. *Cal.* Perianth of one leaf, bell-ſhaped, four-cleft, permanent. *Cor.* none. *Stam.* Filaments four, thread-ſhaped, equal, ſimple, longer than the calyx, a little ſpreading; anthers erect, oblong, obtuſe, ſomewhat quadrangular, of two cells, each burſting by a lateral fiſſure. Abortive germen ſometimes preſent. Female on the ſame plant. *Cal.* as in the male. *Cor.* none. *Piſt.* Germen ſuperior, oblong, compreſſed, of one cell, terminated by an erect leafy appendage; ſtyle none; ſtigma placed on a lateral tooth at one edge of the germen, erect, cylindrical, ſmooth, deciduous. *Peric.* Capſule oblong, compreſſed, crowned with a leafy oblique appendage, of one cell, burſting at its ſtraighteſt edge. *Seed* ſolitary, oblong, inſerted laterally, encloſed in a bivalve, elaſtic, rigid arillus.—Very rarely two capſules are ſaid to be found in one calyx.

Eſſ. Ch. Male, Calyx four-cleft. Corolla none. Sometimes with the rudiment of a germen. Female, Calyx four-cleft, inferior. Corolla none. Stigma cylindrical, ſtanding on a lateral tooth of the germen. Capſule beaked, of two valves. Seed ſolitary, with an elaſtic arillus.

E. *ſerrulatum*. Soland. in Ait. Hort. Kew. v. 3. 340. Sm. Exot. Bot. v. 2. 7. t. 63. (Dioſma unicapſularis; Linn. fil. in Suppl. 155. D. enſata; Thunb. Prod. 43.) This is the only ſpecies hitherto obſerved. Native of the Cape of Good Hope, where Thunberg, Maſſon, and others have gathered it. Maſſon ſent it to Kew in 1774. It requires the ſhelter of a green-houſe, and the ſame treatment as other Cape plants of the Rutaceous order, *Dioſma*, *Erioſtemon*, &c. but is leſs ornamental than moſt of them, on account of the want of petals. The *ſtem* is ſhrubby, and much branched. *Leaves* ever-green, ſmooth, ſhining, alternate, almoſt ſeſſile, linear-lanceolate, acute, bordered with ſhallow glandular ferratures, deſtitute of ſtipulas. *Flowers* on ſimple, axillary, cluſtered ſtalks, reddiſh, but inconſpicuous. *Capſules* more ſtriking, from their enlarged leafy termination. The whole plant, when bruiſed, ſmells ſtrongly of rue or juniper, like moſt of its natural order. See Diosma and Eriostemon.

EMPNEUMATOSIS, from εμπνεω, *I inflate*, in *Medicine*, a word uſed by ſome writers to ſignify an inflation of the ſtomach; but by others, in a more general ſenſe, for inflations of the womb, or of any other part.

EMPOLI, Jacopo da, in *Biography*, a painter of the Florentine ſchool, who was born at Empoli, as his name deſignates, in 1554; and was firſt inſtructed in his art in the ſchool of Maſo di San Friano. He afterwards applied himſelf to ſtudy the works of Andrea del Sarto, and with very conſiderable ſucceſs, acquiring very much his ſtyle of deſign, and hues and tones of colouring. He copied Del Sarto's works very cloſely, and not only his, but thoſe of other maſters, with ſo much accuracy, as to deceive the judgment of thoſe well verſed in the art. So much talent for this kind of exerciſe in art, is ſeldom accompanied by a power of invention or execution of original works. But Empoli had conſiderable reputation for this alſo, and his compoſitions are ſpoken of as poſſeſſing much ſpirit and ingenuity, and alſo exhibiting conſiderable feeling of beauty and elegance.

Empoli, in *Geography*, a town of Italy, in the duchy of Tuſcany, ſituated on the Arno; 15 miles W. of Florence.

EMPORETICA Charta. See Charta and Paper.

EMPORIA, in *Ancient Geography*, a country of Africa, on the Leſſer Syrtis, in which Leptis ſtood. This territory was under the dominion of the Carthaginians, and was put under contribution by Maſiniſſa. Leptis is ſaid to have paid a talent *per* day to the Carthaginians. No part of the Carthaginian dominions was more fruitful than this. Polybius (l. i.) ſays, that the revenue which aroſe from hence was ſo conſiderable, that all their hopes were almoſt founded on it; and he deduces the origin of its name from its great fertility, and the commerce which diſtinguiſhed it. To this were owing the anxiety and ſtate-jealouſy of the Carthaginians, leſt the Romans ſhould fail beyond the fair promontory, that lay before Carthage, and become acquainted with a country

country which might induce them to attempt the conqueſt of it.

EMPORIÆ, Ampourias, a town of Hither Spain, which lay towards the ſouth, and which was, as its name imports, a commercial port. Strabo ſays, that the Maſſilians were eſtabliſhed here: but Pliny and Silius Italicus ſay, that they were the Phocæans; both which reports may agree, as the inhabitants of Marſeilles profeſs to have derived their origin from the Phocæans. According to Livy, this place conſiſted of two towns ſeparated by a wall; that on the ſea-coaſt, encompaſſed by a wall of 400 paces, was inhabited by Greeks, a colony of Maſſilians, who ſprung from the Phocæans; and the other part, which had no communication with the ſea, was ſurrounded by a wall of 3000 paces. This hiſtorian informs us, that Cæſar, after having defeated Pompey's party, eſtabliſhed a body of Romans in this place. The Greeks, who were eſtabliſhed in this place, had previouſly inhabited a ſmall iſland oppoſite to it, from which they paſſed over to the continent. They worſhipped Diana of Epheſus.

EMPORICUS Sinus, a gulf of Africa, in Mauritania. Ptolemy places it in the Adriatic ſea, at 34° 20′ of latitude.

EMPORIUM, a fortreſs of Italy, in Emilia, 5 miles from the Po.—Alſo, a place of Macedonia.—Another of Sicily.—Another of Italy, in Campania.—Another in Celtica. Steph. Byz.

Emporium, in *Phyſiology*, is often uſed for the common ſenſory in the brain. See Brain.

EMPRIMED, among *Sportſmen*, a term applied to a hart, when he forſakes the herd.

EMPRION, from πρίω, *to ſaw*, in the *Medical Writings of the Ancients*, a word uſed to denote a peculiar pulſe, in which the artery is felt to be diſtended in one part more than another at every ſtroke, and by that means is made to reſemble any ſerrated body, or the light teeth of a fine ſaw.

EMPROSTHOTONOS, in *Medicine*, from ἔμπροσθεν, *forwards*, and τείνω, *I ſtretch*, is the term applied to that form of tetanus, or general ſpaſm, in which the muſcles which bend the body forwards are moſt ſtrongly affected, ſo that the whole body is rigidly fixed in a bent poſition, the neck and back being bowed forwards, the chin fixed upon the breaſt, &c. The term is uſed in oppoſition to Opisthotonos, in which the body is bent backwards. (See Tetanus.) The emproſthotonos, however, is a very rare occurrence; and ſome writers have altogether denied its exiſtence, except as a partial affection confined to the neck.

EMPTOR Familiæ, *buyer of a family*, in the *Roman Law*, one who purchaſed the inheritance of a perſon, or the privilege of being appointed his heir by will.

This was done by the ceremony of ſcales and weights, before five witneſſes, with the uſe of a peculiar formula of words.

Such buyer differed from the heir, *hæres*, as the teſtator in ſome meaſure alienated the right to the former during his own life-time, whereas the latter had only a right by his death. Briſſon. de Formul. lib. vii. p. 585. Pitiſc. Lex. Ant. tom. i. p. 713. voc. *Emptor*.

Emptor *fiduciarius*, *fiduciary buyer*, one who receives a thing in the way of pledge, till the money he has advanced be repaid. Salmaſ. de Mod. Uſur. cap. 14. Pitiſc. Lex. Ant. tom. i. p. 713. voc. *Emptor*.

EMPTYSIS, in *Surgery*, bleeding from the mouth and fauces.

EMPUS, in *Geography*, a town of France, in the department of the Var, and diſtrict of Draguignan; 5 miles N.W. of Draguignan.

EMPUSA, Εμπουσα, among the *Ancients*, a kind of hobgoblin, or bugbear, under the direction of Hecate, who uſed to ſend it to frighten people who laboured under misfortunes. Hofm. Lex. in voc.

EMPYEMA, in *Surgery*, ſignifies a collection of matter in the cavity of the thorax. The term is derived from ἐν, *within*, and πύον, *pus*, or *matter*.

The ancients made uſe of the word "empyema" to expreſs every kind of internal ſuppuration. Ætius firſt employed the term to denote the collections of purulent matter, which ſometimes form in the cavity of the pleura, or membrane lining the cheſt; and all the beſt modern ſurgeons invariably attach this meaning alone to the expreſſion.

The operation for empyema means the making of an opening into the thorax, for the purpoſe of giving vent to the matter collected in the cavity of the pleura. The neceſſity for having recourſe to ſuch an operation, however, does not often preſent itſelf. We would not wiſh to be thought to aſſert, that inflammation of the lungs, pleura, mediaſtinum, diaphragm, and even of the liver, does not ſometimes terminate in ſuppuration. Certainly, the latter event is occaſionally produced; but, when it does happen, the matter does not always make its way into the cavity of the cheſt. Very frequently external abſceſſes form, or the pus is either coughed up, or diſcharged with the ſtools.

When the ſurface of the lungs and pleura coſtalis have become adherent together, in the ſituation of the abſceſs, the pus, always diſpoſed by a law of nature to make its way to the ſurface of the body, occaſions ulceration of the intercoſtal muſcles, and collects on the outſide of them. An abſceſs of this kind comes on with a deep-ſeated pain in the part affected; an œdematous ſwelling, which retains the impreſſion of the finger; and a fluctuation, which is at firſt not very diſtinct, but from day to day becomes more and more palpable, and, at length, leads the ſurgeon to make an opening to let out the matter.

If an opening be not made, when the fluctuation becomes perceptible, there is ſome riſk of the matter inſinuating itſelf into the cheſt, in conſequence of the adheſion being in part deſtroyed by ulceration. M. Sabatier affirms, that the caſe may take this courſe, even when the abſceſs has been punctured, and while a free external opening exiſts. This experienced ſurgeon had occaſion to remark ſuch an occurrence in a ſoldier. The patient had a collection of matter in the thorax, which was only indicated by a pain all over the ſide; a difficulty of lying in any other poſition in bed, than on the back; and an undulating noiſe in the cheſt, whenever he altered his poſture. When M. Sabatier made the patient hold his breath, the diſcharge, which was very copious, was not increaſed; the pus did not contain any bubbles of air; there was no emphyſema round the wound; nor any blaſt of air from it in the motions of reſpiration. On opening the body, M. Sabatier found, that the abſceſs had been originally ſituated between the intercoſtal, and the pectoralis minor, and major, muſcles, and that the matter had made its way, by ſeveral ulcerated openings, into the cheſt. The lung, in ſome places, was adherent to the pleura. The quantity of effuſed matter was very conſiderable. See Médecine Opératoire, tom. 2. p. 249.

In the ſame manner, if inflammation ſhould occur in the anterior mediaſtinum and end in ſuppuration, the abſceſs may poſſibly burſt into neither of the cavities of the cheſt; but make its way outward, after having rendered the ſternum carious. The following caſe, illuſtrative of this fact,

fact, is taken from Van Swieten's Commentaries on Boerhaave's 895th Aphorism.

A young man was attacked with a violent pleurisy, which seemed to terminate in copious expectorations, which began about a fortnight after the commencement of the indisposition, and continued for a long while. The patient became exceedingly reduced, and his fate seemed inevitable. In the tenth month of his illness, however, a small soft swelling, about the size of a filbert, made its appearance upon the middle of the sternum, the substance of which bone appeared to be obviously carious round the margin of the tumour. The swelling burst of itself, and a discharge of matter ensued. Pus continued to be emitted from the opening for eight months. The cavity of the abscess was capable of containing a pint of the fluid, which was used as a detergent injection. The matter had collected between the pleura and the ribs. The patient recovered of this alarming disease, and was seen by Van Swieten in good health, eight months afterwards. There only remained a small fistulous opening, from which an inconsiderable quantity of matter continued to be discharged.

The foregoing case of abscess in the anterior mediastinum originated from an internal cause. It was the consequence of a violent pleurisy, or rather of a similar disorder, which is attended with nearly the same symptoms, but has a different situation, and has been very accurately described by Salius Diversus. The same sort of abscess may arise, in consequence of a wound in the forepart of the chest. An interesting case of this description is related by Galen. A young man, who had been wounded in the region of the sternum, seemed to have got completely well. An abscess then formed in the situation where the injury was received; it was opened, and healed. The part, however, soon inflamed and suppurated again. The place could not now be healed. A consultation was held, at which Galen attended. As the sternum was obviously carious, and the pulsation of the heart was visible, every one was afraid of undertaking the cure of the case, since it was conceived, that it would be necessary to open the thorax itself. Galen, however, engaged to manage the treatment without making any opening of the kind alluded to, and he expressed his opinion, that he should be able to effect a cure. Not finding the bone so extensively diseased, as was apprehended, and the mammary vessels being found, he began to indulge considerable hopes of success. After the removal of a portion of the bone, he saw the heart quite exposed, by reason of the pericardium having been destroyed by the previous disease. The patient, after the operation, experienced a speedy recovery.

M. J. L. Petit met with a case of an abscess in the mediastinum, in consequence of a gun-shot wound, in the situation of the sternum. The injury had been merely dressed with some digestive application; no dilatation, nor any particular examination of the wound had been made. The patient, after being to all appearances quite well, and joining his regiment again, was soon taken ill with irregular shiverings, and often febrile symptoms. M. Petit probed the wound, and found the bone affected. As there was a difficulty of breathing, he suspected an abscess either in the diploe, or behind the sternum, and, consequently, he proposed laying the bone bare, and applying a trepan. This operation gave vent to some sanious matter, and, as soon as the inner part of the sternum was perforated, a glass full of pus was discharged. The patient was relieved, and afterwards recovered.

When, in consequence of inflammation, an abscess forms deeply in the substance of the lungs, the pus more easily makes its way into the air-cells, and tends towards the bronchia, than towards the surface of the lungs, and into the cavity of the thorax. In this case, the patient spits up purulent matter. When the opening, by which the abscess has burst, is large, and the pus escapes from it in a considerable quantity at a time, the patient is in some danger of being suffocated. However, if the opening be not immoderately large, and the pus, which is effused, be not too copious, a recovery may follow. Abscesses in the substance of the diaphragm, and collections of matter in the liver, may also be discharged by the pus being coughed up from the trachea, when the parts affected have become connected with the lungs, by adhesions, and the abscesses of the liver are situated on its concave surface. When the collection of matter in the liver occupies any other situation, the abscess frequently makes its way into the colon, and the pus is discharged with the stools. Several cases of this kind are related by authors; Sabatier has recorded two in his Médecine Opératoire; Le Dran mentions his having seen others; and Pemberton, in his book on the diseases of the abdominal viscera, p. 36, relates the occurrence of additional instances of a similar nature.

We shall now proceed to the consideration of empyema, strictly so called. No surgical writer, with whom we are acquainted, has written with more discrimination, than Mr. Samuel Sharp, on the symptoms produced by collections of matter in the cavity of the chest. He remarks, that it has been almost universally taught, that when a fluid is extravasated in the thorax, the patient can only lie on the diseased side, the weight of the incumbent fluid on the mediastinum becoming troublesome, if he places himself on the sound side. For the same reason, when there is fluid in both cavities of the thorax, the patient finds it most easy to lie on his back, or to lean forwards, in order that the fluid may neither press on the mediastinum, nor the diaphragm. But, Mr. Sharp takes notice, that however true this doctrine may prove in most instances, there are a few (Le Dran's Obs. 217. vol. i. Marchetti, 65.) in which, notwithstanding the extravasation, the patient does not complain of more inconvenience in one posture, than another, nor even of any great difficulty of breathing.

On this account, observes Mr. Sharp, it is sometimes less easy to determine, when the operation is requisite, than if we had so exact a criterion, as we are generally supposed to have. However, he informs us, that though this may be wanting, there are some other circumstances, which will generally guide us with a reasonable certainty. He states, that the most infallible symptom of a large quantity of fluid in one of the cavities of the thorax, is a preternatural expansion of that side of the chest, where it lies; for in proportion as the fluid accumulates, it will necessarily elevate the ribs on that side, and prevent them from contracting so much in expiration as the ribs on the other side. Mr. Sharp refers also to Le Dran's Observ. 211. vol. i. to prove, that the pressure of the fluid on the lungs may sometimes be so great, as to make them collapse, and almost totally obstruct their action. When therefore, says Mr. Sharp, the thorax becomes thus expanded after a previous pulmonary disorder, and the case is attended with the symptoms of a suppuration, it is probably owing to a collection of matter. The patient, he observes, will also labour under a continual low fever, and a particular anxiety from the load of fluid.

Mr. Sharp also observes, that, besides this dilatation of the cavity from an accumulation of the fluid, the patient will be sensible of an undulation; and sometimes the undulation is so evident, that a by-stander can plainly hear it in certain motions of the body. Mr. Sharp adds, that this was the cafe with a patient of his own, on whom he performed the operation; but the fluid, in the example alluded to, he fays, was very thin, being a ferous matter, rather than pus.

According to the fame author, it will alfo frequently happen, that though the fkin and intercoftal mufcles are not inflamed, they will become œdematous in certain parts of the thorax; or if they are not œdematous, they will be a little thickened. Thefe fymptoms, joined with the enlargement of the thorax, and the preceding affection of the pleura or lungs, feem unqueftionably to indicate the propriety of the operation. But, obferves Mr. Sharp, amongft other motives to recommend it upon fuch an emergency, this is one, that if the operator fhould miftake the cafe, an incifion of the intercoftal mufcles would neither be very painful, nor dangerous. See Critical Enquiry into the prefent State of Surgery; fect. on Empyema.

Although we would wifh the reader to underftand, that patients with empyema can fometimes lie in any pofition, without any particular aggravation of the difficulty of breathing, yet, we muft diftinctly ftate, that the generality of patients with this difeafe cannot place themfelves on the fide oppofite to that where the collection of pus is fituated, without having their refpiration very materially obftructed. Another circumftance, alfo, which we wifh to mention, now that we are treating of the fymptoms of empyema, is, that the œdema of the integuments is fometimes not confined to the thorax, but extends to more remote parts, on the fame fide of the body as the collection of matter. Both the foregoing remarks are confirmed by an interefting cafe, which Mr. Hey, of Leeds, has lately publifhed.

Sept. 3, 1788, Mr. Hey was defired to vifit John Wilkinfon, who had been ill ten days of the influenza. The patient was found labouring under a fever, attended with cough, difficulty of breathing, and pain in the left fide of the thorax. He was bled once; had repeated blifters applied to the thorax; took nitre and antimonials, with a fmooth linctus to allay his cough. He was repeatedly relieved by thefe means, efpecially by the application of the blifters; but repeatedly relapfed. At laft, he became fo ill, that he breathed with the utmoft difficulty, and "could not lie on the right fide without danger of immediate fuffocation."

Mr. Hey found the patient in the ftate juft now defcribed on the 17th of September. "His face, and efpecially the eye-lid, were a little fwollen on the left fide." The left fide of the thorax was larger than the right, and its integuments were œdematous. Upon preffing the intercoftal mufcles they felt diftended; they yielded a little to a ftrong preffure, and rebounded again. The abdomen, efpecially at its upper part, appeared to be fuller than in its natural ftate. See Practical Obfervations in Surgery, p. 476.

Another remarkable fymptom, which is occafionally produced by collections of matter in the cheft, is an alteration in the pofition of the heart. Mr. Samuel Cooper has made mention of a patient who was in St. Bartholomew's hofpital, whofe heart was pufhed quite to the right fide of the cheft, by an empyema in the left bag of the pleura, and pulfated on the right of the fternum. Firft Lines of the Practice of Surgery; part 2. chap. 29.

The fymptoms of empyema are frequently very equivocal, and the exiftence of the difeafe is generally fomewhat doubtful. Panarolius opened a man, whofe left lung was deftroyed, at the fame time that the thorax contained a confiderable quantity of pus. Although the patient had been ill for two months, he had fuffered no difficulty of breathing, and had had only a flight cough. Le Dran met with a cafe of nearly the fame kind. A patient who had been for three days affected with a confiderable oppreffion, and an acute pain on the left fide of the cheft, got fomewhat better. He felt no material difficulty of breathing, on whatever fide he lay. The only thing which he complained of, was a fenfe of a fluctuation in his thorax, and a little obftruction to his refpiration, when he was in a fitting pofture. Thefe fymptoms did not feem fufficiently decided to juftify the operation, and it was delayed. The febrile fymptoms continued with cold fweats, and the patient died on the eighth day. Five pints of pus were found collected in the cheft.

With refpect to opening fuch abfceffes as prefent themfelves at fome part of the parietes of the thorax, in confequence of a pleurify, or an inflammation of the diaphragm, or mediaftinum, it is not attended with any peculiarity. It fhould be done as foon as a fluctuation can be felt, and the aperture fhould be made of fufficient fize to give free vent to the matter. As fome of thefe abfceffes communicate with the external furface of the lungs, and others with that of the liver; as fome of them are accompanied with a caries of the ribs, or the cartilages of thefe bones, while others are attended with an alteration of the fubftance of the fternum; the cure muft frequently be interrupted by unpleafant fymptoms, and very often retarded for a long while, efpecially when there are fome pieces of bone to exfoliate.

We fhall next confider the operation for empyema, in the common fignification of this term.

Mr. Samuel Sharp advifes the incifion to be made between the fixth and feventh ribs, half way from the fternum towards the fpine; which, fays he, though not the moft depending part of the thorax, when we are erect, yet is fituated fufficiently low to give iffue to the fluid, when we lie down.

This author was certainly miftaken in his opinion, that the expanfion of the lungs always propelled the pus out of the wound, but the action of fuch mufcles, as diminifh the capacity of the thorax, may undoubtedly produce this effect. The reader, on looking over the article EMPHYSEMA, will be perfectly convinced, that the lungs cannot become diftended with air, and expanded on one fide, while, on this fide of the cheft, there exifts a free communication between the outward air and the cavity of the pleura.

Mr. Sharp quotes the practice of Marchetti, who always made the opening between the fifth and fixth ribs, to confirm the prudence of choofing this fituation for the incifion. See Critical Enquiry, &c.

A great many of the moft eminent writers on the operations of furgery have had hardly any other object in view, in the operation for empyema, than making an opening into the thorax in fuch a fituation, as would be a moft depending one, in the erect pofition of the body. Hence thefe authors even fanction and recommend the unneceffary plan of cutting through the mufcles of the back to make an iffue for the matter in the exact place, which, according to their principle, ought to be chofen. We are forry, that the refpectable names of Bertrandi and Sabatier might be adduced in favour of this mode of proceeding.

The fafeft, and moft convenient fituation, for making an opening into the cheft, is between the fixth and feventh true ribs, on either fide, as circumftances may render neceffary. The furgeon fhould only recollect, that the two cavities of the pleura are completely diftinct from each other, and have no communication whatfoever, fo that, if fluid were contained on the left fide of the thorax, making an opening into the right cavity would not ferve for difcharging the accumulated matter. The practitioner fhould alfo remember,

remember, that, when there is a fluid on both fides of the cheft, paracentefis muft never be done for the relief of the two collections at the fame time; becaufe, there is great reafon to believe, that, as the lungs on one fide ufually collapfe, when there is a free communication between the air and infide of the thorax, they would do fo on both fides, were an opening made at the fame time into each bag of the pleura. It is hardly neceffary to remark, that, in this condition, the patient could not breathe and would die fuffocated. The operation confifts, in making an incifion, about two inches long, through the integuments, which cover the fpace between the fixth and feventh true ribs, juft where the indigitations of the ferratus major anticus mufcle meet thofe of the externus obliquus. Here it is unneceffary to divide any mufcular fibres, except thofe of the intercoftal mufcles, and, by putting the patient in a proper pofture, the opening that is made, will be depending enough for any purpofe whatfoever. The furgeon, avoiding the lower edge of the upper rib, where the intercoftal artery lies, is then cautioufly to divide the intercoftal mufcles, till he brings the pleura into view, when this membrane is to be very carefully divided with a lancet. The inftrument fhould never be introduced in the leaft deeply, left the lungs fhould be injured. The fize of the opening in the pleura fhould never be larger than neceffary. The difcharge of blood and matter will of courfe require a freer aperture, than that of air, or water. If requifite, a cannula may be introduced into the wound, for the purpofe of facilitating the evacuation of the fluid, and it may, even in fome cafes, be proper to let this inftrument remain in the part, in order to let the water, or pus efcape, as often as another accumulation takes place. It is obvious, however, that a cannula, for this object, fhould only be juft long enough to enter the cavity of the pleura, and fhould have a broad rim to keep it from flipping into the cheft. A piece of fticking plafter would eafily fix the cannula, which might be ftopped up with a cork, or any other convenient thing, or left open according as the circumftances of the cafe, and the judgment of the furgeon, may direct.

It is proper to ftate, that fome practitioners make the wound between the fifth and fixth ribs: thus, Mr. Hey, in relating an interefting cafe of empyema, informs us, that the pain which the patient had felt in his fide had been moft acute betwixt the fifth and fixth ribs, and that there he (Mr. H.) made an opening into the cavity of the thorax. His firft incifion was about two inches in length. He cut through the ferratus and intercoftal mufcles clofe to the upper edge of the fixth rib, and made an opening into the cheft capable of admitting the tip of his finger. A large quantity of matter was thus difcharged, and a leaden cannula was introduced into the wound on the fecond day after the operation, and was retained in its place by a flannel bandage. Mr. Hey did not allow the patient to leave off wearing the cannula, until the difcharge from the thorax had ceafed, and he had completely regained his ftrength. He wore it fifteen months.

Mr. Hey thinks it of great confequence to retain a cannula in the wound, until all probability of relapfe is removed. This precaution, he apprehends, will not hinder the patient from recovering his ftrength, even when the ufe of the inftrument is not abfolutely neceffary. See Hey's Practical obfervations in Surgery, p. 477, &c.

EMPYEMATA, fuppurating medicines.

EMPYI, patients with empyema.

EMPYREUM, among *Divines*, denotes the higheft of the heavens, where the bleffed enjoy the beatific vifion; called elfo empyrean heaven, and paradife.

The word is formed of εν and πυρ, *fire*, becaufe of its fplendour.

EMPYREUMA, in *Chemiftry*, is that fmell and tafte of fcorching which takes place in moft animal and vegetable fubftances, when heated to that point at which decompofition by fire begins. It is always attended with a darkening of colour of fubftances naturally clear and limpid. The degree of heat at which this change occurs is various, but it is always above that of boiling water, fo that the ufe of a boiling water-bath for digeftions, or deficcations, is an effectual mode of preventing empyreuma. There is, however, a change that takes place in vegetable decoctions or infufions when evaporated to the confiftence of an extract, however low the heat is kept, fince when thefe extracts are again diluted to their original confiftence, they differ both in fenfible and chemical properties, from the original liquor. The caufes of this change are, probably, in part the action of the external air, but principally, feveral complicated chemical actions that take place between the various component parts of the vegetable fubftance itfelf, when their particles are concentrated by evaporation of the water which held them in folution. This circumftance is often confounded with empyreuma, properly fpeaking, or the changes produced by heat pufhed to the degree at which decompofition occurs, and as fome of the effects appear to be nearly fimilar, it is perhaps impoffible to adhere ftrictly to the real diftinction. The leading circumftance that indicates empyreuma in vegetable and animal matters is the *charring*, or converfion into black carbon, of part of the fubftance thus heated, whence a carbonaceous infoluble powder is produced, which partly fubfides on dilution with water, and partly remains finely fufpended.

The fmell and tafte of empyreuma in vegetable infufions, may be in many cafes got rid of by filtering through recently-burned charcoal powder.

Empyreuma is alfo ufed for the heat remaining upon the declenfion of a fever.

EMPYREUMATIC Acid and Oil, in *Chemiftry*. When moft animal and vegetable fubftances are diftilled *per fe* in a heat gradually urged to rednefs, a dark-coloured ftrong fmelling oil almoft invariably rifes towards the end of the procefs, which is ftrongly empyreumatic.

Many vegetable fubftances yield alfo, at the fame time, a ftrongly acid and empyreumatic liquor, which appears to be chiefly acetous acid generated in the procefs, and holding much carbonaceous matter in folution, from which it may be partly freed by a feparate diftillation in a gentle heat. See Pyroligneous and Pyromucous Acid.

EMRODS, or rather Hæmorrhoids. See Hæmorrhoids.

EMS, in Latin *Amifia*, or *Amafius*, in *Geography*, is a confiderable river of Germany, which has its fource in the county of La Lippe, in Weftphalia, flows through Eaft Friefland, and falls into the North fea, near Emden. It gives its name to one of the new departments of Holland, which is the ancient province of Eaft Friefland, whofe chief place is the town of Leuwarden.

Ems, a town of Germany, in the circle of the Upper Rhine, and principality of Heffe-Darmftadt; feven miles E.S.E. of Coblentz.

EMSBACH, a river of Germany, in the circle of the Lower Rhine, which runs into the Lahne, three miles E. of Limburg, in the electorate of Treves.

EMULATION, is a generous ardour kindled by the brave examples of others, which impels us to imitate, to rival, and, if poffible, to excel them. This paffion involves in it efteem of the perfon whofe attainments or conduct

 we

we emulate, of the qualities and actions in which we emulate him, and a defire of refemblance, together with a joy fpringing from the hope of fuccefs.

The word comes originally from the Greek αμιλλα, *difpute, conteft;* whence the Latin *æmulus*, and thence our emulation.

Dr. Hartley refers emulation to a clafs of the fympathetic affections, by which we grieve for the happinefs of others; and Dr. Reid, in his "Effays," (p. 167,) defines it as a defire of fuperiority to our rivals in any purfuit, accompanied with an uneafinefs at being furpaffed. He claffes it, together with refentment, under the head of the malevolent affections, which, though they are parts of our conftitution, given us by our Maker for good only, and, when properly directed and regulated, of excellent ufe, are neverthelefs fubject to excefs or abufe, and thus become the fource and fpring of all the malevolence that is to be found among men. From the obfervations which he has introduced for the illuftration of this affection, he infers, that emulation, as far as it is a part of our conftitution, is highly ufeful and important in fociety; that in the wife and good, it produces the beft effects without any harm; but in the foolifh and vicious, it is the parent of a great part of the evils of life, and of the moft malignant vices that ftain human nature.

Plato obferves of emulation, that it is the daughter of envy; if fo, there is a great difference between the mother and the offspring; the one is a virtue, and the other a vice. Emulation admires great actions, and ftrives to imitate them; envy refufes them the praifes that are their due; emulation is generous, and only thinks of furpaffing a rival; envy is low, and only feeks to leffen him.

Perhaps, therefore, it would be more juft to fuppofe emulation the daughter of admiration: admiration, however, is a principal ingredient in the compofition of it.

EMULGENT, in *Anatomy*, a term applied to the blood-veffels of the kidnies. See Arteries and Veins.

EMULSION, from *emulgere*, to milk, in *Chemiftry* and *Pharmacy*, is any milky opake liquor formed by the diffufion of any oily or refinous matter in water, through the medium either of alkalies, or of mucilage, or any other vifcid matter foluble in water.

Milk itfelf is a natural emulfion, and when viewed in a powerful microfcope is feen vifibly to confift of oily particles fufpended in a ferous liquor. Many vegetable matters form natural emulfions when merely triturated with water, of which kind are almonds, and moft of the oily nuts, the oil being held fufpended by the mucilage or farina with which thefe fubftances naturally abound.

All the oils are rendered mifcible with water, when rubbed with mucilage of gum arabic, or with the yolk of egg, or with a fmall quantity of any alkaline falt, and all thefe mixtures are common in pharmacy. Thick fyrups alfo promote the diffufion of oily matters in water, but lefs perfectly.

This combination, however, is but temporary, as all the emulfions are decompofed by mere reft for fome hours, and as befides they are very apt to ferment, they are only ufed in extemporaneous prefcription.

The common emulfion, now called "Lac Amygdalæ," is made by beating an ounce and a half by weight of fweet almonds, with half an ounce by weight of double refined fugar, in a marble mortar, and rubbing them well together; adding gradually the quantity of two pints of diftilled water, and ftraining the liquid. If two ounces and a half of the mucilage of gum arabic are added to the almonds whilft they are pounded in the mortar, we fhall have the arabic emulfion. Thefe emulfions may be ufed as ordinary drink, in cafes which require foft cooling liquors. The camphorated emulfion is prepared by grinding half a dram of camphor, and half a dozen fweet almonds together in a ftone mortar, and adding by degrees eight ounces of mint water, ftraining the liquor, and diffolving in it half an ounce of white fugar. A table fpoonful of this emulfion may be taken in fevers, and other diforders which require the ufe of camphor, every two or three hours.

The emulfion of gum ammoniac is made by grinding two drams of the gum with eight ounces of water poured gradually upon it till it is diffolved.

This emulfion is ufed for attenuating vifcid phlegms, and promoting expectorations. In obftinate coughs, two ounces of the fyrup of poppies may be added to it. It may be adminiftered in a dofe of two table fpoonfuls, three or four times a day. The oily emulfion, prepared by mixing fix ounces of foft water with two drams of volatile aromatic fpirit, and an ounce of Florence oil, and half an ounce of fimple fyrup, is ferviceable in recent coughs: in more obftinate coughs, it will be better to fubftitute for the aromatic fpirit the paregoric elixir of the Edinburgh Difpenfatory. A table-fpoonful of it may be taken every two or three hours.

EMUNCTORY, in *Anatomy*, from *emungo*, to clean or wipe the nofe, is any part of the body, which feparates from the blood humours judged to be impure or excrementitious, and therefore hurtful. This procefs is fuppofed to purify the blood. The kidnies and fkin are called the common emunctories, as they afford very copious fecretions. This notion of the feparation of noxious particles is built on the opinions of the older phyfiologifts; and confequently the ufe of the term emunctory has at prefent nearly ceafed.

EMUNGS, in *Geography*, one of the Pelew iflands.

ENABY, a town of Sweden, in the province of Eaft Gothland; 20 miles S. of Linkioping.

ENADA, in *Ancient Geography*, a town of Paleftine, in the tribe of Iffachar, according to the book of Jofhua.

ENÆMON, Εναιμον, from αιμα, *blood*, an external medicine which ftops or ftanches the blood; or which, by binding, cooling, or drying, clofes the paffages of the veffels before open, or diminifhes the fluidity and motion of the blood. See Styptic.

ENÆOREMA, Εναιωρημα, from αιωρω, *to exalt*, expreffes fuch contents of the urine as float about in the middle, refembling a cloud; and thence alfo called nubecula. See Urine.

ENAGARA, in *Ancient Geography*, an ifland of Afia Minor, in the Mediterranean fea, placed by Pliny overagainft Lycia, and near the ifle of Crete.

ENAIM, a town of Judea, in the tribe of Judah, according to the book of Jofhua.

ENALLAGE, in *Rhetoric*, a figure whereby we change and invert the order of the terms in a difcourfe, againft the common rules of language.

The word is derived from the Greek, εναλλαγη, formed of εναλλαττειν, which fignifies *to change*, as well as the fimple verb αλλαττειν.

The grammarians too have a kind of enallage, whereby one part of fpeech, or one accident of a word, is put for another.

Such is the change of a pronoun, as when a poffeffive is put for a relative, *e.gr. fuus* for *ejus;* or of a verb, as when one mood or tenfe is put for another.

ENALURON, in *Heraldry*, is ufed by Guillim to exprefs a bordure charged with birds; as an enaluron of martlets,

martlets, &c. but Mackenzie charges this as a miſtake ariſing from ignorance of the French tongue; enaluron properly ſignifying orle, or in manner of a bordure, and being applicable to a bearing of any thing in that form.

ENAMBUSH, in *Military Affairs*, relates to a device uſed for the purpoſe of ſurpriſing an enemy, either on his route, or when purſuing a ſmall body of troops ſent out for the purpoſe of decoying him into the ſnare. This inſidious practice is often of conſiderable ſervice in the minor branches of warfare, but can rarely be practiſed on a great ſcale; though hiſtory furniſhes us with inſtances of armies having been taken by ſurpriſe, owing to the cunning of their adverſaries, in lying concealed in ſuch places as enabled them to take advantage of an unſuſpecting commander. This, however, is not what in ſtrictneſs is termed an *ambuſh*. That term more properly is confined to that kind of preconcertion, which rather leads an enemy into the danger, by ſome ſuppoſed advantage held out to his acceptance, whether it be for forage, the ſeizing of a depot, the interception of a convoy, or the attack upon ſome weak poſt. Here we ſee an immenſe field open for contrivance and ſpeculation. It is to be underſtood, that when a body of troops is placed in ambuſh, certain intelligence has been obtained of the numbers, route, and object of thoſe who are to be intercepted. If theſe be not previouſly aſcertained, the ambuſcade may prove fatal: ſince, ſhould it turn out that, inſtead of five hundred, five thouſand were to be attacked; that, in lieu of their being foragers laden with booty, they ſhould prove to be a body of light horſe, with riflemen at their backs; or that, inſtead of being a detachment ſent to ſurpriſe ſome ſmall outpoſt, they ſhould be the advanced guard of a ſtrong column:—in either of theſe caſes, a ſad reverſe would take place; for, although at the firſt bruſh, there might be ſome ſurpriſe, and poſſibly ſome confuſion, it would in all probability be but for the moment; after which the aſſailed party would preſs forward with great eagerneſs, and by means of their flanking parties cover the ſpeculators with diſgrace and ruin. The moſt deadly kind of ambuſcade is that wherein fire-arms are rejected, the whole depending upon pikes and cutlaſſes: in ſuch, ſilence is an important object, even in the very moment of falling upon the enemy. This not only prevents the other parts of the line from being able to aſcertain the exact ſituation of the aſſailants, as may always be done by obſerving the flaſhes from muſketry, &c.; but renders it impoſſible to aſcertain their numbers. Add to this, that when men fire, in the dark eſpecially, at a moving object, they are by no means certain of their aim; nor can they ſo ſpeedily recover themſelves, after their pieces may have been diſcharged. Beſides, it is well known that pikes cauſe infinite conſternation, when coming to cloſe quarters; being much longer than the muſket with the bayonet attached, they are infinitely more deſtructive, when properly uſed in this ſpecies of warfare. In many countries, it is next to impoſſible to enambuſh the enemy; while, in others, almoſt every ſpot affords the means of concealment. The great art is, to avoid all common-place modes of laying *perdue*: ſuch are rarely ſucceſsful, owing to that invariable attention paid towards the examination of every ſuch ſuſpicious ſituation. On the other hand, thoſe parts which are leaſt ſuſpected often prove particularly formidable; but where ſuch are reſorted to, the means of retreat, or at leaſt of defence, ought to be fully eſtabliſhed. Thoſe ambuſcades which are the moſt collected, always carry the greateſt probability of ſucceſs: they are leaſt liable to detection, far more pointed in their attack, and moſt calculated for reſiſtance, when prematurely diſcovered. Cavalry is rarely employed in ambuſhes, though a conſiderable body may, if convenient, be poſted in a proper direction, for the purpoſe of ſupporting the infantry concealed in woods, &c. On ſome occaſions, it is even advantageous that ſuch cavalry ſhould be viſible, but in an oppoſite quarter; ſo as to cauſe the force to be attacked to be concentrated, by calling in their ſcouts and videttes; by which thoſe in ambuſh might elſe be diſcovered. This device likewiſe occaſions the baggage to be ſent upon the other flank, out of the way of the cavalry, and leaving that flank towards them free from incumbrance. When this happens, and that the cavalry make a ſhew of charging, the baggage will commonly fall into the hands of thoſe in ambuſcade. Naval ambuſcades are by no means uncommon: it often happening that a well-concerted decoy lures an enemy into ſuch a ſituation as at leaſt places him under conſiderable diſadvantage, or eventually cauſes him to ſurrender. Thus, diſguiſing veſſels by means of new painting; changing their mode of rigging; appearing to avoid rather than to purſue; ſending out a ſlow ſailing veſſel to paſs between a cruiſer and an iſland, behind which a ſuperior force is concealed, &c. &c. are all *ruſes de guerre* in common uſe. One device, which probably would otherwiſe be often practiſed, is contrary to the laws of honour and the rules of war, namely, making ſignals of diſtreſs, with the view to draw an enemy's veſſel to give aſſiſtance, and then to capture her. To aſſume the appearance of being damaged, either by weather or by action, is all fair; becauſe then the enemy bears down as upon a prey, and not as a protector. However, the practice of enambuſhing, whatever advantages it may ſeem to offer, is ſubject to extreme danger: unleſs guided by the moſt certain knowledge of the force to be ſurpriſed, it becomes almoſt invariably a loſing concern, and has the pernicious tendency of creating great diffidence in the conduct of that commander by whoſe inſtructions it is made. Nor can the ſmalleſt ſucceſs be hoped for, unleſs where the peaſantry are friendly diſpoſed, and the country around thoroughly known.

ENAMEL, in *Anatomy*, the hard ſubſtance which covers the crown of the tooth. It is deſcribed in the account of the teeth, contained in the article CRANIUM.

ENAMEL, in the *Arts*. Enamels are vitrifiable ſubſtances, and may be arranged into three claſſes, *viz.* tranſparent, ſemi-tranſparent, and opaque. The two former are chiefly employed in enamelling on gold and ſilver, for watch-caſes, trinkets, and other ſmall articles of jewellery; the latter is principally uſed on copper, for the making of clock and watch-dial plates, and for other plates which, when properly fluxed, are fit for the purpoſe of enamel-painting.

The baſis of all kinds of enamel is a perfectly tranſparent and fuſible glaſs, which is rendered either ſemi-tranſparent or opaque, by the admixture of metallic oxyds. White enamels are compoſed by melting oxyd of tin with the glaſs, and adding a ſmall quantity of mangneſe, to increaſe the brilliancy of the colour. The addition of oxyd of lead, or antimony, produces a yellow enamel; and Kunckel affirms that a beautiful yellow may be obtained from ſilver. Reds are formed by an intermixture of the oxyds of gold and iron; that compoſed by the former being the moſt beautiful and permanent. Greens, violets, and blues, are procured from the oxyds of copper, cobalt, and iron; and theſe, when intermixed in different proportions, afford a great variety of intermediate colours. Sometimes the oxyds are mixed before they are united to the vitreous baſes. Such are the principal ingredients employed in the production of the various enamels; but the proportions in which they are uſed, as well as the degree and continuance of the heat

heat neceſſary to their perfection, conſtitute the ſecrets of the art. Other ſubſtances than thoſe here mentioned are occaſionally uſed in the compoſition of enamels; and it has been ſaid, that the peculiar quality of the beſt kinds of hard or Venetian enamel is owing to the admixture of a particular ſubſtance found on mount Veſuvius, and known to be thrown up by that volcano.

The work of Neri on glaſs, with the notes of Merret and Kunckel, afford many good precepts for making enamels; yet the exact nature and methods of compoſition of the beſt kinds, both of the hard and ſoft enamels, ſtill remain among the arcana of enamelling. The ſoft white enamel is generally called glaſs, and is manufactured at the glaſs-houſe, near the ſite of the Albion mills, on the Surrey ſide of Blackfriars-bridge; the hard enamels are chiefly made at Venice, and, from the operations of the war, are not at preſent to be procured in London. In conſequence of this, the beſt enamel, which formerly, when ſmuggled into the kingdom, has been ſold as low as from 2*s.* to 2*s.* 6*d.* *per lb.*, and even when the duty has been paid at the Cuſtom-houſe, at from 3*s.* to 4*s.*, has progreſſively advanced to a guinea, and from that to 50*s.*; and it cannot now be obtained at any price.

Enamel-*Painting.* See Painting *on Enamel.*

ENAMELLING. The art of enamelling is of great antiquity, but of unknown origin. That it was practiſed by the Egyptians is evident, from the remains that have been obſerved on the ornamental envelopes of mummies. From them it probably paſſed to the Greeks, and afterwards to the Romans, who appear to have introduced the art into this country; as various Roman antiquities have been dug up in different parts of Britain, in which enamels have formed portions of the ornaments. That the Britons received the art from their conquerors may be conjectured from the circumſtance of enamelled trinkets having been found in Britiſh barrows. That the Saxons practiſed it is certain, from the jewel found at Athelney in Somerſetſhire, and now preſerved at Oxford; which jewel, as appears by the inſcription, was made by command of the great Alfred. The gold cup, given by king John to the corporation of Lynn in Norfolk, proves that the art was not loſt under the Normans; for the ſides of that cup are embelliſhed with various figures, whoſe garments are partly compoſed of coloured enamels. The tomb of Edward the Confeſſor in Weſtminſter Abbey, conſtructed in the reign of Henry III., was alſo ornamented with enamels, pieces of which ſtill remain. The beautiful crozier of the celebrated William of Wykeham, of the time of Edward III., may be alſo adduced as exhibiting ſome curious ſpecimens of the application of this art: and other examples might be pointed out, of its progreſſive deſcent to our own age.

It would ſeem from the above brief review, that anciently enamels were principally applied to the purpoſes of ornament; but ſince the invention of clocks and watches, their uſefulneſs has been proportionally increaſed. For clock and watch dials there is probably no ſubſtance that could be ſubſtituted, that can equal enamel in permanence and beauty: in ſeveral reſpects, it poſſeſſes advantages even over the rich metals of ſilver and gold. Within the laſt 30 or 40 years, an *imitative enamel* has been uſed, and, through the ſcarcity of real enamel, is now in much demand for clock plates; but it is by no means comparable with its prototype: for, being chiefly compoſed of flake white, ground up with ſpirits of turpentine, and afterwards mixed with copal varniſh, it will neither aſſume an equal brilliancy in colour, nor continue unchanged in different climates; on the contrary, the action of the air occaſions it to become dingy and yellow. In fact, imitative enamelling is nothing more than a branch of the art of *japanning;* which ſee.

The proceſſes of enamelling have never been accurately deſcribed. The jealouſies that exiſt in all arts in which any thing like a ſcientific knowledge is wanting, operate to ſecluſion. The practitioner conceals his information from motives of profit, and the amateur ſeldom acquires an inſight ſufficiently minute to enable him to unfold the modes of operation. Whatever may be the defects of the preſent attempt, it will be found to contain a better account of the practical branches of the art than has before appeared.

Enamels are commonly laid upon a metal ground, yet they have been ſometimes uſed in ſubſtance, for diſhes, flower-pots, ornamental veſſels, figures, vaſes, &c. In theſe caſes, the enamel is run into moulds immediately from the pots in which it has been melted. The metals employed to enamel on are gold, ſilver, and copper. Of the other metals, ſome are too fuſible to endure the action of the fire, and the remainder, as platina, &c. are, to uſe the language of the art, too *ſtrong*, for the enamel: that is, the adheſion between the two ſubſtances is not powerful enough to keep them together, the enamel cracking as it grows cold, and flying off the metal in flakes. It appears, therefore, that a certain, however ſlight, degree of oxydation is neceſſary to make the enamel and the metal unite with ſufficient firmneſs. Gold is unqueſtionably the beſt ſubſtance to enamel on, its richneſs of colour ſhowing a beautiful tinge through the enamel: yet the metal generally uſed, except for watch-caſes, and valuable articles of jewellery, is copper; and that on account of its ſuperior cheapneſs. Both the gold and the copper ſhould be of the finer kinds, the others being too refractory to agree properly with the enamel.

By the cuſtom of the trade, rather than from any principle of utility, enamelling is now divided into two branches, *viz.* dial-plate enamelling, and tranſparent enamelling. The former includes the manufacture of clock and watch plates, with fluxed plates for enamel painting, the latter comprehends the enamelling of watch caſes, broaches, pins, and other bijoux: of late years the making of theſe leſſer articles has gradually grown into great diſuſe in this country.

Dial-Plate Enamelling, conſiſts of the two diviſions of hard-enamelling, and ſoft, or glaſs enamelling; in the firſt branch, the Venetian enamels only are employed, in the laſt, the Engliſh or glaſs enamels. The practice of hard-enamelling requires more ſkill, time, and labour than the others, and is conſequently eſteemed the moſt. In preparing the metals to be enamelled on, whether of gold, ſilver, or copper, the proceſs is ſimilar; one deſcription will therefore ſuffice for the whole:—and firſt of the making of watch dials.

The copper being evenly flatted in long ſlips (which is done at the flatting mills between ſteel rollers) and to a proper thickneſs, pieces are cut off for uſe according to the ſize wanted. They are then annealed in a clear fire, in order to make them ſufficiently pliable to take the required forms which is given to them by means of dies. The dies are ſmall circular plates of braſs evenly turned, varying in thickneſs, perhaps, from the ſixteenth of an inch to an eighth, or more, according to their diameter. Some of them are flat, others are hollowed out for the purpoſe of giving a ſlight curve to the *copper*, as the metal to be enamelled on is technically termed when prepared for uſe: the edges of the dies are turned off in an oblique direction, and in the centre is a ſmall hole, rather larger than that which is wanted in the dial-plate. A complete ſet of dies varies in ſize from about three-fourths of an inch to two inches and a half, the gradations being very ſmall, perhaps not

not more than the thirty-fecond part of an inch between each.

The copper being cut with a pair of fciffars nearly to the fize required and properly annealed, is next placed on the die beft adapted for the purpofe, and the eye, or centre hole, is made. This is effected by firft forcing up the copper into the hole of the die with a fmall round-headed punch ; by this means a fmall concave bulge is formed, the upper fide of which is then filed through with a fmooth grained file ; it is then again placed on the die, and preffed gradually open till it nearly fills the hole with an oval burnifher ; it is afterwards preffed tighter into the hole with a round broach, the burr being occafionally taken off by the file, and care employed to prevent the eye from cracking. The punch, burnifher, and round pin, are all of fteel ; the two latter taper in regular gradation towards the handles.

When the eye is completed, the edge of the copper is cut round, fo as to leave a fmall part, probably about the thirtieth of an inch, projecting beyond the die. The projecting part is then turned up, or burnifhed, againft the edge of the die, the copper being firft laid fmooth and flat by the burnifher. The turned-up edge of the copper is afterwards filed evenly round, and reduced to the proper height, according to the thicknefs of the brafs-edge, or rim, to which it is to be fixed when in the watch. The infide burr is then fcraped off with a graver, and ftill further cleared away by means of a fcratch-brufh : this latter tool is compofed of fmall brafs or fteel wire tied together in a round bundle, about the fize of the little finger. The purpofe for which the eye of the copper is formed, and the edge turned up, is to retain the enamel in its proper place, fo that the plate may be finifhed both fquare and neat.

According to the kind of watch to which the dial is to be applied, the copper, if for a feconds watch, muft be kept almoft flat ; or if for a watch where a greater fpace is wanting beneath, to give more fcope for the wheels, muft be raifed from the edge to the centre in a regular and exact manner. To effect this a fmall circular block or fetting die is ufed, made of box or other hard wood turned out to the neceffary degree of concavity, and having a hole in the middle to receive the eye of the copper when placed within the hollow of the block. The copper is then gradually fet up to the convexity or height required by rubbing it gently yet firmly with a bent, or fetting fpatula, formed of a thin flip of fteel, about five inches long, properly fixed. It is now ready to have the feet foldered on, by which it is to be pinned down to the brafs edge or frame of the watch ; and the places for the feet being marked on the back of the copper, through the holes drilled for the purpofe in the edge or frame, the feet are prepared for foldering.

The feet are always of wire of the fame kind of metal as that to be enamelled on, and the wire is drawn into different thickneffes, proportioned to the fize of the intended dial-plate ; thus varying perhaps from the tenth to the fixteenth of an inch. In the more common kinds of enamelling, the feet are generally cut off from filvered wire, that is, copper wire plated with filver ; the filver itfelf forming the folder when the feet and copper are expofed to the united action of the lamp and blow-pipe. In the beft kind of work plain copper wire is ufed, and the feet are faftened to the copper by means of fpeltre, or of filver folder. When fufficient care is exercifed, either of thefe modes is equally appropriate, but the feet foldered on with fpeltre take the firmeft hold ; thofe with the filvered wire the flighteft. The feet are evenly filed, either to a flat face, or an angular one, according to the defcription of copper for which they are wanted ; and are cut off the wire into proper lengths by a pair of cutting-pliers or nippers. In order to make the feet remain in their places, and facilitate the foldering, the end of each foot, before putting it on the copper (which is done by means of a pair of corn-tongs or tweezers), is dipped into a flight wafh of borax and water, through which it adheres with fufficient force to admit of its being expofed to the power of the blow-pipe. The lamp in common ufe contains from a pint to a quart of oil, and has a cylindrical fpout projecting about three inches, and being an inch or more in diameter. This fpace is filled with cotton, which being lighted, a good ftrong flame is produced. The copper is carefully placed upon a piece of folid charcoal, long enough to be held in the hand, and the flame being then propelled by the blow-pipe againft the folder, or filvered wire, as the cafe may be, the feet are firmly united to the copper. In this operation, attention muft be given to the exact degree of heat required to fufe the folder, for fhould it be too powerful, the copper itfelf will melt at the fame inftant : care muft be taken alfo that all the feet keep in their due places, otherwife the copper will not fit properly, and the feet muft either be cut off, and new ones foldered on, or much trouble will be found in drawing the holes of the brafs-edges or frames, to get the coppers into their proper centrical fituations.

The copper being thus far advanced is thrown into the pickling-pan, in order to free it from the fcale or oxydable covering acquired from the heat. The *pickle* is either oil of vitriol, fufficiently neutralized for the purpofe by water, or elfe a folution of the beft double aquafortis. When the fcale is enough foftened to admit of its being removed by a foft brufh, ufed with water and a little white fand, the copper is taken out of the pickle, and all the impurities being wafhed away, it is dried by means of heat, or elfe with a foft cloth. In this ftate, the copper will generally require to be again put into a proper fhape, by means of the brafs die, and fetting block, as it is fcarcely poffible but that fome irregularities will be produced through the operations laft defcribed. It is alfo hardened in a flight degree by rubbing the under fide with the fetting fpatula, and the furface with the fcratch-brufh. When this is done, the copper is completed, and fit to be enamelled on. It is to be remarked, that when many coppers are prepared at once, much time is faved by turning off the edges by means of the lathe and arbour, inftead of by filing them even in the manner detailed above.

The above are the methods by which the common coppers are prepared ; it is now requifite to defcribe what are called *French edges*, from their having been firft made in France. Thefe are of two kinds, the folid French edge and the laid-down French edge. To make the former, a piece of copper is taken, either about a fixteenth or a twelfth of an inch thick, according to the diameter of the intended plate, and a hole being drilled in the centre, the copper is placed upon an arbour, and fixed tightly by means of a fmall cone and fcrew-nut fitted to the maundrel. The arbour being then fixed upon a lathe, the edge of the copper is next turned off in an oblique direction, inclining inwards, with a graver, and the copper is then reduced to the proper thicknefs for enamelling from the edge to the centre, by means of a fcorper and other tools ; thus leaving the edge folid, and taking care alfo that a fufficient fubftance is left unreduced round the cone, to form the outer circle of the eye. The laid-down French edge is made by preparing a copper in the common way from a thin flip, the edge being left rather higher than ufual, and then fixing it upon the arbour, when the edge of the copper being firft turned perfectly even with a graver,

graver, is next forcibly bent inwards by a fmall triangular tool, (perhaps formed from the end of a three-fquare file worn fmooth,) and afterwards fquared and finifhed by the graver and fcratch-brufh. It is in general neceffary to reverfe the coppers on the arbour, and turn a fmall portion of the under fide away, both of the folid and laid-down kinds, in order to make the edge of a due fharpnefs. The coppers are laftly fet up, and the feet foldered on, as before defcribed. French edges are moftly ufed for watches of a particular kind, where room is wanting, and the dials are fixed upon the frames without a brafs-edge.

When a dial is made for a feconds' watch, or for one requiring ftill more circles than two, the additional eye, or eyes, is made by marking the centres accurately with a point on the under fide of the copper, and then bulging the copper upwards with a fmall punch from each centre, by ftriking it gently with a fmall hammer into a piece of lead, about three times the thicknefs of a die; the lead forms a fufficient refiftance to prevent the eye from cracking, and is yet foft enough to admit of the copper being bulged up evenly. The fmall eyes are afterwards evened with the file, and opened with a fmall needle or round-pin to the required fizes. Some trivial variations in the mode of making the feconds' holes, &c. occafionally occur.

The coppers being thus prepared, the next procefs is that of *enamelling*, properly fo called. Where the operations of *hard* enamelling, and *glafs* enamelling, are diffimilar, the difference will be defcribed in proceeding, but to a certain extent they are the fame.

The enamel, as it comes from the makers, is generally in fmall cakes from four to five or fix inches in diameter. In preparing it for ufe, a fmall hammer is ufed, having one end flat, and the other of the fhape commonly employed to rivet with. With this the enamel is broken into thin pieces or flakes, by ftriking the edge of the cake fmartly as it refts upon the fore finger of the left-hand. The pieces are then put into an agate mortar, and with a peftle of the fame kind are finely pulverized, the fplinters being prevented from flying about, by keeping the enamel covered with pure water all the time the procefs of *grinding* is going on. The point at which the trituration fhould be difcontinued, can only be afcertained from experience, as the different kinds of enamel, and the different modes of its application, require the *ground* enamel to be either more or lefs fine. In general it may be ftated, that the *backing* fhould be much finer than the *firft coat;* the *fecond coat* of an intermediate finenefs; the hard enamels confiderably finer than the glafs, and the flux ftill finer than thofe, as the fire operates with lefs effect upon the flux than upon either of the former fubftances. In grinding, great care muft be taken to keep the enamel free from dirt, and the light flue which arifes muft be wafhed away three, four, or more times, as may be neceffary in the courfe of the operation, till the water comes off quite clear. A fmall tea-pot is commonly ufed to pour the water from, and when the enamel is ground fufficiently, the produce is emptied into fome other fmall cup for ufe, the furface being kept juft covered with water.

The manner in which the grinding is performed, is by placing the mortar upon the work-board, on a coarfe piece of flannel or linen, twice or thrice doubled, and wetted to prevent its flipping. The handle of the peftle is then grafped firmly about the middle with one hand, and the palm of the other being placed upon the top, the operator inclines the upper part of his body over the mortar, and crufhes the enamel by preffing forcibly with his breaft upon that hand which covers the peftle. This motion is repeated in quick fucceffion, till all the larger pieces are reduced into coarfe and uneven grains; which grains are afterwards ground to the requifite equality and finenefs, by holding the mortar firmly down with one hand, and with the other giving a circular direction to the peftle, ufing at the fame time as much ftrength as can be conveniently exerted.

In enamelling watch dials, many coppers are ufually prepared to go on with at once; that method poffeffing the three-fold advantage of faving time, materials, and labour. When the enamel is ground, therefore, the coppers having been firft cleanfed by the pickle, and carefully brufhed out with water, are fpread, face downwards, over a foft half-worn cloth, or fmooth napkin, and a thin layer of hard enamel, called, in its ground ftate, the *backing*, is fpread over the under fides with the end of a quill, properly cut, or with a fmall bone fpoon. The coppers are then flightly preffed on by another foft cloth or napkin, which, by imbibing fome portion of the water, renders the enamel fufficiently dry to be fmoothly and evenly fpread with the rounded fide of a fteel fpatula. The water is then again dried out by the napkin, and a yet further evennefs produced by going over the enamel as before, with the fpatula, and thefe operations are repeated, till the back becomes completely fmooth, and the enamel is of an equal thicknefs all over. It muft be obferved, that the water fhould not be *entirely* abforbed, as in that cafe the enamel would fall off, in powder, before the fubfequent operations are completed. When the enamel is properly fpread, the loofe particles are carefully cleared away from the edge and eye of the coppers; from the former by the fpatula, from the latter by twifting round it the pointed end of a quill, and the procefs of *laying the bottoms* is thus finifhed. Some flight variations to the above method are in ufe among different artifts, but the difference is fcarcely important enough to require defcription. In fome inftances the enamel is laid on with the fpatula itfelf, and the coppers, inftead of being held between the fingers, are placed upon the round pin, by means of the centre holes, till the backs are duly fpread: in both modes due care muft be taken that the coppers are not bent out of their proper forms.

The next operation is to lay the *firft coats;* that is, to fpread a layer of *glafs* enamel over the upper fides of the coppers. In doing this, the furface is firft brufhed flightly over with a fmall camel-hair brufh, or a hare's foot, to remove any dirt or extraneous particles of enamel, as the mixture of any hard enamel with the glafs would infallibly fpoil the work. The glafs is then fpread upon the coppers in a layer, the thicknefs of which is commonly the fame as the height of the edge and eye. The water is afterwards flightly abforbed with a clean napkin fmoothly folded, and the enamel fpread by a thin, flat fpatula, till all unevennefs is removed, and the furface lies regularly from edge to centre. The edge being then gently tapped twice or thrice at different places with the fpatula, the water rifes towards the top, and is again dried off by the napkin, when the enamel is once more made fmooth by the fpatula, and the water being wholly taken up by the napkin, or as nearly fo as can be effected, without difturbing the enamel, the *firft coats* are placed upon rings for *firing*.

The rings ufed in enamelling are generally made of a mixture of pipe-maker's clay and Stourbridge clay, rolled up into the form of cylinders, and turned in a lathe by means of a cylindrical piece of wood forced through the centre of the mafs when wet. Each ring is about a quarter of an inch in thicknefs, and the fame in depth; the upper fide is prepared for ufe by rendering it flightly concave, which is done by rubbing it carefully upon a half globe of lead fprinkled over with fine filver fand: the under fide is nearly flat. Through the concavity thus given to the rings, the

the edge of the copper or dial-plate only is ſuffered to touch, by which means the enamel on the back remains undiſturbed, and the edges are prevented from ſticking by rubbing over the ſurfaces of the rings with ſoft chalk or whiting.

The firſt coats having been placed carefully upon the rings, are next put into a ſhallow tin veſſel, called a tin cover, which is either made ſquare or round, according to the fancy of the artificer, and is commonly about three quarters of an inch in depth. All the moiſture is then ſlowly evaporated from the enamel, by placing the cover upon a German ſtove, or in ſome other convenient ſituation near a fire, where the evaporation can be properly regulated: for, ſhould the water be dried off too quickly, the work would be in danger of ſpoiling from *blebs* or *bliſters*. Theſe are very ſmall air-bubbles, which, by riſing to the ſurface of the dial-plates, deſtroy their ſmoothneſs and beauty. They appear to be occaſioned, partly by want of due care in laying on the enamel, and partly by the confinement of the air which the water contained, and which, in the proceſs of firing, becomes rarefied; throwing off, by its expanſion, a portion of the ſurrounding enamel, yet not entirely eſcaping without a very vivid heat, and even then reſolving into black or green ſpecks, ſo coloured through the oxydation of the copper.

The *firing* is executed beneath a muffle, placed in a ſmall furnace ignited with coke and charcoal. (See Muffle and Furnace *Enamellers*.) The furnace being drawn up to a ſufficient heat by means of a regiſter, the firſt coats are taken ſeparately from the tin covers, and placed upon thin planches of clay, or iron, chalked over, and gradually introduced beneath the muffle; where, in a very ſhort time, the enamel melts, or technically *runs;* and becoming properly conſolidated, the firſt coat is complete. Great attention is requiſite in this operation, to prevent the enamel from being over-fired; as in that caſe, the glaſs would loſe ſome portion of its opacity, and other defects alſo be produced, to the detriment of the work. The planches are placed towards the further extremity of the muffle, by means of a pair of ſpring tongs; and as ſoon as the fuſion is ſeen to take place, are turned carefully round, in order that every part ſhould be equally fired. The planches are generally made circular, and ſlightly concave, for the convenience of moving the work without danger of ſhaking off the enamel before it becomes fixed by the heat.

As all ſolids, when reduced to a granulated ſtate, occupy a greater ſpace than before, *et vice verſâ*, it will be found, that a very conſiderable depreſſion has been produced in the enamel of the firſt coats by the act of fuſion; and that the edge and eye are now much above the ſurface. This deficiency in ſubſtance it is the office of the *ſecond coats* to ſupply. When the work is cooled, therefore, the ſcale is wholly removed from the edges and eyes by means of a fine-grained Lancaſhire file, or a ſmooth grey-ſtone; and being then waſhed and dried, each plate is put upon a ſmall round wax-block, of ſufficient bulk to be held in the hand, and about four or five inches high. The feet are then either preſſed firmly into the wax which covers one end of the block, or the plate is otherwiſe fixed by means of three ſmall cones of wax placed triangular-wiſe upon the block; care being taken not to ſtrain the enamel by too weighty a preſſure. A ſecond layer of ground enamel is then gently ſpread with a quill, and prepared for firing by the napkin and ſpatula as before; after which the ſecond coats are placed upon the rings, and the moiſture being evaporated in the tin-cover, (one edge of which, both in this and in the preceding operation, ſhould be left a little open to give iſſue to the ſteam,) they are ready for a ſecond fire.

The ſecond firing requires an equally cautious management as the former one. The plates muſt not be over-fired, nor muſt the heat be ſuffered to melt the enamel too rapidly; but a kind of rotatory motion, called *coddling*, muſt be given to the work, by holding the loaded planch lightly with the tongs, and gently drawing the edge of it towards the mouth of the muffle, and then returning it to its former place, till the fuſion be complete; a proper knowledge of which can be gained only from practice. The work is now in a fit ſtate for poliſhing.

Poliſhing, in this art, has a twofold ſignification: it not only means to render bright, according to the common acceptation of the term; but alſo to make even, without any reference to gloſſyneſs. The enamel has a natural brightneſs of ſurface acquired from the fire; and when this is removed, it is only neceſſary again to expoſe it to a due heat, to cauſe it to reaſſume its former character. Yet as this brightneſs exiſts independent of evenneſs, and as evenneſs is eſſential to the perfection of enamelling, it is requiſite, in moſt caſes, to produce that quality by the methods next to be deſcribed.

The materials uſed in poliſhing glaſs plates are grey-ſtones, rag-ſtones, ſometimes called burrs, fine ground ſilver ſand, and water. The grey-ſtones ought to be of a fine grain and even texture, without knots, which would be very detrimental by making deep ſcratches in the enamel, inſtead of wearing it away evenly. The plates are taken ſeparately, and the thin edges are firſt worn off by one of the finer grey-ſtones, till they become ſmooth and equal; after which the eyes are rubbed down, till the centre of each plate is even and ſquare. Either the grey-ſtone or the rag-ſtone is next employed, according to the nature of the work, to wear away all the irregularities that may exiſt on the ſurface of the enamel; the rag-ſtones being only uſed for the more common kinds of dials. This is done in different ways; *viz.* firſt, either by holding the plate upon the fore and middle finger of one hand, and giving it a ſort of circular motion by means of the thumb, whilſt with the other hand the poliſhing-ſtone is rubbed with a forward and backward ſtroke over every part of the ſurface; ſecondly, by holding the poliſhing-ſtone on the work-board with one hand, and with the other rubbing upon it the face of the enamel; or, thirdly, by fixing the plate upon a cork, either by means of the feet, or with a piece of wet flannel, and with the fingers giving it a kind of rotatory motion, whilſt the poliſhing-ſtone is rubbed over it in a ſimilar manner. The ground ſilver ſand is uſed to give ſharpneſs to the poliſhing-ſtones, and wear away the enamel with greater celerity than would be otherwiſe acquired; and the act of poliſhing is continued till all the gloſs is ground off the ſurface. In this operation great care muſt be taken that the preſſure be not too powerful, as the plates will then crack in the fire, and can never, or very rarely, be properly mended.

When the enamel is ſufficiently poliſhed, which is eaſily known by the criterion of all the gloſs being removed, the plates muſt be clean waſhed, and the ſpecks of dirt, &c. picked out with a ſharp graver. They are then well rubbed over with ſome fine ground glaſs, either by means of a cloth, a glaſs mull, or perhaps a ſmall bit of fir-wood cut ſmooth, in order to remove the ſtains that may be left by the poliſhing-ſtones; and the clean water being ſuffered to run over them, they are wiped dry, and again placed upon the rings for firing.

The

The degree of heat neceffary for polifhed plates is determined by the finer or coarfer modes in which they were prepared; as the fufion is much facilitated by the enamel being free from fcratches. When the furface is properly run, that is, when it becomes perfectly fmooth, even, and bright, the plate is completed; and when cold, is fit for painting on. See PAINTING *of Clock and Watch Dial-Plates*.

The above defcription regards more particularly the beft kinds of work; but for the more common work there are two other modes of enamelling practifed, which it will be requifite briefly to explain. The plates made in thefe ways are called *run-down plates*, and *run-down fecond coats*.

Run-down plates are thofe which are made by laying the enamel upon the coppers in fufficient quantity to form plates of the required thicknefs, without putting on a fecond coat. Both labour and fire are thus faved; but that neatnefs, regularity, and fquarenefs, which are acquired by the firft method, are rarely obtainable in this: and indeed flat plates can hardly be managed at all in this mode. Run-down plates require more coddling than any other; and a longer continuance of vivid heat is neceffary to make the glafs flow to a proper evennefs of furface: the plates being wholly completed with one fire, and without polifhing. It is obvious that the moft common work only can be thus manufactured; for that of the next fuperior defcription, the run-down *one coats*, are polifhed off with the rag-ftone, and undergo a fecond firing. The run-down fecond coats are thofe which are reduced to a furface comparatively even by the fecond fire, and are then painted on without being polifhed off.

In enamelling *hard-plates* for watches, the coppers and the firft coats are prepared in the manner above defcribed; excepting perhaps that the layer of glafs is rather thinner than in glafs-work only. The hard enamel, which is generally moft valued as it approaches to a rich cream colour, is broken down, and ground in the fame way as the glafs, if a fmall quantity alone be wanted; but if otherwife, it is firft broken from the cake with the hammer, and then pounded in a fteel mortar, till reduced into coarfe grains. Thefe grains are then expofed to the action of a magnet, in order that all the particles of fteel that have been broken off the mortar in the act of pounding may be taken away, as they would infallibly fpoil the work, by rifing in black fpecks to the furface of the enamel, when in the fire. As an additional precaution, alfo, it is neceffary to put the granulated enamel into a fmall bafon, and pouring upon it a ftrong folution of oil of vitriol, or aquafortis, to fuffer it to ftand for fome hours, that the fteel particles, &c. may be wholly diffolved; after which, the enamel muft be very carefully wafhed, till the water comes off pure and taftelefs: for fhould any of the acid remain, the work would certainly blifter. The enamel is then ground to the neceffary finenefs in an agate mortar, and afterwards fpread over the firft coat with a quill, in fmall quantities, and as evenly as it can be laid, that it may require the ufe of the fpatula as little as poffible. The water is then partly abforbed by a very fine and clean napkin, and the enamel fmoothly fpread and clofely compreffed with the fpatula; after which, more water is abforbed, and the fpreading is continued till the furface lies true and equal. The plate is then put upon a ring, and properly fired; and is afterwards polifhed by placing it upon a cork, (the top edge being firft taken off with a fine grey-ftone,) and wearing away the furface, firft, by a very fine-grained Lancafhire file, or fmooth piece of fteel, and filver fand, ground to an almoft impalpable powder; fecondly, by a fine blue-ftone and fand; and thirdly, by the blue-ftone alone. With the latter a fort of half-polifh fhould be given to the enamel; and the nigher that polifh approaches to complete gloffynefs, the better; as the plate will then be finifhed in the third fire with a lefs degree of heat than would be otherwife wanted. In this procefs, much caution is required to prevent fcratches, which cannot be *run up* by the fire without giving the enamel a greater heat than it will well bear. When the polifhing is completed, the plate is carefully cleaned with ground enamel; and fhould there be any fpecks, they muft be picked out with a fmall and fharp diamond, and the hollows very dextroufly filled up with enamel from a quill-point, that they may neither rife above or fink below the common furface, when the plate is again fired: fhould they actually do fo, they muft be made fmooth with a blue-ftone, and the plate muft undergo a fourth fire, to render the furface of one uniform texture and gloffynefs. Hard-enamel dials are always confiderably dearer than glafs ones, through the greater labour, attention, &c. that are requifite in making them; and the beft watches are almoft always made up with dials of this kind.

In the polifhing off both of glafs and hard plates, much addrefs is neceffary to prevent a feparation between the enamel and the edge of the copper; for if too great a preffure is exercifed, or if the grey-ftones, which are employed to wear down the copper, are of too rough a grit, the adhefion will be deftroyed, and various black indents arife round the edge of the enamel, when the plate is again expofed to the fire. In glafs dials, thefe defects may be fometimes amended; but in hard-enamel dials, fcarcely ever.

The operations of *tranfparent enamelling* are nearly fimilar to what have been already defcribed in the making of watch dials. As the work is generally of a more minute kind, greater delicacy of handling perhaps is required; and as the enamels are of various colours and defcriptions, more cups, veffels, &c. and additional foft cloths or napkins, are wanting to keep them from mixing. Watch cafes are commonly enamelled upon gold, as well as moft fuperior articles of the fancy kind; and the furface of the gold is frequently engraved into different figures and compartments, before the enamel is laid on; by which means the work affumes a beautiful variegated appearance through the vitreous coating.

In enamelling the backs and edges of watch-cafes, &c. quince-water is frequently ufed as the medium by which the enamels are laid on; for this poffeffing a more adhefive and retentive quality than common water, better prevents the enamel from flowing from its proper fituations: for where the convexity is confiderable, the enamel will of courfe have a tendency to float towards the loweft part. When enamels of different colours are intended to be employed on the fame article, which is frequently the cafe in ornamental works, fmall edges or prominent lines are left in the fubftance of the metal, for the purpofe of keeping the enamels feparate; and thefe are polifhed with the enamel, and reduced with it to a fimilar equality of furface. Tranfparent enamels are not unfrequently polifhed to complete gloffynefs, without expofing them to an additional fire: in thefe cafes, the work is finifhed with rotten-ftone.

It is fometimes defirable to take off the enamel from a watch-cafe or trinket, without injuring the metallic part. For this purpofe it has been recommended to lay a mixture of common falt, nitre, and alum in powder, upon the enamel requiring to be removed; and afterwards to put it into the furnace: and when the fufion has commenced, to throw

throw the cafe, &c. fuddenly into water, which caufes the enamel to fly off in flakes.

In ornamental tranfparent work, a very pretty effect is often produced by applying fmall and very thin pieces of gold or filver, cut or ftamped, into different figures, as acorns, oak-leaves, vine-leaves, bunches of grapes, fruits, &c. upon the furface of the firft coating of enamel, where they are fixed by the fire; and are afterwards covered over by the fecond layer, through which they appear with confiderable beauty. When any quantity of fancy-works of fimilar defign is wanting, this mode of enamelling is much cheaper to execute than to have the furface of the metal itfelf engraved into the required forms.

Clock Dial-Plate Enamelling, is far more laborious than the other branches, and requires confiderable experience to be properly executed, though the methods of operation are foon explained. The copper, being procured from the flatting mills in thin flips, and of an adequate diameter and thicknefs, is cut to nearly the required fize with a pair of ftrong fciffars, a circle having been firft ftruck with the compaffes. If in a foft ftate, it is then cleaned by the pickle, and having been brufhed out with fand on a flat board, is wafhed and dried for planifhing; if otherwife it muft be well annealed before it is thrown into the pickle, where it muft lie till all the fcale is enough foftened to be removed by the hand-brufh, fand, and water.

Planifhing is a very important part of clock-plate enamelling, and too much care cannot be exerted in the procefs, as the neceffary regularity of furface almoft wholly depends upon it. In large plates the action of the fire has a very confiderable effect, as it caufes an expanfion in the metal, which, unlefs properly guarded againft, cannot but operate to the imperfection, and perhaps total fpoiling of the work. In flatting alfo, a fort of twift is not unfrequently given to the copper, during its paffage through the rollers, that would affuredly caufe the plate to become uneven and out of fhape, were it not to be removed by planifhing and repeated annealings. Another effect produced by the fire, is occafioning the plate to rife, perhaps irregularly, towards the centre, and this can only be checked by counteracting the action which the heat would otherwife generate in the metal by good planifhing. To keep a large plate entirely flat is impoffible; or at leaft no means have as yet been difcovered through which that aim can be attained. The beft way, therefore, to provide againft the irregularities which the fire might caufe, is to give to the copper, in the courfe of planifhing, a flight and even rife or curve from the edge to the centre; this can either be effected by the ufe of large brafs dies, or by a machine adapted for the purpofe.

The *machine* of which, probably, there is only one in the trade, confifts of two principal parts; the one a folid mafs of iron, with a concave and polifhed face, imbedded immoveably in a ftrong oak block, firmly fixed on a foundation of brick-work, and the top edge hooped with a thick iron ring, to prevent fplitting; the other, an anfwering and weighty mafs of iron with a convex face, fimilarly polifhed, and fixed in an upright frame of timber, but fo contrived as to become *moveable* by means of fliding grooves, a rope, a pulley, and a lever, and fo placed as to fall directly upon the mafs beneath, in a fimilar way to the monkey of a pile-driving engine. The diameter both of the hammer and the anvil, as the upper and under maffes of iron may be called, for the fake of perfpicuity, is about thirteen inches; that fize being nearly as large as clock dials are ever made or wanted. The convexity of the hammer is exactly fitted to the concavity of the anvil, and may be defcribed, perhaps, as forming a portion of a circle fifty feet in diameter; and the centres of both are kept true to each other, and confequently to the regularity of curve, by means of large fcrews and nuts, which adjuft the pofition of the hammer by altering the perpendicularity of the bars of iron that the grooves act upon. The power of this machine faves much labour in planifhing, as well as time; yet as it is infufficient wholly to prepare the coppers, and as the charge of erecting one would be very confiderable, it will never, perhaps, come into general ufe.

In planifhing with this machine, it is neceffary to be provided with various thin circular pieces of lead, evenly flatted, and adapted in fize to the diameters of the coppers to be planifhed. Without thefe the ftroke given by the hammer would have a very imperfect effect; and the impulfe given by the weight of its fall would alfo be continually weakening the foundation and bed of the anvil.

The coppers prepared for planifhing by this machine are taken feparately, (the eyes having been previoufly cut out to a proper fize by means of an iron punch, an hammer, and a lead block,) and each one is laid upon a lead of a correfpondent diameter, and placed upon the anvil in fuch a manner that all the centres agree. The hammer, which has been hitherto retained at fome height by an iron ftay fixed in one of the timbers, and moving on a pivot, is then let fall, three or four times in quick fucceffion, it being each time lifted up to the height of three feet or more, by means of the lever. The hammer is then again faftened by the ftay, whilft the copper is turned over on the lead, after which the operation is repeated, and the copper is then taken off, and another laid down till the whole are gone through. The weight of the hammer, and the impetus acquired by its defcent, remove moft of the unevenneffes in the coppers, yet cannot entirely remedy them: a ftrong and unequal fpring will ftill be felt, and the metal being now rendered hard by the action of the hammer, annealing muft again be reforted to, and the coppers muft be pickled and cleaned as before. The machine is then ufed a fecond time in a fimilar way; and afterwards a third, a fourth, a fifth, and even a fixth and feventh time, according to the diameters of the coppers, or to the refractorinefs of the metals, due care being taken properly to anneal and pickle them between every operation.

The coppers will now be found of a regular fhape, and the fpring in the metal tolerably uniform; it is effential, however, to the perfection of the plate, that the fpring fhould be *entirely* uniform from edge to centre, otherwife the plate would warp and cockle in the fire. A kind of intermediate procefs muft therefore be carried on between the taking the coppers from the machine, and before repeating the annealings. This is performed by means of a circular brafs die, about a quarter of an inch in thicknefs, and from fifteen to eighteen inches in diameter, fcrewed firmly down to a ftrong oaken block, having three ftout legs, placed triangular-wife, and of a fufficient height to ufe conveniently when the artift is in a ftanding pofture. The die fhould have the fame degree of curve as the machine, otherwife the effect produced by each would occafion a fort of reciprocal counteraction. The coppers, having paffed through the machine, are placed in fucceffion upon the die, and a wooden box-hammer (fomewhat refembling that ufed by gold-beaters) with two faces, the one a circle about three inches over, the other cut away on the front edges, fo as to leave only a portion about an inch or an inch and a quarter in breadth remaining in the middle, is then taken, and the copper is both rubbed and ftruck with it till the metal becomes too hard for any further impreffion to be made, and requires annealing. The circular end is ufed to ftrike the

copper

copper with, which is done by short, quick beats of the hammer, the artist working from centre to edge, and communicating the necessary motion and direction to the coppers by means of the fingers of one hand, so extended over the work as to give the requisite command in guiding it: the other end is employed in rubbing the coppers strongly with a backward and forward action, under which they are moved upon the die by the fingers as before. Where the machine is not used, the planishing must then be entirely performed in the way just described, and great care must be taken, that in the rubbing, the coppers be not bent, which would occasion both additional labour, and further annealing. No positive direction can be given as to the number of times that the coppers must be annealed in the course of the planishing; as a general rule, it may be said that the larger the size, the more frequently must the annealings be repeated. For plates of from three to four inches, twice or thrice is commonly enough; from five to eight inches, about four or five times are requisite; for larger sizes, the annealings must be continued till the spring or action in the metal becomes uniform, as already mentioned. This is best determined by the regularity with which the copper will flap or jerk into the curve given by planishing when turned either side uppermost upon the die. When the planishing is completed, the coppers are cut exactly to the sizes required, and having been pickled and cleaned, they are then ready to be enamelled on. After the last annealing, it is best to planish but slightly, that the coppers may be left in a state of comparative softness.

For time-pieces, table clocks, and some others, *round* plates are commonly used, and in these cases it is necessary to have moveable brass dies formed into the curves required. Round plates are those which have a considerable rise in the centre, made by a pretty quick forcing up of the copper into a sort of shoulder about where the circles of the hours come, and afterwards continuing the rise more gradually. The bent spatula and the scratch brush are chiefly employed to set the coppers into these curves, and where the rise is very quick from the edge, the copper is sometimes turned up as in small dials, that the enamel may be the better retained in its place.

The quantity of enamel wanting for clock dials renders the grinding it a very laborious and tedious operation; especially as the hard kind only can be used with complete certainty. It is true that plates of from ten to twelve inches diameter have been made with glass enamel, where particular attention has been given to the *annealing up*, and to the *cooling down*, (phrases that will be presently explained,) and where the backing has been of a quality perfectly agreeing with the nature of the glass. Of the experiments made in this way, however, the success has not always been proportionate to the loss, and the few enamellers who have clock-furnaces cannot always be induced to repeat them.

The enamel for clock dials is broken down in a steel mortar, and afterwards cleansed and ground in an agate mortar, in a similar way to that prepared for watch plates. Sometimes, where the enamel is of a good quality, the *washings* are made use of for backing, and no bad consequence results, but this requires considerable care in the laying on as well as in properly drying, in order to prevent the surface of the back from rising in blisters, either entirely or partially. Washings is the name given to the almost impalpable powder which arises in grinding, and floats in the water, intermixed with the dust and minute hairs which are sure to fall into the mortar, and which renders it necessary that the enamel should be several times washed during the process by pouring off the buoyant matter from time to time, and introducing fresh water, from the tea-pot. Pure spring water ought always to be used, and a large bason provided for the reception of the washings.

In the best and largest kinds of work, the washings ought never to be used, as their great propensity to blister can hardly be counteracted; and when the blistering is considerable, the plates will assuredly *cockle*, or get out of shape. The peculiar fineness of the washings, also, occasions it to be very difficult to lay on as backing in an even manner. Where the enamel in substance only is used, the success of the work is rendered more certain; the additional expence therefore is fully balanced by the greater security.

The general way of putting on the enamel is to lay the copper upon a cloth, twice doubled, and placed upon a die or piece of board, for the conveniency of turning. The backing is then spread carefully over it by means of a small ivory or bone spoon, and when the whole surface is covered, the water is partially dried off by another cloth, and the enamel laid even by a large spatula, (see Spatula,) finely polished. These operations are repeated till the back surface is sufficiently evened and dry; when the copper is turned, and the first coat laid on and evened in a similar manner. The work is then placed upon a planch for firing, and is next put into the annealing places in the upper part of the furnace, (see Furnace *for Clock-Dials*,) where the humidity is gradually evaporated as the fire draws up. The planches are from a quarter of an inch to three quarters in thickness, in proportion to the size, and are either made of fine free-stone, or of a composition of Stourbridge clay, pipe clay, and *old stuff*, as the broken muffles, planches, &c. are called, pounded together in an iron mortar, and passed through a coarse sieve. The face of each planch is either flat or rubbed into a similar curve to that given to the coppers, and before the work is put on to it, a slight covering of whiting, dried, is sifted over it, through a small brass-wired sieve: this is done to prevent the enamel from sticking to the planch when in the act of fusion.

The muffle is *got up* or rendered hot with sea-coal, and when sufficiently vivid, which is known by its near approach to a white heat, the first coats are taken from the annealing holes by means of iron prongs, which are slid beneath the planches by a steady and careful motion, lest the enamel should be shook whilst in powder; to prevent this, also, a farther provision is frequently made by means of *irons*, as they are called in the business, which are placed below the planches, and having a round form, and a convex bottom, are extremely useful in moving the work, by admitting the prongs to be readily passed below them. The irons are adapted to the size of the planches, and are formed out of thin iron plates, and are cut into a circular shape; some portions of the metal, to render the irons less weighty, being wholly removed from between the rim and the centre, which from this circumstance appear to be connected by cross bars.

When the first coats are properly fired, which can only be determined from practice, they are replaced in the annealing holes, and there left for some hours to cool down, all the fire having been first raked out from the furnace. The operation of cooling down must be effected in a very gradual manner, for were it done too quickly, the plates would crack in different places, through the action of the metal upon the enamel. The particular cause of this cracking seems to arise from the surface of the enamel being too suddenly fixed by the cold air, to admit of that gradual adjustment to the contraction of the metal, which the latter, by retaining the heat longer than the enamel, renders necessary. On a similar principle, the annealing up of the second coats must be equally progressive; for should they be too fuddenly put into the fire, the metal, by expanding with the heat before the fufion of the enamel has commenced, would caufe the enamel to fly through its brittlenefs, and the furface would be thereby ftreaked with cracks.

The enamel for fecond coats, as in watch plates, muft be ground finer than for firft coats, yet not fo fine as for backing. It is laid on with a fpoon, and reduced to a fmooth and equal furface by the fpatula, in the fame manner as above defcribed; and the plate being enamelled with the requifite attention, is fired a fecond time, and gradually cooled down as before. The next operation is polifhing.

Clock plates are polifhed by a fomewhat different procefs than watch dials. When perfectly cold they are taken off the planches, and either carefully fixed upon a bed of wet fand, fo that not any hollow or vacancy is left below the plate, or imbedded in a fimilar way with fand upon wet flannel, twice or thrice doubled. When thus prepared, the furface is gradually worn even by means of fine filver fand, paffed through a fieve, that the coarfer particles may be prevented from fcratching the enamel, and polifhing-ftones formed of flint pebbles, ground at one end to a regular furface. The fand is ufed with water, and the operation is performed by giving the polifhing-ftone a quick circular direction in progreffive movements over every part of the plate, till the furface is evenly reduced, which is known by the gloffynefs being wholly worn off: this occupies from half an hour to an hour, or more, according to the fize and previous evennefs of the plate. Sometimes the polifhing is accelerated by ufing pieces of lead or iron, as half-pound weights, for inftance, in the early ftage of the procefs, and afterwards finifhing with the flint; and that not only to give a fmooth furface to the enamel, but likewife to remove the general ftain or blacknefs which proceeds from the ufe of the lead or iron. When the polifhing is completed, the plates are well wafhed and brufhed, and afterwards made perfectly clean by fome fine enamel being ground over the face of each with a fmall mull or polifhing-ftone for about a quarter or half a minute; the operation being repeated twice or thrice, as may be neceffary, and the loofe enamel being carefully wiped off with a fmooth cloth or napkin, after the laft cleanfing, inftead of being wafhed away: this is done in order that the fmall pores which are fometimes laid open by polifhing into the fubftance of the plate, may be filled up by the minute particles of enamel that efcape the action of the cloth, but would be removed by the water. Whatever fpecks or blifters may be in the plate, are then opened with the diamond, and the holes neatly ftopped with finely-ground enamel from a quill-point, as in watch-plates; the *ftoppings up* being fuffered to lie rather higher than the furface, to admit of the reduction in bulk occafioned by the fufion. The plates are now again put into the annealing places upon the planches; and the furnace being properly heated, are fired for the third and laft time, before painting. In this latter firing, great care fhould be taken that the enamel be not over-fired, which would occafion a freckled appearance in the plate, when held againft the light; and if the work is drawn out from the muffle after the fufion has commenced, and again returned to complete it, the air will be found to have given additional richnefs to the gloffynefs of the furface. The precife time required for firing polifhed plates can only be known from practice; thofe on which the fineft polifhing-fand was ufed, and, of courfe, where the fcratches are lefs deep, wanting lefs heat than when the fand has been employed in a rougher ftate. After firing, the finifhed plates are returned to the annealing-holes, and gradually cooled down for painting on. See PAINTING *of Clock and Watch Plates.*

In the making of *fluxed plates* for enamel-paintings, fimilar methods of planifhing are practifed to thofe already detailed; and fimilar or even increafed care muft be taken in deftroying or regulating the fpring of the copper. Fluxed plates are commonly either fquare or oval: in the fquare ones, about an eighth of an inch, or fomewhat more, fhould be cut off each angle of the copper, previous to enamelling, to prevent the danger of breaking them. In preparing them for the flux, every thing is conducted in the fame way as for clock-dials, till they are polifhed off, when, inftead of firing them in their polifhed ftate, the flux is laid on as a third coat. In grinding the flux, very particular attention muft be given to keep it free from dirt; and the grinding muft be continued till the flux becomes extremely fine, as it will not otherwife flow to an even furface, when expofed to the fire, without a more intenfe heat than the fubftance will well bear. The flux indeed requires a peculiar delicacy of treatment, and the firing of the fluxed plates muft be managed with great caution and nicety. The heat which they require in fufion is much ftronger than that for enamels only; but the exact point of time for withdrawing them from the furnace muft be dexteroufly feized, left the flux fhould fall into freckles. It is not cuftomary to polifh off the flux, as by fo doing it would be deprived of fome portion of its brilliant richnefs; yet that perhaps would be in fome meafure compenfated for, by the fuperior evennefs that would be attained. Fluxed plates muft be cooled down with great care, as the brittlenefs of the upper coating renders them more liable to crack when too fuddenly made cool. In fluxing, hard enamel muft always be ufed; as the flux will not agree with glafs enamel, but cracks in circles as it grows cold. See FLUX.

The greater ductility of gold, and its fuperior mellownefs of colour, render it by far the beft metal that could be employed for the bafis of fluxed plates; though, on account of the expence, it is feldom ufed. For naked figures, portraits, or other fubjects, where much flefh is exhibited, gold plates ought to be exclufively employed, as their rich hue would fave confiderable labour in the painting.

Till the prefent age, fluxed plates were feldom made of a larger fize than four or five inches; but fince the art of enamel-painting has been carried to fuch great perfection by Mr. Bone, enamel-painter to the king and the prince of Wales, they have been progreffively increafed in extent for his ufe, and are now made of every fize up to twelve and fourteen inches. The largeft ever completed meafures eighteen inches by fixteen and a half; and Mr. Bone is now employed in painting it from Titian's famous picture of Bacchus and Ariadne, in the collection of lord Kinnaird. See PAINTING *on Enamel.*

In chufing enamels for ufe, great experience is neceffary: indeed the moft expert practitioner may be deceived, unlefs he make the requifite trials by aid of the furnace. Some enamels can only be employed alone; others may be ufed for the upper coats, but require a ftronger kind for the backs; and fome can be ufed only for backing. Should a new fort be proffered for ufe, experiment alone is the criterion by which its qualities can be determined. In a fimilar manner, fome fluxes will only agree with particular enamels; others muft be ufed feparately; and others again muft be mixed in grinding, before they can be employed with certainty.

In every branch of enamelling, it is effential that the copper, or other metal employed to enamel on, fhould be of a proper thicknefs. Should the metal be too thick, the plates will always crack, either in their fecond coats, or in their polifhed ftate; and fhould it be too thin, they would be be extremely likely to warp from the too powerful action of the enamel. The due medium can only be afcertained by practice; for even the different kinds of enamel will require a difference in the thicknefs of the metal.

The proper management of the fire, and the mode by which the muffle is heated, will be explained under the words FURNACE and MUFFLE; it need only be ftated here, that the time neceffary to *get up* a clock furnace varies from about an hour and a half to two and three hours, or more, according to the intenfity of the draught, the method of ftoking, and the quality of the fuel. The work is turned in the muffle by means of fpring tongs, fo that each part may have a regular and due heat; and it is returned into the annealing places with the prongs. Should many plates be fired at one time, the labour will be found to be very fevere, and the heat too powerful; as it carries a flux of blood to the head, and occafions languor and oppreffion throughout the whole frame.

ENAMELLING *Flux.* See FLUX.

ENAMELLING *Furnace.* See FURNACE.

ENAMELLING, *Imitative.* See JAPANNING.

ENAMELLING *Muffle.* See MUFFLE.

ENAMELLING *Spatula.* See SPATULA.

ENARA, in *Geography*, the chief lake of Lapland, in the northern extremity, about 70 Britifh miles in length by 30 at its greateft breadth.

ENAREA, a province of Abyffinia, conquered by the troops of the Negus, at the beginning of the 17th century, fituated at the S.W. extremity of the empire.

ENARGEA, in *Botany*, from εναργης, *confpicuous*, or *diftinguifhed*, alluding doubtlefs to the ftriking and elegant appearance of the plant, fo little to be expected in the dreary country about the Straits of Magellan, of which it is a native. Banks in Gærtn. v. 1. 283. t. 59. f. 3. Schreb. 232. Willd. Sp. Pl. v. 2. 230. Mart. Mill. Dict. v. 2. (Callixine; Juff. 41. Lamarck t. 248. f. 2: alfo, Philefia; Juff. 41. Lamarck t. 248. f. 3. Willd. Sp. Pl. v. 2. 231.) Clafs and order, *Hexandria Monogynia.* Nat. Ord. *Sarmentaceæ*, Linn. *Afparagi*, Juff.

Gen. Ch. *Cal.* none. *Cor.* Petals fix, erect, elliptic-oblong, acute, inferior; three of them exterior; three interior, larger. *Stam.* Filaments fix, fhorter than the corolla, equal, awl-fhaped, dilated at the bafe, flightly attached to the bottom of each petal; anthers oblong, verfatile, incumbent. *Pift.* Germen fuperior, globofe; ftyle the length of the ftamens, erect, fwelling, and triangular upwards; ftigma in three obtufe lobes. *Peric.* Berry globofe, of three cells. *Seeds* angular, three or more in each cell.

Eff. Ch. Calyx none. Petals fix, erect; three of them internal. Stigma three-lobed. Berry fuperior, with three cells and many feeds.

1. E. *marginata.* Gærtn. as above. Willd. Sp. Pl. v. 2. 230. Petals nearly equal. Leaves with many ribs.—Our fpecimens of this pretty little plant were, fome of them, gathered by Commerfon in the ftraits of Magellan, and communicated by the celebrated M. de Juffieu; others by Mr. Archibald Menzies in Staten land near Cape Horn, in Feb. 1787, all of them in bloffom. Lamarck's figure is a tolerable reprefentation of the whole plant, except the ftigma, which he erroneoufly draws fimple and entire. His fruit is copied from Gærtner.—The *roots* are creeping, and throw out clufters of branched fibres. *Stems* a fpan high, erect, branched, angular, deftitute of pubefcence, as is the whole herb; branches zig-zag, leafy, fheathed at their bafe. *Leaves* alternate, nearly feffile, upright, about half an inch or more in length, elliptical, acute, entire, fomewhat revolute, their edges rough with minute fpines; their underfide marked with three or five ftrong prominent ribs; the upper even. *Flowers* terminal, folitary, drooping, on fhort fimple ftalks. *Petals* white, ribbed; the three outermoft elliptical; the reft rather broader and obovate; each of the fix is faid by Gærtner to be marked with two green fpots below the middle. Commerfon defcribes three of them only as having a pair of obfolete glands at their bafe. *Berry* the fize of a pea.

2. E. *buxifolia.* (Philefia buxifolia; Willd. Sp. Pl. v. 2. 231.) Inner petals thrice as large as the outer. Leaves with numerous tranfverfe veins.—Commerfon alone feems to have found this fine fpecies, in the ftraits of Magellan. Lamarck's plate, drawn from one of his dried fpecimens, is a very juft reprefentation. We have received feveral of thefe from Thouin and Juffieu. The *fhrub* is two or three feet high, with the afpect of box, much branched and fmooth. *Leaves* ftalked, an inch long, elliptic-oblong, pointed, revolute; green, fmooth, with a longitudinal furrow above; glaucous, with a central prominent rib, a marginal one at each edge, and numerous tranfverfe veins, beneath: their edges are rough with minute teeth near the point. *Flowers* terminal (not axillary), large and very handfome, apparently reddifh; their three outer petals elliptical, flat, about half an inch long; the three inner obovate, thrice as long; all veiny. We prefume to unite thefe two plants under one genus, the differences defcribed in their ftigmas having no foundation in truth, and there being a fufficient difference between the outer and inner petals of the firft, to fhew that a more ftriking difference of the fame kind in the fecond can only make a fpecific, not a generic, diftinction. S.

ENARGIA, Εναργεια, in *Rhetoric*, a figure, which paffing from the narrative ftyle, points out, and as it were, fets the fubject before the eyes of the audience. Voff. Rhet. lib. iii. p. 361.

ENARTHROSIS, in *Anatomy*, is that kind of joint, in which a rounded head of one bone is received into a cup-like hollow of another. See DIARTHROSIS.

ENBAR, in *Geography*, a town of Afiatic Turkey, in the Arabian Irak, on the Euphrates; 40 miles weft of Bagdad.

ENBORNE, a parifh in the hundred of Kentbury-Eagle, Berkfhire, England, is fituated 59 miles from London, and contains 46 houfes, and 275 inhabitants. A remarkable and well-known cuftom is attached to its manors, that if the widow of a copyholder fhould marry again, or be guilty of incontinency, fhe forfeits her free-bench, or life-intereft in her late hufband's copyhold; which is not recoverable but by her fubmitting to ride into court upon a black ram, repeating fome ludicrous lines, which end with a petition for her hufband's land. The fteward of the manor is then obliged to reinftate her. At every court, the jury ftill prefent this as one of the ancient cuftoms of the place. The penalty has not been literally enforced within the memory of man; but it is faid, that a pecuniary commutation has been received in lieu of it, which may perhaps have been more readily accepted, from the difficulty of procuring a proper animal for the purpofe. Lyfon's Magna Britannia, vol. i.

ENCÆNIA, Εγκαινια, a Greek term, fignifying *reftauration*, or *renovation*, being compounded of the prepofition εν, and καινος, *new.*

ENCÆNIA is more particularly ufed for the name of a feaft celebrated by the Jews on the twenty-fifth of the ninth month, in memory of the dedication, or rather purification of of the temple, by Judas Maccabæus, after its having been polluted and plundered by Antiochus Epiphanes.

The Jews had also two other Encænia, *viz.* the dedication of the temple by Solomon, and that of Zorobabel, after the return from the captivity.

ENCÆNIA is likewise applied in the *Fathers*, and *Church-History*, to the dedication of Christian churches. See DEDICATION.

Our translators of the Bible do not retain the word Encænia, in St. John, x. 22. where mention is made thereof; in lieu of that, they call it "Feast of the Dedication," which is less proper. In effect, it is not the feast of the dedication, but of the purification or re-consecration of the temple profaned, that is there spoken of.

St. Augustine assures us, that in his time the use of the word Encænia was even transferred to profane matters; and that they called it *Encæniare*, when they put on a new suit of clothes.

ENCALYPTA, in *Botany*, from εν, and καλυπτος, *covered* or *veiled*, alluding to the extraordinary size of the calyptra or veil, which is a characteristic mark of the genus. Extinguisher-moss; Schreb. 759. Hedw. Sp. Musc. 60. Sm. Fl. Brit. 1180. Turn. 17. (Leersia; Hedw. Fund. v. 2. 88. Bryum; Linn. Gen. 564. Juss. 11. Hudf. 474. Dill. 338.) Class and order, *Cryptogamia Musci*. Nat. Ord.. *Musci*.

Gen. Ch. Male, *Flowers* axillary, composed of imbricated scales. Female on the same plant. *Fl.* terminal, several abortive. *Caps.* stalked, cylindrical, inclining to ovate, erect, regular. *Fringe* simple, of sixteen linear, upright, thin, palish teeth. *Veil* bell-shaped, inflated, membranous, much wider than the capsule, erect, often toothed or fringed at the edge.

Eff. Ch. Capsule cylindrical. Fringe of sixteen linear upright teeth. Veil bell-shaped, inflated, lax.

This is but a small genus, consisting of five species only in Hedwig's Sp. Musc. and of four in the Flora Britannica, to which indeed a new one, E. *alpina*, is added in Engl. Bot. t. 1419. The most common is E. *vulgaris*. "Veil entire and smooth at its margin. Stem nearly simple. Leaves lanceolate." Figured in Engl. Bot. t. 558. (*Bryum extinctorium*); and by Dillenius in his t. 45. f. 8. It occurs not unfrequently on shady banks, and in the crevices of rocks, and is strikingly distinguished by its large and deep veil. E. *streptocarpa*. "Veil contracted and torn at its margin. Stem branched. Leaves oblong. Capsule spirally furrowed." Is the largest and finest species, long much misunderstood by botanists. See its figure in Hedw. Sp. Musc. t. 10. f. 10—15, and Haller's Hist. t. 45. f. 3. Dillenius exhibits the leaves and stem only, t. 43. f. 71.

Mr. Turner, in his Muscologiæ Hibernicæ Spicilegium, suggests an opinion that this genus is not really distinct from *Grimmia*, and we confess that E. *Daviesii*, Engl. Bot. t. 1281, seems not very justly referred to it. It is certain that the fringes of several *Grimmiæ* have the thin pale aspect supposed essential to *Encalypta*, but their veils are truly those of *Grimmia*.

ENCAMPMENT, in *Military Affairs*, implies the position taken for the night, or for any time, of an army, for the purposes of exercise, or for warfare. It is common in all countries for the regular forces to be called out, at stated periods, especially during favourable seasons, from their barracks or quarters, in order to unite for their acting in concert upon a large scale, and for their being reviewed by some superior officer. These camps are usually pitched on certain large commons, whereon evolutions may be conveniently performed by several regiments or brigades, and whose sites are favourable both in regard to salubrity, and the easy supply of water and provisions. When we speak of encampments in a literal sense, we invariably attach thereto the idea of living under canvas; and such is absolutely the case, when troops are called out for the above purposes. But we are not to conclude that in time of war, when on actual service, such takes place on all occasions: far otherwise, for it is a general maxim always to spare the camp equipage, as far as may be practicable; and to keep every thing packed, which is not immediately in requisition: therefore, we usually see regiments, especially of infantry, stationed in towns, with lines of pickets in advance, and along their intervals, when the distances between such towns may not be great, and the enemy not so near at hand as to render such breaks dangerous. Thus, an army of 40,000 men is frequently seen to occupy full 20 miles, or even more, in this manner; the different regiments occupying the several villages along that line, and closing up into more compact arrangement, whenever danger may be apprehended. This manner of disposal not only saves infinite trouble and delay, respecting the camp equipage; but exposes the army less to inclement weather, or to noxious localities; and besides, facilitates its movements very considerably, by allowing the whole to move in separate columns, from one station to another. In this the columns necessarily act nearly parallel, much the same as in the advance of a battalion by the right or left of companies in open column.

Encampments, by which we mean the mode of laying out the camp into streets and divisions, are, with some trifling variation, formed after the same manner in all countries. The general principles are, 1st, That no more ground should be occupied than may be absolutely necessary for the drawing up the troops in order of battle: hence, all additions whatever should be made rather in the depth than in the breadth of the camp. This is done to avoid such breaks as could not fail to weaken the line, and to admit the incursions of the enemy's horse. It is, however, usual to allow the interval of about an eighth of their respective fronts between battalions of infantry, and of 30 or 40 paces between squadrons of cavalry. 2dly, The leaving of passages, or streets, throughout, so that bodies may move from one part to the other without hindrance, and without being compelled to pass along the front of the bells of arms. 3dly, That due precaution should be taken for the prevention of disease, by a judicious arrangement of the regimental and general hospitals, as well as by securing the due facility for the removal of filth, and for abundant ventilation; both which can only be effected by due care founded on the precaution of not allowing the camp to be too crowded, either by its situation, or the number of persons contained therein. It is usual to allow a front of two feet for every file (whether two or three deep) of infantry, and a front of three feet for every file of cavalry: hence camps, wherein the battalions are formed three deep, must have their streets full one-half deeper than where the corps are drawn up only two deep. When the ground may permit, the streets are usually at right angles with the front; each row of tents containing the men of a company, arranged according to their several stations, or numbers, in their companies respectively. Supposing the whole to be standing at the doors of their respective tents, and to be ordered to fall in, they would, by this arrangement, arrive in regular succession, either from right to left, or from left to right, at their several stations. The horses and the tents of a troop of cavalry are arranged in a similar manner. The grenadiers and light infantry are ordinarily encamped in single rows, on the flank; but the battalion companies, in double rows: each two companies thus forming a ſtreet, of which the tent-doors are face to face. This mode certainly looks well, but does not anſwer for all climates. In low latitudes, and in very cold weather, the tent-doors ſhould be pitched from the wind, without regard to appearances. A ſingle row, or one company, occupies nine feet in front; and a double row, or two companies, twenty-one feet; if formed of the old pattern, rectangular tents, which hold only five men each: but if the new bell-tents are uſed, fifteen feet muſt be allowed in front for a ſingle, and thirty feet for a double, row. In the cavalry, a row (or troop) occupies in front as follows:

	Old Tents.		New Tents.
Tent - - - - -	3 yards.	—	5 yards.
From the front pole of the tent to the picket rope -	3 do.	—	3 do.
For the horſe - - - -	6 do.	—	6 do.
For the dung - - - -	2 do.	—	2 do.
Totals - - -	14 yards.		16 yards.

The breadth of a row in front, whether cavalry or infantry, being multiplied by the number of rows, and the product ſubtracted from the whole extent of the front of a battalion of infantry, or of a ſquadron of cavalry, will leave the ſpace for the ſtreets, which are generally divided thus:

For the infantry,	$59\frac{1}{2}$ feet each.
For the cavalry,	30 feet each between the tents.
————	46 feet each between the horſes.

By the foregoing it will be ſeen that the utmoſt order prevails in laying out the tents of the ſoldiery, where the ground will permit. In places abounding with trees, rocks, puddles, &c. it muſt of courſe follow, that the locality of every tent conforms to theſe interruptions: but the main points muſt, nevertheleſs, be ever adverted and conformed to; otherwiſe all thoſe evil conſequences, attendant upon want of management, will inevitably follow. Negligence will admit filth; filth will create diſeaſe; and diſeaſe will produce weakneſs, diſcontent, and deſpair. The following is the diſtribution of the depth of a camp of infantry, or of cavalry, when the ground permits.

Diſtribution of the Depth of a Camp.	Infantry.	Cavalry.
	Yards.	Yards.
From the quarter guard parade to battalion parade - - - - - - - -	62	
From this firſt line of parade to the front of the { ſerjeant's tents / quarter maſter's tents } - - -	16	
N. B. *Theſe tents open to the front.*		
To the firſt picket of horſes - - - - - - - - - - - - -	—	15
Infantry for every tent in depth.		
——, old pattern - 9 feet.		
——, new pattern - 15 feet.		
Cavalry, for every horſe - 3 feet.		
N. B. *The infantry privates' tents open to the ſtreet.*		
The cavalry ditto to their horſes' heads.		
Suppoſe infantry 12 tents deep / ——— cavalry 60 horſes ditto } old pattern - - - - - - - -	36	60
From the laſt tent of infantry, or laſt horſe of cavalry, to the front of the ſubaltern's tent *(openings to the rear)* - - - - - - - - - - -	15	12
To the front line of captains *(openings to the front)* - - - - - - - -	15	15
To the front of the field officers *(open to the front)* - - - - - - - -	10	15
To the colonels - - - - - - - - - - - - - - -	10	10
To the ſtaff officers - - - - - - - - - - - - - -	10	14
To the firſt row of batmens' tents - - - - - - - - - - -	10	
To the firſt row of pickets for bat-horſes - - - - - - - - -	2	
To the ſecond row of ditto - - - - - - - - - - - - -	10	15
To the ſecond row of batmen - - - - - - - - - - -	2	
To the front of the grand ſutlers' tent - - - - - - - - - -	10	
To the centre of the kitchens - - - - - - - - - -	15	20
To the front of the petty ſutlers - - - - - - - - - - -	15	15
To the rear guard *(opens to the rear)* - - - - - - - - - - -	15	15
Total depth required in yards - - - - - - - - - -	253	226

The captains and ſubalterns are pitched in the rear of their reſpective companies; the field officers oppoſite the outſide ſtreets of the battalion; the colonels oppoſite the central, or main, ſtreets; the ſtaff officers next to the main ſtreets; the grand ſutlers in the rear of the colonels; and the petty ſuttlers in the rear of the kitchens.

If the ground on which the camp is to be formed will not, owing to a ſwamp in the rear, admit of each troop, or company, being formed in one row perpendicular to the front; the diſtribution of the front of a battalion, or ſquadron, muſt be more contracted than the above; and be laid down as follows. Find how many perpendicular rows will be required, by dividing the number of men in the battalion or ſquadron, by the number the ground will admit

admit of in one row; then the number of rows being multiplied, by the breadth of one in front, will give that part of the front to be occupied by the rows; and the difference between it and the whole front allowed for the battalion, or fquadron, will be left for the ftreets; which, if the ftreets are to be equal, muft be divided by their number, to find the breadth of each; or is, otherwife, eafily divided into ftreets of unequal breadths.

When two guns are attached to a battalion, they are pofted on the right in the following order; from the right of the battalion to the centre of the firft gun, four yards; from this to the fecond gun, fix yards. The muzzles of the guns in a line with the ferjeants' tents. The fubalterns of artillery, if any, in a line with the fubalterns of infantry; the rear of the gunners' tents in a line with the rear of the battalion tents.

The park of artillery fhould always be placed, if practicable, within a fhort diftance of water carriage, and have the moft ready communication with every part of the line. Its form muft depend on its fituation. Ten feet are ufually allowed in front for one carriage and its interval, and about fifty yards from the hind wheels of the front row to the fore wheels of the fecond: this interval fhould allow fufficient room for putting the horfes to the carriages, and for a free paffage along the line. In parks not on immediate fervice, it is ufual to arrange the guns with their muzzles to the front, but where the guns are likely to be wanted at a fhort notice, appearances muft give way to promptnefs, and the gun-carriages muft be parked with their fhafts to the front, ready to receive the horfes, or other draught animals.

A quarter-guard is placed in front of the park, and the non-commiffioned officers' and gunners' tents on the flanks, at about twenty paces diftant; forty paces to the rear are the fubaltern officers' tents; at ten more the rear of the captains; and ten more to the front of the commanding officers: the mefs-tent is fifteen paces in rear of the line of officers. At a convenient diftance, in the rear of the whole, are the horfes, picketted in one or more lines, with the drivers on their flanks. The horfes are fometimes picketted in lines perpendicular to the front of the park, and on the flanks of the carriages, between the men and the carriages.

An army is fometimes encamped in two, or even in three, or more lines; according to its numbers, and the nature of the ground. The diftance between two lines muft depend entirely on local circumftances, or on the object in view: fometimes they are not more than two hundred yards afunder, and fometimes full five or fix hundred; occafionally they are pitched in reverfe, efpecially when covering a convoy that has taken poft between two hills, or rivers, or woods; in fuch inftances they are "in reverfe," and, in lieu of rear guards, have a central force to act as a referve.

With refpect to the choice of ground for an encampment, it muft be recollected that no pofition is tenable, in a military point of view, which does not ftand exempt from the enfiladeof an enemy. In fact, all commanding grounds ought to be beyond the reach of cannon, fo that the camp fhould not be fubject to moleftation from fuch fituations. Four principal objects demand attention in the choice of a pofition for encampment. 1ft. The advantages of the ground, as arifing naturally, in point of defence. 2d. The accefs to, or the poffeffion of, fupplies for the army. 3d. The particular object to be attained; whether mere fecurity, the covering of any depot, the cutting off of an enemy's refources, the communication with other parts, and efpecially with fhipping. 4th. The means of retreat if too clofely preffed by a fuperior force.

The front of an encampment, or, as already explained, of a pofition, fhould be interfected by rivers, ravines, or broken grounds, or any other obftacles which may prevent the enemy from advancing in order of battle, and oblige him to pafs through defiles: but the front fhould neverthelefs be exempt from fuch obftacles as might debar the army from moving out of its camp, or advancing when neceffary. All obftacles ought to be within reach of the artillery, or the enemy will pafs them unmolefted. In a flat country, where the ground does not afford commanding fituations, a pofition is more or lefs eligible according as it may be covered by obftacles; fuch as very thick woods, in which there are few roads; large rivulets that cannot be croffed but by means of bridges; deep and broken ravines; ground much interfected by ditches and hedges; the poffeffion of mills, churches, convents, and other buildings that are capable of obftinate defence, and are within the encampment. A fituation where the rear is covered by fwamps has certain advantages, but is attended with this danger, that, in cafe of defeat, retreat muft be difficult, if at all practicable. The principal obftacles, if a choice can be made, ought to be thrown upon the flanks, and force the enemy to narrow his front when attacking the encampment; but, if fuch obftacles fhould be of a nature to be eafily poffeffed by him, they will prove peculiarly exceptionable, and ought not to be depended upon, any more than the fupply of water from ponds, wells, or ftreams that lie expofed to his interference. Laftly, the want of wood, or of water, even though provifions fhould be abundant, totally difqualify a pofition; unlefs, indeed, for a very fhort occupancy, and rather as a refting place than an *appui*, or defenfive aid. Thefe deficiencies muft invariably operate, on large armies efpecially, fo as to render fuch fituations untenable, whatever advantages they might offer in regard to natural ftrength, or diftrefs occafioned by their occupancy, to the enemy.

ENCANTHIS, a term in *Surgery*, derived from the Greek ἐν, fignifying *in*, and κανθος, which implies the *angle of the eye*. By a kind of abufe of words, which is too common in every language, the Greek writers have applied the name of "encanthis" to a fmall, roundifh, unequal, more or lefs confiderable, fometimes red, at other times light-coloured tumour, fituated in the caruncula lachrymalis, which every furgeon knows is naturally placed near the angle of the eye.

Profeffor Scarpa, of Pavia, has furpaffed every author, with whom we are acquainted, in the excellent and interefting account which he has given of the difeafe under confideration. To him we feel highly indebted for a great deal of the matter, which we are about to infert. He obferves, that the incipient encanthis is a fmall, foft, reddifh, or fometimes flightly livid, excrefcence, which grows from the caruncula lachrymalis, and alfo from the adjacent femilunar fold of the tunica conjunctiva. In general, the inveterate encanthis is of very confiderable fize, its roots reaching beyond the caruncula lachrymalis and femi-lunar fold of the conjunctiva, and extending along the membranous lining of one, or both eye-lids. In confequence of its being fituated between the internal commiffure of the eye-lids, which it hinders from becoming clofed on the fide next the nofe, it fubjects the patient to a great deal of inconvenience, by keeping up a chronic ophthalmy, obftructing the action of the eye-lids, and, in particular, by rendering the patient incapable of fhutting his eye. Alfo, partly by compreffing the orifices of the puncta lachrymalia, and partly by altering their natural direction, the encanthis becomes an impediment

ment to the free paffage of the tears from the eye into the nofe.

The encanthis, in its early ftate, has ufually a granulated appearance, like a mulberry; or elfe it is compofed of little portions refembling fringe. When the excrefcence has attained a confiderable fize, a certain part of it has a granulated appearance, while the remainder looks like a fmooth, whitifh, or afh-coloured fubftance, ftreaked with varicofe veffels, and fometimes extends fo far over the conjunctiva, covering the fide of the eye-ball next the nofe, that it reaches to the place where the cornea and fclerotica meet. When the encanthis has increafed to this confiderable pitch, it conftantly affects, together with the caruncula lachrymalis and femi-lunar fold of the conjunctiva, the membranous lining of one, or both eye-lids. In this ftate, it may be obferved, that the excrefcence, befides the roots, which it derives from the caruncula lachrymalis, and conjunctiva, has a firm prominent appendage, or elongation, which extends along the inner furface of the upper, or lower eye-lid, in the direction of its edge. In other terms, we may ftate, that the middle portion, or body (as it were) of the encanthis, near the cornea, divides, in the form of a fwallow's tail, into two appendages, or elongations, one of which extends along the infide of the upper eye-lid, covered by the edge of this part, while the other is continued along the inner furface of the lower eye-lid, concealed under its margin, and proceeding in the direction from the internal towards the external canthus of the eye.

Scarpa remarks, that the body of the encanthis, or that middle portion of the excrefcence, which reaches from the caruncula lachrymalis and femi-lunar fold inclufively, over the conjunctiva of the eye-ball, even to the very edge of the cornea, is fometimes as prominent as a common nut or a chefnut. In other inftances, it is of the fame fize, but depreffed and flattened, as it were, in the middle. However, the body of the excrefcence does not now retain the fame granulated appearance which it prefented at an earlier period, while one, or both the appendages, extending along the inner furface of one, or both eye-lids, feem more like a flefhy, than a granulated fubftance.

When the eye-lids are turned out, thefe appendages of the encanthis form a projection forward, and when this is obfervable on both palpebræ, on their being turned out in this manner, the two flefhy appendages make together a kind of ring, which comes into clofe contact with the globe of the eye behind. Scarpa informs us, that Fabricius Hildanus was acquainted with this difeafe, which he fucceeded in curing, and which he named *ficus. fcirrhofus ad majorem oculi canthum*. See Centur. 1. Obf. 2.

However, Scarpa takes notice, with refpect to the cafe recorded by Hildanus, that the encanthis had only one appendage, which was fituated on the inner furface, and below the margin, of the upper eye-lid.

Scarpa, in conformity with moft furgical writers, has very accurately explained, that the encanthis, as well as the pterygium, occafionally puts on a cancerous malignity, which is denoted by the dark-red, or leaden colour of the tumour; by its unufual degree of hardnefs; by its darting pains, which extend to the forehead, and all over the eye and temples, particularly whenever the excrefcence has been even gently touched; by its tendency to bleed; and, laftly, by the ulcerations, which occur in feveral places, emit a fungous growth, and difcharge a thin irritating fanies. Scarpa is of opinion, that this worft form of the encanthis can only receive palliative treatment, unlefs an attempt at extirpation be made, by removing, together with the difeafe, all the parts contained in the orbit, the fuccefs of which operation he alfo reprefents as exceedingly doubtful.

At the fame time, that we profefs the higheft refpect for the fentiments of Scarpa in general, on the fubject of difeafes of the eyes, we cannot filently fubfcribe to his advice, that no endeavour fhould be made to effect a radical cure of any malignant encanthis, without extirpating all the contents of the orbit. If the difeafe were not fo very extenfive, as to prevent the furgeon from making a fair removal of every part of it, without taking away the eye itfelf, what practitioner can doubt, that the latter formidable operation ought to be difpenfed with. It would be full time enough to have recourfe to this fevere ftep, when it had been decidedly evinced, that cutting away the difeafed parts alone was infufficient, and that malignant morbid mifchief ftill prevailed.

Scarpa informs us, that the benign encanthis, whether of fmall, or confiderable fize, may be cured by excifion. The fmall beginning encanthis, whether of a granulated or fringed appearance, and originating from the caruncula lachrymalis and femi-lunar fold, or, alfo, from a fmall portion of the margins of the eye-lids, where they form the internal commiffure, may be raifed with a pair of forceps, and be completely cut away clofely to its bafe with the curved fciffars. In order to accomplifh this operation, it is needlefs to follow the plan, which fome adopt, of introducing a needle and thread through the little excrefcence, with a view of raifing and detaching it more accurately from the parts, to which it is adherent. This object can be fulfilled with the forceps, without annoying the patient by the punctures, and by drawing a thread through the tumour, for the purpofe of making a noofe. However, in taking away fuch portion of the incipient encanthis, as arifes from the caruncula lachrymalis, Scarpa very prudently cautions us againft removing more of the fubftance of that body, than the complete eradication of the difeafe requires, left the lofs of too much fhould occafion an irremediable flux of tears from the eye.

When the little excrefcence has been extirpated, the eye ought to be repeatedly wafhed with cold water to get away the blood, and fhould then be covered with a piece of fine linen and a retentive bandage. About the fifth, fixth, or feventh day, as foon as the inflammation, produced by the operation, has quite fubfided, and fuppuration from the wound has commenced, Scarpa advifes us to touch the cut furface with a fmall button of alum, fcraped into the fhape of a crayon-pencil, and he alfo recommends a collyrium, containing the zincum vitriolatum and mucilage of quince-feeds, to be frequently applied to the eye in the courfe of the day. If this plan of treatment fhould not have the defired effect of making the wound heal; but, on the contrary, if the cut furface of the caruncula lachrymalis and internal angle of the eye fhould, inftead of continuing to heal up, put on a fungous appearance, it fhould be repeatedly touched with the argentum nitratum, care being taken not to apply this cauftic to the conjunctiva, more particularly, if any part of this membrane fhould have been wounded. After the deftruction of the fungous granulations, a collyrium, containing the zincum vitriolatum, will accomplifh the cure, or the practitioner may introduce between the eye-ball and internal commiffure of the eye-lids, three times a day, an ointment compofed of frefh butter, powdered tutty, and armenian bole. Scarpa alfo acquaints us, that Bidloo fpeaks much in favour of ufing for the latter purpofe powdered chalk, either alone, or mixed with calcined alum. See Exercit. Anat. Chir. Decad. 2.

Scarpa informs us, that we may alfo cut away the large inveterate

inveterate encanthis, either with a flat body, or with one, which projects in the ſhape of a common nut, or cheſnut, and having one, or two fleſhy appendages extending along the lining of one or both the eye-lids. In this inſtance, a ligature cannot be properly made uſe of, becauſe the neck of the tumour is never ſmall enough to allow of being advantageouſly tied. On the contrary, the encanthis, when it is very large, is always extenſively connected with the caruncula lachrymalis, and with the conjunctiva, almoſt as far as where the cornea begins, and it has, moreover, one or two fleſhy appendages, which run along the under ſurface of one or both the eye-lids. For this reaſon, even ſhould the middle part of the encanthis be extirpated with a ligature, ſtill one or both the appendages would ſtand in need of removal, which object could only be accompliſhed by exciſion.

The apprehenſion of the bleeding from the latter operation is quite unfounded, as there are numerous caſes on record, where the operator has cut away a large inveterate encanthis, without any ills ariſing from hemorrhage. Scarpa mentions, that he could relate himſelf ſome caſes which he has met with, in confirmation of the truth of the foregoing ſtatement. This candid writer, however, does not diſſemble, that Pellier records an example, in which a troubleſome degree of bleeding followed the exciſion of an encanthis; but, it is juſtly obſerved, that the particulars of the diſeaſe are undeſcribed, as well as the exact way in which the operation was performed. Had theſe circumſtances been detailed, perhaps they would have explained the reaſon of the unuſual occurrence. Indeed, Pellier himſelf has remarked, "j'ai ſouvent fait cette operation a des excroiſſances de cette nature, et jamais je n' ai èprouvé un pareil accident."

In the caſe of the large inveterate encanthis, referred to above, and in which there was only one appendage continued along the inſide of the upper eye-lid, Hildanus, after taking hold of the body of the encanthis with a tentaculum, drawing the tumour towards him, and turning out the upper eye-lid, in order to make the whole of the appendage project forward, detached all this laſt portion from the inſide of the eyelid with a ſmall knife, and afterwards cut away the body of the encanthis from the conjunctiva and caruncula lachrymalis. Scarpa remarks, that as this plan was attended with complete ſucceſs, it ought to be imitated by all practitioners.

However, when the inveterate encanthis, of large ſize, has two appendages, one reaching along the inner ſurface of the upper eye-lid, the other along that of the lower one, Scarpa adviſes the following plan to be adopted. The patient is to be ſeated in a chair, and the upper eye-lid turned out by an aſſiſtant, ſo as to make one of the appendages of the encanthis project forward. This production of the diſeaſe is to be deeply cut into with a ſmall knife, in the direction of the edge of the eye-lid, taken hold of with a pair of forceps, and be completely detached from the inſide of the part, in the longitudinal direction, the diſſection being continued from the external towards the internal angle of the eye, as far as the body of the encanthis. The appendage on the inner ſurface of the lower eye-lid ſhould be ſeparated in the ſame way. Then the middle portion of the encanthis ſhould be lifted up with a pair of forceps, or, (if this cannot be done) with a double hook, and be entirely cut away from the conjunctiva underneath, which covers the eye ball, and from the ſemi-lunar fold, and caruncula lachrymalis. This may be accompliſhed partly by means of a ſmall knife, and partly with the aid of curved ſciſſars. The operator is alſo to cut more or leſs deeply into the caruncula lachrymalis, according as the ſtrength and depth of the roots of the diſeaſe may require; for, it muſt be confeſſed, that, when the encanthis is very large, and of long ſtanding, the ſurgeon cannot always avoid wounding the caruncula lachrymalis ſufficiently to prevent ſome degree of weeping from the eye, after the operation.

The eye ſhould be repeatedly bathed with cold water, and the reſt of the treatment is nearly like that recommended after removing a ſmall incipient encanthis. Scarpa recommends the uſe of collyria of aqua malvæ, and of anodyne and detergent ones, until ſuppuration has fully taken place from the ſurface of the wound. Then mild aſtringents, and the above-mentioned ointment may be uſefully had recourſe to. Scarpa particularly adviſes giving a preference to mild applications, both before and after ſuppuration has taken place, eſpecially when a conſiderable piece of the conjunctiva, covering the white of the eye, has been cut away with the encanthis. See Scarpa Sulle Principali Malattie degli Occhi.

ENCARDION, from καρδια, *heart*, in *Botany*, a name given by the Greeks to what the Latins properly call the mediata in trees, the heart of the wood, or central hard part of it.

ENCATHISMA, from εγκαθημαι, *I ſit in*, in the *Medical Writings of the Ancients*, a term uſed to expreſs a ſort of bath, in which the patient was only to be plunged up to the belly.

ENCAUMA, from εν, and καιω, *to burn*, in *Surgery*, the mark left by a burn; alſo a ſmall abſceſs ariſing from the ſame cauſe. The term is ſometimes applied to a ſuperficial ulceration on the eye.

ENCAUSIS, from εν, and καιω, *to burn*, a burn, or the inflammation produced by this ſort of injury; alſo the operation of external heat on the body, as of the ſun, or fire. In Dr. Cullen's Noſology, the word is ſynonymous with erythema and ambuſtio.

ENCAUSSE, in *Geography*, a ſmall town of France, in the department of the upper Garonne; 12 miles E. of St. Bertrand, remarkable for its ſprings of mineral water.

ENCAUSTIC PAINTING, Εγκαυστικη, from εγκαιω, *inuro*, *I burn in*, is a ſpecies of painting with burnt wax, practiſed by the ancients, and lately revived. Pliny has given the following brief account of the invention and nature of this art: "Ceris pingere ac picturam inurere, quis primus excogitaverit non conſtat; quidam Ariſtidis inventum putant, poſtea conſummatum à Praxitele; ſed aliquanto vetuſtiores encauſticæ picturæ extitere, ut Polygnoti, & Nicanoris, & Arceſilai, Pariorum. Lyſippus quoque, Eginæ picturæ ſuæ inſcripſit ἐνέκαυσεν; quod profecto non feciſſet, niſi encauſtica inventa. Pamphilus quoque Appellis præceptor non pinxiſſe tantùm encauſtica, ſed etiam docuiſſe traditur Pauſiam Sycionium, primum in hoc genere nobilem." Lib. xxxv. cap. 11. From this paragraph we learn, that the method of painting in wax, and burning in the picture, was very ancient; nor is it improbable that in former times, when they were unacquainted with dry oils, and tranſparent varniſhes, they ſhould make uſe of this method for preſerving their colours from damps and heats; though ſome imagine, that by *ceris* is meant a compoſition, different from wax, and capable of bearing the fire; and that burning the picture denotes merely enamelling. Pliny in the ſame chapter informs us, that there were anciently two methods of encauſtic painting in uſe: "Encauſto pingendi duo fuiſſe antiquitùs genera conſtat, cerâ & in ebore, ceſtro, *i. e.* viriculo; donec claſſes pingi cœperè. Hoc tertium acceſſit, reſolutis igni ceris, penicillo utendi; quæ pictura in navibus nec ſole, nec ſale, ventiſque corrumpitur." Dr. Parſons maintains, that the *ceſtrum* was a pointed tool uſed in modelling

delling or carving upon ivory or wax; and he fuppofes that there is a contraft between the ufe of the *ceftrum*, and painting fhips with a brufh, and therefore that the term *pingendi* cannot be underftood to mean the laying on of paint. However, there is a paffage in Vitruvius, lib. vii. cap. 9. which ferves to afcertain the nature of the ancient encauftic painting. "At fi quis fubtilior fuerit, & voluerit expolitionem miniaceam fuum colorem retinere, &c." *i. e.* if any one is more wary, and would have the polifhing, or painting, with vermilion hold its colour, when the wall is painted and dry, let him take Carthaginian wax, melted with a little oil, and rub it on the wall with a hair-pencil; and afterwards let him put live coals into a chafing-difh, and hold it clofe to the wax; when the wall, by being heated, begins to fweat, let it be made fmooth; afterwards let him rub it with wax tapers, and clean linen rags, in the fame manner as they do the naked marble ftatues. This the Greeks call καυσις. The coat of Carthaginian wax is fo ftrong, that it neither fuffers the moon by night, nor the fun-beams by day, to deftroy the colour. From this paffage we learn the ancient method of painting in wax by inuftion, more obfcurely expreffed by Pliny; though Pliny, in another paffage, exprefsly informs us, that they ufed coloured wax: "Ceræ (he fays) tinguntur iifdem his coloribus, quæ inuruntur;" that they employed a pencil to lay on the melted wax; "refolutis igni ceris, penicillo utendi:" that the picture was fixed by inuftion, "picturam inurere." And we learn from Vitruvius, that the whole was cleaned and polifhed with linen rags.

The Punic or Carthaginian wax, the ufe of which is afcribed to the ancient painters by Varro, Vitruvius, and Pliny, was faid to be the beft, as it exceeded in whitenefs the Sardinian and Corfican, probably becaufe it was better purified; for the Africans, as we learn from Pliny, were accuftomed to ufe alkali in order to render this fubftance whiter, and alfo to free it, as fome have fuppofed, from all greafy matter. Wax, however, feems to have formed the only ground of wax-painting. The abbé Requeno, who contributed to prefent to the notice of modern painters wax painting, adds maftic; but Lorgna converts his wax i to foap, as Bachelier does with the alkali of Soda. Aftori adds gum and honey, affirming that thus the wax would be rendered much more yielding and fofter for the brufh. Requeno feems to affign the exclufive poffeffion of this art to the Greeks and Romans; but we have reafon for believing that the knowledge and ufe of encauftic painting were older than their time, becaufe the Egyptians, who with the Etrufcans were the parents of the greater part of the inventions known among mankind, and from whom the Greeks derived much of their knowledge, were acquainted with and employed encauftic painting in the ancient ages of their greatnefs and fplendour. This fact has been deduced from valuable fragments of the bandages and coverings of mummies painted in this manner. A mummy of this kind is mentioned in a treatife entitled "Antichita, &c." referred to at the clofe of this article. No oil-painting, it is faid, perhaps only two or three hundred years old, exhibits a white paint that has kept fo well as that feen on the fragment to which we have alluded; and this circumftance fufficiently proves the valuable advantage which that method poffeffes when compared with the common oil-painting. The wax, inftead of becoming black by the contact of the atmofphere, as drying oil does, acquires increafing whitenefs, and according to its natural quality, is not decompofed in the air, and does not ftrongly attract the oxygen of the calces or metallic afhes, which are commonly ufed in painting. That beautiful white, which may be obferved in the Egyptian encauftic above-mentioned, is, as the author of the treatife juft cited apprehends, nothing elfe but a fimple earth, and according to his chemical experiments a chalk *(creta,)* which is alfo unalterable. If we confider this encauftic fragment, fays our author, as belonging to the epoch of the firft violent change, which the religious fyftem of the Egyptians experienced, it will be a fpecimen of painting about 2500 years old; for fuch is the number of the years that have elapfed fince Cambyfes overturned the ceremonies and religious worfhip of the Egyptians, not only by the fword, but by the ftill more powerful weapons of ridicule. Dead bodies were embalmed there in the time of Herodotus, (fee EMBALMING); but the cloth in which they were wrapped, or the bandages bound round them, were no longer painted with facred characters. The bodies were only inclofed in wooden cafes, which were more or lefs ornamented. If Bochart and Menage be not miftaken, the name "mummia" is derived from "muim," which fignifies wax; and one might therefore believe, that the drefs of embalmed bodies was thus named becaufe wax was employed for painting it; and thence it would follow, that the fragment in queftion may be claffed among the oldeft. Petronius praifes the frefh appearance which the valuable works of Zeuxis and Apelles had, even in his time; but Cicero, on the other hand, fpeaks of the paintings of the ancients having fuffered from blacknefs. The former is fuppofed to have fpoken of wax-painting, and the latter is prefumed to have alluded to paintings in oil. The author, whofe fentiments we are now expreffing, detached 24 grains of the encauftic painting from the above-mentioned Egyptian fragment; and in his mode of examining it, the mixture of 100th part of a foreign fubftance would have been difcovered with the greateft certainty: he muft, he fays, have perceived the refin of Requeno, nor could the alkali of Bachelier and Lorgna have efcaped his notice. But in this Egyptian encauftic he found nothing except very pure wax, though he varied his analyfis in every known method.

From the words of Vitruvius above cited it appears, that the Romans, who copied the Grecian procefs, which was borrowed from the Egyptians, mixed the wax with an oil to make it pliable under the brufh, but no maftic, alkali, or honey, as fome have imagined, was employed; what this oil was it is not eafy to afcertain. It does not appear that they ufed thofe fat oils, which are commonly called drying oils, becaufe they could have employed thofe as we do, without the addition of wax, which would have been altogether fuperfluous. Fat oils, which do not dry, would not have been proper for that purpofe, as they would have kept the wax continually in a foft ftate. Our author fuppofes, that the Egyptians, in order to ufe wax in their encauftic painting, muft have combined it with an ethereal volatile oil, of which no traces fhould afterwards remain, and that though they might be unacquainted with the art of feparating ethereal oils from the many fubftances which they contain, they certainly were acquainted with a very volatile thin oil produced by nature, and which in various places iffues from the earth. This oil was either that called naphtha, which is an exceedingly volatile oil, that entirely flies off and evaporates, without leaving a fingle trace behind; or the common fpirit of turpentine, which would very well anfwer the purpofe. The encauftum, thus formed, was ufed in the time of the Romans to cover parts, which had been already painted either with water-colours or in frefco; and it was alfo, as we have reafon to believe, the fubftance with which Apelles daubed over his paintings, and which, according to Pliny, made them appear as if covered by a thin plate of talc or tranfparent felenite, and gave the colours a wonderful foftnefs.

nefs. It might ftill be employed for preferving paintings in water-colours, or on plafter, and fculptured pieces of marble.

The ancient art of encauftic painting, after having been long loft, was reftored by count Caylus, a member of the Academy of Infcriptions in France; and the method of painting in wax was announced to the Academy of Painting and Belles Lettres, in the year 1753; though M. Bachelier, the author of a treatife "De l'Hiftoire & du Secret de la Peinture en Cire," had actually painted a picture in wax in 1749; and he was the firft who communicated to the public the method of performing the operation of inuftion, which is the principal characteriftic of the encauftic painting. The count kept his method a fecret for fome time, contenting himfelf with exhibiting a picture at the Louvre in 1754, reprefenting the head of Minerva, painted in the manner of the ancients, which excited the curiofity of the public, and was very much admired. In the interval of fufpence, feveral attempts were made to recover the ancient method of painting. The firft fcheme adopted was that of melting wax and oil of turpentine together, and ufing this compofition as a vehicle for mixing and laying on the colours. But this method did not explain Pliny's meaning, as the wax is not burnt in this way of managing it. In another attempt, which was much more agreeable to the hiftorian's defcription of encauftic painting, the wax was melted with ftrong lixivium of falt of tartar, and with this the colours were ground. When the picture was finifhed, it was gradually prefented to the fire, fo as to melt the wax; which was thus diffufed through all the particles of the colours, fo that they were fixed to the ground, and fecured from the accefs of air or moifture. But the method of count Caylus is much more fimple: the cloth, or wood which he defigned for the bafis of his picture, is waxed over, by only rubbing it fimply with a piece of bees' wax; the wood, or cloth, ftretched on a frame, being held horizontally over, or perpendicularly before a fire, at fuch a diftance, that the wax might gradually melt, whilft it is rubbed on, diffufe itfelf, penetrate the body, and fill the interftices of the texture of the cloth, which, when cool, is fit to paint upon; but as water-colours, or thofe that are mixed up with common water, will not adhere to the wax, the whole picture is to be firft rubbed over with Spanifh chalk or white, and then the colours are applied to it; when the picture is dry, it is put near the fire, whereby the wax melts, and abforbs all the colours.

Mr. J. H. Muntz, in a treatife on this fubject, has propofed feveral improvements in the art of encauftic painting. When the painting is on cloth, he directs it to be prepared by ftretching it on a frame, and rubbing one fide feveral times over with a piece of bees'-wax, or virgin's-wax, till it is covered with a coat of wax of confiderable thicknefs. In fine linen, this is the only operation neceffary previous to painting; but coarfe cloth muft be rubbed gently on the unwaxed fide with a pumice ftone, to take off all thofe knots, which would prevent the free and accurate working of the pencil. Then the fubject is to be painted on the unwaxed fide with colours prepared, and tempered with water; and when the picture is finifhed, it muft be brought near the fire, that the wax may melt and fix the colours. This method, however, can only be applied to cloth or paper, through the fubftance of which the wax may pafs; but in wood, ftone, metals, or plafter, the former method of count Caylus muft be obferved.

Mr. Muntz has alfo difcovered a method of forming grounds for painting with crayons, and fixing thefe, as well as water colours, employed with the pencil. On the unwaxed fide of a linen cloth, ftretched and waxed as before, lay an even and thick coat of the colour proper for the ground: having prepared this colour, by mixing fome proper pigment with an equal quantity of chalk, and tempering them with water. When the colour is dry, bring the picture to the fire that the wax may melt, pafs through the cloth, and fix the ground. An additional quantity of wax may be applied to the back of the picture, if that which was firft rubbed on fhould not be fufficient for the body of colour; but as this muft be laid on without heat, the wax fhould be diffolved in oil of turpentine, and applied with a brufh, and the canvas be again expofed to the fire, that the frefh fupply of wax may pafs through the cloth, and be abforbed by the colour; and thus a firm and good body will be formed for working on with the crayons. If cloth and paper are joined together, the cloth muft be firft fixed to the ftraining frame; and then the paper muft be pafted to it with a compofition of pafte made with wheaten flour, or ftarch and water, and about a twelfth part of its weight of common turpentine. The turpentine muft be added to the pafte when it is almoft fufficiently boiled, and the compofition well ftirred, and left to fimmer over the fire for five or fix minutes; let wax be diffolved in oil of turpentine to the confiftence of a thin pafte; and when the cloth and paper are dry, let them be held near a fire; and with a brufh lay a coat of the wax and turpentine on both fides the joined cloth and paper, in fuch a degree of thicknefs, that both furfaces may fhine throughout without any appearance of dull fpots. Then expofe the cloth to the fire or to the fun; by which means the oil will evaporate, and the wax become folid, and be fit to receive any compofition of colour for a ground, which is to be laid on as above directed in the cafe of cloth without paper.

Almoft all the colours that are ufed in oil-painting may be alfo applied in the encauftic method. Mr. Muntz objects, indeed, to brown, light pink, and unburnt *terra di Sienna*; becaufe thefe, on account of their gummy or ftony texture, will not admit fuch a cohefion with the wax as will properly fix them; but other colours, which cannot be admitted in oil-painting, as red-lead, red orpiment, cryftals of verdegris, and red precipitate of mercury, may be ufed here. The crayons ufed in encauftic painting are the fame with thofe ufed in the common way of crayon painting, excepting thofe that in their compofitions are too tenacious; and the method of ufing them is the fame in both cafes.

The encauftic painting has many peculiar advantages; though the colours have not the natural varnifh or fhining which they acquire with oil, they have all the ftrength of paintings in oil, and all the airinefs of water-colours, without partaking of the apparent character or defects of either; they may be looked at in any light and in any fituation without any falfe glare; the colours are firm, and will bear wafhing; and a picture, after having been fmoaked, and then expofed to the dew, becomes as clean as if it had been but juft painted. It may alfo be re-touched at pleafure, without any detriment to the colours; for the new colours will unite with the old ones, without fpots, as is the cafe in common fize painting; nor is it neceffary to rub the places to be retouched with oil, as in oil pictures; it is not liable to crack, and eafily repaired, if it fhould chance to fuffer any injury. The duration of this painting is alfo a very material advantage; the colours are not liable to fade and change; no damp can affect them, nor any corrofive fubftance injure them; nor can the colour fall off in fhivers from the canvas. However, notwithftanding all thefe and other advantages enumerated by the abbé Mazeas, and Mr. Muntz, this art has not yet been much practifed. Many of thefe properties belong to a much higher ſpecies of encauſtic painting lately diſcovered in England, the colours of which are fixed by a very intenſe heat; nor are the colours, or grounds, on which they are laid, liable to be diſſolved or corroded by any chemical menſtruum, nor, like the glaſſy colours of enamel, to run out of the drawing on the fire. See on this ſubject, Phil. Tranſ. vol. xlix. art. 100. p. 652. art. 101. p. 655. Id. vol. li. art. 8. p. 40. art. 9. p. 53. Muntz's Encauſtic Eloge of Count Caylus, in the Hiſt. de l'Acad. Roy. des Inſcript. & Belles Lettres, vol. xxxiv. Antichita, Vantaggi e Metodo della Pittura Encauſta; Memoria del Ch. Sig. Giov. Fabbroni, &c. Roma, 1797, 4to. Handmaid to the Arts, &c. vol. i. ch. ix. p. 245. 26'.

ENCAUSTICE has been ſometimes uſed to denote the art of *enamelling*, which ſee.

ENCAUSTUM CÆRULEUM, is a name given to powder blue.

ENCAUSTUM *ſacrum*, a name given, by many authors, to that fine red colour uſed for illuminating the capital letters in ſome old manuſcripts. Procopius calls it *baphe*, ſome have called it coccus, and ſome cinnabar. It is ſaid that it was made of the purple colour, extracted from the murex, or purple fiſh, with ſome other additions. It is to be obſerved, that however well this colour, when laid on the parchment, or paper, might reſemble the colours of enamel, yet it was as improper to call it encauſtum, which ſignifies a "colour burnt in," as in enamelling it would have been to have called it atramentum, or ink.

ENCEADA DA BELA, in *Geography*, a town of Africa, in the kingdom of Adel, on the coaſt of the Indian ſea; 30 miles S. of cape Guardafu.

ENCEINTE, Fr. from *enceindre, to ſurround*, in *Fortification*, the wall or rampart which ſurrounds a place, ſometimes compoſed of baſtions and curtains either faced or lined with brick or ſtone, or only made of earth.

The enceinte is ſometimes only flanked by round or ſquare towers, which is called a Roman wall.

ENCELIA, in *Botany*, Juſſ. 186. Cavanilles Ic. v. 1. 44, t. 61, and v. 3. 6. t. 210, ſee PALLASIA.

ENCEPHALI, in *Medicine*, a term employed by ſome writers to ſignify certain worms, ſaid to be generated in the head.

ENCEPHALITES LAPIS, in *Natural Hiſtory*, the name given, by authors, to a ſort of coarſe ſtone, ſuppoſed, in ſome degree, to reſemble the human brain. We have, in the foſſile world, many ſtones, named from the parts of animals, which they have, in reality, been formed from, or owed their original to; and theſe are properly enough called by names denoting the things whoſe forms they wear; but it is a very wrong practice, from ſome ſlight external reſemblances, to give ſuch names to things that never can have been ſuppoſed to be ſo entitled to them. No one can be ſo abſurd as to imagine a human brain can be petrified, though a ſtone may accidentally ſomewhat reſemble its form. The perſon poſſeſſed of ſuch an accidental ſpecimen, ſhould have ranked it among the ſtones to which it properly belonged as a ſtone, whether a flint, a pebble, or a nodule, and have named, as an accident only, this form of it; and not have given it a peculiar denomination, as if it were a new ſpecies.

ENCEPHALOCELE, from εγκεφαλος, *the brain*, and κηλη, *a tumour*, in *Surgery*, a hernia of the brain. See FUNGUS.

ENCEPHALON, from εν, *in*, and κεφαλη, *the head*, in *Anatomy*, ſhould ſignify, according to its etymology, all the parts contained in the head; but it is commonly applied to the brain, as conſiſting of cerebrum, cerebellum, and medulla oblongata, excluſive of the ſurrounding and containing membranes. Hence, Soemmerring's tabula baſeos encephali is a repreſentation of the baſis of the brain. See BRAIN.

ENCEPPE, in *Heraldry*, denotes chained, or girt round the middle; as is uſual with monkeys, &c.

ENCERIS, in *Pharmacy*, a word uſed by Galen to ſignify ſmall concretions of wax, which formed themſelves in melted plaſters, of which wax was one of the ingredients. As they cooled, the wax cooling firſt, and collecting itſelf into little grumes, ſpoiled the conſiſtence and form of the whole compoſition.

ENCHANTMENT, of *in*, and *canto*, I ſing, denotes certain words and ceremonies uſed by magicians in the practice of their pretended and deluding art; thus called, becauſe the formulæ of their enchantment were generally compoſed in verſe, and deſigned to be ſung. See CHARM, FASCINATION, MAGIC, SORCERY, and WITCHCRAFT.

ENCHARAXIS, from εν, and χαρασσω, *to ſcarify*, in *Surgery*, a ſcarification.

ENCHASING, INCHASING, or CHASING, the art of enriching and beautifying gold, ſilver, and other metalworks, by ſome deſign or figures repreſented thereon, in low relievo. See SCULPTURE, RELIEVO, &c.

Chaſing is only practiſed on hollow, thin works; as watch caſes, cane-heads, tweezer-caſes, or the like. It is performed by punching or driving out the metal to form the figures from within ſide, ſo as to ſtand out prominent from the plane or ſurface of the metal.

In order to this, they have a great number of fine ſteel blocks, or puncheons, of divers ſizes; and the deſign being drawn on the ſurface of the metal, they apply the inſide upon the heads or tips of theſe blocks, directly under the lines or parts of the figures. Then, with a fine hammer, ſtriking on the metal ſuſtained by the block, the metal yields, and the block makes an indenture or cavity on the inſide; correſpondent to which, there is a prominence on the outſide, which is to ſtand for part of the figure.

Thus the workman proceeds to chaſe and finiſh all the parts, by ſucceſſive applications of the block and hammer to the ſeveral parts of the deſign.

And it is ſurpriſing, with what beauty and juſtneſs, by this ſimple piece of mechaniſm, the artiſts in this kind will repreſent foliages, groteſques, animals, hiſtories, &c.

ENCHEIRESIS, Εγχειρησις, from εν, *in*, and χειρ, *a hand*, in *Anatomy*, denotes manual operation; as diſſection.

ENCHELIS, in *Zoology*, a genus of *Vermes Infuſoria*, deſcribed eſſentially as being inviſible to the naked eye, very ſimple, and cylindrical. Nearly all the ſpecies are found in ſtagnant water.

Species.

PYRUM. Inverſely conic, behind tranſparent. Müll.

Common in ſtagnant waters, where the duck-weed grows. Body obtuſe, and filled with molecules; and when at reſt, appears to have a ſmall tubercle in the middle of the body. This kind is remarkable for the rapidity of its motion.

SPATHULA. Cylindrical, ſtriated, with a tranſparent ſpatulate tip. Müll.

Leſs frequent than the laſt, and found in waters in which the duck-weed is infuſed. The body is cryſtalline, and the creature moves in an undulate manner.

PAPULA. Cylindrical, with the tip papillary. Müll.

Found in the water of dunghills. The body is round, protuberant, opake before, and furniſhed with a papillary finger-ſhaped head; pellucid behind, and both ends obtuſe. Its motion is rotatory and oblique.

Fritillus. Cylindrical, truncated anteriorly. Müll. Hermann.

Met with in water in which grafs or hay is infufed. The body is pellucid, convex, and obtufe behind; moves backwards and forwards with a wavering agitation in a line.

Ovulum. Cylindrical-ovate, and hyaline. Müll.

Found in the water of dunghills. Very minute and pellucid.

Fusus. Cylindrical, narrow, and truncated at both ends. Müll.

Obferved only in pure water.

Epistomium. Elongated, cylindrical, with a flender fub-globular tip. Müll.

Inhabits putrid water. The body is round, obtufe behind, and its fize minute.

Seminulum. Cylindrical and equal. Müll.

In water kept fome days. The body twice the length of its breadth, pellucid before, and opake behind. Moves by alternately afcending and defcending.

Nebulosa. Oval-cylindrical, with vifible moveable inteftines. Müll.

Found in waters with cyclidium glaucoma.

Farcimen. Cylindrical, curved, and truncated at both ends. Joblot.

In water kept a few days. Body opake, and in its motion often appears in the fhape of the letter S.

Viridis. Green, fub-cylindrical, and obliquely truncated before.

Abundant in water kept fome weeks. Tail obtufe, inteftines obfcure.

ENCHELUS, Εγχελυς, in *Ichthyology*, the name given by Ariftotle, Appian, and all the Greek writers, to the eel.

ENCHESON, a French word ufed in our *Law-Books* and *Statutes*, fignifying the occafion, caufe, or reafon, wherefore any thing is done. Stat. 5 Edw. III. cap. 3.

ENCHRI'STA, from εγχριω, *to anoint*, in *Surgery*, liniments with which parts are anointed.

ENCHYMA, of εγχυω, *I pour in*, in the *Medical Writings of the Ancients*, a word ufed in feveral fenfes. Some have made it exprefs only an *infufion;* others have ufed it for what the modern phyficians call *plethora ad vafa*, that is, a fulnefs of the veffels, fimply confidered, as a relative to themfelves; and others have made it the name of certain forms of liquid medicines, to be injected into the ears, into the thorax, or any other part.

ENCHYMOMA, of εγχυμος, from εγχυω, in the *Writings of the Ancient Phyficians*, a word ufed to exprefs that fudden effufion of blood into the cutaneous veffels, which arifes from joy, anger, fhame, or any other violent emotion of the mind, and is what we ufually call blufhing; which, according to Dr. Hunter, is a nervous affection.

Enchymoma is alfo an afflux of the blood, whereby the external parts are rendered black and blue, as in the fcurvy, blood-fhot eyes, &c.

ENCHYMONITES, in *Natural Hiftory*, the name of a kind of ftone found in Macedonia, and fome other places, which was alfo called *pæonites* and *pæanites:* it was fuppofed to be of great virtue to affift women in labour. See Ceanides.

ENCHYMO'SIS, from εγχυω, *to pour into*, in *Surgery*, an extravafation of blood from the veffels, attended with black, blue, or livid appearance of the part. See Ecchymosis.

ENCHYSMA, the fame with clyfter or enema.

ENCHYTA, in the *Medical Writings of the Ancients*, a name given to fuch medicines as were injected into the eyes, or into any part.

Some alfo have ufed the fame word to exprefs a fort of funnel, contrived to convey the fumes of medicines to any part of the body.

ENCKENDORP, in *Geography*, a town of Germany, in the duchy of Holftein; 6 miles S.E. of Rendfburg.

ENCKHUYSEN, or Enkhuizen, a confiderable town of Holland, on the Zuyder Zee, in North Holland; 9 miles N.E. of Horn, and 30 miles N.E. of Amfterdam. N. lat. 52° 40′. Its commerce, and particularly its herring-fifhery, was of great importance in former times; but its harbour is now almoft entirely choaked up with fand.

ENCLAVE', in *Heraldry*, is where one thing is let into another, particularly where the jointure is fquare.

ENCLITICA, of εγκλινω, *I incline*, in the *Greek and Latin Grammar*, certain particles, united fo clofely to the preceding word, that they only feem to form one word therewith; and the word which fuftains them does generally likewife bear the accent that governs them, efpecially when the enclitic is a monofyllable; as in *dominufque*, κυριος τε.

There are three enclitic particles in the Latin, *viz. que*, *ne*, and *ve;* but in the Greek many, as του, μου, μοι, με, σου, σοι, σε, πως, πη, τε, γε, φημι, ειμι, ποτε, and others.

ENCLOS, L', in *Biography*, a mufician in Louis XIII.th's band, an eminent performer on the lute and theorbo, or fingle and double lute.

He was father of the celebrated Ninon, who played on thefe inftruments as well as himfelf.

He dying in 1630, left her an orphan at 15 years old, beautiful, full of wit and talents, and formed to infpire the moft violent paffion. Nor did fhe wrap her talents in a napkin, but availed herfelf of all their influence; and even at more than fourfcore, fhe is faid to have awakened love in the learned abbé Gédoin.

It is pretended that cardinal Richelieu had her firft favours, and that he was the only one to whom fhe furrendered, without confulting her inclinations.

She was then 17, and it is certain that, ever after that time, fhe received a penfion of 2000 livres annually, which was long regularly paid.

Ninon gave concerts at her houfe, where perfons of the firft rank and talents came to admire her performance on the lute and harpfichord. The philofopher, Huyghens, the famous aftronomer, likewife obferved Ninon with great attention and accuracy, and even wrote verfes on her, which Voltaire calls *Geometric.*

> "She has inftruments five, which my brain much difturb,
> The two firft are her hands, the next are her eyes;
> But my tongue for the fifth and the beft I muft curb,
> Nor its beauties attempt to difclofe, if I'm wife."

She was feldom left by her lovers, but fhe left them very foon; yet fhe always retained a friendfhip for her old admirers.

She was fo celebrated, that Chriftina queen of Sweden made her a vifit in 1654, in a fmall villa which fhe had in the neighbourhood of Paris.

Madame de Maintenon was her beft friend; and Voltaire afferts that M. de Villarecau was a lover in common with both, without its occafioning a quarrel.

He had two children by Ninon. The hiftory of the eldeft is known, who at 19 years old became paffionately enamoured of her; but on making the difcovery, he blew his brains out. Her fecond fon, called Boiffiere, died at

Rochelle in 1723, commiffary of marine. She loved ferioufly for fome time the marquis de Sévigné, brother of madame de Grignan; but who never wrote the letters to her, which M. d'Amoure has printed under her name about 40 years ago.

Madame de Maintenon, becoming all powerful, remembered her, and fent her word that fhe would take care of her fortune, if fhe would change her way of living, and think ferioufly of religion: Ninon replied, that fhe neither wanted fortune nor a mafk. Ninon died at Paris, 1705, at the great age of 90.

ENCŒLIA, of ἐν, *in*, and κοιλια, *belly*, a word ufed by many of the ancient medical writers, to exprefs the vifcera contained in the abdomen, or lower belly.

ENCOLPIUM, or ENCOLPION, the pectoral crofs of bifhops, abbots, abbeffes, &c.; being one of the ordinary marks of the dignity of fuch perfons both in the Latin and the Greek church.

ENCONDRUS, of ἐν, *in*, and χονδρος, *grain*, in the *Old Greek Writers*, a word ufed to exprefs any thing made up of a great number of fmall pieces, or flakes, or fmall grains of any thing. The manna of the ancients was not in large flakes, as we have it at prefent, but it was formed of a vaft number of fmall granules, and was therefore called by Diofcorides, and fome others of the Greeks, by this name. The word manna alfo fignified with them the fame thing; and they not only expreffed the fubftance by it which we at prefent call fo, but any other thing that was in fmall flakes, or pieces, was called manna. Thus the manna thuris, fo much talked of among the old Greeks, was only a collection of thofe pieces which flew off from frankincenfe in the breaking. See MANNA *Libanotis*.

ENCOPE, of ἐν, and κοπτω, *I cut*, in *Surgery*, an incifion of any part; as in a gangrene, &c.

ENCOUNTER, in a *Military Senfe*, relates to that kind of deliberate attack, which is totally abftracted from accidental hoftility, and may therefore be confidered in contradiftinction to the rencontre, which ordinarily implies a fortuitous meeting. Thus we find, "to lead troops to the encounter," is a very common expreffion; though we occafionally hear the term mifapplied by perfons who defcribe the loffes, &c. fuftained in accidental warfare, as having taken place, not in the rencontre, but in the encounter. We fhould alfo underftand, that, in the ftrict fenfe, (which relates entirely to the arranging of troops oppofite, that is, *en-contre*, to the enemy,) we ought not to confider circuitous attacks, and thofe feints made merely for the purpofe of diftracting the enemy's attention, as coming under this definition; and, on the other hand, we confider not only thofe who come into actual engagement, perhaps to the point of the bayonet, as is often the cafe in the attacks made by columns of infantry, but the fupporting divifions alfo, to be engaged in the actual encounter. Thus we frequently perceive, that the leading regiment of a column is engaged, while the rear regiments bear no fhare in the conteft; but if their fituations be fuch as to expofe them to the enemy's fire, they muft be as much confidered in the encounter as a veffel coming to the aid of another, fo as to caufe the enemy's fhip to furrender, or to retreat. Hence it has ever been held a rule, that all veffels in fight, when a capture is made, become entitled to fhares in the prize; becaufe, on many occafions, the approach of reinforcements adds to the vigour of one party, while it depreffes the fpirits of the other, and influences it to decline further conteft.

ENCRANIUM, in *Anatomy*, the fame with cerebellum.

ENCRASICOLUS, in *Ichthyology*, a fpecies of clupea. See CLUPEA and ANCHOVY.

ENCRATITÆ, formed from ἐγκρατης, *continent*, in *Ecclefiaftical Hiftory*, a fect of ancient heretics, thus called from their making profeffion of continence, and abfolutely rejecting all ufe of marriage.

The founder of this fect was Tatian, a difciple of Juftin, and one of the moft learned perfons of all antiquity. After the death of that martyr, he made a feparation from the church, and foon had his followers; who, befide the dogma juft mentioned, borrowed a great many things from Saturninius and Marcion; befide feveral errors, which they adhered to in common with the Gnoftics and Valentinians.

They abftained from eating any thing that had life, and denied that Adam was faved. They looked on fuch as drank wine to be great finners; and for this reafon only made ufe of water in celebrating the Eucharift, as holding, that wine came from the devil. To countenance this tenet, they produced paffages out of fcripture, where mention is made of what befel Noah and Lot, when they were drunk.

They only admitted fuch of the books of the Old Teftament as they thought good; but in lieu thereof, they owned feveral fpurious and apocryphal writings for canonical and divine. Such were the Acts of St. Andrew, John, and Thomas.

ENCRAULOS, in *Ichthyology*, the name given by Ariftotle, and many other of the ancient Greeks, to the fifh which we call the anchovy. See CLUPEA and ANCHOVY.

ENCRINITES, in *Natural Hiftory*, a kind of columnar extraneous or organized foffil, found in the earth. See ENCRINUS, PENTACRINI, and ENTROCHI.

ENCRINUS FOSSIL, is the remains of an animal, fo called by fome; by others, this clafs of zoophytic remains is called *encrinites* (Parkinfon's Organic Remains, vol. ii. p. 153.); and by others, denominated *entrochi*, or *pentacrini*. See thofe articles. See alfo Harenberg's Encrinus S. Lilium Lap. 4to.

ENCRINUS, a fpecies of *Pennatula*, in the clafs of zoophyte worms, comprehending the clufter-polypi of Ellis, and inhabiting the Greenland fea.—Alfo, the name given by Ellis to the Afteria, a fpecies of Ifis, inhabiting the ocean that wafhes the coaft of Barbadoes.

ENCRIS, in the *Medical Writings of the Ancients*, fignifies a fort of cake made of fine flour, mixed with oil, and fweetened with honey.

ENCROACHMENT *of the Sea*, in *Geography*, fignifies the fudden or gradual converfion of dry land into the verge of the ocean. Hiftory records numerous inftances of great and devaftating effects of this kind: fome occafioned by the waves of the fea undermining the cliffs on its fhore, and carrying away the matter thereof as faft as they fall, by which the boundaries of the fea have been confiderably enlarged in fome places; and its ravages ftill continue with increafing effect in fome places, as on the chalky fhores of Kent and Suffex. Another kind of marine encroachment, highly interefting to the geologift, is evidently taking place, by flow degrees, on a confiderable portion of the flat fhores of England; and can only be explained by an exceeding flow and gradual fubfidence of the ifland itfelf, or a correfponding rife of the ocean which bounds it. This is particularly vifible in the fens and marfhes of our coaft, which

which are now defended by banks of that magnitude and height, which fcarcely any effort of the prefent day could at once effect; but which, as in the marfhes embanked from the Thames below London, muft have been begun centuries ago, when the tide flowed not fo high by many feet as it does at prefent, and have been gradually raifed, as the height of the water increafed. The finding of immenfe fallen woods of trees, of the recent fpecies, with the marks of human labour on them, and even the very tools by which they were felled, under great thicknefs of peat, the whole of which is now much below the level to which the tide rifes twice each day, are alfo proofs of this general encroachment of the fea; fince neither peat nor trees of any kind will grow where the falt-water of the ocean even faturates, much lefs continually overflows the ground. The mention of various inftances of ancient and high embankments of marfhes and fens againft the tide, will be found under our article Canal, in the divifions *Thames*, *Oufe*, *Welland*, &c. See alfo Embankment.

Encroachment. See Incroachment, and Accroching.

ENCURECK, in *Natural Hiftory*, a venomous infect, found in Perfia, and fuppofed by fome to be a kind of tarantula. It neither ftings nor bites, but lets fall its venom like a drop of water, which caufes infufferable pain in the part for a time; and afterwards fo profound a fleep, that we are told nothing can raife the patient from it but crufhing one of thofe creatures on the part affected. It is neverthelefs faid, that the fheep eat thefe infects without damage. Olearius, ap. Boyle, Works abr. vol. i. p. 37. Ibid. p. 38.

ENCYCLOPÆDIA, the circle or chain of arts and fciences.

The word is compounded of the prepofition εν, *in*, κυκλος, *circle*, and παιδεια, *fcience*, *doctrine*, *difcipline*, *learning*; the root being παις, *child*, *infant*.

The Greeks ufed the term for the knowledge of the feven liberal arts, and the poffeffion of all the fciences. *Orbis ille doctrinæ, quem Græci εγκυκλοπαιδειαν vocant*, fays Quintilian. It is fometimes alfo written κυκλοπαιδεια, *cyclopædia*. Vitruvius, in the preface to his fixth book, calls it *encyclios difciplina*. See Cyclopædia.

ENCYSTED Tumours, in *Surgery*, fwellings, which are formed of a bag, or cyft, which is filled with matter very various in its confiftence and appearance. When the contents of the cyft refemble pap, the tumour is named *atheroma*; when they are of the confiftence of honey and wax, it is called *meliceris*; when they are fatty, it is termed *fteatoma*. See thefe words, and efpecially Tumours.

END *for* End, in the *Sea-Language*. When a rope runs all out of the block, fo that it is unreeved, they fay it is run out end for end.

The fame phrafe is applied to a cable that has wholly run out of the fhip. In general, it denotes the reverfal of the pofition of any object.

End-*on* is applied to a fhip, which advances to a fhore, rock, &c. without any apparent poffibility of preventing her.

ENDE, in *Geography*, one of the fmaller Molucca iflands, S. lat. 8° 30′. E. long. 120°.

ENDEAVOUR River, a river on the N. E. coaft of New Holland, which at its mouth has a fmall bar harbour, or creek, that runs in a winding channel three or four leagues inland, and having at its head a fmall brook of frefh water. There is not depth of water for fhipping above a mile within the bar. This part of the coaft is fo barricaded with fhoals, as to make the harbour difficult of accefs, the fafeft approach to it being from the fouthward. S. lat 15° 26′. E. long. 215°.

Endeavour *Straits*, a channel or paffage, fo called by Cook, between New Guinea and New Holland, the N.E. entrance of which lies in S. lat. 10° 39′. W. long. 218° 36′. It is formed by the main, or the northern extremity of New Holland, on the S.E., and by a congeries of iflands, which Cook called "the Prince of Wales's iflands" to the N.W., which iflands probably extend quite to New Guinea. The length of this channel from N.E. to S.W. is ten leagues, and it is about five leagues broad, except at the N.E. entrance, where it is fomewhat lefs than two miles, being contracted by the iflands which lie there. The depth of water in the ftrait is from four to nine fathom, with every where good anchorage, except upon the bank, which lies two leagues to the northward of Wallis's iflands, where, at low water, the depth is only three fathom.

ENDECAGON, or Hendecagon, in *Geometry*. See Hendecagon.

ENDECASYLLABUS, or Hendecasyllabus. See Hendecasyllabus.

ENDECANDRIA, in *Botany*, from ενδεκα, *eleven*, and ανηρ, *a man*, an order of the Linnæan clafs *Monadelphia*, characterized by having eleven ftamens, whofe filaments are, as the character of the clafs itfelf requires, united into a tube. It contains only the genus *Brownea*, the number of whofe ftamens is different in different fpecies, and this precife number of eleven is fo unufual, and apparently unnatural, in flowers where five and ten fo much predominate, that perhaps the order in queftion might be, without mifchief, abolifhed.

ENDECERES, of ενδεκα, *eleven*, in the *Naval Architecture of the Ancients*, a word ufed to exprefs a galley which had eleven feries or tires of rowers. Thofe with two or three tires were very much in ufe among the ancients, and from thofe to fuch as had five or fix tires. Thofe of nine tires were fometimes ufed, but it was very feldom; and thofe of eleven, fifteen, and fo on, were rather for ftate, than fervice. We read of them carried fo high as to contain twenty, thirty, and forty rows of oars. One of this largeft fort was built for Philopater, which required four thoufand men.

ENDEIXIS, Ενδειξις, in *Antiquity*, an action brought againft fuch as affected any place or thing, of which they were incapable by law. Pott. Archæol. Græc. lib. i. cap. 23. tom. i. p. 125.

ENDELAVE, in *Geography*, a fmall ifland of Denmark; eight miles N. of Funen.

ENDEMIC, or Endemial, *Difeafes*, from εν, *in*, and δημος, *a nation*, or *people*, are thofe difeafes which occur among the inhabitants of a particular region or place, in confequence of certain circumftances belonging to it, and not arifing from contagion, or any other general caufe.

Thus agues, or intermittent and remittent fevers, which are occafioned by the miafms of marfhy ground, are *endemic* in low countries: the *goitre*, or bronchocele, connected with that peculiar intellectual imbecility, which characterizes the Cretin, is *endemic* among the Alps, where its origin has been erroneoufly afcribed to the ufe of fnow-water: the colic, Colica *Pictonum*, is *endemic* in the cyder-counties, efpecially in Devonfhire: the bilious remittent fever, or yellow fever, is *endemic* in the Weft India iflands; and fo forth. In all thefe inftances, fome *local* caufe obvioufly exifts, which produces the difeafe in the refpective diftricts; the difeafe belongs to the diftricts, therefore, and affects thofe who refide there, but extends no farther. Whereas an *epidemic* difeafe is produced, or at leaft propagated among the people, in confequence of fome general caufe; as contagion, famine, or, perhaps, fome change in the condition of the atmofphere at large.

Hence the diftinction between endemic and epidemic difeafes is obvioufly of great importance, for, in both cafes, much more beneficial purpofes may be accomplifhed in the way of prevention, than in that of cure. But the prevention of difeafes depends altogether upon a knowledge of their caufes, which fhould therefore be accurately inveftigated, whenever they prevail extenfively. If a difeafe is endemic, *i.e.* originates in fome local caufe, (from marfh effluvia, for inftance;) it may attack the fame perfon again and again, while he remains in the fame fituation; but he infallibly efcapes it by removing his refidence; or the inhabitants of the diftrict may be all defended from its attacks by draining the marfhy ground, whence the miafmata iffue. Thus we are told by writers on the difeafes of armies, that the diforders which arife from the foul ground of camps, are readily made to difappear by removing but a few hundred yards from the fituation which they previoufly occupied. And of the beneficial effects of attention to the local caufes of endemic difeafes, we have a ftriking example in the changes, which have occurred in London, in refpect to the difeafes of its inhabitants. In the time of Sydenham and Morton, *viz.* in the latter half of the feventeenth century, remittent and intermittent fevers were generally prevalent to a great extent, in the autumnal feafon, and were often extremely fatal to the inhabitants of the metropolis; and the bills of mortality fhew, that formerly the dyfentery, which almoft conftantly appears in the fame places and feafons as the remittent fever, was annually fatal to great numbers. But of late years thefe difeafes have almoft entirely difappeared; intermittents occurring only occafionally after wet feafons, in thofe people who have vifited the fenny counties during the harveft; and dyfentery fometimes prevailing, in a mild way, in thofe feafons only when the heat has been unufually great. This exemption, which London now enjoys from thofe endemic difeafes, is chiefly to be afcribed to the improvements that have been made in the pavement, drains, and fewers, and the attention that is paid to cleaning and fupplying with water the feveral parts of the town. In fome towns where thefe precautions are neglected, the remittent fever is ftill found at times to commit great ravages. It is probable that the fever, which proved fo fatal in Philadelphia, in the year 1793, was of this kind, and produced from the caufes juft mentioned. (See Rufh's Obfervations on the Fever of Philad. 1799. Dr. Miller's Report, New York, 1806.)

Some writers confine the term *endemic* to thofe difeafes which are conftantly prefent in certain diftricts, at all times and feafons, fuch as the *goitre* of the Alps; and call thofe *epidemic*, which are the product of certain feafons, although originating in a local caufe, as the autumnal intermittent and remittent fevers of fenny and hot countries. See EPIDEMIC.

ENDENA, in *Geography*, a town of Italy, in the Bergamafco; feven miles N. of Bergamo.

ENDENTED, DENTED, or *Indented*, in *Heraldry.* See INDENTED.

ENDENTED is alfo applied to a fefs or pale, and other triangular pieces, when divided alternately between two different colours. Coupé, or endented with or and azure.

ENDER, in *Geography*, a town of Italy, in the Bergamafco; 12 miles N.E. of Bergamo.—Alfo, a river of Scotland, which runs into the Garry, feven miles W. of Blair-Athol, in Perthfhire.

ENDERSTORF, a town of Silefia, in the principality of Neyfze; $3\frac{1}{2}$ miles, S. of Ziegenhals.—Alfo, a town in the fame country and principality; $3\frac{1}{2}$ miles S.W. of Grotkau.

ENDESIS, from ἐν and δέω, *I bind*, a word ufed by Hippocrates to exprefs that part of the foot where the bones of the tibia end, and which is connected by ligaments to the ankle.

ENDEW, in *Falconry*, is faid of a hawk that digefts her meat fo well, that fhe not only difcharges her gorge of it, but even cleanfes her pannel.

ENDIAN, in *Geography*, a town of Perfia in the province of Chufiftan; 150 miles S.S.E. of Sufa.

ENDICA, a word ufed by the alchemifts for the fæces which fubfide to the bottom of the veffels in infufions; to fome of which they attribute great virtues.

END-JOINTS, in *Mining*, otherwife called *cutters*, in coal-mining, are the fhorter of the natural joints or upright partings of any meafure or ftratum; the longer of thefe joints being called *Backs*, *Slines*, face or lengthway-joints, or partings: for it feldom happens in any quarry or work, that the face-joints are not much longer than the end or crofs-joints.

ENDINGEN, in *Geography*, a town of Germany, in Auftrian Swabia; feven miles N.W. of Fribourg.

ENDINGS OF STRATA, in *Geology*, fignify the edges of the ftrata, in their greateft advance towards the north weft, or in the direction of their general *rife*, according to the obfervations of Mr. William Smith and his followers; by whom it has been obferved, in all the eaftern parts of England, that the ftrata *end* fucceffively towards the N.W. generally with a fingered or digitated outline, in fome, in places running out for miles in ridges, beyond the general range of the edge or limit of the ftratum: the more recent obfervations in Derbyfhire, at Chelmefton-low, for inftance, and other projecting points of ftrata in that *denudated* diftrict, fhew, however, the neceffity of a careful attention to the fingered or projecting points of ftrata, and to other concurrent circumftances, before fuch fingerings alone are admitted as proofs of the ending of a ftratum, rather than as part of the edge of a denudated tract, on the oppofite fide of which the fame ftratum is to be found again, either on the furface, or abruptly funk beneath it by a fault, and upper meafures occupy that furface. See DENUDATION, and CONCENTRICITY *of Strata.*

ENDITEMENT, or INDICTMENT, in *Common Law* See INDICTMENT.

ENDIVE, in *Gardening*, the common name of an efculent plant which is well known in garden culture. There are different varieties of it, but that which is perfectly curled, is the moft ufeful for culinary purpofes. See CICHORIUM.

ENDIVIA, in *Botany*, *Cichorium Endivia* of Linnæus, the garden endive. Ambrofini derives the word from *edendo*, eating, becaufe the plant is fo grateful to the palate. It appears to us rather a corruption of one of its old names, Entyba, or Intuba.

ENDIVIA MARINA, the *fea-endive*, in *Natural Hiftory*, the name of a fpecies of fea plant, or marine fubftance, defcribed by count Marfigli. There are two fpecies of it, the one having broad and jagged leaves, refembling thofe of the vine, the other much narrower. This laft kind grows on ftones, fhells, pieces of wood, or any other fubftances, accidentally found at the bottom of the fea. It feldom grows in very deep water, and thrives beft in places where the fea is calm and quiet. It is of a dufky greenifh colour, variegated in fome places with yellow. It exactly refembles the fhape of the endive common in our gardens, and its leaves are cut and fringed in the fame manner; but

but they are of fo tender a fubftance, that a flight touch deftroys them; they are indeed tenderer and more delicate than thofe of any other known plant, either of the fea or land. When this fubftance is examined by the microfcope, its furface is found to be compofed of a great number of eminences and cavities, or little holes, between and among them; and when the leaves are cut tranfverfely, there are feen a great number of glandules in them. Marfigli, Hift. de la Mer, p. 72. See Corallines.

ENDLESS Rolls, and *Screw*. See the Subftantives.

ENDOCARPON, in *Botany*, from ενδον, *within*, and καρπος, *fruit*, alluding to the receptacle of the feeds being deeply imbedded in the fubftance of the leaf, or rather frond. Hedw. Crypt. v. 2. 56. t. 20. f. A. Ach. Prod. 140. Meth. 125. (Lichen; Zoega Ifland. 15. Dicks. Crypt. fafc. 2. 22. With. v. 4. 52. Sm. Engl. Bot. v. 9. 595, &c.) Clafs and order, *Cryptogamia Algæ*. Nat. Ord. *Lichenes*.

Gen. Ch. *Frond* cartilaginous, rigid, rounded, peltate, depreffed; naked beneath. *Receptacles* immerfed in the fubftance of the frond, globofe; their edges a little protuberant; their concave difk lodging the *feeds* in vertical cells, and at length expanded and difplayed.

Eff. Ch. Receptacles immerfed, globofe, concave, in which the feeds are imbedded.

This genus is, perhaps, more judicioufly than moft feparated from the great genus or family of *Lichen*, by Hedwig, followed by the accurate Dr. Acharius. The only queftion is whether *Verrucaria* ought not to be joined with it, as differing not at all in the parts of fructification, though its frond is a cruft inftead of a leaf, juft as his various *Parmeliæ* differ, even more widely, among themfelves. Several fpecies of *Endocarpon* are figured in Engl. Bot. t. 593—595. 1512. 1698. 1866. 2012, and 2013. They are fmall roundifh or angular plants, commonly growing clofely preffed to the earth or ftone, of a grey or olive hue, their fructification appearing like little black dots over the furface.

ENDOR, in *Ancient Geography*, a town of Judea, in the half-tribe of Manaffeh, on this fide Jordan, according to the book of Jofhua. Eufebius places it four miles S. from mount Tabor, near Naïm, in the way to Scythopolis.

Endor, *Witch of*. See Witch *of Endor*.

ENDORSE, in *Heraldry*, an ordinary, containing the eighth part of a pale.

This, Leigh fays, is never ufed but when a pale is between two fuch: though others hold, that an endorfe may be borne between birds, fifhes, beafts, &c. Sir J. Ferne adds, that it fhews the fame coat has been fometimes two coats, and afterwards conjoined within one efcutcheon, for fome myftery of arms. He bears azure an endorfe argent.

ENDORSED, Endossé, is where things are borne back to back.

ENDORSEMENT, of *in* and *dorfum*, *back*, is particularly ufed, in *Commerce*, for a writing on the back of a bill of exchange by the proprietor or bearer, either thereby to transfer it to fome other, or to render it payable to the order of fome other, or elfe to ferve for an acquittance or receipt. See Exchange.

The endorfement is only the name of the proprietor, or endorfer. Note, when the endorfement of a bill of exchange is to render it payable to another, it is called an *order*.

To an order it is neceffary the endorfement be dated, and contain the name of him who paid the value thereof; in which cafe, the bill belongs to the perfon with whofe name the order is filed, without any other tradition: without thefe conditions, the bill is judged to belong to the perfon who endorfed it. The bearer of a bill of exchange protefted has a remedy againft the endorfers for the payment of the re-change of the places where the bill was negociated by their order. In cafe a bill or note is refufed to be paid, &c. the bearer has a remedy againft any one of the endorfers, where there are feveral. See Bill.

ENDORSING, or Indorsing, in *Law*, implies the writing on the back fide of a deed, inftrument, &c. fomething relating to the matters contained therein.

ENDOSIS, Ενδοσις, of εν and διδωμι, *I give*, in the *Medical Writings of the Ancients*, a word ufed to exprefs a remiffion of any kind, as when a tumour, inflammation, or hardnefs of any part, becomes lefs violent; and when the patient becomes eafier, after the exacerbations in fevers of the continual kind, and after fits of the intermittent.

ENDOWMENT, or Indowment, the giving or affigning of a dower to a woman. See Dower.

The word is alfo ufed figuratively, for the fetting forth or ferving a fufficient portion for a vicar, towards his perpetual maintenance, when the benefice is appropriated; whence fuch a vicarage is called a vicarage endowed.

ENDRACHIUM, in *Botany*, Juff. 133, fee Thouinia. The name is barbarous, corrupted from the Madagafcar word Endrach, under which it occurs in Lamarck's Encycl. v. 2. 356, who neverthelefs calls the genus *Humbertia*, following Commerfon. See Lamarck's plates, t. 103. Dr. Smith named it *Thouinia*, and is followed by Schreber, Willdenow, and Martyn.

ENDRAPA, in *Ancient Geography*, a town of Afia, in Mefopotamia, fituated on the left bank of the Euphrates.

ENDSCHUTZ, in *Geography*, a town of Germany, in the circle of Upper Saxony, and circle of Neuftadt; 4 miles E.N.E of Weyda.

ENDYMATIA, in *Antiquity*, a kind of dance ufed among the Greeks, performed in Arcadia, to the found of certain airs compofed for the flute.

ENEDA, in *Geography*, a town of Switzerland, in the canton of Glaris; 2 miles E. of Glaris.

ENELIAXIS, Ενηλιαξις, or rather *Enyaliaxis*, Ενυαλιαξις, in *Antiquity*, a feftival in honour of Enyalius, whom fome will have to be the fame with Mars, others only one of his minifters. Pott. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 394.

ENEMA, of ενιημι, *I put in*, in *Medicine*, denotes a clyfter. See Clyster.

ENEMY. See Alien.

ENEOREMA, of εναιρεω, *I lift up*, is ufed by ancient medical writers for thofe parts of the urine which float about in the middle refembling a cloud, formed, according to Boerhaave, principally of muriatic falt. Comm. Inftit. § 382.

ENEOS, of εν and αυω, *I cry*, a word ufed by the ancient writers in *Medicine*, for a perfon born deaf, or unable to perform the common offices of life, for want of any of the principal organs.

ENERGETICAL Bodies or *Particles*, are fuch as are eminently active, and which produce manifeft operations of various natures, according to the various circumftances and motions of fuch bodies or particles.

ENERGICI, in *Ecclefiaftical Hiftory*, an appellation given to certain difciples of Calvin and Melancthon, of the fixteenth century, becaufe they held the Eucharift was the energy and virtue of Jefus Chrift; not his real body, nor a reprefentation thereof.

ENERGUMENUS, Ενεργουμενος, a term fometimes ufed by by divines and fchoolmen, to fignify a perfon poffeffed with a devil, or an evil fpirit.

The word is formed from the Greek, ενεργεισθαι, *to be agitated*, *worked*, of εν, and εργον, *opus*.

Though Papias fays, the Energumeni were fuch as counterfeited the actions of the devil, performing things which feemed fupernatural. The council of Orange debars, or deprives the Energumeni of the functions of the priefthood. See DÆMONIAC.

ENERGY, in *Elocution*, a mode of delivery applicable to particular paffages of a difcourfe that are meant to be rendered particularly impreffive and operative upon the feelings and convictions; like emotion, if not too frequently appealed to, or too extravagantly exerted, it has a great tendency to demonftrate the fincerity and real earneftnefs of the fpeaker; which is always one of the indifpenfible requifites for the conviction of the hearer. In declamation it fhould be manifefted alike in the enunciation, the tones of the voice (which fhould be firm and fervid), and in the gefticulation. It is this quality in the fpeaker that feems to have been defignated by Demofthenes as the firft, fecond, and third requifite of an orator. Action (Ενεργεια, the Latin *actio*,) not being confined in fignification to the mere motion of the limbs, but to the entire and reciprocal exertion of the mental and organic faculties of the fpeaker, the co-operative energy of thought, language, enunciation, tone, look, gefture, and deportment. "Et actio oratoris pronunciatio ac geftus, & ipfa adeo adminiftratio cauffæ." Cic. in Orat. c. 17. "Oratorical action is pronunciation and gefture; hence the very delivery of the fubject." "Eft actio quafi corporis quædam eloquentia, cum conftet e voce et motu." Quintil. Q. 3. "Action is, as it were, a certain eloquence of the body, confifting in voice and motion." See alfo Gefner's Thefaurus in voc. actio.

ENERGY, in *Painting* or *Sculpture*, may be divided into two parts, *viz.* energy of thought, and energy of execution.

The former confifts in deeply inveftigating the nature and intereft of a fubject, and felecting that moft impreffive and decifive moment for reprefentation (and alfo the mode of doing it) which fhall convey to the imagination of the beholder with the greateft intereft, either its hiftory or its moral.

The latter confifts in that fame active, animated fpirit, being accompanied by the power of difplaying the reprefentation of that felection, either on marble or on canvas, with force, with freedom, and precifion; without labouring, at leaft without leaving the appearance of labour, in endeavouring to obtain its expreffion.

The comparifon of two artifts who in their works have each refpectively exhibited the poffeffion of thefe two qualities in the higheft degree, will beft illuftrate our meaning.

Raphael's works are full of energy of thought. Thofe of Tritoretto of energy of execution.

The former always fixes upon that precife moment of time in a ftory which is moft favourable for relating it with fuccefs; and is fure to intereft by the force and truth with which he unfolds the circumftances of it. He fometimes even, and that with the greateft propriety, goes farther than the mere relation of the particular fubject; he accompanies and illuftrates it by allufions to antecedent and fubfequent events connected with it; as in the cartoon of the death of Ananias.

In that picture, fome of the difciples on the right of St. Peter are ftill engaged in diftributing alms, not yet having obferved the inftantaneous punifhment inflicted by Almighty vengeance on the guilty finner; we are thus unaffectedly informed of the object for which the apoftles are affembled, and how they were engaged previoufly to the time of the immediate fubject of the work, and we are led as fimply to underftand fomewhat of that which followed, by the introduction of the figure of Sapphira; who advances on the oppofite fide, intent upon counting the money fhe may be fuppofed propofing either to give to the fund devoted to charity, or to withhold, that fhe might gratify her own, and her now dying hufband's avarice; whofe fate, of which fhe appears to be altogether unapprized, fo nearly awaited herfelf, for her defign of committing the crime for which he was fo awfully punifhed.

Thus we fee, that no part of the intereft of the fubject efcaped the active energy of the mind of Raphael, and many others of his works would as well illuftrate his great ability in this point of the art; *e.g.* the cartoon of St. Paul preaching at Athens, but in neither of thefe noble works is there much energy of execution: that was the *forte* of Tintoretto.

He feldom ftopped to think correctly and refinedly upon his fubject. He rarely pourtrays the paffions with truth in the countenances of his figures, or gives his ftory intereft on the mind; except by the aftonifhing freedom, force, and fire of his pencil in the execution, where it appears to have moved with the utmoft rapidity; the canvas trembles under it. His vigour in colour equals the fkill of his workmanfhip; and thefe united, the obferver forgets the want of more valuable beauties. The fkill of the mafter ftrikes more than the work itfelf. His execution well deferves the appellation beftowed upon it by the Carracci, "Il terribile maniera del Tintoretto." It ftill remains a defideratum in art to fee it united with elegance of defign; with feeling, and truth in thought, and expreffion.

In fculpture the author of the Laocoon has effected their union. We may, therefore, hope its fifter art may fometime arrive at an equal degree of perfection. But there are fo many more points of difficulty to overcome in painting than in fculpture, that he muft be almoft fuper-human who effects it.

Many will rather wifh that Michael Angelo had been inftanced as poffeffing energy of thought in preference to Raphael; and juftly he might have been hailed as a wonderful model of it, as he alfo was to a confiderable degree in the other acceptation of the word, *viz.* in execution. But his energy is lefs underftood than that of Raphael; and is of a lefs valuable kind; as it not unfrequently renders his figures enigmatic, and nature is loft in art. Raphael comes equally with him, home to his fubject; and can fcarcely ever be mifunderftood. Hence, therefore, we think ourfelves juftified in prefenting the latter to the attention of our readers rather than the former; not as willing to depreciate Michael Angelo; but becaufe we conceive, that while the confideration of his energetic powers may invigorate the ftudent, it may divert his mind from truth, and lead him to bombaft and affectation; which the contemplation of the works of Raphael never can do, unlefs he be of a moft perverfe ftamp of nature indeed. If energy of thought may be faid to be characterized by thofe ftrong workings of the imagination alone, which produce the reprefentation of the moft extraordinary and powerful actions of the human body, with bold fore-fhortenings and ftrong expreffions; then M. Angelo claims by far the higheft place, but we do not conceive that to be the beft criterion for judgment on this point. He who fees cleareft, and while he gives it powerfully, moft juftly and beautifully illuftrates his fubject, muft furely have as fully and warmly conceived the nature of it; as he, who, mixing the extravagance of enthufiafm with his energies, permits his mind to run wild upon it; and throws upon his canvas-figures which rather confufe than exemplify, and draw the attention of the obferver from the fubject to the painter. This enthufiafm, we think, does characterize in a great meafure the wonderful works of M. Angelo; whilft Raphael's mind, though full of energy, is pure, and going to the extreme of indulgence in his fubject, ftill keeps within its bounds.

ENERVATING, the act of deftroying the force, ufe, or office of the nerves, either by cutting them, by weakening them with debauchery, or by fome other violence.

Excefs of wine, and other ftrong, hot, fpirituous liquors, enervate or weaken the nerves. When they would render a horfe ufelefs, they enervate him, or cut his nerves.

Enervating, is particularly ufed in the *Manege*, for the cutting two tendons on the fide of a horfe's head, under the eyes, which meet on the tip of the nofe; they thus enervate horfes, to make their heads fmall and lean.

The word is alfo ufed figuratively. It is no fmall artifice in difputing, to be able to enervate and extenuate the allegations of one's antagonift. This author has a weak enervate ftyle. See Nerve.

ENERVATION, a term in the *Ancient Anatomy*, applied to the tendons of the recti, or ftraight mufcles of the abdomen.

The fibres of the recti of the abdomen do not go from one extreme of the mufcles to the other, but are interfected by feveral nervous places, called by the ancients enervations, though they be real tendons.

Their number is not alike in all; fome having three, others four, &c.

ENERVE, Folium, in *Botany*, a leaf deftitute of ribs and nerves. See Leaf, and Costatum Folium.

ENFANS Perdus, a French phrafe, ufed in war to fignify the foldiers who march at the head of a body of forces appointed to fuftain them, in order to begin an attack, make an affault, or force a poft.

The word literally imports *loft children*, on account of the imminent danger they are expofed to.

In Englifh, they are called the *forlorn*, or *forlorn hope*.

At prefent, the grenadiers ufually begin fuch attacks.

ENFIELD, William, in *Biography*, was born at Sudbury in the year 1741, and educated for the miniftry among the Proteftant diffenters at the academy at Daventry, where he diftinguifhed himfelf by the polifh of his early compofitions. He was firft fettled as minifter with the congregation at Benn's garden, Liverpool; this was in the year 1763; and, in 1770, he became refident tutor and lecturer in the belles-lettres in the academy at Warrington. He fhortly after qualified himfelf as mathematical tutor, and in that character publifhed "The Inftitutes of Natural Philofophy," in quarto. A new edition of this work was publifhed after the doctor's death, with confiderable additions, and an introduction to the modern doctrines and difcoveries in chemiftry. It may be reckoned one of the beft popular introductions to Natural and Experimental philofophy. During his labours at Warrington, which were highly prized, the univerfity of Edinburgh conferred upon him the title of doctor of laws. In the year 1785, he removed to Norwich, and became paftor of the congregation of diffenters in that place. With the duties of this office, he fuccefsfully employed himfelf in various literary undertakings, among which was the laborious tafk of tranflating and abridging "Brucker's Hiftory of Philofophy," a work to which we have frequent occafion to refer in the courfe of our own inveftigations of the learning of ancient times. This abridgment was publifhed in two vols. 4to. in 1791, and "probably," fays his friend and biographer, Dr. Aikin, "the tenets of the different fects of philofophers were never before difplayed with fo much elegance and perfpicuity. It was, indeed, his peculiar talent to exprefs the ideas of other men to the greateft advantage. His language, chafte, clear, correct, and free from all affectation, is one of the beft fpecimens of that middle ftyle which is fitted for all topics, and he communicates to his reader all that clearnefs of idea which reigned in his own mind. Thefe qualities, together with the candour and moderation which made part of his very conftitution, efpecially fitted him for the office of literary criticifm, and he was long an affociate in one of the moft refpectable of the periodical journals." He died November 3d, 1797, in the 57th year of his age, generally beloved and lamented. In every relation of life, the benevolence of a kind heart difplayed itfelf in the moft engaging features. He publifhed "Sermons," "Family Prayers," and "The Preacher's Directory." His compilations, entitled "The Speaker," and "Exercifes in Elocution," are perhaps the moft popular works in our language, and they unqueftionably merit the patronage which they have had, and continue to have. After his death three volumes of his fermons were publifhed by fubfcription, and the numerous friends who patronized this work, will prove the attachment which he had infpired. Gen. Biog.

Enfield, in *Geography*, a town and parifh in the hundred of Edmonton, and county of Middlefex, England, is fituated nine miles from London, and contained, according to the late return to parliament, 926 houfes, inhabited by 5881 perfons.

It is ftyled in ancient records Enfen, or Infen, from its fenny foil, which is now, however, converted into good land, by draining, &c. The parifh is very extenfive, the town itfelf being but a fmall part of what bears the name of Enfield. The parifh church is an ancient ftructure, and has been recently repaired. Here are a good free fchool, and two meeting-houfes for diffenters. Part of an ancient royal palace ftill remains, where Edward VI. is faid to have refided, and where queen Elizabeth kept her court in the early part of her reign. One of the rooms appears in its original ftate, with oak pannels, and a richly ornamented ceiling: the chimney-piece is of admirable workmanfhip, and decorated with the arms of England and France quartered. The palace was alienated from the crown by Charles I. and has ever fince been private property. In 1670 it was taken by Mr. Uvedale, mafter of the grammar-fchool, who, being attached to botanical ftudies, planted in the garden a cedar of Libanus, which, in 1793, meafured twelve feet in girth, three from the ground. The town had formerly a good market, which is fallen into difufe. In the fuburbs are a number of boarding-fchools, and feveral elegant villas. Enfield was heretofore much celebrated for its *Chafe*, which comprized a large tract of woodland, well ftocked with deer; but during the civil war it was ftripped both of game and timber, and let out into fmall farms: after the reftoration it was again laid open, woods planted, and filled with deer. In 177, it was difafforefted by act of parliament; parcels were allotted to different parifhes, and the remainder fold. A part was bought by Dr. Jebb, who having fuccefsfully attended the duke of Gloucefter at Trent, the king, on conferring the dignity of baronet on him, gave the name of Trent-place to the villa which he had erected here. South Lodge, alfo on the chafe, was the favourite retirement of the late earl of Chatham. Eaft Lodge was the hunting feat of Charles I.

In this parifh, at a place called "Four-tree hill," or Forty-hill, the late Richard Gough, efq. had a feat, where

where he died, in February 1809. Some account of this eminent topographer and antiquary will be given in a subsequent part of this work. Lyson's Environs of London, vol. ii.

Enfield, a townſhip of America, in Hartford county, Connecticut, on the eaſt bank of Connecticut river, oppoſite to Suffield, and bounded on the north by the Maſſachuſett's line; ſettled in 1681. In 1769 it contained 214 Engliſh families. In the town are two congregational churches, and a meeting-houſe for the ſect called Shakers. The town is pleaſant, and contains 1761 inhabitants; 18 miles N. of Hartford.—Alſo, a townſhip in Grafton county, New Hampſhire, about 11 miles S.E. of Dartmouth college; incorporated in 1761, and containing 1121 inhabitants.

ENFILADE, a French term, ſometimes uſed in Engliſh, ſignifying a ſeries or continuation of ſeveral things, diſpoſed, as it were, in the ſame thread or line; as an enfilade of rooms, of doors, of buildings, &c.

The word is formed of the French verb, *enfiler*, to ſtring a thing, which is compounded of *en*, *in*, and *fil*, of *filum*, thread; *q. d.* a thread or ſtring of any thing.

Enfilade, in *Military Matters*, relates to a certain mode of acting upon the defenders of lines, redoubts, batteries, &c. thereby counteracting the impediments thrown in the way of a direct fire. To explain this, it is neceſſary to obſerve, that defences may be attacked in three modes; *viz. direct*, that is, by a reſponſive fire in front, or, at leaſt, ſo little obliqued as to come under the general acceptation of what the French engineers term *fiſhant*, or, plunging; this fire is commonly at right angles with the line of defence to be battered: when the fire is much obliqued, it is ſaid to be *razant*, or grazing. The ſecond mode of attack is by *reverſe;* that is, where the batteries of the beſiegers can be ſo directed as to command the interior of the rampart, and thus render it impoſſible for the defenders to remain at their guns. This mode generally relates to an angle of at leaſt fifteen degrees from the line of the defence in queſtion, but may extend to any angle up to 90°; remarking, however, that the more direct the fire may be in reverſe, the leſs execution will be done, becauſe the ſhot can only ſtrike one particular object. The third mode is by *enfilade*, and is always the moſt deſtructive, eſpecially if the guns of the enfilading battery can be brought to bear at a right angle with the direction of the battery to be enfiladed. When this cannot be effected, it is neceſſary to make a ſmall angle in reverſe, the leſs the better, thereby to throw the ſhots along the interior of the parapets, and to take the whole in flank. Some fortreſſes are unavoidably ſo ſituated as to have one, or perhaps two batteries expoſed to a very diſtant enfilade. Such a defect is of the utmoſt importance, and cannot be radically overcome; for we ſometimes ſee ſome hill, or what is worſe, ſome ſhifting ſand, which cannot poſſibly be either removed or occupied, but which affords both a command, and a lodgment in ſecurity from the fire of the place. Although this is aſſuredly an immenſe drawback on the ſtrength of the works, it is nevertheleſs in ſome ſituations of little moment; for inſtance, where it is neceſſay to retain a ſmall force for the purpoſe only of preventing an enemy from landing at the only acceſſible ſpot upon a long range of coaſt, preſenting in every other part ſuch natural obſtacles as annihilate all apprehenſions of invaſion. In ſuch place the ſurrounding eminences are of no moment; or if they were, muſt rather be conſidered as offering advantages, and the means of rendering the place untenable to the enemy, ſhould they ſucceed in carrying the works.

Speaking generally, however, a fortreſs that can be enfiladed with tolerable ſafety to the beſiegers muſt be untenable; becauſe it is impoſſible to deviſe effectual means for remedying the evil. It is true, we may raiſe large epaulements, or buttreſſes of ſoil, maſonry, &c. for the purpoſe of preventing the enemy's ſhot from ranging along the rampart; but, in moſt inſtances, where enfilades can be made, theſe epaulements would require to be carried to ſuch an immenſe height, as muſt, in a meaſure, deteriorate the other defences; in ſome inſtances rendering them nugatory, or even advantageous to the aſſailants, whenever they may be able to make a lodgment. Beſides, ſuch epaulements are very liable to be deſtroyed by mortar and howitzer batteries, or by mines. This mode of parrying the enfilade has, with much propriety, been of late years deſignated by the French engineers a *defilade*, a term peculiarly expreſſive of the intention of whatever devices may be uſed for the purpoſe of preventing defences from being enfiladed. It muſt not be forgot, that the approaches of beſiegers ſhould be carefully conſtructed; elſe they may be ſubjected to enfilade from ſome of the defences. That evil is, however, eaſily avoided; and if, through ignorance or inadvertence, found to take place, may be inſtantly corrected, as the beſiegers have, on almoſt all occaſions, ample range for alteration, and can adopt a variety of meaſures totally unattainable to thoſe within the fortreſs.

Where a work is carried over a riſing ground, it is generally very difficult to render the interior of the batteries ſafe from either reverſe or enfilade. The beſt mode is to carry them up the aſcent *en eſcalier*, that is, by ſhort levels, each perhaps capable of mounting four or five guns, and every ſuch level being cut off from its neighbour below, by a heavy epaulement, carried up high enough to prevent the beſiegers from trundling their ſhots along within the parapet. The moſt effectual method of cutting off enfilades is to give the rampart ſuch an augmentation of thickneſs as may allow a free paſſage for cannon, &c. along the rear of thoſe in the embraſures, and to fill up the ſpaces between the latter with *traverſes*, carried to at leaſt ten feet in height. Theſe traverſes are nothing more than regular maſſes of ſoil, properly turfed, or perhaps reveted with maſonry, placed at right angles with the parapet, and uniting therewith: their thickneſs ought not to be leſs than ten feet.

We muſt here obſerve, that with few exceptions, the enfilade commonly takes place from the exterior flank of the battery; therefore that quarter ſhould be chiefly attended to. With this view it is found moſt proper to conſtruct each traverſe partly of maſonry, and partly of ſoil well gazoned, (*i. e.* turfed) or, if on emergency, firmly retained by faſcines. Sometimes ſand bags will be found to anſwer for this part, when the reſidue of the thickneſs is completed with good maſonry, at leaſt four feet in ſubſtance. Where cotton, or wool, or raw hides, are procurable, they will be found to make admirable traverſes, if ſuſtained by a firm wall: theſe being placed neareſt to the enfilading quarter, will, by their elaſticity, completely deaden the force of the ſhot, however great their calibres, and cauſe them, if they ſhould reach ſo far, to be weak and inſignificant in their impreſſion upon the interior buttreſs of maſonry. It ſhould ſeem, to perſons unacquainted with the practice of defending places, that, in conſequence of the great reſiſtance offered by ſolid maſonry to cannon-ſhot, which will often bury themſelves full fifteen feet, or more, in ordinary ſoil, the traverſes ſhould be conſtructed of maſonry only: this would, no doubt, preſent great firmneſs in a contracted ſpace; but the inconceivable deſtruction and diſmay occaſioned by the ſplinters knocked off by ſhots that ſtrike upon bricks or ſtones, oppoſes an inſuperable bar to what would otherwiſe prove a moſt

moſt valuable mode of conſtruction; ſuch, indeed, as would render many places abſolutely impregnable. This compels us to reſort to ſuch materials as are, in a great meaſure, devoid of ſuch miſchiefs, of which turf is the beſt.

It is generally conſidered, that the enfilade is cut off by placing traverſes at from fifteen to twenty toiſes aſunder; but the latter diſtance, (equal to forty yards,) is certainly too great: it would even be adviſeable to bed the guns between traverſes, as we have above ſhewn, were it not that by ſo doing the battery muſt be weakened, owing to the ſpaces occupied by ſo many buttreſſes. However, neceſſity and, generally ſpeaking, locality, muſt give laws for the conſtruction of ſuch impediments to the enfilades. It muſt be underſtood, that the obnoxious battery may be very powerful; that is, it may not only mount heavy cannon, but may be far more numerous than might at firſt be ſuppoſed. To explain this, it muſt be ſtated that the moſt deſtructive enfilade is that which ranges along the interior of a battery, at about from two to ſix feet within the parapet; ſince in that direction it is ſure to deſtroy not only the defenders, but even the cannon, diſmounting them, and cruſhing the gunners, as well as cauſing a variety of ſplinters to ſcatter among them, from the ſeveral parts of the wood and iron work. Sometimes, indeed, when the ſhots touch upon the cannons themſelves, the former, being of caſt iron, and conſequently liable to ſhiver when forcibly ſtruck, break into numerous pieces, or even fracture the latter, ſo as to render them perfectly unſerviceable.

If ſhots were to be fired at ſuch an elevation as barely to graze the creſt, or ſummit, of the parapet, they would certainly prove moſt deſtructive to the defence flanked by ſuch a forcible fire; but this cannot be effected at ſhort diſtances, ſince, it is evident, the ſhots would, at the moment of touching the creſt of the parapet, be *aſcending*, and that too with ſuch force as could not fail to impel them far over every part of the fortreſs, and thus to prove completely unavailing. This mode of enfilade, therefore, commonly takes place where the cannon is not at leaſt on a level with the creſt of the parapet, ſo as to ſend its ſhot through it with ſufficient force to cut clean through, without being thrown upwards into a new direction, and thus to plunge into the more remote part of the defence. When the enfilade is more diſtantly ſituated, the ſhots may certainly be thrown over the parapet as they are *deſcending* upon their long range; but this is very uncertain, and rarely does much execution; to be ſure, when the ſhots can be correctly thrown, the havoc they create is dreadful.

The uſual mode of enfilading is by ricoçhet, that is, by giving the piece, whether mortar, howitzer, or cannon, ſuch an elevation, and ſuch a charge, as may cauſe the ſhot to bound firſt on the glacis, and then over the rampart into the battery. This, our readers will perceive, is exactly on the principle of "a three-quarter ball" at cricket; which, if it paſſes over the wicket, makes ſeveral low bounds, or, as they are technically termed, "lobs," in proceeding along their courſe, until they come to a ſtate of reſt. So does a cannon-ſhot, after bounding over a rampart, keep lobbing, rather more forcibly indeed than a cricket-ball, along the terre-pleine of the rampart. It will not be neceſſary to expatiate on the effects of this dreadful contrivance, they being ſo obvious, and ſo completely ſimilar to what is called "raking fore and aft," in naval warfare.

The moſt powerful ricoçhet takes place at an angle under ten degrees of elevation; fifteen degrees are the utmoſt that are allowed, both becauſe the effect produced is leſs when the elevation is encreaſed, and the gun-carriage is proportionably injured by the direction of the recoil deviating from the horizontal, ſo as to depreſs and ſtrain the hinder parts of the frame work; while, at the ſame time, the wheels are lifted in the fore part, and return to the ground with undue force. When mortars are uſed in ricoçhet firing, they are commonly charged with a number of ſhots, or of ſhells, forming in the whole, what we may term, a round of grape proportioned to the calibre of the piece. In batteries intended ſolely for ricoçhet firing, the embraſures ſhould have their ſuperior ſlope outwards, as ſeen at K in the plate; whereby the enemy could not fire into it ſo eaſily as if the embraſures were made in the uſual way: in fact, they could not diſtinguiſh them, as the whole would be nearly ſolid, much the ſame as a mortar-battery. Where infantry or cavalry are to be fired at in ricoçhet, the pieces muſt not be elevated more than three degrees, otherwiſe their greateſt effect would not be produced. Ships may likewiſe be acted upon by ricoçhet, if the ſhots are cauſed to ſtrike the water at a *depreſſed* (inſtead of an *elevated*) angle of about four degrees, ſo as to touch the ſurface at from two hundred to two hundred and fifty yards from the battery. But this applies only to particular caſes; for if the veſſel be remote, or that any object is to be fired over, the ſame angle of elevation may be uſed, taking care ſo to proportion the charge, that the ſhot may light upon the water at about two hundred yards from the veſſel, if ſhe be large; but if ſmall, the ſhot muſt light nearer to her, in proportion to her want of bulk.

It was neceſſary to ſay thus much of ricoçhet firing, in order to give a complete inſight into the manner of enfilading, by means of ſmall charges of powder. The reader will likewiſe perceive that ſeveral guns may enfilade the ſame battery, in exactly the ſame line, merely by cauſing them to be removed farther from the object of attack, the one behind the other, only taking care that the parapet before each be ſufficiently ſubſtantial to prevent accident to the other batteries in its front, and cauſing the more remote to charge higher, in order that their ſhot may be thrown ſufficiently far to make the firſt bound in a proper manner, over the epaulement of the defence to be enfiladed. We ſhould obſerve that the mode of enfilading before-mentioned, namely, by grazing directly over the creſt of the parapet, may be extended to remote works; but unleſs they are manned for action little damage will be done, as the beſieged will rarely fail to *houſe* their cannon, by pointing them towards the enfilading-battery; ſo that they may be far leſs expoſed than when ſtanding in their proper directions.

We ſhall annex to this article, which we have dwelt upon in deference to its importance in military affairs, a few general principles. 1ſt. That the deſcending enfilade is the moſt deſtructive in long ranges. 2dly. That the ricoçhet-enfilade is peculiarly adapted to ſhort diſtances. 3dly. That the angle ſhould, if practicable, be kept under ten degrees of elevation; the greater effect being generally in proportion to the leſs deviation from the horizontal direction. 4thly. That the more direct the fire may be along the line, or defence, to be enfiladed, the greater will be the damage done thereto, provided it be within ſuch a parallel with the parapet as may ſubject both the cannon and the gunners to its range. 5thly. That if any angle is to be made with the line to be enfiladed, a few degrees in reverſe are better than even half their number in advance; becauſe, though the former may not ſtrike any object in its original courſe, the ſhots may, after having grazed againſt the interior of the parapet, *genouillere*, &c. ſtill do conſiderable damage; and, even though they ſhould not either diſmount a cannon, or kill any of the men on the battery, they muſt tear the garon-revetement far more than one of maſonry, which is oftener put exteriorly, though not within: the latter would turn the ſhots off,

off, in all probability, and caufe them to have only the effect of a weak fire *razant*. 6thly. It will be neceffary to afcertain the thicknefs of the parapet behind which the enfilading fhots are to trundle: in common fortifications it may fuffice to compute, as nearly as may be practicable, upon about four toifes, (or eight yards,) from the extremity of the fuperior flope of the angle; but in places where the parapets are made of mafonry, lefs will commonly be neceffary, for the purpofe of ftriking fomewhere upon the line of platforms, and of thereby difmounting the cannon. 7thly. Where howitzers are ufed for the enfilade, the traverfes muft be very numerous, to prevent the pieces of burften fhells from fpreading to any extent. But, in fuch cafe, the traverfes will not require fo much folidity, as if oppofed to heavy fhots. 8thly. Where a remote battery is to be enfiladed, efpecially if the enfilade be direct, that is, in a line with the prolongation of fuch battery, great care muft be taken to be exact in afcertaining its diftance from that part of the defences which may be neareft to the enfilading party. This may, in general, be done, with precifion, by means of two long ladders placed face to face, and elevated during the night, fo as to give a command of the works then in a ftate of actual oppofition; when the flafhes from their cannon will prove a fufficient guide. This may, however, be done with more precifion during the day time, though certainly with more danger; but the operation being certain and fpeedy, compenfates for the rifk. The enfilade on fuch occafion muft not be by ricoçhet, but by defcent. Thofe who are in front of the enfiladed battery, or nearly fo, will fee the effects of the fhots, and can, by means of pre-concerted fignals, give information accordingly to the enfiladers.

The following references to the figures in *Plate* III. *Fortification, fig.* 1, will explain more fully what has been faid.

Let A B be the face of a baftion, whofe faliant or flanked angle, B, is battered in breach from C C. In fuch cafe, the befieged muft make a very ftrong epaulement from B to P, on the adjoining face, to prevent the fhots from the enfilading battery at D trundling upon the terre-pleine of the face A B; in aid of this refiftance, the traverfes, S, S, S, muft likewife be thrown up. The battery at D being a direct enfilade, that is, in the line of the face A B, is highly deftructive; while that at E, which is only 15° in reverfe, is far lefs fo. It is indeed evident, that one cannon at D would be more effectual than two at E; unlefs the fhots from the latter fhould be thrown in fo as to fall upon the neareft part of the interior of the parapet, as has been already implied: they would then be capable of tearing away the interior of the merlons, and of caufing great numbers of fplinters, &c. The battery at F is a direct-enfilade of the face of the remote baftion H; but its fire muft not be in ricoçhet, (as that could never reach its object,) but by defcent. At I, an enfilading battery is fhewn in profile, the cannon being funk, and the embrafure, K, having an inverted flope, covering the cannon from the fire of the battery at L. This flope being only 10°, admits the fhots from the cannon to afcend, by means of a fmall charge, in a curve meeting the ground at N; thence reafcending over the face L, (correfponding with B P in the upper figure,) fo as to light again at O, upon the terre-pleine of the face M, (here feen in reverfe, and correfponding with the interior of A B in the upper figure;) whence it will again rife, and, if unimpeded, bound on in fucceffively diminifhing curves, until its force be expended. The dotted line, from the cannon I to O, on the baftion M, fhews the direct or plunging enfilade by defcent, which is beft adapted to cannon of a fmaller calibre; the force of the fhot being, in this inftance, unabated by any bound; as muft be the cafe in ricoçhet, wherein, by ftriking at N, the impetus is confiderably diminifhed. This diminution will be greater, in proportion as the elevation of the cannon is increafed. As already ftated, the enfilade of H from F will be of little moment, unlefs the battery at H be in action; but, as the obliquity of the embrafures may enable the enfiladers at F to act either in ricoçhet, or by defcent into the reverfe of A C, or even of A B, there might be confiderable advantage gained by fuch a pofition. It is proper to ftate, that this does not appear to be generally practicable; as the diftance from C C, (the main breaching batteries,) to F muft render the latter rather infecure, and expofe it both to the batteries of the place, and to the fallies of the garrifon: it is therefore given merely as an illuftration of the terms ufed in the explanation of all that relates to enfilade. When fhipping, or craft of any defcription, lie behind a mole, fo as to be fecure from the direct fire of any battery, the ricoçhet-enfilade may be adopted, either by elevation, as fhewn above; or by depreffion, as from the cannon at P directed downwards to Q; whence the fhots will bound over the mole R, and fall among the veffels behind it. This is occafionally done to deftroy veffels in a harbour, or to enfilade fuch as may be actively employed in any attack; and thus to force them to a change of pofition, rather than fuffer themfelves to be raked fore and aft with hot balls.

ENFILED, in *Heraldry*, is applied to a fword, on which is placed the head of a man or beaft, or any other charge.

ENFRANCHISEMENT, the incorporating any man into a fociety or body politic. See FREEDOM and FRANCHISE.

Thus, he that by charter is made denizen of England, is faid to be enfranchifed. The like is underftood of a perfon made a citizen of London, or other city or corporate town; becaufe he is thereby made partaker of the liberties appertaining to the corporation whereof he is enfranchifed.

EN FRAPPANT, *Fr.*, in *Mufic*, a term applied, in beating time, to the firft note of a bar.

ENGADINE, in *Geography*, one of the higheft vallies of Switzerland, in the canton of the Grifons. It is divided into the Upper and Lower Engadine. St. Martin's bridge on the river Inn feparates the Lower Engadine from the Tyrol. The towns of this valley are lefs agreeable than thofe of the upper one; but the foil is uncommonly productive. In fome places the roads are narrow and rocky, and nature difplays its wildeft fcenes. The river Inn is often compreffed in a narrow deep channel: there are, however, a few fine plains, where fruits come fooner to maturity than in the Upper Engadine, from which it is divided by the Pont Alta. The fituation of the upper valley is much higher; it has very long winters, and the air is generally cold. In the midft of fummer, night frofts nip the corn and fruits. The towns are agreeably fituated, and moftly handfome, built of free-ftone, and painted white; even the barns are fine buildings. The river Inn flows flowly in a larger bed; there are feveral beautiful bridges of a fingle arch thrown over it. Near the pretty town of Schoulz are fourteen fprings of mineral water of different qualities. There are feveral manufactures, chiefly iron works and founderies, in the Engadine, which give employment to a great number of its inhabitants, and an appearance of chearfulnefs and comfort to their habitations.

ENGAGE, *To*, when applied to *Military* or *Naval Affairs*, means to attack. Perhaps no circumftance incident to warfare requires more precaution, or indeed more judgment,

judgment, than that relating to the giving battle to an enemy. The general, or commander of any defcription, who neglects to provide againft thofe checks which arife, often when leaft expected, or for following up any advantage he may gain, efpecially if it be within the limits of his anticipations, muft be totally unqualified for fo refponfible and fo important a fituation. We fpeak principally of proceedings in the field, where many alterations and much diverfity may be perpetually offering; for we confider the manner in which battles on the ocean generally proceed, and in which they almoft invariably terminate, to be fo pre-eminent as to leave us only the opportunity of defcribing them, (as we fhall do under the head of ENGAGEMENT,) and to debar us, unlefs indeed we wifhed to incur the charge of prefumption, from ftating when or how fingle fhips or fleets fhould engage the enemy.

In the firft inftance, it will be abfolutely neceffary for the commander of an army to know, with precifion, the ftates of health, of difcipline, of fatigue, of fupply, and of competency in general, of every corps compofing his army. He muft be thoroughly informed as to the condition and numbers of his cattle, of the amount of his provifions, and of the manner in which the feveral corps, the cattle, and the fupplies, are diftributed along his line. He muft have a thorough knowledge of the numbers, the difpofition, the fupplies, and the probable refources, of the forces oppofed to him; as well as of the nature of their warfare, their general habits, the ftrong pofts in their rear, the opportunities they may have of forming ambufcades, or of retreating to advantage; and efpecially whether, in cafe of fuccefs, he may be able to avail himfelf of thofe invaluable opportunities which the valour and difcipline of his troops may offer to his acceptance.

However confident a general may be of fuccefs, he muft never lofe fight of the poffibility of a reverfe: in truth, it is moft generally found, that where the beft preparations are made againft difafter, the moft decided victories are obtained. This is natural, both becaufe the whole of a line feel infpirited by the reflection, that due provifion is made for the worft; and becaufe, where fuch arrangements are carefully preconcerted, the appropriate remedy is prompt for application, and the enemy are rendered unable to continue in that line of fucceffes, which, but for fuch apt oppofition to their momentary or local advantages, muft inevitably be at their command.

Whenever we obferve that a commander courts the opinions of thofe whofe rank and experience may qualify them to offer advice, we may confider it a moft fortunate omen. The immortal Nelfon always difclofed his plans, and opened his mind fully, to the admirals and captains under his command: he folicited the correction of whatever errors might have crept into his projects, and was eagerly anxious that all fhould have a competent underftanding of his intentions. This ought ever to be the ftudy of a commander; elfe, fhould he fall, or fhould unforefeen accidents occur in any part of his line, his fucceffor, as well as his fubordinates, muft be totally at a lofs either to continue victorious, or to arreft the progrefs of the enemy.

But perhaps the moft effential point may be for a commander to afcertain how far his troops are well difpofed to the caufe; whether they proceed to engage with alacrity and zeal; and whether they have an entire confidence in the courage and abilities of their leaders. This part of the fubject is fometimes overlooked, until it is too late to be remedied; and the moment of engaging is the moment of treafon, or of cowardice. It is true, the Britifh army may claim an exemption from thefe ungovernable mifchiefs; but no commander fhould be indifferent to matters which are within the fcope of poffibility, and which may often be avoided by a little courtefy, or by fome well directed policy. We fhould confider, that in our time the moft unforefeen events are daily brought forth; that the opinions of perfons inimical to the welfare of the ftate are every day promulgated; and that, within thefe very few years, even a field officer of our army endeavoured to miflead thofe guards, who are exclufively appointed to protect his majefty's facred and moft valuable life. Fortunately for Britain,

> "Such divinity doth hedge our king,
> That Treafon dared but peep at what it would!"

Therefore we may ever hope that the difpofition of our foldiery will remain unfhaken; and that we may find them, as they ever have been, bold, active, and obedient in the field, and ready on all occafions to engage in fupport of our king, and our conftitution.

It may be proper to add, that too much ardour to engage may exift in an army: this is affuredly dangerous. There is a certain eftablifhed coolnefs in veteran regiments, refulting from the prefence of perhaps only a fmall portion of veterans among them, which is highly conducive to the character and to the prowefs of the corps at large. Such regiments are admirably calculated for refiftance; while new levies are generally more fuited to the charge, and to thofe tremendous conflicts which fpeedily terminate the ftruggle in their quarter. In truth, we are well affured from the moft refpectable authorities, as well as from the numerous facts which proudly and pre-eminently offer themfelves to our notice, that nothing can refift the attack of our new regiments; while, on the other hand, nothing can fubdue the firmnefs and patience of our old ones.

ENGAGEMENT, in the *Military Profeffion*, relates to fuch conflicts as take place between bodies of armed men, generally regular troops, and efpecially to that kind of warfare which is carried on between armies of fome magnitude, in contradiftinction to thofe lefs extenfive contefts, which ordinarily are confidered as fkirmifhes. Engagements may be either partial or general; in the latter cafe, they are commonly attended with marked and decided confequences; whereas, in the former inftance, little or no difference may be made in the pofitions of the contending powers. We generally find, that, according to the modern mode of warfare, great ingenuity and cunning are exerted, for the purpofe of deceiving the adverfary into an opinion of a general attack. This is done with the intention of preventing reinforcements being fent from any part, the whole being kept in action, while the main attack is made on fome point, either naturally weak, or by gaining which the fortune of the day may be determined in favour of the affailants. This, although it bears the appearance of a general engagement, is in fact but a partial affault; the greater portion of the conteft falling upon a few regiments, which, unlefs properly fupported, are commonly fwept away: to fay the leaft, they muft fuffer very confiderably.

Previous to engaging the enemy, every attention muft be paid to fecuring a retreat, in cafe of a check. This precaution is indifpenfable in all ordinary inftances; though, in fome fituations, it may be found the beft policy to deftroy the means of evafion, under the intention of convincing the army that it has only the alternatives of victory or death. Thus, when Cæfar landed in Britain, he deftroyed the fleet which had brought him to our fhores; a meafure which, in thofe times, compelled the invaders to fight to the laft. They knew they had to contend with an enemy, from whom

whom no quarter was to be expected; therefore, like rebels, they ftruggled for life; they fought virtually with halters around their necks; and, thus rendered defperate, contended with fuch favage, fuch unrelenting fury, as neceffarily caufed the engagement to be fanguinary to an extreme.

Engagements are of two kinds; namely, either in the field, where the oppofing parties are both divefted of the protection of fortifications of any defcription, fuch as we ordinarily find to take place in open countries; the other confifting of that mixed kind of warfare, which comprifes the attack and defence of *abbaties*, the croffing of rivers in the face of an enemy, and, on many occafions, the attacks made upon open towns, &c. With refpect to thofe engagements which are connected with the ftorming of lines, or of fortifications of any defcription, we confider fuch to appertain to that protracted fyftem included under the head of *fiege*, which fee; and the attacks upon fuch to be, not engagements, but affaults.

It is fcarcely to be credited upon what very flight incidents the fate of an engagement may depend! Circumftances, which, if confidered in the cabinet, fhould appear to be akin to impoffibility, arife unexpectedly, and change the face of affairs inftantaneoufly. Hence, during the moment of conteft, a commander fhould be intent on obviating thofe mifchiefs which muft refult from the falling back, or the failure, of any part of his army. He muft carry in mind, and perhaps might advantageoufly delineate on a card, the great outline of the engagement; ftudying to choofe fuch a pofition as may give him a general view of the field, but moft efpecially of fuch portions as may either appear to him either weak, *ab origine*, or to be hard preffed by the enemy.

To defcribe an engagement is next to impoffible; for though we might perhaps afford fome general idea of the incidents ufually occurring during a battle, fuch is the diverfity to be found in the localities, as well as in the fyftems of warfare adopted even by perfons in the fame fervice, that to enter upon the inveftigation of the fubject in all its bearings, and throughout its amplifications, would be to comprife a volume of no fmall magnitude. We muft, therefore, content ourfelves with obferving, that the ordinary difpofition for an engagement, where no particular *point d'appui* is in queftion, confifts of two or more lines, compofed chiefly of infantry, properly fupported by artillery of various natures, that is to fay, of brafs 18 pounders, alfo of 12, 9, 6, and 3 pounders, with a portion of howitzers, commonly of $4\frac{1}{2}$, or $5\frac{3}{4}$ inches diameter in the bore, or eventually up to 8 inches. Thefe are placed in the intervals between the feveral regiments, while one or more parks of artillery are arranged in fuch parts of the feveral lines, as may appear to require that powerful aid; or on fuch commanding fpots as may enable the artillerifts to act with greater effect againft the enemy. See TACTICS, *Military*.

Where the ground may admit, the cavalry often commences the action, by endeavouring to prevent the enemy from forming upon, or taking poffeffion of, ftrong pofitions. The horfe artillery, together with the pieces of lighter conftruction which can be fpeedily withdrawn, advance to cannonade; while the infantry may be deploying from column into line, or forming according to the inftructions of the generals commanding in the feveral quarters of the army; to whom the commander in chief previoufly communicates his intentions. During this time, the greateft order, coolnefs, and promptnefs, are indifpenfably neceffary: it is now that fuperior difcipline will manifeft itfelf, and that the real powers of an army will be afcertained. Let it not, however, be fuppofed, that that kind of fymmetrical order which is the boaft of our parade martinets, is to be found in the field of battle! Far otherwife; in lieu of regular firings by divifions, each individual loads and difcharges his piece when, and how he can; in place of a regulated pace conforming to any particular cadence, the advances and retreats are generally too much divefted of that order, and of that fyftematic uniformity, which fo highly delight the fair fex when they vifit our fummer camps, to witnefs the fplendid array attendant upon parade evolutions. In fhort, the celebrated fong in the "Recruiting Serjeant" is the beft, and moft pithy defcription of an engagement we have ever heard, efpecially that part which relates to the moft arduous portions of the conteft.

"But the merrieft joke of all,
Is when to clofe attack we fall.
Killing, wounding, maiming, butting,
Dafhing, flafhing, flaying, cutting:
Horfe and foot,
Both go to't;
Blood and thunder!
Then to plunder,
Oh! what a charming thing's a battle!"

A very charming thing, indeed; efpecially when we confider that many of the wounded are often murdered by perfons, chiefly women, who follow the feveral armies, for the purpofe of plundering fuch unfortunate brave men as may be incapable of making refiftance. It is, indeed, a well-known fact, that this iniquitous and difgraceful practice, is more than ever prevalent in many countries, whofe inhabitants, being at leaft on a par with thofe of the moft enlightened parts of the world, fhould rather endeavour to foften the rigours of war, than to perpetrate the moft favage cruelties on thofe whofe misfortune it may be to be difabled in the courfe of an engagement.

Thefe fluctuations between victory and defeat, which fometimes alternate for hours together between contending armies, muft afford the moft lively intereft to a fpectator, and cannot fail to produce the moft exquifite fenfations of joy, or of mifery, in the breafts of the refpective commanders. What can afford a greater gratification than the complete fuccefs of an army? or what can occafion more pointed chagrin than the evidence of its defeat? Perhaps, of all the men who ever experienced fuch reverfes, the old king of Pruffia may be confidered as the moft illuftrious inftance of fortitude under difafter, and of moderation when fuccefsful. Thefe good qualities, though they may have been coeval with his birth, muft neceffarily have been confiderably enhanced, by that intenfe application the monarch paid to the difcipline of his army. Hence, we are informed, that no reverfe appeared to him irremediable, and that no victory was confidered by him to be permanent. Such a man muft have viewed an engagement under very peculiar impreffions: he muft have been moft ardently intent upon the confideration of what evolutions would be moft fuited to the events paffing under his notice; while at the fame moment, his mind muft have been actively employed in the confideration of refources, wherewith he might, according to the modern cant term, "carry on the war." We muft, however, remark, that the great Frederick rarely had a large army; but that which he had, though comparatively fmall, was of immenfe ftrength: every part was fyftematically organized under the moft fevere code of difcipline, and under the moft penetrating obfervation. We have heard old officers ftate, that the Pruffian army, under their immortal royal general, performed its evolutions, and preferved

6 the

the fame order, and went through their firings, as regularly while in action as when on their feveral parades. We fear this fingular inftance of military confiftency, is not likely to be again difplayed by the Pruffian army at this date; nor, indeed, have we any authority, if paft events are to guide us, for expecting to fee, or hear, that they fhould throughout an engagement difplay thofe qualities which, however much we may commiferate the fufferings of thofe individuals whereof it was compofed, characterized the military eftablifhment of that now ill-fated country! We leave to our readers to contemplate what muft be the feelings of the brave marfhal Mollendorff, who, we believe, is the only furviving general now of the many that held commands under that military prince, whofe exiftence in thefe times would, no doubt, have given a very different afpect to the affairs of Europe.

Engagement, in a *Naval Senfe*, denotes a particular or general battle at fea, or an action of hoftility between fingle fhips, or detachments, or fquadrons of men of war: the whole economy of which may be arranged under the heads of preparation, action, and repair. The preparation is begun by iffuing the order to clear the fhip for action, which is repeated by the boatfwain and his mates at all the hatchways. The hammocks are firft removed; every failor ftowing his own bedding properly and firmly cording it with a lafhing, or line provided for that purpofe: as each fide of the quarter deck and poop is furnifhed with a double network, fupported by iron cranes fixed immediately above the gunnel or top of the fhip's fide; the hammocks, thus corded, are firmly ftowed by the quarter-mafter between the two parts of the netting, fo as to form an excellent barrier or fort of parapet, to prevent the execution of fmall fhot on the quarter-deck: the tops, waifte, and fore-caftle, are fenced in the fame manner.

At this time all heavy luggage, fuch as chefts, &c. are handed down into the hold, and the furgeon, with his mates and affiftants, together with whatever women may be on board, defcend into a part called the cock-pit; which, being below the level of the water, is confidered to be tolerably fecure; various inftances have, however, been known of fhots, between wind and water, finding their way to that retirement.

At the fame time the boatfwain and his mates are employed in fecuring the fail-yards, to prevent them from tumbling down when the fhip is cannonaded, whereby it might be difabled. The yards are fecured by ftrong chains or ropes, befides thofe by which they are ufually fufpended. The boatfwain alfo provides the neceffary materials for repairing the rigging; and the carpenter and his crew prepare fhot-plugs and mauls to clofe up any breach that may be made near the furface of the water, and provide their ironworks neceffary to refit the chain-pumps. The gunner, with his mates and quarter-gunners, examine the cannon of the different batteries, and provide proper charges, &c. The mafter and his mates attend to the number and trimming of the fails, &c. The lieutenants vifit the different decks, taking care that all incumbranees are removed, and giving inftructions to the other officers, that every thing may be ready for the expected engagement at a moment's warning. When the hoftile fhips have approached each other to a competent diftance, the drums beat to arms: the boatfwain and his mates pipe "all hands to quarters!" at every hatch-way. The perfons appointed to manage the great guns immediately repair to their refpective ftations; crows, hand-fpikes, rammers, fpunges, powder-horns, matches, and train-tackles are placed in order by the fide of every cannon. The hatches are laid to prevent any one from efcaping into the lower apartments. The marines are drawn up in rank and file, on the quarter-deck, poop, and forecaftle. The lafhings of the great guns are let loofe, and the tompions withdrawn: the whole artillery, above and below, is run out at the ports, and levelled to the point-blank range ready for firing. When the neceffary preparations are finifhed, the commencement of the action is determined by the mutual diftance and fituation of the adverfe fhips, or by the fignal from the commander in chief of the fleet or fquadron. The cannon being levelled in parallel rows, projecting from the fhip's fide, the moft natural order of battle is evidently to range the fhips a-breaft of each other, efpecially if the engagement is general. The moft convenient diftance is probably within the point-blank range of a mufket, fo that all the artillery may do effectual execution. The combat ufually begins by a vigorous cannonade, accompanied with the united efforts of all the fwivel-guns and fmall arms. Inftead of firing platoons, or vollies of cannon at once, the general rule throughout the fhip on thefe occafions is to load, fpunge, and fire the guns with all poffible expedition, yet without confufion or precipitation. The captain of each gun is enjoined to fire only when the piece is properly directed to its object. The lieutenants who command the different batteries traverfe the deck, to fee that the battle is profecuted with vigour, and to animate the men in their duty. The midfhipmen fecond thefe injunctions, and give affiftance where it is required at the guns committed to their charge. The gunner takes care that the artillery is fupplied with powder, and that the cartridges are conveyed along the decks in covered boxes.

During the action, the captain manœuvres his fhip to the beft advantage; caufing the mafter fo to lay her on the enemies' bows, or quarters, and efpecially under her ftern, as may give thofe favourable refults attendant upon a fafe, but annoying, pofition. Should any intervals arife, owing to the fituations of the feveral fhips, it is employed in clearing the decks, in repairing the damaged rigging, and in providing for a renewal of the engagement. If, as very often happens, the enemy make fail with the view to efcape, the guns are fecured, while all hands turn to for the purpofe of giving chafe: in this inftance, the great object is to come up with the flying foe; therefore all thefe fails which were furled or clued up, with the intention of either having lefs to manage, or to keep them free from danger, are now fpread to the gale, and every effort is made to regain a pofition within fuch a diftance as may caufe the enemy to ftrike his flag, and to furrender. Should he ftill perfift, the engagement muft continue, until, being a complete wreck, he may confider further oppofition ufelefs. So foon as he has ftruck, his fhip is taken poffeffion of by a detachment from the victor's crew, and the whole of the fubdued party are put under hatches in the hold, or, if neceffary, are otherwife fecured in the bilboes, &c. while a prize mafter, generally a lieutenant, is put on board, for the purpofe of navigating the prize, according to fuch orders as he may receive.

It fometimes happens, that, where an enemy is very determined, it is neceffary to board; indeed, this not unfrequently occurs, owing to veffels adventitioufly coming in contact. Previous to the adoption of this defperate meafure, it will be abfolutely neceffary to confider well how far it may be likely to fucceed. If the oppofing crew be numerous, and efpecially if abounding in marines, or if there be any number of military on board, much management, activity, and refolution will be required to carry the point; which is generally effected by laying along the lee waift or quarter, or perhaps upon the bow, and, after having grappled,

grappled, by means of chains, or of fmall boarding grapnails fufpended by chains from the yards, to lower down the boarding platforms, (if there be any,) and thus to rufh upon the enemy's deck. In fome inftances, fhips have been boarded by entering at the ports, ftern, or quarter gallery, &c. either of which modes will often fucceed, where the whole of the oppofing crew rufh with too much precipitation, to the upper works, with the intention of refifting thofe who are about to board upon the deck. The bowfprit is frequently reforted to, as the means of entering an enemy's fhip: this, being laid over the ftern, or tafrail, will generally enable the boarders to proceed with fufficient facility, while the marines are employed in keeping up a fharp fire, to drive the defenders off the poop. It is, however, a very hazardous concern, and chiefly reforted to on defperate occafions, by privateers, or where, though ftrong in point of crew, a veffel may not be of fufficient force to lie alongfide her opponent. A repulfe in boarding is peculiarly dangerous, and very commonly leads to defeat. It almoft invariably happens, that, on fuch occafions, great numbers of the boarders are deftroyed; whereby the refidue of the fhip's company are confiderably difpirited; at leaft, this is an ordinary refult among foreigners; Britifh tars are not fo eafily daunted, but may be again, and again, led to the attack.

When the engagement is concluded, they begin the repair. The cannon are fecured by their breachings and tackles; the fails that have been rendered unferviceable, are unbent; and the wounded mafts and yards ftruck upon the deck, and fifhed or replaced by others. The ftanding rigging is knotted, and the running rigging fpliced wherever this is neceffary. Proper fails are bent in the room of thofe that are become ufelefs. The carpenter and his crew repair breaches in the fhip's hull by fhot-plugs, pieces of plank, and fheet-lead. The gunner and his affiftants replenifh the allotted number of charged cartridges, and refit the damaged furniture of the cannon.

When two fleets or fquadrons are preparing for engagement, it will be the endeavour of the admiral or commander in chief to come to action as foon as poffible. To facilitate the execution of the admiral's orders, the whole fleet is ranged into three fquadrons; each of which is claffed into three divifions, under the command of different officers. Before the action begins, the adverfe fleets are commonly drawn up in two lines parallel to each other, and clofe-hauled. When the admiral difplays the fignal for the line of battle, the feveral divifions feparate from the colours in which they were difpofed according to the ufual order of failing, and every fhip crowds into its ftation in the wake of the next a-head, at the diftance generally of about fifty fathom; which diftance is regularly obferved from the van to the rear: though the admiral may fometimes find it neceffary to contract or extend his line, according to the length of that of his adverfary; always taking care that his own line be fecure from being doubled, which might throw his van and rear into confufion. When the reverfe fleets approach each other, the courfes are commonly hauled up in the brails, and the top-gallant fails and ftay-fails, furled; the frigates, tenders, and fire-fhips, being hauled upon the wind; lie at fome diftance behind the line of battle; and tranfports and ftore fhips lie beyond thefe, at a ftill greater diftance from the fcene of action; and if the number of fhips allows it, a body of referve from the different fquadrons is felected to cover the fire-fhips, &c. and ftationed oppofite to the weakeft parts of the line, fo that they may readily fall into the line in cafe of neceffity. Each fhip forming the line fhould keep clofe to its ftation during the engagement; the affault of boarding being feldom permitted unlefs in fingle action: becaufe the regularity of a clofe line conftitutes the principal force of the fleet; and the fkill of the admiral is greatly concerned in keeping his line, notwithftanding unequal attacks and damage, as complete as poffible. If he proves victorious, he fhould profecute his victory as much as poffible, by feizing, burning, or deftroying the enemies' fhips. If he is defeated and reduced to the neceffity of retreating, he may judge it expedient, for greater fecurity, to range his fleet into the form of a half-moon, placing himfelf in the centre. The enemies' fhips that attempt to fall upon his rear will thus be expofed to the fire of the admiral and his feconds, and the efcape of his own fhips will be facilitated, whilft the purfuit of his averfary is retarded. Upon the whole, the real force of fuperiority of a fleet, confifts lefs in the number of veffels and the vivacity of the action, than in good order, dexterity in working the fhips, prefence of mind, and fkilful conduct in the admiral and captains. Falconer's Marine Dict. art. *Engagement.*

There formerly exifted certain fuppofed axioms, in regard to the feveral modes of forming in line of battle a-head, or a-breaft; and much attention was paid to the weather gage, as well as to other fuch matters: fleets ufed then to manœuvre for feveral days, obvioufly intent upon gaining fome particular pofition, which was fuppofed to be indifpenfably neceffary towards a fuccefsful iffue. Of late years this has been totally, or at leaft very generally neglected; for in lieu of fleets, or fingle fhips, now dancing minuets for fuch a purpofe, we fee them ranging up with little ceremony, and intent only on getting into action; whatever may be the ftate of the wind or of the weather. All that a Britifh commander requires of his mafter, nowadays, is, "Lay me alongfide the enemy;" a few guns more or lefs, or even an extra deck, on the part of the enemy, being difregarded. It is to this fpirit, that our fhores are indebted for fafety, and our commerce to that wide range afforded by the univerfal command which Britain holds over the ocean. It is with the utmoft pride and fatisfaction, we witnefs the glorious exertions of our invincible tars: for fuch we may fairly defignate men who, regardlefs of every danger, and urged by the moft patriotic zeal, bear away the palm when, and wherever the enemy, however fuperior in guns, or in numbers, give them the opportunity of difplaying that valour which, though uncontroulable in oppofing a foe, is rapidly metamorphofed into humanity, fo foon as the victory may be proclaimed, or that the voice of diftrefs may be heard! Surely we never can fufficiently reward thofe heroes who, as Hudibras fays, ftand forward—

"To fight our battles in our fteads,
And have their brains beat out o' their heads;
Encounter in defpite of nature,
And fight at once with fire and water,
With pirates, rocks, and ftorms, and feas."

A naval engagement is a branch of warfare in which the Britifh character appears to the utmoft advantage, and in which we ftand confeffedly pre-eminent over the whole univerfe. We derive the more fatisfaction, from the reflection, that our credit and prowefs are not ephemeral, nor dependant upon any temporary weaknefs on the part of our opponents; we contemplate them as heir-looms, bequeathed to us from a noble and brave anceftry, whofe examples have been duly followed, and whofe reputation has, no doubt, contributed to that zeal, and to that emulation, which pervade every part of the Britifh navy, and induce our tars to perfevere in their ftruggles for the prefervation of our rights and liberties as a people; while, at the fame time, each individual aims to uphold his own character for bravery, fubordination, and generofity. See BATTLE, BOARDING, LINE *of Battle*, and SIGNAL.

ENGAGEMENT, in *Englifh Hiftory*, was the obligation impofed by Oliver Cromwell required to be figned by every member of the Firft Parliament in 1654, affembled by his authority, after he was declared Protector, *viz.* "I *A.B.* do hereby freely promife and engage myfelf to be true and faithful to the Lord Protector, and to the commonwealth of England, Scotland, and Ireland, and fhall not (according to the tenure of the indenture whereby I am returned to ferve in this prefent parliament) propofe or give any confent to alter the government, as it is fettled in one fingle perfon and a parliament." Many, who refufed to fign this engagement, were excluded from the houfe.

ENGALLA, in *Zoology*, the Ethiopian hog or African wild boar. See SUS *Æthiopicus*.

ENGALLIM, in *Ancient Geography*, a town of Judea, in the tribe of Benjamin, fituated on the coaft of the Dead fea, where, according to St. Jerom, the river Jordan difcharged itfelf into that fea.

ENGAMOS, in *Natural Hiftory*, the name given by the people of fome parts of Guinea to a root very common there, and much refembling our larger fort of turnips, but not fo fweet or juicy. They commonly boil thefe with their battatas, in the fame kettle with their meat. The latter of thefe roots, which is confiderably different from our potatoe, gives a fine flavour to the whole, and makes the broth and meat tafte as if rofe-water were added to it. The engamos alfo partakes of the flavour, and in this cafe becomes very agreeable. Phil. Tranf. N° 108.

ENGANNIM, in *Ancient Geography*, a city in the plain belonging to Judah, Jofh. xv. 34.—Alfo, a city of Iffachar; given to the Levites of Gerfhon's family. Jofh. xix. 21. xx. 29.

ENGANNO, or DECEIT *Ifland*, in *Geography*, an ifland in the Eaftern fea, at a fmall diftance from the S. W. coaft of the ifland of Sumatra. S. lat. 5° 9'. E. long. 102° 44'.

Ships that pafs the ftraits of Sunda, in the wefterly monfoon, generally run in fight of Enganno. This ifland is 6 or 7 leagues in length, and not quite half as broad. It is not high, and can only be difcerned at the diftance of 5 leagues. It is covered with trees, and always appears green. For a more particular account of this ifland, fee Phil. Tranf. for 1778.

ENGANO, CAPE, a cape on the eaft coaft of the ifland of St. Domingo, N. lat. 18° 27'. W. long. 68° 52'.

ENGANO, or ENGANNO, *Cape*, the N. E. point of the ifland of Luçon, in the Eaft Indian fea. N. lat. 17° 45'. E. long. 121° 20'.

ENGASTRIMANTES, Εγγαστριμαντεις, in *Antiquity*, called alfo *Engaftrimythi*, Εγγαστριμυθοι, a defignation given to fuch diviners as were poffeffed with dæmons, which either lodged or fpoke within their bodies. Pott. Archæol. Græc. lib. ii. cap. 12. tom. i. p. 301.

ENGASTRIMYTHUS, Εγγαστριμυθος, or *Engaftrimander*, a perfon who fpeaks from, or with the belly, without opening his mouth; or, if open, without ftirring the lips.

Thus called by the Greeks, from εν, γαστηρ, *belly*, and μυθος, *fpeech;* and by the Latins, *ventriloquus, quafi ex ventre loquens*.

The ancient philofophers, &c. are divided on the fubject of the engaftrimythi: Hippocrates mentions it as a difeafe. Others will have it a kind of divination, and afcribe the origin and firft difcipline thereof to one Euryclus, whom nobody knows any thing of. Others attribute it to the operation or poffeffion of an evil fpirit; and others, to art and mechanifm.

The moft eminent engaftrimythi were the Pythians or prieftelfes of Apollo, who delivered oracles from within, without any action of the mouth or lips.

St. Chryfoftom and Oecumenius make exprefs mention of a fort of divine men, called by the Greeks engaftrimandri, whofe prophetic bellies pronounced oracles.

M. Schottus, library-keeper to the king of Pruffia, in a Differtation on the Apotheofis of Homer, maintained that the engaftrimythi of the ancients were only poets; who, when the prieftefs could not fpeak in verfe, fupplied the defect, by explaining or delivering in verfe what Apollo dictated in the cavity of the bafon, placed on the facred tripod.

Leo Allatius has an exprefs treatife on the engaftrimythi. See VENTRI-LOQUISTS.

ENGEDI, in *Ancient Geography*, *q. d.* the fountain of the goat, called alfo *Hazazon-Tamar*, or the palm-tree city, from the great quantity of palm trees that furrounded it, a city of Paleftine, in the tribe of Judah (Jofh. xv. 62.), fituated near the lake of Sodom, 300 furlongs from Jerufalem, not far from Jericho, and the mouth of the river Jordan. It was in a cave of the wildernefs of Engedi, that David had an opportunity of killing Saul, and of fparing his life, then in purfuit of him. 1 Sam. xxiv. 1, 2, 3, &c.

ENGEL. See ANGLEN and ANGLES.

ENGELACH, in *Geography*, a town of Germany, in the circle of Lower Saxony, and bifhopric of Hildefheim; 15 miles S. W. of Alfeld.

ENGELBERG, an extenfive narrow valley of Switzerland, in the canton of Underwalden; its length exceeds twelve miles, and it is hardly fix miles broad. It was formerly called the Hahnenberg (Cocks' mountain), but when the abbey church was confecrated, fome inhabitants pretended they had heard the melodious concerts of the angels in heaven, which made them call it *Engelberg*, (the Angels' mountain). The inhabitants are numerous and remarkable for the innocence of their manners, and for their hofpitality to ftrangers.

The abbey of Engelberg is 9 miles S. W. of Altorf. It was founded in the year 1125.

ENGELBRECHTS, a town of Germany, in the archduchy of Auftria; 95 miles N. N. W. of Bavarian Waidhoven.

ENGELHARTZEL, a town of Germany, in the archduchy of Auftria; 9 miles E. of Paffau.

ENGELHAUS, a town of Bohemia, in the circle of Saatz; 2 miles E. S. E. of Carlfbad.

ENGELHOLM, a town of Sweden, in the province of Schonen, or Scania, fituated at the mouth of a river which runs into the Cattegat, 12 miles from Helfingborg. It is the twentieth town in rank among thofe which vote in the Swedifh diet. Its name is faid to be derived from the Angles, who either firft came from this neighbourhood, or paffed over to it from Denmark, and built the place for the conveniency of trade. The latter conjecture is the moft probable.

ENGELSBERG, a town of Silefia, in the principality of Appau; 5 miles N.N.W. of Freudenthal.

ENGELSBURG, a fmall town of Pruffia, in the diftrict of Culm, with an ancient caftle not far from Graudentz.

ENGELSDORF, a town of Bohemia, in the circle of Boleflaw; 10 miles N.N.E. of Krottau.

ENGELSTEIN, a town of Pruffia, in the province of Natangen; 48 miles S.E. of Konigfberg.

ENGELSTETTEN, a town of Germany, in the archduchy of Auftria, 23 miles E. of Vienna.

ENGEN, a town of Germany, in the circle of Swabia, and principality of Stuhlingen; 12 miles N.N.E. of Schaffhaufen, and 20 N.N.W. of Conftance.

ENGENDERING, or INGENDERING, the act of begetting or producing the kind, by way of generation.

The term is likewife applied to other productions of nature: thus, meteors are faid to be engendered in the middle region of the air. Crude fruits engender worms. The ancients believed, that infects were ingendered of putrefaction.

ENGENTHAL, in *Geography*, a town of Germany, in the circle of Franconia; 13 miles E. of Nuremberg.

ENGER, a town of Germany, in the kingdom of Weftphalia, and county of Ravenfburg; 3 miles W. of Hervorden.

ENGER *Sea*, a lake of Carinthia, 10 miles N.N.W. of Feltkirchen.

ENGERSTORFF, a town of Germany, in the archduchy of Auftria; 10 miles S.W. of Zifterfdorf.

ENGETAL, a valley of Switzerland, in the canton of Bafle, remarkable for its abbey, which was fecularized in 1534, and where a bible was printed at the end of the fifteenth century, with N. Lyra's notes.

ENGGISTEIN, a fmall town of Switzerland, one mile from Worbe, remarkable for its mineral fprings, on whofe account it is much vifited in the fummer feafon. The water contains a little copper. The accommodations of the place are very good.

ENGHELBRECHT, CORNELIUS, in *Biography*, a painter, born at Leyden in 1468. Having imitated the works of John Van Eyck, at Bruges, he returned to his own country, and had the honour of being the firft who taught the Dutch to paint in oil; in which he wrought with very great reputation in his time, as well as in diftemper; and was then accounted among thofe moft deferving of eftimation.

He was not quite fo dry or formal in his manner of defign as the painters of that period; and he caft his draperies with more care, and better ftyle, than they. His moft admired performance is the reprefentation of the "Lamb" in the Revelation, which he painted for a chapel in the church of St. Peter at Leyden. The compofition confifts of an immenfe crowd of figures, angels, martyrs, doctors, and fathers of the church, &c. and all the "holy hierarchy of heaven," combined together with an immenfe multitude of perfons of all nations. This picture is very ingenious in the painting of the various parts, but it muft owe its reputation more to the lack of knowledge of the better qualities of art at the time it was painted, than to its own intrinfic worth. This artift died in 1533, at 65.

ENGHIEN, or ENGUIEN, in *Geography*, a fmall town of France, in the department of Jemmappe, chief place of a canton, in the diftrict of Mons, with a population of 3045 individuals. It is 18 miles S.W. of Bruffels, and 15 N. of Mons. N. lat. 50° 40′.

The canton contains 10 communes, and 13,674 inhabitants, on a territorial extent of 140 kiliometres. It is from this place that the eldeft fons of the princes of Condé in France, the laft of whom was fo bafely murdered by the orders of the French emperor Napoleon, derived the title of duke.

ENGIA, an ifland near the coaft of the Morea, anciently called *Ægina*, which fee. Engia gives name to a gulf on the S.E. coaft of European Turkey, formerly denominated *Sinus Saronicus*. See ÆGINA.

ENGINE, in *Mechanics*, a compound machine, confifting of feveral fimple ones, as wheels, fcrews, levers, or the like, combined together, in order to lift, caft, or fuftain a weight, or produce fome other confiderable effect, fo as to save either time or force.

The word is formed of the French *engine;* of the Latin *ingenium*, wit; becaufe of the ingenuity required in the contrivance of engines, to augment the effect of moving powers.

The kinds of engines are innumerable; fome for war, as the balifta, catapulta, fcorpio, aries, &c. others for the arts of peace, as mills, cranes, preffes, clocks, watches; engines to drive piles, to bore cannon and water-pipes (fee BORING), to raife water, wheel and water-works; to extinguifh fire, fee FIRE-*engine*, &c. See HYDROCANISTERIUM. See STEAM-*engine*, &c. See alfo INSTRUMENT.

ENGINE *for cutting Wheels*. See CUTTING-*Engine*.

ENGINE *for cutting Fufees*. See FUSEE-*Engine*.

ENGINE *for ornamenting a Watch-cafe*. See ROWS-*Engine*, or ROSE-*Engine*.

ENGINE *for dividing Circles*, *Quadrants*, *Sextants*, and *Octants*. It is not our intention in this place to enter into the hiftory of the different methods of dividing aftronomical inftruments into degrees and their fub-divifions, as fucceffively practifed by Tycho Brahe, Hevelius, Dr. Hook, Mr. Abraham Sharp, Olaus Roemer, Mr. Graham, Mr. Jon. Siffon, Mr. Bird, Mr. Ramfden, and Mr. Troughton, without the aid of an engine; but, as we propofe to treat the fubject at fome length under our article GRADUATION *of Aftronomical Inftruments*, we beg leave to refer the reader to that head for fuch particulars as relate to the manual operations performed by the beam-compafs and otherwife, which are neceffary for graduating all circles and other inftruments, that are too large to be graduated by an engine.

Among all the improvements in chronometers and nautical inftruments, that owed their origin, during the laft century, to the munificent encouragement of the honourable Board of Longitude, there is none that has fo much contributed to the intereft of navigation, confidered as a fcience, as the engine at prefent to be defcribed; the facility, and at the fame time the accuracy, with which the meafuring portion of any nautical inftrument, however portable, can now be divided by our beft engines, are truly aftonifhing; the fine dividing ftrokes, which, in many inftances, are fcarcely vifible to, and not legible by the naked eye, when magnified by a fuitable lens, are perceived to be laid down with fuch perfect equality, as to relative diftances, that no one who has not examined the means by which they were effected, can conceive the poffibility that the expedition, with which the divifions are made, is equal to the accuracy with which they are meafured and marked down. In Mr. Smeaton's paper, read to the Royal Society of London, on Nov. 17, 1785, on the "Graduation of Aftronomical Inftruments," he mentions an engine, made by Mr. Henry Hindley of York, which indented the edge of any circle in fuch a way, that a fcrew with fifteen threads acting at once, would, by means of a micrometer, read off any given number of divifions, fo as to anfwer the purpofe of fub-dividing the circle. It does not, however, appear that this engine, though it divided the circles of Hindley's equatorial inftruments, was intended or adapted fo much for graduating circles as for cutting the teeth of wheels in clock-work. (See CUTTING-*Engine*.) The year in which it was feen by by Mr. Smeaton was 1741, and, consequently, was in Graham's time, who died in 1751. According to the same author, Mr. Ramsden, in consequence of the reward offered by the Board of Longitude to Mr. Bird, for his method of dividing, in the year 1760, turned his thoughts towards the contrivance of an engine that would divide nautical instruments with sufficient accuracy, without the tediousness of manipulation. Accordingly, considering the nature and properties of the endless screw, and probably contemplating what Hindley had previously done in this way, he completed an engine with an indented plate, or wheel, of thirty inches diameter, which, though it did not completely answer his expectations to their full extent, yet was found very useful for dividing theodolites and such common instruments with great facility. This was effected before the spring of 1768, and, in 1774, a much larger and better engine was produced, with an indented plate of 45 inches diameter, which divided a sextant for Mr. Bird's examination so accurately, that the Board of Longitude, ever ready to remunerate any successful endeavour to promote the lunar method of determining the longitude at sea, did not hesitate to confer an handsome reward on the inventor, but on condition that the said engine might be at the service of the public, and that Mr. Ramsden would publish an explanation of his method of making and using it, which he accordingly did in a quarto pamphlet in the year 1777. The sum of money given to Mr. Ramsden was 615*l.*, of which 300*l.* was considered as a reward for his improvement in the art of dividing instruments by means of his engine, and the remaining 315*l.* was paid in consideration of his making over the property of the said engine to the Commissioners of Longitude, for the good of the public. The description which Mr. Ramsden published, being short and explicit, cannot well be abridged, and the drawings, intended as a guide for other artists to work by, are explanatory of all the parts of the engine, as detached from one another; we have therefore given reduced engravings of all the figures, as they were originally arranged, and propose to copy the description without any other alteration than what the references to our plates required.

Mr. Ramsden's Engine.—"This engine consists of a large wheel of bell-metal, supported on a mahogany stand, having three legs, which are strongly connected together by braces, so as to make it perfectly steady; *fig.* 1. *Plate* VII. of *Engines*, is a perspective representation of the body thus united. On each leg of the stand is placed a conical friction-pulley, whereon the dividing-wheel rests: to prevent the wheel from sliding off the friction-pulleys, the bell-metal centre under it turns in a socket on the top of the stand. The circumference of the wheel is ratched or cut, by a method to be hereafter described, into 2160 teeth, in which an endless screw acts. Six revolutions of the screw will move the wheel a space equal to one degree. Now a circle of brass being fixed on the screw-arbor, having its circumference divided into 60 parts, each division will answer to a motion of the wheel of ten seconds; six of them will be equal to a minute, &c. Several different arbors of tempered steel are truly ground into the socket in the centre of the wheel. The upper parts of the arbor, that stand above the plane, are turned of various sizes, to suit the centres of different pieces of work to be divided. When any instrument is to be divided, the centre of it is very exactly fitted to one of these arbors, and the instrument is fixed down to the plane of the dividing wheel, by means of screws, which fit into holes made in the radii of the wheel for that purpose. The instrument being thus fitted on the plane of the wheel, the frame which carries the dividing-point is connected at one end by finger-screws with the frame which carries the endless screw; while the other end embraces that part of the steel arbor which stands above the instrument to be divided, by an angular notch in a piece of hardened steel; by these means both ends of the frame are kept perfectly steady and free from shake.

The frame carrying the dividing-point, or tracer, is made to slide on the frame which carries the endless screw to any distance from the centre of the wheel, that the radius of the instrument to be divided may require, and may be there fastened by a pair of clamps; and the dividing-point, being connected with the clamps by the double-jointed frame, admits a free and easy motion towards or from the centre, for cutting the divisions without any lateral shake. From what has been said it appears, that an instrument thus fitted on the dividing-wheel may be moved to any angle by the screw and divided micrometer circle on its arbor, and that this angle may be marked on the limb of the instrument with the greatest exactness by the dividing-point, which can only move in a direct line tending to the centre, and is altogether freed from those inconveniences that attend cutting by means of a straight edge. This method of drawing lines will also prevent any error that might arise from an expansion or contraction of the metal, during the time of dividing. The screw-frame is fixed on the top of a conical pillar, which turns freely round its axis, and also moves freely towards or from the centre of the wheel, so that the screw-frame may be entirely guided by the frame which connects it with the centre: by these means any eccentricity of the wheel and the arbor would not produce any error in the dividing; and by a particular contrivance, hereafter described, the screw, when pressed against the teeth of the wheel, always moves parallel to itself; so that a line joining the centre of the arbor and the dividing-point, continued, will always make equal angles with the screw. The rest of the parts are represented in *Plates* VIII. and IX. of *Engines*, where the figures are numbered in succession from 2 to 14 inclusively, which are more easily referred to than the figures in the original plates. *Fig.* 2 is a plan of reduced dimensions, of which *fig.* 3 represents a section on the line H A. The large wheel, A, is 45 inches in diameter, and has 10 radii, each supported by edge-bars, as seen in *fig.* 3. These bars and radii are connected by the circular ring B, 24 inches in diameter, and 3 deep; and, for greater strength, the whole is cast in one piece in bell-metal. As the whole weight of the wheel, A, rests on its ring B, the edge-bars are deepest where they join it; and from thence their depth diminishes, both towards the centre and circumference, as seen in the figure. The surface of the wheel, A, was worked very even and flat, and its circumference turned true. The ring C, of which a section is seen in *fig.* 3, made of fine brass, was fitted very exactly on the circumference of the wheel, and was fastened thereon with screws, which, after being screwed as tight as possible, were well rivetted. The face of a large chuck being turned very true and flat in the lathe, the flattened surface, A, of the wheel was fastened against it with hold-fasts; and the two surfaces and circumference of the ring C, a hole through the centre, and the plane part round it, together with the lower edge of the ring B, were all turned at the same time. D is a piece of hard bell-metal, having the hole that receives the steel-arbor made very straight and true. This bell-metal was turned very true on its arbor, and its face, that rests against the wheel, was made very flat, so that the steel-arbor might stand perpendicular to the plane of the wheel: this bell-metal was fastened to the wheel by six steel screws. A brass socket, Z, is fastened on the centre of the mahogany stand, and

and receives the lower part of the bell-metal piece D, being made to touch the bell-metal in a narrow part near the mouth, to prevent any obliquity of the wheel from bending the arbor: good fitting is by no means neceſſary here, ſince any ſhake in this ſocket will produce no bad effect, as will appear when the cutting-frame is deſcribed. The wheel was then put on its ſtand, the lower edge of the ring, B, reſting on the circumference of the three conical friction-pulleys W, to facilitate its motion round its centre. The axis of one of thoſe pulleys is in a line joining the centre of the wheel and the middle of the endleſs ſcrew, and the other two placed ſo as to be at equal diſtances from each other. F is a block of wood (*fig.* 1.), ſtrongly faſtened to one of the legs of the ſtand; the piece, *g* (*figs.* 1 and 12.), is ſcrewed to the upper ſide of the block, and has half holes, in which the tranſverſe axis, *h*, (*figs.* 1 and 11.) turns; the half holes are kept together by the ſcrews *i*. The lower extremity of the conical pillar, P, (*figs.* 1 and 11.) terminates in a cylindrical ſteel pin *k*, which paſſes through and turns in the tranſverſe axis *h*, and is confined by a cheek and ſcrew. To the upper end of the ſaid conical pillar is faſtened the frame G, (*figs.* 5 and 9.), in which the endleſs ſcrew turns; the pivots of the ſcrew are formed in the manner of two fruſta of cones joined by a cylinder, as repreſented at X, in *fig.* 9. Theſe pivots are confined between half holes, which preſs only on the conical parts, but do not touch the cylindrical parts; the half holes are kept together by ſcrews, *a*, *a*, which may be tightened at any time, to prevent the ſcrew from ſhaking in the frame. On the ſcrew-arbor is a ſmall wheel of braſs, K, having its outſide edge divided into 60 parts, and numbered at every 6th diviſion with 1, 2, &c. to 10. The motion of this wheel is ſhewn by the index, *y*, on the ſcrew-frame G. H repreſents part of the ſtand (*fig.* 1.) having a parallel ſlit in the direction towards the centre of the wheel, large enough to receive the upper part of the conical braſs pillar P, which carries the ſcrew and its frame; and as the reſiſtance, when the wheel is moved by the endleſs ſcrew, is againſt that ſide of the ſlit, H, which is towards the left hand, that ſide of the ſlit is faced with braſs, and the pillar is preſſed againſt it by a ſteel ſpring on the oppoſite ſide: thus is the pillar ſtrongly ſupported laterally, and yet the ſcrew may be eaſily moved from or againſt the circumference of the wheel, and the pillar will turn freely on its axis, to take any direction given it by the frame L, lying over the wheel in *fig.* 1, and ſeen more diſtinctly in *fig.* 13.

At each corner of the piece I, ſeen in *fig.* 1, and alſo detached in *fig.* 8, are as many ſcrews, *n*, of tempered ſteel with poliſhed conical points: two of them turn in conical holes in the ſcrew-frame, near *o*, *fig.* 9; and the points of the other two turn in holes in the piece Q, *fig.* 7; the ſmall end ſcrews, *p*, are of ſteel, which, being tightened, prevent the conical pointed ſcrews from unturning, when the frame is moved. The braſs frame L, *figs.* 1 and 13, ſerves to connect the endleſs ſcrew, its frame, &c. with the centre of the wheel; each arm of this frame is terminated by a ſteel ſcrew, that may be paſſed through any of the holes, *q*, in the piece Q, *fig.* 7, as the thickneſs of the work to be divided on the wheel may require, and are faſtened by the finger-nuts *r*, ſeen in *figs.* 1 and 2. At the other end of this frame is a flat piece of tempered ſteel *b*, wherein is an angular notch: when the endleſs ſcrew is preſſed againſt the teeth of the circumference of the wheel, which may be done by turning the finger-ſcrew S, ſeen in *figs.* 1 and 2, to preſs againſt the ſpring *t*, this notch embraces and preſſes againſt the ſteel-arbor *d*. This end of the frame, too, may be raiſed or depreſſed, by moving the triangular or priſmatic ſlide *u* (*fig.* 14.), which may be fixed at any height by the four ſteel ſcrews *v*. The bottom of this ſlide has a notch *k*, having its plane parallel to the endleſs ſcrew; and by the point of the arbor *d*, reſting in this notch, this end of the frame is prevented from tilting: the ſcrew, S, alſo is kept faſt by the finger-nut *w*, in *fig.* 2.

The teeth on the circumference of the wheel were cut by the following method. Having conſidered what number of teeth on the circumference would be moſt convenient, which in this engine is 2160 or $\overline{360 \times 6}$, I made, ſays Mr. Ramſden, two ſcrews of the ſame dimenſions of tempered ſteel, the interval between the threads of which being ſuch as I knew by calculation would come within the limits of what might be turned off the circumference of the wheel; one of theſe ſcrews, which was intended for ratching or cutting the teeth, was notched acroſs the threads, ſo that the ſcrew, when preſſed againſt the edge of the wheel and turned round, cut in the manner of a ſaw. Then having a ſegment of a circle a little greater than 60°, of about the ſame radius with the wheel, and its circumference made true from a very fine centre, I deſcribed an arch near the edge, and ſet off the chord of 60° on this arch. This ſegment was ſubſtituted for the wheel, and had its edge ratched or indented; and the number of revolutions and parts of the ſcrew head contained within the arch of 60° were counted. The radius was corrected in the proportion of 360 revolutions, which ought to have been in 60°, to the number actually found; and the radius ſo corrected was taken in a pair of beam compaſſes: while the wheel was on the lathe, one foot of the compaſſes was put in the centre, and with the other a circle was deſcribed on the ring; then half the depth of the threads of the ſcrew being taken in the dividers, was ſet from this circle outwards, and another circle was deſcribed cutting this point; a hollow was then turned on the edge of the wheel of the ſame curvature as that of the ſcrew, at the bottom of its threads; the bottom of this hollow was turned to the ſame radius as the outward one of the two circles before-mentioned.

The wheel was now taken off the lathe, and the bell-metal piece D, *fig.* 3, was again ſcrewed to its place, not to be removed any more. From a very exact centre, a circle was deſcribed on the ring C, *fig.* 4, about $\frac{4}{10}$ths of an inch within where the bottom of the teeth would come; this circle was divided with the greateſt poſſible exactneſs, firſt into 5 parts, and each of theſe again into 3; theſe parts were then biſected 4 times; *i. e.* ſuppoſing the whole circumference of the wheel to contain 2160 teeth, a fifth part would be 432, a fifteenth part (or 5×3) would be 144, and this laſt number biſected four times would give 72, 36, 18, and 9 reſpectively; but as it was apprehended that ſome inaccuracy would ariſe from quinqueſection and triſection, another circle was deſcribed on the ſame ring, at $\frac{1}{10}$th of an inch within the former circle, and divided by continual biſections into the portions 2160, 1080, 540, 270, 135, $67\frac{1}{2}$, and $33\frac{3}{4}$; and as the fixed wire, to be deſcribed preſently, croſſed both the circles, it was a check on their agreement at every 135 revolutions, and after ratching at every $33\frac{3}{4}$; but as no ſenſible difference was perceived in the two circles, the former was choſen for ratching: and as the coincidence of the fixed wire with an interſection would be more exactly determined than with a dot or diviſion, the interſections in both circles were uſed.

The arms of the frame L, *figs.* 1 and 13, were connected by a thin piece of braſs $\frac{3}{4}$ of an inch broad, having a hole of $\frac{4}{10}$ths of an inch diameter in the middle; acroſs this hole a ſilver wire was fixed exactly in a line to the centre of the wheel;

wheel; the coincidence of this wire with the interfections was examined by a lens of $\frac{7}{10}$ths of an inch focus, fixed in a tube, that was attached to one of the arms L. Now a handle, or winch, being fixed on the end of the fcrew-arbor, the divifion marked 10 on the circle K was fet to its index, and, by means of a clamp and adjufting fcrew for that purpofe, the interfection marked 1 on the circle C was fet exactly to coincide with the fixed wire; the fcrew was then carefully preffed againft the circumference of the wheel, by turning the finger-fcrew S; then, the clamp being removed, the fcrew was turned by its handle juft 9 revolutions, till the interfection marked 240, *fig.* 4, came nearly to the wire; the finger-fcrew S was now turned back, and the dividing fcrew releafed from the edge of the wheel, which was here turned back till the interfection marked 2 exactly coincided with the wire; the divifion 10 on the micrometer circle was then fet to its index as before, and the fcrew preffed againft the edge of the wheel by the finger-fcrew S; then, the clamps being removed, the fcrew was turned a fecond 9 revolutions, till the interfection marked 1 nearly coincided with the fixed wire; the fcrew was again releafed, and the fame operation was repeated till the teeth were faintly marked all round the circumference of the wheel. The impreffion was made deeper by thus going three times round; after which the wheel was ratched continually round 300 times in the fame direction, without difengaging the fcrew, when the teeth were found fufficiently indented. Now, it is evident, that, if the circumference of the wheel were even a whole tooth or ten minutes fpace greater than the fcrew would require, this error would, in the firft inftance, be reduced to $\frac{1}{240}$th part of a revolution, or two feconds and a half; and thefe errors or inequalities of the teeth were equally diftributed round the wheel at the diftance of 9 teeth from each other; but, as the fcrew in ratching had continually hold of feveral teeth at the fame time, and as thefe were conftantly changing, the above-mentioned inequalities foon corrected themfelves, and the teeth were reduced into a perfect equality.

The piece of brafs which carries the wire was now taken away, and the cutting-fcrew alfo removed, and replaced by the plane one of the fame dimenfions; on one end of its arbor was put the micrometer circular plate divided into 60, and numbered at every fix divifions, as already ftated; and on the other end was placed a ratchet-wheel of 60 teeth, feen in *fig.* 6, which is covered by the hollowed circle *d*, carrying two clicks, that catch upon the oppofite fides of the ratchet, when the fcrew is to be moved forwards. The cylinder S, *figs.* 5 and 9, turns on a ftrong fteel arbor F, feen in *fig.* 5, which paffes through, and is firmly fcrewed to the piece Y; this piece, for greater firmnefs, is attached to the fcrew frame G by the braces *v*: a fpiral groove or thread is cut on the outfide of the cylinder S, which ferves both for holding the ftring, and alfo for giving motion to the lever J on its centre, *figs.* 9 and 10, by means of a fteel tooth *n* that works between the threads of the fpiral. To the lever is attached a ftrong fteel pin *m*, *fig.* 10, on which a brafs focket *r* turns: this focket paffes through a flit in the piece *p*, and may be tightened in any part of the flit by the finger-nut *f*: this piece ferves to regulate a number of revolutions of the fcrew for each tread of the treadle R, feen in *fig.* 1. T, in *fig.* 1, is a brafs box, containing a fpiral fpring: a ftrong gut is faftened and turned three or four times round the circumference of this box; the gut then paffes feveral times round the cylinder S, *figs.* 1 and 9, and from thence down to the treadle R. Now, when the treadle is preffed down, the ftring pulls the cylinder S round its axis, and the clicks laying hold of the teeth on the ratchet, carry the fcrew round with it, till, by the tooth *n* working in the fpiral groove, the lever J is brought near the wheel *d*, *fig.* 6, and the cylinder is ftopped by the fcrew-head *x*, *fig.* 9, ftriking on the top of the lever J; at the fame time the fpring is wound up by the other end of the gut paffing round the box T, *fig* 1. Now, when the foot is taken from the treadle, the fpring in the box unbending itfelf, pulls back the cylinder, the clicks leaving the ratchet and attached fcrew at reft till the piece *t* ftrikes on the end of the piece *p*, *fig.* 10; and the number of revolutions of the fcrew at each tread is limited by the number of revolutions that the cylinder is allowed to turn back before the ftop ftrikes on the piece *p*. When the endlefs fcrew is moved round its axis with a confiderable velocity, it will continue that motion a little after the cylinder S is ftopped; to prevent which angular motion, the angular lever η was made, that when the lever J comes near to ftop the fcrew *x*, it, by a fmall chamfre, preffes down the piece κ of the angular lever; this brings the other end η of the fame lever forwards, and ftops the endlefs fcrew by the fteel pin μ ftriking on its top; the foot of the lever is again raifed by a fmall fpring preffing on the brace *v*.

Two clamps D, *fig.* 13, connected by the piece *a*, *fig.* 1, flide, one on each arm of the frame L, and may be fixed at pleafure by the four finger-fcrews ϵ, which prefs againft fteel fprings, to avoid fpoiling the arms; the piece *q*, *fig.* 13, is made to turn without fhake between the two conical pointed fcrews *f*, *f*, fet faft by the finger-nuts N, N. The piece M is made to turn on the piece *q*, by the conical pointed fcrews refting in the hollow centres *e*, *e*. As there is frequent occafion to cut divifions on inclined planes, for that purpofe the piece γ, in which the tracer or dividing point is fixed, has a conical axis at each end, which turn in half holes; fo that when the tracer is fet to any inclination, it may be fixed there, by tightening the fteel fcrews $\beta\beta$."

Subfequently to the time of Mr. Ramfden's dividing engine being conftructed, Mr. Edward Troughton conftructed one to anfwer the fame purpofe, which it does in the moft perfect manner; and it was our intention to have defcribed it alfo in this place, but on application to him for permiffion to infpect its parts and manner of operating, we were forry to learn that he has pledged himfelf to give an account of it himfelf in another work.

Engine (by Ramfden) *for cutting the Screws of the circular Dividing-Engine.*—We mean not to enter here into the hiftory of the fcrew-engine, as it may be, and has been applied to various purpofes, but to defcribe the engine made and ufed by Mr. Ramfden for making the individual fcrews which he ufed for ratching his engine for dividing circles, &c., and for meafuring the angular diftance on his circle when ratched. This apparatus, indeed, may be confidered as an appendage to the other, and therefore ought to be introduced in this place. *Fig.* 1. of *Plate* X. of *Engines*, reprefents this engine as feen from one fide of reduced dimenfions; and *fig.* 2, the fame as feen from above, of the fame dimenfions. A reprefents a triangular bar of fteel, to which the triangular holes in the pieces B and C are accurately fitted, and may be fixed on any part of the bar by the fcrew D. E is a piece of fteel whereon the fcrew is intended to be cut, which, after being hardened and tempered, has its pivots turned in the form of two frufta of cones, as reprefented in the drawings of the dividing-engine. Thefe pivots were very exactly fitted to the half holes F and T, which were kept together by the fcrews Z. H reprefents a fcrew of untempered fteel, having a pivot I, which turns in the hole K. At the other end of the fcrew is a hollow centre, which receives the hardened conical point of the fteel pin M. When this point is fufficiently preffed againft the fcrew, to prevent its fhaking, the fteel pin may be fixed by tightening the fcrews Y. N is a cylindrical nut, moveable on the fcrew H, which, to prevent any fhake, may be tightened by the fcrews O. This nut is connected with the faddle-piece P, by means of the intermediate univerfal joint W, through which the arbor of the fcrew H paffes. A front view of this piece, with a fection acrofs the fcrew-arbor, is reprefented at X, *fig.* 3. This joint is connected with the nut by means of two fteel flips S, which turn on pins between the cheeks T, on the nut N. The other end of thefe flips S turn in like manner on pins *a*. One axis of this joint turns in a hole in the cock *b*, which is fixed to the faddle-piece, and the other turns in a hole *d*, made for that purpofe in the fame piece on which the cock *b* is fixed. By thefe means, when the fcrew is turned round, the faddle-piece will flide uniformly along the triangular bar A. K is a fmall triangular bar of well-tempered fteel, which flides in a groove of the fame form on the faddle-piece P. The point of this bar or cutter is formed to the fhape of the thread intended to be cut on the endlefs fcrew. When the cutter is to take proper hold of the intended fcrew, it may be fixed by tightening the fcrew *e*, which prefs the two pieces of brafs G upon it. Having meafured the circumference of the dividing-wheel, it was found to require about one thread in a hundred, coarfer than the guide-fcrew H. The wheels on the guide-fcrew arbor H, and that on the fteel arbor E, on which the fcrew was to be cut, were proportioned to each other to produce that effect, by giving the wheel L 198 teeth, and the wheel Q 200. Thefe wheels communicated with each other by means of the intermediate wheel R, which alfo ferved to give the threads on the two fcrews the fame direction. The faddle-piece P is confined on the bar A by means of the pieces *g*, and may be made to flide with a proper degree of tightnefs by the fcrews *n*.

Engine *for cutting the Screw of Ramfden's Engine for dividing Straight Lines.*—The exactnefs of the ftraight line engine, as made by Ramfden, depends very much on the correctnefs of the endlefs fcrew, which requires fome properties that are not abfolutely neceffary in the endlefs fcrew for the *circular engine.* In that, as there are but a few threads of the endlefs fcrew engaged in the teeth of the wheel, it required only that thofe threads fhould have a fimilar inclination to the axis of the fcrew all round; but in the ftraight-line engine, where the whole length of the fcrew is engaged in the moveable plate, it is neceffary that the diftances alfo between the threads fhould be precifely the fame throughout the whole length of the fcrew: as this is effected in a manner in fome refpects different from the mode of cutting the fcrew we have juft defcribed, we fhall fubjoin it here, that the reader may take a comparative view of the two methods adopted by that great artift Ramfden. In *fig.* 1. of *Plate* XI. of *Engines*, is a plan of the engine for cutting the fcrew for dividing *ftraight lines;* and in *fig.* 2, is an elevation of the fame. The fection, as given in the original account publifhed in 1779, does not feem to be neceffary for explaining the engine, and is therefore omitted in our account. A, in *fig.* 1, reprefents a ftrong circular plate of brafs, having its edge ratched, as defcribed in our account of the circular dividing-engine; on its centre is firmly fixed the pulley B by four fcrews, having a groove turned on its cylindrical part, perfectly concentric with the plate A. C, in *fig.* 2, is a fteel axis two feet long, terminating in a point, whereon it refts; the upper part of the axis being firmly fcrewed to the plate A, and turning in the collar D. E reprefents an endlefs fcrew, *fig.* 1, which being turned on its horizontal axis, moves the circular plate A round its centre: F is a circular divided fmall plate, or micrometer-head, which may be turned with or without the endlefs fcrew; and on the other end of this fcrew-arbor is a large pinion *a*, with levelled teeth on its edge, together with the winch X to turn it by. G, feen in both figures, is a triangular bar of fteel, which paffes over the circular plate A, and is firmly fcrewed to the frame of the engine at H, *fig.* 1, and I, *fig.* 2. K is a piece of fteel forming the arbor of the fcrew intended to be cut, having a wheel L, on one end acting with the pinion *a* before-mentioned. M and N, *fig.* 1, are two ftrong pieces of brafs, in which the arbor juft mentioned turns, and are firmly fixed to the triangular bar G, by means of the fcrews *n*, *n*, feen at I, in *fig.* 2. O, feen in both figures, is a piece of brafs that flides on the triangular bar G, the two extremities of which are made exactly to fit the bar; it flides regularly thereon, and is prevented from rifing by the two fpring pieces *c*, *c*; near one end of the piece O is an angular groove *q*, *fig.* 1, that holds the tool by which the threads are cut, and is pointed with a diamond, in order to cut the fteel after it is hardened and tempered: the cock *w* ferves to faften the tool, which may be fet to take proper hold on the fteel by turning the finger-fcrew *s*, and is fixed there by the fcrew *v*.

To make a perfect fcrew, it is only required to give the point that cuts the threads an uniform motion parallel to itfelf, and alfo to the axis of the intended fcrew, and that this motion be proportioned to the revolutions of the intended fcrew as the number of threads may require. To effect this, a piece of thin tempered fteel *t*, exactly of the fame thicknefs throughout, is faftened to the flide O at *r*; the other end of the fpring being faftened to the pulley B in the groove: now while the circle A, with the pulley, is turned round its centre by turning the endlefs fcrew to the right hand, the fpring *t* draws the flider O, with the attached cutter *q*, along the triangular bar; at the fame time the fteel-arbor K of the fcrew to be cut revolves by means of the communication of its wheel L with the revolving pinion *a*.

The fcrew, E, of the circular plate has 20 threads *per* inch, therefore if the number of teeth on the pinion, *a*, be to the number in the wheel L, as the number of teeth on the circular plate, A, is to the number of 20ths of an inch round the circumference of the pulley B, allowing for part of the thicknefs at the fpring *t*, the fpaces between each of the threads of the fcrew to be cut will be alfo 20ths of an inch. The fize of the pulley, B, was determined thus: the endlefs fcrew, E, being difengaged from the circular plate A, the flider, O, was drawn back till the end of it came nearly to the piece M; the endlefs fcrew was again engaged in the plate A; then having two very fmall dots on the flider O, fet off parallel to one fide, at exactly five inches diftance from each other, the flider was moved by turning the endlefs fcrew E, till one of its dots was bifected by a fmall filver wire fixed acrofs a hole made in a thin piece of brafs faft to the piece N; then O on the micrometer head, F, being put to the index without moving the fcrew, the pulley was tried and reduced, till juft 600 revolutions of the endlefs fcrew, E, brought the fecond dot to be exactly bifected by the fixed wire. Thefe bifections were examined by a lens of half an inch focus, fet in a fmall brafs tube, that was fixed perpendicularly over the wire.

Engine *for dividing ftraight Lines, by Ramfden.*—When Mr. Ramfden had fucceeded in dividing fextants, &c. by his circular dividing engine, and was rewarded by the honourable Board of Longitude, he turned his mind towards

wards the contrivance of an engine that would divide ſtraight lines into any number of aſſignable parts, and that might be uſeful in laying down with extreme accuracy the lines of ſines, tangents, ſecants, &c. on ſectors and plane ſcales. The project was realized, and the account was ordered to be publiſhed by the Board of Longitude, in the year 1779. We do not find, however, that the original model, which we come now to deſcribe, has been found deſirable to copy by ſucceeding mathematical inſtrument makers: more ſimple and leſs expenſive means have been adopted, which are found to anſwer practically as good a purpoſe. A beam-compaſs, aided by proper tables, is quite accurate enough for the niceſt purpoſes of dividing unequal, as well as equal, diviſions by biſection; and a pattern once carefully laid down can be uſed, for transferring the diviſions on the common caſes of inſtruments, with greater facility than the engine itſelf can be worked; and, provided great care be taken to prevent the parallax of the transferring point, the accuracy will be ſufficient for all ordinary uſes. This engine, which profeſſes to divide any line without an error of $\frac{1}{4000}$th of an inch, has its principal parts repreſented in *Plate* XII. of *Engines;* where *fig.* 1, repreſents a plan of the dividing portion, as ſeen from above; *fig.* 2, an elevation of the ſame ſeen acroſs; and *fig.* 3, the under ſide of *fig.* 1, when turned up. The original account contains ſome ſections, which are more uſeful for the workmen as patterns, than for a general deſcription, which may diſpenſe with them altogether. A, in *fig.* 1, is a ſtrong braſs plate, 27 inches long, 4 broad, and $\frac{7}{10}$ths thick; worked exceedingly flat, and of the ſame thickneſs throughout, with its two edges parallel. One of theſe edges is ratched, or cut into teeth, of which there are juſt 20 in an inch, and is moved by an endleſs ſcrew, containing juſt 20 threads in an inch, which actuates the teeth. (See ENGINE *for cutting the Screw of Ramſden's ſtraight-line Engine.*) Each revolution of the endleſs ſcrew round its axis will move the plate $\frac{5}{100}$ths of an inch along an iron frame, hereafter to be deſcribed. A micrometer head is fixed at one end of the ſcrew arbor, divided into 50 diviſions, which, by means of a vernier ſubdividing into 5 parts, meaſures $\frac{2}{10000}$ths of an inch along the frame. Any rule or other inſtrument may be faſtened on this plate, and may have a line drawn on it divided by a point or tracer, fixed in a proper frame, whereby it has a rectilinear motion without any lateral ſhake. When lines are to be divided by diviſions not commenſurable with Engliſh inches, which conſtitute the ſcale, the line to be ſo divided may be laid down, not parallel to the plate A, but obliquely, ſo as to make an angle with it, or become the hypothenuſe line of a right-angled triangle; which line, by calculation, ſhall be to the baſe as the denomination of meaſure, when longer, is to the Engliſh inch; that is, as the ſecant is to the radius of the triangle, provided the tracer draws lines at right angles to the ſide of the plate; but if the traced lines be at right angles to the line to be divided, then the diviſions on that line will be ſhorter than they would be on a parallel line of the plate, and in the proportion of the co-ſine of the angle of inclination to radius. In order to adjuſt the inclination of a ruler laid on the plate A, two ſectoral portions of a circle are laid down on one of its ends, with an extent from the point J, near the fixing ſcrews on the edge of this plate. The outer ſector is divided into proper degrees, and is numbered from 1 to 9, which degrees are ſubdivided into 6, or 10 minutes ſpaces; but the inner ſector is divided into the proportion of the coſines to radius 10,000, and its diviſions are numbered 10, 20, 30, &c. to 140. The uſe of this contrivance will be beſt underſtood by an example: for inſtance, if a line of $9\frac{999}{1000}$ were to be divided into the ſame number of diviſions, and in the ſame manner as if it were 10 inches long exactly; put the ruler to be divided to the cutting frame, hereafter deſcribed, and turn the handle, T, that moves the apparatus, till the ſame edge of the ruler cuts the central point J, and the firſt diviſion from the O of the inner ſector; then ſcrew the ruler faſt to the plate A, and when it has moved ten inches in its own direction, the whole length of the diviſions on the line divided will be only $9\frac{999}{1000}$ inches, though the divided ſpaces will be reſpectively equal among themſelves. It is not neceſſary for us to particularize the precautions taken, in making all the ſpaces of the teeth ratched equal to each other, during the act of ratching, which was done with a notched ſcrew: this was done by means of points previouſly made and examined, with a wire at every 16 revolutions of the ſcrew, till the teeth were a little indented to guide the ſcrew along the whole line by continual revolutions, as was the caſe in the circular dividing inſtrument, more particularly deſcribed, becauſe found more particularly uſeful. B, in *fig.* 1, is a ſtrong iron frame, 48 inches long, having two edges, *a* and *b*, riſing half an inch above its ſurface; theſe two edges are made very ſtraight, and are in the ſame plane; the inſide of the edge *a* is alſo made as ſtraight as poſſible. The plate, A, ſlides on the two edges of the iron frame; beneath it are two ſprings, *c*, *c*, ſeen in *fig.* 3, each faſtened at the extreme ends to the plate A, by the ſcrews, *s*, *s*; at the other end of each ſpring is a roller, *e*, of tempered ſteel, turning on an axis in theſe ſprings; there is alſo a third roller, *d*, of tempered ſteel, let into the iron frame, not ſeen, near where the threads of the endleſs ſcrew act; this roller has a long axis, ſo ſituated that it may be raiſed or depreſſed as occaſion may require, to bear the weight of the plate A, and rule or inſtrument placed on it. C, in *figs.* 1 and 2, is the endleſs ſcrew of tempered ſteel, with pivots of two fruſta of inverted cones, ſimilar to thoſe deſcribed in the engine for dividing circles, &c. which turn in adjuſtable half holes in braſs cocks ſcrewed to the iron frame. G, G, in *fig.* 3, are two ſmall ſteel frames turning on centres, *k*, faſtened to the underſide of the plate A, and equidiſtant from the edge of it; in each frame is a roller, *y*, of tempered ſteel, turning very concentric with their pivots, and exactly of the ſame diameter. The two ſmall frames are connected together by the long braſs bar E, which turns on a ſtud in each frame, and which preſerves its paralleliſm, on the principle of a common parallel ruler. This apparatus ſerves to preſs the edge of the plate, A, with a motion parallel to itſelf againſt the threads of the endleſs ſcrew. On the end of the plate, A, is a ſpring of tempered ſteel, acting as a bent lever. The ſpring end of this lever has a ketch which paſſes under the head of the ſtud *l*, that is on the end of the connecting piece E. While the other end of the lever is preſſed gradually down towards the plate A, by turning the finger-ſcrew F, the connecting piece, E, is drawn forward, ſo that the ſteel rollers, borne by the ſprings T, in *fig.* 3, preſſing againſt the edge, *a*, of the iron frame, in *fig.* 1, may force the ſide of the plate againſt the endleſs ſcrew.

Beſides the micrometer head, already named, the arbor of the dividing ſcrew, which has its threads ſimilar to thoſe of the notched ratching ſcrew, has at its oppoſite end two ſets of ratched wheels; one ſet for turning the ſcrew, and the other ſet for ſtopping it at the proper times. Theſe ſets are each compoſed of three wheels, of which one has 32 teeth, another 48, and the third 50, which afford the means of ſubdividing the inch into ſpaces of different denominations; thoſe wheels uſed in ſtopping the ſcrew are ratched, with the teeth pointing in a contrary direction to thoſe thofe of the wheels for putting it in motion. I reprefents a cylinder of brafs, having on one end two fteel rings, *a* and *b*, with their contiguous edges cut into ratched teeth, in contrary directions, fo as to fit each other as feen in the figure; on one of thefe rings is an index, and the other has its teeth numbered 10, 20, &c. up to 50; the other end of the cylinder is made hollow, and contains one of the fets of ratched wheels, already named. There are two flits oppofite each other, pierced through the hollow part of the cylinder W; in each of which flits is a click turning on an axis, and preffed into the teeth of the ratched wheel by a fmall fpring; thefe clicks may be moved along their axis, fo as to catch in any one of the three ratched wheels, and may be faftened at that place by a fmall tightening fcrew *s*. The cylinder I, with the clicks, &c. turns on a fteel axis, attached to the piece K, in a line with the axis of the endlefs fcrew. Motion is given to this cylinder round its axis by a piece of catgut, which hath one end faftened to the ratched ring *b*; and the other end, after paffing four or five times round the cylinder, is faftened to a treadle, and, on preffing the treadle down, the clicks, *s*, catch in the teeth of one of the ratched wheels; by which contrivance the cylinder I, together with the endlefs fcrew, is turned round its axis, and its motion carries the plate, A, along the iron frame, and at the fame time winds up the fpiral fpring *u*; but on releafing the treadle, the faid fpring unbends itfelf, the clicks quit the ratched wheel, and leave the endlefs fcrew at reft, whilft the cylinder, I, turns in an oppofite direction, and raifes the treadle to its former fituation. V, in *fig.* 2, is a fmall fquare bar of fteel, having both its extremities cylindrical; thefe cylinders move in holes lined with hardened fteel, one in the piece D, and the other in the piece K. This bar carries three different pieces, which are of tempered fteel; the middle one, *t*, is made to lie in the interval between the threads of the fcrew cut on the cylinder, and paffes nearly half round its circumference: it is kept in the threads by a fpring, *e*, that preffes on a piece, *q*, fcrewed to the iron frame; this piece being attached to the bar, V, by a fcrew, turning the cylinder, I, on its axis, will give a longitudinal motion to the bar V. The upper end of the piece *f*, *fig.* 2, is formed into a hook, and may be fet to catch in the teeth of any of the ratchet wheels, and then be faftened to the bar, V, by a fcrew *i*; towards the other end of the bar is a piece *j*, which ferves to ftop the cylinder in turning back, fo as to limit the number of revolutions and parts of a revolution required, and is faftened to any required place on the bar, V, by the finger-fcrew *s*.

When the engine is ufed, the treadle is preffed down, and the catgut turns the cylinder I; in the mean time, the piece, *t*, moves along the thread till a ftud, *r*, on the cylinder, ftriking on the top of the curved piece *t*, bends the fpring *e*, until that piece refts on the piece *q*; by bending this fpring, the fquare bar is turned a little on its axis, and pulls the hook, *f*, into the teeth on the ratched wheel R: then the treadle being releafed, the fpiral fpring turns back the cylinder till the piece, *j*, is brought under the ftop on the ratchet ring *b*. The parts of a revolution are regulated by fetting the number required on the ratchet ring, *b*, to the index on the fixed ring *a*; each of the teeth anfwers to the motion of $\frac{1}{1000}$th of an inch of the plate A; and the number of revolutions, each of which moves the plate, A, $\frac{1}{10}$ths of an inch, is regulated by fetting the piece, *j*, on the bar. I, in *fig.* 1, reprefents the fteel frame in which the tracer is fixed; this frame turns between the conical points of two fcrews, *n*, *n*, of tempered fteel, which are fcrewed in the frame Q, *fig.* 2; there are alfo two fimilar fcrews in the fame frame Q, at *m*, *m*; the points of thefe fcrews, which are alfo of tempered fteel, turn in conical holes in the piece P; by means of this parallel motion, the tracing point, by which the dividing lines are cut, will always defcribe the fame line without any lateral bending; the tracer is put on the hole in the axis *b*, *fig.* 1, and is fixed there by the four tightening fcrews, *f*, that prefs the holding piece, *c*, againft the flattened part of the axis of motion. This fmall axis, which has its pivots formed of double cones, turns between half holes, and may be fixed when the tracer is fet to any required inclination, by tightening the fcrews of preffure, *s*, *s*, *s*, *s*. Befides thefe parts of the engine, there is a brafs ruler made as an appendage for fetting the line to be divided in its true fituation, but is not neceffary to be particularly defcribed: this ruler may be fet parallel to the edge of the plate A, or to any angle of inclination, by turning the handle T, which moves the piece P, with the cutting frame and ruler, on the centre *x*; and the required pofition may be rendered permanent by tightening the capftan fcrew *p*.

ENGINE-*Shaft*, in *Mining*, is generally applied to the fhaft or well wherein the pumps are erected for freeing a mine of its water; but in diftricts where the mines are relieved of water by foughs, as in the mountainous part of Derbyfhire, it is common to find the fhafts at which they draw ore by a horfe-gin, called the engine-fhaft, and the gin itfelf an engine.

ENGINE *to draw Fuzes*, in *Gunnery*, confifts of a wheel with a handle to it, to raife a certain weight, and to let it fall upon the driver, by which the ftrokes become more equal.

ENGINE *to draw Fuzes* has a fcrew fixed upon a three-legged ftand, the bottom of which has a ring to place it upon the fhell; and at the end of the fcrew is fixed a hand-fcrew, by means of a collar, which, being fcrewed on the fuze, by turning the upper fcrew, draws out or raifes the fuze.

ENGINEER, or INGINEER, in its general fenfe, is applied to a contriver or maker of any kind of ufeful engines or machines.

In its more proper fenfe, it denotes an officer in an army or fortified place, whofe bufinefs it is to contrive and infpect attacks, defences, works, &c. The term engineer is faid to be of modern date, and to have been firft ufed in the year 1650, when one Cap. Thomas Rudd had the title of chief engineer to the king. In 1634 an engineer was called camp-mafter general, and fometimes engine-mafter, being always fubordinate to the mafter of the ordnance.

An engineer fhould be an able and expert mathematician, particularly verfed in military architecture and gunnery; being often fent to view and examine the places intended to be attacked; to choofe out and fhew the general the weakeft place; to draw the trenches, affign the places of arms, galleries, lodgments on the counterfcarp and half-moons; conduct the works, faps, mines, &c. and appoint the workmen their nightly tafk; he is alfo to make the lines of contravallation; with the redoubts, &c.

Under the eftablifhment of the office of his majefty's ordnance in England, the corps of *royal engineers* confifts of one colonel in chief, one colonel in fecond, three colonels commandant, fix colonels, 12 lieutenant-colonels, 27 captains, 28 fecond-captains, 55 firft-lieutenants, 28 fecond-lieutenants, an infpector-general of fortifications, his deputy brigade-major, adjutant, and quarter-mafter.

The eftablifhment of the corps of *invalid engineers* comprehends a colonel, lieutenant-colonel, captain, captain-lieutenant and captain, firft-lieutenant and fecond-lieutenant.

The

The corps of *royal engineers* in Ireland confifts of a director, colonel, lieutenant-colonel, major, captain, captain-lieutenant, and captain, and two firft-lieutenants. See Ordnance.

Engineers, *Civil*, a denomination which comprifes an order or profeffion of perfons highly refpectable for their talents and fcientific attainments, and eminently ufeful under this appellation, as the canals, docks, harbours, light houfes, &c. amply and honourably teftify. This order of artifts is faid to have commenced in this country about the year 1760, at which period the advancement of the arts and fciences was fingularly rapid. In 1771, Mr. Smeaton, fo well known in this department of fcience, projected and eftablifhed an affociation, or fociety of engineers. During an interval of 20 years, the number of members of this fociety increafed to 65, of whom 15 were real engineers, and the refidue being compofed either of amateurs, or of ingenious workmen and artificers. In May 1792 this fociety was diffolved in confequence of an unpleafant circumftance, which had interrupted its harmony; but a renewal of it, under a better form, was foon intended, though not accomplifhed during the life-time of Mr. Smeaton. His death happened in October 1792, and the firft meeting of the new inftitution, entitled "The Society of Civil Engineers," was held on April 15, 1793, by Mr. Jeffop, Mr. Mylne, Mr. Rennie, and Mr. Whitworth. According to the new conftitution of the fociety, it is divided into three claffes. The firft clafs, as ordinary members, confifts of real engineers. The fecond clafs, as honorary members, is compofed of men of fcience, and gentlemen of rank and fortune, who have attended to the fubject of civil engineering. The third clafs, as honorary members alfo, confifts of artifts, whofe profeffions and employments are connected with what is called civil engineering. The meetings are held at the Crown and Anchor, in the Strand, every other Friday, during the feffion of parliament. See Reports of the late Mr. John Smeaton, F.R.S. &c. vol. i. 4to. 1797.

ENGISOMA, from ἐγγίζω, *to draw near*, in *Surgery*, an inftrument formerly ufed by furgeons in cafes of fractures of the fkull. Hence, the word has been applied to fuch fractures of the cranium as are attended with a depreffion of the bone in the middle, fo as to produce preffure on the membranes of the brain.

ENGLAND, in *Geography*. The fouthern, moft opulent, and moft important part of Britain, has been diftinguifhed among European nations, ever fince the days of venerable Bede, by the appellation of "Anglia," or England; which has been generally afcribed to the Angles, who conquered and took poffeffion of a confiderable part of the country. (See Anglen, Angles, and *Cimbric* Chersonesus.) England is bounded on the eaft by the German ocean; on the fouth by the Englifh channel; on the weft by St. George's channel; on the north by the Cheviot hills, by the river Tweed, and an imaginary line extending fouth-weft to the Frith of Solway. The extent of England and Wales is eftimated at 49,450 fquare miles, and if we allow the population to be 9,500,000, the number of inhabitants to a fquare mile will be 192. The original population of England is involved in obfcurity; but as far as it can be traced by any authentic records of hiftory, it feems to have confifted of a tribe of Celtæ (fee Celts), denominated Gael or Southern Celts, and diftinguifhed by the Welfh under the appellation of "Gnydels," who migrated hither from the neareft fhores of France and Flanders. Thefe fouthern Celts were compelled to evacuate the country, and to retire to Ireland, by another tribe, compofed of the Cimbri of the north, whence the modern Welfh derive their origin and name of Cymru. The Cimbri, or Northern Celts, were difplaced by the Scythians, or Goths, who, at a period long preceding the Chriftian era, fettled in that part of Gaul which is neareft to Great Britain, and acquired the provincial denomination of Belgæ. (See Belgæ.) We learn from Cæfar (lib. v. c. 10.) that the primitive inhabitants were driven into the interior parts of the country by Belgic colonies, which occupied the regions on the fouth-eaft, probably about three centuries before the Chriftian era. Thefe Belgæ feem to have conftituted the chief anceftors of the Englifh nation; but during a fubjection of four centuries to the Roman power, after Britain was rendered a Roman province by the talents and virtue of Agricola, (fee Agricola,) they loft their primitive valour, and were unable to contend with their fierce invaders from Scotland and Ireland. In thefe circumftances the continent fupplied them either by accident or at their own requeft, with new emigrants. The Jutes arrived in the year 449, and about the year 460 founded the kingdom of Kent. The Saxons firft appeared in 477, and the kingdom of the South Saxons commenced about this period. The Weft Saxons arrived in the year 495, and the Eaft Saxons in the year 527. The Angles, who gave their name to the country, were led by the valiant Ida to Bernicia, in the year 547. The Eaft Angles took poffeffion of Norfolk in 575; and the coafts on the fouth and eaft were over-run by them. Hence they foon penetrated into the interior of the country, and in 585 founded the kingdom of Mercia, which was the laft of the heptarchy. (See Heptarchy and Saxons.) The kingdom of Northumberland exifted under its peculiar fovereign, the laft of whom was Eric, till the year 950; and the three counties of modern Northumberland, Cumberland, and Weftmoreland, were regarded at that period, when Domefday-book was compiled, as part of Scotland. Bernicia (which fee) extended at one period to the Frith of Forth; but in the later Saxon times the boundaries of England on the north fell confiderably within the prefent extent. On the weft the Welfh were reftricted by Offa's dyke, (fee Dyke,) which extended from the river Wye, through the counties of Hereford and Radnor, into that of Montgomery, where it entered North Wales. It afterwards paffes by Chirk-caftle to the river Dee, and terminates in the parifh of Mold. During the Norman period, the northern limits of England were extended to their prefent circuit. Cumberland and Weftmoreland were wrefted from the Scots, and the provinces north of the Humber were completely incorporated. The dominion of the Danes commenced in the year 1016, but returned to the Saxon line in the year 1042. On the death of Edward the Confeffor, the conqueft, as it is called, under William the Norman, took place in 1066. (See Conquest.) For a farther account of the hiftory of England, fee Britain, and the fequel of this article.

The antiquities of England are diftributed by Mr. Pinkerton (Geog. vol. i.) into fix claffes, *viz.* thofe belonging to the primitive Celtic inhabitants; thofe of the Belgic colonies; thofe of the Romans; thofe of the Saxons; relics of the Danes; and Norman monuments. It is not eafy, fays our author, to difcriminate the remains of the earlieft inhabitants from thofe of the Druidic period, which he fuppofes to have originated with the Phœnician factories, eftablifhed in wooden fortreffes on the coaft, which was the ufual practice of commercial nations, when trading with a favage or barbarous race. The tenets of Druidifm correfpond, as he conceives, with the little that is known of Phœnician mythology, in the diffufion of which the miffionaries of thefe refined people might be not a little zealous. However this

be,

be, the ancient authors, from whom we derive our only authentic information concerning the Druids, minutely defcribe their religious rites; but they are altogether filent concerning any monuments of ftone being ufed among them. On the contrary, they mention gloomy groves, and fpreading oaks, as the only fcenes of the Druidic ceremonies. (See Druids.) Neverthelefs, our learned antiquarian, Borlafe, refers to the clafs of Druidic monuments fuch as follow, *viz.* fingle ftones erect; rock idols and pierced ftones; rocking-ftones ufed as ordeals; fepulchres of two, three, or more ftones; circular temples, or rather circles of erect ftones; rock-bafons, fuppofed to have been ufed in the expiations of the Druids; and caves, ufed as places of retreat in time of war. But Mr. Pinkerton obferving, that moft of thefe relics may be found in Germany, (where no Druids exifted,) and Scandinavia, thinks it hazardous to pronounce whether they be Gothic or Celtic. It is moft probable, he imagines, that the earlieft inhabitants, like others who exift in the infancy of fociety, made ufe of wood, not ftone, in their religions, as well as in their domeftic ftructures. He thinks it moft reafonable to refer monuments of this kind to a more advanced ftage of fociety, when the Belgic colonies introduced agriculture, and had made fomewhat farther progrefs in the rude arts of barbarifm. See Barrow and Cromlech, Stone-henge, &c.

The Roman relics are amphitheatres, caftles, ways, or roads, pavements, hypocaufts, walls, infcriptions, altars, &c. &c. which are defcribed under thefe articles refpectively; to thefe we might add coins, gems, weapons, ornaments, and the like. The Saxon antiquities in England are chiefly edifices, facred or fecular, caftles, vaults, fhrines, illuminated manufcripts, &c. The relics of the Danes are caftles, ftones with Runic infcriptions, and camps, which were conftructed in a circular form, like thofe of the Belgæ and Saxons, while thofe of the Roman armies are diftinguifhed by their fquare form. The Norman monuments are reputed to commence after the conqueft, and to extend to the 14th century, when that which is called the rich Gothic began to appear. This latter was fupplanted, in the 16th century, by the mixed, which in its turn yielded to the Grecian. The Norman ftyle in general far exceeds the Saxon in the fize of the edifices, and the decorations of the parts. The churches became more extenfive and lofty; and though the windows retain the circular arch, they are larger and more diverfified, the circular doors are feftooned with more freedom and elegance; and uncouth animals begin to yield to wreaths of leaves and flowers. The folitary keep, or tower, of the Saxon caftle, is furrounded with a double wall, inclofing courts and dwellings of large extent, defended by turrets and double ditches, with a feparate watch-tower, called the Barbican. Among others the cathedrals of Durham and Winchefter may be mentioned as venerable monuments of Anglo-Norman architecture; and the caftles are numerous and well-known. What is called the Gothic, or pointed arch, is generally fuppofed to have firft appeared in the 13th century; and in the next it became univerfal in religious edifices. The windows diffufed to great breadth and loftinefs, and divided into branching interftices, enriched with painted glafs, the cluftering pillars of exceffive height, fpreading into various fret-work on the roof, conftitute, with decorations of fmaller note, what is called the rich Gothic ftyle, vifible in the chapel of King's college at Cambridge, and many other grand fpecimens in the kingdom. The fpire correfponds with the interior; and begins, about the 13th century, to rife boldly from the ancient tower, and diminifhes from the fight in a gradation of pinnacles and ornaments. See Gothic.

England is now diftributed into 40 fhires or counties. See County and Shire.

For a more particular account of each county, fee the feparate articles.

It is hardly neceffary to mention, that London is the capital of England, or in this place to enumerate its principal towns, which are defcribed under their feveral appellations. Canterbury and York are the fees of archbifhops: Oxford and Cambridge are univerfities. The principal rivers of England are the Thames, the Severn, the Humber, the Merfey, &c. which fee refpectively. For an account of our inland navigation, fee Canal; and for our bridges, fee Bridge. The mountains, with their productions, will occur under that article. For the climate, fee Britain; and of the foil, and agriculture, &c. an account will be found under the name and defcription of each county; and under the appropriate terms of cattle, dog, hog, horfe, fheep, goats, &c. and wheat, rye, barley, oats, apples and cyder, pears and perry. Our forefts (fee Forest) anciently abounded in ftags and rein-deer, as the cultivated lands now do with fheep and cattle. The principal wild animals, wolves and bears having been totally deftroyed, are the fox, wild-cat, badger, fitchet, martin, otter, fquirrel, &c. Among our birds of prey may be reckoned the black eagle, and many kinds of hawks. Our fmalleft bird is the gold-crefted wren, and our largeft the buftard. Our poultry feem to have been originally derived from Afia; our peacocks from India; our pheafants from Colchis; the guinea fowl from Africa; and our turkeys from America. One of the moft fingular of our water-fowl is the long-legged plover, and the moft ufeful is the mallard or wild duck, chiefly abounding in the fens of Lincolnfhire. The reptiles of England are the coriaceous tortoife, frogs, toads, and feveral kinds of lizards; among our ferpents are the viper, which alone is venomous, the ringed fnake and the blind worm, all of which, together with other fpecies, are enumerated and defcribed in their proper places. Our edible fea-fifh are very numerous; among which we may reckon the turbot, dorie, feal, cod, plaife, fmelt, mullet, &c. Herrings and mackarel extend to moft parts of the kingdom; but pilchards are reftricted to the coafts of Cornwall. The whale feldom appears on the Englifh coaft, nor the dolphin; but the porpoife is not uncommon. Our principal river fifh comprehend the falmon and trout. The lobfter is found on moft of the rocky coafts, particularly of Scarborough. The craw-fifh, mufcle and oyfters, are abundant. The flora of Britain contains as great a variety of genera and fpecies as any other country of equal extent; and thofe that are moft worthy of notice, on account either of their variety or utility, or other peculiar circumftances attending them, are enumerated and defcribed under their proper heads. Our native fruits are few, but others have been introduced and our own improved, fo that plumbs, cherries, peaches, nectarines, apricots, figs, grapes, &c. are by the fkill and care of the Englifh gardeners raifed in the greateft plenty and variety. The oak and beech are natives of England: the elm is probably an exotic; but there are few plants in any part of the known world, which have not been introduced into our plantations, nurferies, green-houfes, and hot-houfes.

The conftitution of England is a limited monarchy counterpoifed by two fenates, one of hereditary peers, the other of reprefentatives chofen by the people. (See CONSTITUTION, CROWN, KING, COMMONS, PEERS, PARLIAMENT.) For an account of the judicature of England, we refer to the articles JUDGE, JURY, COURT, CIRCUIT, JUSTICE, SHERIFF, &c. The eftablifhed religion of England is that of the reformed church under the adminiftration of the king, as fupreme head, archbifhops, bifhops, deans, archdeacons, rectors, vicars, curates, &c. See each of thefe titles. See alfo CHURCH, CLERGY, CONVOCATION, *Ecclefiaftical* COURTS, &c. Befides thofe who are members of the eftablifhed church, England abounds with diffidents or diffenters of various defcriptions. See thefe terms, and alfo INDEPENDENTS, PRESBYTERIANS, BAPTISTS, QUAKERS, METHODISTS, PAPISTS, &c. For the army and navy of England; its manufactures and commerce; its land and revenue; its population; and various other particulars; fee BRITAIN, and the appropriate articles in this work.

ENGLAND, *hiftory of.* The principal events belonging to the hiftory of our country will be found under the names of the feveral kings who have reigned over it. To the articles attached to thofe names we might refer generally for a compreffed detail of all the changes and revolutions to which England has, at its feveral periods, been fubject; but in conformity to the plan fketched out in the article BRITAIN, we muft in this place give a very brief outline of the hiftory of England, from the Norman conqueft to the acceffion of James I.; and likewife the hiftory from that period to the prefent times. After the conqueft, our hiftory is reprefented in fo clear a light, as leaves little either obfcure or uncertain. The only difficulty we fhall find will be in condenfing into a fmall fpace the leading facts that are not immediately connected with the lives of the fovereigns.

The Saxon monarchy (fee SAXONS) had continued for more than fix hundred years: during which, as we fhall hereafter fee, they enforced many of their own laws and cuftoms, though they readily adopted others congenial to the country; and which were derived, as well from the Romans, as the ancient Britons, and which they found in the ifland upon their invafion of it. The habits and manners of this race were melted down and amalgamated with thofe of Norman inftitutions. Every thing was changed; the laws in fome refpects were improved, but there was ftill little tafte for literature and fcience. From this period, however, we are to date the commencement of certain inftitutions which, though they required centuries to ripen into maturity, have neverthelefs given this country a fuperiority over every other in the civilized world. The variety of difpofitions of feveral foreign countries being imported into our ifland, at length blended into one national character, celebrated for its courage, its love of freedom, and its pride.

Immediately after the victory of Haftings, the conqueror marched towards London, carrying before him a ftandard which had been bleffed by the pope; and to this the clergy, as is ufual, haftily reforted. The bifhops and magiftrates came out to meet him, and offered him the crown, which he had won by his intrigues and valour. They ftipulated terms to which he readily acceded, being defirous of a fovereignty by the free choice of the people rather than as claimed by the power of the fword. Though he knew himfelf to be their conqueror, he defired to be thought their lawful king. William felt that he had power to enforce obedience, but affecting the voice of the people, they imputed his elevation to their own generofity; and when they felt themfelves oppreffed or aggrieved, did not fcruple to refift his power by open revolt and infurrection. The Englifh hated the Normans, and were jealous of the power which they fuftained in the new government; they envied the wealth which went to enrich thofe who were truly denominated adventurers in a foreign land, and which was raifed by loading the natives with heavy taxes, that in thofe times were with difficulty fuftained. At length William faw he muft act with energy if he meant to reign, and from this time he feems to have regarded England rather as a conqueft, than a juftly acquired dominion. He deprived the bifhops of all judgment in civil caufes, a right which they had affumed during the Saxon fucceffion. He reftrained the clergy to the exercife of their ecclefiaftical power, and he endeavoured to abolifh trials by ordeal and camp fight. See CAMP-*fight*, and ORDEAL.

We do not intend to recount the acts of the kings of England in this article, but fhall rather give a general fketch of the changes and revolutions in the conftitution, government, manners, &c. of England. The changes introduced by the Norman conqueft were not very material to the interefts of the people. Thofe who occupied the loweft ranks, ftill continued in a ftate of flavery; and their numbers were rather increafed than diminifhed. The conquerors treated their flaves with fo much feverity, that a contemporary writer declined to give a defcription of it, left its inhuman cruelty fhould appear incredible to pofterity. As the children of flaves were alfo flaves, this order of the people would have increafed exceedingly, if many of them had not from time to time obtained their freedom, either by fidelity, or uncommon acts of diligence. In fome cafes the clergy had the power of granting freedom to flaves, and fometimes the

the office was performed voluntarily by penitents, who hoped thereby to obtain the pardon of their fins. The middle ranks in fociety, that filled up the interval between the freedmen and the barons, were compofed of different bodies of men, from whom, in procefs of time, the yeomanry and many of the gentry of England are defcended. The inhabitants of towns and cities were generally of this middle rank. The barons were a numerous, opulent, and powerful body of men, and comprehended all the confiderable proprietors of land in England. The acceffion of the Normans produced many important changes in the political circumftances of the people—in the tenures by which they held their lands—the fervices to which they were fubjected—the magiftrates by whom they were governed—the courts in which they were judged,—and the laws they were obliged to obey. Thefe changes were chiefly owing to the eftablifhment of the *feudal fyftem* (which fee) of police and government in England, by William, in the fame ftate of maturity to which it had then attained in his dominions on the continent.

As the moft important changes in the Englifh conftitution were made either in the reign of John, by the limitation of the feverities of that fyftem, it will not be neceffary to dwell on the intermediate reigns. The fucceffion of the crown of England, after the death of Edward the Confeffor, became fo unfettled, that it feemed to be the object of ambition to every bold invader, who poffeffed the flighteft pretence, together with power and courage, to feize the glittering prize. The fecond William, Henry, and Stephen, are regarded as ufurpers, and did, at the time, reign with a difputed title. This was a fortunate circumftance to the natives and their pofterity, as it contributed not a little to raife them from that infignificancy into which they had been depreffed, to the prefervation of what was left, and to the reftoration of what had been loft of their ancient liberties. For the Norman barons, having eftates both in Normandy and England, were anxious that the ducal and royal crown fhould reft on the fame head, that they might enjoy their eftates in both countries. Many of thefe barons therefore favoured the pretenfions of Robert duke of Normandy, eldeft fon of William I., to the crown of England. This obliged his opponents William and Henry to have recourfe to the native Englifh, who were ftill formidable by their numbers, after all the loffes which they had fuftained. Hence they felt their own importance in the fcale of being, and obtained for themfelves certain rights and immunities which their fovereigns were ill difpofed to grant of their own free will. Henry I. granted them a charter, which proved a model on which the famous charter of liberties in the reign of John was formed. He alfo promulgated a fyftem of laws confifting chiefly of thofe of Edward the Confeffor. Stephen, as his title to the throne was more difputed, was more liberal of his promifes; but as he was lefs difpofed to perform what he had bound himfelf to do, his whole reign was a fcene of contention and civil war. At this period the civil law was brought into England from Rome, but not without confiderable oppofition on the part of the people, who were fo much enraged againft it, that whenever they met with a copy of the Roman law, they deftroyed it with every mark of indignation. Henry II. conciliated the affections of his fubjects by granting them a charter, confirming that of his grandfather Henry I. To this prince, whofe reign was protracted to a great length, the country was indebted for many improvements in the law, as well in its adminiftration, as in the forms and practice of the courts. At this period the clergy, who were fcreened from punifhment on account of their profeffion, committed every fpecies of crime, which led (A. D. 1164,) to the enactment of the celebrated conftitutions which had the effect of reducing the clergy to the rank of fubjects. Still, however, juftice was not always adminiftered in thofe ancient times with wifdom and impartiality, partly owing to the ignorance of the judges, and partly to the prevalence of faction among the fuitors of the courts. Nor was it an eafy matter to procure relief from an iniquitous fentence pronounced by a baron or fheriff, on account of the great diftance and unfettled ftate of the king's court, which conftantly attended his perfon. To remedy this inconvenience Henry II. with the advice of a great council of his prelates, earls and barons, at Northampton, A.D. 1176, divided the whole kingdom into fix circuits, and appointed three judges to hold courts in each of thefe, by a commiffion from the king, impowering them to hear and determine all caufes not exceeding the value of one half of a knight's fee, unlefs the matter was of fuch importance or difficulty as to require the judgment of the king's court in the royal prefence. Thefe itinerant jufticcs took an oath to adminifter juftice to all perfons with impartiality. They had alfo authority to judge in all criminal caufes and pleas of the crown, and to tranfact a variety of other affairs for the public good. Under the reign of Richard, befides laws relating to the voyage of his fleet to the Holy Land, and thofe connected with commerce, were others of an excellent nature, in which he attempted to eftablifh an uniformity of weights and meafures over the whole kingdom, a thing greatly wanted, but which has not even yet been accomplifhed. The changes introduced by John have been recited under the article CONSTITUTION. The barons, who procured the famous charter, have been viewed as acting in two capacities, 1, as military vaffals of the crown: 2, as fubjects of the kingdom. They confulted their own intereft in the firft capacity, by the limitations of the rigours of the feudal tenures which they procured, and in which all who held lands by military fervices fhared with them. They confulted their intereft in the fecond capacity, by the amendments which they procured in the general police of the kingdom, in which all their fellow fubjects were partakers. Thefe amendments tended to remove or alleviate the feveral grievances of which the people in general complained; of thefe, the greateft and moft important was, that the mere will and command of the fovereign were fubftituted in the place of law, and men were feized, imprifoned, ftripped of their eftates, outlawed, banifhed, and even deftroyed, without the form of trial. Next to the fubftitution of arbitrary will in place of law, was the king's perfonal interference in law-fuits depending before his courts, in order to interrupt or pervert the regular courfe of juftice. Thefe flagrant outrages at length wrought their own cure, and thofe who had tyrannized over the people were obliged to fubmit to their power.

The common, as well as the ftatute law of England, received confiderable improvements in the reign of Henry III.; but his fucceffor Edward I. was, as a general and legiflator, equalled by few of the kings of England, and furpaffed by none. He was fatisfied with a moderate degree of power, and only laboured to render himfelf terrible to his enemies. The Englifh, now incorporated with their fierce Norman conquerors, were no longer the tame confenting people they formerly appeared, but were always prepared to reafon with that authority which could not eafily be refifted. This fpirit of oppofition was tinctured with cruelty; regardlefs of their own lives, the people did not feem very folicitous about the lives of others. Penal laws began to affume more rigour: in the times of William the Conqueror, it was a law, that no man fhould be punifhed with death; in the

the reign of Edward, that law was entirely laid aside, and several crimes were rendered capital. But what gave permanence to the reputation of this monarch, was the degree of power the people began to assume during this period. The clergy and barons he regarded as rivals; and to weaken their force, he gave authority to the commons: a law was enacted, by which no tax could be levied without their consent. On account of the many wise laws made in this reign, the monarch has been styled the English Justinian. Some of these statutes respected the church, and were intended to set bounds to the power of the pope, the riches of the clergy, and the encroachments of the spiritual courts. Others were calculated for explaining, confirming, and enlarging the liberties which had been granted by the great charter. According to sir Matthew Hale, "the model of the common law, especially in relation to the administration of common justice between party and party, as it was rectified by this king, so in a great measure it has continued the same in all succeeding ages to this day; so that the mark or epocha we are to take for the true stating of the law of England, what it is, is to be considered, stated, and estimated, from what it was when this king left it. Before his time it was in a great measure rude and unpolished, in comparison of what it was thus polished and ordered by him, so hath it stood hitherto, without any great or considerable alteration." Edward made great efforts to reduce the whole island of Britain into one kingdom, governed by the same sovereign, and subject to the same laws; and with respect to Wales, he completely succeeded so as to introduce into it many of the English laws, customs, courts, and magistrates. His efforts to unite Scotland with England finally failed, and they served only to kindle a most violent and implacable animosity between the people of these two kingdoms, which graduallyrendered their manners, laws, and customs more dissimilar than they had been in more ancient and amicable times. In the following reign, the Scots gained a complete victory over the greatest army ever sent into their country: but Edward III., the next in order of succession, contested, with Philip de Valois, his right to the kingdom of France. He therefore made an expedition into that country, and in the celebrated battles of Cressy and Poictiers, entirely destroyed the French army, and carried the monarch captive to England. See EDWARD III.

This wise prince never neglected to consult his parliament in affairs of moment. There are still extant his writs of summons to no fewer than seventy parliaments and great councils. The distinction between these assemblies was this; when he desired only the advice and assistance of his great barons who still possessed the greatest part of the power and property of the kingdom, he called the great council, consisting of all the great men, both of the clergy and laity, who held of the crown by barony, and were entitled to a particular summons. When he stood in need of the counsel and aid of all his subjects, he called a full parliament, which consisted not only of the barons spiritual and temporal, but also of the representatives of the inferior clergy,—of the smaller barons, or freeholders,—and of the citizens and burgesses of the kingdom; and those representatives of the clergy and laity, below the rank of barons, were called the spiritual and temporal commons.

Richard II. came to the crown a minor, and by his heroism in crushing the rebellion of Wat Tyler excited considerable expectation, which was completely disappointed by all the subsequent acts of his life. He submitted himself to evil counsellors, who took possession of his mind, and by their advice he sacrificed his best and ablest friends, and endeavoured to render himself despotic. But he was overpowered, subdued, and obliged to resign his crown in favour of his cousin Henry duke of Lancaster; and this was the commencement of those contests between the houses of York and Lancaster, which for several years after deluged the kingdom with blood, and which nevertheless contributed in no small degree to give strength and consistency to the constitution. In the reign of Richard, Wickliffe began the great work of reformation. The deposed monarch was murdered with a pole-ax in Pontefract castle in the 34th year of his age, having reigned 22 years. His successor, Henry IV. surnamed Bolingbroke, had to contend with much internal trouble, and had so little claim to the sovereignty which he assumed, that conspiracies were speedily formed against him; these, however, were quelled and the leaders of them were executed. "If," says a good writer, "we compare the times at this period of our history with those of king John, or those of some reigns before him, we shall find a great change with respect to the insurgent barons. In the former period they made frequent insurrections, were often taken in open rebellion, and as frequently pardoned: but in this period they were seldom taken without suffering the utmost rigour of the law. This plainly shews how much the power of the barons was sunk in the course of a couple of centuries. This revolution of power is, notwithstanding, natural and obvious: as the people began to share the government with the nobles, the king was fixed upon as a third person to secure the balance, and both were contented to make him great from a jealousy of each other. Noblemen were therefore now executed, not as petty monarchs, but offending subjects, and none but kings were considered as exempt from penal laws."

In this reign the suppression of one rebellion seemed only to make way for another more formidable than the former, and more extensive in its consequences. The calamities of this period were not, however, confined to internal factions excited by discontented barons: the country was threatened with foreign invasions, and the clergy added not a little to the disturbance of the public peace. Ever since Wickliffe had published his opinions, his doctrine had been gaining ground, and the clergy were in dread of its prevailing to the exclusion of their system and to the ruin of their emoluments. Henry joined the clergy, considering that they might be made a powerful engine in establishing his usurped throne, and he recommended the parliament to the care of the church. At first the house of commons seemed reluctant in drawing the sword of persecution; they had not, however, vigour sufficient to oppose the power of the court and the clamours of the priests, but became instruments in their hands for the perpetration of much mischief. An act was passed for burning obstinate heretics; and William Sawfre, a follower of Wickliffe, was, by virtue of the king's writ, delivered to the mayor of London, and burned alive. This was the first martyr in England, on account of religion; but the fires, being once lighted, were not suffered to be extinguished. The clergy, under a mask of hypocrisy, and pretending a regard to truth, took every means that cruelty could suggest of establishing that degree of temporal power, which they had possessed three centuries before. They succeeded, but with this striking difference, that, as in the times of the Saxon heptarchy, their power was founded in the love of the people, in the present case it had its origin in, and was wholly maintained by, their fears. By these means, Henry surmounted all his troubles, and the kingdom enjoyed tranquillity. Towards the close of life he determined to embark upon an expedition to Jerusalem, as well to expiate, as he imagined, the sins of former years, as to induce his maker to protract the term of his life. His increafing infirmities prevented him from executing his plan; and in his 46th year he refigned, by death, his crown to his fon Henry V. During this reign, if allowance be made for the rancour of the priefts, to whom the king was too fubfervient, the government may be faid to have affumed a form and liberty; the diftinction between the nobility and the people was rendered lefs confiderable, and the magiftrates were lefs arbitrary and lefs venal.

Henry V. was the great hero of his age, and the courage which he had manifefted from his earlieft years laid claim to the efteem and affection of the people over whom he was deftined to reign. At this period, courage in the great was regarded as almoft the only virtue: courage and fuperftition then made up the whole fyftem of human duty. The clergy, notwithftanding their revenues, paid very little attention to the morals of the people, and were, if poffible, lefs folicitous about their own character: the vices in which they openly indulged, and the paffions to which they gave free reins, drew upon them a juft degree of contempt; of which they avenged themfelves, by having recourfe to the engine of perfecution. In this they were encouraged by the king, who, by not oppofing, may be regarded as a participator of their crimes. One of the early acts of this reign was an attempt to fupprefs the doctrines of Wickliffe; and John Oldcaftle, baron Cobham, was the principal fufferer in their defence. This excellent man was doomed to bear the moft excruciating torments: he was hung up by the middle with a chain, and by a flow fire literally roafted alive. The deed was fcarcely perpetrated when the king, probably difgufted with the cruelty that had been perpetrated by his fanction and authority, refolved to take advantage of the troubles exifting in France to make a conqueft of that country. Thither he led a very large army, with which he defeated and almoft wholly deftroyed one fix times larger than his own: he immediately advanced into the heart of the country, making himfelf mafter of many towns. At length he married Catherine, daughter of the French king, and acquired thereby the adminiftration of affairs in that kingdom, during the life of his father-in-law, fully expecting to be appointed his fucceffor. But his death, in the year 1422, fruftrated his own and the nation's hopes. His fon, an infant, was afterwards declared king of France and England; but, poffeffing none of his father's heroifm, he foon loft in France all that Henry V. had acquired. The triumphs in France produced fcarcely any advantages at home. As the Englifh grew more warlike, they became more brutal; and in their eagernefs after foreign poffeffions, they neglected the cultivation and improvement of thofe at home. The language became more barbarous. Chaucer and others, about a century before, feemed to have drawn it from obfcurity, and enriched it with new terms and combinations; but at this period it relapfed into its former groffnefs.

The reign of Henry VI. witneffed much bloodfhed, owing to the rival families of York and Lancafter. Thefe calamities did not fubfide till the reign of Henry VII., who was himfelf of the houfe of Lancafter, and married the daughter of Edward IV. of the houfe of York, when an end was put to the diffenfions between the different factions of the white and red rofe. In the famous battle that fixed Edward IV. on the throne of England, it is faid that 40,000 men were left dead in the field. In this dreadful conteft, each party, as it happened to be victorious, called in the executioner to complete the bloody tragedy begun in the field. In the reign of Henry VI. the art of printing was firft practifed in England by William Caxton. He tranflated fome French works, which he printed; and, by his new art, gave currency and celebrity to the tranflations of others. The priefts at this period poffeffed no fmall fhare of erudition, as is evident from fome Latin productions ftill extant; but learning was feparated from the purpofes of common life, and though not neglected by the clergy, yet it defcended no lower, the people at large not confidering it as any concern of theirs.

The wars in which Edward IV. engaged were long and bloody; and, upon a fufpenfion of arms at home, he proclaimed war with France, which he knew would gratify his fubjects, who have been, at almoft every period of their hiftory, more fond of fplendid than ufeful acquifitions. To profecute this fcheme, he fent to his ally, the duke of Burgundy, a reinforcement of 8000 men; and foon after followed himfelf, at the head of a very numerous army. The French king was alarmed at this formidable invafion, and feeling that he was unable to contend with his antagonift, he had recourfe to treaty; and for a ftipulated fum, Edward agreed to lead back his forces to England. Towards the clofe of life he indulged the hope of invading France again: his parliament confented, and in that affembly of the nation the project was unanimoufly declared to be juft and neceffary. The people feemed pleafed with the profpect, and great preparations were made for the expedition, when, fortunately for the interefts of humanity, Edward died after a reign of little more than 22 years.

Edward V. fucceeded, as we have feen, (fee EDWARD,) to the kingdom in name, but not in fact: for, long before he was capable of acting for himfelf, he was depofed and murdered at the inftigation of his uncle, the duke of Glocefter, who fecured to himfelf the crown under the title of Richard III. The infamy of this prince's character has been fully defcribed by every hiftorian of authority. As he obtained the government by treachery and murder, fo he loft his life in fupport of what he had unlawfully gained. At the battle of Bofworth Richard had to contend with Henry, earl of Richmond, who was not only completely victorious, but was proclaimed king by the unanimous voice of the army, on the very fpot in which the cruel Richard was flain. By the death of this king, the Plantagenet race, which had been in poffeffion of the throne more than 300 years, became extinct. With him alfo terminated the contefts between the houfes of York and Lancafter, in which, in the courfe of about 30 years, an hundred thoufand lives were loft either in battle or by the hands of the executioner. Thefe diffenfions had reduced the kingdom to a ftate of almoft favage barbarity: laws, arts, and commerce were entirely neglected; every thing laudable gave place to the practice of arms. The people had attained no ideas of pacific government, nor could they applaud or juftify thofe who cultivated it. In their wars, it is recorded to their credit, that the women, however formidable and active, were exempted from capital punifhment, unlefs accufed of the undefined and undefinable crime of witchcraft. The clergy were diftinct from the laity in cuftoms, conftitutions, and learning: they were governed by the common law, which was delivered to them by the traditions of their anceftors. As a body, they did not intereft themfelves in the civil polity; and were not difpleafed to fee the laity, whom they did not deign to regard as fellow-fubjects, but rivals for power, weakening themfelves by continual contefts: the laity, on the other hand, regarded the clergy with blind veneration, which leffened their refpect and attachment to the monarch on the throne. There was little virtue among individuals of the nation, and the government was fubject to diforders of the moft fatal kind, which perpetually produced all the horrors of civil war.

With

With the reign of Henry VII. we commence a new era in the hiftory of our country. Under his fway we behold one of the greateft revolutions that was ever effected by the prudence and perfeverance of one great prince: a nation of tumult reduced to civil fubordination; a haughty ariftocracy humbled; wife laws enacted; commerce reftored; and the arts of peace cultivated and encouraged by a people, to whom before, war only was delightful. The whole government put on a new form, and Henry was one of the moft ufeful monarchs that ever held the fceptre of thefe kingdoms.

The firft care of Henry was to unite the interefts of the houfes of Lancafter and York, by marrying Elizabeth, the daughter of Edward IV. His reign began very aufpicioufly by a ftrict obedience to the laws, which he ever after enforced with firmnefs and dignity. Before his reign it had been ufual to take away the lives of thofe attainted of treafon; but Henry thought it fufficient, in moft cafes, to deprive thofe taken in arms of their fortune and eftates, which he applied to his own ufe. By thefe means he deprived his enemies of the power of injuring him; and he was enabled, by new acceffions of wealth, to perform many acts of liberality. He is faid to have releafed all prifoners for debt in his dominions, whofe debts did not amount to forty fhillings, and paid the creditors their whole demand from his own coffers. He has been accufed of avarice, but it is doubtful whether his conduct in this refpect does not rather merit the applaufe of ufeful economy. His government was difturbed by attempts at fetting on the throne Lambert Simnel, as earl of Warwick; and afterwards by a fimilar attempt with regard to Perkin Warbeck. In the year 1499 he freed himfelf from thefe confpiracies, by the conviction and execution of Perkin and the feigned earl of Warwick. After this, the reign of Henry was truly refpectable: his government was formidable to his own fubjects, and claimed the refpect of rival potentates. He paid much attention to the wants of the lower claffes, and was anxious to deprefs in the fcale of power the nobility and clergy. From thefe moft of the calamities of former reigns had refulted; and on that account he contrived means to leffen their authority in the ftate. He allowed the nobility, by a law paffed in his reign, to alienate their eftates; and he diminifhed, as far as he was able, the privileges claimed by the clergy as their right. He was, at the fame time, a friend to the people, who in former periods were the fure victims of powerful ambition and revenge. They, in all cafes, were the fufferers, on whatever fide they fought, if they had the misfortune to lofe the victory. To remedy this, in a great degree, Henry procured the paffing of an act, by which it was eftablifhed that no perfon fhould be impeached or attainted for affifting the king for the time being. This wife ftatute ferved to reprefs the defire of civil war, as multitudes would naturally take arms in defence of that fide on which they were fure of lofing nothing by defeat, and their numbers would intimidate infurgents. But the greateft efforts of this king were directed to promote trade and commerce, which naturally introduced a fpirit of liberty among the people, and difengaged them from their dependence on the nobility. Before this era, the towns owed their original to fome ftrong caftle in the neighbourhood, where the great lord generally refided, maintaining at his expence a very large retinue, who, as dependents on his bounty, were on all occafions bound to vindicate his caufe. The number of thefe drew together, in or near the fame place, artificers, victuallers, and fhop-keepers, to furnifh the lord and his attendants with the neceffaries of which they ftood in need. It was the wife policy of Henry to bring the towns from fuch a neighbourhood, by inviting the inhabitants to a more commercial fituation. He attempted to teach them frugality and the payment of debts; the life of induftry, by his own example; and never omitted to include the rights and principles of commerce, in all his treaties with foreign princes.

At this period the continent, as well as the Britifh ifles, feemed to be making great advances to improvement. The fovereigns of Sweden, France, and Spain, were the encouragers and protectors of the rifing arts. The Portuguefe had failed round the Cape of Good Hope, and Columbus had juft made the difcovery of a new world. Henry was defirous of following the example fet him, and granted to certain enterprizing merchants to go in queft of new countries. By thefe and fimilar exertions the king faw his country civilized, the people pay their taxes without infurrection; the nobility learning a juft fubordination, the laws alone fuffered to inflict punifhment, towns begun to feparate from the caftles of the nobility; commerce every day increafed, and the fpirit of faction was in a great meafure extinguifhed. He was at peace with all the world, and having iffued a general pardon to his own fubjects, he had reafon to expect the happinefs to which wife meafures and true patriotifm are juftly entitled; when, at the age of 52, he died of the gout in his ftomach. In fome refpects he has been regarded as the fecond Alfred, a title to which he has a good claim, on account of the great changes which he introduced in his kingdom;—changes which had the moft favourable tendency to effect the improvement and happinefs of his fubjects.

Henry VIII., the fon to the late king, affumed the reins of power under the moft fortunate aufpices. He found himfelf in poffeffion of a peaceable and flourifhing kingdom; prudent minifters, who knew the wants of the people, and were ready to provide for them; and a well-ftored treafury. The young king, however, made but an ill ufe of the bounties of providence, with which he was fo abundantly furrounded. He had been diligently inftructed in all the learning of the times; but his ftock of knowledge ferved only to inflame his pride, and not to control his vicious affections. The love of his fubjects was teftified by an adulation, which produced the moft mifchievous effects. His vaft wealth, inftead of relieving his fubjects, or of increafing the national honour, only contributed to fupply his debaucheries, or gratify the rapacity of the minifters of his pleafure. The acts of his life will come more properly under the article devoted to his name. In this place it will be fufficient to obferve, that he was perpetually falling from one extreme to another, and agitated by contrary paffions; it became doubtful to his fubjects in what manner they fhould act, or what they fhould believe, fo as to obtain his approbation. His conduct as a king was marked with the moft atrocious acts of tyranny; he expected every one to fubmit to his will, however frequently that will was changed: yet his reign is memorable on account of the great revolution that was achieved in it by the celebrated Luther, for a full account of which we refer to the article LUTHER. At firft the king wrote againft the doctrines avowed by the former; and for his ability and learning, obtained from the pope the title of "Defender of the Faith," a title which has been continued to his fucceffors to the prefent time. He afterwards revolted from the Roman church, and required that his fubjects fhould acknowledge him, and him only as head of the church of England. The parliament, entirely dependent on the king, fided with him in his views of feparating from the church of Rome, and readily complied with his other meafures to ftrengthen the reformation. Henry, who was an artful politician, knowing that his parliament was devoted to his will, made uſe of the opportunity to render himſelf abſolute. He accordingly oppoſed the parliament againſt the monks, and obtained their ſuppreſſion. While parliament was buſy in ſuppreſſing the religious houſes, moſt of which were houſes of infamy, the king was deviſing methods of deſtroying the power of the ſuppreſſors. This was the origin of the unlimited power which he now aſſumed: he had a moſt complying parliament, ready to ſanction not only what he did, which in many inſtances were deeds of the darkeſt hue, but likewiſe what he intended to do. He was not wanting to ſtrengthen his own power, and claimed the ſame obedience to his proclamation as to the acts of the whole legiſlature. No king of England, as will be ſeen hereafter, lived ſo much the terror of his people. Some perſons wielding a ſceptre have been tyrants, from the frequent revolt of their ſubjects; ſome, from being miſled by favourites; and ſome, from a ſpirit of party: but Henry VIII. was cruel, from a diſpoſition which ſeemed prone to inflict miſery on all about him; he was a ſavage in government, in religion, and in his own family: yet ſuch are the inſcrutable diſpenſations of heaven, that while the harmleſs Henry VI. was dethroned, impriſoned, and aſſaſſinated, the preſent tyrant was permitted to die a peaceable and natural death, if we except the ſufferings which a guilty conſcience cannot fail to inflict. Fortunately perhaps for the people, Henry contrived to diſſipate all thoſe treaſures of which his tyranny plundered his ſubjects: he died poor, and tranſmitted the crown to his ſon and ſucceſſor as dependent on the people for their ſupplies in parliament as at any former period. The wanton profuſion of princes is always hurtful to themſelves; but in many inſtances it has been beneficial to their ſubjects, by preventing greater evils. If Henry VIII. had been more frugal, he would probably have been more dangerous.

The character of Edward VI. has, under his own name, been deſcribed. He died at too early an age to act for himſelf; but during his ſhort reign, the principles of the reformation were encouraged; people were allowed to uſe or diſuſe the practice of confeſſion, as they thought fit; images were taken from the churches, prieſts were allowed to marry, the maſs was aboliſhed, and a liturgy was drawn up, which, with very few alterations, has been continued to the preſent times. Such important changes could not be effected without danger: inſurrections were excited in many parts of the kingdom, which were without much difficulty ſuppreſſed, though many were the victims of the unhappy conteſts.

The reign of queen Mary was marked with cruelty and bloodſhed. She reſtored the Roman Catholic religion, and without heſitation burnt, or otherwiſe deſtroyed, all who fearleſsly oppoſed her will, and the will of her infamous miniſters, Bonner and Gardiner. The reign of this ſovereign was fortunately ſhort; yet, in ſomewhat leſs than four years, five eminent and conſcientious prelates, twenty-one miniſters, and more than eight hundred ſubjects of lower rank in life, were conſigned to the flames for maintaining what they believed to be truth: beſides theſe, we have no accurate account of the numbers who died in priſon, by more lingering and more cruel deaths than even the flames of Smithfield could inflict; nor has it been recorded how many, through fear of death, ſacrificed a good conſcience, and thereby endured for the remainder of their lives ſufferings a thouſand times worſe than the death which a tyrant is enabled to order.

Elizabeth, whoſe character and government have been delineated in the laſt volume, reſtored the principles of the reformation, and advanced the kingdom to the higheſt pitch of ſplendour. She had been nurtured in the ſchool of adverſity, and drew from it leſſons of the higheſt importance to her future conduct. While ſecluded from the buſy world in a loneſome priſon, ſhe was employed in the improvement of her mind, and in deviſing methods of reforming the church, ſo ſoon as providence ſhould make way for her government; and one of her earlieſt acts as ſovereign was to eſtabliſh the reformed religion. The people readily ſeconded her deſigns: they perceived the ill uſe which the papiſts had made of their power in the laſt reign; and they were willing to ſuppoſe that the ſavage acts, which had been committed by Mary and her biſhops, were the neceſſary conſequences of the faith which they eſpouſed, and in behalf of which they effected their cruel purpoſes. Elizabeth ſoon aſſembled her parliament, the reformation was finiſhed, and that form of religion was eſtabliſhed which is now deemed the religion of the country. The clergy, in general, ſubſcribed to the new forms: of nearly ten thouſand who were in poſſeſſion of benefices of different degrees of rank and value, ſcarcely more than an hundred choſe to quit the emoluments of their office, rather than abandon the principles to which they had adhered in the laſt reign. "Thus," ſays an hiſtorian, "England changed its belief four times ſince the acceſſion of Henry VIII." Strange that a people, who are ſo reſolute, ſhould be guilty of ſo much inconſiſtency! that the ſame people, who this day publicly burn heretics, ſhould the next not only think them guiltleſs, but conform to their opinions. Elizabeth, though firmly fixed on her throne, had enemies in almoſt all the neighbouring potentates; who endeavoured by every means in their power to excite diſcontent among her own Catholic ſubjects. In this ſituation, ſhe could only rely upon the reſources which proceeded from the affection of her ſubjects, and the wiſdom of her adminiſtration. Her governing maxim was unqueſtionably founded in wiſdom; it conſiſted in acquiring the eſteem and affection of her people. She was an economiſt of the nation's money, and ſparing in her rewards to her favourites. She diſtributed rewards and puniſhments with impartiality; knew when to flatter and when to upbraid; could diſſemble ſubmiſſion and preſerve her prerogatives; ſhe ſtudied the people ſhe was to govern, and not unfrequently flattered their follies in order to ſecure their hearts.

The errors of this ſovereign, and the acts of cruelty to which ſhe gave her ſanction, have been deſcribed in her own life, or in that of archbiſhop Cranmer, or will be found hereafter in the article Mary queen of Scots, or in other parts of this work of minor conſideration; but it muſt be obſerved here, that whatever puniſhments or cruelties were exerciſed in this reign, they moſtly fell upon the great, and in no inſtance were the people more happy internally, or more formidable abroad, than during this period. It will, however, be readily admitted, that it was not owing entirely to the queen that the nation was ſo completely proſperous at this period; the people, as if ſpontaneouſly, began to exert their native powers, and every art, and every genius put forth all their vigour. The Engliſh could not boaſt of new or ſplendid acquiſitions: their influence in foreign courts was extremely limited, but commerce grew up and flouriſhed. The people began to feel the effects of their own exertions, and to underſtand in what conſiſted the independency of a great nation; and England became at once laborious, enterprizing, powerful, and in a degree poliſhed and polite. The ſucceſsful voyages of the Spaniards and Portugueſe excited their emulation: they fitted out ſeveral expeditions with a view of diſcovering a northern paſſage to China, and, though

though difappointed in their firft and principal object, their voyages were not wholly fruitlefs. Our countrymen, Cavendifh and fir Francis Drake, circumnavigated the globe, and difcovered in the profecution of their voyages a fkill and prowefs very fuperior to the moft experienced navigators of thofe nations who led the way in nautical difcovery. Sir Walter Raleigh, without any affiftance from government, colonized New England; and thefe expeditions at length formed one of the moft powerful marines of Europe, which in a very fhort time was enabled to oppofe the fleet of Spain. (See ARMADA.) The fuperiority obtained by the Englifh at fea, at this period, gave them a fort of naval fovereignty which they have ever fince inviolably preferved, and which, we truft, they will very long maintain, notwithftanding the boaftful language of the prefent emperor of France. If, for wife purpofes, he muft fubject the continent to his power and controul, we truft that our own iflands will, by union among the people, be freed from the tyranny which he has for many years been exercifing among other nations, which have evidently been facrificed by their own want of unanimity, and by the mifmanagement of their fovereigns.

In the reign of Elizabeth, external commerce was not more cultivated than internal manufactures. Flemifh manufacturers, who had been perfecuted at home, fled to England for an afylum, which they found, and for which they made ample amends by the arts which they introduced, and the induftry which was excited by their example, and by the wealth which their labours acquired. In polite arts and in literature the Englifh excelled all other nations. The reign of Elizabeth has by fome writers been denominated the Auguftan age of literature. The difputes caufed by the reformation of religion had retarded the progrefs of our language among the powerful, but they excited a fpirit of enquiry among the middling and lower orders of fociety. The people began to read, and being allowed to perufe the bible in their own language, their morals, and perhaps their tafte, rapidly improved. The reformers, who had fled from the perfecutions of Mary, returned to promulgate their doctrines at home, and by a refidence abroad their language was corrupted by foreign idioms and barbarous phrafes. Thefe archbifhop Parker fet himfelf affiduoufly to reform, as well by his own excellent example as by precept. He corrected the Englifh tranflation of the bible, and printed it with royal magnificence. His own ftyle poffeffed all the eloquence of the times; it was manly and concife, but wanted fmoothnefs.

Such were the leading improvements in Elizabeth's reign; and, fays a good writer, "if we look through hiftory and confider the rife of kingdoms, we fhall not find, in all its volumes, fuch an inftance of a nation becoming wife, powerful, and happy in fo fhort a time. The fource of our felicity may be traced to the reign of Henry VII., and though the ftream was interrupted by intervening tyrannies, yet, before the end of Elizabeth's life, who was his grand-daughter, the people became the moft polifhed and the moft happy people upon earth. Liberty, it is true, as yet continued to fluctuate: Elizabeth knew her own power, and often ftretched it to the very limits of defpotifm; but when commerce was introduced, liberty neceffarily entered in its train; for there never was a nation completely commercial, and at the fame time perfectly defpotic."

On the death of Elizabeth James VI. of Scotland fucceeded to the throne of England, with the univerfal approbation of all orders of the ftate. Elizabeth bequeathed him her crown almoft with her laft breath; he was the neareft in the order of fucceffion, and he had all the fanction which parliament could confer. He began his reign by a laudable attempt to unite both kingdoms into one, which he effected without much difficulty, and from that period the two kingdoms have been governed by one fovereign. James, though ufed to arbitrary power, fet himfelf to ftudy the Englifh laws, by the authority of which he refolved to govern. Whether he did not comprehend their full import, or that his habits were too much fixed to fubmit to the neceffary changes which his new fituation required, it would be ufelefs to enquire; but it is certain that his whole reign was marked with difputes between him and his parliament. The king was ever attempting to keep the royal fplendour unfullied; the other aiming at leffening the dangerous part of the prerogative: the one labouring to preferve the laws and inftitutions of former reigns; the other as ftedfaft in afferting the inherent privileges of mankind. When the parliament refufed a fubfidy, the king was defirous of availing himfelf of the precedents fet by other monarchs, by extorting a benevolence. The houfe of commons felt their confequence as the protectors of the people, and remonftrated againft every act of arbitrary power, as incompatible with their rights and privileges. Thefe attempts of the crown, and the refiftance of the people, continued through the whole reign, and firft gave rife to that fpirit of party which has ever fubfifted in England, the one fide declaring for the king's prerogative, the other for the rights and liberties of the fubject.

James exhibited much moderation with regard to thofe who did not think on religious fubjects as he was accuftomed to think, and who did not conform to the eftablifhed forms of church difcipline, wifely judging that men fhould be punifhed for evil actions, and not for erroneous opinions. The confpirators againft his government, as will be feen in his life, were feverely punifhed; but he cultivated the arts of peace, and obtained as a juft reward the general good will of the nation. It has been afcribed to this monarch that the Englifh have attained to a noble freedom of thought, and the dignity of juftifying their opinions. James neither cultivated nor underftood foreign negociations or alliances. His reign was marked with none of the fplendours of triumph, nor with new conquefts and acquired dominions; but the arts were filently advancing in improvement: reafon was extending her influence, and defcrying a thoufand errors in religion and government that had been rivetted by long prefcription. The people began to think for themfelves, to eftimate their rights and confequence: the reformation had introduced a fpirit of liberty, even at the time that the conftitution and the laws were built upon arbitrary power. "James," fays the hiftorian, "taught them, by his own example, to argue upon thefe topics: he vindicated the divine right of kings againft the natural privileges of the people: the fubject began in the controverfy, and it was foon difcovered that the monarch's was the weakeft fide of the queftion."

Charles I. afcended the throne in the year 1625, and was extremely popular, as well on account of his own virtues and addrefs, as in refpect to the fortunate circumftances in which he was placed. The country was in a peaceable and flourifhing ftate: his title to the crown was undifputed, and he had formed an alliance with one of the moft powerful monarchs that ever reigned in France, whofe fifter he had married. The pleafing profpect was of fhort continuance; the people had learned to reafon: they felt their own power, and it was determined in parliament to oppofe the ancient claims of the crown. Charles had been taught to confider the royal privileges as facred pledges, which it was his duty to defend; his father had implanted the doctrines of hereditary and indefeafible right early in his mind. James contemplated these doctrines in theory, but it was soon the fate of Charles to assert and defend them by action. He mistook the genius of the people he had to govern; they had imbibed the principles of liberty; but he wished to act by maxims and precedents that had their origin in times of ignorance and slavery. The late king had been forced into breach with Spain, and Charles gave early indications of a despotic temper, which rendered the parliament remiss in furnishing him with money for carrying on the war. In a short time his favourite Buckingham persuaded him to take the part of the French Hugonots, in their quarrel with the crown. They were ill supported, and the protestant interest received an irrecoverable blow in France. The blame was attributed by the people and parliament to Buckingham, who was assassinated by Felton. This the king laid seriously to heart, though it did not deter him from his arbitrary proceedings. For several years Charles reigned without assembling a parliament, during which he did as he pleased, promulgating laws, and imposing taxes on his subjects to the great mortification of those who felt for their liberties as men and Englishmen. He laid arbitrary impositions upon trade, which many resisted: he levied monies upon monopolies of salt, soap, and other necessaries of life. His government became every day more unpopular, and Burton and Prynne wrote against the proceedings of the court. They were prosecuted for their writings in the star-chamber in a very arbitrary and cruel manner, and punished with so much severity as excited an almost universal indignation against the authors of their sufferings. The king next made use of Laud and Strafford as instruments in carrying on his despotic measures. These he was in a short time obliged to abandon to an ignominious death on the scaffold. Charles, in the early part of his reign, had passed the petition of rights into a law, which was intended by parliament for the future security of the liberty of the subject, by which it was enacted "that no man hereafter should be compelled to make any gift, loan, benevolence, tax, &c. without common consent of parliament." This principle he perpetually violated till at length a civil war broke out. Notwithstanding the many acts of tyranny and oppression, of which the king and his ministers had been guilty, yet multitudes sided with the court and joined the standard of Charles. Many of the nobility and gentry were attached to the crown, and considered their own honours as connected with it, and no inconsiderable part of the landed interest joined the king. The parliament claimed for themselves the executive power, and were favoured by most of the trading towns and corporations; but its great resource lay in London. The first battle was fought at Edge-hill, in Warwickshire, in which the royalists were so far triumphant that parliament was obliged to invite the assistance of the Scots, who entered England with 20,000 horse and foot. From this period war was carried on with various success, till at length the king was overpowered, reduced, imprisoned, tried, and finally beheaded. The character of this prince will be found under the article CHARLES I. With the death of the king, the miseries of civil war terminated, and the parliament, which was triumphant, had now no enemy to fear, except those very troops which hitherto had been instruments in their hands, in achieving their designs. At first they hoped to disband the troops; but Cromwell, who was the rival power in the state, had other projects to accomplish. He had already rendered the army in a great measure independent of the parliament; and now formed a council of officers, and another of common soldiers, called agitators, who were appointed to enquire into the grievances of the military, and lay them before parliament. As the commons, from necessity, granted their requests, the army rose in their demands, till at length the parliament enjoyed but the shadow of authority. It, however, passed an act, making it high treason to acknowledge Charles Stewart, son of the deceased king, as successor to the throne. They likewise voted the house of lords useless and dangerous, and passed an act for the abolition of all kingly power. A great seal was made, on one side of which were engraved the arms of England and Ireland, and on the reverse was represented the house of commons sitting, with the motto, "The first year of freedom, by God's blessing restored 1648." No measure was omitted that could probably establish the power of the usurper, and exclude for ever the kingly power in England. Much was done for retrieving the glory of England at sea. Cromwell and Ireton excited the jealousy of the republicans, who contrived first to employ them in the reduction of Ireland, and afterwards against the Scots, who had acknowledged and received Charles II. as their king. Almost immediately, by the most unparalleled exertions, a fleet was produced superior to any that had ever been seen in Europe. An act of navigation was passed, and war was declared against the Dutch, who were till then regarded as invincible at sea. Cromwell, from his successes in Scotland, found little difficulty in obtaining the honour of being declared commander in chief of the English army. Admiral Blake, and other naval commanders, carried the terror of the English name by sea to all quarters of the globe, and Cromwell, having little employment, began to think how he might establish his own authority paramount to that of the state. On the 20th of April 1653, at the head of 300 musqueteers, he dissolved the parliament, opprobriously driving the members, about one hundred in number, out of their house. He next annihilated the council of state, with which the executive power was lodged, and transferred the administration of government to about 140 persons, whom he summoned to Whitehall on the 4th of July 1653. After this he was declared lord protector; which, however, did not comport with his ambitious views; he was desirous of the name, as well as the power of king, to which he could never arrive; and in September 1658, he died after an usurpation of nearly five years. See CROMWELL.

From Charles's death in 1648, to the decease of Cromwell in 1658, England was unquestionably improved equally in riches and power; besides the introduction of the navigation act, which was established in the reign of Charles II. and which has been regarded as the palladium of English trade; monopolies of all kinds were abolished, and liberty of conscience to all sects was granted, which was highly advantageous to the population and manufactures of the country. Under Cromwell, the arts, sciences, and literature were not much encouraged, yet he did many things worthy of praise; and as his genius and capacity led him to the choice of fit persons for the several parts of administration, so he paid some regard to men of learning, and particularly to those entrusted with the care of youth at the universities. Richard, his successor, possessed none of the talents for business, nor indeed any activity of disposition, for which his late brother was so celebrated, and was in a very short time driven, without resistance, into that obscurity for which his temper was better adapted, than for the business of government. The resignation of his power made way for

Charles II. who returned to the throne of his father by the general concurrence of the people; this was in the year 1660, and for some time he seemed desirous of promoting the people's happiness, though he did not forget to avenge himself on the enemies of the late king; the bodies of Cromwell, Ireton, and Bradshaw were taken from the tomb,

and

and treated with every indignity. Of thofe who fat in judgment on Charles I. fome were dead, others had left the country, and fome the reigning prince thought deferving of mercy, but ten were devoted to almoft immediate deftruction. Thefe bore their fufferings with the conftancy of martyrs dying in a good caufe, thanking heaven in the extreme of their torments, that they were allowed to be witneffes of the truth. It was now to be feared that the tide of loyalty would bear away in its courfe all the former mounds of freedom. Parliament feemed to concur in all the defigns of the court, and even to anticipate its wifhes; but the monarch was by no means attentive to thofe who had followed him in his misfortunes; his pleafures and his flatteries engroffed all his cares, and exhaufted his finances, fo that he had nothing left, and, apparently, no wifh to pay the debt of gratitude. From thofe who would willingly have expoftulated with him on his mifconduct, he fled, and endeavoured to forget every kind of ferious bufinefs in fcenes of mirth, riot, and debauchery. By his own example, he undermined the principles of religion, and the nation, prone to extremes, exhibited every fpecies of licentioufnefs, which was practifed in the moft diffolute court that ever exifted in England. Charles II. though without a pretence to religion, permitted the perfecution of fectaries, which excited among thofe, who were objects of it, a plan for a general infurrection. The plot was difcovered, and the confpirators were taken and executed. This circumftance afforded a pretext for continuing the parliament then fitting; and repealing the act for triennial parliaments, as being dangerous in times of commotion. This parliament was fo completely fubfervient to the will of the king, that he might, with activity, have become abfolute. They confirmed the infamous doctrine of paffive obedience by a folemn act, and affigned the king a revenue of twelve hundred thoufand pounds, a fum which none of his predeceffors had ever poffeffed; neverthelefs his prodigality rendered him indigent, and inftead of defiring an afcendancy over his parliament, he was content to be a perpetual dependent on their bounty. His prodigality and libertinifm foon alienated the affections of his fubjects, which in the fhort period of two years were changed to a contempt of his perfon and adminiftration. The war, in which he engaged with the Dutch, was unattended with any brilliant fuccefs, and the enemy's attempting to fail up the river Thames excited clamours againft the government. The people began to compare the prefent ftate of things with the meafures and adminiftration of Cromwell; in the one cafe they enjoyed fecurity at home, and claimed the higheft refpect from furrounding nations; in the other every principle, private and public, was forced to give way to the paffions of the fovereign, which he was determined to gratify at any expence. Uniformity in religion became the popular cry, and, in 1673, the teft act was paffed, obliging every perfon in or under government, not only to take the oaths of allegiance and fupremacy, but receive the facrament of the Lord's-fupper in fome parifh church, before competent witneffes, and fubfcribe a declaration renouncing the doctrine of tranfubftantiation. This was levelled againft the duke of York, the king's brother, who was an avowed papift, and whom the parliament wifhed to exclude from the throne. The fears and difcontents of the nation were vented without reftraint, which gave great offence to the court. A great degree of feverity was exercifed againft the nonconformifts to epifcopacy, and every means taken that was likely to reprefs the rifing fpirit of the country. It was known or violently fufpected that Charles was a penfioner on the court of France, his parliament in 1677, addreffed him to make war upon that country, which he refufed. The people became exafperated againft almoft all public meafures; the king was alarmed with the profpect of a civil war, and made confiderable conceffions to avoid the odium which his paft conduct had juftly incurred. Many of the leading members of parliament had however determined on fuch a change as fhould exclude the duke of York from the crown. To forward this the famous plot of Titus Oates was contrived, which charged the papifts with a defign of murdering the king, and of introducing popery by means of the Jefuits, as the eftablifhed religion of the country. Several refpectable perfons were tried and convicted, principally on the evidence of Oates, who was unworthy of credit. A bill was brought into parliament to exclude the duke from the throne, which was paffed in the commons, but was thrown out in the houfe of lords. A plot was now invented on the other fide, in which the principal proteftants were accufed of an endeavour to deftroy the king. For this, on the evidence of lord Howard, a man of infamous character, lord Ruffel, who had been zealous in his oppofition to the popifh fucceffion, Algernon Sidney, and other diftinguifhed characters, were tried and executed. The terror which the meafure carried with it intimidated the beft friends to their country; it filenced the oppofition of the city of London and other corporations, and the duke of York triumphed in the victory which had been obtained by perjury. From this period the reign of Charles was as abfolute as that of any monarch in Chriftendom, but the fpirit of freedom, which the people had imbibed, ftruggled hard againft the fpirit of obedience, which the clergy attempted to inculcate. Another civil war threatened the nation ftill more dreadful than the former, as the forces were more equally divided; but fortunately for the peace of the country, the king was fuddenly feized with an apoplectic fit, and died in the fifty-fourth year of his age.

Though England, during the reign of the fecond Charles, was agitated by contending interefts, yet commerce continued to increafe; its good effects had been duly appreciated, and multitudes were ready to turn their wealth and induftry into this courfe. Many new manufactures were introduced, and many old ones brought to perfection. When France, by fhameful and wicked policy, banifhed her beft fubjects, the proteftants, England opened her arms to receive them, and with them fhe received large acceffions of national wealth. To the afflictions and exile of this monarch we are indebted for many of our beft vegetables which were introduced by his followers from the continent. Science and literature made rapid progrefs during this reign: Newton and Tillotfon; Burnet and Shaftfbury; Butler and Dryden flourifhed at this period: the Royal Society was inftituted, and from this time our countrymen took the lead in every ufeful fcience, and they have maintained their fuperiority to the prefent hour. Nor muft it be forgotten, that if Charles was the firft of our monarchs who claimed the protection of ftanding forces, yet to him and his brother we are indebted for fome very important improvements in the art of fhip-building, an art which has given us a preponderating balance among the nations of the world, and which, we truft, will, in the hands of an over-ruling providence, preferve us from that overwhelming ruin in which almoft all the empires of the continent are involved.

The oppofition, which during the late reign had fhaken the throne, vanifhed almoft entirely at the acceffion of James II. The affection of the people feemed to know no bounds when the king, as it were, fpontaneoufly made a declaration in favour of the church of England. That church, to flatter the prejudices of the prefent and late monarchs, had authoritatively from the pulpit and prefs pronounced all refiftance to a reigning sovereign unlawful: a doctrine which, however pleasing it might be to the feelings of the king, proved fatal to his peace, and, in the event, drove him from the kingdom. The army and people supported him in crushing an ill-concerted rebellion of the duke of Monmouth, who pretended to be the lawful son and heir of Charles II., and had assumed the title of king. The duke was taken and was beheaded; and some hundreds of his adherents lost their lives likewise by the instrumentality of judge Jeffries and colonel Kirke, names that have been deservedly handed down to posterity with every infamy that can attach to human nature. James, with such assistance, determined to try how far the church of England would agree in the practical assertion of the doctrine of non-resistance. He was set upon introducing popery as the established religion of the country. He laid pretensions to a power of dispensing with the known laws; he instituted an illegal ecclesiastical court, and openly received and admitted into his privy council the pope's emissaries, and gave them more respect than was due to the ministers of a sovereign prince. He sent an embassy to Rome, and received, at his court, the pope's nuncio, and, to crown all, his encroachments upon the civil and religious liberties of his people were carried beyond all bounds, even to the disgust of Roman catholics themselves; and the pope was too good a politician not to know that the course taken by James must eventually ruin the cause which he professed to advocate. The church of England took the alarm, when the king had ordered a declaration to be read, by which every restraint on popery was removed. Seven bishops refused to comply with their sovereign's order, and presented a petition to excuse their refusal. They were cited before the council to answer for their conduct, and adhering to their resolution, were committed to the Tower, prosecuted by the attorney-general for sedition, tried, and gloriously acquitted. The joy of the people, on this occasion, was inexpressible: the city and the country seemed at once to catch the shouts of exultation. James heard the intelligence with sullen silence, and evident indignation, while he was at dinner in his camp. From the church he turned to his army, who proved equally hostile to his views. Opposition, however, served only to increase his zeal, till at length some of the principal people in the country resolved to apply for relief to William, prince of Orange, who was at once the nephew and son-in-law of James II. William, who was an able politician, and ambitious of wearing the crown of England, readily listened to the proposals made him, embarked in their cause, and landed a large army almost before his designs were suspected by the court of James, who, in a few days deserted their old master, and sought protection from the new. The old king was now deeply convinced of his errors, and would gladly have retracted his measures, but it was too late: he found himself abandoned by his army and fleet, and learnt, with apparent consternation and horror, that the prince of Denmark and his favourite daughter Anne had gone over to the prince of Orange. On this intelligence he is said to have wept bitterly, exclaiming, "God help me, my own children have forsaken me." He now hung over the precipice of destruction, invaded by one son-in-law, abandoned by another, hated by his subjects, and held in utter detestation by the friends and relations of those who had suffered by his cruelty. He assembled the few noblemen who still adhered to his cause, and demanded their advice and assistance. Addressing himself to the earl of Bedford, father to lord Russel, who had been beheaded at the instigation of James in the preceding reign, "My lord," said the dejected monarch, "you are an honest man, have great credit, and can do me signal service." "Alas! sir," replied the earl, "I am old, and very feeble, and can afford you but little service, but *I once had* a son that could have assisted you in this extremity, but he is no more." James was so struck with the reply, that he could not speak for many minutes. After this he almost instantly resolved to abandon his country, and seek for himself, his queen, and his son, real or pretended, then only six months old, an asylum in France, where he passed the remainder of his life among a people who pitied, ridiculed, and despised him.

From this moment the constitution of England, which had fluctuated for ages, was fixed. The nation, represented by its parliament, determined the long contested limits between the king and the people: they prescribed to the prince of Orange the terms by which he was to rule, and appointed him king jointly with Mary, who was the next protestant heir to the crown. They were shortly after crowned by the titles of William III. and Mary, king and queen of England. The prince had his ambition amply gratified, and his wisdom was repaid with that crown which the folly of his predecessor had thrown away.

The power of William was limited on every side, and he met with an opposition from parliament which he did not expect. His chief object was to humble the power of France, and he fully anticipated the utmost efforts of the English to second his views, but he found them more intent upon guarding their domestic liberties than eager against continental powers; notwithstanding this, his reign was spent in an almost uninterrupted course of hostilities with France, at an expence she had never known before. The nation had grown cautious through the experience of the two last reigns, and he gave his consent to the "bill of rights," by which the liberties of the people were confirmed and secured, though not in so ample a manner as might have been done at a crisis when a crown was bestowed by the free voice of the people. The last two kings had made a very bad use of the whole national revenue, of which they had an unlimited use, and it was found in their hands quite sufficient to raise and maintain a standing army. The revenue was now divided, part of it was allotted for the national service of the year, and was to be accounted for to parliament; and part, which has ever since been denominated the civil list money, was given to the king for the support of his house and dignity.

William was averse from persecution, and began his reign by attempting a repeal of those laws that enjoined uniformity of worship, and though he could not do all he wished, yet he obtained practical toleration for the dissenters; and the laws against the papists were rarely executed. He was, however, a stickler for what he regarded as the privileges of the crown, and often controverted, and remonstrated against the views of his parliament, and was, not unfrequently, arbitrary in his councils. He opposed with the utmost vehemence the bill for triennial parliaments, and, when it had actually passed the two houses, he refused to give it his royal assent. The house of commons, who are or ought to be the representatives of every individual in the country, took fire at this abuse of the royal prerogative, and voted, with becoming spirit, "that whoever advised the king to this measure was an enemy to his country," and no king has since ventured upon so outrageous a proceeding. The bill, thus rejected, lay dormant till the next sessions, when William found himself obliged to comply. The same opposition and the same success attended a bill for regulating trials in cases of high treason, by which the accused was allowed a copy of his indictment, and a list of the names of his jury, two days before his trial, together with counsel to plead in his defence, and that no person should be indicted

but

but upon the oaths of two witneffes. It was by inceffant ftruggles againft the crown that the invaluable rights of the people have been tranfmitted to their pofterity; and a juft regard to thefe rights, civil and religious, was what led them to agree to the revolution. In other refpects they had no reafon to defire a change, nor can it with juftice be imputed to the Englifh that they affect important national revolutions. When James was difmiffed, the wealth and profperity of the nation were at their higheft pitch, the tonnage of their fhipping, both for merchandize and war, had been nearly doubled in the laft 25 years: the increafe of the cuftoms, the fureft teft of increafing commerce, and the annual rental were nearly in the fame proportion. Hence a ftrong party was formed againft the king's ambitious and warlike purfuits, which were not always fuccefsful, and which drained the country of much wealth. The Irifh were ftill defirous of a Stuart king, as were many of the Englifh, though they fpurned the idea of having even James forced upon them by the right of conqueft. Parliament enabled the king to reduce Ireland, and to gain the famous battle of Boyne, (fee BOYNE,) which crufhed all the hopes of the exile king, and in 1692 the marine of France, which had hitherto vied with that of England, received an irrecoverable blow in the defeat at La Hogue.

Invafions were threatened, and confpiracies difcovered every day againft the government, and the fupplies required to carry on a continental war obliged the parliament to open new refources for money. A land-tax was impofed, and every one's lands were taxed according to their valuations given in by the feveral counties. To this reign alfo we are indebted for the moft important operation in finances that ever took place, which was the carrying on the war by borrowing money upon parliamentary fecurities, and which form what are called the public funds. The projector of this fcheme, which has been acted upon, beyond the limits of human imagination, (fee DEBT, *National*,) was Mr. Charles Montague, afterwards lord Halifax. The argument on which he depended to carry his plan into effect, was that it would oblige the moneyed part of the nation to become the zealous and fteady friends of the revolution, becaufe, after having lent their money to the nation, they could have no hopes of repayment or even of intereft for it, but by fupporting the exifting government.

Notwithftanding the advantages which the nation derived from the adminiftration of William, he was fubject to fo many mortifications from his parliament, that he ferioufly refolved to abdicate his throne, a refolution which he with difficulty abandoned, and certainly with the hope of being fupported more effectually in the war with France, but he was in a great meafure difappointed, and obliged to conclude the peace of Ryfwick in the year 1697; and in the general pacification, the only equivalent obtained by the nation for an immenfe wafte of blood and treafure, was the king of France's acknowledgment of king William's title to the crown.

One of the laft and moft important acts of this reign was the paffing of a bill for fettling the fucceffion to the crown in the houfe of Hanover, which received the royal affent in June 1701. Shortly after this the king felt his conftitution giving way, which he endeavoured to counteract by the exercife of riding, and in one of his excurfions to Hampton court, his horfe fell under him, and he himfelf was thrown off with fuch violence that his collar-bone was feverely fractured, an accident which, in a few days, put an end to his life, in the 52d year of his age, and the eleventh of his reign. The character of this prince will be more particularly given under his own name. It may, however, be obferved in this place, that he was ill formed for acquiring popularity: his manners were cold and forbidding, and he fometimes feemed almoft loft to thofe principles of liberty, for the fupport of which he had been raifed to the throne. Neverthelefs, the refcue and prefervation of religion, and public liberty, were the chief glory of William's reign, for under his aufpices England fuffered grievoufly in her actions both by fea and land, and the public debt at the time of his death amounted to the fum of fourteen millions fterling.

The fucceffor to William was Anne, the fecond daughter of king James by his firft wife. She afcended the throne in the thirty-eighth year of her age, having fuffered many fevere mortifications during the reign of the late king, but upon her acceffion fhe followed his fteps, and fhortly after declared war againft France, appointing the earl, afterwards the duke of Marlborough, to the command of her armies. Under this general many important victories were achieved. Thofe of Blenheim and Ramillies gave the firft effectual checks to the French power. By the former, in 1704, the emperor of Germany was faved from impending deftruction, and 20,000 of the enemy were faid to have been killed, wounded, or drowned in the Danube. About the fame time fir George Rooke reduced the famous fortrefs of Gibraltar, which ftill remains in our poffeffion a monument of the bravery and talents of the Englifh admiral. The battle of Ramillies, fought in 1706, was of the utmoft importance to the caufe for which the war was undertaken; *viz.* to place Charles duke of Auftria on the throne of Spain, for immediately after that victory, the ftates of Flanders affembled at Ghent, and recognized Charles for their fovereign. In Spain itfelf the Englifh were unfuccefsful; the burdens of the war falling chiefly on this country, the people, who are ever delighted at victory, began to murmur at the taxes impofed on them. Other circumftances led to difputes refpecting the prerogative, the fucceffion, and religion, which created great ferments in the nation and parliament. Negociations for peace were carried on fome time, but without fuccefs. At this period the leading parties in the nation were whigs and tories, at the head of the former was the duke of Marlborough, who fupported by the queen was for a continuance of the war, in which her majefty concurred, till means were found to convince her, that it would finally prove ruinous to her and the people, and that the whigs were inimical to the national religion. The cry of "the church is in danger," at length difplaced the whigs, and even drove the duke of Marlborough from the command of the army, an act which excited the aftonifhment of all Europe, for fo numerous had been the victories acquired by his valour, and fo high was his reputation, that his name was equivalent to an army. There is little doubt that whatever the faults of the whigs might have been, the honour and interefts of the nation were facrificed to court intrigues and private cabals. In the midft of all the difputes the whigs accomplifhed the union between the two kingdoms of England and Scotland, which has proved of great benefit to both, but which at the time excited the moft violent clamours againft the projectors. The Englifh expected nothing from the union of fo poor a nation, but a participation of their neceffities: they contended it were unjuft that while Scotland was granted an eighth part of the legiflature, it yet fhould be taxed only a fortieth part of the fupplies. The Scots, on the other hand, conceived that their independency would be wholly deftroyed, and the dignity of the crown betrayed; they dreaded an increafe of taxes, and were not very anxious for an increafe of trade. After fome ineffectual ftruggles the Union was effected: Scotland was no longer to have a parliament, but to fend ſixteen peers, choſen by their nobility, and forty-five commoners, to the Engliſh parliament, and from that period the two kingdoms were called by the common name of Great Britain, and all the ſubjects of both were to enjoy a communication of privileges and advantages.

In 1712 conferences for negociation between England and France were opened, which led to peace. This was condemned by the whigs as injurious to the honour and intereſt of the nation. The majority of the houſe of lords inclined to that party, but that of the other houſe was tories. The queen, dreading that the lords might reject the terms of peace, by an unprecedented exerciſe of her authority, created twelve peers at one time, which ſecured the approbation of the parliament for the peace. The remainder of this reign was a ſcene of contention between the two parties. Each reviled the other in turn, and theſe commotions ſerved ſtill more to impair the queen's health, till at length ſhe felt herſelf unequal to the duties of her ſtation. She ſunk into a ſtate of inſenſibility, and found a refuge from her anxiety and cares in lethargic ſlumber. Every precaution was taken to ſecure the ſucceſſion in the houſe of Hanover, and orders were ſent to the heralds at arms to be in readineſs to proclaim the elector of Brunſwick king of Great Britain. The day before the queen died ſhe ſeemed to revive, roſe from her bed, and walked about, when, caſting her eyes on the clock that ſtood in her chamber, ſhe continued to gaze for ſome time, and being aſked what ſhe ſaw more than uſual, ſhe replied only with an expreſſive but dying look, and about ſeven o'clock the next morning, Aug. 1, 1714, ſhe expired in the thirteenth year of her reign. The national debt had, during this reign, encreaſed from fourteen to fifty millions. See Anne, Churchill, &c.

With this princeſs terminated the line of Stuarts, which, from the acceſſion of James I. 1603, had ſwayed the ſceptre of England one hundred and eleven years, and that of Scotland 343 years. On the death of queen Anne, there was ſtill left the ſon or ſuppoſed ſon of James II. who had been acknowledged king by the court of France on the deceaſe of his father in 1701. In behalf of this prince, rebellions were excited in England in 1715 and 1745. He reſided at Rome, and kept up an appearance of a court till his death in 1765, leaving two ſons, who are ſince dead and without iſſue.

By the act of ſucceſſion George I. ſon of Erneſt Auguſtus, firſt elector of Brunſwick, and Sophia grand-daughter of James I. aſcended the Britiſh throne; his mother, who would have been next in ſucceſſion, having died a ſhort time before. He arrived in England with ſtrong prepoſſeſſions againſt the tory miniſtry, moſt of whom he diſplaced, without producing much effect in England, but in Scotland a rebellion was excited by ſome of the leading men of that country, who paid for their temerity the forfeit of their lives. Commotions and riots were raiſed in London, Oxford, and other parts, but theſe were happily ſuppreſſed, and the ringleaders in various inſtances were made examples of juſtice. The earl of Oxford, who had negociated the peace of Utrecht, was charged with high treaſon on that account, but the proſecution was abandoned. The ſituation of affairs would not permit the miniſtry to venture upon a new parliament, and the members of that which now exiſted voted a continuance of their duration from three to ſeven years, one of the greateſt and moſt indefenſible ſtretches of parliamentary power ever known. Several other meaſures, hoſtile to liberty and the principles of the exiſting conſtitution, took place at the ſame time. Mr. Shippen, a member of parliament, was committed to the Tower for aſſerting in his place, that the king's ſpeech was better calculated for the meridian of Hanover than of London; and a young man, a printer, was actually hanged for a pamphlet, ſaid to have been ſcarcely deſerving of animadverſion. George I. however ſagacious, and in many reſpects moderate, was too much attached to his German dominions, and rendered England in a great meaſure ſubſervient to them. He quarrelled with the czar of Muſcovy about their German concerns, and had nearly involved this country in a war with Charles XII. of Sweden, for having as elector of Hanover purchaſed Bremen and Verden of the Danes. In 1718, he quarrelled with Spain on account of the quadruple alliance that had been formed between Great Britain, France, Germany, and the States General, and admiral ſir George Byng, by his orders, deſtroyed the Spaniſh fleet. The war was quickly terminated by the Spaniards delivering up Sardinia and Sicily, the former to the duke of Savoy, and the latter to the emperor, and by the king of Spain conſenting to ſign the quadruple alliance; in which England was very little if at all intereſted. See Alliance.

The next thing of importance was the ſecuring the dependency of the Iriſh parliament upon that of Great Britain. The houſe of peers in England had reverſed a decree made by the Iriſh houſe, which excited long, animated, and even bitter diſcuſſions, till at length a bill was brought into the Engliſh parliament, by which the Iriſh houſe of lords was deprived of all right of final juriſdiction, which, notwithſtanding the moſt violent oppoſition from ſeveral leading members of both houſes, was carried by a great majority. The ferment occaſioned by theſe diſcuſſions was followed by the South Sea ſcheme, which promiſed immenſe wealth to thoſe who engaged in it, but which left a large part of the nation in diſtreſs and ruin. (See Bubble.) Juſtice was demanded, by petitions from all parts, upon the contrivers of the ſcheme, and the nation ſeemed, as to a man, highly exaſperated. During theſe tranſactions, the king, with ſerenity and wiſdom, preſided at the helm, influenced his parliament to purſue equitable meaſures, and, by his councils, endeavoured to reſtore the credit of the nation. The diſcontented availed themſelves of public calamities, and made another attempt againſt the reigning ſovereign. Their deſigns were ſoon detected, and Chriſtopher Layer, a young gentleman of the Middle Temple, was convicted of treaſonable acts, and ſuffered death on the account. Several noblemen and other perſons of diſtinction were ſuſpected of being in the plot, but of theſe the biſhop of Rocheſter was the only victim who was baniſhed the kingdom for life. After the ferment which this plot occaſioned was over, the tranſactions of the reign were few and leſs important in their conſequences. The miniſtry, who were all in the intereſt of Hanover, ventured upon ſeveral bold meaſures, in ſome of which the national intereſt, if not honour, was evidently ſacrificed to that of the electorate. The crown of Great Britain was engaged in every continental diſpute, however remote it was from her own intereſt. Treaties lately concluded with Spain were again broken, and admiral Hoſier was ſent to intercept the Spaniſh galleons from America, an expedition which proved as fatal as it was inglorious. The admiral and moſt of his men periſhed by epidemical diſeaſes, and the hulks of his ſhips rotted ſo as to render them utterly unfit for ſervice. To retaliate, the Spaniards undertook the ſiege of Gibraltar, and with ſimilar ſucceſs. New treaties were ſet on foot, France offered its mediation, and a reconciliation was effected. The king died, as he was travelling to his Hanoverian dominions, at Oſnaburgh, on the 11th June 1727, in the thirteenth year of his reign. During his reign the ſinking fund for diminiſhing the national debt was inſtituted. See Debt *National*, Funds, &c.

Upon

Upon the death of George I. his ſon George II. aſcended the throne, with a predilection for his Hanoverian dominions ſimilar to that of the late king. He choſe for his firſt miniſter ſir Robert Walpole, who had filled the ſame high office under his father. This able miniſter was a decided enemy to war, which, in ſome inſtances, led him into difficulties both at home and abroad. His adminiſtration will be more properly conſidered under the article attached to his name, (ſee WALPOLE,) but juſtice requires of us to obſerve, that notwithſtanding ſome of his meaſures, as an attempt at the introduction of the exciſe laws, were liable to great cenſure, yet he was friendly to the exiſting laws: he filled the courts with able and upright judges, and he has not been charged with any attempt at the violation of the known law of the kingdom, and under his adminiſtration the preſs was under little or no reſtraint. His pacific ſyſtem more than repaid to the nation all that was required to ſupport it, by the increaſe of her trade and the improvement of her manufactures. The great objects of controverſy during the early part of this reign were the national debt, and a ſtanding army. Demands for new ſupplies were made every ſeſſion of parliament, either for the purpoſe of ſecuring friends on the continent, or of guarding the internal polity, or for enabling the miniſtry to act vigorouſly in conjunction with their allies abroad. Theſe were as regularly oppoſed as they were made: the ſpeakers of the country party ever inſiſted, that the Engliſh had no buſineſs to embroil themſelves with the affairs of the continent; that expences were incurred without prudence or neceſſity; and that the increaſe of the national debt by multiplying taxes, would in the end become intolerable to the people. A motion was made to revert to the old ſyſtem of triennial parliaments, as they had been ſettled at the revolution. The advocates for this meaſure aſſerted that the ſeptennial act was an encroachment on the rights of the people; that it was introductory to the monſtrous corruptions of government: that during the continuance of that parliament which prolonged its exiſtence from three to ſeven years ſeveral ſevere laws had been enacted; that by one of theſe a man might be removed, and tried at any place where the jury might be found favourable to the crown, and where a priſoner's witneſſes could not and dared not come; that by another, a juſtice of peace was empowered to put the beſt ſubjects to death after reading the riot act. The miniſtry was, however, triumphant, and the oppoſition, who, unqueſtionably, had the weight of argument on their ſides, complained that debate was uſeleſs, and that it was wholly impoſſible that reaſoning could prevail over the corruptions that were ſecretly practiſed by the miniſter. Deſpairing, therefore, of being able to ſtem the torrent of corruption, they retired to their ſeats in the country, and left the miniſtry an undiſputed majority in the houſe.

In November 1737, queen Caroline, conſort to the king died; at this time the king and his ſon Frederick the prince of Wales were at variance. The latter complained that through Walpole's influence he was deprived not only of the power but the proviſion to which his birth was entitled. The king forbade him his preſence, and gave orders that none of his friends ſhould be admitted at court. A motion was made in the houſe of commons for increaſing the prince's ſettlement, which was fifty thouſand pounds; this was oppoſed by ſir Robert Walpole, and rejected by a large majority. The prince now placed himſelf at the head of the oppoſition with ſo much firmneſs, that it was ſeen Walpole's power was drawing to a criſis; but it was not till the year 1742 that he reſigned his employments and was created earl of Orford. The king bore the loſs of his miniſter with the greateſt equanimity, and even conferred titles of honour, and poſts of diſtinction upon the heads of oppoſition. Circumſtances alſo aroſe which induced him to take a leading part in a continental war: in oppoſition to which a rebellion in behalf of the pretender was excited in 1745 in Scotland. Charles, the ſon of the pretender, landed in the Scottiſh iſlands, and ſoon found himſelf at the head of 1500 men. Manifeſtoes were widely diſperſed, inviting the highlanders to join in the cauſe: few, however, ſeemed willing to hazard the dangers of the enterprize. Its boldneſs aſtoniſhed Europe; it awakened the fears of the puſillanimous, the pity of the wiſe, and the loyalty of all. The whole kingdom ſeemed unanimouſly bent upon oppoſing the enterprize which they were ſenſible, as being ſupported only by papiſts, would be inſtrumental in reſtoring popery. The rebels advanced to Perth, where, inſtead of proceeding with increaſed rapidity, they ſtaid to proclaim the prince's father king. The prince was again ſucceſsful at Preſton Pans, and marched to Edinburgh; here he waſted his time in diſſipation and parade, till an opportunity was given to the king to ſend againſt him an effectual force under the duke of Cumberland. The battle of Culloden on the 15th of April 1746, put an end to all hopes of the pretender: the victory on behalf of the king was complete, but the mercileſs fury of the conquerors upon the fallen diſgraced the cauſe, to which every friend of his country wiſhed ſucceſs. The duke ordered nearly forty deſerters to inſtant execution, and the royal army ſpread terror wherever it came, and after a few days the whole country was one ſcene of ſlaughter, deſolation, and plunder; juſtice was forgotten, and every virtue ſeemed to be loſt in the moſt ſavage vengeance. The government on this occaſion was not a little indebted for the ſupport it received to the national debt. The Jacobite party had hoped to ruin public credit, but common danger aboliſhed all diſtinctions, and united them in defence of private property. The merchants agreed to receive bank notes in payment, which prevented the miſchief that was hoped for by a run upon the bank. The defeat of this rebellion in the year 1746 did not reſtore tranquillity to Europe; it was not till after various ſucceſſes in different parts of the globe that the preliminaries of peace were ſigned in April 1748, and in the October following a definitive treaty was concluded at Aix-la-Chapelle. In the proſecution of this war the balance of gain, as far as wealth was concerned, was evidently in favour of Great Britain, and many private perſons made it ſubſervient to the attainment of vaſt fortunes. In the following year, the intereſt of the national debt was reduced from four to three and a half *per* cent. at which rate it was to continue for the next ſeven years, when it was to ſuffer a farther reduction to three *per* cent. This, ſays the hiſtorian, was the boldeſt ſtroke of financing that ever was attempted perhaps in any country, conſiſtently with public faith, for the creditors of government, after a trifling ineffectual oppoſition, continued their money in the funds, and a few who at firſt ſold out were glad, in a ſhort time, to have it placed under the ſame ſecurity.

At this period Mr. Pelham was the miniſter of the country, who turned his attention to the improvement of commerce, manufactures, and fiſheries, the benefits of which deſcended to poſterity. A new treaty of commerce was ſigned at Madrid, between Great Britain and Spain, by which, in conſideration of 100,000*l.* the South Sea Company gave up all their future claims to the Aſſiento contract, by virtue of which that company had ſupplied the Spaniſh Weſt Indies with ſlaves from the coaſt of Africa. (See ASSIENTO.) In March 1750, his royal highneſs Frederic prince of Wales died, to the regret of the nation: and in the following year an act was paffed for regulating the commencement of the year, by which the old ftyle was abolifhed, and the new ftyle eftablifhed, which was done by finking eleven days in 1752, and from that time the year was to begin the firft of January inftead of March. (See CALENDAR.) In 1753 the famous act was paffed for preventing clandeftine marriages, which at the time excited the moft violent oppofition, as replete with the moft injurious confequences to the liberties and morality of the people, and as making an impaffable line between the rich and the poor: and about the fame time an act equally, or even more unpopular, as attacking the religious prejudices of the people, was paffed. This was a law for naturalizing the Jews, which, though carried through great oppofition, was in the next feffion repealed. The game laws were alfo introduced about this period; by thefe none but men poffeffed of certain property could have the privilege of carrying a gun, or of otherwife deftroying game, though on grounds which they rented themfelves. This meafure was fuppofed to be a violent encroachment on the liberty of the fubject; that it would neceffarily damp the martial fpirit of the lower orders of fociety, by preventing them from handling thofe arms which might one day be neceffary to defend their country; and at the fame time, that it gave the rich the fole enjoyment of a pleafure, which before had been confidered as the common privilege of humanity. "Such," fays a contemporary writer, "were the laws paffed at this period, through all which a fpirit of ariftocracy was difcerned by fome. The body of the rich, no longer fearing oppreffion from the throne, or an infringement of their own liberties, now began to lean heavy on the poor, and to confider the interefts of that ufeful part of the fociety as entirely diftinct from their own. They never omitted, however, their ufual addreffes to the throne; and this feffion (1756) was remarkable for an addrefs of thanks to his majefty, for maintaining, and rendering permanent, the general tranquillity of Europe, at a time when war was kindling in almoft every quarter of the world."

To the conduct of this war Mr. Pitt was called, as fecretary of ftate, and head of the adminiftration. He had long fignalized himfelf as a bold, eloquent, and energetic fpeaker, and he foon proved himfelf a moft able and fpirited minifter. In this war the Englifh in Europe, in Afia, and America, achieved wonders: they were every where victorious: almoft all the poffeffions of the French in North America and in India fell into our hands; and at the battle of Minden, in Germany, feven thoufand of our countrymen defeated an army more than ten times as large. The Englifh for fome time bore the increafing burdens of warfare with cheerfulnefs; and rendered, by every means in their power, the juft tribute of praife to the talents and activity of the minifter. But at length, glutted almoft with victory fucceeding upon victory, they began to reflect upon the proble advantages that might refult from a continuance in war, when it was evident that the conquefts made in Germany muft ever be foreign to the real interefts of Great Britain; that they were waging an unequal war, and adding new loads of taxes to thofe already difficult to be borne, for conquefts which they could neither preferve nor enjoy. Such were the growing difcontents of the people, when the French fhewing fome difpofition to treat for peace, and the charges of the war beginning to amount to eighteen millions a-year, inclined the Britifh miniftry to liften to the propofals offered them. A negociation was accordingly entered upon, but without fuccefs. This was in the autumn of the year 1760, and on the 25th day of October, 1760, George II., without any apparent fymptoms of diforder, was found expiring in his chamber. He had arifen at his ufual hour, intending to walk out, but being left alone, he was heard to fall down upon the floor; the noife of the fall brought his attendants into the room; he defired, in a faint and faultering voice, that the princefs Amelia might be fent for, but before her arrival he expired, in the 77th year of his age, and the 33d of his reign, in the midft of victory, and at that very period, when the univerfal enthufiafm of conqueft began to fubfide into more fober reflections. The character of this prince will be given under his own name. He was fucceeded by his grandfon George III., the prefent fovereign, who afcended the throne with great advantages. He took the opportunity which his firft fpeech to parliament gave him, of appealing to the prejudices and affections of his people. "Born and educated in this country," faid he, "I glory in the name of Briton, and the peculiar happinefs of my life will ever confift in promoting the happinefs of a people whofe loyalty and warm affection to me I confider as the greateft, and moft permanent fecurity of my throne. The civil and religious rights of my loving fubjects are equally dear to me with the moft valuable prerogatives of my crown." The firft acts of this reign were calculated to convince the people that the war in which they were engaged fhould be carried on with energy; very brilliant fucceffes, and important conquefts, were the refult of the plans adopted by Mr. Pitt, who felt himelf refponfible for almoft all public meafures. When, however, he found his influence in the cabinet declining, through the fuppofed intrigues of the earl of Bute, he refigned his high fituation, declaring he would no longer lie under the refponfibility of meafures which he was not allowed to guide. Mr. Pitt retired in October 1761, upon a penfion of 3000*l.* *per ann.* and, at the fame time, a peerage was conferred upon his lady. Thefe grants were, by his enemies, held out as proper fubjects to excite the popular clamours againft the patriotic minifter. At firft they fucceeded, but in a fhort time an almoft general difcontent prevailed in the nation, on account of his removal from office, in the midft of a war, which he had conducted with fo much honour to himfelf and to his country, and in a manner that had excited the aftonifhment of Europe. The war was ftill purfued with vigour, and the plans of Mr. Pitt, of which the new minifter availed himfelf, led to important victories both by fea and land.

Early in the year 1763, peace was agreed upon, and of fo little importance had the war been to the interefts of the Englifh, who had been almoft uniformly victorious, and who had acquired by their valour many foreign poffeffions, that it was agreed a mutual reftitution and oblivion fhould take place, and each party fit down at the end of the war in the fame fituation in which they began it. The peace excited much oppofition, becaufe the terms were thought extremely inadequate to what might have been expected from the numerous and brilliant victories and advantages obtained in the courfe of a long war. From this period various caufes contributed to occafion a fpirit of difcontent in the nation. On the 30th of April, 1763, three of the king's meffengers entered the houfe of Mr. Wilkes, member of parliament for Aylefbury, and feized his perfon by virtue of a warrant from the fecretary of ftate, which directed them to feize the authors, printers, and publifhers, of a feditious and treafonable paper, entitled the North Britain, N° 45. This work contained ftrictures on his majefty's fpeech, and Mr. Wilkes was fufpected to be the author. He was accordingly arrefted, examined, and clofely imprifoned, which gave rife to difcuffions on the legality of general warrants, which were in the end declared illegal, and a grofs violation of the liberty of the fubject. (See WARRANTS, *General.*) Mr. Wilkes was for this and other publications expelled the houfe, houſe, and in 1764 a ſentence of outlawry was iſſued gainſt him.

In 1765, under the adminiſtration of Mr. George Grenville, an act was paſſed for laying a ſtamp-duty on the Britiſh colonies of North America. This kindled a flame in that quarter of the globe, which finally led to a ſeparation of the colonies from the mother country, and eſtabliſhed the independence of America. (See AMERICA and UNITED STATES.) In the year 1768 Mr. Wilkes returned to England, was proſecuted, convicted, and fined in the ſum of 1000*l*. He carried with him the voice of the people, whoſe cauſe he was ſuppoſed to vindicate, and was again elected member for Middleſex; and was again expelled. After the expiration of the term of his impriſonment, in the year 1771, he was elected ſheriff of London, and afterwards choſen member for the county of Middleſex, when he was permitted quietly to take his ſeat; and in the year 1775 he was elected lord mayor of London, an office which he executed to the ſatisfaction of his fellow-citizens. In 1783 all the declarations, orders, and reſolutions of the houſe of commons, reſpecting his election for the county of Middleſex, were ordered to be expunged from the journals of that houſe.

In the year 1772 the clergy petitioned the parliament for relief in matters of ſubſcription to the 39 articles, praying to be reſtored to their undoubted right of interpreting ſcripture for themſelves, without being bound by any human explanation of it, or being required to acknowledge by ſubſcription or declaration, the truth of any formulary of religious faith and doctrine whatever, excepting the Holy Scripture itſelf. The petition was preſented by ſir William Meredith, who, with other members favourable to the principle, enforced it by many arguments drawn from the principles of toleration. It was, however, rejected by a large majority. A bill was ſhortly after brought into the houſe to prevent the deſcendants of his late majeſty from marrying without the conſent of his majeſty, his heirs, and ſucceſſors, which was carried very rapidly through both houſes, and paſſed into a law. A petition was now preſented by the diſſenters, praying to be relieved from the hardſhip of ſubſcribing to the articles of a church to which they did not belong. This petition was received, and a bill brought into the houſe founded upon it, which was carried by a large majority in the commons, but which was rejected in the houſe of lords. From this period the whole intereſt of the country was turned to the conteſts with America, to which we have already referred. The enormous expences occaſioned by this war excited much and almoſt general diſcontent among the people, who began to call aloud for an economical reform in the various departments of the ſtate. Meetings were held in various counties of the kingdom, at which great numbers of freeholders were preſent, who agreed to petition the houſe of commons, "that before any new burdens were laid upon the country, effectual meaſures might be taken by that houſe to inquire into, and correct the abuſes in the expenditure of the public money; to reduce all exorbitant emoluments; to reſcind and aboliſh all ſenecure places, and unmerited penſions; and to appropriate the produce to the neceſſities of the ſtate." In the beginning of the year 1780 theſe petitions were taken into conſideration, and ſome trifling reforms took place. In ſome inſtances, the miniſter, lord North, was left in a minority, and in many others he was obliged to uſe every exertion to carry his meaſures. In a very full houſe, and by a ſmall majority, certain officers under the crown were excluded from having ſeats in the houſe of commons: this they hoped to follow by other arrangements favourable to the rights of the people; but, in a ſhort interval, the miniſter was enabled to apply arguments not generally underſtood, but ſtrongly ſuſpected, which gave him a preponderance in the houſe, and which enabled him to ſtop the progreſs of reform. The people were diſſatisfied, and a ſpirit of diſcontent prevailed in almoſt every part of the kingdom. About this period, the hardſhips which individuals, profeſſing the Roman Catholic religion, had laboured under, awakened the conſideration of the liberal part of the people: and ſome perſons of high conſideration in the ſtate undertook their cauſe, and fully expected they ſhould obtain for them that relief which the nature of their caſe required. The Catholics preſented a dutiful and loyal addreſs to the king, containing the ſtrongeſt aſſurances of affection and fidelity to his perſon and the civil government of the country. This addreſs, which was drawn up with great care, and which contained ſentiments of the moſt unexceptionable nature, was ſigned by ſeveral Roman Catholic peers, and 163 commoners of rank, fortune, and influence in the country. The advocates of the cauſe were aware that the prejudices of the lower claſſes were hoſtile to an extenſion of the privileges of the Catholics, whom they had been accuſtomed to regard as perſecutors from principle, and as deſirous of ſubverting the Proteſtant faith. But ſir George Saville made a motion for the repeal of certain penalties which were attached to the profeſſion of the Catholic religion. He was ſeconded in his exertions by Mr. Dunning, who laid before the houſe an account of the ſtatutes ſtill exiſting againſt the Catholics, by which, among other grievances, it was made high treaſon in any native of theſe realms to teach the doctrines or perform divine ſervice according to the rites of that church; the eſtates of perſons educated abroad in that perſuaſion were forfeited to the next proteſtant heir; a ſon, or any other, the neareſt relation being a Proteſtant, was empowered to take poſſeſſion of his own father's or neareſt of kin's eſtate, during their lives; a Roman Catholic was diſabled from acquiring any legal property by purchaſe. In conſequence of theſe and ſuch like repreſentations, the motion made in favour of the Roman Catholics was received without a diſſenting voice, and a bill in purſuance of its intent was brought in and paſſed both houſes. This act ſeemed to give little offence to perſons of any claſs in England, but in Scotland it excited much indignation, riots enſued, and ſome houſes and chapels were deſtroyed. The contagion at length reached England: a number of perſons aſſembled themſelves together with a view of promoting a petition to parliament for a repeal of the late act in favour of the Papiſts, and they aſſumed the title of "The Proteſtant Aſſociation." Of this aſſociation lord George Gordon was the preſident: who, at the head of 50,000 men, preſented a petition to the houſe of commons on the 2d day of June 1780 At firſt the petitioners behaved with order and decency, but they ſoon became violent againſt the members of the two houſes who had been friendly to the cauſe of toleration, ſome of whom narrowly eſcaped with their lives. From this time till the 7th of June, London was the ſcene of the moſt atrocious crimes: houſes, chapels, and priſons, were broken open, plundered, and burnt. In one night, and at the ſame hour, it is ſaid, there were 36 buildings on fire. Attempts were made on the bank, but ſuch precautions had been taken as to render that place invulnerable. At length by the exertions of the military, who killed and wounded great numbers of the rioters, the tumult was ſuppreſſed, and the metropolis reſtored to order and tranquillity. Numbers were afterwards tried for aiding and abetting in theſe ſcenes; ſome were convicted and executed, and others acquitted; and the preſident lord George Gordon

Gordon was committed to the Tower on a charge of high treafon, for which he was afterwards tried and found ' Not Guilty."

War continued to rage, and from America it had fpread to almoft every part of the world, and the Englifh found themfelves engaged in a conteft with France, Spain, and Holland: but in the beginning of the year 1782 the oppofition fucceeded in forcing minifters to a pacification. Peace was accordingly concluded, but not fuch a peace as met the general wifhes of the people, and thofe who had made it were obliged to refign their places to the famous coalition miniftry under lord North and Mr. Fox. By the latter a bill was brought into parliament, for newly regulating the government of the Eaft India Company, which occafioned a great ferment in the country, and which finally drove the author of it, and his party from the helm, who were fucceeded by the late Mr. Pitt and his friends. One of the firft acts of this minifter was a new Eaft India bill, which was paffed by a great majority: and fhortly after, he became the advo ate of parliamentary reform, a caufe which he had efpoufed before he came into place, and which he pledged himfelf to ufe his utmoft endeavours to carry into effect. His plan was rejected, and from that time he never ferioufly attempted to realize the expectations which he had excited among the friends of liberty. The next important meafure which he introduced to the notice of parliament was the propofal of a finking fund to be applied towards difcharging the national debt. (See Debt, *national. Sinking* Fund, &c.) We fhall alfo refer our readers to the life of that minifter for a more comprehenfive view of his public adminiftration: to the article Revolution, *French*, for the various occurrences that took place in this country from the year 1788; to the article Slave *Trade* for an account of the proceedings on that fubject to its final abolition: to the article Test *act* for the attempts made in this reign to obtain a repeal of thofe obnoxious laws, &c. &c. Henry's Hift. Rapin. Act. Regia. Hume. Belfham. Biog. Brit. &c.

England, *Little, beyond Wales*, in *Geography*, is a portion of country lying along the fouth-weftern coaft of South Wales, inhabited by the defcendants of a colony of Flemings; who came over from Flanders, and fettled here in the reign of king Henry I. Camden fays, the occafion of their emigration was an inundation of the fea, by which a great part of the Low Countries was overflowed. But it has been ftated, with more probability, that it was the policy of that wife monarch to place a people oppofite in their language, manners, and opinions to the Welfh, to affift in his favourite project—the fubjugation of the country. Another colony from the fame country was incorporated with the firft, in the time of Henry II., to which occafionally were added numerous Anglo-Normans, and others from the Englifh army. At firft thefe people were confined to the commot of Rhos, which diftrict ftill more *particularly* retains the name of Little England beyond Wales. But their numbers increafing in the courfe of time, they foon fpread along the whole coaft, from the lordfhip of Comes to the mouth of the river Tave. And this part of the principality is ftill divided into two diftricts, denominated Englifhery, and Welfhery. The latter, occupied by the original inhabitants, contains the cantreves of Comes, Cilgerran, part of Arberth, and Dewifland. The former comprifes the remainder of Arberth, and the cantreves of Rhos, Caftel-Martins, and Dougleddy; and is inhabited by the defcendants of the Flemings. Like their anceftors, they are a hardy, induftrious, and adventurous race. The difpofitions of the two people are equally ftriking and adverfe. While the Welfh are hot, eafily irritated, and obftinately tenacious; thefe are not eafily provoked, are averfe to contention, and avoid litigation. Both are diftinguifhable by their mode of drefs, manner of living, the ftyle of their buildings, particularly in their churches; and the names they refpectively give to places. All thefe ftrongly point out the line of demarcation between them. In the Welfhery, not a word of Englifh is heard fpoken, while in the next village within the Englifhery, not a word of Welfh. The language of the latter diftrict is not much different from the common dialect of England, except in fome parts of Rhos and Caftle-Martin. The two people avoid all commerce as much as poffible, mutually confidering each other in a degrading light; and even a pathway will divide them in the fame parifh. To fuch an extent is this perfonal deteftation carried among the lower claffes, that a matrimonial connection between the oppofite parties is confidered by both an unfortunate event. The Flemings, however, eventually proved a bleffing to Wales, as well as England; by their introduction of the woollen manufactures. And a work, which proves their induftry and improving fpirit, is yet vifible. It is a road of great extent made by them, and ftill called Fleming's way. Evans's Tour in South Wales.

England, *New*, comprehending the *Northern* or *Eaftern States* of North America, lies around the great bay which fets up N.W. between cape Cod and cape Sable, between 41° and 48° N. lat., and between 1° 30′ and 10° 15′ E. long. from Philadelphia, and is bounded N. by Lower Canada; E. by the province of New Brunfwick and the Atlantic ocean; S. by the fame ocean and Long-ifland Sound; and W. by the ftate of New York. It lies in the form of a quarter of a circle; its W. line beginning at the mouth of Byram river, which difcharges itfelf into Long-ifland Sound at the S.W. corner of Connecticut, lat. 41°, runs a little E. of N. until it ftrikes the 45th degree of latitude, and then curves to the eaftward, almoft to the gulf of St. Lawrence. Its extreme length is about 626 miles; its breadth is very unequal, from 100 to 200 miles; containing about 72,000 fquare miles. This grand divifion of the United States comprehends the ftates of Vermont, New Hampfhire, Maffachufetts (including the diftrict of Maine), Rhode Ifland and Providence Plantations, and Connecticut; which fee refpectively. The climate of New England is falubrious, as we may infer from the longevity of its inhabitants; one in feven living to the age of 70 years, and about one in thirteen or fourteen to 80 years and upwards. The moft prevalent winds are the N.W., W., and S.W.; but the E. and N.E winds, which are infalubrious, occur frequently at certain feafons of the year, particularly in April and May, on the fea-coafts. The weather is lefs variable than in the middle, and efpecially the fouthern ftates, and more fo than in Canada. The extremes of heat and cold are, according to Fahrenheit's thermometer, from 20° below to 100° above 0; the medium being from 48° to 50°. The quantity of water which annually falls in New England is from 42 to 48, and yet they fuffer here more from drought than in England, where the annual quantity of water is eftimated at about 24 inches. Hence it is inferred that the atmofphere is remarkably dry, and thus fome have accounted for its fingular falubrity. Winter commonly commences, in its feverity, about the middle of December; fometimes earlier, and fometimes not till Chriftmas. The difeafes moft prevalent in New England are alvine fluxes, St. Anthony's fire, afthma, atrophy, catarrh, colic, inflammatory, flow, nervous, and mixed fevers, pulmonary confumption, quinfy, and rheumatifm. The general condition of the New Englanders, which precludes the luxury of the rich and the extreme diftrefs of the poor, affords them an exemption from a variety of difeafes, to which a greater degree of inequality might expofe them. This country prefents to the traveller a great variety of furface, confifting of extenfive plains, intermixed with vallies of different breadths from 2 to 20 miles, and with mountains of different elevations. Although it may be deemed, upon the whole, to be high and hilly, its mountains are comparatively fmall, and run nearly N. and S., in ridges parallel to one another. The wefternmoft range begins in the county of Fairfield, and, paffing through the counties of Litchfield and Berkfhire, unites with the Green mountains at Williamftown, in the N.W. corner of the Maffachufetts, being feparated only by the narrow valley of Hoofack river. The higheft part of this range is Toghkonnuck mountain in Egremont, the fouth-weftern corner of the fame ftate. Over this mountain, elevated probably more than 3000 feet above the ocean, runs the boundary between Maffachufetts, Connecticut, and New York. The fecond range is that of the Green *mountains;* which fee. The third range has the fame commencement with the fecond at New Haven, in a delightful eminence called the Eaft rock, and paffing through the counties of New Haven, Hartford, and Hampfhire, extends into Canada. The Blue hills in Southington, mount Tom, which is the principal eminence, mount Holyoke, and mount Toby in Sunderland, are the principal fummits of this range S. of New Hampfhire. This range, which is precipitous and romantic, croffes Connecticut river juft below Northampton and Hadley in Maffachufetts. The fouth or eaftern range begins at Lyme in Connecticut, and forms the eaftern boundary of the Connecticut valley, until it unites with the laft-mentioned range in the county of Hampfhire; but is lefs diftinctly marked by eminences than the others. The chief fingle mountains are Saddle-mountain in Maffachufetts, computed to be about 4000 feet above the fea, Watchufett in the county of Worcefter, Afclutney in the ftate of Vermont, Monadnock in New Hampfhire, and the White mountains in the fame ftate, of which the higheft fummit is Mount Wafhington, probably between 10,000 and 11,000 feet above the ocean, and the higheft land in the United States. This mountain is covered during a great part of the year with fnow, and is feen in fair weather at the diftance of 90 miles from the fea, and 160 from its bafe. New England abounds in cataracts and cafcades; thofe of the White mountains being fingularly romantic and beautiful. The principal rivers of New England are the Schoduck, Penobfcot, Kennebeck, Amarifcoggin, Saco, Pifcataqua, Merrimack, Parkers, Charles, Taunton, Providence, Thames, Connecticut, Hooeftonnuck or Stratford, Onion, La Moille, and Miffifconi. The largeft of thefe are Penobfcot, Kennebeck, Merrimack, and Connecticut. The chief lakes are Champlain and Memphremagog, lying partly in Vermont and partly in New York; Winnipifiogee and Umbagog in New Hampfhire; Sebago, Moofehead, Willeguenguagun, and Chilmacook or Grand lake in Maine. The moft important and ufeful harbours are thofe of Machias, Frenchman's bay, Wifcaffet, Portland and Wells, in Maine; Pifcataqua in New Hampfhire; Newbury port, Salem, Marble head, Bofton, Provincetown, and New Bedford, in Maffachufetts Proper; Newport, Briftol, and Providence, in Rhode ifland; and New London, New Haven, and Black rock, in Fairfield, in Connecticut. Burlington bay is the moft confiderable harbour in lake Champlain, on the Vermont fhore.

The foil of New England is diverfified by every variety from a lean and barren fand to the richeft clays and loams. The hills are covered with a brown loam intermixed with gravel, which is favourable to the production of grafs, and in the weftern parts of the country, of wheat, and all other kinds of grain and fruits fuited to the climate. Clayey foils, when well manured, are very productive. A rich loam, varying towards clay, is prevalent in Connecticut, and is favourable to every kind of cultivation. Sand is generally found on the plains; and the yellow pine plains, which are commonly a mixture of fand and gravel, are friendly to every production that does not require a richer foil. The white pine plains are ufually covered with loam, and thefe, as well as fome of the laft-mentioned in the fame condition, are uncommonly fertile. The vallies are a rich mould; and the intervals, bordering the various ftreams, are generally fands formed by earth depofited by the floods in the fpring, and are of the richeft quality.

New England, generally fpeaking, is better adapted for grazing than for grain, though a fufficient quantity of the latter is raifed for home confumption, if we except wheat which is largely imported, particularly into Maffachufetts, from the middle and fouthern ftates. Indian corn, rye, oats, barley, buck-wheat, flax and hemp, generally fucceed very well. Fruits of every kind, which fuit a temperate climate, may be obtained in abundance. The fummer heat brings to perfection peaches, apricots, and nectarines. Orchards of apple-trees cover a confiderable part of the whole country, and cyder is the common drink of the inhabitants. Pears, plums, cherries, currants, goofeberries, whortleberries, blackberries, bilberries, &c. abound. Perry is made in fome parts of the country, but not in great quantities. Various fpecies of the hickery and hazle-nuts, and chefnuts are plentifully furnifhed by the fouthern half of New England. Gardening is much improved, and its productions are daily varying and increafing. But the moft important production of New England is grafs. The high and rocky ground is in many parts covered with clover, and affords excellent pafture to fome of the fineft cattle in the world. The quantity of butter and cheefe made for exportation is very great. Confiderable attention is now paid to the raifing of fheep; and the wool is in a ftate of progreffive improvement. The principal exports of New England are mackarel, falmon, cod, and other fifh; whale-oil and whale-bone, timber, mafts, boards, ftaves, hoops and fhingles; horfes, mules, falted beef, and pork, pot-afh, pearl-afh, flax-feed, apples, cyder, corn, butter, and cheefe. New England is the moft populous part of the United States; it contained, in 1790, 1,009,522 perfons, and, in 1800, 1,233,011. The great body of the inhabitants confifts of landholders and cultivators of the foil. As they poffefs in feefimple the farms which they cultivate, they are all naturally attached to their country; and the cultivation of the foil makes them robuft and healthy. New England has been not unaptly denominated a nurfery of men; and hence are annually tranfplanted into other parts of the United States, thoufands of its natives. They are almoft univerfally of Englifh defcent; and to this circumftance, as well as to the general attention that has been paid to education, it is owing that the Englifh language has been preferved among them in fo confiderable a degree of purity. The New Englanders are generally tall, ftout, and well-made. Their education, laws, and fituation ferve to infpire them with high notions of liberty, of which they are jealous, in fome cafes perhaps, to excefs. A chief foundation of freedom in the New England ftates is a law, by which inteftate eftates defcend to all the children, or other heirs, in equal proportion; and hence it happens, that the people of New England enjoy an equality of condition, that is unknown in any other

other part of the world. Befides, they are frugal and induftrious, and inured to habits of fobriety and temperance. Learning is more generally diffufed among all ranks of people in New England than in any other part of the globe; which is owing to the excellent eftablifhment of fchools in every town. In thefe fchools, generally fupported by a public tax, are taught the elements of reading, writing, and arithmetic; and in fome of the principal and more wealthy towns they are purfuing education in a higher fcale, and introducing the fuperior branches of grammar, geography, and other fciences. Literature is alfo encouraged and diffufed by the circulation of newfpapers and periodical publications, and by the eftablifhment of reading focieties and parochial libraries. Curiofity, and a defire of information, are very prevalent in New England; and the common people, it is faid, are diftinguifhed by attention and civility to ftrangers. In former times the New Englanders were ftrict, to a degree of punctilioufnefs, in their obfervance of the fabbath; and hence, as well as from fome other traits of their character, they acquired the character of a fuperftitious and bigotted people. But fince the war, a catholic, tolerant fpirit, occafioned by a more enlarged intercourfe with mankind, has much increafed, and is becoming univerfal. "If," fays Dr. Morfe, "they do not go beyond the proper bounds, and liberalize away all true religion, of which there is very great danger, they will counteract that ftrong propenfity in human nature which leads men to vibrate from one extreme to its oppofite." A cuftom ftill prevails, tranfmitted to the prefent race from their anceftors, of annually celebrating fafts and thankfgivings. In fpring, the governors of the feveral New England ftates, Rhode ifland excepted, proclaim a day of fafting, humiliation, and prayer; and in autumn, after harveft, they appoint a day of public thankfgiving. Many of the women in New England are handfome. Thofe, who have enjoyed the advantages of a good education, and they are numerous, are genteel, eafy, and agreeable in their manners, and are fprightly and fenfible in their converfation. And it is a laudable practice among the females to accuftom themfelves at an early period to the management of domeftic concerns with neatnefs and economy. Employment at the needle, in cookery, and at the fpinning-wheel, is honourable. The women in country towns manufacture the greater part of the clothing of their families. Their linen and woollen cloths are ftrong and decent. Among the amufements of the people of New England is dancing, of which the young people of both fexes are extremely fond. The athletic and healthy diverfions of cricket, foot-ball, quoits, wreftling, jumping, hopping, foot-races, and prifon-bars, are univerfally practifed in the country, and fome of them in the moft populous places, and by people of almoft all ranks. Of the religion of the New Englanders, and of the provifion that is made for the fupport of it, we fhall have occafion to fpeak under the article United States. We fhall here merely obferve, that the conftitution of thefe ftates provides againft the making of any law refpecting an eftablifhment of religion, or prohibiting the free exercife of it. And in the conftitution of the refpective ftates, religious liberty is a fundamental principle. Without the aid of civil power, religion is left to be fupported by its own evidence, by the lives of its profeffors, and the almighty care of its divine author. Its public teachers are maintained by an equal tax on property, by pew-rents, monies at intereft, marriage and burial fees, fmall glebes, land rents, and voluntary contributions. Chriftians profefs their religion under various forms, and with different ideas of its doctrines, ordinances, and precepts. Accordingly the fects of Chriftians are very numerous and various. Of thefe fects, thofe that are called Congregationalifts are the moft numerous. In New England there are about 1200 congregations of this denomination. Next to thefe in refpect of number are Prefbyterians. In New England there are between 40 and 50 Proteftant epifcopal churches.

New England owes its firft fettlement to religious perfecution; and the inhabitants of this country are defcended from thofe that were called Puritans in the mother-country. The firft attempt to form a regular fettlement in this part of America was at Sagahadock in 1607; but in the following year, the whole number of thofe who furvived the winter returned to England. The firft company, that laid the foundation of the New England ftates, planted themfelves at Plymouth, in November, 1620; though this appellation was given to North Virginia by Capt. Smith in Auguft 1614. The founders of the colony confifted of 101 perfons. In 1640, the importation of fettlers ceafed, in confequence of the abatement of perfecution by the change of affairs in England. At this time the number of emigrants, who had traverfed the feas in 298 veffels, from the commencement of the colony, amounted to 21,200 men, women, and children, forming, perhaps, about 4000 families. In 1760, the number of inhabitants in Maffachufetts bay, New Hampfhire, Connecticut, and Rhode ifland, amounted, probably, to half a million. Morfe.

ENGLANTERIA, in *Botany*. See Eglanteria.

ENGLECHERIE, Engleschery, or *Englefchyre*, a term of great import among our anceftors, though now obfolete; properly fignifying the quality of an Englifhman.

If a man were privately flain or murdered, he was anciently accounted francigena (which comprehended every alien, efpecially the Danes) till englecherie was proved, *i. e.* till it was made to appear that he was an Englifhman. Bracton, lib. iii.

The origin of the cuftom anciently fubfifting among the Goths in Sweden and Denmark, was thus: king Canutus, having conquered England, at the requeft of his nobles, fent back his army into Denmark, only referving a guard of Danes for his perfon; and made a law, that if any perfon was murdered, he fhould be fuppofed to be a Dane, if he was not proved to be an Englifhman by his parents or kindred, and, in default of fuch proof, if the murderer was unknown, or had made his efcape, the townfhip where the man was flain fhould be charged to pay fixty-fix marks into the exchequer: or if by reafon of the poverty of the townfhip, that fum could not be raifed from thence, it was to be paid by the hundred. After this law, which was continued by William the Conqueror, for the like fecurity to his own Normans, whenever a murder was committed, it was neceffary to prove the party flain an Englifhman, that the penalty of fixty-fix marks might not be charged on the village. The manner of proving the perfon killed to be an Englifhman was by two witneffes, who knew the father and mother, before the coroner, &c. This practice was abolifhed by ftatute 14 Edw. III. cap. 4. See Murder.

ENGLESQUEVILLE, in *Geography*, a fmall town of France, in the department of the Lower Seine, 18 miles S.W. of Arques. There are feveral fmall towns of the fame name, in the department which comprifes the former province of Normandy.

ENGLISH, in a general fenfe, fomething that relates to the country or people of England. Thus we fay, the Englifh crown, Englifh copperas, Englifh names, Englifh money, Englifh meafures, Englifh weights, &c. The fweating-ficknefs is called by foreigners *fudor Anglicanus*, the

English sweat. (See SUDOR-ANGLICUS.) Dr. Cheyne calls the vapours the English malady.

ENGLISH *Borough*. See BOROUGH.

ENGLISH *Cape*, in *Geography*, a cape on the south coast of Newfoundland. N. lat. 46° 49′. W. long. 53° 29′.

ENGLISH *Cove*, a harbour, or bay, on the coast of New Ireland, about 3 or 4 miles from cape St. George.

ENGLISH *Drops*, *Guttæ Anglicanæ*. See DROP.

ENGLISH *Harbour*, in *Geography*, one of the best harbours in the island of Antigua, situated on the S.W., a little to the E. of Falmouth harbour. It is well fortified, and has a royal navy-yard and arsenal, with conveniences for careening ships of war. N. lat. 17° 8′ 25″. W. long. 61° 27′ 30″.

ENGLISH *Point*, a cape in the river St. Lawrence, on the coast of Canada. N. lat. 49° 40′. W. long. 61° 45′.

ENGLISH *Reach*, a reach in the straits of Magellan, about 3 leagues broad, between cape Gallant and cape Holland.

ENGLISH *Road*, a road in the island of Eooa, or Middleburgh, in the South Pacific ocean, having 25 fathoms water. S. lat. 21° 20′. W. long. 174° 34′.

ENGLISH *School of Engraving*. See ENGRAVING.

ENGLISH, or the ENGLISH *Tongue*, the language spoken by the people of England; and with some variation, by those of Scotland, as well as part of Ireland, and the rest of the British dominions.

The English is of Gothic, or Teutonic extraction; this was the root or stock upon which several other dialects have been since grafted, particularly the Latin and French. See TEUTONIC, &c.

The language anciently spoken in our island was the British, or Welsh, which was common to the Britons and Gauls; and which still subsists, in more or less purity, in the principality of Wales, the islands and Highlands of Scotland, part of Ireland, and some provinces of France, particularly Bretagne, and very lately subsisted in the county of Cornwall. (See CORNISH *Language*.) This language was the Celtic or Gaelic, which is said to be very copious and expressive, and is, probably, one of the most ancient languages in the world. It once obtained in most of the western regions of Europe: and now remains in the different dialects of the Irish, Welsh, and Erse. See CELTS.

As the Roman empire, extending itself towards the western parts of Europe, under Julius Cæsar, Claudius, and Domitian, came to take in Gaul and Britain, the Roman tongue became propagated therewith; all the edicts, &c. relating to the public affairs, being designedly wrote in that language.

The Latin, however, it is certain, never got so much ground, or prevailed so far in England, as in Lombardy, Spain, and the Gauls; partly on account of its great distance from Rome, and the small resort of Romans hither; and partly, because the entire reduction of the kingdom was not effected till so late as the reign of Claudius, when the empire was on the declining hand, and the new province was forced to be soon deserted by its conquerors, called to defend their territories nearer home.

Britain, thus left naked, became an easy prey to the Angli, or Anglo-Saxons, a strolling nation, from Jutland and Norway, who took an easy possession thereof about the year 450, much about the time that the Franks, another German nation, entered Gaul. The Gauls and Franks, it seems, at length came to terms; found means to unite into one nation; and thus, the ancient Gaulish, with its mixture of Latin, continued the prevailing tongue, only farther intermixed with the Francic or lingua Franca of the new inmates; but the Britons were more constant, and determined absolutely to refuse any such coalition: they had embraced Christianity, Augustine being sent from Rome to convert them about the year 570, and their competitors were heathens; rather than admit of such an union, they therefore chose to be shut up, with their language, in the mountainous parts of Cambria or Wales.

The English Saxons, thus left absolute lords, changed every thing; their own language, a dialect of the Gothic or Teutonic, and altogether distinct from the Celtic, was now fully established, and laid the foundation of the present English tongue: and the very name of the country was henceforth to be Anglo-Saxon. (See ANGLO-SAXON.) The new language remained, in good measure, pure and unmixed, till the Norman invasion: the attempts of the Danes, and the neighbourhood of the Britons, indeed, wrought some lesser innovations therein; but, in the main it preserved itself; for, as to the Danes, their language was, probably, from the same root with the Saxon; and it did not long remain a distinct tongue in any part of England, but was blended with the Anglo-Saxon, and formed a particular dialect of that language.

This Dano-Saxonic dialect was principally spoken in the kingdom of Northumberland, where the Danes chiefly prevailed: that the Anglo-Saxon language was spoken in the S.E. parts of Scotland at this time is undeniable. When Edgar the Peaceable, king of England, yielded Lothian to Kenneth II. king of Scotland, A.D. 975, it was on these express conditions; that the people of that country should still be called Englishmen, be governed by the English laws, and be allowed to speak the English language.

Edward the Confessor, however, who had lived long in France, might possibly bring in a little mixture of the dialect of that country.

But William I. and his Normans, having got possession of England, an alteration was soon attempted: the conquest was not complete, unless the Conqueror's language, the French and Franco-Gallic, were introduced; and accordingly all his acts, diplomas, edicts, pleadings, and other judicial matters, were written, &c. in that tongue.

But his attempts proved unsuccessful; the number of Normans he brought over being very small in comparison of the English, with whom they were incorporated, they lost or forgot their own language, sooner than they could make any change in the English. This, however, did not hinder, but, by the endeavours of the Conqueror, abundance of French words, though many of them of Latin original, crept into the English; and many English words, by degrees, grew out of use. Hence it happened, that the English, which was spoken afterwards, and continues to be spoken now, is a mixture of the ancient Saxon and this Norman French, together with such new and foreign words as commerce and learning have in the progress of time gradually introduced. See ANGLO-SAXON.

Upon the whole it appears, that the Teutonic dialect is the basis of our present speech. It has been imported among us in three different forms, the Saxon, the Danish, and the Norman; all which have mingled together in our language, so that it may be supposed to exist in three different periods, *viz.* Anglo-Saxon, Danish-Saxon, and Norman-Saxon. The first begins with the Saxon invasion, the second with the Danish, and the third with the Norman. Some have made the properly English period to commence with Edward I., towards the close of the 13th century; others have referred it to the 14th century; and others again have thought that it ought rather to commence with Henry VIII.; as the controversies of the Reformation were in fact the cause which then abolished the Norman dialect of the court, and introduced the present common English to our worship and to our literature. Many of our words are alfo plainly derived from the Latin. But thefe were not introduced directly from the Latin; whereas moft of them, probably, entered into our tongue through the channel of that Norman French, which William the Conqueror introduced. For, as the Romans had long been in full poffeffion of Gaul, the language fpoken in that country, when it was invaded by the Franks and Normans, was a fort of corrupted Latin, mingled with Celtic, to which was given the name of Romanfh; and as the Franks and Normans did not, like the Saxons in England, expel the inhabitants, but, after their victories, mingled with them; the language of the country became a compound of the Teutonic dialect imported by thefe conquerors, and of the former corrupted Latin. Hence, the French language has always continued to have a very confiderable affinity with the Latin; and hence, a great number of words of Latin origin, which were in ufe among the Normans in France, were introduced into our tongue at the conqueft: to which, indeed, many have been fince added, directly from the Latin, in confequence of the great diffufion of Roman literature throughout all Europe. From the influx of fo many ftreams, or the junction of fo many diffimilar parts, it naturally follows that the Englifh, like every compounded language, muft neceffarily be fomewhat irregular. We cannot expect from it, fays Dr. Blair (Lectures, &c. vol. i.) that correfpondence of parts, that complete analogy in ftructure, which may be found in thofe fimpler languages, which have been formed in a manner within themfelves, and built on one foundation. Hence, it has but fmall remains of conjugation or declenfion; and its fyntax is narrow, as there are few marks in the words themfelves that can fhew their relation to each other, or, in the grammatical ftyle, point out either their concordance, or their government, in the fentence. Our words having been brought to us from feveral different regions, ftraggle, if we may fo fpeak, afunder from each other; and do not coalefce fo naturally in the ftructure of a fentence, as the words in the Greek and Roman tongues. But thefe difadvantages, if they be fuch, of a compound language, are balanced by other advantages that attend it; particularly by the number and variety of words with which fuch a language is likely to be enriched.

As to the origin and etymology of many of our words, Dr. Wallis lays it down, that fuch words of German original as we have, in common with the French, are to be reckoned as our own, rather than as words borrowed from them; and that the old Gaulifh words, common to the French and the Welfh, which are found in our language, have been likewife taken from the Welfh, rather than from the French. Hence, alfo, the fame author accounts why the names of the divers forts of cattle are Saxon; as ox, cow, calf, fheep, hog, boar, deer, &c. and yet that their flefh, when prepared for food, is French; as beef, veal, mutton, pork, brawn, venifon, &c. the Norman foldiers not concerning themfelves with paftures, parks, and the like places, where fuch creatures are fed and kept, fo much as with markets, kitchens, feafts, and entertainments, where the food was either prepared, fold, or eaten.

Under Henry II., Dr. Swift obferves, the French made a ftill greater progrefs; becaufe of the large territories he poffeffed on that continent, both from his father and his wife, which occafioned frequent journies thither, with numerous retinues, &c. And for fome centuries after, there was a conftant intercourfe between France and England, by the dominions we poffeffed there, and the conquefts we made; fo that the language, two or three hundred years ago, feems to have had much more French than at prefent.

Befides this alteration from the conquerors, the language in procefs of time underwent feveral others; and at length came to have numerous words and phrafes of foreign dialects ingrafted into it, in lieu of the ancient Saxon; particularly, by means of negociations and commerce with other nations; by the marriages of royal families; by the affectation of many writers, in moft ages, who are fond of coining new words, and altering the ufual forms of fpeech, for the greater delicacy; and, by the neceffity of framing or borrowing new words, according as new things and inventions turn up: and by fuch means was the old Anglo-Saxon converted into the prefent Englifh tongue. See ANGLO-SAXON.

Having traced the rife and progrefs of our language hiftorically, we think it may be no incurious amufement to reprefent by actual examples the feveral fucceffive changes and ftages it has paffed through, to arrive at its prefent perfection: in order to which, we fhall make ufe of the collections of the ingenious Mr. Greenwood.

From the Saxon invafion, we have no memorial extant of the language for 250 years: the oldeft Saxon writing in being is a glofs on the evangelifts, written in the year 700, by Eadfride, bifhop of Holy Ifland; in which the three firft articles of the Lord's Prayer run thus:

" Uren Fader thic arth in heofnas, fic gehalgud thin noma, to cymeth thin ryc. Sic thin willa fue is in heofnas, and in eortho," &c. See ANGLO-SAXON.

Two hundred years after, in the year 900, the fame was rendered thus:

" Thu ure Fader the eart on heofinum, fi thin nama gehalgod; cum thin ric. Si thin willa on eorthan fwa, fwa on heofinum."

In the following age it was turned thus in the Saxon Homilies, faid to be tranflated by king Alfred:

" Fæder ure thu the earth on heofenum, fi thin nama gehalgod, to be cume thin rice, gewurthe thin willa on eoarthan fwa, fwa on heofnum," &c.

About the year 1160, under Henry II., near which period the Saxon began to affume a form in which the beginning of the prefent Englifh may be difcovered; it was thus rendered by pope Adrian, an Englifhman, in rhyme:

" Ure Fader in heaven rich,
Thy name be hayled ever lich,
Thou bring us thy michell bliffe:
Als hit in heaven y-doe
Evar in yearth beene it alfo," &c.

About 100 years after, in the time of Henry III., it was tranflated thus:

" Fadir that art in heaven bliffe,
Thin helge nam it wurth the blifs,
Cumen & mot thy kingdom,
Thin holy will be it all don,
In heaven and in erdh alfo," &c.

Two hundred years after, under Henry VI., it was rendered thus:

" Our Fadir that art in hevenes, halewid be the name, thi kingdom come to thee, be thi will don in eerthe, as in hevene."

Dr. Hickes furnifhes an extraordinary fpecimen of the Englifh, as fpoken in the year 1385, in his Thefaur. Liter. Septent. which we fhall the rather amufe the reader with, as it is on this very fubject, the Englifh tongue; and contains not only the hiftory, but the reafon of the changes and differences therein:

" As it is knowe how meny maner peple beeth in this lond; there beeth alfo fo many dyvers longages and tonges. Nothelefs Walfche men and Scots that beeth nought medled with

with other nations, holdeth wel nyh hir firſt longage and ſpeche: but yif the Scottes that were ſometime confederat and woned with the Pictes drawe ſomewhat after hir ſpeche; but the Flemynges that woneth in the weſte ſide of Wales, haveth left her ſtrange ſpech, and ſpeketh Sexonliche now. Alſo Engliſhe men, they had from the bygynnynge thre maner ſpeche; northerne, ſowtherne, and middel ſpeche in the middel of the londe, as they come of three maner of peple of Germania: nothelefs by commyxtion and mellynge firſt with Danes, and afterwards with Normans, in meny the contrary longage is apayred [corrupted.] This appayrynge of the burthe of the tunge is bycauſe of tweie thynges, oon is for children in ſcole agenſt the uſage and maner of all other nations, beeth compelled for to leve hire own longage, and for to conſtrue hir leſſons and here thynges in French, and ſo they haveth ſethe Normans come firſt into Engelond. Alſo gentlemen children beeth taught to ſpeke Frenſche from the tyme that they beeth rokked in here cradel, and kunneth ſpeke and play with a childes broche; and uplondiſſche men will linke hymſelf to gentilmen, and fondeth with great beſyneſſe for to ſpeake Frenſche to be told of. Hit ſeemeth a greet wonder how Engliſche men and her own longage and tonge, is ſo dyverſe of ſown in this oon ilond; and the longage of Normandie is comlynge of another lond, and hath oon manner ſoun amonge alle men that ſpeketh hit arigt in Engelond. Alſo of the foreſaid Saxon tonge that is deled [divided] a three, and is abide ſcarceliche with few uplondiſſche men, is greet wonder. For men of the eſt, with men of the weſt, is, as it were, under the ſame partie of hevene acordeth more in ſownygne of ſpeech, than men of the north, with men of the ſouth. Therefore it is that Mercii, that beeth men of myddel Engelond, as it were parteners of the endes, underſtondeth bettre the ſide longages northerne and ſoutherne, than northerne and ſoutherne underſtondeth either other. All the longage of the Northumbers, and ſpecialliche at York, is ſo ſcharp, ſlitting and frotynge, and unſchape, that we ſoutherne men may that longage unnethe underſtonde. I trow that that is by cauſe that they beeth nyh to ſtrange men and nations, that ſpeketh ſtrongliche, and alſo bycauſe that the kinges of Engelond wonneth alwey fer from that cuntry," &c.

The firſt of our authors, who can properly be ſaid to have written Engliſh, was ſir John Gower, who, in his Confeſſion of a Lover, calls Chaucer his diſciple.

How the Engliſh ſtood about the year 1400, may be ſeen in Chaucer, who refined and improved it very conſiderably; though he is charged with the affectation of mixing too many French and Latin words with his Engliſh, and by that means, with too much altering and corrupting the primitive language.

In the year 1537, the Lord's Prayer was printed according to the following verſion:

" O oure Father which arte in heven, halowed be thy name: let thy kingdome come, thy will be fulfiled as well in erth as it is in heven," &c.

Where the reader will obſerve the diction almoſt brought to the preſent ſtandard; the variations being principally in the orthography. See an hiſtorical view of the progreſs of the Engliſh language, with ſpecimens at different periods, from the age of Alfred to that of Elizabeth, in the Introduction to Dr. Johnſon's Engliſh Dictionary, vol. i. fol.

Spencer, who lived in the ſame age, contributed not a little to the improvement and refining of the tongue: he threw aſide abundance of the outlandiſh ornaments, and wrote a purer Engliſh, yet with more elegance and variety than had been known before. He was ſucceeded by Shakeſpeare, Ben. Johnſon, lord Bacon, Milton, Cowley, Waller, Tillotſon, Dryden, Addiſon, and Pope, &c. whoſe works are in every body's hands; and by whom the language has been tranſmitted to us under all its preſent advantages.

The perfections aſcribed to the Engliſh, and alſo in a degree ſuperior to any of the modern tongues, are, 1. That it is very ſtrong and ſignificant; to which our finely compounded words, formed on the model of the Greeks, do not a little contribute.

This may alſo be partly aſcribed to the national character of the people who ſpeak it, from which language is apt to receive its predominant tincture. Thus, the gravity and thoughtfulneſs, as well as the ſtrength and energy, of the Engliſh, and alſo the gaiety and vivacity of the French, are ſufficiently impreſſed on their native tongues. However, though the Engliſh language poſſeſſes diſtinguiſhing ſtrength and energy, it is naturally prolix, on account of the great number of particles and auxiliary verbs, which in the uſe of it we are obliged conſtantly to employ; and this prolixity muſt, in ſome degree, enfeeble it. We ſeldom can expreſs ſo much by one word as was done by the verbs, and by the nouns, in the Greek and Roman languages. Our ſtyle is leſs compact; our conceptions being ſpread out among more words, and ſplit, as it were, into more parts, make a fainter impreſſion when we utter them. Notwithſtanding this defect, as our language abounds in terms for expreſſing all the ſtrong emotions of the mind, and we have the liberty, in a greater degree than moſt nations, of compounding words, it may be eſteemed to poſſeſs conſiderable force of expreſſion; more eſpecially when we compare it with the other modern tongues, though much below the ancient. The ſtyle of Milton alone, both in poetry and proſe, affords ſufficient evidence, that the Engliſh tongue is far from being deſtitute of nerves and energy.

2. The Engliſh language is copious; of which Mr. Greenwood gives us inſtances in the word ſtriking; which we have above thirty different ſynonymous expreſſions for; as *to ſmite*, *bang*, *beat*, *baſt*, *buffet*, *cuff*, *hit*, *thump*, *thwack*, *ſlap*, *rap*, *tap*, *kick*, *ſpurn*, *box*, *yerke*, *pummel*, *punch*, &c. and the word *anger*, for which he enumerates above forty. So we ſay *to ſeeth* or *boil* fleſh, *ſtew* prunes, *poche* eggs, *coddle* apples, *bake* bread; for which expreſſions, *to ſeeth*, *ſtew*, *poche*, *coddle*, and *bake*, the Latins, with all the boaſted copia of the tongue, have only one word, *coquere;* and the French, as much as they abound with terms of cookery, not many more; the word *cuire* ſerving indifferently for *ſeething*, *boiling*, *baking*, *ſtewing*, and *codling*.

Indeed, few languages are more copious than the Engliſh. In all grave ſubjects eſpecially, hiſtorical, critical, political, and moral, no writer can juſtly complain of the barrenneſs of our tongue. We are alſo rich in the language of poetry. Our poetical ſtyle differs widely from proſe, not in point of numbers only, but in the very words themſelves; which ſhews what a ſtock and compaſs of words we may ſelect and employ, ſuited to different occaſions. In this reſpect we are infinitely ſuperior to the French, whoſe poetical language, if it were not diſtinguiſhed by rhyme, would not be known to differ from their ordinary proſe. It is chiefly, however, on grave ſubjects, and with reſpect to the ſtronger emotions of the mind, that our language diſplays its power of expreſſion. But, in deſcribing the more delicate ſentiments and emotions, our tongue is not ſo fertile; and we muſt acknowledge its inferiority to the French. This is, perhaps, the happieſt language for converſation in the known world; but, on the higher ſubjects of compoſition, it is much excelled by the Engliſh.

3. The

3. The Englifh language is not deftitute of flexibility, This power of accommodation to different ftyles and manners, fo as to be either grave and ftrong, or eafy and flowing, or tender and gentle, or pompous and magnificent, as an author's genius prompts or occafions require, is a quality of great importance both in fpeaking and writing. This property of a language feems to depend upon three things: its copioufnefs; the different arrangements of which its words are fufceptible; and the variety and beauty of the found of thofe words, fo as to correfpond to many different fubjects. The Greek poffeffed this property in a fupereminent degree; the Latin was, in this refpect, inferior to it; and among the modern tongues, the Italian poffeffes flexibility in a greater degree than the French; and though our language has lefs of it than the Italian, it poffeffes a confiderable degree of this quality. If any one will confider the diverfity of ftyle which appears in fome of our claffics; that great difference of manner, for inftance, which is marked by the ftyle of lord Shaftefbury, and that of dean Swift; he will perceive, in our tongue, fuch a circle of expreffion, fuch a power of accommodation to the different tafte of writers, as redounds not a little to its honour.

4. Some have challenged to the Englifh language the praife of being mufical and harmonious; and in this refpect Mr. Dennis makes no fcruple to affert it fuperior even to the French. This, which fome may think ftrange, he proves hence, that we have blank verfe which is harmonious by mere force of numbers and quantity; whereas the French have long ago defifted from all pretenfions to poetical numbers, without the affiftance of rhyme.

It may be added on this laft head, from Mr. Welftead, that the Englifh has many meafures, the iambic and trochee, for inftance, in common with the Greek and Latin; an advantage arifing from the variation of the accent; and that rhyme is peculiarly natural to it, varying itfelf to the ear with exceffive fweetnefs; not to mention the cæfuras, paufes, tranfpofitions, and numberlefs other graces, which the Englifh verfification is capable of, probably beyond every other living language.

The Englifh has, indeed, been reproached on account of its deficiency in harmony of found; but the charge has been extended too far. The melody of our verfification, and the power which our language poffeffes of fupporting poetical numbers, without any affiftance from rhyme, afford fufficient proof that our language is far from being unmufical. Next to the Italian, our verfe is the moft diverfified and harmonious of any of the modern dialects; and far exceeds the French in variety, fweetnefs, and melody. Mr. Sheridan has fhewn, in his Lectures, that we abound more in vowel and diphthong founds than moft languages; and thefe, too, fo divided into long and fhort, as to afford a proper diverfity in the quantity of our fyllables. Our confonants, he obferves, though they appear crowded to the eye on paper, often form combinations not difagreeable to the ear in pronouncing; and, in particular, the objection which has been made to the frequent recurrence of the hiffing confonant *s* in our language is unjuft and ill-founded: for this letter frequently lofes the hiffing found, efpecially in the final fyllables, and is transformed into a *z*, affording a found on which the ear can reft with pleafure. After all, it muft be allowed, that ftrength and expreffivenefs, more than grace and melody, are the diftinguifhing properties of the Englifh tongue. It is a remarkable peculiarity of Englifh pronunciation, that the accent is thrown farther back, or nearer the beginning of a word, than is done by any other nation; and the general effect of this practice of haftening the accent is to give a brifk and a fpirited, but at the fame time a rapid and hurried, and not very mufical tone to the whole pronunciation of a people.

5. The Englifh tongue is, without doubt, the moft fimple in its form and conftruction of all the European dialects. It is free from all intricacy of cafes, declenfions, moods, and tenfes. The words are fubject to fewer variations from their original form than thofe of any other language. Its fubftantives have no diftinction of gender, except what nature has made, and but one variation in cafe. Its adjectives admit of no change at all, except what expreffes the degree of comparifon. Its verbs, inftead of running through all the varieties of ancient conjugation, fuffer no more than four or five changes in termination. By the help of a few prepofitions and auxiliary verbs, all the purpofes of fignificancy in meaning are accomplifhed; while the words commonly preferve their form unchanged; which ftructure, though it has its difadvantages in point of elegance, brevity, and force, contributes to facility. However, bifhop Lowth has obferved in the Preface to his Grammar, that the fimplicity and facility of our language occafion its being frequently written and fpoken with lefs accuracy. See Grammar, Language, Style, Syntax, &c.

Some object to the Englifh, that it confifts too much of monofyllables; which others reprefent as an excellence, becaufe it argues a greater antiquity, if what Salmafius fays be true: Certum quippe eft, linguas omnes, quæ monofyllabis conftant, cæteris effe antiquiores;" he adds, that the "ancient Greek abounded herein, as appears from the ancient poets, and fuch as affected antiquity." De Re Hellenift.

But we have a farther advantage from our monofyllables, *viz.* "concifenefs;" as we are hereby enabled to exprefs more matter in the fame compafs of letters than any other modern tongue. The only thing we fuffer by it, is, fomething in point of foftnefs and numbers; and yet we have verfes compofed wholly of monofyllables, that do not want harmony; as that of Creech,

"Nor could the world have borne fo fierce a flame."

Others object to our language, that it does not equal the foftnefs, the delicacy, of the more fouthern languages, of France, Spain, and Italy. It feems to retain fomewhat of the Gothic roughnefs of the people who framed and introduced it; the foil and climate it was planted in, not tending much to mellow and refine it.

To this purpofe does Dr. Swift fpeak, who accounts for the effect hence, that the Latin tongue was never in its purity in our ifland; and befides, it was removed, in its imperfect ftate, before it could have time to incorporate with the language of the country, and fubdue and foften it, as it did in the other provinces of France and Spain, &c. But it is to be obferved, that, upon the whole, this, fuppofing it true, does not lie as an objection againft the language, but the people: our manners are alfo lefs polifhed than fome of our neighbours; we are not yet arrived at that pitch of moleffe, of delicateffe, of foupleffe, which we cenfure in them; and it is but juft our language correfpond with the reft of our character.

Mr. Welftead is of opinion, that the Englifh language is not capable of a much greater perfection than it has already attained. We have trafficked, he obferves, with every country for the enriching of it; the ancients and moderns have both contributed to give it fplendour and magnificence; the faireft cyons that could be had from the gardens of France and Italy, have been grafted on our old ftocks, to refine the favagenefs of the breed; we have laid

afide

aſide moſt of our harſh, antique words, and retained few but thoſe of good and ſound energy: the moſt beautiful poliſh is at length given to our tongue that it will bear, without deſtroying and altering the very baſis and ground work of it; its Teutonic ruſt is worn away, and little or nothing is wanting either of copiouſneſs or harmony. He goes on to argue the maturity and perfection of the Engliſh, from another very extrinſic principle, *viz.* by comparing the time and circumſtances of the improvements made ſince the firſt refiners of it; with thoſe of the Greek, Latin, French, and other tongues that confeſſedly have riſen to their height.

Every civilized nation, that author thinks, has its claſſical age; and he ſuggeſts, that the Engliſh are not far from it. So that what remains to be done for the Engliſh tongue, ſhould not be to advance, but to fix it where it is, and prevent its declining. There is, in effect, a point of perfection, which when a language has once arrived at, it cannot exceed, though it may degenerate from it; and thus it happened to the two fineſt languages that the world has known.

It may ſeem odd to talk of fixing ſo unſtable a thing as language: the Greek liturgies of St. Baſil, and St. Chryſoſtom, ſtill uſed in that church, the one for ſolemn, the other for common days, have been a long time unintelligible to the people; ſo much has the vulgar Greek degenerated from its original purity! Polybius teſtifies, that the articles of truce between the Romans and Carthaginians could ſcarcely be underſtood by the moſt learned Roman antiquaries, three hundred and fifty years after the time in which they were made. In effect, from the days of Romulus to thoſe of Julius Cæſar, the Latin was perpetually changing; and what was written three hundred years before Tully, was as unintelligible in his time as the Engliſh and French of the ſame period are now; and theſe two have changed as much ſince William the Conqueror, in about eight hundred years, as the Latin appears to have done in a like term.

Whether our language will decline as faſt as the Roman did, may admit of ſome doubt; there being many circumſtances in the affairs of the nation, which contributed to that ſpeedy corruption, that may not, in all probability, find place among us. The French, for about two centuries paſt, has been poliſhing as much as it will bear; and it appears to be now declining, by the natural inconſtancy of that people, and the affectation of ſome late authors, to introduce cant words, which is the moſt ruinous corruption in any language. But without ſome ſuch conſideration there does not ſeem any abſolute neceſſity, why a language ſhould be perpetually changing.

We find examples to the contrary: from Homer to Plutarch, are above a thouſand years; and ſo long, at leaſt, Dr. Swift thinks, we may allow the purity of the Greek; the Grecians ſpread their colonies round all the coaſts and iſlands of Aſia Minor, and the Ægean ſea, where the language was preſerved entire for many ages after they themſelves became provinces to Rome, and were over-run by the barbarous nations. The Chineſe have books in their language above two thouſand years old; neither have the frequent conqueſts of the Tartars been able to alter it. And the German, Spaniſh, and Italian, have admitted few or no changes for ſome ages paſt.

On ſuch conſiderations, that author moved the then prime miniſter, the earl of Oxford, to eſtabliſh a ſociety, or academy, for the ſettling, and aſcertaining, the purity of our tongue; to ſet a mark on the improprieties which cuſtom has made familiar, to throw out vicious phraſes and words, to correct others, and perhaps retrieve ſome others now grown obſolete, and to adjuſt the orthography, pointing, &c.

Without ſome ſuch means, he complains that the fame any writer can expect will be ſo ſhort and ſcanty, as by no means to be a ſufficient motive to call forth, and engage a man to exert his genius. Our language is chiefly confined to theſe two iſlands; and it is hard our authors' fame ſhould be limited in time as well as place. Were it not for the Bible and Common-Prayer, we ſhould hardly have been able to underſtand any thing written about two centuries ago.

It is a melancholy reflection, that Petrarch ſtill ſpeaks good Italian; whereas Chaucer, who lived an hundred years later, is not to be underſtood by an Engliſh reader without a Saxon and French gloſſary. And what ſecurity has Dryden himſelf, while things continue on their preſent footing, that he ſhall not, in a like ſpace of time, become as obſolete as Chaucer is?

Grammars and dictionaries, with whatever care and judgment they are compoſed, will prove but a feeble ſtay to a fleeting language, unleſs they have ſome extraordinary ſanction and authority. And, what is to be lamented, ſuch writings have contributed to the corruption almoſt as much as the perfection of our tongue.

Dr. Gill, Ben Johnſon, and Hexham, it is certain, by forcing the Engliſh tongue to the Latin method, have clogged and perplexed it with abundance of uſeleſs precepts concerning caſes, genders, and declenſion of nouns, tenſes, moods, and conjugations of verbs, and other things which our language has nothing to do with. Nor have even Dr. Wallis, Greenwood, &c. though ſenſible of the fault in thoſe others, been able wholly to keep clear of it themſelves. See STYLE.

ENGLISH *Town*, in *Geography*, a ſmall village in the north-weſtern part of Monmouth county, in New Jerſey, on the road from Princeton to Shrewſbury; 21 miles from the former, and ſix W. of Monmouth court-houſe.

ENGLISH *Turn.* See DETOUR *Des Anglois.*

ENGLSTAIN, a town of Germany, in the archduchy of Auſtria; ſix miles N.W. of Zwetl.

ENGONASIS, Εγγονασις, in *Aſtronomy*, Hercules; one of the northern conſtellations. See HERCULES.

ENGOUTED, in *Falconry*, is ſaid of a hawk's feathers, when they have black ſpots in them.

ENGRAFTING. See GRAFTING.

ENGRAILED, or INGRAILED, in *Heraldry*, (from the French *grêle*, hail) is when a thing is repreſented with its edges ragged, or notched, ſemi-circularly, as if broken by ſomething falling on it. See INDENTED and INVECTED.

Spelman expreſſes it in Latin by *imbricatus;* others by *ingrediatus;* and others by *ſtriatus.*

ENGRAPPLE. This is a device in uſe principally in *Naval Warfare*, where it is intended to retain an enemy's veſſel in ſome particular poſition, eſpecially for the purpoſe of boarding. When an opportunity may offer of grappling acroſs a ſhip's bows, or ſtern, ſo as to allow raking her fore and aft, the battle is uſually but of ſhort duration; it being almoſt impoſſible for a crew to ſtand to their guns while ſubject to ſo deſtructive a fire. Generally we find, that when a commander is intent on boarding his opponent, he has his yard-arms ſupplied with ſmall grapnails, which being lowered down at pleaſure, among the enemy's rigging, hook therein, and thus prevent her from retiring to avoid the boarders. Sometimes poles, having long barbs at their ends, are uſed for the ſame purpoſe; theſe are chiefly managed by the forecaſtle-men, and have their butts laſhed to the *davit*, or to the *cat-head.* Whatever contrivance may be in uſe for engrappling, it is expedient that the implement be every where ſufficiently ſolid or firm to retain its hold, and

and to refift the hatchet, otherwife the enemy would fpeedily cut them away: thus, all grap-nails fhould be fufpended by means of chains, paffed through blocks at the yard-arms; nor fhould the tackle, by which they are acted upon, be hauled tight until the points of the grap-nails may be firmly hooked among the fhrowd-hawfers, or fome fuch fubftantial part of the enemy's rigging, which he could not, with fafety to his mafts or yards, cut away. Where it is practicable, a very ftrong chain fhould be paffed round the whole of the fhrowd-hawfers of that maft, refpectively, oppofite which the veffel is engrappled; or, if that be too hazardous, the chain-plates may be fecured in a fimilar manner. It is evident, that were the former to be all included, the enemy muft cut away every fupport on that fide his maft, before he could extricate himfelf: in the latter inftance, as the chain-plates are of iron, and very fubftantial, nothing but the chain, whereby they are embraced, giving way, could afford the means of feparation.

Sometimes fhips become fortuitoufly engrappled, by the flukes of their anchors hooking among the rigging of the veffels oppofed to them: this, however, is feldom permanent; for as the engrappling arifes from accident, fo does a lift, or heave of the fea, ordinarily fet the parties at liberty, either by tearing away whatever hitches upon the fluke, or by caufing the latter to unhook itfelf. Where the fea runs high, this is often the cafe; expofing both veffels to the moft imminent danger, and always caufing confiderable damage. Hence, it fhould ever be confidered by a commander, how far the fafety of his fhip may become queftionable in the attempt to approach his opponent, when there is much fwell. The practice of engrappling is, indeed, but rarely reforted to in fhips of the line, or even by frigates; but is extremely common among privateers abounding in men, and intent upon bringing an engagement to a very fpeedy iffue, fo as to fave their hulls and rigging from fuch damages as might compel them to feek a port wherein to re-fit.

ENGRAVER, one who practifes the art of engraving. See ENGRAVING.

ENGRAVER'S *Act*, the act for fecuring the copy-right of engraved prints. That engravers might enjoy the fair advantages arifing from the exercife of their own talents, and that the public at large might in due time fucceed to fuch advantages, an act of parliament was paffed in the 8th year of Geo. II., "for the encouragement of the arts of defigning, engraving, and etching hiftorical and other prints, by vefting the properties thereof in the inventors and engravers, during a time therein mentioned."

After thus vefting the property for the term of *fourteen* years, to commence from *the day* of publication, it enacts that the name of the proprietor fhall be engraved on each plate; "and any printfeller, or other perfon, who fhall engrave, etch, or in any other manner copy, and fell, or caufe to be engraved, etched, or copied and fold, in the whole or in part by varying, adding to or diminifhing from the main defign, or fhall print, reprint, or import for fale any fuch print or prints, "without the confent of the proprietor firft had and obtained in writing," figned by him in the prefence of two credible witneffes, or knowing the fame to be fo printed, &c. without confent of the proprietor, fhall publifh, fell, or expofe to fale, then fuch offender "fhall forfeit the plate or plates" on which fuch print or prints are or fhall be copied, and all and every fheet or fheets (being part of or whereon fuch print or prints are or fhall be fo copied or printed) "to the proprietor or proprietors of fuch original print or prints," who fhall forthwith deftroy the fame. And further, that every fuch offender fhall forfeit five fhillings for every print which fhall be found in his cuftody, either printed and publifhed, or expofed to fale; one moiety to the king and the other to the informer.—*Note*, Thefe penalties do not extend to purchafers of plates from the original proprietors (f. 2.): and actions for offending againft this act muft be brought within three months (f. 3.)

The act of 7 Geo. III. c. 38. after reciting that the preceding act had been found ineffectual, enacts, that the original inventors, defigners, or engravers of any print, "map, chart, or plan, or any other print whatfoever," taken from any picture, drawing, or fculpture, are entitled to the benefit and protection of the recited and prefent acts; and by (fect. 7,) *extends* the rights intended to be fecured by this and the former act to the term of *twenty-eight* years.

A fubfequent act (paffed in the 17th of Geo. III.) ftates, that the former acts have not anfwered the purpofes for which they were intended, and that it is neceffary for the encouragement of artifts, that further provifions fhall be made. It therefore enacts, that if any engraver, etcher, printfeller, or other perfon, fhall, within the time limited by the aforefaid acts, engrave or etch, or caufe, or procure to be engraved or etched, or worked, in "mezzotinto, or chiaro-fcuro, or otherwife," copy; or who fhall print, re-print, or import for fale, any copy of any hiftorical print, or any portrait, converfation, landfcape, or architecture, map, chart, or plan, or any other print whatfoever, which hath, or have been, or fhall be engraved, etched, drawn, or defigned "in any part of Great Britain," without the exprefs confent of the proprietors firft had and obtained in writing, then every fuch proprietor fhall and may in a fpecial action on the cafe to be brought againft the offending party, recover *fuch* damages *as a jury* on the trial of fuch action, upon the execution of a writ of enquiry thereon, "fhall give or affefs," together with "double cofts of fuit."

The following are the moft important cafes which have fubfequently occurred, and which are introduced to fhew the legal conftruction which has been put upon the aforefaid act of parliament, by magiftrates of high authority.

In the fittings after Hilary term, 25 Geo. III. before lord chief juftice Mansfield, Sayer brought an action againft Moore for pirating fea charts. The charts which had been copied were four in number, which Moore had made into one large map. It appeared in evidence that the defendant had taken the body of his publication from that of the plaintiff; and that the plaintiff had originally been at great expence in procuring materials for thefe maps; but it was alfo proved that the defendant had made many material alterations and improvements thereupon. Lord Mansfield's addrefs to the jury upon this occafion is remarkable and important. "The rule of decifion in this cafe, he obferved, is a matter of great confequence to the country: in deciding it we muft take care to guard againft two extremes equally prejudicial; the one, that men of ability who have employed their time for the fervice of the community, may not be deprived of their juft merits, and the reward of their ingenuity and labour; the other, that the world may not be deprived of improvement, nor the progrefs of the arts be retarded: the act that fecures copy-right to authors, guards againft the piracy of the words and fentiments; but it does not prohibit writing upon the fame fubject, as in the cafes of hiftories and dictionaries: in the firft a man may give a relation of the fame fact, and in the fame order of time; in the latter an interpretation is given of the identical words: in all thefe cafes, the queftion of fact to come before a jury, is whether the alteration be colourable or not; there muft be fuch a fimilitude as to make it probable and reafonable to fuppofe that one is a tranfcript of the other; fo in the cafe of of prints, no doubt different men may take different engravings from the fame picture. The fame prineiple holds with regard to charts: whoever has it in his intention to publifh a ehart, may take advantage of all prior publieations; there is no monopoly of the fubject here, any more than in the other inftanees, but upon any queftion of this nature the jury will decide whether it be a fervile imitation or not. If an erroneous ehart be made, God forbid it fhould not be eorrected, finee it thereby becomes more fervieeable and ufeful for the purpofes to which it is applied: but here you are told that there are various and very material alterations: the defendant therefore has been correcting errors, and not fervilely copying. If you think fo, you will find for the defendant; if you think it a mere fervile imitation, and pirated from the other, you will find for the plaintiff." [Verdict for defendant.] No action therefore lies in future for publifhing fea eharts on an improved and more ufeful prineiple, even though many of the lines fhould be eopied from older charts.

In Eafter term, 10 Geo. III. Wil. 60. Sayer loft his action againft Diecy for eopying and felling a print, beeaufe though the *year* of our Lord, wherein the original plate was publifhed was engraved thereon, the *day of the month* was not.

In Miehaelmas term, 33 Geo. III. 5 T. R. 41. an action was brought againft Symonds and others, for pirating a portrait of the eountefs of Huntingdon. Bowyer was the original proprietor, and had affigned his right through Fittler to Thompfon, by whom the action was maintained. On becoming poffeffed of the plate, Thompfon had inferted his own name in the infeription inftead of Bowyer's, "preferving the original date" of 26th day of Auguft, 1790; but the objection ftarted on this ground was over-ruled by the court, and the plaintiff obtained a verdict and 10*l.* damages.

ENGRAVING, English, *Origin and Progrefs of.* In England, the *art* of engraving has gradually arifen from its rude mechanieal practice by our Britifh aneeftors. It may be faid to be indigenous to our foil. Roman and Saxon improvements have from time to time been engrafted; and more reeently, fhoots from the engraving of Germany, Italy, and France, have alfo been engrafted by the enterprize of individuals, not by the wifdom or authority of the ftate, on the original ftoek. It will probably exeite the furprife of pofterity, that *this* art has hitherto been cultivated, (if fueh might be called cultivation,) in Great Britain in no other way, though Great Britain be the chofen feat of modern commerce; and engraving, being in its nature the moft eommercial of thofe arts which adminifter to calm and elegant enjoyment, affords the moft effieient means of diffufing through the world a juft and general tafte in the fine arts, and, eonfequently, in thofe numerous branches of manufacture whieh are derived from, and fuftained by, thofe arts.

That it was rudely practifed in this ifland from a very early period, may be feen by the remains of inftruments of war, and other antiquities which have been found in the Celtic and Saxon tumuli; thefe, as is obferved by that intelligent artift and antiquary, the late Mr. Strutt, frequently bear marks of the graver, or of fome tool whieh cannot have been very diffimilar; and the numerous eoins of Cunobelin muft fatisfy every inquirer of the early Britifh exiftenee of this fpecies of engraving, an art whieh was probably introduced from Rome during the reign of that prince.

The art of die-engraving could not have exifted alone; it implies the exiftence of other modes of ingenuity; and, with the ufe of money, muft have fpread the ameliorating influenee of art. But all rifing ingenuity, and even this mode of engraving, appears to have funk under the Roman and Danifh ravages, whieh foon fucceeded. Excepting thefe coins, thofe of Caraufius, and a few others of lefs certain date, and the war implements mentioned above, faint indeed are the traees of Britifh engraving, until the time of Alfred the Great.

"Under the protection of that excellent monarch," fays Strutt, "the arts begun to manifeft themfelves in a fuperior degree. He not only eneouraged fuch artifts as were in England at the time, but invited others from abroad; and the works of the Anglo-Saxon goldfmiths, who were the prineipal engravers of that day, were held in the higheft efteem upon the continent as well as in their native eountry. The eafkets which they made for the prefervation of the relics of faints, and other pious purpofes, were ornamented with precious ftones and engravings in fo excellent a ftyle, as to excite the admiration of *all who faw* them." Wonder is the eoncomitant of ignoranee. There is, however, yet preferved in the Mufeum at Oxford a very valuable jewel of gold, adorned with enamelling, and a kind of fillagree work, in the midft of which is feen the half figure of a man, whieh is fuppofed by Hickes and Wooton to reprefent Jefus Chrift, and eonjectured by Strutt to be rather intended for St. Cuthbert. The back of this curious remnant of antiquity is ornamented with engraved foliage and flowers. From the unqueftionable teftimony of its own legend, this jewel is known to have been made at the eommand of Alfred the Great, and was one of the very few artieles he could have carried with him when he retreated to the ifle of Athelney; where it has fince been found.

Archbifhop Dunftan is faid to have worked in the precious metals, frequently adorning his works with images and letters whieh he engraved thereon. Ofbern (his biographer) calls him the firft of engravers; but it has been emphatieally obferved, that he who eould add the title of *Saint* to the name of Dunftan, would not hefitate to call him a Raphael in painting, or an Audran in engraving; and the fpeeimen of his drawing, whieh is ftill preferved in the Bodleian library, leaves us little to regret in the entire lofs of his engravings.

The engraving of Dunftan and his contemporary *workmen*, was doubtlefs the degenerate iffue of the art whieh the patronage of Alfred had called forth. In the tempeft of war, and the night of ignorance and fuperftition that fueceeded, feareely a glimmering of its light was feen. The mingled work of the engraver, chafer, enameller, and goldfmith, which is feen in Alfred's jewel, entirely difappeared, but die-engraving, as it afforded the means of iffuing money, became to the Anglo-Saxon prinees an art of neeeffity, becaufe infeparable from the exifting fyftem of government and polity; and henee, while other arts pined and perifhed, it was enabled to furvive the inclemeney of thofe barbarous ages, and to preferve and tranfmit to better times the art of the engraver.

Laws of Athelftan and Canute, appointing the number of minters who fhall refide in their prineipal towns, and for the punifhment of thofe who fhall dare to adulterate the coinage of the realm, are ftill extant, and may be read in Thwaite's obfervations on Anglo-Saxon and Anglo-Danifh Coins.

It may be prefumed, that the art of die-engraving, and the weak tenures by which landed property was previoufly held, gave rife to the engraving and the ufe of feals. Before their introduction, Ingulphus exprefsly fays, that lands were fometimes difpofed of by word of mouth; fometimes by laying a turf of the land granted with religious folemnity on the holy altar; and in other inftances the lord gave to the tenant a fword, bow, helmet, arrow, or drinking-horn to to certify the transfer; a drinking-horn is mentioned by Lewis as being in the poſſeſſion of a Mr. Pyſſey of Berkſhire, on which was engraven, "I king Knoute (Canute) have given thee this horn to hold thy land by."

In corroboration of the idea that the numiſmatic proceſs ſuggeſted both the manner of engraving and of *uſing* ſeals, we may mention that the matrices of ancient Engliſh ſeals, of which ſome few are yet remaining, are formed with the ſame kind of cutting and punching implements which were uſed by the die-engraver; they were of braſs, as were probably the dies of that period, and from that time to the preſent, metal ſeals have continued to be executed with the ſame implements uſed in the ſame manner, or with no other variations than have been produced by the gradual improvement of ſociety operating on the peculiarities of individual talent: alſo (ſee Seal-engraving,) that they were at firſt impreſſed as money is coined, namely, by a forcible blow, and that *lead* received the impreſſion; and from the teſtimony of Ingulphus it further appears, that ſeals were by no means common in England before his time; he ſays that, "the Normans, diſliking the Engliſh manner of ratifying their chirographs (or charters), ordered them to be confirmed by impreſſions on *wax* from the ſpecial ſeals of the parties concerned. The only ſeal in England that is known to have been impreſſed on wax before this period, is that of Edward the Confeſſor; but as this prince is known to have received his education in Normandy, the ſingularity is accounted for.

From this time the uſe and ſacredneſs of ſeals went on increaſing in the public eſtimation, ſo that before the lapſe of a century, their devices, forms, and ſizes, appropriated to the different ranks in ſociety, were gradually ſettled. Even the etiquette of ſealing on different coloured waxes, was aſcertained with ſufficient ſcrupuloſity.

An impreſſion from the ſeal of Anſelm, the primate, has been copied, and is introduced (ſee *Pl. of Britiſh Engravings, fig.* 2.) from which ſome idea may be formed of the Anglo-Norman ſtyle of deſign and engraving, as compared with what had preceded it. The archbiſhop has loſt his head, and has probably been decapitated in effigy, on account of his cropped hair, and by ſome of thoſe reſentful partizans of the long and curled locks, which were faſhionable at the court of William Rufus. Againſt long hair, Anſelm had preached with ſome apparent ſucceſs, and with a vehemence which is highly extolled by Eadmer, his companion and ſecretary; but it has been obſerved, that though the clergy at that time could overturn thrones, and had authority ſufficient to ſend above a million of men on *their* errand, to the deſarts of Aſia, they could not prevail againſt certain faſhions.

It appears that ſome argillaceous ſubſtance, apparently pipe clay, has in this inſtance been mixed with the wax of the ſeal; which has afterwards been painted either with a view to its better preſervation, or to give the true tint of the rank of a Norman archbiſhop. The ſmall folded parchment to which it is appendant, or rather which depends from it (ſee the engraving) is a grant of church land. The prolixity of modern legal forms might bluſh before its brevity.

About, or ſoon after, the time now under our obſervation, a new ſpecies of engraving, more ſimple in its nature than thoſe which had preceded it, was either introduced into or invented in England; of which there is ſcarcely an old country church of any conſequence, but affords ſome curious ſpecimens, and England more than any other nation in Europe. The braſs plates on our old ſepulchral monuments are executed entirely with the graver; the ſhadows, where ſhadowing is attempted, being expreſſed by lines (or ſtrokes,) ſtrengthened in proportion to the required depth of ſhade, and occaſionally croſſed with other lines a ſecond, and in ſome inſtances a third time, preciſely in the ſame manner as a copper plate is engraven that is intended for printing. On other occaſions a mere outline only has been cut.

Theſe engraved effigies are often found cemented on thoſe horizontal tomb-ſtones, which form part of the pavement within the churches, where the feet of the congregation, which kept the lights bright by friction, filled the inciſions with duſt, and thus darkened the ſhades; very neat or exquiſite workmanſhip was not therefore aimed at, and is not to be expected; yet ſome of theſe engravings bear no ſmall evidence of the abilities of thoſe by whom they were performed, and conſidering the dark period during which they were executed, are entitled to more praiſe than many engravings which have been ſubſequently produced. The engraver's ſtyle of drawing the human figure differs little from that of the contemporary illuminators of miſſals, and though the hands, feet, and other nudities are rarely tolerable, the ſtiffneſs of the draperies does in many inſtances bear conſiderable reſemblance to the tiſſued and embroidered veſtments of the entombed abbots, and other dignitaries of the early Catholic church; while the faces occaſionally diſplay attempts not altogether ſucceſsleſs, as it ſhould ſeem, at individual portraiture.

That which has been ſelected as a ſpecimen of this mode of engraving, is from the tomb of William de Fulbourn, in Fulbourn church, Cambridgeſhire, and is copied, with the permiſſion of the Meſſrs. Lyſons, from their Magna Britannia. William de Fulbourn was appointed a baron of the exchequer in the year 1328, and is here repreſented (ſee the *Plate* of *Engliſh Engravings, fig.* 3.) "with the effigies of an eccleſiaſtic in a richly ornamented cope, under an elegant canopy, engraved on braſs," &c. &c. See Lyſons's Cambridgeſhire, p. 64. Part of the canopy and finale have been omitted on account of the ſmaller dimenſions of our plate. The pattern of the embroidery, as may be ſeen, is far from being inelegant, and the recurring initials, (W. F.) roſes, and other ornaments, are engraved with no inconſiderable care and neatneſs.

Philoſophers have remarked how frequently man has ſtumbled or ſtopt ſhort at the very threſhold of improvement. From the time of the Cruſades, Great Britain has been in poſſeſſion of an art of engraving from which ink might have been delivered, and conſequently impreſſions multiplied, either on the ſame vellum on which books were formerly written, or, ſince the middle of the 12th century, on paper itſelf: yet until about the year 1460, no man appears to have thought of delivering ink from the inciſions of the graver.

Whether accident or deſign, and whether Italy or Germany had the honour of giving birth to an invention, of which three centuries and a half have not ſerved fully to develope the important conſequences to ſociety, has been much diſputed among the curious. Mr. Strutt is among the number of thoſe who have purſued theſe inquiries with conſiderable diligence. After diſcuſſing the German and Italian pretenſions, he at length brings forward an impreſſion from an engraved braſs plate in his own poſſeſſion, which he conceives to be Engliſh, and which he thinks *may* claim the palm of early date. Its ſtyle of art is truly that of the early German ſchool, and alſo that of the engravers of the Engliſh ſepulchral braſſes of the fifteenth century; yet from another circumſtance, which ſhall be mentioned anon, the writer of this article is led to think that Mr. Strutt's

Strutt's plate, and the tenor of his reafoning thereupon, are more curious, than his conclufion is well founded.

Mr. Strutt fays, "no one feems to have fuppofed that we could lay even the moft diftant claim to a rivalfhip (much lefs to a priority) with refpect to the early practice of engraving, with any of the continental nations famous for the arts. But when we confider how many engravers we had in England, about the time in which the difcovery of taking impreffions from copper-plates was made, as the many monumental engravings remaining in our churches to this day fufficiently teftify, (and a little examination of thefe early fpecimens of the art will prove how well they were adapted to the purpofe of printing,) we fhall readily conceive that if they did not themfelves difcover this mode of multiplying their works, they would at leaft have inftantly adopted it, as foon as the knowledge of fuch an invention had reached them."

There can be little doubt of the antiquity of the engraving here produced; and that it was made for the purpofe of printing, the letters being reverfed upon the plate fufficiently prove. So that if it fhould be urged, though we fee no kind of reafon for fuch a fuppofition, (this is furely more than ftrict criticifm will concede to Mr. Strutt,) that the plate itfelf was executed abroad, at the command of fome Englifh devotee, it muft at leaft be granted that the mode of taking impreffions from it was underftood in England, or the plate could not have been of any ufe to the owner of it; and that the engraving was the work of fome Englifh artift, *or* executed at the defign of fome Englifh perfonage; no one, I conceive, will doubt on examining the contents of the infcriptions. They confift of particular invocations to faints, comprehended in feven compartments, the initial letters of each invocation or prayer being ornamented with the reprefentation of the perfonages to whom it is addreffed." Here follows a particular defcription of the feveral compartments.

"The addrefs to the Englifh faints in the fifth petition, plainly, we think, determines the country to which it belonged. The ftyle of the drawing, and the manner in which the little figures are compofed, being placed in the initial letters, bear an exact refemblance to the illuminated delineations which we meet with in manufcripts of the fifteenth century, efpecially towards the commencement of it; and the writing alfo has every appearance of equal antiquity."

If we fhould proceed thus far with Mr. Strutt, and admit his reafoning, it will fcarcely be practicable to travel with him further, though he be in general, as to matters of fact, an excellent guide. The invocations, which cover the far greater part of the plate, are not in the Englifh, but the Latin language, and Mr. Strutt informs his readers, that they are "evidently ftamped upon the plate with fmall punches, and re-touched afterwards with the graver." Now, no man would cut an alphabet of punches, (or puncheons, as they are fometimes technically termed,) for the fake of engraving, or ftamping, fuch a plate as Mr. Strutt has brought forward, nor would probably any caufe of lefs magnitude than the formation of matrices for an alphabet of moveable types, induce an artificer to beftow the time and pains, neceffary to the production of fuch an alphabet of puncheons. From this fingle circumftance, the prefent writer is inclined to refer the engraving in queftion, in whatever country it may have been executed, to a period fubfequent to the invention of moveable types; confequently if it was executed in England, it muft have been after the year 1471, when, according to Dr. Middleton, Caxton had returned from abroad, and began to print books in Weftminfter Abbey.

Another reafon, which does not feem to have prefented itfelf to Mr. Strutt, why the invention of printing with the rolling prefs from plates of metal cannot, in fairnefs, be affigned to England, is that to fuppofe this art to have been known here before the experiments of Finiguerra, we muft alfo fuppofe that almoft a century elapfed between the firft and fecond examples of Englifh copper-plate printing, which is a thing not to be fuppofed for a moment.

Of the engravings that accompanied an edition of Vefalius's anatomy, which was printed in England in the year 1545, Mr. Ames fays, "thefe plates are fome of the firft rolling prefs printing in England." Of thefe plates, Thomas Geminus, or Gemini, was the engraver: they were not the very firft that were *publifhed* here. "The birth of Mankind, otherwyfe called the Woman's book," made its appearance in 1540, and contains fome fmall anonymous copper-plate cuts, yet Geminus might poffibly have begun his engravings more than four years before the date of their publication: at leaft he is the firft engraver in England of whofe name we are in poffeffion, and whofe works were printed on paper.

The firft edition of Geminus's Vefalius was dedicated to king Henry VIII. He publifhed a tranflation by Nicholas Udal, of the fame work, in 1552, and dedicated it to Edward VI. The tranflator in his preface fays, "Accepte therefore jentell reader, this treatife of anatomie, thankfully interpreting the labours of Thomas Gemini, the workman. He that with his great charge, watch and travayle, hath fet out thefe figures in pourtrature, will moft willingly be amended, or better perfected of his own workmanfhip, if admonifhed."

Thofe who have feen the mafterly wood engravings to the original Vefalius, publifhed at Padua, in 1542, engravings that were done under the eye, and, as fome have faid, touched by the hand, of Titian, will perceive that Gemini has left abundant room for admonition: yet the confideration that his work was a firft attempt, at once to tranfplant a new art to England, and to extend the knowledge of anatomy, will probably be received as no unfatisfactory apology for the defects of thefe engravings.

Gemini lived in Black-Friars: he printed and publifhed other books, among which are a fmall tract on midwifery, with copper-plate engravings, (which is, perhaps, the fame that is mentioned above, under the title of "the Birth of Mankind, &c.") a prognoftication relating to the weather, the phenomena of the heavens, &c. decorated with a number of cuts, and another edition of his Vefalius, printed in 1559, and dedicated to queen Elizabeth

Lord Orford has obferved that, "fo congenial an art as engraving, when once difcovered, could not fail to fpread in an age of literature. That accomplifhed prelate, archbifhop Parker, who thought that whatever tended to enlighten and cultivate the human mind, was within his province, feems to have been the moft confpicuous patron of the art, in the reign of Elizabeth. He employed, in his palace at Lambeth, a painter and two or three engravers. Of thefe engravers, the chief was Remigius Hogenbergh, who twice engraved the archbifhop's head, which, if Vertue be right, was the firft portrait printed in England, from an engraving on copper; Remigius had a brother whofe name was Francis, by whofe hand is extant a print of queen Mary I. dated in the year 1555. Under it is written "Veritas Temporis Filia." In the fet of Saxton's maps, thofe of Gaul and Belgium are by this artift, and he has alfo engraved *views* both in Bruin's Civitates Orbis Terrarum, printed in 1572 at Cologn, and in Abraham Ortelius's Theatrum Orbis Terrarum, printed in 1570 at Antwerp. On the foreground of one of the views contained in the latter work, are two figures dreffed in the coftume of the times, one of which is the portrait of Ortelius himfelf, (as the infcription beneath informs us); and the other that of Hoefnagle the engraver, who, though a native of Antwerp, was among the firft of thofe who practifed the art in England. The map of England in this work was by Humphrey Lhuyd of Denbighfhire, and that of Spain by Thomas Geminus, whom we have already mentioned. Lord Orford thinks it creditable to England, that we had at this time, "profeffors worthy of being employed to adorn Flemifh editions; Flanders being at that time a capital theatre of arts and learning;" and Ortelius himfelf commends the Englifh engravers, fpecifying befides thofe whom we named, Antony Jenkenfon, and Robert Leeth.

Chriftopher Saxton deferves mention here, for at once extending the knowledge of our national geography, enlarging the field of engraving, and raifing himfelf to eminence from the condition of a fervant. He was a native of Yorkfhire, and lived at Tingley, near Leeds, in the fervice of Thomas Sekeford, efq. mafter of the Requefts, and of the court of Wards. Encouraged by this gentleman, who kindly affifted him with money, Saxton undertook to make a complete fet of maps of the counties of England and Wales. Many of the plates he engraved himfelf, and in others was affifted by Francis Hogenbergh, Nicholas Reynold, and Auguftin Ryther. Six years were employed in the work, which commenced in the year 1573. Thefe were *the firft* county maps that ever appeared in England, and Thorefby fays of that of Yorkfhire, which is three feet wide, that it is "the beft that ever was made of that county." Ryther had the chief hand in engraving it, and at the corners are views of the city of York, and the port of Hull. Thefe maps are alfo adorned with the royal arms, and thofe of the patron "Mafter Sekeford," and are dedicated to the queen.

In lord Orford's catalogue is a worthlefs portrait of George Hoefnagle, who engraved about this time a map of Briftol, and a view of the palace of Nonfuch, which, though once fo magnificent, is now only known from defcription and the print of Hoefnagle. He worked entirely with the graver, and, as has already been mentioned, was one of thofe employed by Ortelius, in his great work, which may truly be called fo, when we confider the time when, and the circumftances under which, it was produced.

We have paffed over Cole, Bettes, the de Brees, and others: and even the names of many of thofe who ferved to mark no era in the art of which we are here tracing the progrefs in England; who neither invented nor introduced a new ftyle, nor diftinguifhed themfelves in thofe which were previoufly known and practifed; we fhall pafs over them with a general reference to Strutt, Grainger, and lord Orford's catalogue, where their names and the dates of their works may be found, with fuch lifts of their performances as thofe authors, with the affiftance of George Vertue, were able to form or collect.

Notwithftanding the praife of Ortelius, Englifh copperplate engraving retained, for more than an hundred years, much of its original coarfenefs and vulgarity. The ftyle of Reginald Elftracke, who lived at the clofe of the fixteenth and beginning of the feventeeth centuries, is occafionally fomewhat neater than that of his predeceffors, but ftill deftitute of tafte. His inftrument was the graver, but faint indeed are the mental rays that attended its progrefs.

Elftracke worked chiefly for the bookfellers; and his beft works are portraits, which are for the moft part, if not entirely, after his own drawings. They are in number at leaft thirty; and among the beft of them are thofe of fir Philip Sydney, engraved foon after his death, and "ΒΑΖΙΛΙΩΛΟΓΙΑ, or the true and lively Effigies of all our Englifh Kings from the Conqueft to the prefent time" (1618.) His portrait of queen Mary of Scotland is probably, on the whole, his beft performance.

Francis Delaram was contemporary with Elftracke. His workmanfhip, for it can fcarcely yet be called art, and certainly not fine art, was fomewhat neater than that of Elftracke, but equally taftelefs. The fquarenefs or rectangularity of his croffings gives a peculiar drynefs to his ftyle of engraving; he drew but indifferently, his outlines are hard, and his draperies heavy. Unlefs we may except the following plates, which are after his own defigns, his portraits are the beft of his works. The frontifpiece for "Wyther's Preparation to the Pfalter," ornamented with emblematical figures, and dated 1619. The frontifpiece to "The Seven golden Candlefticks," 1624. "Nero Cæfar, or Monarchie Depraved," 1627; this alfo is a frontifpiece. And the beft of his portraits are thofe of "James the Firft," an upright whole fheet print, as large as life. "Queen Mary and Queen Elizabeth," fmall uprights. "Henry Percy, Earl of Northumberland," dated 1619. "Frances, Duchefs of Richmond and Lenox," and "Sir Thomas Grefham."

But the family of the Paffes, or *de* Paffes, of whom the elder came hither from Utrecht, early in the feventeenth century, introduced a better tafte, and a neater and more elaborate ftyle of engraving than had hitherto been practifed in England.

Crifpin de Paffe was a man of letters, ftudious, and of a liberal mind. Holland's Heroologia was embellifhed and publifhed at his expence; and in the preface to a drawing-book, publifhed by him at Amfterdam, in the year 1643, (after his departure from England,) he difcovers fome knowledge in geometry and perfpective; gives directions for the proportions of the human body; for drawing in the academy by lamp light, and for the ufe of the lay-figure in ftudying draperies; and details the proportions of horfes, lions, and other quadrupeds, and of birds and fifhes. In the fame preface he fays of himfelf that he applied early to the ftudy of the arts, and mentions Rubens, Bloemart, and other diftinguifhed contemporary artifts, as his friends and encouragers: but he appears alfo to have looked with advantage at the neater productions of the German fchool of engraving. The following is a tolerably juft eftimate of his powers as an artift, and is from the pen of the late Mr. Strutt.

"Paffe worked entirely with the graver, in a neat, clear ftyle, which has much originality; and, excepting fome little ftiffnefs which frequently appears, and the want of harmony with refpect to the diftribution of the light and fhadow, (a fault which prevailed at the time in which he lived,) his beft works poffefs a very confiderable fhare of merit, efpecially his portraits, many of which he drew from the life; and the far greater part of his hiftorical and emblematical fubjects are engraved from his own compofitions. He drew the human figure very correctly," (but the proportions and ftyle of his figures are thofe of the fchool of Rubens,) "and marked the extremities with a degree of exactnefs, not ufually found in the works of thofe mafters who employed themfelves upon fmall fubjects."

Mr. Strutt ſhould have recollected here, that exquiſite examples of delicate marking and elaborate workmanſhip might then have been ſeen, and, probably, were ſeen by Criſpin Paſſe, in the works of the Behams, Penz, and thoſe other German artiſts who are emphatically termed the *little* maſters; particularly in the engravings of Bartholomew Beham, who had ſtudied under Marc Antonio.

The ſons of this artiſt, who were Criſpin junior, William, and Simon, and his daughter Magdalen de Paſſe, followed the inſtructions and the ſtyle, and in ſome inſtances ſurpaſſed the merits, of their father; though the works of Magdalen, the firſt female engraver we read of who practiſed the art in England, are not equal to the beſt of thoſe of her brethren. In three plates from Ovid's Metamorphoſes, which ſhe has engraved after pictures by Elſheimer, ſhe has judiciouſly imitated the ſtyle of count Goudt, but has not produced the ſame forcible effect, nor attained the ſame exquiſite degree of finiſh. Liſts of the numerous portraits and other engravings by this family, may be ſeen in lord Orford's Catalogue, and Mr. Strutt's Dictionary of Engravers; and in the Royal library at Paris, before the revolution, was a collection of their works in large volumes, of which there were either two or three.

From Simon Paſſe the art deſcended to his pupil John Payne. Other engravers were practiſing in England at the time, but of inferior merit. Payne had caught the mantle of the Paſſes. Strutt ſays of him that "he was a man of genius, and though his works are not very numerous, they neverthelefs manifeſt his ſuperior abilities. He was recommended to Charles I., and had a fair proſpect of making his fortune; but careleſs of that as he was of his fame, he neglected his buſineſs and died in indigence, A.D. 1647 or 48, before he had reached his 40th year. His chief engravings conſiſt of frontiſpieces and other book-plates, and portraits. But he alſo engraved a variety of other ſubjects, ſuch as landſcapes, flowers, &c. His portraits, however, are, in my opinion, by far his beſt works. Thoſe he executed entirely with the graver in a free open ſtyle, ſo managed as to produce a very pleaſing effect. Mr. Evelyn, ſpeaking of this artiſt, commends him alſo for a ſhip which he engraved. This ſhip, as Vertue informs us, was the Royal Sovereign, built by Phineas Pett. The print was of a prodigious ſize, and engraved on two plates, being, when joined, three feet long, by two feet two inches high." His beſt portraits are from Cornelius Janſen.

Having proceeded thus far with the progreſs in England of the art of engraving on *copper*, it behoves us to attend to the introduction and early progreſs of that of engraving on *wood.*

The art of engraving, and printing from, blocks of wood, was introduced into England about the ſame time with the mode of printing with the rolling preſs from engravings on copper: if, indeed, *wood* were really the material uſed for thoſe engravings which are called, and generally ſuppoſed to be, wood engravings, and which are common from the time of the firſt promulgation of the art through the fifteenth and the two following centuries, and where the printing ink is evidently delivered from "lines croſſing each other," and with the letter-preſs.

The earlieſt Engliſh engravings of this kind which the preſent writer has examined, unleſs thoſe which are publiſhed with the mark of Holbein are really by his hand, and were any of them performed after his arrival in this country, are thoſe of Chriſtopher Switzer, who lived at the cloſe of the ſixteenth and beginning of the ſeventeenth centuries. He was probably a German by birth, though he reſided in England. Vertue ſays, he cut a ſet of the broad ſeals of England, which may be ſeen in the Harleian library, but impreſſions from the blocks of coins and ſeals which he cut for Speed's hiſtory are not uncommon; and here the remarkable dark croſſings occur, and may be particularly obſerved in the four blocks which are entitled "portraitures of the ancient and of the more civil Britons." Speed calls this artiſt "the moſt exquiſite and curious hand of that age," and he probably was ſo, if we confine the remark to wood-engraving, and to England. Evelyn ſays of Switzer's ſon, who ſucceeded him in his profeſſion, and was alſo named Chriſtopher, "we have likewiſe a Switzer for cutting in wood, the ſon of a father, who diſcovered his dexterity in the herbals ſet forth by Mr. Parkinſon, Lobel, and divers other works with due commendation;" which ſhews that the elder Switzer engraved the blocks of botanical ſubjects for Lobel's obſervations, and Parkinſon's "Paradiſus Terreſtris," which was publiſhed in 1629.

It may have been perceived that of the fact of dark lines croſſing each other, being printed from the ſurfaces of engraved blocks and with the letter-preſs, the preſent writer entertains conſiderable doubt. His doubt is founded on the extreme difficulty, amounting to impracticability, though not to abſolute impoſſibility, of cutting away the minute lozenges of wood, or interſtices between the croſſed lines, ſo as to leave ſuch a ſurface of dark croſſings as muſt have preſented itſelf to the letter preſs printers of this period.

To print dark croſſings from the inciſions of the graver, and with the rolling-preſs, may be conceived to be comparatively eaſy: but as printing from the *ſurface*, and with the letter preſs, was preferred on account of its ſuperior facility, we are reduced in reaſoning upon theſe engravings, if we ſuppoſe them to have been performed on *wood*, to the monſtrous abſurdity of ſuppoſing, that a difficult and tedious, was preferred to a ſimple and eaſy proceſs, and that on account of its ſuperior facility!

Theſe conſiderations have led to the ſuppoſition that the prints in queſtion were not taken immediately from the engravings, but from caſts of ſome kind, for which the engravings, on whatever ſubſtances they were performed, did but ſerve as matrices or moulds. Yet wood cannot be caſt in moulds: and in the library of Mr. Anthony Carliſle, profeſſor of anatomy to the Royal Academy (whoſe name is, undeſignedly on the part of the author, omitted in a note to the volume of lectures on engraving delivered at the Royal Inſtitution, p. 205.) are two books illuſtrated with letter preſs engravings, which appear to contradict the above hypotheſis. It may not be impertinent here to tranſcribe a paſſage from the *manuſcript* of the lecturer.

"I have to regret that this part of the lecture is ſo little better than a ſtatement of doubts. Since this volume has been in the preſs, I have ſeen, in the library of Mr. Carliſle the anatomiſt, a copy of Johnſon's tranſlation of Ambroſe Parey's anatomy, printed in 1691, which is illuſtrated with letter preſs engravings where dark croſſings frequently occur, and in the preface to which the author ſays, 'the figures in this work are not the ſame uſed by my author; but according to thoſe of Bauhine, which were uſed in the work of Dr. Crook.' Upon referring to the latter work, which I found in the ſame library, and which was printed in 1631, it was evident that the prints were not copies, but impreſſed from the very ſame engravings: but there was this remarkable difference which *ordinary* incredulity could ſcarcely ſtand againſt, that in Johnſon's work the prints were obviouſly impreſſed from ſome ſubſtance which had been *worm-eaten* in the courſe of the ſixty years it had lain by, and which could not therefore have been *metal.*" The remainder of this note would be ſuperfluous: the inference is obvious,

obvious. But, the public muſt not be led aſtray, nor muſt the author of that note let paſs this opportunity of controverting himſelf.

It has ſince come to his knowledge, and is an undoubted fact, that old lead is not unfrequently found perforated by worms, or by ſome ſmall animalculæ, which leave behind circular holes of exactly the ſame kind and ſize, which we ſo frequently ſee in old wooden furniture, books, &c. He reſumes therefore his opinion, and indeed a further and more particular inſpection of the productions of this kind, of the German ſchool, has confirmed his belief, that the numerous prints produced at this early period in Germany and the Low Countries, which are ſuppoſed to be impreſſed from engravings on wood, are really printed from metal caſts.

As Dr. Crook's anatomical work was publiſhed but two years after Parkinſon's Paradiſus Terreſtris, it is probable that one of the Switzers engraved the anonymous anatomical figures which are the ſubjects of the above comments. The art of engraving, on whatever ſubſtance was then employed to enable the printer to produce dark croſſings from the ſurface of the work, was an exotic tranſplanted from Germany or the Low Countries, and appears never to have taken root in our ſoil. It died away with or ſoon after the Switzers, and has never revived ſince: for the art of engraving on wood, as practiſed by the Bewicks of Newcaſtle and their diſciples, and imitators, is to be conſidered as quite a diſtinct art. But, for further information on this ſubject, ſee Letter Press Engraving, and Wood Engraving.

Contemporary with the younger Switzer and with Hollar, of whom we ſhall preſently treat, were Robert VanderVoerſt and Lucas Vorſterman, who were rival competitors for public fame, and rivals alſo in the favour of king Charles I. Charles was the firſt Engliſh monarch who was ſufficiently ſenſible of the beauty of engraving, and of the popular and important purpoſes to which it might be applied, to appoint an engraver royal. The king took care to ſee that the title was not worthleſsly thrown away, in mere kindneſs to a courtier, and Voerſt was the firſt artiſt on whom that honour was conferred. He was a native of Holland, and in what year he came hither is uncertain. He was an able draftſman, and hatched his drawings with pen and ink, as was the general cuſtom of the artiſts, particularly the engravers, of that period. A drawing of this kind performed on vellum, and of which the ſubject was the Madonna with the infant Jeſus and St. John, he had the honour of preſenting to the king, for whom he afterwards engraved a portrait of his majeſty's ſiſter, and a plate from a picture which Vandyke painted to ſupply the place of that one of Titian's Cæſars which by ſome accident had been loſt or deſtroyed: ſo that Voerſt's title was not merely nominal. He engraved alſo from Vandyke, the portraits of Charles I. and his queen; (from the ſame celebrated picture which has been ſubſequently engraved by Vertue) that of the queen alone; ſir Kenelm Digby, Inigo Jones, and ſeveral others, of which a liſt may be ſeen in lord Orford's catalogue. He handled his graver in a bold, free, and commanding ſtyle.

The ſtyle of Vorſterman exhibits more careful finiſhing and painter-like feeling, and muſt on the whole be allowed to be ſuperior to that of his rival. He was to Rubens and Vandyke in England, and the Low Countries, what Marc Antonio was to Raphael in Italy. He may be ſaid at once to have ſucceſsfully tranſlated and ſtereotyped the great originals of thoſe very diſtinguiſhed painters.

Mr. Strutt ſays of him with great truth that no one ever engraved more ſucceſsfully from the pictures of Rubens: than whom, no painter that ever lived had the pleaſure of ſeeing ſo great a number of his pictures finely engraved. Vorſterman drew the human figure with correctneſs and taſte. He was maſter of the graver, and could handle it with the utmoſt facility; but he paid much greater attention to the general effect of his prints, than to the regularity of the ſtrokes; and like Gerard Audran, wiſhed to enter into the thoughts of the maſter, and tranſcribe on copper the very life and ſpirit of his pictures, rather than ſhew his own dexterity in the mere mechanical part of the workmanſhip. The heads of his figures are finely drawn, and the extremities marked in a very maſterly manner. Vertue mentions with approbation two drawings by Vorſterman, namely, a portrait of prince Henry, and a woman's head, after Leonardo da Vinci.

This celebrated engraver was a native of Antwerp, but from whom, or whether from any maſter, he learned the principles of painting and engraving, does not appear. He came over into England about the year 1623, and was occaſionally employed both by king Charles I. and the earl of Arundel. His engravings are numerous, and chiefly from Rubens, Vandyke, and Holbein. Among thoſe which may be mentioned with diſtinction are; from the former maſter, "The fall of the Damned," (a large upright); "The battle of the Amazons," a large and grand plate, printed on ſix ſheets; "Lot leaving Sodom;" "The temptation of Job;" "Suſanna and the Elders," and ſeveral others, particularly the "Return from Egypt," which he has treated in a manner differing from his uſual ſtyle, and more bold and open. From Vandyke he has engraved a dead Chriſt, ſupported on the lap of the Virgin, and a conſiderable number of admirable portraits, among which are thoſe of Charles I. and Vandyke himſelf; and from Holbein, he has engraved "Thomas duke of Norfolk," with the ſtaves of lord treaſurer, and earl Marſhal, "Eraſmus, ſir Thomas More," and the painter himſelf. Sir Thomas has here a flatter face and ſmaller bonnet than in other pictures of him; and from the circumſtance of Holbein's pencil being placed in his left hand, may be inferred, not that this print was a copy from another without being reverſed on the copper (as lord Orford has ſurmiſed) but that Holbein painted with his left hand: a truth which the painter here meant to ſay of himſelf, and which the engraver has faithfully reported.

Nor muſt the illuſtrious name of ſir Anthony Vandyke be omitted, in enumerating thoſe of the artiſts who contributed to accelerate the progreſs of Britiſh engraving. The portraits which he etched of Snyders, Vorſterman, Paul Pontius, and other diſtinguiſhed artiſts who were his contemporaries and friends, excited the juſt ſurpriſe and emulation of the painters and engravers of that age, and the beſt of them have continued to the preſent to be examples of excellence. Among the beſt may be reckoned that head of himſelf, looking over his ſhoulder, where he has introduced the golden chain which he had the honour of receiving, together with his majeſty's picture in miniature, at the hands of Charles I. a circumſtance which ſerves to ſhew that he etched this plate at leaſt, and preſumptively others, after his arrival in England. In ſome of thoſe which he had previouſly executed, we ſee him contending, as it were, againſt the difficulties of his own imperfect knowledge of the newly acquired art, and that his plates are accordingly blurred with accidental ſcratches, and blotted and ſtained with foul biting, which all the ſkill of Bolſwert, Neeffs, and Vorſterman, who ſeverally employed the graver in finiſhing moſt of his draperies and ſome of his faces, has not been ſufficient to obliterate or conceal. His ſtyle of etching is original, vigorous, free, and expreſſive, and in ſome inſtances he has finiſhed his heads with conſiderable care. The tranſcendental taſte

taſte and judgment which he has ſo amply diſplayed in his pictures, guided and determined his hand in etching, and though nearly two centuries, which have boaſted of their refinements, have elapſed ſince the period of their production, his "Ecce Homo" and his portraits, ſtill preſerve their ſtations in the collections of the taſteful, and are ſtill eſteemed among the moſt highly valued ſtudies both of the portrait painter and engraver. By liberating Britiſh portrait engraving from the ſtiff regularity of the graving tool, which had before been too much regarded as a teſt of merit, Vandyke extended the views of the taſteful, while he taught the true value of outline, and light and ſhade.

It would not now be eaſy to aſcertain the preciſe time when that important branch of engraving, which is technically termed *etching*, (for an explanation of its proceſs, ſee the article ETCHING,) was introduced into England. Ortelius's and Bruin's publications contain ſome prints where etching appears to be mingled with the work of the graver, but if they are by Engliſh artiſts, thoſe artiſts probably acquired their knowledge of etching in Flanders, where they practiſed it; and on the whole it ſeems highly probable, that no etching was performed in England till the period of Vandyke's and Hollar's reſidence in London, and that the honour of having introduced it belongs to one or the other of theſe diſtinguiſhed characters. Vandyke was here and in high favour at the court of Charles I. when Hollar arrived, but whether he had then performed any of his admirable etchings is no where recorded; and as they are without dates, cannot now be eaſily aſcertained. As neither of theſe diſtinguiſhed men was the diſcoverer of an art, though each was the inventor of a ſtyle, it may be enough to believe it highly probable, that Vandyke was the firſt perſon who etched portraits in England, and Hollar the firſt who etched landſcape and natural hiſtory.

It is not certain, that William James Delft, or *Van* Delft, (for he was ſo named from the place of his nativity,) was ever in England. Yet from his ſtyling himſelf the king of England's engraver, and engraving portraits of Charles I., his queen Henriette Maria, and the duke of Buckingham, it ſhould ſeem to be not improbable that he ſucceeded Voerſt. Strutt ſays of him, that "he drew and painted portraits with great taſte, and in a ſtyle that acquired him conſiderable reputation; but as an engraver of portraits he is more generally known, and in that light only I ſhall conſider him. He worked entirely with the graver, and handled that inſtrument with the greateſt facility. He drew correctly, and his beſt prints are very finely finiſhed. Conſidering the great number of plates which were completed by the graver of this artiſt, it is not reaſonable to ſuppoſe they ſhould be all alike or equal in merit. Accordingly I ſhall diſtinguiſh two manners in which he engraved, and produced many excellent plates in both: firſt, a bold, powerful open ſtyle, productive of a fine effect; and as a ſpecimen of it I would refer the reader to the portrait of Hugo Grotius, dated 1652: ſecondly, a neat and much more finiſhed manner, as we find in the admirable portrait of Michael Miravelt (a near relation to the engraver,) from a picture of Vandyke." From the pictures of Michael and John Miravelt, he engraved a conſiderable number of portraits.

Wenceſlaus Hollar, who has been already named, if not the firſt perſon who practiſed the art of etching in England, was the firſt who particularly diſtinguiſhed himſelf in etching landſcape, ſhipping, antiquities, and natural hiſtory.

This diſtinguiſhed artiſt, a gentleman by birth, was a native of Prague in Bohemia, and intended by his parents to have been educated to the ſtudy of the law; but the civil commotions which happened in his youth, and which led to the memorable battle of Prague, obliging them to abandon this intention, and his genius for art diſcovering itſelf about the ſame time, he was placed under Marian, an able deſigner and engraver of views, and by the time he had attained the age of nineteen, Hollar produced two plates, of which the ſubjects were an Ecce Homo and a Madonna, and child, (the latter from Albert Durer,) which drew forth the notice of the public, and confirmed the hopes of his friends. In the courſe of the next year (1636,) he engraved another of Albert Durer's Madonnas, and a plate which the ſuperſtitious might regard as ominous of his future fate, of "Fortune ſurmounting a Globe," which was alſo from Albert Durer.

He ſoon afterwards excelled in drawing geometrical and perſpective views and plans of buildings; ancient and modern churches and abbies, cities and towns; landſcapes; and various kinds of natural and artificial curioſities, ſome of which he executed with a pen in a very maſterly and peculiar ſtyle. To this art of drawing with a pen, he ſubſequently added the uſe of water-colours, which he occaſionally, in the treatment of ſuch ſubjects, as butterflies, beetles, &c. heightened and enriched with gilding in a very beautiful manner, as the volume of his drawings now in the poſſeſſion of John Townley, eſq. F. R. S. and F. A. S. of Park-ſtreet, Weſtminſter, abundantly teſtifies.

After paſſing ſome years in travelling through Germany, during which he drew and engraved views of Frankfort, Wurtſburg, Cologn, and other of its principal cities; but where he met with little encouragement: the earl of Arundel, then on an embaſſy to the Imperial court, met with him at Cologn, and being ſtruck with his uncommon abilities, and particularly delighted with a large drawing of Prague, which Vertue ſays, "was curiouſly and exactly done with the pen and pencil," took him under his protection, and Hollar travelled in the ambaſſador's ſuite, from Cologn to Mentz, Prague, Nuremberg, Augſburg, Wurtſburg, Frankfort, Regenſburg, Vienna, and finally to England, where it is ſaid the noble earl recommended him to the favour of king Charles I.

There is ſome reaſon to fear that lord Arundel's patronage of Hollar was more nominal than real; and that the vanity of the patron was more gratified, than the fortune of the artiſt was promoted, by their connection. That Hollar was left deſtitute by the death of this nobleman, notwithſtanding that political, were then added to his profeſſional, merits, (for he was a zealous adherent to the cauſe of royalty and lord Arundel,) is freely excuſed on the ground of his lordſhip's own reverſe of fortune, but it appears to imply more neglect than the liberal would elſe be diſpoſed to impute to this nobleman, that during the firſt year of Hollar's arrival in England he was under the neceſſity of drawing and etching his view of Greenwich, which is more than two feet in length, for the paltry ſum of thirty ſhillings! Yet the reader muſt wiſh in vain for a more honourable contraſt between the parſimony of Stent, who purchaſed a *commodity* of Greenwich, with no other view than to enrich himſelf by the profits it might produce; and the liberality of the exalted peer, who deſerved his exaltation as the patron and protector of talent, alive to the charms of art, and kindling with the flame of contemporary genius.

But it muſt be candidly allowed that the art of Hollar had little affinity with that of Vandyke, and, ſo dependent is the judgment in fine art of ſome men, upon the opinions of others, that the merit which lord Arundel thought he had diſcovered at Cologne or at Prague, might have faded in his own eſtimation when he approached the light of the court of London. Notwithſtanding his own partiality and

native

native feeling for the merits of Hollar, Vertue is obliged to confefs of him that " it is certain he could not fo well enter into that mafter's (Vandyke's) true manner of drawing in his grace and touches, as other engravers, fome in England and others abroad, who had ftudied his way or manner of drawing and painting; for which reafon " he could not obtain Vandyke's recommendation, nor that of his admirers." Portrait painting was then the reigning fafhion in England, and as the national tafte for art was bafking in the meridian fplendour of the powers of Vandyke, it is not furprifing that the lefs fortunate and more humble claims of Hollar were little feen, and met with fmall comparative encouragement.

Though the warmth of lord Arundel's patronage might perhaps be damped by thefe caufes, he continued in fome degree to befriend our artift. On his arrival in London, Hollar fat down with his habitual induftry to engraving, and after producing his large plate of Greenwich, which fhewed what he could do in this department of engraving, put afide for a time his talents for landfcape and natural hiftory, in order to accommodate himfelf to the public occafions and the prevailing tafte, and foon completed an equeftrian portrait of his patron, with two plates of king Richard II. kneeling before his patron faints, from an ancient altar folding table, and fome other works from the Arundelian collection, including the curious cup which was defigned by Andrea Mantegna.

In the year 1641, which was the year of Vandyke's deceafe, he engraved fome portraits, including thofe of the king and queen, from the pictures of that celebrated painter. He had now been introduced to teach drawing to fome branch of the royal family. Vertue thinks it was to teach prince Charles, having " feen a book mounting the arms or badge of the prince of Wales, (the crown and feathers,) wherein were drawings of parts of faces, &c. to begin to learn from, with fome of Hollar's hand-writing :" but in an infcription under his portrait, publifhed at Antwerp in 1648, and which infcription is fuppofed to have been fupplied by himfelf, he fays, he " had been domeftic fervant to the duke of York."

However this may have been, the civil wars which broke out foon after this mafterfhip or fervitude, toffed Hollar about with the royal party, ruined his better hopes, and obliged lord Arundel to return into Flanders. The engraver being left behind, refolved to try the fortune of war, and entering the army under the command of the marquis of Winchefter, was made prifoner at Bafing-houfe, in Hampfhire, from which having, with fome difficulty, effected his efcape, he went over to Antwerp, in the year 1645, and once more fought the patronage or confolation of the earl of Arundel. He remained in that city for fome years, endeavouring, through means of his art, to retrieve his fhattered circumftances; but his patron going to Italy for the benefit of his health, and dying at Padua in 1646, Hollar was left to the accidents of precarious encouragement and the avarice of trade. He fell again into diftrefs, and was obliged to work for the book and printfellers at very low prices.

Under fuch circumftances were produced his book of heads, after da Vinci; his thirty-eight plates of fhells, with many other fubjects from the Arundelian collection; a confiderable number of landfcapes after Breughel, Elfheimer, Teniers, and other mafters, and a ftill greater number of portraits, among which were thofe of Charles I., Charles II. when a youth, after Vandyke, the duke of York, after Teniers, which is now become very fcarce, and his own portrait, after Meyfens. At the period of the reftoration Hollar returned to England, where, though he found fufficient employment to occupy his time, the prices he received for his engravings were fo very inadequate to the labour which they neceffarily required, that he could but barely fubfift; and the plague putting for fome time an effectual ftop to bufinefs, and being foon after fucceeded by the fire of London, the pecuniary embarraffments of our artift were greater than ever, of which Leake, Jennings, Mark, and thofe other dealers, for whom, in the courfe of the years 1666 and 67, he engraved various views and plans of London, before and after the great fire, did not fail to take advantage.

" Born to misfortune as the fparks fly upwards," it was foon the fate of Hollar to turn his hopes once more toward the court, for that protection and encouragement which commerce blindly refufed him; and in the years 1668 and 69 he was employed by government under the orders of lord Howard, to make drawings of the town and forts of Tangiers, which he afterwards engraved. In this perilous fervice, he narrowly efcaped being killed or made prifoner by the Turks. The fhip, on board which he had embarked for England, the Mary Rofe, Capt. Kempthorn, fought feven Algerine Corfairs off Cadiz, and had eleven men killed and feventeen wounded; but Hollar efcaped unhurt, and had afterwards the honour of engraving a plate of the battle.

On his return to England, he received no more for the difficulties and dangers which he had encountered, the drawings he had made, and the year he had fpent in this arduous fervice, than one hundred pounds; and this, according to Vertue, was not obtained till after long attendance at the public offices, and experiencing many of thofe rebuffs " which patient merit from the unworthy takes."

From this time till the year 1677, when death put a final period to his exertions, he fpent much of his time in travelling through the northern counties of England, and delineating and engraving their topography, and produced thofe plates which are now objects of fo great curiofity, and will be yet more highly valued by pofterity, as fhewing what England was (and what Hollar was) during the reign of Charles II. The plates for Thoroton's Nottinghamfhire and Sandford's Genealogical Hiftory, were engraved in the courfe of the three laft years of his life.

He ufed to work for the mercenary book and printfellers at the rate of fourpence an hour, always having an hourglafs before him; and was fo fcrupuloufly exact, that when obliged to attend the calls of nature, or whilft talking, (though with the perfons for whom he was working, and about their own bufinefs,) he conftantly laid the glafs on its fide, to prevent the fand from running. Yet notwithftanding his exemplary induftry, and this rigid adherence to principle; notwithftanding his extraordinary merit as an artift; notwithftanding his loyalty and the paft favour of lord Arundel and Charles I., Hollar died poor and miferable, after a life of viciffitude, and for the moft part of fuffering.

During the diffolute reign of the fecond Charles, who was to liften to the claims of modeft and retired merit? The delighted purchafers of his " Seleucus," after Julio Romano; his " Fountain of Pleafures;" or his " Queen Sheba vifiting Solomon," (as will be the cafe under any reign where *patrons* are content to be acquainted with contemporary art only through the medium of parafites and dealers,) were either heedlefs of what befel their author, or were deceived into the belief that he was at leaft comfortably provided for; and while Stent, Overton, Green, and the reft of the dealers of that day, enjoyed their fire-fides in comfort, or rioted in the lap of luxury, on the profits of his works, the engraver of more than two thoufand plates, which are fince fought for through Europe, and moft of which

which are after his own deſigns, expired in the very act of intreating the bailiffs, who had entered his wretched apartment, for a little forbearance.

Hollar's plates are for the moſt part etchings, touched here and there, where ſuperior clearneſs was wanted, or the aqua-fortis had not accompliſhed its purpoſe, with the graver. His ſmall plates are ſuperior to his larger; his ſtyle of handling his etching-needle is pleaſing, and was original; and, in the accuracy, freedom, lightneſs, ſpirit, and finiſh of his cities, abbies, cathedrals, and ſome other of his landſcapes, and his plates of natural hiſtory and ſtill life, he much excelled his contemporaries; even thoſe on the continent: but in drawing the human figure he was not equally well informed, and his hands and feet are therefore often defective.

In conformity with the falſe preference which faſhion had conferred on works performed ſolely with the graving-tool, he attempted to execute ſome plates with the graver only, but has here failed of the ſucceſs that attended him in etching.

Hollar appears to have been a meek-tempered man, and to have wanted the neceſſary confidence in his own powers or the public taſte, to venture on publiſhing any of his own engravings; though Vertue aſcribes this effect to a different cauſe, which, no doubt, was at leaſt a concomitant, he ſays, "I don't find that at any time he worked for himſelf, to ſell or publiſh, as has been cuſtomary with profeſſors of that art (engraving) when they had ſubſtance of their own, or friends and intereſt ſufficient." Alas! what is ſociety if it befriend not the ingenious.

The innate love of engraving muſt be ſtrong in ſome minds, or the neceſſity of practiſing that art muſt be imperious, for Hollar to have left ſucceſſors. The truth, however, is, that in the department of his art, in which Hollar's merit chiefly reſided, he had no ſucceſſor, for Barlow, of whom we ſhall preſently ſpeak, was an Engliſh painter, who merely learned of him the proceſs of laying etching-grounds and uſing aqua-fortis; and William Carter, Daniel King, and Thomas Dudley, who were all natives of England, and pupils of Hollar, rather followed him to the grave, than ſucceeded him in art. The former was uſed occaſionally to aſſiſt his maſter; imitated feebly his ſtyle of etching; and is the engraver of the vignette head-pieces to Ogilby's Homer, and probably of many other of thoſe anonymous book-plates that ſome collectors aſcribe to Hollar. King is ſomewhat more conſpicuous. He publiſhed "The Vale Royal of Cheſhire" from his own drawings; and engraved for Dugdale's Monaſticon, and ſome other plates of topographical ſubjects. Dudley has occaſionally ſubſcribed himſelf "quondam condiſcipulus W. Hollar," and Mr. Strutt's account of him is as follows. "He was a native of England, and one of the pupils of the famous Hollar, whoſe manner of engraving he imitated. But though he never equalled his maſter in the lightneſs of his point or freedom of execution, his etchings are not without merit. His moſt conſiderable work was a ſet of cuts for the life of Æſop, prefixed to the laſt edition of his Fables, publiſhed by Barlow. He alſo etched the portrait of biſhop Ruſſel, which is ſubſcribed Thomas Dudley Anglus fecit 1679."

R. Gaywood has alſo been mentioned as a diſciple of Hollar, but he etched no views, or other landſcapes, and in engraving portraits employed leſs of etching; and, in ſhort, did not confine himſelf to the ſtyle of that maſter, but blended with it what he acquired from ſtudying Vorſt, Vorſterman, and the other engravers of the Vandyke ſchool.

Gaywood engraved a conſiderable number of portraits, among which are thoſe of queen Mary of Scotland, with a croſs; the counteſs of Portland, Holbein, Vandyke, and Dr. Fauſtus. The only hiſtorical engraving of any conſequence from his hand is the couchant Venus of Titian, which was once in king Charles's collection, and ſince in that of the earl of Cholmondeley.

Of Francis Barlow much more may with the greateſt truth be aſſerted. This artiſt was a native of Lincolnſhire, but in what year he was born was not known. He received his firſt inſtructions in art from a portrait painter of ſmall note of the name of Shepherd, and if he learned the uſe of the engraver's inſtruments from Hollar, he formed a ſtyle for himſelf.

The inventive powers of Barlow were extremely fertile. His great merit lay in deſigning and etching quadrupeds, birds, fiſhes, inſects; in ſhort, the whole volume of animated nature appears to have been open to his view, and in this reſpect, he is the fitteſt of all men to be the companion of that great moral philoſopher Æſop, whoſe fables he has ſo admirably embelliſhed. His human figures, which with conſiderable judgment he occaſionally introduced, exhibit the dreſſes and manners of his age; he had obſerved the natural inſtincts and cuſtoms of animals, and has delineated them with a fidelity which is ſurpriſing; and his landſcape back grounds often aſſume a grandeur which could only reſult from elevated ideas of art.

His compoſitions ſhew that he had ſtudied the animal and landſcape painters who preceded him, as well as nature herſelf, with advantage. In forming his ſtyle of etching, he has evidently looked at the animals of Hollar, yet is original, vigorous, free, and ſo happily varied, as to expreſs the feathery and hairy ſurfaces of birds and quadrupeds with a degree of ſucceſs which none of his predeceſſors, and only Hollar among his contemporaries, will bear to be compared with.

The frontiſpiece to his Æſop's fables, where Æſop himſelf appears ſurrounded by animals; the angler and entreating fiſh, with its landſcape accompaniments; the proſtrate camel; the battle of the frogs and mice; and the oak, and reed bending before the ſtorm, may be mentioned with diſtinguiſhed praiſe. His foxes, camels, aſſes, and wolves, are in general moſt excellent, and all his birds are ſo, without exception: but his lions, wherever they occur, are either ideal lions, and not well conceived, or ſhew that he had once ſeen and drawn from a bad model, and repeated it wherever he had occaſion for a lion.

Part of "Monk's funeral" is Barlow's engraving: and ſeveral of the plates for Edward Benlowe's "Theophila," publiſhed in folio, A. D. 1652; and ſome of thoſe for Ogilby's Virgil, are alſo deſigned and etched by Barlow.

That at ſome period of his life he had travelled northward, may be ſeen in the print which F. Place has engraved after his drawing of "the Baſs Iſland," wherein he has introduced ſoland geeſe, curlews, gulls, and all the varieties of Northern ſea fowl; and if he failed thither from any port of Scotland, it was probably during this journey that he ſaw in the latter country an eagle ſoaring with a cat in its talons, of which he afterward engraved a ſpirited plate. This anecdote is recorded both by lord Orford and Mr. Strutt, who agree in ſtating that Barlow witneſſed this contention in the air whilſt he was drawing a view in Scotland, and that the cat's reſiſtance had the effect of bringing both animals to the ground.

At one period of his life, probably towards its cloſe, he reſided near the ſign of the Drum in Drury-lane. That he was induſtrious is atteſted in the great number of his productions: yet notwithſtanding this circumſtance, and the praiſe of ſuperior excellence to which he is ſo juſtly entitled: and notwithſtanding the aſſiſtance of (Mr. Strutt ſays) "a conſiderable ſum of money," (he does not ſay how much) which was

left

left him by a friend, he died in indigent circumftances in the year 1702.

Francis Place has fometimes been fpoken of as if he had learned etching of Hollar, but in a letter to Mr. Vertue he denies this; and indeed the ftyle which he adopted and the number of plates which he has engraved after the drawings and pictures of Barlow, teaches us rather to think he muft have ftudied under that mafter, if under any mafter at all. Lord Orford fays " his prints are very fcarce," but in a book which contains " fixty-feven excellent and ufeful prints of birds and beafts" after Barlow, to which modern ftudents and even academicians are not a little indebted, and worn impreffions of which book may now be purchafed of Carington Bowles for half a guinea the fet, are twenty plates of a moderate fize, which bear the name of Place, befide others which on a critical infpection may be feen to be from the fame hand. The birds in thefe prints are etched with fo much of the fpirit and feeling of Barlow himfelf, that they might well be fufpected to be his own performance, but for the name of Francis Place, which is annexed; nor are his graffy foregrounds, and the foliage and ramifications of his trees lefs excellent.

" This ingenious artift was the fon of Mr. Rowland Place, of Dinfdale, in the county of Durham." When young he was articled as clerk to an attorney in London, where he continued till the year 1665, when certain officers coming to fhut up the houfe where he refided, on account of the plague, he took the opportunity of quitting a profeffion that did not accord with his inclination, " and of following (fays lord Orford) the roving life he loved, and the arts for which he had talents."

In the courfe of his various rambles, he drew, painted, and engraved, as inclination prompted or opportunity occurred, befides difcovering fome occafional difpofition to mineralogical refearch, and fkill in the manufacture of pottery.

He drew and engraved views of Tinmouth caftle and light houfe, the cathedral of York; Scarborough caftle, feveral plates for Thorefby's Topography of Leeds, befide various other views in England, Wales, Scotland, and Ireland, and the figures for Godartius's book of infects.

His former biographers agree in affirming that during the reign of Charles II. he was offered a penfion of 500*l. per annum*, to draw the royal navy, but declined accepting it, having a competence without, and from his natural love of independence and diflike of confinement. He died in the manor houfe of York in the year 1728.

Befide the etchings which are here enumerated, and feveral others, Place engraved the portaits of bifhop Crewe, general Lambert, and Richard Thompfon, in mezzotinto: to treat of the difcovery and introduction of which art, we muft return back a few years.

Mr. Evelyn has been juftly ridiculed by lord Orford, for the myfterious and paradoxical manner in which he announces prince Rupert's difcovery of mezzotinto. It is, perhaps, one of the moft honeft, moft candid, and moft happily expreffed, of the numerous pages which his lordfhip has written on the fubject of fine art. " Ancient fages, fays he, ufed to wrap up their doctrines, difcoveries or nonfenfe, in fuch unintelligible jargon: (as Mr. Evelyn's) and the baby world, who preferred being impofed upon to being taught, thought themfelves extremely obliged for being told any fecret which they could not comprehend. They would be reckoned mountebanks in this age, who fhould pretend to inftruct without informing; and one cannot help wondering that fo beneficent a nature as Mr. Evelyn's fhould juggle with mankind, when the inventor himfelf had confented that the new art fhould be made public.

" It is a trite obfervation that gunpowder was difcovered by a monk, and printing by a foldier. It is an additional honour to the latter profeffion to have invented mezzotinto. Few royal names appear at the head of difcoveries; nor is it furprifing. One cannot expect that many of the leaft common rank fhould be bleffed with uncommon abilities. Quicknefs to feize and fagacity to apply are requifite to fortuitous difcoveries. Gunpowder, or printing, might have fallen in many a prince's way, and the world have been ftill happy or unhappy enough not to poffefs thofe arts. Born with the tafte of an uncle whom his fword was not fortunate in defending, prince Rupert was fond of thofe fciences which foften and adorn a hero's private hours, and knew how to mix them with his minutes of amufement without dedicating his life to thefe purfuits; (like us, who, wanting capacity for momentous views, make ferious ftudy of what is only the tranfitory occupation of a genius.) Had the court of the firft Charles been peaceful, how agreeably had the prince's congenial propenfity flattered and confirmed the inclination of his uncle! How the mufe of art would have repaid the patronage of the monarch, when for his firft artift fhe would have prefented him with his nephew! How different a figure did the fame prince make in a reign of diffimilar complexion! The philofophic warrior, who could relax himfelf into the ornament of a refined court, was thought a favage mechanic, when courtiers were only voluptuous wits. Yet if the prince was defective in the tranfient varnifh of a court, he at leaft was adorned by the arts with that polifh which alone can make a court attract the attention of fubfequent ages.

" Going out early one morning during his retirement at Bruffells, he obferved the centinel at fome diftance from his poft, very bufy doing fomething to his piece. The prince afked the foldier what he was about? he replied, the dew had fallen in the night, had made his fufil rufty, and that he was fcraping and cleaning it. The prince looking at it, was ftruck with fomething like a figure eaten into the barrel, with innumerable little holes clofed together like friezed work on gold or filver, part of which the fellow had fcraped away.

" The *genie fecond en experiences*, from fo trifling an accident conceived mezzotinto. The prince concluded that fome contrivance might be found to cover a brafs plate with fuch a grained ground of fine preffed holes, which would undoubtedly give an impreffion all black; and that by fcraping away proper parts, the fmooth fuperficies would leave the reft of the paper white."

Communicating his idea to Wallerant Vaillant, a reputable painter then in the neighbourhood of Bruffells, they made feveral experiments, and at laft invented a fteel roller with projecting points or teeth like a file, which effectually produced the black ground, and which being fcraped away, or diminifhed at pleafure, left the gradations of light.

Such was the invention of mezzotinto according to lord Orford, Mr. Evelyn, and Mr. Vertue; but the baron Heinnekin affirms that " it was not prince Rupert who invented the art of engraving in mezzotinto, as Vertue and feveral other authors pretend to fay; but it was the lieutenant colonel de Siegen, an officer in the fervice of the landgrave of Heffe, who firft engraved in this manner; and the print which he produced was a portrait of the princefs Amelia Elizabeth of Heffe, engraved as early as the year 1643. Prince Rupert, he adds, learned the fecret from this gentleman, and brought it into England when he came over the fecond time with Charles II."

The prefent writer has not feen the print thus fpoken of of by the baron: and the precife date of prince Rupert's difcovery is no where mentioned. But if a mezzotinto engraving dated feventeen years before the reftoration can be produced, and the date be genuine, it certainly goes far toward proving Heinnekin's affertion. Vertue acknowledges to have feen an oval head of Leopold William, archduke of Auftria, in mezzotinto, that was dated in 1656, which he efteems the earlieft. It is infcribed "Theodorus Cafparus á Furftenburgh canonicus ad vivum pinxit et fecit;" but this argues little againft prince Rupert's difcovery, fince it is quite within probability that Cafparus might have learned the art from the prince or Vaillant during their refidence in the Low Countries.

The earlieft of Rupert's engravings in mezzotinto, that is now extant, is dated in 1658. It is an half length figure from Spagnoletto: the fubject, an executioner holding a fword in one hand and in the other a head, which is probably intended for that of John the Baptift, and upon the fword are the initials R. P. F. furmounted with a coronet. It is further diftinguifhed by the following infcription on a tablet beneath "SP in RVP. P. fecit. Francofurti. anno 1658 M. A. P. M."

Return we now to the hiftorical progrefs of Englifh *engraving*, properly fo called; referring to the word Mezzotinto, for the improved modern procefs of that branch of the art.

Lord Orford fpeaks of William Faithorne the elder with diftinguifhed praife, and has given a tolerably correct lift of his engravings, which he has feparated into five claffes, and to which the reader, who may wifh to arrange the works of Faithorne, is referred. He lived at the fame period with Hollar, and about the year 1654 in the very fame houfe; but the year of his birth has not been afcertained. He was the difciple of Peak, the painter and print-feller, who was afterwards knighted, for whom he worked three or four years. With Peak he efpoufed the royal caufe, when the civil wars broke out between king Charles and his parliament; and with him, and probably with Hollar alfo, was taken prifoner at Bafing-houfe; from whence he was fent to London, and confined for fome time in the prifon of Alderfgate. In this uncomfortable fituation he exercifed his fkill as an engraver; and here he produced a fmall head of the firft Villiers duke of Buckingham, which is in the circular ftyle of Mellan.

At the folicitation of his friends, he was releafed from confinement, and permitted to retire to France: though Graham fays, he was banifhed for refufing to take the oaths of allegiance to Cromwell, and that he ftudied feveral years under Champagne.

Vertue, who received his accounts of Faithorne from Mr. W. Hill Clark, and Mr. Bagford, lord Orford's librarian, feems to difcredit thefe facts; but all agree that he found protection and encouragement in France from the abbe de Marolles, and obtained improvement under the juftly celebrated Nanteuil.

The latter indeed is fufficiently obvious in his engravings. At his return to England, which lord Orford thinks was before the time of the protectorate, he married a fifter of captain Cround, by whom he had two fons, and opened a print-fhop oppofite the Palfgrave-head tavern, without Temple-bar, affuming the fign of the Ship. Here he not only followed his art, but fold Italian, French, and Dutch prints, and alfo the engravings of other Englifh artifts; fome of which are ftill to be feen with the fubfcription "fold by William Faithorne." And here he appears to have remained about 30 years.

"Some time after the year 1680," fays lord Orford, "Faithorne quitted his fhop, and retired to a more private life in Printing-houfe yard, Blackfriars; ftill engraving, but chiefly painting from the life in crayons, in which art he had formerly received inftructions at Paris from Nanteuil." He alfo painted miniatures, and drew portraits in black and white. Faithorne was a robuft and vigorous man; but the mifconduct and confequent misfortunes of his fon William, broke down his frame and fpirits, and he died in the year 1691, and was interred in the church of St. Anne, Blackfriars.

The principal part of his engravings appears to have been executed during his refidence near Temple-bar, where he alfo wrote and publifhed a "Treatife on Engraving," A.D. 1662, which he dedicated to his former mafter, fir Robert Peake. The contents of this book, as difplayed in the title page, are as follows: "The Art of Graving and Etching, wherein is expreffed the true way of graving on Copper; alfo, the Manner and Method of that famous Callot and Mr. Bofs, in their feveral ways of Etching."

Portraits conftitute by far the moft numerous part of this artift's works. He worked almoft entirely with the graver, in a free and clear ftyle, paying more attention to the beauty of his lines than moft of his Britifh predeceffors. In the early part of his life, he feems to have followed the Dutch and Flemifh manner of engraving; but on his return from France, his improvement was evidently confiderable. His portraits are his beft works; and the beft of his portraits are juftly admired for their delicacy, freedom, and force of chiaro-fcuro.

Mr. Strutt has diftinguifhed the following among the more valuable of Faithorne's hiftorical engravings: "a holy Family," from S. Vouet, a middling fized plate, in the ftyle of Couvy; "a dead Chrift," from Vandyke; "the laft Supper," without any painter's name, in folio; "Chrift praying in the Garden," the fame; "the Marriage of Cana in Galilee," an etching, the fame; "the Scourging of Chrift," from Deepenbeck. Under this latter print is written "Faithorne Sculp. Antwerp, 1657," which date feems to have efcaped the notice of Vertue, and to falfify the opinion that lord Orford, on his authority, had formed, that "Faithorne returned to England before the protectorate."

His portraits, as has been already intimated, are too numerous to be detailed in this place.

William Faithorne the younger was far inferior to his father as an artift. His principal works are portraits, fcraped in mezzotinto, of which Vertue has particularized about thirty, with three prints of fancy fubjects, and a head of St. Mary Magdalen.

John Fillian was alfo a difciple of the elder Faithorne, whofe ftyle and fome of whofe portraits he copied. He was living in 1656, but died at an early age. His principal works are, "a Head of his Mafter," looking over his fhoulder, which is copied from a print by Faithorne himfelf; the portraits of "Thomas Cromwell," and "Paracelfus," and the "Frontifpiece" to Heylin's Cofmography, in folio.

Of Peter Lombart, Vertue has been able to trace little, but that he came from Paris, and returned thither after remaining for fome years in England; to which Strutt adds, that he was a native of France, and came into England before the revolution.

He worked in a neat, laboured ftyle, and difcovers but little tafte. His drawing is frequently incorrect; his outlines hard; his fhadows deficient in force and boldnefs; his lights of too low a tone, and even his engravings after Vandyke are deficient in *force*, though he has difcovered a tolerable

tolerable eye for the *harmony*, of chiaro-fcuro. Yet he worked after the pictures of the greateft mafters: after Raphael, Guido, Pouffin, Annibal Carracci, and Vandyke. Among the beft of his engravings are, "the laft Supper," a large upright, from Nicholas Pouffin; "the Angel appearing to Jofeph," after Ph. Champagne; "the Crucifixion," from the fame mafter; the "Frontifpiece," and feveral other plates for Ogilby's Virgil. Among his portraits from Vandyke is that of "Charles I." on horfeback, a large half-fheet print. From this plate he afterwards erafed the face, and fubftituted that of "Cromwell;" and at a fubfequent period, "with the vicar of Bray's graver," as lord Orford wittily fays, reftored the king's.

Vertue has enumerated twenty other of his portraits, which are chiefly after the fame mafter; and to them may be added a fet of twelve half-lengths of rather a large fize, of which ten are portraits of celebrated ladies of the court of king Charles.

Notwithftanding his referve in communicating prince Rupert's difcovery of mezzotinto, John Evelyn, efq. of Wooton, in Surrey, is entitled to honourable mention in this place. He was the firft Englifh gentleman who wrote upon the fubject of engraving; and though his "Sculptura" be deficient in artiftical knowledge and feeling, it is a work of confiderable erudition, and has contributed not a little to the advancement of the art; while it clearly evinces his love for engraving, the excellence of the example which he wifhed to fet, and the general goodnefs of his heart. Lord Orford handfomely fays of him: "If Mr. Evelyn had not been an artift himfelf, as I think I can prove [that he was], I fhould yet have found it difficult to deny myfelf the pleafure of allotting him a place among the arts he loved, promoted, patronized; and it will be but juftice to infcribe his name with due panegyric iu thefe records, as I have once or twice taken upon me to criticife him: but they are trifling blemifhes, when compared with his amiable virtues and beneficence; and it may be remarked, that the worft I have faid of him is, that he knew more than he always communicated."

The duration of the life of this great contributor to learning and the arts was protracted to 86 years, and he died in 1705.

It appears now to be agreed among the connoiffeurs, that the five fmall prints of Mr. Evelyn's "Journey from Naples to Rome," which his biographer thought were etched by Mr. Hoare, are Evelyn's own performances; and to thefe Mr. Strutt has added a "Portrait of Dobfon" the painter, from a picture by himfelf.

David Loggan was a native of Dantzick; he was born about the year 1635, and died in 1693. From Simon Pafs, in Denmark, he is faid to have received his earlieft inftructions in engraving; he afterwards refided in Holland, where he ftudied under Hondius; and a fhort time before the reftoration he came to England.

His drawings of All-Soul's college being taken great notice of at Oxford, he was requefted to undertake plates of the public buildings in that univerfity. By thefe engravings he firft diftinguifhed himfelf; and at Oxford he remained a confiderable time, and married Mrs. Jordan of a good family, near Witney. In the latter part of his life he refided in Leicefter fields, London; where he died.

In fatirifing the vanity of a certain dramatic poet, Dryden fays,

> "And in the front of all his fenfelefs plays,
> Makes David Loggan crown his head with bays."

Yet as Loggan's merits as an engraver were not fuch as to crown his own with lafting reputation: his *name* will probably live much longer than his works will be cared for. He etched very little, and his ftyle of engraving, though it has a certain degree of neatnefs, is ftiff and taftelefs. His portraits, of which he executed a confiderable number, are chiefly after his own drawings in black lead, which he handled with more ability, at leaft with a better tafte, than his graver.

Vertue has enumerated 76 portraits from the hand of Loggan, of which the principal are, three plates of "Charles II.;" "Mother Loufe of Loufe-hall," which it feems added much to his contemporary reputation; and "George duke of Albemarle," a half-fheet print, and probably his beft portrait from the life. He alfo engraved two views of "Cambridge;" a whole fheet view of "King's "College Chapel" in that univerfity; feveral views of public Buildings at Oxford; and eleven plates of the "Habits of the Academics" at that univerfity, which are entitled, "Habitus Academicorum Oxoniæ à Doctore ad Servientem;" and had (what feems an odd thing) a licence for fifteen years for vending his "Oxonia Illuftrata."

With David Loggan came over from Holland Abraham Blooteling and Gerard Valck, men of fuperior talents, though probably of inferior addrefs. Vertue informs us, that whilft in England, Blooteling received thirty guineas (a large price in thofe days) for an etching of the duke of Norfolk. His powers were various: he etched, engraved, and fcraped in mezzotinto. His etchings are fpirited and free; and his mezzotintos of a clear grain, and tolerably well drawn. About eighteen of his portraits are enumerated by Vertue, of which the principal are, "Anthony earl of Shaftefbury," one of the fcarceft of Blooteling's works; and "Prince Rupert," after fir P. Lely. The portrait of "Admiral Kortenaer," a large upright, from Bartholomew Vander Helft, is not among thofe mentioned by Vertue.

After remaining fome few years in England, Blooteling returned to Amfterdam; and in the year 1685, publifhed there the "Gems of Leonardo Auguftino," from plates etched by himfelf.

Gerard Valck was originally Blooteling's fervant, (perhaps apprentice,) but afterwards married his fifter. Some of the beft engravings, or beft parts of thofe engravings, which were publifhed in the name of Loggan, are probably the performances of Valck, who alfo affifted Peter Schenck in his large Dutch Atlas, publifhed in 1683. Lord Orford fays, that he "engraved one of the fineft prints we have: it is the famous "Duchefs of Mazarine," fitting in very loofe attire, with one hand on an urn;" but this praife is more than the engraving deferves. His other works are, a "Bathfheba bathing," from B. Graat; and the portraits of "Robert Lord Brooke," and "John Duke of Lauderdale." Vertue knew of no other plates that were entirely engraved by Valck.

Notwithftanding the "Sculptura" of Evelyn, and the merits of Hollar, Barlow, Faithorne, and the engravers of the Vandyke fchool, the tafteleffnefs and diffolute manners of the court of Charles II. had now reduced the art of engraving to a very low ebb. Its records are fcarcely more than thofe of the commoneft trade.

Edward le Davis was of Welfh extraction, and, having fome inclination for the arts, was articled as an apprentice to David Loggan. Being maltreated by his miftrefs, who obliged him to wear a livery, and follow her as a fervant, he abfented himfelf, went over to France, and became a dealer in pictures. On his return he drew and engraved feveral portraits, and fome other fubjects; but their merits are inconfiderable. Vertue mentions the names of nine of thefe portraits,

portraits, of which the moſt remarkable are, "King Charles II." ſeated, whoſe face was afterwards eraſed from the copper, and that of William III. ſubſtituted in its ſtead; "Queen Catherine of England," a large whole length; and "James Duke of York," a large head in an oval, ſurrounded by flowers. Le Davis alſo engraved an "Ecce Homo," after Caracci, which is become ſcarce; and "a Merry Andrew," after Frank Hals.

About the ſame time with Blooteling, Michael Burghers was alſo driven hither by the troubles in the United Netherlands, and ſettled at Oxford. His works are executed entirely with the graver, in a ſtiff, laboured ſtyle: and his drawing of the human figure very defective. The moſt valuable of his engravings are the antiquities, conſiſting of ancient pavements, ruined monaſteries, &c. which he executed for that indefatigable antiquary, Thomas Hearne. Mr. Strutt, ſpeaking of them, ſays, "though we cannot admire the taſte with which they are executed, yet they become eſtimable, becauſe they ſtill continue to us an idea of thoſe monuments of antiquity, which time had otherwiſe obliterated for ever."

Excepting theſe, his beſt prints are probably a few which he copied from Mellan, wherein he imitated the ſpiral ſtyle of that ſingular maſter, and among which are, a large "Face of our Saviour," executed in a ſingle ſpiral line; and "a Frontiſpiece" to Creech's tranſlation of the Satires of Horace, a much ſmaller plate. He alſo engraved ſome few of the "Oxford Almanacks," beginning (though the plate appears without his name) in the year 1676, and did ſeveral other plates, among which are the old chapel of Queen's college, before it was pulled down, for that learned univerſity; ſometimes adding to his name, when he inſcribed it beneath his engravings, "Academiæ Oxon. Calcographus."

Peter Vanderbank was an engraver of more merit. He was born at Paris, though probably of Dutch anceſtors, and ſtudied under De Poilly. He arrived in England about the year 1674, and here he married the ſiſter of Mr. Foreſter of Bradfield, in Hertfordſhire. Lord Orford ſays, he "was ſoon admired for the ſoftneſs of his prints, and ſtill more for the ſize of them; ſome of his heads being the largeſt that had yet appeared in England." But ſoftneſs and admiration are comparative terms; and the reader muſt not ſuppoſe that his portraits are in that reſpect comparable with thoſe of Nanteuil or Houbraken. Yet the merit of paying more attention than had hitherto been paid in England to the manual part of engraving is certainly his; and this circumſtance, added to the large dimenſions of many of his plates, occaſioned them to occupy ſo much time, that he was by no means adequately compenſated for his labour. After ſtruggling for a time with poverty, print-dealers, and the low taſte of the times, he retired without compromiſing his merits, and found an aſylum under the friendly roof of his brother-in-law at Bradfield, where he died in the year 1697.

"After his death, his widow diſpoſed of his plates to Brown, the print-ſeller, who made great advantage of them, and left an eaſy fortune."

Vanderbank engraved ſome plates after Verrio's pictures at Windſor, but by far the greater part of his works are portraits, of which Vertue has enumerated no fewer than fifty! which, conſidering the large ſize of ſome of them, is no trifling evidence of his profeſſional diligence. Thoſe of moſt importance are, "King Charles II." in his greater robes, after Gaſcar, (done the year after Vanderbank's arrival;) another portrait of Charles, two feet four inches high, by two feet wide! "King James II." after ſir Godfrey Kneller, large; "Mary his Queen," ditto; ſeparate plates of "King William" and "Queen Mary;" "Thomas Lamplugh, archbiſhop of York," which is one of the fineſt of his works; and two heads of Waller the poet, at the ages of twenty-three and ſeventy-ſix.

Arthur Soly, William Elder, John Drapentier, Robert Jackſon, Francis Bragge, Paul Vanſomer, Nicholas Yates, John Collins, Simon Gribelin, William and John Clarke, and R. Tompſon, who all lived and engraved about the time now under our obſervation, are unworthy of particular notice. "The art of engraving," ſays Vertue, "had ſunk ſo low about the cloſe of the century, that Verrio, Cooke, and Laguerre, could find no better artiſts to engrave their deſigns than Gribelin and Vanſomer." "He might in juſtice have added," obſerves lord Orford, "that the engravers were good enough for the painters."

Of Robert White, who was born in London in the year 1645, and died in 1704, little more can be ſaid, except on the ſcore of his drawings in black-lead, and his profeſſional induſtry, which, judging from the number of his engravings, may well excite our ſurpriſe. Vertue praiſes his portraits more than they will be found to deſerve as engravings. Yet all his biographers agree that the merit of producing a ſtrong likeneſs was certainly his, and in portrait engraving this is the firſt of merits.

The preſident of the Royal Academy (Mr. Weſt) is in poſſeſſion of ſome of his pencil drawings on vellum, which are ſuperior to his prints; and ſir Godfrey Kneller thought ſo well of them, that he painted White's portrait in return for drawings of his own and his brother's, from the hand of the engraver. The reader will find White's portrait of ſir Godfrey in Sandrart's lives of the painters.

From David Loggan he learned the rudiments of engraving, and in the year 1674, which is two years before Burghers was employed on the "Oxford Almanack," White produced the firſt of that ſeries.

For the generality of his portraits for books, which are disfigured by the broad borders that were then the faſhion, he received at the rate of four pounds each, with the occaſional addition of ten ſhillings; thirty pounds, which was paid him by Mr. Sowters of Exeter for a portrait of the king of Sweden, (which the preſent writer has not ſeen, but which was probably of much larger dimenſions,) has been ſpoken of as an extraordinary price. So great, however, is the number of his engravings, that in the courſe of forty years he ſaved from four to five thouſand pounds; and yet, ſay his biographers, (with little reflection copying each other,) by ſome misfortune or ſudden extravagance, he died in indigent circumſtances at his houſe in Bloomſbury. The reader, probably, will not readily believe, that the habits acquired by the patient profeſſional induſtry of forty years, could plunge into ſudden extravagance.

Of his own works he made no regular collection, but when he had done a plate, rolled up two or three proofs, and flung them into a cloſet, where they were found in heaps. Many of theſe proofs may now be found in the collections of thoſe curious perſons who take Grainger for their guide.

The plates which he had by him were, after his deceaſe, ſold to a printſeller in the Poultry, who in a few years, according to lord Orford and Mr. Strutt, enriched himſelf by the purchaſe. Vertue expreſſes his honeſt diſpleaſure that ſo large a portion of the produce of our engraver's induſtry ſhould devolve to the dealer; but ſo it has ever been: and if he complains for White, how loudly ſhould he complain for Milton!

The number of his portraits of which Vertue has collected the names, are two hundred and ſeventy-five, of which,

which, two are ſcraped in mezzotinto, and all the reſt engraved in lines. Some few of Robert White's plates are finiſhed by his ſon George, who chiefly practiſed in mezzotinto, but engraved a few plates in lines, of which the principal one is a large portrait of "James Gardiner," biſhop of Lincoln.

John Sturt, the pupil of White, who was born in London in the year 1658, and lived to the age of ſeventy-two, was a man of ignorant ingenuity. His principal work is the "Book of Common Prayer," which he engraved on ſilver plates. The top of every page is ornamented with a ſmall hiſtorical vignette. Prefixed is the buſt of George I. in a circle, and facing it the prince and princeſs of Wales. The peculiarity of this work is, that the lines of the king's face are expreſſed by writing, ſo ſmall that few perſons can read it without a magniſying glaſs, and that this writing conſiſts of the Lord's prayer, the Ten Commandments, prayers for the royal family, and the 21ſt Pſalm. So that here are prayers which cannot be read, and a head which might have been better produced with a hundredth part of the labour. This *uncommon* Common Prayer Book was publiſhed by ſubſcription in London in the year 1717. It was in large octavo, and was followed by a "Companion to the Altar" of the ſame ſize, and executed in the ſame manner. Sturt was alſo the firſt man who poſed the wondering multitude of "microſcopic wights," by engraving the Lord's Prayer within the area of a circle of the dimenſions of a ſilver penny.

To this wonder-niggling ſtate was engraving reduced, when, at the commencement of the new century, ſir Nicholas Dorigny ſhone forth on the darkened arts of England. He was born in France, and was a younger ſon of Michael Dorigny, by a daughter of Vouet the painter. His father dying whilſt he was young, he was brought up to the ſtudy of the law, which he purſued till he was about thirty years of age: being then examined, in order to his admiſſion into the corps of advocates, the judge found him very difficult of hearing, and accordingly adviſed him to relinquiſh a profeſſion for which he was in this reſpect ſo ill qualified by nature. He took the advice, and immediately applied himſelf to drawing with great aſſiduity. After a year's experience in this art he repaired to Rome, where his brother at that time reſided, and here he followed painting for ſome years; when, having acquired great freedom of hand, and being uncommonly docile and flexible in his diſpoſition, he followed the recommendation of certain friends, who adviſed him to ſtudy etching. In this art he produced ſeveral works of merit, but the engravings of Audran, which were now the topic of general and juſt encomium, convinced him that the ſtyle he had adopted was ſuſceptible of great improvement; and he employed *ten years* in emulating the vigour and grandeur of that diſtinguiſhed artiſt. He had now etched many plates, and among them the ſeries from the fable of "Cupid and Pſyche," after Raffaelle, when, feeling that he had not acquired that command of the graver which was neceſſary to the harmonious perfection which he contemplated, he abandoned engraving for a ſhort time and returned to his pencils. "A word from a friend," ſays lord Orford, "would have thrown him back to the law:" this, however, it is not eaſy to believe.

After two months re-application to painting, he reſolved to acquire that power over the graver, of which he had ſo ſtrongly felt or fancied the neceſſity. All theſe feelings and reſolutions are thoſe of an artiſt of genius. With a little inſtruction, he rapidly acquired the knowledge and power of which he was in queſt, and begun to engrave the ſet of "Seven Planets," after Raffaelle; in which he ſucceeded ſo well, that he was now emboldened to undertake Raffaelle's "Transfiguration," the accompliſhment of which raiſed his reputation to an extraordinary height.

Being known to ſeveral Engliſh noblemen and gentlemen of rank, who at that time reſided in Italy, he was perſuaded to come to England, and undertake to engrave the Cartoons. He arrived in June 1711, but experienced ſome diſappointment, and was not enabled to begin his drawings till the year following, the intervening time being ſpent in raiſing a fund to enable him to proſecute his intended work.

At firſt it was propoſed that the plates ſhould be engraved at queen Anne's expence, and that the impreſſions ſhould be given as preſents to the nobility, foreign princes, miniſters, &c.; but this was too liberal even for what has been emphatically called the Auguſtan age of England, which had now commenced. Dorigny eſtimated the expences at four or five thouſand pounds, but though the lord treaſurer Orford exerted himſelf greatly in the cauſe of the artiſt, he could not obtain the ſum, and this plan was conſequently rendered abortive.

The engraver had, however, an apartment aſſigned him in Hampton Court palace, and the work was at laſt undertaken by a public ſubſcription, at four guineas the ſet.

The labour of ſeven plates of the large dimenſions that were reſolved on, appearing too great for the hand of a ſingle individual, who was not young, Dorigny was induced to ſend to Paris for aſſiſtance; and for the firſt two or three years obtained that of Dupuis and Duboſc, who both quitted him before the engravings from the Cartoons were half completed.

In ſomewhat leſs than ſeven years, however, from the date of his arrival, (namely, on the 1ſt day of April, 1719,) Dorigny had the honour of preſenting two complete ſets of theſe celebrated engravings (with an engraved dedication) to king George I., one ſet to the prince, and another to the princeſs, when he received from his majeſty a purſe of a hundred guineas, and a medal from the prince; and the duke of Devonſhire, of whom he had borrowed four hundred pounds, freely remitted the intereſt for four years. His reputation from this time continued to increaſe through Europe, and in the year following he received the further honour of knighthood from the hand of his majeſty.

In a few years after the completion of the Cartoons, the eyes of our engraver began to grow dim, and either this circumſtance, or the natural inclination of man to return to the place of his nativity, occaſioned his return to Paris, where, in the year 1725, he was made a member of the Royal Academy of Arts, and where he died at the advanced age of eighty-nine.

His drawings from the old maſters, chiefly after Raffaelle, Dominichino, Guercino, and Daniel de Volterra, have been much admired, and have ſold for conſiderable ſums; and beſides the plates mentioned above, he engraved "St. Peter curing the lame Man," a large upright from Civoli, which is one of his early works, and in the dark manner of his father; "The Deſcent from the Croſs," after Daniel de Volterra, a very fine engraving; the "Martyrdom of St. Sebaſtian," after Dominichino, an upright, and equally meritorious; "The Holy Trinity," from Guido; and a few other plates from A. Carracci, Lanfranc, and Louis Dorigny, his brother.

When the late period of life at which Dorigny began to uſe the graver is conſidered, the power which he acquired over that inſtrument muſt be regarded as extraordinary: the art with which he mingled the lines of the graver with thoſe of the etching-needle is alſo much to be admired; and though it muſt be allowed that in copying Raffaelle's forms he has often loft much of their exquifite grace and chaftenefs, and has rendered the characters of his heads but coarfely, yet on the whole he rides his graphic Pegafus with mafculine grace. There is a manly energy and freedom in his ftyle, bridled by fimplicity; his fhadows are full-toned, clear, and rich; and though his flefh be deficient in characteriftic texture, the lines are often conducted over his draperies with unprecedented freedom and elegance, of which the figure of "St. Paul preaching at Athens," and that of the fame apoftle in the Cartoon of "Elymas the forcerer, ftruck blind," may be fufficient examples. Indeed, a critical eye may trace in the arrangement of Dorigny's lines, the rudimental principle of that fimple fyftem of drapery-engraving, which Mr. Heath and his fchool have fince polifhed and rendered more perfect.

Charles Dupuis, who has been mentioned as the affiftant of Dorigny, engraved fome plates from the hiftory of the misfortunes of Charles I., but the climate of England not agreeing with his conftitution, he returned to Paris, and died there in the year 1743. A younger brother of his alfo came over, but returned in difappointment, finding Britifh encouragement lefs than he had expected.

Claude Dubofc quitted Dorigny's fervice at the fame time with Dupuis, but fettled here, and, with more boldnefs than ability, undertook to engrave the Cartoons on a fmaller fcale than Dorigny's for the printfellers, who prefumptively, were *cunning* enough to think, not of tranfcending, but of *underfelling* the engravings of that diftinguifhed artift. He next engaged himfelf to engrave a fet of the duke of Marlborough's battles, for which he received at the rate of four-fcore pounds *per* plate. At firft he had no affiftance but what he received from du Guernier, but afterwards fent to Paris for Beauvais and Baron, who affifted him in the completion of thefe engravings. He now commenced printfeller, and publifhed in numbers a tranflation of Picart's "Religious Ceremonies," in engraving which, he was affifted by Gravelot and Scotin, who came over to England for that purpofe.

Dubofc's ftyle of engraving is heavy, and his drawing of the naked very indifferent, which renders it not improbable that the worft parts of Dorigny's Cartoons are by his hand. Among his works, which are not very numerous, the "Continence of Scipio," from that picture of Nicholas Pouffin, which was in the Houghton Collection, is probably the beft.

Of the Winftanleys, as engravers, little can be faid. Henry (the elder) etched feveral views of "The Palace at Audley-end;" and Hamlet (fon of the former) etched twenty plates from the earl of Derby's Collection, and a fet of prints from fir James Thornhill's "Cupola of St. Paul's Cathedral."

The father was projector and builder of the Eddyftone light-houfe, and when it was thrown down by a dreadful tempeft, was buried in its ruins. To his etchings of Audley-end, which were dedicated to king James II., he added an infcription in honour of fir Chriftopher Wren, and the plates being "referved by the defcendants of the earl of Suffolk," (according to lord Orford,) the impreffions are now become fcarce.

The fon ftudied under the Knellers, and afterwards in Italy, yet he made no great figure as an artift. The nobleman quoted above, fpeaks of his houfe at Littlebury, where "were feveral mechanic tricks to furprife the populace, which were known by the name of "Winftanley's Wonders." Thefe childifh contrivances, I fuppofe, he learned in Italy, where they do not let their religion monopolize *all* kinds of legerdemain. In the noble palace of the villa Borghefe," adds his lordfhip, "was the noble ftatue of Seneca dying in the bath, and a devil that ftarted out of a clock-cafe as you entered the room." Hamlet painted a few portraits with moderate ability.

The affiftance which du Guernier rendered to Dubofc in his "Battles of the Duke of Marlborough," has been already mentioned. He ftudied under Chatillon, at Paris, and came to England in 1708. The London Academy, as it was called, was then eftablifhing under the aufpices of fir Godfrey Kneller, and du Guernier was chofen director of it, and continued fo to the time of his death, which was occafioned by the fmall-pox, and happened Sept. 19, 1716, when he was but thirty-nine years of age. Befides his fhare of the Marlborough's battles, he engraved a few frontispieces, chiefly for plays, and, at the inftance of lord Halifax, a large print of "Lot and his Daughter," from Caravaggio, and the portraits (large) of the "Duke and Duchefs of Queenfbury."

Bickham, Coignard, Johnfon, George King, Nichols, and Simpfon, who were all contemporary, are paffed over for reafons which have formerly been given. John Kip engraved a confiderable number of the palaces and feats of the nobility and gentry from Knyff, but they were indifferent, and were far from advancing the art.

It has been already mentioned, that Girard Scotin, the younger, came over from Paris to affift Dubofc. He ftudied under his father, who was an engraver and a difciple of De Poilly, but was a man of more induftry than talent. His principal works are, "Belifarius," a large plate, after Vandyke, or Murillo, for it does not appear to be afcertained to which of thefe mafters this celebrated picture fhould be afcribed; and "Alfred receiving the Account of the defeat of the Danes," from Blakeney. He alfo affifted Hogarth in fome of his feries, and engraved a few portraits.

Henry Gravelot, who came hither at the fame time, was an artift of much more tafte. His opportunities of obferving nature had been more various and extenfive than fell to the lot of many of his contemporary profeffors of the fine arts. He was a native of France, but had been in America as fecretary to the governor of Canada: the climate difagreeing with him, he returned to Paris, whence he was invited to England by Dubofc.

He was for fome time employed in Gloucefterfhire, drawing churches and antiquities, and, according to lord Orford, he drew the monuments of kings for Vertue. For the bookfellers he made a very great number of defigns, both hiftorical and ornamental, wherein his tafte and the fertility of his inventive powers are eminently confpicuous. From many of thefe he made etchings, as alfo many after the defigns of Hayman, and the fame tafte and facility attended his etching-needle, which is confpicuous in the productions of his pencil.

In fir Thomas Hanmer's and Theobald's editions of Shakefpeare, a great number of his engravings, and feveral of his defigns, may be found. His principal work on copper is a large print of "Kirkftall Abbey," which Strutt fpeaks of as a fine fpecimen of his abilities, but which the prefent writer has not feen. He lived to the age of feventy-four, and died at Paris in the year 1773.

Bernard Baron was alfo tranfplanted hither from the continent by Dubofc, who appears to have been a great fpeculator in this fpecies of culture. They differed, and went to law, on the fubject of a fet of engravings after Dr. Mead's pictures from the hiftory of Ulyffes, by Rubens, but were afterwards reconciled, and went to Paris together in the year 1729. After engraving fome plates for Monf. Crozat,

Crozat, from the royal collection, he returned to England, and here he executed a conſiderable number, and had the ſatisfaction of working after ſome of the fineſt pictures in the kingdom.

His ſtyle is chiefly ſtudied from that of ſir Nicholas Dorigny, generally coarſe, but occaſionally ſomewhat ſoftened and incorporated with the prevailing taſte of the French ſchool. His principal engravings are as follow, and are all large plates. "Vandyke's equeſtrian figure of Charles I." from the royal gallery at Kenſington; the "Cornaro family," from the celebrated Titian at Northumberland houſe; the "Pembroke family," from the ſame maſter, at Wilton houſe; the "Naſſau family," from the ſame, in the collection of earl Cowper; the "Jupiter and Antiope," alſo after Titian, executed in Paris; "Henry VIII. granting the charter of incorporation to the company of Surgeons" from Holbein. Baron died in Panton ſquare, Piccadilly, in the year 1762.

Chereau, the younger, was alſo imported from Paris by Duboſc, and engraved a profile likeneſs of George I. which poſſeſſes ſome merit, but finding or fancying, that his talents were undervalued in England, he ſoon returned.

Michael Vandergucht, originally of Antwerp, ſtudied under Boutats, but was the maſter of Vertue. The year of his arrival in England is not known: here, however, he met with ſome encouragement, and reſided in London. His chief employment was to engrave anatomical figures, but he ſometimes undertook ſubjects of a different kind. His maſter-piece, according to Vertue, was a portrait of Mr. Savage. He alſo engraved a very large plate of the royal navy from Baſton.

John Vandergucht, ſon of the preceding, was born in 1697, and acquired from his father the manual practice of engraving, but ſtudied drawing under Lewis Cheron, and afterwards at the London Academy. He was employed by Cheſelden to draw and engrave the ſubjects for his Oſteology, a work by which he obtained much credit; and he had a conſiderable ſum for engraving "Sir James Thornhill's cupola of St. Paul's cathedral." The ſix academy figures which he engraved from the drawings of his maſter Cheron, ſhew that he underſtood drawing better than he could manage the graver. He alſo engraved Pouſſin's "Tancred and Erminia."

He produced a great number of book-plates, of which the merits were not great, and ſome were alſo engraved by his brother Gerard Vandergucht, who was a great dealer in pictures, lived to the age of eighty years, and died in 1778 at his houſe in Brook-ſtreet, the ſame that is now inhabited by Treſham the academician.

George Vertue was born in the year 1684, in the pariſh of St. Martin in the Fields, London, and was put apprentice at the age of thirteen to a maſter who engraved heraldry on plate. This perſon being obliged to leave the kingdom by the time Vertue had been three or four years under him, our artiſt returned to his parents. He then gave himſelf entirely to the ſtudy of drawing for two years, when he became the pupil of Michael Vandergucht; with whom he engaged to remain three years, but protracted his ſtay to ſeven, when he quitted his maſter on handſome terms, and begun to engrave book-plates for himſelf.

"The art was then, ſays lord Orford, at the loweſt ebb in England. The beſt performers were worn out; the war with France ſhut the door againſt recruits; and the animoſity of faction diverted public attention from the common arts of amuſement." At this period our young engraver was recommended to the notice of ſir Godfrey Kneller, whoſe reputation ſuſtained the remaining dignity of art: Kneller befriended him, and he was ſoon after employed by lord Somers, who, according to Strutt, "rewarded him generouſly," and by his talents and induſtry he was now enabled to ſupport his widowed mother, with her family of ſeveral children.

In the year 1711 he begun to ſtudy at the academy which ſir Godfrey had recently inſtituted; where he continued to draw for ſome years with great aſſiduity. He had now produced his famous head of archbiſhop Tillotſon, which lord Orford emphatically calls "the ground-work of his reputation," and ſoon after the acceſſion of the preſent royal family, he publiſhed a large portrait of king George I. from a picture by Kneller. "As it was the firſt portrait of that monarch, many thouſands were ſold, though by no means a laborious or valuable performance. However it was ſhewn at court, and was followed by his undertaking to engrave portraits of the prince and princeſs."

Vertue had now commenced thoſe biographical and antiquarian reſearches, in which he has been ſo eminently ſucceſsful. In theſe purſuits he made many journeys to different parts of our iſland, and his time was induſtriouſly employed in making drawings, catalogues, and various memoranda.

"His thirſt after Britiſh antiquities ſoon led him to a congenial Mæcenas. That munificent collector, Robert Harley, ſecond earl of Oxford, diſtinguiſhed the merit and application of Vertue;" and the invariable gratitude of the latter, expreſſed on all occaſions, atteſts at once the bounty of his patron and his own humility.

Another of his patrons was Heneage Finch, earl of Winchelſea, whoſe portrait he painted and engraved, and who, being preſident of the Society of Antiquaries on its revival, in 1717, appointed Vertue, who was a member, engraver to that learned body.

Henry Hare, the laſt lord Coleraine, was alſo one of his antiquarian benefactors, and the univerſity of Oxford employed him for many years to engrave the head pieces for their almanacks.

With lord Orford, lord Coleraine, and Mr. Stephens the hiſtoriographer, he made ſeveral tours to various parts of England. For the former he engraved portraits of "Matthew Prior," "ſir Hugh Middleton," and other diſtinguiſhed men: for the duke of Montague he engraved, "ſir Ralph Windwood;" for ſir Paul Methuen, the portraits of "Cortez," and "Archbiſhop Warham" from Holbein's original at Lambeth; and for lord Burlington, Zucchero's "Queen Mary of Scotland," a plate which evinces more felicity, and a better taſte of execution, than moſt other of his works.

In the year 1727 he travelled with lord Orford to Burleigh, Lincoln, Welbeck, Chatſworth, and York, at which latter place he obtained from Francis Place, whom we have mentioned, many of thoſe anecdotes of Hollar which are inſerted in his biography.

In the next year, the duke of Dorſet invited him to Knowle. From the gallery there, he copied the portraits of ſeveral of the poets. Here he was on fairy ground, and Arcadia was on the confines; but he was diſappointed on an excurſion to Penſhurſt, at not finding there any portrait of ſir Philip Sydney.

In 1730 appeared his twelve heads of diſtinguiſhed poets, one of his capital works, which he meant to have followed with the portraits of other eminent men, arranged in claſſes, but this ſcheme was taken out of his hands by the Meſſrs. Knapton; and there is reaſon to think that Vertue's rigid regard for veracity, which made him juſtly ſcrupulous of authenticating the likeneſſes of deceaſed characters without the cleareſt proofs, and not the ſuperior taſte or diſcernment of the Knapton's, made them engage the fuperior talents of Houbraken and Gravelot, to finifh a work which our artift had begun, and had himfelf projected.

His next confiderable production was, the portraits of king Charles I. and the loyal fufferers in his caufe, with their characters fubjoined from Clarendon. But this was fcarcely finifhed, before Rapin's hiftory of England appeared, "a work, (fays he,) which had a prodigious run, infomuch that it became all the converfation of the town and country, and the noife being heightened by oppofition and party, it was propofed to publifh it in folio by numbers, of which thoufands were fold every week." The Meffrs. Knapton engaged Vertue to accompany it with effigies of the kings and other fuitable embellifhments, an undertaking which occupied three years of his life. He prefented a copy of this work, when finifhed, richly bound, to the prince of Wales, at Kenfington.

He now renewed his topographical journies, accompanied fometimes by the earl of Leicefter, fometimes by lord Oxford, and fometimes by Roger Gale the antiquary; and between the years 1734-38, vifited St. Albans, Northampton, Oxford, Penfhurft, Warwick, Coventry, Stratford, and travelled through the counties of Kent, Suffex, and Hampfhire, where he made various fketches, drawings, and notes, always prefenting a duplicate of his obfervations to his patron lord Oxford.

In 1739, he travelled eaftward with lord Coleraine, through the counties of Effex, Suffolk, and Norfolk, ftopping as ufual to make drawings and obfervations at every memorable church, feat, or other fpot congenial to his purfuits. In 1741 he loft his noble friend and patron the earl of Oxford, who died on the 16th of June. But his merit and modefty ftill raifed him benefactors. The countefs dowager of Oxford, even, alleviated his lofs, and the duchefs of Portland (their daughter), the duke of Richmond, and lord Burlington, did not forget him among the artifts whom they patronized.

In the year 1749, he found a yet more exalted protector in the prince of Wales, whom he often had the honour of attending, and to whom he fold many prints, miniature pictures, &c.

"He had now reafon to flatter himfelf with permanent fortune. He faw his fate linked with the revival of the arts he loved; he was ufeful to a prince who trod in the fteps of the accomplifhed Charles, and no Hugh Peters (adds lord Orford) feemed to threaten havoc to the growing collection." But the death of this prince fuddenly blafted the hopes of Vertue, and affected him with confiderable dejection of fpirits, from which, according to his lordfhip, he never perfectly recovered. He died in the year 1756, and was buried in the cloifters of Weftminfter abbey.

By the majority of connoiffeurs, Vertue's talents as an engraver have been over-rated. He rarely rifes above mediocrity, and fometimes finks below it, yet the prefent writer muft freely declare his furprife when he firft faw a good impreffion of Vertue's print of "Mary Queen of Scotland," after Zucchero, at the fuperior merits which it difplayed.

A much more copious biography of this artift will be found in the printed works of lord Orford, and alfo a catalogue of his engravings (amounting to near five hundred!) claffed under the heads of "Royal Portraits," "Noblemen," "Bifhops," "Poets," "Antiquaries," "Tombs," "Hiftoric Prints," "Coins," "Medals," "Frontifpieces," &c. &c. &c.

To all the diftinguifhed notice and patronage with which Vertue was honoured, and to the repeated praife of lord Orford, who was one of his friends, he was entitled lefs by his talents as an artift, or native independence of mind, than by his patience and accuracy of refearch as an antiquary, and as his noble biographer cannot boaft of his genius, it might, perhaps, have been thought that he did right to dwell with fo much feeming approbation on his diligence and humility; if he had not himfelf left pofterity fuch abundant room to wifh that he had refpected genius more, and been lefs completely fatisfied with the blandifhments, which plodding mediocrity may with little difficulty acquire.

We now approach the lefs patronized and more highly refpectable name of William Hogarth, upon whofe valuable works as painter and engraver, fo many volumes might be profitably written. The able pen to which the biography of the former defcription of artifts is confided, will doubtlefs claim Hogarth as a painter, yet, as he was both by education and long practice an engraver alfo, he muft not here be paffed in filence.

In the narrative which he left behind of his own life and opinions, where his philofophy is not lefs confpicuous than his manly franknefs, and where his forefight with refpect to the well-being of Britifh art has fhewn itfelf prophetic, he informs us, that he was born in London in the year 1697; that during his infancy he derived uncommon pleafure from fhews and mimickry; that an early accefs to a neighbouring painter drew his attention from play; and that when at fchool his exercifes were remarkable for the ornaments with which they were adorned.

He was fcarcely more attracted by art, than driven from literature, which was the profeffion of his father. "Befides the natural turn I had for drawing," proceeds he, "I had before my eyes the precarious fituation of men of claffical education. I faw the difficulties under which my father laboured, and the many inconveniences he endured from his dependance being chiefly on his pen, and the cruel treatment he met with from bookfellers and printers. It was, therefore, very conformable to my own wifhes that I was taken from fchool, and ferved a long apprenticefhip to a filver-plate engraver.

"I foon found this bufinefs in every refpect too limited. The paintings of St. Paul's cathedral and Greenwich hofpital, which were at that time going on, ran in my head, and I determined that filver-plate engraving fhould be followed no longer than neceffity obliged me to it.

"Engraving on copper was, at twenty years of age, my utmoft ambition. To attain this it was neceffary that I fhould learn to draw objects fomething like nature, inftead of the monfters of heraldry, and the common methods of ftudy being much too tedious for one who loved his pleafure, I was led to confider whether a fhorter road than that ufually travelled was not to be found. I had learned by practice to copy with tolerable exactnefs in the ufual way; but it occurred to me that there were many difadvantages attending this method of ftudy, as having faulty originals," &c. Drawing in an academy, (Hogarth means a fchool,) though it fhould be after the life, will not make the ftudent an artift, for as the eye is often taken from the original to draw a bit at a time, it is poffible he may know no more of what he has been copying when his work is finifhed, than he did before it was begun.

"More reafons, not neceffary to enumerate, ftruck me as ftrong objections to this practice, and led me to wifh that I could find the fhorter path, fix forms and characters in my mind, and inftead of copying the lines, try to read the language, and if poffible find the grammar of the art, by bringing into one focus the various obſervations I had made, and then trying, by my power on the canvas and copper, how far my plan enabled me to combine and apply them to practice.

"For this purpoſe, I conſidered what various ways, and to what different purpoſes the memory might be applied; and fell upon that which I found moſt ſuitable to my ſituation and idle diſpoſition.

"Laying it down firſt as an axiom, that he who could by any means acquire and retain in his memory perfect ideas of the ſubjects he meant to draw, would have as clear a knowledge of the figure as a man who can write freely hath of the twenty-four letters of the alphabet and their infinite combinations (each of them being compoſed of lines), and would conſequently be an accurate deſigner.

"This I thought my only chance for eminence, as I found that the beauty and delicacy of the ſtroke in engraving was not to be learnt without much practice, and demanded a larger portion of patience than I felt myſelf diſpoſed to exerciſe. Added to this, I ſaw little probability of acquiring the full command of the graver in a ſufficient degree to diſtinguiſh myſelf in that walk, nor was I at twenty years of age much diſpoſed to enter on ſo barren and unprofitable a ſtudy as that of merely making fine lines.

"I therefore endeavoured to habituate myſelf to the exerciſe of a ſort of technical memory, and by repeating in my own mind the parts of which objects were compoſed, I could by degrees combine and put them together. Thus, with all the drawbacks which reſulted from the circumſtances I have mentioned, I had one material advantage over my competitors, *viz.* the early habit I thus acquired of retaining in my mind's eye whatever I intended to imitate. Sometimes, but too ſeldom, I took the life for correcting the parts I had not perfectly enough remembered, and then I transferred them to my compoſitions."

Such parts only of Hogarth's valuable narrative as are to the preſent purpoſe, are here extracted. Thoſe who would read the whole are referred to "A ſupplement to Hogarth illuſtrated, compiled from his original manuſcript by John Ireland," 1798, publiſhed for the author by Nicol, and the Meſſrs. Boydell. Our artiſt proceeds:

"Inſtead of burthening the memory with muſty rules, or tiring the eyes with copying dry and damaged pictures, I have ever found ſtudying from nature the ſhorteſt and ſafeſt way of attaining knowledge in art."—"Had I not ſeduloufly practiſed what I thus acquired, I ſhould very ſoon have loſt the power of performing it."

In a ſubſequent chapter he ſays, "in purſuing my ſtudies, I made all poſſible uſe of the technical memory which I have before deſcribed, by obſerving and endeavouring to retain in my mind lineally, ſuch objects as beſt ſuited my purpoſe, ſo that be where I would my eyes were open, I was at my ſtudies, and acquiring ſomething uſeful in my profeſſion, and thus the more ſtriking objects, whether of beauty or deformity, were by habit the moſt eaſily impreſſed and retained in my imagination. A redundancy of matter being by this means acquired, it is natural to ſuppoſe I introduced it into my works on every occaſion that I could.

"By this idle way of proceeding, I grew ſo profane as to admire nature beyond the firſt productions of art, and acknowledge I ſaw, or fancied, delicacies in the life, far ſurpaſſing the utmoſt efforts of imitation.

"To return, the inſtant I became maſter of my own time, I determined to qualify myſelf for engraving on copper. In this I readily got employment; and frontiſpieces to books, prints to Hudibras, &c. ſoon brought me into the way. But the tribe of bookſellers remained as my father had left them when he died, (about five years before,) which was of an illneſs occaſioned partly by the treatment he met with from this ſet of people, and partly by diſappointment from great men's promiſes; ſo that I doubly felt this uſage, which put me upon publiſhing on my own account. But here again I had to encounter a monopoly of printſellers, equally mean and deſtructive to the ingenious; for the firſt plate I publiſhed, called "The Taſte of the Town," had no ſooner begun to take a run, than I found copies of it in the print-ſhops vending at half price, while the original prints were returned to me again, and I was thus obliged to ſell the plate for whatever theſe pirates pleaſed to give me, as there was no place of ſale but at their ſhops. Owing to this and other circumſtances, by engraving until I was near thirty, I could do little more than maintain myſelf."

At the age of two and thirty, he married the daughter of ſir James Thornhill, and commenced painter of ſmall converſation pieces, which, having novelty, ſucceeded for a few years, but were afterwards not ſufficiently profitable to pay the expences of his family. "I therefore," ſays he, "turned my thoughts to a ſtill more novel mode, *viz.* painting and engraving modern moral ſubjects, a field not broken up in any country or any age.

"I thought that both writers and artiſts had overlooked that intermediate ſpecies of ſubject, which may be placed between the ſublime and the groteſque; I therefore wiſhed to compoſe pictures on canvas, ſimilar to repreſentations on the ſtage.

"Ocular demonſtration will carry more conviction to the mind of a ſenſible man than all he would find in a thouſand volumes; and this has been attempted in the prints which I have compoſed.

"After having had my plates pirated in almoſt all ſizes, I, in 1735, applied to parliament for redreſs, and obtained it in ſo liberal a manner, as hath not only anſwered my own purpoſe, but made prints a conſiderable article in the commerce of this country; there being now more buſineſs of this kind done here, than in Paris or any where elſe.

"The dealers in pictures and prints found their craft in danger, by what they called a new-fangled innovation. Their trade of living and getting fortunes by the ingenuity of the induſtrious has, I know, ſuffered much by my interference; and if the detection of this band of public cheats and oppreſſors of the riſing artiſts be a crime, I confeſs myſelf moſt guilty."

The obtainment of this act, which ſecures the copy-right of engravings, was certainly a great benefit, not only to artiſts, but to the public, and even to the print dealers themſelves, who now were ſecured in the poſſeſſion of any engraved property which they might purchaſe. The remainder of Hogarth's narrative chiefly reſpects his profeſſion as a painter, and the incidents of his private life. His reputation was now extending far and wide: he had publiſhed his "Harlot's Progreſs" in ſix plates, beſide many other prints of leſs importance, which Mr. Ireland has enumerated, and now brought forth his "Rake's Progreſs" in eight, which are replete with moral leſſon and the moſt pointed ſatire. Swift about this time wrote

"How I want thee, hum'rous Hogarth!
Thou, I hear, a pleaſant rogue art,
Were but you and I acquainted
Ev'ry monſter ſhould be painted:
You ſhould try your graving tools
On this odious group of fools, (the Legion Club.)
Draw the beaſts as I deſcribe 'em,
Form their features, while I gibe 'em."

In the courſe of the next year he engraved "The Sleeping Congregation;" "The Diſtreſſed Poet," which in its original ſtate repreſents Pope thraſhing the bookſeller Curl, and "The Arms of the Undertaker's Company." He alſo publiſhed a whole length portrait of lady Byron, from a picture of his own, engraved in mezzotinto by Faber.

In the year 1737, he produced only "The Lecture." In 1738, he publiſhed "Morning," "Noon," "Evening," and "Night." The third plate was engraved by Baron, except the figure of the girl with a fan, which was an afterthought of Hogarth's, and is from his own graver. The "Saliſbury" flying coach in the engraving of Night, is thought to be a ſatire on a certain peer who delighted to drive his own horſes. He alſo produced this year "Strolling Actreſſes in a Barn;" the original picture of which he ſold to Francis Beckford, eſq. for 27*l.* 6*s.* who returned it, though charged at ſo low a price, and it was afterwards ſold to Mr. Wood of Littleton for the ſame ſum.

Until the year 1741, he publiſhed nothing more, when "The enraged Muſician" made its appearance, in which the principal figure has been ſpoken of as being the portrait of Cervetto, but on better authority, is now ſuppoſed to be that of Feſtin.

In 1742, he engraved and publiſhed the portrait of "Martin Foulkes, eſq." "The Charmers of the Age," (a ſketch,) and "Taſte in High Life," which latter is replete with the moſt pointed ſatire on the reigning follies and faſhions which then prevailed in the higher circles. A more ſophiſticated aſſemblage of objects cannot be imagined, and the elderly lady of the Cheſterfield ſchool, who holds the ſmall Dreſden tea-cup with ſo much exquiſite delicacy of fingering, and a countenance ſo truly expreſſive of the affectation of intenſe enjoyment of its beauties, has never been ſurpaſſed.

From this time, till the year 1745, he was employed on his "Marriage A-la-Mode," and only publiſhed three portraits, engraved by other artiſts, from his own pictures. The ſeries of ſix plates of the Marriage A-la-mode were chiefly engraved by Scotin and Baron, who have been already mentioned, and S. Ravenet. Hogarth engraved on the plates from time to time, which has occaſioned thoſe variations which certain adorers of rarity look for with more eagerneſs, than they appear to poſſeſs feeling or judgment in eſtimating the general deſign. This ſeries comprehends indeed maſter-pieces of art in their kind, and places Hogarth's fame on the broadeſt and moſt durable baſis.

In the following year, he etched and publiſhed his characteriſtic portrait of "Lord Lovat," which, by thoſe who have ſeen him, has been atteſted to be "in air, character, and features, a moſt faithful reſemblance of the original." He is repreſented ſeated in his old faſhioned chair with the lofty back, and in the act of enumerating by his fingers the rebel forces. It is etched with uncommon ſpirit, and what was of more pecuniary importance, (adds Mr. Ireland,) was ſo well timed, that Mrs. Lewis told me, they for many weeks received more than ten pounds a day from the ſale. It was publiſhed the 25th Auguſt, 1746, and the peer was beheaded the 9th April 1747, in the eightieth year of his age. The portrait of Garrick, in the character of Richard III. engraved by Hogarth, and C. Grignion, was alſo publiſhed this year, of which Mr. Grignion, (who has done ſo much for an art which has done ſo little for him, and is ſtill living,) ſays, that Hogarth etched the head and the hands, but eraſed the head twice before he could ſatisfy himſelf. In the courſe of the preſent year Hogarth alſo iſſued the ſubſcription ticket to "The March to Finchley."

The ſeries of "The Idle and Induſtrious Apprentices," in twelve plates, deſigned and engraved by William Hogarth, were publiſhed in 1747. Of this ſeries, ſo replete with moral leſſon, and heightened with ſuch admirable ſtrokes of humour, Hogarth himſelf has written as follows. "The effects of idleneſs and induſtry exemplified in the conduct of two fellow-'prentices. Theſe twelve prints were intended for the inſtruction of young people, and, conſidering the perſons they were intended to ſerve, I have endeavoured to render them intelligible and cheap as poſſible:" (the twelve were originally publiſhed at the low price of twelve ſhillings.) "Fine engraving is not neceſſary for ſuch ſubjects, if what is infinitely more material, *viz.* character and expreſſion, be properly preſerved." "The Stage Coach or Country Inn Yard," and two portraits of Gibbs the architect, engraved by Baron and Mc. Ardell, he alſo publiſhed in the courſe of this year.

In 1748, he etched a view of Mr. Ranby's houſe at Chiſwick, but nothing elſe of any conſequence. In 1749, was produced "The Gate of Calais," or, "Roaſt Beef of Old England." It appears that ſoon after the peace of Aix-la-Chapelle, Hogarth went over to France, and as he was ſauntering about at Calais, and contemplating the difference between England and France, he obſerved over the gate of the town ſome appearance of the arms of England; he was prompted to make a ſketch, and being obſerved, was taken into cuſtody: his own account of this affair is as follows: "Not attempting to cancel any of my ſketches or memorandums, which were found to be merely thoſe of a painter for his private uſe, without any relation to fortification, it was not thought neceſſary to ſend me back to Paris." (This word contradicts the aſſertion of thoſe who ſay he never went further into France than Calais.) "I was only cloſely confined to my own chamber till the wind changed for England; where I no ſooner arrived, than I ſet about the picture (of roaſt beef) and made the gate my back ground; and in one corner introduced my own portrait, which has generally been thought a correct likeneſs, with the ſoldier's hand upon my ſhoulder. By the fat friar, who ſtops the lean cook that is ſinking under the weight of a vaſt ſurloin, and two of the military who are bearing off a great kettle of ſoup maigre, I meant to diſplay to my own countrymen the ſtriking difference between the food, prieſts, ſoldiers, &c. of two nations ſo contiguous, that in a clear day one coaſt may be ſeen from the other. The melancholy and miſerable highlander, browzing on his ſcanty fare, conſiſting of a bit of bread and an onion, is intended for one of the many that fled from this country after the rebellion in 1744." In the courſe of this year, he alſo engraved and publiſhed his own portrait in a cap, with his favourite pug dog and palette, on which is drawn that myſterious "line of beauty and grace," which excited, and was meant to excite, the attention of the public in no ſlight degree.

Fourteen years afterwards, Hogarth eraſed his own head from the plate, and in its place engraved a caricature of Churchill as a bear, and inſcribed it, "The Bruiſer C. Churchill (once the Reverend!) in the character of a Ruffian Hercules," &c. &c.

In the year 1750, appeared his "March to Finchley," which was engraved by Luke Sullivan, and dedicated to the king of Pruſſia. The original picture he preſented to the Foundling hoſpital. "Gin-lane" and "Beer-ſtreet" appeared in the following year, of which prints Hogarth himſelf gives the following account. "When theſe two prints were deſigned and engraved, the dreadful conſequences of gin drinking appeared in every ſtreet. In Gin-lane, every circumſtance of its horrid effects is brought to view *in ter-*

rorem. Idlenefs, poverty, mifery, and diftrefs, which drive even to madnefs and death, are the only objects that are to be feen; and not a houfe in tolerable condition, but the pawn-brokers and gin fhop."

"Beer-ftreet," its companion, was given as a contraft, where that invigorating liquor is recommended in order to drive the other out of vogue. Here all is joyous and thriving, &c. &c."

He alfo now publifhed his "Four Stages of Cruelty," of which he has thus ufefully, honeftly, and proudly written. "The leading points in thefe, as well as the two preceding prints, were made as obvious as poffible, in the hope that their tendency might be feen by men of the loweft rank. Neither minute accuracy of defign, nor fine engraving, were deemed neceffary, as the latter would have rendered them too expenfive to the perfons to whom they were intended to be ufeful: and the fact is, that the paffions may be more forcibly expreffed by a ftrong bold ftroke, than by the moft delicate engraving." (The artift probably meant this obfervation to be applied to the violent, and not to the tender paffions.) "To expreffing them as I felt them, I have paid the utmoft attention, and as they were addreffed to hard hearts, have rather preferred leaving them hard, and giving the effect by a quick touch, to rendering them languid and feeble by fine ftrokes and foft engraving, which require more care than can often be attained, except by a man of a very quiet turn of mind. Maffon, who gave two ftrokes to every particular hair that he engraved, merited great admiration, but at fuch admiration I never afpired, neither was I capable of attaining it if I had.

"The prints were engraved with the hope of, in fome degree, correcting that barbarous treatment of animals, the very fight of which renders the ftreets of our metropolis fo diftreffing to every feeling mind. If they have had this effect and checked the progrefs of cruelty, I am more proud of having been the author, than I fhould be of having painted Raphael's cartoons."

The humorous "Paul before Felix" was alfo the produce of this year, which in the earlieft impreffions is fubfcribed, "defigned and fcratched in the true Dutch tafte by William Hogarth," and in the fubfequent impreffions (where he has introduced a little fiend fawing off the leg of the Apoftle's ftool,) "defigned and etched in the ridiculous manner of Rembrandt by Wm. Hogarth." This whimfical little print was originally given with the receipts to the fubfcription for the ferious "Paul before Felix," and "Pharoah's Daughter," both of which he produced in the courfe of the enfuing year.

The former of thefe he engraved from his original picture in Lincoln's-inn Hall; another plate of which fubject, with fome variations, was publifhed by Hogarth at the fame time, (which is remarkable, both being dated Feb. 5,) engraved by Luke Sullivan.

"Mofes brought to Pharaoh's Daughter" is engraved by William Hogarth and Luke Sullivan from the original painting in the Foundling hofpital, and was alfo publifhed on the fame day.

His "Columbus breaking the Egg" was given in the November of this year, with the receipt for "the firft payment of a fhort tract in quarto, called the Analyfis of Beauty; wherein forms are confidered in a new light;" and in the next year came forth his far famed "Analyfis of Beauty, written with the view of fixing the fluctuating ideas of tafte," and embellifhed with two folded and very curious illuftrative engravings.

With fome fmall literary affiftance from Dr. Hoadly, Mr. Ralph, and Dr. Morell, he here maintained an hypothefis refpecting undulating forms as effential to grace and beauty, the merits of which have, by fubfequent writers on the fubject of tafte, been varioufly eftimated, but of late have been utterly denied by Mr. P. Knight, who (in his analytical enquiry into the principles of tafte) fays, that the qualities of eafe, grace, elegance, &c. do not "confift in any lines of beauty, or depend upon the impreffions which any fpecific forms make on the organs of fight. On the contrary, they arife wholly from mental fympathies and the affociation of ideas."

An impreffion from the firft plate of the Analyfis of Beauty, which is in the poffeffion of Mr. G. Baker, has this fingularity, that the words "et tu Brute," are engraved on the pedeftal on which ftands Quin in the character of Brutus, which were afterwards erafed.

In the year 1754 his admirable fatire on parliamentary elections, which was engraved on four plates, began to appear. Of the firft plate, which is "An Election Entertainment," it has been faid that Hogarth completed the engraving without taking from it a fingle proof by which to afcertain the progrefs of his work. It might be fo, but if this were wife it would more frequently be practifed, and Hogarth himfelf is known to have repented of his imprudence when a proof was taken.

This performance, in its original ftate, is by far the moft finifhed and carefully executed of Hogarth's engravings, and he therefore, confcious of the fuperior pains which he had beftowed on it, infcribed beneath it, "painted, and *the whole* engraved by Wm. Hogarth," but thefe two words were afterwards erafed, for the number fold was fo confiderable, that by the time the fecond plate of this feries made its appearance, the firft had been touched and retouched fo often, that all the original and delicate lines were either hidden by others, or utterly obliterated, and it has been compared, wittily enough, to fir John Cutler's ftockings, which, from frequent mending, from filk degenerated into worfted.

The fecond of the election feries, of which the fubject is "Canvaffing for Votes" is engraved by C. Grignion, and was publifhed in the year 1757. On which occafion Hogarth apologized in the public prints for the delay which had taken place, afcribing it to the difficulty of procuring able hands to engrave the plates. In the early impreffion this is an excellent engraving.

The third plate of this feries is entitled "The Polling," is engraved by Hogarth and Le Cave, and was publifhed in the following year.

The fourth plate, which completes the feries, and is entitled "Chairing the Members," was alfo publifhed in the courfe of the year 1758, and is engraved by Hogarth and Aveline.

In all thefe plates the fatire of Hogarth is moft poignant and abundant; and notwithftanding the number of portraits our engraver has introduced, his meaning is fo general, that the election-prints continue to be applicable to the prefent time.

In the year 1758 he alfo engraved and publifhed "the Bench," with explanations and illuftrations of the words, "character" and "caricature." The print exhibits the infide of the court of common pleas, over which is the king's arms, and beneath are the portraits of the following judges, *viz.* honourable William Noel, fir John Willes; the lord chief juftice; honourable Mr. juftice (afterwards lord) Bathurft, and fir Edward Clive.

His own portrait, a whole length figure, was alfo the produce of this year, in which plate the face only is engraven

graven by Hogarth. He has here reprefented himfelf in profile, fitting, with a cap on his head, and engaged, in a very appropriate manner, in painting the mufe of comedy. His analyfis of beauty lies on the floor, and underneath is his title of ferjeant painter to his majefty. It may be obferved of this likenefs, and that which he has introduced in his "Gate of Calais," that they both correfpond much better with the buft of Hogarth, which was modelled by Roubilliac, and is now in the collection of M. G. Baker, than the three-quarter face which was publifhed in 1749, and afterwards metamorphofed to that of Churchill the poet.

"The Cockpit," defigned and engraved by W. Hogarth, was produced in 1759. In this engraving is introduced a portrait of Nan Rawlins, a very ugly old woman (commonly called Deptford Nan, and fometimes the duchefs of Deptford), who is well remembered at Newmarket. She was a famous cock-feeder, and did the honours of the gentlemens' ordinary at Northampton. The figure with the hump back is that of Jackfon, a once noted jockey, and the blind prefident is lord Albemarle Bertie, who conftantly attended this refined and elegant diverfion.

In the next three years he produced nothing of his own engraving, though he made fome defigns from Triftram Shandy; one for Brook Taylor's perfpective, and a few others, which were engraved by Woollett, Ravenet, and Grignion: but in 1762, he produced his "Credulity, Superftition, and Fanaticifm," which is chiefly meant to ridicule certain methodiftical fectaries, and is preferred by lord Orford to all his other works "for deep and ufeful fatire."

"The Times" was alfo produced in the year 1762. This is a political print, which Mr. Nichols explains as follows: "Europe on fire; France, Germany, and Spain, in flames, which are extending to Great Britain. This defolation continued and affifted by Mr. Pitt under the figure of king Henry VIII. with bellows encreafing the mifchief which others are ftriving to abate. He is mounted on the ftilts of the populace. A Chefhire cheefe depends from his neck with 3,000*l*. on it. This alludes to what he had faid in parliament, that he would fooner live on Chefhire cheefe and a fhoulder of mutton, than fubmit to the enemies of Great Britain. Lord Bute, attended by Englifh foldiers, failors, and highlanders, manages an engine for extinguifhing the flames, but is impeded by the duke of Newcaftle with a wheel-barrow full of monitors and North Britons, for the purpofe of feeding the blaze. The refpectable body under Mr. Pitt are the aldermen of London worfhipping the idol they had fet up; whilft the mufical king of Pruffia, who alone is fure to gain by the war, is amufing himfelf with a violin amongft his miferable country women. The picture of the Indian alludes to the advocates for retaining our Weft Indian conquefts, which it was faid would only increafe excefs and debauchery. The breaking down of the Newcaftle arms, and the drawing up the patriotic ones, refer to the refignation of that noble duke, and the appointment of his fucceffor. The Dutchman fmoking his pipe and a fox peeping out behind him and waiting the iffue; the waggon with the treafures of the Hermione; the unneceffary marching of the militia, fignified by the Norfolk jigs; the dove with the olive branch, and the miferies of war, are all obvious, and perhaps need no explication."

In 1763, he publifhed a caricature of "John Wilkes," efquire, drawn from the life, and etched in aquafortis by William Hogarth. To which was ironically added "this is a direct contraft to the print of Simon lord Lovat."

Of this caricature, Wilkes with his ufual good humour has been heard to fay, that he was every day growing more and more like his portrait by Hogarth.

In the fame year was publifhed alfo, "the Bruifer C. Churchill," which has been already mentioned, and which neither added to his fame, nor in its confequences to his happinefs.

"The Bathos," publifhed in 1764, was his laft engraving of any confequence, if not his very laft work. In the month of October of this year being feventy-four years of age, he departed this life, and was buried in the church yard of Chifwick, where a monument, with an excellent epitaph by Garrick, is erected to his memory.

His engravings, like the tenour of his life, are characterized not by delicacy, but by ftrength of thought and expreffion. He did not aim at captivating by the beauty of his art, but at excelling by the power which he poffeffed of combining a number of particular and congenial truths into one impreffive whole: agreeably to his own declarations, we perceive in his prints, that he difcovers little dexterity in the arrangement of his lines, and ftill lefs folicitude about their beauty: yet in his pictures, and efpecially in thofe of the Marriage A-la-Mode, now in the collection of J. J. Angerftein, efquire, are fome paffages which no Dutch painter and no other painter could have more exquifitely touched. No artift whatever, and fcarcely any man more than Hogarth, deferves the praife of original and independent thinking. His engravings are in fome inftances taken from no pictures, and his pictures from no books. Without having recourfe to hiftory or poetry he *invented* his fubjects. The world of moral art "was all before him where to choofe:" he marked out and took poffeffion of an ample province for himfelf, replete with the riches of nature; a province which few have fince dared to invade, and to which none have difputed his title.

Luke Sullivan, who has been already mentioned, was Hogarth's moft valuable coadjutor in engraving. He was a native of Ireland, an eccentric character, and much addicted to women. Whilft engraving the march to Finchley (according to Mr. Ireland,) "Hogarth held out every poffible inducement to his remaining at his houfe in Leicefter fquare night and day; for if once Luke quitted it he was not vifible for a month." If Hogarth gave him but one hundred pounds for this plate, as his biographers fay, Sullivan's inducements to ftay at home were certainly ftrong.

Befide what he did after Hogarth, Sullivan engraved "the Temptation of St. Anthony," after Teniers, and feveral garden fcenes and other landfcapes, which he drew from nature with fome ability. He alfo painted miniatures with fuccefs. His own portrait may be feen in the character of an angel, in Hogarth's humorous print of "Paul before Felix." He died of a confumption in the year 1750.

About this time John Pine, whofe portrait Hogarth painted in the manner of Rembrandt, was in good repute, but the years of his birth and death are uncertain. His chief works are, "the Ceremonies ufed at the revival of the order of the Bath;" "The Deftruction of the Spanifh Armada," from the tapeftry of the houfe of lords; a fplendid edition of Horace, illuftrated with copies of antique bas reliefs, gems, coins, &c. and a print of the houfe of commons.

The paftorals and Georgics of Virgil were publifhed by his fon after his death, adorned in the fame manner as the Horace, but printed with letter-prefs types.

Now alfo flourifhed Arthur Pond, another native of England. He etched feveral portraits with freedom, tafte, and fpirit, among which are thofe of Mr. Pope (an excellent likenefs), lord Bolingbroke, Dr. Mead, and himfelf. He was

was concerned with the Meffrs. Knapton in publifhing the volume of portraits of illuftrious men which were engraven by Houbraken, Vertue, Gravelot, &c. and in promoting other meritorious works, particularly a fet of plates from the great Italian mafters in imitation of chalk and biftre drawings, which he accomplifhed with great fuccefs. He alfo etched a fet of caricatures from the chevalier Ghiffi, and a few landfcapes, chiefly after Rembrandt.

Simon Francis Ravenet was another of Hogarth's occafional coadjutors. He was a native of France, came into England about the year 1750, and fettled in London. In the latter part of his life he refided at Mother Red Cap's, near Kentifh Town, where he died in 1774. He was of an amiable difpofition and much refpected, and had the honour of inftructing both Ryland and Hall in the art of engraving.

The fhadows in his engravings are deep toned, and his ftyle both of drawing and engraving vigorous, though fomewhat mannered. Befide what he produced after Hogarth, the following are efteemed among his beft prints: "The Prodigal Son," (a large upright) from Sal. Rofa; "Lucretia deploring her Misfortune," from A. Cafali; "The Manifeftation of the Innocence of the Princefs Gunhelda," (its companion) from the fame; "The Death of Seneca," (a large plate) from Lucca Giordano; "The Arcadian Shepherds," from N. Pouffin; "The portrait of Lord Camden," from fir Jofhua Reynolds. He is alfo the author of a confiderable number of vignettes, book plates, and fmall portraits.

William Wynne Ryland was born in London in the year 1732. His genius for the fine arts manifefted itfelf at an early period of his life, and he was accordingly placed under Ravenet. At the expiration of the term of his engagement he went to Paris, at that time the chief feminary of engraving, for improvement; and remained there five years.

Under the guidance of Boucher, who at that time led the fafhion in art, he applied with great affiduity to the ftudy of drawing, but did not neglect to improve himfelf alfo in the practical part of engraving. From the defigns of this principal mifleader of the tafte of France, Ryland engraved feveral plates, of which the principal and probably the beft engraving he ever performed, is rather a large work, of which the fubject is "Jupiter and Leda."

He has here difplayed great power as an engraver in lines. The print has a fine tranfparent tone; he has tempered the flimfy touchinefs of the French tafte with a portion of Ravenet's folidity; the foft firmnefs of flefh is ably characterized in the figure of Leda, and the delicacy of the fwan, and various textures of the furrounding objects, are rendered with much feeling and judicious fubferviency to the principal parts.

In one of his amatory poems, M'Kenzie emphatically exclaims, "Alas! are there fafhions in love!"—Alas! there are alfo fafhions in fine art. Unmeaning glitter, unprecedented foftnefs, unprincipled novelty, fhall fometimes fet afide for a while the truth and fimplicity of nature, and the approbation of ages.

It was not, however, the falfe tafte of Boucher that turned afide Ryland's talents from the mark at which he was evidently and fuccefsfully aiming, when he produced his "Jupiter and Leda," but a fafhion of ftippling which he learned in France, and introduced, with his own modifications, into England. Stippling with the graver had been occafionally practifed both by Martin Schoen and Albert Durer in the very infancy of the art: the latter employed it in imitating the foft texture of beaver hats, as well as on fome other occafions. Perceiving that it was peculiarly expreffive of foftnefs, Agoftino Veneziano and Boulanger fometimes ftippled their flefh, and Julio Campagnola his back grounds alfo. Almoft a century afterward it was obferved by De Marteau, who was now living, that by etching fome of the dots of which this kind of engraving confifts, and engraving others, very fuccefsful imitations of drawings hatched with chalk, might be produced. But Ryland employed ftippling, fo as rather to imitate fuch drawings as are ftumped than fuch as are hatched with chalk, by which means he foftened down all energy of ftyle, and has left pofterity to regret the voluntary emafculation of the powers he had manifefted in the engraving, which is the fubject of the above comments.

Soon after his return to England, he, however, engraved in lines a portrait of the queen, after Coates, and that portrait of his majefty, after Allen Ramfay, which Strange, from a mifunderftanding either with the earl of Bute or Ramfay, had declined, but they poffefs neither the vigour nor tafte of his "Jupiter and Leda." From this time he was appointed engraver to the king, and received an annual falary.

His fubfequent engravings, in the chalk manner, are chiefly after Angelica Kauffman, and confift of four half-fheet circles, of which the fubjects are, "Juno obtaining the Ceftus of Venus," "A Sacrifice to Pan," "Cupid bound," and "Cupid afleep;" "Queen Eleanor fucking the poifon from the wounded Edward I.;" (an excellent engraving of the kind;) "Lady Elizabeth Grey foliciting the reftoration of her Lands;" "Maria;" from Sterne's Sentimental Journey, and "Patience," both upright ovals; alfo "King John ratifying Magna Charta." The laft plate being left, by Ryland's unfortunate death, in an unfinifhed ftate, has fince been completed by Bartolozzi. This artift alfo engraved in lines, "Antiochus and Stratonice," from Pietro de Cortona, and "The firft Interview between Edgar and Elfrida," from Angelica Kauffman, both large plates.

Ryland's engravings in the novel manner were, for the moft part, printed in red, and this manner of engraving foon obtained the name of "the red chalk manner," and was run after with avidity by the public. With fo much heedlefs anxiety was it purfued, that people never ftopt to confider whether even red-chalk or ftumped drawings themfelves, of which thefe prints were profeffed imitations, were fo good reprefentations of nature, or afforded a means fo happy and efficient of transfufing the foul of painting, as the art which previoufly exifted, of engraving in lines, and which was then exercifed in high perfection by Bartolozzi, Strange, Vivares, and Woollet: it was enough that it was new and red; Ryland and novelty led the way, and fafhion and the printfellers followed.

The print-dealers, upon miftaken notions of private advantage, are ever exhaufting the permanent hopes of the art. Like favages, who are recklefs of the future, they cut down the tree in order to obtain its fruit. The novelty of chalk engraving, by calling forth their ignorant exertions, coincided with, and encreafed, the mania of the public, and except for the landfcapes of Vivares, Rooker, and Woollett, which required and exhibited more vigour and more detail of drawing than ftippling could beftow; and that now and then an hiftorical engraving by Strange and Bartolozzi, and the feries from Weft's hiftory of England, (of which the death of general Wolfe was the firft,) attefted the exiftence and maintained the dignity of the legitimate art, the engravers of Great Britain were compelled to feel, and filently to acknowledge, that

"Since

"Since ignorance was blifs,
'Twas folly to be wife."

This mode of engraving, however, has fince been greatly improved, and this improvement has been effected chiefly by living profeffors. For an account of its procefs and fufceptibilities, fee the article Stippling.

Engraving, a mode or fpecies of fculpture performed by incifion. The radix of the word fhould rather be fought in the Hebrew, than in the Greek language, becaufe the art itfelf was practifed by the Hebrews and their Chaldean anceftors for centuries before Greece had exiftence.

There are feveral words ufed by the facred hiftorian to exprefs or denote the work of the engraver. In the 28th chapter of Exodus, verfe 9, פתח fignifies to make an opening, or incifion; and hence come both the noun and its plural, פתוחים engravings.

One of the original fenfes of the root is *to plough up*, fo that the engraver is called *the plougher*; and frequently the word אבן, *a ftone*, is added for the fake of diftinction, and both together may be properly tranflated *the plougher* or *engraver in ftone.*

Mr. Strutt with much truth obferves, that "no word can exprefs more perfectly the operation of the engraver on metals of the prefent day (when performed fimply with the graver) than the verb *to plough.*" His line is a furrow, and in cutting it he turns up the copper, or other metal, as the hufbandman turns up the earth. The metal fo turned up is termed the *burr*, which is afterwards removed with a tool termed by engravers a *fcraper.*

In the 6th chapter of the firft book of Kings, the word קלע is ufed to exprefs the hollowing out of the carved work upon the cherubim, palm trees, and open flowering in the fanctuary, which were afterwards filled up with gold; which word in the Latin Vulgate is rendered *fculpfit*; by others *cælavit*, and by others *incidit.*

Engraving has been performed in different countries and at different periods of time, on various fubftances; chiefly on metals, wood, and the oriental precious ftones, which are called gems, but with inftruments that have varied but little fince they were firft invented. For the latter arts, fee Gem *Engraving* and Wood *Engraving.*

The metals upon which engraving is chiefly employed are copper and fteel, the former for producing impreffions on paper in various ways; the latter for ftriking coins, medals, &c.

Engraving on copper, for the purpofe of producing impreffions, may be divided into five fpecies, engraving in aqua-tinta, for which fee Aqua-tinta; engraving in the chalk manner, for which fee Stippling; engraving with aqua-fortis, for which fee Etching; engraving on mezzotinto, for which fee Mezzotinto *Engraving*, and the original art of engraving *in lines.*

Engraving in lines, for the purpofe of producing impreffions on paper, may almoft be faid to be an art of modern invention, for though the ancients ornamented their pateras, armour, metal vafes, &c. by this means, they appear never to have thought of printing from the incifions, or lines cut with the graver; nor was it thought of at all until about the middle of the 15th century, for which fee our accounts of the German and Italian *Schools of Engraving.*

This art is chiefly employed in reprefenting hiftorical fubjects, landfcapes, portraits, &c. &c. after pictures, or other defigns made for the purpofe.

It is performed, as we have ftated, with the graver, dry point, or more frequently with the work of both thefe tools, mingled with lines corroded with aqua fortis. For the firft there need but little apparatus, and few inftruments. The plate you work on being well polifhed, (for the method of preparing which, fee Copper-*plates*,) is covered over with a thin fkin of virgin-wax, and on this the outline of the draught, or defign, done in black lead, red chalk, or other ungummed matter, is laid; and rubbed down for the wax to take off. The defign, thus transferred upon the wax, is traced through on the copper, with a point, or needle; then heating the plate, and taking off the wax, the ftrokes remain; to be followed, heightened, &c. according to the tenor of the defign, with the graver, which is to be very fharp, and well tempered.

The dry point, or needle, which has been of late much ufed in engraving, is a tool like an etching point, which being drawn hard on the copper, cuts a ftroke, and raifes a burr; the burr is fcraped off, and there remains a ftroke more foft and delicate than can be produced in any other way. See Dry *Point.*

In the adroit conduct of the graver and dry point the art chiefly confifts; for which there are no rules to be given; all depending on the habitude, difpofition, and genius, of the artift. However, fome general obfervations and directions may not be improper. As the principles of engraving are the fame with thofe of painting, a perfon cannot expect to attain any confiderable degree of perfection in this art who is not a good mafter of defign; and therefore he ought to be well acquainted both with perfpective and architecture: for the former, by the proper degradations of ftrong and faint tints, will enable him to throw backward, or bring forward, the figures and other objects of the picture or defign which he propofes to imitate; and the latter will teach him to preferve the due proportion of its feveral orders, which the painter often entrufts to the difcretion of the engraver. In order to preferve equality and union in his works, the engraver fhould always fketch out the principal objects of his piece before he undertakes to finifh them. Care fhould be taken that the graver be carried level upon the plate, and be preffed, as occafion requires, with greater or lefs force, carrying the hand as evenly as poffible. In engraving ftraight lines, a lefs degree of preffure ferves for thofe that are finer, and a greater is required to form the broader and deeper lines. In forming circular or curved lines, the hand and graver muft be held fteady, and the plate is to be moved upon the cufhion under the graver. In large works a cufhion is ufelefs. The engraved work may be rendered more vifible, by rubbing it over with a roll of felt, dipt in oil, and which is called an oil rubber. The ftrokes of the graver fhould never be croffed too much in the lozenge manner, particularly in the reprefentation of flefh, becaufe fharp angles produce the unpleafing effect of lattice-work, and take from the eye the repofe which is agreeable to it in all kinds of picturefque defigns: we fhould except the cafe of clouds, tempefts, waves of the fea, the fkins of hairy animals, or the leaves of trees, where this method of croffing may be admitted. But in avoiding the lozenge, it is not proper to get entirely into the fquare, which would give too much of the hardnefs of ftone. In conducting the ftrokes, the action of the figures, and of all their parts, fhould be confidered; and it fhould be obferved how they advance towards, or recede from, the eye; and the graver fhould be guided according to the rifings or cavities of the mufcles or folds, making the ftrokes wider and fainter in the light, and clofer and firmer in the fhades. Thus the figures will not appear jagged; and the hand fhould be lightened in fuch ſuch a manner, that the outlines may be formed and terminated without being cut too hard: however, though the ſtrokes break off where the muſcle begins, yet they ought always to have a certain connection with each other, ſo that the firſt ſtroke may often ſerve by its return to make the ſecond, which will ſhew the freedom of the engraver.

In engraving the fleſh, the effect may be produced in the lighter parts, and middle tints, by long pecks of the gravers, rather than by light lines; or by round dots, or by dots a little lengthened by the graver, or, beſt of all, by a judicious mixture of theſe together.

In engraving the hair and the beard, the engraver ſhould begin his work by laying the principal grounds, and ſketching the chief ſhades in a careleſs manner, or with a few ſtrokes; and he may finiſh it at leiſure with finer and thinner ſtrokes to the extremities. When architecture is to be repreſented, except it be old and ruinous buildings, the work ought not to be made very black; becauſe, as edifices are commonly conſtructed either of ſtone or white marble, the colour, being reflected on all ſides, does not produce dark ſhades, as in other ſubſtances. Where ſculpture is to be repreſented, white points muſt not be put in the pupils of the eyes of figures, as in engravings after paintings; nor muſt the hair or beard be repreſented as in nature, which makes the locks appear flowing in the air; becauſe in ſculpture there can be no ſuch appearances.

In engraving cloths of different kinds, linen ſhould be done with finer and cloſer lines than other ſorts, and be executed with ſingle ſtrokes. Woollen cloth ſhould be engraved wide, in proportion to the coarſeneſs or fineneſs of the ſtuff; and when the ſtrokes are croſſed, the ſecond ſhould be ſmaller than the firſt, and the third than the ſecond. Shining ſtuffs, which are generally of ſilk or ſatin, and which produce flat and broken folds, ſhould be engraved more hard and more ſtraight than others, with one or two ſtrokes, as their colours are bright or otherwiſe; and between the firſt courſe of lines other ſmaller muſt be occaſionally introduced, which is called interlining. Velvet and pluſh are expreſſed in the ſame manner, and ſhould always be interlined. Metals, as armour, &c. are alſo repreſented by interlining, or by clear ſingle ſtrokes. In architecture, the ſtrokes which form the rounding objects ſhould tend to the point of ſight; and when whole columns occur, it is proper to produce the effect as much as poſſible, by perpendicular ſtrokes. If a croſs ſtroke is put, it ſhould be at right angles, and wider and thinner than the firſt ſtroke. The ſtrokes ought to be frequently diſcontinued and broken, for ſharp and craggy objects. Objects that are diſtant towards the horizon ſhould be kept very tender. Waters that are calm and ſtill are beſt repreſented by ſtrokes that are ſtraight, and parallel to the horizon, interlined with thoſe that are finer; omitting ſuch places as, in conſequence of gleams of light, exhibit the ſhining appearance of water; and the forms of objects, reflected from the water at a ſmall diſtance upon it, or on the banks of the water, are expreſſed by the ſame ſtrokes, retouched more ſtrongly, or faintly, as occaſion may require, and even by ſome that are perpendicular. For agitated waters, as the waves of the ſea, the firſt ſtrokes ſhould follow the figure of the waves, and may be interlined, and the croſs ſtrokes ought to be very lozenge. In caſcades, the ſtrokes ſhould follow the fall, and be interlined. In engraving clouds, the graver ſhould ſport, where they appear thick and agitated, in turning every way according to their form, and their agitation. If the clouds are dark, ſo that two ſtrokes are neceſſary, they ſhould be croſſed more lozenge than the figures, and the ſecond ſtrokes ſhould be rather wider than the firſt. The flat clouds, that are loſt inſenſibly in the clear ſky, ſhould be made by ſtrokes parallel to the horizon, and a little waving; if ſecond ſtrokes are required, they ſhould be more or leſs lozenge; and when they are brought to the extremity, the hand ſhould be ſo lightened, that they may form no outline. The flat and clear ſky is repreſented by parallel and ſtraight ſtrokes, without the leaſt turning. In landſcapes, the trees, rocks, earth, and herbage, ſhould be etched as much as poſſible: nothing ſhould be left for the graver but perfecting, ſoftening, and ſtrengthening. The dry point produces an effect more delicate than the graver can, and may be uſed to great advantage in linen, ſkies, diſtances, ice, and often in water, eſpecially in ſmall engravings. In moſt things it is proper to etch the ſhadows, only leaving the lighter tints for the dry point, graver, &c.

The other inſtruments, beſides the graver and dry point, are, a cuſhion, or ſand-bag, to lay the plate on, to give it the neceſſary turns and motions: a burniſher, round at one end, and uſually flattiſh at the other, to rub out ſlips and failures, and to ſoften the ſtrokes, &c. A ſcraper, to pare off the ſurface, on occaſion, and remove the burr; and a rubber of black cloth, or hat, to fill up the ſtrokes, that it may ſhew how the work proceeds: but the latter ſhould be ſparingly uſed.

Engraving *on ſteel*, is chiefly employed in cutting punches, matrices, and dies, proper for ſtriking coins, medals, and counters.

The method of engraving, with the inſtruments, &c. are the ſame for coins as for medals and counters: all the difference conſiſts in their greater, or leſs relievo; the relievo of coins being much leſs conſiderable than that of medals; and that of counters ſtill leſs than that of coins. The engraver in ſteel uſually begins with punches, or punchions, which are in relievo, and ſerve for making the creux, or cavities of the matrices, and dies; though ſometimes he begins immediately with the creux; but it is only when the intended work is to be cut very ſhallow. The firſt thing is to deſign his figures; then he moulds them in white wax, of the ſize and depth required; and from this wax he graves his punch.

This punch is a piece of ſteel, or, at leaſt, of iron and ſteel mixed; on which, before they temper, or harden it, the intended figure, whether a head, or a reverſe, is cut, or carved, in relievo. The inſtruments uſed in this *graving* in relievo, which are much the ſame as thoſe wherewith the finiſhing of the work in creux is effected, are of ſteel: the principal are, gravers of divers kinds, chiſſels, flatters, &c. when the punch is finiſhed, they give it a very high temper, that it may the better bear the blows of the hammer, wherewith it is ſtruck, to give the impreſſion to the matrice.

What they call *matrice*, or *matrix*, is a piece of good ſteel, of a cubic form, called alſo the *dye*, whereon the relievo of the punch is ſtruck in creux: it is called *matrix*, becauſe in the cavities, or indentures, thereof, the coins, or medals, ſeem formed, or generated, as animals are in the matrix of their mother. To ſoften this ſteel, that it may more eaſily take the impreſſions of the punch, they make it red-hot; and, after ſtriking the punch thereon in this ſtate, they proceed to touch up, or finiſh, the ſtrokes and lines, where, becauſe of their fineneſs, or the too great relievo, they are in any reſpect defective, with ſome of the tools above-mentioned.

The figure thus finiſhed, they proceed to engrave the reſt of the medal; as the mouldings of the border, the engrailed ring, letters, &c. all which, particularly the letters, and graining, or engrailment, are performed with little fteel punches, well tempered and very fharp. Add, that as they fometimes make ufe of puncheons to engrave the creux of the matrix, fo, on fome occafions, they make ufe of the creux of the matrix to engrave the relievo of the punch.

To fee and judge of the engraving in creux, divers means have been devifed to take the impreffions therefrom, as the work proceeds; fometimes they make ufe of a compofition of common wax, turpentine, and lamp-black; which, always retaining its foftnefs, eafily takes the impreffion of the part of the graving it is applied to; but this only ferving to fhew the work piece-meal, they have had recourfe to other ways to fhew the whole figure. The firft by pouring melted lead on a piece of paper, and clapping the matrice thereon; the fecond, with melted fulphur, managed the fame way; and the third, proper only where the graving is fhallow, by laying a piece of foft paper on the graving, and over the paper a leaf of lead; when giving two or three blows with a hammer on the lead, the paper takes the impreffion of the work.

When the matrix is quite finifhed, they temper it, rub it well with a pumice-ftone, and clean out the ftone again with a hair-brufh; and, laftly, polifh it with oil and emery: in this condition it is fit for the mill, to be ufed to ftrike coins, medals, &c.

After the like manner are the matrices for cafting of printing letters engraven. See *Letter* Foundery.

Engraving *of feals, ftamps, puncheons, marking irons, gilding irons*, and other matters, for goldfmiths, pewterers, bookbinders, &c. either in relievo, or indenture, is performed after the manner laft defcribed.

Engraving *in wood*. See Cutting *in wood*, and Wood *Engraving*.

ENGRAULIS, in *Ichthyology*, a name given, by fome authors, to the anchovy, called alfo, by fome, lycoftomus, and, by others, halecula. See Encrasicolus.

ENGROSSING, the writing a deed over fair and in proper legible characters. Among lawyers it more particularly means the copying of any writing fair upon parchment, or ftamped paper. See Copy, Calligraphus, &c.

Engrossing, in *Law*, denotes the getting into one's poffeffion, or buying up large quantities of corn, or other dead victuals, with intent to fell them again. This muft of courfe be injurious to the public, by putting it in the power of one or two rich men to raife the price of provifions at their own difcretion. And fo the total engroffing of any other commodity, with intent to fell it at an unreafonable price, is an offence indictable and fineable at the common law. (Cro. Car. 232.) And the general penalty for this offence, as well as for *foreftalling* and *regrating* (which fee), by the common law, (for all the ftatutes concerning them were repealed by 12 Geo. III. c. 71.) is, as in other minute mifdemefnors, difcretionary fine and imprifonment. (1 Hawk. P. C. 235.) Among the Romans thefe offences, and other mal-practices to raife the price of provifions, were punifhed by a pecuniary mulct. "Pœna viginti aureorum ftatuitur adverfus eum, qui contra annonam fecerit, focietatemve coierit quo annona carior fiat." (Inf. 48. 22. 2.)

ENGSTLEN, in *Geography*, a remarkable fpring of Switzerland, in the canton of Berne, in the valley called Gentel. The water flows only from the beginning of May till the latter end of Auguft, and that twice a day towards eight o'clock in the morning, and towards four in the afternoon. This circumftance is confidered as miraculous: the inhabitants fancy that providence purpofely fends them this water in the feafon, and at the time when they are to water their cattle. Nothing, however, is more eafily explained than this phenomenon. Many brooks iffue from mount Engftlen, and form a fmall lake. In the fummer months, the fnow water caufes this lake to overflow; and the melting of the fnow begins with the day, and ceafes towards night. F. I. Durand's Statiftique élémentaire de la Suiffe, 1795.

ENGUELEGUINGIT, a town of Africa, in the empire of Morocco, not far from Mogador.

ENGUICHE, in *Heraldry*, is applied to the great mouth of a hunting horn, when it has a rim of a different colour from the horn itfelf.

ENGYSCOPE, from εγγυς, *near*, and σκοπεω, *I obferve*, a machine better known under the name of microfcope. See Microscope.

ENGYTHECA, from εγγυς, *near*, and θηκη, *repofitory*, in *Antiquity*, a cup-board, or place where cups and other veffels ufed to be laid.

ENGYUM, or Enguyum, in *Ancient Geography*, a town of Sicily, fituated near mount Maurus, at the fprings of Alæfus. Cicero (in Verr.) reprefents it as one of the moft confiderable cities of that ifland. It was founded by the Cretans, and famous for a temple dedicated to Ceres, in which, it was conftantly affirmed, certain goddeffes, called the "Mothers," appeared from time to time. Plutarch fays, that this temple was built by the Cretans, and dedicated to thefe goddeffes fo called, *viz.* Cybele, Juno, and Vefta. This writer adds, that in the temple were lodged javelins and brazen helmets, which had been confecrated to the goddeffes of the place by Meriones and Ulyffes. The town was fituated in the interior of the ifland, to the weft of Hubita.

ENHADDAD, a town of Judea, comprifed in a part of the tribe of Iffachar.

ENHALLOW, in *Geography*, one of the fmaller Orkney iflands, between Rowfa and Pomona.

ENHANCE, *To*, in *Law*, is to raife the price of goods or merchandize. See Engrossing and Forestalling.

ENHANCED, in *Heraldry*, a term applied to any ordinary, when removed from its ufual fituation, and placed higher in the field.

ENHARMONIC Genus, in the *Ancient Greek Mufic*. The Greeks included all mufical founds in three genera or kinds of interval: the diatonic, for tones and femi-tones; the chromatic, for femi-tones and minor thirds; the enharmonic, for quarter-tones and major thirds. The fcale of each genus was arranged in tetrachords, or fyftems of four founds, of which the firft and laft were ftantes, immobiles, or fixed; while the two middle founds were termed mobiles, or changeable: and it is by thefe changes that the genera are diftinguifhed.

Each of the three genera had fome founds in its fcale that were peculiar and characteriftic, and fome that were in common with the other two. For inftance, B C E F A Bb and d, were ufed in all the three genera, whereas D G were peculiar to the diatonic, C✻ and F✻ to the chromatic, and B× E× and A× to the enharmonic. A complete fcale of each genus in modern notes will explain this matter better than words.

This ſubject will be further purſued under the articles *Ancient Greek* Music, Genera, and Tetrachords.

As modern melody is built upon harmony, derived from the harmonics of a fundamental-baſe, we have no inſtruments with quarter-tones, or which can furniſh a baſe to an enharmonic melody, if we had the power of framing and executing it with the voice or violin. We have, therefore, only two genera in our muſic, with all our refinements in melody of nominal enharmonic ſharps, dieſes, double flats, and ſharps, &c.: which two genera, the diatonic, conſiſting of five tones and two ſemi-tones in the octave, ſuch as the key of C natural ſupplies upon keyed inſtruments; and the chromatic, conſiſting entirely of ſemi-tones, twelve in number, ſuch as moving from any given note to its octave by ſemi-tones will furniſh. See Tone, Semi-tone, and *Enharmonic* Sharps or Dieses.

Enharmonic *Dieſis*, is an interval whoſe ratio is $\frac{125}{128} = 21\Sigma + 2\,m$. See *Enharmonic* Diesis.

Enharmonic *Degree of Ariſtoxenus*, otherwiſe his dieſis quadrantalis, was a quarter of the major tone, or $26\Sigma + \frac{1}{2}f + 2\frac{1}{4}m$.

Enharmonic *Degree of Euclid*, otherwiſe his dieſis quadrantalis, was three-thirtieths of a minor fourth, or $25\frac{2}{5}\Sigma + \frac{1}{2}f + 2\frac{1}{5}m$.

Enharmonic *Ditone of Euclid*, was twenty-four thirtieths of a minor fourth, or $203\frac{1}{4}\Sigma + 4f + 17\frac{3}{4}m$.

Enharmonic *Quarter of a tone*, is the ſame with *enharmonic dieſis*, above.

ENHYDRI, in *Chemiſtry*, are ſmall nodules of chalcedony, each containing a drop of water, which are found in the porous trap of the picentine. They are often poliſhed and ſet in rings, rather as an object of curioſity than of much beauty; and after a time the water uſually diſappears by evaporation.

ENHYDRIA, in *Ancient Geography*, a town of Phœnicia, between Caranus and Marathus. Strabo.

ENHYDRIS, the ancient Greek name for the otter.

ENJEDIM, George, in *Biography*, a learned Unitarian divine, who flouriſhed in the 16th century, was a native of Hungary, whence he removed to Tranſylvania, where he became a ſuperintendant of the Unitarian churches. He died in the year 1597, and was regarded as one of the beſt writers in what is called the Socinian cauſe. His principal work was entitled "Explicatio Locorum Scripturæ Veteris et Novi Teſtamenti, ex quibus Dogma Trinitatis ſtabiliri ſolet," 4to. The firſt impreſſion of this work was burnt by the orthodox, but a new edition was afterwards publiſhed in the Netherlands. Moreri.

ENIF, in *Aſtronomy*, a fixed ſtar of the third magnitude, in Pegaſus's mouth.

ENIGMA. See Ænigma.

ENIMIE, Sainte, in *Geography*, a ſmall town of France, in the department of Lozere, 12 miles S.W. of Mende, in a country formerly known by the name of le Gévaudan.

ENINGIA, in *Ancient Geography*, a country or iſland in the north of Europe, in the Serius Codanus or Baltic ſea, according to Pliny; ſuppoſed by ſome to be Finland.

ENIPEUS, or Enipe, a river of Greece, in Triphylia, which ran W. of Heraclea. In the time of Strabo, it was called *Barnichius*.

ENIPPA, or Agonippa, a mountain of Greece, in Bœotia.

ENISEI and Eniseisk. See Yenisei and Yeniseisk.

ENISIPIA, an iſland of the Mediterranean ſea, near Egypt, called *Æneſyppa* by Ptolemy, and *Eneſipaſta* by Strabo.

ENISPA, a town of the Peloponneſus, in Arcadia, called *Eniſpæ* by Seneca the tragedian.

ENIX, in *Geography*, a town of Spain, in the province of Grenada; 8 miles W. of Almeria.

ENIXUM Sal, in *Chemiſtry*, is the ſulphat of potaſh remaining after the preparation of nitrous acid. It is pure, if only nitre and ſulphuric acid have been made uſe of: but as the manufacturers of aquafortis uſually employ green vitriol inſtead of ſulphuric acid, the reſidual ſalt is much mixed with colcothar or oxyd of iron; from which, however, it may be ſeparated by ſubſequent ſolution and cryſtallization.

ENKIANTHUS, in *Botany*, from εγκυος, *pregnant*, and ανθος, *a flower*, "becauſe," ſays Loureiro, "its flowers are pregnant with others." Loureir. Cochinch. 276. Claſs and order, *Decandria Monogynia*. Nat. Ord. ——.

Gen. Ch. *Common Cal.* of ſix roundiſh, concave, pointed, coloured leaves. *Common Cor.* of eight oblong, flat, ſpreading petals, containing five florets, on long reflexed ſtalks.

 Perianth

Perianth of five fmall, permanent, acute, coloured leaves. *Cor. proper* of one petal, bell-fhaped; tube wide; limb fhort, in five rounded fegments. *Stam.* Filaments ten, awl-fhaped, tumid at the bafe, hairy, attached to the bottom of the corolla, and fhorter than its limb; anthers ovate, incumbent. *Pift.* Germen five-fided, fuperior; ftyle thick, as long as the ftamens; ftigma fimple, coloured, fhining. *Peric.* Berry ovate-oblong, five-fided, of five cells. *Seeds* numerous, oblong, fmall. *Loureiro.*

Eff. Ch. Common Calyx to feveral flowers; proper one inferior, of five leaves. Corolla bell-fhaped, five-cleft. Berry of five cells, with many feeds.

The fpecies are two.

1. E. *quinqueflora.* "Calyx containing five flowers. Stem arboreous." Tfiau tfung hōa of the Chinefe. Cultivated at Canton. Its branches laden with red flowers, before the leaves expand, are kept for feveral days in china vafes of water among the opulent Chinefe, and are very ornamental, though deftitute of fcent. The *tree* is of a middle fize, with a fmooth *bark*, and fpreading *branches*. *Leaves* crowded, oblong, pointed, entire, fmooth. *Flower* folitary, of a beautiful red, crowned with a white fringe, and containing five florets within.

2. E. *biflora.* "Calyx containing two flowers. Stem fhrubby." Sān lièo hōa of the Chinefe. Native of Canton. A *fhrub* three feet high, with fpreading *branches*. *Leaves* lanceolate-ovate, entire, hairy, fmall, crowded, with fhort footftalks. *Flowers* fcarlet, terminal, crowded, feffile. *Common Calyx* of five coloured, ovate, concave, deciduous leaves. *Common Corolla* none. Florets two in each common calyx. *Perianth* fmall, deeply five-cleft; its fegments lanceolate, hairy, fpreading. *Cor.* bell-fhaped, fpreading; tube with five furrows or plaits; limb in five deep, ovate, large fegments. *Filaments* ten, thread-fhaped, erect, unequal, rather fhorter than the corolla, inferted into the receptacle; anthers ovate, incumbent. *Germen* ovate, very hairy; ftyle thread-fhaped, longer than the corolla; ftigma thickifh, five-cleft, gaping. *Berry?* (not feen ripe), ovate, with five cells and many very fmall roundifh feeds.

The above is Loureiro's account of the genus in queftion, concerning which we confefs ourfelves unable to form any decided opinion. His defcription of the fecond fpecies is a little at variance with the generic characters, and what he every where terms a common calyx and common corolla muft of courfe be bracteas. Some particulars indicate a plant of the *Arbutus* or *Vaccinium* tribe, but others difagree. Ornamental fcarlet flowers, fo well known at Canton, muft long ago have been introduced to the acquaintance of European botanifts. This is one of thofe botanical enigmas with which the good father Loureiro's book abounds, in confequence of his having ftudied almoft entirely without communication with other botanifts. Hence he took the *Hydrangea* for a *Primula*, and made a new genus of *Argemone mexicana*. See ECHTRUS.

ENKIOPING, or ENDKIOPING, in *Geography*, a fmall town of Sweden, fituated on a river clofe to an inlet of the lake Mæler, and confifting chiefly of wooden houfes painted red. It ftands on a ridge of ground compofed of fand and gravel, which once formed the fhore of the lake; 21 miles S.W. of Upfal.

ENKIRCH, a town of Germany, in the circle of the Upper Rhine, and county of Sponheim; 3 miles N. of Traarbach.

ENKUSEN, a town of the ifland of Borneo.

ENLARGE, in the *Manege*, is ufed for making a horfe go large, that is, making him embrace more ground than he before covered. This is done when a horfe works upon a round, or upon volts, and approaches too near the centre, fo that it is defired he fhould gain more ground, or take a greater compafs. To enlarge your horfe, you fhould prick him with both heels, or aid him with the calves of your legs, and bear your hand outwards. If your horfe narrows, he is enlarged with pricking him with the inner heel, and fuftaining him with the outer leg, in order to prefs him forwards, and make his fhoulders go. Upon fuch occafions the riding-mafters cry only large, large. See IN.

ENLARGER L'ESTATE, in *Law*. See RELEASE.

ENLARGING STATUTE. See STATUTE.

ENMANCHE', in *Heraldry*, is when a chief has two lines drawn from the middle of the upper edge, to the fides, the depth of half the chief; the two lines including an obtufe angle, whofe vertex is the centre of the top of the chief.

The heralds conceive this, as bearing fome refemblance to fleeves; whence the etymology of the word, from the French *manche*, fleeve. It differs from chappe, where the lines come from the top to the bottom of the chief.

ENNA, in *Ancient Geography*, now *Caftro Giovani*, a city of Sicily, fituated on an eminence in the middle of the ifland, whence, according to Diodorus, it was called the "navel of Sicily." It was one of the ftrongeft places in the ifland, and remarkable for its beautiful plains, fruitful foil, and the numerous lakes and fprings which watered its territory; and the waters of which were highly commended for their limpidity and falubrioufnefs. Diodorus informs us, that Ceres was born in this diftrict; and that fhe firft taught the inhabitants of Enna the art of agriculture. He adds, that the rape of Proferpine by Pluto happened near Enna, while the young goddefs was gathering flowers in a neighbouring meadow. The Enneans fhewed a large cavern, which, as they believed, opened of itfelf, to make the god a way to his infernal kingdom. Hence originated the worfhip which the Sicilians paid to thefe two divinities; the magnificent temple which Gelo erected to Ceres in this city; and the folemn feftival, which the Syracufians annually celebrated near the fountain Cyane, fuppofed to have fprung up when the earth opened under Pluto's feet. The temple of Ceres was famous and reforted to from all parts of Italy, Greece, and Afia, and was deemed one of the richeft in Italy.

ENNEACHORD, in *Ancient Mufic*, an inftrument with nine ftrings.

ENNEACRUNOS, q. d. *the nine fountains*, in *Ancient Geography*, a fountain of Greece in Attica, at the foot of mount Hymettus, the waters of which were conveyed through nine pipes or channels into the town, conftructed by order of Pififtratus.

ENNEACTIS, in *Natural Hiftory*, a name given by Linkius to a fort of ftar-fifh, of the more branched or aftrophyte kind, which has only nine rays, where they firft part from the body, but thefe divide into a vaft number of others afterwards.

ENNEADECATERIS, in *Chronology*, a cycle, or period, of nineteen folar years.

The word is formed of ἐννεα, *nine*; δεκα, *ten*; and ἐτος, *year*.

Such is the lunar cycle invented by Meton, at the end whereof the moon returns nearly to the fame point from which it departed. Whence the Jews, Athenians, and other nations, who were difpofed to accommodate the lunar months to the folar years, made ufe of the enneadecateris; allowing to feven of the years thirteen months apiece, and to the reft twelve. See CYCLE, and EMBOLISMIC.

ENNEADECATERIS, *the Jewifh*, is properly a cycle of 19 lunar years, beginning from *molad tohu*, and returning again and again; whereof every 3d, 6th, 8th, 11th, 14th, 17th, and 19th, are embolifmic, or of 383 days 21 hours apiece; the reft common, or of 354 days 8 hours apiece. See Year.—Confequently, the Jewifh enneadecateris is 6939 days 18 hours.

ENNEAGON, in *Geometry*, a figure of nine angles, and nine fides.

The word is formed of εννεα, *nine*; and γωνια, *angle*.

Enneagon, in *Fortification*, denotes a place with nine baftions. See Fortified *Place*.

ENNEAHEDRIA, derived from the Greek εννεα, *nine*, and εδρα, a *fide*, in *Natural Hiftory*, the name of a genus of fpars.

The bodies of this genus are fpars, compofed of nine planes, in a trigonal column, terminated at each end by a trigonal pyramid. Of this genus there are four known fpecies. Hill's Hift. of Foff. p. 208.

ENNEANDRIA, in *Botany*, from εννεα, *nine*, and ανηρ, *a man*, the ninth clafs of the fexual or artificial fyftem of Linnæus, confifting of plants with nine feparate or diftinct ftamens in the fame flower with the piftil or piftils. It contains three orders, *Monogynia*, of which the valuable genus *Laurus*, including the Cinnamon, Caffia, one fort of Camphor, Sweet Bay, &c. is an example, and there are fome other fine plants in this order; *Trigynia*, of which *Rheum* or Rhubarb, nearly allied to *Rumex*, is the only inftance, and *Hexagynia*, confifting of *Butumus umbellatus* alone. Hence it appears that nine is an unufual number in the parts of flowers, though not quite fo uncommon as feven.

ENNEAPYRGÆ, in *Ancient Geography*, a town of Greece, in Attica, 7 or 8 leagues from the promontory of Sunium.

ENNEATICAL Days are every ninth day of a ficknefs; which, fome imagine, naturally occafion a great alteration, either for the better or worfe.

Enneatical *Years* are every ninth year of a man's life. See Climacteric.

ENNEBACKA, in *Geography*, a town of Norway; 26 miles S.E. of Chriftiania.

ENNEEMIMERIS is one kind of the cæfura of a Latin verfe, where, after the fourth foot, there is an odd fyllable ending a word, which helps to make the next foot with the following word; as in this inftance,

"Ille latus niveum molli fultus hyacintho,"

where all the four kinds of the cæfura occur.

ENNEL-Lough, in *Geography*, a lake of the county of Weftmeath, Ireland, near Mullengar.

ENNEOPHTHALMOS, from εννεα, *nine*, and οφθαλμος, *eye*, in *Zoology*, a name given by fome to the lamprey.

ENNERIS, in the *Ancient Ship-Building*, a name given to thofe galleys, or veffels, which had nine tires of rowers. Thefe were of a very confiderable fize; though Meibom has found fo convenient a method of placing the rowers that he has taken off very much from that immenfe height others fuppofed they had above the water. We read of the teffaracontes, and other amazing veffels of this fabric; and that of Philopater having forty rows of oars, and that of Ptolemy Philadelphus, thirty; and fome others which are fpoken of, twenty. It has been difputed by many, whether fuch large veffels as thefe were ever actually built, or ufed; but Meibom gives great reafon to believe that they really were, though he, at the fame time, alleges againft Salmafius, and the more fanguine admirers of the works of the ancients, that very few veffels were built larger than thefe enneres, or nine tiered ones, and proves it from Livy and Plutarch, and from Polybius. We are apt to admire, in many cafes, what we ought alfo to imitate, but never attempt it. This is the cafe in thefe galleys; and Meibom, who has given the rules of this ancient naval architecture, is of opinion, that by imitating it at prefent, modern galleys and galleaffes might be built much more conveniently both for ftrength and celerity, and alfo at lefs expence, than they are at prefent. Meibom. de Trirem.

The modern form is indeed allowed to be better than theirs; but if in the ftructure, the proportion of the long fhips of the ancients were obferved, they might be greatly improved: in the modern way of five men fitting at one oar in the galleaffes, much ftrength is wafted to no purpofe, becaufe they fit too near to the fulcrum, or ftay, whereas a fmaller number of rowers, at a greater diftance from the ftay, would give more ftrength, and throw the veffel along much more fwiftly, and would require lefs charge. Galleys of this fort, thus managed at a fmall expence, would be found of great ufe in the large rivers, and in the fhallow feas, and therefore convenient for the Baltic, the Britannic, and the Mediterranean feas, and would be the moft ufeful of all veffels for tranfporting great numbers of forces.

ENNEZAT, in *Geography*, a fmall town of France, in the department of the Puy de Dôme, chief place of a canton in the diftrict of Riom, with a population of 2393 individuals. The canton contains 8 communes and 9168 inhabitants, on a territorial extent of 142½ kiliometres.

ENNIS, a poft-town in the county of Clare, Ireland, of which it is the capital. It is large and populous, and has the advantage of a fmall port at Clare, which is fituated a few miles lower on the river Fergus; the tide bringing up large boats thence to Ennis. There are at this town the remains of one of the fineft abbey-churches in Ireland, built in an elegant ftyle of Gothic architecture. It is a borough town, and fends one member to the united parliament. It is 112½ Irifh miles S.W. by W. from Dublin, and 17 N. by W. from Limerick. W. long. 8° 54'. N. lat. 52° 49'.

ENNISCORTHY, a poft-town of the county of Wexford, Ireland. It is fituated on the river Slaney, which is navigable for fmall floops to this town. Its fituation is agreeable and picturefque; and there are the remains of a confiderable caftle built by the firft Englifh fettlers. It is the eftate of the earl of Portfmouth. Ennifcorthy has a manufacture of coarfe woollen-cloth, and is a thriving town. Near it are lead mines, which are very productive. Vinegar-hill, near this town, was a ftrong hold of the infurgents in 1798; and the loyal inhabitants were great fufferers at that eventful period. Ennifcorthy was reprefented in parliament before the union. It is 60 miles S. from Dublin, and near 12 N. from Wexford.

ENNISKILLEN, a poft-town of the county of Fermanagh, Ireland, and the place where the affizes are held. It is built in an ifland, formed by the river which unites the two lakes, and is the fingle pafs of communication between the parts of the county which thefe waters feparate. The ftrength of its fituation pointed it out as a military poft; and when the adherents of James II. excited a juft alarm throughout the country, numbers flocked to this place, where they bravely refifted a much fuperior force, and even gained feveral important victories. Thefe valiant men were formed into a regiment, which rendered effectual fervice to king William; and to this day the 27th regiment glories in the name of the *Ennifkilliners*. There is a fchool here, founded by James I. on the plantation of Ulfter, the income of which, by the great rife in the value of lands, has become very confiderable. Ennifkillen returns one member to to the imperial parliament. Diſtance from Dublin N.W. 79 miles.

ENNISTYMOND, or Innistymond, a ſmall poſt-town of the county of Clare, Ireland; ſituated 118 miles W. by S. from Dublin, and 13 W. from Ennis.

ENNIUS, Quintus, in *Biography*, an ancient poet, was born at Rudiæ, a city of Calabria, near Tarentum, about the year of Rome 514, B. C. 237, and flouriſhed about the cloſe of the firſt Punic war. According to Silius Italicus, he ſerved as a centurion in Sardinia, when that iſland was ſubdued by T. Manlius, and diſtinguiſhed himſelf by his valour. After the war he probably remained in Sardinia; for Cornelius Nepos informs us, that Cato, the cenſor, when prætor, brought back with him from his government of Sardinia, the poet Ennius, who muſt at this time have been in his 35th year. Another of his patrons was Scipio Africanus the elder, who made him his companion in moſt of his campaigns. This fact we learn from Claudian. He was alſo intimate with Scipio Naſica. The notice taken of him by theſe eminent perſons affords favourable teſtimony to his general character and manners; although Horace (Epiſt. xix. l. 1.) repreſents him as warming his heroic vein by liberal potations. The gout, with which he was afflicted, and his depreſſed circumſtances, were probably owing to his intemperance. Theſe evils, however, he bore with great equanimity; and his life was prolonged to the age of 70. He is ſaid to have been the father of epic or heroic poetry among the Latins, though the Greek was his mother-tongue. He was diſtinguiſhed by that ruſtic vigour, which is the uſual characteriſtic of genius in an unpoliſhed age. Thus Ovid repreſents him;

"Ennius ingenio maximus, arte rudis."

Lucretius mentions his having firſt brought the muſe to Latium; and Virgil has tranſcribed into his works many whole or half lines from Ennius, thus teſtifying his eſteem of him. The events of Roman hiſtory formed the leading ſubjects of a large performance entitled "Annals," ſubſequently divided into eighteen books. On certain days he was accuſtomed to recite portions of this poem. He alſo compoſed tragedies, comedies, epigrams, and ſatires; and alſo ſome didactic works. By his life of Scipio Africanus, he engaged the affection of the Cornelian family, who manifeſted their gratitude to him even after his death, depoſiting his aſhes in the ſame tomb with thoſe of Scipio, and erecting a marble ſtatue to him near that of this great commander. The poet Nævius, who was his contemporary, after having made ſome campaigns in the firſt Punic war, wrote the hiſtory of that war in verſe, according to the taſte of thoſe times. Fragments only of the works of Ennius remain; theſe have been publiſhed ſeparately, Amſt. 4to. 1707, and alſo in Mattaire's Corpus Poetarum.

ENNODIUS, Magnus Felix, biſhop of Pavia in the ſixth century, was born of illuſtrious parents about the year 473. His education and maintenance devolved upon an aunt, by whoſe death, before he was ſixteen years of age, he was reduced to diſtreſſing circumſtances, but afterwards, by a fortunate marriage, he attained to a ſtate of affluence. Notwithſtanding this union, he had a ſtrong inclination for the eccleſiaſtical profeſſion, and obtained his wife's conſent to enter into holy orders, whilſt ſhe at the ſame time embraced a religious life. He was ordained a deacon by Epiphanius, biſhop of Pavia, with whom he lived in habits of the ſtricteſt intimacy and friendſhip. He had an early taſte for literature, which he cultivated in connection with his theological ſtudies, with ſo much ſucceſs as obtained for him the reputation of an excellent ſcholar. On the death of his friend Epiphanius, he was admitted among the deacons of the church of Rome, and for ſome ſervices done for the popes and church, he was promoted to the ſee of Pavia about the year 510, and appointed on the commiſſion for negociating a re-union between the eaſtern and the weſtern churches. The only reward for his ſervices in this reſpect, was drawing down upon his head the reſentment of the emperor Anaſtaſius, who, after much ill treatment, diſmiſſed him home in a ſhattered veſſel, with a ſtrict prohibition of never again landing at any port in Greece, by which his life was expoſed to the moſt imminent danger. He arrived ſafe in Italy, but died as he was on his journey to Pavia, in the 48th year of his age. His works are numerous, and have been frequently printed; they were publiſhed, with many uſeful explanatory notes, at Paris, in the year 1611. Moſheim Eccl. Hiſt. Moreri.

ENNUI, a French term which is ſometimes uſed to denote a kind of liſtleſſneſs or unaptneſs for mental exertion; or which may be more ſcientifically defined to mean the uneaſineſs that prevails during the abſence of mental impreſſions. The averſion from *ennui*, or the deſire of intellectual emotion, is deſcribed by Helvetius, in his work "On Mind," as a very powerful and general ſpring of conduct, and he aſcribes to this law of the mind, perhaps, a greater degree of influence than that which properly belongs to it, conformably to the avowed ſentiments of a writer, who maintains that "to judge is to feel," (juger c'eſt ſentir.")

ENO, in *Geography*, a town of European Turkey, in the province of Romania; the ſee of a Greek archbiſhop; 28 miles N.W. of Gallipoli.—Alſo, a river of America, in North Carolina, which unites with Little and Flat rivers in Orange county, and forms the Negus, about 17 miles below Hillſborough.

ENOCH, in *Biography*, the ſon of Jared and father of Methuſelah, was the ſeventh in lineal deſcent from Adam, and born in the year B. C. 3382. Eminently diſtinguiſhed by his piety and virtue in a corrupt age, he was tranſlated to heaven in the 365th year of his age, without undergoing the pains of diſſolution. An apocryphal book, entitled "The Book or Prophecies of Enoch," has been aſcribed to this celebrated antediluvian, and is cited, as ſome ſay, by Jude in his epiſtle, and more certainly by Irenæus, Clement of Alexandria, and other ancient fathers. But this book was probably forged in the ſecond century. The Mahometans mention Enoch under the appellation of Edriſs, or Idriſs, and record many fables concerning him, which it is needleſs to mention.

Enoch, in *Ancient Geography*, a city ſaid to have been built by Cain in the land of Nod, where he and his family ſettled, and called after the name of his ſon Enoch. (Gen. iv. 16, 17.) Moſes places it, according to our tranſlation, on the eaſt of Eden; and Ptolemy mentions a city called Anuchtha in Suſiana, or Chuſiſtan, a country lying eaſtward from Chaldæa, which the learned Huet ſuppoſes to have been the ſame with that built by Cain. But it ſeems very improbable, that the city of Enoch, built before the flood, ſhould either withſtand the deluge or retain its ancient name, after ſo great a change in the ſurface of the earth. Beſides, Suſiana being a very fertile and pleaſant country, it is not likely that Cain ſhould be baniſhed thither, but rather to ſome barren and deſolate land, remote from the place of his nativity, and ſeparated by mountains, or other natural impediments, from intercourſe with his relations. As there was another Enoch (ſee the preceding article) beſides the ſon of Cain, it is not improbable that the city Anuchtha mentioned by Ptolemy, might have taken its name from him, whoſe memory would be held in veneration, or or from ſome other Enoch or Anoch, who might have lived after the flood. Grotius and Junius are of opinion, that the country into which Cain retired was the deſart of Arabia; but as this country lies on the weſt, and not on the eaſt of Eden, it is ſaid, that the words which we tranſlate "on the eaſt" of Eden ſignify no more than "before" or "over-againſt" Eden, according to the tranſlation of the Septuagint. According to this opinion; the land of Nod muſt have been Arabia Deſerta, or ſome part of it, and not Suſiana. Wells's Geog. vol. i.

ENODIS, Culmus, in *Botany*, a culm or ſtraw deſtitute of any knot, joint, or prominent tranſverſe interruption. See Culmus.

ENOLA, in *Geography*, a town of Naples, in the province of Lavora; 4 miles N. of Fundi.

ENOLMIS, Ενολμις, in *Antiquity*, a deſignation given to Apollo's prieſteſs at Delphi, becauſe ſhe ſat on the tripod which was called olmos, ολμος. Hence alſo Apollo is called Enolmos, Ενολμος. Pott. Archæol. Græc. lib. ii. cap. 9. tom. i. p. 275.

ENOMTEKIR, in *Geography*, a town of Swediſh Lapland; 150 miles N. of Tornea.

ENON, in *Ancient Geography*, a place of Judea, ſituated near Jordan in the half-tribe of Manaſſeh; which was the place in which John baptized, (John iii. 23.) becauſe there was abundance of water. This place was between Shalim and Jordan, about 8 miles from Scythopolis.

ENOPA, a town of the Peloponneſus, in Meſſenia, ſituated on an eminence at a ſmall diſtance N. of Cardamyla.

ENORAINE, in the *Manege*, a wither-wrung horſe, or one that is ſpoiled in the withers. The word is obſolete.

ENORCHIS, in *Natural Hiſtory*, the name given by many authors, to that ſpecies of ætites, or eagle-ſtone, in which the callimus, or internal nucleus, is not looſe, ſo as to rattle in it when ſhaken, but remains fixed to one ſide. The Germans call this *hodenſtein*. The outer cruſt is uſually of a whitiſh colour, and the internal nucleus is yellowiſh or browniſh, and it is uſually of the ſize of a pigeon's egg, and of the ſhape of the human teſticle; whence the name.

ENORMOUS, ſomething exceſſive, or monſtrous, eſpecially in bulk. The coloſſus of Rhodes was of an enormous ſtature.

The word is formed of the privative *e*, and *norma*, *rule;* q. d. *void of, or contrary to, rule or meaſure; contra normam.* In the corrupt ages of Latinity, they uſed *innormis*, and *inormis*.

In the French juriſprudence, *læſio enormis*, *enormous damage*, is that which exceeds half the value of the thing ſold.

ENOTAEVSK, in *Geography*, a town of Ruſſia, in the government of Caucaſus, on the Volga; 72 miles N.N.E. of Aſtrachan.

ENOUREA, in *Botany*, (a barbarous name, from the Caribæan word *Enourou*.) Aublet Guian. v. 1. 587. t. 235. Juſſ. 249. The only ſpecies is E. *capreolata*, a climbing ſhrub, with ſomething of the habit of a *Paullinia*, furniſhed with circularly-turned tendrils, pinnated leaves, ſpiked flowers, and a remarkable globular capſule of three valves, containing a globular ſeed imbedded in farinaceous pulp. Juſſieu has copied its characters from Aublet, but Schreber has paſſed it by.

ENQUEST, or Inquest, in *Law*, denotes an inquiſition of a jury by hearing of witneſſes.

This is the moſt uſual manner of trial, in all cauſes, both civil and criminal, within this realm. In civil cauſes, after proof is made, on either ſide, of ſo much as each party thinks good for himſelf; if the doubt be in the effect, it is referred to the diſcretion of twelve indifferent men, impanelled by the ſheriff for that purpoſe; and as they bring in their verdict, ſo judgment paſſeth: for the judge ſaith, *the jury findeth the fact thus*. See Writ *of Enquiry*. For the enqueſt in criminal cauſes, ſee Jury.

ENRICHED Column. See Column.

ENRICHING Plants, a term uſed, by the Engliſh farmers, to expreſs ſuch plants as are found to do good to land, rather than to exhauſt it, and in conſequence of which the ſame piece of land will produce a good crop of corn, though it would, without the aſſiſtance of their having been planted on it, have yielded a very poor one. The myſtery of this difference between plants, ſome of which are found to burn up, that is, impoveriſh lands, while others enrich it, and leave it fitter for ſucceeding crops than they found it, is explained by Mr. Tull. This author having obſerved, that breaking the earth, by digging, or horſe-hoeing, between the plants, gave them great increaſe, found that it was this practice that enriched the earth: and that, while corn and ſuch plants as ſtand cloſe, and cannot be hoed between, impoveriſh the ground, and ſuffer no means of enriching it again to be uſed, there were ſome other things, the crops of which being planted thinner, gave room to the earth to be ploughed, dug, or hoed between, and that theſe were the plants which were called the enriching kind by the farmers; and the whole ſecret lay in this, that the hoeing, ploughing, or otherways breaking the earth between them, in order to kill the weeds, enriched the ground greatly more, in proportion, than theſe plants exhauſted it; and the conſequence was, that though they had thriven very well, yet the earth was left richer than before, notwithſtanding all that they had imbibed from it. Tull's Horſehoeing Huſbandry, p. 37.

On this obſervation, this excellent author ſeems to have founded the ſyſtem of what he calls horſe-hoeing huſbandry, concerning which he has written a large and uſeful treatiſe. He found that this ſtirring up of the earth enriched it ſo greatly, that, where it was uſed in a proper manner, the kind of plant need not be changed, but that the ſame earth would yield a ſucceſſive ſeries of crops of the ſame plant, and that even without dunging, or ever lying fallow, and every crop, for a long time, would be better than the former ones. The method of ſowing, to this purpoſe, is not by ſcattering the corn with the hand, but ſowing it in rows, and leaving large intervals between, the naked earth of which might be turned up by the hoe. See Alley and Hoeing.

ENROL, in *Military Matters*, ſignifies the regiſtering of ſuch perſons as, being inliſted, or appointed, are placed upon the rolls, or ſtrength, of any particular regiment, troop, company, or portion of the military eſtabliſhment. The act of enrolment ſeems to be held neceſſary in proof of a ſoldier's having become a ſervant of the ſtate; equally ſo with the circumſtance of his having received pay, or ſome money, however trifling, in advance. For it does not appear reaſonable, that a ſoldier ſhould be puniſhed for abſenting himſelf from that employ in which he has not received either pay, or ſubſiſtence. It is not, however, to be underſtood, that, after being duly inliſted in the preſence of a magiſtrate, the recruit is at liberty to quit the party by whom he has been entertained: far otherwiſe; for though we hold a decided opinion regarding the devices often practiſed, to enſnare young men from their homes and families, we conſider it indiſpenſible that the ſacred engagement ſhould remain purely inviolate, after being once legally acknowledged

knowledged by the party to be enrolled. See INLIST and ENTERTAIN.

In regiftering, that is to fay in enrolling, a recruit, it is ufual to be very exact in afcertaining the place of his nativity, his religion or fect, his age, his ftate of health, efpecially whether he be fubject to fits, or be ruptured; while, for the purpofe of apprehending him in cafe of defertion, his height, complexion, general figure, the colour of his hair, and of his eyes, together with any particular diftinguifhing marks, whether natural or accidental, are all noted; comprifing, in the aggregate, what is called "defcription roll," of which a tranfcript is fent with each foldier, whenever draughted from one company or regiment to another.

Although a recruit is bound to the fervice after being examined and deemed competent to ferve, by the infpecting furgeon, and the fupervifor of the recruiting fervice of the diftrict refpectively, and after having acknowledged his being duly inlifted in prefence of a magiftrate, by whom the oath of allegiance fhould be tendered as fpeedily as convenience might admit, he is not faid to be enrolled until he is efficiently placed upon fome lift, whether under the recruiting officers, or in any particular regiment, troop, or company. In fome inftances, efpecially in the fervice of the Eaft India Company, the whole of the recruits are lodged at a general depot, under the charge of officers fixed thereat, but without being attached to any particular regiments until their arrival in India: in the mean while they are formed into fquads, under the immediate controul of noncommiffioned officers, by whom they are trained in the rudiments of military difcipline. We cannot with ftrict propriety fay, that fuch men are enrolled; nor, indeed, do we hold the term to be applicable until they are in a certain degree fixed in fome particular company, and entered upon its mufter-roll, as well as upon the long-roll of the regiment.

ENROLLMENT. See INROLLMENT.

Clerk of the ENROLLMENT *of fines*. See CLERK *of the Inrollments*.

ENS, in Latin *Anifia*, *Anafum*, or *Enfia*, in *Geography*, a town of Auftria, in the province called Upper Auftria, or the country above the Ens, in the diftrict of Traun. It is fituated on an eminence in the river Ens, which, not far from this place, falls into the Danube, 15 miles S. E. of Lintz, and 108 miles W. of Vienna. N. lat. 48° 11′. Its origin dates from the year 900, and it is built on the fame fpot where ftood the Laureacum of the Romans, one of their colonies, which was deftroyed by the Huns about the year 450. Ens is ftrongly fortified; its citadel is called *Enfeek*, or the corner of Ens.

ENS, in Latin *Anifus*, or *Anafus*, a river of Germany, which has its fource in the mountains of the former bifhopric, now grand duchy of Saltfburg, flows through Upper Auftria, and falls into the Danube near the town of Ens.

ENS, *Entity*, *Being*, in *Metaphyfics*, is applied, in a general fenfe, to every thing which the mind any way apprehends, and whereof it affirms, denies, proves, or difproves, any thing. This other philofophers call cogitable, and intelligible; and the logicians, thema.

ENS, in a lefs general fenfe, fignifies fomething that is, or exifts, fome way farther than by being conceived, or being capable of being conceived, in the mind. This is particularly called ens pofitivum, or reale; pofitive, or real, being. In oppofition to which ftands non ens.

ENS, in its proper, or reftrained fenfe, is that to which there are real attributes belonging, or that which has a reality, not only out of the intellect, but in itfelf. This is what is properly meant by *res*, thing; and what we otherwife call ens reale, and alfo fubftance.

ENS *rationis*, is that which depends wholly on the mind, or which exifts only in the imagination: of which they diftinguifh three kinds: ens rationis affectivum, which is done or produced by the mind, as knowledge; ens rationis fubjectivum, which is received into the mind, as fcience; and ens rationis objectivum, which is reprefented by the mind, as a chimera, a golden mountain, or the like. Which laft, if it have no other manner of being, i. e. if it be prefented fo as it does not, or cannot be, is what we moft properly call ens rationis. The generality of fchool philofophers, and the Peripatetics among the reft, affert, that there are of thefe entia rationis objectiva. Others deny there are, or can be, any fuch things.

ENS, or ENS *primum*, in the *Ancient Chemiftry*, denotes the moft efficacious part of any natural mixed body, whether animal, vegetable, or foffile, wherein all the qualities or virtues of the ingredients of the mixed are comprehended in a fmall compafs.

Paracelfus pretends to have been able to feparate the ens primum from bodies, and with it to effect prodigious things towards the renovation and reftoration of youth; but his proceffes are fo obfcurely delivered, that no body has been induced to try them.

ENS *primum falium*, a name given by Paracelfus to a preparation of fea falt, which he calls alfo a perpetual oil, and *fal circulatum*, which fee.

ENS *martis*, and *Ens veneris*. If the filings of iron or of copper be mixed with fal ammoniac and ftrongly heated, a decompofition, greater or lefs in proportion to the quantity of metal employed, will take place: the ammonia will be liberated in the form of gas, while the muriatic acid will combine with the metal. The metallic muriat thus formed will fublime at nearly the fame heat as the undecompofed refidue of the falt, whence will refult an accurate mixture of the two in the form of flowers, or a cruft of a red colour: if iron filings have been ufed, and of a green colour if copper has been employed. The former of thefe is ens martis, the latter, ens veneris.

ENSATÆ, in *Botany*, from *enfis* a fword, alluding to their fword-fhaped leaves, a name very happily applied by Mr. Gawler to the natural order of *Irides* of Juffieu, it being defirable that, if poffible, every natural order fhould have an expreffive name, independent of any particular genus it may contain; or at leaft that its name fhould not be a mere unchanged repetition of that of any fuch genus. This order is illuftrated by the able botanift above-mentioned, in Sims and Konig's Annals of Botany, v. i. 219, and efpecially in Curtis's Botanical Magazine.

ENSCONCED, in the *Military Art*. See INSCONCED.

ENSEELED, in *Falconry*, a term ufed for a hawk which has a thread drawn through her upper eyelids, and made faft under her beak, to obfcure her fight.

ENSEINT, in *Law*, a term ufed to denote a pregnant woman.

ENSEMBLE, a French term, fometimes ufed in our language, literally fignifying *together*, or *one with another*; being formed from the Latin, *in*, and *fimul*.

In *Architecture*, we fay, the enfemble, or tout enfemble of a building; meaning the work or compofition, confidered together, and not in parts; and fometimes alfo the relative proportion of the parts to the whole. All thofe pieces of building make a fine enfemble.

To judge well of a ftatue, or other work of fculpture, one muft firft examine whether the enfemble be good.

The tout enfemble of a painting, is that harmony which refults from the diftribution of the feveral objects of figures whereof

whereof the whole is compofed. This picture is good, taking the parts feparately: but the tout enfemble is bad.

Ensemble, *Fr.* together. This adverb, ufed fubftantively, and received in the French mufical technica, is, according to Rouffeau, invefted with a very extenfive fignification. To regard an object in its enfemble or totality, is to confider the effect which the feveral parts produce, when united in a whole.

It is only in the execution of a piece of mufic, that this term is applicable, when the performers are fo perfectly together in time and tune, feeming to be all fo much animated by one foul, that they communicate exactly to the ear, all that the eye can fee in the fcore.

The being together does not merely depend on the accuracy with which each reads his part, but in the intelligence with which he feels its peculiar character and connection with the whole; whether in the exactitude of phrafeology, the precifion of the movements, or feizing the inftant and degree of pianos and fortes; or finally in the nice attention to fuch ornaments, which the author has thought fo neceffary as to be indifpenfible. It is in vain for muficians to have abilities, they can never be together without an intelligence of the author's defigns, and perfectly underftanding each other: for it would be impoffible to keep together a band of performers that are deaf, nor in the execution of mufic in a ftyle with which they are totally unacquainted. It belongs to the mafters, conductors, and leaders of an orcheftra, to guide, check, or accelerate individual performers, and to keep them together in the aggregate, which is always the office of a judicious firft violin: who, by a certain firmnefs and energy in his manner, ftrongly impreffes the character of the piece in every ear. The vocal part is fubordinate to the bafe and the time; the firft violin ought to watch and follow the voice; the repienos fhould liften to and be guided by the firft violin: and, finally, the harpfichord or piano-forte, at an opera where the compofer is fuppofed to fit, fhould be the principal and moft important guide of the whole. In general, the more character there is in the ftyle, periods, phrafes, melody, and harmony, the more eafy it will be to feize the enfemble; becaufe the fame idea, ftrongly impreffed on all minds, will prefide in the whole execution. On the contrary, when the mufic fays nothing, and nothing is heard but a fucceffion of notes without meaning: then as there is no whole to which each performer can refer his part, the enfemble goes ill.

This (fays M. Rouffeau) was the reafon why French performers could never be together.

ENSENE', called alfo *Infiné*, *Scheick Abadè*, and by the Arabs *Enfiné*, in *Geography*, a town of Egypt, fituated towards the middle of the Said, eaft of the Nile, and dependent on the province of Achmounain, which is on the other fide. Abulfeda reprefents it as an ancient city, furrounded by a well cultivated country, abounding in fruits and harvefts. But thefe fertile plains have difappeared with their inhabitants, and given place to fands and deferts. See Antinoe.

ENSHEMESH, i. e. *the fountain of the Sun*, a town or fountain, which lay on the frontiers of Judah and Benjamin. (Jofh. xv. 7.) The Arabians give this name to the ancient metropolis of Egypt, which the Hebrews called *On*, and the Greeks *Heliopolis*.

ENSIFORM, in *Anatomy*, a term equivalent to xiphoid, and meaning dagger-fhaped. It is applied to the cartilage placed at the lower end of the fternum. See Trunk.

Ensiform *Leaf*, in *Botany*, a vertical two-edged leaf like a fword, as in many fpecies of Iris. See Leaf.

Ensiform *Cartilage*. Dr. Hunter remarks, that, "if this cartilage be forced inwardly by a blow, it will occafion vomiting and violent pains, by preffing againft the pylorus: in this cafe, it would be proper to lay it bare and elevate it." However, the fame eminent writer admits, that as part of the diaphragm arifes from the cartilage, the latter would be likely to be drawn out of its proper fituation again by the action of fo powerful a mufcle.

ENSIGN, in *Military Affairs*, is an officer whofe duty it is to carry the colours; hence, when a youth firft obtains a commiffion in the infantry, he is faid to "receive a pair of colours." This is the firft gradation above the rank of cadet, or volunteer, but is the loweft of all the ranks in which commiffions are held, and though obtainable by purchafe, cannot be realized without fatisfactory recommendations, and the approval of the commander of that regiment to which the nomination is to be made. From this, of courfe, fome deviations are occafionally admitted; but the neceffity for afcertaining that none but proper perfons be included within the circle of commiffioned officers, occafions confiderable ftrictnefs to be obferved in this particular; notwithftanding which, inftances have occurred of men, by no means eligible to fo honourable a diftinction, having obtained commiffions even in fome of what are technically termed "crack regiments."

The duty of an enfign requires much attention, and at times fome fhare of bodily ftrength; for, on a windy day, when the colours are fully difplayed, a puny perfon might fuffer confiderable inconvenience; and, indeed, at all times, though fupported in a fling, the colours are rather oppreffive; efpecially to thofe unaccuftomed to carrying them. With regard to the ftation of the enfign when acting with his company, or when bearing the colours, we refer to the head of Evolution; where the various changes of locality to which this officer is fubject will be exhibited.

It is proper to remark, that although there are two ftands of colours to each regiment, only one of them is properly called "the enfign." The flag, confifting of the union only, is called the king's colour, and always takes poft of the other, which being in general of the fame colour as the facings of the corps, and bearing any device or motto, by which it is diftinguifhed, is appropriately called "the regimental enfign."

In cafe of defeat, the enfigns bearing the colours muft be very careful to collect as many of the fugitives as poffible for the purpofe of rallying the corps, or, at leaft, of preventing it from being further difgraced by the lofs of their facings, which formerly was an infeparable confequence annexed to the lofs of the colours. This regulation certainly muft often produce confiderable enthufiafm; and we may reafonably conclude, that the attack made by a regiment under fuch a privation, (which could only be remedied by its taking the colours of their opponents,) muft be of the moft arduous defcription. In truth, we find in every walk of life, that when an imputation is to be removed, confiderable energy is created by the exifting difgrace; and, that the moft determined refolution is formed not only to remove it, but to obtain a claim to pre-eminent confideration in future.

The pay of an enfign in the Guards is five fhillings and tenpence daily; in the line, only four fhillings and eightpence: a fum by no means adequate to the maintenance of a young gentleman in fuch ftyle as is at prefent too generally prevalent in almoft every regiment. So far is this carried, that many young men of confiderable merit are often compelled to exchange, or even to fell out; becaufe their finances are inadequate to bearing a fhare in the mefs expences,

expences. Nor is it unufual for a notice to be given by the agent, or other perfon, to the candidate for a pair of colours, that fuch a certain fum annually will be needful, beyond his pay, to enable his keeping on a par with his brother officers. We are credibly informed, that in fome regiments it is actually impoffible for an officer to affociate with his peers, unlefs he may poffefs from 500 to 1000*l.* income, over and above his allowances!

When we analyfe this, we cannot but confider it to be a national evil, and that too of no fmall extent. We are far from wifhing to fee the refpectability of our officers, in the fmalleft degree, tarnifhed; but it certainly cannot fail to ftrike, even the moft fuperficial obferver, that fuch an excefs of expence amounts nearly to a prohibition of the middling claffes, and operates in the fame manner, though not fo avowedly, as the ancient regime of France, which profcribed all but thofe of noble family, or of eftablifhed defcents through generations devoid of mercantile fpeculation, from entering within the military pale. The very drefs of fome corps muft coft fo much as to preclude the poffibility of moderate fortunes being admitted. What fhall we fay to the charges made on a young gentleman's purfe, when it is ftated, that in fome regiments of horfe, full fix hundred pounds may be required to equip him as a cornet! While an equal fum per annum, will be *in requifition* (here the term feems peculiarly appropriate) to enable him to eat, drink, and appear in the fame company with his brother officers. Nor is this all; for the commiffion may coft a large fum, fuch as added to the other items would form a capital wherewith the youth might purchafe an annuity, far exceeding the pay he would be likely to receive, for at leaft ten or twelve years. We believe the Scotch regiments are no flouches in the field, and that they bear as many good characteriftics as any in our fervice; yet their drefs is generally very plain, and their fare very far from fumptuous. They are born economifts; and from being brought up in a hardy, active routine, are capable of enduring great fatigue, and of putting up with various privations, which, to a perfon brought up with lefs ceremony, and habituated to the enjoyment of various luxuries, might be at leaft unpleafant, if not abfolutely diftreffing.

The Turkifh enfigns are horfes' tails; the number of which diftinguifhes the rank of their commanders; the fultan has feven, the grand vizier only three, &c. Thofe of the Europeans are pieces of taffety, with divers figures, colours, arms, and devices, thereon. Xenophon tells us, that the enfign borne by the Perfians was a golden eagle on a white flag; the Corinthians bore the winged horfe, or Pegafus; the Athenians, an owl; the Meffenians, the Greek letter M; the Lacedæmonians, the Λ.

The Romans had a great diverfity of enfigns; the wolf, minotaur, horfe, boar, and at length the eagle. See Signa.

A military enfign, on a medal of a Roman colony, denotes it a colony peopled with old foldiers.

Ensign, in *Naval Affairs*, is the large flag hoifted at the ftern of a fhip, whether of war or in the merchant fervice, and denotes the country to which fhe appertains, or the government under whofe protection and authority fhe is navigated. Of the feveral diftinguifhing enfigns, a more ample defcription will be found under the head Flag: we fhall briefly obferve in this place, that this, as well as moft of the colours of fhips, whether *jacks* or *pennants*, are commonly conftructed of bunting, and, that it is ufual to make them fo ample as to occupy two-thirds of the flag-ftaff in height, and to give them depth enough juft to touch the furface of the water, when in a quiefcent ftate. All enfigns are hoifted with their unions, or diftinguifhing cantons, uppermoft, next to the truck on the head of the flag-ftaff: when hoifted in the fhrowds with the union, or diftinguifhing canton, lowermoft, fo as to reverfe all the figures, decorations, or infcriptions, it is indicative of diftrefs. The liberality of fome nations has been confpicuous in forbearing from making prizes of veffels fo circumftanced, provided their commanders have engaged to return to the neareft port, without intermediately offering any violence to fuch as they might meet, there to remain in ordinary until the conclufion of the war.

The difplay of an enfign in prefence of a ftrange fail is generally confidered a mark of civility during times of peace, and in times of war ferves to diftinguifh between friends and foes. During the latter period, fuch veffels as do not hoift their enfigns may be reafonably fufpected to be privateers, or to be defirous of evading every kind of communication. So long as the enfign remains hoifted, during an engagement, the fhip is to be confidered in a ftate of defiance; but when it is lowered, fhe is faid to ftrike; that is, to give up the conteft, and to fubmit, as a prize to her opponent. It occafionally happens that a fhip's enfign ftaff, or the haulyards by which the enfign is hoifted to the mizen-peak, is fhot away; this does not indicate fubmiffion; on the contrary, the annals of warfare exhibit many inftances of extraordinary courage in individuals, who, at fuch moments, have ran aloft, or even ftood on the poop, there to fuftain a portion of the enfign as a token of the moft determined oppofition. In the Britifh fervice we have three enfigns, namely, the white, the red, and the blue; the firft is divided into equal portions, by a broad St. George's crofs of red, of which the upper canton, or quarter, is filled up with the union. The fecond and third are both plain, with the exception of the union in the fame canton. Thefe feveral enfigns indicate the rank of the admiral under which a fhip of war is commiffioned, or employed. Thus, an admiral of the white bears a white, or, as it is commonly called, a St. George's enfign, at the main top-gallant maft head; a vice admiral of the white has one at the fore top-gallant maft head; and a rear admiral one at the mizen top-gallant maft head; the fame rules of precedence obtain, with the admirals, vice-admirals, and rear-admirals of the red and blue refpectively; each bearing a flag of his proper colour at that maft head correfponding with his rank. When fleets are feparated into fquadrons or divifions, each fhip affumes for the time the enfign of that admiral who commands the fquadron, or divifion, in which it acts. The fame is obferved by all veffels acting under any particular port-admiral; all under his authority invariably bearing an enfign conformable to his defignation, whether of the white, red, or blue.

ENSIGNCY, denotes the rank of that officer who bears the enfign or colours of a regiment of foot; and correfponds with that of "cornet" in the cavalry, and of "fecond-lieutenant" in the artillery. It is, perhaps, one among the curious anomalies which pervade many parts of our fyftem, that an enfigncy fhould exift in the engineer department, there being no colours to be carried in that corps, while the colours of the artillery battalions are borne by the fecond lieutenants.

An enfigncy in a marching regiment may generally be obtained for about three hundred pounds, when ferving within the realm: but in various fituations abroad, efpecially in the Eaft Indies, where an increafe of pay is given, the price is ufually much higher. See Ensign, *military*.

ENSISHEIM, in *Geography*, a handfome town of France, in the department of the Upper Rhine, in the diftrict of Colmar, with a population of 1809 individuals. It is ſituated on the river Ill, 12 miles N. of Mulhauſen, 12 miles S.W. of Briſack, 294 miles S. by E. of Paris. N. lat. 47° 52′, and is the chief place of a canton, which has a territorial extent of 257½ kiliometres, 17 communes, and 10,122 inhabitants.

ENSTASIS, Ενστασις, of εν and ἵστημι, *ſtatuo*, in *Logic*, a manner of replying to an opponent, either by confuting his argument, or denying the juſtneſs of his concluſion. Voſſ. Rhet. lib. iii. p. 380.

Enstasis, in *Medicine*, a term uſed to expreſs the ingreſs of moleculæ into the vacuity of the pores which obſtruct them, and thereby cauſe diſeaſes. It is a word familiar with Eraſiſtratus and Aſclepiades, who was a follower of Democritus, and taught that moſt diſeaſes were cauſed by ſuch an ingreſs of matter into the pores. Thus Aſclepiades defined a phrenzy to be ſuch an enſtaſis in the membranes of the brain. Plutarch, in his precepts of Health, alſo mentions this enſtaſis: and Galen and Caſſius, who is ſuppoſed to have been of the ſect of the Rationaliſts, expreſſes the ſame ſenſe by the ſame word.

ENSTORF, in *Geography*, a town of Germany, in the circle of Bavaria and Upper Palatinate; 22 miles N. of Ratiſbon.

ENT, *Sir* George, in *Biography*, an eminent phyſician, was born at Sandwich, in the county of Kent, on the ſixth of November, 1604. After going through the uſual courſe of claſſical inſtruction, he was ſent to Sidney college, in Cambridge. He afterwards travelled to the foreign ſeats of learning, received the degree of doctor of phyſic at Padua, and on his return was incorporated in the univerſity of Oxford, on the ſeventh of November, 1638. During the uſurpation of Cromwell he ſettled in London, where he obtained conſiderable eminence in the practice of his profeſſion: he was elected a fellow, and afterwards preſident of the College of Phyſicians; and at length his merits were rewarded with the honour of knighthood by king Charles II. He enjoyed for a long period the eſteem and confidence of the public, and died at the age of eighty-five, on the 13th of October, 1689. He was buried in the church of St. Lawrence in the Jewry. He was a very intimate friend of the celebrated Dr. Harvey, and wrote a defence of his great diſcovery, entitled "Apologia pro circulatione ſanguinis contra Æmilium Pariſanum," which was publiſhed in 8vo. in the year 1641, and again in 4to. in 1685. About 1651 he prevailed with Dr. Harvey to conſent to the publication of his "Exercitationes de generatione animalium," which he ſuperintended, and preſented to the College of Phyſicians in a ſenſible and elegant dedication. He likewiſe publiſhed a treatiſe of his own in 1679, which was reprinted in 1682, entitled, "Animadverſiones in Malachiæ Thruſtoni, M. D. diatribam de reſpirationis uſu primario," in 8vo. His works were collected, and publiſhed in one volume 8vo. at Leyden in 1687, under the title of "Georgii Entii Opera omnia Medico-Phyſica, &c.:" and after his death, his "Obſervationes ponderis teſtudinis, cum in autumno terram ſubiret, cum ejuſdem ex terra verno tempore exeuntis pondere comparati, per plures annos repetitæ," were printed in the Philoſophical Tranſactions, N° 194, anno 1691. See Eloy Dict. Med. Biog. Dict.

ENTABLATURE, in *Architecture*, is that part of an order of column which is over the capital, comprehending the architrave, frize, and corniche.

The word ſeems formed of *tabulatum* or *intabulamentum*.

The entablature is alſo called the *trabeation*, and by Vitruvius and Vignola *ornament*. It is different in the different orders; indeed, it conſiſts of the three grand parts or diviſions above-mentioned, in all; but thoſe parts conſiſt of a greater or leſs number of particular members or ſubdiviſions, as the orders are more or leſs rich.

Vignola makes the entablature a quarter of the height of the whole column, in all the orders.

In the Tuſcan and Doric, the architrave, frize, and corniche, are all of the ſame height; in the Ionic, Corinthian, and Compoſite, the whole entablature being fifteen parts, five of them are allowed for the architrave, four for the frize, and ſix for the corniche. See Ionic, Corinthian, &c. and Column.

Entablature, or *Entablament*, is ſometimes alſo uſed for the laſt rows of ſtones on the top of the wall of a building, whereon the timber and covering reſt.

As this is frequently made to project beyond the naked of the wall to carry off the rain, ſome authors call it in Latin *ſtillicidium*, or *drip*. Such an entablature does not ſtand out far enough; it lets the water fall on the foot of the wall.

ENTABLER, in the *Manege*, is ſaid of a horſe whoſe croupe goes before his ſhoulders, in working upon volts; for, in the regular manege, one-half of the ſhoulders ought to go before the croupe. Thus we ſay, your horſe entables; for, in working to the right, he has an inclination to throw himſelf upon the right heel; which fault you may prevent, by taking hold of the right rein, keeping your right leg near, and removing your left leg as far as the horſe's ſhoulder. A horſe cannot commit this fault without committing that called aculer; but aculer may be without entabler.

ENTAIL, in *Law*, ſignifies fee tail, or fee entailed, that is, abridged, curtailed, or limited to certain conditions. For the docking of an entail, ſee Docking and Recovery. See Tail and Estate, &c.

ENTALIUM, the *pipe-ſhell*, in the *Materia Medica*, a ſhell of the ſame genus with the dentalia, being a ſpecies of the tubuli marini. It is frequent in the Eaſt Indies, and ſometimes is found on our own ſhores. The virtues aſcribed to it are the ſame with thoſe of the dentalium; but neither of them have any title to more than thoſe of alkaline abſorbents, like the other teſtaceous powders.

ENTE', in *Heraldry*, literally implies *engrafted*, and is uſed by foreign heralds to expreſs a method of marſhalling, little known among us; yet we have an inſtance of it in the fourth grand quarter of his majeſty's royal enſign, whoſe blazon is Brunſwick and Lunenburgh, impaled with ancient Saxony, *enté in pointe*.

ENTELECHIA, Εντελεχεια, of εντελεχης, *perfect*, a Greek term, by which Ariſtotle defines the ſoul; and which, not occurring in any other author, has given the critics and philoſophers infinite perplexity to diſcover its true meaning. See Soul.

Hermolaus Barbarus is even ſaid to have conſulted the devil about it; after which, in his paraphraſe on Themeſtius, whether from the devil or himſelf, we know not, he renders it by *perfectihabia*, which is not a whit the clearer.

Cicero, whoſe interpretation ſhould be preferable to that of any modern, defines entelechia (Tuſc. Queſt. lib. i. cap. i.) to be, "a certain, continued, and perpetual motion;" whence it ſhould ſeem, that Ariſtotle took the ſoul for the mode of the body; a continuous motion being, doubtleſs, a mode of body.

The common Peripatetics hold entelechia to ſignify act, and under it ſuppoſe the form of the compound or animal to be underſtood.

Laſtly, others, and thoſe the lateſt Peripatetics, agree, that the act, or entelechia, whereby Ariſtotle meant to explain

plain the nature of the foul, is either fome mode of the body, as motion, or it is nothing.

ENTENDEMENT, in *Law*. See INTENDMENT.

ENTER, *To, a Hawk*, among *Sportfmen*, is ufed of a hawk when fhe begins to kill.

ENTER, *To, a Hound*. See ENTRANCE *of Hounds*.

ENTERADENES, of εντερον, *inteftine*, and αδην, *gland*, in *Anatomy*, a name by which many authors have called the inteftinal glands.

ENTERENCHYTÆ, of εντερα, *the vifcera*, and εγχυω, *I infufe*, in *Medicine*, a name given by authors to the feveral inftruments contrived for throwing clyfters into the bowels; fuch as the bladder and pipe, the fyringe, and the like, for liquid clyfters; and the box with the double pipe for conveying the fmoke of tobacco. See CLYSTER, and FUMIGATOR.

ENTERFERING, in the *Manege*. See CUTTING.

ENTERITIS, in *Medicine*, from εντερον, *inteftine*, fignifies an inflammation of the inteftines. The difeafe has been varioufly denominated *ileus*, ειλεος, *iliac paffion*, *chordapfus*, &c.

The fymptoms of inflammation of the bowels generally come on fuddenly. An acute and fixed pain, with a fenfe of heat in the abdomen, more efpecially about the umbilicus or navel, often with a feeling of twifting in that part, attacks the patient; this pain is increafed by preffure. Previoufly to its occurrence, or together with it, the ufual fymptoms of fever come on, fuch as rigor or fhivering, followed by flufhes of heat, thirft, and drynefs of the tongue; the pulfe becomes frequent, hard, and commonly fmall; confiderable anxiety enfues; the bowels are obftinately coftive; the ftomach is foon deranged; and eructations, naufea, and vomiting fucceed. As the diforder advances, the pain becomes more acute, without any difpofition to evacuation; the abdomen becomes diftended with flatulence, and more tender under preffure; and the urine is often voided with difficulty and pain. If the inflammation be not alleviated, gangrene generally enfues, often within twenty-four hours from the commencement of the difeafe, and terminates the life of the patient.

The occurrence of gangrene is indicated by a fudden remiffion of the pain, while, at the fame time, the ftrength fails, the pulfe finks, the voice grows feeble, the countenance fhrinks, and affumes even a cadaverous afpect, yet the diftenfion of the belly is not diminifhed, but often increafed. This tendency to terminate fpeedily in mortification conftitutes the great danger of inflammation of the inteftines. Sometimes the difeafe terminates in fuppuration, which, though lefs rapidly fatal, moft commonly wears out the patient's ftrength and life in a lingering manner; but occafionally this condition ends in recovery. The formation of pus is indicated in this difeafe, as in other internal inflammations, by the remiffion, but not total ceffation of the pain, and by the occurrence of frequent fits of rigor, and fometimes by a purulent difcharge by ftool. But the difeafe, efpecially when the aid of medicine is early and actively obtained, frequently terminates favourably, by refolution, as it is called; *i. e.* by a gradual diminution and ceffation of the fymptoms. If the pains abate gradually, and the tendernefs and diftenfion of the abdomen leffen, while the pulfe becomes fofter and fuller, natural evacuations of fæculent matters are paffed, and a free general perfpiration breaks out, this favourable termination may be anticipated. Whereas, the continuance of the conftipation, and of the fixed pain, the increafe of the ficknefs and vomiting, the occurrence of the fymptoms juft defcribed as indicative of gangrene, efpecially if accompanied with hiccup and cold fweats, are among the unfavourable prognoftics.

The principal fource of miftake, into which the practitioner is likely to fall in treating this difeafe, is in confounding it with *colic*; a fpafmodic diforder, which requires a treatment effentially different, but which, neverthelefs, occafionally terminates in enteritis. The diagnoftic fymptoms of the two complaints have been already ftated at length, under the former article. See COLICA.

Enteritis occurs moft commonly in perfons fomewhat advanced in life, generally after the age of forty, or fifty; and it feems to be moft frequent in plethoric habits, and in thofe particularly who indulge in indolence and full living. In fome individuals there appears to be a conftitutional irritability of the inteftines, which renders them liable to attacks of inflammation, upon the application of flight caufes.

The *exciting caufes* of enteritis are various; among the moft common are obftructions in the bowels, which neceffarily retain the fæces, until thefe, by their quantity or quality, become extremely irritating, and excite inflammation. Thefe obftructions to the paffage of the ftools through the inteftinal canal are occafioned by different circumftances. A fpafmodic contraction of any part of the canal, as in colic, if it continue for any confiderable time, is liable to induce inflammation: a ftricture, occafioned by a chronic thickening of the coats of the bowels, fometimes brings it on: *intro-fufception*, or the inverted paffage of one part of the gut into the adjoining part, produces a fimilar effect; as well as the ftrangulation of the inteftine from *hernia*, or rupture: the formation of calculus in the inteftinal canal, which, though a rare occurrence, fometimes takes place, may alfo occafion a fimilar obftruction, and confequent inflammation. Enteritis is likewife excited by irritating fubftances conveyed into the inteftines, which, by their bulk, fhape, or indigeftibility, or by their chemical or fpecific acrimony, produce much excitement in the canals. Thus, the fwallowing of hard kernels, feeds, or ftones of fruit, of pieces of metal, &c. has often induced the difeafe; and the prefence of *fcybala*, or hardened fæces, and of calculous concretions, operates partly by the immediate irritation which they occafion. Thus alfo, ftrong concentrated acids or alkalis, fpirituous liquors, high feafoned food in large quantities, draftic purgatives, worms, &c. in the inteftinal canal, have excited inflammation in it in different inftances. Hence the difeafe has fometimes been the immediate effect of repletion, or of a fit of intoxication: and even a mild cathartic, when the bowels were loaded with much hardened fæces, which the medicine was incapable of removing, has, in fome rare cafes, produced inverted motion and *intus-fufception*, terminating in enteritis. A very common caufe of inflammation in the bowels is the application of cold to the legs and feet, or to the abdomen itfelf, efpecially if fudden or long continued. The retroceffion of gout, rheumatifm, eryfipelas, or chronic eruptions, from the external parts, is fometimes followed by fymptoms of inteftinal inflammation.

In the *cure* of enteritis, as in all other acute inflammatory difeafes, the leading object is to remove the inflammation, from which all the other fymptoms of the difeafe originate. This, though apparently an identical propofition, cannot be too ftrongly inculcated, in the treatment of enteritis; becaufe the exceffive conftipation of the bowels, which, in common with the reft of the fymptoms, is in general merely an effect of the inflammatory condition of the bowels, in fome part, is often attacked by the inattentive practitioner with active purgative medicines, as if it were the primary object, and the fource of all the mifchief. The inflammation is to be fubdued by blood-letting, from a large orifice, to an extent which muft be various according to the conftitution of the patient, and the violence of the fymptoms. This depletion may be aided in its effects by the application of leeches, and afterwards of a blifter to the abdomen; and by the ftricteft abftinence from all ftimulating and nutritious aliment. The blood-letting muft be repeated in a fhort time, if the fymptoms do not abate, and the ftrength of the patient is fufficient to fupport the evacuation; which can only be determined by the obfervation and experience of the practitioner. If the pulfe fhould become fuller and lefs wiry after the operation, it will afford a ftrong reafon for the repetition of it, fhould the continuance of other fymptoms appear to require it. The ufe of emollients externally was in great vogue among the ancients; and fomentations, or, what is better, the warm bath, may be reforted to with advantage. Celfus recommends the ufe of warm cataplafms, frequently changed, and covering the greater part of the trunk, "à mammis ufque ad inguina et fpinam," and alfo a bath of warm oil;—"demittere totum hominem in calidum oleum." De Medicinâ, lib. iv. cap. 13. The dirty applications of living animals, or the fkins of thofe recently killed, can only operate as emollients, and are neceffarily lefs effectual than fomentations; they are at prefent, therefore, fallen into difufe. Sydenham recommended the application of a live whelp to the abdomen in thefe cafes. Opera, fect. i. cap. 4. p. 77. Edit. Lugd. 1726.

It muft be obvious, that before the inflammation of the inteftines is leffened or removed by thefe meafures, any additional irritation to the membranes, already in an acute ftate of fenfibility, whether by the immediate ftimulus of a cathartic medicine, or by the contents of the bowels being forced forwards to the inflamed part, muft tend to aggravate the diforder, rather than to relieve it. In fact it is ufually found, that purgatives, given by the mouth, are not fuccefsful, where this previous diminution of the inflammation has not been effected. And when this has been accomplifhed, fome of the milder purgatives, as the neutral falts, fhould firft be adminiftered, the action of the inteftines downwards being at the fame time folicited by emollient glyfters, which alfo contribute to the fame relaxant purpofes as the external fomentations. Dr. Gregory ufed to remark, in his lectures, that a purgative medicine had often been known to operate as foon as a blifter, applied to the belly, began to rife, which had not acted previoufly: and this obfervation is ftill more commonly verified, after a free evacuation by blood-letting. See Edinburgh Med. and Surg. Journal, vol. i. p. 64. Some practitioners have attempted to open a paffage for the fæces, by mechanically diftending the large inteftines, by throwing up five, fix, or feven pints of warm water with an injecting fyringe. This expedient may be ufeful in fpafmodic colic; but it is objectionable, in enteritis, on feveral grounds. Such diftenfion can only be accomplifhed in the colon, or great gut; whereas the obftruction by inflammation is commonly in fome portion of the fmall inteftines, and therefore out of the reach of the enema. In the next place, any forcible diftenfion of an inflamed and thickened canal, if it could be accomplifhed, would rather conduce to an increafe of the inflammatory condition, than to leffen it by the removal of fæces. In a word, all meafures applied to the inflamed inteftine fhould be mild; fince forcible ones cannot but augment the inflammation, upon which the impeded function of the organ depends. By way of glyfter, therefore, a little common falt, magnefia vitriolata, or infufion of fenna, with gruel or warm water, will probably anfwer every good purpofe that can be expected from fuch an expedient. Tobacco fmoke has been often injected when milder means have failed, or infufions of tobacco; but their fuccefs, we believe, has not been often experienced. Indeed tobacco injections are liable to produce great ficknefs and irritation, if that herb be not ufed in very fmall quantities.

The extreme ficknefs which often accompanies enteritis, and by which every thing that is taken into the ftomach, whether liquid or folid, is rejected, renders it difficult, in fome cafes, to produce any effect upon the bowels by internal medicine. In this cafe, the irritability of the ftomach may be quieted by the faline effervefcing draught, or by a fmall opium pill, or, if this be rejected, by an opiate given in a glyfter; after which the neceffary laxative medicines may be retained, and accomplifh the intended object. It fhould be obferved, however, that the ftimulus of opium will prove rather injurious than ufeful, while the inflammation is unfubdued.

Where the inflammation has arifen from ftrangulated hernia, the operation, by which the ftrangulation is removed, and the inteftine returned into its place, can alone fave the life of the patient. See Hernia.

We have already had occafion to allude to a remedy for conftipation of the bowels, which has been recommended as a laft refource, namely, a quantity of crude quickfilver; and to point out the abfurdity of the hypothefes, which have led to its ufe, as well as fome of the ill confequences of it. Sydenham reprobates the practice, which appears to have been firft adopted about his time. Loc. cit. p. 76. See Constipation.

When the inflammation of the inteftines has been fubdued, the utmoft caution fhould be employed, with a view to the prevention of a relapfe, to which the convalefcent from enteritis is extremely liable. A thin, fpare, and laxative diet, confifting of vegetable fubftances, of gruels, or barley water, or thefe mixed with milk, muft be adhered to moft rigidly for a confiderable time after recovery; and all acrid, ftimulating fubftances, or thofe which are difficult of digeftion, fhould be moft fcrupuloufly avoided. The moft fatal effects have been obferved to take place, in fome inftances, from returning too foon to ordinary diet, after the removal of inflammation of the bowels. In order to guard againft a future recurrence of the difeafe, the application of cold to the abdomen and feet fhould be prevented by warm cloathing; and the occurrence of coftivenefs at all times avoided, by laxative diet or medicine, fo that no accumulation of fæces can take place, and the fteady action of the bowels be conftantly preferved.

ENTERMEW. See Falcon.

ENTEROCE'LE, (from ἔντερον, *an inteftine*, and κήλη, *a tumour*, or *rupture*,) in *Surgery;* a hernia is fo termed, when its contents are entirely compofed of inteftine.

ENTERODYNIA, from ἔντερον, *inteftine*, and ὀδύνη, *pain*, in *Medicine*, a term ufed by fome writers, as nearly fynonymous with colic, but expreffing a minor degree of pain; fuch, for inftance, as arifes from the irritation of vitiated bile, loaded bowels, worms, &c. and which, therefore, laxative medicines generally relieve.

ENTERO-EPIPLOCE'LE, (from ἔντερον, *an inteftine*, ἐπίπλοον, the *omentum*, and κήλη, *a tumour*,) in *Surgery*, a term applied to a hernia, which contains both a portion of the bowels, and a piece of the omentum.

ENTERO-HYDROCE'LE, (from ἔντερον, *an inteftine*, and ὑδροκήλη, *a dropfy of the fcrotum*,) a fcrotal hernia, containing a good deal of fluid.

ENTEROLOGY, from ἔντερον, *inteftinum, a gut*, and λόγος, *fermo, difcourfe*,) is properly a treatife of the bowels. Though the word is generally underftood to include the contents

contents of three cavities, head, breaft, and all the vifcera or belly.

ENTERO'MPHALOS, (from ἐντερον, *an inteftine*, and ὀμφαλος, the *navel*,) a hernia at the navel, and containing inteftine.

ENTERORA'PHE, (from ἐντερον, *an inteftine*, and ῥαφη, *a future*,) a future of the bowels.

ENTERO'SCHEOCELE, (from ἐντερον, *an inteftine*, and οσχεοκηλη, *a rupture, or hernia fituated in the fcrotum*,) a fcrotal hernia, the contents of which are entirely compofed of inteftine.

ENTERPEN, *To*, in *Falconry*, is a term applied to a hawk, when her feathers are wrapped up, fnarled, or entangled.

ENTERPLEADER, in *Law*. See INTERPLEADER.

ENTERPRISE, denotes an undertaking attended with fome difficulty and danger.

ENTERPRISE, in *Military Affairs*, appertains rather to thofe defultory expeditions which often prove of confiderable importance in their confequences; though, perhaps, apparently trivial, when compared with thofe great events that fometimes characterize a campaign. In fome inftances we fee the moft decided effects produced by the operations of enterprifing partifans, who, exclufive of the quantity of forage, and the intelligence they generally afford, diftrefs the enemy feverely, by compelling him to act with fuch circumfpection, and fo to ftrengthen his pofitions, as inevitably muft weaken his other operations, as well as create confiderable alarm among his troops, efpecially when detached in expofed fituations.

In fome countries, detached enterprifes feem to conftitute the chief incidents in warfare; thus, we find that irregular corps commanded by baron Trenck were peculiarly active, and haraffed the enemy beyond meafure! Thus, alfo, the Croats, the Pandours, and the Pindaries, of the Mahratta empire, the Sooties under the late Tippoo, and various other fuch predatory eftablifhments, commanded by officers of a fuitable difpofition, have ever been famous for annoying, and for cutting off the fupplies of their adverfaries.

No enterprife, whether military or naval, fhould be entrufted to the charge or conduct of an individual deficient in any one of the requifites for fuch a refponfible, and, indeed, fo arduous an appointment. In the firft place, a knowledge of the geography of that country he is to infeft, and of the language of its inhabitants, is indifpenfably requifite. His character for marked perfonal courage, and for the prompt application of fuitable remedies againft every fpecies of difafter, or of difappointment, fhould be confpicuous. He fhould poffefs that kind of deportment which preferves the ftricteft fubordination, while it fecures the affection, and excites the admiration, of all under his command. He fhould be expert in all military exercifes, and poffefs both an active mind, and the foundeft conftitution. With fuch valuable gifts, added to a certain conciliatory mode of conduct towards the peafantry, &c. of the diftrict in which he is to carry on his enterprifes, a partifan may perform wonders, and far outdo all the exploits an equal number of regulars could achieve under a lefs capable leader. The truth is, that, generally fpeaking, foldiers and failors are mere automatons, acting under the direction of an expert machinift, whofe character is ever appreciated according to the fuccefs of his movements. How far permanent reputation may be eftablifhed by the commander of fuch an auxiliary force, may be collected from that dread which was created by the Tarleton legion among the Americans, during their ftruggle with the mother country. That legion, even at this day, are fpoken of in terms of admiration, by the very people who fuffered fo feverely from the exertions and abilities of its commander.

It being obvious that, on many occafions, an army muft depend greatly for fupplies on the activity and talents of a partifan, we cannot too forcibly point out the peremptory neceffity which exifts, for the rejection of all who may be deficient in the above qualities, without which, it is unreafonable to expect that any enterprife of moment fhould ever be fafe to thofe who might be employed; much lefs could it be of fervice to thofe in whofe behalf it might be undertaken. Naval enterprifes require no lefs attention in fome cafes; though, for the moft part, we find them rather indebted for fuccefs to undaunted bravery, and a moderate portion of judgment. Thefe ordinarily are made under cover of, or fupported by, fome fufficient force; whereby, in cafe of defeat, they are refcued from total ruin: whereas, the military partifan rarely has fuch protection at hand.

ENTERSOLE. See MEZANINE.

ENTERTAIN. This term has, no doubt, crept into military phrafeology in confequence of the entertainment afforded at public-houfes, &c. to fuch candidates as prefer a fcarlet coat and a mufket, to a frock and a pitch-fork. We cannot fufficiently exprefs our regret, that no better mode has been ordinarily brought into practice, than that of plying men with liquor for the purpofe of inducing them to inlift. We are, indeed, rather infidels on the fubject of any numerous acceffions to the real ftrength of our armies, in confequence of this cuftom: for we have had occafion to learn, that a very large portion of the recruits obtained in confequence of inebriety, either abfcond at fome favourable moment, or prove to be the worft foldiers in their regiment. If drunkennefs has been habitual to them, they rarely relinquifh their addictednefs to liquor; and if, on the contrary, they had, until the moment of being inlifted, been of a fober difpofition, their peace of mind is totally deftroyed, and they ferve without alacrity, without zeal, and generally, too, without health: they are often known to fall a prey to remorfe!

We are fenfible that, fpeaking abftractedly, the affording of entertainment to perfons who appear defirous of inlifting, may be defended under the plea of ftate neceffity; but it becomes a very ferious queftion, whether the nation does not pay confiderably more in confequence of the monies expended in this way? alfo, whether it is found policy to allow military perfons to be in any fhape concerned in overwhelming the fenfes of that man, who is to be for life affociated with them, and who will not always be unmindful of the condition to which they may have brought him? To condemn a practice, faid to be fo neceffary towards our fafety as an independent nation, without offering a fubftitute of a more favourable defcription, might, perhaps, juftly fubject us to the imputation of prefumptuoufly branding the exifting cuftom with obloquy; we fhall, therefore, briefly remark, that, in all probability, not only as many, but more, valuable recruits would be obtained by defifting from what is vulgarly called *entertaining* the candidates; and from expending a very large portion of his bounty in liquor, rareefhows, and fuch diffipations as "make him poor indeed!" In place of this, let the whole of his bounty-money be given to the parifh from which he may have been taken, for the fupport of his family; and let the recruit himfelf be fubfifted and cloathed entirely at the expence of the ftate. Should the recruit have no family fubject to parochial aid, or likely to be fo, let his bounty money be referved until he fhould have ferved a certain time, and then to be given to him in inftalments; fo that he might not diffipate the whole adventitioufly, ventitiouſly, and that he ſhould be enabled, from time to time, to provide himſelf with various articles of apparel, or of comfort, ſuited to his profeſſion.

We cannot cloſe this ſubject without ſtrongly reprobating the practice of ſtopping certain ſums, for off reckonings, and neceſſaries. If the ſoldier is to pay for them, let it be by a plain and peremptory reduction of his pay, in exchange for which he ſhould receive certain articles from government; but let there be no account-current between the ſoldier and his officer, for feathers, lace, buckles, canteens, knapſacks, and ſuch like: this kind of dealing ſets aſide that reſpect which the former ought always to entertain for the latter, and, not unfrequently, occaſions a certain kind of ſuſpicion by no means tending to promote either eſteem or ſubordination. While reform ſeems to be the order of the day, it may, perhaps, be at leaſt faſhionable, if not praiſeworthy, to point out this as an inſtance in which much melioration might be very eaſily, and ſafely, effected.

ENTERTAINMENTS, *epulæ*, among the ancients, were of various kinds, as, 1. Funeral entertainments, *epulæ funebres*. 2. Entertainments given by the huſband on bringing home his wife, called *epulæ geniales*. 3. Thoſe beſtowed on the ſoldiers, called *epulæ militares;* which was done before or after an engagement, or on occaſion of proclaiming the general imperator. 4. Birth-day entertainments, *epulæ natalitiæ*.

There were many other kinds, denominated either from the place where, the perſons by whom, or the occaſion for which they were given.

ENTERVIEW, in *Falconry*, a term uſed for the ſecond year of a hawk's age.

ENTHALIUM, in *Natural Hiſtory*, a name given by ſome to a ſpecies of the tubuli marini, more uſually known by the name of penicillum marinum, and pinceau de mer. See Penicilli *Marini*.

ENTHUSIASM, Ενθουσιασμος, a poetic, or prophetic rage or fury, which tranſports the mind, inflames and raiſes the imagination, and makes it conceive and expreſs things extraordinary and ſurpriſing.

The word is derived from the Greek, ενθεος, or ενθους, a man animated in an extraordinary manner with the ſpirit of God; in whom God is, or whom God animates. Whence the verb ενθουσιαζω, or ενθουσιαω, and the noun ενθουσιασμος, *enthuſiaſm:* and ενθουσιαστης, *enthuſiaſt*, a perſon ſubject to ſuch tranſports.

M. de Piles defines enthuſiaſm to be a tranſport of the mind, whereby it is led to think and imagine things in a ſublime, ſurpriſing, yet probable manner.

The ſublime he thinks a neceſſary ingredient in the definition, as being the proper effect and production of enthuſiaſm.

This is the enthuſiaſm felt in poetry, oratory, muſic, painting, ſculpture, &c. (ſee the next article); but this enthuſiaſm which belongs to the works of art, is very different from that attributed to the ſibyls and prieſteſſes of the oracles, and heathen gods, which was little elſe but fanaticiſm, and conſiſted principally in grimace, and contortions of the body. See Oracle and Pythian.

There is a degree of aſſent, ſays Mr. Locke, which, with ſome men, has the ſame authority as either faith or reaſon; and that is enthuſiaſm, which, laying by reaſon, would ſet up revelation without it; whereby, in effect, it takes away both reaſon and revelation, and ſubſtitutes in the room of it the ungrounded fancies of a man's own brain, and aſſumes them for a foundation, both of opinion and conduct.

Immediate revelation being a much eaſier way for men to eſtabliſh their opinions, and regulate their conduct by, than the tedious labour of ſtrict reaſoning; it is no wonder, that ſome have been very apt to pretend to it: eſpecially in ſuch of their actions and opinions as they cannot account for by the ordinary methods of knowledge and principles of reaſon. Hence we ſee, that in all ages men in whom melancholy has mixed with devotion, or whoſe conceit of themſelves has raiſed them into an opinion of a greater familiarity with God than is allowed others, have often flattered themſelves with the perſuaſion of an immediate intercourſe with the Deity, and frequent communications with the Divine ſpirit.

Their minds being thus prepared, whatever groundleſs opinion comes to ſettle itſelf ſtrongly upon their fancies, is an illumination from the ſpirit of God; and, whatſoever odd action they find in themſelves an inclination to do, that impulſe is concluded to be a call or direction from heaven, and muſt be obeyed.

This we take to be properly enthuſiaſm; which, though riſing from the conceit of a warm and over-weening brain, works, where it once gets footing, more powerfully on the perſuaſions and actions of men than either reaſon or revelation, or both together; men being moſt forwardly obedient to the impulſes they receive from themſelves.

When men are once got into this way of immediate revelation, of illumination without ſearch, and certainty without proof, reaſon is loſt upon them; they are above it; they ſee the light infuſed into their underſtanding, and they cannot be miſtaken: like the light of bright ſun-ſhine, it ſhews itſelf, and needs no other proof but its own evidence; they feel the hand of God moving them within, and the impulſes of the ſpirit, and cannot be miſtaken in what they feel. But, of this ſeeming and feeling, it is a perception of an inclination to do ſomething, or of the Spirit of God moving that inclination: theſe are two very different perceptions, and ſhould be carefully diſtinguiſhed.

If they know the thing to be a truth, they muſt do it, either by its own ſelf-evidence, or by the rational proofs that make it out to be ſo: if they know it to be a truth, either of theſe two ways, they in vain ſuppoſe it to be a revelation; for thus, all truths, of what kind ſoever, which men uninſpired are enlightened with, come into their minds. If they ſay, they know it to be true, becauſe it is a revelation from God, the reaſon is good; but then it will be demanded, how they know it to be a revelation from God? If they ſay, by the light it brings with it, they ſhould conſider, whether this be ſaying any more than that it is a revelation, becauſe they believe it to be true; for all the light they ſpeak of is but a ſtrong perſuaſion of their own minds that it is a truth, which is a very unſafe ground to proceed on, either in our tenets or actions. True light in the mind is nothing elſe but the evidence of the truth of any propoſition; and if it be not ſelf-evident, all the light it can have is from the clearneſs of thoſe proofs upon which it is received. See Evidence.

God, when he makes the prophet, doth not unmake the man; he leaves his faculties in their natural ſtate, to enable him to judge of his inſpirations, whether they be of divine original or not. If he would have us aſſent to the truth of any propoſition, he either evidences that truth by the uſual methods of natural reaſon, or elſe makes it known to be a truth which he would have us aſſent to by his authority; and convinces us that it is from him, by ſome marks which reaſon cannot be miſtaken in. Eſſay on Hum. Underſt. book iv. chap. 19.

The holy men of old, who had revelations from God, had ſomething elſe beſides internal light, of aſſurance in their

their own minds, to teftify to them that it was from God; they had outward figns to convince them of the Author of thofe revelations; and when they were to convince others, they had a power given them to juftify the truth of their commiffion from heaven; and by vifible figns, to affert the divine authority of the meffage they were fent with. Mofes faw the bufh burning without being confumed, and heard a voice out of it. God, by another miracle, of his rod turned into a ferpent, affured him likewife of a power to teftify his miffion, by the fame miracle repeated before thofe to whom he was fent.

Enthufiafm is defined by Dr. Hartley (Obf. on Man) to be a miftaken perfuafion in any perfon, that he is a peculiar favourite with God; and that he receives fupernatural marks thereof. The vividnefs of the ideas of this clafs eafily generates this falfe perfuafion in perfons of ftrong fancies, little experience in divine things, and narrow underftandings, (and efpecially where the moral fenfe, and the fcrupulofity attending its growth and improvement, are but imperfectly formed,) by giving a reality and certainty to all the reveries of a man's own mind, and cementing the affociations in a preternatural manner. It may alfo be eafily contracted by contagion, as daily experience fhews; and indeed more eafily than moft other difpofitions, from the glaring language ufed by enthufiafts, and from the great flattery and fupport which enthufiafm affords to pride and felf-conceit. The ingredients, fays lord Lyttelton in his "Obfervations on the Converfion, &c. of St. Paul," of which enthufiafm is generally compofed, are great heat of temper, melancholy, ignorance, credulity, and vanity, or felf-conceit.

The true fources of enthufiafm, fays Mr. Hume in his "Effay on Superftition and Enthufiafm," are hope, pride, prefumption, a warm imagination, together with ignorance. From the influence of thefe caufes arife raptures, tranfports, and furprifing flights of fancy; and whilft confidence and prefumption ftill increafe, thefe raptures, being altogether unaccountable, and feeming quite beyond the reach of our ordinary faculties, are attributed to the immediate infpiration of that Divine Being, who is the object of devotion. In a little time the infpired perfon comes to regard himfelf as a diftinguifhed favourite of the Divinity; and when this phrenfy once takes place, which is the fummit of enthufiafm, every whimfy is confecrated. Human reafon, and even morality, are rejected as fallacious guides; and the fanatic madman delivers himfelf over, blindly, and without referve, to the fuppofed illapfes of the fpirit, and to infpiration from above.

Devotion, undirected, or unreftrained by reafon, degenerates into enthufiafm, or a religious phrenfy, founded in an apprehenfion of a prefent Divine energy on the mind, to which all its powers are fuppofed to be fubject, and by which a perfon is carried on without attention to any thing elfe as his guide, and producing not only great perturbation of mind, but moft amazing agitations of body. Many inftances of this kind occur, both in ancient and modern times, to the difgrace and injury of rational religion.

Mr. Hume (ubi fupra) makes feveral reflections concerning the different influences of enthufiafm and *fuperftition* (which fee) on government and fociety. He obferves, *firft*, that fuperftition is favourable to prieftly power, and enthufiafm not lefs, or rather more, contrary to it than found reafon and philofophy. He obferves, *fecondly*, that religions, which partake of enthufiafm, are, on their firft rife, more furious and violent than thofe which partake of fuperftition; but in a little time become more gentle and moderate. When enthufiafm rifes to that height as to infpire the deluded fanatic with the opinion of divine illuminations, and with a contempt for the common rules of reafon, morality, and prudence, it produces the moft cruel diforders in human fociety; but its fury is like that of thunder and tempeft, which exhauft themfelves in a little time, and leave the air more calm and ferene than it was before. When the firft fire of enthufiafm is fpent, men naturally, in all fanatical fects, fink into the greateft remiffnefs and coolnefs in facred matters; there being no body of men among them, endowed with fufficient authority, whofe intereft is concerned to fupport the religious fpirit: no rites, no ceremonies, no holy obfervances, which may enter into the common train of life, and preferve the facred principles from oblivion. For the influence of fuperftition, fee that article. He obferves, *thirdly*, that fuperftition is an enemy to civil liberty, and enthufiafm a friend to it.

ENTHUSIASM, in *Poetry*, *Eloquence*, and *Elocution*, is a fpecies of rapturous elevation and fervour, which tranfports the writer or fpeaker beyond the limits of apparent rule, and mere methodical propriety. Like genuine fublimity, to which it is very nearly allied, and with which it occafionally co-operates, in producing the higheft impreffions that can refult from human eloquence, it defies, perhaps, the exactnefs of logical definition; its very effence confifting in a ftate of feeling, at once fo potent and fo evanefcent, as to elude the cautious touch of analyfis. It belongs, therefore, only to perfons of fuperior genius, and by fuch alone muft be attempted; fince, like all fuperlative excellencies, it verges for ever on the brink of abfurdity; and criticifm has never yet been able to erect a fufficient barrier to defend its utmoft limits. Like every other paffion, it muft be felt before it can be expreffed; and the mind of the writer or the fpeaker muft be well fortified with knowledge on the fubject he is handling, and the judgment well exercifed in the nice difcriminations of tafte, of feeling, and of decorum, before he ventures to indulge it in compofition or in delivery, if he addreffes himfelf to the enlightened or educated portions of the community, or he will be worfe than difappointed of his object. In circles of a different defcription, however, it is evident that the mere femblance of enthufiafm, unaided by thefe preliminary qualifications, feldom fails of a very powerful effect: and, by this quality alone, bigotry and fanaticifm frequently accomplifh their end, and maintain abfolute dominion over the minds of their ignorant votaries. It is therefore fufficiently obvious, that it is a quality the orator, if he be fufceptible of it, fhould never fail to cherifh; and if he be not fufceptible of it, he is but a fragment of an orator. As for poetry, enthufiafm is admitted to be its very foul and effence. In the delivery of eloquence, or the recitation of poetry, genuine enthufiafm is expreffed by a deep and powerful afpiration, by an increafe of quantity in all the fyllables principally produced by the prolongation and increafe of the power of the voice on the liquids and liquifiable confonants; a reftrained vehemence, which, without any of the difgufting effects of vociferation, fpreads the undulations of found through an extended circle. It is generally accompanied by a confiderable dilatation of the noftrils, a protrufion of the eye-balls, and great tenfion and rigidity of the whole mufcular fyftem. Shakefpeare, who felt its influence fo frequently, has finely defcribed its operation in the fpeech of Henry V. before Harfleur:

> "Now fet the teeth, and ftretch the noftrils wide,
> Hold hard the breath, and bend up every fpirit
> To its full height."

The whole fpeech is one of the fineft effufions of enthufiafm ſiaſm ever penned, and requires in the reciter all the inſpiration of that powerful feeling.

ENTHUSIAST, Ενθυσιαστης, a perſon poſſeſſed with enthuſiaſm. See Enthusiasm, Fanatic, &c.

The word is generally underſtood in an ill ſenſe. It was applied by the ancients to a ſect of heretics, called alſo Maſſalians and Euchites; who, as Theodoret expreſſes it, were denominated enthuſiaſts, becauſe being poſſeſſed by the devil, they believed themſelves divinely inſpired. See Massalians and Euchites.

Among us, enthuſiaſt is ſometimes of like import with fanatic, and is applied to the Quakers, and ancient Anabaptiſts, and modern prophets, from their pretences to extraordinary lights, revelations, viſions, impulſes, &c. from heaven.

ENTHYMEME, in *Logic* and *Rhetoric*, an argument conſiſting only of two propoſitions, an antecedent, and a conſequent deduced from it.

The word is Greek, ενθυμημα, formed of the verb ενθυμεισθαι, to think, conceive, a compound of εν and θυμος, *mind.*

Ariſtotle calls it the rhetorical or probable argument; the ſchools, the imperfect ſyllogiſm, in contradiſtinction to the perfect, which conſiſts of three propoſitions, and is called the dialectical argument.

It muſt be obſerved, however, that the enthymeme is really a perfect ſyllogiſm in the mind, and only imperfect in the expreſſion, becauſe one of theſe premiſes is ſuppreſſed, as being ſufficiently clear and obvious, and eaſily ſupplied by the underſtanding of thoſe with whom we diſcourſe.

Thus, in every right-lined triangle, the three angles are equal to two right ones; and conſequently, they are ſo in an iſoſceles triangle, is an enthymeme; the propoſition, that an iſoſceles triangle is a right-lined triangle being omitted, as being ſufficiently known and granted.

The enthymeme is the moſt ſimple and elegant of all argumentations; being what a man, in arguing cloſely, commonly makes, without attending at all to the form. Thus, that verſe remaining of Ovid's tragedy, entitled Medea, contains an enthymeme: "Servare potui, perdere an poſſum rogas:" "I was able to ſave you; conſequently, to have deſtroyed you." All the beauty would have been loſt, had all the propoſitions been expreſſed; the mind is diſpleaſed with a rehearſal of what is no ways neceſſary.

Sometimes, alſo, the two propoſitions of an enthymeme are both included in a ſingle propoſition, which Ariſtotle calls an enthymematical ſentence, and gives this inſtance thereof: "Mortal, do not bear an immortal hatred." The whole enthymeme would be, "Thou art mortal; let not, therefore, thy hatred be immortal."

ENTIER, in the *Manege*, is uſed for a ſort of reſty horſe, that refuſes to turn, and is ſo far from following or obſerving the hand, that he reſiſts it. If your horſe is entier, and refuſes to turn to what hand you will, provided he flies, or parts from the heels, you have a remedy. by putting the Newcaſtle on him; that is a caveſſon, made after the duke of Newcaſtle's way.

The word is French, and is alſo uſed among them to denote a ſtone-horſe.

This term, in its common acceptation, is applied to a horſe that refuſes to turn, and whoſe refuſal proceeds from the awkwardneſs and ſtiffneſs of the body and limbs, and ſometimes from malice and bad habits. In ſome caſes, a hurt in his foot, leg, or ſhoulder, may be the cauſe of his refuſing to turn to that ſide where he feels any pain. A hurt in his reins or haunches, a curb or ſpaving, which, by hindering him to bend and reſt upon his hocks, may make him guilty of this diſobedience. Theſe are evils which art can do little towards curing. The term entier, in its figurative ſenſe, in which it is always to be underſtood in horſemanſhip, means a ſtiff horſe, or one that is not ſuppled, and therefore refuſes to turn, from the pain and difficulty which he finds in putting himſelf into a proper poſture. Accordingly the Italians, from whom the terms of horſemanſhip are chiefly taken and adopted, or naturalized by other nations, figuratively call a ſtiff and undiſciplined horſe, a whole, entire, or unbroken horſe; which, from the ſtiffneſs and tightneſs of his joints and muſcles, is not able to bend himſelf, but in turning moves all of a piece, like a beam, or bar of iron; while the active and ſuppled horſe, who can bend himſelf readily, and becomes part of the circle he deſcribes in turning, may be ſaid, like a chain, ſo to looſen and ſhift his limbs, as to break and divide himſelf, as it were, into parts; whence, perhaps, the term "horſe-breaker," for one who forms the paces, and qualifies horſes for being rode. Berenger's Hiſtory and Art of Horſemanſhip, vol. ii.

ENTIERTIE, from the French *entier*, is uſed in our *Law-books*, in contradiſtinction to moiety, and denotes the whole. Thus a bond, damages, &c. are ſaid to be entire, when they cannot be divided or apportioned.

ENTIRE Leaf, in *Syſtematic Botany*, *folium integerrimum*, a leaf whoſe edge is not cut or toothed; the term has no reference to *folium integrum*, an undivided leaf, which laſt is deſtitute of lobes or ſegments, without regard to its margin.

Entire *Tenancy*, in *Law*, is contradiſtinguiſhed to *ſeveral tenancy*, and ſignifies a ſole poſſeſſion in one man; whereas the other denotes a joint, or common one, in ſeveral. See Tenant and Joint-tenant.

Entire *Arms*. See Arms.

ENTITATIVELY, Entitative, implies an abſtraction, or ſeparation of all the circumſtances, from a thing under conſideration.

Thus, a thing is ſaid to be taken or conſidered entitatively, or ſecundum entitatem, when conſidered nakedly and preciſely, according to what it is in itſelf, without any thing extrinſic. *E. gr.* Peter entitatively taken, is Peter, as a thing, a ſubſtance, a man, &c. without any regard to his being a lord, a huſband, learned, &c.

ENTITY, in the *School Philoſophy*, a phyſical ens, or being, conſidered according to what it is in its natural capacity.

Some dealers in diſtinctions give us ſeveral kinds of entity.

Or, entity denotes the actual eſſence or exiſtence of any thinking thing. See Ens.

ENTLIBUCH, in *Geography*, a village of Switzerland, in the canton of Lucern, the principal place of a bailliage, which extends from the Emme-thal in the canton of Bern to the bridge near Wertenſtein, about 15 miles in length and 9 in its greateſt breadth; and contains 11,000 perſons. It is governed by a bailiff, who is always a ſenator of Lucern; he continues in office two years, and generally reſides in that capital. The bailliage is divided into three diſtricts; the upper, or Eſchliſmat, the middle, or Shuepfen, and the lower, or Entlibuch; each of which has its ſeparate courts of juſtice, from which an appeal lies to Lucern. The valley of Entlibuch is watered by ſeveral rivulets, winding for ſome way between two ridges of well-wooded hills, and abounding in pictureſque ſcenery. It contains ſeveral villages, of which the principal are Eſchliſmat, Shuepfen, and Entlibuch, which takes its name from the river Entle, and gives it to the whole diſtrict. The inhabitants chiefly follow

low agriculture; they rear large quantities of horned cattle, ſheep, goats, and ſwine; they alſo make and export cheeſe in great abundance. The peaſants of Entlibuch are much eſteemed for their independent ſpirit, vigour, and ſtrength; and are remarkable for keenneſs and vivacity, for great quickneſs in repartee, for a peculiarity of garb, and for many ſtriking cuſtoms, which diſtinguiſh them from the natives of circumjacent diſtricts. The valley of Entlibuch may be conſidered as one of thoſe parts which unite with the mild and cultivated the wild and rugged ſcenery of Switzerland; its acclivities gradually aſcend and terminate in mount Pilate, whoſe barren top is ſeen towering above the fertile and well-wooded hills. In the 13th century, Entlibuch was ſubject to the counts of Wolhauſen, and came by purchaſe, in 1299, to the emperor Albert. In the following century it was held as a fief from the houſe of Auſtria by ſeveral ſucceſſive counts; till the nation, grievouſly oppreſſed by Peter of Torrenberg in 1386, threw itſelf under the protection of Lucern. That republic continued to poſſeſs Entlibuch, as a feudal tenure under the houſe of Auſtria, till the year 1405; when the archduke Frederic renounced all the rights of ſovereignty. For above a century and a half, the inhabitants, inflamed with a deſire of independence, and excited by the example of the popular cantons, frequently roſe in arms, and attempted to eſtabliſh a democracy, but without ſucceſs. Their laſt inſurrection broke out in 1653; ſince which time they have continued in a ſtate of perfect tranquillity under the adminiſtration of Lucern, enjoying, with contentment, the privileges with which they are endowed. The peaſants of Entlibuch were diſtinguiſhed by their attachment to the government, and by their decided oppoſition to French principles, during the late revolution. Coxe's Travels in Switzerland, vol. i.

ENTOGANUM, in *Botany*, Gærtn. t. 68. See Melicope.

ENTOMOLITHUS, in *Natural Hiſtory* and *Mineralogy*, is the name of a genus of the animal order of remains (*reliquia*, or relicts) of a former race of beings, which inhabited the earth or its waters, and includes the different kinds of inſects found in a foſſil ſtate. According to Mr. William Martin (Outlines of the Knowledge of extraneous Foſſils, p. 191), the eſſential characters, or diagnoſtics of the permanent ſpecies in this genus, are to be ſought, in "the upper external covering of the thorax, united to that of the abdomen;" the temporary ſpecies of this genus are to compriſe the detached head, thorax, abdomen, limbs, &c. of foſſil animals, reſembling the recent ſpecies of inſects. See Reliquia.

ENTOMOLOGY, the ſcience of inſects, or, as literally rendered from the Greek, a *diſcourſe on inſects;* the term by which the ſtudy of theſe animated beings is expreſſed.

Inſect, from *inſectum*, Latin, is of later origin than ἔντομα, the term made uſe of by Ariſtotle, who flouriſhed in the fifth century, before the Chriſtian era, and was invented much earlier than the time of that celebrated philoſopher. Ariſtotle defines it to ſignify an animal which by inciſions is nearly ſevered into two or more parts, and the Latins, long before the time of Pliny, (who lived in the reign of Titus,) employed the word *inſectum*, from *inſecor*, which preciſely bears the ſame interpretation.

The inſect race conſtitutes the moſt conſiderable portion of the whole claſs of organized bodies poſſeſſing the vital principle of life. The number of aquatic beings concealed from our reſearch in the depths of the ocean cannot be within the reach of human eſtimate; it is to the terreſtrial tribes, or thoſe which inhabit the ſurface of our globe, that we alone allude; and the entire amount of theſe, including every order, is confeſſedly inferior in point of number to the ſingle claſs of inſects. Among the larger animals the diſcovery of a few new ſpecies, or of individuals not correctly aſcertained before, is eſteemed of conſequence; but ſo extenſive are the limits of entomology, that the diſcovery of a multitude of inſects under the ſame circumſtances fail to excite aſtoniſhment, though it may awaken curioſity; and, indeed, its frequency ſeems calculated to confirm the commonly received opinion, that the inſect race, in the diverſity of ſpecies, much more in the number of its individuals, muſt be almoſt boundleſs.

In this view the ſcience of entomology becomes one of the moſt important that can engage the mind of the natural philoſopher. It is the difficulty of diſcriminating the particular affinities and characters of theſe beings, ariſing from their amazing number and variety of form, in addition to their minuteneſs, that more ſtrongly enforces their claim to his conſideration. The naturaliſt who neglects the ſtudy of inſects, cannot deſerve our reſpect as a general obſerver of nature. His views are partial; his enquiries circumſcribed; he regards only an inconſiderable portion of animated nature; and his remarks are confined chiefly to thoſe which, from their magnitude and diſtinctneſs of character, preſent the leaſt obſtacle to inveſtigation.

The ſtudy of every claſs of animals is indiſputably attended with peculiar advantages; and in none is this aſſurance more clearly manifeſted than in the tribe of inſects. In the mazy labyrinths of entomology, the naturaliſt will find abundant ſcope for the exerciſe of his zeal and application, and in the courſe of his enquiries the full exertion of his penetration will be oftentimes required to the aſcertainment of truth. The amazing number of ſpecies it embraces; their forms ſo extraordinary; ſo infinitely varied; and yet ſo gradually approximating through an endleſs ſeries of tranſitions from one ſpecies to another; the diverſity of ſtructure obſervable in their antennæ, their limbs, bodies, wings, and every other particular which conſtitute the eſſential differences of their orders, genera, and ſpecies; added to the ſurpriſing changes in form which the generality of inſects undergo at ſtated periods of their life:—theſe are circumſtances which contribute to render them objects of the moſt curious ſpeculation to the naturaliſt, and we ſhall venture to affirm, that it is from a knowledge of theſe, their characters, tranſitions, metamorphoſis, and the various modes of life theſe little beings are deſtined to purſue, that he will obtain a more intimate acquaintance with the great laws of animated nature, than can poſſibly be derived from the contemplation of any other tribe in the creation.

As inſects ſurpaſs all other animals in their number, variety, and ſingularity, ſo alſo it is a natural inference that they muſt deſerve the greateſt ſhare of attention. The hiſtory of theſe creatures abound with the moſt valuable information in a philoſophic view, and ſtrongly recommend the ſtudy to the attention of every curious obſerver. Entomology poſſeſſes many other attractions, ſome at leaſt of which have not been well conſidered. The only one to which we ſhall particularly advert at this moment, is the beauty of inſects in general, a point on which there can be no difference of opinion. Theſe little creatures are rendered engaging from the gaiety of their natural hues: from combining oftentimes with the moſt graceful forms a diſplay of colouring very far excelling in ſplendour, vivacity, delicacy, and harmony of diſpoſition, that beſtowed by the hand of nature on her other works. One defect in their appearance muſt be nevertheleſs conceded; and this may be regarded in point of beauty as a material deficiency indeed: they are not always ſo conſiderable in magnitude, as to become, even with theſe embelliſhments, lifhments, ftrikingly attractive: were they only equal in fize to the minor tribes of birds and animals, their unrivalled elegance would certainly render them objects of high efteem in the general opinion of mankind.

But the diminutivenefs of infects ought to operate in a contrary manner on the mind of the philofopher. While this caufe oppofes the greater difficulty to the ftudy, it fhould more ftrongly incite inveftigation. This we are aware is not always confidered as an inducement, and the diminutivenefs of thefe creatures has been fometimes urged as a reafon that they do not merit the attention beftowed upon them. However injudicious this opinion ought in candour to be conceived, it has obtained the countenance of many; and among the number, of fome men at leaft who, from their fuperiority of talent, might be deemed incapable of advancing fuch an argument againft the ftudy of any department of natural fcience. Thus the ingenious Buffon, whofe attention, as is well known, was reftricted to the larger tribes of animals, intimates its inferiority in language fufficiently pointed. "Who (fays this lively author) gives us the grandeft and moft magnificent ideas of the creator of the univerfe? he who reprefents him in the plenitude of his power, directing the formation of funs and of planets, and guiding the revolutions of worlds, or he who difcovers him bufied in regulating the economy of a hive of bees, or deeply engaged in folding the wings of a beetle?"

How different is this from the fentiments expreffed by other philofophers, who, with more enlarged and liberal views, have held every branch of natural fcience in its proper eftimation! There are many who even affign a higher degree of perfection to the infect race than to other claffes of animals. We learn the opinion of Pliny from his own words. "In his tam parvis tamque fere nullis quæ ratio! quanta vis! quam inextricabilis perfectio!" Boyle declares, that for his own part his wonder was more excited by the contemplation of a mite than an elephant; and Reaumur fpeaks more decidedly to the fame effect, in language worthy of repetition. Pourquoi, (fays this author,) craindrions-nous de trop louer les ouvrages de l'Etre Suprême? Une machine nous paroît d'autant plus admirable, et elle fait chez nous d'autant plus d'honneur à fon inventeur, que, quoiqu' auffi fimple qu'il eft poffible par rapport à la fin à laquelle elle eft deftinée, il entre dans fa compofition un plus grand nombre de parties, et de parties très-différentes entre elles. Nous avons une grande idée du génie de l'ouvrier qui a fu réunir et fait concourir à la même fin, autant de parties différentes et néceffaires. Celui qui a fait, les machines animées que nous appelons des infectes, n'a affurément fait entrer dans leur compofition que les parties qui devoient y être. Combien, malgré leur petiteffe, ces machines nous doivent-elles paroître plus admirables que celle des grands animaux, s'il eft certain qu'il entre dans la compofition de leur corps beaucoup plus de parties qu'il n'en entre dans celle des corps énormes des élephans et des baleines! Pour faire paroître au jour un papillon, une mouche, un fcarabée, en un mot, tous les infectes, qui ont à fubir des transformations, il a fallu au moins faire l'equivalent de deux animaux, faire une chenille dans laquelle le papillon prit tout fon accroiffement, faire des larves dans lefquelles la mouche et la fcarabée puffent croître". Swammerdam is impreffed with the fame idea. "After an attentive examination (fays this writer) of the nature and anatomy of the fmalleft as well as the largeft animals, I cannot help allowing the leaft an equal or perhaps a fuperior degree of dignity to the former. If, while we diffect with care the larger animals, we are filled with wonder at the elegant difpofition of their parts, to what an height is our aftonifhment raifed, when we difcover all thefe parts arranged in the leaft, in the fame regular manner! Notwithftanding the fmallnefs of ants, nothing prevents us from preferring them to the larger animals, if we confider either their unwearied diligence, their wonderful ftrength, or their inimitable propenfity to labour."

Another objection, for we fhall not term it argument, has been advanced againft this ftudy, the validity of which cannot be fo thoroughly examined in this place as we could wifh; it has been ftated, that becaufe infects furnifh few of the articles of life they deferve no confideration. This is the language of ignorance, and fuch as we could eafily fhew to be of the moft futile kind. The ftudy of thefe creatures is as replete with utility; and the knowledge of them as effential to the benefit of mankind, as moft other branches of fcientific purfuit; nor fhall we fcruple to aver, that in this particular refpect entomology claims a decided fuperiority over every other department of zoology. But the fact is evident, that the importance of this fcience, at leaft in Britain, has never been duly appreciated, and this arifes from the moft obvious of all caufes, that it has not been fufficiently explained.

Infects may properly be divided into two kinds, thofe which are either directly or remotely beneficial, or injurious to the purpofes of mankind. Many infects, it is true, do not feem to affect us in any manner; but appearances in this refpect, let it be obferved, are not always to be relied upon. Others, and the number of thofe is very great, moft affuredly fall within the denomination of one or other, and even both the firft mentioned kinds, and for this reafon ought furely to demand our attention. In the ordinary concerns of life it is deemed of as much, if not greater confequence, to know our enemies, and afcertain the powers of annoyance they poffefs, as it is to learn what benefit we may be able to derive from our friends: let us apply this plain and rational argument to the ftudy of infects, and we think it will appear equally confiftent, when we affert that it is as important to know thofe which are injurious to our interefts, as thofe which contribute to our advantage. When we are convinced in what refpects particular infects have the means of doing us injury, we may guard againft their attacks, or apply a remedy to the evil, and if we neglect to obtain thofe fervices from the beneficial kinds which they are defigned by nature to afford us, it can be no proof of our wifdom.

Left, to the fuperficial obferver, our allufion to the utility of infects fhould appear theoretical, while the noxious propenfities of others may be too fully experienced in the affairs of agriculture, horticulture, and throughout the various branches of domeftic economy, to admit of doubt, we fhall be more explicit in this obfervation. The ravages of infects upon vegetation are detrimental to us; but let it be remembered alfo, that even in thefe depredations they fometimes repay the injury they commit. The locuft itfelf, the moft deftructive of all infects, and whofe myriads fpread defolation through the vegetable world, are not unproductive of advantage, except on fome very extraordinary occafions, when their multiplication exceeds all bounds. At other times they deprive mankind of a certain portion of his vegetable food, and, in return, their bodies afford him animal nutriment of a wholefome and palatable kind, and in infinitely greater abundance. The various forts of locufts are the common food on which the inhabitants of many parts of the world, at particular feafons, chiefly fubfift. The honey of bees, both of the wild and domeftic kinds, conftitute another primary article of food in many warm countries, in the prefent as in ancient times. The hydromel of the Ruffians, an excellent and delicious drink, is prepared

pared from honey, as our beverage is from malt. The various tribes of filk worms, (for of this kind there are feveral fpecies,) furnifh materials for the raiment univerfally worn by all ranks in the eaftern parts of the world, and hence in thofe countries the filky produce of thefe induftrious little beings is of as much real confequence to them, as the fleecy coat of the fheep is to us the ftaple article of clothing; as an object of traffic, filk is one of the utmoft importance in China and Tartary, and in thofe parts the paper in common ufe is alfo manufactured from the refufe of the fame material. The extenfive ufe of wax in all ages is well known; but it is lefs generally underftood that wax is not the produce of the bee alone; the wax infect of China is a very different creature, a fpecies of cicada in the larva ftate, and which, with the addition of a vegetable oil, forms the mixture of which the candles of that country confift. (Donov. Inf. China.) Certain infects are employed with fuccefs in medicine, and a further number might be applied to the fame purpofe; many others might be alfo rendered ufeful in the arts, and laftly, we need only advert to the valuable properties of the different fpecies of cochineal in the art of dyeing, to prove the abfurdity of an opinion very generally prevalent among us, that infects are a race of creatures too infignificant to deferve the notice of mankind!

But, were all thefe benefits unknown; and allowing that the ftudy of infects did not feem to be productive of any fubftantial advantages, how abfurd would it ftill be to treat fuch a fair and extenfive portion of the creation with neglect. The objection that they are in no manner conducive to our interefts, even if founded in truth, would be no evidence of the frivolity of the fcience itfelf, unlefs we are to conclude that the only enquiries which merit the rational attention of mankind, are thofe which tend to the gratification of felfifhnefs. If this be admitted as a plaufible objection, how many objects of philofophical inveftigation muft be rejected as frivolous!

From the earlieft period of which any authentic records remain, this race of animals has obtained the attention of every civilized age. The ftudy of thefe creatures has not affuredly been cultivated with equal ardour at all times, nor has every country produced entomologifts of confiderable talent. It will be fufficient to fhew, that the fcience itfelf has never remained in utter neglect, from the remoteft period in which the light of natural knowledge dawned upon the intellectual horizon of man. The experience of all ages diftinctly proves the charge of frivolity to be inapplicable to this ftudy: many advantages, befides thofe above enumerated, have been, and continue ftill to be, derived from this fource; and it is furthermore deferving of our obfervation, that among the number of its votaries in diftant periods of the world, we trace the names of the moft diftinguifhed characters that adorn the page of hiftory. Perhaps we are at this moment addreffing, among the circle of our readers, fome at leaft who, nurtured in habitual indifference towards the fubject under difcuffion, have incautioufly fallen into the error of confidering it as a trivial purfuit. But we are not without expectation, that even the flight obfervations which the limits of our paper allow, will direct their attention with more liberality towards this fubject, and we fhall not hefitate to think in the refult of this, they will eafily conceive much ftronger arguments in its favour than we have adduced. To the idle, or the thoughtlefs confirmed in prejudice, it would be in vain to offer any reafon in its behalf, and to thofe we fhall obferve with brevity, that whatever opinion they may be inclined to entertain of its frivolity, the fcience of entomology will be found in every civilized age and country to have engaged the ftudy of men endowed with talents as fplendid and judgment as refined, as the moft exalted for ability among thofe who affect to treat it unworthily.

Thefe obfervations opportunely introduce to our confideration a review of thofe writings which have contributed to enlighten the paths of fcience in this particular ftudy. The number of thefe; the value and intereft which muft unavoidably attach to their contents; and the names of thofe illuftrious characters by whom many of them were produced, will fully fanction, it is prefumed, the affurances before advanced. Thefe works, even in point of number alone, we have no doubt will be found infinitely more confiderable than moft imagine; and this circumftance, independently of any other, tends to prove that we are not fingular in our commendation of entomology either as an inftructive or ufeful fcience; as morally, and intellectually beneficial; for thofe who write on any fubject like the prefent, muft be impreffed with fome idea of its importance, and thefe opinions may be collected uniformly from the labours of writers on the ftudy of infects.

As we deem this fubject of confequence, it is our decided wifh, even in the curfory view to which our limits are reftricted, not to omit the mention of any work, however flight, that has been productive of material information. Our ftrictures, it will be underftood, are confined to thofe we have had fufficient opportunity to confult with fome attention; for this we confider due, in candour, to the refpective writers whofe labours are devoted to the elucidation of fcience. Sometimes we may be inclined to exprefs ourfelves with warmth in favour of merit, neglected, forgotten, mouldering in decay, or which, from latent motives, has never been fufficiently appreciated by later authors. If we err in this, let it be remembered, that in the truth of criticifm we oftentimes evince more judgment in beftowing praife, than awarding cenfure. But we wifh it to be explicitly underftood, that we do not confider it within our province, at prefent, to enter at large upon a critical analyfis of the multitude of writings before us. Our only object is to point out the exiftence of the moft valuable works that are extant within our own knowledge, defcribing at the fame time the leading intention of their authors refpectively: the collateral remarks can be only thofe immediately incidental to fuch inveftigation. The feveral works enumerated will be adverted to, as nearly as poffible, according to the order in which they appeared before the world; and hence our review, however curfory, will be attended with this peculiar advantage, that it will ferve to point out the progreffive improvements the fcience has derived from the labours of each fucceeding author, in a more perfpicuous form than could perhaps be accomplifhed in any other manner. It will alfo by this means be found calculated to afford the general reader

An Hiftorical view of the Rife, Progrefs, and Prefent State of Entomology.

The deftruction of the great public libraries of antiquity has for ever deprived us of the means of afcertaining precifely to what ftate of perfection this branch of fcience had attained, till within about two thoufand years of the prefent period. Of thofe times a few fcanty memorials alone remain, fufficient, however, to teftify that the ftudy of infects had then made fome progrefs, and was held in eftimation. Whatever may be our ideas with regard to ftill earlier times, it would be needlefs to obtrude them in this place. We fhall obferve only, that fome books muft have been written on the fubject before the exiftence of thofe which have defcended down to us: the reputation of fuch writings is preferved, and in certain inftances the names of authors recorded in the very earlieft of thofe works at prefent extant, which clearly demonſtrates the truth of this opinion. Time has not ſpared the labours of any writer on this ſubject of more remote date than the third, fourth, and fifth century before the Chriſtian era, and the amount of thoſe which have ſurvived is ſmall indeed; but inconſiderable as they are, in point of number, we may, notwithſtanding, collect from them that the ſtudy of inſects, in thoſe days, held a rank among the liberal purſuits of their philoſophers.

We may, indeed, proceed ſtill farther in this retroſpect, if the ſacred writings of the Hebrews be conſidered. Theſe abound with paſſages relating to particular kinds of inſects, as the locuſt, the caterpillar, flies, and vermin. Moſes, the earlieſt of the inſpired writers, had probably acquired ſome knowledge of this ſubject, in common with the other ſciences, from the ſages of Egypt; and among the books of Solomon, now loſt to the world, it is recorded that he treated on inſects, or "creeping things."

Hippocrates flouriſhed in the 80th Olympiad, or fifth century before the Chriſtian era; he wrote on inſects, as we are told by Pliny, in whoſe time ſome remains of the entomological obſervations of this celebrated character were probably extant. The writings of the early Greek and Latin writers, quoted by Pliny, afford extracts from this production of his labour.

The ſucceeding age gave birth to that diſtinguiſhed natural hiſtorian and philoſopher Ariſtotle: the production of whoſe labour, his hiſtory of animals, is worthy of the patronage beſtowed on its author by the conqueror of the univerſe. No one can impartially peruſe this ineſtimable treaſure of antiquity without confeſſing the intimate knowledge its writer muſt have poſſeſſed of the great arcana of nature.

This work of Ariſtotle is rather of an elementary kind, embracing a general, wide, and comprehenſive view of the animated creation, and does not, except on particular occaſions, deſcend to the deſcription of individuals or ſpecies. The inſect tribe is treated under different points of compariſon and view in ſeveral parts of the work. In the ſeventh chapter of his firſt book, he informs us, that the name ἔντομα is generic, or that of a family, and that they conſtitute one of his four orders of exſanguineous animals, and points out with great accuracy in what reſpect they differ from the molluſca, cruſtacea, and teſtacea, the other three families of this claſs of animals. By exſanguineous he means only that they have no red blood, for he ſpeaks generally to their bodies being retained in a ſtate of moiſture by other fluids. The firſt chapter of the fourth book affords a definition of the eſſential character of inſects, which conſiſts in the inciſions or cuts either on the back or belly, and ſometimes on both, by which their bodies appear to be almoſt divided into two or more parts. But that portion of his work which is more particularly devoted to inſects, is entitled Περὶ τῶν ἐκτὸς κο ρίων τῶν ἐν τόμων. In this he more fully deſcribes inſects to conſiſt of three parts, the head, trunk, and belly or abdomen; the ſecond part, or trunk, is denominated an intermediate portion, correſponding with the back and breaſt in other animals; and he alſo mentions as a character of inſects that they are furniſhed with feet.

The ſubſequent paſſages deſcribe different genera, or, as termed, tribes of inſects, in which he treats of thoſe which fly and thoſe which walk. Among thoſe furniſhed with wings, he ſpeaks of ſome having theſe parts entirely naked, and others that have them protected by a ſheath, or covering, as in the beetle kind: as he furthermore ſtates, that in ſome beetles theſe ſheaths divide or open when the inſect flies, and that in others they are inſeparably united. The inſects which have naked wings, he obſerves, poſſeſs either four, as in the bee, or two, like the muſca or common fly. Some of thoſe with four naked wings have ſtings at the end of the body, while beetles, and inſects with two naked wings, are deſtitute of this apparatus; but ſome of the latter, he tells us, have a proboſcis or inſtrument at the mouth, by means of which they draw blood from other animals. The horns before the eyes (by which he means the antennæ) attract his obſervation, and thoſe of the papiliones and grylli are particularly deſcribed. In his remarks on the different ſtructure of the feet, thoſe formed for leaping are exemplified by thoſe of the locuſt, and are compared to the poſterior feet of ſpringing animals. The humming noiſe of certain inſects in flight, the eruca, and various other circumſtances relative to this claſs of animated beings, have intereſted the philoſopher in this chapter.

The attentive entomologiſt will feel deeply ſenſible of the accuracy of every expreſſion, thought, and ſentiment, implied in the above-mentioned paſſages. He will be ſurpriſed at their conſiſtency. Their accordance with the entomological definitions of the beſt modern ſyſtematiſts will excite farther compariſon; and in the reſult of this inquiry it muſt be obvious, that with the acquired knowledge of two thouſand years ſince his time, ſo far as he does proceed, we cannot materially amend his obſervations. This will be admitted; and at the ſame time we believe even a curſory peruſal of the whole work will ſerve to ſhew, that whatever might be the merits of Ariſtotle, and we allow them to be tranſcendent, theſe writings evince too much acquaintance with the ſcience of nature, to be the produce of any individual genius ſhining with unborrowed light. When we reflect upon the ſlow and gradual progreſs with which all human knowledge is developed, we are really convinced that the ſcience of nature muſt have made ſome conſiderable advancements before his time; and that he has derived many eminent advantages from conſulting the works of more ancient naturaliſts: men whoſe original labours have been loſt to poſterity for ages, and the only traces of which at preſent extant are to be found embodied in his pages.

Ælian, in his work on animals, ΠΕΡΙ ΖΩΩΝ ΙΔΙΟΤΗΤΟΣ, appropriates ſeveral detached chapters to particular kinds of inſects, without entering in a methodical manner into the hiſtory of the tribe. Thoſe he does include are deſcribed with attention: as, for inſtance, the ſcorpions, Σκορπίων; ants, Μυρμήκων; ſpiders, Ἀράχνῃ; crickets, Τεττίγων; the generation of waſps, Περὶ τῆς Σφηκῶν γενέσεως; of cantharides, τῶν καλουμένων Κανθαρίδων, &c.

The Greek poet Phile, called alſo, from his ſuperior knowledge of natural hiſtory, "Phile Sapientiſſimi," introduces ſome pleaſing poetical effuſions relative to inſects among his poems on animals. The manners of the cicadæ, and the bees, τεττίγων, and μελιττῶν, are very prettily deſcribed in verſe by this writer. He entertains the ſame idea as Ælian, that the cicadæ, by which he means the cricket, (not the inſect named cicada by Linnæus,) lived on dew; and that the female was mute, while the male "enchanted the grove with the harmony of ſong." He ſpeaks alſo of the lampyris, and various other inſects. The beautiful ode of Anacreon to the cicada is familiar to many.

Among the Greek writers who immediately, or within a few centuries after, followed Ariſtotle in treating upon inſects, were Democritus, Neoptolemus, Ariſtomachus, Philiſtus, Nicander, Menecrates, Dionyſius Mago, Empedocles, Callimachus, Attalus, Apollodorus, Eriphilus, Eraſiſtratus, Aſclepius, Themiſo, Poſidonius the ſtoic, Meander of Priene, Euphronius of Athens, and Meander of Heraclea, Theophraſtus, and Heſodius. Theſe were authors after the time of Ariſtotle, and preceding or contemporary with Pliny. The Latin writers, during the ſame fame interval, were alfo numerous, and appear to have been influenced to purfue this ftudy in imitation of the Greeks, or were infenfibly led into it from attending to the culture of bees. The moft eminent among the latter were M. Varro, Hyginus, Scropha, Sarcana, Celfus Cornelius, Æmilius Macer, Virgil, Columella, Julius Aquila, Tarquilius, Umbritius, Cato Cenforius, Domitius, Calvinus, Trogus, Meliffus, Favonius, Fabianus, Mutianus, Nigidius, Manilius, and Opius. The cultivation of bees was attended to in thofe times with the moft enthufiaftic ardour, and their hiftory detailed by many eminent writers. We are told that Ariftamachus of Soli wrote upon this fubject, from the refult of fixty years experience; and that Philifcus the Thafian acquired the name of Agrius, from having employed his whole life in forefts and deferts, attending to thefe infects. The culture of filk-worms was another favourite object with the ancients, as we learn from Pliny, who relates that in his days garments of filk were greatly admired by the fair fex, becaufe, from the delicacy of its texture, it difplayed the beauty of their perfons almoft as diftinctly as though they were naked.

The eleventh book of Pliny treats of infects, as the moft fubtle of all animals in nature. He fpeaks of thofe which fly; fome with naked wings, and others with wings protected by a covering, as Ariftotle had previoufly obferved. The bees, wafps, hornets, fpiders, grafshoppers, locufts, ants, &c. are among the number of infects defcribed by this writer.

From the time of Pliny till the overthrow of the Roman empire, a period of feveral centuries, the fcience of infects feems to have made fome progrefs, though to what extent we may probably never learn. The names of writers in thofe times, and fome few fcattered memorials of their labours, are to be found recorded in the voluminous works of authors that appeared at the revival of learning in the fixteenth and following century. The number of thefe could not have been very inconfiderable: among the principal of them were Ætius, Paulus Ægineta, Alexander, Trallian, and Oribafius.

The laft-mentioned authors lived between the fourth and feventh century. After this time, through the dark ages, while ignorance in every fcience prevailed nearly over the whole world, this ftudy might have been little attended to. But we are not to conclude that even during this time it was utterly neglected. Learning had then taken a retrograde courfe from Greece and Rome towards thofe eaftern regions, from whence they had originally emanated; and the fciences, during this interval, were cultivated with fome fuccefs in Arabia. The advancement made by the Arabians in the ftudy of botany, between the ninth and twelfth century, is known to have been rather confiderable. Among the entomologifts of thofe ages we recognize fome of thofe Arabian botanifts; feveral of whom were diftinguifhed for their acquaintance with plants, as Rhazes, Avicenna, Avenzoar, and Averrhoes, each of whom wrote on infects.

From the twelfth to the fifteenth century, a darker period than the preceding, there are few writers on this fubject. The principal of thofe, at leaft within our knowledge, during this period, are Myrepfus, Hildegardis, Platerus, Arnoldus de Villa Nova, and Petrus Crefcentienfis. There are a few others, but they are too obfcure to deferve mention.

Some part of the general zoological work of Albertus Magnus, "De Animalibus," &c. relates to infects. Its author was bifhop of Ratifbon, and died in 1280; but his work, which is written in the Latin tongue, and was printed at Venice, did not appear till the year 1519.

In 1549, the work of Agricola, entitled, "De Animantibus fubterraneis," made its appearance; and in this we find one of the earlieft fyftematic arrangements of infects extant. This author reduces all infects to three principal claffes, namely, * thofe which walk, ** thofe which fly, and *** thofe which fwim; and under each clafs defcribes a number of fpecies.

About the middle of the fame century, Edward Wotton, a doctor of medicine in London, publifhed "De Differentiis Animalium;" a work relating, among other tribes of animals, to that of infects, a fcience in which its author excelled. This work is in folio, and bears date 1552; from which it muft have appeared three years before the author's death, which happened in 1555.

The work of Rondeletius of Montpellier, "Libri de Pifcibus Marinis," publifhed in 1555, or rather earlier, treats, as the title intimates, on fifhes, and other aquatic animals; to which, however, it is not entirely confined; for he alfo fpeaks of infects, and even accompanies fome of his defcriptions of thefe infects with figures cut on wood. Leffer mentions that in the library of the Jefuits at Ratifbon, there is a copy of this work in two volumes; on the margins of the leaves of which are large notes, faid to be in the hand-writing of Gefner. Whether thefe notes have in any manner appeared before the public we know not: the circumftance is repeated only for the purpofe of inquiry. If Leffer afforded any intimation of the nature of thofe notes, we might afcertain whether they are the fame with the obfervations of Gefner on Rondeletius, in his "Hiftoria Animalium," an edition of which we fufpect was printed foon after the work of Rondeletius appeared.

Conrad Gefner, efteemed the moft diligent inquirer into nature which his age produced, and who, in reward for his affiduity, obtained the title of the German Pliny, has treated flightly on infects in that part of his work which relates to the nature of ferpents, "De Serpentium Natura," &c. printed in 1587. His difcourfe is chiefly concerning the fcorpion tribe. Some tracts of this author appear to have been publifhed fo late as 1620; neither of thefe, however, are on the fubject of entomology.

A far more voluminous work than either of the foregoing was produced by the induftrious and learned Aldrovandus, in 1602; a folio volume of feveral hundred pages, with the title "De Animalibus Infectis," and forming part of his grand work on animals. Aldrovandus has not efcaped cenfure. In the "Amœnitates Academicæ," Forfkal confiders him as an indefatigable compiler, celebrated for the number of his works, but who thought he had acquitted himfelf in collecting together the undigefted obfervations of the ancients. We cannot avoid expreffing other fentiments; and notwithftanding that he has fallen into many errors of his predeceffors, this work entitles his memory to refpect. Aldrovandus was not merely a compiler; he availed himfelf of the labours of former writers, and in this refpect with lefs fervility, and certainly with more candour, than many who advance this objection againft him: for he generally refers to his authorities. Aldrovandus was profeffor of medicine in the univerfity of Bologna, and, according to his biographers, the ftudy of infects was his favourite object. In this purfuit he expended large fums of money, travelling for information, and in the employment of artifts; as he was unfortunately, like fome other eminent naturalifts, himfelf deficient in the talent of drawing. During the fpace of thirty years, he paid two hundred florins annually to a painter, folely occupied in the delineation of infects for him. From the fatigue of his refearches, this indefatigable naturalift was unhappily deprived of fight in his old age.

In

In his claſſification of inſects, he divided all theſe animals into two primary orders, the terreſtrial and the aquatic; the firſt called favica, the other non-favica. Theſe two claſſes are ſubdivided into many orders; the characters of which are determined by the number, nature, and poſition of the wings and feet.

The repreſentations of the inſect tribes, from their inferiority of ſize, added to the general minuteneſs of their characters, are rather more rudely expreſſed in the work of Aldrovandus, than the figures of the larger animals, which theſe volumes contain. A defect of this kind is leſs excuſable, becauſe from the liberality of Aldrovandus towards his artiſt it might not be expected; and furthermore, becauſe about that period a better taſte, and a deſire for more expenſive embelliſhments in works of this deſcription, began to prevail. The graphic art, or engraving on copper, though ſcarcely emerged from infancy, was now introduced in aid of this ſcience, in preference to cuts on wood, and with no ſmall ſucceſs, as we obſerve in the works of Hoefnagle, Hollar, and others of that period, whoſe labours are well known. Thoſe embelliſhments, though greatly admired in their time, were, however, too coſtly to be introduced into works of the ordinary kind; they were confined to the more expenſive productions, and, indeed, almoſt excluſively to thoſe produced by artiſts themſelves; for we ſeldom meet with them in any work of which the artiſt is not alſo the author. The beſt book of that period in our own country, for ſuch we conſider Mouffet's "Inſectorum Theatrum," affords only cuts on wood, an inſtance ſufficiently corroborative, as this work was printed in 1634. Even for the ſpace of nearly a century after this, copper-plate engravings were ſparingly introduced. The learned Liſter, in his edition of the works of Geodartius, ſo lately as 1682, laments the great expence of engravings, at the ſame time that he expreſſes his conviction that they are indiſpenſable in works of this kind. "I have taken great care of the deſigns," ſays this writer, "in transferring them upon copper plates, which I dare promiſe are exquiſitely performed by the beſt of our Engliſh artiſts, which was at my expence; and the bookſellers were not willing to reimburſe me."—"And upon this occaſion I muſt needs ſay, that natural hiſtory is much injured, through the little encouragement which is given to the artiſt, whoſe noble performances can never be enough rewarded; being not only neceſſary, but the very beauty and life of this kind of learning." But, to reſume the courſe of our ſubject in hiſtoric order, the next work immediately in ſucceſſion to Aldrovandus is that of Wolfang Frenzius, publiſhed in 1612, and called "Hiſtoria Animalium Sacra," a valuable work, as containing much original obſervation. After the manner of Agricola, he diſtributes all inſects into three claſſes, which he names aërea, aquatica, and terrea et reptantia. A ſmall octavo, printed three years after, though a ſlight production, ſhould be mentioned in this place; it is a treatiſe on ants, a pamphlet of about one hundred pages, and is written in Latin; the title "De formica," &c. by Jeremiah Wilde. The work of Fabius Columna, "Aquatilium et Terreſtrium aliquot Animalium Obſervationes," printed at Rome in 1616, relates alſo, in ſome degree, to inſects; and finally, in point of precedence to Hoefnagle, we have to notice another, a work of ſome moment, that appeared ſoon after, from the pen of Archibald Simpſon: this was publiſhed in North Britain, and from the motives of the author and ſingularity of its contents claims explicit mention. From the title of this book, which is ſufficiently explanatory, it will be perceived that entomology was only a remote object in the mind of the writer. The work derives its greateſt ſhare of intereſt, in our preſent view, from being one of the firſt publications connected with the ſtudy of inſects printed in Britain. This book, which is in quarto, was printed at Edinburgh in the year 1622, and bears the following title: "Hieroglyphica Animalium terreſtrium, volatilium, natatilium, reptilium, inſectorum, vegetivorum, metallorum, lapidium, &c. quæ in Scripturis Sacris inveniuntur et pluriorum aliorum, cum eorum interpretationibus."

At length our enquiry arrives at that particular period when the painting of inſects was eſteemed ſuitable and worthy of the pencil of the moſt ſkilful artiſts of the age, the painters retained with magnificent ſalaries in the courts of princes, and in the moſt poliſhed ſtates of Europe. Under the foſtering influence of ſuch patronage, it ought not to excite ſurpriſe that ſome advancement was made in this branch of the art. For our own part, we are not impreſſed with any very high opinion of the talents evinced in depicting theſe pleaſing objects, at leaſt by ſome of the artiſts thus employed. With ſuch inducements for the exertion of genius, and with the reward and credit naturally attached to their productions, they ought certainly to have ſucceeded better. But though the arts derived no very material advancement from their attention to this ſubject, to the cauſe of ſcience their aſſiduities were productive of infinite benefit. The cultivation of exotic plants, which about that time began to be held in proper eſtimation, afforded an ample field to thoſe artiſts whoſe labours were dedicated to the taſk of pourtraying theſe pleaſing objects. Their great forte prevailed in painting flowers, and though inſects offered ſo many charms of attraction, they appear at firſt to have been only introduced occaſionally, and as ſecondary objects, to their pictures. Theſe embelliſhments were attended with ſucceſs in proportion to their fidelity, force, and truth. In a ſtate of nature theſe lively creatures are conſtantly ſeen ſporting about the unfolding bloſſoms of the vegetable creation in ſearch of their nectareous ſuſtenance, and their introduction could not fail to infuſe a ſpirit of ideal animation into their beſt performances. Hence it ſeems, that inſects were afterwards repreſented in their compoſitions with a leſs ſparing hand; and, in the courſe of time, became with many artiſts the principal, inſtead of ſecondary object of imitation. Thus alſo, from caſual obſervers, thoſe artiſts were progreſſively led to a more intimate acquaintance with theſe creatures, and to an inquiry into their hiſtory, the novelty of which may be perceived to have amply gratified their curioſity, and rewarded their application. Their example fortunately inſpired a congenial taſte among their patrons, and hence, in the ſpace of a few years, a new and more propitious era ſeemed to dawn upon the ſcience of inſects. The ſtudy was by this means promoted, and rendered an object of attention among the higher orders connected with the moſt enlightened courts of Europe; as for inſtance, that of France, the imperial court of Germany, and thoſe of the princes of the empire.

An obſervation of the celebrated Juſſieu in the beginning of the laſt century is altogether applicable to this inveſtigation. "The arts and ſciences," ſays this writer, "owe their perfection to circumſtances which may appear the effect of chance," and the truth of this remark is completely verified in this particular inſtance; for, it muſt be recollected that the art of embroidery, a mechanical proceſs, and which in our days is ſuperſeded by the more dignified production of the pencil, is that which called forth the talents of the painter to the delineation of natural objects in the age adverted to. It was to the improvement of embroidery that his merits were at firſt ſubſervient; or at all events to a peculiar train of circumſtances ariſing originally from this cauſe, that we are to aſcribe the progreſs made in this branch of the profeſſion, from the cloſe of the ſixteenth till the middle of the ſucceeding century. About the reign of Henry IV. and Lewis XIII. of France, embroidery was in the zenith of faſhion, for the decoration of magnificent furniture, and drawings of the moſt beautiful plants were made expreſsly for the embroiderer's imitation. The obligation which botany lies under to this cauſe is well known, and that of entomology during the ſame period, if attentively conſidered, will be found no leſs conſpicuous.

The painters eminent for their abilities in this line, were Hoefnagle, Robert, Aubriet, De Bry, Vallet, and Robin. There were others to whom we ſhall advert more particularly afterwards. In order to demonſtrate the benefit which botany derived from the labours of ſuch artiſts, it need only be mentioned, that the celebrated Tournefort founded and arranged his ſyſtem of plants upon the drawings made by Robert and Aubriet for the royal library of France. The other artiſts alluded to were ſtill more converſant with the ſcienee of inſects than the former, and the labours of their pen have contributed, in uniſon with their pencil, to promote this ſpecies of knowledge. Some eſpecially were very ſuceeſsful in this reſpect.

Merian, Admiral, Schwertz, and Goedart, and alſo our own countryman Albin, were among the number of thoſe moſt eminent for their acquaintance with the hiſtory of inſects; and, were this liſt to be augmented with the names of other artiſts of ſomewhat later date, who have likewiſe diſtinguiſhed themſelves in the ſame manner, the reſult would teſtify that entomology, like many other branches of natural hiſtory, is greatly indebted for its advaneement to this claſs of authors. It is from the works of the artiſt, or of thoſe who by their application have rendered themſelves competent to delineate the objects they deſcribe, that the moſt valuable information has been obtained. The works of Röſel will ſufficiently teſtify the truth of this obſervation, but were any other confirmation neceſſary, we would advert to Lyonet who, though not an artiſt by profeſſion, felt proudly conſcious of his ſuperiority as a naturaliſt, becauſe from perſeverance he had acquired the talents of an artiſt. Are they not the imitative labours of this claſs that furniſh ample materials for the productions of thoſe who are mere deſcribers: writers, who oftentimes like hornets enter the hives of induſtry, and plunder without moleſtation?

The work of Hoefnagle, a thin volume in 4to. was publiſhed in 1630, under the title of "Diverſæ Inſectorum volatilium icones ad vivum depictæ per D. J. Hoefnagle, typiſque mandatæ à Nieolao Joannis Viſcher."

The plates altogether contain figures to the amount of three hundred and twenty-ſix. The execution of theſe acquired the artiſt no ſmall ſhare of celebrity, yet it muſt be acknowledged that they are not invariably deſerving of approbation; ſome at leaſt are very indifferent. Hoefnagle does not adopt any particular mode of arrangement, and he contented himſelf with repreſenting the inſects in the ſtates in which chance preſented them, without always following them through their progreſſive changes.

Only four years elapſed after this volume of Hoefnagle's plates were brought forward, before another production of infinitely greater conſequence as a work of ſcience appeared in our own capital, namely, the entomological work of Thomas Moufet. This, as it profeſſes to be, is an improvement on the work of Dr. Wotton, begun in the year 1550, about five years before his death: it was continued by Conrad Geſner, was afterwards enriched, as it is expreſſed by Thomas Penny, and at length aſſumed the improved form in which it was publiſhed in 1634, from the hands of Moufet. This laſt mentioned editor reviſed the order of its arrangement, corrected and enlarged the deſcriptive matter, and embelliſhed its pages with nearly five hundred wood-cuts, the greater portion of which, though rudely executed, are not deſtitute of merit. The work is intitled "Inſectorum ſive minimorum animalium theatrum: olim ab Edoardo Wottono, Conrado Geſnero, Thomaque Pennio inchoatum; tandem Tho. Moufet Londinâtis operâ ſumptibuſque; maximis concinnatum auctum, perfectum: et ad vivum expreſſis iconibus ſupra quingentis illuſtratum." This author divides his work into two parts, the firſt containing twenty-nine chapters, the latter forty-two, under which he reſpectively deſcribes the ſeveral tribes of inſects, known among the early writers by the names of veſpis, muſcis, papilionibus, cicindela, blattis, cantharide, bupreſti, meloe, &c. terms familiarized to the Linnæan ſcholar, but which are not always applied by Linnæus to the particular tribes of inſects, deſignated by theſe names in the work of Moufet and his predeceſſors: a fault we truſt to ſee one day amended.

Hollar gained conſiderable reputation by his iconical work, "Muſcarum, Scarabeorum Vermiumque variæ figuræ et formæ omnes primo ad vivum coloribus depictæ et ex collectione Arundeliana," &e. publiſhed at Antwerp in the year 1646. The drawings were preſerved in the Arundel cabinet; the plates are etchings in the uſual ſtyle of its author.

About an hundred and fifty pages of the extenſive work of J. Jonſton, "Hiſtoria Naturalis" is devoted to the ſubject of inſects, which tribes he diſtributes into four books, the firſt of which treats on terreſtrial inſects provided with legs and wings, the ſecond of terreſtrial inſects which have feet and no wings, the third of the terreſtrial apodal order, and the fourth of aquatic inſects. Theſe are illuſtrated by twenty-eight plates engraved on copper by the author, who was doctor in medicine.

Few authors are condemned with more critical ſeverity than Jonſton; his work is certainly a compilation, and as it has been ſtated, his materials are moſtly taken from the works of Aldrovandus, Moufet, and others. Forſkal denominates him a perſevering compiler, and at the ſame time obſerves that he has not added a ſingle remark to what was before diſcovered. Theſe obſervations appear in the "Amœnitates Academicæ," in which there is alſo another paper by Bladh, where we find the ſame ſentiments repeated. The opinion thus expreſſed is known to have the ſanction of Linnæus. This deficiency in the arts, to which he aſpired, is warmly cenſured by Lyonet, who declares his butterflies to be of unſufferable deformity, and in form, or outline, to be conſtantly alike in all the figures. As an artiſt, nevertheleſs, he had his admirers: if we can place any reliance on the truth of his biographers, he was not deſtitute of ability. Moncoyns ſays, he ſaw in the hand of Mr. Platern of Baſil a ſet of drawings executed by him with tolerable accuracy. And Leſſer himſelf owns that many years ago he was ſhewn others very prettily painted by him on blue paper, in the poſſeſſion of a nobleman belonging to the houſchold of one of the kings of Poland.

The work of Jonſton, which is in folio, and dated 1657, was publiſhed at Amſterdam. In the year following, we meet with an Engliſh tranſlation of Moufet's work, printed by Topſal, chaplain of St. Botolph's, in London. Nearly about the ſame time the work of Goedart, a Flemiſh painter, made its appearance in Holland in the language of that country. The laſt mentioned production deſerves more explicit mention, for we think its merits have never been very candidly eſtimated.

eſtimated. The engravings are deſcribed as of miſerable execution, and the figures ſo indifferent in point of reſemblance to the objects intended, that they could only in particular inſtances be underſtood; and again, on the contrary, the details are repreſented as ſo defective, that unleſs accompanied by his valuable plates, they would be uſeleſs. So much is advanced by his various annotators, and yet with all theſe imperfections, thoſe individuals have condeſcended at different times to favour the world with tranſlations of his work, originally written in Dutch, into the Latin, French, German, and Engliſh; and with various editions of the plates alſo. The truth is, that Goedart was a painter; the mere deſcribers, from unworthy motives, were offended that he ſhould preſume to write, while they profeſſed to be enraptured with his talents in the arts; and the artiſts denied him praiſe becauſe they conſidered him as a naturaliſt, not a painter. Were this work of Goedart the production of our days, it would be undeſerving of comment; but let us conſider the period in which it was produced, and abating our expectation of excellence in thoſe times either in the accuracy of obſervation, the hiſtory of inſects, the ſtyle of language, or correctneſs of deſign; and we muſt acknowledge it in every reſpect as a valuable performance. The beſt of his annotators, even the ingenious Liſter, to whom the original work was certainly under moſt obligation, has committed ſeveral errors in endeavouring to correct him.

For the ſpace of about twenty years Goedart devoted great attention to the ſtudy of inſects. He followed them through their progreſſive changes with great preciſion: this renders his book more extenſively acceptable, and his figures, which have never been ſurpaſſed by his predeceſſors, are for the moſt part ſo far correct as to be underſtood. The Dutch edition of Goedart's work being ſoon ſold off, the firſt volume of a Latin tranſlation, by Dr. Mey, miniſter of Middleburgh, was brought forward under the title of "Metamorphoſes et Hiſtoria Naturalis Inſectorum," in the year 1662; and a ſecond volume alſo, in the ſame language, tranſlated by M. P. Veezaerdt, miniſter in Zealand, who added thereto ſome remarks of his own. Another tranſlation of this latter part was afterwards publiſhed by Dr. Mey, with a farther addition of notes. Liſter allows thoſe annotators no credit for their labours; Goedart, he obſerves, left his writings in Dutch; "His Latin interpreters," ſays he, "have added comments indeed, but were men wholly ignorant in natural hiſtory, and their comments are mere rhapſodies, and altogether impertinent to the explication of any one hiſtory of Goedartius." Dr. Liſter re-arranged and corrected this work, and added at the ſame time many curious obſervations.

A hiſtory of animals and minerals, in the courſe of which the ſubject of inſects is noticed at ſome length, appeared in London in 1661, under the title of "Πανζωορυκτολογια."

The invention of the microſcope opened to the curious a new opportunity of penetrating into the myſteries of nature, and diſcriminating with accuracy the moſt delicate organs of the minor tribes of animals, which from their minuteneſs had evaded obſervation before, and among theſe the inſect race alone conſtituted ſuch a vaſt proportion, that we may attribute to this cauſe that ſpirit and perſeverance with which the ſtudy of theſe minute bodies was purſued about this particular period, and for the ſpace of ſome years after. The era of this invention is aſcribed to the year 1680, and although this does not appear to be ſtrictly accurate, ſince an apparatus correſponding with it was in uſe at the earlier date of 1618, and that glaſſes poſſeſſing the power of enlarging the appearance of objects very conſiderably were known among the ancients; yet, upon the whole, it may be concluded, that what is now underſtood by the microſcopical inſtrument, received ſo much improvement about the time firſt mentioned, that, in qualified terms, we muſt date its invention from that period. The diſcoveries made by the aſſiſtance of the microſcope within a few years after this time renders it a memorable epoch in the ſcience of natural hiſtory, and ſo far as relates to inſects, it is probably owing to the introduction of this valuable inſtrument into general uſe, that the names of Hooke, Power, Pierre Borel, Bonomo, Antoine Van Leuwenhöek, Joblot, and Hartſoeker (the latter of whom detected the circulation of the fluids in inſects); and many other inquiſitive individuals appear in the liſt of entomological phyſiologiſts, or anatomiſts.

The work of Power is in quarto, and was printed in 1664; this relates ſlightly to inſects as objects of microſcopical inveſtigation. Hooke's "Micrographia" appeared the year after, and treats of inſects in the ſame view. In the memoirs of the French Academy of Sciences in Paris, for 1666, there are ſome entomological obſervations by Mignot de la Voye; and in the fifth volume of the Philoſophical Tranſactions a paper relating to "inſects lodging themſelves in willows," by King and Willughby. But the letters of Liſter, which alſo appeared about the ſame time, or within the courſe of five or ſix years after, are ſtill more valuable; among theſe are "letters concerning a fly that is viviparous, and concerning an inſect feeding on henbain." "A conſiderable accompt touching vegetable excreſcencies;" "Letters about muſk-ſcented inſects, vegetable excreſcencies, and ichneumon-worms;" "A Letter containing the projection of the threads of Spiders, and Bees breeding in caſes made of leaves, a viviparous fly, &c."

A ſmall number of the inſects indigenous to Britain is deſcribed by Chriſtopher Merret, in his "Pinax rerum naturalium Britannicarum," &c. publiſhed at London in the year 1667.

An account of the tarantula engaged the pen of Wolferdas Sanguerdius (a medical profeſſor) about the middle of this century; his work, entitled "Tractatus phyſicus de Tarantula," appeared in the year 1668; it is a ſmall duodecimo of ſeventy pages, and was printed at Lyons. The general work of an Engliſh entomologiſt, Charleton, was the ſame year publiſhed in London, under the title of "Onomaſticon Zoicon, pluriorumque animalium differentias et nomina propria pluribus linguis exponens," in which we have a ſyſtematic arrangement of inſects after the manner of Aldrovandus. There is a mantiſſa of this work printed in folio in Oxford, in 1677.

Another work on entomology, a treatiſe profeſſedly elementary, was publiſhed at Leipſic, the year after the firſt part of Charleton's work appeared. It is in quarto, and is entitled "Diſſertatio de Inſectis in Genere," &c. Jacob Wolff, profeſſor of medicine at Jena, was the author.

Redi's "Experimenta circa Generationem Inſectorum," for the time in which it appears (1671), is an intereſting little book. Its author combats the doctrine of equivocal generation, maintained among the ancient philoſophers; and deduces its fallacy from a variety of experiments and obſervations of great critical accuracy; in the courſe of which he demonſtrates that every living creature is produced from an egg. The ſame work contains about thirty figures of the lice peculiar to particular birds, ſuch as the pigeon, ſwan, pie, heron, &c. The ſame writer alſo publiſhed his work on the generation of inſects in his native language, "Eſperienze in torno alla Generazione degl' Inſetti," 1688. There are ſeveral uſeful tracts by Redi on natural hiftory; but the above-mentioned is that which principally relates to entomology.

Another curious work, "Experienze intorno alla Generazione delle Zanzare," a fmall tract of about twenty pages, and embellifhed with one plate, was publifhed in 1679. It is entirely confined, as the title implies, to the common gnat (culex pipiens), and is written by F. P. Sangallo.

A writer, whofe celebrity for his anatomical knowledge of infects can never be erafed, while the fcience itfelf continues to be refpected, is the next in order for our confideration: this is the indefatigable Swammerdam. One of the moft important works of this acute obferver of nature, his general hiftory of infects, bears date 1669. We allude to the firft edition printed at Utrecht, in the Dutch language, under a Latin title, "Hiftoria Infectorum Generalis; ofte algemeenver handeling van de bloedeloofe Dierkens." Of this work it has been well obferved by a German critic, that it has no other fault than that of being written in a language not generally known. The work, in this original ftate, is in the quarto form, comprifing rather more than two hundred pages, and is illuftrated by figures contained in thirteen copper-plate engravings.

Some years paffed away before the excellence of this work, the admiration of the learned in later times, was in any manner acknowledged; and the fate of Swammerdam, a man who, in the generofity of his mind, had exhaufted the greater portion of his life in the completion of a work, fo wifely calculated to enlarge the boundaries of human knowledge, affords another and very ftriking inftance of genuine worth neglected:—another example of that culpable fpirit of ingratitude which living merit fo rarely fails to experience, in reward for the moft fplendid fervices their talents confer upon an illiberal world!—Chilling thought! that gloomy reflection which oftentimes fuppreffes the bright, the enviable, but too fatal exertions of genius, and fhrouds the mind in apathy and indifference! No fooner was the death of Swammerdam announced, than his merits were difcovered; and an anonymous tranflator rendered his book into French. Almoft immediately after, another appeared in Latin; and after fome time, another in Englifh: all which contributed, but too late, to the author's fame. He died in 1680. The firft French tranflation is dated 1682, and, like the original, is in quarto, and embellifhed with plates. The Latin tranflation correfponds with the two preceding, except that Hennius, in a fecond edition of the Latin copies, enlarged one chapter which treats on the analogy between infects and other animals and plants. The firft Latin edition, "Hiftoria Generalis Infectorum, Latinam fecit H. C. Henninus," was printed at Lyons in 1685; the augmented copy in 1693, at Utrecht. The Englifh tranflation is by Thomas Flloyd, and is printed with the edition of the "Biblia Naturæ," in our own language, publifhed in London, in 1758.

The latter work of Swammerdam was introduced to the public under very extraordinary circumftances. Such was the ill fuccefs of his former writings, that the "Biblia Naturæ," after being prepared in manufcript for prefs, was left unpublifhed. No bookfeller would venture to print it at his own rifk; and the means of Swammerdam were inadequate to its production. At the death of the writer, M. Thevenot, his friend, became poffeffed of his papers, and with the copy of this among the reft. With him they remained fome time, and then paffed into the hands of Du Verney, an able anatomift, who enriched his own cabinet with the manufcript of this work. With him it lay buried, till the zealous and illuftrious Boerhaave purchafed them; and he was no fooner poffeffed of it than he haftened to communicate this treafure to the world, and it was accordingly put to prefs in 1736. He included in this publication the former works of the author, and publifhed the whole under the title of "Biblia Naturæ, five Hiftoria Infectorum Belgice, cum Verfione Latina H. D. Gaubii, et Vita Auctoris per H. Boerhaave." This work is in folio: the firft volume, confifting of five hundred and fifty pages, appeared in 1737; and the fecond volume, of much greater bulk, and with many plates, in the year following.

The fyftem propofed by the author of this work, for the arrangement of infects, differs fo materially from that given by any preceding author, that we cannot avoid confidering it immediately relevant to our prefent fubject. The general or principal claffes into which infects are divided in his fyftem amount to four; and the characters of thefe relate to the metamorphofes the infects undergo, rather than to their appearance in the perfect ftate, the firft clafs excepted.

The firft of thefe four claffes comprehends thofe fubject to no change of form, but which quit the egg in the fame ftate and appearance they are to retain during life. This clafs includes fpiders, onifci, &c.; and muft be therefore underftood as admitting of an increafe in bulk, though not undergoing any change in form.

The fecond clafs includes thofe which, after leaving the egg, appear under the form of an infect without wings, the other members formed; in which ftate it eats and grows, till, having paffed into the fecond or nymph ftate, it iffues from thence with wings, and is in a condition capable of propagating its kind. The locufts and dragon-flies are included by its author in this clafs.

In the third clafs, the animal, after having iffued from the egg, where it remained in a difguifed ftate, and without food, appears under that of an infect which eats and grows, while the members of the animal into which it is to be converted are formed under the fkin, and which it at laft quits, and becomes a nymph or chryfalis (of the dormant kind). This clafs includes moths and butterflies, &c.

The fourth clafs confifts of thofe which, having arrived at the nymph ftate, like thofe before mentioned, do not divest themfelves of the fkin, in order to enter into that ftate, but affume the form of the nymph under its fkin, where it continues fhut up, till, quitting two fkins at once, it comes forth in the perfect ftate. The infects of this clafs, according to its writer, are exemplified in the ichneumon.

There are fome few fmall tracts publifhed by this author during his life, neither of which is of material confequence, except that on the natural hiftory and anatomy of the ephemera horaria, "Ephemeri Vita, of afbeeldingh van 's menfchen leven, vertoont in de Hiftorie van het uligent ende een-daghlevent Haft of Oever-aas," a work in octavo, printed at Amfterdam in 1675. Immediately after the author's deceafe, namely in 1681, there were no lefs than two tranflations of this work; one in quarto, in Englifh, and printed at London; the other by M. Thevenot, at Paris.

No work materially important on the fubject of entomology appeared after the firft edition of the work of Swammerdam, till the years 1678 and 1679, in which Lifter publifhed his valuable hiftory of Englifh fpiders, and Madame Merian her extenfive work on the metamorphofes of lepidopterous infects. In the interval between there were feveral publications, which, though not of the moft valuable kind, are fufficiently interefting to claim remark. Claude Perrault, one of the ableft writers on exotic infects of his age, and author of feveral papers in the Memoirs of the French Academy, produced a work in folio at Paris, in 1671, which treats

treats on insects, under the title of "Memoirs pour servir à l'Histoire naturelle des Animaux;" and to this some additions were made in 1676. The work of Ferrand of Naples also relates to insects, among other animals; and this appeared in 1672. The year after Frenzelio submitted his "Insecta novifolii cum nive delapsa;" and at Franckfort on the Main, D. W. Mollerus brought forward his "Meditatio de Insectis quibusdam Hungaricis prodigiosis anno proxime præterito, ex aëre una cum nive in agros delapsis," an useful treatise of 120 pages, with two wood cuts. In 1675, George Berclio printed at Upsal his elementary tract, περὶ τῶν ἐντόμων. The same year also, Samuel Bochart published his "Hierozoicon, sive bipartitum Opus de Animalibus sanctæ Scripturæ." Müller, in 1676, gave an orationary paper on the tarantula spider, "Dissertatio de Tarantula;" and Hermannus Grube, a curious little octavo volume on the same subject, "De Tarantula, et vi Musices in ejus curatione, conjecturæ physico-medicæ.

Dr. Lister distinguished himself in the annals of entomology about this period. Previous to the publication of his "Historia Animalium Angliæ Tractatus de Araneis," several papers by this author appeared in the Philosophical Transactions, the principal of which relate to this tribe of creatures; such as his observations on the darting of spiders, in the fourth and fifth volume; his paper entitled, "Some Inquiries concerning Spiders;" and his "Tabulæ compendiariæ Araneorum Angliæ," in the sixth volume. Lister's work on spiders, before mentioned, relates chiefly to those indigenous in England, and are arranged and designated by concise specific characters with much science, corresponding with that adopted afterwards by Linnæus. This is in quarto, and was printed at London in 1678; the appendix, "De Araneis addenda et emendanda," &c. in 1681. There is a translation of this work in the German language, by F. W. H. Martini, printed in 1778.

We are in possession of the first translation of the works of Goedart by Lister, a book printed at York in 1682, under the following title, "Johannes Godartius of insects, done into English and methodized, with the addition of notes; the figures etched upon copper by Mr. F. Pl." The name of Lister does not appear; but the initials at the close of the address to the reader are M. L.; and in our copy, the letter L is rendered Lister, in the hand-writing of an entomological collector well known in the earlier part of the last century. The latter circumstance, though not apparently of much moment, is related because the fact might admit of doubt, the work being anonymous, and perhaps forgotten. The impression consisted, as the preface acquaints us, but of 150 copies, which were intended only for the curious; and in the course of nearly 130 years, it may be naturally concluded many of these must have been lost. The notes in this book are very copious. In 1685, an edition of Goedart by Lister appeared in Latin. The translator in this, as in the former work, distributes the materials of Goedart's performances into a new form of arrangement, the merits of which are too obvious not to be considered as an improvement on the original production. He divides them altogether into ten sections; for they are not strictly, in every instance, what we might denominate *orders;* in some they certainly are. The first, second, and third sections are of the lepidoptera kind, and very clearly discriminate the papiliones from the moth tribe.

The 1st includes those with erect wings; these are the butterflies which fly by day, and the chrysalids of which are angular.

2d. Moths with the wings placed horizontally, and which proceed from the caterpillars called geometræ by Goedart, because of their gait, which is like that of a measurer of land.

3d. Moths with deflected wings, or those with hanging wings sitting closer to the body than in either of the two preceding.

4th. Libellulæ, or dragon flies.

5th. Bees.

6th. Beetles.

7th. Grasshoppers.

8th. Dipterous flies.

9th. Millepedes.

10th. Spiders.

Goedart spent forty years of his life, as he expresses it, "daily conversing with insects;" and from the course of his observations, it is manifest he was well acquainted with his subject. Lister is nevertheless unwilling to concede this point: he neither allows him credit as a naturalist or a writer, at the same time that he extols his excellent skill in limning. These opinions are delivered in a style of affected superiority over his author, neither becoming, nor strictly true; and seem to be dictated so nearly in the spirit of some more modern critics, that one cannot avoid smiling at the comparison. "Goedart," says he, "after forty years attention, seems to have made little advancement in his skill in the nature of insects: he seems rather to have diverted himself with them, than to have given himself any trouble to understand them; and yet after all, you will find him every where very just, and true in his observations, but in many places very short, and hardly intelligible." Our English annotator gained no reputation on the continent for these general remarks, although the merit of his notes relating to the metamorphoses of insects was acknowledged; the works of Goedart still maintained their credit.

Maria Sybilla Merian, vel Gräffinn, the wife of John Andrew Gräffinn, was a native of Franckfort on the Main, and early in life imbibed a taste for the study of insects, from being occupied at times in painting these pleasing objects as embellishments to her flower-pieces. The task of painting insects was performed by this fair artist with no very fastiduous share of accuracy. In point of drawing she rarely excels; and her productions, though splendid memorials of her talents, and the great encouragement she obtained, are marked by a peculiar exuberance of style incompatible with any faithful resemblance of nature. Her first work was published in 1679, and relates to European insects, chiefly those of the lepidopterous order, with their changes, and is entitled "Der Raupen wunderbare verwandeleng, und sonderbare blumen-nahrung:" another part appeared in 1683. These were published at Nuremberg. In 1718, another work by the same authoress was published at Amsterdam, called "Erucarum ortus, Alimentum et Paradoxa Metamorphosis." After this we have an history of the European insects, rendered from the Dutch text of Madame Merian into French, with an augmentation of the description of the plants by J. Marret, a work printed in folio at Amsterdam, in 1730. But the best of all her publications came out at the Hague in 1726, in a folio of superior size, with the title "De Generatione et Metamorphosibus Insectorum Surinamensium," &c.; the materials for which were collected by herself, or under her own inspection in Surinam. This lady had made a voyage from Holland to South America in 1699, for the avowed purpose of forming a collection of natural curiosities for this work, and was occupied at Surinam during the space of two years in taking drawings and descriptions of various objects for this purpose. This work is not entirely devoted to entomology, as, besides insects, it contains a miscellaneous

laneous aſſemblage of toads, lizards, ſerpents, and other reptiles, and likewiſe a pretty extenſive number of plants.

In the Philoſophical Tranſactions are to be found ſome obſervations concerning inſects, made in Virginia in 1680, with remarks by J. Petiver. Hoppio, in 1682, publiſhed at Jena a diſſertation on the gryllus migratorius. Two years after, another ſmall tract appeared alſo at Jena, a paper on ants, "Reſpublica Formicarum," by A. Schmidt. The fifteenth volume of the Philoſophical Tranſactions affords an account of the "Connough-worm," by Wm. Molyneux, a paper afterwards tranſlated into Latin, and inſerted in one of the continental journals under the title of "Obſervatio de Inſecto Hibernico vocato Connough-worm." Some few entomological obſervations of a miſcellaneous nature, extracted from the manuſcript hiſtory of Pembrokeſhire by George Owen of Henllys, lord of Kemmes, occurs in the eighteenth volume of the ſame Tranſactions. The original MS. of this hiſtory we have ſeen in the Britiſh Muſeum. Beſides the above, the Tranſactions about the ſame time contain ſeveral intereſting papers relative to inſects; as Allen's account of the gall-bee, and the death-watch, in vol. 20. "A Letter concerning an Inſect commonly called the Death-watch," vol. 22. which reſpects both ptinus pulſator, and hemerobius pulſatorius, written by William Durham; and alſo a ſupplement to an account of pediculus pulſatorius or death-watch, in vol. 24.

But, in point of priority, we ought previouſly to have mentioned the earlier works of Leeuwenhoek, a writer whoſe aſtoniſhing aſſiduity, aided by means of powerful microſcopes, has contributed more than any other man, except Swammerdam, to diſcloſe to our view the wonders of the inviſible creation, in the ſphere of which the minima of the inſect race become of the firſt conſideration. One of the firſt papers of this intelligent obſerver appears in the eighth volume of the Philoſophical Tranſactions, and is entitled "A Specimen of ſome Obſervations made by a Microſcope contrived by M. Leeuwenhoek." His communications to the world after this became numerous; and, as the object of his purſuit was of a nature to ſtimulate a ſpirit of inveſtigation, it could ſcarcely at the ſame time fail to excite controverſy. It led, therefore, to the production of many papers by different writers, all which tended, in ſome degree, to the further elucidation of the ſubject. As theſe, however, are only in part connected with entomology, it would be fruitleſs for us to follow, through the varied branches of diſcuſſion, and to ſelect thoſe particular paſſages which relate to our preſent inquiry; for theſe we refer the curious reader to Tranſactions of the Royal Society, from the eighth to the thirty-ſecond volume; and to various publications printed at Leyden and Delft in 1686, 1693, 1697, 1704, &c. Among the principal works of Leeuwenhoek, are "Anatomia, ſeu interiora rerum, cum animatarum tum inanimatarum (ſic) ope et beneficio exquiſitiſſimorum microſcopiorum detecta," 1687; "Arcana naturæ detecta," 1695; and "Opera omnia," 1722; an Engliſh edition of the ſelect works of this author was undertaken in London in 1798.

Geyerus, in 1687, was author of a medical tract in quarto printed at Leipſic and Frankfort, called "Tractatus phyſico-medicus de cantharidibus," and which, as the title implies, relates to the medicinal properties of thoſe well known inſects, the cantharides. Bononius, in the ſame year, publiſhed a letter at Florence, in which he enters on an extenſive detail of his obſervations on many inſects, with the microſcope, and lays claim to ſeveral diſcoveries. And J. F. Griendel, Von Ach, canon of the order of the Holy Ghoſt, produced his "Micrographia nova" at Nuremberg alſo at this time; a quarto volume of ſixty-four pages, ſome of which are dedicated to his microſcopical obſervations on inſects.

The work of Stephen Blankaart of Amſterdam made its appearance in 1688. Its author, a Dutch phyſician, was an aſſiduous collector, and in this inſtance produced a work, the plates of which have been as much admired for the beauty of their execution as the work in other reſpects has been condemned. Friſch, and after him Lyonet, conſider it as an indifferent production. It relates chiefly to the larva of different inſects, as the caterpillars of ſeventeen lepidopterous inſects, twelve maggots of flies, and a few other inſects, amounting altogether to forty-ſeven ſubjects. The title is, "Schou Berg der Rupſen, Wormer, Maden en vliegende Dierkens daar uit voort-kommende." The paper of John de Muralto, and alſo that of C. Mentzelius, relating to different inſects, appeared about this period; and the work of John Cyprien, "Hiſtoriæ Animalium," was alſo printed in 1688; it was publiſhed at Frankfort, and relates to inſects among other animals. A ſmall tract, an orationary paper of eight pages, with a ſingle plate, entitled "Chymica Formicarum," is from the pen of profeſſor Sperling in 1689. Koenig's "Regnum Animale," &c. printed in 1690; Bilberg's "Locuſtæ," a diſſertation, printed at Upſal in 1690; and "Hiſtoria Vermium" by Jungius, printed at Hamburgh in 1691, are all intereſting, and a paper by Sedileau, publiſhed in 1692 in the Memoirs of the French Academy, is rather curious; this latter is denominated "Obſervations ſur l'origine d'un eſpece de Papillon," and the inſect treated upon is bombyx pavonia γ major. The prodigious ravages occaſioned by the ſwarms of locuſts which, in the month of Auguſt 1693, over-ran Germany, and extended their ſcattered legions throughout the reſt of Europe, even to the borders of the moſt northern countries, were an event of ſuch an afflicting nature, that it could not fail to engage the obſervations of many writers, in the number of which we meet with the names of ſome naturaliſts of ability, whoſe diſſertations on this occaſion are acceptable. Treunero, Hebenſtreit, Woollenhaupt, Crellius, Kirkmajor, and Ludolfus, wrote at this time on the ſubject, relating the particulars of their appearance, the devaſtations committed, and the moſt effectual means of deſtroying them. The ſpecies was the common migratory kind, gryllus migratorius. Theſe tracts were generally trifling in point of ſize, that of Hebenſtreit, however, "De Locuſtis immenſo agmine aërum noſtrum implentibus, et quid portendere putentur," conſiſts of 65 pages and one plate, and that of Ludolphus, entitled "Diſſertatio de Locuſtis, anno præterito immenſa copia in Germania viſis, cum diatriba, qua ſententia autoris de שלוים defenditur," is a folio of eighty-eight pages, and embelliſhed with figures.

Albino publiſhed a ſmall tract on the cantharides in 1694, and the following year "Jacobi Petiveri Muſæum," a ſmall octavo, was publiſhed in London. Theſe, with the elementary work of Jacobæus, "Diſſertatio de vermibus et inſectis," and that of Baglivus, printed at Rome in 1696, on the effects of the bite of the tarantula, and a paper of Homberg on the libellula virgo in the Memoirs of the French Academy for 1699, appear to be the only publications deſerving of mention till the commencement of the eighteenth century.

The earlier part of the eighteenth century forms an era in which the ſcience of entomology was cultivated with the happieſt ſucceſs. It is with ſome pride alſo, we obſerve, that even in the comparatively improved ſtate to which the ſcience had then attained, it derived no incon-

 ſiderable

fiderable advancement through the labours of our own countrymen. The works of Ray and Lifter, with thofe of Petiver in England, and thofe of the indefatigable Reaumur in France, contributed effentially to this purpofe, and to the prefent day ferve in fome meafure to maintain the reputation of fcience. The works of thofe authors were fucceeded within the firft fifty or fixty years by other works of high confideration, as will be found hereafter. In the interval of time that elapfed between the publications of thofe more extenfive and valuable works, others of lefs importance, but which yet deferve mention, made their appearance; as, for inftance, in 1701 the fmall, but curious differtation of Heucherus, called "Araneum homini perniciofum et falutarem;" the little treatife by Vallerio of Upfal on the tarantula, publifhed the year after; the entomological part of the work of G. B Rumphius, in 1705, and that of Ruifch, "Theatrum univerfale omnium animalium," publifhed in 1710—1718. Henninger produced a fmall medical tract relating to millepedes, in 1711. Wedelio on an old fubject, the utility of the cantharides, in the Materia Medica, at Jena, in 1717; and Whitaker, the year following, on the fame infect: the remarks of J. Pontedera, "De Cicada," &c. annexed to his botanical work; and two tracts by Laurentius Roberg, medical profeffor at Upfal, "Formicarum Natura," and "Libella infecta."

It was in the year 1702 that Petiver produced the firft decade of his "Gazophylacium naturæ et artis," the publication of which was carried on progreffively till for about ten years after, during which period the work was extended to ten decades, each containing plates exclufive of the "claffical and topical catalogues." This work relates to infects among other animals, plants, and foffils. About twelve months before the author's death, which happened in 1718, there was, however, another work printed by him under the title of "Papilionum Britanniæ Icones," &c. and which, as the title expreffes, relates to the Englifh butterflies, and is entirely confined to entomology.

A work by Ray, appropriated to this branch of fcience, was publifhed in 1705, under the title of "Methodus Infectorum, feu in methodum aliqualem digefta," and which can be confidered only as the introduction or prelude to the great work, "Hiftoria Infectorum," which the world received in 1710, through the care of Dr. Derham; for Ray did not live to fee it publifhed.

This celebrated naturalift divides all infects into two principal claffes, thofe which undergo transformation in their form, and fuch as do not pafs through any tranformation after being produced in the firft inftance. Each of the two principal claffes are fub-divided into feveral orders, which are varioufly characterized, as by the number of the feet, or by being deftitute of thofe limbs. Some are determined by the habitation of the infects; by the fize or conformation of various parts of the body; by the odour they emit; the form of the caterpillars, and various other peculiarities. This arrangement is in part conformable with the writer preceding; the intranfmutablia, or order of thofe which do not pafs through any metamorphofes, is due to Willughby; and the three orders of changeable infects correfpond with the 12th, 13th, and 14th orders of Swammerdam's claffification. His clafs of changeable infects is divided into feveral families, as vaginipennes, from having the wings covered with a fheath, papiliones, quadripennes, bipennes, &c. There is an appendix to this work by Lifter, "Appendix de Scarabæis Britannicis," &c. Ray, like many other writers, includes certain tribes of the vermes with infects, from which they are feparated by Linnæus; it is poffible that Ray might conceive what has been fince proved by indubitable authority, that fome few, at leaft, of the fuppofed vermes are no other than the larvæ of infects.

The work of Albin, for the time in which it was executed, was confidered as an elegant publication; it is in one volume quarto, containing one hundred copper plates, with a brief defcription of the objects reprefented in each, and was originally fold at four guineas a copy, a great price in thofe times, being publifhed in the year 1720. If we miftake not, another edition is dated a few years later; there is certainly one printed with notes and obfervations by Dr. Derham, in 1749. Albin was author of a work on Englifh fpiders, in which the lice of feveral animals and birds are reprefented from the plates of Redi.

At the fame time that Albin was engaged in the preparation of the above-mentioned work in England, J. L. Frifch, rector of the Royal Academy at Berlin, was occupied on his hiftory of the infects of Germany, "Befchreibung von Infecten in Deufchland," the firft part of which appeared in 1720; the whole work confifts of thirteen parts, and each part is embellifhed with three plates. Copies of this work have been printed fince that time; the lateft we have feen bears date 1766.

Valifinieri, in his work, entitled "Efperienze et Offervazioni intorno agli infetti," publifhed in 1730, diftributes all infects into four claffes, according to the different places in which they are found. The firft comprehends thofe infects which live on plants; the fecond, fuch as live in water and other fluids; the third, thofe that live in the earth, or among ftony fubftances; and the fourth, thofe which fubfift on the other animals, or in their bodies.

Reaumur produced the firft volume of his "Memoirs pour fervir à l'Hiftoire des Infectes," at Paris, in the year 1734. The five fucceeding volumes appeared between that time and 1742. This voluminous work contains fome thoufand pages, and nearly two hundred plates; and is one of the beft productions on the fubject that has been fubmitted to the world. There are two editions of this work, one publifhed in Paris by its author, in quarto fize; the other is in octavo, a pirated concern by the Dutch bookfellers.

After the works of Ray, Lifter, and Petiver, the intelligent entomologifts of our own country, in the commencement of this century, the name of Bradley ought perhaps to have been introduced. His publication, "A Philofophical Account of the Works of Nature," which was printed in London fo early as the year 1721, contains a brief account of infects. This author, though a profeffor of botany in one of the univerfities, feems not to have been poffeffed of any very extenfive or accurate information on this fubject of entomology; his work at leaft abounds in the marvellous, but was, perhaps, for this very reafon, more likely in his time to have been perufed with pleafure by the common reader. As a popular work, it was not in other refpects without its advantages. The works of Reaumur in France contributed materially to facilitate the ftudy of entomology on the continent. And about the fame time that he was engaged in this field of enquiry, feveral tracts and papers made their appearance from other individuals. In the memoirs of the French Academy for 1731, there is one entitled "Efperiences fur les Scorpions," by Maupertuis; and in 1734, fome others by Trew, as "Infectorum quodam genere," "De duabus Erucis," and "Peculiare quoddam Quercus excrefcentiarum genus," all which are inferted in the "Commerc. Literar." of Nuremberg. Thefe papers immediately preceded the publication of the firft entomological work which the celebrated Linnæus produced to the world.

The principal writings of Linnæus on this branch of natural

tural ſcience are to be found in his deſervedly eſteemed production the "Syſtema Naturæ, ſive regna tria naturæ ſyſtematice propoſita per claſſes, ordines, genera, et ſpecies;" the firſt edition of which is in folio, and was publiſhed in 1735. Linnæus in this work diſtributes inſects into four orders, according to the number and form or nature of their wings, under the ſeveral names of coleoptera, angioptera, hemiptera, and aptera. The firſt order contains thoſe inſects which have covered wings; the ſecond thoſe with naked wings, as butter-flies, dragon-flies, ephemeræ, &c. In the third, he enumerates crickets, locuſts, bugs, &c.; and in the fourth, thoſe which have limbs, but no wings, as the ſpider, lobſter, &c. Beſides theſe four orders, this primary arrangement of inſects comprehends three other orders of animals, referred ſince to the vermes claſs, but which, at the period of the firſt publication of the "Syſtema," Linnæus conſidered to be genuine inſects. The firſt of theſe includes all creeping "inſects" whoſe body is naked and deſtitute of limbs, as the earth-worm and the leech: the ſecond, both land and ſea-ſhell animals; and the third, thoſe furniſhed with limbs, as the echinus, aſterias, &c.

Linnæus by no means deviated from the received opinion of his time, in placing the firſt and third of theſe laſt mentioned tribes of animals with inſects. Theſe bodies were conſidered as appertaining to the inſect race by moſt of his immediate predeceſſors, and by ſome naturaliſts in earlier times. In a ſubſequent edition of the Linnæan work, theſe orders are ſeparated, and the latter conſtituted into a diſtinct claſs after the manner of Ariſtotle, who points out the natural obvious difference which prevails between theſe two orders of animals with ſo much clearneſs, that we are not without ſome ſurprize his example was overlooked by Linnæus in the firſt inſtance. Linnæus, according to this plan, in his later works, ſeparates the echini, &c. under the denomination of vermes. The inſects alone were then extended by him from four to ſeven orders. This is the arrangement which his claſs "Inſecta" finally aſſumed in the edition of 1767, and which is ſtill adopted by the admirers of Linnæus. The following are the definitions of the ſeveral orders eſtabliſhed by this eminent naturaliſt.

Coleoptera, ſuch as have cruſtaceous elytra, or ſhells, which ſhut together, and form a longitudinal ſuture down the back of the inſect, as in the chafer-beetle. In moſt inſects of this claſs, the elytra cover the abdomen entirely, in others but partially, as in the ear-wig, &c. The word is derived from κολεὸς, *a ſheath*, and πτερὸν, *a wing*.

Hemiptera, which have their upper wings moſt commonly half cruſtaceous, and half membranaceous, not divided by a longitudinal ſuture, but incumbent on each other; as in the water ſcorpion and graſshopper. From ἥμισυ, *half*, and πτερὸν, *a wing*.

Lepidoptera, having four wings covered with fine ſcales in the form of powder or meal; as in the butterfly and moth, from λεπὶς, *a ſcale*, and πτερὸν, *a wing*.

Neuroptera. In this order the wings are membranaceous, tranſparent, and naked, and are generally reticulated with veins or nerves; the tail is without a ſting, as in the libellula or dragon-fly. The term is derived from νεῦρον, *a nerve*, and πτερὸν, *a wing*.

Hymenoptera, have four membranaceous wings, and the tail furniſhed with a ſting for various purpoſes, as in the waſp, ichneumon, &c. From ὑμὴν, *a membrane*, or *pellicle*, and πτερὸν, *a wing*.

Diptera, with two wings only, and poiſers as in the houſe-fly; from δύω, *two*, and πτερὸν, *a wing*.

Aptera, have no wings; as the ſpider, &c. from ἀ, *without*, and πτερὸν, *a wing*.

The great perſpicuity of the Linnæan ſyſtem of entomology aroſe from its author having made choice of the moſt obvious characters which inſects afford for the leading diſtinctions of his orders, ſuch for inſtance as the number, texture, and poſition or folds of the wings, or the abſence of theſe parts; and in the conſtruction of the genera, the like attention being devoted to the form of the head, thorax, and wings; and in particular to the ſtructure of the antennæ: theſe latter being conſpicuous in moſt inſects, and ſo infinitely varied in their appearance as to conſtitute in general a permanent definition. That there are other characters which, in the opinion of later entomologiſts, are better adapted to the purpoſe of claſſification the reader muſt be aware, but theſe, although really preferable in ſome reſpects, are perhaps too minute to become always uſeful. The ſtructure of the various parts of the mouth, the character on which the Fabrician ſyſtem is founded, however definitive, and therefore excellent, requires that degree of attentive ſcrutiny in their examination, which is rarely beſtowed by the ordinary obſerver of nature; and which cannot for this reaſon be ſo well calculated for the general purpoſe of diſcriminating the families of inſects, as thoſe which are at once too obvious to be miſtaken.

The ſimplicity of the arrangement adopted by Linnæus, the celebrity of his name, and the princely patronage under which he wrote, conſpired with other favourable circumſtances to render this ſcience more univerſally cultivated, admired, and reſpected about his time, than it had probably been at any former period. The credit due to this naturaliſt for his labours in entomology is great. This we allow, but, let us alſo remember, that he is not alone entitled to our commendation for the arrangement propoſed in his work. We muſt in candour acknowledge the merits of many among his predeceſſors, who wrote under circumſtances of leſs encouragement, and have nevertheleſs excelled in this ſcience: men to whom the writings of Linnæus ſtand in a very high degree indebted, and without the aid of which it is impoſſible to imagine the ſyſtem, which now commands our admiration, could have been produced, at leaſt in its preſent ſtate of purity.

From the various entomological works extant before the time of Linnæus, it may be collected that the hiſtory of theſe creatures was deeply inveſtigated prior to the appearance of his writings; and even that ſyſtem itſelf, the prominent feature of his labours, from progreſſive advancement, had gradually attained to a ſtate of conſiderable perfection. In the works of Ariſtotle and Pliny, in thoſe of Agricola, Aldrovandus, Frenzius, Mouſet, Swammerdam, Ray, Willughby, Liſter, Valliſnieri, and various others whoſe names have been already repeated, we diſtinctly perceive, with ſome occaſional variation, the outline of the ſuperſtructure raiſed in the "Syſtema Naturæ."

Theſe valuable ſources of information furniſhed him with abundant materials, from which he ſelected with profound judgment, and interwove with ability, induſtry, and ſucceſs. Linnæus was in this reſpect commendable; he did not ſuffer his mind to be ſwerved on this occaſion from any ambitious or innovating motives; and ſo far as he deemed it conſiſtent with his plan, he appears to have adhered to the examples of his predeceſſors. The characters of his ordines are to be found in ſeveral earlier publications than his own, and ſo likewiſe are moſt of his genera, and the far greater number of his ſpecies. But theſe he remoulded throughout with ſo much ſkill, that this "Syſtema" conſtitutes the central point in which the ſcattered rays of natural ſcience are concentrated with more preciſion than they really appear in the original authors, to whoſe induſtry he ſtands indebted. It was

was in the concife and very expreffive ftyle which Linnæus adopts in all his works, and which was almoft peculiar to himfelf, that he excelled.

Our limits are inadequate to the fair difcuffion of this important fubject; and of this we feel fo deeply fenfible, that for the prefent we fhall wave all further comment, referving to ourfelves a future opportunity for entering upon a more extenfive view of the merits of the Linnæan fyftem, as contrafted with thofe of other authors who have appeared fince his time, and which have obtained the fanction of public approval.

After the firft edition of the "Syftema Naturæ," Linnæus wrote feveral papers on the fubject of entomology; fome of which are printed in the Tranfactions of the Royal Society of Upfal. One of the earlieft of thefe appeared in 1739, under the title of "Om Renarus Brömfkulor i Lapland;" and another dated Stockholm, in the fame year, "Tal om Märkwardighter uti Infecterne." In 1746, we find a paper, jointly the production of Linnæus and Degeer, relative to the lantern-fly of China (fulgora candeleria); and about the fame time, his "Fauna Suecica," an enlarged and improved edition of which was publifhed in 1761. That elegant infect, panorpa coa, a fcarce fpecies at that period, forms the fubject of a fmall Linnæan paper in 1747. His differtations "Miracula Infectorum," and "Noxa Infectorum," bear the fame date, 1752: they were both printed at Upfal, and poffefs merit: the latter is in particular valuable, from the object in the contemplation of the writer. Six years after this he produced a differtation, called "Pandora Infectorum;" the year after, a paper on the coccus; and in 1761, his "Fundamenta Entomologiæ," a book in thofe days of confiderable value as an elementary work, or introduction to this ftudy. There is a tranflation of the tract by W. Curtis, printed at London in 1772. His laft entomological paper is upon the genus paufus, a curious coleopterous tribe, diftinguifhed by the comparatively enormous magnitude of the antennæ.

The work of L'Admiral, entitled "Naawkeurige Waarneemingen van Geftaltverwiffelende gekorwene Diertjes," appeared in 1740 at Amfterdam. It is in folio, and contains a feries of elaborately finifhed etchings, which, though engraven in a diffimilar ftyle, have fomewhat the air of Merian's work on the infects of Surinam, or as is diftinctly copied in the Aurelian of Mofes Harris. The work of L'Admiral is confined to the European infects, of which it comprehends about fifty fpecies of the larger kinds, and thofe principally of the lepidopterous tribe. Thefe are reprefented in a heavy, though not unpleafing, and often very beautiful manner, in various attitudes, with large branches of the different kinds of plants on which they feed; and in moft inftances, the perfect infect is accompanied on the fame plate with the larva and pupa. L'Admiral's work began in numbers, and was intended to contain, according to its author, one hundred plates and four hundred pages of letter-prefs. This defign was never completed. There are few copies with more than twenty-five plates, and about five pages of letter-prefs. Our copy contains thirty-two plates and twenty pages, and is the moft complete in this refpect we have feen.

A fmall treatife relative to the larvæ of phalænæ, by Dethardiug, "Difquifitio Phyfica Vermium in Norvegia, qui novi vifi," was publifhed in quarto in 1742. The fame year, the tarantula fpider engaged the attention of Francefco Serao of Naples, who on this fubject only has given a quarto of two hundred and fixty pages, entitled, "Della Tarantola o vero Fala gio di Puglia." The hiftory of the tarantula about this time engaged the pen of feveral curious perfons; and, among others, N. Caputus had the year preceding publifhed a book nearly the fame fize, "De Tarantulæ Anatome et Morfu."

The work of Leffer, "Infecto-theologia," &c. written in the German language, and better known from the French tranflation by Lyonet in 1742, entitled "Theologie des Infectes," is rather a curious than valuable publication. The fuccefs of this book in Germany renders it worthy of particular mention. The views of its author, (a clergyman at Nördhaufen,) as he himfelf explains, was to "promote the glory of God." He does not afpire to the eftablifhment of any new facts relative to entomology: his attention is directed folely to the felection of fuch anecdotes and particulars of the hiftory of infects, gleaned from other works, as could be rendered a convenient medium for the theological remarks with which his pages abound. The piety of his mind we fhall not diftruft: to an entomologift his work is of no material worth; he was not very well acquainted with this fubject, and his remarks are often erroneous. As a theological production, and in this view the author wifhed it to be confidered, certain paffages in the work of Leffer may have an ufeful tendency: it is calculated to expofe fome glaring errors in the writings of other theologians, who in a fpirit of fanaticifm had entered upon the fame fubject. One of his beft chapters on this head is that relating to the "abufe of infects in theology;" in which he points out the grofs outrage on reafon committed by the pagans, in making certain infects the idols of their worfhip; and remarks how much more abfurd it muft appear, that the Jews and even Chriftians fhould have followed their example: a fact inferred by him from various authorities. The Jews are accufed of ftating many wonderful things relative to infects, which can only be confidered as fables. Among others, after repeating the facred text, 1 Kings, vi. 7. concerning the erection of the temple, which was "built of ftone made ready before it was brought thither; fo that neither hammer, nor ax, nor any tool of iron was heard in the houfe, while it was building," he ftates, that the Jews explain this paffage in the following manner. The workmen, they affirm, employed a worm to fhape the ftones; which infect, named fchamir, cut and broke them to pieces in places where applied. They add, that it was the figure of a grain of barley, and was kept in a leaden box, becaufe, had it reached any rocks, it would have cleft and deftroyed them. This fable, with fome others invented by the rabbis, is particularly mentioned. Among the legends of Catholic fuperftition he felects other anecdotes equally remarkable. Baldus, he fays, in order to prove the real prefence in the eucharift, relates that a number of bees being found on holy ground, paid it homage, and carried a portion of it refpectfully to their hive. Baptifte tells us, that a fpider having accidentally fallen into the chalice, while St. Francis was faying mafs, the holy man determined to fwallow it; and adds, that the fpider came afterwards out of the bone of his leg. But to conclude with one of thefe tales of fanaticifm not unworthy of record with the reft: it is gravely ftated that St. Francis, once walking in a garden, faw a grafshopper, which immediately quitted the plant it fat upon, and perched on his hand; he ordered it to fing to the praifes of God, and with a pretty loud voice it immediately began a very fine pfalm! If fuch holy impoftures were actually liftened to with any faith, the time of Leffer could not be mifapplied, as a divine, in endeavouring to expofe their abfurdity.

Degeer publifhed at Stockholm, in the year 1744, an interefting little octavo on the utility of the ftudy of infects, called "Tal om nyttan, fom Infecterne och deras fkärfkådande,

dande, tilſkynda oſs;" in which he points out the advantages likely to reſult from our acquaintance with this tribe of animals, and which appears to be the firſt tract expreſsly written under this view of entomology. About this ſame period, Röſel of Nuremburg, by profeſſion a miniature painter, was engaged in the preparation of a valuable entomological work, the firſt part of which was ſhortly after produced to the world. This work bears the title "Der Monatlich-heraufgegebenen Inſecten-Beluſtigung," and conſiſts of ſeveral volumes in quarto. The firſt part was produced in 1746, and two ſucceeding volumes in 1749 and 1755; to theſe a fourth volume was added by his relation Kleemannin, 1761, two years after the death of Röſel; and ſince that period Kleemanahus publiſhed three other parts in continuation.

Röſel does not adopt any ſcientific order of arrangement: his work was produced as a miſcellany, and, according to the title, as an amuſement in the ſtudy of inſects. Many of the inſects included are European; others are natives of Aſia, America, &c. Beſides inſects, ſome few of the cruſtacea are contained; and a portion of the third volume is devoted to the vermes tribe. The text is in the German language, and exceedingly copious; the ſlighteſt peculiarity in every individual inſect being deſcanted upon with as much minuteneſs as the more important details of its hiſtory. The plates are numerous and intereſting. The ſupplemental faſciculi given by Kleemann, "Beyträge zur Natur-und Inſecten-Geſchichte," &c. relate to European inſects, and a ſmall number of the extra European kinds.

A tract, dedicated to the purpoſe of explaining the advantages ariſing from the ſtudy of inſects, was printed in 1747, by C. F. Mennander, "Diſſertatio de Uſu Cognitionis Inſectorum." Bazin, the ſame year, publiſhed his "Abregé de l'Hiſtoire des Inſectes, pour ſervir de ſuite à l'Hiſtoire naturelle des Abeilles," in Paris; and in London, William Gould, "An Account of Engliſh Ants." T. C. Hoppe publiſhed, the year after, two ſmall entomological tracts, as "Antwort-Schreiben auf Hrn Schreibers zweifel," at Gera; and "Eichen-Weiden-und Dornroſen," at Leipſic; and J. Dutfield of London, ſix numbers of a natural hiſtory of Engliſh moths and butterflies, after which the work diſcontinued.

About this ſame period, or rather earlier, but certainly before the year 1749, a work was undertaken in London by Benjamin Wilks, under the title of "The Engliſh Moths and Butterflies, together with the Plants, Flowers, and Fruits whereon they feed, and are uſually found." This publication, conſiſting originally of plates only, appeared in the firſt inſtance without a date. From collateral circumſtances we are, however, enabled to ſtate that it muſt have preceded the year laſt mentioned; becauſe at that time the whole work, conſiſting of 120 plates, was nearly completed, as we learn from comments upon that work in the third volume of Röſel's Inſecten Beluſtigung. The nature of this work is rather incorrectly ſtated in its title page; for the plants on which the groups of inſects are reſpectively diſplayed are not thoſe which conſtitute their natural food: they conſiſt of gaudy flowers, auriculas, roſes, monſtrous varieties of cultured plants, fruits, &c. the introduction of which, in preference to their natural food, has incurred blame. But another charge, and one in our opinion of more importance, is brought againſt our author by Röſel; an imputation tending to depreciate the reſpectability of the Engliſh entomologiſts of that particular criſis, when the ſcience ought, from the labours of former writers, to have ſtood in this country on very high ground, and the public judgment to have been ſo far matured as to diſcover impoſition. He plainly accuſes our author of piracy; and when we reflect on the celebrity this work has heretofore enjoyed as an original production, it does attach ſome little reproach at leaſt that facts ſtated with the utmoſt publicity on the continent ſhould have remained unknown to us. The remarks are curious; and as in all probability they have not before met the eye of the Engliſh reader, we ſhall tranſlate the paſſage in this place: "In dem nachtragoder 3," &c. "In the ſupplement, or third part of my Amuſements of Inſects, I have mentioned a certain work which Mr. Wilks in London publiſhes monthly, and promiſed that I would be more circumſtantial at another time. Since then the plates amount to ninety, all which I have examined with great attention: they are as yet deſtitute of any deſcription, which, however, is to appear at ſome future period. If the notice which accompanies theſe plates deſerves credit, all thoſe inſects are drawn after life; but to thoſe who know other works, and examine theſe plates with caution, it ſoon appears that the author has copied ſeveral from Albin's inſects, from Merian's book, and a great many from my own. Whether he has been ſucceſsful in his attempt, I leave to the judgment of others. An ape mimicks every thing, but does not always ſucceed. This may appear to many to be too ſevere; but let them conſider that the author counterfeits the works of others, and gives them out as his own. I venture to aſſert that in the future deſcription of his work, he will take care not to tell us from what books he has compiled his own; for he already ſtrives to hide on his plates whatever he has copied from others, by reverſing the figures, or by giving them a different poſition." Vol. iii. p. 192, A.D. 1749. This we muſt conſider as in ſome meaſure the language of reſentment for the liberties taken with his work: it is neverthele ſs in ſubſtance true; for the eye of the artiſt will perceive, on comparing the two publications, that Wilks has taken an unlimited range through the firſt volume of Röſel. The remarks are repeated at length, becauſe we wiſh to impreſs on the public mind the value and importance of any genuine work, in preference to productions of this nature. Wilks was the publiſher of "Twelve new Deſigns of Butterflies," in which the inſects are diſpoſed in ſtars, feſtoons, circles, or other whimſical groups, forming what are uſually denominated "Butterfly pictures."

The firſt volume of the invaluable work of baron Charles de Geer, the "Memoirs pour ſervir à l'Hiſtoire des Inſectes," was printed at Stockholm in 1752, and was received with every demonſtration of praiſe, to which its merits are entitled. From the teſtimony of the author's talents which this volume afforded, the continuation was expected with impatience; but nine years elapſed before the ſecond volume appeared, and it was altogether twenty-ſix years from its commencement to its termination. It was completed in 1778, in which year the labours of its author cloſed with his life. De Geer was the author of many other publications, which are to be found diſperſed through the Tranſactions of various learned ſocieties; but that above noticed is the moſt conſiderable of his works.

Dr. Hill, in his hiſtory of animals, publiſhed in London in the year 1752, divides inſects into three claſſes: the firſt of which, apteria, comprehends all inſects without wings; the ſecond, pteraria, is devoted to the winged kinds; and the third, called gymnarthridia, conſiſts of thoſe which have ſoft and naked bodies, and are furniſhed with limbs. The apteria is divided into two families; and pteraria, or the winged inſects, into diptera and tetraptera, or thoſe with two wings and four wings.

The "Entomologia Carniolica" of Scopoli appeared in 1753.

1753. This author diftributes all the infects of which he treats into orders, genera, fpecies, and varieties, nearly after the manner of Linnæus; changing, neverthelefs, the names they bear in the works of the latter for others he deemed more appropriate. Thus, for example, probofcidea is fubftituted for hemiptera, in reference to the beak by which thefe infects are diftinguifhed; aculeata for hymenoptera, from the abdominal fting; halterata for diptera; and pedeftria for aptera.

As a fyftematic work, this publication of Scopoli is of fmall importance; in other refpects it is valuable. The arrangement of infects, better known on the continent as the fyftem of Scopoli, appeared in a work, entitled "Introductio ad Hiftoriam naturalem," printed fo lately as the year 1777, and which, as the title expreffes, does not relate exclufively to the fcience of entomology. He divides infects into five tribes, under the fingular appellations of Swammerdamii-lucifuga, Geoffroy-gymnoptera, Roefelii-lepidoptera, Reaumurii-probofcidea, and Frifchii-coleoptera: by this means, identifying each particular tribe with the name of an author, who in his opinion had been moft fuccefsful in the explanation of that to which his name is attached.

The order lucifuga includes two genera, cruftacea and pedicularia; gymnoptera comprehends halterata, aculeata, and caudata; lepidoptera, the genera fphinx, phalæna, and papilio; probofcidea are divided into two parts, the terreftrial and aquatic; and the coleoptera, in the fame manner, confift of two families, the inhabitants of the water and thofe of the land.

The ardour with which the fcience of entomology was cultivated about this period in various parts of Europe, is to be afcribed to the occafional labours of Linnæus and his immediate coadjutors, whofe example excited the moft laudable affiduity; and though no work of any material confequence appeared exactly at this time, we may fafely conclude that this fpirit of emulation laid the foundation of feveral which were fubmitted to the world a few years after. Among the entomological tracts and papers of this time, fome only are worthy of notice. Kalm, a name familiar to the botanift, beftowed attention on this fubject, as we perceive from a paper on a fpecies of cicada, (feptemdecim,) written in the Swedifh language; and alfo from another by the fame author on acarus americanus: thefe appeared in 1754. The year after G. W. Sigwart treats flightly on coleopterous infects; and Sauvages produced fome papers of little moment in the Memoirs of the French Academy. And now we proceed gradually to the confideration of other works of greater confequence; the ufeful work of Clerk on the fpiders of Sweden, printed in 4to. at Stockholm, in 1757, is one of the beft works extant on this curious tribe. Another production by the fame author is alfo valuable, his "Icones infectorum rariorum," a thin and fmall quarto, publifhed two years after. Indeed, this laft mentioned work may be confidered as having the immediate fanction of Linnæus, from being produced under his own direction, and, we believe, infpection. The work contains a moderate number of coloured plates, fome of which are appropriated to the difplay of felect exotic infects of the moth and butterfly tribe, and others to the more choice and rare lepidopterous infects of Europe, all which are highly finifhed in colours. There were only a few copies of this work printed off, and it is now become fcarce, and bears a confiderable piece. Dr. Smith poffeffes one copy, that originally in the library of Linnæus, and there is another in that of fir Jofeph Banks.

An interefting little work, called "Infecta Mufei Græcenfis," from the pen of Nicolaus Poda, publifhed in 1761, affords an account of the infects of Greece, arranged in the Linnæan manner. The fame year an introductory work to the ftudy of infects by J. H. Sulzer, was printed at Zurich: it is in quarto, with a number of plates, and bears the title of "Die Kennzeichen der Infekten durch 24 kupfertafeln erläutert, und mit derfelben natürlichen gefchichte begleitet." The fame writer, in 1776, produced another publication alfo introductory to the fcience of infects, called "Abgekürtze gefchichte der Infecten," illuftrated with thirty-two coloured plates; which latter, with five or fix additional plates, form the hiftorical part of the quarto work publifhed in Switzerland, in 1789, by J. J. Roemer, as an elucidation of the Linnæan and Fabrician fyftems. The title of the latter is "Genera Infectorum Linnæi et Fabricii iconibus illuftrata." The outline of the Fabrician fyftem, which this work contains, is conformable with that propofed in the earlieft work of the laft mentioned entomologift.

As a fyftematic production, the work of Geoffroy, printed at Paris in 1762, demands the particular attention of the modern entomologift. The work is entitled "Hiftoire abrégée des Infectes," and comprifes all the infect tribes in the fix following claffes: 1ft, coleopteres; 2d, hemipteres; 3d, tetraptères à ailes farineufes; 4th, tetrapteres à ailes nues; 5th, dipteres; 6th, apteres. The firft clafs correfponds with the Linnæan coleoptera; the fecond is more accurately regulated by the form of the probofcis; the third agrees with the lepidoptera, having the wings covered with fine powder; the naked-wing tribe unite the neuroptera and hymenoptera; the dipteres and apteres are the fame with the Linnæan orders. It is a material diftinction of this fyftem, that the characters of the orders are determined chiefly by the number of joints in the feet; the generical characters are taken from various parts of the body, wings, &c. The genera differ exceedingly in their conftruction from thofe of Linnæus, and many of them are in ufe to this day among the continental writers.

Brünniche is the author of two entomological tracts, printed about the fame period, as, "Prodromus Infectologiæ Siællandicæ," and an elementary work in Latin and Danifh, called "Entomologia fiftens Infectorum tabulas fyftematicas, cum introductione et iconibus." Sepp began his work, "Befchouwing der wondern gods in de minftgeachte fchepzelen of Nederlandfche Infecten," in the year 1762; it is dedicated entirely to the more uncommon moths and butterflies of Holland; the text is in the Dutch language, and the plates, which are not numerous, are admired for their peculiar neatnefs, being engraven in the dot or ftipple ftyle, with confiderable delicacy.

This elaborate kind of engraving was in great efteem about the period adverted to, as appears from the encomiums beftowed on the plates executed by the hand of Lyonet, for his laborious work, "Traité Anatomique de la Chenille," printed in Holland the fame year. This work of Lyonet is a treatife dedicated folely to the anatomy of the caterpillar, which lives in the wood of the willow, (phalæna coffus,) upon the diffection of which this author enters with fuch minutenefs of inveftigation, that his defcriptions of this object alone occupy rather more than fix hundred quarto pages. The plates, eighteen in number, with the exception of the firft, which reprefents the microfcope employed in his examinations, are entirely appropriated to the reprefentations of the mufcles, tendons, fibres, medullary veffels, fpiracles, &c. every part of which throughout the whole animal are exhibited in their natural and magnified appearance. Thefe plates, as before intimated, are finifhed fpecimens of the ftipple ftyle of engraving then prevalent, and which,

which, from the cloſeneſs of its texture, nearly reſembles mezzotinto.

Lyonet is ſaid to have left at his death two manuſcripts on the ſubject of entomology, neither of which have, to our knowledge, appeared before the world. One of theſe is inſcribed "Œuvres Melées ſur les Inſectes," and contains his obſervations on the inſects found in the environs of the Hague, where he reſided. The other, an "Eſſai Anatomique ſur la Chryſalide et la Phalene qui range le bois de ſaule," a work on the ſame plan, and forming a continuation of the hiſtory of the ſame inſect, as his former eſſay on the caterpillar. This unpubliſhed work on the chryſalis and fly was to be accompanied by no leſs than fifty-four plates, all the drawings of which were executed, and ſome of the plates engraved, previouſly to the death of the author, which happened, at an advanced age, in 1789.

The ſcience derived ſome improvement from the various publications of Schæffer between the years 1764 and 1777. He produced, among others, an elementary work in German, "Zweifel und Schwürigkeiten, welche in der Inſectenlehre annoch vorwalten," and another, entitled "Elementa Entomologica," containing no leſs than 132 plates, appropriated to the illuſtration of the principles of his ſyſtem; and an additional ſection with two more plates, deſcribing the various apparatus for catching, and the manner of feeding inſects, microſcopes for examining them, &c. "Vierter abſchnitt von den Werkzeugen der Bedhandlung und Sammlung der Inſecten." The moſt important of Schæffer's works, is that entitled "Icones Inſectorum circa Ratiſbonam indigenorum," compriſed in three volumes 4to. with a vaſt number of coloured plates, the latter of which poſſeſs a character of great peculiarity in having two impreſſions on every print, one on the front of the leaf as uſual, and the other on the back; by which means the plates are compriſed in half the number of leaves they would otherwiſe occupy. The claſſification of Schæffer differs extremely from that of Linnæus; it approaches that propoſed by Geoffroy, from which, however, it is ſtill ſo far diſtinct, that being a ſyſtem in ſome repute, it may not be amiſs to preſent an outline of it in this place.

Schæffer divides all inſects into ſeven claſſes, in the following manner;

1. Inſecta coleoptero-macroptera, inſects whoſe elytra are cruſtaceous throughout their whole length, and extend beyond the abdomen when cloſed.

2. Inſecta coleoptero-microptera, differ from the former only in having the wing-caſes ſhorter than the abdomen.

3. Inſecta coleoptero-hymenoptera, or hemiptera, ſuch as have the elytra half cruſtaceous, or becoming membranaceous towards their extremity.

4. Inſecta hymeno-lepidoptera, or having wings imbricated with ſcales.

5. Inſecta hymeno-gymnoptera, or with naked and membranaceous wings, comprehending the two Linnæan orders neuroptera and hymenoptera.

6. Inſecta diptera, or inſects having two wings.

7. Inſecta aptera, or without wings.

The ſecond part of "Zoophylacium Gronovianum," by Laur. Theod. Gronovius, contains the deſcription of about ſix hundred inſects with ſynonyms after the Linnæan manner, accompanied by four illuſtrative plates. The work is in folio, and was printed at Leyden in 1764.

Seba, in his ſplendid folio work, "Theſaurus Naturæ," publiſhed at Amſterdam in 1765, deſcribes a number of the larger kinds of extra European inſects, with figures executed with great force, and in a ſtyle correſponding with the other plates of his work.

In 1769, Berkenhout publiſhed the firſt edition of his "Outlines of Natural Hiſtory of Britain;" ſince which time two other editions of the ſame work have appeared. That portion of the work which is devoted to entomology includes a ſmall ſelection of the ſpecies moſt conſpicuous for their ſize, under each of the Linnæan genera, the inſects being arranged throughout in the order of that ſyſtem. The number of inſects deſcribed amount to about ſix hundred. The work is deſtitute of figures.

Among the number of exotic inſects figured in the plates of "The Hiſtory of Birds," and the "Gleanings," by George Edwards, ſome are intereſting from their beauty. There are a few alſo remarkable for their rarity, particularly ſcarabæus atlas, one of the three larger "Indian beetles;" libellula chinenſis, called "the green-winged libellula;" and the larva or pupa of an extraordinary gibbous kind of locuſt, repreſented only, we believe, in this work. Inſects were not ſparingly introduced, notwithſtanding that they were conſidered only as ornamental objects, the work being devoted principally to ornithology. In the courſe of the whole of this voluminous production, more than fifty ſpecies of the inſect tribes are noticed, the greater part of which are butterflies. Edwards began this publication in 1743, from which period it was continued progreſſively till 1764. The catalogue was publiſhed in 1770, and forms part of the tracts entitled "Edwards on Natural Hiſtory."

John Reinhold Forſter, one of the eminent naturaliſts who accompanied the celebrated Capt. Cook in his voyage round the world, has left us a catalogue of Britiſh inſects printed in 1770. It is only a liſt of Latin names of a certain number of ſpecies, and was intended as a prelude to the copious work on the inſects of this country, which its author intended to write. This catalogue, however, and his "Novæ Inſectorum Centuriæ," which appeared in London the year after, are the only entolomogical works that author publiſhed. Of the latter we ought to ſpeak more at large. The avowed purpoſe of this little book, as the reader is informed in the preface, was to give a deſcription of one hundred inſects not mentioned in the lateſt work of the illuſtrious Linnæus. The inſects included are partly indigenous, ſome are from China, and others from South America. The greater number of theſe are coleopterous inſects, and are arranged after the manner of Linnæus, though the genera anthribus and ciſtela are taken from Geoffroy. It may be laſtly obſerved, that although theſe inſects do really appear to be undeſcribed by Linnæus, ſome few of them were previouſly made known to the world by the works of Schæffer and Drury. This its author was aware of, but as they had eſcaped the obſervation of the author, whoſe work he was ſolicitous to improve, it was ſtill conſidered right to introduce them.

The firſt volume of the "Illuſtrations of Natural Hiſtory, wherein are exhibited figures of exotic inſects," &c. by D. Drury, was publiſhed in 1770. The plates, fifty in number, form a miſcellaneous aſſemblage of the more beautiful extra European inſects, which the extenſive collection of its author afforded. The ſecond volume was produced three years after the firſt; and the third, which concludes the work, ſo far as the author proceeded with the publication, appeared in 1782. Beſides the inſects repreſented in theſe volumes, the extenſive cabinet of the author contained many very choice ſpecimens, reſerved as materials for the fourth volume which was in contemplation; and among the reſt, a number of curious ſpecies collected in the interior of Africa, and other countries rarely viſited by Europeans, the introduction of which would have rendered the fourth volume of much greater intereſt to the entomologiſt than either

either of the preceding; this may be collected from the manuſcripts of Mr. Drury, in the poſſeſſion of the writer of this article, and which are now before us. From an inſpection of theſe papers, it likewiſe appears, that the author intended, in a reviſal of his former volumes, to have aſſigned the Fabrician names to all the inſects contained, ſo far as theſe could be obtained, and that for this purpoſe Fabricius had himſelf furniſhed Mr. Drury with a number of names and references, independently of thoſe which had been publiſhed in his "Species Inſectorum," a paper by Sebaſtiani, "Inſecta ad aquas Mattiacas ſuper nive deprehenſa," bears the ſame date with Drury's firſt volume of exotic inſects, and as nearly as we can aſcertain Kahn was about this very period engaged at Berlin in his publication "Anecdoten zur Inſekten-geſchichte," a work written in German, and publiſhed in numbers. The tract of Kahn, relative to the mode of catching and preſerving inſects, called "Kurze anleitung Inſecten zu ſammlen," is dated 1773.

The "Inſtitutions of Entomology," by Thomas Pattinſon Yeats, is the only production of its unfortunate author relative to this ſubject: it is a tranſlation of the Linnæan orders and genera, collated with three other ſyſtems, namely, thoſe of Geoffroy, Schæffer, and Scopoli, together with obſervations by the tranſlator. This was a valuable book at the time of its production. In the preſent day it is become rather obſolete; and it is in particular defective in the compariſon drawn between the Linnæan ſyſtem and that of Scopoli; not from any error of the tranſlator, but an event that could not be anticipated. Scopoli coincided nearly with Linnæus in his arrangement of inſects, when he wrote his "Entomologia Carniolica;" after which, however, he abandoned that method, and adopted another; that which has ſince obtained currency on the continent under the name of "Scopoli's Syſtem." This laſt mentioned work was not printed till four years after the tranſlation by Yeats.

"The Aurelian's Pocket Companion," by Moſes Harris, is a kind of alphabetical catalogue of the larger butterflies, ſphinges, and moths collected in England by its author: a tract of no utility to the naturaliſt, unleſs he firſt condeſcends to become an adept in the jargon of the aurelian, or, as now termed, the entomological ſociety; the inſects being throughout deſignated by the ſilly names impoſed by the few illiterate perſons aſſociated under this denomination. In this Engliſh lexicon of entomology, we have "The Wall," "The Bark," "The Turnpike-gate Keeper," "Ghoſt," "Old Woman," "Diſh-clout," and a vaſt number of others equally capricious and replete with abſurdity.

J. C. Fabricius, the indiſputable founder of a new ſyſtem of entomology, publiſhed in the year 1775, his "Syſtema Entomologica," in which the principles of his novel mode of claſſification is for the firſt time developed. The eſſential characters of the claſſes are determined from the organs of manducation, or mouth (inſtrumenta cibaria). In this work inſects of every deſcription are comprehended in eight claſſes to which the ſeveral names of eleutherata, ulonata, ſyneſtata, agonata, ungonata, gloſſata, rhingota, and antliata, are aſſigned.

This work obtained for its author very high reputation, and ſuch further inducements to the proſecution of his entomological ſtudies, that in the courſe of a few years after ſeveral other works appeared from his pen on the ſame ſubject, among which were his "Species Inſectorum," "Entomologia Syſtematica," &c. in all which his original manner of claſſification was adopted with progreſſive improvement. His "Supplementum Entomologiæ Syſtematicæ," preſents an outline of his ſyſtem in its lateſt ſtate, and is the baſis on which the laſt work in which he was engaged, his "Syſtema Eleutheratorum" was undertaken. Part only of this valuable work has hitherto appeared, its completion being impeded, if not finally interrupted, through the death of the author; but ſo far as he did proceed, the arrangement propoſed in his ſupplement is adopted, and we cannot entertain any other concluſion than that it would have been acceded to throughout. This may hence be admitted as the beſt he had formed in the opinion of its author, and a concluſion, the reſult of ſo much extenſive knowledge in the ſcience as Fabricius poſſeſſed, deſerves our ſerious conſideration.

In this ſyſtem Fabricius diſtributes all inſects into thirteen claſſes, the characters of which are as follow:

Claſs 1. *Eleutherata.* Jaws bare, free, and bearing feelers.

2. *Ulonata.* Jaws covered by an obtuſe mouth-piece

3. *Syniſtata.* Jaws elbowed near the baſe, and connected to the lower lip.

4. *Piezata.* Jaws horny, compreſſed, and uſually elongated.

5. *Odonata.* Jaws horny, dentated; palpi two.

6. *Mitoſata.* Jaws horny, vaulted; no palpi.

7. *Unogatæ.* Jaws horny, unguiculated.

8. *Polygnata.* Jaws ſeveral (uſually two) within the lip.

9. *Kleiſtagnatha.* Jaws ſeveral, outſide the lip.

10. *Exochnata.* Jaws ſeveral, outſide the lip, and covered by the palpi.

11. *Gloſſata.* Mouth compoſed of a ſpiral tongue, ſituated between two palpi.

12. *Rhyngota.* Mouth compoſed of a beak or articulated ſheath.

13. *Antliata.* Mouth compoſed of a ſucker, not articulated.

This able entomologiſt is the author of various tracts on entomology, written in the Latin and German languages; and alſo of two principal introductory works, "Genera Inſectorum," and "Philoſophia Entomologia."

The inſects of Switzerland are deſcribed by J. C. Fueſſlin, in an intereſting little work, to which its author gives the title "Verzeichnis der ihm bekannten Schweitzerſchen Inſeckten," printed at Zurich, and bearing the ſame date (1775) with the Fabrician "Syſtema Entomologica."

The number of inſects figured in the "New Illuſtrations of Zoology," by Peter Brown, in 1776, is by no means conſiderable; ſome few of which it does contain are nevertheleſs ſufficiemtly important in point of rarity to deſerve explicit mention. The purple-winged locuſt is, in particular, a magnificent inſect: at the time this artiſt made his drawing, the ſpecimen, which is preſumed to be unique, was in the poſſeſſion of Mr. Tunſtal; at preſent it enriches the ſplendid collection of Mr. Macleay. The work of Stoll, it ſhould be obſerved, affords likewiſe a figure of this ſpecies, and which, it is believed, was taken from the ſame ſpecimen previouſly to its being purchaſed in Holland for Mr. Tunſtal.

The extenſive ſyſtematic work of J. A. E. Goeze, called "Entomologiſche beyträge zu des Ritter Linné zwölften aufgabe des Natur ſyſtems," began to be publiſhed at Leipſic in 1777, and was continued progreſſively in parts till 1783. In the ſame year, with the commencement of this publicaton, Eſper produced in Germany the firſt part of his uſeful book on the lepidopterous tribe of inſects, "Die Schmetterling in Abbildung nach der natur mit beſchreibungen," a work with many plates, and of which a ſecond part was publiſhed in 1779. Between that time and 1786 two other parts appeared likewiſe, and which altogether form a very a very extenfive publication. Two other very coftly works, devoted exclufively to this beautiful order of infects, were alfo begun in 1779, one at Paris in the French language; the other in Holland, and in the language of that country: the firft of thefe is entirely appropriated to the infects of Europe, and is named "Papillons d'Europe, peints d'après nature;" the latter is by Pieter Cramer, and confifts of the extra European fpecies. The title of this work is, "De uit landfche kapellen, voorkomende in de drie waereld deelen Afia, Africa, en America," and including the continuation publifhed about the year 1782, confifts of four volumes quarto, with many plates. The production of thefe expenfive works fufficiently demonftrates the encouragement beftowed on the fubject of entomology upon the continent of Europe.

An elementary work by James Barbut, bearing the title of "The Genera Infectorum of Linnæus, exemplified by various fpecimens of Englifh Infects," was publifhed in London in 1781; and which, befides the text, contains altogether about twenty-two plates, two of which are explanatory, and the reft comprehend indifferent figures of a fmall number of fpecies in each genera. As an illuftration of the Linnæan fyftem, this work may be in fome refpects ufeful to the Englifh reader: its views are too limited to admit of more general utility. The author does not feem to be aware of the improvements the fcience had undergone upon the continent, in the interval between the publication of the "Genera Infectorum" of Linnæus, and the time in which he wrote, and has not therefore drawn thofe comparifons between them, which, without innovation on either, could not fail to have placed the fcience in a more lucid point of view. It is, indeed, to the filence of Englifh writers in this refpect, generally arifing either from the want of information, from fentiments of illiberality, or from negligence, that we muft afcribe the very low ftate of entomological knowledge in Britain, even to the prefent period. Francifcus de Paula Schrank diftinguifhed himfelf by his enumeration of the infects of Auftria in 1781, written in Latin, "Enumeratio Infectorum Auftriæ indigenorum," afterwards rendered into German by Fuefsly. The fame year John Nepomuk von Laicharting publifhed at Zurich his catalogue of the infects of the Tyrol, "Verzeichnifs und befchreibung der Tyroler Infecten," a fecond part of which appeared in 1784. Laicharting adopts a fyftem fomewhat different from that of Linnæus; he divides infects into ten claffes, characterized from various parts of the body. His claffes are fcarabæides, grylloïdes, cimicoïdes, papilionoïdes, libelluloïdes, vefpoïdes, mufcoïdes, cancroïdes, aranoïdes, and onifcoïdes. In 1782, a paper by Morand was publifhed in the Tranfactions of the Paris Academy, entitled "Memoire fur les vers de Truffes, et fur les mouches qui en proviennent." A fmall octavo by J. S. Semler, in the German language, bears the fame date, and is worthy of attention, "Verfuch eines Diarium über die Œconomie mancher Infecten im Winter," and there is befides this another more extenfive book printed in 1783, relative to the aphides, called "Nachlefe zur Bonnetifchen Infektologie." A catalogue of lepidopteræ, written by Lang in the German language, came out in the fame year. And, laftly, a "Short hiftory of the brown tail Moth," by W. Curtis. The caterpillars of this moth, it may be recollected by many readers, appeared in fuch immenfe fwarms in the fields furrounding London during the fummer of 1782, and from their ravages defpoiled fo many trees of their foliage, as to create very ferious apprehenfions of approaching deftruction to the whole vegetable tribe. The object of this pamphlet was to prove that graminiferous plants, not being the natural food of thefe voracious vermin, would efcape their attack. This circumftance alone will ferve to teftify, that fome benefit at leaft may refult from an acquaintance with the fcience of infects. Its author was by this means enabled to difpel the uneafinefs occafioned through the appearance of thefe fuppofed minifters of famine; and which prevailed to fuch an alarming extent throughout the whole population of this vaft metropolis, that prayers were ordered to be read in all the churches to avert the impending calamity.

An elementary work by J. A. B. Bergftræffer, a fmall octavo, entitled "Entomologia, fcholarum in ufus concinnata," was publifhed in 1784; this author had previoufly diftinguifhed himfelf by his German work, entitled "Nomenclatur und befchreibung der Infecten in der Grafschaft Hanau-Müntzenberg," &c.

The entomological tracts publifhed about this period, and rather earlier by Thunberg, contributed to promote this fcience; his differtations, named "Novæ Infectorum," of which feveral appeared between 1781, and ten years after; and alfo his "Differtatio fiftens Infecta Suecica," the firft of which occurs in 1784, are interefting. The relation of his travels to the Eaft abounds with information refpecting natural hiftory, and relates in fome degree to entomology; and he alfo produced a curious memoir on the paufus genus, called "Befkrinfning poa tuänne nya Infecter," befides other tracts in the Swedifh and Latin languages.

Retzius, in 1783, produced his "Genera et Species Infectorum," in which the method of Degeer is fimplified, and the Linnæan terminology adapted to that performance. Infects, according to this fyftem, are divided into fourteen claffes; namely, lepidoptera, alinguia, neuroptera, hymenoptera, fiphonata, dermaptera, hemiptera, coleoptera, halterata, probofcidea, fuctoria, ancenata, atrachelia, and cruftacea.

Harrer wrote on the infects of Germany, in a fmall book printed in 1784. The year after Jablonfky began the important fyftematical work, called "Natur fyftem aller bekannter in-und aufländifchen Infecken," printed at Berlin; about the fame time Fourcroy publifhed his catalogue of the infects found in the neighbourhood of Paris in Latin, under the title of "Entomologia Parifienfis;" and another illuftration of the elements of entomology, written in German, appeared at Leipfic from the pen of Schmiedlein. Some African infects, that inhabit the Cape of Good Hope, were defcribed in 1786 by Xavier Walfen; and two publications on the lepidopteræ of Germany, and both written in the language of that country, came out in the fame year, one by W. Gefenius, the other bearing the title of "Beitrage zur gefchichte der Schmetterlinge," and printed at Augfburg, is by Hübner.

The infects of Naples are defcribed by Dominicus Cyrillus in a folio work publifhed in 1787, called "Entomologiæ Neapolitanæ." A curious and ufeful little tract on the oeftrus, or gad-fly genus, was the fame year printed at Leipfic by J. S. Fifcher under the title of "Obfervationes de Œftrovino atque bovino factæ," to which a copious appendix was annexed in 1788. The cochineal infects difcovered at Madras fome few years before, gave rife to a feries of letters on this important fubject, by James Anderfon, addreffed from Madras to fir Jofeph Banks, fourteen of which were printed together in that country in the year 1788; there are, befides thefe, two other letters which have been publifhed fince, alfo a feparate publication by the fame author, containing an account of the importation of American cochineal infects into Hindooftan. Swederus, in 1788, publifhed a monograph on that curious coleopterous genus

cerapterus,

cerapterus, in a memoir entitled " Beſkrifning poa elt nytt genus ibland inſecterna, hörande til Coleoptera."

The ſcience of entomology obtained ſome further advantages about this period, from the publication of the enlarged edition of the Linnæan " Syſtema Naturæ," by J. F. Gmelin; not from poſſeſſing in itſelf any peculiar merit, but becauſe as a general, and therefore uſeful work, it combines much valuable information, compiled from the labours of various naturaliſts of the firſt conſequence ſince the time of Linnæus. In the entomological part, conſiſting of three volumes, publiſhed at Leipſic in 1788, the editor is conſiderably indebted to the writings of Fabricius; for although he rejects his mode of claſſification, his orders, and moſt of his genera, he has copied no inconſiderable portion of his new ſpecies, and by that means very materially augmented and improved the original work of Linnæus. Beſides this, the pleaſing works of Stoll contributed about this time to facilitate the ſtudy of the hemipterous order of inſects, from affording figures of many extraordinary ſpecies of the locuſt, fulgora, cicada, cimex, and other tribes, extant in the various continental cabinets at that time, and, among others, that of the prince of Orange. His firſt work is called " Natuurlykye af beeldingen en beſchryvingen der Cicaden in alle vier waerelds deelen." The two publiſhed ſince are only a continuation, including other genera beſides the cicadæ, as the locuſtæ, phaſmæ, &c. Theſe works were printed at Amſterdam. The work of M. B. Borkhauſen, written in the German language, relates entirely to European inſects of the lepidoptera kind, and bears the title of " Naturgeſchichte der Europaiſchen Schmetterlinge nach Syſtematiſcher ordnung." The firſt part appeared at Franckfort in 1788; and ſince that time the work has been conſiderably extended. The article entomology, inſerted in Hall's Encyclopædia, as it appeared originally in 1788, was written by Marſham, and is exemplified by three plates; and about the ſame time, Roemer publiſhed in Switzerland his " Genera Inſectorum Linnæi et Fabricii iconibus illuſtrata," including thirty-ſeven explanatory plates, nearly all of which, however, had previouſly conſtituted the work of Sulzer.

Immediately after this, the publication of one of the moſt voluminous works on entomology that has been attempted was undertaken at Paris, by G. A. Olivier. Its title is conciſely " Entomologie, ou Hiſtoire naturelle des Inſectes;" from which we may infer, that its author propoſed to have treated on every claſs and order, and, in conformity with the firſt part, to have accompanied the whole with figures. Several faſciculi or numbers were publiſhed, amounting altogether to about three volumes; the whole of which are confined to the order coleoptera, and that even remains very incomplete. So far as it does proceed, the work is valuable. Olivier is the author of ſeveral other entomological writings. In the " Journal d'Hiſtoire Naturelle," he has a memoir, " Sur l'Utilité de l'etude des Inſectes, relativement à l'Agriculture et aux Arts." He is alſo the propoſer of a methodical diviſion of inſects, in the " Dictionnaire Entomologique." According to this plan, inſects are to be divided into four parts, namely, 1. Inſects with four wings; 2. Inſects with two wings and two wing-caſes; 3. Inſects with two wings; 4. Inſects without wings in either ſex. Theſe are ſubdivided into eight orders, the characters of which are taken from the mouth.

The inſects of Europe were further deſcribed by C. de Villers, in a ſmall work publiſhed at Lyons, in 1789, under the title of " Linnæi Entomologia," &c.; in which he profeſſes to avail himſelf of the works of Scopoli, Geoffroy, Degeer, Fabricius, and others. Paykull was at this time engaged alſo upon the inſects of Sweden, at leaſt on the coleopteræ; and this year he publiſhed his " Monagraphia Staphylinorum Sueciæ;" and which, a while after, was ſucceeded by two other tracts on the curculiones and the carabi, " Monagraphia Curculionum Sueciæ," and " Monagraphia Caraborum Sueciæ." But the moſt extenſive of the works of Paykull is his " Fauna Suecica," in three octavo volumes, printed at Upſal in 1799.

In the " Journal für die Entomologie," the name of Meyer occurs as the author of ſome remarks on the melolontha. Preyler, in the year 1790, publiſhed at Prague a " Verzeichniſs," or catalogue of the inſects of Bohemia. Quenſel is the author of a tract on the papilio, entitled, " Beſkrifningar öfer 8 nya Suenſka Dagfjärillar;" and alſo of another on noctua pruni, " Beſkrifning öfver en y Nattfjäril."

The firſt part of a conſiderable work, " The Natural Hiſtory of Britiſh Inſects by E. Donovan," appeared in the early part of the year 1792; and having obtained a favourable reception, has been continued in a courſe of monthly numbers from that period to the preſent time (1809). The deſign of this undertaking is to afford ſcientific and general deſcriptions, accompanied by appropriate coloured figures of every inſect diſcovered in this country; and ſo far as that deſirable object could be accompliſhed, in all their various ſtates of transformation. In its preſent form, the work conſiſts of fifteen volumes; the number of plates exceed 500, and theſe include an extenſive variety of ſpecies. Without incurring the charge of preſumption, the writer of this article believes he may be allowed to obſerve that the preſent conſtitutes the moſt copious work of its kind that has hitherto, or probably ever may be undertaken, as an elucidation of the entomology of Britain.

The inſects of Germany afforded materials for another entomological work of a local nature, commenced by Dr. G. W. F. Panzer, in 1793, under the title of " Faunæ Inſectorum Initia, oder Deutſchlands Inſecten;" and this was ſhortly after ſucceeded by his " Entomologia Germanica," &c.; both which are written in German and Latin, and are illuſtrated by plates. Dr. Smith's " Tour on the Continent in 1786-7," was publiſhed alſo in 1793; and this claims our particular mention, as it will be found to contain ſome curious obſervations reſpecting the inſects of the countries he viſited. About the ſame time, a French edition of Fueſsly's " Archiv der Inſektengeſchichte" made its appearance in quarto, with the original plates.

A valuable ſyſtematic paper, propoſing " a new arrangement of the papilios" by Mr. William Jones, occurs in the ſecond volume of the Tranſactions of the Linnæan Society, printed at London in 1794. The object of this communication is to point out, that the ſhape of the wings, which form a principal character with Linnæus in his diſtribution of this genus into families, though various at the firſt view, approach each other ſo gradually, that it is impoſſible to draw from them the diſtinguiſhing line between each family. The number of ſpecies known to Linnæus are eſtimated at rather more than 274, whereas the writer obſerves he had ſeen above 1000 in various cabinets, and about 400 more repreſented in various publications; and from an attentive examination of theſe is induced to offer the following amendments to the characters of each family, as defined by Linnæus. The latter author deſcribes the *Equites* as having " the upper wings longer from the poſterior angle to the point than to the baſe; and the antennæ often filiform:" this is corrected by ſaying, " the upper wings are longer from the poſterior angle to the point than to the baſe, occaſioned by having four nerves inſtead of three, viſible in every other family. The palpi frequently only a brush; under wings, with a connecting nerve in the centre, and without an abdominal groove."—*Heliconii.* "Wings narrow, entire, often naked, or deprived of scales; the upper wings long, the inferior short." Linn. To this character is added, that the upper wings have "a connecting nerve in the centre, very slightly grooved to admit the abdomen, which is in general long, as are also the antennæ."—*Danai.* "Wings entire." Linn. Addition: "the under with a connecting nerve in the centre, and a deep abdominal groove; palpi projecting."—*Nymphales.* "Wings denticulated." Linn. Addition: "the under without a connecting nerve in the centre, and with a deep abdominal groove; palpi projected."—*Plebeii.* "Small, rurales; spots on the wings obscure." Linn. Addition: "thorax and abdomen slender; under wings without a connecting nerve; antennæ clubbed:" and these are divided into two sections, those with long, weak, flexible tails; and those without tails, and having the wings entire.—*Plebeii urbicolæ.* "Spots on the wings for the most part transparent." Linn. These Mr. Jones divides into three families, according to the following character. * Thorax and abdomen short, thick, or broad; under wings without a connecting nerve; antennæ uncinated, or crooked at the extremity. ** With upper wings pointed at the extremity, and long in proportion to their width. *** Upper wings less extended, and together with their under wings more rotund; their margins entire. There still remain some papiliones, which do not rank with any division above mentioned: these are generally of a large size, without an abdominal groove; have no connecting nerve; their antennæ generally acuminated; and the veins of both upper and under wings extending from their root to the extremity nearly in straight lines. The author of this paper constitutes these as a new family, under the name of romani.

We ought not to dismiss our abstract of the above paper, without observing that, from the great attention bestowed on the papiliones by Mr. Jones, his opinion is of unquestionable authority. The species, which it is intimated the writer has seen in various cabinets to the amount of 1000, or perhaps more, have not to our own knowledge been observed merely: Mr. Jones has taken the trouble, for the gratification of himself and his scientific friends, to paint every species, and that in a very correct and elegant manner. The collection of drawings thus formed affords an unparalleled display of this beautiful tribe of insects.

In 1795, "The Papilios of Great Britain," a quarto work with plates, by William Lewin, was published in London. Whether it was the intention of the author to have proceeded further with this publication is uncertain: it finally terminated with the completion of the butterflies. About the same period the coleopterous insects of Sweden were published in the language of that country, by D. E. Naezén, some part of whose works had, however, been produced to the public before that period. His books (for there are two) are entitled "Beskrifning poa noagra, vid Umeoa fundene okände arter ibland Skalbaggarne," and "Beskrifning poa noagra vid Umeoa fundne Insecter, dels okande, dels foorut otydeligen bemarkte ochi Fauna Suecica ej uptagne." A Latin tract, printed in 1795, by D. H. Hoppe, contains an enumeration of the coleopterous insects found in the invirons of Erlang, in Franconia; and in the same year, Latreille published his work, entitled, "Precis du Charactére des Genres." In this last-mentioned work, insects are divided into two principal classes, namely, those with wings, and those without wings. The orders are coleopterès, orthopterès, hémipterès, neuropteres, lépidoptères, suceurs, thysanoures, parasites, acéphales, entomostracés, crustacés, and myriapodes. An arrangement of the insect tribes, in a manner somewhat different, occurs in "Tableau Methodique des Insectes," by the same author. An important paper on the oestrus genus, by B. Clark, inserted in the third volume of the Linnæan Society Transactions, is duly noticed under the article Bot. The last production we have to mention in the present year is a small tract, accompanied by a coloured figure of an extremely beautiful and singularly formed beetle, in the cabinet of Mr. Francillon; a species of scarabæus, having the posterior legs remarkable both for their length and thickness, and hence denominated the kangaroo beetle (scarabæus macropus). The insect is presumed to be a native of Potosi, in South America.

The second volume of "Catalogus Bibliothecæ Historico Naturalis, Josephi Banks baroneti," &c. by J. Dryander, comprehending the entomological works of that invaluable library, issued from the press in 1796. From the classic manner in which each production is arranged in an appropriate department, according to its leading character, this work must be considered as forming in itself a valuable bibliothecal system of entomological writers. As an assemblage of references, we cannot speak too highly of its contents.

"The Natural History of the rarer Lepidopterous Insects of Georgia," in North America, forms a pleasing accession to our knowledge of those particular species which it is the object of this work to elucidate. The number of insects contained in the two costly volumes, of which the work consists, amounts to about one hundred. These constitute an ample selection of the larger kinds of the butterfly, sphinx, and moth tribes, peculiar to that region. Each insect is represented with its larva, pupa, and an example of one of the plants on which it is known to subsist. This work is written by Dr. J. E. Smith, from a series of notes and drawings made by Mr. Abbot, an assiduous collector in North America; and besides combining the practical information derived from the latter source, is rendered valuable by the numerous additional observations of the author. This work appeared in 1797.

Clairville, the author of a work on the insects of Switzerland, published in 1798, proposes to divide insects into eight orders, somewhat after the manner of Linnæus, but to distinguish them under other names, and to denominate them classes instead of orders. The names he proposes are elytropteres, dictyopterès, thlebopteres, halterepteres, lepidopteres, hémiménoptères, rophoptères, and pododunères.

In the same year with the preceding, "Donovan's Natural History of the Insects of China" appeared in London. This is the only work dedicated to the display of the entomological productions of that vast empire that has been published. The materials which constitute the basis of this volume, and from which it was in a great measure composed, were obtained from the first and most authentic sources; including examples of the insects collected at the time of the embassy of lord Macartney, in addition to many others obtained from various cabinets of the highest celebrity, and the communications of friends. The work is embellished with fifty coloured plates. A translation of this publication has appeared on the continent in the French, and another in the German language.

The year 1800 was productive of several valuable works on the subject of entomology; in Sweden, Paykull this year published his "Fauna Suecica," a much admired publication, in three volumes octavo. Cuvier, with the assistance of

Duméril,

Dumèril, brought forward in Paris his celebrated "Anatomie Comparée," a work which, however ill fuited to the philofophic tafte of our own country, is a production of very extraordinary merit. The organization of the various tribes of infects is treated at great length in the lectures relating to invertebral animals. This work affords us alfo a new fyftematical arrangement, in which all infects are divided into two principal fections; thofe with jaws, and thofe without jaws. In the firft of thefe orders are comprehended the gnathaptères, neuroptères, hymenopteres, coleopteres, and orthopteres; the fecond, confifting of fuch as are deftitute of jaws, are, hemipteres, lepidopteres, dipteres, and apteres. The fifth volume of "Bibl. Hift. Nat. Bankfiana," the addenda of which contains fome further mention of entomological writers, was alfo publifhed in 1800. The laft work that appeared in the prefent year was "Donovan's Infects of India," a publication correfponding in fize, and ftyle of embellifhment, with the "Infects of China," and, like that work, embracing in a general, though fcientific view, a comprehenfive difplay of the more curious, rare, and fplendid fpecies peculiar to thofe fertile regions, the entomology of which it is defigned to explain. This work, as in the former inftance, is conftituted from the firft fources of original information. The more immediate intention is the elucidation of the entomological production of the Britifh poffeffions in India; but it contains alfo a variety of infects of the more beautiful kinds difcovered in the interior of that vaft continent, and in the iflands fituated in the Indian feas.

Lamarck's "Syftême des Animaux fans Vertèbres," printed at Paris in the 9th year of the revolution (1801), prefents a new mode of arrangement for infects. Thefe its author propofes to divide into three primary claffes; namely, 1ft, thofe with mandibles and jaws; 2d, thofe with mandibles and a kind of trunk; 3d, thofe without mandibles, but having a trunk or fucker. The firft of thefe claffes contains the coleopteres, orthopteres, and neuropteres; the fecond is confined to the fingle order hymenopteres; and the third includes the lepidopteres, hemipteres, dipteres, and apteres. The coleopteræ are fub-divided into three families, according to the number of joints in the feet, as thofe with five joints in all the feet; thofe with five joints in each the four anterior feet, and four in thofe of the pofterior pair; and thofe with only three jcints in all the feet. Moft of the Linnæan aptera are removed to another clafs preceding the infect tribe; the only Linnæan genus of aptera, admitted by Lamarck into his order apteres, is the pulex.

The publication of "Marfham's Entomologia Britannica" commenced in the year 1802, with the production of the volume in which the coleopteræ are defcribed. As the outline of the arrangement adopted by this author is ftrictly Linnæan, thofe after the manner of that naturalift conftitute the firft feries, and are to be fucceeded progreffively by the hemiptera, lepidoptera, and other remaining tribes. For the purpofe of this continuation very ample materials are provided. Mr. Marfham, whofe abilities as an entomologift are well known, has devoted many years of his life to this laudable object: his collection of Britifh infects is of the firft clafs, and his manufcripts of the moft valuable kind. The completion of this work muft be therefore anticipated as a defirable event. The merit of the firft volume is acknowledged, and fhould the future part appear with correfponding excellence, we could not hefitate in pronouncing it one of the moft important works of its kind that has appeared.

Kirby's "Apum Angliæ" was alfo printed in 1802. This work contains much curious information relative to the bees of this country; a path of entomology in which its ingenious author has trod with great fuccefs. The Linnæan genus apis Mr. Kirby conceives it neceffary to divide into two genera, to one of which he retained the original name, the other he terms melitta, and under both genera he defcribes many fpecies, fome of which are noticed for the firft time in this interefting work. Latreille, who has written on the Linnæan genus apis, and is efteemed an entomologift of ability, pronounces this "un bon travail." The ninth volume of the Tranfactions of the Linnæan Society contains an ingenious paper on the apian genus of Herbft by Kirby; and there are alfo two or three other papers difperfed in thofe volumes, by the fame writer, well deferving of attention.

The contents of the fecond and third volumes of Turton's tranflation of the Linnæan "Syftema Naturæ a Gmelin," relate entirely to entomology This work deferves further obfervation. The editor does not, in treating of infects, confine himfelf to the direct tranflation of his author; he introduces fome commendable improvements in the arrangement after the Fabrician manner; and he befides incorporates from other entomological works of credit, publifhed fince the time of Gmelin, whatever prominent traits of information he conceived calculated to amend the original work. We may eafily perceive that Dr. Turton has availed himfelf of the Fabrician "Entomologia Syftematica" to a greater extent than Gmelin, and has by this means rendered more effential fervice to the Englifh reader.

The pages of "Donovan's Tour through South Wales and Monmouthfhire," lately publifhed, are interfperfed with obfervations on the various natural productions of the interefting tract of country immediately under confideration. Thofe digreffions, from objects of more general moment, if fuch the reader be inclined to deem them, we at leaft may prefume to think important; and fo far as thefe relate to the fcience of entomology in particular, conceive they may, without impropriety, be adverted to in this place.

"Donovan's Infects of New Holland," including alfo thofe of New Zealand, New Guinea, and the feveral iflands in the Great Southern and Pacific ocean: this accords with the "Infects of India," already mentioned, being in quarto, with fcientific and general defcriptions, and in having the fimilar accompaniments of accurately coloured plates. Of this work it will be alone fufficient to obferve, that through the diftinguifhed favour beftowed on the defign, the author was allowed to enrich his volume with delineations of thofe uncommon infects collected during the voyage of captain Cook, by thofe celebrated naturalifts who accompanied that circumnavigator round the world, and which appear for the firft time in this work.

The fixth volume of "Shaw's General Zoology" is offered as an illuftration of the fcience of entomology. The work profeffes only to elucidate the Linnæan genera of infects, with the hiftory of the principal fpecies. This being the intention of its ingenious author, the work is comprized in a very moderate compafs. The plates are rather numerous, and in general remarkable for the neatnefs of engraving. Thefe, however, are not original, being compiled from the plates of Seba, Rofel, Swammerdam, Barbut, and others. The "Naturalift's Mifcellany" contains a variety of coloured figures of the more fplendid kinds of exotic infects, with defcriptions extremely fuitable to the general clafs of readers, for whofe purpofe they are defigned.

Laftly, we ought to mention the work of Coquebert, entitled "Illuftratio iconographia," recently publifhed in France: the late entomological tracts of Olivier and La-

treille,

treille, the "Faune Parifienne" of Walcknaer, and the papers on different tribes of infects inferted in the Tranfactions of the Linnæan Society of London; the Societé d'Hiftoire Naturelle of Paris, and thofe of various other learned inftitutions, through the medium of which they are diftributed to public obfervation.

Our review of entomological writings is at length drawn to conclufion. In its progrefs we have endeavoured to include every work of importance in this department of fcience, that has appeared. To what has been advanced refpecting thefe, nothing material can be added in this place; it was our aim, throughout the prefent inquiry, to point out the leading character of each work, while paffing under immediate confideration, and for this reafon we fhall abftain from offering any general comments. By connecting the whole in the order of time in which they were produced, our object has been to fhow at one glance, fo far at leaft as our flight comparifons would permit, thofe effential refpects in which each has materially improved upon his predeceffor; and by that means mark the progreffive advancement made in the fcience with fome precifion. We fhall finally difmifs this part of our fubject with obferving, that it is poffible fome few works of real worth may have efcaped our mention; the number of thefe, however, we are perfuaded, muft be very inconfiderable, and confined to fuch as have recently appeared in countries remote from Britain.

Claffification.

It will be obferved, from the preceding obfervations, that naturalifts entertain very diftinct opinions as to the principles on which the claffification of infects ought to be founded. This diverfity of idea arifes from the different views under which they have been confidered. Valifneri divides infects into four claffes, according to the places in which they live, as plants, in water, in the earth, or upon the bodies of other animals. Agricola into three, namely, thofe which walk, fly, and fwim; Frenzius, into flying infects, aquatic infects, and terreftrial or creeping infects. Swammerdam diftributes them into claffes from their appearance in the ftates preceding their final transformation, without particular regard to the laft or complete ftate. In this refpect Swammerdam is followed by Ray, whofe two primary claffes are, of thofe which undergo transformation, and thofe which do not; and his orders are determined from their metamorphofes, and the number of their feet. Lifter has given a fyftem founded on the figure of the egg in which the infect is inclofed, and the number of the feet. The difference obfervable in the texture, and alfo in the number of the wings, form the diftinctions of the primary divifions of Linnæus. And laftly, the principal characters upon which infects are diftributed, in the arrangement of Fabricius, is taken from the ftructure of the mouth. Each of the fyftems founded on thofe diffimilar characters have gained admirers. The characters of the Linnæan and Fabrician fyftems appear the beft, and are moft univerfally approved.

General obfervations on Infects.

Infects are a race of animals deftitute of internal bones, in which refpect they accord with a very extenfive number of natural families in the lower orders of animated beings. Their bodies are kept in a ftate of moifture by the circulation of lymphatic tranfparent juices inftead of red blood, and in this particular agree with the worm tribe. They have no diftinct heart, external ears, openings at the nofe, or noftrils, nor teeth in the mouth; and fome affert that they are deftitute of voice. An infect is divided into fegments, or joints, and covered externally with a tough or bony fkin, which is either naked or clothed with down. The head is furnifhed with moveable antennæ, and the body with feet.

Thefe animals are deftitute of vifible external organs of breathing at the mouth, their refpiration is performed through the lateral apertures, or fpiracles of the body and thorax.

They have two eyes, in which refpect they agree with the larger tribe of animals: they have no eyelids, and their eyes are rarely placed on a pedicle; the diopfis is an exception.

The antennæ are fituated on the head before the eyes; and are compofed of an indefinite number of articulations; in genuine infects, the antennæ never exceed two. The cancri have a greater number, and many of the Linnæan apteræ have none.

The feelers are articulated, moveable, variable in number from two to fix, and are affixed contiguous to the mouth.

The mouth is ufually fituated beneath the head.

The jaws are difpofed tranfverfely in the head, and move laterally, by which means they are diftinguifhed from moft other animals.

The trunk is placed between the head and the abdomen.

The abdomen is ufually annulated with five fegments, and is fometimes armed at the end with a fting.

The legs are ufually fix in number, and are attached to the trunk. Each leg confifts of three diftinct divifions, the thigh, fhank, and feet.

The wings are either two or four; fome of thofe with two wings only are protected by a fhelly covering, as in the coleopteræ.

Infects are oviparous; depofit their eggs in an impregnated ftate in general, and do not brood over them, or their young. Moft infects undergo a triple transformation, the egg producing a grub or larva, which becomes, when full grown, a pupa, and the later producing the perfect fly. The fexes are male and female; there are alfo neuters in fome fpecies devoted to labour for the former. Infects caft their fkins, and therein agree with reptiles. They are faid to inhabit thofe plants on which they ufually feed.

Defcription of the component parts of Infects.

The external parts of which infects confift are divided into four principal fections, the head, trunk, abdomen, and members, each of which require to be feparately confidered.

Caput, or *Head.*—Under this term is included the firft, or principal organ, the head, properly fo denominated in its collective form. This part is fuppofed to be the principal feat of the fenfes, as in all others of the larger and apparently more perfect animals. Internally it contains the medullary fubftance or brain; its exterior characters are, the mouth, eyes, ftemmata, antennæ, front, vertex, and throat.

In fome infects the head is very large in comparifon with their body. The proportion between the head and body is not the fame in all infects, even in the different ftages of growth or transformation. In the caterpillars, which have this part horny, it is generally fmall before they moult, or change their fkin, and becomes larger after each moulting.

This part is almoft conftantly diftinct from the thorax: in the coleoptera it is connected clofe to the latter: the hemiptera offer many examples in which the head is flightly attached, as in the genera blatta, acheta, phafma, mantis, &c.: in the lepidoptera order the head is not always very intimately fituated to the thorax; there is a fmall interval fometimes between which the articulation of the neck may be feen,

feen, when the head is inclined downward. The fucceeding order, neuroptera, afford numberlefs inftances of the head being placed upon a flender ligamentous pedicle at a diftance from the thorax : in hymenoptera and diptera the head is rather remote, fometimes being placed on a fmall tubercle in the anterior part of the thorax ; and in the laft, or apterous order of Linnæan infects, feveral of the genera are diftinguifhed by having the head and thorax confounded with each other, as in fcorpio, aranea, monoculus, &c.

The connection between the head and thorax in infects fubfifts by one of two modes of articulation ; the firft, in which the point of contact is folid, and the motion depends upon the fhape of this part, or another in which the articulation is formed by a ligament. In the articulation of the head by the contact of the folid parts, the head has commonly, at the part anfwering to the neck, one or two fmooth tubercles, which are received into correfpondent cavities on the anterior part of the thorax. This is exemplified in the genera fcarabæus, lucanus, cerambyx, and moft other coleoptera, and which hence have the power of moving the head backward or forward, and thus of directing the mouth downward. Another mode of folid articulation takes place when the pofterior part of the head is rounded, and turns on its axis in a correfpondent focket on the anterior part of the thorax, as in the brentus, &c. The axis of motion is then in the centre of the joint, and the mouth of the infect can be directed either upward or downward, or to the right and left. A third fort of articulation occurs when the head is truncated behind, and joins by a flat furface either to a tubercle of the thorax or to another flat and correfponding furface, as is feen in many of the hymenoptera and diptera. In fome kinds of the Fabrician attelabi, this folid articulation is accomplifhed by another means : the head of thefe infects terminate behind in a round tubercle, which is received into a correfpondent cavity of the thorax : the inferior edge of this cavity is notched, and thus confines the motion of the head to one direction.

The ligamentous connection of the head and thorax is fhewn in the blatta, forficula, mantis, and feveral of the neuroptera. In this mode of articulation, the motion of the head is very extenfive, and confined only towards the back, in which direction it is oppofed by the projection of the back. The mufcles which move the head are fituated within the thorax : the membranes or ligaments extend from the anterior part of the collar to the furface of the occipital foramen.

Brain, or Medullary Subftance.—According to the " Fundamenta Entomologiæ," it was the idea of Linnæus, that infects have no brain in the head ; an opinion often repeated fince his time, but which, from the obfervations of the ableft phyfiologifts of the prefent period, proves to be unfounded. Linnæus does not deny the exiftence of a medullary thread in this part of infects, but ftates that he never could difcover it to be organifed; and hence, he fays, the hippobofca equina, or horfe-fly, will run, live, nay even form an union with the oppofite fex, after being deprived of its head, to fay nothing of many others, which are capable of living for a confiderable while in a decapitated condition. From the anatomical inveftigations of Cuvier it is, neverthelefs, fufficiently obvious, that independently of a nervous medullary thread, infects have a brain diftinctly organifed, from which this thread and other nerves arife, and that its feat is in the head, as in the more noble tribe of animals. The exiftence of a true brain in infects was believed by many writers before the time of Linnæus, and by fome after ; but, generally fpeaking, the opinion of this celebrated naturalift was affented to, and enquiry ceafed, till its confideration was revived by Fabricius, and the phyfiologifts of France, the moft diftinguifhed of whom is Cuvier, and from the refult of their obfervations it may be affirmed, that infects, as well as moft other animals, have a genuine brain.

Fabricius is reputed to be the firft who difcovered the true brain in infects. That Fabricius affirms the fact, and that as an entomologift his affertion was fuccefsfully oppofed to the opinion of Linnæus in this refpect, is not to be denied, yet the merit of difcovery is by no means due to this writer. His obfervations on the brain, the organs of hearing, and other fenfations of infects, were made chiefly on the lobfter or cray-fifh, animals of the cruftaceous kind, and which, though in fome refpects analogous, we do not admit to be of the infect race. But if they were, can we have fo entirely forgotten the anatomical inveftigations of cancer aftacus by Roefel, as to allow Fabricius the credit of difcovering thofe very organs which he defcribes many years before ; and if he really obferved thofe organs in genuine infects, can we overlook the laborious anatomical enquiries of Swammerdam, or the minute refearches of Lyonet, in which the exiftence of fuch an organ is rendered manifeft, with no other view than to award the merit of its difcovery to Fabricius ?

No phyfiologift whatever has purfued this interefting fubject of enquiry fo far as Cuvier. This attentive and fkilful obferver examined a confiderable number of the different tribes of infects, in order to afcertain their internal organization, and has eftablifhed, beyond difpute, if any doubt could ftill remain, that infects have a brain in the head. From Cuvier we alfo learn that the brain is not conftantly of the fame ftructure in all infects ; in fome tribes this organ confifts of one lobe, in others of two, and in others again of four ; and the nerves arifing from them differ alfo very materially in different families, and fometimes even in fpecies. But befides this diffimilarity, there is another circumftance infinitely more remarkable, the form of the brain and medullary nerves in certain infects, are afcertained to undergo a confiderable change, as well as the external organs, in paffing from the larvæ to the perfect ftate. The moft extraordinary of thefe deferve notice, and the circumftance being ftated may ftimulate others, perhaps, to a farther enquiry, in the refult of which, it is apprehended, a fimilar change, will be obferved, in a far greater number of the infect race than may be at prefent conceived.

Brain in Coleopterous Infects.—The larva of a large beetle, common in Europe, and known by naturalifts under the name of fcarabæus nafícornis, affords a favourable opportunity for the afcertainment of this fact ; it is of a large fize, and the change it undergoes in paffing to the winged ftate is very confiderable. The brain in this larva is fituated under the great fcale which covers the head, immediately above the origin of the œfophagus. It confifts of two approximate lobes, which are very diftinct at the front and back part. Four nerves arife from the anterior part, two on each fide, which are loft in the cirri and parietes of the mouth, one pair of nerves arifes alfo from the lateral and fomewhat pofterior part of the brain, which, embracing the œfophagus, proceeds below to form a nervous cord ; and another pair is produced from the lower furface of the brain. In the perfect infect, the nervous cord prefents a very confpicuous difference ; in the larva there is only a fingle ganglion, but the perfect infect has feveral, and which are very diftinct. The firft is fituated above the condyle : it proceeds from the two pofterior filaments of the brain, and is diftributed to the mufcles which move the head on the corfelet. Its pofterior part produces two filaments, which pafs into the breaft, where they unite towards the middle,

middle, and form a triangular ganglion, from the fides of which three pairs of nerves arife, and are diftributed to the mufcles. Its pofterior angle detaches two parallel nerves which proceed into the breaft, where they form a third and fourth ganglion, fituated very near each other, and apparently divided into two lobes by a longitudinal furrow. All the other nerves of the body proceed from thefe two ganglia, by an irradiation precifely in the fame manner as in the larva.

The nerves in the larva of the ftag beetle (lucanus cervus) differ greatly from that of the foregoing infect. The brain confifts of two contiguous and almoft fpherical lobes, which produce four nerves anteriorly; two beneath and two behind, which latter form a collar round the œfophagus, and uniting underneath compofe the nervous cord of the body. The cord is formed of eight ganglia, and extends to the ninth ring of the body. In the perfect ftate the brain confifts likewife of two approximate lobes of a fpherical form. There are alfo two ganglia on the lateral parts of the brain, which are almoft as large as each of the lobes: in form they refemble a pear, and reft on the brain by their bafe: the two anterior pairs of nerves arifing from the brain terminate in the palpi and other parts of the mouth. The brain produces alfo two very long and flender nerves behind, and the difpofition of the nerves arifing from the various parts differ very much from thofe obfervable in the larva.

The nervous fyftem of the larva of hydrophilus piceus, or great water beetle (dytifcus, Linn.), will ferve to illuftrate thofe of an extenfive number of other coleopterous infects, fuch as the larva of cerambyces, dytifci, carabi, ftaphylini, &c. Some little variation will be found, but the analogy is very confpicuous. The brain in the larva of this infect is fituated in the head above the origin of the œfophagus; it is formed of two lobes, which lie very clofe together. From its anterior part it detaches fome filaments to the palpi, the antennæ, and the parietes of the mouth. Its lateral parts produce two cords, which furround the œfophagus, and which are the origin of the nervous cord fituated inferiorly. The chief nervous cord is compofed of ten ganglia, each of which produces three pairs of nerves, which are loft in the mufcles of the abdomen. In the perfect infect the brain confifts of two fpherical bulbs, which are clofely united. The lateral parts give origin to the optic nerves. The anterior part of the brain detaches fome filaments intended for the parietes of the mouth. In the fame place is alfo a fmall fpherical ganglion, which feems to belong to the recurrent nerve that accompanies the œfophagus. The brain in the larva of dytifcus marginalis is different from that in the larva of hydrophilus piceus, although thofe two infects are fo clofely allied in genera; in the latter it is fpherical, and confifts of a fingle lobe, it is fituated in the head above the origin of the œfophagus: its anterior part produces fome filaments for the mouth, and its lateral parts the two optic nerves: the latter are compofed of two parts, which are very diftinct in form. That portion next to the brain is of an oval figure, pointed at the extremity which joins the brain, the other extremity is rounded, and produces a flender nerve, which paffes directly to the eye.

Hemiptera.—The ftructure of the nervous fyftem in the larvæ of hemipterous infects does not often differ very fenfibly, it is faid, from that which is exhibited in the perfect infect to which they refpectively belong. But the fmall number of this tribe already examined do not authorife us to fpeak on this fubject with much confidence. A confiderable difference prevails in this refpect between the perfect infects of fome oppofite genera, as appears from thofe which Cuvier defcribes. In the cock-roach, blatta americana, the brain is compofed of two lobes, feparated by a very diftinct notch anteriorly. The optic nerves arife on the fides, and its anterior part detaches fome filaments to the parietes of the mouth, and to the inftruments of manducation. The nervous cords, which form the medulla, arife from its inferior furface. In the great green locuft (gryllus viridiffimus) the brain is fituated in the head above the œfophagus; it confifts of two lobes, which are pyriform, united at their bafe, and prolonged at their other extremity into an optic nerve for the eye of each fide. The anterior part alfo produces two nerves of a pyramidal form, the bafe of which refts upon the brain. The brain of the mole-cricket (acheta gryllo-talpa) is compofed of two rounded lobes, which are particularly diftinct at the pofterior part. The nervous fyftem of the water fcorpion (nepa cinerea) is different. This confifts of three ganglia, the firft of which (properly the brain) is fituated in the head. It is formed of two approximate pyriform lobes, which touch each other at the bafe, while their fummits are directed obliquely forward towards the eyes in which they terminate: the middle and anterior part of thefe lobes alfo produce filaments for the parts of the mouth; the third, which is more voluminous than the brain, lies near the bafe of the fecond pair of legs.

Lepidoptera.—The nervous fyftem of caterpillars, or lepidopterous infects in the ftate of larvæ, confifts of a feries of thirteen principal ganglia, which furnifh filaments to all the other parts of the body. The firft of thefe ganglia is what may properly be confidered as the brain: it is fituated in the cavity of the head above the œfophagus, and confifts of two round tubercles, which are concave beneath, and correfpond to the convexity of the œfophagus. This ganglion communicates with the reft of the nervous cord by two thick filaments, which embrace the œfophagus, and which are united below it to the anterior and lateral parts of the next ganglion; and it befides produces eight pairs of nerves. The firft partly unites with other filaments; produces fome for the œfophagus, and forms feveral remarkable ganglia below the lower lip. The largeft and moft pofterior, which Lyonet has named the firft frontal ganglion, is prolonged behind into a thick recurrent nerve, which is continued the whole length of the body contiguous to the back. The fecond pair of the brain appears chiefly intended for the antennæ, though it furnifhes feveral filaments to the neighbouring parts, and the others for the more remote portions of the body. Thefe obfervations are from Lyonet, and relate principally to the larva of the goat moth (phalæna coffus of Linnæus.) Few of the lepidopterous infects in the winged ftate have yet been examined for the purpofe of afcertaining the ftructure of the brain. In phalæna difpar this organ is almoft fpherical; there is, however, a longitunal furrow on the middle line. Its anterior part produces fome exceeding flender nerves. There are alfo two large optic nerves on the fides which proceed into the concavity of the eye, where they terminate by a bulb, from whence arife a great number of filaments.

Neuroptera.—In the larva of the lion-ant, (myrmellon formicarius) the nervous medulla, proceeding from the brain in the head, confifts firft of two ganglia, which are compofed of two lobes fituated clofe together, and are placed in the thorax; the remainder of the nervous medulla, confifting of eight ganglia placed in very clofe feries, and each formed of two lobes, is contained in the abdomen. The larva of the ephemeræ has eleven ganglia, exclufive of the brain, which furnifhes two large optic nerves. The larvæ of the libellulæ, or dragon flies, have a fmall two-lobed brain, which produces optic nerves, larger or fmaller in different fpecies.

The Fabrician genus æſhna has the largeſt. The reſt of the nervous ſyſtem forms a ſeries of ganglia of different ſizes. In the æſhna the thorax contains ſix, the two laſt of which are the largeſt, and there are ſeven ſmall and equal ganglia in the abdomen. In the winged ſtate the brain is formed of two very ſmall lobes, and the optic nerves are dilated into the form of two very large plates, which have the figure of a kidney, and which is ſpread upon all the inner ſurface of the eye next the head. The remainder of their medullary cord is exceedingly ſlender, and furniſhed with twelve or thirteen ſmall ganglia, the laſt of which is, as uſual, connected with the organs of generation.

Hymenoptera.—The brain in the larvæ of ſome kinds of tenthredines, which have the head large, is broad and ſhort, and ſeems to conſiſt of four bulbs of equal magnitude, and the form of which is nearly ſpherical; the two external ones ſerve as the baſe of the optic nerves, which are ſlender, and enlarge a little at their other extremity. The firſt ganglion is produced by two very ſmall nerves, which ariſe from the inferior ſurface of the brain, and which, after having embraced the œſophagus, unite under the firſt ring of the body; it furniſhes filaments to the muſcles of the feet, and terminates poſteriorly in two other nerves, which, at the diſtance of one line, produce a ſecond ganglion, and ſo on in ſucceſſion: the nervous cord is in this manner formed of eleven ganglia, excluſive of the brain: all the ganglia are of a roundiſh form, and diminiſh in thickneſs as they recede from the head. The brain of one of the hymenopterous tribe in the winged ſtate (the common bee) is rather ſmall, and is divided into four lobes. It produces the nerves which are diſtributed to the different parts of the mouth, and the two large optic nerves which are dilated, and applied behind each eye, as in the libellulæ. There are afterwards ſeven ganglia, three of which are in the thorax and four in the abdomen. The nerves of the laſt chiefly ſupply the ſexual organs.

Diptera.—The nerves of the larvæ, in ſome of the Linnæan muſcæ, as m. chamæleon, &c. (ſtratiomys, Fabr.) have ſome reſemblance to thoſe of the larva of ſcarabæus naſicornis. The brain is formed of two lobes placed cloſe together and almoſt ſpherical; it is ſituated above the œſophagus, on a level with the ſecond ring of the body. A number of ſmall nervous filaments ariſes from its anterior part, and they are diſtributed to various parts of the mouth. The poſterior part of theſe two lobes ſends forth two thick branches, which embrace the œſophagus, and form the origin of the nervous medulla. This nervous cord is very ſhort, and in diameter one half leſs than that of the brain. It conſiſts of eleven ganglia placed very near each other, each of which produces one pair of nerves.

A more ſingular appearance is exhibited in the ſtructure of the nervous ſyſtem of muſca putris than that juſt deſcribed. The brain is ſituated immediately above the origin of the œſophagus behind the head; it is very large in proportion to the reſt of the body. The anterior part is notched, poſterior rounded, and appears altogether as if formed of two lobes. A pair of nerves ariſes from the anterior part of the brain, proceeds forward, and is diſtributed to the mouth. Theſe nerves become conſpicuouſly large previouſly to diſtribution. Poſteriorly the brain preſents an aperture which affords a paſſage for the œſophagus: the nervous part, ſituated at the ſides, may be regarded as cords which produce the medulla, and all below the œſophagus as the medulla itſelf.

Muſca tenax (Linn.) in the perfect ſtate has a ſmall brain, formed of two lobes, which are ſituated very near together, but diſtinguiſhed by a longitudinal furrow; the anterior part produces a large nerve, which is afterwards diſtributed to the antennæ and the proboſcis. In aſilus crabroniformis is a ſingle cord uniting the abdominal ganglia, which are ſix in number. The brain itſelf is ſimilar to that of the ſyrphus (as in muſca inanis, &c.) but the bulbs formed by the optic nerves are ſtill broader in proportion to the extent of the eyes they have to inveſt.

Aptera.—In the great centipede, ſcolopendra morſitans, the brain has a very ſingular form: the two lobes of which it is compoſed are almoſt ſpherical; the optic nerve is produced laterally and is very ſhort. The filaments are four in number, but two nerves ariſe anteriorly which are ſo very thick, that they appear part of the brain, to which they are equal in diameter. Theſe nerves are particularly intended for the antennæ, into which we obſerve them enter. The two cords which embrace the œſophagus proceed directly downward, and form a large ganglion at the union of the firſt ring with the head. The firſt ganglion produces two nerves poſteriorly, and ſeveral towards the ſides. A ganglion, preciſely of the ſame ſhape, is placed above each of the articulations: thus there are in all twenty-four very diſtinct ganglia in this inſect, from each of which are detached three pairs of nerves.

Mouth.—In order to afford ſome idea of the amazing difference that prevails in the ſtructure of the ſeveral parts or organs which conſtitute the mouth, it will be only requiſite to obſerve that the claſſification of all inſects, in the Fabrician ſyſtem, is founded on this character. There are ten principal parts of which the mouth conſiſts; and it is from the relative proportion of each, from the diſſimilarity in the form, poſition, variation in number, or occaſional peculiarities, that the moſt permanent characters are deduced. Theſe parts have one diſadvantage: they are generally ſmall, and from this circumſtance have not been ſo univerſally adopted in the arrangement of inſects as they would otherwiſe. Without, however, beſtowing ſome little attention to theſe organs, it is impoſſible to diſtribute inſects into their natural order with any great degree of certainty.

The organs of the mouth were ſlightly regarded by Linnæus; and to this cauſe alone we may attribute ſome few ſerious errors in the works of that naturaliſt. The parts he deſcribes are the roſtrum (or proboſcis), maxillæ, lingua, and labium ſuperius. Some of theſe are not ſufficiently diſcriminated; his roſtrum and proboſcis are not different; the maxillæ are confounded with the mandibulæ; and the labium ſuperius is not, as the expreſſion implies, the upper lip of the inſect, this latter part being ſituated under it. Fabricius defines theſe parts with more preciſion, as he derives his eſſential characters from them. In the arrangement of Olivier, in the works of Latreille, and moſt other modern writers on entomology, the eſſential characters are eſtabliſhed chiefly on the peculiarities of theſe organs.

The ten principal parts of which the mouth conſiſts are the following.

Labium ſuperius, or upper lip: a tranſverſe, ſoft, moveable piece of a coriaceous or membranaceous nature, known from its ſituation at the anterior or upper part of the mouth. This part is very diſtinct in many of the coleoptera, and in the gryllus, apis, and ſome other genera. Linnæus ſometimes confounds the upper lip with the clypeus or ſhield of the head; and ſimilar inſtances occur in the works of Fabricius. Theſe two parts may be diſtinguiſhed by one invariable character; the clypeus is fixed, and forms a portion of the head; the upper lip is moveable.

Labium inferius: the piece which terminates the mouth beneath, and which is ſometimes lengthened, ſo as to form the inſtrument called ligula. It is ſoft, flexible, uſually bifid,

bifid, and has the posterior pair of feelers placed at the base.

Mandibulæ, mandibles: two hard pieces, in substance resembling horn, which are placed one at each side of the mouth, below the upper lip. These have a lateral motion, while the upper and lower lip move up and down, as in other animals. These differ from the maxillæ, with which they are sometimes confounded, by not having any of the palpi or feelers attached to them. In rapacious insects, these are larger and more powerful than in those which perforate wood; and the latter again have stronger mandibles than insects which feed only on herbage or leaves.

Maxillæ: two small pieces of a somewhat membranaceous consistency, and in figure different from the mandibles. These are commonly indented at the extremity, and nearly all ciliated at the inner edge. They are placed under the mandibles, and above the lower lip; their motion is lateral. In those insects which have more than one pair of feelers, the posterior ones take their origin from the sides of the maxillæ.

Galeæ.—Shields of the mouth, two membranaceous appendages, usually of a large size and cylindrical form, placed one on each side, at the exterior part of the jaw, and which cover and protect the organs of the mouth, conjointly with the lips. The galeæ are inserted at the back of the jaws, as is well exemplified in the gryllus tribe.

Organs of Taste.

These appertaining of course, like the foregoing, to the mouth, and of which they constitute the most material part, admit of considerable variety in their formation, and in some particular tribes differ so greatly as to have obtained distinct names in the works of entomologists, according to their precise form; such, for example, as ligula, lingua, rostrum, proboscis, and haustellum.

Ligula.—This is the part considered by many authors as the lower lip; its situation is immediately under the jaws; and it consists of a single piece, which is of a soft texture, often bifid, and, if attentively examined at the base, will be found of a horny substance.

In the coleoptera, and some of the hemiptera, as the blatta, phasma, gryllus, &c. this tongue terminates at the point in a membranaceous substance: its form is extremely various in the different genera. The hymenoptera and some neuroptera have the tongue or ligula situated in the same manner; but it is in these concave, and is frequently prolonged into a sort of proboscis, which sometimes exceeds the length of the whole body. It is membranaceous, but of a soft and spongy texture, and well suited for receiving the impressions of taste. This kind of tongue is extremely well exemplified in the bee.

Lingua: tongue, the involuted tubular organ which constitutes the whole mouth in lepidopterous insects. This is of a setaceous form, and either very long, as in the papilio and sphinx genera, or short, as in most of the bombyces and other moths. It consists of two filamentous pieces, which are externally convex, concave within, and connected longitudinally by a suture along the middle above and beneath. These in uniting form a cylinder, through which the nectareous juices of the flowers on which these insects subsist are drawn up with facility. These two pieces are not very closely united, and may be separated by means of a needle point. When the insect takes its food, this tube is exserted; at other times it is rolled up spirally between the palpi.

A curious circumstance is mentioned by Degeer, relative to the tongue of the butterfly. Having cut off the tongue of a papilio antiopa, almost as soon as it was emancipated from the chrysalis, it moved and rolled itself up at intervals for a considerable time: an hour after it had been cut off it repeated the same motions, recommencing them every time it was touched. It was observed that the same effect did not follow, if the butterfly had been liberated from the chrysalis for a few days.

Rostrum, or beak: the part which forms the mouth in many of the hemipterous order of insects. This instrument is moveable, articulated, and bent under the breast. Within this beak is hollow, and contains, as in a sheath, three or more very fine and delicate bristles, the points of which these insects introduce into the body of the animal, or substance of the plants, from which they draw nourishment. The rostrum is conspicuous in the genera cicada, nepa, and cimex.

Proboscis.—The trunk is inserted in place of the mouth, in most dipterous insects. It is rather fleshy, retractile, of a single piece, and often cylindrical; the end forming two lips, which are of a soft substance, and from the delicacy of their teguments must possess the faculty of taste in a very high degree.

Haustellum.—Formed of two or more very small and delicate filaments, inclosed in a sheath of two valves.

Lingua, rostrum, and proboscis, are Linnæan terms: the first is adopted according to the definition of that system; the two latter are synonymous with Linnæus. Ligula is a Fabrician expression, indicating the lower lip.

Palpi.—Feelers. These are the small, moveable, filiform organs, or appendages, placed at each side the mouth in the generality of insects. In some respects they resemble the antennæ, but are more distinctly articulated. They vary in number in different insects, being either two, four, or six, and are commonly inserted at each side the exterior part of the jaw. In those which have only one pair, they are usually situated on the upper lip; when two or more, the posterior ones are generally on the lower lip; and in some insects furnished with a sucking trunk, they are oftentimes found inserted at each side of that organ. These feelers are composed of several joints, the number of which vary. Like the antennæ, to which they bear analogy, they are endowed with powers of motion, but still more extensively. They also serve, like the antennæ, as an essential character in the construction of genera; and from their situation, the number of joints, termination, and relative proportion and size, are exceedingly useful for that purpose.

These feelers, as their name implies, are considered as the organs of touch; and this is conceived probable, because the insect agitates these parts, and presses its food with them before it begins to eat. Some have supposed them to be the organs of hearing; and others of a sense peculiar to insects, which we are ignorant of. It has been ascertained from experiment, that they are not absolutely necessary to the life of the insect, and that it even sustains their loss without much apparent inconvenience. Feelers are not common to all insects. There are many whole genera destitute of them; as, for example, the fulgora, cicada, the several genera of the Linnæan cimices, nepa, notonecta, and various others.

Certain kinds of insects are provided with feelers, both in the larva and perfect state, as is particularly exemplified in the dytiscus and hydrophilus genera, and again in the libellulæ; and it is worthy of remark, that these organs appear to be more immediately useful to the carnivorous tribes of insects than to those which feed on plants.

Olfactory organs.—Nature has denied the insect race that particular part which is properly called the nose; and it is further

further evident, that there is no organ within the head appropriated to the fenfe of fmell. From analogy, and comparifon with other animals, naturalifts have been led to feek this organ in the head: and as infects afford the moft convincing evidence of being poffeffed of this faculty, fome have placed it in the antennæ, and others in the feelers; neither of which, from attentive examination, appears calculated for this purpofe.

It is fufficiently clear that infects poffefs the faculty of fmell, if not in a very eminent degree, and that in many refpects they are rather guided by this fenfe than by the force of inftinct. Infects difcover their food at a great diftance, and, as it is fuppofed, by this means; and it is concluded likewife, that butterflies and moths are directed by the fame fenfe to the difcovery of their mates. A female of phalæna quercus (eggar moth), inclofed in a box, and thus expofed in an avenue of a wood, will attract the males in numbers to the fame fpot; and though fhe cannot poffibly be feen, they will appear fully fenfible of her prefence. Admitting that thefe circumftances may be otherwife accounted for, one argument at leaft bears ftrongly in its favour, namely, that of the flefh fly (mufca vomitoria) being fo far deceived by the fimilarity of odour, as to lay its eggs on plants of the ftapelia genus inftead of animal fubftances. Thefe infects, as the name implies, fubfift in the larva ftate on flefh, preferring that which is putrid, or haftening to the ftage of putrefaction, and from whence, in confequence, a powerful odour arifes. The plants of the ftapelia genus have the fame fmell; and the parent infect, mifled by this means, actually depofits her eggs on thefe plants.

As inftinct never errs, though judgment may, it is a natural inference that the infect is not in this inftance under the controul of inftinct, but of her own will, becaufe otherwife fhe would not fail to lay thofe eggs in flefh, where the larva, when hatched, would be provided with food; while, on the contrary, the plants refemble this food only in its offenfive odour, and thus, when hatched, the infant brood inevitably perifh. Does not this afford prefumptive evidence at leaft, that the infect is directed to thefe plants by the organs of fmell?

If infects then evince fuch apparent proofs that they do poffefs this faculty, and that it appears likewife the feat of this faculty does not refide in the head, it muft be fought after in fome other part. The organs of fmell, in all animals which refpire air, is fituated at the entrance of the organs of refpiration: from this circumftance it is conceived moft likely that the refpiratory fpiracles on each fide the body muft be the true organs of that fenfe. This idea was advanced by Bafter; yet it feemed to imply fuch an inverfion in the ordinary courfe of nature, that it gained little credit. Of late years the fame opinion has obtained the concurrence of the beft anatomifts. Cuvier is decidedly in favour of this conclufion, and, in addition to the reafons hitherto ftated in its fupport, obferves, that the internal membrane of the tracheæ appears well calculated to perform this office, being foft and moiftened; and that the infects in which the tracheæ enlarge, and form numerous or confiderable veficles, are thofe which feem to poffefs the moft perfect fenfe of fmell. Olivier endeavours to maintain that the palpi or feelers, and alfo the antennæ, are the olfactory organs in infects.

Eyes.—Moft infects have two eyes. Thefe are placed in the anterior part of the head, and vary very much in their external figure in different tribes. Some of the Linnæan infects of the apterous order have a greater number, the fcorpions have eight, and the fpiders from fix to eight, and there are befides other genera in which the eyes amount to more than two.

This pair of eyes in the infect race is of a compound kind, while thofe of the fcorpion and fpider are fimple, and in this refpect the difference is very remarkable. The compound eye is one of the moft extraordinary deviations from the ordinary courfe of nature in the conformation of the organ of fight; the fimple eyes approach much nearer thofe of other animals. By compound eyes we mean thofe kinds which are reticulated, and when magnified are found divided into a great number of compartments, and of thefe every genuine infect appears to poffefs two. Befides thefe eyes, many of the neuropterous and hymenopterous families have three fmall fhining convex points placed in the middle of the head, and called by entomologifts ftemmata, the utility of which has never been afcertained. The extreme minutenefs of thefe organs does not allow the comparative anatomift the means of diffecting them, but we ftill think they can be no other than organs of fight. Should this appear doubtful, becaufe we obferve them in thofe infects, which are befides furnifhed with a pair of eyes of the compound kind, it fhould be recollected that fcorpions and fpiders, as before-mentioned, have feveral more eyes than a pair; and if, on the other hand, the fimplicity of their ftructure be confidered as an argument againft this conclufion, let it be obferved that they poffefs every character in their form, appearance, fituation, and immoveability, which the only kind of eyes thefe creatures are furnifhed with are known to poffefs. We, indeed, conceive it very probable, that thofe three fhining points, called ftemmata, are truly organs of fight; and that, confequently, many infects which appear to have only two eyes, have in reality no lefs than five.

The compound eye in infects is fo very different from that of other animals, that it would be difficult to perfuade ourfelves of its being an organ of fight, had not experiments, purpofely made, demonftrated its ufe. If we cut out, or cover with an opake matter the eyes of a libellula, or dragon fly, it will ftrike againft walls in flight. The wafp is faid to afcend perpendicularly in the air till it completely difappears, when the compound eyes are treated in the fame manner, and to remain perfectly immoveable when both the compound eyes and the ftemmata are covered; in the firft cafe it feems to follow the direction of its fight upwards, in the other to be deprived entirely of the vifual organ, and uncertain whither to direct its flight.

The compound eyes are generally convex, and when viewed by the microfcope exhibit an innumerable multitude of hexagonal facets, flightly convex, and feparated from one another by fmall furrows, which frequently contain fine hairs, more or lefs long. Thefe facets give, to the naked eye, the appearance of net work, and amount to a greater or lefs number in different infects. Leeuwenhoek counted 3181 in the eye of a beetle, and in that of the common houfe fly about 8000.

Thefe facets form altogether a hard elaftic membrane, which, when freed from the fubftances that adhere behind, is very tranfparent. Each of thefe fmall furfaces may be confidered either as a cornea, or a cryftalline, for it is externally convex, and concave internally, but thicker in the middle than at the edges, and it is alfo the only tranfparent part in this fingular eye. Behind this tranfparent membrane is a fubftance, which varies greatly as to colour in different fpecies, and which fometimes forms, even in the fame eye, fpots or bands of different colours. Its confiftence is the fame as that of the pigment of the choroides; it entirely covers the pofterior part of the tranfparent facets, without leaving any aperture

aperture for the paſſage of the light. Behind this pigment we find ſome very ſhort white filaments, in the form of hexagonal priſms, ſituated cloſe to each other, like the ſtones of a pavement, and preciſely equal in number to the facets of the cornea; each penetrates into the hollow part of one of theſe facets, and is only ſeparated from it by the pigment mentioned above. If theſe filaments are nervous, we may conſider each as the retina of the ſurface behind which it is placed; but it will always, in the opinion of Cuvier, remain to be explained how the light can act on this retina through a coat of opake pigment. This multitude of filaments, perpendicular to the cornea, have behind them a membrane, which ſerves them all as the baſe, and which is conſequently nearly parallel to the cornea: this membrane is very fine, and of a blackiſh colour, which is not cauſed by a pigment, but extends to its moſt intimate texture; we obſerve in it very fine whitiſh lines, which are tracheæ, and which produce ſtill finer branches that penetrate between the hexagonal filaments as far as the cornea: this membrane by analogy Cuvier calls the choroides. A thin expanſion of the optic nerve is applied to the poſterior part of the choroides. This is the real nervous membrane, perfectly ſimilar to the retina in red-blooded animals; it appears that the white filaments, which form the particular retinæ of the different ocular ſurfaces, are productions of this general retina, which perforates the membrane named choroides by a multitude of ſmall and almoſt imperceptible holes. To obtain a diſtinct view of all theſe parts, it is neceſſary to cut off the head of an inſect which has the eyes of large ſize, and diſſect it behind, each part will then be removed in an order, the reverſe of that above deſcribed.

The conſtruction of theſe compound eyes is admirably adapted to the convenience of the inſect, for as the eyes of inſects are immoveable, they would have loſt ſight of many objects, if their eyes had been framed like thoſe of other animals, but by theſe means they can eaſily view ſurrounding objects. It ſeems a falſe concluſion that as each of the facets which compoſe the compound eye is a diſtinct organ of ſight, any ſingle object muſt appear multiplied as often as there are facets; it is, on the contrary, far from improbable, that as objects do not appear double to our eyes, but that the viſual organ is ſtrengthened, and many illuſive appearances are corrected by the uſe of both, ſo the numerous inlets to ſight in an inſect may increaſe their field of view, and be productive of other advantages, of which we are ignorant.

Stemmata: the three ſmooth, gloſſy, hemiſpherical dots, ſituated at the vertex of the head, and which, as juſt obſerved in ſpeaking of the eyes, are ſuppoſed to be organs of ſight. Theſe are moſt conſpicuous in the hymenopterous order of inſects.

An experiment made by abbé Catalan tends to confirm the truth of this conjecture. With the view of obſerving whether an inſect could ſee equally well with both the eyes and ſtemmata, he covered the reticular eye of a fly with fluid pitch, leaving the ſtemmata open; he then put it under a glaſs, where it ran up and down without ſtriking againſt any object, and when he lifted the glaſs, it flew away towards the window. He took another fly, and covered with pitch the ſtemmata, leaving the reticular eyes open, and found that with theſe it ſaw equally well as before. Laſtly, he took a third fly, and covered both the reticular eyes and the ſtemmata, and this he found completely blind; it walked ſlowly under the glaſs, and when removed would not venture to fly. Act. Erudit. A.D. 1682.

Antennæ are thoſe delicate moveable horns which appear on the fore part of the head in all perfect and genuine inſects; and which, in many inſtances, are very remarkable for their beauty and elegance of ſtructure. The antennæ are extremely diverſified in form, and vary conſiderably in their proportional dimenſions in different tribes; and for this reaſon are conſidered by entomologiſts of material conſequence in diſtinguiſhing the various orders, genera, and ſpecies. Theſe parts are always articulated, or conſiſt at leaſt of more than one joint, including the baſe, and moſt commonly are compoſed of a far greater number; few leſs than eight, ten, or twelve, and ſome amounting to twenty, or even more. This articulated ſtructure of the antennæ is of infinite utility to the inſect, as it is thereby enabled to move theſe organs in every direction their wants or wiſhes may require.

Antennæ are not entirely peculiar to inſects; the cruſtaceous animals poſſeſs the ſame organs, though in other reſpects they differ ſo eſſentially, (ſee article CANCER,) as do likewiſe ſome of the apterous order of Linnæan inſects, which modern naturaliſts exclude from this claſs. Nor will it be amiſs to obſerve that, even according to Linnæus, many of his apterous inſects are deſtitute of antennæ, and are conſequently inadmiſſible on this account, upon his own definition, into the ſyſtem of entomology. Spiders and ſcorpions are of the latter deſcription. The organs termed antennæ are eaſily diſtinguiſhed from the tentaculæ of vermes, by having a ſhelly covering, and from the palpi or feelers of inſects, the latter being more numerous, and ſituated at the mouth. The Linnæan and Fabrician entomologiſts admitting the cancer, and other cruſtacea among the inſect tribes, allow four, or in ſome caſes even ſix antennæ to this race, but as we refer theſe to another claſs, we apprehend that the number of antennæ in all genuine inſects invariably amounts only to two. Thoſe inſects which have attained their laſt ſtate, and are therefore denominated perfect, and which poſſeſs ſix legs, are always provided with two antennæ. It is true that the larvæ of many inſects are not furniſhed with theſe organs, yet they are ſtill genuine inſects, becauſe in their complete ſtate they poſſeſs them; ſpiders and ſcorpions on the contrary, with all their organs complete, have no antennæ. A very conſiderable number of inſects, even in the larva ſtate, are not deficient in theſe organs, and in many, though not in all, there is no difference whatever between the antennæ of the larva and perfect inſect. The genera blatta, gryllus, mantis, phaſma, cimex, and various others of the hemiptera order, are furniſhed with antennæ, which exactly reſemble thoſe of the ſame ſpecies in their perfect ſtate.

No writer, who has attentively regarded the ſtructure of the antennæ in inſects, has hitherto pretended to determine preciſely the purpoſe for which nature has deſigned them, and thoſe who have not very maturely conſidered them cannot poſſibly be competent to decide ſuch a doubtful circumſtance. We know of nothing analogous to theſe organs in larger animals whoſe manners we might be ſuppoſed to have a better acquaintance with, and it is not therefore by analogy that this point can be determined. Some naturaliſts conceive that they are appropriated to a feeling more delicate than our own, and that they are ſenſible to the leaſt motion or diſturbance in the ambient fluid, or that they are the organs of ſome ſenſe unknown to us, and of which we cannot conſequently form the leaſt conception. Some ſuppoſe they ſerve to ſound, and occaſionally to probe the earth on which they move, or that they are the organs of hearing, of feeling, or ſmelling, and by the means of which they diſtinguiſh their proper food. Each of theſe conjectures

is

is liable to objection, and can be conſidered as an opinion merely, while the real purpoſes of theſe organs may perhaps for ever remain unknown.

Though it is difficult even to conceive the immediate object for which the Creator has aſſigned theſe organs to the inſect race, we muſt reſt perſuaded that they are intended to anſwer ſome very important deſtination in the economy of the animal, as the medullary nerves, ariſing directly from the brain, may be traced into theſe parts, and followed throughout their whole extent. In ſome inſects alſo, which have the antennæ ſmall. the palpi are obſerved to be very large, as if they were intended to anſwer the ſame purpoſe, or partake of the ſame ſenſe, as the antennæ, and thus, by their mutual aid, ſupply the deficiency of antennæ. This will in ſome degree account, perhaps, for the manner in which nature ſeems occaſionally to counterbalance the want of antennæ in the larvæ of certain kinds of inſects which have palpi, but no antennæ; others in the ſame ſtate have antennæ and no palpi. Many that are deſtitute of both the two firſt-mentioned kinds are thoſe chiefly which prey on inſects, and the latter ſuch as feed on plants.

The antennæ, nevertheleſs, appear to us to be rather connected with the organ of hearing, than either that of feeling or ſmelling. The palpi, we have little doubt, are the organs of feeling, both from their texture, and the manner in which inſects are oftentimes obſerved to make uſe of them in touching their aliments; and the organs of ſmelling in inſects, however ſingular it may be imagined, we conceive to be no other than the apertures diſpoſed on each ſide the thorax and body. By the organs of hearing, we do not mean to conſider them as external ears, but as being in ſome manner auxiliary to the organ of hearing, the ſeat of which we ſuſpect to be contiguous to the baſe of the antennæ, the ſpot in which the ſame organ has been diſcovered in the cray-fiſh. They may anſwer this and ſome other purpoſe likewiſe.

We have previouſly obſerved, that nothing can be diſtinctly inferred of the actual utility of the antennæ from analogy; nor do the purpoſes to which inſects appear ſometimes to appropriate them aſſiſt our concluſions in a ſatisfactory manner. Many inſects, when they walk, fly, or take their food, have the antennæ directed forward; others, on the contrary, carry them inclining backward, like the cerambyces; ſome kinds lay them along their back; and others, as the elater tribe, diſpoſe them on each ſide the thorax. The ſpheges and the ichneumons bear their antennæ directly before them, and continually agitate them, whether in flight, when ſtanding, or ſeizing on their prey. In others, the antennæ have little perceptible motion. Some inſects are ſaid to cover their eyes with their antennæ when they ſleep; the diminutive ſize, compared with the magnitude of the eyes in moſt inſects, will not permit us to believe that this is the principal object of their deſtination.

Notwithſtanding the direct connection of the antennæ with the brain, inſects, it has been affirmed, can undergo their partial privation, or total loſs, without experiencing any ſenſible injury; and hence it has been concluded they cannot be neceſſary to the life of the inſect. If the fact be true, the latter inference muſt ſurely be admitted, but this will not diſprove their utility: nor will it diſcountenance the idea that the antennæ are requiſite for ſome important end. We well know, that in the animal economy of larger beings, not only the medullary nerves may be in part deſtroyed, but even the animal be deprived of a portion of the brain itſelf, without ſuſtaining mortal injury. The antennæ of inſects may not be abſolutely neceſſary to the life of the inſect, but are certainly ſo to its well being, and to the perfect exerciſe of all its functions.

The antennæ of the male inſects generally differ from thoſe of the females. It is principally the antennæ of the former that are plumoſe, or furniſhed with teeth, or tufts of feathers, while thoſe of the female appear like a delicate thread, entirely ſmooth, or only ſlightly pectinated. This is obſervable throughout the moth tribe. In coleopterous inſects the males are often diſtinguiſhed by the ſuperior ſize and beauty of the antennæ from the other ſex. The antennæ are characterized by entomologiſts according to their ſtructure under different names. Linnæus deſcribes the following: 1, Setaceæ, thoſe which gradually become taper towards the extremity; 2, Filiformes, ſuch as are of an equal thickneſs throughout; 3, Moniliformes, are filiform like the preceding, but conſiſt of a ſeries of round knobs, like a neck-lace of beads; 4, Clavatæ, ſuch as gradually increaſe in thickneſs from the baſe, and form a club at the end; 5, Capitatæ, like clavatæ, increaſe in thickneſs towards their extremity, but are diſtinguiſhed from thoſe by the form of their laſt articulation, which is larger and more rounded than the others; 6, Fiſſiles are like the laſt, but are divided longitudinally into three or four plates or laminæ; 7, Perfoliatæ are alſo capitatæ, but have the head divided horizontally, the plates being connected by a kind of thread paſſing through their centre; 8, Pectinatæ are thoſe which have lateral appendages, like the teeth of a comb, or plume of a feather, as in the moth tribe. 9. Ariſtatæ, ſuch as have a lateral hair, which is either naked, or furniſhed with leſſer hairs, as in the muſca genus. Each of theſe is alſo diſtinguiſhed according to their length, as breviores, thoſe which are ſhorter than the body; longiores, thoſe which are longer than the body; and mediocres, ſuch as are of the ſame length with the body, all which varieties are conſpicuous in the Linnæan tribe of cerambyces.

The ſtructure of the antennæ in inſects is of ſuch vaſt importance in the definition of genera, ſpecies, and ſexual diſtinctions, that it is to be regretted we have not a more comprehenſive number of terms by which their particular forms might be minutely diſcriminated. Linnæus affords us ſome, the utility of which is univerſally allowed; others which he propoſes require ſome reviſal and modification; and among the immenſe number of inſects diſcovered ſince the time of Linnæus, the antennæ of many exhibit characters which cannot be expreſſed by any of thoſe his work preſents. Fabricius has others, but theſe, even in addition to thoſe of Linnæus, are not adequate to the purpoſe.

Organs of hearing at the baſe of the Antennæ.

The organs deſtined by nature for the conveyance of ſounds to the ſeat of the ſenſes in the inſect race have never been clearly aſcertained. This can be attributed only, perhaps, to their minuteneſs, which defies inveſtigation, except in ſome few of the larger kinds, and theſe even phyſiologiſts ſeem never to have examined. In the cray-fiſh the organs of hearing are exemplified by Fabricius and Scarpa. Theſe were diſcovered within the head, at the baſe of the antennæ, through the hollow tube of which it is ſuppoſed the ſound muſt be conveyed. Perhaps, from the analogy in certain reſpects, which this tribe of cruſtaceous animals bears to inſects, it may be imagined that the organs of hearing in both are ſimilar: this is very probable; but theſe two orders of creatures differ ſo eſſentially in ſeveral particulars, that we wiſh to expreſs ſuch an opinion with caution.

In

In the cray-fiſh the labyrinth of theſe organs is very ſimple, reſembling a ſmall purſe, encloſed in a ſcaly cylinder open at both ends. The extremity by which this ſmall cylinder joins the baſe of the antennæ affords a paſſage for the nerves into the purſe. The oppoſite extremity is cloſed by an elaſtic membrane, which may be named tympanum, or, with more propriety, Cuvier thinks, feneſtra ovalis. The air, or water in which the animal lives, acts immediately on this membrane, the external part of which is obſervable at the lower ſurface of the baſe of the antennæ. That inſects are ſenſible of ſounds, and, conſequently, are furniſhed with organs of hearing, is demonſtrated by numberleſs obſervations.

Front: the anterior or fore part of the head, the ſpace between the eyes and the mouth.

Clypeus: ſhield of the head in coleopterous inſects, the part correſponding with the front of the head in the other orders. In the beetle kind it is advanced more or leſs upon, or over the mouth, and in ſome forms a ſort of cap, the rim of which extends ſo far over the head as to conceal the mouth beneath. The anterior edge of the clypeus is ſometimes miſtaken for the upper lip.

Vertex: the crown, or ſummit of the head.

Gula: that part which is oppoſed to the front of the head, uſually called the throat.

Trunk: the ſecond principal diviſion of which an inſect conſiſts, comprehending that portion which is ſituated between the head and the abdomen. The trunk includes the thorax, collar, ſternum, and ſcutel.

Thorax: a term indefinitely applied ſometimes to the whole trunk, the ſcutel excepted: in a ſtricter ſenſe it implies only the dorſal part of the trunk, and may be conſidered as expreſſive of that portion of the ſuperior ſurface which lies between the head and the baſe of the wings. Linnæus is not ſo explicit as could be wiſhed in his definition of the word thorax; according to this author, it is "the back part of the breaſt," and "upper part of the trunk between the head and ſcutel," yet it is evident, from the diſſimilar ſtructure in this part of the trunk in different inſects, that the definition requires rather more preciſion. It is not unuſual in the ſpecifical deſcriptions of inſects, both by Linnæus and Fabricius, to read of "thorax beneath," and "lower ſurface of the thorax," for the under ſurface of the trunk; though both endeavour to eſtabliſh it as a principle, that the word thorax applies to the back or upper ſurface of the trunk only. The appropriation of ſuitable terms, by which a thorax conſiſting of one, or of ſeveral pieces, may be diſcriminated from each other, is deſirable. In ſome the thorax is of a ſingle piece, as in the orders coleoptera and hemiptera; in that of lepidoptera it comprehends ſeveral ſegments, and a ſimilar ſtructure is ſtill more conſpicuous to view in the order hymenoptera. The firſt or anterior ſegment of the thorax in thoſe conſiſting of ſeveral pieces has been ſometimes called the collar; but in admitting this, we muſt by analogy define the coleopterous and hemipterous orders of inſects as having no thorax. This will be rendered plain, when we conſider that in the latter kinds of inſects the firſt pair of legs ariſes from what is uſually underſtood by the lower ſurface of the thorax; the interior ſegment in hymenopterous correſpond with the whole thorax in the former, for the firſt pair of legs ariſes from it exactly in the ſame manner. In the former the thorax of a ſingle piece is immediately ſucceeded behind by the ſcutel, while in the hymenoptera and lepidoptera a large plane of one or more joints intervene between this true thorax and the ſcutel; and it is to this laſt mentioned dorſal ſpace that the term thorax is aſſigned. Hence it is evident that the language of entomology in this point is not altogether conſiſtent; becauſe what we denominate the collar in hymenoptera, is the thorax in coleoptera, and in coleoptera we find nothing analogous to the thorax of the other order, except the collar.

The thorax in thoſe inſects, which have that part conſiſting of a ſingle piece, or the firſt ſegment in ſuch as are of a compound nature, have the firſt pair of legs ariſing from the lower ſurface, and it is in this part that the muſcles that move the head, as well as this pair of legs, are ſaid to be contained. The thorax in different kinds of inſects varies conſiderably in form, and affords very excellent generical and ſpecifical diſtinctions. Some are armed with ſpines, others denticulated, marginated, &c.

Pectus.—The breaſt is the third ſegment of the body, or that to which the four poſterior feet are attached, and which is longitudinally divided at the anterior part by the ſternum. The wings in lepidopterous, and moſt other inſects, have their origin or baſe in the ſuperior part of the breaſt. The wings and elytra in the coleoptera and hemiptera deviate a little from this, as they are placed more immediately on the back, than in a lateral poſition; the breaſt contains the muſcles that move the wings, and give action to the four poſterior legs. This part is capable of being compreſſed and dilated, the alternate motion of which is very evident in ſome inſects of the butterfly or moth kind, when held between the fingers. The power of compreſſion and dilatation is ſuppoſed to ariſe from the action of ſome very ſtrong muſcles, which ſeem to approximate the dorſal and ventral ſurfaces. They are four in number on each ſide, and differ very much in colour and texture from the other muſcles, being reddiſh yellow, and extremely looſe. It has been conjectured theſe muſcles may aſſiſt the motions of the organs of flight.

Sternum, or breaſt bone.—By this term entomologiſts define that portion of the middle part of the breaſt which is ſituated between the baſe of the four poſterior legs. This piece terminates inſects anteriorly in a ſomewhat acute point, in others it appears rather bilobate, and in the far greater ends obtuſely or in an obtuſe lobe. There are few inſects in which the ſternum is remarkable, either from its magnitude or figure. In ſome of the coleopterous tribes, as hydrophilus and dytiſcus, this part is moſt conſpicuous.

Scutel, or eſcutcheon (ſcutellum, Linn.) the lobe-like proceſs, ſituated immediately at the poſterior part of the thorax, in ſcutellate inſects. The ſcutel is not of the ſame form in all inſects, yet its general tendency is towards a ſub-triangular figure. In the coleopterous tribes it approaches neareſt to this form; its deviations incline more or leſs to heart-ſhaped, with the tip pointing backwards. The ſame figure prevails in ſome of the hemiptera order. In the neuroptera, hymenoptera, and diptera, the triangular contour is ſtill obſervable under various modifications, and moſt commonly with the poſterior tip rounded off. Sometimes, as in ſeveral of the hymenopterous inſects, the poſterior end is armed with ſpines, or denticulations; this is, however, not uſual, the ſcutel in the far greater number of inſects, whether terminating in a point, or rounded, is commonly unarmed. In point of ſize the ſcutel is more variable than in figure; in ſome it is ſo ſmall as almoſt to eſcape notice, merely forming a point at the extremity of the thorax, as we obſerve in certain kinds of the beetle tribe; in others it is very conſpicuous; ſometimes it is ſo large as to cover the middle of the back, and in others, as the ſcutellate kinds of cimices, and a few of the genus acrydium, it expands over the back, entirely concealing the wings and wing-caſes, and covering the margin of the abdomen.

Abdomen is the laſt principal diviſion, or poſterior part of the body, and is connected with the breaſt, either cloſely, or at a diſtance, by means of a fillet. The abdomen is compoſed of annular joints or ſegments, the number of which vary in different inſects. Each of theſe rings is pierced at the ſide with a ſingle pore, which in ſome kinds are of conſpicuous ſize, in others ſcarcely perceptible, and theſe are the orifices of the ſpiracles through which the inſects breathe. The upper part of the abdomen is called by entomologiſts tergum; the inferior, or belly, venter. The opening at the poſterior part of the abdomen is the vent, and the extremity in moſt inſects contains the organs of generation: there are exceptions to the latter.

The total movement of the abdomen is not very obvious, except in inſects which have that portion of the body pediculated, as in many of the hymenopterous genera. It has then a real joint, in which the firſt annulation is indented above, and receives a projecting proceſs from the breaſt on which it moves. This joint is rendered ſecure by elaſtic ligaments, which have a conſiderable degree of force. Some muſcles which ariſe within the breaſt are inſerted into the firſt ring, and determine the extent of its motions. The partial motion of the rings is produced by very ſimple muſcles, conſiſting of fibres which extend from the anterior edge of one ring to the poſterior edge of that which immediately precedes it. When the dorſal fibres contract, the ſuperior part of the abdomen being ſhortened, it turns up towards the back, but when the contraction takes place in the ventral or lateral fibres, the abdomen is inflected towards the belly, or directed towards one of the ſides. The extent of the motion, however, depends upon the number of the rings, and their mode of junction. In the coleoptera, for example, the rings only touch each other by their edges, and the motion is very limited, but in the hymenoptera they are ſo many ſmall hoops, which are incaſed one into another like the tubes of a teleſcope, ſo that ſcarcely half, and ſometimes not above one-third, of their extent appears viſible externally.

The form, connection, proportions, and appearance of the ſurface of the annulations of the abdomen, afford numberleſs ſpecifical diſtinctions; and ſo likewiſe do the appendices at the extremity of the abdomen.

The abdomen contains the inteſtines, the ovary, and part of the organs of reſpiration: it is affixed to the thorax, and in moſt inſects diſtinct from it, forming the poſterior part of the body. The abdomen is compoſed of rings or joints, by which means the inſect can lengthen or ſhorten it, or even move it in different directions. The upper part of the abdomen is called tergum, the under part venter, the vent is in the poſterior part.

Tail.—An appendage of any kind terminating the abdomen is uſually denominated the tail. Theſe appendages vary in figure conſiderably in different inſects, and many tribes are totally deſtitute of them. They are ſuppoſed to be deſtined to direct the motion of the inſect in flight, to ſerve for its defence, and for the depoſition of its eggs. In ſome inſects this tail is ſimple, (ſimplex,) and yet capable of being extended and withdrawn at pleaſure. In others elongated (elongata). Some are ſetaceous (ſetacea) or briſtle-ſhaped, as in the raphidia. Thoſe termed triſeta have three briſtle-ſhaped appendices, as in the ephemera. In ſome it is forked (furcata), as in podura. When it terminates in a pair of forceps it is called forcipata. In the blatta and others it is folioſa, or reſembling a leaf. In the panorpa it is furniſhed with a ſting, and is called telifera; this laſt may be more properly referred to the next.

Aculeus, ſting, an inſtrument with which inſects wound and inſtil a poiſon. The ſting generally proceeds from the under part of the laſt ring of the belly; in ſome it is ſharp and pointed, in others ſerrated or barbed. It is uſed by many inſects both as an offenſive and defenſive weapon: by others it is uſed only to pierce wood, or the bodies of animals, in order to depoſit their eggs. In waſps and bees the ſting is known to be retractile: in the ſcorpion fixed or immoveably connected to the laſt ſegment of the body. In ſome inſects it is the male only, and in others the female only, which nature has provided with this inſtrument; it is not frequently met with in both ſexes of the ſame ſpecies; and the far greater number of inſects have no ſuch organ.

Spiracles.—Theſe are the apparent orifices to the organs of reſpiration in inſects, and which are known to many entomologiſts by the name of ſtigmates. The ſpiracles are a ſeries of ſmall apertures diſpoſed along both ſides of the abdomen: ſome few appear on each ſide the thorax, the remainder on the abdominal rings, every one of which is pierced on each ſide with a ſingle aperture. Among the ancients it was generally believed that inſects had not the power of breathing, and this they concluded becauſe they have no reſpiratory organs, as in larger animals. The moderns are better informed; from the effects produced on inſects by the pneumatic machine it is demonſtrated, beyond diſpute, that they do reſpire, though not in the manner of other animals. An inſect placed in the receiver of this machine, upon the air being exhauſted, becomes ſuffocated, and dies in a very ſhort time; and the ſame reſult will be produced by cloſing the apertures of the ſpiracles with wax, oil, or other glutinous ſubjects, in a ſufficient degree to preclude the paſſages of air through theſe openings, a fact which in itſelf may be regarded as concluſive, that theſe are the true organs of reſpiration in inſects. They are alſo conſidered, and with much probability, as the organs of ſmell, as will be ſhewn hereafter.

Reſpiration being one of the moſt important actions in the life of every animal, it can be no matter of aſtoniſhment that great pains have been taken by naturaliſts to inveſtigate the organs of breathing in inſects; numberleſs facts contributed to prove its exiſtence, but this being accompliſhed by means unknown in the other tribes of animals, it became an object of the greater ſolicitude to explain the manner in which it was effected. Malpighi, Swammerdam, Reaumur, and Lyonet, are among the number of the earlieſt writers on this ſubject, and from their obſervations it appears, that in the caterpillar there are two air-veſſels, called tracheæ, which extend throughout the whole length of the inſect; from theſe proceed an infinite number of ramifications, which are diſperſed in various directions through the body; but the principal are thoſe which form a direct communication between the tracheal veſſels and the openings in the ſides of the body. Of theſe there are nine on each ſide placed nearly at equal diſtances, one extremity terminates in the orifice of the ſpiracle, and the other enters the principal tracheal veſſel diſpoſed neareſt, or on that ſide of the body. Theſe lateral or ſpiracular veſſels ſeem calculated for the reception of air; they are of a cartilaginous nature, and when cut preſerve their figure; they are conſtantly obſerved in a temperate ſtate of moiſture, and communicate in many inſects in the form of conſiderable veſicles, at their junction with the principal tracheæ.

Some writers have imagined, that though the air entered by the ſpiracles into the trachea, it did not come out by the ſame orifice, but was expired through a number of ſmall holes in the ſkin of the caterpillar, after being conveyed to them through the extremities of the finer ramifications of the tracheal veſſels. Others ſuppoſed, that the inſpiration and

and expiration of air through the ſpiracula, and that there was no expiration of air through the pores of the ſkin. Experiments were made to aſcertain the truth of theſe opinions, by plunging the caterpillars into water, or anointing them with fat and greaſy ſubſtances, either partially or entirely. The number of ſmall bubbles which are obſerved to cover the ſurface of their bodies when they are immerſed in water, is ſaid not to ariſe from the air included in them, and then proceeding from them, but to be formed by the air which is lodged near the ſurface of their bodies, in the ſame manner that it is about all other ſubſtances. To render the experiment more accurate, and prevent the air from adhering to the ſkin, before the caterpillars were plunged into water, they were bruſhed all over with a hair pencil, and after this, it is affirmed, that few air bubbles were found on their bodies when immerſed in water. The latter experiments were made chiefly by Bonnet, in order to aſcertain the truth of ſome opinions previouſly advanced by Reaumur.

A caterpillar, according to Bonnet, may be retained a conſiderable time under water, without deſtroying the principle of life, and will recover ſoon after being taken out of the water, when it has lain till all apparent ſigns of life have ceaſed. A caterpillar partially immerſed in water, or with two or three of the ſpiracles remaining in the open air, does not become torpid for a conſiderable time. One caterpillar lived eight days ſuſpended in water, with only two of its anterior ſpiracles in the air. During this time it was obſerved, that when the inſect moved itſelf, little ſtreams of bubbles iſſued from the ſpiracles on the left ſide; from this and other experiments, however, it appeared, that the anterior pair of ſpiracles, together with the poſterior pair, are of the greateſt uſe in reſpiration.

It has been remarked, that "when we conſider the great ſolidity of the caſes or cones of certain kinds of inſects, it is not eaſy to conceive how they can live ſeveral months under the earth in ſpaces ſo confined, and almoſt impervious to the air. If reſpiration was abſolutely neceſſary to their exiſtence, and indeed if they did reſpire, the ſame ſituation ſeems to preclude a continuance of the operation, as the air would ſoon be corrupted, and unfit for the offices of life."

But though it is difficult to aſcertain the reſpiration of ſome inſects at certain periods of exiſtence, except from its effects in preſerving life, which from analogy and collateral circumſtances we are aſſured muſt depend on this cauſe, there are others to whom reſpiration ſeems neceſſary in a very extraordinary degree. Many inſtances of this might be adduced; but in no tribe is this more clearly ſhewn than in thoſe of the aquatic kinds. There are a number of the latter which are obliged to keep their tails ſuſpended on the ſurface of the water for this reaſon, and in proof of which, if they be plunged entirely under water, they become agitated and uneaſy, firſt endeavouring to eſcape and riſe again to the air, or, if prevented, ſhortly fall to the bottom and die. Some aquatic beetles reſiſt the trial for a conſiderable time, while their larvæ can ſupport the privation of air only for a few minutes. A remarkable evidence of the ſame kind occurs in the larvæ of muſca pendula, which, though they live in the mud at the bottom of the water, have the power of extending the tube of the tail to a great length, in order to elevate it to the ſurface of the water; and the extremity of it is furniſhed with a tuft of fine hairs, which preſerves that part buoyant on the ſurface, while the creature remains in a ſtate of quieſcence. A ſimilar verticillated organ is placed at the tip of the tail in the larva of muſca chameleon, which alſo lives in the water; this is expanſile or retractile at the pleaſure of the inſect; when at reſt the expanded tail reſts upon the ſurface of the water, the remainder of the body being ſuſpended in that element with the head downwards, and when it is inclined to deſcend, it has only to retract or cloſe up the rays of the tail to effect its purpoſe; an expanſion of the tail will again raiſe the larva to the ſurface.

Upon anatomical examination, it has been found that the body of this laſt mentioned larva contains two large tracheal veſſels: theſe air-veſſels extend from the head to the tail, terminate in the reſpiring tubes, and receive the air from them. The larva quits the water when the time of its transformation approaches, and enters into the earth, where the ſkin hardens and forms a caſe, in which the pupa is formed: ſoon after the change, four tubes or horns are ſeen projecting from the caſe, which ſome ſuppoſe to be the organ for communicating air to the interior parts of the inſect: they are connected with little veſicles which are filled with air, and by which it is conveyed to the ſpiracles of the pupa. The larvæ of gnats, and various other little aquatic inſects of the ſame kind, are furniſhed with ſmall tubes that play on the ſurface of the water, and convey the air from thence into the body of the inſect.

Nothing can be more evident than that inſects do not reſpire by the mouth, like other animals. To determine the reſpiratory organs in inſects, and alſo to aſcertain in what manner this function of life is performed, has been an object of ſolicitude with many. The experiments made with this view are numerous and concluſive, the reſult demonſtrating, beyond diſpute, that the ſpiracles are the apertures through which the air is drawn into the body. This may be inferred from the writings of Swammerdam, Malpighi, Reaumur, Muſchenbröek, Degeer, and many others, who treat at large on this particular ſubject.

Theſe ſpiracles exiſt in every ſtage of life, in the larva and pupa as well as perfect ſtate. They are viſible externally as a ſmall knob of a roundiſh or oval form, ſlightly elevated and perforated in the middle: the aperture is uſually oblong or ſubovate, and is the orifice of the channel which communicates with the trachea, one of which is diſpoſed lengthwiſe on each ſide of the body.

The extreme tenacity with which many inſects retain life, while deprived of air, ſeems to indicate that they exiſt much longer without the benefit of this renovating fluid than moſt other animals; and that in certain caſes they may endure a temporary ſuſpenſion of the functions of reſpiration. But nevertheleſs every experiment tends to confirm the fact, that ſo far as reſpiration is neceſſary, it is performed only by means of theſe ſpiracles, the cloſing of which, to the total ſecluſion of the air, will at length deſtroy the vital principle.

Lyonet has obſerved, that although it is a general rule that every thing which lives reſpires, it is not perhaps without exceptions in inſects. Many give reaſon to doubt of their reſpiration, at leaſt in certain ſtages of their exiſtence. "I took, for inſtance," ſays he, "ſome of thoſe large cantharides of the willow, whoſe ſtrong ſmell, though not very diſagreeable, is felt at a conſiderable diſtance. I put them under a glaſs, where for a long time ſulphur had been burning on a piece of copper made red-hot, that the ſulphur might continue to burn in the midſt of its own vapours; and although there aroſe ſo thick a ſmoke that it almoſt hid the inſects from ſight, they ſupported theſe vapours for more than half an hour, without ſuffering, that I could perceive, the ſmalleſt injury." Inſects, we are aware, may live ſome time confined in this manner amidſt the vapours of burning ſulphur, but the inſtance adduced by Lyonet is ſtill remarkable, for we have known the ſame experiment tried with theſe cantharides, in the reſult of which the inſects died within

within the fpace of time mentioned by Lyonet; and if, inftead of fulphur, we employ camphor, the refpiratory powers ceafe, and life becomes extinguifhed in a fhorter period.

This author argues, that from the folidity of the greater number of the cones made by the pfeudo-caterpillars, and moft of the ichneumon flies, it cannot be conceived poffible how thefe infects fhould live feveral months under ground, in a place fo clofe and impenetrable to the air, if they were to breathe in it. "Neither," fays he, "would I maintain the refpiration of chryfalids; at leaft one experiment convinces me there are fome which do not breathe. I took the chryfalis of the fphinx liguftri, which being one of the largeft is the moft proper for experiments. It had, befides, the two anterior fpiracles fo open, that with a common magnifier I could fee into the fubftance of its body, and obferve a fmall vacuum between it and the cover. This made me hope, that if refpiration took place in the chryfalis this would give me certain proofs of it. Two or three months before the perfect infect iffued from its cover I dug it up, and covered feveral times, firft one and then two, and afterwards fucceffively, the whole of its fpiracles with foap water. At each time I obferved, for a confiderable fpace, with the glafs, the fpiracles thus covered, to fee if any bubbles of air were formed above, which would naturally have happened, had thefe fpiracles ferved as conduits to the air in refpiration; but with all my attention I could perceive none. Some days afterwards I repeated the fame experiment, in a manner to me ftill more decifive. Inftead of covering the fpiracles with foap-water, I covered each with a little bubble of air, taken from the froth of the fame water, that the air might enter and go out more freely. But my curiofity was not more gratified: thefe bubbles, which ought to have rifen or funk at each expiration or infpiration of the chryfalis, preferved conftantly the fame appearance, till their pellicle becoming dry, they burft. When the perfect infect had iffued from this chryfalis, I took it up inftantly, wafhed the infide of it, and obferved at the fpiracles little bundles, compofed of a great number of very white threads, of which the longeft were about two lines in length. Thefe appeared to me the exuvia of the pulmonary organs. I blowed on each of the fpiracles with all my force, by means of a very flender tube, but my efforts could neither fwell nor move any of thofe fragments of the veffels which were attached to them internally; but this muft neceffarily have happened, had the communication of the external air by thefe fpiracles in the bronchiæ remained open, or had the infect, when inclofed in its chryfalis, been able to breathe through them. It may be inferred from this, that the chryfalis of fphinx liguftri lives for fome time without refpiration, and that its two anterior fpiracles ferve only to facilitate the evaporation of the fuperabundant humours, and to permit the external air to fupply their place." Lyonet, however, admits, that it is not on the fingle experiment here related that the knowledge of the refpiration in infects is founded; and that this experiment does not appear decifive. We have unequivocal proofs of the refpiration of infects; a fact demonftrated beyond all doubt in numbers of the aquatic kind, and as to lungs, he fays, we may affure ourfelves that infects poffefs them without being at the trouble of diffection. The fpiracles are called ftigmata by the modern naturalifts; ftigmates of the French.

Members.

Legs.—In all infects that are furnifhed with wings the pedes or legs amount to fix, and never exceed that number; and the fame is obfervable of the true feet in the larvæ of thofe infects; the latter have fpurious feet to a greater amount, but the true feet do not exceed fix. The apterous tribe in this, as in other particulars, afford exceptions: thofe of the pediculus, pulex, lepifma, podura, and acarus genera have only fix legs, and thefe are attached to the body in the fame manner as in winged infects: the fcorpio, aranea, and phalangium genera have eight; the cancer, if admitted, have as many; and in the onifcus, julus, and fcolopendra, they are far more numerous, varying from ten or twelve to twenty, fifty, or even thrice that number.

The leg of an infect may be divided into four, or, more correctly, into five parts; coxa, the firft joint, or haunch, at the bafe; femur, the thigh; tibia, the fhank; tarfus, the foot; and unguis, the claw. Each of thefe parts is enveloped in a hard cafe of a horny fubftance, and varies in fhape in different infects; the form of the feet in all the kinds being admirably adapted to their mode of life, and convenience of their motion. Some of thefe are diftinguifhed by particular terms, as, curforii, thofe formed for running (and which are the moft numerous); faltatorii, thofe conftructed for leaping; natatorii, thofe employed in fwimming, &c. From the different conformations of thefe limbs, it is eafy to recognize, even in the dead infect, the mode of life which the fpecies is deftined by nature to purfue. Thofe which have the legs adapted for running or walking have them long and cylindrical; the thighs of the leapers are remarkably large and thick, with the fhank long and commonly arched, by which means they poffefs great ftrength and power for leaping: the legs are broad, ferrated, and fharp at the edge, in thofe accuftomed to dig in the earth; and fuch as are of the aquatic kind have the legs, efpecially the pofterior pair, long, flat, and ciliated, or fringed at the edge with hair. The leapers are well exemplified in the faltatorial kinds of curculio; and the fwimmers in the genera hydrophilus and dytifcus.

The coxa, or fmall joint at the bafe, connects the leg to the body, and moves in a correfponding cavity of the collar or thorax in the firft pair, or breaft in the two pofterior ones. This part varies in form: in the cerambyx coccinella, and other tribes in which the feet ferve for walking only, its fhape is globular: fuch as require that the feet fhould have a lateral motion, and which is neceffary to thofe that dig into the earth, have the coxa broad and flat; this is alfo obfervable in fome of the aquatic beetles; in the dytifcus, the coxa of the pofterior legs is confolidated with the trunk, and immoveable; and in the blatta, lepifma, and others which walk very rapidly, it is compreffed into a lamellate form.

There is more diverfity in the form of the thigh than the coxa to which it is united. The articulation of thefe two parts is internal, and is produced in fuch a manner, that when the animal is in a ftate of repofe, it is parallel to the inferior furface of the body. It is limited to a forward and backward motion, with refpect to the firft piece. The nature and extent of the motions of the thigh appear to determine its form. In thofe infects which walk much and fly little, as the carabus, cicindela, &c., the thigh has two little prominences at the bafe, which appear to be intended for removing the mufcles from the axis of the articulation. Thofe which require ftrong mufcles adapted to leaping have the thigh not only thick but greatly elongated, as in the gryllus and locufta tribes, the pulices, or fleas, &c. And in the fcarabæi, fcarites, and other coleoptera, and alfo in the mole cricket (acheta gryllotalpa), all which burrow in the earth, the thigh is moved with much force, and has an articulated furface correfponding to the flat part of the coxa on which it refts. This part is fometimes fpinous.

Tibia, or fhank, is the third joint of the legs, and moves in

an

an angle, according to the direction of the thighs. The figure of this part depends effentially on the ufes to which the habits of the infect require it to be applied; in the natatorial kinds it is ufually flat and ciliated, at leaft the tibia of the pofterior pair, and in many others, as in a variety of the burrowing kinds of beetles, it is ferrated. In the mantis genus, to which fhanks of the anterior pair of legs ferve as weapons of defence, they are broad, flat, and acute at the edge, and thefe they wield with dexterity in the manner of a fabre. The fhank is more frequently ferrated or fpinous than the thighs.

The tarfus, or foot, is the fourth joint, or laft portion of the leg, except the claw. This part confifts in general of five joints: this is ufually the number in the coleoptera, hymenoptera, and diptera; in fome of thefe, however, and alfo in the hemiptera, there are only four articulations in this part of the leg, as we obferve in cerambyx, gryllus, and others; in libellula, forficula, &c. three: in the anterior feet of mantis and nepa only one; and in thofe of the nymphales family of butterflies none. The figure of the tarfus is more variable than any other portion of the leg, and is in a moft fingular manner adapted to the infect's mode of life. The articulations in fuch as walk on the furface of the earth are flender, thofe which burrow in the earth have them more robuft. Many of thofe which inhabit waters have them flat and ciliated at the edges, as in the hydrophilus. Others are furnifhed with briftly tufts, or vafcular flefhy tubercles, which enable them to move with fecurity on fmooth and flippery bodies in any direction; an admirable example of this prefents itfelf in the common houfe fly, which "treads the ceiling, an inverted floor," with the fame facility that other infects walk on the furface of the ground. An occafional difference in the number and form of the joints of the tarfus is fometimes obferved in the two fexes of the fame fpecies. The motion of each joint of the tarfus is performed in a fingle plane, and is directed by two mufcles in each joint, one of which is fmall, and placed on the dorfal furface, the other larger, and fituated beneath.

Unguis, or claw, the termination of the tarfus; in the greater number of infects there are two claws attached to each tarfus: fome have only one, and in others furnifhed with two, there is an intermediate procefs forming by this means three. An appearance fimilar to this is feen in the legs of the lucanus, but this, on minute examination, is found to be a diftinct joint alfo, armed with a pair of claws, precifely refembling thofe which, more obvioufly from their fize, appear to terminate the tarfi. It is confiderably fmaller, but as perfectly well defined.

Reaumur, Weifs, Borelli, and Cuvier, have publifhed fome curious remarks on the laws of motion obferved in the legs of infects, fome of which are very interefting. The relative proportion of the feet feems to determine, in a certain degree, the particular manner in which each infect moves either in walking or leaping. When, for example, the legs are all equal, the movement is uniform, but when fhort it is flow, and when long, it moves with rapidity. Thofe infects, therefore, which have the legs long, as in the phalangium, and fome others, run very quickly: and, on the contrary, the acarus, pediculus, and thofe others, which have the legs fhort, are remarkable for the flownefs of their pace. When the anterior feet are longeft, as in certain cerambyces, their fpeed is retarded when moving on even ground, though, in climbing, this length of the anterior legs is an advantage. When the pofterior feet are longeft, they ufually afford the infect the ability of leaping, as in the locuft, acheta, and other families; but fuch a ftructure impedes its fpeed in walking; and does not always enable it to leap; the infects of the leucopfis and chalcis genus, though their pofterior thighs are very large and thick, are fuppofed to be incapable of this action. The latter inability is attributed to the great curvature of the legs, thofe infects which are truly of the faltatorial kind, as in the gryllus genus, being remarkably ftraight.

Alæ, or *wings*.—Wings, the organs appropriated to flight. Thefe in different infects vary from two to four, and are attached to the lateral part of the breaft, clofe to the lower margin of the thorax. They are placed to an equal amount, and in a correfponding fituation on both fides of the infect, whether the number be two or four. Thofe infects which are furnifhed with only one pair of wings, have both of an uniform appearance and fize. Such as have two pair moft frequently differ, the firft being larger than thofe behind: there is alfo a difference in fhape, and very commonly a confiderable variation in the fpots, markings, and other particulars, notwithftanding the prevailing hues in all the wings may be the fame. In general, the pofterior pair is paler, and the marks obfcure.

The wing properly fo denominated fhould be diftinguifhed from the elytra or wing-cafes, thofe hard fhelly coverings of the true wings in the alated kinds of coleoptera. Thefe wing-cafes, or fheaths, are often confounded with the wings; but they are really not wings from their ftructure or fubftance, nor do they anfwer the purpofe of flight: they merely open to afford the true wing, concealed beneath, the power of expanfion and motion, and clofe down upon the wing, when the infect is at reft, to preferve it from injury. Of this we have fpoken more largely in defcribing the elytra. The femi-cruftaceous wings of the hemipterous orders partake of an intermediate character between the wing-cafes and wings, as already noticed in its proper fection. The wings and elytra in fome infects, and the wings and hemelytrous wings in others, are fo intimately connected, that we conceived it requifite, in order to avoid mifconception, to advert again to this circumftance.

A fkeleton of nerves, more or lefs numerous, and differing exceedingly in difpofition, placed between two thin and clofely united membranes, conftitute the true wing in infects. This conformation is very clearly exemplified in that defcription of wings which is ufually termed tranfparent, as in the common houfe-fly and the bee. The true wing, by means of which the infect is enabled to fly, is always conftructed in this manner, whatever may be its appearance externally, arifing from a fuperficial covering of down, feathers, hair, or any other caufe. The variety in the form and ftructure of the wings, in the number, figure, and difpofition of the nerves, or the colours with which they are adorned, is infinite. The diverfity in the difpofition of the nerves is evident from a comparifon of the fimply conftructed wing of the common houfe-fly (mufca domeftica) with the complex wing of the panorpa, or the ephemera, or the wing of the forficula (earwig), which confifts of a feries of fingle nerves, with the elaborately wrought lattice-work of the wing of the libellula. The whole of the lepidoptera tribe exhibit the fuperficial coating of feathers, down, or hairs; and upon the removal of thefe, the wings are found conftructed exactly in the fame manner as the tranfparent wings of the other tribes. A variation in the form of the wing, as well as its texture, is manifeft throughout all the infect tribes of the winged kind. Thofe of the coleoptera have two membranous wings, which fold upon each other, forming a plait, or double at their external margin; which fold is accommodated by a peculiar joint in the main rib of the wing, and the peculiar difpofition of the nerves in the middle of the wing contiguous. In the hemiptera

miptera the wings generally fold longitudinally, without any tranfverfe double, fo that in expanfion. thefe parts open fomewhat like a fan: the forficula is an exception in this order, the wing in this genus being doubled acrofs as in the coleoptera. The wings of the lepidoptera are neither doubled acrofs nor folded longitudinally; they are entirely flat, and incapable of contraction and dilatation. In the papilio genus they are endowed with the power of erection, which is not the cafe in the phalæna genus, though occafionally obferved among the fphinges; the phalænæ have the lower wings concealed under the anterior pair, the latter being laid in a flat pofition over them. The wings of the lepidoptera are downy, and often decorated with very beautiful colours difpofed in the moft pleafing and varied manner. The neuroptera in general have the wings flat; this is not invariable: they are conftantly membranaceous, and reticulated with nerves. In the hymenoptera the wings are membranaceous, generally flat, but fometimes folded, when the infect fettles, as in the wafp genus. The dipterous order cannot be confounded with the preceding, as they have only two wings, without any wing-cafes: they are membranaceous as in the former.

Infects of the dipterous family, bees, and various kinds of hymenoptera, and many others, poffefs the powers of flying in a more perfect degree than any clafs of animals befides; furpaffing in this refpect even the bird tribe. All infects that are furnifhed with wings have not an equal celerity of motion in the air; the movements of the wings in fome infects is more circumfcribed than in others. The mufcles that move the wings are not yet very well afcertained: they are faid to be fituated in the breaft, and to be of two kinds; the firft of thefe are fmall and fhort, and are intended to extend or fold the wings, at the fame time that they move them to and fro from the body; the others, which are fomewhat longer, are calculated to produce thefe motions of elevation and depreffion which the wings perform, very ftriking examples of which are found in the two genera papilio and libellula. The wing-cafes of the coleoptera are not moved, it appears, by the pectoral mufcles like the wings.

The dipterous infects, when flying, emit a loud buzzing found, occafioned, as it is believed, by the wings and balancers ftriking againft each other. The noife of the cricket and locuft is produced by the friction of the wings, or bafe of the wing-cafes againft the pofterior edge of the thorax; and which is obferved likewife to be the cafe with the cerambyx, leptura, and various other infects.

In all infects of the winged kind thefe organs prefent the greateft diverfity, and afford characters both of genera and fpecies lefs liable to fluctuation than common obfervers would conceive. The number, figure, conftruction, proportion, confiftence, and texture of the wings have enabled naturalifts to diftribute infects into principal families with confiderable precifion; and their minor peculiarities of fpots, marks, and colours, have furnifhed fubordinate characters of the utmoft utility in defining fpecies. Linnæus derived much affiftance from an attention to thefe parts; later writers have in many inftances regarded them more clofely; and in the further progrefs of the fcience, we are perfuaded thefe parts may be confulted with much greater advantage ftill.

There are many terms at prefent in ufe, intended to defcribe the different kinds of wings, the principal of which fhould be underftood by the ftudent in entomology.

The wing in all infects is diftinguifhed, with refpect to its furfaces, into fuperior and inferior; that above is denominated the fuperior, and that beneath the inferior. In the defcription of wings, the terms anterior, pofterior, interior, and exterior parts, and fometimes the difk, occur very frequently. The anterior part or margin is that next the head; the pofterior, that towards the vent; its exterior, that towards the outer edge; and the interior, that next the abdomen: the difk is the centre of the wing. Thefe terms are not always applied with precifion by entomologifts: the bafe of the wing, next the point of connection to the breaft, is fometimes called the anterior part; and in this cafe, every other part varies its name in a relative proportion: and this appears to be a correct method of defcribing the parts of a wing in its natural ftate, while the infect is at reft, with the wings down; but it applies only to thofe which difpofe their wings longitudinally: it would be altogether inapplicable in defcribing a papilio, in which the wings are expanded and ftretched forward; or in the libellula, which refts with the wings in the fame pofition. The anterior margin of a wing is, therefore, generally underftood as implying the coftal edge, and which is fo named becaufe it is formed by the main rib that extends from the bafe to the tip of the wing.

The wings are called plicatiles, when they are folded at the time the infect is at reft; planæ, when ftretched out their whole length without folds, and incapable, from the ftructure of their nerves, to be folded up; erectæ, fuch as have an erect pofition when the infect is at reft, the fuperior furfaces being brought in contact above the back, and the extremities oftentimes meeting, as in the butterfly tribe; patentes, thofe like the geometra family of moths, and moft of the libellula, which have the wings expanded horizontally when at reft; incumbentes, fuch as cover in an horizontal manner the fuperior part of the abdomen, when the infect is at reft. Thefe differ from deflexæ, in having the outer edges declining towards the fides, like the ridge of a houfe; reverfæ are alfo deflexæ, with this addition, that the edge of the inferior wings projects from under the anterior part of the fuperior ones; dentatæ are thofe with the wings indented or fcolloped; caudatæ, thofe in which one or more of the nerves of the pofterior wings extends beyond the margin, and forms a procefs, fuch as occurs in the equites family of papilio, and the genus hefperia, and in a far more remarkable manner in phalæna argus; reticulatæ, thofe in which the veins or membranes of the wing form a kind of lattice-work, as in the genus libellula.

The colours (colores) are named in terms agreeably to their common acceptation; but according to the various forms of the fpots, bands, ftreaks, &c. in which they appear on the wings, they have various fignificant appellations. Maculæ are fpots; punctæ, dots; fafciæ, bands; ftrigæ, ftreaks; and lineæ, lines. Ocellus is a round fpot, containing a fmaller fpot of a different colour in its centre. Stigmata is a term in the Linnæan language, introduced to fignify a fpot or anaftomofis in the middle of the wing, near the anterior margin: this is confpicuous in moft of the hymenoptera and neuroptera. Stigmates is a term alfo applied to the fingle or double kidney-fhaped fpot fituated in the middle of the anterior wings in many of the moth tribe, in the noctua family, and in fome of the bombyces. Several modern naturalifts call the refpiratory fpiracles at the fides of the body in infects ftigmates, the application of which may create confufion; ftigmata, and ftigma, ought for this reafon to be admitted in the fenfe Linnæus intended: the fpiracles bear already a name fufficiently indicative of their ufe and appearance, and do not require this alteration. Moft of thefe terms apply only to the lepidoptera tribe, in the markings of whofe wings the moft beautiful colouring prevails.

Halteres,

Halteres, poifers, or balancers, appendages peculiar to infects of the diptera order, and which, with fufficient reafon, are deemed an effential character of that tribe. Thefe poifers are two fhort, moveable, clavated filaments, placed one contiguous to the origin of each wing. They feldom exceed one-tenth the length of the wing, though in certain genera they are rather longer. The capital, or head, in which the filament terminates is either roundifh, oval, truncated at the end, or compreffed at the fides: in fome infects its fituation is directly under a fmall, arched, filmy fcale, which alfo varies in fize and form; and in feveral families is entirely wanting.

The exact purpofe to which nature has deftined thefe organs has not been hitherto afcertained in a very fatisfactory manner. The moft prevalent, and perhaps in fome meafure the moft confiftent, opinion feems to be, that they balance or counterpoife with the action of the wings, when the infect is in flight, in the fame manner as rope-dancers exercife a pole to preferve their equilibrium. The diminutivenefs of their fize is a plaufible objection to this idea. Others confider thefe as the organs of that vibratory found which dipterous infects emit in flight: they compare the filmy fcale to a kind of tambour, and liken the balancer to a drum-ftick, which ftriking repeatedly upon it, they conceive muft occafion this noife. In the conformation of the drum-like organs under the breaft of fome fpecies of tettigoniæ, this conception is fully realized; a found is actually occafioned by fimilar means. (Vide Donov. Inf. China.) But with regard to the diptera, it is apprehended the founds they emit in flight cannot be traced to this caufe: in fome we know it cannot, for the beft of all poffible reafons, namely, that though, like others of the fame tribe, they have balancers, they have no fcale to ftrike with them. It fhould be obferved alfo, that this buzzing found is obfervable in a vaft number of infects which have no poifers or balancers, fuch as wafps and bees. The two genera, afilus and bombylius, have no fcale, and yet the noife perceptible in their flight is louder than in moft of thofe which have both fcale and poifers, as in the mufcæ, for example. Nor does this noife iffue from the poifer, either by ftriking on the fcale, or by any other means, as muft be admitted, fince it is known that if the poifers, or both poifers and fcales, be cut off, the fame found continues to be heard from the mutilated infects as before.

The motion of thefe poifers, when the infect flies, is very lively: they are longeft in the tipula, diopfis, and afilus; in mufca, fcarcely apparent, and accompanied by a fcale of large fize.

Elytra, or wing-cafes, appertain to the coleopterous tribe: thefe are two in number, of a fubftance refembling leather, for the moft part moveable, and opening by a longitudinal future along the middle of the back. The elytra are extended or raifed up when the infect is in flight. They do not appear to affift the infect in its flight; the mufcles, by which they are connected to the body, have not their feat in the breaft, like thofe of the true wings; and its movement in the air is accomplifhed by means of the latter, which are tranfparent, folded between the body and elytra when at reft, and expanded when the infect flies. Some have the elytra united, and may with more propriety be named elytron, for it confifts only of a fingle piece marked with a longitudinal line fuperficially, inftead of being divided by a future; this is lifted up, or rather, the abdomen depreffed downwards, to admit the paffage of the wings laterally, when the infect is preparing for flight. Others furnifhed with elytra, or wing-cafes, feem to render the term for thefe parts exceptionable; for in reality they have no wings beneath them: the number of thefe, however, is not confiderable, and they cannot employ their elytra as organs of flight.

The fuperior furface of the wing-cafes is more or lefs convex, and the lower furface correfpondently concave: the texture in fome, as in fome of the curculio and bupreftis, fo hard, that it is pierced with difficulty by means of a ftrong pin; in others fo flexible, that they fpring into their proper form immediately after being bent double. The proportions of the elytra, compared with the body, are various, their form diffimilar, and the diverfity of their furface, arifing from dots raifed or depreffed, protuberances, flutings, colours, and other circumftances, endlefs. Thefe differences in the elytra furnifh fome excellent generical diftinctions, and are ftill more extenfively ufeful in conftituting the characters of fpecies. When the wing-cafes are fhorter than the abdomen they are termed abbreviata, unlefs they terminate in a tranfverfe line, when they are called truncata; faftigiata, when of equal or greater length than the abdomen, and terminating in a tranfverfe line; and ferrata, when the exterior margin towards the apex is notched or ferrated, as in fome of the bupreftis genus. The appearance of the furface is varioufly diftinguifhed; fpinofa is the term implying that the furface is covered with fharp points or fpines; fcabra, rough; ftriata, marked with flender furrows longitudinally; porcata, with elevated longitudinal ridges; fulcata, with concave ridges, &c.

The want of appropriate terms for thofe kinds of wing-covers, which partake of a middle texture between the elytra and the wings; and alfo for thofe in which the characters of both are united, muft be obvious in the prefent ftate of entomology. To the firft of thefe no fuitable name has been given: the French "ètius molle," and "ètius prefque membranaceux," are not fufficiently expreffive; the firft is deficient in precifion, and in the other there is too much latitude. Linnæus once propofed the term hemelytra, by which he intended to defignate both kinds, whether, as in the grylli, thofe parts were of an intermediate fubftance between leather and membrane; or, as in cimices and nepæ, one half was coriaceous, and the remainder membranaceous. The term, in this general fenfe, could not be ftrictly proper; it was, notwithftanding, preferable to that of elytra, admitting the latter to be rightly applied to the wing-cafes of the coleoptera; and we are therefore the more furprifed it was not afterwards adopted by that naturalift, or fome other fubftituted. So lately as the tenth edition of the Linnæan Syftema, the word elytra is employed indifcriminately for the hard and ftubborn wing-cafes of beetles, the foft wing-covers of the blatta, and the membranaceous reticulated wing-covers of the gryllus, all which genera were included at that time in coleoptera; and by an overfight equally extraordinary, the half-coriaceous wing-covers of the cimices, the nepæ, and notonectæ, were then confounded with the delicate covers of the aphis, thrips, and chermes, under the indifcriminate title of wings. The diftinction of coleoptera and hemiptera is rendered rather more clear in the laft edition of that work, the blattæ and grylli being removed from the former to the latter order; yet the application of the word elytra to the wing-cafes of the hemiptera is not by that means rendered lefs improper. The difference in the conformation and confiftence of the wing-covers in the two tribes is too evident to leave this a matter of doubt. But cuftom has fo far fanctioned this impropriety, that our beft entomologifts to this period defcribe all thefe kinds of wing-covers under the name of elytra. Fabricius has not even attempted to correct this error in the Linnæan phrafeology; he adopts the fame term.

Among the principal differences in the form and texture of the elytra, fome, at leaft, are very remarkable. In the beetle, or coleoptera tribes, thefe parts are coriaceous, very hard throughout, convex in form, and divided by a ftraight future. Thofe of the cimex genus have the upper half only of a coriaceous texture, the lower half being foft and membranaceous, and the latter portion of one elytron is folded acrofs the correfponding part of the other when the infect is at reft. The coriaceous half of the elytra in many fpecies is as hard and tough in texture as the entire elytra in the coleoptera, and the membranaceous part as foft as in the hymenoptera and diptera. In the genera blatta, forficula, acheta, and others, the elytra is of an uniform fubftance throughout, fomewhat refembling parchment; a fimilar texture prevails in the elytra of nepa, notonecta, and naucoris genera, but rather like the cimices, there is a diftinction between the upper and lower portions, the firft being of a firmer texture, and thicker than the other part. The fulgora genus, like the gryllus, affords examples of another kind, thick, membranaceous, and ftrongly reticulated elytra, divided in the middle by a longitudinal future. In the tettigonia, another of the hemipterous genera, the elytra are often perfectly membranaceous and tranfparent in texture, though not in form refembling thofe of the hymenoptera and diptera; yet thefe are called elytra, and fo likewife are the weaker and more flexible tranfparent anterior wings of the aphis, thrips, and chermes, for thefe two are included in the order hemiptera! From a due confideration of thefe decided differences, we cannot hefitate to admit that the term elytra is not applicable to all. In a treatife of this kind it might, perhaps, create confufion to introduce any other terms than thofe in common ufe; we only intimate our perfuafion, that reformation in the language of entomology is neceffary. In the formation of any new fyftem, and which in the prefent ftate of fcience appears requifite, we may reafonably hope to fee thefe and fimilar objections obviated.

In conclufion of thefe remarks, it may be mentioned that nature has herfelf pointed out certain difcriminating characters in thofe parts called the elytra which do not feem to have been fufficiently attended to, and which not only relate to their figure and appearance, but likewife to their utility, or the benefit the infects derive from thefe organs. The wing-covers in the coleoptera do not, it is generally believed, in the leaft degree, affift the infect in flying: in the cimices, and others which have thofe parts of a more flexible texture, they do not materially aid its celerity of motion in the air; but in thofe which have the wing-covers completely fupple, they concur immediately to its velocity in flight.

Sexes of Infects.

The fame difference of fex exifts throughout the infect race as in moft other animals. The fexes cannot be afcertained in the larva and pupa ftate, except in fome few inftances; but when they arrive at their laft ftate, both kinds poffefs permanent characters, by which they may be eafily determined: thefe confift in a comparative difference in their fize, and vivacity of colour, form of the wings, bulk of the abdomen, fhape and dimenfion of the antennæ, and various other external peculiarities.

In moft infects the male is fmaller than the female, their comparative difference varies confiderably in different fpecies. In the lepidopterous tribe the female is only perceptibly larger than the other fex in general; in the ant it is fix times larger than the male: in the coccus twelve or fifteen times, and in the termes the female is at leaft two hundred times larger than the male. This latter fex is commonly decorated with colours more lively and brilliant than the females, a diftinction obfervable in a very remarkable degree in many of the butterfly tribe, the males of which are very beautiful, and the females obfcure. There is alfo fome difference in colour between the two fexes in fome coleopterous infects.

Many of the larger tribes of beetles (geotrupes) prefent a wide diffimilarity in the conformation of the two fexes: in the males the head is embellifhed with one, two, or more diftinct and prominent horns, and which, in a number of fpecies, are very confiderable in fize; thefe are entirely peculiar to the males; the head of the female has only a few flight protuberances inftead of horns, and is fometimes even deftitute of them.

In the moth tribe the antennæ of the male are almoft invariably larger or more deeply pectinated than in the female, and this difference may be traced from the broad feather antennæ of the largeft bombyces, to the fetaceous antennæ of the noctuæ; however flightly the antennæ of the male appear pectinated, thofe of the female will be found ftill lefs fo. The abdomen in this order is alfo fmaller than that of the female. The colours of the wings alfo differ amazingly in the two fexes, of which phalæna humuli (Linn.) affords a very ftriking example, the wings of the male being of a beautiful fnowy white; that of the female bright yellowifh, with orange fpots.

Another diftinction, but which is not a general character, confifts in the female being apterous, or without wings, the male being furnifhed with thofe organs of flight. Among the coleoptera we find the lampyris of this kind; in the hemiptera the blatta; among the moth tribe, phalæna antiqua, gonoftigma, brumata, &c. Thefe winglefs females are indeed fo much unlike the other fex, that no one unacquainted with infects could believe them to be of the fame fpecies. The females of thefe lepidopterous infects are not entirely apterous; they have four very minute wings attached to the thorax, in the fame place as is occupied by the bafe of the wings in the other fex, otherwife they refemble an apterous infect. In the aphis tribe the male has fometimes wings, and is fometimes without; and the female, it is faid, differs in the fame manner.

Thefe are the principal external characters, by means of which the two fexes in infects may be difcriminated.

Generation.

That general law of nature which prevails among the larger tribes of animated beings, and ordains an intercourfe of the two fexes as indifpenfable to the production of their young, does not regulate the multiplication of all infects: there are fome fingular deviations to the contrary. The doctrine held by the ancient fages of Egypt, that in certain infects both fexes are united, is perhaps inadmiffible: we ought not to fpeak with too much confidence on this fubject, notwithftanding the affurance of Linnæus, that there are no hermaphrodite infects. The obfervations of naturalifts leave us in no uncertainty with refpect to another order of beings, namely, thofe which belong to neither fex; and indeed the exiftence of thefe is demonftrated daily in every hive of bees.

The myfteries of generation are only in part unveiled to the philofophical enquirer. Some leading points appear equivocal, and remain inexplicable. This is the cafe with larger animals, where we have external circumftances to direct our judgment. With refpect to infects, in particular, the hiftory of their generation, in certain inftances, at leaft, is more obfcure. Many of them, like the larger animals, produce their young in confequence of an immediate union of of the fexes. But among the numerous families which compofe this extenfive clafs of creatures, there are fome deviations from this ordinary courfe of nature, and thefe partaking of incidents fo remarkable, that no pofitive and uniform conclufion of their mode of increafe can be laid down. The notions entertained by fome philofophers in the middle ages, that infects are the offspring of corruption and putridity, have no foundation in reafon or analogy. It is impoffible to conceive that organized bodies, poffeffed of life, and endowed with fenfibility, can owe their origin to chance. But beyond this we are authorized in the belief of circumftances, that militate very ftrongly againft eftablifhed opinions. The courfe of generation and mode of increafe, obferved in certain tribes of infects, have no parallel among thofe of the larger kinds of animated beings: we need only mention a few particulars of the aphides in fupport of this.

Of the aphis genus there are not lefs than feventy fpecies known, and the females of every one of thefe, fo far as it has been poffible to inveftigate their manners, are capable of producing their young without the concurrence of the male fex! A female aphis, brought up in the moft perfect feclufion from the very inftant of its production from the egg, will in the courfe of a few days be found in the midft of a numerous family of females only, brought forth alive. An individual taken from thefe, or even felected at the moment of its birth from the brood, and kept alone, will in a fhort time produce another brood, and in like manner a repetition of the fame experiment will be again attended with the fame refults.

It would be only a natural inference drawn from the above mentioned circumftances, that in the fame individual of this kind the two fexes muft be united. This we know is not without example in the inferior order of animals, the greater part (we fhall not fay the whole) of the vermes tribe being probably of this defcription. Such is not apparently the cafe however with regard to the aphis; the real truth appears ftill more aftonifhing. To render thefe fertile, the intervention of the male feems to be requifite in autumn, and hence the power of impregnation devolves down to the tenth, or, as fome naturalifts affirm, to the twenty-feventh generation. The eggs of the firft, or parent brood, are laid in autumn, thefe hatch in the enfuing fpring, and this fertile produce perpetuate the race through many generations till the autumn following; every brood, after thofe hatched in fpring from the egg, being viviparous.

The generality of vermes are believed to unite the two fexes in the fame individual, and thus poffefs the power of felf-production. Later obfervations feem to prove, that moft animals of this tribe have both male and female organs, but that the union of two individuals are ftill requifite, each performing at the fame time the office of male and female, and by this reciprocity of their functions both become fertile. Among the cancri, which Linnæus confiders of the infect race, we are affured fome monftrous lufi have been obferved, in which the organs of both fexes were apparent; but probably thefe might not poffefs the ability to perpetuate their natural race. Thefe we pafs over therefore for the prefent as irrelevant. There is no infect, perhaps, fuch accidents excepted, in which the two fexes are united. We advance even this with caution, becaufe there is reafon to imagine the contrary in certain inftances. From our own obfervation we are perfuaded that fome few at leaft of the fuppofed vermes are the larvæ of genuine infects. Let us for a moment imagine thefe larvæ to be really vermes! And let us farther conceive that thefe larvæ, like the true vermes, are of the hermaphrodite kind! What an extraordinary deviation from the ufual courfe of nature would fuch a prodigy prefent!

Here, however, be it explicitly underftood, that we do not affert the latter part of this obfervation as abfolutely certain. Such an affertion is countenanced by no opinion except our own, and fuch opinion ought not to be advanced without being at the fame time fupported by argument and proof, the production of which would extend the limits of our obfervations very far beyond our prefent defign. It is only our wifh to intimate at this time, that there are certain animals of the fuppofed vermes, and which are defcribed by Linnæus and others as appertaining to this clafs, which are in reality the larvæ of infects; and that we are not without fufpicion that fome of thefe larvæ are fertile, and produce an increafe in a manner not very clearly known, before they affume their final form. Among the fuppofed vermes of the marine kind, the larvæ of certain coleopteræ will perhaps be recognized. Thefe are fimply larvæ, and apparently deftitute of any fexual functions till they arrive at their laft ftate. Some of the frefh water larvæ, miftaken for vermes, are in all probability of the fame defcription. But have we fufficiently examined the inteftinal vermes? Are any of thofe peculiar to different animals, or man, capable of producing young vermes, like themfelves, and afterwards becoming infects? One fact may be important, and we ftate it upon the teftimony of our own knowledge, that certain kinds of thefe fuppofed vermes, which infeft the human race to the deftruction of thoufands in the age of infancy, are really no other than the larvæ of infects.

Linnæus affirms that no infect can form an union with the oppofite fex, or propagate its kind till it arrives at the laft ftate, and offers this as a proof that gryllus pedeftris is not a pupa which its appearance implies, becaufe it is found connected with the female. This obfervation of Linnæus is pretty generally correct, and it may be further added, that in the different ftates, prior to the perfect condition, there are no fexual organs, or at leaft none that are developed. This is the fact with regard to moft infects, certainly not to all. Among the cimices there can be no doubt in our own mind from actual obfervation, that the femi-nymphs of certain fpecies do unite with their mates, and afterwards become winged infects. We are not without fufpicion that many of the grylli, like the pedeftris, poffefs the fame faculty, and are afterwards furnifhed with wings.

With refpect to the infects of neither fex, or neuters, it fhould be obferved that thofe appertain to fpecies in which there are the two diftinct fexes befides, as in the bee tribe. It is chiefly among the hymenopterous infects that we meet with thefe neuters; the formicæ afford examples of other infects of the fame kind, and it is believed there are likewife neuters among the coleoptera. They are called neuters becaufe they are of no apparent fex. Some have pretended that they are no other than females, in which the fexual parts are not yet developed. This cannot, however, be the fact; neither can they be of the male fex under the fame difguife, becaufe they are conftantly diffimilar in their characters from both, and could fcarcely be fuppofed, from their appearance in many inftances, to belong to the fame fpecies they really do, had not this been afcertained by their production from the fame brood with the two diftinct fexes.

Of infects in general it may be obferved, that the males and females of the fame fpecies are not unerringly faithful; they deviate occafionally from the path appointed by nature. This is moft obfervable in the coccinella genus. Thefe hybrid infects are conceived to be unfruitful; they refemble the

the female in form, but in point of colours and fpots have fome refemblance to the male parent.

There is an accordance in the ftructure and fituation of the fexual organs in infects, whether male or female, with thofe of larger animals, and their union is accomplifhed in the fame manner. Thefe organs are ufually placed at the extremity of the abdomen. This is not conftantly the cafe; there are infects, and among thofe the fpiders, which have the male organs placed at the tip of the feelers, one at the extremity of each; every individual of thefe creatures being furnifhed with two. The female organ is beneath the abdomen. Another fingularity is obfervable in the libellulæ (dragon flies), the males of which have the fexual organ fituated under the breaft, while that of the female is at the extremity of the abdomen. When in union they are feen flying in the air, the female under the male with her flender body incurvated, and the tip of the abdomen bent under his breaft.

Except at the period of their amours the fexual organs of infects are not perceptible, thofe of the male at other times are drawn within the body. Their union in fome fpecies continues for a fhort time only; others remain in this ftate for hours, or even days together.

Transformation of Infects.

Moft animals retain during life the form which they receive at their birth. Infects are diftinguifhed from thefe by the wonderful changes they undergo. The exiftence of an infect partakes of two, three, or four diftinct ftates, and in each of thefe differs moft effentially in appearance, organization, and manners of living.

The ancients were not unacquainted with the fingular metamorphofes of infects. Ovid has drawn many beautiful fables from this fource. The fongs of Anacreon afford certain paffages to the fame effect; and we might alfo mention others. An inquiry into the knowledge of the ancients in this refpect might be interefting; but we cannot now purfue the inveftigation, as it would lead to digreffions the limits of this article will not allow. Our ideas have been offered at fome length in another place. (Donov. Hift. Inf. China.) We fhall only obferve for the prefent, that they were not unacquainted with the metamorphofes which certain infects undergo. Their poets wantonly intermingled fable with truth, to improve their allegories; but their hiftorians were more correct, and feldom formed erroneous conclufions, unlefs deceived by fpecious appearances. In the fixteenth century, with the revival of learning and philofophical difcuffion, and from that period to the prefent, this fubject has engroffed much attention. The labours of Swammerdam, Goedart, Merian, Malpighi, and others, contributed materially to its advancement in the firft inftance. Their difcoveries induced others to regard the transformations of thefe curious creatures with attention; and hence, in the courfe of years, their hiftory became pretty generally underftood. Thofe who afterwards contributed moft effentially to the improvement of this branch of entomological knowledge were Reaumur and Degeer. In the progrefs of time, other valuable works appeared in elucidation of the fame fubject. The moft ufeful of thefe, perhaps, to the general reader, are thofe denominated "Entomologi Topographici," or fuch as relate to the infects, with their transformations peculiar to, or inhabitants of particular countries. Among the number of thefe may be mentioned the two works of Merian, "Erucarum ortus, Alimentum et Paradoxa Metamorphofis," and "Infecta Surinamenfia." "Hiftoire abregée des Infectes, qui fe trouvent aux Environs de Paris," by Geoffroy; "Naauwkeurige Waarneemingen," &c. of Admiral; Roefel's "Infecten Beluftigung;" Abbot's "North American Infects," by Smith; and Donovan's "Infects of Great Britain."

The changes through which the greater number of infects pafs are from the egg to the larva, from the larva to the pupa, and from the pupa to the laft or perfect ftate. Exceptions occur to this: for fome infects are viviparous; the number of thefe is not confiderable: and there are others of the apterous or winglefs kind, which undergo no change, iffuing from the egg in the perfect form.

Of the Egg State.

The egg, containing the infect in its fmalleft fize, is expelled from the ovary as in oviparous animals. They are contained and arranged in the body of the infect, in veffels which vary in number and figure, in different fpecies. The fame variety is found in the eggs: fome are round, others oval, fome cylindrical, and others nearly fquare. The fhells of fome are hard and fmooth, while others are foft and flexible. It is a general matter of obfervation, that eggs do not increafe in fize after they are laid: among infects we find, however, one exception to this rule, for the eggs of a fpecies of tenthredo are known to become larger after being depofited. The fhell is membranaceous, which admits of this dilatation.

The eggs of infects are of various colours; fome are found of almoft every fhade of yellow, green, and brown, a few are red, and others black. Green and greenifh are not unufual, and they are fometimes fpeckled with darker colours, like thofe of birds. Some are fmooth, and others befet in a pleafing manner with little raifed dots.

Infects are inftructed by nature to depofit their eggs in fituations where their young ones will find the nourifhment moft convenient for them. Some depofit their eggs in the oak-leaf, producing there the red-gall; others chufe the leaf of the poplar, which fwells into a red bladder: to a fimilar caufe we are indebted for the knob, which is often feen on the willow leaf, and the three-pointed protuberances upon the termination of the juniper branches. The leaves of the veronica and ceraftium are drawn into a globular head, by the eggs of an infect lodged in them. The phalæna neuftria glues its eggs with great fymmetry in rings round the fmaller twigs of trees; others affix them to the furface of leaves; and again, others lodge them in the crevices of trees.

The gnat, the ephemera, phryganea, and libellula, hover over the water all day to drop their eggs: thefe hatch in the water, and continue there while in the larva and pupa form, quitting the water only when they attain the winged ftate. The mafs formed by the eggs of the gnat refembles a little veffel, and floats on the furface. This infect depofits only one egg at a time; the firft is retained by means of the legs, when dropped, till a fecond is depofited next to it, then a third, fourth, and further number, till the mafs becomes capable, from its fymmetry, to fupport itfelf upright. Many moths cover their eggs with a thick bed of hair or down, collected from their own body; others cover them with a glutinous fubftance, which, when hard, protects them from the ill effects of moifture, rain, and cold. The folitary bees and wafps prepare nefts in the earth, hollow trees, or cavities in old walls, wherein they place a quantity of food for the fupport of the young brood, when they break from the egg. Some of the fpiders carry the eggs on their back in a fmall filky bag. The ants are known to conftruct nefts in the earth, in which their eggs are placed

placed with the utmoſt care. Some depoſit their eggs in the larvæ of other inſects, chiefly thoſe of the moth and butterfly kind; and having paſſed through all their changes in their bodies, become what is termed the ichneumon fly. In the Lapland Alps there is an inſect called the rein-deer gad-fly (oeſtrus tarandi), the attacks of which are greatly dreaded by the rein-deer. It hovers all day over theſe animals, who betray every mark of fear; their legs tremble under them; they prick up their ears, and ruſh to the mountains covered with ice and ſnow, to eſcape from the fly, but often in vain; for the inſect follows, and generally finds means to lodge its egg in the back of the deer. The worm hatching penetrates the ſkin, and remains under it in ſecurity during the winter; in the year following it falls out, changed to a pupa, and becomes a winged inſect. The oeſtrus bovis is an equal terror to oxen; the hippoboſca equina to horſes; and oeſtrus ovis to ſheep: the latter inſinuates its eggs into the head of thoſe uſeful animals, through the naſal organs.

The neſt formed by the female of hydrophilus piceus, for the preſervation of their eggs, is altogether remarkable, and is deſcribed with much minuteſs by Lyonet. This neſt is whitiſh, its figure an oblate-ſpheroid, three-fourths of an inch in length, and its breadth two-thirds of its length; on the upper ſurface it is terminated by a lengthened horn-like proceſs, an inch long, ending in a point, and of a browniſh colour. In this neſt the eggs are depoſited, and left floating on the water till in due time they hatch, and the larvæ deſert the little bark contrived for their preſervation in the ſtate preceding, committing themſelves to the water. Theſe coques generally float among reeds and duck-weed. The purpoſe of the conical projection is ſuppoſed to be that of ſuſtaining the caſe in an upright poſition, when aſſailed by the wind: but this is mere conjecture; we may have yet to learn its actual deſtination. Another aquatic inſect, (one of the nepa genus,) that inhabits the waters of China, exhibits a far more extraordinary inſtance of the parental care which the inſect race evince for the preſervation of their eggs. This diminutive creature, ſcarcely an inch long, and of a ſubrotund figure, with the upper and lower ſurfaces flattened, is ſeen at particular ſeaſons bearing a large cluſter of eggs on its back, which, though diſpoſed as compactly as poſſible, by being placed on one end, and having the ſides touching each other, cover no inconſiderable portion of the whole ſurface of the diſk. In this manner they are conveyed by the inſect, wherever it goes, till the larvæ hatch, and drop inſtinctively into the water; when the parent inſect caſts off the exuvia of the nidus, and reſumes its former appearance. (Donov. Inſ. China.)

Of all the productions of nature inſects are ſuppoſed to be the moſt numerous and fertile. With the exception of fiſhes and cruſtacea, they are apparently the moſt prolific. Lyonet has offered a curious eſtimate of the increaſe of inſects, taken from their eggs. From a brood of 350 eggs, which he obtained from a ſingle moth, he ſelected 80. Theſe, when arrived at their perfect ſtate, produced 15 females; and hence he deduces the following concluſion. If 80 eggs give 15 females, the whole breed of 250 would have produced 65. Theſe 65, if equally fertile, would have produced 22,750 caterpillars, among which there would have been 4265 females. Theſe, in the third generation, by the ſame mode of calculation, muſt amount to 1,492,750 caterpillars. The number would have been ſtill greater, if in the firſt inſtances a larger number of females had been ſelected.

Of the Larva State.

Coleoptera.—The larva of all the coleopterous tribes of inſects is produced from an egg, in which the growth of the creature in an embryo or infant ſtate may be eaſily traced ſome time previouſly to its birth. They are either of a heavy, ſlothful, and voracious diſpoſition, as may be obſerved moſt commonly of thoſe which paſs their lives under ground, in putreſcent ſubſtances, or the trunks of trees; or briſk and active, like the generality of thoſe in the ſucceeding or hemipterous order. Among the coleopterous larvæ of lively manners we muſt rank ſome of the terreſtrial kinds, which, though they live in the earth, are always found cloſe to the ſurface, and affect particular ſoils; and thoſe of ſands, in maritime ſituations eſpecially: to theſe we ſhould add the inhabitants of the watery element, or thoſe which, in the ſtate of larva, are of the aquatic kind; and in ſhort, all that are carnivorous: theſe being more remarkable for their activity than ſuch as are deſtined by nature to feed on plants only. A ſuccinct account of the larvæ belonging to a few of the principal genera, and a conciſe deſcription of their manners, will be ſufficient to afford an accurate idea of the modes of life purſued by the larvæ of coleopterous inſects in general.

We know nothing from actual obſervation of the larvæ, from which the larger kinds of extra European beetles are produced: the transformations of the ſpecies hercules, alcides, actæon, atlas, and goliathus, and a hoſt of other gigantic animals of the ſame kind, (the largeſt of the inſect race,) remain at preſent in obſcurity. Yet we are at no loſs to conceive what the appearance of ſuch inſects in the larva ſtate muſt really be, ſo far as we already know their affinities; becauſe, from analogy, we can conclude they muſt be ſimilar, or at leaſt, generally ſpeaking, we may preſume with ſafety they differ only in ſome ſlight degree. The transformations of the ſpecies naſicornis, a native of Europe, an inſect of large ſize, and from its conformation poſſeſſing habits ſimilar to ſome natural family of exotic beetles, will, for example, aſſiſt our concluſions as to thoſe reſembling it; and, in like manner, the transformations of other extra European kinds may be determined with ſome preciſion, from the known changes of thoſe inſects naturally allied to it, or, in other words, of the ſame natural family.

Scarabæus naſicornis, or, as it is ſometimes called, the rhinoceros beetle, from the conſpicuous horn placed erect on the head of the male, reſembles an extenſive family of ſcarabæi, the inhabitants of Aſia and Africa. The larva is hatched from an egg of a roundiſh form. The body is like that of a thick and ſomewhat broadiſh annulated worm, of a pale yellowiſh-white colour, flattiſh on the belly, and with the ſkin much wrinkled. The lateral breathing ſpiracles are very diſtinct, the head is hard and ſcaly, and armed with powerful jaws; and the three anterior rings of the body are furniſhed each with a pair of ſcaly jointed feet. It is found in the earth and in hollow trees, and ſeveral times caſts its ſkin before it changes into the pupa ſtate. The larva of the cock chafer, another of the ſcarabæi, (melolontha, Fabr.) reſembles this, except in being ſmaller: like the reſt of its family it ſpends the greater part of the time, while it remains in the larva form, in the earth, where it ſubſiſts on the roots of plants. It is two, and ſometimes three years in paſſing from the egg to the perfect ſtate.

The ſtag beetles, (lucanus,) in the larva ſtate, bear a ſtrong ſimilarity with the preceding; they reſide chiefly in rotten wood. The larvæ of ſome cerambyces reſemble theſe in being ſoft, and in having the head and feet ſcaly. It is the

the larva of an infect of this genus (C. damicornis) which is eaten, and confidered as a delicacy in the Weft Indies. The fpecies is a native of this and other parts of America, and it is credibly affirmed, on the beft authority, that fome people of fortune in the Weft Indies keep negroes for the fole purpofe of going into the woods in queft of them, and fcooping them out of the trees. Their general length is about three inches and a half, and their thicknefs that of the little finger. Dr. Browne, in his hiftory of Jamaica, particularly defcribes this infect; he informs us it is chiefly found on the plumb and filk cotton trees; that they are commonly called macaccos, or macokkos; and that the mode of drefsing them, after opening and wafhing, is to broil them carefully over a charcoal fire. The epicures of thefe tranf-Atlantic regions only imitate the epicures of antiquity: they alfo efteemed the larvæ of the beetle tribe as a delicacy, and introduced them to their tables.

Many fpecies of that elegant tribe of beetles, the curculiones, are the offspring of larvæ, bearing fome refemblance to the former: their body is covered with a wrinkled fkin, their head with a fcaly covering, and the three anterior rings of the body furnifhed each with a pair of feet. Thefe infeft plants of various kinds; fome fubfifting on the flowers, others the leaves, the roots, feeds, &c. One of thefe, the larva of curculio palmarum, deferves notice for the fame reafon as that of cerambyx damicornis. This larva is about two inches long, and of an oval fhape. It lives in vaft numbers in the middle of the trunk of the young palm trees, and feeds on its juices. Thefe trees are fometimes cut down, when about the height of a man, and the tendereft part of them eaten; the worms are alfo taken care of, being confidered as highly agreeable food when roafted.

The larvæ of the coccinellæ have the body long, annulated, and furnifhed with fix feet; they run brifkly over plants, and feed chiefly on plant lice. The larvæ of the genus caffida are generally found under the leaves of plants on which they feed, to which they adhere by means of their lateral fpines, and a briftle at the end of their tail. They form a kind of umbrella with their excrement, under which they are fheltered from the fun and rain. The larvæ of the cicindelæ are foft and white, long fix-footed, and have a brown fcaly head. Thefe creatures employ great addrefs to entrap their prey: like the lion ant, in fome degree, the larva lurks in a round perpendicular hole in the ground, with its head at the entrance, to draw in and devour whatever infects come within reach. The larvæ of dermeftes live in leather, fur, and other fimilar fubftances, to which they do confiderable mifchief. The larva of the ptini infinuates itfelf into wood, and deftroys it.

That fimilarity in exterior characters, which we obferve fo prevalent in the perfect ftate of all coleopterous infects, whether of the terreftrial or aquatic kinds, is not apparent in the larvæ of thofe two natural tribes: they are in this ftate altogether remote, and have no greater analogy in their conformation than in their manners of life, or the elements in which they exift.

The larvæ of the dytifci conftitute a link of beings clofely allied to fome of the neuroptera; and this refemblance is fo remarkable, that certain fpecies of dytifci and hydrophili in that ftate differ more from each other than they difagree with the larvæ of the libellula; thefe latter prefenting creatures of an intermediate character, and which, to an ordinary obferver, would feem to unite them. Thus, the larva of libellula grandis more clofely correfponds with thofe of dytifcus marginalis or punctulatus, than the latter with dytifcus caraboides; and in external afpect the affinity of the larva of dytifcus caraboides may be even ftronger towards that of ephemera marginata or hemerobius lutarius, than to either of the former. There is certainly a difference between thefe in the ftructure of the jaws, &c.; but we fpeak only of thofe obvious characters and general appearances which firft excite attention.

Dytifcus marginalis, the fpecies before mentioned, is common in many ftagnant waters; and, from refembling the fhrimp in fome diftant degree, bears the name of fquilla aquatica in the writings of Mouffet and Aldrovandus. It meafures, when full grown, about two inches and a half in length, and is of a pale yellowifh-brown colour, and very tranfparent. The head is large, fomewhat flattened, and furnifhed in front with a pair of very ftrong curved forceps, which, when magnified, are found to be perforated at the tip: thefe are the inftruments with which it feizes upon its prey, and fucks its animal juices. The legs are flender and fmall in proportion to the body; the tail terminates in a trifurcated procefs, ciliated at the margin. This larva is a fierce deftructive creature, and not only commits vaft depredations among the weaker kinds of water infects, but preys alfo on the fry of fifhes, and is for this reafon highly injurious in fifh-ponds. It is fuppofed, like fome others of the fame genus, to remain two years in the ftate of larva. Dytifcus cinereus is produced from a larva fomewhat fimilar, but remarkable for the length of the legs: its habits are the fame. Caraboides is an hydrophilus, having the antennæ clavated inftead of filiform; the body of the larva is fhaped like the former, but on each fide is a fingle feries of plumofe branchiæ, or breathing organs, like thofe obfervable in the larvæ of ephemera marginata. In the firft ftages of growth this larva is fufcous; when full grown, the pofterior part is greyifh and rather pellucid. The gyrinus is another aquatic genus, and, from its form in the perfect ftate refembling the dytifci, has been fuppofed fimilar in that of larva; an argument, as already fhewn, not always admiffible. From the reprefentations given by fome authors, it is not unlike that of H. caraboides, in the fpecies natator, only of a more elongated form, and having four ciliated appendages at the pofterior end.

Hemiptera.—The larvæ of all hemipterous at prefent known are furnifhed with fix legs, antennæ, and organs of the mouth, as in the perfect infect from which they originate; and agree with them in moft other refpects, except in being entirely deftitute of wings. The larvæ of the mantes are carnivorous; thofe of the grylli feed on plants and farinaceous matter; the nepæ are aquatic, and fubfift on water infects; the cimices, inhabitants of the land, and a moft extenfive tribe, are entirely carnivorous, and like that odious and well-known infect of the fame genus, (the common bug,) derive their fuftenance from the blood and juices, extracted by means of their probofcis, from the bodies of other animals, thofe of the largeft kinds, and man not excepted.

Lepidoptera.—The caterpillars of the butterfly, fphinx, and moth tribes form a very numerous feries; and thefe, from a variety of concurrent circumftances, have been more particularly obferved than any others. The greater part of thofe lepidopterous infects which come forth in the fpring or fummer perifh or difappear at the approach of winter. There are few, the period of whofe life exceeds that of a year. Some furvive the rigours of winter from being concealed under ground, and others remain hid in the bark of trees, or in the chinks of old walls, but the proportion of thofe which out-live the inclemency of the winter feafon is very inconfiderable, unlefs it be thofe in the egg ftate. Thofe which

which are hatched in the autumn, and live under ground or in other places of fecurity during winter, ufually come forth in the fpring, take proper nourifhment, and undergo their feveral changes to the perfect ftate. The eggs, which have been carefully depofited by the parent fly in thofe places where they could remain in the greateft fafety, are alfo hatched in general by the genial influence of the fpring, and the infant brood called into life and action.

All caterpillars are hatched from the egg, and when they firft proceed from it are generally fmall and feeble, but grow in ftrength as they increafe in fize. The body of the caterpillar confifts of twelve rings; the head is connected with the firft, and is hard and cruftaceous. No caterpillar of the moth or butterfly has lefs than eight, or more than fixteen; thofe which have more than fixteen belong to fome other order of infects. The fix anterior feet, or thofe next the head, are hard and fcaly, pointed and fixed to the firft three rings of the body, and are in number and texture the fame in all lepidopterous larvæ. The pofterior feet are foft, flexible, or membranaceous; they vary both in figure and number, and are obfervable only in the caterpillar ftate, the perfect infect having only fix feet, the rudiments of which are the fix anterior fcaly feet before-mentioned. Thefe fpurious feet are either fmooth or hairy, foft to the touch, or hard, like fhagreen. On each fide of the body are nine fmall oval apertures, which are confidered as the organs of refpiration, and are called fpiracles. The head is covered with a fhelly fubftance, and on each fide are five or fix fmall black fpots, which are fuppofed to be the eyes. Some caterpillars grow to a very large fize.

The caterpillar, whofe life is one continued fucceffion of changes, often moults its fkin before it attains its full growth. Thefe are the more fingular, becaufe when it moults it is not fimply the fkin that is changed; for we find in the exuvia the fkull, jaws, and all the exterior parts, both fcaly and membranaceous, which compofe its upper and under lip; its antennæ, palpi, and even thofe cruftaceous pieces within the head, which ferve as a fixed bafis to a number of mufcles; we alfo find in the exuvia the fpiracles, the claws, and fheaths of the anterior legs, and in general the traces of all that is vifible in the external figure of the caterpillar.

The change in the caterpillar is effected by the creature withdrawing itfelf from the outer fkin as from a fheath, when it finds itfelf incommoded from being confined within a narrow compafs. But to accomplifh this change is the work of fome labour and time. Thofe caterpillars who live in fociety, and have a kind of neft or habitation, retire there to change their fkin, fixing the hooks of the feet, during the operation, firmly in the web of their neft. Some of the folitary fpecies fpin at this time a flender web, to which they affix themfelves. A day or two before the critical moment approaches, the infect ceafes to eat, and lofes its ufual activity; in proportion as the time of its change approaches, the colour of the caterpillar declines in vigour, the fkin hardens and becomes withered, and is foon incapable of receiving thofe circulating juices by which it was heretofore nourifhed and fupported. The infect is now feen at intervals with its back elevated, or with the body ftretched to the utmoft extent: fometimes raifing its head, moving it from one fide to another, and then letting it fall again. Near the change the fecond and third rings are feen confiderably fwollen. By thefe internal efforts, the old parts are ftretched and diftended as much as poffible, an operation attended with difficulty, as the new parts are all weak and tender. However, by repeated exertions, all the veffels which conveyed nourifhment to the exterior fkin are difengaged, and ceafe to act, and a flit is made on the back, generally beginning at the fecond or third ring. The new fkin may now be juft perceived, being diftinguifhed by its frefhnefs and brightnefs of colour. The caterpillar then preffes the body like a wedge into this opening, by which means it is foon torn down from the firft to the fourth ring: this renders it large enough for the caterpillar to pafs through.

The caterpillar generally fafts a whole day after each moulting, for it is neceffary that the parts fhould acquire a certain degree of confiftency before its organs can perform their ordinary functions. Many perifh under this operation. The caterpillar always appears much larger after it has quitted the exuvia than before; for the body had grown under the old fkin till it was become too large for it, and the parts being foft they were much compreffed, but as foon as this fkin is caft off, the parts diftend, and with them the new fkin, which is yet of a flexible and tender texture, fo that their increafe in fize at each moulting is confiderable. Some caterpillars in changing their fkin alter very much in colour and appearance, fometimes the fkin from being fmooth becomes covered with hair, or fpines, or tubercles, and others that are in one ftage hairy, have the fkin fmooth in the next. No fex is developed in the caterpillar ftate.

The caterpillars of lepidopterous infects feem deftitute of all means of defence, and are the prey of birds and other voracious creatures. Nature has not, however, left the whole tribe in this defencelefs ftate, fome kinds are armed with ftrong and powerful fpines difpofed in a verticillate manner round the annulations of the body, and which, if they be infufficient to annoy others, ferve at leaft, in fome meafure, as the means of felf protection. There are others, chiefly the inhabitants of the warmer climates, whofe bodies prefent an armament of fpines not unlike that of the hedgehog or porcupine, and thefe placed in fuch a formidable manner, as muft either forbid the approach of other fmall creatures, or punifh their temerity. Some few of the North American fpecies are of this defcription. In others, we fee the rings tuberculated, and every tubercle befet with ramofe fpines, the branches of which intertexting with each other, form an almoft impenetrable net-work of fpines. Others again are thickly clothed with fpines and hair intermingled, which may be fufficient to guard them againft the attack of fome of their inferior enemies. Some fpecies with the body covered only with a thin fkin, and therefore apparently expofed to the annoyance of every other, has the jaws fo powerful, and the difpofition fo ravenous and fierce, that they conftantly attack, and moft commonly with fuccefs, the larva of other fpecies much larger than itfelf. At the extremity of the body in the larva of the fphinges, is a remarkable recurvate fpine or horn, formidable in appearance, but harmlefs in its nature, and which is vulgarly fuppofed to be its weapon of defence. Thefe infects, or at leaft fome of them, are not, however, without the means of annoyance, for it appears they poffefs the ability of difcharging from their mouth or vent a fœtid liquor, the fcent of which, fhould it fall on the fkin, cannot eafily be removed even by wafhing, and which may be fuppofed powerful enough to repel other infects. This ability in the fphinx tribe of caterpillars is admitted on the authority of fome credible authors; the like circumftance is more commonly obferved in the larvæ of fome fpecies of tenthredo.

The caterpillars of many infects of the butterfly tribe feed clofe to the ground, or under the furface, fubfifting on the lower parts or roots of plants; and for this reafon many kinds are feldom feen, and others remain unknown. The larvæ of the fphinx kind live chiefly on the leaves. Thofe of the fefia genus are ufually denominated internal feeders, or fuch as refide in hollow cavities, which they form

in

in the trunks or branches of trees, the fubftance of which alfo affords them nourifhment. Many of the moth tribe are of the fame kind, and have the fame habits; others eat the leaves of different plants, and a few of the fmaller forts feed on woollen, paper, and other fubftances, not of a vegetable nature. Some of the lepidopterous caterpillars are folitary, others live in fociety.

Neuroptera.—The larvæ of neuropterous infects are carnivorous, and in the vivacity of their manners exhibit a very ftriking contraft with thofe of the generality of infects. They are nearly all of the aquatic kind, paffing their whole life, till they affume the winged ftate, in the water; and are diftinguifhed for the peculiar addrefs with which they conftantly wage war, not only againft every other diminutive inhabitant of their natural element, but alfo againft each other. Thefe larvæ are hexapode, or furnifhed with fix feet of a fcaly nature, and having the head protected by a fimilar fubftance.

The libellulæ, or dragon-flies, form an interefting genus of the neuroptera order, and the habits of their larvæ illuftrate, in the ftrongeft manner, the nature of thefe aquatic creatures. The egg, when depofited by the parent in the water, finks to the bottom, and remains there till the young infect has acquired fufficient maturity and ftrength to burft from its confinement. The larva, at firft fmall, increafes to nearly half the fize of the perfect fly, by changing its fkin at different intervals like the caterpillars of moths and butterflies. The appearance of the little cafes containing the rudiments of the wings, at the lower margin of the thorax, denotes its change to the ftate of pupa. The head of this larva is exceedingly fingular, being covered with a mafk extending over the whole of the fore part of the head, with cavities in the interior furface to fuit the different prominences of the face to which it is fitted with perfect neatnefs. Its form is triangular, growing fmaller towards the bottom: in the latter part there is a knuckle which fits a cavity near the neck, and on this part it turns as on a pivot. The upper part of this mafk is divided into two pieces, which the infect can open or clofe at pleafure, and it can alfo let down the whole mafk, fhould occafion require. The inner edges of thefe two pieces are toothed like a faw, and ferve the animal as a pair of forceps to feize and retain its prey. This is the general principle on which thefe projecting forceps are conftructed in the larva of the libellulæ; they differ in fhape in the feveral fpecies, but uniformly act in a fimilar manner.

Thefe animals generally live and feed at the bottom of water, fwimming only occafionally. Their motion in the water can fcarcely be called fwimming, it is accomplifhed by fudden jerks repeated at intervals. This motion is not occafioned by their legs, which at this time are kept immoveable and clofe to the body: it is by forcing out a ftream of water from the tail that the body is carried forward, as may be eafily perceived by placing them in a flat veffel, in which there is only juft water enough to cover the bottom. Here the action of the water fquirted from their tail will be very vifible; it will occafion a fmall current, and give a fenfible motion to any light bodies that are lying on the furface. This action can only be effected at intervals, becaufe after each ejaculation the infect is obliged to take a frefh fupply of water. The larva will fometimes turn its tail above the furface of the water, and force out a fmall ftream, as from a little fountain, and with confiderable force.

The larvæ of the ephemeræ, another of the neuropterous tribes, differ in various particulars from thofe of all other infects: its length, in the larger fpecies, about an inch; the form rather long, and fub-cylindrical, tapering a little towards the tail: the head is furnifhed with antennæ, trunk with fix legs, abdomen with feveral finny plumes each fide, and the tail with three long proceffes. They live in the water, where earth and clay, it is affirmed, form their principal nourifhment for the fpace of two or three years, the time they confume in preparing for their metamorphofis, and which is accomplifhed in a few moments. The larva, when ready to quit that ftate, arifes to the furface of the water, and inftantly cafting off its fkin becomes a pupa. This is furnifhed with a kind of wings, by the affiftance of which it efcapes to the fhore, and there fettling, in the fame moment, quits a fecond fkin, and becomes the perfect fly. In this ftate, which has been fo long preparing, the pleafures it enjoys muft be very fenfible, if they are lively in proportion to the fhortnefs of their duration, the infect celebrating its nuptials, producing the fruit of them, and dying within the fpace of a few hours; the vital principle, though fo evanefcent in the complete infect, is extremely tenacious in the larva.

The phryganeæ, a genus of this order, very much refembling, in general appearance, certain families of the moth kind, are the offspring of aquatic infects, not much unlike the larvæ above defcribed; only that inftead of inhabiting the waters in a defencelefs ftate, they conftantly live in fmall cylindrical cafes of their own conftruction, which they drag after them in the water wherever they go. Thefe cafes are tubular and open at both ends: externally they are formed with fmall bits of reed, gravel, fmall fhells, and other fubftances curioufly cemented together, and lined with fine filk. The animal never quits its habitation till it becomes too fmall for its body, when it conftructs another. Like the hermit crab, when it is defirous of moving from one place to another, the animal advances the fore-part of the body out at one end of the tube, fo as to admit the free ufe of its legs, which are fix in number, and placed contiguous to the head, and by this means it is able to crawl or walk with perfect facility at the bottom of the water. The body in moft fpecies is fmooth, and the back ufually furnifhed with a tubercle, which prevents the cafe from flipping too forward while the animal is feeding, and which ferves alfo to retain the cafe more firmly to the pofterior part of the body in the action of walking. Thefe, in common with other aquatic larvæ, are frequently ufed by anglers as bait, and are called cadew-worm, ftone bait, or cod bait, and in the perfect ftate is known by the name of fpring fly. The larvæ of the phryganeæ prefer running waters.

Thofe above-mentioned are the larvæ of the amphibious kinds of neuropterous infects; there are others which live only on land, and differ much from thefe both in appearance and mode of life. Thofe of the myrmeleon, panopa, hemerobius, and raphidia, are of the terreftrial order. They are carnivorous as well as the aquatic kinds, preying on other infects. The moft extraordinary of thefe in their manners of life are fuch as have been denominated by naturalifts the lion-ants, or lion-pifmires (the myrmeleon of Latin writers). Of this genus there is nearly a dozen fpecies, or, indeed, if we include the afcalphi which Fabricius removes from that genus, there are altogether fixteen fpecies at prefent known. The larvæ of this family prey with the moft favage ferocity on all the fmaller kinds of infects: it is not, indeed, this difpofition, fo common to all carnivorous larvæ, that renders them remarkable, but the extraordinary and peculiar contrivances they adopt to enfnare their prey. We are beft acquainted with the hiftory of the fpecies formicarius, the formica-leo of Linnæus, and this may ferve as an example of the genus, the habits of which, fo far as we are acquainted with them, being alike in all, with this difference, however, in their predatory powers, that formicarius

is

is one of the fmaller kinds, and lefs capable, from its inferiority in ftrength and fize, to commit devaftation, than moft of the extra European fpecies, thofe of Africa efpecially.

Myrmeleon formicarius is found in France, Spain, and Germany, and is an inhabitant of fandy places. The egg is depofited by the parent infect in the fand, and this hatching produces a larva of an ovate form, armed with a long and powerful pair of jaws. The larva, as foon as produced, begins to exercife its talent of preparing a pitfall in the fand, by turning itfelf rapidly round, and which, when formed, is fomewhat funnel-fhaped, or rather concave, with a very fmall aperture in the centre under which the animal conceals itfelf with only its pincers advanced through the hole, ready to feize on any infect that may unwarily fall into the hollow. Sometimes the whole head is protruded through the hole, but when it lies in wait the body is always concealed under the fand. From the ftructure of this trap, fuch infects as crawl to the edge or fides are almoft fure to fall in, and be devoured by the larva. But fhould the fides of the pit not give way, or the unfortunate infect appear to be able to make its efcape, its mercilefs enemy immediately difcharges from its head fhowers of fand, the repeated force of which is irrefiftible; the infect falls within reach of the larva, who, after fucking out its juices through the tubular forceps, by a fudden exertion throws the remains of its carcafe out of the hollow to a confiderable diftance, and again, after repairing its den, renews its vigilance for prey. As the larva increafes in fize, it enlarges this cavity; at firft it is only a flight depreffion in the fands half an inch in diameter, in its next ftage it is increafed to twice that diameter, and when the larva attains its full fize is between two and three inches acrofs. In the preparation or enlargement of its pit, when it grows to its full fize, it fhews much addrefs: its operation commences by tracing an exterior circle of the intended circumference of the cavity, and continuing its motion in a fpiral direction till it reaches the centre, thus marking each revolution in the faud like the impreffion of a large fhell of the whorled kind, the breadth of each whorl correfponding with that of the infect's body; and which, in the circumference of the whole cavity, amounts to four or five circles. After having fufficiently deepened the cavity by a repetition of this motion, it fmooths the fides into a regular fhape, by throwing out the fuperfluous fand by means of its forceps, which, when clofed, together with the head, forms a convenient kind of fhovel for the purpofe. The grains of fand thus difcharged often fall to the diftance of ten or twelve inches beyond the verge of its cavity. The depth of the cavity is ufually equal to its diameter. The fingular larva, whofe manners of life appear fo interefting when it has attained its full fize, is about three quarters of an inch long, and has much the afpect of a large fpider in the form of its body: its head and legs more nearly refemble thofe of the pediculi of fome particular animals, and are very fmall, and in the ftructure and proportion of the jaws or forceps its character is peculiar, thefe being enormous. Its general colour is pale reddifh, very prettily variegated with diftinct marks and fpots of deep ferruginous both on the back and belly; the whole is befet with a few hairs, fome of which appear in tufts. It remains two years in the larva ftate; in the fummer it is active, but it is torpid during winter; when full grown it changes into a pupa, the animal previoufly enveloping itfelf in a round ball of fand agglutinated and connected by a very fine filk, which it draws from a tubular procefs at the extremity of the body: with this filk it alfo lines the internal furface of the ball. The complete infect is furnifhed with four tranfparent fpotted wings, and, like the larva, preys on infects.

Hymenoptera.—The larvæ of the tenthredines bear the neareft refemblance poffible to thofe of fome lepidopterous infects, and have for this reafon acquired the name of baftard caterpillars, or falfe caterpillars; the fpiral manner in which they roll themfelves up is one character that feems to remove them from the true caterpillar, but they are more clearly diftinguifhed by the number of feet, which, though varying in different fpecies of both families, may be faid to be conftantly more numerous in the tenthredo genus than in any of the lepidoptera orders. The firft have from eighteen to twenty-two feet; the latter never more than fixteen, including the fpurious or pofterior ones. Thefe live chiefly on the rofe and willow trees. The larvæ of the firex genus is cylindrical, and furnifhed with fix feet, and the head rounded; they perforate wood, and frequently eat their way into the bodies of other infects, or their larva, and confume their vitals. Thefe are the principal hymenopterous larvæ that are furnifhed with feet: the fucceeding infects are deftitute of thofe organs when in the larva ftate.

One of the moft curious tribes of larva among the hymenopterous genera are thofe called the gall-flies; they are in no particular manner remarkable in appearance, but the effects they produce render them extraordinary. Every one muft have obferved thofe vegetable excrefcences, of a globular form, which appear on the leaves and foot ftalks of the oak at particular feafons of the year, and which in autumn have acquired the fize of a cherry or a fmall plumb, its colour a bright red, and forming a pleafing contraft with the verdure of the leaves; thefe are the habitations formed by the punctures of the gall-fly, in which the eggs were depofited each fingly in its globule by the parent infect, and each of thofe excrefcences at this feafon, on being opened, will be found to contain a larva; a fmall worm of a cylindrical form and without feet. There are an amazing number of fpecies of the gall-fly (cynips) that conftruct their dwellings, and fubfift on the juices of the oak, and many others that attack in like manner the maple and the willow. The larva is found like a nucleus, in a fmall cavity immediately in the centre of each excrefcence.

The manners of the ichneumon, as popularly defcribed, are fully known, and the hiftory of the ichneumon flies feems to accord in a peculiar degree with all that has been fabuloufly related of the former. They are entirely parafitical, and derive their fuftenance, till they arrive at the perfect ftate, from the vital juices of other infects. Their eggs are depofited only in the bodies of other living infects, generally thofe of the caterpillar kind. The female, felecting her victim, faftens upon it, plunges her abdominal tube into the body, and, in defpite of all refiftance, maintains her hold till fhe has lodged her ftore of eggs. In the courfe of a few days the young larvæ, which refemble minute maggots, are hatched. Thefe nourifh themfelves with the juices of the caterpillar, which, notwithftanding it affords fuftenance to the parafitical brood, continues to move about, and feed till the time of its change into the chryfalis ftate, when the larvæ creep out by perforating the fkin in various directions, and form little oval filken cafes, the whole of which with the fpinning forms an envelope to the withered remains of the infect from which they derived nurture. The latter inevitably perifhes from the injury fuftained; in a fhorter or longer period, according to the fpecies, the ichneumons appear in a perfect ftate. This parafitical family, when produced, are found to be either entirely of the winged kind, or to confift both of alated and apterous infects, the females in certain fpecies being deftitute of wings. Thefe are, notwithftanding, perfect infects, as they never acquire thofe organs afterwards, and being befides, after an intercourfe with the

the other ſex, in a condition to depoſit fertile eggs, and thus perpetuate the breed. The apterous females attack caterpillars and other inſects in the ſame manner as the winged kinds, and depoſit their eggs in the living body.

So far as we are acquainted with the natural hiſtory of the ſphex tribe, the larvæ of theſe are lodged in the bodies of other inſects, in a manner ſimilar to that adopted by the ichneumons, with this difference, that the ſphex generally deſtroys the principle of life in thoſe creatures it attacks, inſtead of leaving them to linger through a tedious exiſtence of torture. Theſe inſects are very abundant in wood and hedges, and the larvæ feed chiefly on dead inſects, in the bodies of which they are produced from the egg. Some ſpecies dig holes in the earth with their fore feet, in which they bury their dead inſects, conſiſting chiefly of ſpiders and caterpillars, having previouſly depoſited their eggs therein; theſe holes are carefully cloſed with earth or clay, through which the larvæ force a paſſage when hatched. The larvæ are vermiform. The manners of theſe inſects is ſtrongly exemplified in the ſpecies figulus, a native of Upſal, and which is deſcribed by writers with conſiderable attention. This ſphex inhabits the holes in old wooden partitions, abandoned by other inſects, the interior of which the female cleanſes by gnawing the ſurface of the cavity throughout, and prepares it for the reception of her victim, by placing a piece of clay in the bottom. She then ſeizes on a ſpider, which having killed, and faſtened upon the clay, ſhe next proceeds to the depoſition of the egg, which is lodged in the dead body. This laid ſhe cloſes up the opening with clay. The larva hatched from the egg reſembles the maggot of the bee, and which, having devoured the food provided for it, ſpins itſelf a ſilken web, and changes to the pupa ſtate. In this manner each female inſect prepares ſeveral ſeparate holes, in each of which a dead inſect and an egg are depoſited. The larvæ of waſps and bees are ſoft, without feet, and feed on the nectar and honey collected by the parent inſects. The larvæ of the ants are alſo well known. The three latter mentioned families live in ſocieties, and with thoſe already noticed form the principal kinds of hymenopterous inſects.

Diptera.—Theſe larvæ vary much in different genera. Commonly they appear like a ſmall worm, the likeneſs to which is heightened by the animal having no feet, and in ſome ſpecies by the head being ſoft, like the body. Others differ in having the head ſcaly. The larva of the oeſtri, or gad-flies, depoſits its eggs in various parts of the bodies of cattle, which, when hatched, produce the moſt painful tumours. Some lay their eggs under the ſkin of cows or oxen, which they perforate for that purpoſe: others enter the inteſtines of horſes by the vent; and others, again, depoſit them in the noſtrils of ſheep. The larva of oeſtrus bovis is brown, and conſiſts of eleven ſegments, with tranſverſe rough interrupted lines. That of equi, known by the name of bots, depoſits its eggs on the hairs of horſes, and always on thoſe parts which are moſt likely to be licked with the tongue, and are thus conveyed into the ſtomach. The eggs of hæmorrhoidalis are laid on the lips of horſes, occaſioning a titillation, which cauſes the animal, when attacked by it, to move its head violently, and gallop about with every ſymptom of diſtreſs: this larva is carried into the inteſtines like the former, and is voided with the dung when its period of change to the pupa ſtate approaches.

In the genus tipula the larvæ are ſoft, cylindrical, and truncated at the head: theſe feed on the roots of plants. The larvæ of the different natural tribes, comprehended among the Linnæan muſcæ, exhibit ſome very diſſimilar appearances in form and habit. Generally, they poſſeſs a worm-like aſpect, ſometimes blunt at the anterior part, and acute behind, and at others pointed at both ends. Many live in watery places and devour inſects; others feed on decaying animal matter, or on the juices of vegetables. The larvæ of muſca vermileo preys on inſects, and in its mode of entrapping its prey imitates the manners of myrmeleon formicarius, like that ferocious inſect forming a circular den in the ſands which it inhabits, and watching in an aperture at the bottom for the unwary inſects that unfortunately wander too cloſe to its cavity. But of all the peculiarities related of the muſca tribe, nothing appears in any degree ſo extraordinary as the hiſtory of the larva of muſca tenax, recorded on the authority of Linnæus, and ſanctioned by that of Fabricius. The larva is repreſented as a brown maggot with a long tail, which latter is extenſile, and conſiſts of a double tube, the exterior annulated into numerous ſegments, and the interior ſlender and terminated by a circle of hairs, ſurrounding a ſpiracle. This maggot is ſeen in muddy ſtagnant waters, drains, and other ſimilar places; and is, according to Linnæus, a frequent inhabitant of the turbid pulp uſed in the operation of paper making. Hence it is often in this ſtate expoſed to the action of the wooden mallets uſed in this proceſs, as well as ſqueezed in the ſtrongeſt preſſes, and yet it ſurvives uninjured theſe ſeemingly deſtructive operations.

This circumſtance is deſcribed in a paper entitled "Miracula Inſectorum," inſerted in Am. Acad. 3. p. 331, and though purporting to be the production of Emanuel Avelin, obtained the ſanction of Linnæus. The ſame obſervation is confirmed in the "Syſtema Naturæ;" and is repeated in this place as a moſt extraordinary trait in the hiſtory of this inſect, without deeming ourſelves in the leſt reſponſible for its veracity.

The tabani nouriſh themſelves with the blood of horſes and cattle; and ſome think the larvæ are aquatic, though Degeer aſſerts they live under ground. The larvæ of culices (gnats) are very curious in their conformation: the body conſiſts of nine ſegments, which become gradually ſmaller from the head towards the extremity. The head is very large, and furniſhed on each ſide with a pair of pointed forceps, or hooks, with which it ſeizes its prey. The tail terminates in a tubular opening, at the tip of which are four ovate ſcales, two of which exceed the others in ſize. At the end of the body, near the tail, is a ſmall elevated reſpiratory tube, which the creature frequently raiſes above the ſurface of the water, while the head remains ſuſpended downwards. The colour of the larva is browniſh, extremely pellucid, and its motions remarkably lively. The larva, when firſt hatched, is extremely minute, and in the ſpace of fourteen days from its birth attains its full ſize, its length being then about half an inch. The painful ſenſation occaſioned by the ſting of the gnat, or, in other words, its ſucking proboſcis, is well known, and hence we are taught to conſider the gnat as an inſect ſubſiſting only on the blood of other animals: this is not, however, the opinion of ſome naturaliſts, who, reflecting on the myriads of theſe creatures, with which every watery place is infeſted, conclude they could not find ſufficient ſuſtenance, unleſs they ſubſiſted equally on the juices of vegetables and animals. Whatever may be the truth in this reſpect, the weapons of annoyance with which nature has furniſhed the larva indicate very clearly to us that in that ſtate, at leaſt, it is of the carnivorous kind. We ſhall laſtly mention the hippoboſcæ, a dipterous genus in the Linnæan ſyſtem, and which, unlike thoſe before adverted to, do not appear to have any larva; they are the produce of an egg which partakes of the two-fold

fold character of being at the fame time an egg and a pupa. The female, at diftant intervals, depofits an egg, which in magnitude is nearly equal to the whole bulk of its parent's body: the figure of this egg is oval, with an excavated depreffion at the lower end; the colour, at its firft exclufion, is milk white, except a large black fpot on the fore part, from which it afterwards becomes brown, and then of a jet black, with a very high polifh. This change in colour marks the progreffive advancement of the infect inclofed towards its maturity of formation, the parts becoming gradually developed. The egg depofited in autumn acquires its deepeft colour in the fummer following, at which time the infect burfts from its confinement in the winged form.

Aptera.—No infect of this order, except the common flea, are fuppofed to undergo thofe fucceffive changes which are ufual in moft other infects. They are almoft entirely produced from the egg in their perfect form, and cannot therefore be faid to have any larva. In the flea, however, the fmall worm which correfponds with the larva in other infects is clearly afcertained; and if we may place fufficient reliance on the evidence of certain naturalifts, one or two more of the apterous genera exift for a fhort period in a ftate fomewhat analogous either to the larva or pupa. Leeuwenhoek obferved that the mite was oviparous, laying very fmall oval whitifh eggs, from which proceeded the young animals, refembling their parents in all refpects, except in the number of their legs, thefe being only fix in number, inftead of eight; and after they caft their fkin another pair of legs appear, a fact that evidently implies two periods of transformation, the firft of which may be compared with that of larva. An advancement, or progreffive increafe in the number of feet, is alfo well known to take place in fpecies both of the julus and fcolopendra genera, after they are produced from the egg ftate. The julus fabulofus, when firft excluded, is furnifhed with three pair of legs, which are fituated at each fide near the head: fome days after about fourteen become vifible, and the remainder, to the amount of one hundred and twenty on each fide, are gradually acquired afterwards. The fame remark will apply to certain fpecies, if not the whole of the fcolopendræ genus. Scorpions are produced by the female parent in a living ftate; they are at firft very fmall and white, and become of a darker hue in a few days: thefe, like the fpiders, caft their fkin as they increafe in fize.

Of the Pupa ftate.

By this term, as underftood in the very extenfive fenfe Linnæus propofes, we comprehend that ftate of an infect which fucceeds the larva and precedes the pupa, without any regard to the particular appearance it affumes in this ftage of transformation. From this latitude of meaning it includes, therefore, with equal precifion, and no lefs propriety, ftates of the moft difcordant character. It alike implies the uncouth grub incafed in its fhelly repofitory, and immured in the earth, fluggifh, almoft deftitute of motion, or the appearance of any other animal function, with the lively half-winged locuft, or the cicada, animals fporting in the full enjoyment of life. The bot, imprifoned in its oval covering, without the leaft external fign of animation, is termed a pupa. The moth, quiefcent and abftinent for months, concealed in its fhelly covering in the earth, or fufpended aloft in its filky envelope to the branch of a tree, is a pupa; and we denominate thofe pupæ alfo which have the wings only half expanded; though, like the nimble-footed cimex, they are perpetually roving, and deriving fuftenance from the blood of other animals; and fo alfo the reftlefs libellula, which is continually traverfing the watery element, with the facility of fifhes in fearch of prey. Surely the difference between thefe is too great to be defined by any fingle term.

Writers have obferved, that before the time of Linnæus this ftate of transformation was known only by the term chryfalis, a word derived from the Greek, and expreffive of that golden luftre peculiar to certain butterflies; but this appearance not being general, the word was changed by Linnæus to that of pupa, in allufion to the indiftinct refemblance which many infects in that ftate bear to a child fwathed or dreffed in fwaddling clothes. Thefe obfervations are certainly incorrect, for the word nymph, implying exactly the fame fanciful comparifon, was in ufe before the time of Linnæus; the earlier authors fo named one particular tribe of infects in this ftate, namely, thofe having all their limbs inclofed within a fkin: Linnæus adopted the idea but changed the word to pupa, and affigned it indifcriminately to all infects in that period of transformation from which the perfect fly is produced.

If we take a retrofpective view of the ftate of entomology before the time of Linnæus, and confider attentively the terms by which the different ftates of infects were then known, there does not appear much reafon to commend the alterations which he has introduced. From the labours of Swammerdam, Reaumur, Roefel, Lifter, Ray, and others, the transformations of infects were then generally known, and particular terms had become eftablifhed by which the feveral ftates, appearances, &c. might be difcriminated. Thefe were not fufficiently numerous, and of thofe in ufe fome were lefs expreffive than could be wifhed; but it is ftill not to be concealed that fome, at leaft, were preferable to thofe introduced by Linnæus. This is the more to be regretted, as Linnæus wrote under favourable circumftances, and on his authority the introduction of a few expreffive terms would have been attended with particular advantage. For inftance, we fhould have conceived it defirable if he had defignated this ftate of infects, which he calls pupa, by different terms, applying to each particular family a name at once expreffive of their ftate, and the order to which they belong. When, in the works of his predeceffors, we read either of the aurelia, nymph, or femi-nymph, we know that in a word it implies the fame ftate as Linnæus means by pupa, with this additional information, that it is either of the dormant kind, like the moth, or active, like the nepæ, &c.; the Linnæan name conveys no fuch additional information; it applies without diftinction to all, and merely intimates its ftate of transformation.

Perhaps the alteration of the word chryfalis to pupa may be thought by fome an amendment; we do not difapprove of it, but object to the very indifcriminate fenfe in which it is employed. As it applies to the nymphs of one family defcribed by earlier writers, it is admiffible; to others it is not. Or if the term pupa were adopted in its moft extenfive fenfe, to comprehend this ftate throughout the whole race of infects fubject to this period of transformation, the want of terms to diftinguifh the particular tribes of which they confifted would be equally felt. The general manner in which the term pupa is applied by Linnæus, and the inconfiftency attending it, cannot be more fully exemplified than by the following circumftance. Linnæus, we are told, changed the word chryfalis to pupa, becaufe the former implied a golden appearance not obfervable in all the fpecies; yet he applies the word pupa, which he defines as alluding to the appearance of a child in fwaddling clothes, fuch as we fee in the moth and butterfly tribe, to the blatta, gryllus, cimex, and a hoft of other active creatures which exhibit no fuch refemblance, and which bear no relation whatever to the others either in manners or aſpect! The firſt of theſe were called by old writers nymphs, the latter ſemi-nymphs; but theſe diſtinctive terms are confounded by Linnæus under the ſingle term pupa. Surely the impropriety is as great in the alteration made as in the error it is deſigned to remedy.

To obviate, in ſome degree, the confuſion ariſing from this general adoption of the word pupa, Linnæus propoſed afterwards to divide them, according to their form, into five families, to each of which he aſſigns a trivial or ſecondary name.

Theſe diſtinctions are not objectionable, but are rather too few in number, and they are certainly not expreſſed in terms ſuitable for general uſe. Nor does Linnæus himſelf appear ſatisfied with them, for although they are inſerted with definitions at ſome length in the "Fundamenta Entomologia," they are not adopted in the "Syſtema Naturæ," and are for this reaſon rather to be regarded as matter of curioſity than of utility. The pupæ are divided into ſections, according to the following circumſtances. When confined in a caſe of a globular form, which has no reſemblance to the inſect it contains, it is called coarctata, or ſtraightened, the examples of which are the muſci and oeſtri; obtecta, diſguiſed or ſhrowded, when the inſect is wrapped up in a ſhelly covering of ſuch a form that the part which contains the head and thorax may be diſtinguiſhed from that wherein the abdomen is lodged, as in lepidopterous inſects. It is termed incompleta when the pupa has perceptible wings and feet, but cannot move them: ſemi-completa, theſe can walk or run, but have only the rudiments of wings. The difference between the pupa and the larva of this claſs is very inconſiderable; in the firſt ſtate they have no wings, and in the pupa the wings begin to be developed as in the graſshopper: completa, in which the egg may be conſidered analogous to the pupa, the inſect being produced in its perfect form from the egg without paſſing through any other change.

Swammerdam divides inſects into four claſſes, the characters of which are founded principally upon their appearance in this ſtate of transformation, and the particulars attendant thereon.

The firſt of theſe comprehends thoſe inſects which, after being formed in their egg without the aid of food, and which, after having acquired, by the evaporation of the ſuperabundant humidity, the neceſſary conſiſtency, quit that ſtate, and iſſue from the ſhell under the form they are to retain during life, without undergoing any other transformation, as inſtanced in the ſpider.

The ſecond conſiſts of thoſe inſects which, after leaving the egg, are without wings, but with all the other members, as in the perfect inſect; in this ſtate they eat and grow, paſs into the nymph form, and from that iſſue with perfect wings, and with the ability to propagate their ſpecies. The dragon flies, graſshoppers, and cimices are of this family.

The third includes all kinds of butterflies and moths. They iſſue from the egg which lay in a diſguiſed ſtate and without food; the ſecond ſtate eats and grows, and the members of the animal into which it is to be transformed are formed under the ſkin, which it at laſt quits and becomes a nymph, and then after the evaporation of the ſuperfluous humidity produces the perfect inſect.

The fourth family, after having arrived at the nymph ſtate, like thoſe before-mentioned, does not diveſt itſelf of the ſkin in order to enter into that ſtate, but aſſumes the form of a nymph under its ſkin, where it continues ſhut up, till quitting two ſkins, at once it comes forth in its perfect ſtate. This is the metamorphoſis which ichneumons undergo. Theſe are the four families into which Swammerdam divides inſects, and the explanations he affords; and theſe, with ſome improvements and modifications, form the baſis upon which the pupæ are arranged by many of the continental naturaliſts at this time.

The following obſervations on the ſame ſubject by Lyonet deſerve attention. "By the term nymph (ſays this writer) is meant a ſtate of imperfection, attended ſometimes with inactivity, inaction, abſtinence, and weakneſs, through which the inſect paſſes, after having attained a certain bulk, and in which its body receives the preparatives neceſſary for its paſſing to a ſtate of perfection, all the external parts of the inſect are then found enveloped, either with their natural ſkin, or with a fine membrane, or with a hard and cruſtaceous cruſt. In the firſt caſe the limbs of the inſect remain free, it preſerves its power of acting, it eats, and its form is little different from what it was before. In the ſecond caſe the limbs of the inſect are folded over the breaſt but ſeparate; it can neither eat nor act, it retains hardly any traces of its former figure, and has only a confuſed reſemblance to that which it is going to aſſume. In the third caſe, the cover brings all theſe parts of the animal into one maſs; it makes it equally incapable of eating and acting; it has no reſemblance either to what it formerly was, nor what it is to be. Theſe three ſorts of change are evidently very different, and yet we have only two words in our language (French) to diſtinguiſh them by. We ſay of the inſects in the two firſt caſes, that they are changed into nymphs, and of thoſe in the laſt caſe that they have aſſumed the form of chryſalids. To theſe terms it would be proper to add a third, in order to mark the difference between the two firſt. It might be done I think very conveniently by allowing the laſt to retain the name of nymph, and calling thoſe of the firſt kind ſemi-nymph, or demi-nymph, a name which would not perhaps be inapplicable to them, conſidering the ſmall degree of change they have undergone. Graſshoppers, which, inſtead of the long wings they acquire, have ſtill only on their backs the ſmall caſes in which theſe wings are formed, are nymphs of this kind; they may properly be called ſemi-nymphs. Thoſe who have had an opportunity of examining a bee hive, cannot fail to have remarked bees ſtill imperfect in the ſhut cells; theſe are the nymphs of the ſecond order. The ſilk-worm furniſhes a well known example of inſects under the form of chryſalis.

"Inſects which undergo no other metamorphoſis than that which has converted them from the ſoft ſubſtance of an egg to a well formed and living body, are thoſe which conſtitute the firſt claſs of transformations ſpoken of. They increaſe in ſize, the greater part caſt their ſkin; ſome of their parts acquire greater ſize than the reſt, and ſometimes take a different colour from what they had before. This is almoſt the only change they undergo. The tranſformations of the inſects of the other three claſſes do not terminate here; after having caſt off their ſkins for the moſt part ſeveral times, and after having acquired their deſtined bulk, all become either ſemi-nymphs, nymphs, or chryſalids. They paſs a certain time under this form, and upon quitting it aſſume that of a perfect inſect, capable of generation. It is from the diverſity which takes place in theſe three ſorts of changes that the principal characters, which diſtinguiſh the inſects of the ſecond from thoſe of the third, are taken."

The inſects of the ſecond claſs are thoſe that paſs through the ſtate which Lyonet calls ſemi-nymphs. They do not undergo a transformation which is entirely complete, but in their laſt change they have ſtill generally all the members they had before, without having acquired any others, ex-

cept

cept they have wings; and as already remarked the semi-nymph differs very little from the animal which produced it. What always distinguishes it is, that there are seen upon its back at the base of the thorax the cases in which the wings are formed, which before that appeared but little, and often not at all. In other respects it walks, runs, leaps, and swims as before. The difference between the semi-nymphs, and the winged insect which it produces, is not always so obscure. In some species it is so large that it is with difficulty we can discover its first form. But the greater part in their last state differ chiefly in the wings.

The insects of the other two classes do not enjoy the same advantages as the other. They lose the use of all their members when they enter upon their transformation, and have no resemblance to what they were before. An animal of these two classes which before had no legs, or had five, six, seven, eight, nine, or ten pairs, has now no more than three pairs, which, with the wings and antennæ, are folded up under the breast and remain immoveable.

What distinguishes these two last classes from each other is, that the insects of the third class quit their skin, when they change into nymphs or into chrysalids, and that those of the fourth change into nymphs under their skin, which hardens round them, and forms a case.

Reaumur found, in the transformation of insects of the fourth class, a character that seems to distinguish it essentially from the rest, namely, that they changed into nymphs without quitting their skin. He discovered that they undergo one transformation more than other insects; because before they become nymphs, they assume under their skin an elliptical form, or that of an elongated spheroid, in which no part of the animal is discernible; that in this state the head, thorax, wings, and legs of the nymph are inclosed in the interior cavity of the abdomen, from which they issue successively by the anterior part, nearly in the same manner as the extremity of the finger of a glove, which has been drawn in, is pushed out again. Thus, the insects of this class are not solely distinguished from others by their changing into nymphs under their skin, but principally in undergoing a double transformation before they become nymphs.

Bergman distinguishes three kinds of pupa, which he calls chrysalids, nymphs, and semi-nymphs. The first he describes as hard and motionless, that does not eat, and shews obscurely the members of the future insect; the nymph is tender, lying at rest, not eating, and which shews clearly the separate members of the future insect; the semi-nymph is furnished with legs, and runs, eats, and is hardly different from the larva, except in having the rudiments of the wings, which the larva wants.

This inquiry, if duly pursued, would lead to much farther digression. From what is already advanced we presume it will be apparent, that the writers prior to the time of Linnæus, or cotemporary with him, (for those alone are mentioned,) are not agreed in their manner of distinguishing insects in this third state of transformation; and that their appearance is so various in different tribes, while in this state, that they ought to be distinguished by several, instead of a single name. Fabricius, one of the most considerable entomological writers since the time of Linnæus, employs the word pupa in the same general sense as the latter; but he is the principal late continental writer worthy of consideration, who has imitated this example. The French naturalists chiefly follow Lyonet, with some slight variation. This arrangement is still susceptible of much improvement, but is notwithstanding perhaps the most perspicuous yet proposed. To the chrysalis properly so called, namely, those of the butterfly tribe, this name given to them by the Greeks is retained; the rest of those which have their members enveloped in a common skin are called nymphs, and are divided into three or four families, according as those parts are more or less visible through the exterior membrane. The term féve (bean) is also introduced, to express in a general manner this state of the insect, when of an oblong form, and distinguished only by a few annulations and eminences. Insects in the third state, which differ only from the perfect form in having half-wings, are called semi-nymphs.

In the present section, to avoid confusion, it may be more convenient to adopt the Linnæan term, and under this head describe such of the leading differences in insects as are observable in this state of transformation.

Coleoptera.—The nymphs or pupæ of this order have commonly the limbs detached or not laid under the exterior envelope close to the body, as in lepidopterous insects. Most of them bury themselves in the earth previously to this change; some form cells in decayed trees, others perforate seeds and nuts, and great numbers remain in the dung of animals, or other filthy substances, where the larvæ have been nourished. Their appearance, while in this state, is nearly the same in all, an emollient pupa of a whitish colour tinged more or less with brownish, and in form remotely resembling that of the moth kind, but with the limbs distinct. The mutations of scarabæus nasicornis affords an interesting description of the pupa of a coleopterous insect, and may serve as an example for the rest of the tribe. When the time approaches for this larva to change into the pupa form, it penetrates deeper into the ground than the larva had done before. Having found a proper place, it forms with the posterior feet a polished cavity, in which it remains for some time immoveable; after this, by voiding excrementitious substances, and the evaporation of moisture, it diminishes in size, and the skin becomes furrowed and wrinkled, as if the animal were partly starved. If dissected at this time, the head, belly, and thorax may be distinguished. While some external and internal parts are changing by a slow accretion, others are gently distending by the force of its impelled humours. The body, contracting itself while the fluid is propelled towards the fore parts, forces the skull open in three parts, and the skin in the middle of the back is separated by means of an undulating motion of the incisions of the back; at the same time the eyes and the horns, &c. cast off the exuvia. During this operation, a thin watery humour is diffused between the old and new skin, which renders the separation easier. The process going on, the larva is at last disengaged from its skin, and the limbs and parts are by continual unfolding transformed into the pupa state: after which it twists, and compresses the exuvia at the vent, and throws it towards the hinder parts under the belly. The pupa is at this time very delicate, tender, and flexible, and affords a curious spectacle.

The pupa of this beetle weighs, a little time after its change, much heavier than it does in the beetle state, which is also the case with the bee and the hornet, which latter have been known to weigh ten times as much as the insect when perfect. If the skin be taken off at this time, many curious circumstances may be noted, but what claims our attention most, is, that the horn which is so hard in the male beetle when in a state of maturity, that it may be sharpened on a grind-stone, in the pupa is quite soft and like a fluid. How long this particular remains in this state is uncertain, some beetles of the same kind rest in this form the whole winter, more particularly those who quit the larva state in autumn. Some beetles go through all the stages of their

 existence

exiftence in a feafon, while others remain two or three years even in the pupa ftate.

When the proper time for their final change arrives, all the mufcular parts grow ftrong, and are thus able to fhake off their laft integuments, which is performed exactly in the fame manner as in the paffage of the infect from the larva to the pupa ftate, fo that in this laft fkin, which is extremely delicate, the traces of the pulmonary tubes that have been pulled off and turned out again become vifible.

Hemiptera.—The pupæ in this order are the femi-nymphs of the old writers, and refemble the perfect infect in fize and figure, but are without wings. The rudiments of thefe members, of larger or fmaller dimenfions in different fpecies, are fituated at the pofterior parts of the thorax. They have the fame manners, and fubfift on the fame food as the perfect infects; and we have reafon for fufpecting that fome at leaft of thefe are not deficient in any of the animal functions.

Lepidoptera.—When the caterpillar of a butterfly or moth has attained its full growth, fome writers affirm, that the rudiments of the perfect fly may be diftinguifhed upon accurate inveftigation beneath the fkin. This is afferted by Swammerdam, who declared he could demonftrate all the parts of the future butterfly in a caterpillar near the change. To difcover this, it is directed, that the caterpillar be taken at the time the fkin begins to open, when it is to be drowned in fpirit of wine or fome ftrong liquor, and to be left therein for feveral days, that it may take more confiftency and harden itfelf, the fkin of the caterpillar muft be then removed, which will be eafily accomplifhed, and the inclofed moth will appear. The rudiments of the future infect are extremely tender, and fhould be touched with the utmoft delicacy, when the legs, antennæ, and other parts, may be unfolded and difplayed to view. The parts of the moth or butterfly are not exactly difpofed in the fame manner in the body of the caterpillar, as when left naked in the chryfalis. The wings are faid to be longer and narrower, being wound up in the form of a cord, and the antennæ are rolled up on the head, but in a very different manner from what it is in the perfect infect, and different from that in which it lies in the chryfalis; fo that it is by a progreffive and gradual change that the interior parts are prepared for the moth and pupa ftate; and even the eggs, hereafter to be depofited by the perfect animal, are to be found both in the caterpillar and pupa, the whole arranged in their natural and regular order.

Many of the chryfalides of the butterfly tribe poffefs a peculiar luftre in colour and brilliancy, refembling gold. It is not an appearance common to all butterflies, it is confined to certain fpecies, and is not feen in any of the pupæ belonging to the moth tribe. This colour does not appear immediately in the chryfalides, but is affumed by degrees as the inclofed infect acquires confiftency. It owes its fplendour to the luftre of the white or light colour of the inclofed animal fhining through the yellow tranfparent membrane of the cafe, as M. Reaumur has defcribed in his work. This metallic appearance feems to have afforded a favourable pretext to the alchemifts of former days, who were weak enough to draw delufive hopes from this appearance, and conceive it would afford them gold.

The following very curious and indeed inftructive defcription of the chryfalis of a butterfly is given by our countryman Lifter, nearly half a century before the fcience of entomology had made any confiderable progrefs on the continent of Europe, and from which it would appear, that in his time the knowledge of that fcience was in a great meafure confined to this country: it is from his annotations on the works of Goedartius,

"The middle ftate or difguife of a butterfly is called by the Greeks chryfalis, or a thing gilt, as the word importeth: the Latin hath left us no name that I know of: we have tranflated it aurelia. The Latins, however, call the caterpillar eruca; which is a word (as I guefs from a place in Vitruvius), which fignifies in the old Tufcan language viride æris, and thence borrowed to fignify a caterpillar: for fome caterpillars there are, which I have feen in Languedoc feeding on a certain common tithymal, very notably painted with a fea-green colour, or blue. So that as the gilding of fome few chryfalifes gave a denomination to all; in like manner, the blue colour of fome one caterpillar gave the name to all the reft: as for the gilding itfelf, I take it to be nothing elfe but the fcum of an evaporated juice between the fkin of the caterpillar and the fhell of the chryfalis, which laft it covers."

The butterfly remains only a fhort time in the chryfalis ftate, the interval between the larva and perfect ftate feldom exceeding ten, twenty, or thirty days. Thefe chryfalides are commonly fufpended by means of a few filken threads with the head downwards to the leaves or ftems of trees, or againft palings, &c. The chryfalis of the "common garden white" is a familiar example of this mode of fufpenfion, and of the brilliant appearance which this order of infects affume in this ftate.

The moth tribe remain much longer in the pupa form, and evince more care towards themfelves, in making choice of a fituation adapted to this defencelefs ftage of life. The caterpillar having acquired its full fize, feeks for a proper place in which it may remain in fafety during this period, and having made choice of this, prepares for the important change. Some fpin webs or cones in which they inclofe themfelves, others conceal themfelves in little cells which they form under ground, &c. Preparatory to the change the larva ceafes to take any food, empties itfelf of all the excremental matter which the inteftines contained, voiding at the fame time the membrane which ferves as a lining to thefe of the ftomach. It generally perfeveres in a ftate of reft and inactivity for feveral days about this time. In proportion as the change into the pupa form approaches, the body is obferved to extend and contract itfelf very often: the hinder part is firft difengaged from the fkin, and after a while the fkin is entirely caft off.

The caterpillar, thus ftripped from its fkin, is called the pupa; the exterior covering gradually becomes hard, while the interior remains fo foft that the flighteft touch will decompofe them. The exterior covering is at firft covered with a vifcous fluid, which thickening and drying up, forms a thin fkin or coat capable of refifting external injuries. Thofe who are defirous of tracing the various members of the future butterfly or moth in the pupa, fhould examine it before this fluid dries up.

The length of time an infect remains in the pupa form varies much in different fpecies. As foon as the inclofed animal acquires fufficient ftrength to break the bonds of its confinement, it makes a powerful effort to efcape. The moth frees itfelf from the pupa with greater facility than the pupa from the caterpillar; for the cafe of the pupa becomes fo dry, when the moth is near the time of throwing off its covering, that it will crack and break to pieces if it be only gently preffed between the fingers; and very few of the parts will be found, on examination, to adhere to the body. Hence, when the infect has acquired a proper degree of folidity, it does not require any great exertion to fplit the membrane which covers it: a fmall degree of motion, or a little inflation of the body, is fufficient for this purpofe; thefe motions reiterated a few times enlarge the hole,

hole, and afford the moth room to escape from its confinement. The opening through which they pass is always at the same part of the skin, a little above the trunk, between the wings and a small piece which covers the head: the different fissures are generally made in the same direction. If the outer case be opened, it is easy to discover the efforts the insect makes to emancipate itself from the shell. When the operation begins, there seems to be a violent agitation in the humours contained in the little animal; the fluids being driven with rapidity through all the vessels, the limbs and various parts of the body are put in motion, and by repeated efforts it breaks through the brittle skin that envelopes it. Those inclosed in cones or cases, after bursting through the pupa covering, have another difficulty to overcome, that of piercing through the inclosure, which, in many instances, is of a stronger texture than the case of the pupa. For the accomplishment of this, most insects are provided with a liquor, which they discharge from the mouth upon that part of the cone through which they intend to escape, and this so moistens and weakens it, that after a short time they force their passage through with some facility. Some insects not provided with this fluid leave one end of their cone weaker than the rest, and close it only with a few threads, so that a slight effort of the head enables the insect to burst from its prison.

The butterfly or moth, on emerging from the pupa, is moist and humid, the abdomen swollen, the antennæ bent down, and the wings crumpled, small, and shapeless. These parts gradually change and assume their destined form. The wings extend, and the fibres, which were at first flexible, become hard and rigid like bone. In proportion as the fibres lose their flexibility, the fluids which circulate within them extend, and the wings cease to act; so that if any extraneous circumstance arrests the progress of this fluid through the fibres, at the first instant of the moth's escape, the wings immediately become crippled, and never afterwards assume any other form. These parts expand with such rapidity, that the naked eye cannot entirely trace their developement. The wings, which at one instant are small and like four little buds at the sides of the thorax, in a few minutes after acquire their full size, so as to be nearly five times as large as they were before. Nor are they the wings only which are thus increased: all their spots and marks, heretofore so indistinct and small as to be scarcely discernible, are proportionally extended, so that what before appeared as only so many unmeaning and confused points, become distinct and beautiful ornaments. When the wings are unfolded, the tongue rolled up, the mouth sufficiently dried, and the different members strengthened, it takes its flight. Most insects, soon after they have attained their perfect state, void an excrementitious substance, which some suppose to be the last they eject during life.

If the moth be now opened down the belly, and the fatty parts which fill it be removed, the gross artery or heart will be visible, and the contractions and dilatations, by which it pushes forward the liquor it contains, may be easily observed. One of the most remarkable circumstances is, that the circulation of this fluid in the moth is directly contrary to that which took place in the caterpillar. In this it moved from the tail to the head, whereas in the moth its current is from the head to the tail. The intestines are now formed in a more delicate manner, and suited to a purer aliment than that on which it subsisted before its change into the pupa: the caterpillar devoured the grosser parts of vegetables; the nutriment of the perfect insect is the nectar of flowers. Many internal parts of the caterpillar disappear in the pupa, and many that could not be before perceived are at length rendered visible. And thus the creature, which heretofore crept on the earth, flies freely through the air, and, far from creating aversion by its foul appearance, now attracts attention by the elegance of its form and beauty of colour.

The industry of the caterpillar in the construction of its cocoon, or other repository, in which it passes the time destined for it to remain in the pupa state, is highly worthy of remark. Some caterpillars, towards the time of their change, suspend themselves from the branch of a tree, with the head downward, and are transformed in this position. Many of the moth kind cover with threads that part of the branch from which it means to suspend itself: it places these in different directions, and then covers them with other threads successively, till the cone in which it is to become a pupa is finished. The caterpillar hooks itself by the hinder feet to this hillock; and when it has found by several trials that it is strongly fixed thereto, throws itself forward, letting the body fall with the head downwards. Soon after it is thus suspended it bends the fore part of the body, which posture it retains for some time; then stretching the body, again in a little time bending it, and so on, repeating this operation till it has formed a slit in the skin upon the back. Part of the pupa soon forces itself through this, and extends the slit as far as the last crustaceous feet: the pupa then forces upwards the skin, by means of its little hooks, and the motion of the body, till it has slipped it off to that part from which the caterpillar had suspended itself.

The mode of suspension adopted by some insects is very different from that pursued by others. Some fix themselves in an horizontal position, by means of a girdle, which they tie round the body, so as to support the caterpillar, and yet leave it at full liberty to effect the changes: others suspend themselves in webs, in temporary habitations, formed by weaving together two or three leaves of the plant on which they feed, by means of silken threads. The industry of those which spin cones or cases, in which they inclose themselves, in order to prepare for their transformation, is very generally known from the familiar history of the common silk-worm, an insect from which man derives the most essential benefits. In northern Europe these advantages are scarcely known, and are esteemed valuable only in proportion as they contribute to the luxury of dress; because our woollens are better suited to the vicissitudes of the climates. But in a far more extensive portion of the habitable globe, silk constitutes an article of the first necessity in useful clothing; and hence the labours of this industrious little creature become in the highest degree important and beneficial to the human race.

The silky tissues of this insect are spun by the caterpillar, for the sole purpose of enveloping and suspending itself in security during its pupa state. The substance of which the silk is formed is a fine yellow transparent gum, contained in two reservoirs that wind about the intestines, and which, when unfolded, are about ten inches long; they terminate in two exceeding small orifices near the mouth, through which the silk is drawn or spun to the degree of fineness which its occasions may require. This apparatus has been compared to the instrument in use for drawing gold and silver into threads. Each thread proceeds from the two reservoirs at the same time, but they are united as the thread forms; so that, if examined by the microscope, it will be found to consist of two cylinders or threads glued together, with a groove along the middle, and in which sometimes even a separation may be perceived.

When the silk-worm is near the time of change to the

pupa,

pupa, the refervoirs of filk are full, and it is preffed by its fenfations to relieve itfelf from this incumbrance. Having made choice of a convenient fituation, the operation of fpinning commences. At firft it throws out fome loofe thread, which ferves to fupport the future fuperftructure: upon thefe it forms an oval of a loofe texture, confifting of what is called flos filk; and within this it forms a firm and more confiftent ball of filk. It is now inclofed within the circumference of the fpheroid, the interior of which is the fcene of its further operations: in this it is feen refting on its hinder parts, and with its mouth and fore legs directing and faftening the threads. Thefe threads are not directed in a regular circular form, but are fpun in different fpots, in an infinite number of zig-zag lines; fo that, when wound off, it proceeds in a very irregular manner. This thread, when meafured, has been found to be about three hundred yards long, and fo fine that eight or ten are generally rolled off into one by the manufacturer. The filk-worm ufually employs about three days in finifhing this cone; the infide is generally fmeared with a kind of gum, which is defigned to keep out the rain. It next affumes the pupa form, in which it remains from fifteen to thirty days, in different climates, before the moth is produced. When the infect intends breaking from the cocoon, it moiftens one end of the cone, and by frequent motions of the head loofens the texture of the filk, fo as to form a hole without breaking it. See Silk-Worm, *Phalæna Mori*.

From a feries of experiments made by Reaumur on the filk of this infect and that of the fpider, in order to afcertain their comparative excellence, it was found that the thread would bear the weight of thirty-fix grains, while that of the fpider could not fuftain twelve grains, breaking under its weight. There are filks fpun by other infects, with which we are little acquainted, that in point of ftrength far exceeds that of the common filk-worm. The popular opinion, that the filk worn in different parts of the world is the fole produce of this fpecies (phal. mori), is erroneous. This kind of filk is generally efteemed for its peculiar beauty and delicacy of texture. There are others lefs coftly, which, from their fuperior ftrength, are better adapted to common wear, and are for this reafon in more general ufe in fome parts of the globe. The filk obtained from the cocoons of the two fpecies of bombyces paphia and cynthia are of this kind, as appears from an interefting paper on thefe infects by Dr. Roxborough, F.L.S., inferted in the feventh volume of the Tranfactions of the Linnæan Society.

Thefe infects bear the names of tuffeh and arrindy filk-worms in India: both exceed the common filk-worm in fize, the firft efpecially, which is one of the largeft of the attaci family of bombyies, and the filk of which appears to be more valuable than that of the other kind.

The tuffeh filk-worm is found in fuch abundance over many parts of Bengal, and the adjoining provinces, as to have afforded the natives from time immemorial an ample fupply of a moft durable coarfe filk, commonly called tuffeh filk, which is woven into a kind of cloth called tuffeh doot'hies, much worn by the Bramins, and other fects of Hindoos. This fubftance would no doubt be highly ufeful to the inhabitants of many parts of America, and the fouth of Europe, where a cheap, light, cool, and durable drefs, fuch as this filk makes, is much wanted. The caterpillar, when full grown, is about four inches in length, and bulky in proportion; its colour green, with a lateral ftripe of yellow edged with red. The plate in which the caterpillar is reprefented, if we miftake not, is engraven from a drawing executed by an Indian artift, and muft be received with fome allowance for inaccuracy; but from this we may collect that it has a fingle feries of yellow oval dots beneath the lateral line, (amounting to fix or feven in number,) which are perhaps its fpiracles; and thefe, in the defcription, are denominated fpecks of gold colour. When thefe are ready to fpin, each connects, by means of the recent glutinous filament of which the cafe is made, two or three leaves of the jujube tree, the vegetable on which they feed. Thefe connected leaves form an exterior envelope, which ferves as a bafis to fpin the complete cafe or cocoon in; and "befides this," fays the writer, "the cafe is fufpended from a ftrong branch of the tree in a wonderful manner by a thick, ftrong, confolidated cord, fpun of the fame materials from the bowels of the animal." It remains nine months in the pupa ftate. The infect, when produced, expands to the breadth of five or fix inches, and thofe of the female to eight inches.

There is another kind of wild filk-worm produced in the Burbhoom hills, which is faid to be more capable of being domefticated; and a fourth fort, a fuppofed variety of the tuffeh-worm, in the hills near Bauglipore, the cocoon of which is fmaller than that of either of the two firft mentioned.

The arrindy filk-worm ftill remains to be noticed. This is of a fpecies altogether different from the former, and is the bombyx cynthia of entomologifts. This infect, known to the Hindoos by the name of arrindy in fome parts, and in others arrundi, appears to be peculiar to the interior parts of Bengal; and it is prefumed, may be even confined to the two diftricts Dinagepore and Rungpore, where the natives breed and rear it in a domeftic ftate, as they do the common filk-worm. The food of the caterpillar confifts entirely of the leaves of the common ricinus or palma chrifti, which plant is cultivated abundantly over every part of India, on account of the oil obtained from the feed. The Hindoos call this plant arrindy, and hence is derived the name of the infect. The caterpillar, when full fed, is about three inches long; the colour pale green; and each fegment verticillated with a few conic tubercles difpofed in a fingle line. The cocoon is white or yellowifh, of a very foft and delicate texture, about two inches long, and three in circumference, and pointed at each end. There is a wide diftinction between this fpecies and B. paphia, in the period it remains in the pupa form; this requiring at the utmoft not above twenty days, inftead of nine months, to complete its laft transformation.

The filaments of which the cocoon is compofed are fo exceedingly delicate, that it is faid to be impracticable to wind off the filk: it is therefore fpun like cotton. The cotton, thus manufactured, is wove into a coarfe kind of white cloth, of a feemingly loofe texture, but of incredible durability; the life of one perfon being feldom fufficient to wear out a garment made of it, fo that the piece defcends from mother to daughter. Some of the Indians, however, have a method of fpinning the filk of this fpecies, and the procefs is related as follows. Four or five of the cocoons are faftened to a piece of wood, with fomething heavy to make it fpin round, while fufpended by the thread. When they let out a fufficient quantity of the cocoons from their hand, it is twifted by this piece of wood fpinning round; and when well twifted, it is wound round the wood, and another length let out of the hand. The cocoons are fpun wet, but only with cold water. The cloth is woven in fmall pieces in a loom: its ufes are for clothing for both men and women; it will conftantly wear ten, fifteen, or twenty years. This filk muft be always wafhed in cold water; for if put into boiling water, it will tear like old rotten cloth. Some

manufacturers

manufacturers feem to be of opinion that fhawls, and other filken articles of drefs, equal in quality to any manufactured in India, could be fabricated with this material. There is reafon to apprehend that this filk is highly valued in India; nor can we entertain the leaft diftruft of its want of durability, fince it is well known that the coverings of their palanquins are of this particular kind of filk.

On further inveftigation and refearch into the hiftory of the larger fpecies of the bombyx tribe, we are perfuaded others will be found to form cocoons or pupa fpinnings, which, with proper attention and culture, may hereafter be productive of fimilar advantages. We are not ignorant that in other parts of Afia, and in America, there are many fpecies that fpin in the fame manner an envelope round the pupa; and fome of thefe at leaft, we muft fuppofe, capable of producing a filk of beauty and durability equal to fome of thofe in prefent ufe. We fhould not be furprifed to learn that bombyx atlas, the moft confiderable in magnitude of all the moth tribe, is exprefsly reared in China for the fake of its filk. We fufpect this to be the truth. It would be defirable alfo to afcertain whether the cocoons of the fpecies hefperus, cecropia, cytherea, promothea, and fome others, could not be beneficially employed in the production of filk. Mr. Abbot, in his Infects of North America, fpeaks generally of fome attempts being made to fabricate the filk of one or two of the larger moths of that country; the cloth prepared from which is reprefented as ftrong and durable: but he expreffes doubt how far the experiment might be ufeful, as the infects which produce the filk are not abundant. This objection might eafily, we fhould imagine, be obviated by cultivation: infects are highly prolific, and if they could be reared in what may be termed a domefticated ftate, could be produced in any numbers.

Among a variety of other curious information which this paper conveys, the following circumftances appear fo amufing, and feem to reflect fuch new light on the hiftory of thefe ufeful infects, that we cannot refrain repeating them. The cocoons of this infect, bombyx paphia, feed on the leaves of a plant called byer by the Hindoos (rhamnus jujuba), and likewife on the plant they call affeen (terminalia alta glabra of Roxb.). They are annual, remaining nine months in the pupa ftate, and three months in that of the egg and caterpillar. The fpecies cannot be domefticated, nor can the natives even retain any for feed. The hill people fay, they go into jungles, and under the byer and affeen trees they find the excrement of the infect; on which they examine the tree, and, on difcovering the fmall worms, they cut off branches of the tree fufficient for their purpofe, with the young brood on the branches. Thefe they carry to convenient fituations near their houfes, and diftribute the branches on the affeen tree, in proportion to the fize of them; but they put none on the byer tree. The Parieahs, or hill people, guard the infects night and day, while in the worm ftate, to preferve them from the crows and other birds by day, and from bats by night. As foon as the moth pierces the cafes, it efcapes; nor do the people prevent this, as they have learnt by experience that it cannot be kept alive more than a few days, and that retaining it would not be attended with any advantage.

To wind off thefe cocoons, the natives put them into a ley made of plantain afhes and water for about two hours; after which they take them out of the ley, and put them in their wet ftate into an earthen pot: thofe which are properly foftened are firft applied to the reel, and fo on as the cocoons become foft, for four or five days, till the whole are wound off. The implement ufed for taking off the thread is a fmall common reel of four bars. The cocoons are laid in a fmooth earthen difh without water; the reel is turned by the right hand, whilft the thread of four or five cocoons paffes over the left thigh of the fpinner, and he gives the thread a twift with his left hand upon his thigh. The thread is exceedingly apt to come off double and treble for feveral yards together, which is not regarded by the natives, as breaking off double threads would diminifh the produce, and moreover would occafion lofs of time: a very even thread, however, with care may be reeled off. The bughy filk-worm feeds indifferently on byer or affeen leaves.

The jarroo cocoon is the pupa fpinning of an infect clofely allied to the preceding, but whether a diftinct fpecies or variety, from the knowledge we at prefent poffefs, feems difficult to determine. Thefe are called the jarroo cocoon, from being produced in January, the coldeft month of the year; and the natives affirm, that they are different from the bughy. The jarroo will eat the byer leaf, if it cannot get the affeen; but will always prefer the latter, and will produce better cocoons when fed on it. The filk is duller in colour. The natives are able to retain part of the jarroo cocoons for feed. Thefe they hang out on the affeen trees, when the proper feafon of the moth arrives. The males, when hatched, invariably fly away; but the females remain on the trees. Thefe are not impregnated by the males bred along with them, but in ten or twelve hours, or perhaps two or three days, a flight of males arrive, fettle on the branches, and impregnate the females; and it is worthy of remark, that the hill people confider it good or ill fortune, in proportion to the fpeedy or tardy arrival of thefe male vifitors. The purpofes of nature accomplifhed, the males expire, and the females live only long enough to depofit the eggs in fafety on the branches of the trees. Thefe males are fuppofed by the natives to come from a vaft diftance: it is affirmed even, that by marking the wings of a number of males, previoufly to letting them fly, their progrefs in queft of the females has been traced to the diftance of one hundred miles and upwards. This, though remarkable, is not more extraordinary or unworthy of credit than the circumftance (if truly ftated), that the males and females of the fame brood never affociate together in any manner, when they enter the fly ftate; the males regularly flying off in fearch of another brood of females, and leaving thofe of their own family to the embraces of another flight of males.

There is a caterpillar which forms its filken cone in the fhape of a boat turned bottom upwards, whence it is called by Reaumur "coque en batteau." It confifts of two principal parts, each of which is framed by itfelf, and formed of an innumerable quantity of minute filk rings; in the fore part there is a projection, in which a fmall crevice may be perceived, which ferves when opened for the efcape of the moth; the fides are framed with fo much art, that they open and fhut as if framed with fprings; fo that the cone from which the fly has efcaped appears as clofe as that which is ftill inhabited.

Thofe caterpillars which do not fpin a cone fupply that want with various materials, which they form into a habitation to fecure them from injury while in the pupa ftate: fome form a covering with leaves and branches tied or made faft together, others connect the leaves with great regularity; many ftrip themfelves of their hairs and form a mixture of hair and filk, others conftruct a cone of fand or earth, cementing the particles together with a kind of glue:

ſome gnaw the wood into powder, or like ſaw-duſt, and cement it together; and others make caſes in holes, which they form in the trunks of trees.

The period of their change into the chryſalis or pupa ſtate is very regular in moſt inſects, unleſs in ſeaſons peculiarly unfavourable. Some change in May, others in June, July, Auguſt, and September, and the time of emerging from the ſtate of pupa is fixed with no leſs preciſion. This is a fact well known to every practical entomologiſt. Some remain in the pupa ſtate only twelve or fifteen days, others twenty or thirty, and theſe are chiefly of the butterfly tribe. Thoſe of the moth kind are commonly much longer, ſome remaining in this ſtate only two or three months, others ſix, nine, or twelve, ſome two years, and others even it is known ſo long as three years. Lyonet has remarked, that the periods of change to the chryſalis ſtate is not ſo conſtant, but that a degree more or leſs will affect it. The ſame inſect, he ſays, which in the middle of ſummer would have acquired its utmoſt ſize in leſs than three weeks, will require as many months, and even much more if it comes forth at the end of the ſeaſon. And again, he obſerves, that ſuch a nymph or chryſalis which in ſummer will change into a winged inſect in fifteen days, will employ ſometimes ſix, ſeven, or eight months for the ſame purpoſe, merely from having gone into the chryſalis ſtate a few days later than thoſe which have changed ſo rapidly. That particular incidents may occaſionally juſtify theſe remarks of Lyonet, we ſhall not diſpute, but this can be only underſtood of in-inſects hatched in ſeaſons of unuſual inclemency, or under circumſtances in the higheſt poſſible degree uncongenial to their transformations. Irregularities will ariſe from this cauſe. In general, however, the appearance of every ſpecies (whoſe hiſtory is once correctly aſcertained) whether in the larva, pupa, or winged ſtate, may be determined by the time of the year. Moſt inſects perform all their changes within the courſe of twelve months, and are found in their ſeveral ſtates at particular periods annually; others have two broods in the courſe of that time, and conſequently appear in the ſame ſtate at two different periods of the year.

Neuroptera.—Some of this order are ſemi-nymphs, as the libellulæ and ephemeræ, in which the rudiments or half-wings are developed, and which eat and purſue the ſame manners of life as the larva. Others are like the nymphs of the coleopterous order in appearance, and lie dormant in the ground, generally in caſes conſtructed of extraneous materials. The myrmelion forms a hollow ball of ſand for this purpoſe.

Hymenoptera.—In the pupa of the cynips the limbs are partially diſcloſed in its external figure, and it remains in the central cavity of the gall in which it lives during the ſtate of larva, while in the pupa form. The tenthredo forms a kind of exterior caſe or envelopement, within which it aſſumes the pupa form, and which in ſome kinds reſembles the texture of thin parchment. The pupa of the ſirex is quieſcent, and is uſually found lodged in timber: this has the limbs diſtinctly formed. The pupæ of the ichneumons are incloſed in oblong ſilken cones. Thoſe of the waſps and bees are well known. In the ants the limbs are diſtinct.

Diptera.—The pupæ of the tipulæ are uſually cylindrical like the larva, and quieſcent; many of the muſcæ appear of an elongated egg ſhape, without any ſegmental diviſions, and totally devoid of motion. The pupa of the culex is curiouſly incurvated and ovate, with reſpiratory tubes, through which it breathes; it is an inhabitant of the waters. The egg of the hippoboſcæ ſerves in lieu of a pupa, or in other terms the hippoboſcæ are oviparous, and have no pupa.

Aptera.—As the individuals of this order are produced with few exceptions in the perfect form from the egg, they have no pupa, at leaſt the common flea is the only inſtance to the contrary; this undergoes the uſual transformations from the egg to the perfect ſtate; its pupa reſembles that of ſome coleopterous inſects when magnified.

Imago: the final or perfect ſtate which all inſects aſſume after paſſing through the ſucceſſive changes from the egg, the larva, and pupa form; which latter it quits in the imago ſtate. This might, with more ſimplicity, be termed the winged ſtate, were it not that ſome inſects, after quitting the pupa, are apterous, or without wings. In the imago form the inſect is in every reſpect perfect in all its parts, and poſſeſſed of every function which nature has intended the ſpecies to enjoy.

Habitation of Inſects.

Inſects are of two kinds, aquatic and terreſtrial, and their habitation muſt be conſidered ſeparately.

Some live only in watery places, appearing occaſionally on the ſurface of that element, and which very rarely plunge themſelves in, or if they fall in, either riſe again immediately to the ſurface or periſh. Others live only in water, and cannot ſubſiſt out of it. Many, after having lived in the water while in the larva and pupa ſtate, come out afterwards with wings, and become entirely terreſtrial. Some undergo all their transformations in the water, and then become amphibious. Others again are born and grow in the water, but remain during the pupa ſtate on dry land, and after they attain their perfect form live equally in air and water. There are, laſtly, ſome who live at the ſame time occaſionally both in the water and on land, and which, after their transformation, ceaſe to be aquatic.

Among the inſects which remain on the ſuperficies of the water, are ſome ſpiders which run with great addreſs and agility, without moiſtening their feet or their body. There are aquatic cimices which ſwim or rather run on the water with great velocity, and by troops, as may be often ſeen on the ſurface of ſtill water. Some walk ſlowly on the ſurface. The gyrinus moves ſwiftly and in circles. The nepæ are of that kind which live only in the water, and cannot ſubſiſt out of it, or at leaſt can remain out of it only a ſhort time. The number of thoſe which, after having lived in the water, leave it when in a winged ſtate is very great: among theſe are the libellula, the ephemera, the phryganea, culex, tipula, and ſome other ſpecies of muſcæ; all theſe are of the aquatic kind, both in the larva and pupa ſtate, but when they have aſſumed their perfect form are entirely terreſtrial, and would be drowned therein. The kinds moſt ſtrictly amphibious are the water beetles, ſuch as the dytiſcus and hydrophilus; theſe remain in the water all day, but towards evening come upon the ground and fly about, plunging themſelves again into the water at the approach of ſun-riſe: the larvæ of theſe inſects are entirely aquatic; but when the time of their pupa ſtate arrives they deſcend into the earth, where they make a ſpherical caſe, thus becoming entirely terreſtrial, and in the perfect ſtate are amphibious.

Moſt inſects of theſe tribes prefer ſtagnant waters, others thoſe of a purer nature, and we have inſtances of certain inſects which inhabit, with perfect convenience, ſprings of a warm and mineral nature. At the baths of Abano, in the Venetian ſtates, is a ſpring of this deſcription, impregnated with ſulphur, in which ſmall water beetles are ſeen ſwimming about, and which die on being taken out and plunged into cold water.

Many

Many insects that live under the surface of the earth in the perfect state crawl out occasionally, as the mole cricket, and some of the aptera, as the julus and scolopendra; these are generally found in the earth under stones, or beneath rotten wood in damp situations. Some insects remain underground part of their life, but quit that situation after their change, as in the coleoptera. A vast number of others live in animal substances of every kind. The habitation of some, as the myrmeleon formicarius, is curiously constructed in the sands.

There is a species of spider found in Jamaica (aranea venatoria) which burrows in the earth like a rabbit; it is of a size very far surpassing the largest of the European spiders, and is not uncommon there. This creature forms a hole twelve or fifteen inches deep, of a cylindrical shape, rather more than an inch in diameter, and which it lines with a thick coat to prevent the earth from tumbling in. The aperture is closed with a kind of lid or door attached by a single hinge, and which open outwardly, falling down and shutting the aperture by its own gravity. Into this the spider retires with its prey, and devours it in safety, as few insects can penetrate into its cell. These nests or cases form a complete habitation, should the sands in which they are constructed give way.
