Insects of the lepidopterous order are very rarely carnivorous; there are instances of this, but these are uncommon. Their food and that of many other insects are of the vegetable kind, and their habitations are trees and plants. The oak and the willow among trees, and numbers of different plants among herbage, are the natural habitation of insects in great abundance. Some live in the roots, others in the wood; in the leaves, and in galls formed therein; in flowers; in fruit; and in grain. Some caterpillars form a kind of hammock, in which they eat and go through their various changes; while others construct a tent, under which they live till they have consumed the surrounding herbs, when they leave their abodes and pitch their tents in another spot, where they can find abundance.

Many insects associate together all their lives, others only for a certain period. Those who live together proceed from the same moth who deposited the eggs near each other, or laid them in a heap, and thus formed a kind of nest. These are generally hatched about the same time, and live together, forming a kind of republic. These societies include two, three, or four hundred individuals, and usually live inclosed in a large web, like the lackey moth, (phal. neustria) and the ermine moth. Of these social caterpillars there are some kinds which never quit the society to which they belong, but pass into the pupa form in the same nest. One of the most remarkable of these caterpillar communities is that of the bombyx processionea. These live on the oak separate till they arrive at a certain age, when they associate together, and do not quit their society till they acquire their perfect form. As the number of the caterpillars thus assembled is considerable, the nest is also very large. They remain in their habitation till sun set. When they go out one of the body precedes the rest as a chief, whom they regularly follow. When the leader stops the rest do the same, and wait till it goes on again before they recommence their march. The first file generally consists of a single caterpillar, which series is succeeded by a double file, these by three in a row, which are then followed by files of five, and so on. They keep close to each other, not leaving any interval either between the ranks or between those in each rank, all following their captain in compact order, whether in a straight or irregular course. After they have taken their repast they return to the nest in the same order as they set out. This conduct is regularly pursued till they are full grown, when each spins a cone for itself in the nest. It has been remarked, that though these caterpillars proceed often very far from the nest, it is by no means difficult for them to get back again, because they spin a thread in their route. The first leads the way, the second follows spinning, the third spins after the second, and soon forming thus a path of threads.

Upon the same tree, shrub, or plant, we often find numbers of caterpillars which have no affinity to each other, and of which the actions of one have no influence over the manners of the other; they may in this respect be considered solitary. There are others who seem still more independent of each other even than these, because they shun all intercourse, constructing lodgments formed of leaves tied together with considerable ingenuity, in which they live as in an hermitage. The operation by which these caterpillars tie the leaves together is far surpassed by another kind, who fold and bend one part of the leaf till it meets the other. These are again excelled by those who roll the leaves which they inhabit. For this purpose the caterpillar makes choice of part of a leaf which it finds in some degree bent; here its work commences, the caterpillar moving the head with great velocity in a curved line, or rather vibrating it like a pendulum, the middle of the body being the centre on which it moves. At each motion of the head a thread is spun and fixed at that part to which the head seems to be applied. The threads are extended from the bent to the flat part of the leaf, and the curvature which is to be given to it. There is another species of which it is observed, that at each new thread it spun, the edges of the leaf insensibly approached to each other, and were bent more and more, in proportion as the caterpillar spun new threads; when the last thread was spun, that which preceded it was loose and floating in the air. To effect this the caterpillar, after it has fixed a thread to the two edges of the leaf, and before it spins another, draws it towards itself by the hooks of its feet, and by this means bends the leaf; it then spins another leaf to maintain the leaf in this position, which it again pulls towards itself, and repeats the operation till it has bent the leaf in its whole direction. It now begins again placing the threads further back, upon the bent part of the leaf, and by proceeding in this manner it is rolled up; when it has finished this business it strengthens the work by fastening the ends of the leaf together. The habitations thus formed are open at both ends, and within which the insect feeds in safety. At the approach towards the pupa state, the caterpillar lines the rolled leaf with silk, that the rougher parts may not injure it.

A great number of the smaller larvæ require an artificial covering to protect them. Some inhabit the interior part of leaves in which they form large oval or circular spaces; others form a kind of gallery within, which in some is straight, in others crooked. Many of the tineæ are found lodged in cylindrical tubes or cases, which they form of different substances closely woven with fine silken threads. The small caterpillar found in neglected woollens and other similar articles is of this kind, living in a cylindrical case, and producing a small moth.

The phryganea larvæ construct cases somewhat similar in form, and which are also open at both ends; in these the larvæ reside, the outside is formed of different substances, such as bits of reed, stone, gravel, and small shells, which they arrange and manage with singular dexterity. When they walk they only advance a few of the anterior rings of the body, training the case after them. When they are

about

about to aſſume the pupa form they cloſe up the ends with ſilken threads.

But the habitations of theſe inſects, though conſtructed with ingenuity, are in no manner comparable with the architectural fabrications of many other inſects, as thoſe of the waſp, the bee, the common ant (formica), the white ant (termes), &c. The ſtructure of the neſts conſtructed by the common waſp, and the common honey bee, cannot be unknown to any reader. Among the habitations of the ſolitary, or thoſe called the wild bees, there are many which deſerve remark. Some of the bee tribe penetrate into the earth, where they form ſmall contiguous cavities, in each of which they depoſit an egg, with a ſufficient quantity of proviſions for the ſuſtenance of the larva. There is one kind whoſe neſt conſiſts of ſeveral cells artfully let into each other, but not covered with a common incloſure; each cell conſiſts of two or three membranes, inexpreſſibly fine, and placed over each other. The cavity in which the neſt is placed is ſmeared over with a layer of matter, like that of which the cells are formed, and apparently ſimilar to that viſcous humour which ſnails ſpread in their paſſage from one place to another. An egg is depoſited at the bottom of each cell, where, after it is hatched, the grub finds itſelf in the midſt of a plentiful ſtock of proviſion, for in each cell there is placed a quantity of paſte, or a kind of wax, which is to ſerve as food for the worm, and as ſupport to the wall of the cell.

Another ſpecies that forms its neſt under ground makes a perpendicular hole in the earth about three inches deep and cylindrical, till it comes within three-fourths of an inch of the bottom, when it begins to open wider. The ſuitable proportions being given, the bee proceeds to line with tapeſtry not only the whole of the inſide, but alſo the entrance; the ſubſtance with which it is lined is of a crimſon colour, and appears as very beautiful. This lining is formed of fragments of the flowers of the poppy, which the bee cuts out curiouſly, and then ſeizing them with her legs conveys them to her neſt. If theſe pieces are rumpled, ſhe preſſes them ſmooth, and then affixes to the walls of her cell; or if the piece ſhe has cut and tranſported is found too large, ſhe clips off the ſuperfluous parts, and conveys the ſhreds out of the apartment. After the bee has lined the cell, ſhe fills it nearly half an inch deep with a kind of paſte, proper to nouriſh the larva when hatched from the egg. When the bee has amaſſed a ſufficient quantity of paſte, ſhe folds the tapeſtry over the paſte and the egg, which is by this means incloſed as it were in a bag of paſte; and the bee then fills up with earth the empty ſpace that is above the bag. Another of the bee tribe is ſaid to conſtruct its neſt in the ſame way, with this difference only, that the lining is of the corolla of the roſe.

The carpenter bee (apis centuncularis) conſtructs her neſt in pieces of wood, whence the name; in this ſhe perforates long cylindrical hollows, which ſhe divides into ſtages, and depoſits her eggs, each incloſed in a curious cylindrical caſe formed of leaves, not quite an inch in length, and leſs than half an inch in diameter, and theſe are diſpoſed endwiſe one above another to the amount of ten, twenty, or more, the cylindrical perforation in the wood being two or three feet long, or ſometimes more. They bore the wood moſt commonly in the longitudinal direction of its ligneous fibres, but this is not always the caſe. There are ſeveral ſpecies of this order in appearance much like each other. The leaves which form the lining of the caſes in one ſpecies is that of the roſe.

The former are called the carpenter bees on account of the holes which they bore in the wood; there is another which bears the name of maſon bee, from the peculiar ſtructure of the neſt. Their manner of building is this: the bees collect with their jaws ſmall parcels of earth and ſand, which they glue together with a ſtrong cement, which is furniſhed from the proboſcis; and of this they form a ſimple but commodious habitation, which is generally placed along walls that are expoſed to the ſouth. Each neſt reſembles a lump of rude earth of about ſix or ſeven inches diameter, thrown againſt the wall; the labour of conſtructing an edifice of ſuch magnitude muſt be conſiderable, as the bee can only carry a few grains at a time. The exterior form is rude and irregular, but the art exhibited within more than compenſates for the ruggedneſs of the external appearance. The interior is divided into twelve or fifteen cells, ſeparated from each other by a thick wall; in each of theſe an egg is depoſited by the parent bee. The cells are conſtructed progreſſively, for when one is finiſhed ſhe places an egg in it, with a ſufficient quantity of honey to nouriſh the larva; ſhe then builds another, and ſo proceeds till all her eggs are depoſited. When the young are hatched the ſtrength of their jaws enable them to penetrate through their cells with perfect eaſe.

There is a ſpecies of ſphex called the ichneumon waſp, whoſe manner of conſtructing the neſt is ſtill different from either of thoſe before mentioned. This little creature generally begins its work in May, and continues its labours through the greater part of June. The object of her labour ſeems at firſt to be the digging of a hole a few inches deep in the ground, in the conſtruction of which ſhe forms however a hollow tube above ground, the baſe of which is the opening of the hole, and which it raiſes as high above ground as the hole is deep below; it is formed with great care, reſembling a coarſe kind of fillagree work, conſiſting of the ſand drawn from the hole. The ſand out of which ſhe excavates her cell is nearly as hard as a common ſtone. This it readily ſoftens with a penetrating liquor, with which ſhe is well provided; a drop or two of it is imbibed immediately by the ſand on which it falls, which is inſtantly rendered ſo ſoft, that ſhe can ſeparate and knead it with her jaws and fore feet, forming it into a ſmall ball, which ſhe places on the edge of the hole as the foundation ſtone of the pillar ſhe is about to erect; the whole of it is formed of ſuch balls, ranged circularly, and then placed one above the other. She leaves her work at intervals, probably in order to renew her ſtock of that liquor which is ſo neceſſary for her operations; theſe intervals are of ſhort duration; ſhe ſoon returns to her work, and labours with ſo much activity and ardour, that in a few hours ſhe will dig a hole two or three inches deep, and raiſe a hollow pillar two inches high. After the column has been raiſed to a certain height perpendicularly from the hole, it begins to curve a little, which curvature increaſes till it is finiſhed, though the cylindrical form is preſerved. She conſtructs ſeveral of theſe holes, all of the ſame form and for the ſame purpoſe. It is evident the hole was dug in the ground to receive the egg, but the purpoſe of the tube of ſand is not very apparent. By attending to the labours of the waſp, one end, however, may be diſcovered; it will be found to ſerve the purpoſe of a ſcaffold, and that the balls are as uſeful to the waſp as materials to the builder, and are therefore placed as much within her reach as poſſible. She uſes it to ſtop and fill up the hole after ſhe has depoſited an egg in the cell, ſo that the pillar is then deſtroyed, and not the leaſt remains left in the neſt. The parent inſect generally leaves ten or twelve worms as proviſions for the young larva.

In

In all thefe fabrications there is a degree of ingenuity in defign, and exactnefs of execution, which, independently of the labour required in their conftruction, excites our admiration. The talent, if it may be fo expreffed, of the infect race, is more obvioufly difplayed in the formation of the dwellings than in moft other particulars of their hiftory. It is a pleafing fubject of inquiry, and extremely worthy of attention, but for an elementary difcourfe we have, perhaps, already purfued thefe obfervations to a due extent, and fhall therefore conclude with a concife account of one other, which, from its ftupendous dimenfions, the order, regularity, and beauty of its architectural defign, and inimitable convenience to the purpofes for which it is intended, cannot fail to excite the aftonifhment of every obferver: it may be anticipated that the allufion is to the buildings of the termites. Thefe diminutive infects, known more generally by the name of the white ants, though, technically fpeaking, they are entirely of a diftinct genus, are natives of the Eaft Indies, Africa, and the fouthern parts of America. They live in focieties, each of which is compofed of fome thoufand individuals, all of whom are accommodated in the fame habitation. Their ftructures are of a pyramidal form, rifing to the height of ten or twelve feet, and covering no inconfiderable extent of ground at the bafe. They ufually build in the plains feveral contiguous to each other, and from their fize and form may fometimes be miftaken at a diftance for the huts of the natives.

Thefe nefts are fo common all over the ifland of Bananas, and the adjacent continent of Africa, that it is fcarcely poffible to ftand on an open place where one of thefe buildings is not to be feen. The domes are fo ftrong that they will eafily bear the weight of three or four men ftanding on them at once, and fhelter the interior from every attack of the weather. The interior is divided with the utmoft regularity into an immenfe number of apartments, arched chambers, magazines, and avenues leading to them; and the centre, on a level with the ground, contains the royal apartment, in which the queen refides, furrounded by the nurfery, &c. The white ant is the termes fatale; there are two, if not more, fpecies befides, namely, deftructor and arda, both inhabitants of Africa, which build nefts of a fimilar form, but of much fmaller fize. See the article TERMES.

Food of Infects.

Infects feed on all kinds of vegetable and animal fubftances. There is fcarcely any production of thefe two kingdoms which does not ferve for food to fome kinds of infects. They may therefore be confidered under two heads; thofe which live on vegetables alone, and thofe fupported chiefly on animal food. The organs of the mouth point out the very wide diftinction nature intended in this refpect, fome being adapted to the purpofes of maftication, others to that of fuction only; fome, like ruminating animals, have two ftomachs, others only one; the alimentary canal in fome is fhort, in others long, and upon the whole, their internal conformation, as well as external form, prefents the moft ftriking differences, each being in a peculiar manner adapted to the nature of the food upon which the animal fubfifts.

There is yet another circumftance well worthy of remark; in all thofe infects which undergo material change, the transformation of their external figure is accompanied with an entire revolution in their internal ftructure and economy; the larvæ deftined to feed on vegetables, or the grub on carrion, after effecting their transformation, prefent no longer the fame appearance within; parts adapted to their former mode of life, and inapplicable to their prefent one, totally difappear, and other organs, either before not exiftent, or which remained concealed, are now developed. The ftomach of the butterfly, when in the larva ftate, is adapted to the reception and digeftion of its vegetable food, as its organs of maftication are to its previous preparation; but this ftomach and this mouth both difappear in the butterfly, and other organs make their appearance; its mode of life is totally changed; it derives its fuftenance from the nectar of flowers, and its whole conformation is adapted to its new mode of life. Thefe arguments are not inferred from a few folitary inftances; they are exemplified in numberlefs examples: nothing is more common than to find the larvæ fubfifting on food altogether different from that which fupports the fame infect in the winged ftate.

Among thofe numerous tribes which feed on vegetables, fome fink into the earth, where they feed on the roots of grafs, and do confiderable injury to gardens. The food of others is dry and hard; they pierce the wood, reduce it to powder, and then feed on it: in this manner many of the cerambyx tribe and other coleoptera feed in the larva ftate. Some attack the leaves, eating the whole fubftance, except the principal nerves; while others feed only on the parenchymous parts which are contained between its fuperficial membranes, forming paths and galleries within. Thefe infects are not always content with the leaf; fome eat the flowers, and even this food is too grofs for many; the bee, the butterfly, the mufca, and a hoft of others, feed only on the nectareous juices, or the farina which they collect from flowers, or the delicious fluids of fruits. Corn and other grain are not free from them; they divide the produce with us, or often deprive us of large quantities. They infinuate their larvæ into the moft tender parts, and each oftentimes deftroys more than would be fufficient to feed fifty of them. We frequently find the larvæ of fome infects in pears, plumbs, peaches, and other fruit. There, indeed, appears fcarcely any part of a plant which does not ferve as food to different infects; each has its appropriate food, and though the parent animal does not, perhaps, fubfift on the fame vegetable, yet fhe inftinctively depofits her eggs on that particular fhrub or plant which will be food for her young. Some more voracious than the reft feed upon all with equal avidity; the migratory locuft, gryllus migratorius, is a ftriking example of this. The ravages of this infect have been at particular times fo extenfive as to lay wafte the vegetation of whole diftricts, of even kingdoms; an inftance is mentioned in the Amœnitates Academicæ, in which they overran all Sweden, and devoured all the plants, infomuch that cattle perifhed with hunger, and men were forced to abandon their country, and fly to the neighbouring regions. Similar refults have arifen from the ravages of locufts in various parts of the world at various periods, as appears from the moft credible hiftorians. The facred writings are not filent on this fubject. In the year 593 of the Chriftian era thefe animals appeared in fuch vaft numbers, as to caufe a famine in many countries. Syria and Mefopotamia were over-run by them in 677. In 852 immenfe fwarms took their flight from the eaftern regions into the weft, and deftroyed all vegetables, not even fparing the bark of trees, and the thatch of the houfes, after devouring the crops of corn, grafs, &c. Their daily marches were obferved to be about twenty miles each, and it is faid their progrefs was directed with fo much order, that there were regular leaders among them, who flew firft and fettled on the fpot which was to be vifited at the fame hour the next day by the whole legion; their marches were always undertaken at fun-rife. In 1541 incredible hofts afflicted Poland, Wallachia, and all the adjoining territories, darkening the fun with their num-

 bers,

bers, and ravaging all the fruits of the earth. The years 1747 and 1748 afforded a memorable inftance of the ravages of thefe animals in Germany and other parts of Europe, as far north as England. In the eaftern parts of the world fuch flights of locufts appear more frequently than in Europe, and it is often found neceffary for the governors of particular provinces to command a certain number of the military to take the field againft armies of locufts with a train of artillery.

The far greater number of infects feed, however, more difcriminately; fome are confined to one particular plant, and others only to two or three kinds; and neither in many cafes will eat any other food; they often perifh in the midft of abundant vegetation, becaufe they cannot procure that kind which is their natural food. The quantity of food which a caterpillar will devour is aftonifhing; that which feeds upon the cabbage (papilio brafficæ) deftroys in twenty-four hours more than twice its weight. If larger animals required a proportionable quantity of food, the earth would not be able to nourifh its inhabitants. It fhould, however, be remembered, that it is only during one period of their lives that they are fo voracious, or fubfift on fuch food; after they quit the larva form they are nourifhed in a different manner.

A vaft number of infects reject vegetabes in the larva ftate, and live only on animal food; fome feeking that which is beginning to putrefy, while others delight in that which is entirely putrid, or on the dung of animals. Some attack and feed on man himfelf, while others are nourifhed by his victuals, clothes, furniture, and habitation; and again others prey on his cattle. No animal whatever is exempt from thefe depredators. Some fubfift on the blood and humours of quadrupeds, others of birds, and a great proportion of them prey on infects of other kinds, or often attack their own, and thus perpetuate an endlefs war among each other.

Every larger animal has its appropiate lice, which feed on and infeft it: thefe in fize or voracity bear no regular proportion to the animal they fubfift upon. Thofe of man are diminutive in the extreme, compared with thofe which torment fome animals. The hippobofcæ and the tick, though not in technical terms the lice of the animals they infeft, have the fame habits, and draw nourifhment from the body in the fame manner; and thefe, in comparative bulk with the victims of their depredation, are an hundred, nay even, in fome inftances, a thoufand times larger than thefe uncleanly vermin in man. Some are not content with the blood and juices which they fuck from animals; they feek their food in the flefh, and that while full of life and health. The oeftri, or gad-flies, are familiar examples of this, the larva feeds upon the flefh beneath the fkin in cattle. The parent lodges its eggs in the flefh by making a number of little wounds, in each of which it depofits eggs, fo that every wound becomes a neft, and the eggs are hatched by the heat of the animal. Here the larva finds abundance of food, and is at the fame time protected from the changes of the weather, and they undergo their transformations in fecurity. The parts they inhabit are often difcovered by a lump or tumour which they occafion; this fuppurates, and is filled with matter, in which the head of the larva is always found plunged. When the time of change arrives the larva drops out, and feeks a convenient place in the ground, where it paffes to the pupa ftate. The ravages of the larva hatched from the ichneumon eggs, in the body of the caterpillar, are ftill more deftructive, as they entirely deftroy the vitals of their victims. The number of infects which are of a carnivorous difpofition is very great; and it is among thefe we find the traces of the greateft art and cunning, as well for attack as defence. Every one is acquainted with the dextrous arts of the fpider, to feize his prey, the curious neft he fpins, and the central pofition he affumes in order to watch more effectually the leaft motion communicated to its tender threads when the incautious infects fettle upon it. D.

ENTONNER, *Fr.* in *Roman Catholic Churches*, is announcing to the choir the tone or found with the organ, or the voice of the officiating prieft, with which a chant, hymn, pfalm, or anthem is to begin. In our cathedrals this is done for the refponfes by a canon, vicar choral, or by a fingle note on the organ.

ENTORSIS, in the *Manege*. See Pastern.

ENTOYER, or Entoire, in *Heraldry*, is ufed to exprefs a bordure, charged entirely with things without life. See Bordure.

ENTRACQUE, in *Geography*, a town of Italy, in the principality of Piedmont, on the Geffo; 5 miles S.S.E. of Demont.

ENTR'ACTE, *Fr.* the fpace of time which elapfes between the end of one act of a drama and the beginning of another; and during which the reprefentation is fufpended, while the action is fuppofed to be advancing elfewhere. The orcheftra fills up this fpace by performing a fymphony, which fupplies the place of what ufed, in England, to be called an *act-tune*.

It does not appear that the Greeks ever divided their dramas into acts; confequently, they had no act-tunes. The reprefentation was never fufpended on their ftage empty from the beginning of the piece to the end.

The Romans, lefs interefted in thefe exhibitions than the Greeks, were the firft who divided their pieces into feveral diftinct parts, the intervals of which afforded a relaxation to the attention of the fpectators; and this cuftom has been continued elfewhere ever fince.

But as the entract was intended to fufpend the attention, and give fome repofe to the mind of the audience, the ftage fhould have remained vacant. But the interludes with which the vacuity was formerly filled furnifhed an interruption in a very bad tafte, which infallibly injures the piece in breaking the thread of the action.

However, Moliere himfelf did not fee fo fimple and obvious a truth; the fpaces between the acts of his laft pieces were filled with interludes.

The French, whofe public fpectacles have more reafon than enthufiafm in them, and who dread being long kept in filence, have fince reduced their interacts to their due fimplicity, and it is to be wifhed for the perfection of the drama, that they were imitated, in that particular, every where elfe.

The Italians, whom an exquifite fenfibility often guides better than reafon, have profcribed the dance of the dramatic action (fee Opera); but by an inconfiftence arifing from the too long duration which they allow to their reprefentations, they fill their interacts with ballets, which banifh them from the piece in reprefentation, and if they avoid the abfurdity of a double imitation, they give into an equal abfurdity by a tranfpofition of fcene, and by haraffing the fpectator from object to object, they make him forget the principal action, lofe the intereft, and, in order to give pleafure to his eyes, rob him of thofe of the heart.

They began, however, to feel (in 1768) the defect of this monftrous affemblage; and after having already almoft driven intermezzi from their ftage, they will doubtlefs, ere long, get rid of the dance, referving it only as a brilliant and detached fpectacle at the end of the grand piece.

 But

But though the ftage remains vacant during the interact, it is not to be underftood that the mufic ought to be filenced; for at the opera, where it conftitutes the principal exiftence of every thing, the fenfe of hearing ought to be fo connected with that of fight, that as long as the ftage is feen the harmony fhould be heard, which is fuppofed infeparable from it; fo that its concurrence may not appear afterwards foreign or new, but united with the melody of the vocal performers. Chiefly from Rouffeau.

The difficulty which prefents itfelf on this fubject, is to fuggeft what the compofer ought to dictate to the orcheftra when nothing is doing or tranfacting on the ftage: for if the fymphony, as well as all dramatic mufic, is only a continued imitation, what is it to fay when nobody fpeaks? What ought it to do when there is no action? "I anfwer to that (fays Rouffeau) that though the ftage is vacant the heart of the fpectator is not; there ought to remain a ftrong impreffion of what has been feen and heard. It is for the orcheftra to cherifh and fuftain this impreffion during the interact, that the fpectator at the beginning of the enfuing act may not find himfelf as cold as at the beginning of the piece, but that the intereft may be as much linked in his mind as the events are in the action reprefented.

By this means the mufician will always have an object of imitation, either in the fituation of the perfonages, or in that of the fpectators. Thefe fhould hear nothing from the orcheftra but expreffions of what they have felt, identified with what they hear; and their fituation will be fo much the more delicious, as there fhall be a more perfect accord between that which ftrikes their fenfes and which touches the heart.

An able mufician will draw from the orcheftra another advantage, which will contribute to give the reprefentation all the effect poffible, in conducting the fpectator, by degrees, to the ftate of mind the moft favourable to the effect of the fcenes which are going to be reprefented in the following act.

The interact has no fixed duration; but it is fuppofed to be more or lefs confiderable, in proportion to the time neceffary for that part of the action, which is paffed behind the fcenes. However, that duration fhould have its bounds of fuppofition, relative to the hypothetic duration of the whole action; and the real bounds relative to the duration of the whole reprefentation.

This is not the place to examine whether the rule of 24 hours is well founded, and if it ought never to be violated. But if we would give to the fuppofed duration of an interact bounds regulated by the nature of things, I fee no other rule than that of the time during which no fenfible and regular change happens in nature, which cannot be made apparently tranfacting on the ftage during the interact. Now this time being 12 hours, which compofe a day or a night, if that is exceeded, there is no longer any poffibility of illufion during the fuppofed length of the act."

This is reviving the old contention concerning the unities, which have never been received as a law in this country. And as to act-tunes analogous to the bufinefs of the drama, it is an idea which was executed by Purcell in many of the plays of Dryden and Congreve; and Arne, when compofer in falary at Drury-lane theatre, compofed very pleafing and appropriate act-tunes to many of the ftock plays, which never were printed, but preferved in MS. in the archives of the old theatre; but we fuppofe that the ftrains of Orpheus or Amphion might be as eafily recovered now as thefe compofitions.

ENTRAIGUES, in *Geography*, a fmall town of France, in the department of the Aveyron, chief place of a canton, in the diftrict of Efpalion, with a population of 1748 individuals. It is fituated near the place where the river Truyere falls into the Lot, 18 miles S. of Aurillac. Its canton contains 6 communes, and 6691 inhabitants, on a territorial extent of $147\frac{1}{2}$ kiliometres.—Alfo, a fmall town of France, in the department of the Ifére, chief place of a canton, in the diftrict of Grenoble, with a population of 521 individuals. The canton contains 10 communes and 4988 inhabitants, on a territorial extent of 355 kiliometres.—Alfo, a fmall town of France, in the department of Vauclufe, 6 miles N.E. of Avignon.

ENTRAILS, the inteftines or guts of an animal. See INTESTINES.

Menage derives the word from the barbarous Latin, *interalia*, formed of the Greek, εντερον, *inteftine*.

ENTRAILS is alfo ufed, in a more extenfive fenfe, for the vifcera, or all the parts contained in the cavities of the bodies of animals. See VISCERA.

The arufpicina of the ancients was employed in confidering the entrails of victims; as the heart, lungs, liver, &c. See ARUSPICES, &c.

ENTRANCE, in *Sea Language*, is a name often given to the foremoft part of a fhip under the furface of the fea.

ENTRANCE *of hounds*, a phrafe ufed by our *Sportfmen*, to exprefs the inftruction of thefe creatures in the art of hunting. They are faid to be entered when they are thoroughly taught this.

The time of entering of hounds is when they are about twelve months old; when they are firft brought up from their walks, they fhould be kept feparate from the pack: they are then to be taught to take the water and fwim; they are to be laid abroad in the heat of the day, to enure them to fatigue and exercife; and they muft be frequently led through flocks of fheep, and warrens, to ufe them to be under command, and to know that they are to run at nothing but what the huntfman orders. They muft be carefully inftructed each to know his own name, and to underftand the voice of the huntfman, and the notes of the horn ufed in hunting; and finally, to ufe their own language in a proper manner. When young hounds well know and anfwer to their names, they fhould be put into couples, and walked out amongft fheep; and if any be particularly fnappifh leave the couples loofe about their necks in the kennel, till they are more reconciled to them. If any of them fhould be very troublefome, couple them to old hounds, always avoiding coupling two dogs together, if poffible, and taking care that the couples be tight enough to prevent their heads being flipped out of the collar. After being walked out frequently amongft the fheep, they may be uncoupled, a few at a time, and fuch as offer to run after them fhould be well chaftifed; the cry of *ware, fheep*, will afterwards ftop them, without further application of the whip; proper attention will foon make them afhamed of it; but if once fuffered to tafte the blood, it will be difficult to reclaim them. If young and old hounds are aired together, let the former be in couples; they are always ready for mifchief, and idlenefs may induce even the latter to join in it. It may be as well to air the young hounds in that country where they are defigned to hunt, as they thus acquire fome knowledge of it, and if at any time they fhould be left behind, they will more readily find their way home. Young hounds fhould be entered as foon as you can; in woodlands and grafslands, it will of courfe be earlier than in corn countries. Sport in fox-hunting cannot be faid to begin before October; but in the two preceding months, a pack is either made or marred.

The beſt time of entering them is about noon; and it ſhould be in a fair warm day; for if they be entered in the morning, they will give out when the heat of the middle of the day comes on, and betake themſelves to ſhady places to reſt and ſleep. Accordingly it is ſaid that hounds ſhould be entered in the heat of the day, and about October or November, for hare-hunting, the weather being then temperate, and young hares that have not been hunted are then more eaſily taken for their encouragement. A neceſſary caution is alſo added, never at the entering of young hounds to help them to kill the hare with grey-hounds, for this will deter the hounds from putting their noſes to the ground, or trying to hunt her themſelves. Take the moſt advanced, that the game may not ſtand long before them, and let them be well rewarded when all is over. This ought to be repeated at leaſt once a week, for two months ſucceſſively; by this means they will be ſo fleſhed and ſeaſoned with what game you may enter them at, that they will never afterwards leave off the purſuit. Hounds, after two years old, ſhould be hunted three times a week, if they feed well, and may be kept out the greateſt part of the day to try their ſtoutneſs. The new hounds ſhould always be entered with the beſt and ſtauncheſt hounds that can be had; and there is not to be one barking dog ſuffered in the field on this occaſion.

Whatever chace the hounds are intended for, it has been ſaid that the hare is the beſt game to enter them at, becauſe in this chace, they will learn all the turns and doubles that they can poſſibly meet with in any other kind, and how to come to the hollo. They will learn alſo from this chace, to have a perfect and nice ſcent, and hard feet, by being uſed to highways, beaten paths, and dry hills.

On the other hand, it has been more reaſonably maintained, that young hounds ſhould always be entered at their own game; becauſe it is a ſtrange contradiction to enter them at a hare, and then to cut them to pieces for afterwards hunting the hare. This, it is ſaid, is laying a foundation for future cruelty and vexation. Moſt dogs like that ſcent beſt, which they were firſt blooded to; and if the blood of the fox be of ſo much ſervice, that of the hare cannot be deemed a matter of indifference. It is, therefore, without doubt moſt rational to uſe them to that ſcent *only*, which it is intended they ſhould hunt. It has been aſſerted, that the way to render hounds ſteady from hare, is to encourage them to hunt her. The advantage reſulting from this kind of paradoxical practice is ſaid to be, that hounds are thus taught to hunt, and made to learn obedience; but the ſurer method to make hounds obedient is calling them over often in the kennel, to accuſtom them to their names, walking them out frequently amongſt ſheep, hares, and deer, from which they are to be ſtopped, to make them know a "rate;" and by this practice they will learn obedience. Nature will inſtruct them how to hunt: art is only neceſſary to prevent their hunting what they ought not to hunt. Should any young hounds be very fond of hare, let ſome be found ſitting, and ſtarted before them, and they will ſoon be checked and ceaſe to run after them. If they are to be ſteadied from deer, they ſhould often ſee deer, and they will not regard them. After this probation, a cub ſhould be turned out before them, with ſome old hounds to lead them on, and they will not long give trouble. After young hounds ſtoop to a ſcent, are become handy, know a "rate," and ſtop eaſily, put them, a few only at a time, into the pack after the old ones have been hunted and had blood; let them be taken the firſt day where they are certain of finding. Hounds ſhould be low in fleſh when hunting commences; becauſe the ground being generally hard at that ſeaſon, they are liable, if luſty, to be ſhaken. If foxes are plentiful, take the young, with ſome of the ſteadieſt of the old hounds, where there is leaſt riot, and ſhould you there find a litter of foxes, the young hounds will be ſo much improved as to need little ſubſequent inſtruction. If any cubs be ran to ground, and blood be not then wanted, let them be brought home, and they will be ſerviceable, ſhould blood be neceſſary at any time for the young hounds. Frequent hallooing is of uſe with young hounds, as it keeps them forward, prevents their being loſt, and from hunting after the others: the more, therefore, a fox is ſeen and hallooed, the better. Young hounds are thus made eager, and taught to exert themſelves. At their firſt entering, hounds cannot be encouraged too much: when they are handy, love a ſcent, and begin to know what is right, it will be ſoon enough to chaſtiſe them for doing wrong; in which latter caſe, one ſevere beating will ſave much trouble. The whipper-in ſhould uſe his voice as well as his whip, when he flogs a hound, and take care that the ſtroke precedes the "rating;" and he ſhould remember, that the ſmack of the whip is often as ſerviceable as the laſh to one who has already felt it. The day after young hounds have had blood is a proper time to take them where there is riot, and if they merit it, to chaſtiſe them: it is always beſt to correct them, when they cannot help knowing what they are corrected for. When hounds go out for this purpoſe, it ſhould be at a late hour; as the worſe the ſcent is, the leſs inclinable will they be to run it, and the ſtopping of them will be more eaſy and immediate. Upon the day when a fox is propoſed to be turned out, young hounds ſhould draw ſmall covers and furze brakes, where are hares or deer; a little rating and flogging, before they are encouraged to vermin, teaches them both what they ſhould not and what they ſhould do. A hound that hears a voice which has often rated him, and the whip he has often felt, ought to ſtop: when hounds are rated, and do not anſwer the rate, they ſhould be coupled up immediately, and made to know the whipper-in. A moſt eſſential point in rendering hounds obedient is to make them underſtand you; and therefore the language ſhould be appropriate and uniform. Young hounds ſhould be hunted in large covers to tire them out, provided the whipper-in can eaſily get at them; but when there is much riot there are no openings, the purpoſe will not be anſwered, unleſs you have a body of old hounds to carry on the right ſcent: for the young hounds, as ſoon as the ground becomes foiled, will be ſcattered about the cover, hunting old ſcents, and will not proceed faſt enough to tire themſelves. Beſides, every fox-hound will leave a bad ſcent of a fox for a good one of either hare or deer, unleſs he has been made ſteady from both. Young hounds are all given to riot; but the better they are bred, the leſs trouble will they be likely to give: high bred fox-hounds love their own game beſt: they ſhould have little reſt; one day they ſhould be hunted in large covers, where foxes are plentiful; the next, they ought to be walked out amongſt hares and deer, and ſtopped from riot; and the day following, be hunted again as before. By this management young hounds will ſoon become ſteady. At firſt young hounds ſhould be entered to vermin only; and they ſhould be uſed as early as poſſible to the ſtrongeſt and thickeſt woods and furzes, and they will ſeldom be ſhy of them afterwards. By being awed from hare and deer, and being taught to hunt only vermin, hounds will ſtop at a word, becauſe that word will be underſtood by them; and a ſmack of the whip will ſpare the inhuman trouble of cutting hounds in pieces for faults, which, if entered at hare, they have been invited to commit.

In

In hare-hunting the hounds, when firſt entered, muſt have all the advantages given them that can be. When the hare is put up, from her form, it muſt be obſerved which way ſhe went, and the ſcent muſt be left to cool a while, and then they muſt be laid in, and helped as much as can be, by wind, view, hollo, or pricking the paſſage; nor will it be amiſs, for the firſt time, to give them a hare tired the ſame morning in her courſe.

Some are of opinion, that the beſt way to enter young hounds is, to take a live hare, and trail her upon the ground, ſometimes one way, and ſometimes another, and then to draw her off to a convenient diſtance, and hide her, that the dogs, taking the ſcent, may follow all the traces through which ſhe was drawn, and at length find her.

It has been ſaid, however, that beating the hare up from her ſeat is a ſhorter way than trailing her from her feed to her form. Great exactneſs was formerly obſerved in the firſt entering of hounds, not to uncouple them repeatedly in the ſame ſort of ground, leſt by being uncoupled conſtantly in an open field, they would be at a loſs what to do when turned into a cover. It was a received opinion, that according to the places where hounds were firſt entered, they would ſhew a preference: *e. g.* if entered in a champaign country, they would always hunt better there than in covers, marſhy, or mountainous grounds. Hence it was deemed right to uſe them to every ſort of ground, and diverſity in the country was ſtrongly recommended, that they might be perfect in all. Some lands, which were of a glutinous and greaſy ſhining mould, never bore any ſcent, and there the huntſman was to help out the dogs by pricking the hare. In plains and downs where the graſs was ſhort, and the ſcent dried immediately, there alſo he was allowed to follow his game by the eye, in order to aſſiſt the noſe of the hounds. Some of the early ſportſmen never permitted the hare to be hallooed, or the hounds to be aſſiſted when they were at fault, but ſuffered them to work it out by themſelves; and this, though tedious, was conſidered a ſure way to aſcertain the goodneſs of the hounds: others took all advantages, and killed them as ſpeedily as poſſible. The method of rewarding the young hounds was curious. The hare, after being laid upon the graſs, and bayed by the hounds, was ſkinned before them; and after the gall and lights were taken away, which were ſuppoſed to make the hounds ſick, the huntſman, who carried a wallet with bread cut in ſmall pieces, dipped them in the blood, and with the entrails gave them to the hounds; the hare was afterwards diſtributed, and if any young hound was fearful to come in among the reſt, he had the head given him by himſelf. After this feaſt, the hounds had bread given them to prevent ſickneſs.

The huntſman ought very well to underſtand the nature and diſpoſition of his hounds, in finding out the game; for ſome hounds are of that temper, that when they have found the ſcent, they will run forward with it, not making any noiſe, nor ſhew of the tail; others, when they have found a head, will ſhew the game; and ſome, having found the footings of the beaſt, will prick up their ears a little, and either bark, or only wag their ears, or the hinder part of their bodies. This difference of natural diſpoſition, the huntſman is particularly to obſerve in the young and newly entered pack, otherwiſe he will never underſtand them, nor ever be able to hunt them to any credit or advantage.

For entering the hound at hart or buck, he ſhould be in the prime of greaſe, for then he cannot ſtand up, or hold the chace ſo long. The foreſt pitched upon ſhould have all the relays at equal diſtances, as nearly as may be; but then the young hounds ſhould always have ſome old ſtaunch ones to enter them, and they ſhould be led to the fartheſt and laſt relay, and the hart or buck ſhould be hunted to them. Being come up, the old hounds ſhould be uncoupled; and when they have found the hart, and well entered the cry, then the young ones are to be uncoupled alſo; and if any of them are found to lag behind, they muſt be whipped and beaten forward.

In whatever place the hart is killed, the neck ſhould be immediately flayed, and the hounds rewarded; for it is beſt always to do this while the fleſh is hot. Another very good method of entering hounds at the buck, is to take one in the toils or nets, and to wound one of his legs, ſo as to diſable him from running either very ſwiftly or very far: then let him looſe, and firſt let a blood-hound trace the creature, then let looſe all the young hounds; and when they have run down the animal, reward them with the neck.

Some enter their hounds with a toil; but this is a bad way; for the hart being in this caſe always in ſight, and not able to run an end, makes a great number of doubles and turnings: this is very different from the chaces they are to meet with afterwards; and when they find a hart run in the common way, ſtraight forward, and out of ſight, they will leave the chace, as unlike that by which they were taught. Daniel's Rural Sports. See HUNTING.

ENTRASME, in *Geography*, a ſmall town of France, in the department of Mayenne; 6 miles S. of Laval.

ENTRAVES, ENTRAVONS, in the *Manege*. See LOCKS.

ENTRE AMBOS OS RIOS, in *Geography*, a town of Portugal, in the province of Entre Minho Douro; 8 miles S.S.W. of Amarante.

ENTRE *Minho Douro*, a province of Portugal, ſo called from its ſituation between the rivers Minho and Douro, bounded on the north by Gallicia, a province of Spain; on the eaſt by Trazos Montes and Spain; on the ſouth by the province of Beira, from which it is ſeparated by the Douro; and on the weſt by the Atlantic ocean; and extending from 40° 50′ to 42° N. lat., and from 8° 55′ to 7° 55′ W. long., being 70 miles in length and 52 in breadth. It contains 963 pariſhes, 1460 churches, 1130 convents, 6 ſea-ports, and 804,000 inhabitants. This is the moſt northerly, the moſt fertile, and the moſt populous territory in the kingdom. Its numerous and fine vallies are ſhaded by beautiful trees, and watered by limpid ſtreams. Its air is pure and healthy; and it produces corn, wine, oil, and flax in abundance, with a great number of ſheep, and plenty of game and fiſh. The principal towns are Braga, Oporto, Viana, Amarante, Guimaræns, Ponte de Lima, and Pezo de Regna. Its chief rivers are the Minho, Lima, Neiva, Cavado, Ave, and the Douro or Duero, augmented by the Tamega; all of which run weſtward to the ſea.

ENTRECASTAUX, a ſmall town of France, in the department of the Var, near Barjols.

ENTRE'E, *Fr.*, the overture to a ballet, and ſometimes the beginning of the dance itſelf. In the firſt operas in France, the overture was called the entrée.

ENTREPAS, in the *Manege*, is a broken pace, or going, properly a broken amble, that is, neither walk nor trot, but has ſomewhat of an amble. This is the pace, or gait, of ſuch horſes as have no reins or backs, and go upon their ſhoulders, or of ſuch as are ſpoiled in their limbs.

ENTREVEAUX, in *Geography*, a ſmall town of France, in the department of the Lower Alps, chief place of of a canton in the diſtrict of Caſtellane, with a population of 1326 individuals. It is ſituated at the foot of the Alps, on the river Var, near Glandeves. N. lat. 44°.1′. Its canton has a territorial extent of 197½ kiliometres, eight communes, and 2694 inhabitants.

ENTRICOMA, from εν and θριξ, *hair*, in *Anatomy*, the name of the outer edge of the eye-lid, on which the hairs grow.

ENTRIES, amongſt *Hunters*, thoſe places in thickets through which deer are found lately to have paſſed; by means whereof their bigneſs or ſize is gueſſed at; and at which the hounds or beagles are put to them for the view.

ENTRIES, *Books of*, in *Law*, are ancient and modern, and contain tranſcripts of proceedings that have been had in ſome particular actions; the principal of ſuch are neceſſary for gentlemen educated to the profeſſion of the law.

ENTRING *a Ship*, in *Sea Language*, the ſame with boarding her. See BOARDING.

ENTRING-*Ladder*, in a *Ship*, is of two ſorts; one is uſed by the ſhip's ſides, in a harbour, or in fair weather, for perſons to go in and out of the ſhip: the other is made of ropes, with ſmall ſtaves for ſteps, and is hung out of the galley to enter into the boat, or to come aboard the ſhip from thence, when the ſea runs ſo high that they dare not bring the boat to the ſhip's ſide for fear of ſtaving her. See GANG-WAY.

ENTRING-*Ropes*. See ROPE.

ENTROCHUS, in *Natural Hiſtory*, the name of a genus of foſſils of a very regular figure and ſtructure, ſuppoſed by many authors to be lapides ſui generis, and ſtones in their native ſtate. They are, however, in reality, the foſſile remains of ſome marine animal, probably either of the echinus, or of the ſtar-fiſh kind, filled like the foſſile ſpecies of the echini, with a plated ſpar. Our imperfect knowledge in the animal hiſtory has not yet been able to aſcertain to what creature they really belong; but their analogy, with the other animal remains, found in the foſſile world, plainly evince, that they are of that origin. They are cylindric columns, uſually about an inch in length, and are made up in a number of round joints, like ſo many ſmall wheels or ſegments of cylinders. Theſe joints, when found ſeparate, and naturally looſe, as they ſometimes are, are called trochitæ. They are all ſtriated, from the centre to the circumference, and have a cavity in the middle, which is ſometimes found empty, but more frequently filled up with various matter, of the nature of the ſtratum, in which they have lain, or of other of the native foſſile ſubſtances.

The entrochi are compoſed of the ſame ſort of plated ſpar with the aſteriæ, and the ſpines and ſhells of the foſſile echini: and this is in theſe uſually of a blueiſh-grey colour, and very bright and gloſſy, where freſh broken. They are ſubject to accidental injuries, like the other extraneous foſſils, which have been formed in animal moulds, and are frequently met with compreſſed, or crooked.

That the entrochi are of marine origin, is evident from this, that they have not unfrequently ſea-ſhells found adhering to them; and when theſe are broken off, there remain on the entrochi no deficiencies, but the ſhells themſelves ſhew that they have been formed upon, and have grown to the entrochi, there being always natural hollows in them to anſwer to that part of the entrochus from which they have been ſeparated; whence it appears very plainly, that theſe entrochi, however altered ſince in their ſubſtance, were, however, exiſting in their preſent ſhape, in thoſe very ſeas where theſe ſhells had their growth.

There are not unfrequently found among the entrochi, larger or ſmaller fragments of plated bodies.

We meet with the entrochi of all the ſizes, from that of a pin's head to a finger's length, and the thickneſs of one's middle finger. They are, in ſome places, found looſe upon ploughed lands; in others, they are lodged in great quantities in the ſtrata of clay, and very often in ſtones of different kinds, and different hardneſs.

Mr. Parkinſon, in his ſecond volume of "Organic Remains," treats very largely of this claſs of animals; and Mr. William Martin, in his recent and valuable work, the "Petrificata Derbienſia," has paid conſiderable attention to the curious remains of this kind which Derbyſhire affords: among which he enumerates, 1ſt, the even-jointed entrochite (Entrochites lævis); 2d, the convex-jointed entrochite (E. prominens); 3d, the warted entrochite (E. verrucoſus); and 4th, the ring-jointed entrochite (E. cannulatus).

Entrochi abound in ſome particular beds of the firſt or upper lime-ſtone rock of the Derbyſhire lime-ſtone or toad-ſtone ſeries, and from hence the beautiful figured marbles are principally obtained, at Ricklow-dale, Bricks, and High-low, near to Monyaſh; at Foolow, Calver, Lexley in Aſhover, Crick-Cliff, and other places. The three other lime-ſtone rocks, which lie below the above, contain ſome few beds with a ſprinkling of entrochi in them; but they are very inferior in number or ſize to thoſe in the upper rock.

Entrochi are alſo found in ſmall numbers, in the yellow or magneſian range of lime-ſtone, which traverſes the country from Wetherby in Yorkſhire to near Nottingham; appears again at Bredon, Cloud's-hill, Barrow-hill, and Gracedieu in Leiceſterſhire; again at Ruſhall and Walſall; between Wolverhampton and Dudley in Staffordſhire; at Abberley in Worceſterſhire, &c.

The foſſil deſcribed by Mr. Walcot, in his "Petrifications found near Bath," p. 46, under the name of an entrochus, is more properly a trochus or top-ſtone, very different from the entrochi of which we have been ſpeaking: it belongs to the Bath free-ſtone ſtrata.

ENTROCHO *Aſteriæ*, the name given by authors to a peculiar kind of entrochus, differing from the common kind, in having a ſtellar cavity inſtead of a round one, in its centre.

ENTROCHUS *Pyramidalis*, a name given by ſome writers to the ortho-ceratites, or tubulus marinus concameratus, a ſpecies of ſhell-fiſh, not known to us in its recent ſtate, but very common in the ſtones brought over from Sweden for pavements. Klein. de Tubul. Marin. p. 7. See TUBULI *Concamerati*.

ENTROCHUS *Ramoſus*, the name of a foſſile body, the ſeveral parts of which reſemble the entrochi; but as they are joined together in this body when perfect, they ſhew themſelves in their proper light, and a ſight of them in this ſtate is ſufficient to explode the opinion advanced by ſome perſons, of the entrochi being of a vegetable nature; or, as they have pleaſed to call them, "rock-plants." The foſſil has evidently once been a ſtella-marina, or ſea ſtar-fiſh, conſiſting of twenty rays at the extremity of the body. The manner of inſertion of theſe has been this: the body is of a pentagonal figure, and from this there have ariſen five rays; theſe, at their extremity, have been divaricated, each into two, ſo as to make the number ten in the ſecond progreſſion; and each of theſe laſt being again divaricated into two at its extremity; the third and laft progreffion is of twenty rays. All this is eafily diftinguifhable in the foffil, when perfect, and feems to have been the whole figure of the animal while living. The prototype, or living animal, however, is not found; but this is not an accident peculiar to this foffil, the cornua ammonis, and conchæ anomiæ, with many other bodies that have been once evidently fhell-fifh, being no where at this time found in their recent ftate, though fo very numerous in the foffile world. This remarkable foffile ftar-fifh is the body called by fome authors, lilium lapidium. Keppeler's Epift. ad Klein de Entrochis.

ENTROCHORUM Radix. See Radix.

ENTROPIUM, (from ἐν and τρέπω, *to turn*,) a furgical difeafe, in which the eyelid turns inward towards the eye, fo as to occafion, by the friction and irritation of the eyelafhes, chronic ophthalmy, and various inconveniences. See Trichiasis.

ENTRUSION, in *Law*. See Intrusion.

ENTRY, or Entrance, in its general fenfe, denotes a door, gate, paffage, &c. through which to enter, or arrive within a place.

Entry, in *Book-keeping*. See Book-keeping.

Entry, *Bill of*. See Bill.

Entry, is fometimes alfo ufed to denote a duty or impoft laid on commodities imported into a ftate, either by land or fea.

The duties of entry, or importation, are paid according to a tariff fettled for that purpofe. Where the duty of entry of any commodity is not fixed by the tariff, it is paid by eftimation, *i. e.* in proportion to what fome other commodity of nearly the fame quality and value ufes to pay. In making entries inwards, it is ufual for merchants to include all the goods they have on-board the fame fhip in one bill, though fometimes there may happen to be upwards of twenty feveral kinds; and in cafe the goods are fhort entered, additional or port entries are now allowed; though formerly the goods fo entered were forfeited. As to bills of entry outwards, of including goods to be exported, upon delivering them and paying the cuftoms, you will receive a cocket, which teftifies your payment thereof, and of all duties for fuch goods. If feveral forts of goods are exported at once, of which fome are free, and others pay cuftoms, the exporter muft have two cockets, and therefore muft make two entries. Entries of goods, on which a draw-back is allowed, muft likewife contain the name of the fhip in which the goods were imported, the importer's name, and time of entry inwards. The entry being thus made, and an oath taken, that the cuftoms for thefe goods were paid as the law directs; you muft carry it to the collector and comptroller, or their deputies; who, after examining their books, will grant a warrant, which muft be given to the furveyor, fearcher, or land-waiter, that they may certify the quantity of goods; after which the certificate muft be brought back to the collector and comptroller, or their deputies, and oath made, that the faid goods are really fhipped, and not landed again in any part of Great Britain. See Debenture, Importation, and Exportation.

Entry, alfo denotes a folemn reception, or a ceremony performed by kings, princes, ambaffadors, legates, &c. upon their firft entering a city, or their return in triumph from fome expedition.

Entry, in *Law*, fignifies the taking poffeffion of lands or tenements by the legal owner, when another perfon, who hath no right, hath previoufly taken poffeffion of them. See Possession.

In this cafe the party entitled may make a formal, but peaceable entry thereon, declaring that thereby he takes poffeffion; which notorious act of ownerfhip is equivalent to a feodal inveftiture by the lord (fee Investiture); or he may enter on any part of it in the fame county, declaring it to be in the name of the whole (Litt. § 417.); but if it lies in different counties, he muft make different entries; for the notoriety of fuch entry or claim to the *pares* or freeholders of Weftmorland, is not any notoriety to the *pares* or freeholders of Suffex. Alfo, if there be *two* diffeifors, the party diffeifed muft make his entry on *both*; or if *one* diffeifor has conveyed the lands with livery to *two* diftinct feoffees, entry muft be made on *both* (Co. Litt. 252.); for as their *feifin* is diftinct, fo muft alfo be the act which divefts that feifin. If the claimant be detained from entering by menaces or bodily fear, he may make *claim*, as near to the eftate as he can, with the like forms and folemnities; which claim is in force for only a year and a day. (Litt. § 422.) And this claim, if it be repeated once in the fpace of every year and day (which is called *continual claim*) has the fame effect with, and in all refpects amounts to, a legal entry. (Litt. § 419, 423.) Such an entry gives a man feifin, (Co. Litt. 15.) or puts into immediate poffeffion him that hath right of entry on the eftate, and thereby makes him complete owner, and capable of conveying it from himfelf by either defcent or purchafe. This remedy by entry takes place in three only of the five fpecies of oufter, *viz.* abatement, intrufion, and diffeifin (Co. Litt. 237, 238.); for as in thefe the original entry of the wrong-doer was unlawful, they may therefore be remedied by the mere entry of him who hath right. But, upon a difcontinuance or deforcement, the owner of the eftate cannot enter, but is driven to his action; for herein the original entry being lawful, and thereby an apparent right of poffeffion being gained, the law will not fuffer that right to be overthrown by the mere act or entry of the claimant. Yet a man may enter on his tenant by fufferance; for fuch tenant hath no freehold, but only a bare poffeffion; which may be defeated, like a tenancy at will, by the mere entry of the owner. But if the owner thinks it more expedient to fuppofe or admit fuch tenant to have gained a tortious freehold, he is then remediable by writ of entry, *ad terminum qui præteriit*. (Co. Litt. 57.) On the other hand, in cafe of abatement, intrufion, or diffeifin, where entries are generally lawful, this right of entry may be *tolled*, that is, taken away by defcent. Defcents, which take away entries (Litt. § 385—413.) are, when any one, feifed by any means whatfoever of the inheritance of a corporeal hereditament, dies, whereby the fame defcends to his heir; in this cafe, however feeble the right of the anceftor might be, the entry of any other perfon who claims title to the freehold is taken away; and he cannot recover poffeffion againft the heir by this fummary method, but is driven to his action to gain a legal feifin of the eftate. In general it appears, that no man can recover poffeffion by mere entry on lands, which another hath by defcent. And this title of taking away entries by defcent is ftill further narrowed by the ftatute 32 Hen. VIII. c. 33. which enacts, that if any perfon diffeifes, or turns another out of poffeffion, no defcent to the heir of the diffeifor fhall take away the entry of him that has right to the land, unlefs the diffeifor had peaceable poffeffion five years next after the diffeifin. But the ftatute extendeth not to any feoffee or donee of the diffeifor, mediate or immediate. (Co. Litt. 246. 256.) By the ftatute of limitations it is enacted by ftatute 21 Jac. I. c. 16, that no entry fhall be made by any man upon lands, unlefs within 20 years after his right fhall accrue: and by ftatute 4 and 5 Ann. c. 16, no entry fhall be of force to fatisfy the faid ftatute of limitations,

tions, or to avoid a fine levied of lands, unlefs an action be thereupon commenced within one year after, and profecuted with effect. Moreover, this remedy by entry muft be purfued, according to ftatute 5 Ric. II. ft. 1. c. 8. in a peaceable and eafy manner; and not with force or ftrong hand. For, if one turns or keeps another out of poffeffion forcibly, this is an injury of both a civil and criminal nature. The civil is remedied by immediate reftitution; which puts the ancient poffeffor *in ftatu quo;* the criminal injury, or public wrong, by breach of the king's peace, is punifhed by fine to the king. Blackftone's Comm. b. iii. See FORCIBLE *Entry*.

ENTRY, *writ of*, is a poffeffory remedy, which difproves the title of the tenant or poffeffor, by fhewing the unlawful means by which he entered or continues poffeffion. (Finch. L. 261.) This writ is directed to the fheriff, requiring him to "command the tenant of the land that he render (in Latin, *præcipe quod reddat*) to the demandant the land in queftion, which he claims to be his right and inheritance; and into which, as he faith, the faid tenant had not entry but by (or after) a diffeifin, intrufion, or the like, made to the faid demandant, within the time limited by law for fuch actions; or that upon refufal he do appear in court on fuch a day, to fhew wherefore he hath not done it. This is the original procefs, the *præcipe*, upon which all the reft of the fuit is grounded; wherein it appears, that the tenant is required, either to deliver feifin of the lands, or to fhew caufe why he will not. This caufe may be either a denial of the fact, of having entered by or under fuch means as are fuggefted, or a juftification of his entry by reafon of title in himfelf, or in thofe under whom he makes claim; whereupon the poffeffion of the land is awarded to him who produces the cleareft right to poffefs it.

Writs of entry are of divers kinds, diftinguifhed into four degrees, according to which the writs are varied. The *firft* degree is a writ of entry *fur diffeifin*, that lieth for the diffeifee againft a diffeifor, upon a diffeifin done by himfelf; and this is called a writ of entry in the nature of an affife. The *fecond* degree, by fome reckoned the firft, is a writ of entry *fur diffeifin in le per* and lies againft the heir by defcent, who is faid to be in the *per*, as he comes in by his anceftor; and fo it is if a diffeifor make a feoffment in fee, gift in tail, &c. The feoffee and donee are in the *per* by the diffeifor. The *third* is a writ of entry *fur diffeifin in le per and cui*, where the feoffee of a diffeifor maketh a feoffment over to another; when the diffeifee fhall have this writ of entry fur diffeifin, &c. of the lands in which fuch other had no right of entry, but by the feoffee of the diffeifor, to *whom* the diffeifor demifed the fame, who unjuftly and without judgment diffeifed the demandant. (1 Inft. 238.) Thefe three degrees thus ftate the original wrong, and the title of the tenant who claims under fuch wrong. If more than two degrees (that is, two alienations or defcents) were paft, there lay no writ of entry at the common law. For, as it was provided, for the quietnefs of men's inheritances, that no one, even though he had the true right of poffeffion, fhould enter upon him who had the apparent right by defcent or otherwife, but he was driven to his *writ of entry* to gain poffeffion; fo, after more than two defcents or conveyances were paffed, the demandant, even though he had the right both of poffeffion and property, was not allowed this *poffeffory* action, but was driven to his *writ of right*, a long and final remedy, to punifh his neglect in not fooner putting in his claim, while the degrees fubfifted, and for the ending of fuits, and quieting of all controverfies. (2 Inft. 153.) But by the ftatute of Marlbridge, 52 Hen. III. c. 30, it was provided, that when the number of alienations or defcents exceeded the ufual degrees, a new writ fhould be allowed without any mention of degrees at all. Accordingly a new writ, or a *fourth*, has been framed, called a writ of entry in the *poft*, which only alleges the injury of the wrong-doer, without deducing all the intermediate title from him to the tenant; ftating it in this manner; that the tenant had not entry unlefs *after*, or fubfequent to, the oufter or injury done by the original diffpoffeffor; and rightly concluding, that if the original title was wrongful, all claims derived from thence muft participate of the fame wrong. Upon the latter of thefe writs it is (the writ of entry *fur diffeifin* in the *poft*) that the form of our common recoveries of landed eftates is ufually grounded. See FINE and RECOVERY.

This remedial inftrument of writ of entry is applicable to all the cafes of oufter (fee OUSTER), except that of difcontinuance by tenant in tail, and fome peculiar fpecies of deforcements. Such is that of deforcement of dower, by not affigning *any* dower to the widow within the time limited by law; for which fhe has her remedy by writ of *dower, unde nihil habet.* (F. N. B. 147.) See DOWER. But in general the writ of entry is the univerfal remedy to recover poffeffion, when wrongfully withheld from the owner. It would, therefore, be endlefs to recount all the feveral divifions of writs of entry, which the different circumftances of the refpective demandants may require, and which are furnifhed by the laws of England. (See Bracton, l. 4. tr. 7. c. 6. § 4. Britton, c. 114. fol. 264.) Of thefe the moft ufual were, 1. The writ of entry *fur diffeifin*, and of intrufion (F. N. B. 191. 203.), which are brought to remedy either of the fpecies of oufter. 2. The writs of *dum fuit infra ætatem*, and *dum fuit non compos mentis* (Ibid. 192. 202.) which lie for a perfon of full age, or one who hath recovered his underftanding, after having, (when under age or infane,) aliened his lands; or for the heirs of fuch alienor. 3. The writs of *cui in vita*, and *cui ante divortium* (Ibid. 193. 204.) for a woman, when a widow or divorced, whofe hufband during the coverture hath aliened her eftate. 4. The writ *ad communem legem* (Ibid. 207.) for the reverfion, after the alienation and death of the particular tenant for life. 5. The writs *in cafu provifo*, and *in confimili cafu*, (Ibid. 205, 206.) which lay not *ad communem legem*, but are given by ftat. Gloc. 6 Edw. I. c. 7. and Weftm. 2. 13 Edw. I. c. 24, for the reverfioner after the alienation, but during the life of the tenant in dower or other tenant for life. 6. The writ *ad terminum qui præteriit* (Ibid. 201.) for the reverfioner, when the poffeffion is withheld by the leffee or a ftranger, after the determination of a leafe for years. 7. The writ *caufa matrimonii prælocuti* (Ibid. 205.) for a woman who giveth land to a man in fee or for life, to the intent that he may marry her, and he doth not: and the like in cafe of other deforcements. Thefe writs are plainly and clearly chalked out in that moft ancient and highly venerable collection of legal forms, the "regiftrum omnium brevium," or regifter of fuch writs as are fueable out of the king's courts, upon which Fitzherbert's "Natura Brevium" is a comment.

In the times of our Saxon anceftors, the right of poffeffion feems only to have been recoverable by writ of entry (Gilb. Ten. 42.); which was then ufually brought in the county-court. The proceedings in thefe actions were not then fo tedious, when the courts were held, and procefs iffued from and was returnable therein at the end of every three weeks, as they became after the conqueft, when all caufes were drawn into the king's courts, and procefs iffued only from term to term, which was found exceedingly dilatory, being at leaft four times as flow as the other. Hence a new a new remedy was invented, in many cafes, to do juftice to the people and to determine the poffeffion in the proper counties, and yet by the king's judges. This was the remedy by *affife*, which fee. Blackft. Comm. b. iii. For other particulars on the fubject of this article, fee Jacob's Law Dict. by Tomlins.

ENTRY *Ifland*, in *Geography*, one of the Magdalen iflands in the gulf of St. Lawrence. N. lat. 46° 18'. W. long. 61° 20'.—Alfo, an ifland in the Pacific ocean, about nine leagues N. from Cape Tierawite and under the fame fhore, which may be diftinctly feen from Queen Charlotte's Sound, at the diftance of about fix or feven leagues. The name was given to it by lieutenant Cook, who paffed it in January 1770.

ENTYPOSIS, from ἐντυπόω, *I make an impreffion*, in *Anatomy*, the articulation of the fhoulder with the arm.

ENTZERSTORFF, in *Geography*, a town of Germany, in the archduchy of Auftria; fix miles S. of Laab.—Alfo, a town of Germany, near the conflux of the rivers Reftinpach and Reifenpach; 10 miles W.N.W. of Bruck.

ENTZERSTORFF in *Logenthal*, a town of Germany, in the archduchy of Auftria; two miles S.E. of Corn Neuburg.

ENTZERSTORFF or *Statl-Entzerftorff*, a caftellated town of Germany, in the archduchy of Auftria, on the north fide of the Danube, belonging to the bifhop of Freyfingen; 24 miles W. of Prefburg and nine E. of Vienna.

ENVERMEU, a fmall town of France, in the department of the Lower Seine, chief place of a canton in the diftrict of Dieppe, with a population of 896 individuals. The canton contains 40 communes and 13,402 inhabitants, on a territorial extent of 265 kiliometres.

ENVELOPE, in *Fortification*, denotes a mount of earth fometimes raifed in the ditch of a place, and fometimes beyond it, being either in form of a fimple parapet, or of a fmall rampart bordered with a parapet.

Thefe envelopes are made where weak places are only to be covered with fingle lines, without advancing towards the field, which cannot be done but by works which require a great deal of room: fuch as horn-works, half-moons, &c. Envelopes are fometimes called fillons contregards, conferve, lunettes, &c.

ENVIRON, among *Military Men*, relates to that complete inveftment of a town, or fortrefs, which utterly precludes the acquifition of fupplies, or of reinforcements, and, in a general fenfe, may be faid to be the bafis of a blockade. When we fay that a place is environed, we are not indifcriminately to conclude, that any circumvallation has taken place; but, that the country round is fo completely poffeffed by the enemy, as to render any attempt to afford fuccour to the inhabitants unavailing. Thus, if there be feveral paffes leading to a town fituated in a valley, furrounded by mountains inacceffible, or impaffable in every part, except at thofe paffes; or if a town ftands on a peninfula, of which the ifthmus is cut off by the enemy, who likewife poffefs the navigation of the circumferent waters, fuch towns are, to all intents and purpofes, environed; and, if the blockade be duly fupported, muft in time furrender merely from a want of fupplies.

If, however, the enemy fhould not be ftrong enough to keep the inhabitants within clofe bounds, or if, notwithftanding the whole of the adjacent country may be under his controul, fupplies may be attainable from the exterior, whether by connivance among the peafantry, or by the operations of enterprifing partizans, then the place cannot be faid to be environed. When we confider the many chances arifing in favour of fuch garrifons as make a good defence, it fhould appear to be the beft policy, as well as the moft honourable conduct, to hold out to the very utmoft, and never to furrender except under the laft extremity. As to being environed, or blockaded, it is fometimes a very important advantage gained by the defending power, becaufe it muft prove a complete diverfion, by caufing a very large force to be occupied in fhutting up a comparative hand-full.

It, however, very rarely happens, that towns are, properly fpeaking, environed: the old fyftem of circumvallation is now obfolete, except in very confined cafes, and where there is no army in the field capable of raifing the fiege. We have, indeed, a recent inftance of a large city, namely, Saragoffa, having been environed; but it was under moft peculiar circumftances; for the place fell rather from a want of an adequate force to cope internally with the affailants, though, on the other hand, the want of fupplies was feverely felt. If any thing could ftrengthen the recommendation we have juft given, of continuing a defence to the laft moment, furely the noble example fhewn by that loyal and illuftrious, but moft unfortunate city, muft ferve as a ftimulus, and prompt every perfon in charge of a befieged fortrefs, or town, to defpife the efforts of the environing army, and to fell every inch of ground at the higheft price that valour can impofe on a fuperior force.

Thofe who undertake a blockade, by completely environing a town, &c. have a moft arduous tafk to perform. They have not only to oppofe the fallies of the garrifon, but to keep a very fharp look-out againft exterior attacks, which may often be fo effectually made, by an enterprifing partizan, as to coerce a very numerous army to confiderable relaxation, fuch, indeed, as muft prove favourable to the defenders. When we confider thefe circumftances, we fhall be lefs furprifed at the great loffes fuftained by befiegers, who, as well as the befieged, fuffer under all the difadvantages attendant upon fixed camps; whereby not unfrequently the moft deftructive difeafes are engendered.

ENVIRONNE', in the *French Heraldry*, is when a lion or other figure is environed, or encompaffed round with other things. Environné with fo many bezants, &c. in orle.

ENULA, in *Botany*. See INULA.

ENULION, from ἐν and οὖλον, the *gums*, a word ufed by fome medical writers for the flefh of the gums.

ENUMERATION, the act of enumerating, or counting. At the time of our Saviour's birth, Auguftus Cæfar had commanded an enumeration to be made of all the world, or rather of all the people under his empire: though feveral able authors are of opinion, that the cenfus, tax, or enumeration mentioned by St. Luke, did not extend to the whole empire, but only to the people of Judæa. See Perizonius de Cenfu Judaico, and Berger de Viis Militaribus.

At Rome, it was an ufual thing to have an enumeration made of all the families: the firft of thefe was under Servius Tullius, when the men amounted to eighty thoufand. Pompey and Craffus made another, when they reached to four hundred thoufand. That of Cæfar did not exceed one hundred thoufand; fo that the civil wars muft have deftroyed three hundred thoufand Roman citizens. Under Auguftus, in the year 725, the Roman citizens throughout the empire were numbered at four millions fixty-three thoufand. In the year of Rome 746, the citizens, being numbered again, were found four millions two hundred and thirty-three thoufand. In the year 766, being the laft year of Auguftus's reign, that prince, together with Tiberius, made another enumeration of the citizens of Rome, when they were found four millions one hundred and thirty-feven thoufand perfons.

Claudius made a new computation in the year of Chrift 48, when, as Tacitus relates it, the Roman citizens throughout the whole empire amounted to fix millions nine hundred and fixty-four thoufand; though others reprefent the number as confiderably greater. A very rare, yet indifputable medal of Claudius, never yet made public, expreffes the precife number in this lift made by Claudius, which was called oftenfio, to be feven millions of people fit to bear arms, befide all the foldiers on foot in the armies, which amounted to fifty legions, fifty-feven cohorts, and fixty foldiers. After this enumeration, we find no more till that of Vefpafian, which was the laft.

ENUMERATION, in *Rhetoric,* denotes a part of the peroration, wherein the orator, collecting the fcattered heads of what has been delivered throughout the whole, makes a brief and artful rehearfal or recapitulation thereof. See RECAPITULATION.

ENUMERATION is alfo a rhetorical figure: for which fee APARITHMESIS.

ENUMERATION *of the parts,* amounts to the fame with what we more ufually call diftribution. In this part of rhetoric, the orator acquaints his hearers with the feveral parts of his difcourfe, upon which he defigns to treat. See DISTRIBUTION and PARTITION.

ENUNCIATION, a fimple expreffion or declaration of a thing, in terms either of affirmation or denial.

The fchoolmen ufually diftinguifh three operations of the underftanding; apprehenfion, enunciation, and reafoning.

ENUNCIATION, among *Logicians,* denotes the fame as propofition.

ENUNCIATION, which, without violation of etymology, might be applied to fignify the whole act of fpeech or delivery of language, is, in conformity with the theory and fyftem laid down under the article ELOCUTION, confined to the utterance and combination of the elements, and the confequent pronunciation of fyllables, words, &c. as contradiftinguifhed from the tones, and tuning of the voice, and all that belongs to the melody of fpeech.

The perfection of enunciation confifts in the following particulars; 1. *Diftinctnefs,* or the clear and perfect formation of the refpective elements by right motions and pofitions of the organs of the mouth, accompanied by proper degrees of energy and impulfe to imprefs thofe elements fully and contradiftinctly on the ear. 2. *Articulation,* or the act of combining and linking together of the refpective elements, fo as to form them into intelligible fyllables and words, capable of being again combined into claufes and fentences for the proper conveyance of our ideas, thoughts, and determination. 3. *Implication,* or the combination and apparent union of words in oral utterance, which are graphically feparated; and by which, without injury to the intelligible diftinctnefs of the refpective words, all differences of auditory impreffions are removed between monofyllabic and polyfyllabic compofition in language.

The faults immediately oppofed to diftinctnefs are, 1. *Mumbling,* or an indolence or want of precifion in the action of the lips, affecting, of courfe, principally the labial founds, but impeding, to a certain degree, the clear progrefs of the fpecific impulfes given to other elements, by the interior organs of the mouth. 2. *Thicknefs,* or indolence and imperfection in the action of the tongue, and affecting, more or lefs, the whole or part of the lingual founds. 3. *Drawling,* which refults from indolence or inaptitude of the whole organs of fpeech, vocal as well as enunciative. Thefe are defects of lethargy, or deficiency of organic action. Thofe that follow are of another defcription. 4. *Mouthing,* a pompous but dull fpecies of indiftinctnefs, which refults from affectedly purfing up the mouth, and confequent drawing the cheeks too clofe upon, or even between the teeth, during the act of fpeaking: it is one of the unfuccefsful theatrical means of aiming at fublimity and pathos. 5. *Cluttering,* a fpecies of St. Vitus's dance of the organs; hurrying them with too much rapidity and indecifion from one elementary pofition to another, before the refpective elements are completely formed, or have had time to make their refpective impreffions diftinctly on the ear. This laft is one of the fruitful fources of impediment of fpeech.

The faults oppofed to articulation and implication are, a *fau-ul-ter-r-ring he-e-fi-i-ta-a-tion,* a *pŭl,fă,tĭve ĭn,tĕr, rŭp,tion,* (fuch as is almoft univerfally obfervable in the early reading of fchool boys, and which fome people in their reading never get rid of as long as they live,) and a pèdán-tic fòr-má-lì-ty', fuch as was ridiculed in a gentleman, who, afking his friend if he came to town in his *cha-ri-ot,* was anfwered, no, fir, I came in my *co-ach.* But the contradiftion, and even oppofition, thus marked between diftinctnefs and articulation, though fo indifpenfible to the intelligible treatment of the fubject of elocutionary fcience and inftruction, is fo little authorized by thofe who have hitherto treated upon thefe fubjects, that the writer of this article deems it neceffary controverfially to refer to thofe authorities, and to ftate the objections to the cuftomary and confufed phrafeology which they have fanctioned. Among thefe, fome have defined the term articulation as if it embraced the whole art and practice of enunciative utterance, as the ingenious, and generally fpeaking, profound and accurate Mr. Gough,—"Articulation," fays he, "is the art of modifying the founds of the larynx by the affiftance of the cavity of the mouth, the tongue, teeth, and lips." (Manch. Mem. vol. v. pt. ii. p. 645.) But much more frequently it is ufed as a pure fynonym with *diftinctnefs.* (Mr. Sheridan, in his lectures, confounds it not only with diftinctnefs but with enunciation generally, and even with idiomatic pronunciation, Lect. ii. p. 21. 8vo. edit.) But, not to infift particularly upon the important axiom, that the very admiffion of fynonyms is inconfiftent with the progrefs and communication of fcientific truth, if fuch were the ufe to which the term articulation were to be applied, why did the Englifh grammarian go to the Greek language and to the fcience of anatomy to borrow a name for an idea which he had already a good and familiar Englifh word fully and completely to convey? How came he to apply that word fo fuperfluoufly borrowed in a fenfe diametrically oppofite to that which it bears in the fcience from which it is taken? For articulation in anatomy fignifies the *juncture of bones,* or that flexible combination of joints or elementary portions into a limb, or of limbs into a body, by which the unity of the whole is conftituted, without injury to the individuality of the parts. And laftly, how came he to look out for a fupernumerary name to one idea, while another idea equally indifpenfible to his fcience (for the combination of elements is as neceffary to fpeech as their formation) without any feparate or fpecific defignation? Without going further, therefore, into critical difquifition, we may venture to lay down, as one of the canons of elocution and grammatical nomenclature, the following definition.—Articulation (as one of the effential properties of human enunciation, is the jointing or linking together of the refpective elements, and fyllables, and words (the portions, limbs, and members of fentences) as the bones themfelves, (the portions, limbs, and members of the anatomical frame) are linked or jointed together, by an analogous articulation in animal economy. Implication will then remain to be confidered merely as that part of articulation which relates feparately to the articulation

tion of ſeparate graphic words in the act of oral delivery, and conſequently as indicating rather a grammatical diſtinction, than a diſtinct ſpecies or modification of organic action: for in well delivered ſpeech (it is contended, by the authority ſo frequently referred to in the different articles relative to elocution) the ear, unaſſiſted by the memory of the eye, knows of no ſuch thing as a diviſion or diſtribution of ſpeech into ſuch ſeparable portions as in graphic compoſition are denominated words. The proceſs of enunciation and implication conſiſts in a delicate preciſion of the motion of the organs, without ceſſation of ſound, from one elementary poſition to another, by which the termination of the perfect ſound is glided more or leſs intimately into the ſucceeding element or commencement of the enſuing ſyllable. Thus literal ſounds, intimately glided into each other, are articulated into ſyllables; as, *a* and long *l* into *all*. Syllabic ſounds, intimately glided into each other, are articulated into words; as, *all* and *ways* into *always*. The terminations of words (as they are called in conformity with graphic diſtinctions) glided into the initial ſounds of ſucceeding words, are implicated into clauſes, or parts of clauſes; as

the man, a ſhip, an apple,

Harry to Harry might, and horſe to horſe, &c.

A good enunciation, then, conſiſts in that clear and accurate delivery of verbal language, by which the requiſite qualities of diſtinctneſs and articulation are combined and modified; and the due proportions and alterations of ſound and interruptions, conſtituting the ſpecific relations of letters, ſyllables, members, clauſes, and ſentences, are preſerved in diſcourſe or reading.

ENUNCIATIVE Organs, thoſe portions and members of the human mouth, by the motions, poſitions, and contact of which, ſpecific character is ſuperadded to the original impulſes of voice, ſo as to render them communicable ſigns of diſtinct ideas. See Organs *of Speech*.

ENVOICE. See Invoice.

ENVOY, a public miniſter ſent by one ſovereign prince or independent ſtate to another to negociate ſome affair, or to watch over the intereſts of that ſtate or prince in general, and furniſhed with the credentials of an envoy. Like embaſſadors, envoys may be either *ordinary*, who reſide permanently at the court of a foreign prince, or *extraordinary*, who are diſpatched for one particular purpoſe, and retire when their miſſion is accompliſhed. Envoys hold the ſecond rank among public miniſters ſent to foreign courts: but they are alike under the ſpecial protection of the law of nations, and enjoy all the privileges and immunities of embaſſadors, except thoſe relating to the ceremony of their reception, public entry, and ſolemnity of their audiences. See Embassador.

The quality of envoy extraordinary, Wicquefort obſerves, is very modern; more modern than that of reſident: the miniſters inveſted therewith, at firſt, took on them moſt of the airs of embaſſadors; but they have ſince been taught otherwiſe.

In the year 1639, the court of France made a declaration, that the ceremonies of conducting envoys extraordinary to their audience in the king and queen's coaches, with divers others, ſhould no longer be practiſed to envoys.

S. Juſtiniani, the firſt envoy extraordinary from Venice, after that regulation, offered to cover in ſpeaking to the king, but it was refuſed him; and the king of France himſelf declared, that he did not expect his envoy extraordinary at the court of Vienna ſhould be regarded any otherwiſe than as an ordinary reſident. Since this time, thoſe two kinds of miniſters have been treated alike. Wicquefort.

ENURE, in *Law*, ſignifies to take place, or be available, and is as much as to have effect. Thus for inſtance, a releaſe made to tenant for life ſhall enure, and be of force and effect to him in the reverſion.

ENURESIS, in *Medicine*, from ἐν and οὔρησις, *mingendi actus*, the noſological term for incontinence of the urine. See Urine, *incontinence of*.

ENVY, in *Ethics*, is defined by Mr. Locke to be an uneaſineſs of mind, occaſioned by the conſideration of a good we diſcover in poſſeſſion of another perſon, whom we deem leſs worthy of it than ourſelves. It is a compoſition of ſorrow and hatred, and ſtands in direct oppoſition to congratulation. Otherwiſe, envy entertains a degree of ſorrow that the good contemplated ſhould eſcape ourſelves, and of anger that it ſhould fall to the ſhare of another. Or, it is that ſpecies of malevolence which is inſpired by the conjoined influence of pride, ſorrow, and anger. It differs from *emulation* (which ſee), or a diſquiet, occaſioned by the felicity of another, not becauſe he enjoys it, but becauſe we deſire the like for ourſelves; as it occaſions an uneaſineſs not merely from the want of the felicity poſſeſſed by another, but becauſe he enjoys it. Envy, in its nature and effects, is the baſeſt, moſt miſchievous, and moſt tormenting of all paſſions. Ariſtotle (De Rhetor. l. ii. c. 12.) obſerves, that this paſſion moſt uſually affects perſons who were once upon a level with thoſe they envy. The method preſcribed by Cicero (De Orat. l. ii. c. 52.) for leſſening or removing the influence of this paſſion is to ſhew that the things which occaſioned it, have not happened to the envied perſon undeſervedly; but are the juſt rewards of his induſtry or virtue; that he does not ſo much convert them to his own profit or pleaſure, as to the benefit of others; and that the ſame pains and difficulties are neceſſary to preſerve them, with which they were at firſt acquired.

Envy, in *Mythology*, is repreſented by the Greek and Roman poets as an infernal divinity, with ſquinting eyes, lean body, pale countenance, diſturbed air, head encompaſſed with ſerpents, &c.

ENURNY, is the *herald's* term for the bordure of a coat of arms being charged with any kind of beaſts.

ENXYLON, of ἐν and ξύλον, *wood*, a name uſed by the Greek authors for a ſpecies of worm or maggot, hatched from the egg of a beetle, and having its habitation in wood; which, in this ſtate, it erodes and burrows into, in various directions. The old Greeks called it alſo *dex* and *thrips*, and uſed the pieces of wood eroded by it in remarkable figures, as ſeals. See Thrips.

ENY, Saint, in *Geography*, a ſmall town of France, in the department of La Manche; 9 miles S. W. of Carentan.

ENYDRA, in *Botany*, (ἔνυδρος, *living in the water*,) a Syngeneſious genus of Loureiro's Fl. Cochinch. 510, which appears to belong to the 4th ſection of Juſſieu's *Corymbiferæ*, and to the order *Polygamia-ſegregata* of Linnæus. The character is, Common Calyx of four leaves; partial of one leaf, rolled up into a tube, ſingle-flowered. Corollets all tubular; thoſe of the radius three-cleft. Receptacle naked. Down none. The ſpecies is E. *fluctuans*, a native of the marſhes of Cochinchina, with oppoſite, ſerrated, rather haſtate leaves, and a white terminal flower. We know not whether it be reducible to any previouſly-deſcribed genus.

ENYSTRON, of ἐν and ὕστερος, *poſterior*, a word uſed by Ariſtotle for the ſecond ventricle in ruminating quadrupeds, in which the food is elaborated and concocted.

ENZ, in *Geography*, a river of Germany, which riſes about 10 miles W. of Altenſtadt, in the circle of Swabia, paffes by Wildbad, Neuenburg, Pfortzheim, &c., and joins the Neckar at Beffigheim, in the duchy of Wurtemberg.

ENZELLI. See Einzellee.

ENZIG, a lake of Germany, in the circle of Upper Saxony, and new mark of Brandenburg; 12 miles W.S.W. of Dramberg.

ENZINAS, Francis, in *Biography*, was born at Burgos, in Spain, about the year 1515. In Moreri and other works he is known by the name of Dryander, which is a Greek tranflation of his family name. He was educated in Germany, and became a zealous difciple of Melancthon, who thought very highly of his talents, and wrote a letter in his favour to archbifhop Cranmer in the year 1548. He publifhed a Spanifh tranflation of the New Teftament, which he dedicated to the emperor Charles V.; and which drew down upon him the vengeance of the higher powers, and he fuffered an imprifonment of 15 months duration. He efcaped in the year 1545, and went to Calvin, who refided at Geneva. He publifhed "A hiftory of the State of the Low Countries, and of the Religion of Spain," which is very rare, and forms a part of the "Proteftant Martyrology," printed in Germany.

Enzinas, John, brother of the former, refided a confiderable time at Rome, and became a convert to the proteftant religion, and was fetting out for Germany to join his brother John, when fome expreffions which he dropped, relative to the corruptions and diforders of the church, occafioned his being accufed of herefy, and thrown into prifon. The terrors of a dungeon, and the profpect of a cruel death, did not daunt his noble foul, but when brought before the pope and cardinals to be examined, he refufed to retract what he had faid, and boldly avowed and juftified his opinions, for which he was condemned to be burnt alive, a fentence which was put into execution at Rome in the year 1545. Moreri, under the word Dryander.

ENZOWAN, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; four miles E. of Leitmeritz.

EO, Eu, or *Miranda*, a river of Spain, which rifes in the mountains of Afturias, feparates the province of Afturias from Galicia, and runs into the Atlantic, a little to the north of Rivadeo.

EOA, in *Ancient Geography*, a town of Africa Propria, according to Ptolemy; called Oea by Mela.

EOBANUS, Helius, in *Biography*, an eminent Latin poet, was born, in 1488, on the confines of Heffe; hence he obtained the name of Heffus. His parents were fo poor, that it has been faid he was born in the open air under the fhade of a wide fpreading tree; but his education was not neglected. He was taught Latin at a fmall fchool, and purfued his more advanced ftudies at the univerfity of Erfurt, where he afterwards taught the belles lettres till the year 1526, when Philip Melancthon procured him an invitation from the city of Nuremberg. Here he taught for feven years and then returned to Erfurt, where his reputation was fo high and fo firmly eftablifhed, that he is faid to have had 1500 fcholars at a time. His fame produced him but very trifling emoluments, and he was often labouring under the greateft poverty. He at length obtained through the intereft of Philip, landgrave of Heffe, a good fituation at the univerfity of Marpurg, where he died on the 5th of October 1540. Camerarius, who wrote his life, praifes his good qualities, his application to labour, and his talent at poetry. He was a man of great good nature, fincere in his attachments, and averfe from contention. He took credit to himfelf for being a hard drinker, and would challenge any man as to the quantity of liquor which he would drink, and in a conteft of this kind his antagonift fell dead on the floor. He wrote many books, a lift of which is given by Moreri: his poems and epiftles have been frequently publifhed. Moreri.

EODANDA, in *Ancient Geography*, a defert ifland, fituated E. of Arabia Felix.

EOLIAN, in *Ancient Mufic*. The Eolian tone or mode was one of the mean or principal modes of the Greek mufic, and its fundamental found was immediately above the Phrygian.

The Eolian mode was grave, according to Lafus. "I fing (fays he) Ceres and her daughter Melibæa, the fpoufe of Pluto, upon the Eolian mode, full of gravity."

The name of Eolian, given to this mode, is not derived from the Eolian ifles, but from Eolia, a country of Afia Minor, where it was firft ufed.

EOLIC, or rather *Æolic*. See Æolic.

EOLIPILE. See Æolipile.

EOLUS, and Eolus's *harp*. See Æolus.

EON, or Æon. See Æon.

Eon, a word ufed by fome anatomical writers to exprefs the whole ambit or compafs of the eye.

Eon, de l'Etoile, in *Biography*, a French fanatic, who, from the refemblance of his name to the word *eum*, applied to himfelf this paffage, "per Eum qui venturus eft judicare vivos et mortuos," and was fatisfied that he was the perfon alluded to, *viz.* the fon of God. This doctrine he taught with much fervour, and fucceeded, like other enthufiafts, in making many converts, who gave him the homage due to one on whom their future deftiny depended. At Rheims he drew down the notice of the clergy, who caufed him to be apprehended, and after an examination he was committed to prifon, where he languifhed a few days, and miferably died. Many of his adherents perfifting in the fame follies which had characterized their mafter, were apprehended, and, refufing to abjure their errors, were delivered over to the fecular power, and were burnt alive in the neighbourhood of Rheims. Such was the perfecuting fpirit of the priefts who never fail to abufe the power entrufted to them, and who would, in this inftance, have been better employed in inftructing their own flocks than in murdering thefe deluded fanatics. Moreri.

EOOA. See Ea-oo-wee.

EORDÆA, in *Ancient Geography*, a country of Macedonia, in Mygdonia.

EORIA, in *Mythology*, a feaft celebrated by the Athenians in honour of Erigonus, who, by way of punifhment, for their not avenging the death of his father Icarus, engaged the gods to inflict the curfe on their daughters, that they fhould love men who never returned their paffion. The feaft was inftituted by the order of Apollo.

EOSTRE, a Saxon goddefs, to whom they facrificed in the month of April, called the month of Eoftra; and thence the name Eafter, which the Saxons retained after their converfion to Chriftianity, applying it to the feftival celebrated in commemoration of our Saviour's refurrection. Bed. de Rat. Temp. cap. 13.

EPACRIA, in *Ancient Geography*, a town of Greece, in Attica.

EPACRIS, in *Botany*, from επι, *upon*, and ακρις, *the fummit of a mountain*, alluding to the native fituation of feveral of the fpecies. Mountain-bloffom. Forft. Gen. t. 10. Linn. Suppl. 19. Schreb. 113. Willd. Sp. Pl. v. 1. 834. Mart. Mill. Dict. v. 2. Gærtn. t. 94. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Ericæ*, Juff.

Gen. Ch. *Cal.* Perianth of feveral imbricated, ovate, acute leaves; the five innermoft longeft and equal. *Cor.*

of one petal, funnel-ſhaped; tube dilated upwards; limb in five equal, ovate, ſpreading ſegments. Nectary of five obovate blunt ſcales, cloſely ſurrounding the baſe of the germen. *Stam.* Filaments five, equal, very ſhort, inſerted into the ſummit of the tube of the corolla; anthers incumbent, roundiſh oblong, of two cells and two lobes, burſting longitudinally, deſtitute of any appendage. *Piſt.* Germen ſuperior, roundiſh, with five furrows; ſtyle cylindrical, rather ſhorter than the tube; ſtigma capitate. *Peric.* Capſule roundiſh, ſomewhat depreſſed, with five furrows, of five valves and five cells, the partitions from the centres of the valves. *Seeds* numerous, minute, angular, affixed to the central column.

Eſſ. Ch. Calyx imbricated. Corolla tubular. Stamens inſerted into its orifice. Scales five, at the baſe of the germen. Capſule ſuperior, of five cells and five valves, with partitions from their middle. Seeds numerous, chaffy.

The numerous ſpecies of this elegant genus, but few of which have, as yet, found their way into botanical books, are all natives of New Holland or New Zealand. They bear a general reſemblance to the vaſt Cape genus *Erica*, with which botaniſts have aſſociated them in natural order, not without ſome uncertainty. Willdenow enumerates but four ſpecies, of which the fineſt is E. *grandiflora*, Sm. Exot. Bot. v. 1. 75. t. 39. Curt. Mag. t. 982. (E. longiflora; Cavan. Ic. v. 4. 25. t. 344.) "Leaves heart-ſhaped, pungent, recurved, on footſtalks. Flowers pendulous." Native of dry ſandy places in New South Wales, flowering in October. Its chief beauty conſiſts in its copious long pendulous flowers, with a crimſon tube and white border.

To theſe are now added, E. *obtuſifolia*, Sm. Exot. Bot. v. 1. 77. t. 40. "Leaves elliptic-lanceolate, very obtuſe, and pointleſs, on ſhort footſtalks. Flowers drooping toward one ſide." Grows in a ſandy ſoil near Port Jackſon, New South Wales, bloſſoming in October. The flowers are cream-coloured, with a browniſh calyx.

E. *pulchella*, Cavan. Ic. t. 345. Curt Mag. t. 1170. Branches clothed with ruſty down. Leaves heart-ſhaped, recurved, pungent. Flowers axillary, crowded. Native of Port Jackſon. Flowers white, ſweet-ſcented.

E. *pungens*, Cavan. Ic. t. 346. Branches ſmooth. Leaves ovate, pungent. Flowers axillary, crowded. Tube cylindrical. Common about Port Jackſon. The flowers are copious, large, ſnow-white, and very fragrant, reſembling thoſe of a *Phlox* in ſize and figure. Cavanilles' plate, a truly miſerable repreſentation of this magnificent ſpecies, miſled Dr. Sims in Curt. Mag. to confound it with the laſt. We apprehend this laſt writer has committed a further error in taking the red-flowered ſpecies, repreſented in his t. 1199, for a variety of the *pungens*. They ſeem to us very diſtinct.

Forſter and Cavanilles confounded with the genus of *Epacris* that of *Styphelia*, whoſe fruit is a drupa, with five ſeeds.

EPACTHES, Επαχθης, in *Antiquity*, a feſtival celebrated in honour of Ceres, named Αχθεια, from αχθος, *i. e. grief*, in memory of her ſorrow, when ſhe had loſt her daughter Proſerpine.

EPACTS, in *Chronology*, the exceſſes of the ſolar month above the lunar ſynodical month; and of the ſolar year above the lunar year of twelve ſynodical months; or of ſeveral ſolar months above as many ſynodical months; and ſeveral ſolar years above as many dozen of ſynodical months.

The epacts, then, are either *annual* or *menſtrual*.

Epacts, *Menſtrual*, are the exceſſes of the civil or calendar month above the lunar month.

Suppoſe, *e. gr.* it were new moon on the firſt day of January; ſince the lunar month is 29 days, $12^h\ 44'\ 3''$; and the month of January contains 31 days; the menſtrual epact is 1 day $11^h\ 15'\ 57''$.

Epacts, *Annual*, are the exceſſes of the ſolar year above the lunar.

Hence, as the Julian year is 365 days 6^h, and the Julian lunar year 354 days $8^h\ 48'\ 36''$, the annual epact will be 10 days $21^h\ 11'\ 22''$; that is, nearly 11 days. Conſequently, the epact of two years is 22 days; of three years, 33 days; or rather three, ſince 30 days make an emboliſmic, or intercalary month.

Thus the epact of four years is 14 days, and ſo of the reſt; and thus, every 19th year the epact becomes 0; conſequently, the 20th year the epact is 11 again; and ſo the cycle of epacts expires with the golden number or lunar cycle of 19 years, and begins with the ſame, as in the following table; which is formed by the conſtant additions of 11, caſting off 30; ſuppoſing the lunar month to conſiſt of 29 and 30 days, and the civil year of 365 days, with a biſſextile every fourth year. This natural order of the epacts is ſuch as was eſtabliſhed by the council of Nice, A.D. 325.

				19	XXIX

Again, as the new moons are the ſame, that is, as they fall on the ſame day every 19 years, ſo the difference between the lunar and ſolar years is the ſame every 19 years. And becauſe the ſaid difference is always to be added to the lunar year, in order to adjuſt or make it equal to the ſolar year; hence the ſaid difference reſpectively belonging to each year of the moon's cycle is called the "epact of the ſaid year," that is, the number to be added to the ſaid year, to make it equal to the ſolar year, the word being formed from the Greek επαγω, *induco, intercalo*.

Upon this mutual reſpect between the cycle of the moon and the cycle of the epacts, is founded this rule for finding the Julian epact, belonging to any of the moon's cycle. Multiply the year given of the moon's cycle into 11; and if the product be leſs than 30, it is the epact ſought; if the product be greater than 30, divide it by 30, and the remainder of the dividend is the epact. For inſtance, we would know the epact for the year 1712, which is the third year of the moon's cycle. Wherefore 3 is the epact for 1712, for $11 \times 3 = 33$, and 33 being divided by 30, there is left three of the dividend for the epact. But the difference of the Julian and Gregorian years being equal to the exceſs of the ſolar above the lunar year, or 11 days, it happens that the Gregorian epact for one year is the ſame with the Julian epact for the preceding year.

By the help of the epact may be found what day of any month in any year the new moon falls on, thus: to the number of the month, from March incluſively, add the epact of the year given: if the ſum be leſs than 30, ſubtract it out of 30; if greater, ſubtract it out of 60; and the remainder will be the day whereon the new moon will fall.

If the new moon be ſought for in the month of January or March, then nothing is to be added to the epact; if for February or April, then only one is to be added.

For

For example: we would know what day of December the new moon was on A.D. 1711, the epact, whereof is 22. By the aforesaid rule, we find it will be December the 28th; for $22 + 10 = 32$, and $60 - 32 = 28$. (See MOON.) The day whereon the new moon falls being thus found, it is easy to infer from thence what the age of the moon is on any day given. See MOON.

However, there is a peculiar rule commonly made use of for this purpose, which is this: add the epact of the year, the number of the month, from March inclusively, and the given day of the month all into one sum; this, if it be less than 30, shews the age of the moon; if it be greater than 30, divide it by 30, and the remainder of the dividend shews the age of the moon, or how many days it is from the last new moon: this method will never err a whole day.

For instance; what was the age of the moon on December 31st, A.D. 1711? by this rule, we find, that the moon was then three days old; that is, it was then three days from the last new moon. For $22 + 10 + 31 = 63$, and 63 being divided by 30, there will remain of the dividend 3. And this exactly agrees to the other foregoing rule, whereby it was found, that the new moon was on December 28, 1711.

It must be observed, that at the time of the general council of Nice in 325, it was thought, that 19 Julian solar years were exactly equal to a cycle of 19 lunar years, or 235 synodical months; and therefore, that at the end of 19 years the new moons would happen exactly at the same time as they did 19 years before: but this a mistake;

	days.	h.	′	″	‴
For 19 Julian solar years contain	6939	18	0	0	0
Whereas 235 synodical months contain only	6939	16	31	56	30
And are therefore less than 19 Julian solar years, by	0	1	28	3	30

Hence it appears, that the cycle of 19 years anticipates the new moons by one day in 310.7 years very nearly; and therefore the same cycle of epacts will not always hold; the moon's anticipation lessening the several epacts by one every 310.7 years.

To have the epacts, therefore, point out the new moons perpetually; that epact given in the calendar is not sufficient; but all the 30 epacts should be bestowed throughout the whole year, that the calendar may exhibit all the cycles of epacts. See a table of this kind in Wolfius's Elementa Chronologiæ, apud Opera, tom. iv. p. 133.

It is plain, that whenever the fore-mentioned anticipation takes place, or it becomes necessary to set the golden numbers one day back in the calendar, the epact must be increased by an unit more than usual, *e.gr.* 12 must be added instead of 11, to the epact of the preceding, in order to form the epact of the current year; and thus the subsequent epacts, increasing constantly by 11, will be greater by unit than the corresponding epacts of the preceding 19 years. If the epacts were once properly prefixed in the calendar, to denote the days on which the new moons fall in those years, of which those numbers are the epacts, they might remain in the calendar without shifting their places; since the augmentation of each epact by an unit extraordinary would answer the purpose, and preserve the Julian account tolerably exact. But the Gregorian account is not so easily adjusted; for it will require more consideration to determine when the epacts are to be more than ordinarily augmented, and at what times they are to continue in their usual course; nay, to know when they are to be diminished by an unit, which will most commonly be the case; because, in every Gregorian solar year, consisting of any number of entire centuries not divisible by four, the equinox is supposed to have anticipated one whole day; and therefore the bissextile, or intercalary day, is omitted; consequently the preceding solar year, where one day was lost, exceeded the lunar year by 10 days only instead of 11.

Lord Macclesfield has given the following directions for this purpose:

In the years 1800, 2100, 2700, 3000, &c. where the number of centuries is divisible by 3 only, the Gregorian solar as well as the lunar year will have lost a day; and consequently the difference between them will be the same as usual; therefore in those years the epacts and golden numbers will remain unaltered; the former will go on in the same manner, and the latter stand prefixed to the same days in the calendar for another century as they did for the last. The case will be the same in the years 2000, 2100, 3200, &c. where the number of centuries is divisible by 4 only. But in the years 2400, and 3600, whose number of centuries is divisible both by 3 and 4, the Gregorian solar year remains as usual, and the lunar year has lost a day: the difference betwixt them being 12, the epact of the preceding year must be augmented by that number instead of 11, in order to form the epact of the then present year; and thus a new set of epacts will be introduced, each exceeding the precedent corresponding epacts by unit; and the golden numbers must be set one day back in the calendar. Again, in the years 1900, 2200, 2300, 2500, &c. where the number of centuries is divisible neither by 3 nor 4, the Gregorian solar year loses one day, and the lunar none; and the difference between them, *viz.* 10, and not 11, must be added to the epact of the preceding for that of the current year; and thus a new set of epacts will be introduced, less by unit than their precedent corresponding epacts; and the golden numbers must be set a day forwarder in the calendar. By this method the new moon might be pointed out, either by the golden numbers or the epacts placed in the calendar for that purpose; according to the Julian account for ever, and according to the Gregorian account till the year 4199 inclusive. Phil. Transact. vol. xlvi. p. 417. or N° 495, art. v.

Rule for finding the Gregorian Epact.

Divide the centuries of any year by 4; multiply the remainder by 17, and to this product add the quotient multiplied by 43 and the number 86, and divide this whole sum by 25; multiply the golden number by 11, from which product subtract the last quotient, and the remainder, rejecting the thirties from it, will be the epact.

Example for 1809.

1. $18 \div 4 = 4$ — Remr. 2.
2. $2 \times 17 = 34$.
3. $43 \times 4 + 34 + 86 = 292$.
4. $292 \div 25 = 11$.
5. 5 (G. N.) $\times 11 = 55$.
6. $55 - 11 = 44$. And,
7. $44 \div 30$.

leaves a remainder 14 for the epact required.

The reason of the operation may be evinced in the following manner.

If the new moons returned exactly at the same time after the expiration of 19 years, the product of the golden number, or year of the lunar cycle, multiplied by 11, would give the Gregorian epact; but we have already shewn, that they anticipate a day in 310.7 years, and, therefore, in a Julian

Julian century, they muſt anticipate $\frac{100}{310.7}$, or nearly $\frac{8}{25}$ of a day; and in a Gregorian common century, which is one day ſhorter than a Julian century, they happen 1 day $-\frac{8}{25}$, or $\frac{17}{25}$ of a day later; and $3\times\frac{17}{25}=\frac{51}{25}$ of a day in 3 common centuries; but in four Gregorian centuries, one of which is biſſextile, they will happen later by $\frac{51}{25}-\frac{8}{25}=\frac{43}{25}$ of a day; and in this proportion muſt the epacts be decreaſed. At preſent the Gregorian epact is 11 days ſhort of the Julian; but the quotient of the number of centuries divided by 4, which at this time is 4, multiplied (as the rule directs) by $\frac{43}{25}$, with the addition of the remainder 1 multiplied by $\frac{17}{25}$ amounts only to $\frac{189}{25}$, or 7 days $+\frac{14}{25}$; therefore, $\frac{86}{25}$ *i. e.* 3 days $+\frac{11}{25}$ muſt be added to complete the 11 days.

The epact may be found till the year 1900, by ſubtracting one from the golden number, multiplying the remainder by 11, and rejecting the thirties; becauſe the laſt quotient mentioned in the foregoing rule will be always 11 till the year 1900.

In the following table, the golden numbers, with their correſponding epacts, till the year 1900, may be ſeen at one view.

EPAMINONDAS, in *Biography*, a famous Theban general, who was the ſon of Polymnis, diſtinguiſhed by his family and rank, and a native of Thebes in Bœotia. Although his deſcent was honourable his patrimony was ſmall, and was wholly exhauſted in procuring the means of every kind of inſtruction. Not ſatisfied with acquiring under the beſt maſters all the ſolid and ornamental accompliſhments, which diſtinguiſhed the poliſhed Grecian, he alſo habituated himſelf in early life to play on the harp and flute, to ſing and dance, and by the exerciſes of the palæſtra, to improve the vigour of his corporeal powers, and thus to qualify himſelf for encountering the toils of a military character. Having expended to the moſt important and uſeful purpoſes the ſlender pittance which he derived from his family, he exemplified, in an humble and indigent condition, the principles of philoſophy which he had imbibed. Superior to any temptations which affluence or ambition could offer, he maintained, during the whole courſe of his life, an uncorrupt mind, an invariable regard to truth, and an irreproachable rectitude of conduct. If we contemplate him in his public character, we cannot leſs than admire the ſublime philoſophy, which enlightened and directed all his actions; that genius, which was ſo rich in information and ſo fruitful in reſources; and thoſe plans which were concerted with ſuper-eminent prudence and executed with equal celerity. In private life, he was no leſs diſtinguiſhed above all his cotemporaries, by equanimity and ſelf-command, by the purity of his morals, by the dignity of his demeanour, and the ſuavity of his manners, by his mildneſs, benignity, and modeſty, and by the forbearance and patience with which he endured the injuſtice of the people and the unmerited ſeverity of ſome of his friends. Formed for friendſhip and ſociety by the amiableneſs of his diſpoſition, and the unaſſuming and condeſcending freedom with which he engaged in occaſional intercourſe with his companions, he engaged the eſteem and confidence of thoſe with whom he aſſociated. Although he had enriched his mind with every kind of knowledge, he choſe rather to hear than to ſpeak. His reflections were always juſt and profound. On occaſions of controverſy, when it was neceſſary to defend himſelf, his anſwers were prompt, energetic, and preciſe; and his converſation was peculiarly intereſting when it turned on philoſophical or political topics. Theſe traits of his character might be exemplified by a variety of inſtances that are furniſhed by the hiſtorians of his life. His houſe was leſs the aſylum than the ſanctuary of poverty. When Epaminondas was ſetting out on an expedition into Peloponneſus, he was obliged to borrow 50 drachmas (about 1*l.* 17*s.* 6*d.*) to purchaſe the neceſſary equipage; and yet it was about the ſame time that he indignantly rejected 50 pieces of gold, which a Theſſalian prince had ventured to offer him. When a young man announced to him the orders of Artaxerxes, king of Perſia, for delivering to him a conſiderable ſum, and informed him that he himſelf had been forced to accept five talents, Epaminondas receiving the meſſenger, ſaid to him, "Hear me, Diomedon, if the views of Artaxerxes be conſiſtent with the intereſts of my country, I do not need his preſents; if not, all the gold in his empire would not induce me to betray my duty. You have judged of my heart by your own; I forgive you this miſtake; but depart inſtantly from the city, leſt you ſhould corrupt the inhabitants." To the young man who had received the preſent he ſaid, "As for you, Mycithus, if you do not this moment return the money you have received, I ſhall deliver you up to the magiſtracy." When he was at the head of the army, and was informed that his ſhield-bearer had ſold a captive his liberty; "Give me back my buckler," ſaid Epaminondas; "ſince your hands are foiled with money, you are no longer worthy to follow me in dangers." But we muſt haſten to give a ſhort abſtract of his military exploits. Pelopidas, an affluent fellow-citizen, attached himſelf to Epaminondas by the moſt intimate friendſhip, and when he could not prevail with this illuſtrious youth to partake of his fortune, he reſolved to ſhare in the poverty of his friend and to form himſelf upon the model of his conduct. Accordingly they concurred in the noble deſign of raiſing the Theban republic to eminence among the ſtates of Greece: they began with jointly ſuccouring the Lacedæmonians, whilſt they were in alliance with the Thebans. In this ſervice a battle occurred in which Pelopidas and Epaminondas were both wounded; but when the former fell, the latter protected him and continued to fight over him againſt a hoſt of foes, till they were both reſcued by their friends. At a ſubſequent period the citadel of Thebes

Thebes was taken by the Lacedæmonians, and Pelopidas with others attached to liberty and independence were expelled, but Epaminondas was ſuffered to remain, as one whoſe poverty and philoſophy would prevent him from taking any part in political concerns. When the exiles, about four years afterwards, regained the city, they were joined by Epaminondas, and the Thebans regained their liberty. Theſe two friends concurred in improving the military diſcipline of their fellow-citizens; and Epaminondas in particular took pains by his counſel and example, in promoting among them that frugality and contempt of pleaſure which lie at the foundation of all manly exertions. By ſuch conduct he gained the confidence of the Thebans, and being raiſed to a high rank in the army, he was deputed as a delegate to Sparta for the purpoſe of negociating a peace. On this occaſion, when the other deputies were overawed by Ageſilaus, who guided the operations of the Lacedæmonians, Epaminondas aſſerted the dignity of his character as the repreſentative of an independent ſtate, and infiſted that the Thebans ſhould retain the ſame authority in Bœotia with that of the Spartans in Laconia. The Spartan king was incenſed, and war was immediately declared againſt the Thebans. The Lacedæmonians gave orders to their king Cleombrotus, to march into Bœotia at the head of an army conſiſting of 10,000 foot ſoldiers and 1000 horſe. The army of the Thebans was made up of only 6000 infantry and a ſmall body of cavalry; but Epaminondas commanded it, and under him was Pelopidas. The two armies met at Leuctra, a ſmall town of Bœotia, and on the 8th of July, B.C. 371, a battle was fought, which by the wiſdom and valour of Epaminondas terminated in the defeat of the Lacedæmonians, and the death of Cleombrotus. It afforded ſingular ſatisfaction to the victorious general that his father and mother had lived to witneſs the glory he now acquired. Two years after (B.C. 369) Epaminondas and Pelopidas were nominated Bæotarchs, or chiefs of the Bœotian league. The concurrence of circumſtances, mutual eſteem, friendſhip, and an uniformity of ſentiments and views, formed an indiſſoluble union between theſe two great men. With Pelopidas, the companion of his labours and his glory, Epaminondas entered Peloponneſus, ſpreading terror and deſolation through the ſtates in alliance with Lacedæmon, haſtening the defection of others, and breaking the yoke under which the Meſſenians had groaned for centuries. Seventy thouſand men of different nations marched under his orders with an equal confidence, and he led them on to Lacedæmon. Ageſilaus, appriſed of his approach, was anxious and alarmed; but ſuch was his reſiſtance, and the delay occaſioned by it, that Epaminondas thought it moſt prudent to retreat. After quitting the Spartan territories, he rebuilt the ancient city of Meſſene, and recalled its diſperſed inhabitants from the ſurrounding countries, in which they had long lived as aliens. It was the eſtabliſhed rule of the Bœotian league, that the chiefs ſhould hold their office only for a year, and then reſign to their ſucceſſors. Epaminondas and Pelopidas, however, retained their authority four months longer than the term preſcribed by law. For this they were accuſed, and judicially proſecuted. Pelopidas puſillanimouſly ſunk under the charge; but Epaminondas appeared before his judges with the ſame tranquillity as at the head of his army, and thus addreſſed them: "The law condemns me, I merit death, I only demand that this inſcription be engraven on my tomb: the Thebans have put Epaminondas to death, becauſe at Leuctra he forced them to attack and vanquiſh thoſe Lacedæmonians, whom they did not before dare to look in the face; becauſe his victory ſaved his country, and reſtored liberty to Greece; becauſe under his command the Thebans beſieg ed Lacedæmon, which deemed herſelf too fortunate to eſcape from ruin: and becauſe he rebuilt Meſſene, and ſurrounded it with ſtrong walls." The people preſent applauded this ſpeech, and the judges did not dare to condemn Epaminondas. In the next year Epaminondas marched again into Peloponneſus to aid the Arcadians againſt the Spartans; and having taken ſome towns and laid waſte the country, he marched to Corinth, which was ſucceſsfully defended againſt him. Upon his return, ſo uncertain is popular favour, he was deprived of his command, and reduced to the condition of a private citizen. After ſome time, an army being ſent to reſcue Pelopidas, who had been ſeized and impriſoned by the tyrant Alexander the Pheræan, Epaminondas ſerved in it as a private ſoldier, and in that humble rank preſerved the army from being utterly deſtroyed. His fellow-citizens reinſtated him in his command, and ſent him with freſh forces to recover his friend, whoſe life was ſuppoſed to be in imminent danger. Alexander was ſo intimidated that he acquieſced in a ceſſation of arms, on condition of releaſing Pelopidas and another deputy. Thebes had now arrived at ſuch a degree of importance among the Grecian ſtates, as to be preferred to Sparta and Athens by the Perſians, who, therefore, wiſhed to enter into a treaty with the Thebans. Pelopidas concluded the treaty, though the Theban allies demurred againſt it. Epaminondas was therefore deputed with an army to force the Achæans to continue the alliance; and in this buſineſs he ſucceeded, and a general peace ſoon followed. Epaminondas wiſhed to render his country as powerful by ſea as it was by land; and with this view he was deputed to negociate with the Rhodians, Chians, and other maritime people. The Thebans were ſtill purſuing their ambitious deſigns; and Epaminondas marched a powerful army into Peloponneſus: but, as a confederacy was formed againſt the Thebans, the troops of which aſſembled at Mantinea, Epaminondas, apprehending that Sparta would be left defenceleſs, made a ſudden march in order to ſurpriſe it. But Ageſilaus was ready to receive him. Informed by a deſerter of Epaminondas's march, he returned home with extraordinary celerity, and placed his ſoldiers in the moſt important ſtations. The Theban general ordered ſeveral attacks. He had penetrated to the forum, and made himſelf maſter of one part of the city, when Ageſilaus, then near 80 years of age, liſtening only to the dictates of deſpair, ruſhed into the midſt of danger, and ſeconded by the brave Archidamus his ſon, repulſed the enemy and compelled them to retire. Epaminondas was not moleſted in his retreat; but a victory was become neceſſary, that the failure of his enterpriſe might be forgotten. He therefore marched ſuddenly to Mantinea, expecting to find it unguarded; but here he was diſappointed. He determined, however, to riſk a battle for the purpoſe of retrieving his honour. The army of the Lacedæmonians and their allies conſiſted of more than 20,000 foot and near 2000 horſe; the army of the Theban league of 30,000 infantry and about 3000 cavalry. Never did Epaminondas diſplay greater abilities than on the preſent occaſion; ſo that the enemy, diſmayed at his appearance, betook themſelves to flight. But whilſt he was purſuing them with great ardour, they ſuddenly rallied, and poured upon him a ſhower of darts. At length one of them pierced his breaſt with a javelin, the point of which was left in his body. When he was carried off the ground to his tent, and had recovered his ſpeech, his firſt queſtion was, what was become of his ſhield? when it was brought him, he kiſſed it as the inſtrument of his labours and his glory. He then inquired concerning the event of the battle; and being informed

formed that the Thebans were victorious, he said, "It is well; I have lived long enough;" or, as others report his declaration, "I die unconquered. Advise the Thebans to conclude a peace." The javelin being then extracted, he expired, B. C. 363. Epaminondas was never married; and he seems to have regarded celibacy as most favourable to his philosophical pursuits in private life, and to his active services in a public station. On the plain where he fell, two monuments were raised to him, *viz.* a trophy and a tomb. Epaminondas is represented by Cicero as one of the greatest men that any age or nation ever produced: and why, it is said, should we not grant this honourable distinction to the general who perfected the art of war, who eclipsed the glory of the most renowned commanders, and who was never vanquished but by fortune; to the statesman, who gave to Thebes a superiority she had never possessed, and which she lost immediately upon his death; to the negociator who, in the general assemblies and congresses of Greece, always maintained a superiority over the other Grecian deputies, and found means to retain in the alliance of Thebes, his country, even the states who were jealous of the growth of this new power; to the man who equalled in eloquence the greater part of the Athenian orators, was no less devoted to his country than Leonidas, and perhaps more just even than Aristides? Travels of Anacharsis, vol. ii. Corn. Nep. Vit. Epam. Plutarch Vit. Pelop. & Agesil. Univ. Hist. vol. v. and vi.

EPANALEPSIS, Επαναληψις, called also *Epanadiplosis*, in *Rhetoric*, the repetition of the same word in the beginning of one sentence, and at the end of another. Thus Virgil,

"Ambo florentes ætatibus, Arcades ambo."

Such also is the expression of Plautus (Amph. Act ii. Sc. 2. v. 21.): "Virtue contains all things: he wants no good thing who has virtue." The figure is the same, though the principle is less honest, which occasions the advice given by the writer in Horace, (Epist. i. 1. 65.) "Get money, if you can, honestly; but, however, get money." This figure adds force to an expression, when the principal thing designed to be conveyed is thus repeated, so as to leave its impression last upon the mind. And the beauty is heightened, when the sentence has an agreeable turn arising from two opposite parts; as in Cicero's compliment to Cæsar, (Pro Marcell. c. 6.): "We have seen your victory terminated by the war: your drawn sword in the city we have not seen." Hermogenes (Sturm. de Univers. Eloc. p. 410.) calls this a *circle*, because the sentence returns again to the same word. See ANADIPLOSIS.

EPANAPHORA, Επαναφορα, the same with anaphora.

EPANA'STASIS, (from επι, and ανιστημι, *to excite*,) in *Surgery*, a tumour, or tubercle.

EPANASTROPHE, Επαναστροφη, in *Rhetoric*, the same with what is otherwise called anadiplosis.

EPANCYLO'TUS, (from επι, and αγκυλος, *crooked*), in *Surgery*, a bandage described by Oribasius.

EPANODOS, Επανοδος, in *Rhetoric*, an inversion of a sentence, or a repetition of the same words in an inverted order; thus:

"Nox brevis nimis, ah! nimis brevis nox." Voss. Rhet. lib. v. p. 298.

This figure comprehends both *anadiplosis* and *epanalepsis*; for it both begins and ends with the same word, and the same word is likewise repeated in the middle. This turn of expression has a beauty in it, and shews a readiness of thought. Minutius Felix has given an example of it, when he is exposing the folly of the Egyptian superstition. "Isis," says he, "with Cynocephalus, and her priests, laments, bemoans, and seeks her lost son; her attendants beat their breasts, and imitate the grief of the unhappy mother: in a little time the son is found, upon which they all rejoice. Nor do they cease every year to lose what they find, or to find what they lose. And is it not ridiculous to lament what you worship, or to worship what you lament?" This figure serves likewise to illustrate and enforce the sense by setting it in two opposite views. Such is the expression of the prophet (Is. v. 10.) "Wo unto them, who call good evil, and evil good: who put darkness for light, and light for darkness."

EPANORTHOSIS, or CORRECTION, in *Rhetoric*, a figure by which the orator revokes and corrects something before alleged, as too weak, and adds something stronger and more conformable to the passion by which he is agitated.

The word is formed of ορθος, *right, straight*; whence ορθοω, *I straighten*; ανορθοω, επανορθοω, *I redress, straighten, correct*, and επανορθωσις, *correction*. Accordingly the Latins call it *correctio* and *emendatio*.

This figure is used in different ways. Sometimes one or more words are recalled by the speaker, and others substituted in their room. At other times, without recalling what has been said, something else is introduced as more suitable, instances of both kinds follow.

Such, *e. gr.* is that of Cicero for Cœlius: "O stultitia! stultitiamne dicam, an impudentiam singularem? Oh folly! folly did I call it, or rather intolerable impudence?" And in the first Catilinarian: "Quanquam quid loquor? Te ut ulla res frangat? Tu ut unquam te corrigas? Tu ut ullam fugam meditare? Tu ut ullum exilium cogites? Utinam tibi istam mentem dii immortales donarent." Thus also Terence, in the Heautontimo-rumenos, introduces his old man Menedemus, saying.

"Filium unicum adolescentulum
Habeo. Ah! quid dixi habere me? imo habui, Chreme.
Nunc habeam necne, incertum est." "I have an only son, Chremes. Alas! did I say, that I have? I had indeed; but it is now uncertain, whether I have or not."

Cicero, in his defence of Milo, speaking to the judges concerning Clodius says; "Are you only ignorant, what laws, if they may be called laws, and not rather torches and plagues of the state, he was about to impose and force upon us?" Again, in his defence of Plancius he says; "What greater blow could those judges, if they are to be called judges, and not parricides of their country, have given to the state, than when they banished him, who, when prætor, freed the republic from a neighbouring war, and when consul from a civil one?" Here he is speaking of Opimius: but in commending the moderation of Lucius Mummius who did not enrich himself, but his country, by demolishing the wealthy city of Corinth, he thus recalls his whole expression, and by giving it a new turn, heightens the compliment he designed him. "He chose rather," says he, "to adorn Italy, than his own house, though by adorning Italy his house seems to have received the greatest ornament." De Off. l. ii. c. 22. Sometimes the correction is made by substituting something contrary to what had been said before: as in the following passage of Cicero (Philipp. iii. c. 2.): "Cæsar" (meaning Augustus), "though but a youth, by an incredible and surprising resolution and courage, when Antony was most enraged, and we dreaded his cruel and pernicious return from Brundisium, at a time when we neither asked, nor expected, nor desired it (because it was thought impossible) raised a very powerful army of invincible veterans, to effect which he threw away his whole estate. Although I have used ufed an improper word; for he did not throw it away, but employed it for the fafety of the government." At other times, as we have before obferved, the correction is made by adding a more fuitable word, without any repetition of the former. Thus Cicero, after he has inveighed againft the crimes of Verres (lib. ii. c. 29.) breaks out into this pathetic exclamation: "O the clemency, or rather wonderful and fingular patience of the Roman people!" The word *clemency* not being, in his apprehenfion, ftrong enough, he adds *patience*, as better anfwering his purpofe. The fudden and unexpected turn of this figure gives a furprife to the mind, and by that means renders it the more pathetic.

EPANTHE'SMA, or Epanthísma, (from επι, and ανθος, *a flower*), in *Surgery*, an efflorefcence; exanthema.

EPAPHÆ'RESIS, (from επι, importing *a repetition*, and αφαιρησις, *a removal*). In Galen it is employed in the fenfe of a repeated evacuation by bleeding.

EPARCHA, in the *Mufic of the Ancients*. Pollux, (Onomaft. lib. iv. cap. 9.) tells us, that the eparcha was one of the ftrains of the Citharian mode, according to the divifion of Terpander. It was probably the prelude, for that is the fignification of the word eparcha.

EPARCHUS, Επαρχος, an officer under the Greek emperors of Conftantinople, who had the command of the guards, or government of a province.

EPARER, in the *Manege*, is ufed to fignify the flinging of a horfe, or his yerking or ftriking out with his hind legs. In caprioles, a horfe muft yerk out behind with all his force; but in ballottades he ftrikes but half out; and in croupades he does not ftrike out his hind legs at all. All horfes that yerk are reckoned rude. See Yerking.

EPA'RGEMOS, (from επι, and αργεμον, fignifying a white ulceration, or opacity of the eye), in *Surgery*, an epithet applied to a perfon affected with the diforder called argemon.

EPARITA, in the *Materia Medica*, a name given by Paracelfus to a fort of fine earth, of a liver colour, feemingly the fame with the Tokay bole.

EPA'RMA, or Epa'rsis, (from επι, and αιρω, *to elevate*,) in *Surgery*, a tumour of any fort. The term, however, is ufually confined to a fwelling of the parotid gland.

EPARRES, in *Geography*, a fmall town of France, in the department of the Ifére, near Vienne.

EPAULE, or Espaule, in *Fortification*, the fhoulder of the baftion, or the angle made by the face and flank, otherwife called the angle of the epaule. See Bastion and Angle.

The word is pure French, and literally fignifies *fhoulder*.

Epaule *en dedans*, in the *Manege*, a leffon of late invention, which, rendered into Englifh, denotes that attitude in which, as the horfe goes forward, he is fo bent through his whole frame, that if he goes to the right hand, he muft crofs the right fore-leg over the left, and fo *vice verfâ*; or, in the language of the Manege, his inner fhoulder, or leg, over the outward. The old mafters worked their horfes upon circles, when they intended to fupple the fhoulders and haunches; but to this mode of working upon circles, it has lately been objected that it conftrains the fore-part too much, and throws the horfe upon his fhoulders. To remedy this evil, M. de la Guerriniere, an accomplifhed horfeman at Paris, invented the leffon called "epaule en dedans," and eftablifhed it in his Manege. This new method, however, differs very little from the old practice, to which it owes its origin, and from which it is extracted and formed. The only objection againft the circle is, that the horfe, when worked circularly, has his haunches too much at liberty, by which means the weight of his body is thrown upon his fhoulders, which are thereby impeded in their motion; and the animal compelled to work in a manner directly oppofite to what he fhould do. The blame, however, inftead of being laid on the circle, fhould have been afcribed folely to the falfe and fenfelefs manner in which horfes were formerly worked in it; when heavy large bitts and cavefons were ufed, with which the heads of horfes were loaded, and brought down to a level with their knees, fo that they carried them, like rams, when they fight, and batter one another with their foreheads. Had thefe old practitioners known the advantage, and, indeed, the neceffity of raifing the head, in order to prefs and bend the haunches, and of doing this by means of a fnaffle with double reins, one being tied over the withers, on the oppofite fide to which the horfe is to turn, the head would at once have been raifed, the outward fhoulder brought in, and the horfe bent from nofe to tail; but this difcovery was referved for fir Sidney Medows, who has made many important improvements in the art of horfemanfhip. Berenger's Hift. &c. of Horfemanfhip. vol. ii.

EPAULEMENT. In treating of the enfilade, we had occafion to notice this part of the defences of batteries expofed to a flanking-fire. The defignation is derived from the French word *epaule*, meaning "a fhoulder," to which the epaulement bears a ftrong refemblance. Wherever a work, whether on the defences, or in the approaches of the befiegers, is fubject to be enfiladed, and efpecially where that enfilade is *direct*, it becomes indifpenfibly neceffary to raife an epaulement, for the purpofe of warding off the fhot. The thicknefs of fuch a buttrefs muft always be proportioned to its height, which again muft be carried up fo far as may render the fartheft gun, upon the battery to be fecured, fufficiently fafe from the ordinary *lobs* of fhot fired en ricochet, as well as fuch as may enfilade by defcent. A general rule may be eafily formed; namely, that the epaulement fhould be full as thick as the parapet, be about ten feet, if practicable, beyond the prolonged line of the inner revetement of the terre-pleine, and be raifed high enough to make an angle of ten degrees from the horizontal; the farther end of the battery being the angular point formed by the meeting of the terre-pleine, with a line drawn from the creft of the epaulement. If this proportion be properly attended to, it will be almoft impoffible to enfilade the defences with effect; becaufe few ricochet fhots, fired at an angle of ten degrees, will rife more than eight at their fecond flight. This mode gives a kind of ftandard, which proportions the height of the buttrefs to the length of the battery it is to protect.

Where there is fpace for fuch a work, it is often found highly advantageous to raife cavaliers at the extremities of the baftions, &c. which by their height ferve as epaulements; but, as fuch defences, when they fall into the hands of the befiegers, not only afford a lodgment, but command the adjacent works, it is abfolutely neceffary they fhould be ruined; fo that they may be completely annihilated whenever they are wrefted from the defenders. It being a general rule, that the creft of the parapet fhould be full feven feet in height, very little elevation thereof will make a competent epaulement for a battery of fmall force, and efpecially where the cannon are placed as clofe up to the flank as circumftances may admit. This cannot be done fo eafily in faliant angles which are acute, that is, under 90°; but, in the flanked angles of baftions, &c. is generally very practicable. In the batteries and places of arms conftructed by the befiegers, the epaulements may be made within ten feet of the outer cannon, and may be run up to any height, provided they do not obftruct the operations of other batteries; which, indeed, can be the cafe only in very peculiar

fituations.

ſituations. The beſt engineers recommend, that the epaulement ſhould be merely temporary, except at the orillons on the extremities of the flanks of baſtions, where they are always requiſite to prevent ſuch ſhots as may paſs over the proximate baſtion, when its angle or face may be battered, from enfilading the battery or the face of that baſtion next to ſuch orillon. When made on emergency, ſand bags are found to anſwer admirably in the conſtruction of epaulements; but when intended to be permanent, the buttreſſes ſhould be made of the firmeſt ſoil, well compacted, and properly gazoned (*i. e.* turfed.) As we have remarked, while ſpeaking of enfilades, no maſonry ſhould be expoſed in the conſtruction of epaulements any more than in traverſes and parapets; on account of the incalculable miſchief done by the numerous ſplinters which are knocked off by ſuch ſhots as ſtrike thereon.

EPAULETTE, is a diſtinguiſhing ornament, worn upon the ſhoulders of commiſſioned and of non-commiſſioned officers of ſome deſcriptions. The epaulette is always made to correſpond in colour with the bindings and lace of the uniform: therefore where yellow binding is in uſe, gold embroidery, &c. are employed, and where white binding is adopted, ſilver embroidery only is ſuitable. The military ſervice is by no means uniform in this ornament, ſome being epaulettes of one, ſome of another pattern; according to the fancies of the commandants reſpectively. The general rule is, that all general and field officers, as well as all ſuperior ſtaff officers, wear two epaulettes, the reſt of the officers in a corps wearing but one. Though, as above ſtated, variety obtains, yet the generality conſiſt of a rich ſtrap, of gold or ſilver lace, cuſhioned below, to give it a ſquare appearance upon the ſhoulder, and ornamented at its lower extremity with rich bullion, and fringe of a correſponding deſcription; the upper end ordinarily faſtens under, or on the cape, to a button; ſome being moveable, for the purpoſe of admitting a belt to paſs underneath. The flank companies, *i. e.* the grenadiers and light infantry, generally wear wings, not altogether unlike creſcents as they fit on the ſhoulder; of theſe the edges are ornamented with ſhorter bullions and fringe than are uſed in epaulettes. Some wings have ſhoulder-ſtraps, others have none; and ſome are ribbed, or ſtriped with narrow lace; but the generality are plain. In the navy, only large gold epaulettes are worn; all captains having two, and all under that rank but one. Formerly ſhoulder-knots, preciſely reſembling thoſe in uſe among ſervants, were worn by many corps, eſpecially the artillery. Theſe originated in the uſe of chains, ſuſpended from the collar down the arms, for the purpoſe of warding off the cuts of ſabres; but they ultimately became merely decorative, and were from that period made of ſilver cords, plaited, looped, and tagged, which hung down generally in front of the ſhoulder. For the ſame purpoſe of defence, the cavalry have in ſome inſtances adopted a laminated epaulette, conſiſting of metal plates of various patterns, but commonly circular or oval, overlapping each other a little, ſo as to allow due play to the limb, yet forming no ſlight reſiſtance againſt a ſabre. It cannot be expected, that the ſhoulder ſhould altogether eſcape injury, even though the edge of the weapon ſhould be averted; ſince the ordinary force of an attempt to cut down the ſhoulder muſt prove extremely painful, and generally benumb the part for a while; or eventually cauſe a bruiſe of ſome conſequence.

It is evident, from what we have detailed, that the epaulette may be conſidered as the type of a certain portion of armour, in uſe not many years ago; but which has become leſs neceſſary ſince diſcipline has empowered infantry to reſiſt cavalry; and as the former laid aſide their broad-ſwords in deference to the adoption, and to the ſuperiority of the muſquet and bayonet.

Though, in ſome parts of the Britiſh ſervice, the corporals ſtill wear ſhort ſhoulder-knots, and the ſerjeants retain their epaulettes, both being of cotton, worſted, or ſilk, the generality of them now wear the diſtinguiſhing marks of their reſpective ranks, in the form of fleches, or angular lacings on their ſleeves. Some variation exiſts in this particular, according to the nature of their employ; but, in general, one, two, and three fleches are the ordinary indications of rank. Thus, where an order of merit is eſtabliſhed among the privates, ſuch as appertain thereto wear one fleche, the corporals having two, and the ſerjeants three. This mode does not, however, ſeem to carry ſo much notoriety with it as the epaulette, which can be ſeen both from before and from behind the individual wearing it; whereas the fleche can be diſtinguiſhed but in one particular point of view.

EPEE, in *Geography*, a port of Africa, in the country of Benin.

EPEMBOLE, Επεμβολη, in *Rhetoric*, the ſame with parembole.

EPENCRANIS, a name by which ſome of the old authors, particularly Eraſiſtratus, have called the cerebellum.

EPENDYTES, Επενδυτες, among the Greeks, a garment worn under the pallium, and above the interula or inner coat, called, in Greek, ὑποδυτης.

EPENTHESIS, formed of επι, εν, and τιθημι, *q. d.* επεντιθημι, *inſero*, *immitto*, in *Grammar*, the addition, or inſertion of a letter or ſyllable, in the middle of a word; as *relligio* for *religio*, *Mavors* for *Mars*, *alituum* for *alitum*. Virg. Æn. lib. vii. ver. 27.

In the Hebrew language, there are ſome letters which are called *epenthetic*, and they occur without any apparent neceſſity in the middle of words; ſuch are אהוין. Maſclef's Heb. Gram. v. i. p. 191.

EPERIES, in *Geography*, a town of Hungary, celebrated for its mines of ſalt; 20 miles N. of Caſchau.

EPERLANUS, in *Ichthyology*, a name ſometimes given, on account of its pearl colour, to the ſmelt. See Salmo *Eperlanus*.

EPERLEQUE, in *Geography*, a town of France, in the department of the Straits of Calais; 2 leagues N.W. of St. Omer.

EPERNAY, or Espernay, an ancient and handſome town of France, in the department of the Marne, chief place of the diſtrict of the ſame name, with a population of 4430 individuals. It is pleaſantly ſituated on the river Marne, 21 miles N.W. of Châlons ſur Marne, 18 miles S. of Rheims, and 88 miles E. by N. of Paris. N. lat. 49° 2'. The canton has a territorial extent of 110 kiliometres, 11 communes, and 13,958 inhabitants.

As chief place of a diſtrict, Epernay has a ſub-prefect, a ranger, a court of juſtice, and a regiſter office. There are ſeveral manufactures of woollen ſtuffs, hoſiery, cutlery, leather, and writing-paper; but the moſt remarkable is that of a ſort of glazed earthen-ware, which ſtands the hotteſt fire.

The diſtrict of Epernay has 10 cantons, 215 communes, and 87,413 inhabitants, on a territorial extent of $2592\frac{1}{2}$ kiliometres. Its ſoil is uncommonly fertile, and produces corn, but eſpecially that excellent red and white champaign of the very firſt quality, which is ſo much ſought for all over the world. Epernay is the centre of the beſt champaign wines; its own vineyards and thoſe of Ay produce the beſt; and the town has a great trade not only with

 theſe,

thefe, but alfo with the famous wines of the hills of Hautvilliers, Pierry, and Cumieres, which are not far diftant.

EPERNON, a town of France, in the department of the Eure and Loire; 4 leagues N.E. of Chartres.

EPERON, in *Natural Hiftory*, the fpur-fhell, fo called from its refembling, in fome degree, the rowel of a fpur. It is a fpecies of fnail, of the round-mouthed kind, or clafs of the cochleæ lunares; all its volutæ are furrounded with double rows of prickles. See LUNARIS *Cochlea*.

EPERONNIER, in *Ornithology*. See PAVO *Bicalcaratus*.

EPERUA, in *Botany*. See DIMORPHA.

EPERVIER. See FALCO.

EPERVIERS, in *Natural Hiftory*; a name given by the French authors to a clafs of butterflies, which make the fixth in Reaumur's method. They have a way of poizing themfelves on the wing in the manner of kites, and other birds of prey; and always live upon the wing, never fettling themfelves upon the flowers they feed upon, but keep flying with a humming noife like a humble bee, while they thruft in their trunk and fuck the juices of the flower.

EPETIUM, in *Ancient Geography*, a town of Illyria, on the coaft of Dalmatia, between Salone and Pegentium, near the mouth of a river, now called Xarnouvriza. The town which has fucceeded to Epetium is named *Strobez*.

EPHA, a dry meafure in ufe among the Hebrews.

The epha was the moft common meafure they ufed, and that whereby the reft were regulated. It is commonly fuppofed that the epha, reduced to the Roman modius, contained four modii and a half. Now the Roman modius of grain or flour contained twenty libræ or pounds, confequently the epha weighed ninety pounds. Dr. Arbuthnot reduces the epha to three pecks three pints, Englifh meafure. See MEASURE.

EPHALGIA, in *Ancient Geography*, now *Elpifara*, a town of Afia, in Mefopotamia, upon the banks of the Euphrates, W.N.W. of Circefium.

EPHEBÆUM, Εφηβαιον, in *Antiquity*, the place where the ephebi or youth exercifed; or, as fome fay, where thofe who defigned to exercife met, and agreed what kind of exercife they fhould contend in, and what fhould be the victor's reward.

EPHEBI, Εφηβοι, among the Athenians, a defignation given to their young men when they arrived at eighteen years of age, at which time they had their names entered in a public regifter. Pott. Archæol. Grec. lib. 1. cap. 9. tom. i. p. 48.

EPHEDRA, in *Botany*, (εφεδρα is an ancient name for a climbing or parafitical plant, and expreffes a fitting upon any thing; hence it feems to allude to the fquat or decumbent and crowded habit of this fhrub.) Sea-fide Grape. Linn. Gen. 532. Schreb. 707. Willd. Sp. Pl. v. 4. 858. Mart. Mill. Dict. v. 2. Juff. 411. Clafs and order, *Dioecia Monadelphia*. Nat. Ord. *Coniferæ*.

Gen. Ch. Male, *Cal.* the fcales of a catkin, few, fingle-flowered, roundifh, concave, each the length of the perianth, which is of one leaf, cloven half way down, roundifh, inflated, compreffed, fmall and blunt. *Cor.* none. *Stam.* Filaments feven, united into an awl-fhaped column, cloven at the top, and longer than the calyx; anthers roundifh, turned outwards, four of them below the reft. Female, *Cal.* Perianth five-fold, one placed upon another fo that their fegments are alternate, forming an ovate figure; each is nearly ovate, of one leaf, cloven, the outer or lower ones fmalleft. *Cor.* none. *Pift.* Germens two, ovate, the fize of the innermoft perianth on which they ftand; ftyles two, fimple, thread-fhaped, fhort; ftigmas fimple. *Peric.* none; except the perianths, all become fucculent and thickened, conftituting a divided berry. *Seeds* two, ovate, acute, convex on one fide and flat on the other, compreffed by the perianth which inclofes them on every fide.

Eff. Ch. Male, Calyx the fcale of a catkin, in two fegments. Corolla none. Stamens feven. Anthers four inferior; three fuperior. Female, Calyx cloven, five-fold. Corolla none. Piftils two. Seeds two, inclofed in the pulpy calyx.

The fpecies known are but two.

1. E. *diftachya*. Linn. Sp. Pl. 1472. Duhamel Arb. t. 92. (Uva marina; Ger. emac. 1116. f. 1, and 1117. f. 2.) "Flower-ftalks oppofite. Catkins in pairs." Native of various parts of the fouth of Europe, in a fandy foil about the fhores of the fea or of lakes, flowering in June and July. It bears our climate, efpecially if led upright againft a wall. A fine bufh of this kind may be feen in the Oxford garden, ten or twelve feet high. It is a bufhy, fmooth, leaflefs fhrub, always green, with the habit of an *Equifetum*. The *catkins* are yellowifh. *Berries* fcarlet, fweetifh, vifcid, eatable but not agreeable.

2. E. *monoftachya*. Linn. Sp. Pl. 1472. (E. polygonoides; Pall. Roff. v. 1. t. 83.) "Flower-ftalks feveral. Catkins folitary." Native of Siberia. Linnæus fufpected this to be only a variety of the laft, and Pallas confirms his opinion.

EPHELÆUM, in *Anatomy*, is the place from the hypogaftrum, or lower part of the abdomen, to the fecret parts.

EPHE'LCIS, from επι, and ἑλκος, *an ulcer*, in *Surgery*, a fcab, or cruft, upon a fore.—Alfo, a fmall portion of blood, voided by coughing.

EPHELIS, from επι and ἡλιος, *fun*, a name ufed by the ancient writers on *Medicine*, for a diforder of the face, brought on by the fun and drying winds, and of the nature of what we call fun-burning. It was a certain roughnefs, hardnefs, and bad colour of the fkin.

The ephelis, or fun-burning, is removed by an application of refin, to which a third part of foffile falt, and a little honey are added; but all thefe diforders, as alfo the unnatural colour of cicatrices, are remedied by the following preparation, afcribed to Trypho the Elder:

Take equal quantities of myrobolans, crocomagna, cimolian earth of a blueifh colour, bitter almonds, the meals of barley and bitter vetch, dyer's weed (ftruthium album); all thefe are to be triturated together, and made up with the moft fharp honey. With this preparation the parts affected are to be anointed at night; and the medicine carefully to be wafhed off the next morning. James Med. Dict. See FRECKLES.

EPHEMERA, from ἐπὶ and ἡμερα, *a day*, in *Medicine*, the name given by the Greek writers to the mildeft form of fever, which runs through its courfe within the period of one day. By the Romans the fame fever was termed *diaria*, from *dies*, a day.

A fever which terminates in the courfe of twelve, eighteen, or twenty-four hours, is not a common occurrence in this climate; unlefs the flight difturbance of the fyftem, which fatigue, repletion, a fleeplefs night, &c. induce, is to be called an ephemeral fever: and fuch, indeed, appears to be the diforder to which the term ephemera has been applied by writers in general, and which conftitutes the ephemera fimplex, or legitima, in their nomenclature. When the febrile condition is more fevere, and therefore of longer duration, extending to the third or fourth day, by a folecifm in language, it has been denominated ephemera extenfa, or ephemera plurium dierum. Any flight fever, of three or four days duration, is occafionally called an ephemera at prefent; the flight derangement of the habit, from the operation of the caufes juft mentioned, being fcarcely deemed a difeafe worthy of a diftinct appellation.

The ephemera fimplex is a flight febrile paroxyfm, marked by languor, lofs of appetite, thirft, headache, and flight pains in the limbs, with fome heat of fkin terminating in a gentle perfpiration, and with drynefs of the tongue and fauces. Thefe fymptoms, from their mildnefs, imply a very flight derangement of any of the functions of the body: they originate from fome evident caufe of diforder in what have been abfurdly termed the non-naturals, and ceafe fpontaneoufly when the influence of thefe caufes no longer operates. The mildnefs of the fymptoms, and the nature of the evident caufes, are mentioned as the principal means of difcriminating the ephemera from the various forms of continued fever at their commencement. Among the caufes of the ephemera are enumerated the various paffions of the mind, when ftrongly excited, as grief, anger, joy, or care and anxiety, likewife lofs of fleep, exceffive heat of the weather, fatigue from labour or exercife, a fit of intoxication or of repletion, fudden expofure to cold, fafting, too great evacuations, &c. It is admitted, indeed, that many of thefe caufes occafionally give rife to continued fevers of long duration; but, in thefe cafes, the attack is preceded by cold chills and fhiverings, by languor and laffitude, loathing of food, &c. and is accompanied by more fevere diforders of the functions, as by violent headache, pains in the back and limbs, naufea or vomiting, with great anxiety and reftleffnefs. The prefence or abfence of thefe fymptoms, in the commencement, will enable us to anticipate the future progrefs of the difeafe, whether it will be a mere ephemera or a more ferious continued fever.

Befides the fimple ephemera, arifing from the caufes already enumerated, which Sauvages has included under the four heads of ephemera plethorica, ephemera naufeativa, ephemera à frigore, and ephemera à calore, thofe flight febrile derangements, connected with bruifes, diflocations, parturition, congeftion of milk in the breafts, dyfmenorrhœa, &c. have been alfo defignated by the term ephemera; which, in this cafe, is a fecondary or fymptomatic ephemera. Avicenna, among the ancients, and Foreftus, among the modern phyficians, have made a ftill more extenfive divifion of ephemera; namely, into as many fpecies as there are evident caufes which induce it. Hence they ufelefsly diftinguifh ephemera from grief, from joy, from hope, from fear, from thirft, from fafting, &c.

The original fignification of the term implied a completion of all the ftages of a fever, *viz.* the beginning, increafe, acmè, and decline, (in the language of the ancients,) within the compafs of a natural day. By this definition, Van Swieten obferves, the moft acute fevers, which often kill a patient in twenty-four hours, are excluded from the term; fince they do not arrive at their declenfion in that fpace of time, although they end in death. Yet Caius has defcribed that fatal epidemic, the *fweating ficknefs*, or *fudor Anglicus*, under the term of ephemera; becaufe, on the one hand, it often terminated in the fpace of twenty-four hours, by deftroying the patient; and, on the other, by a fweating, continued for the fame fpace of time, the patients were often cured. But in this cafe, though immediate danger was removed, yet great debility and other injuries to the functions ftill remained, for fome time afterwards; fo that the difeafe belonged to the clafs of continued malignant fevers. This difeafe, under the appellation of ephemera fudatoria, conftitutes the feventh fpecies of Sauvages. It has been alfo denominated ephemera Britannica, ephemera maligna, ephemera Anglica peftilens, &c. See SWEATING *Sicknefs*.

With refpect to the *cure* of the ephemeral fever, little remains to be faid. The term implies that its natural termination will occur within the period of a day, if left to itfelf: we here fpeak of the fimple ephemera, arifing from a flight temporary caufe. Abftinence alone, or the moft light and flender diet, with diluent drinks, is all that is required. The bowels may be opened by gentle aperients, as neutral falts, infufion of fenna, &c.: and this ought not to be omitted, where the difeafe has arifen from over-repletion, or intoxication; in which cafe, it will contribute directly to remove the exciting caufe of the diforder. Thin drinks, fuch as fpring-water, or barley-water, acidulated or not with the juice of lemons, tea, or the infufions of other grateful herbs, may be ufed, and animal food abftained from.

The fame treatment will be ufeful in the fecondary or fymptomatic forms of ephemera; in which cafes, however, the cure or alleviation of the original diforder muft be the firft ftep towards removing the ephemera. See Galen Method. Medend. lib. viii. De Febribus, lib. i. &c. Van Swieten, Comment. App. 728. Burferius Inftit. Med. tom. i. fect. 198. Sauvages Nof. Meth. clafs ii. genus 1.

EPHEMERA, in *Entomology*, a genus of the neuroptera order. This genus has the mouth deftitute of mandibles; feelers four, very fhort, and filiform; jaws fhort, membranaceous, cylindrical, and connected to the lip; antennæ fhort and fubulate; ftemmata too large above the eyes; wings erect; the lower fmaller; tail terminating in briftles.

The ephemeræ are proverbially a race of beings deftined to enjoy the functions of life for a much fhorter period than any other animals. This is a popular opinion, and, in a partial view of their hiftory, not altogether incorrect; but it muft be underftood only of the laft or winged ftate, after attaining which they exift but for a few hours. The duration of this period varies in different fpecies. It is devoted folely to the pleafures of fulfilling the ordinary purpofe of nature, the propagation of their kind; in the accomplifhment of which the ephemeræ may be obferved in myriads, during the fummer feafon, fporting on the wing, juft above the furface of the water. In the larva and pupa ftates the ephemeræ live one or two years; and fome fpecies, it is believed, live even three years from the time of hatching from the egg ftate, before they arrive at the perfect form. The larvæ are found in the water, wherein they conftantly refide, and are the favourite food of fifhes. They are active, furnifhed with fix legs, a tail, fix lateral fins or gills, and prey on fmaller infects. The pupæ, like the larvæ, are carnivorous, and refemble the former ftate, except in having the rudiments of the wings apparent. The ephemeræ are fo abundant in fome countries, that they are ufed for the purpofe of manure, the fpecies vulgata efpecially. This is the common practice with the hufbandmen in Carniola. They are alfo very numerous on fome parts of the Rhine, the Maes, and Ifel. The feafon of their appearance in fuch multitudes continues, however, only for about three days annually. The ephemeræ are arranged in two fections, according to the number of briftles at the extremity of the tail.

Species.

* *Tail with three hairs or briftles.*

VULGATA. Wings reticulated, and fpotted with brown; body yellowifh, fpotted with black. Scop. Donov. Brit. Inf., &c.

Inhabits

Inhabits watery places throughout Europe.

Lutea. Wings tranfparent, reticulated; body yellow. Fabr.

Native of Europe, and is found in Britain.

Marginata. Wings white; exterior margin fufcous; body black. Fabr.

Similar to E. vulgata, but fmaller.

Vespertina. Wings black; pofterior ones white. Linn.

Native of Sweden, and other parts of Europe.

Halterata. Wings two, white; abdomen whitifh, with fufcous tail. Fabr. *Phryganea caudâ trifeta*, &c. Degeer.

Inhabits ftagnant waters in the north of Europe.

Inanis. Wings hyaline; body black; fegments of the abdomen from the fourth to the feventh pellucid. Linn.

Native of Europe.

Maroccana. Wings white, immaculate; body yellowifh. Fabr.

Found in Morocco.

Brevicauda. Wings two, cinereous, with a black rib; abdomen pale; tail brown. Fabr.

A fmall fpecies, found in the vicinity of Paris.

** *Tail with two hairs or briftles.*

Bioculata. Wings white reticulated; head with two yellow tubercles; tail yellow. Fabr. Geoff., &c.

Native of European waters.

Renosa. Wings white reticulated; body brown. Fabr. Inhabits Denmark.

Nigra. Body black; wings blackifh; pofterior pair very fmall. Linn.

Defcribed by Linnæus as a native of Sweden; alfo inhabits other parts of Europe.

Culiciformis. Wings white; body brown. Linn.

Found in Greece by Pada; alfo in Sweden by Linnæus, and in France by Geoffroy.

Horaria. Wings white; thicker-margin blackifh. Linn. *Ephemera minima*, Swammerdam.

Very abundant in Europe.

Striata. Wings hyaline, ftriated; thorax fufcous; abdomen white. Fabr. *Ephemera mutica*, Linn. Fn. Suec.

An European fpecies.

Diptera. Wings two; coftal margin brown, with cinereous fpots. Linn.

The abdomen in this infect is marked with red lines. The fpecies inhabits Sweden.

Fuscata. Wings hyaline; abdomen brown, with the bafe whitifh; legs pale. Fabr.

Albipennis. Wings white, immaculate; abdomen pale at the bafe; tail blackifh. Fabr.

This and the preceding inhabit France, and other parts of Europe.

Notata. Yellow; wings white; abdominal fegments with a fufcous fpot each fide. Linn.

Ephemera notata and the three following are inhabitants of watery places in Europe.

Testacea. Wings brownifh; body brown teftaceous; foles of the feet fufcous. Linn.

Ferruginea. Wings yellowifh; body ferruginous. Linn.

Stigma. Wings brownifh; body pale yellow; thighs with a black dot in the middle.

Ephemera, is alfo applied among *Botanifts*, to a kind of flowers which open and expand themfelves at funrifing, and wither or clofe up again at his fetting. Such are the dent de-lion, vulgarly dandelion, and divers others.

EPHEMERIDES, in *Aftronomy*, tables calculated by aftronomers, fhewing the prefent ftate of the heavens for every day at noon; that is, the places wherein all the planets are found at that time.

It is from thefe tables that the eclipfes, conjunctions, and afpects of the planets are determined; horofcopes, or celeftial fchemes, conftructed, &c.

We have ephemerides of Regiomontanus from 1475 to 1506, of Engel from 1494 to 1500, of Staeffler from 1499 to 1531, of Origan from 1595 to 1654, of Kepler from 1617 to 1628, of Argoli from 1620 to 1700, of Heckerus from 1666 to 1680, of Wing from 1652 to 1671, of De la Hire from 1701 to 1703, of Manfredi from 1715 to 1750, of Parker, &c. S. Caffini has calculated ephemerides of the fidera medicæa, or fatellites of Jupiter, which are of good ufe in determining the longitude.

In England the Nautical Almanac or Aftronomical Ephemeris, publifhed annually by anticipation, under the direction of the Commiffioners of Longitude, is the moft confiderable. See Almanac.

In France they have preferved in the national library ephemerides of 1442; and celeftial ephemerides have been publifhed by M. Defplaces every ten years, from 1715 to 1745: they were afterwards continued by the abbé Caille, with many additions, from 1731 to 1774, of which an account may be feen in the Hiftory of the Academy of Sciences for 1743, &c.; they were further continued by Lalande from 1775 to 1810. The Academy of Sciences have likewife publifhed annually, from the year 1678, a kind of ephemeris, under the title of Connoiffance des Tems. This has been continued fince the revolution under the direction of the "Bureau des Longitudes." The two volumes for the years 8 and 9, edited under the infpection of M. Lalande, contain, befides other important articles, new catalogues of the ftars; tables of the moon's horary motion by Delambre; obfervations of Mercury by Videl, &c. They have alfo ephemerides at Bologna; thofe for 23 years from 1787 to 1810, being computed by C. Mateucci, affifted by Ifolani, Guglielmini, Sacchetti, Zanotti, and Canterzani. The ephemerides of Milan contain the refult of an important labour of C. Oriani, on the method of correcting the elements of the tables of Mercury by obfervation, and many interefting obfervations of C. Reggio and De Cefaris, &c. &c. The ephemerides of Berlin are now conducted by M. Bode, and contain many aftronomical obfervations and memoirs by German, French, and Englifh aftronomers. The aftronomers of Vienna commenced a fimilar work in 1757. The geographical ephemerides, undertaken by M. Von Zach, of Gotha, at the commencement of the year 1798, contain many curious obfervations; information refpecting new books and charts, new voyages and geographical maps, portraits of eminent philofophers, and, in a word, every thing that can be interefting to aftronomers, geographers, and navigators. The meteorological obfervations of the electoral Academy of Sciences at Manheim, from 1781 to 1792, are comprehended in 12 volumes 4to. under the title of "Ephemerides Societatis Meteorologicæ Palatinæ."

EPHEMERUM, in *Botany*, from ἐφήμερος, lafting but a day, in allufion to its tranfient bloffoms; fee Lysimachia. The name has alfo been given in ancient times to the hemlock, on account of the celerity of its deftructive action upon animal life.

EPHESIA, in *Mythology*, a feaft inftituted at Ephefus, in honour of Diana.

EPHESIANS, Epistle *to*. See Epistle.

EPHESIORUM Portus, in *Ancient Geography*, a port

port of Afia Minor, upon the Bofphorus of Thrace; the modern name of which is *Aphofiati*.

EPHESIUM, the name of a plafter, which is defcribed by Celfus.

EPHESIUS, in *Biblical Hiftory*, a manufcript of the gofpels written in 1166, and formerly in poffeffion of a bifhop of Ephefus, whence it has taken its name. It is noted 71 in the firft part of Wetftein's N. T. It is at prefent in the archbifhop's library at Lambeth, to which it was prefented by Trahern, together with the extracts which he had made from it. Thefe were inferted by Mill, in his collections of readings.

EPHESTIA, in *Mythology*, a feaft celebrated in honour of Vulcan, in which three young lads ran for a prize.

EPHESTRIA, were feafts celebrated at Thebes, in honour of Tyrefias.

EPHESUS, in *Ancient Geography*, a city of Afia Minor, in Ionia, formerly reputed the metropolis of Afia. Stephanus ftyles it "Epiphaneftata," or moft illuftrious. Pliny reprefents it as the ornament of Afia; and Strabo defcribes it as the largeft and moft frequented emporium of that continent. The ancient city, which was originally a fmall village, ftood about 50 miles S. of Smyrna, near the mouth of the river Cayfter, and the fhore of the Icarian fea, which is a bay of the Ægean; but its precife fituation cannot be afcertained, as it was often deftroyed and rebuilt. Some modern travellers maintain that the ancient city ftood more to the fouth than the prefent town, or rather village, which they infer from the ruins that ftill remain. It was known in ancient times by the names of Alopes, Ortygia, Morges, Smyrna, Trachæa, Samornion, and Ptela. Its name Ephefus is derived, according to Heraclides, from the Greek word *ephefus*, fignifying permiffion; becaufe Hercules, as he fays, permitted the Amazons to live and build a city in that place. Others allege, that Ephefus was the name of the Amazon that founded the city: for Pliny, Juftin, and Orofius unanimoufly affirm, that it was built by an Amazon; while others afcribe the honour to Androclus, the fon of Codrus, king of Athens, who was the chief of the Ionians that fettled in Afia. However this be, it is acknowledged, that the city, which in the Roman times was the metropolis of Afia, was founded by Lyfimachus; who, having caufed the ancient city to be demolifhed, rebuilt a new one, at a vaft expence, in a place more convenient, and nearer the temple. We learn from Strabo, that when the inhabitants manifefted a reluctance to quit their ancient habitations, this prince caufed all the drains, that conveyed the water into the neighbouring fens and the Cayfter, to be privately ftopped up: fo that the city on the firft violent rains that fell was in great part laid under water, and many of the inhabitants were drowned: and he thus conftrained thofe who remained to retire into the new city. This new Ephefus was greatly damaged by an earthquake in the reign of Tiberius, but that emperor repaired and adorned it with feveral ftately buildings, of which there are now fome few ruins that teftify its exiftence. The aqueduct, of which a part ftill fubfifts, is generally believed to have been the work of the Greek emperors; the pillars, that fupport the arches, are of fine marble, and they are higher or lower as the level of the water required. This aqueduct ferved to convey water into the city from the fpring of Halitee, mentioned by Paufanias. The gate, now called for fome unknown reafon the gate of perfecution, is remarkable for three bas-reliefs on the mould, of exquifite tafte. The port, of which many medals have been ftruck, is at prefent merely an open road, and not much frequented. The Cayfter was formerly navigable, and afforded a fafe place for fhips to ride in, but it is now almoft choaked with fand. Ephefus is now venerable for nothing but the ruins of palaces, temples, and amphitheatres. It is called by the Turks *Ajafaluk* (which fee), or the temple of the moon, from the magnificent ftructure formerly dedicated to Diana. The church of St. Paul, faid to have been founded by the apoftle, is wholly deftroyed; the little which remains of that of St. Mark is finking to ruin. The only church remaining is that dedicated to St. John, who refided here, and this is now converted into a Turkifh mofque. The town is merely a miferable village, the habitation of herdfmen and farmers, living in low and mean huts, fheltered from the extremities of weather by mighty maffes of ruinous walls; the pride and oftentation of former days, and the emblem in thefe of the tranfient vanity of human glory. All the inhabitants of this once famous city amount not to above 40 or 50 families of Turks, without one Chriftian family among them; fo ftrikingly hath the fcripture denunciation been fulfilled, that "their candleftick fhould be removed out of its place."

The ancient city, whether it was firft built by Androclus, who conducted the Ionians hither and drove out the Carians and Leleges, by whom this fituation was occupied before his arrival, or by one Crœfus or Ephefus, long before the Ionic migration, as others maintain, became foon the metropolis of Ionia. It was at firft governed by Androclus and his defcendants, who affumed the royal title, and exercifed regal authority over the new colony; whence, even in Strabo's time, the pofterity of Androclus were ftyled kings, and allowed to wear a fcarlet robe, with a fceptre, and all the enfigns of royal dignity. In procefs of time, a fenate was eftablifhed and a new form of government introduced, which continued to the time of Pythagoras, who lived before Cyrus the Great, and was one of the moft favage tyrants whofe name and character hiftory records; for having expelled the fenate and engroffed the whole power, he filled the city with blood and rapine, not fparing even thofe who fled for fhelter to Diana's temple. His fucceffor Pindarus governed the city with a milder fway; and in his time Ephefus was befieged by Crœfus, king of Lydia, who advifed the inhabitants to devote their city to Diana, and in confequence of their following his counfel, treated them with kindnefs, and reftored them to their former liberty. The other tyrants of Ephefus, mentioned in hiftory, are Athenagoras, Comes, Ariftarchus, and Hegefias; the laft of whom was expelled by Alexander, who, having defeated the Perfians on the banks of the Granicus, beftowed upon Diana all the tributes which the Ephefians had paid to the Perfians, and eftablifhed a democracy in the city. After his death, this city became the prey of his fucceffors. Lyfimachus took it, and afterwards Antigonus had poffeffion of it and plundered it. Ephefus for a little while was reftored to its ancient fplendour; but it was always fubject to the kings of Syria. In the war between Mithridates and the Romans, the Ephefians took part with the former, and by his order maffacred all the Romans that refided in the city; for which barbarity they were feverely fined, and reduced almoft to beggary by Sylla, but afterwards treated kindly and fuffered to live according to their own laws. It was under the reign of the emperor Alexius, father of Anne de Comnena, that the Mahometans made themfelves mafters of Ephefus. The Greeks retook it in 1206, but they loft it again 1283. At the commencement of the 14th century it became a part of the Turkifh dominions; and both the place itfelf and its vicinity exhibit melancholy traces of indolence and inactivity. The Ephefians were much addicted to fuperftition, forcery, and curious arts, as the Scripture ftyles them (Acts, xix. 19.); whence came the proverb "Ephefian letters," fignifying all forts of fpells or charms. By thefe Ephefian letters were meant certain obfcure words and incoherent fentences, which fuperftitious bigots ufed to write on their girdles, and even imprint on their feet, and other parts of their bodies. They were alfo noted for their luxury and lafcivioufnefs. See Ephef. v. 5.

Ephefus, in its relation to ecclefiaftical hiftory, may be confidered, firft of all, as the abode of many Jews, who obtained the privilege of citizens (Joseph. Cont. Appian. l. 2.), and afterwards, as the place where St. Paul took up his refidence for three years (Acts, xx. 31.), where he wrought miracles (Acts, xix. 11. 1 Cor. xvi. 9.), and was refifted by the Jews, (Acts, xx. 19.); and where Timothy was bifhop; and where John refided; and, moreover, as containing one of the feven churches, whofe character and doom are recorded in the book of Revelations, ch. ii.

Ephesus, *Temple of*. See Diana.

EPHETÆ, of ἐφίημι, *I fend forth*, in *Antiquity*, a fort of magiftrates among the Athenians, inftituted by king Demophoon, to take cognizance of murder, manflaughter, and chance-medley.

Their number was one hundred, whereof fifty were Athenians, and fifty Argians: they were not admitted to the poft till upwards of fifty years of age. Demophoon fubmitted to be tried by this court, for having unfortunately killed one of his fubjects by the turn of his horfe, as he was coming from Troy. It fubfifted for a confiderable time in the fame form; but at length Draco new-modelled it, excluded the Argians, and made it to confift of fifty-one Athenians, each above fifty years of age: Ubbo Emmius de Rep. Athen. fays, he transferred to them part of the jurifdiction of the Areopagites. See Areopagus.

The occafion of erecting this court and of admitting the Argives to fit as judges, is faid to have been as follows. Agamemnon, or, as others fay, Diomedes, returning with his forces from Troy, were driven one night into an Athenian port called Phalerus, and thinking themfelves in an enemy's country, began their ufual practice of ravaging and plundering; upon which the Athenians fell upon and killed a confiderable number of them. Next morning they found the palladium, or ftatue of Minerva, which was brought from Troy, lying upon the ground among the flain; by which circumftance they knew that they were their friends the Argives. The oracle having been confulted, ordered them to give the flain an honourable burial in the place where they fell, to build a temple there, dedicated to Minerva, and to fet up the palladium in it. Immediately after this tranfaction, it was ordered that this court fhould be erected to try all cafes of perfonal injury and property. It confifted of 50 members, who were to be above 50 years of age, men of fenfe and known probity, and who had power of life and death. Upon its firft inftitution Agamemnon infifting that there fhould be an equal number of Athenians and Argives, the Athenians readily agreed to the propofal.

EPHIALTES, ἐφιάλτης, in *Medicine*, from ἐπι, *upon*, and ἅλλομαι, *I leap*, is fynonymous with the Latin *incubus*, and the Englifh *night-mare*, which fee.

EPHIALTEUM, in *Ancient Geography*, the moft northern promontory of the ifle of Rhodes.

EPHIDROSIS, in *Medicine*, from ἐπι, and ἱδρώς, *fweat*, a term ufed by the ancient writers to denote the appearance of a fweat, whether critical or not, and whether general, or on the upper parts of the body only. The modern nofologifts have conftituted a *genus* of difeafe under this appellation; under which Sauvages comprifes every variety of morbid perfpiration that occurs as a fymptom of different maladies. He enumerates feventeen fpecies of ephidrofis. See his Nofol. Method, Clafs IX. Gen. 20. Cullen, Gen. 118.

EPHIELIS, in *Botany*, from ἐφιελις, *a little cup*, or fomething like it, in a crown or garland, which alludes, happily enough, to the nectary forming a fort of cup, or crown, within the circle of the corolla. Schreb. 253. Willd. Sp. Pl. v. 2. 328. (Mataiba; Aubl. Guian. v. 1. t. 128. Juff. 249.) Clafs and order, *Octandria Monogynia*. Nat. Ord. Near the *Sapindi*, Juff.

Gen. Ch. *Cal.* Perianth of one leaf, in five deep, fpreading, roundifh, acute fegments. *Cor.* Petals five, roundifh, fpreading, notched, with a fmall point, and having claws as long as the calyx. Nectary of ten roundifh hairy fcales, fmaller than the petals, two of them affixed to the bafe of each petal. *Stam.* Filaments eight, briftle-fhaped, longer than the corolla, inferted into a gland; anthers roundifh, with four angles. *Pift.* Germen ovate, encompaffed with the gland which bears the ftamens; ftyle none; ftigma obtufe. *Peric.* Capfule oblong, compreffed, with a furrow on each fide, of one cell and two valves. *Seeds* two, kidney-fhaped, one attached to the middle of each valve, one above the other.

Eff. Ch. Calyx in five deep fegments. Petals five, with claws. Nectary of ten fcales, two to each petal. Capfule compreffed, of one cell and two valves. Seeds two, attached to the valves.

The only known fpecies is E. *fraxinea*, Willd. a tree 50 or 60 feet high, with copious *branches*, of which the central ones are erect, the reft widely fpreading. *Leaves* alternate, pinnate, fmooth; leaflets four or fix, oppofite, oval, pointed, entire, bright green, fometimes eight inches long. *Flowers* on long axillary branching ftalks, very fmall, white. It grows in the forefts of Guiana, flowering in October. Juffieu fufpects this genus may be more akin to the *Leguminofæ* than to his *Sapindi*, but he obferves that the fruit requires further inveftigation.

EPHIPPIA, of ἐπι and ἵππος, *horfe*, denoted certain cloths or houfings, which were faftened on a horfe by a girth or furcingle, in ancient Greece, before the ufe of faddles were known. They were compofed of different materials, as leather, cloth, and the fkins of wild beafts, and fometimes adorned with gold, filver, and precious ftones. When thefe coverings were common, it was reckoned more manly to ride without them. Varro boafts of having rode, when a young man, without a covering to his horfe; and Xenophon reproaches the Perfians becaufe they placed more clothes on the backs of their horfes than on their beds, and gave themfelves more trouble to fit eafily than to ride fkilfully. Thefe coverings were, therefore, for a long time not ufed in war; and the old Germans, who confidered them as difgraceful, defpifed the Roman cavalry who employed them. (Cæf. de Bell. Gall. l. iv. 2.) Dion Caffius (l. lxiii. 14.) fays, that they were firft allowed to the Roman cavalry by Nero. But it has been fuggefted that this author alludes merely to reviews, at which the cavalry were probably obliged before this time to appear always without them. In the time of Alexander Severus, the horfes of the whole Roman cavalry had beautiful coverings. (Lamprid. Vit. Alex. Severi. c. 50.) Saddles were firft denominated ephippia, which originally fignified nothing more than a covering for a horfe. Beckmann Hift. Inv. vol. ii. Berenger's Art of Horfemanfhip, vol. i. p. 41. See Saddle.

EPHIPPITES. See Hippurites.

EPHIPPIUM, in *Anatomy*, the excavation in the upper furface of the fphenoid bone, called alfo fella turcica. See Cranium.

EPHOD,

EPHOD, אפד, derived from אפד, *aphad, to clothe*, a ſacerdotal garment, in uſe among the ancient Jews, ſuppoſed to have been a kind of linen alb, or ſurplice, wore by perſons of diſtinction, of various characters; the ſame with what the Latins call ſuper-humerale. 2 Sam. vi. 4. 1 Sam. xxii. 18. 1 Sam. ii. 18.

It is very hard to ſay preciſely what the ephod was; and there is room enough for the interpreters to be divided about it. The only point they are agreed upon is, that it was an upper garment worn over all the reſt, immediately under the pectoral or breaſt-plate. Some hold it had ſleeves, others deny it. The generality agree, that it was very ſhort, though ſome maintain that it hung down to the feet behind.

There were two kinds of ephods; the one, common to all who aſſiſted in the temple, being only made of common linen, mentioned in the firſt book of Samuel, ii. 18; the other, peculiar to the high-prieſt, mentioned Exod. xxviii. 6. 15. to be made of gold, of blue, and of purple, of ſcarlet, and fine twined linen, with cunning work; having two ſhoulder-pieces, with a curious girdle of the ſame matter, and two onyxes, with the names of the children of Iſrael engraved thereon, ſix upon each ſtone. Theſe onyxes were ſet in gold, and ſerved as buttons upon each ſhoulder. As for the ſhape of the ephod, the LXX call it ἐπωμὶς, which ſignifies that it was worn on the ſhoulders.

Joſephus ſays (Antiq. l. iii. § 5), that it was a cubit long. It conſiſted, as ſome ſuppoſe, of two parts, the one an oblong rectangular piece, hanging down behind from the ſhoulders to the feet; the other a ſhort rectangular piece, which hung down before, the length of a cubit. Theſe two pieces were joined together upon the ſhoulders, with ſome proper faſtening, as loops, buttons, or the like.

It is alſo expreſſed in the ſecond book of Samuel, vi. 14. that upon the removal of the ark of the covenant from the houſe of Obed-Edom, David danced for joy, girt with a linen ephod; whence ſome authors have concluded, that the ephod was alſo a regal garment, worn on ſolemn occaſions. It is probable that the peculiarity of the ephod of the high prieſt did not conſiſt in its being of a different ſhape from that which was worn by other perſons; but in the richneſs of the materials of which it was made, and the fine embroidery and jewels with which it was adorned.

EPHORI, Εφοροι, magiſtrates eſtabliſhed in ancient Sparta, to balance and check the power and authority of the kings; as at Rome, there were tribunes created to controul the power of the conſuls.

The word is formed of the Greek, ἐφοραω, *intueor*, formed of the prepoſition ἐπι, and the verb ὁραω, *to ſee*; whence ἐφορος, *q. d. inſpector, overſeer.*

Lycurgus, being ſenſible that a perfect underſtanding between the prince and the people was the baſis and foundation of both their happineſs, to maintain that good underſtanding, eſtabliſhed ephori, or inſpectors, as a kind of mediators, who ſhould have an eye to the meaſures and conduct on both ſides, and preſerve ſo equal a balance between them, that the regal power ſhould never decline into ſeverity and tyranny, or the liberty of the people run into licentiouſneſs and rebellion.

This is the account of their inſtitution given by Herodotus and Xenophon. (Her. lib. i. Xen. de Rep. Lacedæm.) The authority of the ephori was very great; they preſided in popular aſſemblies, collected their ſuffrages, declared war, made peace, treated with foreign princes, determined the number of forces that ſhould be raiſed, appointed the funds to maintain them, and diſtributed rewards and puniſhments in the name of the ſtate: they likewiſe held a court of juſtice, enquired into the behaviour of all magiſtrates, inſpected the education and conduct of youth, had a particular juriſdiction over the helotes, and by degrees drew the whole adminiſtration into their own hands. On certain occaſions, they expelled, and even put to death the kings; and aboliſhed or ſuſpended the power of the other magiſtrates, calling them to account at pleaſure. Ageſilaus, in the height of all his conqueſts, which even ſtruck terror on the great king of Perſia, ſtopped, and turned back, out of deference to the ephori, when they recalled him.

Some authors deny that the ephori were eſtabliſhed by Lycurgus, dating their origin 130 years after the time of that legiſlator.

Thus Plutarch, in his life of Cleomenes, aſcribes their inſtitution to Theopompus, king of Sparta, which is alſo confirmed by the authority of Ariſtotle. (Polit. lib. v.) The ephori were five in number, and annually choſen by the people out of their own body: though ſome have imagined, that they were at firſt appointed by the kings at their pleaſure, but that afterwards the people obtained the power of electing them. The year was denominated from the firſt election of theſe magiſtrates; and the Lacædemonian armies took their names from the principal ephori, as thoſe of Athens did from their firſt archon. The ephori did not riſe up at the entrance of the kings, as all the other magiſtrates did; and if even the kings offended againſt the laws, the ephori took cognizance of their conduct, and puniſhed them.

EPHORUS, in *Biography*, a Greek orator and hiſtorian, was a native of Cuma or Cyme in Æolia, and flouriſhed about the year 352 B. C. He was a diſciple of Socrates, at whoſe inſtigation he wrote hiſtory; which he commenced after the fabulous periods, with the return of the Heraclidæ into Peloponneſus, and brought down to the 20th year of Philip of Macedon. This work, which was divided into 30 books, was held in eſtimation by the ancients, and is frequently cited by Strabo and other writers; though the hiſtorian is charged with errors and miſrepreſentations, and plagiariſms. Beſides the hiſtory, the loſs of which is regretted, Ephorus wrote ſeveral other books on moral, geographical, and rhetorical ſubjects, none of which are extant. Bayle. Voſſ. Hiſt. Græc. Gen. Biog.

EPHRA, in *Ancient Geography*, a city of Judea, in the half-tribe of Manaſſeh, on this ſide of Jordan. It was ſituated on the frontiers of the tribe of Ephraim; ſuppoſed to have been the ſame with Ophrah. Judg. vi. 11.

EPHRAIM, *Tribe of*, ſo denominated from Ephraim, the grandſon of Joſeph by Aſeneth, the daughter of Potiphar, who was born in Egypt about A. M. 2294, occupied the ſouth ſide of Samaria, and extended, like that of Manaſſeh, from the Mediterranean on the weſt, and the river Jordan on the eaſt; bounded on the ſouth by the territory of Benjamin and part of Dan, and on the north by the half-tribe of Manaſſeh. The extent of this tribe from north to ſouth was about 7 leagues; and though ſome parts were mountainous and rocky, they were covered with trees and good paſture, and the low lands were rich and fertile, and even luxuriant. The cities and towns were numerous, large, and well-peopled. Joſhua was of this tribe; and the ark and tabernacle remained in it at Shiloh for a conſiderable time. After the ſeparation of the 10 tribes, the ſeat of the kingdom of Iſrael being in Ephraim, Ephraim is frequently uſed to ſignify the whole kingdom. The diſtrict belonging to this tribe is called Ephratah. Pſ. cxxxii. 6. (See alſo Judg. xii. 5. 1 Sam. i. 1.) Ephraim was led captive beyond the Euphrates, with all Iſrael, by Salmaneſer, king of Aſſyria, A. M. 3283. B. C. 721.

Ephraim, or *Ephræm*, a city of Ephraim, towards Jordan, whither Jesus is supposed to have retired before his passion. John, xi. 54.—Also, a city of Benjamin, 8 miles from Jerusalem, according to Eusebius, near the wilderness of Judea, in the way from Jerusalem to Jericho, not far from Bethel.—Also, a considerable mountain in the tribe of Ephraim, and extending to that of Benjamin, on which several towns were built.—Also, an extensive forest situated on the other side of Jordan, not far from Mahanaim, where David abode while the battle was fought, in which Absolom received the due reward of his unnatural rebellion.

EPHRATA, or Dunkard-*Town*, in *Geography*, a village of America, in Lancaster county, Pennsylvania, on the N.W. side of Calico creek, which, joining the Conestoga, falls into the Susquehanna; 12 miles N. of the town of Lancaster, and more than 40 W. of Philadelphia. It is situated in a romantic and sequestered vale, and inhabited by a community of religious people, called "Tunkers," who are mostly of German descent and believers in the doctrine of general redemption. They are very plain in their dress and language; and will neither swear, nor fight, nor go to law, nor take interest for the money they lend. They have many peculiarities; but their inoffensive manners have occasioned their being called the harmless Tunkers. This settlement is called "Tunkers' town," and consists of about 40 buildings, of which three are places of worship. They subsist by cultivating their lands, by attending a printing office, a grist-mill, a paper-mill, an oil-mill, &c. and the sisters by spinning, weaving, sewing, &c. Beside this congregation at Ephrata, there were, about 30 years ago, some few others of this sect in various parts of Pennsylvania, and in Maryland. The whole community, exclusively of those in Maryland, comprehended upwards of 2000 persons.

EPHRATAH. See *Tribe of* Ephraim and Bethlehem.

EPHREM, or Ephraim, denominated the *Syrian*, and honoured with the appellation of *Saint*, in *Biography*, was a native of Nisibis in Mesopotamia, and born during the reign of Constantine the Great. Devoting himself at an early period to the monastic life, he sedulously applied to his studies, and to the composition of various theological and moral works. Towards the close of his life he resided at Edessa, where he began to distinguish himself by his writings about the year 370, and was ordained deacon, determining not to accept of any higher ecclesiastical order. His works were all written in the Syriac language, and several of them were translated into Greek, with which he does not seem to have been acquainted, during his life. He was held in high estimation, on account both of his virtues and his writings. From Dr. Assemann we learn, that the Syrians gave him the titles of Doctor or Master of the whole world, and of their Prophet; and St. Jerome informs us, that his works were so much esteemed as to be publicly read in some churches after the Scriptures. Sozomen highly commends them both for style and sublimity of sentiment; which excellencies are said by this father, and also St. Jerome, to have been transfused into the Greek version of them. The subjects of these works were commentaries upon the Old and New Testaments; homilies, or sermons; exhortations to the monks; controversial pieces against Sabellius, Arius, Apollinaris, the Anomians, and the Novatians; treatises of morality; hymns to be sung in the churches; panegyrics, &c. of which we have an account by Cave, Du Pin, and Lardner. The most complete edition of the works of this writer was published at Rome, by Dr. Jos. Assemann, assisted by father Benedatti, a Jesuit, and Evodius Assemann, bishop of Apamea; which was begun in 1732, and finished in 1747, in 6 vols. folio, of which three are Syriac and Latin, and the other three Greek and Latin. St. Ephrem died about the year 378, under the reign of the emperor Valens; ordering his funeral to be conducted in a plain manner, and forbidding any eulogium to be delivered on the occasion, or any monument to be erected to his memory. With the acknowledged and applauded learning of Ephrem, a considerable degree of enthusiasm and fanaticism was blended; but his charitable disposition, which he manifested on a variety of occasions, endeared his name to survivors, and entitles him to honourable remembrance. Cave. Du Pin. Lardner. Jortin. Gen. Biog.

EPHREMI Codex, in *Biblical History*, a manuscript of the New Testament, written on vellum, and supposed to be of very high antiquity. It is "Codex Regius 1905," noted in the catalogue of MSS. in the royal library in Paris IX., and in all the four parts of Wetstien's Greek Testament by the letter C. It is particularly described by Griesbach in his "Symbolæ," p. iii.—liv. The first part of it contains several Greek works of Ephrem the Syrian, written over some more ancient writings, which had been erased, though the traces are still visible, and in most places legible. These more ancient writings were the whole Greek Bible. The New Testament has many chasms, which are specified by Wetstein. Besides these chasms, it is in many places illegible. Wetstein contends that this MS. was written before the year 542, though his arguments are not wholly decisive. Its readings, like those of all other very ancient MSS., are in favour of the Latin; but no proof can be given that this has been corrupted from the Latin version. It has been altered by a critical collector, who, according to Griesbach, must have lived many years after the time in which the MS. was written, and has probably erased many of the ancient readings. Kuster was the first who procured extracts from it, and he inserted them in his edition of Mill's Greek Testament. Wetstein has repeatedly collated it with very great accuracy; and the numerous readings, which he has quoted from it, greatly enhance the value of his edition. A fac-simile of the characters of this MS., which is written without accents, is given by Montfaucon in his "Palæographia Græca." It has many marginal notes, written in uncial letters without accents. In this MS. the disputed, or rather spurious verse, John, v. 4, is written, not in the text, but as a marginal scholion. Wetstein supposed, that this was one of the MSS. which were collated at Alexandria in 616 with the new Syriac version; but though this does not appear to have been the case, it is certainly as ancient as the seventh century. Wetstein argues, from a marginal note to Heb. viii. 7, that it was written before the institution of the feast of the purification of the virgin Mary, that is, before the year 542. March's Michaelis, vols. ii. and iii.

EPHREMOF, or Yephremof, in *Geography*, a town and district of Russia, in the government of Tula, situated on the river Metcha, falling into the Don.

EPHRON, in *Ancient Geography*, a place of Palestine, in the tribe of Judah, about 15 miles from Jerusalem, according to Eusebius and Jerome.—Also, a mountain of Palestine, on the confines of the tribes of Judah and Benjamin, according to the book of Joshua.—Also, a large and strong town of Judea, in the half-tribe of Manasseh, on the other side of Jordan, over-against Scythopolis. It was situated near the torrent of Jabok. This town was taken and sacked by Judas Maccabæus, and razed to its foundations.

EPHYDOR, Εφυδωρ, in *Antiquity*, an officer in the Athenian courts of justice, who was to provide the plaintiff and

and defendant with equal water hour-glaffes. When the glafs was run out, they were not permitted to fpeak any farther; and therefore we find them very careful not to lofe or mifpend one drop of their water. Whilft the laws quoted by them were reciting, or if any other bufinefs happened to intervene, they gave order that the glafs fhould be ftopped. Pott. Archæol. Græc. lib. i. cap. 21. lib. i. p. 118.

EPHYRA, in *Ancient Geography*, a town of Greece, in Thefprotia, a province of Epirus; mentioned by Velleius Paterculus and Strabo; the latter of whom fays, that it was afterwards called *Cichyrus*.—Alfo, a town of Greece, in the Pelafgiotide, a country of Theffaly. This town was alfo called *Cranon*. Steph. Byz.—Alfo, a town of the Peloponnefus, in Arcadia. Steph. Byz.—Alfo, a town of the Peloponnefus, in the territory of Elis, fituated on the river Selleis. This place was famous for the deadly poifons which it produced.

EPI, *Gr.* in *Mufic*, a prepofition, which, like *hyper*, fignifies *fupra*, above. We find one of thefe words frequently added to the Greek names of fome of the intervals of mufic; as

$$\text{Epi, or hyper,}\begin{cases}\text{Diapafon,}\\\text{Diapente,}\\\text{Diateffaron,}\\\text{Ditonum, \&c.}\end{cases}$$

When we meet with them thus in conjunction, they imply that the voice, in canons, is to follow the dux, or guide an octave, a fifth, a fourth, &c. below it. The third part is to obferve the fame rule with refpect to the fecond, and the fourth to the third, and fo on, whatever the number of parts may be.

EPIACUM, in *Ancient Geography*, a town of Albion, in the country of the Brigantes, according to Ptolemy. Camden places it at Elchefter, on the river Derwent; Horfley at Hexham, in Northumberland; and Baxter fuppofes it was originally written Pepiacum, and places it at Papcaftle, in Cumberland.

EPIALOS, from ηπιος, *gentle*, and αλς, *fea*, in the *Medical Writings of the Ancients*, the name of a fever, in which the patient labours under a preternatural internal heat, while he at the fame time fhivers with cold. It has by fome been called the fhivering-fever, and the Romans named it quercera. Galen fays, it proceeds from a putrified acrid phlegm. The word is, by fome, alfo applied to any gentle fever, or feverifh complaint; and by others, to the cold or fhivering fit preceding a fever. Hippccrates calls by this name that peculiar fever which attends young women, whofe menfes are ftopped by taking cold, or other accidents.

EPIAULIA, a name which the Greeks gave to the Miller's Song. It is conftantly confirmed, in inquiries after Greek mufic, that every profeffion, trade, and occupation, had its peculiar *nome*, tune, or fong. Rouffeau, fo often fatirical and farcaftic, but who feldom aims at pleafantry, has condefcended to be jocular upon the Greek name for the miller's tune, by afking whether the burlefque word *piauler*, (whimpering, whining,) was not derived from the Greek; as the whimpering, whining, and fqualing of women and brats, who cry and complain a long time in the fame tone, fufficiently refemble the fong or noife of a mill, and, by a metaphor, the miller?

EPIBATÆ, Επιϐαται, among the Greeks, marines or foldiers who ferved on board the fhips of war. They were armed in the fame manner as the land-forces, only that more of them wore full or heavy armour. Pott. Archæol. Grec. tom. ii. p. 140.

EPIBATERION, a poetical compofition, in ufe among the ancient Greeks. When any perfon of condition and quality returned home after a long abfence or journey, into another country, he called together his friends and fellow-citizens, and made them a fpeech, or rehearfed them a copy of verfes, wherein he returned folemn thanks to the immortal gods for his happy return; and ended with an addrefs by way of compliment to his fellow-citizens.

Thefe verfes made what the Greeks call επιβατηριον, *epibaterium*, of επιβαινω, *I go abroad*. At going away they had another, called *apobaterium*.

EPIBATERIUM, in *Botany*, from the Greek adjective επιβατηριος, *climbing*. Forft. Gen. 54. Schreb. 640. Willd. Sp. Pl. v. 4. 397. Juff. 285. Clafs and order, *Monoecia Hexandria*. Nat. Ord. *Menifperma*, Juff.

Gen. Ch. Male, *Cal.* Perianth double, deciduous; outer minute, flat, of fix leaves; inner thrice as large, of three ovate fpreading leaves. *Cor.* Petals fix, fmaller than the inner calyx, roundifh; three of them external, placed between the calyx-leaves; three internal. *Stam.* Filaments fix, capillary, incurved, the length of the petals; anthers roundifh. Female, (on the fame plant,) *Cal.* and *Cor.* as in the male. *Pift.* Germens three, fuperior, nearly globofe; ftyles three, minute, incurved; ftigmas fpreading, compreffed. *Peric.* Drupas three, roundifh, pointed with the permanent ftyles. *Nut* kidney-fhaped, compreffed, flightly furrowed.

Eff. Ch. Male, Calyx double; the outermoft of fix, the inner of three leaves. Petals fix, in two feries. Stamens fix. Female, Calyx and Corolla as in the male. Styles three. Drupas three, globular, pointed. Nuts folitary, kidney-fhaped.

E. *pendulum* is the only fpecies defcribed, a native of the ifland of St. Jago. The *ftem* is fhrubby, climbing, with long pendulous branches. *Leaves* alternate, pointing one way, on fhort foot-ftalks, oblong, entire, obtufe with a point, fmooth and without ribs, about an inch long. *Flowers* minute, pale, on folitary, axillary, fimple ftalks.

EPIBOMEUM, the name of a canticle in the Greek mufic, which was fung before the altar.

EPIC POEM, an heroic poem, or a poem reciting fome great and fignal tranfactions of a hero; called alfo *epopœia*. This kind of poem is univerfally allowed to be, of all poetical productions, the moft dignified, and, at the fame time, the moft difficult in execution. To contrive a ftory which fhall pleafe and intereft all readers, by being at once entertaining, important, and inftructive; to fill it with fuitable incidents; to enliven it with a variety of characters, and of defcriptions; and to maintain, in the courfe of a long work, that propriety of fentiment, and that elevation of ftyle, which the epic character requires, is unqueftionably the higheft effort of poetical genius. Hence it is that fo few have fucceeded in the attempt, and that ftrict critics will hardly allow any other poem to bear the name of epic, except the Iliad and the Æneid.

An epic poem, according to Boffu, is a difcourfe invented with art, to form the manners, by inftructions difguifed under the allegory of an important action related in verfe, in a probable, entertaining, and furprifing manner.

This definition, it has been obferved, would fuit Æfop's fables, if they were extended, and put into verfe. Accordingly the critic draws a parallel between the conftruction of one of Æfop's fables and the plan of Homer's Iliad. The firft thing, he fays, which a writer of fables, or of heroic poems, does, is to choofe fome maxim or point of morality, defigned to be inculcated in the work. He next invents a general ftory, or a feries of facts, without any names, fuch as he conceives moft proper for the illuftration of of his intended moral. Laſtly, he particularizes his ſtory; that is, if he be a fabuliſt, he introduces his dog, his ſheep, and his wolf; and if he be an epic poet, he draws from ancient hiſtory ſome proper names of heroes to be applied to his actors; and thus his plan is completed. This, ſays Dr. Blair, is one of the moſt frigid and abſurd ideas that ever entered into the mind of a critic; nor can any perſon of juſt reflection and taſte ever imagine, that Homer could have proceeded in this manner. No one, indeed, can entertain a doubt that the firſt objects which ſtrike an epic poet are, the hero whom he is to celebrate, and the action, or ſtory, which is to be the ground-work of his poem. "He does not ſit down, like a philoſopher, to form the plan of a treatiſe of morality. His genius is fired by ſome great enterpriſe, which to him appears noble and intereſting; and which, therefore, he pitches upon as worthy of being celebrated in the higheſt ſtrain of poetry. There is no ſubject of this kind, but will always afford ſome general moral inſtruction, ariſing from it naturally. The inſtruction, which Boſſu points out, is certainly ſuggeſted by the Iliad; and there is another which ariſes as naturally, and may juſt as well be aſſigned for the moral of that poem; namely, that Providence avenges thoſe who have ſuffered injuſtice; but that when they allow their reſentment to carry them too far, it brings misfortunes on themſelves. The ſubject of the poem is the wrath of Achilles, cauſed by the injuſtice of Agamemnon. Jupiter avenges Achilles, by giving ſucceſs to the Trojans againſt Agamemnon; but by continuing obſtinate in his reſentment, Achilles loſes his beloved friend Patroclus."

An epic poem is in its nature the recital of ſome illuſtrious enterpriſe in a poetical form. This definition is ſufficiently exact; and hence it appears to comprehend ſeveral other poems beſides the Iliad of Homer, the Æneid of Virgil, and the Jeruſalem of Taſſo; which are, perhaps, the three moſt regular and complete epic works that were ever compoſed. But to exclude all poems from the epic claſs, which are not formed exactly upon the ſame model as theſe, is, ſays Dr. Blair, the pedantry of criticiſm. This writer, therefore, does not ſcruple to claſs ſuch poems, as Milton's Paradiſe Loſt, Lucan's Pharſalia, Statius's Thebaid, Oſſian's Fingal and Temora, Camoen's Luſiad, Voltaire's Henriade, Cambray's Telemachus, Glover's Leonidas, Wilkie's Epigoniad, under the ſame ſpecies of compoſition with the Iliad and Æneid. They are all, undoubtedly, epic; that is, poetical recitals of great adventures, and conſequently belonging to this denomination of poetry.

The epic poem is diſtinguiſhed from comedy, in that the action of the latter is not important, nor is related by the poet, but acted by the perſons introduced for that purpoſe; which circumſtance, likewiſe, diſtinguiſhes it from tragedy. It differs alſo from tragedy in the event, or concluſion; which, in the latter, is generally unfortunate, but ſeldom or ever ſo in the former. See Action.

Nor is it a philoſophical poem, as that of Lucretius, or the Creation of ſir R. Blackmore; nor a treatiſe of agriculture, or the like, as the Georgics of Virgil; thoſe poems not being intended to form the manners: beſide, that the inſtructions they contain are naked, ſimple, and direct, without any diſguiſe or allegory. Which ſecond circumſtance likewiſe diſtinguiſhes it from a treatiſe of morality, written in verſe; or a ſimple hiſtory in verſe: add, that its being confined to one important action, diſtinguiſhes it from a poem which relates all the actions of a perſon's life.

M. de la Motte, indeed, in his controverſy with madam Dacier, on the ſubject of Homer, maintains, that the whole life of a hero may juſtly be made the ſubject of an epic poem: and even that the Lutrin of M. Boileau might paſs for an epic poem; but he ſeemed afterwards to return to the common ſentiment. In effect, the queſtion is not as to the ſenſe which may be annexed to the words epic poem, but the ſenſe which cuſtom has actually annexed to them.

If we had only regard to the etymology of the word epic, of ἐπος, *verſe, poetry*, from ἐπω, *dico, I ſpeak (relate)*, all poems wherein the poet ſpeaks or rehearſes things himſelf, without making the perſons of his poems ſpeak, except at ſecond-hand, as he relates what they ſpoke on this or that occaſion, would be properly epic poems; and ſo there is not an epigram, ſonnet, or madrigal, but would come under that denomination: but this were wild.

In effect, the term epic poem is only attributed to a compoſition whoſe ſubject is great, inſtructive, and ſerious; that only comprehends one ſingle principal event, to which all the reſt refer; which principal action is to be terminated in a certain ſpace of time, ordinarily about a year. It is true, all this is arbitrary; but the ſenſe of all words is ſo too; and in matters of language we muſt be guided by cuſtom.

If M. de la Motte had only pretended, that one might make a fine inſtructive poem on the whole life of a hero, or an agreeable and diverting poem on ſome humorous adventure, all the world would have been on his ſide. But it is enough that cuſtom has not thought good to apply the term epic either to ſubjects of too much extent, and that are crowded with too many incidents no-way connected together; or to burleſque poems, as the Batrachomyomachia of Homer, the Secchia Rapita of Taſſoni, the Défaite de Dulot, the Lutrin of Boileau, the Hudibras of Butler, the Rape of the Lock of Mr. Pope, or the Diſpenſary of Dr. Garth.

Dr. Blair cannot allow with Boſſu and others, that it is the eſſence of an epic poem to be wholly an allegory, or a fable contrived to illuſtrate ſome moral truth; nevertheleſs, he admits, that no poetry is of a more moral nature than this. The effect, however, in promoting virtue is not to be eſtimated by any one maxim or inſtruction, which reſults from the whole ſtory, like the moral of one of Æſop's fables; but from the impreſſion which the parts of the poem ſeparately, as well as the whole taken together, make upon the mind of the reader; from the great examples which it ſets before us, and the high ſentiments with which it warms our hearts. Its propoſed end is to extend our ideas of human perfection, and thus to excite admiration; an end, which can be accompliſhed only by proper repreſentations of heroic deeds and virtuous characters. Epic poems muſt, according to this ſtatement of their object, be favourable to virtue. Moreover, the general ſtrain and ſpirit of epic compoſition ſufficiently mark its diſtinction from the other kinds of poetry. In paſtoral writing, the reigning ideas are innocence and tranquillity; compaſſion is the great object of tragedy; and ridicule the province of comedy. But the predominant character of the epic is admiration excited by heroic actions. It is ſufficiently diſtinguiſhed from hiſtory, both by its poetical form, and the liberty of fiction which it aſſumes. It is a more calm compoſition than tragedy. It admits, nay, requires the pathetic and the violent on particular occaſions; but the pathetic is not its general character. It requires more than any other ſpecies of poetry, a grave, equal, and ſupported dignity. It takes in a greater compaſs of time and action than dramatic writing admits; and thereby allows a more full diſplay of characters. Dramatic writing diſplays characters chiefly by means of ſentiments

ments and passions; epic poetry chiefly by means of actions. The emotions which it excites are, therefore, not so violent, but they are more prolonged. These, says Dr. Blair, are the general characteristics of this species of composition.

The epic poem may be considered under three heads; first, with respect to the subject, or action; secondly, with respect to the actors, or characters; and lastly, with respect to the narration of the poet.

The action must possess the following properties; it must be one, and entire, great, and interesting. (See ACTION and EPISODE. See also ÆNEID, ILIAD, PARADISE LOST, &c.) The actors or personages introduced in an epic poem must be discriminated by appropriate and well-supported characters; which is denominated by Aristotle giving manners to the poem. See CHARACTER, in *Poetry*.

If we examine the characters of Milton, we shall find that he has introduced all the variety which his fable was capable of receiving. The whole species of mankind was restricted to two persons at the time to which the subject of his poem relates. We have, however, four distinct characters in these two persons. We see man and woman in the highest innocence and perfection, and in the most abject state of guilt and infirmity; the two last characters are, indeed, very common and obvious, but the two first are not only more magnificent, but more novel than any characters either in Virgil or Homer, or indeed in the whole circle of nature. Milton was so sensible that the subject of his poem afforded him but few characters, as to be led to introduce two actors of a fictitious nature, in the persons of "Sin" and "Death," by which means he has wrought into the body of his fable a very beautiful and well invented allegory. However, it has been thought, that persons of such a chimerical existence are not proper actors in an epic poem; because there is not that measure of probability annexed to them, which is requisite in writings of this kind.

There is one circumstance, relating to the principal actors of the Iliad and Æneid, that merits particular notice, because it gives a peculiar beauty to these two poems, and was, therefore, contrived with very great judgment. This is the choice for their heroes of persons nearly related to the people for whom they wrote. Achilles was a Greek, and Æneas the remote founder of Rome. Their countrymen were thus rendered particularly attentive to all the parts of their story, and sympathized with their heroes in all their adventures. Milton's poem is also admirable in this respect; since it is impossible for any of its readers, to whatever nation, country, or people he may belong, not to be related to the persons who are the principal actors in it; but what is still infinitely more to its advantage, the principal actors in this poem are not only our progenitors, but our representatives. We have an actual interest in every thing they do, and no less than our utmost happiness is concerned, and lies, as it were, at stake in their whole behaviour.

Besides human actors, there are personages of another kind, that usually occupy no small place in epic poetry; such are the gods, or supernatural beings. This constitutes what is called the machinery of the epic poem; and it is the most nice and difficult part of the subject. About the necessity and use of machinery in an epic composition, critics have been divided. The French critics consider it as essential to the constitution of an epic poem; and they allege that a poem, though it should possess every other requisite, has no pretension to be ranked in the epic class, unless the main action be carried on by the intervention of the gods. This decision seems to be principally, if not solely, founded on a superstitious reverence for the practice of Homer and Virgil. But, although these poets very properly embellished their respective story by the traditionary tales and popular legends of their own country, according to which, all the great transactions of the heroic times were intermixed with the fables of their deities; does it hence follow, that in other countries, and in other ages, which do not possess a similar advantage of current superstition, and popular credulity, epic poetry must be confined to antiquated fictions, and fairy tales? Lucan has composed a very spirited poem, certainly of the epic kind, where neither gods nor supernatural beings are at all employed. The author of Leonidas has also succeeded in an attempt of the same kind; and, without doubt, wherever a poet gives us a regular heroic story, well connected in its parts, adorned with characters, and supported with proper dignity and elevation, though his agents be every one of them human, he has fulfilled the chief requisites of this kind of composition, and has a just title to be classed with epic writers. Dr. Blair, whilst he cannot admit that machinery is indispensibly necessary or essential to the epic plan, differs from those critics of considerable name, who are for wholly excluding it, as inconsistent with that probability and impression of reality, which, as they conceive, should prevail in this kind of writing. (See Elem. of Criticism, ch. 22.) In epic poetry, where admiration and lofty ideas are supposed to reign, the marvellous and supernatural find, if any where, their proper place. They both enable the poet to aggrandize his subject, by means of those august and solemn objects which religion introduces into it; and they allow him to enlarge and diversify his plan, by comprehending within it heaven, and earth, and hell, men and invisible beings, and the whole circle of the universe.

In the use, however, of this supernatural machinery, a poet should be prudent and temperate. The system of the marvellous, which he introduces, should have some foundation in the popular belief, so that events, which are most contrary to the common course of nature, may derive from it an air of probability; and he should guard against excess in the use of it. As to allegorical personages, fame, discord, love, and the like, they form, says Dr. Blair, the worst machinery of any; and though they may serve for embellishment, they should not be permitted to bear any share in the action of the poem.

With regard to the narration in an epic poem, it is not of any great moment, whether the poet relate the whole story in his own character, or introduce some of his personages to relate any part of the action that had passed before the poem opens. Homer follows one method in his Iliad, and the other in his Odyssey. Virgil has, in this respect, imitated the conduct of the Odyssey; Tasso that of the Iliad. Where the subject is of great extent, and comprehends the transactions of several years, as in the Odyssey and the Æneid, the latter method seems preferable. When the subject is of smaller compass, and shorter duration, as in the Iliad and the Jerusalem, the poet may, without disadvantage, relate the whole in his own person. It is of very considerable importance in the course of the narration, that it be perspicuous, animated, and enriched with all the beauties of poetry. No sort of composition requires more strength, dignity, and fire, than the epic poem. "It is the region," says Dr. Blair (Lectures on Rhetoric, &c. vol. iii.) "within which we look for every thing that is sublime in description, tender in sentiment, and bold and lively in expression;" and, therefore, though an author's plan should be faultless, and his story ever so well conducted, yet, if he be feeble, or flat in style, destitute of affecting scenes, and deficient in poetical colouring, he can have no success. The ornaments which epic poetry admits must all

all be of the grave and chaste kind. Nothing that is loose, ludicrous, or affected, finds any place there. All the objects which it presents ought to be either great, or tender, or pleasing. Descriptions of disgusting or shocking objects should as much as possible be avoided; and, therefore, the fable of the Harpies, in the third book of the Æneid, and the allegory of Sin and Death, in the second book of Paradise Lost, had been better omitted in these celebrated poems. Mr. Addison, in his critique on the Paradise Lost (Spectator, vol. iv.), has introduced several pertinent remarks on this subject. The sentiments, which in an epic poem are the thoughts and behaviour ascribed by the author to the persons whom he introduces, should be conformable to the respective characters of these persons, and when this is the case they are said to be *just*. The sentiments have likewise a relation to *things* as well as to *persons*, and they are then perfect, when they are adapted to the subject. If in either of these cases the poet endeavours to argue or explain, to magnify or diminish, to raise love or hatred, pity or terror, or any other passion, we ought to consider whether the sentiments he makes use of are proper to those ends. Homer is censured by the critics for his defect as to this particular in several parts of the Iliad and Odyssey; but candour ascribes this defect to the times in which he lived. Virgil has excelled all others in the propriety of his sentiments. Milton is likewise commended in this respect; and he claims peculiar praise from the consideration, that most of his characters lie out of nature, and were to be formed purely by his own invention. The loves of Dido and Æneas are merely copies of what has passed between other persons. Whereas Adam and Eve, before the fall, are a different species from that of mankind, who are descended from them; and no one but a poet of the most unbounded invention, and the most exquisite judgment, could have introduced into their conversation and behaviour so many apt circumstances during their state of innocence. An epic poem should abound not only with such thoughts as are natural, but also with such as are sublime. In this respect Virgil is inferior to Homer. Indeed, Virgil seldom rises into sentiments that are astonishing, where he is not fired by the Iliad. He every where charms and pleases us by the force of his own genius; but seldom elevates and transports us where he does not deduce his hints from Homer. Milton's chief talent, and distinguishing excellence, lie in the sublimity of his thoughts. In the greatness of his sentiments he triumphs over all the poets both ancient and modern, Homer only excepted. As sentiments that are natural and sublime are always to be pursued in an heroic poem, there are two kinds of thoughts, which should be carefully avoided; the first are such as are affected and unnatural, and the second such as are mean and vulgar. In Virgil we meet with little or nothing that resembles the first kind of thought: none of those trifling points and puerilities that often occur in Ovid, none of the epigrammatic turns of Lucan, none of the swelling sentiments that are so frequent in Statius and Claudian, and none of the mixed embellishments of Tasso. Every thing is just and natural. Milton has sometimes erred in this respect; and it is urged as his apology, that he was infected by the taste and practice of the age in which he lived. Mean and vulgar thoughts have rendered Homer obnoxious to censure; but his advocates have imputed sentiments of this kind to the age in which he wrote, and to that which he described, rather than to any imperfection in that divine poet. No blemish of this kind is observable in Virgil, and Milton is seldom chargeable with it.

We have already observed, that the language of an heroic poem should be both perspicuous and sublime. In proportion as either of these two qualities are wanting, the language is imperfect. See farther of the nature of the epic poem under FABLE. For its matter, see ACTION. For its form, see NARRATION. For its versification, see HEXAMETER. See also MANNERS, CHARACTERS, MACHINE, &c. See also ÆNEID, ILIAD, TASSO's *Jerusalem*, CAMOENS' *Lusiad*, FENELON's *Telemachus*, VOLTAIRE's HENRIADE, and MILTON's PARADISE *Lost*.

EPICAIROS, in *Ancient Geography*, a town of Palestine, E. of Jordan. Ptolemy.

EPICARIA, a town of Illyria, in Dalmatia. Ptol.

EPICAU'MA, (from επι, and καιω, *to burn*). See ENCAUMA.

EPICEDION, Επικηδιον, formed of επι, *upon*, and κηδος, *funeral*, in the *Greek and Latin Poetry*, was a funeral eulogy, or a composition in prose or verse, delivered over the corpse of a friend or neighbour, commemorative of the virtues of the deceased. In celebrating the obsequies of distinguished persons three kinds of funeral discourses were used on the occasion. One, delivered when the friends were assembled to perform the last mournful offices for the dead, was termed *epicedium;* another, at the rogus, bustum, or funeral pile, *nænia;* and that inscribed on the tomb or cenotaph, *epitaphium*. In the early ages of society, the epicedium was generally an extemporaneous effusion of some near relative or affectionate friend, expressive of the sentiments he felt at the loss, and calculated to excite the common sympathy of the surrounding attendants. Beautiful specimens are given of this species of postobituary respect by Virgil in the Æneid: the one (lib. ix.) on the death of Euryalus, and the other (lib. xi.) on the death of Pallas. But in subsequent periods, when wealth and luxury had supplanted the simplicity of nature, and truth of feeling had been obliged by fashion to yield to the flattery of pomp; the custom, though preserved, materially differed in its character and form. What once had been the proper expression of undissembled esteem, was changed into a degrading system of pageantry and venality. In most public funerals, but more especially in those called *vindictivi*, the corpse, previous to interment, was carried into the forum, attended by a vast train of invited or hired followers, when one of the relatives, or some orator of eminence, ascended the rostrum, and harangued the audience in praise of the departed friend or hero. The origin of this custom is attributed to Valerius Publicola, after the expulsion of the regal title. He having honoured the obsequies of his colleague with a funeral oration, so pleased the vanity of the Roman people, that it soon became fashionable to celebrate the funerals of great or distinguished characters with panegyrics, or encomiastic orations. The practice became at length so popular, that the younger Pliny, in his epistle, lib. ii. ep. 1. considers it as the last, but not the least addition to the happiness of a great and good man, to have had the enviable honour of being commended at his funeral by the eloquence of the consul, Tacitus. Nor was this privilege exclusively confined to men; for Livy relates that the Roman matrons, having been extremely liberal and active in raising a collection of gold to enable the government to deliver the city from the hands of the Gauls, were allowed, by an act of the senate, to have the privilege of epicedia being pronounced at the celebration of their obsequies, equally with the other sex. The abuses to which this custom was liable, and to which it actually became in time subservient, are made the subjects of just complaint, and pointed animadversion, both by Cicero and Livy; as tending, by the fulsomeness of flattery, to weaken the motives to virtue, and by the greater attention which those posthumous orators paid to the blandishments of eloquence, than to the accurate statement of facts, to falsify the page, and corrupt the source of history. For on such occasions the orator did not fail to extol the deceased in the most unqualified terms of praise, to emblazon his virtues in the most brilliant colours, and to place to his credit noble actions which he had never achieved. Particularly when the orator entered on an investigation of the lineage of the party, he seldom failed to ally him to some patrician family, or dignify his pedigree, by associating with his name some of the most renowned characters in the commonwealth to illustrate and confirm the descent, so that gradually, by means of these misrepresentations being recorded, the epicedia tended to obliterate the just distinctions of consanguinity, and throw down the barriers of property. From this heathen custom are derived obituary masses, oraisons funebres, and funeral sermons.

EPICERASTICS, Επικεραστικα, formed of επι and κεραννυμι, *I moderate*, in *Medicine*, remedies which, by their temperate moisture, soften the acrimony of a humour, and assuage the painful sensation of a part irritated or afflicted by it; such are the roots of althæa, mallows, liquorice; leaves of lettuce, mallows, water-lily, purslain; the seeds of flax, poppy, &c. See EMOLLIENTS.

EPICHARMUS, in *Biography*, a native of the island of Cos, who flourished in the 5th century, B. C. His father removed him at an early age to Megara, and afterwards to Syracuse, where he became a disciple in the Pythagorean school. Being prevented, by the tyranny of Hiero, from assuming the public profession of philosophy, he chiefly applied himself to the study of dramatic poetry, and offended the Pythagoreans, by introducing the doctrines and precepts of Pythagoras upon the stage. His comedies were numerous, of which Suidas assigns to him 52; but only some few fragments remain. He taught a school at Syracuse, and is said to have invented the two Greek letters θ and χ. He also wrote commentaries upon physical and medical subjects. We have no accurate account of his philosophical tenets: but some of his apophthegms deserve to be recorded; such are the following: "To die is an evil; but to be dead is no evil." "Every man's natural disposition is his good or evil dæmon." "He who is naturally inclined to good is noble, though his mother was an Ethiopian." "Be sober in thought, be slow in belief; these are the sinews of wisdom." "The gods set up their favours at a price, and industry is the purchaser." "Live so as to be prepared either for a long life or a short one." According to Lucian, the life of Epicharmus was prolonged to the age of 97 years. Laert. l. viii. § 78. Suidas. Fabr. Bib. Græc. v. i. p. 676. Brucker's Phil. by Enfield, vol. i.

EPICHIREMA, Επιχειρημα, in *Logic*, an argumentation, consisting of four or more propositions, some of which are proofs of others.

Thus, that oration of Cicero for Milo may be reduced to the epichirema: "Those who way-lay a man to kill him, it is lawful for him to kill, as is allowed by the laws of nature and nations, and by the practice of the best men; but Clodius way-laid Milo with that view, as appears from his forming an ambuscade before his country-house, and from his provision of weapons, soldiers, &c." Therefore it was lawful for Milo to kill Clodius.

EPICHIROTONIA, among the Athenians. It was ordained by Solon, that once every year the laws should be carefully revised and examined; and if any of them were found unsuitable to the present state of affairs, they should be repealed. This was called επιχειροτονια των νομων, from the manner of giving their suffrages, by *holding up their hands*. See a farther account of this custom in Pott. Archæol. Græc. lib. i. cap. 26. tom. i. p. 142.

EPICHORDIS, from χορδη, *an intestine*, in *Anatomy*, a name given by some to the mesentery.

EPICHUS, or TACAPE (*Gabs*), in *Ancient Geography*, a town of Africa, on the coast of the Mediterranean sea, S. of Tephrura. See GABS.

EPICITHARISMA, in the *Ancient Music*, an air for the cithara, said to be played at the end of dramatic pieces; which, consequently, must have been to Greek plays what a terminating ballet is now to an opera.

EPICLEROS, Επικληρος, among the Athenians, a daughter that had no brothers, and therefore inherited her father's whole estate. See EPIDICASIA.

EPICŒNE, Επικοινοι, in *Grammar*, a term applied to nouns, which, under the same gender and termination, mark, indifferently, two kinds of sexes. See GENDER.

Such in Latin, are *aquila*, *vespertilio*, &c. which signify equally a male or a female eagle, or bat.

Grammarians distinguish between epicœne and common. A noun is said to be common of two kinds, when it may be joined either with a masculine or a feminine article; and epicœne, when it is always joined to some one of the two articles, and yet signifies both genders.

EPICOLIC REGION, in *Anatomy*, from επι, *upon*, and κοιλιον, *the colon*, that part of the abdomen which is above the colon.

EPICRANIUS, a thin and broad muscle, covering the superior arched portion of the cranium, and called also fronto-occipitalis, and occipito-frontien; or described as two muscles by the names of frontalis and occipitalis.

If we describe this as a single muscle, which we consider as the most natural and correct method, it will belong to the class of digastric muscles, or of such as possess a middle tendon, with fleshy fibres connected to its two ends. The aponeurosis is a very broad but thin plane, made up of tendinous fibres, variously interwoven, covering the upper part of the cranium, and hence called by Soemmerring galea cranii aponeurotica. It is separated, along the middle, by a narrow interval from the opposite muscle, and it extends externally as far as the semicircular line, to which the temporal fascia is affixed. Its outer surface adheres closely to the scalp, while the inner is much more loosely connected, by a yielding cellular substance free from fat, to the pericranium. Its edges are insensibly continued into the neighbouring cellular substance.

The frontal portion is a thin flattened layer of muscular fibres, commencing by a semilunar edge from the front of the aponeurosis, and descending in a straight course to the eyebrow. Internally it is continuous with the opposite muscle, and detaches a portion of fibres along the side of the nose, to join the compressor narium, and levator labii superioris and alæ nasi. It then terminates by joining the orbicularis palpebrarum, through the whole of its upper convexity, and it is also connected with the corrugator supercilii. The external surface of this muscle is covered by the integuments of the forehead; and its inner surface lies on the frontal bone and os nasi.

The occipital portion is not so broad as the preceding. Arising from the back edge of the aponeurosis, it is inserted into the upper part of the external transverse ridge of the occipital bone. It covers the occipital and a little of the temporal bone, and is covered by the scalp.

It is very obvious that the occipito-frontalis cannot affect the bones of the head; but it moves the integuments in different directions, in consequence of the connection between its

its tendon and the fcalp. When the frontal and occipital portions act alternately, they draw the common tendon backwards and forwards, and thereby impart confiderable motion to the whole hairy fcalp. If they act together, they will render the aponeurofis tenfe. When the frontal acts feparately, it draws up the eyebrow and fkin of the forehead, and throws the latter into tranfverfe wrinkles. Hence it is concerned in the expreffion of the countenance, and acts more efpecially in the gay and joyful emotions, directly antagonifing the corrugator fupercilii, which throws the forehead, and particularly the eyebrows, into longitudinal wrinkles. It contributes alfo, by means of its connection with the upper eyelids, to the opening of the eyelids, when we carry that to as great an extent as poffible. The feparate action of the occipital can only produce a flight effect on the integuments of the back of the head. Its contraction, however, fixes the aponeurofis, and renders it a firm point for the contraction of the frontal in raifing the eyebrow and eyelid. This mufcle, on the whole, is ftrongly analogous to the panniculus carnofus of quadrupeds.

EPICRASIS, in *Medicine*, is a gradual evacuation of ill humours in the blood.

EPICRISIS, Επικρισις, in *Rhetoric*, a clear and brief declaration of the fpeaker's judgment concerning the fubject in hand. Thus, "ego fic ftatuo, in optimo imperatore quatuor has res ineffe oportere, &c." Voff. Rhet. lib. vi. p. 495.

EPICTETI, in *Ancient Geography*, a people, who, according to Strabo, bounded Bithynia on the eaft. Hence the weftern part of Phrygia obtained the appellation of "Phrygia Epictetus." In this territory was the fource of the river Hermus, and the town of Ancyra was fituated in it, on the frontiers of Myfia.

EPICTETUS, in *Biography*, an eminent Stoic philofopher, no lefs diftinguifhed for his virtues than his wifdom, was born in a fervile condition at Hierapolis in Phrygia, and flourifhed in the firft century of the Chriftian era. At an early age he was fold as a flave to Epaphroditus, a celebrated freedman of Nero, to whom Jofephus infcribed moft of his works, and who was afterwards put to death by Domitian. Epictetus was lame; and of this infirmity various caufes have been affigned by different writers. Celfus relates, that when his mafter, in order to torture him, fqueezed his leg very hard, the philofopher betrayed no fymptoms of fear, but faid very calmly to his tormentor; "You will break my leg;" and when it was broken, he only faid with a fmile, "Did I not tell you that you would break it." Some fay, that he was born lame; and others afcribe his lamenefs to the heavy chains with which his mafter loaded him. Epictetus, having, by fome means which are not recorded, obtained his freedom, retired to a fmall hut within the city of Rome, where, in an indigent condition, he devoted himfelf to the ftudy of philofophy. Having in his retirement acquired a competent knowledge of the principles of the Stoic fect, and having alfo received inftructions in rhetoric from Rufus; he became, notwithftanding his poverty, a popular preceptor of morals. He was an acute and judicious obferver of manners; his eloquence was fimple, majeftic, nervous, and penetrating: his doctrine inculcated the pureft morals; and his life was an admirable pattern of fobriety, magnanimity, and the moft rigid virtue. His reprehenfions of vice were bold and animated; his inftructions and precepts impreffive and conciliating; and they were communicated without that dogmatifm, vanity, and rudenefs, which were too generally affected by the philofophers. He was accuftomed to obferve, that the fum of moral inftruction may be comprifed in two words, ανεχε και απεχε, *i. e.* endure and abftain, or bear and forbear. Aulus Gellius reprefents him as the greateft man the fect of the Stoics ever produced. The tyranny of Domitian, notwithftanding his extreme poverty and fingular merit, included him in the number of thofe philofophers who were banifhed from Italy; and to the arbitrary decree of this monfter, he calmly fubmitted, confidering himfelf as a citizen of the world, and fully apprifed, that wherever he went he carried his beft treafure along with him. At Nicopolis in Epirus, which he chofe as the place of his refidence, he purfued his defign of correcting vice and folly by the precepts of philofophy. The wifdom and eloquence of his difcourfes were held in fuch high eftimation, that his hearers were very numerous, and it became a common practice among them to commit his inftructions to writing. It is not certain whether he returned to Rome after the death of Domitian; but the refpect which Adrian entertained for him renders it probable, that he fpent the latter part of his life in that city. Here, however, he obtained no favours, that could induce him to abandon that humble condition of contented and independent poverty, which he had felected, and in which he determined to remain. Of the time and manner of his death we have no certain account. Themiftius and Suidas affert that he lived till the time of the Antonines; but from the mention that is made of him by Aulus Gellius and Marcus Aurelius, it is probable that he died towards the clofe of the reign of Adrian. His name and memory were fo much refpected after his deceafe, that, according to Lucian, the earthen lamp, by which he ufed to ftudy, was fold for 3000 drachmas, or more than 90*l.* of our money. The teftimony of Suidas, who afferts that Epictetus wrote many books, is not fupported by any ancient author; however this be, the only remains of this philofopher are his beautiful moral manual, entitled "Enchiridion," and his "Differtations," felected by Arrian, which were drawn up from notes taken by his difciples from his lips. Arrian's account of his life and death is not now extant. Simplicius has left a commentary upon his doctrine, in the eclectic manner. There are alfo various fragments of his wifdom preferved by Antoninus, Gellius, Stobæus, and others. Although the doctrine of Epictetus is lefs extravagant than that of any other Stoic, his writings every where breathe the true fpirit of Stoicifm. The tenet of the immortality of the foul was adopted and maintained by him with a degree of confiftency fuited to a more rational fyftem than that of the Stoics, who inculcated a renovation of being in the circuit of events, according to the inevitable order of fate; and his exhortations to contentment and fubmiffion to Providence are enforced on much founder principles than thofe of the Stoics. He alfo ftrenuoufly oppofed the opinion held by the Stoics in general, concerning the lawfulnefs of fuicide; and his whole fyftem of practical virtues approaches nearer than that of any other inftructor, unenlightened by revelation, to the purity of Chriftian morality. We have various editions of the remains of this philofopher, publifhed at Leyden in 1670, in 8vo. cum notis variorum; at Utrecht in 1711, in 4to.; at Oxford, in 1740, in 8vo. by Jofeph Simpfon, together with the Table of Cebes, &c.; at London in 1742 by J. Upton, in two volumes 4to. which is the moft valuable of all. The Enchiridion was publifhed by C. G. Heyne, in 1776, in 8vo. and, together with Cebes's table, by Schweighaufer, in 1798, 8vo. Thefe have been tranflated into various languages; but the moft efteemed verfion in our country is that by Mrs. Carter, publifhed in 1758, with notes. Fabr. Bib. Græc. v. iii. Aul. Gell. l. i. c. 2. EPICUREANS, a sort of ancient philosophers, who adhered to the doctrines and opinions of Epicurus. See EPICURUS.

The doctrines of Epicurus, as they are stated in a just, comprehensive, and elaborate detail by Brucker in his "History of Philosophy," translated and abridged by Dr. Enfield, are arranged under the distinct heads of Philosophy in general, canons or rules of philosophising, Physics, and Ethics. Philosophy is the exercise of reason in the pursuit and attainment of a happy life; whence it follows, that those studies which conduce neither to the acquisition nor the enjoyment of happiness are to be dismissed as of no value. The end of all speculation ought to be, to enable men to judge with certainty what is to be chosen, and what to be avoided, to preserve themselves free from pain, and to secure health of body and tranquillity of mind. Accordingly, the young should apply to the study of it without delay, nor should the old be ever weary in the pursuit of it. As nothing ought to be dearer to a philosopher than truth, he should prosecute it by the most direct means, devising no fictions himself, nor suffering himself to be imposed upon by the fictions of others, neither poets, orators, nor logicians; making no other use of the rules of rhetoric or grammar, than to enable him to speak or write with accuracy and perspicuity, and always preferring a plain and simple to an ornamented style. A wise man will embrace such tenets, and only such, as are built upon experience, or upon certain and indisputable axioms. Philosophy consists of two parts:—physics, which respect the contemplation of nature; and ethics, which are employed in the regulation of manners. Of these, the latter is the most important; the knowledge of nature being only necessary as a means of promoting the happiness of life. Philosophers have added a third part, dialectics; which ought to be rejected, as only productive of thorny disputes, idle quibbles, and fruitless cavilling. In order to facilitate the pursuit of knowledge, a few plain maxims and rules may be useful. Truth is of two kinds; that which respects real existence, and that which consists in a perfect agreement between the conception of the mind and the nature of things. In order to judge rightly concerning truth, it is necessary to use some criterion, or instrument, of judging. This criterion will vary according to the nature of the object which the mind contemplates. In judging of natural and moral objects, the three instruments employed are sense, preconception, and passion. The maxims, or canons, pertaining to sense, are four: First, that the senses can never be deceived, and consequently, that every perception of an image, or appearance, is true; that is, that the perception, or simple apprehension, and its efficient cause, the species or image flowing from the object, really agree. Secondly, opinion, or judgment, is consequent upon perception, and admits of truth or falsehood. Perceptions, or sensations, are the effect of real external *phenomena*; but when the mind judges concerning these appearances, the opinion may be either right or wrong. Thirdly, every opinion is to be admitted as true, which is attested, or not contradicted, by the evidence of the senses, after a careful and deliberate examination of every circumstance which can be supposed to affect the question. Fourthly, an opinion contradicted, or not attested by the evidence of the senses, is false. Thus, the opinion of a *Plenum* must be false, because it contradicts the evidence of the senses, which attest, that there is such a thing as motion. Concerning the second instrument of judgment, *viz.* πρόληψις, or pre-conception, four canons may be laid down. First, that all pre-conceptions are derived from the senses, either by immediate impression, as of an individual man; by enlargement or diminution, as of a giant or dwarf; by resemblance, as of an unknown city to one which has been seen; or by composition, as of a centaur. Secondly, pre-conception is necessary to enable us to reason, inquire, or judge of any thing. Thirdly, pre-conceptions, or universal notions, are the principles of all reasoning and discourse; and we easily refer to these in comparing one thing with another. If these notions be agreeable to nature, and distinctly conceived, artificial reasoning will be unnecessary. Fourthly, truths, not self-evident, are to be deduced from manifest pre-conceptions; or, where the relation of ideas is obscure, it is to be made evident by the intermediate use of some acknowledged principle. The third instrument, passion, or affection, which comprehends pleasure and pain, admits of the following four evident maxims. First, all pleasure, to which no pain is annexed, is for its own sake to be pursued. Secondly, all pain, to which no pleasure is annexed, is for its own sake to be avoided. Thirdly, that pleasure, which either prevents the enjoyment of a greater pleasure, or produces a greater pain, is to be shunned. Fourthly, that pain, which either removes a greater pain, or procures a greater pleasure, is to be endured. As to the use of words, two canons are sufficient. First, in speaking, use terms in common use, and in the sense in which they are commonly understood. Secondly, in hearing, or reading, attend carefully to the signification which the speaker or writer affixes to his terms. Attention to these maxims would prevent much obscurity and confusion, and terminate many disputes. By these rules Epicurus undertook to conduct his followers into the secrets of nature, and to lay open to them the origin of things.

The physical doctrine of Epicurus was as follows: Nothing can ever spring from nothing, nor can any thing ever return to nothing. The universe always existed, and will always remain; for there is nothing into which it can be changed. There is nothing in nature, nor can any thing be conceived, besides body and space. Body is that which possesses the properties of bulk, figure, resistance, and gravity: it is this alone which can touch and be touched. Space, or *vacuum*, destitute of the properties of body, incapable of action or passion, is the region which is or may be occupied by body, and which affords it an opportunity of moving freely. The existence of bodies is attested by the senses. Space must also exist, in order to allow bodies place in which to move and exist; and of their existence and motion we have the certain proof of perception. Besides body and space, no third nature can be conceived. But the existence of qualities is not precluded, because these have no subsistence except in the body to which they belong. The universe, consisting of body and space, is infinite. Bodies are infinite in multitude; space is infinite in magnitude. The universe is immoveable, because there is no place beyond it into which it can move. It is also eternal and immutable, since it is liable to neither increase nor decrease, to production nor decay. Nevertheless, the parts of the universe are in motion, and are subject to change. All bodies consist of parts, which are either themselves simple principles, or may be resolved into such. These first principles, or simple atoms, are divisible by no force, and therefore must be immutable. The existence of such atoms is indisputable, because it is impossible that any thing which exists should be reduced to nothing. A finite body cannot consist of parts infinite either in magnitude or number; and therefore divisibility of bodies *in infinitum* is inconceivable. All atoms are of the same nature,

nature, without any difference in effential qualities; and yet it appears, from their different effects upon the fenfes, that they differ in magnitude, figure, and weight. Atoms exift in every poffible variety of figure; and yet on account of their folidity, they are infrangible, or incapable of actual divifion. Gravity is an effential principle of atoms; for being perpetually in motion, or making an effort to move, they muft be moved by an internal impulfe, which may be called gravity. By this internal force, atoms are carried forward in a direction, which is nearly rectilinear; and whilft they pafs through free fpace, their declination from a right line occafions a cafual concurrence of corpufcles of different forms. Thus various kinds of curvilinear motion will be produced. Moreover, when one atom is reflected from another, and again repelled by a third, it will acquire a kind of vibratory or tremulous motion. Hence an univerfal agitation will enfue. The principle of gravity, being effential to the primary corpufcles or atoms, thefe muft have been inceffantly, and from eternity, in actual motion; and with a velocity, when no obftacle intervenes, which will caufe them to pafs through the greateft imaginable fpace in the fmalleft imaginable portion of time. All atoms are alfo fuppofed, whilft they pafs without refiftance through the fame empty fpace, to move with equal velocity; and though, by collifion, their direction may be changed, their velocity is not diminifhed. Atoms are the elements from which all things are compounded, and into which they are refolved; and the energy, or principle of motion, which effentially belongs to them, is the fole agent in the operations of nature. Action originates in atoms, and from thefe proceeds to compound bodies. All the changes which take place in the figure, and other properties of bodies, confift in local motion. Bodies are more or lefs rare, in proportion to the fize of the vacuities which intercept the folid atoms of which they are compofed. Tranfparency depends partly upon the fame caufe, and partly upon the pofition of the vacuities between the particles: for rays of light will pafs eafily through a denfe body, as glafs, if its vacuities be placed in a ftraight line. Hardnefs and foftnefs, flexibility, ductility, and other qualities, may be explained in a fimilar manner. The weight of a body is the refult of the weight of all its atoms; and fince gravity is an effential property of all atoms, all bodies muft be heavy; and the only reafon why fome bodies appear to have the contrary principle of levity is, that they are driven upwards by the denfer mafs in which they are placed. Heat is the influx of certain fmall, round, foft corpufcles, which infinuate themfelves into the pores of bodies in continual fucceffion, till by their perpetual action, the parts are feparated, and at length the body diffolved. The fenfe of heat is the perception of the feparation of parts, which were before contiguous. Cold is the influx of certain irregular atoms, whofe motion is flower than that of thofe which occafion heat, and their effect the reverfe of the former. Pleafure and pain, motion and reft, and even time, are actions of bodies. Production and diffolution are nothing more than a change of the pofition of atoms, or an increafe or diminution of the particles of which bodies are compofed. The world is finite and terminable, and muft have fome figure, though this cannot poffibly be afcertained. It is not eternal, but began at a certain time to exift; for fince every thing in the world is liable to viciffitudes of production and decay, the world itfelf muft partake of them. This may alfo be inferred from the fhort date of hiftory, and the late invention of arts.

The formation of the world may be conceived to have happened in the following manner: a finite number of that infinite multitude of atoms, which, with infinite fpace, conftitutes the univerfe, falling fortuitoufly into the region of the world, were in confequence of their innate motion collected into one rude and indigefted mafs. In this chaos, the heavieft and largeft atoms, or collections of atoms, firft fubfided, whilft the fmaller, and thofe which from their form would move moft freely, were driven upwards. Thefe latter, after many reverberations, rofe into the outer region of the world, and formed the heavens. Thofe atoms, which by their fize and figure were fuited to form fiery bodies, collected themfelves into ftars: thofe which were not capable of rifing fo high in the fphere of the world, being difturbed by the fiery particles, formed themfelves into air. At length from thofe which fubfided was produced the earth. By the action of air, agitated by heat from the heavenly bodies upon the mixed mafs of the earth, its fmoother and lighter particles were feparated from the reft, and water was produced, which naturally flowed into the loweft places. In the firft combination of atoms, which formed the chaos, various feeds arofe, which, being preferved and nourifhed by moifture and heat, afterwards fprung forth in organized bodies of different kinds. Of the animal productions of the earth, fome may be conceived to have been produced imperfect, and therefore incapable of life, but others would come forth more perfect. Thefe, after the earth was exhaufted of its feminal virtues, would refpectively continue their fpecies. The world, thus formed, would be preferved by the fame mechanical caufes which produced it; but by the inceffant motion of atoms, which alone are folid and incorruptible, it would gradually tend to diffolution. In procefs of time nothing will remain but feparate atoms and infinite fpace. As atoms are infinite, the number of worlds may alfo be infinite. The earth occupies the middle part of the world; but no point within it is properly the centre of gravity, for all heavy bodies fall in nearly parallel lines. The doctrine of Antipodes, according to the Epicurean philofophy, is falfe. The figure of the earth is a circular plane; and it is preferved from falling towards the lower region by the air, with which it is congenial, and upon which therefore it does not prefs; their mutual action deftroying the effect of gravity. Earthquakes are caufed by the agitation of internal winds and water, or by the decay or fudden fall of columns, that fupport portions of the earth's furface. Or, the internal winds may be converted into fires, which may caufe fudden and violent eruptions, as in mount Ætna. Waters paffing out of the fea into the crevices of the earth, undergo a filtration, by which the particles of falt received by them from the bed of the fea are feparated. Foffils and plants are produced by the motion of atoms, that caufe the continual tranfpofition, accretion or diminution of individual bodies. Having no vital principle, they can only be faid analogically to live or die. Animals having been once formed, at the beginning of the world, by the cafual conjunction of fimilar atoms, the production of animal bodies is ftill continued in a confiftent and determinate order. The parts of animals were not originally framed for the ufes to which they are now applied; but, having been accidentally produced, they were afterwards accidentally employed. The eye, for example, was not made for feeing, nor the ear for hearing, but the foul, being formed within the body at the fame time with thefe organs, and connected with them, could not avoid making ufe of them in their refpective functions. The foul is a fubtle corporeal fubftance, compofed of the fineft atoms; which, by the extreme tenuity of its particles, is able to penetrate the whole body, and to adhere to all its parts. It is compofed

of

of four diftinct parts; fire, which caufes animal heat; an ethereal principle, which is moift vapour; air; and a fourth principle, which is the caufe of fenfation. Thefe four parts are fo perfectly combined as to form one fubtle fubftance, which, whilft it remains in the body, is the caufe of all its faculties, motions, and paffions, and which cannot be feparated from it, without producing the entire diffolution of the animal fyftem. Different fenfations are the cafual effects of the different organs, which the foul in its union with the body is capable of employing, and of the different properties and qualities of external objects. Thefe become fenfible by means of certain fpecies, or images, which are perpetually paffing like thin films from bodies, in form fimilar to the furfaces of the bodies themfelves, and ftriking upon organs fitted to receive them. The mind, or intellect, which is endued with the power of thinking, judging, and determining, is formed of particles moft fubtle in their nature, and capable of the moft rapid motion. This intellect is a portion of the foul, forming with it one nature, and yet retaining its diftinct character, which is the power of thinking; the fuppofed feat of it is the middle of the breaft, or the heart, which we perceive to be the region of thofe affections which are excited by cogitation. Thought is produced by fubtle images, which find their way through the body, and, when they arrive at the intellect, move it to think. The affections and paffions of the foul may be reduced to two, pleafure and pain. Voluntary motion is the effect of images conveyed to the mind, by which pleafurable or painful conceptions are formed, and fubfequent defires or averfions are produced, which become the immediate fprings of action. Sleep is produced, when the parts of the foul, which are at other times diffufed through the body, are expreffed or feparated by the action of the air, or of food. Dreams are the effect of images cafually flying about, which from their extreme tenuity penetrate the body and ftrike upon the mind, exciting an imaginary perception of thofe things, of which they are images. Death is the privation of fenfation, in confequence of the fep ration of the foul from the body; in which cafe, the foul is difperfed into the corpufcles or atoms of which it was compofed, and therefore can no longer be capable of thought or perception. The knowledge of things, which belong to the regions above the earth, whether aërial or celeftial, is to be purfued only for freeing the mind from imaginary fears, and fettling it in a ftate of tranquillity. In the heavens, or ethereal regions, the fun, moon, and ftars appear to be fiery bodies; or they may be fmooth mirrors, from which bright fiery particles flowing through the ethereal regions are reflected to the earth; or they may be deep veffels, containing fires; or they may be circular plates heated like mortar, or ftones in a furnace. The apparent motion of the heavenly bodies may arife from the revolution of the whole heaven in which they are fixed, like nails in a folid body: or by the revolution of the bodies themfelves through the heaven as a fluid and permeable medium. The caufe of this motion may be, either an internal neceffity in the natures of the bodies themfelves, or the external preffure of fome ethereal fluid.

In the univerfe there are, according to Epicurus, without contradiction, divine natures: becaufe nature itfelf has impreffed the idea of divinity upon the minds of men. The notion is univerfal, nor is it eftablifhed by cuftom, law, or any human inftitution; but it is the effect of an innate principle, producing univerfal confent, and therefore it muft be true. This univerfal notion has probably arifen from images of the gods, which have cafually made their way into the minds of men in fleep, and have afterwards been recollected. But it is inconfiftent with our natural notions of the gods, as happy and immortal beings, to fuppofe that they encumber themfelves with the management of the world, or are fubject to the cares and paffions which muft attend fo great a charge. Hence it is inferred, that the gods have no intercourfe with mankind, nor any concern with the affairs of the world. Neverthelefs, on account of their excellent nature, they are objects of reverence and worfhip. In their external fhape the gods refemble men; and though the place of their refidence is unknown to mortals, it is without doubt the manfion of perfect purity, tranquillity, and happinefs.

Upon a review of the preceding fummary of the Epicurean fyftem, furnifhed chiefly by Laertius and Lucretius, it muft appear to be a feeble and ineffectual effort to explain the phenomena of nature upon mechanical principles. With this view Epicurus adopts a variety of wild and fanciful hypothefes, which evince his incapacity of folving the grand problem concerning the origin and formation of the world. But the greateft defect of this fyftem is the attempt of its author to account for all the appearances of nature, even thofe which refpect animated and intelligent beings, upon the fimple principles of matter and motion, without introducing the agency of a Supreme Intelligence, or admitting any other idea of fate, than that of blind neceffity inherent in every atom, by which it moves in a certain direction. Hence he leaves unexplained thofe appearances of defign, which are fo manifeft in every part of nature, and abfurdly fuppofes, that the eye was not made for feeing, nor the ear for hearing. Befides the idea which he gives of the nature of the gods, whofe exiftence he admits, as fimilar to man; and of their condition, as wholly feparate from the world, and enjoying no other felicity except that which arifes from inactive tranquillity, falls infinitely fhort of the true conception of Deity, as the intelligent Creator and Governor of the world.

The doctrine of Epicurus concerning nature differs from that of the Stoics, (fee Stoics,) chiefly in the following particulars: while the latter held God to be the foul of the world, diffufed through univerfal nature, the former admitted no primary intelligent nature into his fyftem, but held atoms and fpace to be the firft principles of all things; and whilft the Stoics conceived the active and paffive principles of nature to be connected by the chain of fate, Epicurus afcribed every appearance in nature to a fortuitous collifion and combination of atoms. See Atomical and Corpuscular *Philofophy*.

The ethics of Epicurus are much lefs exceptionable than his phyfics; of which we may judge from the following fummary. The end of living, or the ultimate good, which is to be fought for its own fake, according to the univerfal opinion of mankind, is happinefs: which men generally fail of attaining, becaufe they form wrong notions of the nature of happinefs, or do not ufe proper means for attaining it. The happinefs, which belongs to man, is that ftate in which he enjoys as many of the good things, and fuffers as few of the evils incident to human nature as poffible, paffing his days in a fmooth courfe of permanent tranquillity. Perfect happinefs cannot poffibly be poffeffed without the pleafure that attends freedom from pain, and the enjoyment of the good things of life. Pleafure is in its nature good, and ought to be purfued; and pain is in its nature evil, and fhould be avoided. Befides, pleafure or pain is the meafure of what is good or evil in every object of defire or averfion. However, pleafure ought not in every inftance to be purfued, nor pain to be avoided; but reafon is to diftinguifh and compare the nature and degrees of each, that the refult may be a wife choice of that which fhall appear to be, upon the whole, good. That pleafure is the firft good appears from the inclination which every animal, from its firft birth, difcovers to purfue pleafure and avoid pain; and is confirmed by the univerfal experience of mankind, who are incited to action by no other principle, than the defire of avoiding pain, or obtaining pleafure. Of pleafure there are two kinds; one confifting in a ftate of reft, in which both body and mind are free from pain: the other arifing from an agreeable agitation of the fenfes, producing a correfpondent emotion in the foul. Upon the former of thefe, the enjoyment of life chiefly depends. Happinefs may, therefore, be faid to confift in bodily eafe and mental tranquillity. It is the office of reafon to confine the purfuit of pleafure within the limits of nature, fo as to attain this happy ftate; which neither refembles a rapid torrent, nor a ftanding pool, but is like a gentle ftream, that glides fmoothly and filently along. This happy ftate can only be attained by a prudent care of the body, and a fteady government of the mind. The difeafes of the body are to be prevented by temperance, or cured by medicine, or endured tolerably by patience. Againft the difeafes of the mind philofophy provides fufficient antidotes; the virtues are its inftruments for this purpofe; the radical fpring of which is prudence, or wifdom, and this inftructs men to free their underftandings from the clouds of prejudice; to exercife temperance and fortitude in the government of themfelves: and to practife juftice toward all others. In a happy life, pleafure can never be feparated from virtue. A prudent man will confult his natural difpofition in the choice of his plan of life. Temperance is that difcreet regulation of the defires and paffions, by which we are enabled to enjoy pleafures without fuffering any confequent inconvenience. They who maintain fuch a conftant felf-command, as never to be enticed by the profpect of prefent indulgence to do that which will be productive of evil, obtain the trueft pleafure by declining pleafure. Sobriety, as oppofed to inebriety and gluttony, teaches men that nature is fatisfied with a little, and enables them to be contented with fimple and frugal fare: thus health is preferved; the offices of life are performed with alertnefs and activity; and the occafional varieties of a plentiful board acquire an excellent relifh, and a perfon is prepared to meet every reverfe of fortune without the fear of want. Continence, which is a branch of temperance, prevents the difeafes, infamy, remorfe, and punifhment to which thofe are expofed, who indulge themfelves in unlawful amours. Mufic and poetry, which are often employed as incentives to licentious pleafure, are to be cautioufly and fparingly ufed. Gentlenefs, as oppofed to an irafcible temper, greatly contributes to the tranquillity and happinefs of life, by preferving the mind from perturbation, and arming it againft the affaults of calumny and malice. Moderation in the purfuit of honours or riches, is the only fecurity againft difappointment and vexation. A wife man will, therefore, prefer the fimplicity of ruftic life to the magnificence of courts. As the events of futurity are uncertain, he neither will be elated with confident expectation, nor depreffed by doubt and defpair; the one and the other being equally deftructive of tranquillity. It will contribute to the enjoyment of life, to confider death as the perfect termination of a happy life, which it becomes us to clofe like fatisfied guefts, neither regretting the paft, nor anxious for the future. Fortitude, by enabling us to endure pain and banifh fear, is of great ufe in producing tranquillity. Philofophy inftructs us to pay homage to the gods, not through hope or fear, but from veneration of their fuperior nature. It enables us alfo to conquer the fear of death, by teaching us, that it is no proper object of terror; fince, whilft we are, death is not, and when death arrives, we are not; fo that it concerns neither the living nor the dead. The only evils to be apprehended are bodily pain and diftrefs of mind. It becomes a wife man to endure the former with patience and firmnefs, becaufe, if it be flight it may be eafily borne; and if it be intenfe, it cannot laft long. Mental diftrefs commonly arifes, not from nature, but from opinion; a wife man, will, therefore, arm himfelf againft this kind of fuffering, by reflecting that the gifts of fortune, the lofs of which he may be inclined to deplore, were never his own, but depended upon circumftances which he could not command. If, therefore, they happen to leave him, he will endeavour as foon as poffible to obliterate the remembrance of them, by occupying his mind in pleafant contemplation, and engaging in agreeable avocations. Juftice refpects man as living in fociety, and is the common bond without which no fociety can fubfift. This virtue, like the reft, derives its value from its tendency to promote the happinefs of life. It is the intereft of every individual in a ftate of fociety to conform to the laws of juftice, for in fociety, the neceffity of the exercife of mutual juftice, in order to the common enjoyment of the gifts of nature, is the ground of thofe laws by which it is prefcribed. Nearly allied to juftice are the virtues of beneficence, compaffion, gratitude, piety, and friendfhip. He who confers benefits upon others, procures to himfelf the fatisfaction of feeing the ftream of plenty fpreading around him from the fountain of his own beneficence; at the fame time he enjoys the pleafure of being efteemed by others. The exercife of gratitude, filial affection, and reverence for the gods, is neceffary, in order to avoid the hatred and contempt of all men. Friendfhips are contracted for the fake of mutual benefit; but by degrees they ripen into fuch difinterefted attachment, that they are continued without any profpect of advantage. A true friend will partake of the wants and forrows of his friend, as if they were his own; if he be in want, he will relieve him; if he be in prifon, he will vifit him; if he be fick, he will come to him; nay, fituations may occur, in which he would not fcruple to die for him. It cannot then be doubted, that friendfhip is one of the moft ufeful means of procuring a fecure, tranquil, and happy life.

From the preceding fummary of the ethics of Epicurus, we may be enabled to refute the cenfures which many writers have paffed upon him, as the preceptor of luxurious and licentious pleafures. Thefe cenfures have originated in a mifconception of the nature of that pleafure which he recommends and juftifies, and which, in his fyftem, is only another name for happinefs. Whilft the Stoics taught that virtue itfelf is happinefs, Epicurus maintained, that the motive by which men are induced to practife virtue is the defire of happinefs. Both taught, that it is impoffible to be happy without virtue, and both fuppofed virtue to confift in a conformity to nature. Whatever errors and abfurdities may be juftly charged on the Epicurean fyftem, it muft be allowed that, when candidly and fairly interpreted, it afforded no encouragement to immoral conduct. However, it cannot be denied by its moft zealous advocates, that by the erroneous reprefentations of the gods, and the difbelief of providence and the immortality of the foul, which this fyftem propagated, it ferved very much to relax the obligations and enfeeble the fanctions and motives of virtue. This was actually the cafe both at Athens and at Rome, where thofe who belonged to the fchool of Epicurus, partly diffeminating his genuine doctrine and partly perverting it, difgraced the fyftem to which they adhered by the laxity and diffolutenefs of their manners. Some indeed have expreffed preſſed a doubt, whether Epicurus himſelf diſbelieved the immortality of the ſoul. (See the notes upon "Cudworth's Intellectual ſyſtem of the Univerſe," ſubjoined by Dr. Moſheim to his Latin tranſlation of that learned work, vol. i. p. 66. 500. vol. ii. p. 1174.) His followers, however, ſeem to have been more explicit on this ſubject; and Moſheim aſſerts (Eccl. Hiſt. v. i. p. 167.) that towards the cloſe of the ſecond century of the Chriſtian era, of all the philoſophers, the Epicureans enjoyed the greateſt reputation, and had undoubtedly the greateſt number of followers, becauſe their opinions tended to encourage the indolent ſecurity of a voluptuous and effeminate life, and to baniſh the remorſe and terrors that haunt vice, and naturally incommode the wicked in their ſenſual purſuits. Hence it is certain, that in the common uſe of the appellation, Epicurean has been underſtood to ſignify an indolent, effeminate, and voluptuous perſon, who only conſults his particular and private pleaſure, without concerning himſelf with any thing ſerious. Accordingly it has been maintained, that there were always two kinds of Epicureans, the rigid and the remiſs. The rigid Epicureans were thoſe who were ſtrictly attached to the ſentiments of Epicurus, and who placed their whole happineſs in the true pleaſures of the mind, reſulting from the practice of virtue. The looſe or remiſs Epicureans, taking the words of that philoſopher in a more groſs ſenſe, placed all their happineſs in corporeal gratifications and pleaſures, in eating, drinking, &c. Thoſe of the former claſs, who were the genuine Epicureans, called the others the "Sophiſts of their ſect." In the "Nouveau Dictionaire Hiſtorique" the reader may find a ſhort account of modern Epicurean ſchools in France, the members of which were more diſtinguiſhed by their literary refinement, poliſhed manners, and luxurious indulgence, than their culture of the genuine doctrine of the Greek philoſopher.

Before we cloſe this article, we ſhall briefly trace the ſubſiſtence and progreſs of the Epicurean ſchool, after the death of its founder. From Epicurus the charge of it devolved upon his friend Hermachus; and it was continued in ſucceſſion by Polyſtratus, Baſilides, Protarchus, and others. The ſect ſubſiſted, in a depraved and degraded ſtate, till the decline of the Roman empire. It entered Rome, indeed, in conſequence of the oppoſition excited againſt it by the Stoics in Greece, under a heavy load of obloquy. This was much increaſed by the vehemence with which Cicero, (De Fin. l. ii. Tuſc. Qu. l. 1. 3. Fam. Ep. xiii. 1. Orat. in Piſon. c. 22.) inveighed againſt this ſect, and by the eaſy credit which he gave to the calumnies induſtriouſly circulated againſt its founder. It was, however, patronized by ſeveral perſons of diſtinction in Rome, and particularly by Atticus, the boſom friend of Cicero. Nevertheleſs, the true doctrine of Epicurus was not fully ſtated by any Roman writer, till Lucretius, with much accuracy of conception and clearneſs of method, as well as with great ſtrength and elegance of diction, unfolded the Epicurean ſyſtem in his poem, "De Rerum Naturâ," "On the Nature of Things." The Epicurean ſect, though much degenerated from the ſimple manners of its founder, continued to flouriſh through a long courſe of years under the Roman emperors. This was owing in part to the freedom of manners which it permitted, and in part to the boldneſs with which it combated ſuperſtition; but principally to the ſtrict union which ſubſiſted among the members of this ſchool, and the implicit deference which they unanimouſly agreed to pay to the doctrines of their maſter. The ſucceſſion of diſciples in this ſect was, as Laertius atteſts (l. x. § 9.) uninterrupted, even when other ſchools began to fail. In many places the doctrine of Epicurus was publicly taught, and at Athens the Epicurean ſchool was endowed with a fixed ſtipend. Among the learned men of this period there were ſome, whoſe whole concern was to tranſmit the tenets and maxims of Epicurus uncorrupted to poſterity; and others, who held the memory of Epicurus in high eſtimation, and in many particulars adopted his doctrine, and who, therefore, may not improperly be ranked in the claſs of Epicureans. The principal of theſe are Pliny the elder, Celſus, Lucian, and Diogenes Laertius. After the revival of letters at a much later period, there were not wanting ſeveral learned men, who, finding little ſatisfaction in the obſcure and ſubtle ſpeculations of metaphyſics, had recourſe to the doctrine of Epicurus, as the true key to the myſteries of nature. The firſt reſtorer of the Epicurean ſyſtem among the moderns was Daniel Sennert, an eminent phyſician of Wittemburg, who flouriſhed at the beginning of the 17th century. Sennert, however, confounded the corpuſcles of the more ancient philoſophers with the atoms of Democritus and Epicurus, and held that each element has primary particles peculiar to itſelf. The ſame doctrine was taught, with ſome inconſiderable variations, by Chryſoſtom Magnenus, profeſſor of medicine in the univerſity of Pavia, who, in the year 1646, publiſhed "A treatiſe on the Life and Philoſophy of Democritus." His ſyſtem is rendered obſcure by an attempt to unite the incompatible dogmas of Epicurus and Ariſtotle. The ableſt and moſt ſucceſsful attempt towards the revival of the phyſical and moral philoſophy of Epicurus was made by Peter Gaſſendi, who, beſides a variety of other learned treatiſes, wrote a life of Epicurus, in which he undertakes to reſcue that philoſopher from the load of calumny under which his memory had lain for many ages, as well as to give a fair and impartial repreſentation of his doctrine. The moſt celebrated followers of Gaſſendi were Francis Bernier, a phyſician of Montpelier, who wrote an "Abridgement of Gaſſendi's Philoſophy," Par. 1678, and Walter Charlton, an Engliſhman, who wrote a treatiſe, entitled "Phyſiologia Epicuro-Gaſſendo-Charletoniana," Lond. 1654, in which he attempts to eſtabliſh natural ſcience upon atomic principles. Indeed, the doctrine of atoms and a vacuum has been embraced by the moſt eminent philoſophers. Huygens applies it to explain the cauſe of gravitation, and Newton admits it into his theory of natural philoſophy. (See Atomical *Philoſophy*.) Diogenes Laertius. l. x. Lucretius de Rerum Natura. EPICURUS, in *Biography*, the founder of the ſyſtem deſcribed in the preceding article, was an Athenian, of the Ægean tribe, the ſon of Neocles and Chæreſtrata, perſons of honourable deſcent but reduced condition, and born at Gargettus in the vicinity of Athens, at the beginning of the third year of the 109th olympiad, B. C. 342. Neocles, being reduced to poverty, was ſent with a colony of 2000 Athenian citizens to the iſland of Samos, where he occupied a ſmall farm, and took up the profeſſion of a ſchool-maſter; and where his wife Chæreſtrata performed the arts of incantation and luſtration, for the purpoſe of curing diſeaſes and driving away ſpectres, in which, it is ſaid, ſhe was aſſiſted by her ſon, Epicurus, who furniſhed her with luſtral ſongs for her ſolemn rites. Epicurus remained at Samos and in the neighbouring iſland of Teos, till he was 18 years of age, and then removed, with a view to farther advantage for improvement, to Athens. Upon the death of Alexander, he left Athens, and went to his father at Colophon. Soon afterwards he removed to Mitylene, and after paſſing one year in that city, he reſided for 4 years at Lampſacus. In the 36th year of his age, he returned to Athens. From his

his 14th year to this time, he was induftrioufly employed in the ftudy of philofophy. At Samos he was inftructed in the Platonic philofophy by Pamphilus, as Cicero informs us (De Nat. Deor. l. i. c. 26.), and, as we learn from Clement of Alexandria (Strom. l. i.); he attended in his early years upon Naufiphanes a Pythagorean, and Pyrrho the fceptic. During his abode at Athens he could not fail to derive confiderable benefit from Xenocrates, who taught in the Academy, and from Theophraftus, who delivered lectures in the Lyceum. His fyftem of philofophy, however, was the refult of his own reflections, after comparing the doctrines of other fects. About the 32d year of his age, he opened a fchool, firft at Mitylene, and afterwards at Lampfacus; but not fatisfied with thefe obfcure retreats, he determined to make his appearence on the more public theatre of Athens; and purchafed for his own ufe, at the expence of 80 minæ, a pleafant garden, where he taught his fyftem of philofophy. From this circumftance the Epicureans were denominated "the philofophers of the garden." During the fiege of Athens by Demetrius, when Epicurus was 44 years of age, and while the city was diftreffed with famine, he is faid to have fupported himfelf and his friends on a fmall quantity of beans, which he fhared equally with them. The period in which he introduced his philofophy was peculiarly favourable for his purpofe: for in the room of the Socratic philofophy nothing remained but the fubtlety and affectation of Stoicifm, the unnatural feverity of the Cynics; or the doctrine of indulgence taught and practifed by the followers of Ariftippus. The younger citizens were, therefore, difpofed to liften to a preceptor who fmoothed the ftern and wrinkled brow of philofophy, and, under the notion of conducting his followers to enjoyment in the bower of tranquility, led them, unawares, into the paths of moderation and virtue. This circumftance rendered his fchool popular, fo that difciples flocked into the garden, not only from different parts of Greece, but from Egypt and Afia. Seneca, though a Stoic philofopher, bears this teftimony to Epicurus (Ep. 21.): "I the more freely quote the excellent maxims of Epicurus, in order to convince thofe who became his followers from the hope of fcreening their vices, that to whatever fect they attach themfelves, they muft live virtuoufly. Even at the entrance of the garden they will find this infcription: "The hofpitable keeper of this manfion, where you will find pleafure the higheft good, will prefent you liberally with barley cakes, and water from the fpring. Thefe gardens will not provoke your appetite by artificial dainties, but fatisfy it with natural fupplies. Will you not then be well entertained?" The difciples of Epicurus were fo cordially attached to one another, that each individual cheerfully fupplied the neceffities of his brother. The friendfhip fubfifting in the Epicurean fraternity is defcribed by Cicero (De Fin. l. i. c. 20.) as unequalled in the hiftory of mankind; and Valerius Maximus (l. i. c. 8.) relates a memorable example of indiffoluble friendfhip between Polycrates and Hippoclides, two philofophers of the garden. Epicurus, that he might not be interrupted in the profecution of his ftudies, lived in a ftate of celibacy; and he exhibited an example of that temperance and continence, which he inculcated on his difciples. Towards the clofe of his life, however, his conftitution was enfeebled, and he was afflicted with the ftone. When he perceived his end approaching, he wrote a will, in which he bequeathed his garden and its appurtenances to Hermachus, and in fucceffion to the future profeffors of his philofophy. On the laft day of his life, he informs his friend Hermachus, that his pain was extreme: but he adds, "All this is counterbalanced by the fatisfaction of mind, which I derive from the recollection of my difcourfes and difcoveries." He concludes with intreating his friend by the affection which he had always manifefted to him and to philofophy to take care of the children of Metrodorus. The emperor Marcus Antoninus confirms this account, and further fays, that Epicurus, in his ficknefs, relied more upon the recollection of his excellent life, than upon the aid of phyficians, and inftead of complaining of his pain, converfed with his friends upon thofe principles of philofophy which he had before maintained. At length, finding nature juft exhaufted, he ordered himfelf to be put into a warm bath, where, after refrefhing himfelf with wine, and exhorting his friends not to forget his doctrines, he expired. His death happened in the fecond year of the 127th olympiad, or B. C. 271, and in the 72d year of his age. He is faid to have written a greater number of original works than any other Grecian philofopher; but none of them are extant, except a compendium of his doctrine preferved by Laertius, and fome few fragments difperfed among ancient authors. His memory was held in high eftimation, not only by his immediate followers, but by eminent writers, who difapproved his philofophy, but entertained a refpect for his perfonal merit. Neverthelefs his character and his philofophy have been feverely cenfured; and the accufations againft the Epicurean fchool have been more or lefs confirmed by men diftinguifhed for their wifdom and virtue: Zeno, Cicero, Plutarch, Galen, and a long train of Chriftian fathers. But a candid examination of his doctrine and character will obviate many of thofe charges that have been alleged againft them, and prove, that though in fome refpects this philofopher is highly cenfurable, in others he has been unjuftly and too feverely condemned. The charge of impiety admits of no refutation. The doctrine of Epicurus concerning nature not only militated againft the fuperftitions of the Athenians, but againft the agency of a fupreme deity in the formation and government of the world, and he divefted the Deity of fome of his primary attributes. Whilft he profeffed the utmoft contempt for popular fuperftitions, the gods, whofe exiftence he allowed, were deftitute of many effential characters of divinity, and his piety was of a kind very different from that which is infpired by juft notions of Deity. Befides, it has been fuggefted, that his fentiments concerning the gods were adopted and profeffed for the purpofe of avoiding the odium and difgrace which would have attended a direct avowal of atheifm. Epicurus has alfo been charged with infolence and contempt towards other philofophers: but this feems to be fcarcely compatible with the general air of gentlenefs and civility, which appears in his character. The charge of intemperance and incontinence is unqueftionably an atrocious calumny. That he was eminent for the contrary virtues has been amply attefted by Laertius, and alfo by thofe who were adverfe to his doctrine, particularly Cicero, Plutarch, and Seneca. Epicurus has been with equal injuftice reprefented as uninftructed and an enemy to liberal fcience. "We ought to be thankful to nature," fays this philofopher, cited by Stobæus, "for having made thofe things which are neceffary, eafy to be difcovered, and thofe things which are difficult to be known, not neceffary."

The temper and character of Epicurus were altogether the reverfe of thofe of Zeno and the Stoics; his mode of inftruction was very different; and his fchool was eftablifhed in direct oppofition to that of the Stoics; and, therefore, we need not wonder, that he fhould become the object of detraction and calumny. Befides, the defign of his philofophy and its general principles were very different, and they endeavoured to to fecure their own declining popularity by mifreprefenting his principles and character, and holding him up to the public as an advocate for infamous pleafures. For thefe, and fimilar reafons, Epicurus encountered the violent oppofition of the Stoics; and yet he had many friends and followers during his life, and his memory was venerated after his death. His three brothers, Neocles, Chæredamus, and Ariftobulus, devoted themfelves to the ftudy of philofophy, and were fupported by his liberality. Of his intimate friends the moft celebrated were Metrodorus, Polyænus, and Hermachus. After his death his birth-day was celebrated by his followers as a feftival; and they preferved his image in their rings or cups, or in pictures, which they either carried about their perfons, or hung up in their chambers. Their reverence for his authority was fuch, that they committed his maxims, and fome of them the whole body of his inftructions, to memory; and for a long period, it was deemed a kind of impiety to innovate upon his doctrine: fo that the Epicureans formed a philofophical republic, regulated by one judgment, and animated by one foul. Laertius, l. x. Brucker's Hift. Phil. by Enfield, vol. i.

EPICYCLE, formed of the Greek επι, *upon*, and κυκλος, *circle*, q. d. *a circle on a circle*, in the *Ancient Syftem of Aftronomy*, was a fubordinate orbit, or circle, which moved on the circumference of a larger one, which latter was called the *deferent*. By means of this epicycle, one motion, apparently irregular, was refolved into two that were circular and uniform; and when the obferved motion was fo irregular and complicated as not to be reprefented by one epicycle, the method was to add others, till a nearer approximation was obtained. This fyftem owed its origin to a prejudice that feems to have been extremely ancient, in favour of uniform and circular motion; and the problem that chiefly occupied the aftronomers in thofe times, was to affign the proper proportion of the deferent and epicycle which fhould approximate neareft to the actual obfervations.

The reprefentation made by this concentric theory of the folar inequalities in longitude, was as follows:

Let C (*Plate* XII. *Aftronomy*, *fig.* 105.) be the centre both of the earth and of the circle F B D, and let H G K be a fmaller circle, called an epicycle, whofe centre B moves uniformly in the circumference F B D from weft to eaft, or in confequentia, while the fun moves alfo uniformly, and with the fame velocity, in the circumference of the epicycle, in antecedentia in the upper part, but in confequentia in the lower. If the point G of the epicycle, called the apogee, as being moft diftant from the earth, be fuppofed, at the beginning of the anomaliftical revolution, to be placed in the point A of O F produced; and if when it comes to G the arch G H be taken fimilar to F B, the point H will be the place of the fun when the centre of the epicycle has moved from F to B. If then in O F, to which B H is parallel, we take O E = B H, and on E, as a centre, with the diftance E A = C F, defcribe the circle A H P, the fun would be feen from E to move in this circle equably; for the angle A E H is equal to the angle F C B; but feen from C, the centre of the earth, he will appear to move in it inequably, for the angle A C H in the firft femicircle of anomaly, that is, in the paffage of the fun from A to P, is always lefs than A E H or F C B: and his true place H will be lefs advanced in longitude than his mean B. When, again, the centre of the epicycle, or the mean place of the fun, having defcribed a femicircle of the epicycle, will be found in P, the perigée of the orbit A H P, and his mean and true places B and H, will be feen from C to coincide as they did in A, the apogee; but in the fun's paffage from P to A, that is, in the fecond femicircle of anomaly, his true place H, as feen from C, will be always more advanced in longitude than his mean place B; for in this femicircle the angle P C H is always greater than P E H in D C B. The angle E H C, or B C H, which is the difference between the mean and true places of the fun, is called the equation of the orbit, as being that quantity which, added to the true motion A C H of the planet in its orbit A H P, in the firft femicircle of anomaly, and fubtracted from it in the oppofite femircircle, will render it equal to the mean motion A E H or F C B; and it is evident that the equation, or difference, will be greateft in N or M, where the centre B of the epicycle is 90° diftant from either apfis. Any lines drawn from E, the centre of the orbit A H P, to the true place of the fun in H, and from C the centre of the earth, and of the deferent F B D, to the mean place of the fun in B, are equally called the line of the mean motion of the fun, becaufe thefe lines are always parallel, and mark the fame point in the zodiac; and any line drawn from C to the true place of the fun is the line of the fun's true motion.

It was thus that the ancients originally proceeded in their reprefentation of the folar inequalities, and the reprefentation feemed to be fufficiently juftified by obfervation; at leaft till the days of Tycho Brahe no obfervations had been made with fufficient accuracy to fubject it to fufpicion. Their fuccefs alfo, while no lunar inequality, except the fimple anomaliftical one, was difcovered, was equal in the application of the fame concentric theory to the motions of the moon; and having in two cafes thus fuccefsfully, by means of one fubordinate fphere, or epicycle, reconciled apparent inequality of motion with real uniformity, it was natural to fuppofe that other inequalities, though more various and complicated, might be explained in a fimilar manner, and required only the addition of other epicycles. The fame method of procedure, therefore, was continued, and every new inequality which obfervation difcovered was accounted for by a new fphere, or epicycle, producing it, till the whole number employed in the fyftem amounted to 34. Ariftotle, on narrower examination, found thefe infufficient, and added to them 22: but ftill they were deemed infufficient, and the number was at laft increafed to 72; but though it was not till long after the days of Ariftotle that the theory was carried to fuch a degree of extravagance, the multiplication of epicycles rendered it, even in his time, almoft as intricate and complex as the appearances which it was intended to explain. Some examples of this kind occur on the revival of it by Copernicus and Tycho Brahe; and when Hipparchus and Ptolemy introduced eccentric orbits, and by means of them fomewhat diminifhed the multiplicity of the fpheres employed by their predeceffors, they were thought to do a fignal fervice to aftronomy. See EXCENTRIC *Theory*.

What was principally required in thefe theories was to afcertain in the one the ratio of the excentricity; in the other, the ratio of the femi-diameter of the epicycle to the femi-diameter of the deferent. If we make the radius of Jupiter's deferent circle to that of the epicycle as 52 to 10, the epicyclical motion arifing from this conftruction will very nearly agree with obfervation: only we may obferve, that the oppofitions which fucceed each other near the conftellation Virgo, are lefs diftant from one another than thofe obferved in the oppofite part of the heavens; fo that the centre of the epicycle feems to move flower in the firft cafe than in the laft. To reconcile this with the perfect uniformity of the motion of that centre in the circumference of the deferent circle, the ancient aftronomers faid that the earth was not exactly in the centre of the deferent, but fo placed that the equable motion of the centre of the epicycle appeared flower, becaufe it is then more remote, and after various trials they fixed on a degree of excentricity for the deferent, which accorded better than any other with the obfervations, and really differed very little from them. Copernicus fhews that their hypothefis for Jupiter never deviates more than half a degree from obfervation, if it be properly employed. They found that the epicycle moved round the deferent in 4332⅓ days, with an equation gradually increafing to near fix degrees; fo that if the place of the epicycle be calculated for a quarter of a revolution from the apogee, at the mean rate of 5′ a day, it will be found too far advanced by near ten days' motion. See Dr. Small's account of Kepler's difcoveries, where this fubject is treated at great length.

EPICYCLOID, in *Geometry*, denotes a curve generated by the revolution of a point of the periphery of a circle, along the convex or concave part of another circle.

A point of the circumference of a circle, proceeding along a plane in a right line, and at the fame time revolving on its centre, defcribes a cycloid. And if the generating circle, in lieu of moving on a right line, moves along the circumference of another circle, whether equal or unequal, the curve defcribed by any point in its circumference is called an epicycloid. Indeed the common cycloid has been fometimes reprefented as an epicycloid formed by the revolution of a finite circle on an infinite circle.

If the generating circle proceeds along the convexity of the periphery, it is called an upper, or exterior epicycloid; if along the concavity, a lower, or interior epicycloid.

In an epicycloid, the part of the circle the generating point moves along, is called the bafe of the epicycloid: thus in *Plate* V. *Analyfis*, *fig.* 9. D C is the bafe of the epicycloid; V its vertex; V B its axis; D P V half of the exterior epicycloid, made by the revolution of the femicircle V L B (which is called the generant) along the convex fide of the bafe D B; as D P U is the interior epicycloid, formed by the generant's revolving along the concave fide of the bafe.

The length of any part of the curve, which any given point in the revolving circle has defcribed from the time it touched the circle whereon it revolved, is to double the verfed fine of half the arc which all that time touched the quiefcent circle, as the fum of the diameters of the circles to the femidiameter of the quiefcent circle; provided the revolving circle moves upon the convex fide of the quiefcent circle; but if upon the concave fide, as the difference of the diameters to the femidiameter. Otherwife: the circumference of the epicycloid G E F (*fig.* 10.) is to four times the diameter of the generating circle B E, as the fum of the diameters of the two circles is to that of the bafe, in the former of the cafes above mentioned; but in the fecond, *e.g. f e g*, in the fame figure, as the difference, &c. In the firft cafe, if the generating circle be fuppofed to have its diameter equal to half that of the bafe, the epicycloid F H E G is equal to 6 B E. In the fecond cafe, when F I is a quarter of F G, the curve F *e g* will be found equal to 3 F I. When the generating circle is half the bafe-circle, as in *fig.* 11, the epicycloid degenerates into a right line, or the diameter of the bafe. Hence it appears, that in order to deduce the known property of the common cycloid, or that its circumference is equal to four times the diameter of the generating circle, we need only fuppofe the bafe-circle to be infinite; an infinite, augmented or diminifhed by a finite quantity, being always the fame.

Dr. Halley gives us a general propofition for the meafuring of all cycloids and epicycloids: thus, the area of a cycloid, or epicycloid, either primary, or contracted, or prolate, is to the area of the generating circle; and alfo the areas of the parts, generated in thofe curves, to the areas of analogous fegments of the circle; as the fum of double the velocity of the centre, and velocity of the circular motion, to the velocity of the circular motion. The demonftration hereof, fee in Phil. Tranf. N° 218.

The areas of epicycloids may be determined by the following proportion: as the radius of the circle of the bafe to three times that radius together with twice that of the generating circle, fo is the circular fegment *b* H to the epicycloidal fector *b* H F, or the whole generating circle to the whole area of the epicycloid F E G B. As to the tangents, it is known from the time of Des Cartes, that the line H *b*, drawn from any point H, to that of the bafe which touches the circle, whilft this point is defcribed, is perpendicular to the curve, and confequently to the tangent. Maupertuis in difcuffing this fubject, conceived a polygon to revolve upon another, the fides of which are refpectively equal, one of the angles defcribed a curve, the periphery of which is formed of arcs of circles, and the area is compofed of circular fectors and right-lined triangles. He determined the proportion of the area and of the periphery of this figure to thofe of the generating polygon. He moreover fuppofed thefe polygons to become circles, the figure defcribed to become an epicycloid; and the above-mentioned proportion, modified agreeably to this fuppofition, gave him the area and the periphery of the epicycloid. Mem. de l'Acad. 1727.

The invention of epicycloids is afcribed to M. Roemer, the celebrated Danifh aftronomer, during his refidence at Paris, about the year 1674. Thefe curves appeared to him to be fuch as beft fuited the teeth of wheels, conftructed fo as to diminifh their mutual friction, and to render the action of the power more uniform; hence he was led to confider them, and to this purpofe they have been applied. However, M. de la Hire in his "Traité des Epicycloides," printed in 1694, makes no mention of Roemer, and feems to claim the merit of this geometrical and mechanical invention. But M. Leibnitz, who refided at Paris in 1674 and the two following years, fays, that the invention of epicyloids, and their application to mechanics, were the work of this Danifh mathematician, and that he was efteemed the author of it. It does not appear that any writer publifhed an account of epicycloids before the celebrated Newton, who, in the firft book of his "Principia" propofed a general and very fimple method of rectifying thefe curves. After him J. Bernouilli, during his refidence at Paris, fhewed how, by means of the integral and differential calculus, to determine their area, rectification, &c. Many of his "Leçons du calcul integral" are devoted to this object. In 1694, M. de la Hire publifhed his "Traité des Epicycloides;" and in the "Memoires of the Academy for 1706" he communicated to the public an extenfive and elegant treatife on thefe curves.

Spherical epicycloids are formed by a point of the revolving circle, when its plane makes an invariable angle with the plane of the circle on which it revolves. Meffrs. Bernouilli, Maupertuis, Nicole, and Clairaut, have demonftrated feveral properties of thefe epicycloids, in Hift. Acad. Sc. for 1732.

Epicycloids, *Parabolic*, *Elliptic*, &c. If a parabola be made to revolve upon another equal to it, its focus will defcribe a right line perpendicular to the axis of the quiefcent parabola; the vertex of the revolving parabola will alfo defcribe the ciffoid of Diocles; and any other point of it will defcribe fome one of Newton's defective hyperbolas, having a double a double point in the like point of the quiefcent parabola. In like manner, if an ellipfe revolve upon another ellipfe equal and fimilar to it, its focus will defcribe a circle, whofe centre is in the other focus, and confequently, the radius is equal to the axis of the ellipfe; and any other point in the plane of the ellipfe will defcribe a line of the 4th order. The fame may alfo be faid of an hyperbola, revolving upon another, equal and fimilar to it; for one of the foci will defcribe a circle, having its centre in the other focus, and the radius will be the principal axis of the hyperbola; and any other point of the hyperbola will defcribe a line of the 4th order. Concerning thefe lines, fee Newton's Principia, lib. i. De la Hire's Memoires de Mathematique, &c. where he fhews the nature of the epicycloid and its ufe in mechanics. See alfo Maclaurin's Geometria Organica. For the method of forming the epicycloidal teeth of wheels, fee Wheel.

EPICYEMA, from κυω, *I conceive*, a word ufed by Hippocrates to fignify a fœtus, or a falfe conception, or mole coming on after the conception of a former or regular fœtus.

EPIDAMNUS, in *Ancient Geography*, a town of Illyria, upon a fmall promontory between Nymphæum and Petra, built by the Corcyreans. Its name, which the Romans confidered as inaufpicious, was afterwards changed into Dyrrhaicum, now *Durazzo*, which fee.

EPIDAURIA, Επιδαυρια, in *Antiquity*, a feftival celebrated by the Athenians, in honour of Efculapius. See Æsculapius.

EPIDAURUS, in *Ancient Geography*, a town of Greece, in the ancient kingdom of Argos, mentioned by Homer in the enumeration of its fhips, and which he reprefents as fertile in the production of vines. It was fituated on the eaftern coaft of the peninfula of the Argolide, near the Saronic gulf, and oppofite to the ifland of Ægina. This town was celebrated among the ancients for the temple of Æfculapius, fituated about a mile from the river, whither the inhabitants of moft parts of Europe and Afia reforted for the cure of all diftempers. It is pretended that this was the birth-place of Efculapius. (See Æsculapius.) Antoninus Pius, after having been adopted by Adrian, conftructed in this place a temple dedicated to the deities called "Epidotes," and another dedicated to the goddefs of health, to Efculapius, and to Apollo, furnamed the "Egyptian." He moreover built a houfe, for the accommodation of perfons who inhabited the diftrict confecrated to Efculapius, and alfo for lying-in women. He alfo re-eftablifhed the portico of Cotys, which had been demolifhed. The grove of Efculapius near this town was enclofed by two mountains, one called "Titthion," and the other "Cynortion," upon which was conftructed a temple dedicated to Apollo Maleates, and upon its fummit another dedicated to Diana Coryphæa. In a rotundo near this town were preferved fome curious pieces of painting, the performances of Paufias, a famous painter of Sicyone, and contemporary of Apelles. The Epidaurians had a beautiful theatre in the temple of Efculapius, conftructed by Polycletus, who alfo built the rotundo at the entrance of the town. Bacchus and Venus had alfo temples in this town. Epidaurus was alfo famous for its temple of Diana the Huntrefs, and a grove confecrated to her, in which was a ftatue of Epione, fuppofed to be the wife of Efculapius. In this grove was a fuperb fountain, fplendidly ornamented. In the citadel of the town was a very beautiful ftatue of wood, which reprefented Minerva, denominated by the Epidaurians "Ciffea." The temple, dedicated to Juno, was on the fide of the port, on a promontory which commanded a view of the fea. The Dorians, having been driven from this town by Deiphon and the Argians, united with the Ionians and with them inhabited the iflands of Samos and Chios. Epidaurus is now a fmall place, called "Pidavra."

Epidaurus *Limera*, or *Epidaurus Malvafia Vecchia*, *i. e.* the ancient Malvoifia, is a port of Laconia, feated on the gulf of Argos, now "Golfo di Napoli," S. E. of Zarex. It is pretended that this place was founded by a colony of Epidaurians from the Argolide. Having embarked, as it is faid, for the ifland of Cos, they were driven by contrary winds on this coaft of Laconia. They were cautioned in a dream from fettling here; but a ferpent which they brought with them left the fhip and conducted them to the land. This fable was credited in the country, and the worfhip of Efculapius was eftablifhed along this whole coaft. The Epidaurians thus contrived to obtain a confiderable part of the wealth which fuperftition had accumulated in the Epidaurus of the Argolide: and hence the new town acquired the appellation annexed to it. It was denominated *Limera*, *i. e.* famifhed, a name which was not improperly applied to a town, the inhabitants of which contrived to exift at the charge of another. It was built upon an eminence, at the bottom of a fmall gulf; it was well-peopled, and was famous among other things for its excellent wine, called Malvesfy or Malmefy, which grew round the vicinity of it, and with which it fupplied other parts of Greece. The moft remarkable objects of this place in the time of Paufanias were two temples; one of Venus, another of Efculapius, with a ftatue of this god. Its port was honoured with the appellation of the "Port of Jupiter Confervator."

Epidaurus, a town of Illyria, in Dalmatia, according to Ptolemy and Pliny, the latter of whom gives it the title of a colony; in whofe time it was joined to the continent, though, as he fays, it had formerly been an ifland. It is now "Ragufi-Vecchio."

EPIDELICUM, a town of Laconia, on the Argolic gulf, S. E. of Epidaurus.

EPIDELOS, a word ufed by Hippocrates for a youth in the time of his growth, from the age of feven to that of fourteen. The fame author alfo ufes it in a very different fenfe, expreffing by it the obfervable days in a difeafe, fuch as the fourth, eighth, and eleventh, which indicate what fort of crifis is to be reafonably expected on the great critical day.

EPIDEMIA, Επιδημια, in *Antiquity*, feafts of Apollo, at Delphos, and Miletus; and of Diana, at Argos.

Thefe feafts bore the name epidemia (from επι, *in*, and δημΘ-, *people*,) becaufe thefe gods were imagined to be prefent on thofe days among the people. Accordingly, on the laft day of the epidemia they fung an hymn called αποπεμπτικος, to bid them adieu, and fet them forwards on their journey.

As thofe gods could not be every where, and yet were honoured in many different places, there were times allowed them to pafs from one place to another, to receive the vows of their adorers. See Scaliger, Poet. lib. iii. cap. 114.

Epidemia were alfo private feftivals, and times of rejoicing, when a friend or relation had returned from a journey. Pott. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 394.

EPIDEMIC Diseases, from επι, and δημος, *the people*, are thofe difeafes which prevail extenfively, at different times and feafons, among the inhabitants of cities, or countries: when they occafion great mortality among the perfons feized; they are termed *peftilential*.

The diseases, which are liable to occur epidemically, or to attack a great number of individuals about the same time, or in rapid succession, are principally those of the acute or febrile class. Thus the plague, the sweating sickness, the yellow fever, contagious fever, or typhus, intermittent and remittent fevers, scarlet fever, small-pox, measles, dysentery, catarrh, (denominated influenza under such circumstances,) ophthalmia, hooping cough, &c. are the diseases which have at different times spread over extensive districts epidemically, some of them occasioning the most destructive mortality. Of these the influenza, or epidemic catarrh, appears to be the most extensive in the range which it takes, and the most independent of local causes: in some instances, as in the years 1781 and 1782, this disease appears to have originated in China, and thence to have spread through Asia, to Europe, and in the year following to have visited America.

The other fatal epidemics, such as the plague, yellow fever, and small-pox have been in general the calamities more particularly, though not exclusively, connected with large towns, camps, or other congregations of men. Some of these diseases, as the plague and sweating sickness, are scarcely known except as epidemical; and are altogether unknown, but as diseases of a malignant and fatal tendency: but many of the others, as small-pox, measles, scarlet fever, and typhus, are common and familiar appearances, which seldom cease to exist among us; but which, nevertheless, only occasionally assume those fearful and fatal characters, which belong to them as epidemics.

No circumstance, connected with diseases, has been the subject of more general inquiry, among the physicians of all ages, than this variation in their tendency to spread at one time to multitudes of individuals, to put on a malignant character, and to prove generally destructive; whilst at others they exist in milder forms, affecting few, and destroying scarcely any. Yet the most comprehensive views of the concomitant circumstances, in regard to the obvious conditions of the seasons, and of the moral and political state of the districts, where epidemic diseases arise or disappear, continued with the most minute observation during a succession of seasons, have failed to elucidate satisfactorily this interesting topic. Hippocrates, who has noted with accuracy the peculiarities of various years, together with the prevalent species of disease, attributes the variation of the maladies to a divine something, τὸ θεῖον; which some of his commentators consider as signifying merely the atmosphere at large; but others, among whom is Galen, suppose that he intended to express a latent and inscrutable cause in the air, which produced these surprising effects. (See Hippoc. lib. i. de Prognost. Galen in Com,—also, Sennert. lib. iv. cap. ii. de Causis Pestilentiæ.) Galen observes, in his commentary upon this point, "non quæcunque causas habent abditas et obscuras, *divina* vocamus; sed ubi admirabilia videntur duntaxat." The modern Hippocrates, Sydenham, states, that he had observed with the utmost diligence the different peculiarities of different years, as to the obvious changes and conditions of the atmosphere, with a view to ascertain the causes of the great varieties of epidemic disorders; but that he had not made the smallest approximation to such a discovery; on the contrary, that he had remarked, that seasons of the most decided similarity, in respect to the manifest qualities of the air, were infested by diseases altogether dissimilar; and *vice versâ*. "For the *constitutions* of different years are various;" he says, "yet they do not depend upon the degree of heat or cold, of dryness or humidity, which accompanies them; but probably originate from some occult and inexplicable changes, wrought in the bowels of the earth itself, by which the atmosphere is contaminated with certain effluvia, which predispose the bodies of men to one or other form of disease. This predisposition continues during the prevalence of the same constitution, which, in an uncertain period of time, is superseded by another." (Sydenham, sect. i. cap. 2. De Morbis Epidem. See also Van Swieten Comment. ad Aph. 1408.)

From a consideration of the same facts, several writers have attempted to account for these supposed occult changes in the qualities of the atmosphere, which induce epidemic diseases, by tracing them to some of the obvious phenomena of nature, by which such changes may be supposed to be effected. Thus a coincidence has been attempted to be traced between the appearance of comets and of meteors, the occurrence of earthquakes, the eruptions of volcanoes, the conjunction of certain planets, &c.; by all of which it is presumed that some important operations are accomplished in the condition of our atmosphere. Of the effects of planetary influence, indeed, in inducing or diminishing the morbific qualities of the air, nothing is to be found in the writings of the present times: the hypothesis originated and has gone by with the age of astrology. But a very late writer has filled two volumes with evidence, which he believes goes far to prove the existence and operation of some general agent, or *pestilential principle*, throughout the physical world. To this agent he ascribes the origin of earthquakes, and volcanoes, and meteors; and he seems to consider it as the medium by which comets affect the earth, producing tempestuous seasons, great heats, and great colds. (See a brief History of Epidemical and Pestilential Diseases, by Noah Webster, 1800.) This, as a mere hypothesis, would be scarcely less visionary and futile, than the supposition of planetary influence, just noticed. Mr. Webster, therefore, has collected, with great industry, an historical account of the various epidemic and pestilential visitations on record, which have successively occurred to different countries, and has connected with it a chronological view of the appearance of comets, the eruptions of volcanoes, the commotions of the earth, and of the various atmospheric phenomena, which have been described by authors in order to prove their coincidence. "It is certain," we are told, "that comets have a very sensible effect on the weather;" (loc. cit. vol. ii. p. 122.) and Aristotle, Pliny, and Seneca, are quoted to prove that great heat, tides, and winds, are among the general concomitants of comets. "All the comets," Mr. W. affirms, "which have approached this earth, in their passage to and from the sun, especially those which have passed very near us, have been preceded, attended and followed by most extraordinary effects, as great heat and drought in summer, and severe cold in winter; deluging rains, violent tempests, and unusual tides. They occur so uniformly, with the appearance of these bodies, and for some months preceding and following, as to leave no room to question the influence from which they proceed." Ibid. Whatever may occasion extreme variations in the condition of the atmospheric temperature, produce inundations, dearth, &c. will thus remotely, no doubt, induce epidemic diseases, as will be shewn in the sequel. A great number of records are quoted by Mr. Webster, to prove the connection of earthquakes with epidemics (an opinion which many writers have adopted); and also to shew that sensible vapours have issued from the earth, contaminating the atmosphere, about these periods, or sometimes without any earthquakes. From these sensible exhalations an inference is readily drawn of the existence of vapours incognizable by our senses, according to the conjecture of Sydenham. It appears, however, that great pestilence, even when occurring within

within a ſhort period of earthquakes, has generally appeared *before* the earthquakes: nor does it occur in the ſeat of the earthquakes. Thus *after* the plague in London, in 1665, ſhocks are ſaid to have been felt *on the continent*. But Mr. Webſter does not conceive this to be any objection to the hypotheſis. He believes "that peſtilence and earthquakes depend on one common cauſe; which excites into action the internal fires." But he ſuppoſes that "the action or fermentation may precede, for months, and even years, the exploſion in earthquakes and volcanoes; and by means of an inſenſible vapour or heat, or electrical diſcharges, the elements of water and air may be eſſentially affected in ſuch a manner as to impair the principle of animal and vegetable life." P. 137.

This hypotheſis, which was held by the ancients, (as Claudian writes,

"In cœlo nunquam ſpectatum impune cometam,")

has been adopted by Horſtius, Riverius, and echoed by ſeveral other writers on the ſubject of peſtilence; but, like many other ſuppoſitions upon the ſame ſubject, it is altogether gratuitous, and has been received only in the abſence of all poſitive knowledge of the real ſources of peſtilential diſeaſes. The ſame obſervation applies to the ſuppoſed influence of earthquakes, and diſtant volcanic eruptions; more particularly, as the former are allowed to have often followed the effect aſcribed to them, and the countries immediately in the vicinity of volcanoes are admitted to have been not more liable to epidemic diſeaſes than other regions.

Two other points have been generally ſtated as proving the exiſtence of a *peſtilential principle*, which is diffuſed through the atmoſphere at large: one is, that trees and vegetables are affected with mildew, and other diſeaſes; the other, that the animal creation alſo often ſuffers, when peſtilence is committing ravages among mankind. A *rubigo*, or mildew, *i. e.* "a dew impregnated with highly corroſive powers," (ſee Hird on Peſtilence, p. 91.) was anciently deemed one of the cauſes of epidemic diſeaſes. The Romans, appriſed of the pernicious effects of theſe mildews, inſtituted what they denominated *Feſta rubigalia*, and worſhipped an imaginary god, under the name of Robigus. The appropriated ſacrifice was a ſucking whelp; whence Columella,

"Hinc mala rubigo, virides ne torreat herbas,
Sanguine lactentis catuli placatur et extis."

Hoffmann mentions ſuch a dew, "ros valde corroſivus," as having infeſted vegetables in 1693-4, whence the cattle died in multitudes. (Tom. i. de Temp. Ann. Inſalub.) And Ramazzini aſcribes an epidemic to ſimilar dews; at which time the vegetables, corn, and fruit became black, being affected with a "lues rubigalis." (Conſtitut. Epidem.) The ſame year was remarkable for the ſcarcity of honey; and moſt creatures that live upon what they extract from vegetables died, or languiſhed. Probably ſimilar occurrences led many of the ancient writers to mention the ſilence of the graſshopper, and the drooping inactivity of the bee and the ſilk-worm, among the preſages of impending peſtilence. As to the ſpots, which are ſaid to have aſſumed various forms, eſpecially thoſe of *cruciculæ*, or little croſſes, and to have appeared ſuddenly on garments, utenſils, &c. as they are recorded chiefly on the authority of monks, whoſe writings are highly tinged with ſuperſtition, they are ſcarcely worthy of ſerious conſideration.

The exiſtence of epidemic diſeaſe among cattle is neceſſarily much connected with the diſeaſed condition of vegetables; and epidemics among cattle ſeem to have moſt commonly occurred after exceſſive humidity. (Webſter.) The calamity among brutes has ſometimes proved the forerunner of peſtilence among mankind; ſometimes its follower; and at other times, they have raged concomitantly: but, in general, their appearance has been remote and unallied. (Hird, loc. cit.)

It is curious, again, and not eaſily explicable on the principle of a peſtilential effluvium, unfriendly to every form of life, pervading the atmoſphere, that, while vegetables droop and are mildewed, the graſshopper is ſilent, the bee and the ſilk-worm are idle, and cattle die, from its influence, ſwarms of inſects and creatures of other ſpecies are ſaid to be among the precurſors and attendants of peſtilence. It is ſurely an abſurdity to contend for the exiſtence of a poiſonous atmoſphere, deſtructive to the life of both animals and vegetables; and at the ſame time to deſcribe the myriads of noxious inſects, frogs, mice, locuſts, ſnails, ſerpents, and other animals, which appear during an epidemic peſtilence! Is one kind of life poſſeſſed by man and the animals uſeful to him, and another by thoſe which are noxious? This contradiction in the hypotheſis appears to be very general among writers. The author, whom we have already often quoted, obſerves, "one thing is very evident, that what I denominate a *peſtilential principle* does, at certain times, pervade not only the element of air, but the water alſo. The proofs of this are abundantly numerous and convincing. In all the great plagues which have afflicted the human race, other animals, as horſes, cattle, ſheep, ſometimes cats, dogs, and fowls, together with the fiſh in rivers and the ocean, and even vegetables, have borne their ſhare in the calamity. The peſtilential principle has extended to every ſpecies of life. The beaſts of the field periſh with deadly epidemics; the fiſh die on the bottom of rivers and the ſea, or become lean and ſickly; while corn is blaſted on the moſt fertile plains, and the fruits in gardens and orchards wither, or fail to arrive at their uſual ſtate of perfection." (Webſter, Hiſt. of Epidemics, vol. ii. p. 153.) And immediately afterwards (p. 166.) we are called upon to "attend to the effects of a peſtilential" (*i. e.* univerſally deleterious) "ſtate of air, and in the *production* of inſects and ſmall animals. This is one of the moſt remarkable ſymptoms of a *ſickly* ſtate of the elements, &c."

It is only againſt ſuch hypotheſes that we have any objection. The fact, that myriads of inſects have ſometimes been produced, about the time when epidemics prevailed, cannot, we apprehend, be queſtioned; although probably many of the accounts tranſmitted to us on this point are much exaggerated. In ſome inſtances, ſuch a profuſion of inſect life may be a reſult of the ſame cauſe with the epidemic, *viz.* extraordinary heat, or heat and moiſture: in others, it may contribute to produce the epidemic, by deſtroying grain and fruits, the food of man; or graſs and herbs, the food of cattle, fowls, and other animals which conſtitute a part of his ſubſiſtence. It proves nothing in reſpect to any occult quality pervading the atmoſphere.

Beſides, the inſtances of the copious generation of inſects and ſmall animals have not been univerſal, but partial: ſome particular ſpecies have been generated in profuſion; and, therefore, the origin of them muſt be aſcribed to ſome partial, and not to a general cauſe. In the plague of Lauſanne, in 1613, according to Diemerbroeck, flies were produced in an incredible abundance; as well as during or preceding that of Holland, in 1635. The approach of the plague at Dantzick, in 1709, is ſaid to have been announced by an immenſe number of ſpiders in the preceding year. The year 1633, which produced a peſtilential fever among the ſettlers at Plymouth, in America, was remarkable for ſwarms of large flies, which filled the woods with their humming ſounds. (Webſter.) We cannot but conſider, therefore, that the ſtatement above quoted of the univerſal failure of animal and vegetable life, on the one hand, or the general diſpoſition in the air to generate noxious animals, on the other, as equally erroneous, inconſiſtent, and abſurd. How the individual ſpecies of inſect or animal is generated, in ſuch caſes, or what connection the production of them may have with the peſtilence, which ſometimes concurs in point of time, we cannot eaſily aſcertain. But where the means of obſervation fail us, gratuitous hypotheſes add nothing to our knowledge.

There are, however, ſeveral circumſtances which are open to our obſervation, which, if they do not abſolutely produce epidemics of the moſt peſtilential kind, certainly contribute to give them birth, and to aggravate them when produced, and are notoriouſly the ſource of epidemics of a leſs deſtructive ſpecies. Of theſe obvious cauſes of the origin or aggravation of epidemic diſeaſes, ſome contribute directly to excite diſeaſe; others to induce, what is ſcarcely leſs neceſſary to their occurrence, a prediſpoſition to them. In fact, the operation of ſome general agent, inducing a prediſpoſition to be affected by contagion, or other exciting cauſe of diſeaſe, would appear to be the principal ſource of the predominance of ſome epidemics. For if the exciting cauſe never, or ſcarcely ever, ceaſes to exiſt, its occaſional activity in inflicting diſeaſe among multitudes can only be aſcribed to the caſual operation of ſome general prediſpoſing cauſe, which renders them temporarily ſuſceptible of its influence. This is particularly exemplified with reſpect to contagious diſeaſes. The contagion of ſmall-pox, meaſles, and ſcarlet-fever perpetually exiſts among us; yet it is only at particular times that theſe diſeaſes attack ſo many individuals, as to be called epidemic. In crowded towns, like this metropolis, the infection of typhous fever is perpetually generated in the cloſe, dirty, and unwholeſome habitations of the poor: yet there has been no epidemic typhus in London for ſeven years paſt. Nay, even the plague itſelf exiſted year after year in this city, without ſpreading generally. It muſt not be imagined that the diſeaſe was accidentally imported juſt at the periods when it raged ſo extenſively, and with ſo much deſtruction. The principal plague-years of the ſeventeenth century were 1603, 1625, 1636, and 1665; in which the number of deaths from the plague, independent of thoſe from other diſeaſes, are reported in the bills of mortality to have been 36,269, 35,417, 10,400, and 68,596, reſpectively. But ſo far was the diſeaſe from being extinct in the intermediate periods, that from the year 1603, when the regiſter begins, till 1667, the bills of mortality exhibit only three years entirely free from the plague. It is obvious, therefore, that the preſence of infectious matter, or other exciting cauſe, is not alone ſufficient to produce an epidemic diſeaſe. Some concurrent circumſtances are likewiſe neceſſary, to give a prediſpoſition to the human body to be readily acted upon by ſuch cauſe. Now, ſome of theſe circumſtances have been well aſcertained, namely, particular ſeaſons, marſhy and other effluvia, a crowded and filthy population, deficient or depraved aliment, certain paſſions of the mind, exhauſtion of the conſtitution by fatigue, &c. We ſhall illuſtrate the operation of each of theſe prediſpoſing cauſes by a few obſervations.

1. *Seaſons.*—The influence of certain ſeaſons, in favouring the propagation of epidemic diſeaſes, has been obſerved and confirmed by all the medical writers on the ſubject, from the days of Hippocrates downwards, and was noticed by the earlieſt poets, even before the time of that great phyſician; eſpecially the influence of the heats of ſummer and autumn, and of the ſultry ſouth winds, which blow at thoſe ſeaſons. In many paſſages of the Iliad, Homer has alluded to theſe cauſes of peſtilential diſeaſes. Thus, in book v.

> " As vapours blown by Auſter's ſultry breath,
> Pregnant with plagues, and ſhedding ſeeds of death,
> Beneath the rage of burning Syrius riſe." Pope, 1058.

And again in book xxii. 37.

> " Not half ſo dreadful riſes to the ſight,
> Through the thick gloom of ſome tempeſtuous night,
> Orion's dog (the year when autumn ſways),
> And o'er the feebler ſtars exerts his rays:
> Terrific glory! for his burning breath
> Taints the red air with fevers, plagues, and death."

In the firſt book, peſtilence is alſo aſcribed to the anger of Apollo, an allegorical expreſſion for the extreme heat of the ſun. (See Pope's verſion, lines 83, and 87.)

Theſe poetic ſtatements accord moſt accurately with the obſervations of Hippocrates, who frequently mentions epidemic fevers as common in the ſummer and autumn, and as prevailing moſt extenſively when wet ſprings with ſoutherly winds were ſucceeded by hot and cloſe ſummers. A remarkable conſtitution of this kind, which continued for two years, is deſcribed in his treatiſe on Epidemics, (De Morbis Vulgaribus, lib. iii.) at which time ardent remitting and intermitting fevers of a bad kind prevailed, attended with fluxes, parotids, and eruptions of a peſtilential nature. The autumn and ſpring were wet, cloſe, and cloudy, without wind, the breezes from the ſouth; and theſe continued during the hot and ſultry ſummer, when the uſual refreſhing Eteſian winds did not blow.

Exceſſive heat of the ſummer, without moiſture, has occaſionally accompanied an epidemic ſeaſon. Thus in the year of Rome 325, there was a moſt grievous famine, occaſioned by a ſevere drought, in all the Roman territory. " Siccitate eo anno plurimum laboratum eſt; nec cœleſtes modo defuerunt aquæ, ſed terra quoque, ingenito humore egens, vix ad perennes ſubſecit amnes;" the cattle thronged in multitudes round the arid fountains, and periſhed with thirſt, diſeaſes followed among the cattle, from which they were propagated by contagion among men (" vulgatique contactu in homines morbi"), the peaſantry firſt ſuffering, then the lower claſſes, and at length the whole city was infected. (Tit. Liv. lib. iv. 30.) In more modern times, great droughts have been accompanied by epidemic diſeaſes, eſpecially in cities ſituated in low and damp countries. In the autumn of 1652, Bartholine informs us that a malignant fever appeared at Copenhagen, after an unuſually hot and dry ſummer. And a ſimilar fever raged at Leyden in the year 1669, as deſcribed by Silvius de la Boe. The ſpring and beginning of ſummer were cold, but the remainder of ſummer, and the autumn, were unuſually hot, with little or no rain, and with a conſtant calm or ſtagnation of the air. (See Pringle on Dif. of the Army, p. iii. claſs 4.)

But epidemic diſeaſes are ſtill more fatal in thoſe ſeaſons, in the damp countries of the ſouth, where the heats are longer and more intenſe, and much moiſture is combined. In ſome parts of Italy, and in other tracts of the ſame latitude, epidemic fevers have appeared with ſuch alarming ſymptoms, as not only to have been called peſtilential, but confounded with the plague itſelf. In this ſenſe we are to underſtand Celſus, (De Medicina, lib. i. cap. 10. lib. iii. cap. 8.) in the terms *peſtilentia* and *febris peſtilentialis*, which he deſcribes as peculiar to the " grave anni tempus," and the " graves regiones." His meaning is, that this bad fever is the diſeaſe of the latter part of ſummer, and of autumn, when the air is thickeſt and moſt foggy, and that is moſt frequent in low and marſhy countries. Rome was always liable to theſe fevers. Galen calls the *hemitritæa* the epidemic of that city, and ſpeaks of its moiſt air. (De Temperament. lib. ii.)

In fact the chief malignancy of the worſt epidemic diſeaſes, and of the plague itſelf, has always been felt in the ſummer and autumn; as the hiſtories of that diſeaſe in all the large towns in Europe will teſtify. Diemerbroeck has juſtly obſerved, that when the plague has been excited out of its proper ſeaſon, it has not ſpread: and Dr. Ruſſell tells us, that in the winter time, when infected perſons have come to places about Aleppo, ſome of whom have died in the families where they lodged, the diſtemper by ſuch means was not propagated. In the four great plagues of London, during the ſeventeenth century, the mortality invariably increaſed, as the ſeaſon advanced, reaching its acmè in Auguſt and September, and thenceforth gradually declining. (See the Bills of Mortality.—See alſo Dr. Heberden, jun. on the Increaſe and Decreaſe of Diſeaſes, 1801.). Thus in the laſt plague in London, in the year 1665, the mortality of the reſpective months was as follows; in the ſpring very few perſons had died of the plague, in June 590 perſons died of it, in July, 4,129, in Auguſt, 19,046, in September, 26,230, in October, 14,372, in November, 3,349, and in December a few hundreds. (See Plague.) The progreſs, in the other three inſtances, was exactly ſimilar.

Again, the regular decreaſe of peſtilential diſeaſes, with the declining ſummer, equally demonſtrates the neceſſity of the preſence of the hot ſeaſon for their propagation; which may operate either by rendering the contagion more virulent, by producing certain pernicious effluvia from the earth in moiſt places, or by inducing a prediſpoſition in the human body to receive the influence of thoſe exciting cauſes. At Grand Cairo putrid and peſtilential fevers prevailed annually in March, April, and May, which the ſoutherly winds make the hotteſt months in that country; but they ceaſed at the overflowing of the Nile, when the cold winds ſet in. (Proſper. Alpin. de Med. Egypt, lib. i. cap. 14. Mead on the Plague, p. 30.) And "at Smyrna the annual plague conſtantly ceaſes about the 24th of July, by the *dry and cold weather* they always have at that time." (Mead, p. 56.) Indeed, when this change of ſeaſon takes place, while every place abounds, it muſt be preſumed, with the contagion, yet it ceaſes to be detrimental. Proſper Alpinus remarks, that when this change of ſeaſon comes, in the month of June, even the clothes imbued with the moſt peſtiferous contagion then infect no one. "Sed quod valde mirabile creditur, omnia ſupellectilia peſtifero contagio infecta tunc nullum contagii effectum in eam gentem edunt."—And this inertneſs of the contagion in the moſt infected places, on the approach of winter, was moſt remarkable in the laſt plague of London. "Many who made moſt haſte in retiring," ſays Dr. Hodges, "made the moſt to return, and came into the city without fear: inſomuch, that in December they crowded back as thick as they fled: the houſes, which were before full of the dead, were now again inhabited by the living; the ſhops, which had been moſt part of the year ſhut up, were again opened, and the people again cheerfully went about their wonted affairs of trade and employ: and even what is almoſt beyond belief, thoſe citizens, who before were afraid even of their friends and relations, would, without fear, venture into the houſes and rooms where infected perſons had but a little before breathed their laſt: nay, ſuch comforts did inſpire the languiſhing people, and ſuch confidence, that many went into the beds, where perſons had died, before they were even cold, or cleanſed from the ſtench of the diſeaſed." (Loimologia, or Hiſt. Acc. of the Plague in 1665, p. 27.) In the ſame way we read, that when the plague was in Italy, the Neapolitans uſed no artifice to purify either their goods or houſes; yet the diſeaſe ceaſed among them as entirely as in the beſt regulated towns. (Heberden, loc. cit.)

Theſe facts amply prove the extenſive influence of certain ſeaſons, in favouring and interrupting the progreſs of the moſt peſtilential epidemics; and that not in conſequence of any occult, but of certain ſenſible and obvious conditions of the weather. The ſame circumſtances of the ſeaſons modify the propagation and diminution of the minor epidemics, ſuch as dyſentery, remittent and intermittent fevers, &c. and even the ſmall-pox. Of the former of theſe, we ſhall more properly ſpeak under the ſecond head of cauſes; namely,

2. *Marſhy and other Effluvia.*—Galen aſſigns two cauſes for peſtilential fevers; the firſt of which is great heat of the weather, and the ſecond, which he conſiders as moſt frequent, a corrupted ſtate of the air, ariſing either from a multitude of dead bodies left unburnt, as after a battle, or from the evaporation of corrupted lakes and marſhes. (De Febr. Diff. lib. i. cap. 4.) Other authors of antiquity have noticed the coincidence of epidemic fevers with marſhy ſituations. Thus Diodorus, the hiſtorian, has recorded the occurrence of a peſtilential diſeaſe among the Carthaginians at the ſiege of Syracuſe, which he attributes to the combination of the following circumſtances; the multitude of people confined within a narrow compaſs, the ſituation of the camp in a low and wet ground, and the ſcorching heats in the middle of the day, ſucceeded by cold and damp air from the marſhes in the night. (Bibl. Hiſt. lib. xiv. cap. 70.) In more modern times the origin of epidemic diſeaſes from marſh effluvia had been very generally obſerved. Fracaſtorius aſcribes a malignant epidemic fever, in Italy, in the ſixteenth century, to an extraordinary inundation of the Po, which, happening in the ſpring, left marſhes, and thoſe corrupting infected the air through the ſummer. Foreſtus remarks, that, from the putrefaction of the water only, the city of Delft, where he practiſed, was ſcarcely ten years free from the plague or ſome peſtilential diſtemper. (Obſervat. lib. vi.)

The effects of marſh or putrid effluvia in giving riſe to epidemic diſeaſes have, indeed, been evinced in moſt of the large cities, and ſtill more obviouſly in the camps of modern times. Sir John Pringle, ſpeaking of the hot weather, during one of the campaigns in the Netherlands, in 1748, obſerves, that though the heats were great, yet they were the cauſe of little ſickneſs, till the troops were cantoned in the marſhes, where a conſiderable degree of putrefaction and moiſture being joined, ardent, remitting, and intermitting fevers, and fluxes became general. It is remarkable that theſe pernicious exhalations do not riſe high, nor ſpread far from their ſource, at leaſt without ſuch dilution as diminiſhes their deleterious qualities. Dr. J. Hunter has affirmed, that in the barracks at Spaniſh Town, in Jamaica, (which conſiſted of two floors, the firſt upon the ground, the ſecond over the firſt,) the difference in health of the men on the two floors was ſo great as to engage the attention of the aſſembly of the iſland, and upon inveſtigation it appeared that three were taken ill on the ground floor for one on the other. Even at a few hundred feet above the level of the marſhes, the ſituations are extremely healthy. (Obſerv. on the Dif. of the Army in Jamaica, note B. p. 268, 3d edit.) The air of a marſh or of a foul camp, the ſame author obſerves, may deſtroy an army almoſt as ſoon as the true plague. But the remedies in fuch cafes are obvious, and confift in getting at a proper diftance from the noxious exhalations, or removing the caufes of them. "A very fmall fpace frequently includes the limits of healthy and unhealthy ground." It is not now neceffary to ftate that agues, or intermittents, originate folely from the effluvia of marfhes.

Another fpecies of effluvia, which is the fource of epidemic difeafes in camps and in towns, when ill conftructed and neglected, arifes from ground contaminated with human and other excrements, the remains of victuals, the water ufed in cookery, for wafhing, the foul ftraw rotting in tents, &c. Whenever a camp remains long on the fame ground, efpecially in hot and moift weather, fluxes, and intermitting and remitting fevers, feldom fail to become epidemic, unlefs great precautions are ufed to bury all excrementitious matter, and proper receptacles and drains under ground are prepared for the urine, water of cookery, &c. (See Dr. Hunter, loc. cit. p. 285.) In this cafe, however, as in that of marfh effluvia, the difeafes produced will difappear, by moving the camp a few hundred yards from the foul ground.

Thefe facts throw great light on the epidemics of large cities, which were formerly fo frequent and fatal. A large town may be confidered as an extenfive camp, but deftitute of the means of changing its fituation, and, confequently, liable to be infefted with the fame difeafes as are endemic and epidemic in camps, unlefs the precautions juft alluded to, for the purpofe of removing the fources of the peftilential effluvia, be fully adopted. And we find, accordingly, that during and previous to the 17th century, (and even later, in fome countries,) the large towns were almoft conftantly infefted, in the fummer and autumnal months, with the plague, malignant, intermittent, and remittent fevers, and dyfentery; the fame diforders to which camps are liable. This was the condition of London during the period fpecified. We have already remarked, that the plague was feldom abfent from the beginning of the 17th century to the year 1669, and that four dreadful vifitations of that calamity occurred within the fame fpace of time. Of the extent to which intermittent and remittent fevers prevailed, in this metropolis, we have alfo ample evidence. Dr. Short remarks, that early in the century, *viz.* between 1629 and 1636, "one of 40 of the whole that died of fevers, died of agues;" whereas, "now (1750) fcarce *one* of 1100 that die of fevers die of this difeafe." (New Obf. Nat. Moral, &c. on Bills of Mortality, 1750, p. 208.) Burnet, in his "Hiftory of the Reformation," fays, that in the laft year of queen Mary's reign "intermitting fevers were fo univerfal and contagious, that they raged like a plague." Both Sydenham and Morton have left us abundant evidence of the frequent epidemic prevalence of agues, as well as of remitting fevers, which laft Morton affirms to have been extremely deftructive for feveral years before the great plague, *viz.* from the year 1658 to 1664. He ftates that Oliver Cromwell died of this fever in 1658; and that his own father, himfelf an experienced phyfician, alfo died of it; when his whole family, the writer included, were infected. (Morton, Pyretologia, App. ad Exercit. ii.) Even fo late as from 1720 to 1729, according to Dr. Short, "they (intermittents) and remittents afflicted the whole nation grievoufly."

Sometimes together, and fometimes alternating with thofe autumnal fevers, the dyfentery was a frequent epidemic in London, in the times to which we allude, and was often attended with great fatality. For five and twenty years fucceffively, from 1667 to 1692, the bills of mortality fhew the fum of deaths under the titles of "bloody flux," and "griping in the guts," which muft both be confidered as dyfentery, to have amounted every year to above 2000. During the laft century, the difeafe has gradually declined, (Dr. Heberden on Increafe and Decreafe of Diff. Difeafes, p. 34.) and the other fatal epidemics, juft mentioned, have quite difappeared. See Annual Medical Regifter for 1808, vol. i. where the changes of difeafe in London are difcuffed at length.

We cannot doubt, that the prefent comparative healthinefs, and efpecially the great freedom from all epidemics (the contagions of fmall-pox, fcarlet fever, and meafles excepted) which this metropolis now enjoys, is to be afcribed altogether to the meafures, by which the fources of the effluvia, which excite them, have been removed, and to the general habits of cleanlinefs and ventilation which are at prefent obferved by the people. Thefe falutary meafures are principally the conftruction of privies, drains, and common fewers; a hard and regular pavement, with a proper level for carrying off the humidity, and well cleanfed by fcavengers; an abundant fupply of water to every part of the town, &c.

In all thefe points, the condition of London, like that of moft other large cities in Europe, during the 17th century, was extremely defective. In the preceding centuries its condition muft have been ftill more incommodious and filthy, fo that few years elapfed without the occurrence of a confiderable peftilence. We have not room, in this place, to enter more at large into a defcription of its circumftances; but muft content ourfelves with referring to the work of Dr. Heberden, jun. juft quoted, where an abundant collection of evidence, as to the connection of thofe epidemics with filth and negligence in the economy of this and of other large towns, will be found. (See alfo the Ann. Med. Regifter for 1808. Maitland's and Nourthouck's Hiftory of London.) See Plague.

It is extremely gratifying, both in a phyfical and moral point of view, to obferve that the fame means which contribute to our perfonal comforts, and to elevate us above the favage, *viz.* the progrefs of civilization and refinement, have led to banifh the moft loathfome and fatal diftempers, to prolong life, and to diminifh the prevalence and fatality of other difeafes of lefs fatality. "While the metropolis has extended itfelf in all directions, and multiplied its inhabitants to an enormous amount, *i.e.* while the apparent caufes of its unhealthinefs have been augmented, it has actually become more favourable to health. In the year 1697, for example, the total mortality of London was 20,970; whereas, the total mortality of 1797 amounted only to 17,014: and when we take into confideration the great increafe of the population of the out-parifhes at the latter period, the *comparative* healthinefs of London will appear in very ftrong colours." Ann. Med. Regifter, p. 321.

Sometimes the air of a particular diftrict feems to have been impregnated with effluvia from putrefying animal and vegetable matter, which has occafioned an epidemic in that neighbourhood. Foreftus has mentioned the putrefaction of a large fifh, of the whale kind, which was left by the tide, and died, on the coaft of Holland, and, during its putrefaction, infected the country with a horrid ftench, in confequence of which a fatal epidemic fever broke out in the diftrict of Egmont. (Obf. lib. vi. 9. tom. i.) The fame author informs us of a peftilential fever, which raged at Venice in his time, and was produced by the corruption of a fmall kind of fifh in that part of the Adriatic. (Ibid.) Inftances are alfo on record of epidemic fevers occafioned by the effluvia of putrid cabbages, as well as of plants

plants in marſhes. (Rogers on Epidem. p. 41.) Theſe ſources of epidemics, however, are rare, and can ſeldom occur under a well regulated police.

3. *A crowded Population.*—From the earlieſt periods of time, of which we have any record, peſtilential diſeaſes were known to be the effect of crowded population, and to rage peculiarly in cities, forts, and other confined places. In the ſacred writings peſtilence is every where mentioned as the peculiar ſcourge of *cities*. "The ſword is *without*," ſays the prophet Ezekiel, chap. vii., "and the peſtilence and famine *within*; he that is in the field ſhall die with the ſword; and he that is in the *city*, famine and peſtilence ſhall devour him." And again, chap. xxxiii., it is ſaid, "they that be in the *forts* and the caves ſhall die of the peſtilence." The city of Rome was ſubject to the moſt fatal epidemics from a very early period of its hiſtory: Athens ſuffered alſo extremely; and in modern Europe the great cities have been the common ſeats of plagues, from Conſtantinople to Moſcow, and from Cadiz and Marſeilles, to Copenhagen and Dantzic. (See an enumeration of the cities infected with the plague, and the dates of its occurrence, by Dr. Heberden, *loc. cit.* p. 81, *et ſeq.*) The ſame obſervation applies to the cities of Aſia and Africa; to Aleppo, Cairo, &c. &c., as well as to thoſe of America.

We have already ſtated, that the prevalence of epidemic and peſtilential diſeaſes in this metropolis was obviouſly connected with the exiſtence of filth of every ſpecies, and that their gradual diſappearance has been coeval with the improvements of the city, and the removal of theſe nuiſances. The ſame fact is obſervable in all the cities of Europe: and thoſe which, from natural or political cauſes, have been backward in adopting the improvements of modern times, have more lately exhibited the ſame effects of their negligence. The plague appeared at Copenhagen in 1764; and at Moſcow ſo late as the year 1771. It is farther obſervable, that peſtilential diſeaſes generally appear firſt in the moſt crowded and uncleanly parts of towns, and rage moſt ſeverely in the moſt crowded and dirty habitations, *i. e.* among the poor. The plague of 1665, in London, is ſaid to have been by many perſons called "the poor's plague." Thoſe of 1626 and 1636 broke out at Whitechapel, a part of the town which abounded with poor, and with ſlaughter-houſes: and that of 1665 is ſaid to have broke out firſt at St. Giles's; and there, Dr. Heberden remarks, it would probably break out again, if ever we ſhould ſuffer ſuch another calamity.

For it muſt be obſerved, that a crowded and uncleanly population contributes, in a double manner, to the origin and propagation of epidemic and peſtilential diſeaſes. It not only occaſions the accumulation of every ſpecies of filth externally, from which effluvia ariſe to contaminate the atmoſphere, in hot and moiſt ſeaſons, thus producing all the diſeaſes of camps; but it produces another ſpecies of effluvia, internally, in the habitations of men; *viz.* from the bodies of the ſick, and even of the healthy, which at once generate malignant fevers, and aggravate thoſe which ariſe from the other ſources. (See CONTAGION.) So that under the circumſtance of the combination of theſe cauſes, namely, when the heat and moiſture of autumn generate the effluvia from external filth, and contagion is ſuperadded from the accumulation of the corporeal effluvia, from the want of internal cleanlineſs and ventilation, diſeaſes of an epidemic nature are readily excited, and are propagated extenſively and fatally. Hence, before the value of theſe internal cautions was underſtood, malignant fevers ſo frequently occurred in hoſpitals and gaols, that they obtained the appellation of hoſpital-fever and gaol-fever. Indeed we are told that, ſo late as the latter end of the 17th century, in the gaol of Newgate, a contagious fever uſed to break out annually, in hot weather; and that the ſame was true of moſt gaols in Europe; (The City Rembrancer, quoted by Dr. Heberden) and ſeveral facts on record, prove, how readily any acute diſeaſe is thus propagated by contagion, under theſe circumſtances of crowded and filthy habitations; although originally, and in cleanly and airy apartments, it was incapable of ſpreading from one individual to another. Thus ſir John Pringle obſerved, that, "in autumn 1757, ſeveral ſoldiers were brought into the hoſpital at Portſmouth, with a diſorder compounded of the autumnal and gaol-fever; for when theſe men, upon being ſeized with the common fever of the ſeaſon, were confined to the holds of the crowded tranſports, their diſtemper aſſumed that form. (Diſ. of the Army.) So Dr. Lind has ſtated, that, upon admitting into an hoſpital one perſon with a flux, ſeveral other patients in the ſame ward have had this ſymptom added to their other complaints. (Lind on Fever and Infection.) And Dr. Blane has obſerved generally, that, ſuppoſing a ſhip's company be prediſpoſed to acute diſtempers, and one man or more ill of a dyſentery be brought on board, this will become the prevailing diſeaſe. (On the Diſeaſes of Seamen.)

Theſe facts, which evince the facility with which any acute diſeaſe, or its leading ſymptom, is communicated from individual to individual, in a cloſe and crowded apartment, when extreme cleanlineſs and ventilation are not attended to, will ſerve to explain ſeveral apparent anomalies in the hiſtory of ſeveral diſeaſes, which have been ſtated as the reſult of ſome myſterious epidemic principle in the atmoſphere. We allude to the occaſional ſpreading of particular maladies in hoſpitals, in a ſort of epidemic way; ſuch as the appearance of eryſipelas, connected with all ſlight injuries of the ſcalp, or other ſuperficial parts, as related by ſir William Blizard, of the London hoſpital, and as occurred in the ſurgical ward of the Royal Infirmary at Edinburgh, many years ago; the diſpoſition to inflammation and abſceſs about the perineum and neighbouring parts, mentioned by the ſame writer, &c. (See a Paper "On ſome epidemical Effects," Med. Facts and Obſ. vol. ii. 1792.) Such occurrences, we believe, are rare in proportion to the degree of cleanlineſs in thoſe receptacles of the ſick. We have been aſſured that the occurrences of this nature at Edinburgh have ceaſed, ſince a more rigid ventilation and purification have been adopted in the Royal Infirmary.

4. *Deficient and Depraved Aliment.*—The obvious cauſes of epidemic diſeaſes, already mentioned, may operate both as exciting and as prediſpoſing cauſes; but that to which we now direct our attention, perhaps, chiefly acts in inducing a debilitated and half-morbid condition of the body, which renders it liable to be affected by thoſe exciting cauſes. Certain it is that famine and peſtilence have been obſerved to go together, ſince the earlieſt ages of the world; and are conſtantly mentioned in combination, in the ſacred writings; to which war is frequently added. Dearth is almoſt neceſſarily a part of the deſolation of war; which, therefore, contributes to the production of peſtilence indirectly by producing dearth. Ὁ λοιμὸς μετὰ λιμὸν, "the plague after famine," was an old Greek adage. Where articles of food are extremely ſcarce, they are often alſo corrupted, and may thus contribute to reduce the human conſtitution to a ſtate prediſpoſed to diſeaſe. Foreſtus imputes the plague at Delft, in the year 1557, to the eating of mouldy grain, which had been long kept up by the merchants in a time of ſcarcity. (*Loc. cit.*) And ſir J. Pringle ſays, he had heard it obſerved, that in this iſland the dyſentery is frequent among the common people, in thoſe parts where they live

live moftly on grain, when the preceding crop has been damaged in a rainy feafon, or kept in damp granaries. (*Loc. cit.* cap. vii. p. iii.) In ancient times the corruption, as well as fcarcity of food, was affigned as the caufe of peftilence; as by Cæfar himfelf when befieging Marfeilles, (De Bello Civili, lib. ii. 20.) "Panico enim vetere, atque hordeo corrupto, omnes (*fcil.* Maffilienfes) alebantur; quod ad hujufmodi cafus antiquitus paratum, in publicum contulerant." When we advert to the fatal epidemic difeafe, termed Feu facrè, Mal des ardens, &c. by the French, and known to originate from *ergoted* rye, ufed as food, we fhall not hefitate to afcribe confiderable effects to the fort of food juft mentioned. (See Philof. Tranfact. vol. lv. p. 110, and Mem. de la Soc. Royale de Medecine, for 1776.) Dr. Willan has obferved, that the Morbus Hungaricus, defcribed by Sennertus, "and fome other difeafes reputed peftilential, might be added to the lift of epidemics, occafioned by the *ergot;* or by a fimilar degeneration in other grain. The fweating-ficknefs, which occurred more than once in England, at the beginning of the fixteenth century, was perhaps owing to fome difeafe or depravation in wheat, &c." (On Cutaneous Difeafes, part iv. p. 499.) It may be added, that the only epidemic occurrence of contagious fever in London for feveral years back, occurred after the exceffively wet autumn of 1799, when corn was exceedingly damaged, and a confiderable fcarcity enfued.

5. *Exhauftion by Fatigue, &c.*—Befides the debility of conftitution, and confequent predifpofition to difeafe, induced by imperfect nourifhment, during a famine, the exhauftion produced by exceffive corporeal exertions, lofs of fleep, and the depreffing paffions, probably contributes in no fmall degree to predifpofe the body to difeafes. Thus epidemic fevers have been obferved to arife after great battles. Dr. Gottwald traced the origin of the plague at Dantzick to Pinozow, foon after the battle of the Swedes and Saxons, in 1702. (Ingram, Hift. of Plagues, p. 86.) To the fame caufe, perhaps, we may impute the contagious fever, which raged among the troops of the late fir John Moore, on their return from the haraffing campaign in Spain. (1809.) Van Swieten obferves, that "ftrong paffions of the mind, particularly terror, augment the efficacy of infection, as all writers on the plague unanimoufly allow," and that the fame paffion contributes to render the difeafe more fatal. If this be correct, the extenfive operation of fear in befieged towns, and countries which are the feat of war, muft produce confiderable influence; and it cannot be doubted, that the general panic, which rapidly fpreads among the inhabitants of a town, where the plague is difcovered to exift, contributes materially to its propagation.

On reviewing the facts above ftated, it is obvious that the fources of epidemic and peftilential difeafes have been often traced to manifeft circumftances, in combination with one or more of which they have generally been obferved to occur: and more efpecially that the heats of fummer and autumn appear to be abfolutely neceffary to the propagation of a general peftilence. The obfervation of Celfus, in regard to the falubrity of the different feafons, has been confirmed by thofe who have practifed in warm climates, (Cleghorn on difeafes of Minorca) by the phyficians of camps, (Pringle, *loc. cit.* part ii. chap. i.) and by the condition of this country in the time of Sydenham. "Saluberrimum ver eft; proxime deinde ab hoc, hiems; periculofior æftas; *autumnus longe periculofiffimus.*" (Celfi De Med. lib. ii. cap. i.) But the experience of the laft century, during which this order of the feafons, in point of falubrity, has been almoft reverfed, (for we now find July and Auguft the moft healthy months of the year, and February and March the moft productive of difeafe,) has thrown confiderable light even on the occult principle, the το θεῖον, of the epidemic atmofphere. It has fhewn us, what Sydenham could not have anticipated, and what to him indeed muft have been incredible, that, while the feafons continue to occur, with their former viciffitudes, and while the bowels of the earth (for aught that we know) continue to fend forth their vapours as ufual, yet thofe fatal peftilential *conftitutions* of the air no longer appear; the plague has not been feen, fince the rebuilding of the city (1667); intermittents no longer infeft the metropolis, and the autumnal remittents are alike almoft unknown; efpecially fince the covering of Fleet ditch, and the other improvements, made in 1766; and the dyfentery, or bloody flux, now fcarcely adds twenty to the annual bills of mortality! This occult principle, then, this epidemical *fomewhat*, it muft be inferred, neither owed its origin to the atmofphere, nor to the bowels of the earth, nor to the eruptions of Ætna, nor to the approach of comets. For the former of thefe are, doubtlefs, unchanged; and the latter have continued to occur at intervals as ufual.

To what, then, are we to attribute the origin of thofe *epidemic conftitutions*, as they have been called, of particular years, in which certain difeafes extenfively prevail? We have not, perhaps, a fufficiency of facts to enable us to deduce a decided conclufion; but the following inference feems to approximate to the truth, and to fpring out of the facts already detailed.

The experience of camps, efpecially in moift feafons, teaches us how readily epidemical difeafes are produced, from the contamination of the lower portion of the atmofphere with the effluvia of foul ground, and alfo how confined and local that contamination is, fince a fmall elevation, or a removal to the diftance of a few hundred yards, from the fource of the effluvia, is fufficient to enable us to efcape their noxious effects. The experience of gaols and hofpitals, and other crowded and uncleanly habitations, has alfo demonftrated the facility with which human effluvia, accumulated about the fick, become contagious to thofe in their immediate vicinity; and alfo how readily, in this predifpofed and contagious ftate, any acute difeafe, *accidentally* introduced, is carried from individual to individual, fo as to become the prevalent or epidemic difeafe. Now, London, and all other crowded cities in the 17th century, combined within themfelves both thefe peculiarities of condition, belonging as well to camps as to gaols and hofpitals. The atmofphere was contaminated with the local effluvia, which rendered it peftilential externally; and, within the dwellings, efpecially in the poorer parts of the town, infectious atmofphere was produced, and thus whatever difeafe was generated, was propagated readily, and gave a character to the particular *conftitution* of the epidemic feafon. How varioufly the epidemics muft be modified, according to the various degrees and combination of the exciting and pre-difpofing caufes, muft be obvious on reflection. When the bodies of the people happen to be pre-difpofed to difeafe by want of food, or actually difordered by corrupted food, when the accumulation of filth, or the increafe of marfhy ground from rains or inundations, fend forth miafmata in a moft abundant and concentrated form, in confequence of a peculiar autumnal feafon, the moft extenfive epidemic difeafes may be expected to arife. And we believe, that under fuch a combination of obvious circumftances, peftilence never fails to appear.

On the other hand, although a large city cannot, like a camp, be removed from the fource of the peftilential effluvia, which it generates, yet induftry may remove the fource of thefe effluvia from it. And it appears to be a perfect

perfect confirmation of the preceding conclufions, that, as this removal has been accomplifhed in London, (for example,) as the arts of peace and civilization have advanced, and wealth has introduced the difpofition and the power to multiply perfonal comforts and conveniences; and as habits of cleanlinefs and ventilation have been generaly diffufed; in the fame proportion, and with equal fteps, the improvement of the general health, the abfolute difappearance of the plague and the other epidemics, and the increafe of longevity, are to be remarked. Hence it is only within the laft few years, that the deaths have fallen fhort of the number of births within the bills of mortality of London.

We cannot, from our prefent knowledge of facts, however, account for all thofe modifications of difeafes, nominally the fame, which are obferved to prevail at different feafons, and which require different modifications of the treatment. It can only be ftated as highly probable, that whether the epidemic difeafes originate from contagion, or human effluvia, or from the effluvia of foul ground, their degrees of violence may depend on the degrees of concentration of thofe effluvia; and the contagion of a mild or fevere difeafe may tend to propagate more particularly a difeafe of fimilar character. We have already feen that peculiar fymptoms, fuperadded to an acute difeafe, as affections of the lungs or of the bowels with general fever, are readily propagated along with that fever, and have modified both its character and the requifite treatment.

It has been juftly obferved, that "in military phyfic," (and the obfervation applies to epidemic difeafes in general,) "the great improvements to be made are not fo much in the cure as in the prevention of difeafes, which depends altogether upon the knowledge of their caufes." (Dr. John Hunter, *loc. cit.* p. 281.) Now one of the moft important circumftances to afcertain, during the prevalence of an epidemic is, whether it arifes from contagion, that is, from the influence of effluvia from the bodies of the difeafed, or from the contamination of the air by the effluvia of foul ground, &c. For "if a difeafe arife from contagion, as the author juft quoted remarks, "there are fure remedies againft it, which are fo well afcertained, that while the plague, the moft contagious and the moft fatal of all difeafes, commits its greateft ravages in large cities, individuals remain in the midft of them in perfect fecurity, trufting to a careful feclufion under proper regulations. (See Contagion.) Again, if difeafe arife from the air contaminated by the foul ground of a camp, or the exhalations of a marfh, it can only be avoided by a change of fituation, or by taking care not to come within the fphere of activity of fuch noxious caufes." Or in a large town, it may be added, by a ftrict enforcement of public and private cleanlinefs. But it is often extremely difficult to decide upon this point; a generally operating caufe affects fuch a number of individuals about the fame time, in the fame fituation, that they may feem to be infected by each other. So that, in fact, it has been difputed whether the plague itfelf be a contagious difeafe; and in regard to the dreadful epidemics of America, medical obfervers are by no means agreed as to their contagious origin. The contagion of the plague will be difcuffed hereafter. In the mean time we fhall ftate fome obfervations which may help to guide our decifion in fuch cafes.

By a contagious difeafe, is to be underftood a malady in the courfe of which a poifon is generated in the body of the fick, which produces in others a fimilar difeafe. The poifon in fome difeafes, as the fmall-pox and chicken-pox, is fufficiently apparent; and the other difeafes, which alfo arife from fpecific contagion, and occur but once during life, as meafles, fcarlet fever, hooping-cough, &c. are well known. In others, again, as in typhus and the plague, it almoft eludes our fenfes, and is only active when concentrated or accumulated, or clofe to the body of the fick. Now thefe contagious difeafes equally affect all ages and defcriptions, who fuffer expofure to their caufe: wherever they prevail, the old inhabitants of a country fuffer as much as thofe that have lately arrrived. But this is never the cafe in the yellow fever, remittent fever, or even intermittent fever, which arife from external miafmata; for fuch as are feafoned to the country or climate fuffer infinitely lefs than new-comers. Again, difeafes proceeding from fuch a caufe, generally diffufed, and operating upon all, do moft conftantly recur in the fame perfons as long as they remain expofed to the original caufe; thus in camps and marfhy fituations, the fick are conftantly relapfing in remittents and intermittents, till they change their fituation. Dr. Hunter particularly obferves, that the mortality among foldiers in the Weft-Indies is, in a great meafure, owing to thefe repeated attacks. But what the fame writer confiders as the *experimentum crucis*, to prove the non-exiftence of contagion, is, when the fick leave their ufual refidence, and go to other places which are healthy, without fpreading the difeafe. This conftantly happens in the remittent fevers of the Weft-Indies; for the good effects of changing the air of the towns for that of the mountains is fo well known, that it is very generally practifed; but certainly without the flighteft fufpicion of any mifchief arifing from any contagion carried by the fick. If we try by this rule the fever epidemic in Philadelphia in 1793, we fhall not pronounce it to be contagious. One obfervation more may be added: when difeafe arifes from a caufe generally diffufed, feparation, which in contagious difeafes is commonly effectual, is here of no avail. Thus, fhips of war have gone into a harbour in the Weft-Indies, and have had no intercourfe with the people on fhore, or with the crews of other fhips, and yet in a few days the men have been feized with the prevailing fever in great numbers. (Hunter, ibid.)

With refpect to the laft argument but one, indeed, the inference is not perfectly conclufive; for malignant typhoid fevers, (and the plague, which is probably but an extreme degree of the fame fever,) although they produce a contagion that is active and virulent in a confined and clofe atmofphere, neverthelefs become much lefs contagious, in a clear and open air; fo that we fhould expect that, on a removal of the fick to the country, the difeafe would affume a lefs virulent form. In the plague at Mofcow in 771, we are told by Dr. Mertens, that the patients, who were conveyed to the neighbouring villages, communicated the difeafe to the inhabitants of thofe places; which they would the more readily do, as probably their cleanlinefs was not fuperior to that of Mofcow itfelf.

The fpecific contagions, as they have been called, as fmall-pox, meafles, and fcarlet-fever, which occur but once in the courfe of life, and chiefly attack children, become epidemic generally at pretty regular periods, in large towns. This may be principally explained, perhaps, by the circumftance of the neceffary interval requifite for the production of fubjects, who have not undergone thefe difeafes.

On the whole, however, although the progrefs of refinement in the comforts of human life, during the laft century, have thrown much light on the nature and origin of epidemic conftitutions, in different years; it muft be allowed, neverthelefs, that much farther obfervation of facts will be requifite, in order to illuftrate the fubject completely.

EPIDENDRA, from ἐπὶ, *upon*, and δένδρον, *tree*, in *Natural Hiſtory*, a word uſed by ſir Hans Sloane, and ſome other authors, to expreſs thoſe plants which grow upon others, ſuch as the miſletoe, which grows upon the apple-trees, &c. Theſe are more commonly diſtinguiſhed by the name of paraſitical plants. See Dodder.

EPIDENDRUM, in *Botany*, ſo named by Hermann, Linnæus, and others, from ἐπὶ, *upon*, and δένδρον, *a tree*, becauſe moſt of the ſpecies, if not all, grow paraſitically on the trunks or branches of trees. Linn. Gen. 464. Schreb. 606. Willd. Sp. Pl. v. 4. 114. Mart. Mill. Dict. v. 2. Juſſ. 66. Swartz. Act. Holm. 1800. p. 240. Tracts on Botany, 182. Schrad. Journal, 1799. 209. t. 1. Orchid. in Schr. Neues Journ. v. 1. 79. Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*, Linn. Juſſ.

Gen. Ch. reformed. *Cal.* three-leaved. *Cor.* Petals two, nearly equal to the calyx-leaves, ſpreading; nectary a lip, turbinate and tubular at the baſe, connected with the ſtyle, deſtitute of a ſpur, its termination dilated, aſcending, ſpreading, either undivided or lobed. *Stam.* Anther an hemiſpherical, deciduous, terminal lid, of two or four cells; maſſes of pollen ſtalked, in pairs. *Piſt.* Germen inferior, oblong or obovate, erect, furrowed; ſtyle ſemi-cylindrical, often gibbous, concave in front; ſtigma either concave or convex, in the fore-part of the ſtyle near the top. *Peric.* Capſule oblong or obovate, with three or ſix ribs, with one cell and three valves, opening by clefts between the ribs. *Seeds* numerous, minute, each clothed with a chaffy tunic, inſerted into the downy internal ridges of the valves.

Eſſ. Ch. reformed. Calyx-leaves ſpreading. Lip tubular at the baſe, attached to the fore-part of the ſtyle, deſtitute of a ſpur. Anther a terminal lid, deciduous.

The original genus of *Epidendrum* in Linnæus, whoſe eſſential character is "Nectary turbinate, oblique, reflexed," comprehends many ſpecies which do not anſwer to that character, and which have, indeed, in ſeveral inſtances, been referred to this genus without a ſufficient knowledge of their flowers. Hence profeſſor Swartz has chiefly derived his genera of *Cymbidium*, *Dendrobium*, (ſee thoſe articles,) *Oncidium*, *Aërides*, and *Vanilla*, ſo that his *Epidendrum*, whoſe characters we have given above, is become a much ſmaller, as well as a more intelligible genus, though perhaps not more natural, it having the cloſeſt poſſible affinity to *Cymbidium* and *Dendrobium*. The ſpecies in Swartz are 23, in Willdenow 26. Profeſſor Martyn has, with great induſtry, collected 124 under the original genus. Dr. Swartz mentions 19 new ones as diſcovered in South America by the authors of the Flora Peruviana and Chiloenſis.

Among the genuine ſpecies of *Epidendrum*, as the genus ſtands at preſent, are

E. *cochleatum*, Linn. Sp. Pl. 1351. Curt. Mag. t. 572. Jacq. Ic. Rar. t. 605. Andr. Repoſ. t. 13. A native of Jamaica, and the firſt of its tribe that ever flowered in England. It is cultivated in a ſtove, in rotten bark, contrived ſo as to imitate, as much as poſſible, its natural ſituation in the clefts of aged trees, with occaſional ſupplies of water. The *bulbs* are green and ſmooth, of a compreſſed oval figure, each throwing out from its baſe numerous thick entangled fibres, which naturally adhering to the rugged bark, ſtrongly fix the plant and imbibe nouriſhment for its ſupport. A pair of oblong, rigid, recurved *leaves*, entire, as in all this natural order, ſpring from the ſummit of each bulb, and between them grows a *ſtalk*, about a foot high, bearing a ſpike of ſeveral *flowers*. Theſe are reverſed, the long pale-greeniſh calyx and petals hanging down, while the broad, concave, ſomewhat cordate nectary, of a chocolate hue ſpeckled with green, ſtands erect. The flower has little or no ſmell.

E. *fragrans*. Sw. Prod. 123. (E. cochleatum; Curt. Mag. t. 152.) A native alſo of Jamaica, flowered in the ſtove of Chelſea garden, under Mr. Fairbairn's care, in Feb. 1789. This has much reſemblance to the foregoing, but the *petals* are broader, the *nectary* pale ſtreaked with red, and tipped with a long point, and the flowers have a ſweet ſmell. The *ſtalk* moreover is ſhorter in this ſpecies than the *leaves*.

E. *amabile*. Linn. Sp. Pl. 1351. (Angræcum album majus; Rumph. Amb. lib. xi. 99. t. 43.) Native of the Eaſt Indies. This has beautiful white *bloſſoms*, twice as large as in Rumphius's plate, on a long ſlender branched *ſtalk*. The lip is five-lobed, and terminates beſides in a pair of very long, taper, almoſt capillary points. It would be a great acquiſition to our ſtoves.

E. *nutans*. Sw. Prod. 121. A native of Jamaica, flowered in Kew gardens in March 1791. This has a leafy *ſtem*, terminated by a ſtalk bearing a few pale *flowers*, whoſe lip is four-lobed. They are about the ſize of E. *fragrans*.

E. *ciliare*. Linn. Sp. Pl. 1349. Curt. Mag. t. 463. is a beautiful and magnificent plant, native of the Weſt Indies, which flowered at Mr. Whitley's nurſery, Old Brompton, for ſeveral years before 1799. (*Curtis.*) The *flowers* are numerous and fragrant; their calyx-leaves and petals each near two inches long, of a yellowiſh buff-colour; lip white, with two elegantly fringed lobes. This ſpecies is now not very rare in the Engliſh ſtoves.

E. *fuſcatum*. Sm. Spicil. t. 23. is rather ſingular than ornamental. The late Hon. Mrs. Barrington received it from Jamaica, and it bloſſomed in her garden in 1791. The *ſtem* is leafy, and terminates in a very long ſimple ſcaly ſtalk, bearing a denſe corymbus of ſmall *flowers*, which, like the whole plant, are of a brown purpliſh hue.

Several ſpecies, more or leſs a-kin to this laſt, occur in the works of Jacquin, as well as ſome more ſplendid ones with tall branching ſtalks, none of them yet introduced into our gardens.

EPIDERMIS, in *Anatomy*, is the thin inſenſible membrane which covers the true ſkin, and which conſtitutes, therefore, in all parts, the external ſurface of the body. See Skin.

Epidermis, in *Vegetable Anatomy*, from ἐπὶ, *upon*, and δέρμα, the *ſkin*, or *hide*, is the ſcarf ſkin, or pellicle, which covers every part of a living plant, as a ſimilar cuticle covers the human ſkin. In the tender growing parts of vegetables this membrane is of the moſt delicate texture, pellucid and colourleſs, extremely thin, yet not deſtitute of tenacity, being wonderfully extenſible on ſtalks, or other parts, of quick growth. Under a high magnifier it is found to be porous in a regular manner, and differently in different plants, ſo as to allow of the paſſage of fluids in a definite degree, in either direction, according to the nature of each plant. Hence ſome leaves perſpire ſlowly, but imbibe moiſture with great rapidity, as thoſe of the ſucculent tribes; while others tranſmit their fluids, or imbibe external moiſture, with nearly equal facility, as aquatics. Such differences are detected by experience, but ſcarcely diſcoverable by microſcopical inveſtigation.

The *Epidermis* is of the moſt eſſential importance to the life of the plant, as of the animal, protecting the living parts which it covers from the injuries of the air, while it allows of due perſpiration and abſorption, as well as of the action of light through its nearly colourleſs ſubſtance. It differs greatly in thickneſs according to the part of the plant to which it belongs. Exquiſitely delicate on the fine organs of a flower, like the cuticle of the animal eye, it has conſiderably more ſubſtance on the leaf, and ſtill more on the branch

branch of a tree. On old trunks it is generally obliterated or deftroyed, being there no longer neceffary, the dead layers of bark, (fee BARK and CORTEX,) anfwering all the purpofes of protection, while the peculiar functions of an organized porous *epidermis* are not wanted. Yet in the birch, and a few other trees, the membrane in queftion confifts of multiplied permanent layers, like the bark, and clothes the trunk as long as that part exifts. The cuticle is eafily feparable from young ftalks in a rapid ftate of vegetation, and from any part of a plant by means of maceration, boiling or putrefaction, being nearly, if not abfolutely, deftitute of vitality, and very little fubject to decompofition.

Befides the effential office of a guard to the living vegetable body againft all hurtful ftimulants, the *epidermis* anfwers many fecondary purpofes of protection. When naked, as ufual, it proves but a feeble defence againft heat or cold, but it is often covered with hair or wool, in which cafe it becomes a very powerful one, particularly againft the too violent action of a burning fun. Flowers indeed, though peculiarly prefented to all the force of this luminary, have fcarcely ever any fuch woolly or downy defence; for the functions which they have to perform are often urgent with refpect to light and heat. Many petals, notwithftanding, are filky or downy on their outfide, apparently to protect them from cold, or poffibly from too fcorching a heat before they are full-grown, examples of which may be feen in *Convolvulus*, *Anemone*, and feveral other genera; but the infides of fuch petals are exquifitely fmooth.

Examples of a very firm fmooth *epidermis*, of confiderable ftrength and thicknefs, may be found in the common currant, *Ribes rubrum*, the elder, *Sambucus nigra*, and the laburnum, *Cytifus Laburnum*. On the branches of the latter it acquires almoft a horny hardnefs; but it is ftill more cartilaginous in the hard white tubercles fprinkled over the leaves of *Aloe perlata*, and in the teeth of the foliage of fome *Saxifragæ*, as well as the briftly warts of feveral fpecies of *Echium* and others of the *afperifoliæ*. On the leaf of the white willow, and the *Protea argentea*, the cuticle has a fine filky clothing of a filvery hue; while in many more plants it is equally white, but deftitute of glofs. In the leaf of many kinds of mullein, *Verbafcum*, and the fruit of the peach, we find it denfely covered with hairs, more or lefs branched. The herbage of the betony, *Betonica officinalis*, is clothed with rigid briftles, fixed upon the cuticle, which in a dry ftate excite fneezing. Similar hairs on the cuticle of the ftinging nettle are curioufly perforated, to tranfmit a venomous fluid lodged in bags at their bafe, like the poifon in a ferpent's tooth. Graffes, corn and horfetail, *Equifetum*, have much flinty earth in their *epidermis*; while in the cork-tree, the common maple, and the Dutch elm, the fame part is of a foft elaftic fungous fubftance. The fruit of the plum, and leaves of the cabbage, have their *epidermis* covered with a fine blueifh powdery refinous fecretion, which will fcarcely allow rain to come in contact with them, yet fuch plants readily abforb moifture.

Nothing can be more abfurd than the idea which fome philofophers have formerly entertained, that the *epidermis* was deftined to give fhape to a plant, and that certain lumps or excrefcences on the ftems of trees were originally owing to a cafual wound or crack in this membrane. This opinion is eafily refuted by purpofely making fuch a wound or opening, when it will be found that no tumour can be produced by any fuch means; fpontaneous tumours being in reality the caufe, not the effect, of the burfting of the *epidermis*. S.

EPIDICASIA, Επιδικασια, among the *Athenians*. Daughters, inheriting their parents' eftate, were obliged to marry their neareft relations; which gave occafion to perfons of the fame family to go to law with one another, each pretending to be more nearly allied to the heirefs than the reft. The fuit was called επιδικασιας δικη; and the virgin, about whom the relations contefted, επιδικος. Pott. Archæol. Græc. lib. 1. cap. 24. tom. i. p. 147.

EPIDIDIUM, in *Ancient Geography*, is the name which Ptolemy gave to that peninfula on the weftern coaft of Scotland, which forms part of the county of Argyle, called Cantyre and Knapdale; and including the ifles of Iflay and Jura, which the Roman geographer confidered as being part of it: but whether it then was integral, or not, cannot be afcertained from his account. The peninfula might at an early period have been an ifland; fuch changes has the fea made upon our furge-beat coafts: for "Dr. Smith derives this name from a fimilar Celtic word, fignifying the ifle of the Picts, who at that time were the principal inhabitants of that part of Scotland." Sir John Sinclair's Stat. Acc. vol. x. p. 519. But fuch a conclufion is not juftifiable by the rules of Celtic derivation. *Cyn*, in that language, fignifies a wedge, and *tor*, land or territory; it is, therefore, obvioufly derived from thofe two etymons conjoined, perfectly defcriptive of fuch a tongue of land, *i. e.* a wedge-fhaped territory. Mr. Baxter imagines the Pepidii, fynonymous with Epidii, to have derived their name from the Britifh word Papidiauc, which fignifies any thing fhaped like a flute or pipe, as was the peninfula of Cantyre, the country of the Pepidii. From the fouthern point, called the mull of Cantyre, promontorium Epidium, the coaft of Ireland may be plainly feen; it being only 16 miles to the fouth foreland in Coleraine.

EPIDIDYMIS, in *Anatomy*, a part of the tefticle, fituated behind the body of that organ, and confifting of its excretory duct in a wonderfully convoluted form. It ends in a ftraight tube, called the vas deferens. See TESTIS.

EPIDO'SIS, from επιδιδωμι, *to increafe*, in *Surgery*, a preternatural enlargement of parts.

EPIDOT. See STRAHLSTEIN.

EPIDOTES, from επιδιδωμι, *I caufe to grow*, in *Mythology*, deities which were fuppofed to prefide over the growth of infants.

EPIDROME, from επι, *upon*, and δρεμω, *to run*, in *Surgery*, an afflux of fluids, or, as they were formerly phrafed, humours, efpecially when it arofe from the application of a ligature round any part.

EPIDROMUS, of επι and δρομος, *courfe*, in the *Ancient Shipping*, a fail near the ftern, which was the largeft but one in the fhip.

EPIECIA, in *Ancient Geography*, a town of Greece, towards the fea, and not far from Corinth; N. of Tenea.

EPIEZ, in *Geography*, a town of France, in the department of the Loiret, and diftrict of Beaugeney; 12 miles E. of Orleans.

EPIGÆA, in *Botany*, from επι, *upon*, and γεα, *the earth*, expreffive of the proftrate growth of this humble fhrub. Linn. Gen. 219. Schreb. 295. Willd. Sp. Pl. v. 2. 615. Mart. Mill. Dict. v. 2. Juff. 161. Clafs and order, *Decandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Ericæ*, Juff.

Gen. Ch. *Cal.* Perianths double, clofe together, permanent; the outer of three ovato-lanceolate, pointed leaves, of which the external one is larger than the reft; inner in five deep, upright, lanceolate, pointed fegments, fomewhat longer than the outer. *Cor.* of one petal, falver-fhaped; tube rather longer than the calyx, hairy within; limb fpreading, in five deep ovate-oblong lobes. *Stam.* Filaments ten, thread-fhaped, the length of the tube, and inferted into its bafe; anthers oblong, acute. *Pift.* Germen globofe,

globofe, with five furrows, downy; ftyle cylindrical, as long as the ftamens; ftigma obtufe, in five lobes. *Peric.* Capfule nearly globular, depreffed, with five angles, five cells, and five valves. *Seeds* numerous, roundifh. *Receptacle* large, feparating into five parts.

Eff. Ch. Outer calyx of three leaves; inner in five deep fegments. Corolla falver-fhaped. Capfule of five cells, with a central five-parted receptacle bearing the feeds.

The fpecies are two.

1. E. *repens.* Linn. Sp. Pl. 565. Swartz Prod. 74. Andr. Repof. t. 102. Lamarck Illuftr. t. 367. f. 1. "Leaves ovate, inclining to heart-fhaped, entire. Tube of the corolla cylindrical." Native of pine forefts in Virginia and Canada, but, like many plants of a cold or alpine climate, difficult to preferve in our gardens. It flowers in April or May. The *root* throws out many woody, procumbent, creeping, branched, hairy, leafy *ftems*, which form wide-fpreading patches. *Leaves* alternate, on hairy foot-ftalks, ovate, obtufe, entire, heart-fhaped at the bafe, veiny, fhining, but roughifh to the touch. *Stipulas* none. *Flowers* in terminal, denfe, bracteated clufters, fragrant, of a pale blufh-colour, each about the fize of a fmall cowflip. It is increafed by parting the roots, thrives in a light fandy loam, but requires the fhelter of a long-continued deep fnow, or fome equivalent protection, to furvive our winters. We faw it in great perfection at Meffrs. Lee and Kennedy's nurfery, Hammerfmith, in 1797.

2. E. *cordifolia.* Swartz Prod. 73. Lamarck Illuftr. t. 367. f. 2. "Leaves heart-fhaped, roundifh, ferrated, convex, hifpid, rigid. Tube of the corolla ovate." Native of boggy places on the higheft mountains of Guadaloupe and Cayenne. Smaller than the former, with pointed and more hifpid *leaves*, whofe foot-ftalks are very fhort. *Flowers* in like manner terminal, but with a more inflated tube. The young fhoots are very hairy.

Epigæa, in *Gardening*, comprehends a plant of the low, trailing, fhrubby, flowering kind. This is the creeping epigæa, or trailing arbutus (E. repens).

Method of Culture.—This is readily effected in this plant by the trailing ftalks, which foon put out roots at the joints, and may then be cut off from the old or parent plants, and be fet out in a fhady fituation, where the foil is moift, in the autumnal feafon, that the plants may be well eftablifhed before the fpring. In cafes where the winter proves fevere, it may be neceffary to lay a few dried leaves, or other light covering over them, to protect them from froft; but after they become well rooted, they feldom require more than being kept clean from weeds.

Thefe are ornamental plants in the fronts of the borders of fhrubberies.

EPIGASTRIC Artery, in *Surgery.* The proper mode of operating in certain cafes of ruptures, fo as not to run any rifk of wounding this veffel, will be explained in the article Hernia.

Epigrastric *Region*, in *Anatomy*, one of thofe portions, into which the cavity of the abdomen is divided by anatomifts in their defcriptions. "The epigaftric region," fays Winflow, "begins immediately under the appendix enfiformis at a fmall fuperficial depreffion, called the pit of the ftomach, and in adult fubjects ends above the navel at a tranfverfe line, fuppofed to be drawn between the laft falfe ribs on each fide.

"This region is fubdivided into three parts, one middle, named epigaftrium, and two lateral, termed hypochondria. The epigaftrium takes in all that fpace which lies between the falfe ribs of both fides, and the hypochondria are the fpaces covered by the falfe ribs." Sect. 7. § 79, and 80.

EPIGASTRIUM. See Epigastric.

EPIGINOMENA, of επιγινομαι, *I fupervene*, in *Medicine*, are new fymptoms which occur in the progrefs of a difeafe. See Epiphenomena.

EPIGLOTTIS, in *Anatomy*, is a fmall and thin piece of cartilage, placed at the back of the tongue, and having the office of clofing the glottis, or opening of communication between the larynx and pharynx, when the food is paffing into the latter cavity from the mouth. The anatomical defcription of this part will be found in the article Larynx; its offices are defcribed in that of Deglutition.

EPIGONIUM, επιγονιον, a mufical inftrument among the ancients, with forty ftrings, fo called from its inventor Epigonius, a native of Ambracia, a city of Epirus. Mem. Acad. Infcript. vol. v. p. 167.

EPIGONIUS, in *Biography*, was a mathematician of Sicyon, and a native of Ambracia, who is celebrated by the ancients for the invention of an inftrument of forty ftrings, which was called after his name, Epigonium. When he lived is uncertain, but as it was in times of fimplicity, we may fuppofe that thefe ftrings did not form a fcale of forty different founds, but that they were either tuned in unifons and octaves to each other, or accommodated to different modes and genera. The 12 femi-tones of our three-ftopt harpfichords included thirty-fix different ftrings.

The Greeks were divided into numerous fects of mufical fpeculators, before and after the time of Ariftoxenus: as the Epigonians, Damonians, Eratoclians, Agenorians, and many others enumerated by Porphyry, in his Commentary on the Harmonics of Ptolemy. Of thefe, however, all we know is, that they *differed*; it is, perhaps, little to be lamented, that we no longer know about *what*.

Mufic has many obligations to Epigonius. He was the firft who played on ftringed inftruments without a *plectrum*. And, according to Athenæus, he firft united the melody of flutes to that of the citharas; and by this means foftened the harfhnefs and inflexibility of the citharas when played alone. He invented the chromatic genus, and was the original author of chorufes.

EPIGRAM, in *Poetry*, a fhort poem, or compofition in verfe, treating only of one thing, and ending with fome point, or lively ingenious thought.

The word is formed of επιγραμμα, *infcription*, of επιγραφειν, *to infcribe*, or *write upon*.

Epigrams then, originally, fignify *infcriptions*, and they derive their origin from thofe infcriptions placed by the ancients on their tombs, ftatues, temples, triumphal arches, &c. See Inscription.

Thefe, at firft, were only fimple monograms: afterwards increafing their length, they made them in verfe, to be the more eafily retained: Herodotus, and others, have tranfmitted to us feveral of them.

Such little poems retained the name of epigrams, even after the defign of their firft inftitution was varied, and people began to ufe them for the relation of little facts and accidents, the characterifing of perfons, &c.

The Greeks confine their epigrams to a very narrow compafs; for though, in the Anthology, we here and there meet with a very long one; yet, ordinarily, they do not exceed fix, or, at moft, eight verfes. The Latins were not always fo fcrupulous, and the moderns much lefs, as to thefe bounds.

M. le Brun, in the preface to his "Epigrams," defines an epigram a little poem, fufceptible of all kinds of fubjects, and ending with a lively, juft, and unexpected thought; which are three qualifications effential to the epigram; particularly

ticularly the firſt and laſt of them, *viz.* brevity, and the point or cloſe of the epigram.

To attain brevity, only one thing is to be aimed at in the poem, and that to be purſued in the conciſeſt terms poſſible. Authors are much divided as to the length the epigram is to be confined to; the ordinary limits are from two to twenty verſes; though we have inſtances, both among the ancients and moderns, where they extend to fifty. But ſtill it is allowed, that the ſhorter the better, and more perfect, as it partakes more of the nature and character of this kind of poem. The point or turn is a quality much inſiſted on by the critics, who require the epigram conſtantly to cloſe with ſomething poignant and unexpected, to which all the reſt of the compoſition is only preparatory. Others there are, who exclude the point, and require the thought to be equally diffuſed throughout the whole poem, without laying the whole ſtreſs on the cloſe: the former is uſually Martial's practice, and the latter that of Catullus. Which is the moſt beautiful and perfect manner is diſputed by a third claſs of critics.

The Greek epigrams have ſcarce any thing of the point or briſkneſs of the Latin ones: thoſe collected in the Anthology have moſt of them a remarkable air of eaſe and ſimplicity, attended with ſomething juſt and witty; ſuch as we find in a ſenſible peaſant, or a child that has wit. They have nothing that bites, but ſomething that tickles. Though they want the ſalt of Martial, yet, to a good taſte, they are not inſipid; except a few of them, which are quite flat and ſpiritleſs. However, the general faintneſs, and delicacy of the pleaſantry in them, has given occaſion for a Greek epigram, or "epigram à la Greque," to denote, among the French, an epigram void of ſalt or ſharpneſs.

It is principally the point that characterizes the epigram, and diſtinguiſhes it from the madrigal. See POINT.

In the modern verſification, as obſerved by F. Mourgues, the epigram and madrigal are diſtinguiſhed by the number of verſes and the cloſe. 1. By the number of verſes, which in the modern epigram does not go beyond eight, nor in the modern madrigal comes ſhort of ſix; and, 2. In that the cloſe, or period, of the epigram, has always ſomething more lively and ſtudied than that of the madrigal.

The epigram is the loweſt, and leaſt conſiderable of all the productions of poetry; and it is in general rather an effect of good luck, than of art, to ſucceed therein. The fineſſe, and ſubtilty, of the epigram, M. Boileau obſerves, ſhould turn on the words rather than the thought; which ſeems very little to the credit of this kind of compoſition, as it reduces it to the nature of the pun, or equivoque. F. Bouhours confirms the hint, in adding that the equivoque is what uſually ſhines the moſt in the epigram.

One great beauty of the epigram is, to leave ſomething for the reader to gueſs, or ſupply. Nothing pleaſes the mind ſo much, as to find ſomething in itſelf in the objects preſented it; nor does any thing diſguſt it more than to preclude it from ſhewing and exerciſing a faculty it values itſelf for. Segrais.

The epigram admits of great variety of ſubjects: ſome are made to praiſe, and others to ſatirize, which laſt are much the eaſieſt; ill-nature ſerving inſtead of point and wit. Boileau's epigrams are all ſatires on one or another. Thoſe of Des Reaux are all made in honour of his friends; and thoſe of Mad. Scudery are ſo many eloges. The epigram being only a ſingle thought, it would be ridiculous to expreſs it in a greater number of verſes; it muſt have its unity like the drama. The comedy has an action for its ſubject, and the epigram a thought.

We might ſelect a number of excellent epigrams in our own language, if our limits allowed of enlarging this article. We ſhall content ourſelves with ſubjoining the following. The firſt is that of Mr. Pope, ſaid to be written on a glaſs with the earl of Cheſterfield's diamond pencil.

"Accept a miracle, inſtead of wit,
See two dull lines by Stanhope's pencil writ."

The next is an epigram, expreſſed conciſely and cloſing beautifully, which was written on the leaves of a fan by Dr. Atterbury, late biſhop of Rocheſter:

"Flavia the leaſt and ſlighteſt toy
Can with reſiſtleſs art employ.
This fan in meaner hands would prove
An engine of ſmall force in love;
Yet ſhe with graceful air and mien,
Not to be told or ſafely ſeen,
Directs its wanton motion ſo,
That it wounds more than Cupid's bow.
Gives coolneſs to the matchleſs dame,
To every other breaſt a flame."

Mr. Prior laſhed the impertinence of a bad writer, who had taken the liberty of cenſuring him, in the following epigram:

"While faſter than his coſtive brain indites,
Philo's quick hand in flowing letters writes.
His caſe appears to me like honeſt Teague's,
When he was run away with by his legs:
Phœbus, give Philo o'er himſelf command;
Quicken his ſenſes, or reſtrain his hand.
Let him be kept from paper, pen, and ink,
So he may ceaſe to write, and learn to think."

The following epigram was written by Mr. Weſley, on occaſion of erecting a monument to Mr. Butler, author of Hudibras, in Weſtminſter Abbey:

"While Butler, needy wretch, was yet alive,
No generous patron, would a dinner give.
See him, when ſtarv'd to death, and turn'd to duſt,
Preſented with a monumental buſt!
The poet's fate is here in emblem ſhown,
He aſk'd for *bread*, and he receiv'd a *ſtone*."

See BUTLER.

EPIGRAPHE, Επιγραφη, *Superſcription*, an inſcription on a building, to ſignify its uſe, occaſion, the time when, and the perſon by whom it was built.

EPIGRAPHES, Επιγραφεις, among the Athenians, officers that rated all thoſe of whom taxes and contributions were required, according to every man's ability, kept the public accounts, and proſecuted ſuch as were behindhand with their contributions. Potter. Archæol. Græc. lib. i. cap. 14. tom. i. p. 81.

EPILA, in *Geography*, a town of Spain, in the province of Arragon, on the Xiloca; 17 miles W. of Saragoſſa.

EPILEPSY, in *Medicine*, ἐπιληψία, and ἐπιληψις, ſignifying *ſudden ſeizure*, is a diſeaſe which conſiſts of convulſions of the greater part of the muſcles of voluntary motion, attended with a loſs of ſenſe and feeling, and ending in a ſtate of inſenſibility, and ſeeming ſleep.

This diſeaſe has received a variety of denominations, eſpecially among the ancient writers. By the early Greeks it was called the *ſacred diſeaſe*, from a notion of its origin in ſupernatural fupernatural influence ; fome of the exorcifts and impoftors of thofe times even pretended to decide, from variations in the fymptoms, whether the fits were occafioned by Cybele, Neptune, Mars, or fome of the heroes. Hippocrates feems to have been the firft who combated thefe abfurd notions of his countrymen ; and feverely reprehends the impoftures of the exorcifts, in pretending to fet afide what more than human power had inflicted, by incantations, magic ceremonies, and fometimes by the moft contemptible juggling. (See Hippoc. de *Morbo Sacro.*) Aretæus, however, remarks that it might have the denomination of *facred* on other accounts ; either from its magnitude, every thing great being deemed facred ; or becaufe it could not be removed by human means, but only by divine power ; or from the opinion that a dæmon had entered into the patient, or for all thefe reafons together. (De Caufis Affect. lib. i. See alfo Cæl. Aurelian. De Morb. Chron. lib. i. cap. iv.) In like manner the Romans call every thing remarkable and great "facred :" "*facra* anchora," "auri *facra* fames," &c. (Van Swieten. § 1071.) Upon the fame ground epilepfy has been called morbus *Herculeus*, the Herculean difeafe. By the Romans, it was fometimes termed morbus *comitialis*, "the affembly difeafe ;" either becaufe epileptic perfons were more frequently obferved to be feized in a crowd of people, or becaufe the public meetings, called *comitia*, were adjourned if any one happened to be attacked with an epileptic fit. It has likewife been termed morbus *caducus*, or "falling ficknefs," becaufe the patients, when they are feized with the paroxyfm, fall down.

The leading features and principal circumftances of the epileptic convulfions are nearly the fame in all the different perfons whom the difeafe affects. The difeafe confifts of fits, which attack fuddenly often thofe who are feemingly in perfect health, and, after lafting for fome time, pafs off, and leave the perfons again in their ufual ftate.

The individual attacked lofes fuddenly all fenfe and power of directing his mufcular actions ; fo that, if ftanding or fitting, he falls immediately, or perhaps with convulfions is thrown to the ground. In that fituation he is agitated with violent convulfive actions, varioufly moving his limbs and the trunk of his body, with a force that is altogether preternatural. Commonly the limbs on one fide of the body are more violently agitated than thofe upon the other. In all cafes the mufcles of the face and eyes are much affected, exhibiting various and violent diftortions of the countenance. The tongue is often affected, and thruft out of the mouth, while the mufcles of the lower jaw are alfo affected, and, fhutting the mouth with violence, often wound the tongue grievoufly. While thefe convulfions continue, the face becomes red, then livid and fwelled, from the interruption to the circulation through the head, and there is commonly at the fame time a frothy moifture iffuing from the mouth ; and in the moft fevere cafes the urine and alvine excrements are involuntarily difcharged. In fome inftances a hiffing or ftertorous noife is emitted. The convulfions have for a few moments fome remiffions, but are fuddenly again renewed with great violence. Generally, after no long time, this terrible ftruggle ceafes altogether, and the patient remains for fome time without motion, in a ftate of abfolute infenfibility, and under the appearance of a profound fleep. After fome continuance of this feeming fleep, he fometimes fuddenly, but for the moft part by degrees only, recovers his fenfes and power of motion, but without any memory of what had paffed from the firft feizure of the fit, and complaining of head-ache, and exceffive pain in all the limbs as if from fevere fatigue. During the convulfions the pulfe and refpiration are hurried and irregular ; but, when the convulfions ceafe, they return to their ufual regularity and healthy ftate.

In moft cafes the attack of epilepfy comes on fuddenly, without any warning fymptom : but fometimes it is preceded by certain fenfations for a few moments previous to its actual commencement. Of thefe the moft remarkable is that, which has been termed the *Aura epileptica ;* which is a fenfation of fomething moving in fome part of the limbs or trunk of the body, and from thence creeping upwards to the head ; and when it arrives there, the perfon is immediately deprived of fenfe, and falls into an epileptic fit. This feeling is defcribed fometimes as refembling that of a cold vapour, fometimes as like a fluid gliding, and fometimes like the fenfation of a fmall infect creeping along the body ; and very often the patients can give no other diftinct idea of their fenfation, than as in general of fomething moving along. It might be fuppofed that this fenfation arofe from fome affection of the extremity or other part of a nerve, acted upon by fome irritating caufe ; and that the fenfation, therefore, followed the courfe of fuch a nerve. But it is not found to follow the courfe of any nerve diftinctly, and it generally feems to pafs along the integuments. There are occafionally alfo other fymptoms immediately preceding the fit, and generally referred to the head, where no *aura* is perceived. In fome perfons a giddinefs comes on ; in others a fpark of light, which increafed to a bright beam, ufually ufhers in the paroxyfm ; depending probably on the fudden turgefcence of the veffels in the head, which produces preffure on the optic nerve, and occafions this depraved fenfation. Dr. Gregory ufed to mention in his lectures, at the college of Edinburgh, the cafe of an officer, who had a more fingular perverfion of fight, previous to the fit of epilepfy ; he always fancied that he faw an apparition of an old woman, with a blue cloak, holding a ftaff in her hand, with which fhe knocked him down. He alfo mentioned an inftance of vifual depravation which occurred to Dr. Fothergill ; a young lady, whom the Dr. was attending as an epileptic patient, remarked that he was covered with fpangles, (the more unufual as an ornament to a quaker's coat,) and immediately fhe fell down in a fit.

Under the article CONVULSIONS we have entered into a detail of the circumftances which conduce to their origin and production ; and as the whole of thofe obfervations apply to the epileptic convulfions moft particularly, it will not be here neceffary to repeat them. We have there ftated that convulfions occur under two oppofite conditions of the body, *viz.* of *repletion* and *inanition ;* or, in the language of Dr. Cullen, of *excitement* and *collapfe* (Firft Lines, § 1286.) : and that various *irritations* in different parts of the body, but efpecially in the head, give rife to them in different inftances.

Sauvages has defcribed a great variety of fpecies of epilepfy, which he has diftinguifhed chiefly according to the caufes which produced them. Dr. Cullen has mentioned only three fpecies, which (as to the utility of divifion with a view to the curative indications) might be reduced to two. His firft fpecies is epilepfia *cerebralis* (from *cerebrum*, the brain), which attacks fuddenly, without any evident caufe, or preceding fenfation, except perhaps a giddinefs or deprivation of fight ; and includes the *plethoric* epilepfia and eclampfia of Sauvages, as well as his *cachectic* epilepfy. The fecond fpecies, is E. *fympathica*, in which the *aura epileptica*, before defcribed, precedes the attack ; a circumftance which is fcarcely of fufficient importance to defignate a fpecies. The third, E. *occafionalis*, includes thofe inftances of epilepfy which originate from manifeft and accidental irritation, and which fubfide when the irritation

tation is removed. Thefe various caufes of irritation are, wounds, or blows of the head, from falls, and other external injuries; pain in various degrees, as from parturition, dentition, worms in the alimentary canal; indigefted food, or other fubftances in the ftomach, as narcotic poifons, fpirituous liquors, &c; paffions of the mind, efpecially fear; and a variety of other fources of difturbance to the fyftem, as the eruption of fmall-pox, and other febrile irritations, the venereal orgafm, intenfe ftudy, the fuppreffion of cuftomary difcharges, &c.; and, laftly, the imitative propenfity, which is particularly confpicuous in women and children, as illuftrated at large under the head of CONVULSIONS.

We have there ftated the impoffibility of explaining the proximate caufe of convulfive difeafes, in confequence of our ignorance of the nature of the nervous power, or of the connection between the action of the mufcles and the brain, or the faculty of volition, in a ftate of health. And it were fufficient to mention the attempts to reafon upon the fubject, which the ableft phyficians have made, in order to prove their futility. The learned Boerhaave fays, (*Aph.* 1086.) "Et patet quidem, caufam proximam omnis epilepfiæ exquifitæ femper effe nimiam cerebri in nervos motorios, nullam in fentientes, actionem." "It is obvious that the proximate caufe of every perfect epilepfy is always too great an action of the brain upon the nerves of motion, and too little upon thofe of fenfe:" which is only ftating the fact in other words; for it amounts merely to this: "in every true epilepfy the motions of the body are violent, and the fenfe is loft: the proximate caufe is ftill as obfcure as before." Dr. Cullen fcarcely pretends to form a theory upon the fubject. "I might fay," he obferves, "that it is an affection of the energy of the brain, which, ordinarily under the direction of the will, is here, without any concurrence of it, impelled by preternatural caufes. But I could go no further: for as to what is the mechanical condition of the brain, in the ordinary exertions of the will, I have no diftinct knowledge; and therefore muft be alfo ignorant of the preternatural ftate of the fame energy of the brain under the irregular motions here produced." (Firft Lines, § 1284.) The indications of cure therefore cannot be formed from a knowledge of the proximate caufe of the difeafe; but we obtain fome ufeful intimations for the treatment, by diligently attending to the various remote caufes; both thofe which induce a predifpofition, and thofe which occafionally excite the difeafe. Our principal object, then, will be to avoid the occafional caufes, and to remove or correct the predifponent.

The predifpofition to epilepfy, in the majority of inftances, feems to confift partly in what may be termed a morbid irritability, or mobility, of conftitution, in which the action of flight irritations (which are applied to moft perfons with impunity) excites great commotion in the nervous fyftem; and partly in a turgefcence of the veffels of the head, which accompanies a general plethora. This appears from the circumftances, that plethoric perfons are very frequently the fubjects of epilepfy; that it is often brought on by caufes inducing any unufual turgefcence of the blood-veffels; and that it has been frequently cured by diminifhing the plethoric ftate of the body, more frequently, we believe, than by any other fyftem of practice. This principle was inculcated by Dr. Cullen, and is ftrenuoufly adopted by the prefent Dr. Gregory, his fucceffor. It was likewife maintained by the late Dr. Fothergill, who has left us the following excellent remarks on this point of practice.

After ftating that many epilepfies occurred to him, which eluded all his endeavours to relieve them by means of the medicines ordinarily recommended as fpecifics, and which therefore fuggefted the neceffity of adpoting fome other mode of procedure, he fays, "I had obferved that fits were moft liable to return in the plenitude of health; that epileptics were often extremely incautious in refpect to diet; that children, highly indulged, were liable to the difeafe; that in every other period of juvenefcence, and in middle aged adults, if they were at all fubject to the difeafe, it was when they had either committed fome exceffes, or, by one means or another, were plethoric; and that, in habits fubject to epilepfy, the difeafe feldom recurred, without either an habitual indulgence in eating, or a neglect of neceffary exercife. This induced me to recommend, in many cafes, a total abftinence from all animal food, and from all fermented liquors. Care was taken to regulate the fecretions, and fuch a courfe of medicine prefcribed, as might feem expedient to induce the patients, or their friends, fcrupuloufly to comply with fuch a courfe of diet. It was in vain to reftrict the quantity of animal food. There are few who have, at all times, refolution enough to fubmit to the firft intimations of fatiety. It was, therefore, neceffary to enjoin fuch a kind of diet, as was accompanied with but flender provocations to excefs, and which, at the fame time, would afford the leaft quantity of nutriment; by which that fullnefs, which, in many epileptic cafes, appears to be a ftimulus fufficient to produce the fpafms, would be avoided, and the parts, which were the immediate feat of irritation, might gradually recover a degree of ftrength and firmnefs, that would be proof againft every flight impreffion.

"It often happens in difeafes, that a proper plan of diet is of much more importance in the cure than any thing we are acquainted with in the *Materia Medica*: it is, however, of not lefs neceffity to engage the patients and their friends in a fteady perfeverance of the method we direct. The generality of people have very little notion that diet can do more than merely fupport their ftrength; that it can be made fubfervient to the cure of their difeafes, they cannot eafily be brought to comprehend, &c.

"In young boys, I apprehend, the epilepfy moft generally proceeds from their own craving appetites, and the neglect of thofe who are about them. It may not be improbable, but in fuch cafes worms may alfo have a fhare in producing the fits. Be this as it may, anthelmintics, however powerful, feldom cure the difeafe; they may abate occafionally the frequency, or the violence of the attacks, but they too often, at the fame time, bring on a greater degree of irritability, and at length, if repeated frequently, and in confiderahle dofes, feldom fail of confirming the difeafe. Moderate laxatives, with a light chalybeate interpofed, and fteadily continued, with a courfe of diet, confifting of milk, vegetables, fruit, and things prepared from them, and in moderate quantities, feldom fail of removing the difeafe in fuch habits. Riding and bathing in cold water, and the ufual means of eftablifhing good health, muft, at the fame time, be attended to, and the plan purfued with patience; for it is not to be expected in difeafes that affect the nervous fyftem, the moft remote and fineft part of the economy, when once they have debilitated, or otherwife difordered, thefe very feeling parts, and their influence is become habitual, that after-medicines, however active, penetrating, and efficacious, can, in a very fhort time, reftore the ability to perform their functions as they ought to do." (See Medical Obf. and Inquiries, vol. vi. p. 72.)

This plan of light and moderate living, with occafional laxatives, fhould be adopted in every cafe of epilepfy, where it does not arife from lofs of blood, or other caufes of inanition, or is not connected with a cachectic or emaciated habit: and even in the laft cafe, the plan is often ufeful, efpecially

cially where a morbid change, fuch as exoftofis, fuppuration, or tumour of any kind, is going on in the head.

It might be fuppofed that artificial evacuations, efpecially blood-letting, would be the moft effectual means of diminifhing the plethoric ftate of the fyftem: and fuch it certainly proves, when the plethora has become confiderable; and if it threatens immediate difeafe, this evacuation ought to be made to the quantity that the urgency of the fymptoms feems to require. It is, however, a matter of old obfervation, that blood-letting is not the proper mode of preventing the recurrence of the plethoric ftate; but, on the contrary, that it is often the means of favouring it, efpecially when the operation is performed at regular periods. There is, however, a cafe of epilepfy, as Dr. Cullen remarks, in which there is a periodical or occafional recurrence of the fullnefs and turgefcence of the fanguiferous fyftem, giving occafion to a recurrence of the difeafe. In fuch cafes, when the means of preventing plethora have been neglected, or may have proved ineffectual, it is abfolutely neceffary for the practitioner to watch the returns of thefe turgefcences, and to obviate their effects by the only certain means of doing it, that is, by a large blood-letting. When the general plethora is not great, but the fymptoms indicate confiderable local turgefcence in the head, the application of cupping-glaffes, after fcarification of the neck, or the ufe of a feton, blifter, or iffue, near the fame part, will afford the means of fome relief, by the evacuations which they produce. An open iffue, indeed, in diftant parts, as in the arm, has been found ufeful in fome inftances of epilepfy, by tending to obviate the plethoric ftate, or, as Dr. Cullen fuggefts, by determining occafional turgefcences to thofe parts, and, therefore, diverting them, in fome meafure, from their action upon the brain.

Epilepfy, however, as we have already ftated, is alfo the refult of a ftate of debility, with which the exceffive nervous mobility that is eafily excited to convulfions is, in many other inftances, obferved to be connected; efpecially in hyfteria, in the condition of infancy, &c. Where this debility has been the confequence of inanition, as from lofs of blood, from previous difeafe, and fo forth, a nourifhing generous diet will be requifite to reftore the ftrength; and inftances are occafionally feen, in which the propriety and fuccefs of this practice are manifeft. Where there is obvioufly a feeble ftate of body, with pale complexion, and without any appearances of local plethora, the propriety of being much in the open air, of ufing the cold bath frequently, and of regular exercife, adapted to the ftrength and habits of the patient, muft be equally evident. He may ftill farther contribute to remove debility, and its confequences, efpecially that great mobility which is a principal part of the predifpofition to epilepfy, by the ufe of tonic and antifpafmodic medicines.

By a fort of routine, too generally purfued by indifcriminating practitioners, remedies of the laft mentioned claffes are moft commonly given in epileptic cafes, more particularly of late the metallic tonics, while the diet and regimen are not fufficiently attended to. However, as the circumftances of the conftitution occafionally favour their operation, it cannot be doubted that the difeafe has, in many inftances, been removed by thefe means; and numerous cafes are on record, in which particular fpecies of tonic remedies have effected the cure of epilepfy. The preparations of iron have been moft commonly employed for this purpofe, as the rubigo ferri, or the fulphat of iron, or its combination with ammonia (ferrum ammoniacale); and cures have been faid to be accomplifhed by all thefe preparations. Dr. Cullen, however, obferves, that he never found them effectual; which he attributes partly to their not having been always employed in the proper circumftances of the difeafe, and partly to the inadequate quantities in which they have been given. (Firft Lines, § 1335.) A preparation of copper, the cuprum ammoniacum of the Edinburgh Difpenfatory, has been one of the moft celebrated of the metallic tonics, and Dr. Cullen admits it to have been often fuccefsful. It fhould be given in the dofe of one grain at firft, twice in the day, and gradually increafed to as much as the ftomach will bear. Zinc, efpecially in the form of flowers of zinc, (as the oxide was formerly denominated,) has been much extolled for its virtues in the cure of epilepfy, and other fpafmodic difeafes, when it was ufed in fmall dofes. Much larger quantities of it, however, have been adminiftered lately, and its character of efficacy has been confiderably diminifhed. The fulphat of zinc, or white vitriol, appears to be a more efficacious tonic. Arfenic has more recently been introduced as a remedy for epilepfy. The fafety and great powers of this metal, as a medicine, efpecially in the cure of *periodical* diforders, fuch as intermittent fevers, megrim, or intermittent head-ache, &c. have been fully eftablifhed, and afford an analogy in its favour. A writer on this fubject, in the Edin. Med. and Surg. Journal (for July 1809) ftates, that he has found arfenic fuccefsful in the cure of epilepfy, when it "occurred in young fubjects, principally anterior to the age of puberty, and of what is termed a delicate make, and feeble ftamina, efpecially when the difeafe affumes, or very nearly approaches, a periodic form. The drunken epileptic likewife, when not of a full plethoric habit, has found a cure from the firm and judicious ufe of this potent remedy, due attention having been paid to the alvine evacuations." There is ftill another tonic of the metallic clafs, which has lately been recommended as an efficacious remedy for epilepfy, the nitrat of filver (or lunar cauftic), and is faid to have cured the difeafe, when it had already been of many years ftanding. (See two cafes of this nature, Med. and Phyf. Journal, vol. i. p. 184. vol. ii. p. 70.) A quarter of a grain of this active fubftance, given three times a day, is a fufficient dofe for an adult in the beginning; it may be afterwards carefully increafed.

The vegetable tonics are admitted to poffefs lefs efficacy in alleviating this dreadful diforder. Among thefe the bitters have chiefly been employed, and the cinchona is the moft active. Like the arfenic, it is efpecially adapted to thofe epilepfies which recur at certain periods, and which are not at the fame time accompanied with any plethoric ftate, or turgefcence of the blood: in fuch periodical cafes, if the bark is employed fome time before the expected recurrence, it may be ufeful; but it muft be given in large quantity, and as near to the time of the expected recurrence as poffible. The leaves of the orange tree have fometimes proved ufeful in this difeafe, probably by the bitter quality which they poffefs.

But this caution muft again be given, with refpect to the employment of any of the above-mentioned tonics in this difeafe, that in all cafes where it depends upon conftant or occafional plethoric ftate of the fyftem, thefe medicines are likely to be at leaft ineffectual; and if fufficient evacuations be not made at the fame time, they are likely to be very hurtful. The various fuccefs with which fuch remedies have been adminiftered is, doubtlefs, to be afcribed partly to inattention to thefe circumftances; although it is equally clear, that many epilepfies, connected with organic lefion in the head, or a connate diforder of the habit, are beyond the power of any medicine.

With a view of diminifhing the tendency to the convulfions of epilepfy, various antifpafmodic medicines have been employed,

employed, ſuch as valerian, caſtor, muſk, the fœtid gums, empyreumatic oils, and other ſubſtances of ſtrong and offenſive odour. But, although theſe remedies were generally adminiſtered at one period, and were much extolled for their antiſpaſmodic powers, they ſeem to have loſt their high character, in a great meaſure, and are much leſs employed than heretofore.

Several remedies have alſo been introduced, as *ſpecifics*, in the diſeaſe in queſtion; *i. e.* as remedies which poſſeſſed a peculiar influence over it, independently of any ſenſible quality or operation. Such are the viſcus quercinus, or miſletoe, the cardamine pratenſis, agaricus muſcarius, &c. Experience has not ſanctioned the recommendation of theſe medicines, which appear to be nearly inert. If the miſletoe were ever beneficial, it was probably in thoſe times when it was an object of religious ſuperſtition, and operated through the medium of an impreſſion on the mind. On the ſame principle, taking remedies that excited horror may have ſometimes ſucceeded in curing the diſeaſe; ſuch as the powder of human ſkulls, (pulvis cranii,) &c. A pamphlet has been publiſhed lately, however, in which the ſpecific efficacy of the miſletoe is again contended for by Dr. H. Fraſer. But the caſes, there related, are mentioned ſo briefly and uncircumſtantially, that no juſt inference as to the means of cure can be deduced; and the weight of negative evidence is, on the other hand, ſo great, that we are diſpoſed to attach little credit to the miſletoe. We have employed it, ſince the publication of the pamphlet alluded to; but without any effect.

Dr. Fothergill, whoſe experience and ſound obſervation led him to infer, that plethora was the moſt frequent cauſe of *curable* epilepſies, and the ſyſtem of diet and evacuation, before mentioned, the moſt effectual means of cure, was diſpoſed to attribute the reputed efficacy of all the laſt-named remedies for epilepſy to a very different operation, than was intended by the preſcriber: namely, to their impeding digeſtion, and conſequently preventing incurring plethora. "Valerian," he ſays, "caſtor, the fœtid gums, empyreumatic oils, and, if there be any thing ſtill more diſguſtful, commonly make a part of the medicines propoſed for this diſeaſe. There are ſome others, whoſe qualites, indeed, are not quite ſo repugnant to our taſte and ſmell, ſuch as the miſletoe, and the *flores cardamines*; but to balance this difference, it is requiſite to take theſe ſuch a length of time, and in ſuch quantities, as make them not leſs diſguſtful at length. May not, therefore, both theſe kinds of medicines, and moſt of thoſe made uſe of as ſpecifics from ancient authority, now and then confirmed with inſtances of benefit, derive the greateſt part of their conſequence from their quantity, or their diſguſting qualities, which, by leſſening the appetite, allow nature to recover herſelf, and ſhake off a diſeaſe, which indulgence principally produced." (Med. Obſ. and Inquir. vol. vi. p. 77.)

The ſight of others in a fit of epilepſy is the moſt common of the mental irritations which produce epilepſy: this, therefore, ſhould be guarded againſt, eſpecially among children, and more particularly in a family where epilepſy has already appeared. The famous caſes of epilepſy, thus communicated among the orphans at the hoſpital at Haerlem, are well known; (ſee Convulsions,) as well as Boerhaave's ſucceſsful cure, by threatening a ſevere puniſhment (burning with a hot iron) to the firſt who ſhould be ſeized with a fit. This counter-impreſſion upon the mind, which Dr. Cullen whimſically terms the *tonic* of fear, was ſufficient to obviate the effects of the other. (See Kaau Boerhaave impetum faciens, § 406.)

Some anti-epileptic powers have been attributed to opium, hyoſcyamus, or henbane, digitalis, and ſome other ſedative medicines; but it is obvious that theſe ſubſtances can only be ſerviceable in thoſe caſes where the diſeaſe depends upon irritation, or increaſed irritability, when their effects will be temporary; and that, when there is any plethoric or inflammatory condition preſent, they muſt, with the exception of digitalis, prove hurtful, eſpecially opium.

With reſpect to the fit itſelf nothing can be done, in general, except reſtraining the patient from injuring himſelf. He ſhould be removed from the ground, or from the vicinity of any hard body, againſt which he might be bruiſed by the convulſive motions of the limbs; and in thoſe caſes in which the tongue is apt to be protruded, and lacerated by the teeth, a ſort of gag ſhould be introduced. In very plethoric habits, where the determination of blood to the head is very great, it may be adviſeable to open a vein during the fit, in order to obviate the immediate danger of life, from a rupture of the veſſels of the brain.

When the fit is preceded by an *aura*, as before mentioned, which has been ſuppoſed to ariſe from irritation propagated along the courſe of ſome particular nerve, various means of preventing the fit have been ſuggeſted; ſuch as deſtroying the part, in which the *aura epileptica* ariſes, by means of the knife or cauſtic, applying a bliſter, or making an iſſue in it, or cutting the branch of the nerve along which the *aura* ſeems to paſs, or laſtly, applying a ligature upon the limb, above the part from which the *aura* ariſes. A tourniquet has been recommended for the laſt purpoſe, to be worn looſe upon the limb, and tightened the inſtant that the *aura* is perceived; by which means the epilepſy has been ſaid to have been prevented in ſeveral inſtances.

On diſſection after death from epilepſy, a variety of morbid and preternatural appearances have been in the head, to which the ſymptoms might be juſtly attributed, in conſequence of the mechanical irritation of the brain. Thus irregularity in the arrangement of the bones, or ſome other malformation of the cranium, inequalities or protuberances on its interior ſurface, ſplinters, or depreſſion of the bones from fracture; tumours, thickening, and oſſification in the membranes enveloping the brain; fluids of various acrimony effuſed, or collected within the brain, or on its ſurface, and tumours formed in the ſubſtance of the brain; have in various inſtances been diſcovered after epilepſy had proved fatal.

EPILESMON, from ἐπιλήθω, *I cauſe to forget*, a term uſed by the old writers in *Medicine*, to expreſs a loſs of memory.

EPILOBIUM, in *Botany*, a name adopted by Conrad Geſner, and explained by him as indicative of the character of this genus, ἐπὶ λοβοῦ ἴον, *a violet*, or beautiful flower, growing upon a pod; in which he is followed by Dillenius and Linnæus. See Bauhin's Pinax 245, ſect. 7; Dill. Plantæ Agri Giſſenſis, 132; and Linn. Phil. Bot. 176. Willow-herb.—Linn. Gen. 188. Schreb. 251. Willd. Sp. Pl. v. 2. 313. Sm. Fl. Brit. 409. Mart. Mill. Dict. v. 2. Juſſ. 319. Gærtn. t. 31. (Chamænerion; Tourn. t. 157.) Claſs and order, *Octandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Onagræ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, deeply four-cleft; ſegments oblong, pointed, coloured, deciduous. *Cor.* Petals four, roundiſh, broadeſt upward, cloven, ſpreading, inſerted into the calyx between its ſegments. *Stam.* Filaments eight, awl-ſhaped, alternately ſhorter; anthers oval, compreſſed, obtuſe. *Piſt.* Germen inferior, cylindrical, very long; ſtyle thread-ſhaped; ſtigma thick, obtuſe, either undivided or four-cleft, the lobes revolute, downy. *Peric.* Capſule very long, cylindrical, with four furrows, four

four cells, and four valves, with a longitudinal linear partition originating from the centre of each. *Recept.* columnar, fquare, its angles attached to the partitions, which at length feparate from it. *Seeds* numerous, oblong, crowned with down, and affixed in two rows to each angle of the receptacle.

Eff. Ch. Calyx in four deep fegments. Petals four. Capfule oblong, inferior. Seeds feathered.

An elegant genus of plants, with flowers of a paler or deeper rofe-colour, natives of watery or boggy fituations, chiefly in the cooler or mountainous parts of Europe. The *roots* in all are perennial, and often creeping. *Leaves* undivided. *Flowers* fpiked or racemofe, terminal. *Stamens* in fome direct, in others declining.

The fpecies in Willdenow are twelve, to which are to be added E. *rofeum,* Schreb. Lipf. 147. Sm. Fl. Brit. 411. Engl. Bot. t. 693, and E. *alfinifolium,* Villars Dauph. v. 3. 511. Engl. Bot. t. 2000, both by him made varieties of E. *montanum.* The Britifh fpecies therefore, at prefent afcertained, are nine.

E. *anguftifolium,* Linn. Sp. Pl. 493. Curt. Lond. fafc. 2. t. 24. Engl. Bot. t. 1947, called the French or Perfian Willow, or Rofebay Willow-herb, is one of the moft handfome, though moft common, of the whole. It rarely with us occurs wild, but thrives and bloffoms abundantly in any garden, whether the fituation be moift or dry, even in almoft any part of London. Linnæus fays, Fl. Lapp. n. 146, "it frequently, like a garden, furrounds the hut of the wild Laplander, who vies with Diogenes in the fimplicity of his houfehold furniture, but whofe habitation feems the palace of a divinity, when this ftately plant is in bloom." This is an inftance, among many, of a truly alpine plant fucceeding well in the fmoke of a city, while others require the pureft air poffible.

EPILOGUE, Epilogus, in *Oratory,* &c. The peroration, or laft part of a difcourfe, or treatife; containing ordinarily a recapitulation of the principal matters delivered.

The word is Greek, επιλογος, formed of the verb επιλεγω, *I fay after;* the epilogue being the end, or conclufion of a difcourfe.

Epilogue, in *Dramatic Poetry,* is a fpeech addreffed to the audience, when the play is over, by one of the principal perfons or actors in the piece; containing ufually fome reflections on certain incidents in the play, particularly thofe of the part of the perfon who fpeaks it.

In the modern tragedy, the epilogue has ufually fomewhat of pleafantry in it; intended, perhaps, to compofe the paffions raifed in the courfe of the reprefentation, and fend the audience away in good humour; though how far that defign is good and laudable will bear fome difpute: an ingenious author in the Spectator compares it to a merry jig on the organ, after a good fermon, to obliterate any impreffions that might have been made thereby, and fend the people away juft as they came.

In effect, though the epilogue, in this fenfe, may feem an abufe, yet has it the countenance of antiquity; the Romans had fomething of the fame nature, though under another name. Their exodium was a kind of farce, brought on the ftage when the tragedy was over: "ut quicquid lacrymarum ac triftitiæ cepiffent ex tragicis affectibus, hujus fpectaculi rifus detergeret," fays the fcholiaft of Juvenal. The epilogue is but of modern date, much later than the prologue. Many, indeed, have taken the exodium of the ancient Greek drama for an epilogue, becaufe Ariftotle defines it to be a part rehearfed after the chorus had fung for the laft time; but in reality, it was of a quite different nature. The exodium was the laft of the four parts of the tragedy: containing the unravelling and cataftrophe of the plot, and anfwering to our laft, or fifth act.

EPIMEDIUM, in *Botany,* as at prefent underftood, is certainly different from the επιμηδιον of Diofcorides, which feems to be *Ofmunda Lunaria,* though his defcription does not exactly agree even with that plant. The derivation of the name has always appeared obfcure. Ambrofini deduces it "from επιμυω, *to clofe,* or *fhut up,* becaufe the leaves conceal the flowers; or from επι μηδια, becaufe of its growing frequently in Media." Neither of thefe is fat sfactory, and the word feems rather to have a reference to the plant μηδιον, a *Campanula,* or fomething very near that genus, which immediately precedes it in Diofcorides. However this may be, the name *Epimedium* is now univerfally applied to the Barren-wort. Linn. Gen. 59. Schreb. 79. Willd. Sp. Pl. v. 1. 660. Sm. Fl. Brit. 187. Prod. Fl. Græc. 103. Mart. Mill. Dict. v. 2. Juff. 287. Tourn. t. 117. Clafs and order, *Tetrandria Monogynia.* Nat. Ord. *Corydales,* Linn. *Berberides,* Juff.

Gen. Ch. *Cal.* Perianth inferior, of four ovate, obtufe, concave, fmall, fpreading, deciduous leaves, placed directly under the petals. *Cor.* Petals four, ovate, obtufe, concave, equal, fpreading. Nectaries four, pouch-fhaped, blunt at the bafe, the fize of the petals and lying upon them, fixed to the receptacle by the edge of their orifice. *Stam.* Filaments four, awl-fhaped, preffed clofe to the ftyle; anthers oblong, erect, of two cells and two valves, the latter feparating from their bafe upwards, leaving the partition free. *Pift.* Germen fuperior, oblong; ftyle fhorter than the germen, as long as the ftamens; ftigma fimple. *Peric.* Pod oblong, pointed, of one cell and two valves. *Seeds* numerous, oblong.

Eff. Ch. Petals four. Nectaries four, pouches lying on the petals. Calyx oppofite to the petals, caducous. Pod fuperior, of one cell, with many feeds.

E. *alpinum.* Linn. Sp. Pl. 271. Engl. Bot. t. 438. Fl. Græc. ined. t. 150. Ger. em. 480. The only fpecies, a native of fhady mountainous places in feveral parts of Europe, not very difficult of cultivation in our gardens, flowering in May. The *root* is perennial, creeping, flender, blackifh. *Stems* upright, fimple, about a foot high, round, fmooth, bearing one large, twice or thrice compound leaf, divided irregularly in a three-fold order, and compofed of large, pendent, tremulous, thin, delicate, heart-fhaped, pointed, finely ciliated, fmooth leaflets, glaucous beneath; and one upright *panicle,* alternately branched, whofe ftalks are red, and rough with glandular hairs. *Flowers* fingular and elegant, drooping, with dark red petals, and yellow pellucid nectaries. Dr. Smith, in his Englifh Botany, fuggefts that "perhaps what is called the ftem ought to be reckoned only the footftalk of the leaf, which, as in *Turnera,* bears the flowerftalk."

EPIMENIDES, in *Biography,* a Cretan philofopher and poet, who was contemporary with Solon, and of whom many fables are related. Among others it is faid, that, being fent by his father in fearch of a ftraying fheep, he flept in a cave, where he repofed himfelf for 50 years, and when he awoke, found to his furprife, that he was become an old man, that every thing about him was become new and ftrange. It is alfo recorded of him, that he could difmifs the foul from his body, and recal it at pleafure; and that he had familiar intercourfe with the gods, and poffeffed the gift of prophecy. Moft of thefe fictions may probably have originated with the Cretans, who were, to a proverb, famous for their powers of invention. (Titus, i. 12.) The more credible account of Epimenides is, that he was a man of fuperior talents, who pretended to intercourfe with the

the gods, and in order to justify his pretensions, lived in retirement upon the spontaneous productions of the earth, and practised various arts of imposture. At the time of his pretended inspiration he might, possibly, have the art of appearing totally insensible and entranced, which would be considered by ignorant and deluded spectators as a power of dismissing and recalling his spirit. Such was his reputation for sanctity, and for the performance of religious rites, that, during a plague in Attica, which happened in the 46th olympiad, about 596 years B.C., the Athenians sent for him to perform a sacred lustration: in consequence of which, as it is said, the gods were appeased and the plague ceased. Of this ceremony we have given a particular account under the article ALTAR. On occasion of this visit to Athens, Epimenides became acquainted with Solon, the Athenian legislator, who is said to have disapproved the conduct of the Athenians in this instance of superstition; and yet availed himself of the advice of the philosopher in compiling his celebrated code. The Athenians, however, were delivered from the pestilence, and were disposed liberally to requite Epimenides for his services. The philosopher declined accepting their offered recompence, and contented himself with a branch of the sacred olive, which grew in their citadel, and with this he returned to his native country, after having concluded a league between the Gnossians of Crete and the Athenians. Soon after his return to Crete he died, as Laertius says, at the age of 157 years, or, as the Cretans pretend, at the age of 299 years. The superstitious Cretans paid him divine honours after his decease; and he has been reckoned by some the 7th wise man of Greece, to the exclusion of Periander from this number. Laertius enumerates a variety of pieces written by Epimenides, both in prose and verse. Among the former was a treatise "On Sacrifices," and "An Account of the Cretan Republic;" and among the latter "The Genealogy and Theogony of the Curetes and Corybantes," in 5000 verses; "Of the Building of the ship Argo, and Jason's Expedition to Colchis," in 6500 verses; "Of Minos and Rhadamanthus," in 4000 verses; and a treatise "Of Oracles and Responses," mentioned by St. Jerome, from which St. Paul is said to have taken the quotation in his epistle to Titus, ch. i. 12. Laert. l. i. c. 10. Brucker's Hist. Phil. by Enfield, vol. i.

EPIMETRON, επι and μετρον, *measure*, in *Antiquity*, an allowance given the tax-gatherers in the Roman provinces, over and above the just quantity of wine or grain they were obliged to furnish. The epimetron, or over-measure, in different provinces, was different, being always greater in those that were remote, than in the nearer provinces. The different kinds of things wherein it was given made likewise a difference in the quantity allowed. The reason of allowing an epimetron, or over-measure, was to make good the leakage of the wine and waste of grain, that would necessarily happen by transporting it to Rome.

The provinces whose taxes were converted into money, and paid in specie, were free from epimetron.

EPIMORIOS, Επιμοριος, *superparticular*, of μειρω, *I divide*, an epithet given by Galen to certain differences in the pulses with respect to their inequality as to the time of their beating. All times, rythms, or modulations of the pulse, according to number, consist, he observes, of equal or unequal proportions. Of equal, when the time of the distension is equal to that of contraction; and of unequal, when the one of these exceeds the other; and this inequality may be from certain or uncertain excesses. The certain excesses may be either in multiple proportion, or as number to number, which is the epimorion.

EPIMULIS, of επι, *upon*, and μυλη, *whirle bone on the top of the knee*, a name given, by some anatomists, to the patella, or knee-pan.

EPIMYLIA, in the *Ancient Music*. We are told, in Athenæus, that the epimylia, and the song called "Hymæus," were the same (see HYMÆUS): Athenæus adds, that it is probable that the word epimylia comes from εμυλις, which in Dorian signifies sometimes the return, and sometimes the augmentation and surplus of nourishment given to those who labour at the mill. But perhaps after all, this word comes from μυλα, *a mill*.

EPIMYTHION, Επιμυθιον, in *Rhetoric*. See FABLE.

EPINA, or HARPINA, in *Ancient Geography*, a town of Triphylia, upon the river Parthenia, N. of Phryga.

EPINAC, in *Geography*, a small town of France, in the department of Saône and Loire, chief place of a canton in the district of Autun, with a population of 1128 individuals. The canton contains 11 communes and 5802 inhabitants, on a territorial extent of 155 kiliometres.

EPINAL, or ESPINAL, a town of France, in the department of the Vosges, chief place of the district of the same name, with a population of 7321 individuals. It is situated on the river Mosello, 12 miles N.W. of Remiremont, and 480 miles of Paris, and 42 miles S.E. of Nancy. N. lat. 48° 22′. The canton has a territorial extent of 297½ kiliometres, 19 communes, and 14,709 inhabitants.

As chief place of a district, Epinal has a sub-prefect, a ranger, a brigadier-general, who commands in the department, a captain of the national gendarmerie, two courts of justice, and a register office. It has several paper-mills. The soil produces wheat, rye, oats, hemp, and flax. Its principal trade is with hemp and flax, hemp and flax seed, oil, and the produce of a few manufactures of linen and cotton stuffs, and writing paper. The whole district comprises five cantons, 116 communes, and 62,592 inhabitants, on a territorial extent of 1285 kiliometres.

EPINAY, a small town of France, in the department of l'Ille and Vilaine; three miles W. of Vitré, which, before the revolution of 1789, conferred the title of marquis on the lord of the manor.

EPINENEUCOS, from νευω, *I nod*, in the old writers of *Medicine*, a word used to denote a sort of unequal pulse, beating differently in the different parts of the same artery; as when it rises strongly against the two middle fingers of the physician who feels it, and weaker at the extremes; this sort of pulse is described by Galen as common to hectic patients, and is called also perineneucos.

EPINEPHELOS, of επι and νεφελη, *clouds*, in the *Writings of the Ancient Physicians*, a term used to express the cloudy matter seen floating in the urine in fevers, &c. See ENEOREMA.

EPINETTE, *Fr.* in *Music*. See SPINET.

EPINEU *le Chevreuil*, in *Geography*, a town of France, in the department of the Sarte and district of Sillè; 12 miles W. of Le Mans.

EPINEUL, a town of France, in the department of the Yonne, and district of Tonnerre; 1½ mile N. of Tonnerre.

EPINEUX *des Lombes*, in *Anatomy*, a name given by Winslow, and some other of the French authors, to certain small muscles of the loins, not mentioned by the old anatomists; but called by Albinus interspinales lumborum.

EPINICINION, Επινικινιον, in the *Ancient Music*, a song of victory, by which the Greeks celebrated the triumph of conquerors.

EPINICION, Επινικιον, from επι, *on*, νικη, *victory*, in the *Greek and Latin Poetry*, denotes, 1. A feaft, ceremony, or rejoicing, on occafion of a victory obtained. 2. A poem or compofition, on the fame fubject. Scaliger treats exprefsly of the epinicion in the Poetics, lib. i. cap. 44.

EPINOI, in *Geography*, a fmall town of France, in the department of the North; 9 miles S. of Lille, and 9 miles N. of Douai.

EPINYCTIS, (from επι, and νυξ, *night*,) in *Surgery*, a kind of puftule, of the nature of the furunculus, originating in the night-time; or, according to Ætius and Paulus, attended at this period with the moft pain.

EPIODIUM, in the *Ancient Mufic*, a funeral fong or dirge with the Greeks; called Mænia by the Romans.

EPIPACTIS, in *Botany*; according to Hederic, from επιπηγνυμι, or επιπηγνυω, to congeal, or to grow together at the fummit. In this fenfe the name may very well apply to the *Helleborine* of fome authors, for which Haller and Swartz retain it, and which has always been taken for the επιπακλις of Diofcorides, whofe account of the matter is too fhort and vague to afford much light. The petals of this plant do indeed approach each other, towards the upper part, more than in many of the *Orchideæ*, and fuch an explanation is more correct than that of Ambrofini, who derives the word from παγος, ice, or πηκλος, frozen, "becaufe the herb grows in very cold places, as it were upon or above the ice;" which circumftance by no means applies to it. Haller in Act. Helvet. v. 4. 100. Hift. Stirp. Helvet. v. 2. 147. Swartz. Act. Holm. 1800. p. 231. t. 3. f. N. Tracts on Botany, 159. Sehrad. Neues Journ. v. 1. 62. Willd. Sp. Pl. v. 4. 83. (Helleborine; Tourn. t. 249. Serapias; Linn. Gen. 462. Schreb. 503. Juff. 65. Gærtn. t. 14.) Clafs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*.

Gen. Ch. reformed. *Cal.* three-leaved; leaflets direct, a little fpreading, concave, acute. *Cor.* Petals two, rather fmaller than the calyx, flightly fpreading. Nectary a lip proceeding from the lower part of the ftyle, tapering, or concave, or keeled, at the bafe, ufually longer than the calyx, deflexed, entire or cloven, concave or flattifh, often furrowed above. *Stam.* Anther an hemifpherical, moveable, permanent, terminal lid, of two cells, attached by its pofterior edge to the top of the ftyle; maffes of pollen oblong, powdery, granulated, fometimes lobed. *Pift.* Germen inferior, obovate, erect, furrowed, fometimes twifted; ftyle erect, roundifh, notched at the top; ftigma in front, oblique, under the anther. *Peric.* Capfule inferior, oval, with fix ribs and one cell, opening by clefts between the ribs. *Seeds* numerous, minute, tunicate.

Eff. Ch. reformed. Calyx-leaves direct, flightly fpreading. Lip without a fpur. Anther a terminal permanent lid. Pollen powdery, granulated.

Swartz and Willdenow enumerate fourteen fpecies of this genus, eight or nine of which are Britifh. They are divided into two fections, eight of them having an undivided lip, and fix a cloven one. The former are,

1. E. *latifolia*. (Serapias latifolia; Linn. Syft. Veg. ed. 14. 814. Sm. Fl. Brit. 942. Engl. Bot. t. 269.) A native of cool, fhady, rather mountainous woods, throughout Europe. The *roots* are perennial and creeping. *Stems* fimple, about two feet high, leafy, roughifh. *Leaves* ovate, or broad-lanceolate, ribbed and plaited, clafping the ftem alternately. *Flowers* in a long terminal fpike, with bracteas at leaft as long as the germen, the lower ones longer than the whole flower. *Calyx* and *petals* of a brownifh green. *Nectary* fhorter than either, heart-fhaped in front, purplifh, acute.

2. E. *paluftris*. (Serapias paluftris; Scop. Carn. v. 2. 204. Lightf. 527. Sm. Fl. Brit. 943. Engl. Bot. t. 270.) An elegant native of watery, boggy meadows, in England and other parts of Europe, flowering in July and Auguft. The *flowers* are fewer, but larger and more fpecious than the laft, being variegated with white, purple and yellow, and the lip is crenate. Linnæus has called this S. *longifolia*, but very incorrectly, and from miftake.

3. E. *microphylla*. Sw. (Serapias parvifolia; Ehrh. Herb. 120.) A native of Germany and Switzerland; poffibly alfo of England, as we have fome fufpicion of its being the Helleborine altera, atrorubente flore, of Ray's Synopfis, 383. It moft refembles the firft fpecies, but has much fmaller leaves.

4. E. *grandiflora*. (E. pallens; Sw. Serapias grandiflora; Sm. Fl. Brit. 944. Engl. Bot. t. 271.) Frequent in the beech woods of Berkfhire and other midland counties of England, flowering in June. The *flowers* are few, clofed, large and elegant, white with yellow lines upon the lip. *Leaves* elliptical.

5. E. *enfifolia*. Willd. (Serapias enfifolia; Sm. Fl. Brit. 945. Engl. Bot. t. 494. S. xiphophyllum; Linn. Suppl. 404.) Confounded by Haller, Hudfon and others with the laft, from which it differs in its minute *bracteas*, narrower and longer *leaves*, fhorter *lip*, and more flender *germen*. It grows in Switzerland, and very rarely in the mountainous parts of Yorkfhire and Worcefterfhire.

6. E. *rubra*. (Serapias rubra; Linn. Syft. Veg. ed. 14. 816. Sm. Fl. Brit. 946. Engl. Bot. t. 437.) Native of fhady mountainous woods in feveral parts of Europe, rare in England. It is diftinguifhed by its elegant rofe-coloured *flowers*, whofe lip is marked with yellow wavy ridges, and auricled at its bafe.

7, 8. E. *erecta* and *falcata*, natives of Japan, are the only remaining fpecies of this fection; and thefe, as Willdenow obferves, appearing to have a fpur to the flower, are perhaps fpecies of *Limodorum*.

The fpecies in Swartz and Willdenow with a cloven lip are,

9. E. *Nidus avis*. (Ophrys Nidus avis; Linn. Sp. Pl. 1339. Sm. Fl. Brit. 931. Engl. Bot. t. 48.) A parafitical plant, growing in fhady beech woods, chiefly on a chalky foil, and fingular for its uniform pale brown hue. The *root* confifts of numerous cluftered juicy fibres. *Leaves* none, except fmall fcales on the ftem. *Flowers* numerous, forming a denfe fpike, inodorous, with a cloven divaricated lip.

10. E. *ovata*. (Ophrys ovata; Linn. Sp. Pl. 1340. Sm. Fl. Brit. 932. Engl. Bot. t. 1548. Curt. Lond. fafc. 3. t. 60.) Frequent in woods, flowering in June like moft of its genus. The *ftem*, a foot high, bears only two oppofite, broad, oval leaves, and a fpike of numerous fmall green *flowers*, whofe long pendulous lip produces a fmall drop of honey in front, thus proving its right to the title of nectary. See Sm. Introd. to Botany, 461.

11. E. *cordata*. (Ophrys cordata; Linn. Sp. Pl. 1340. Sm. Fl. Brit. 933. Engl. Bot. t. 358.) Grows on boggy mountainous heaths in Scotland and the north of England, as well as in Switzerland, &c. It is fcarcely a quarter fo large as the laft, and has heart-fhaped *leaves*, and a four-lobed lip.

12. E. *convallarioides*. Sw. in Web. and Mohr. Beitr. v. 1. t. 1. (Ophrys cordata; Michaux Fl. Boreali-Amer. v. 2. 158.) Native of the Weft Coaft of North America, and of Newfoundland. A flender delicate fpecies, with a pair of roundifh heart-fhaped *leaves*, capillary racemofe *flower-ftalks*, narrow *calyx* and *petals*, and a dilated lip.

13. E.

13. E. *camtſchatca.* Sw. and Willd. (Ophrys camtſchatca; Linn. Sp. Pl. 1343. Neottia; Amœn. Acad. v. 2. 361. t. 4. f. 24.) Native of Siberia. Deſtitute of *leaves*, except a few ſheathing ſcales. The *flowers* are much like the laſt, but have a more linear nectary.

14. E. *unifolia.* (E. porrifolia; Sw. and Willd. Ophrys unifolia; Forſt. Prod. 59.) Found by Forſter in New Zealand. The *leaf* is ſolitary and ſheathing, riſing above the ſtalk, which it embraces, and which bears a ſhort denſe ſpike of ſmall *flowers*. We ſee no advantage in changing the original ſpecific name.

EPIPEDOMETRY, of επι, πους, *foot*, and μετρω, *I meaſure*, in *Mathematics*, ſignifies the meaſuring of figures that ſtand on the ſame baſe.

EPIPETRON, in *Botany*, a name given, by Theophraſtus and Ariſtotle, to a plant, ſuppoſed by many to be the ſame with the empetrum of Dioſcorides. But there is great reaſon to doubt whether the epipetron of the two older authors be the ſame plant; and whether, if they mean two different plants by this name, either of them agree with the empetrum of Dioſcorides. Theophraſtus ſays, that his epipetron never flowers: and Ariſtotle ſays, that his epipetron grows on rocky places, and continues to grow after it is taken up, as the orpin and ſome other plants will do.

EPIPHÆNOMENA, of επι and φαινομενον, *ſymptom*, in the *Writings of the Ancient Phyſicians*, a term uſed to expreſs ſuch of the ſymptoms, in certain diſeaſes, as did not uſually appear till the time that the diſeaſe was actually formed, called alſo epiginomena.

EPIPHALLUS, in the *Ancient Muſic*. It appears by a paſſage in Euſtathius, often quoted by Meurſius, that this was alſo the name of a dance, performed to flutes.

EPIPHAN, in *Geography*, a town and diſtrict of Ruſſia, in the government of Tula, ſituated on the Don.

EPIPHANES. See EPIPHANIUS. This term in Greek, Επιφανης, denoted eminent or illuſtrious, and thus it was applied to Antiochus, which ſee.

EPIPHANES, of επι and φαινομαι, an epithet given to Jupiter, becauſe he manifeſted his preſence by lightning and thunder, &c.

EPIPHANIA, a word uſed, by ſome of the ancient phyſicians, to expreſs the external habit of the body.

EPIPHANIA, in *Ancient Geography*, a town of Aſia Minor, in Cilicia, near the Mediterranean, between the branches of mount Amanus, on the river Carſus; probably denominated Epiphania in honour of Antiochus Epiphanes, king of Syria, who poſſeſſed Cilicia. We learn from Tacitus, that the part in Cilicia, in which this town was ſituated, became ſubject to the dominion of Rome under Lucullus, about the year of the city 683. It was afterwards epiſcopal under the metropolis of Anazarba.

EPIPHANIA *on the Euphrates*, a town of Aſia, ſituated on that river.

EPIPHANIA, a town of Syria, on the Orontes; which was ſubjected to the Romans about the year 690, during Pompey's expedition into the territory of Apamæa and into Coeleſyria. This town was ſituated between Lariſſa and Arethuſa; and it was reckoned by the Orientals one of the moſt ancient towns in the world, founded, as they imagined, by Hamath, one of the ſons of Canaan; and that its name was changed by the Macedonians in honour of Antiochus Epiphanes. (See HAMATH.) It was epiſcopal under the metropolis of Apamæa.

EPIPHANIA, a town of Aſia Minor, in Bithynia. Steph. Byz.—Alſo, a town of Aſia, on the banks of the Tigris, called by Steph. Byz. *Arſecicerta.*

EPIPHANIUS, or EPIPHANES, in *Biography*, the ſon of Carpocras, or Carpocrates, an hereſiarch in the ſecond century, was inſtructed by his father in the whole circle of the ſciences, and particularly in the Platonic philoſophy; but his death, when he was 18 years of age, diſappointed the hopes which the Carpocratians entertained concerning him. After his death he was honoured by them as a god, particularly in the iſland of Cephalonia, where a temple was erected to him, with altars, a grove, and a muſæum, and where the day of his nativity was celebrated with hymns, libations, ſacrifices, and feaſtings. Theſe are the reports of Clement of Alexandria and of Epiphanius, unconfirmed by the teſtimony of other writers. Epiphanes is now claſſed with the Valentinians. Lardner Hiſt. Heret. c. iii. § 1.

EPIPHANIUS, biſhop of Salamis in the iſland of Cyprus in the fourth century, and dignified by the Catholics with the title of Saint, was born in the vicinity of Eleutheropolis, in Paleſtine, about the year 320. In his youth he went into Egypt, where he inclined to the ſect of the Gnoſtics, but ſeparating from them, he joined himſelf to the Egyptian Aſcetics, imbibing their principles and conforming to their manners. In his 20th year he returned to his own country, and became a diſciple of Hilarion, the father of Paleſtine monkery. After ſome time he founded a monaſtery at Bezanduce, the village in which he was born, over which he preſided for the greateſt part of his life. In 367 or 368, he was appointed biſhop of Salamis, afterwards called Conſtantia, where his piety and ſanctity were held in high eſtimation, and where he was aſſiduouſly employed in writing defences of the orthodox doctrines againſt the attacks of heretics. His zeal, however, involved him in many troubles, which embittered a conſiderable portion of his life. One of the principal circumſtances which contributed to embarraſs and embroil him, and to entail diſgrace on his memory, was his inveterate oppoſition to the opinions of Origen. This produced a conteſt with John biſhop of Jeruſalem, who favoured theſe opinions, which, after many mutual invectives and recriminations, terminated in a breach between the two biſhops, that convulſed the eaſtern churches by the hatred and perſecuting ſpirit manifeſted in the conduct of their reſpective partiſans. Theophilus, biſhop of Alexandria, was an active adherent to the cauſe of Epiphanius, and held a council in 399, which condemned the writings of Origen, and prohibited all perſons from reading them, or having them in their poſſeſſion. This example was followed by a council of the biſhops of Cyprus, ſummoned by Epiphanius himſelf in the year 401. Failing of ſucceſs by the decrees of theſe councils and by the perſecution againſt Origen, which they were the means of inſtigating, the determined and zealous prelate took a voyage to Conſtantinople, in order to induce the biſhops in that city to adopt and ſanction the decrees of Alexandria and Cyprus. On his arrival, he declined holding any intercourſe with Chryſoſtom, biſhop of that city, unleſs he joined in the condemnation of Origen, and in withdrawing his protection from the exiled Egyptian monks. Exaſperated by the diſappointment of his views, he reſolved to preſent himſelf to the people in the church of the Apoſtles, and openly to condemn the books of Origen, and all his advocates. But before he could execute his purpoſe, he was warned of the irregularity of his proceedings, and of the ſedition which they might occaſion; and he, therefore, thought it moſt prudent to abandon his deſign. His next attempt was that of intereſting the court in his favour; and ſo violent and implacable was his zeal againſt thoſe who favoured Origen, that

that when the empress Eudoxia besought his prayers in behalf of the younger Theodosius, who was dangerously ill, he assured her that he should not die, if she would consent to discard the heretics, who were sheltered under the imperial patronage. The princess very properly reproved this arrogant and impious message; and his impetuosity was also checked by the Egyptian monks, who convicted him of being unacquainted with the principles of the persons, against whom he had been industriously exciting universal indignation. Thus foiled and abashed, he set out on his return to Cyprus, and died either on his voyage, or soon after his return, in the year 402 or 403, at a very advanced age. The piety of Epiphanius was unquestionable; but it was blended with a gloomy superstition, which led him to promote the austere discipline of the cloister, and to employ his episcopal influence in multiplying monastic institutions. In offices of charity for the relief of the indigent, he expended not only his own private fortune, but the greatest part of the revenues of his church, and large sums entrusted to his disposal. His learning was considerable, for, according to St. Jerome, who mentions him in terms of high commendation, and calls him πενταγλωττος, a man of five languages, he understood Greek, Syriac, Hebrew, Egyptian, and partly Latin. It is allowed, however, that he was deficient in judgment, and unskilful in wielding the weapons of controversy. Careless in his transcripts from ancient authors, and credulous in admitting unauthenticated reports, he has been betrayed into various contradictions and absurdities, so that his works, with respect to authority and reference, are depreciated in value. His style is mean, harsh, and unpolished, without perspicuity, and without connection. In his remaining works he has given several catalogues of the books of the Old and New Testament. His canon of the Old Testament was much the same with that of the Jews. (See Canon.) The books of the New Testament received by him are the same with those generally received by us. For both these classes of sacred books he professes the highest regard; nor does he ever make use of Christian apocryphal books, written in the name of apostles and falsely ascribed to them. With respect to the books of the New Testament, he says, that Matthew preached, and wrote his gospel in Hebrew, and that he was the only writer of the New Testament who used this language. He had heard, however, that the gospel of St. John, and the Acts of the Apostles, had been translated from Greek into Hebrew, and were in the library of the Jews at Tiberias. Matthew wrote first, and soon after Mark, who was Peter's companion at Rome. The third gospel, in his enumeration, was that of Luke. John wrote his gospel at the age of 90 years, and Epiphanius says, that it was occasioned by the errors of the Ebionites, the Cerinthians, the Merinthians, and Nazarenes. He ascribes the book of the Acts to Luke. He frequently quotes the epistle to the Hebrews as Paul's; he also cites the epistle of James, the two epistles of Peter, John's first and second epistles, and the Catholic epistle of Jude. He also received the book of Revelation. Of the baptism of Christ, he says, that it took place when he was 29 years and 10 months, thus understanding St. Luke's words, iii. 23. He says, there are two passovers in our Lord's ministry, according to St. John's gospel, and that he suffered at the third passover, in the 33d year of his life on earth; and therefore he did not think the "feast of the Jews," mentioned John, v. 1. to be a passover. He says, that the apostles did not preach themselves, but Jesus Christ, Lord. Therefore there was no sect, or church, called after the apostles; for we never heard of Petrians, or Paulians, or Bartholomeans, or Thaddeans, but of Christians only; as they were called at Antioch. The works of Epiphanius were first printed in Greek at Basil by Oporinus in 1544; and the subsequent impressions have been numerous, of which the most valuable is that published at Paris in 1622, in two volumes folio, by the learned Petavius, who gave a new Latin version, with critical notes and observations. This edition was afterwards printed at Cologne in 1682, in two volumes folio. Cave's H. L. vol. i. sub sæc. Arian. Lardner's Works, vol. iv.

Epiphanius, surnamed "The Scholastic," a native of Italy, and an eminent Greek and Latin scholar, was born about the year 510. At the request of Cassiodorus he translated into the Latin language the ecclesiastical histories of Socrates, Sozomen, and Theodoret, a version more entitled to commendation for its fidelity than its elegance. Cassiodorus was also indebted to Epiphanius for the improved version of the "Codex encyclicus," or collection of synodal letters of the year 458, addressed to the emperor Leo, in defence of the council of Chalcedon. Cave H. L. vol. i. sub sæc. Eutych.

Epiphanius, patriarch of Constantinople in the 6th century, strenuously vindicated the orthodox doctrines against the Eutychians, and after elevation to his dignity in the year 520, procured the condemnation of the latter in a synod of bishops held at Constantinople. Whilst he was patriarch, the decrees of the council of Chalcedon were confirmed, and a reconciliation was completed between the churches of Constantinople and Rome, after a schism which lasted 35 years. Five letters of this patriarch to pope Hormisdas on the subject of the union are extant in the 4th volume of the collection of the Latin councils. Cave H. L. vol. i. sub sæc. Eutych.

EPIPHANY, in *Ecclesiastical Antiquity*, the feast of kings; a double festival, of the first rank, solemnized on the sixth of January, commonly called "Twelfth day," in honour of the appearance of Jesus Christ to the three kings, or magi, who came to adore, and bring him presents.

The feast of Epiphany, now held in honour of the adoration of the magi, had its first institution among the Greeks, from a different object, *viz.* our Saviour's birth; and was called theophany, and epiphany, that is, appearance, and manifestation, of God.

Pope Julius, who reigned from the year 337 to 352, was the first who taught the church to distinguish the feasts of the nativity and epiphany. Papebroch. Paral. ad Conat. p. 23. Act. SS. Maii, tom. vii.

The word in the original Greek, επιφανεια, signifies *appearance*, or *apparition*; and was applied, as some critics will have it, to this feast, on account of the star which appeared to the Magi. St. Jerom and St. Chrysostom, take the Epiphany for the day of our Saviour's baptism, when he was declared to men by the voice, "Hic est Filius meus dilectus, in quo mihi complacui: This is my beloved Son, in whom I am well pleased." And accordingly it is still observed by the Cophtæ and Ethiopians in that view. (See Ludolph. Hist. Æthiop. lib. xxi. cap. 2.) Others contend, that the feast of Christmas, or the nativity of our Saviour, was held in diverse churches on this day; which had the denomination Epiphany, or appearance, because of our Saviour's first appearance on earth, as at that time. And it must be allowed, that the word is used among the ancient Greek fathers, not for the appearance of the star to the magi, but for that of our Saviour to the world. In which sense, St. Paul used the word επιφανεια, *epiphania*, in his second epistle to Timothy, chap. i. ver. 10. Ammianus Marcellinus makes mention of this feast, lib. xxi. cap. 2. and

and obferves, that it was held in January. Upon which paffage Valefius, in his notes, endeavours to fhew, that the hiftorian meant by Epiphany the feaft of the nativity.

The heathen writers ufed the word epiphania in the like fenfe, *viz.* to exprefs the appearance of their gods on earth. And the Chriftians, after their example, applied it, in the general, to exprefs any appearance, or manifeftation of the Deity.

EPIPHEOS, in *Botany*, the name given by the ancients to the dodder, or cufcuta, which grew upon the fhrub they called phæos. This was the ftæbe of the modern Greeks, defcribed by Honorius Bellus. It was a cuftom, among the old writers, to name the cufcuta, or dodder, from the plant it was found growing upon, as they fuppofed that it in fome degree partook of the virtues of that plant. Thus that which grew upon thyme was called epithymum, and that upon the nettle, epiurteca, and that upon flax, epilinum; fo of many others.

The fhrub phæos was alfo called ftæbe by Diofcorides and Theophraftus; and hence this dodder was fometimes called epiftæbe.

EPIPHLEBOS, of επι and φλεψ, *a vein*, in the *Writings of the Old Phyficians*, a term ufed to denote fuch perfons as were lean, and of a hot temperament, and whofe veins, for that reafon, appeared ufually very turgid and prominent in the hands, &c.

EPIPHLOGISMA, (from επι, and φλογιζω, *to inflame*,) in *Surgery*, a violent inflammation, accompanied with pain, fwelling, and rednefs. Alfo, a great internal heat: likewife, the affection ufually called eryfipelas.

EPIPHONEMA, Επιφωνημα, *Acclamation*, in *Rhetoric*, a fententious fort of exclamation, which is frequently added after a narrative, or rehearfal of any thing remarkable; containing ufually a lively, clofe reflexion on the fubject there fpoken of and intended to give it greater force, and render it more affecting to the hearers.

Such is that of St. Paul, when, after difcourfing of the rejection of the Jews, and the vocation of the Gentiles, cries out,

"O the depth of the wifdom and knowledge of God!"

Such alfo is that of Lucretius, after relating the ftory of Agamemnon's facrificing his daughter Iphigenia:

"Tantum religio potuit fuadere malorum."

This figure is frequently expreffed in a way of admiration. Such is that of Cicero, when after having obferved, that all men are defirous of living to an advanced age, but uneafy under it when attained, he makes this juft reflection upon their conduct: "So great is their inconftancy, folly, and perverfenefs!" (Cic. de Senect. c. 2.)

The epiphonema is ufually expreffive of the milder and more gentle paffions, and is not fo vehement and impetuous as exclamation.

EPIPHORA, (from επιφερω, *to carry with force*,) in *Surgery*. The original import of the word "epiphora" feems to have been a violent determination of fluids to any part of the body. At prefent, however, all furgeons confine the meaning of the term to an affection, in which the tears, not being able to pafs in a proper manner down into the nofe, accumulate in front of the eye, and trickle over the cheek. The diforder is alfo not unfrequently denominated the "watery eye."

Whoever is in the habit of confulting furgical books, will foon perceive, that writers do not make a clear diftinction between the epiphora, and fome ftates of the fiftula lachrymalis. Thus Mr. Ware has particularly confidered the fpecies of epiphora, which, he fays, "is produced by an obftruction to the free paffage of the tears from the eye into the nofe. This obftruction (he adds) may take place either in the ducts leading from the puncta lachrymalia into the lachrymal fac, or in the fac itfelf. When the ducts are obftructed, a cafe which rarely occurs, the tears fall over the cheek, and the fac is conftantly empty. Preffure on the fac, therefore, can produce no regurgitation, either of tears, or mucus, into the eye. The method of cure is here evident. A fmall probe of a fuitable fize muft be introduced through the puncta of the obftructed ducts into the fac, and this operation be daily repeated until the obftruction be removed. But, (continues Mr. Ware,) the part in which the obftruction more commonly lies, is in the fac itfelf; and in this cafe, the tears, mixed fometimes with mucus, flow back into the eye through the puncta, when preffure is made on the fac." Now, this latter kind of difeafe, Pott, Scarpa, and other diftinguifhed furgical authors, confider only as one ftage of the fiftula lachrymalis.

We do not mean, however, by what has been ftated, to make any attempt to defend the manner in which the expreffion "fiftula lachrymalis" is employed; our fole aim is to fhew, that, unlefs a line of diftinction is drawn between what fhould be called "epiphora," and what "fiftula lachrymalis," the comprehenfion of the fubject is rather embarraffed, than promoted, by having two different terms, which fo glaringly encroach upon each other in the extent of their fignification. The epiphora, in the meaning of a mere weeping of the eye, may arife from a variety of caufes, which muft be removed, ere the complaint can be cured. An encanthis, or any other kind of tumour in the inner angle of the eye, a polypus in the nofe, an ectropium, a trichiafis, &c. may obftruct the due flowing of the tears into the nofe, and thus make them fall over the fubjacent cheek, fo as to occafion an epiphora. This latter diforder may alfo be the confequence of a part of the caruncula lachrymalis having been loft, either by difeafe, or an unfkilful employment of the knife in fome previous operation. An epiphora is always attendant on obftructions in the ductus nafalis. Mr. Ware obferves, with regard to another fpecies of epiphora, originating from a too copious fecretion of tears, that, if it does not depend on an affection of the mind, its more remote caufe is ufually an inflammation of the eye. In this inftance, a cure is to be effected by fubduing the ophthalmy, and afterwards ftrengthening the eye by mild aftringent applications, fuch as cold water, either alone, or containing a fmall quantity of the zincum vitriolatum.

When the membrane, which lines the lachrymal fac, is in a morbid ftate, the mucus which it fecretes is often fo thickened, that it becomes incapable of paffing through the fac, and lodging in this fituation, prevents the natural and regular defcent of the tears from the eye into the cavity of the nofe.

This fpecies of epiphora has occafionally been benefited by the unguentum hydrargyri nitrati, applied to the edges of the eye-lids, and rubbed into the fkin over the lachrymal fac. Relief is alfo alleged to have been derived from the ufe of ftimulating applications to the infide of the nofe, which applications are fuppofed to have acted by increafing the fecretion from the pituitary membrane.

However, we muft confefs, that no men of experience, at the prefent day, place fufficient reliance on the preceding methods, to recommend them to be tried by their patients. At the fame time it fhould be underftood, that thefe plans are fometimes exceedingly proper to be adopted in conjunction with other more efficacious meafures.

In

In the year 1712, M. Anel recommended the introduction of a probe, and then the injection of a fluid, through the puncta lachrymalia, with a view of clearing away whatever matter might prevent the tears from readily finding their way through the lachrymal fac and nafal duct into the nofe. M. Anel relates, that he accomplifhed many ftriking cures in this manner; and Heifter confirms the efficacy of the plan, by appealing to his own practice, in which he had often produced a complete recovery in the fhort fpace of three days.

In the year 1780, fir William Blizard confidered, that when water was injected through the punctum lachrymale, it not only had but very little fpecific weight, but was driven through the lachrymal fac in an unfavourable direction. Thefe reflections led him to make the propofal of introducing quickfilver through a fmall pipe, which communicated with a long tube full of this metal. Sir William Blizard was of opinion, that the quickfilver, in confequence of its great weight, would have more power when the fac was filled with it, of removing the obftruction, than the mere injection of water. This gentleman alfo, in a paper read to the Royal Society, ftates, that he had produced a cure by the introduction of quickfilver in an example which had lafted feven months; and that the mercury paffed readily through the ductus nafalis, at the third and fourth times of repeating the operation.

When the celebrated Mr. Ware was in Paris, in the year 1791, he learnt from Meffieurs Grandjean and Monfieur Arrachart, eminent oculifts in that city, that the plan of injecting water through the puncta lachrymalia, in incipient cafes of fiftula lachrymalis, was not given up in France. Mr. Ware even faw fome troublefome cafes cured on the continent in this way. Hence he was determined, on his return to London, to give Anel's operation a fuller trial than he had previoufly done. For this purpofe he got Mr. Pepys, in the Poultry, to conftruct a fmall filver fyringe, with pipes of different fizes adapted to it.

The following cafe, which afforded Mr. Ware the firft opportunity of afcertaining more carefully the efficacy of Anel's treatment, is related in his own words, and will ferve to inform the reader of feveral ufeful practical circumftances.

"A lady in Great Ruffel-ftreet came under my care, who for many months had been fubject to an epiphora of the left eye, which prevented her both from reading and working with her needle, without undergoing great inconvenience. Whenever fhe employed herfelf in any way that required clofe attention, her eye became overfpread with tears, and the fight was fo much confufed, that it obliged her to leave off almoft as foon as fhe began. A great variety of remedies had been applied, under the direction of different medical men, but none of them produced any effential amendment. On examining the eye, I obferved that the tunica conjunctiva, near the inner angle of the eye-lids, was flightly inflamed; and on preffing the lachrymal fac with my finger, I perceived that a tear regurgitated through the lower punctum. This appearing to be a proper cafe for the ufe of the fyringe, I immediately determined to employ it. But I found, that though a tear came through the lower punctum on my preffing the fac, yet this punctum was fo fmall that it would not admit the point of the fmalleft fyringe I then had. I introduced into it, however, a fmall probe, and by means of this I fo far dilated the orifice, that it admitted the point of the fyringe on the next day without any difficulty. Upon my firft ufing the injection, the water efcaped through the upper punctum almoft as faft as it was introduced through the lower; but, notwithftanding this, I perfevered in urging the liquor on, until the whole contents of the fyringe were exhaufted. I repeated the injection three times the fame day in immediate fucceffion. The lady, however, was not fenfible that any part of the water paffed through the duct into the nofe during either of thefe operations; and indeed it foon became evident that none had paffed; for, having cleared her nofe before I began, on her blowing it again immediately afterwards, fhe could produce no moifture on her handkerchief. I repeated the operation three times, both on the fecond and on the third day; and each day, during the time that the water was paffing, I not only endeavoured to prevent it from coming through the upper punctum, by covering it with the point of my finger, but I occafionally preffed the lachrymal fac in order to give the water an inclination downward. On the fourth day I very plainly perceived, on the patient's clearing her nofe after the operation, that a part of the water had paffed through the duct; and, the next morning, I had the fatisfaction to hear, that the eye, on the preceding day, had watered much lefs frequently than it had done for a confiderable time previous to it. I repeated the procefs above-mentioned about ten times, in as many days, and I obferved that the quantity of water which paffed through the duct was augmented every time I ufed it. The tears, after this, refuming their natural courfe, the lady recovered the power to read and work without any inconvenience." (See Ware on the Epiphora.)

Mr. Ware, in his practice, ufes common water for the injection, fometimes in a cold ftate, but more frequently warmed. The pipes which this gentleman employs, are alfo much fhorter than the one reprefented by Mr. Benjamin Bell in his Syftem of Surgery, (vol. iii. pl. 37). They are alfo a little arched towards their point. Mr. Ware thinks, that when they are made in this manner, they can be more conveniently introduced into the punctum lachrymale, than when long and ftraight. He recommends always having ready feveral pipes of different fizes, and ufing the largeft one which can be introduced without pain. He finds it alfo advantageous to ftand either behind the patient or on the fide oppofite to that of the difeafed eye; and high enough to have a full command of the patient's head. Thus the operator will gain a complete view of the lower punctum, which will alfo be in a convenient pofition to receive the pipe of the fyringe. Mr. Ware, moreover, advifes us to remove the finger from the lower eye-lid as foon as the pipe is introduced, and to place it over the upper punctum, fo as to prevent the fluid from efcaping through this aperture. The fame finger is likewife to be occafionally ufed in making preffure on the lachrymal fac, in order to aid in forcing the injection down into the nofe.

Mr. Ware has publifhed fome additional remarks on the epiphora, and makes fome very valuable obfervations on the treatment of another fpecies of the diforder; we allude to that kind which proceeds from a thickening of the membrane which lines the lachrymal fac and duct, and a fpafmodic conftriction in any part of this paffage, conjoined, perhaps, with a morbid fecretion of thickened mucus. Mr. Ware imputes a few occafional failures, in the above fimple mode of treatment, to the caufes of the difeafe being fometimes of this nature. The following extract will explain the different methods to which this celebrated oculift has recourfe in different cafes.

"I in general begin the treatment by injecting fome warm water through the inferior punctum lachrymale, and I repeat the operation four or five days in fucceffion. If, in this fpace of time, none of the water pafs through the duct

duct into the nofe, and if the watering of the eye continue as troublefome as it was before the injection was employed, I ufually open the angular vein, or direct a leech to be applied near the lachrymal fac; adding here a caution, that the leech be not fuffered to fix on either of the eye-lids, left it produce an extravafation of blood in the adjacent cells. About the fame time that blood is taken away in the neighbourhood of the eye, I ufually vary the injection, and try the effects either of a weak vitriolic, or anodyne, lotion. In fome inftances alfo, when I have found it impoffible, after feveral attempts, to inject any part of the liquid through the duct, I have introduced a golden probe, about the fize of a briftle, through the fuperior punctum lachrymale, and, attending to the direction of the duct, have infinuated its extremity through the obftruction, and conveyed it fully into the nofe; immediately after which I have found, that a liquid, injected through the inferior punctum, has paffed without any difficulty; and, by repeating thefe operations, for a few fucceffive days, I have at length eftablifhed the freedom of the paffage, and completed the cure. In other inftances, I have recommended a ftrongly ftimulative fternutatory to be fnuffed up the nofe, about an hour before the time of the patient's going to reft, which, by exciting a large difcharge from the fchneiderian membrane, has fometimes alfo greatly contributed to open the obftruction in the nafal duct.

"Cafes occur very rarely which may not be relieved by fome of the means above related." (Ware's Additional Remarks on the Epiphora.)

When the difcharge has been fetid, Mr. Ware has fometimes found, that a vitriolic lotion, injected into the fac, has quickly corrected the quality of the matter.

Scarpa, in his "Offervazioni fulle principali Malattie degli Occhi," maintains, that the chief part of the yellow vifcid matter, which accumulates in the lachrymal fac, is fecreted by the lining of the eye-lids, and by the little glands of Meibomius; and that the altered quality of this fecretion has a principal fhare in the caufe of the difeafe. He ftates, that the truth of this fact may at once be afcertained by everting the eye-lids; and efpecially the lower one of the affected fide; and by comparing them with thofe of the oppofite eye. The former will always exhibit an unnatural rednefs of the internal membrane, which has a villous appearance, all along the extent of the tarfus, while their edges are fwollen; and numerous varicofe veffels are diftinguifhable on its furface. The follicles of Meibomius are alfo turgid and prominent.

Hence, Scarpa advifes making fuch applications to the infide of the eye-lids, as have a tendency to improve the quality of the fecretion from them, at the fame time, that attempts are made to remove the obftruction in the ductus nafalis. Mr. Ware, indeed, had previoufly noticed, that fuch treatment may occafionally be proper.

"When an epiphora is occcafioned by an acrimonious difcharge from the febaceous glands on the edges of the eye-lids, it muft be evident, that injections into the fac will be very infufficient to accomplifh a cure, becaufe the fac is not the feat of the diforder. The remedies that are employed muft be directed, on the contrary, to the ciliary glands themfelves, in order to correct the morbid fecretion that is made by them; and for this purpofe, I do not know any application that is fo likely to prove effectual as the unguentum hydrargyri nitrati of the new London Difpenfatory, which fhould be ufed here in the fame manner in which it is applied in common cafes of the pforophthalmy. It will be proper to cleanfe the eye-lids every morning, from the gum that collects on the edge during the night, with fome foft unctuous application; and I ufually advife to apply to them two or three times in the courfe of the day a lotion compofed of three grains of white vitriol, in two ounces of rofe, or elder-flower, water."

Mr. Ware very judicioufly cenfures the plan of applying collyria to the eye by means of linen, wet in them; and he recommends eye-glaffes for the purpofe, or infinuating the fluid, between the eye and eye-lids, with a camel-hair pencil, thoroughly wet in the application. (Additional Remarks on the Epiphora.)

Scarpa alfo extols wafhing the eye, three or four times a day, with a vitriolic collyrium; and, befides praifing the ointment recommended by Mr. Ware, he recommends Janin's ophthalmic ointment, to be fmeared over the margins and lining of the eye-lids every morning and evening.

℞. *Adipis Suillæ. Tutiæ præp. Bol. Armen. fing.* ʒij. *Calcis Hydrarg. alb.* ʒj. *Mifce.* To be ufed at firft lowered with a larger proportion of lard, than is above ordered. See Fistula *Lachrymalis*.

EPIPHYLLOSPERMOUS Plants, of επι, φυλλον, *leaf*, and σπερμα, *feed*, are the fame with the capillaries, herbs which bear their feed on the back part of their leaves. See Capillary.

EPIPHYLLUM, in *Botany*, επι, *upon*, and φυλλον, *a leaf*, from the mode in which the flowers grow upon a flat ftem refembling a leaf, fee Cactus *Phyllanthus*, fp. 40.

EPIPHYSIS, in *Anatomy*, is a name given to certain parts of bones at a particular period of their formation. See Bone.

EPIPLA'SMA, from επι, and πλασσω, *to fpread*, in *Surgery*, the name of an application to wounds: it confifted of wheat meal boiled in hydrelæum.

EPIPLOCE, Επιπλοκη, in *Rhetoric*, the fame with climax, which fee.

EPIPLOCE'LE, from επιπλοον, *the omentum*, and κηλη, *a tumour*, in *Surgery*, an omental hernia, or a rupture formed by a protrufion of a piece of omentum from the cavity of the abdomen.

Le Dran informs us, that in an epiplocele there is nothing to be felt, except a doughy foftnefs, which neither abfolutely yields to the touch, nor very fenfibly refifts it. The tumour has a flabby unequal feel; and, when there is no ftricture, is perfectly indolent. It is more compreffible than that arifing from protruded inteftine, and, when the quantity of omentum is large, the epiplocele may, in fome meafure, be diftinguifhed by its weight.

As the fubject of omental ruptures will be particularly confidered under the head Hernia, we fhall, for the prefent, content ourfelves with referring to the latter article.

EPIPLOIC, in *Anatomy*, a term applied to parts which belong to the epiploon, or omentum; thus we have epiploic arteries, &c.

EPIPLOO'MPHALON, from επιπλοον, *the omentum*, and ομφαλος, *the navel*, in *Surgery*, an omental hernia protruding at the navel.

EPIPLOON, in *Anatomy*, called alfo omentum or cawl, is a membranous expanfion contained in the cavity of the abdomen: and continued from the peritoneal covering of fome of the vifcera. There are two very diftinct productions, of the nature juft defcribed, diftinguifhed by the appellations of minus and majus, from their difference in fize; and by thofe of hepatico-gaftricum, and colico-gaftricum from their fituation. But when the epiploon, or omentum, is fpoken of generally, the greater or colico-gaftric portion is underftood. To the peritoneal furface of the large inteftine are attached numerous fmall proceffes, which refemble the epiploa in their apparent ftructure, and are called *appendices epiploicæ*.

Although the omenta are ufually reprefented by anatomifts as proceffes of the peritoneum, their organization differs effentially from the ftructure of that membrane. Their groundwork or bafis confifts of the moft delicate and tranfparent membrane of the body; which is lacerated on the application of very flight force. This membrane is compofed obvioufly of two layers, connected by cellular tiffue, and containing numerous venous and arterial ramifications. A greater or fmaller quantity of fat is depofited between thefe layers, and in the courfe of the veffels. When this depofition is very confiderable, as in very corpulent individuals, or in animals who have been fattened for the flaughter, the peculiarly tranfparent delicate appearance of the omental membrane is entirely deftroyed, and the part is converted into a layer of fat. Ordinarily, however, the adipous fubftance is confined to the neighbourhood of the blood-veffels, accompanying them in their fubdivifions, but leaving intervals in which the membrane exhibits its diftinguifhing diaphanous appearance. In emaciated fubjects, during the period of infancy, and particularly in the fœtal ftate, the quantity of fat is very trifling. Under fuch circumftances we can obferve moft diftinctly that the depofition of fat is confined to the courfe of the veffels. As the omenta are entirely unconnected to the parts on which they lie, as well as to thofe by which they are covered, both their furfaces are fmooth and gliftening, and moiftened like thofe of other ferous membranes, by a ferous exhalation, which facilitates their motions over the neighbouring organs. Analogy warrants us in afcribing this fecretion to the arteries of the omenta; and we confequently confider thefe organs as an extenfion of the general ferous furface of the abdominal cavity.

Experiments on living animals, and furgical operations, clearly prove that the membrane of the omenta poffeffes little, if any, fenfibility in its healthy ftate.

The *leffer epiploon*, *mefogafter*, *omentum minus*, or *hepatico-gaftricum*, is the portion extended from the fmall arch of the ftomach to the concave or under furface of the liver. It arifes, behind, from the pofterior half of the tranfverfe fiffure of the liver; on the right it is continuous with the peritoneum covering the neck of the gall-bladder and the beginning of the duodenum; towards the left it is reflected immediately from the diaphragm. Advancing from thefe points, in two clofely united layers, towards the ftomach, it is attached to the end of the œfophagus, to the whole leffer arch of the ftomach, to the pylorus, and commencement of the duodenum. At this line its layers divide, and expand over the ftomach, one of them forming the fuperior, and the other the inferior peritoneal covering of this vifcus. Between the layers of the leffer omentum are contained the hepatic veffels and biliary ducts, the coronary veffels of the ftomach, fome branches of the cœliac plexus of nerves, and of the par vagum, and a few abforbent glands. Fat is rarely depofited here in fo large a quantity as in the large epiploon, fo that we can ufually fee through it that portion of the liver called lobulus fpigelii, which is in contact with its inferior furface.

The biliary ducts, the hepatic veffels with numerous accompanying branches of nerves from the cœliac ganglia, and a confiderable portion of the hepatic and cyftic abforbents, connected and furrounded by adipous and cellular fubftance, are inclofed in the right edge of the leffer omentum. This part is called *capfula Gliffoni*, from an Englifh anatomift, who defcribed it minutely in a work entitled "De Hepate." The very margin of the omentum is occupied by the biliary ducts, and the neck of the gall-bladder. At this border the two furfaces of the little omentum are continuous. Behind the unconnected edge, round which the peritoneum turns, is found the foramen of Winflow, or *foramem epiploicum*, large enough to admit one or two fingers, which can thus be placed in immediate contact with the back part of the liver, and the inferior furface of the little omentum. This opening is fituated between the neck of the gall-bladder, and the beginning of the duodenum, with the hepatic veffels in front, and the vena cava behind. It is not unufual to find its edges adhering together. We fhall have occafion to mention it again after defcribing the large omentum.

The great omentum, *epiploon majus*, *vel gaftro-colicum*, is the loofe membrane, more or lefs loaded with fat, lying in front of the bowels, and generally meeting our eye in laying open the abdomen. It differs extremely in length and fituation; in fome cafes reaching as low as the pelvis, and often defcending in ruptures to the very bottom of the fcrotum; while in others it extends but a fhort way below the umbilicus. It is always fhorter in children than in adults. We often find it folded, or rolled on itfelf, and drawn to fome one part of the abdomen, or tucked up over the ftomach, fo as to leave the fmall inteftines expofed to our immediate view. Its natural fituation between the bowels, and the parietes of the abdomen, explains the frequency of its protrufion, together with the inteftines, in herniæ. Some anatomifts affert that it hangs lower on the left than on the right fide of the abdomen.

The great omentum is a continuation of the peritoneal covering of the ftomach. We have already defcribed this as being formed by the feparation of the two layers which conftitute the little omentum. At the great curvature of the ftomach thefe layers again coalefce into one fheet of membrane, are produced till they meet with the tranfverfe arch of the colon, to inclofe which they again feparate. Meeting at the oppofite line they once more unite, and are continued under the name of the tranfverfe mefocolon to the root of the mefentery. The origin of the great epiploon, when minutely examined, commences in the left from the end of the œfophagus, and from the notch of the fpleen (where it forms a membranous connection between this organ and the ftomach) and includes the whole of the great arch of the ftomach nearly as far as the pyloris. The portion of membrane thus formed defcends loofely before the tranfverfe arch of the colon, and reaches to different lengths beyond it, conftituting the anterior layer, or *lamina gaftrica* of the great epiploon. At the lower or floating border this membranous expanfion is doubled on itfelf, and turning upwards again to meet the tranfverfe arch of the colon, forms the pofterior layer, or *lamina colica* of Haller. On the right fide the great omentum is not only attached to the tranfverfe portion of this inteftine, but is continued along its hepatic flexure, and for fome way down the afcending colon. In fome inftances it reaches as low as the cœcum. It is this lateral extenfion of the great omentum which conftitutes the *omentum colicum* of Haller. Each of the layers is compofed of a duplicature of peritoneum, as we have before ftated, containing its proper veffels, and fat, and united clofely by cellular tiffue. It will be evident, from our defcription, that the great omentum is formed by the anterior layer alone in the fpace between the ftomach and tranfverfe arch of the colon; below the latter it is compofed of the two layers, the lamina gaftrica, and the lamina colica lying in contact with each other, but having no further connection in a healthy ftate of the oppofing furfaces.

From this difpofition of the great and little epiploa, there

there refults, in conjunction with the inferior furface of the ftomach, and the fuperior furface of the tranfverfe mefocolon a membranous bag, called ufually the bag of the omentum. It offers every where on the infide a continuous ferous furface, where the fides of the cavity are in clofe contact, but not adherent. The communication between this pouch, and the general cavity of the peritoneum, is formed by the foramen of Winflow. In order to demonftrate this fact, as well as to difplay the bag formed by the omenta, we introduce into this opening a pipe, furrounded by fome foft fubftance, to prevent the efcape of the air. By blowing gently we are enabled to feparate the layers of the great omentum, which were in contact, and give to the whole the form of a large membranous bag, interfected by veffels and bands of fat, between which the membrane rifes in pouches of various fizes. The lines formed by the ftomach, and tranfverfe arch of the colon, are but faintly feen, owing to the diftention of the epiploon, which appears, as it were, fufpended between them. To infure the fuccefs of this experiment fome conditions are neceffary, which we are not always happy enough to bring together. There muft be no adhefion of furfaces, no large accumulation of fat, the fubject young, and the whole conducted with the greateft delicacy, as the flighteft rent in the membrane is fufficient to prevent fuccefs. In the fœtus, and in young children, the laminæ of the great omentum are eafily feparable throughout their whole extent. In adults, and more fo in old perfons, they are generally more or lefs united, fo that the cavity of the omenta is confined to the fpace contained between the little omentum, the under furface of the ftomach, and the tranfverfe mefocolon.

The arteries of the great omentum are derived from the right and left gaftro-epiploic veffels. They are in general fmall, and defcend between the layers of the lamina gaftrica, giving off branches on either fide, which anaftomofe freely in every direction. At the lower border of the omentum the trunks turn up again to meet the tranfverfe arch of the colon, with the arteries of which inteftine they form communications. The veins accompany the arteries in their courfe, and join the large venous trunks which end in the vena portarum. The few nerves it poffeffes are derived from the hepatic, and fplenic plexufes.

The *appendices epiploicæ*, or *omentula*, are principally obferved on the firft parts of the great inteftine, being in lefs number on the figmoid flexure of the colon and the rectum. They are irregularly difpofed, hanging in fringes, generally unconnected with each other, fometimes united by intermediate membranous productions. They are ufually dependent from the pouches of the inteftine, and not from the longitudinal bands. They are obvioufly formed by the peritoneal covering of the inteftines, united by cellular membrane, and containing a depofit of fat in almoft every inftance.

The ufe of the omenta is entirely unknown: The leffer epiploon offers a covering, and connecting medium to fome nerves belonging to the ftomach, and to the hepatic veffels and ducts. To the great epiploon many offices have been afcribed, none of which are fatisfactorily afcertained. It varies fomewhat in fize according to the ftate of the ftomach; fince, when the latter is diftended, it appears to enter between the layers of peritoneum forming the anterior fold, which lofe in this cafe their form of omentum, and become the temporary covering of this organ. What may be the probable advantages of this conftruction it is not eafy to decide. It has been fuppofed again to fecrete a lubricating fluid from its furface, which preferves the free motion of all the chylopoietic vifcera between each other. That it increafes the ferous furface of the abdominal cavity is evident; but in what manner this becomes an advantageous difpofition is more than we have the means of determining. The omentum colicum, and appendices epiploicæ are fubject to the fame obfervations, being fimilar in ftructure, and confequently in ufes. It is certain that a confiderable portion of the great omentum may be cut away, without any fubfequent inconvenience to the patient, as has been frequently obferved in cafes of omental hernia.

An epiploon is found in all the mammalia, where it is feen under every variety of form and fize; fo that no inferences can be drawn from its difpofition in thefe particulars. In all it contains more or lefs of fat between its membranes, the accumulation of which would appear to bear fome proportion to the active, or fluggifh habits of the animal. In the hybernating fpecies during the winter, it is loaded with fat, which exifts but in minute quantities during the fummer. The epiploon is not found in the other claffes of animals, at leaft there is nothing analogous to it, but a membranous production between the liver and ftomach, anfwering to the little omentum.

EPIPLO'SCHEOCE'LE, from ἐπίπλοον, *the omentum*, ὄσχεον, *the fcrotum*, and κήλη, *a tumour*, in *Surgery*, an omental rupture, fituated in the fcrotum.

EPIPOGUM, in *Botany*, ἐπὶ, *upon* and πώγων, *a beard*, becaufe the beard, or rather lip, is turned upwards. Gmel. Sib. v. 1. 11. t. 2. f. 2. is *Satyrium Epipogium* of Linnæus; *Limodorum Epipogium* of Swartz and Willdenow. See LIMODORUM.

EPIPOLÆ, in *Ancient Geography*, was originally a piece of high ground without the city of Syracufe, and afterwards fo little inhabited that it is not mentioned by Cicero in his defcription of this city. As it was the moft elevated fituation, and commanded Tyche and Neapolis, it was judicioufly inclofed by Dionyfius I., who encompaffed it with a wall nearly 4 miles in extent. Its additional defence was the fortrefs of Labdalon, at its bottom, on the eaft; and that of Euryalus, at its top, on the north. See SYRACUSE.

EPIPOMPEUTICA, in the *Ancient Mufic*. Voffius, in his poetical inftitutes, informs us, that this was a title given to fongs compofed and fung on occafions of great magnificence.

EPIPORO'MA, from ἐπιπωρόω, *to harden*, in *Surgery*, a hard tumour on a joint: a tophus.

EPIPROSLAMBANOMINOS, *Gr.* in the *Ancient Mufic*, a name given to the ftring or found below proflambanominos, which word correfponds with gamut in the Guido fcale.

EPIRE, in *Geography*, an ancient kingdom of Greece, now united with Albania, and included in that country, of which it forms the fouthern part, extending from Valona to Arta.

EPIROTS, in *Ancient Geography*. See the next article.

EPIRUS, a country of Greece, bounded on the eaft by Ætolia, on the weft by the Adriatic, on the north by Theffaly and Macedon, and on the fouth by the Ionian fea. This was the ancient kingdom of the Æacidæ, and was firft called "Epirus Dodonæa," *i. e.* the continent of the Dodonæans, and afterwards Epirus, or "the continent," that being the import of the Greek word Ἤπειρος. It was anciently divided into three diftricts or provinces; *viz.* Chaonia, Thefprotia, and Moloffis; to which fome authors add Caffopia, Caffiope, or Cæftrine, and Pindus. This country is faid to have been firft peopled by Dodanim, the fon of Javan, and grandfon of Japhet, or at leaft by fome of his pofterity. We find among the nations which occupied Epirus, before they were united into one people under the common name of Epirots, the Selli, who are thought to have been the

firft

firſt inhabitants of Epirus, and to have miniſtered in the temple of Dodona, the Chaones, the Moloſſi, the Dolopes, the Dryopes, the Ænianes, the Pelaſgi, &c. The form of government which prevailed in Epirus was unqueſtionably monarchical, the whole country being divided into many ſmall independent kingdoms. Homer, and other ancient writers, mention ſeveral kings who reigned here at the time of the Trojan war. But while the other Epirotic nations continued to be governed by princes of their own blood, the Moloſſi became ſubject, at an early period, to the power of Pyrrhus, a foreign prince, whoſe deſcendants were denominated Æacidæ, from Æacus, the founder of his family. Some of theſe petty kingdoms, in proceſs of time, exchanged the monarchical into a republican form of government; for Thucydides informs us, that in his time the Theſprotæ and Chaones were governed, not by kings, but by annual magiſtrates. However, the kingdom of the Moloſſi ſoon eclipſed all others; the Moloſſian princes having ſubjected the whole country, and united the ſeveral ſmall kingdoms of which it conſiſted into one, known to the ancients under the name of Epirus.

Pyrrhus, the firſt of the Æacidæ, was the ſovereign of this country at the period when regular and authentic hiſtory commences; and he is ſaid to have diſtinguiſhed himſelf at the ſiege of Troy, when his father was killed. His reign ſoon terminated by a premature death; for he was murdered by Oreſtes in the temple of Delphi, on account of his having married Hermione, the daughter of Menelaus, who had been betrothed to Oreſtes. He was ſucceeded by his ſon Moloſſus, and ſeveral other princes, whoſe names it is needleſs to record. At length Admetus was the ſovereign of Epirus, when Xerxes invaded Greece. This prince, upon the defeat of the Perſians, wiſhed to enter into an alliance with the Athenians, about the year 478 or 479 B. C. The ſucceſſors of Admetus were Tharymbas, who is ſaid to have introduced the ſciences into this country, and to have formed an excellent code of laws; and Alcetes, at whoſe death the kingdom was divided between his two ſons, Neoptolemus and Arybas, the latter of whom, when his brother died, became ſole ſovereign of the country, and conducted the government with great prudence, equity, and moderation. He alſo encouraged literature by extending his patronage to thoſe who excelled in it. His niece Olympias, of whoſe education he had taken great care, was married to Philip, king of Macedon, who had by her Alexander the Great. At his death, he was ſucceeded by Alexander, one of his nephews; who is ſaid to have been little inferior, in courage and conduct, to his nephew Alexander the Great; but he had the misfortune to engage, on his firſt ſetting out, with nations inured to the toils of war, and no leſs brave than his own Epirots; whence he uſed to ſay, that the country, which he propoſed to conquer, was inhabited by men, whereas the provinces his nephew Alexander went to ſubdue, were peopled by women only. (Aul. Gell. l. xvii. c. 21.) The immediate ſucceſſors of Alexander were Æacides and Alcetes II.; and the latter was ſucceeded by Pyrrhus, deſcended by the father from Achilles, and from Hercules by the mother. (See Pyrrhus.) After two or three ſhort reigns, Deidamia, great grand-daughter to Pyrrhus, ſucceeded her father Pyrrhus III. and having no iſſue, ſhe gave the Epirots their liberty, who formed themſelves into a republic, which was governed by magiſtrates annually elected in a general aſſembly of the whole nation. The Macedonians on one ſide, and the Illyrians on the other, taking advantage of the inteſtine diviſions, which generally attend a popular government, feized on ſeveral provinces belonging to the Epirots, and annexed them to their reſpective crowns. The Romans, after having conquered Philip of Macedon, reſtored them to their ancient liberty; but they ungratefully took up arms againſt their benefactors, and joined Perſes; which induced the Romans to ſend orders to Paulus Æmilius, after the reduction of Macedon, to plunder their cities and level them with the ground. This order was punctually, though reluctantly, executed throughout the whole country in one day. One hundred and fifty thouſand of the inhabitants were made ſlaves, and ſold to the beſt bidder for the benefit of the republic. All the cities of Epirus, to the number of 70, were diſmantled, and the chief men of the country carried to Rome, where they were tried, and moſt of them condemned to perpetual impriſonment. After this cataſtrophe, Epirus never recovered its ancient ſplendour. Upon the diſſolution of the Achæan league, it was made part of the province of Macedon; but when Macedon became a dioceſe, Epirus was made a province of itſelf, called the province of Old Epirus, to diſtinguiſh it from New Epirus, another province lying to the eaſt of it. On the diviſion of the empire, it fell to the emperors of the eaſt, and continued under them till the capture of Conſtantinople by the Latins, when Michael Angelus, a prince nearly related to the Greek emperor, ſeized on Ætolia and Epirus. He was ſucceeded by his brother Theodorus, who ſo far enlarged his dominions, that, diſdaining the title of deſpot, he aſſumed that of emperor, and was crowned by Demetrius archbiſhop of Bulgaria. Charles, the laſt prince of this family, dying without lawful iſſue, bequeathed Epirus and Acarnania to his natural ſons, who were expelled by Amurath II. Great part of Epirus was afterwards held by the noble family of the Caſtriots, who, though they were maſters of all Albania, yet ſtyled themſelves princes of Epirus. Upon the death of the famous George Caſtriot, Epirus fell to the Venetians, who were ſoon diſpoſſeſſed of it by the Turks, in whoſe hands it ſtill continues; being now known by the name of Albania, which comprehends the Albania of the ancients, all Epirus, and that part of Dalmatia which is ſubject to the Turks. Plutarch tells us, that the Epirots enjoyed the beſt ſort of liberty under their kings; for, as he ſays, a general aſſembly of the people was annually convened at Paſſaron, a city in the province of Moloſſis, where the king bound himſelf by a ſolemn oath to govern agreeably to the laws, and the people to obey and ſupport him as long as he ſhould make the laws the rule of his government.

EPISARCIDIUM, from επι and σαρξ, *fleſh*, a name given by many of the old authors to an anaſarca.

EPISCAPHIA, from επι and σκαφη, *boat*, feaſts celebrated by the Rhodians.

EPISCENIA, from επι and σκηνη, *tent*, feaſts celebrated by the Lacedæmonians.

EPISCENIUM, Επισκηνιον, in *Antiquity*, a place upon the top of the theatre, where all the machines for moving the ſcenes were kept. Potter. Archæol. Græc. lib. i. cap. 8. p. 42.

EPISCEPSIS, Επισκηψις, an action brought to prove the diamartyria, or proteſtation, that the perſon deceaſed had left an heir, to be falſe and groundleſs. Potter. Archæol. Græc. lib. i. cap. 24. i. p. 128.

EPISCIRA, Επισκιρα, or Episcirosis, a feſtival celebrated at Scira in Attica, in honour of Ceres and Proſerpine. Potter. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 395.

EPISCHESES, from επεχω, or επισχω, *I reſtrain*, in *Medicine*, a term uſed by Dr. Cullen to denote the fifth order of his fourth claſs of diſeaſes, which includes the retention

tention of accuſtomed evacuations, *viz.* conſtipation of the bowels, ſuppreſſion of urine, of the catamenia, &c.

EPISCHION, from ἐπι and ἰσχιον, *iſchium*, a name given by the old Greek writers to the pubes.

EPISCOPACY, the quality of epiſcopal government, or that form of church diſcipline, wherein dioceſan biſhops are eſtabliſhed, diſtinct from, and ſuperior to, prieſts or preſbyters. See BISHOP, EPISCOPAL, EPISCOPALIANS, and HIERARCHY.

Epiſcopacy, and preſbytery, have been alternately eſtabliſhed and aboliſhed in Scotland.

EPISCOPACIDE, from ἐπισκοπος, *biſhop*, and *cædo*, *I kill*, the crime of murdering a biſhop by one of his own clergy. By the ancient laws of England, the ſame obedience is due from a clergyman to his biſhop as from a ſervant to his maſter; and therefore the offences of murdering either are made equal, that is, they are both petty treaſon.

EPISCOPAL, ſomething that belongs to a biſhop.

The word is formed of the Greek ἐπισκοπος, *overſeer*, derived from ἐπισκοπεω, *inſpicio*, *I inſpect*, or *overlook*.

Epiſcopal government, is the government of a dioceſe, wherein one ſingle perſon, legally conſecrated, preſides over the clergy of a whole diſtrict, in quality of head, or ſuperintendant thereof; conferring orders, and exerciſing a ſort of juriſdiction.

The preſbyterians reject the epiſcopal eſtabliſhment, and condemn the epiſcopal orders as a human inſtitution, the mere reſult of ſecular policy, or of pride and ambition.

Among the epiſcopal functions, the principal part is that of holding frequent viſitations of the dioceſe.

EPISCOPALES VALVULÆ, called alſo, by ſome, valvulæ mitrales, two valves in the pulmonary vein, which prevent the reflux of the blood to the heart.

EPISCOPALIA, is ſometimes uſed in the ſame ſenſe with pontificalia.

EPISCOPALIA, is alſo uſed to denote ſynodals, or cuſtomary payments, due to the biſhops from the clergy of their dioceſe.

Theſe cuſtomary payments have been otherwiſe called onus epiſcopale; and were remitted, by ſpecial privilege, to free churches and chapels of the king's foundation which were exempt from epiſcopal juriſdiction.

EPISCOPALIANS, or EPISCOPISTS, a name given to thoſe who adhere to the church of England, and particularly to the eccleſiaſtical hierarchy, ſuch as it was in the Romiſh church before the Reformation; who affect the diſcipline of biſhops, prieſts, canons, the office, or liturgy, &c. and retain the greateſt part of the canon law, with the decretals of the popes, more cloſely than the Catholics themſelves of ſeveral countries; though, as to matters of doctrine, or faith, they agree in moſt points with the Calviniſts, or Reformed.

In Scotland, the principal diſſenters are the Epiſcopalians; lay Epiſcopalians enjoy all the ſame civil privileges with thoſe of the eſtabliſhed church. They are under no reſtrictions; tied to no teſts, but are employed in all places of truſt, upon taking the oaths to the government. But the epiſcopal miniſters are liable to ſeveral penal laws; many of them having been nonjurors.

EPISCOPI MULTA. See MULTA.

EPISCOPISSA, a word uſed by writers of the middle ages, to denote a biſhop's wife.

EPISCOPIUS, SIMON, in *Biography*, a Dutch divine of the Arminian perſuaſion, was born at Amſterdam in the year 1583. Having entered on his academical ſtudies in the univerſity of Leyden in 1600; and graduated M. A. in 1606, he purſued his theological ſtudies with great aſſiduity; but on account of the diſputes that ſubſiſted between the Gomariſts and Arminians, he found obſtacles in the way of his admiſſion to the miniſterial office, which the burgomaſters of Amſterdam wiſhed him to aſſume. Diſguſted by this illiberal treatment, he left Leyden in 1609, and removed to the univerſity of Franeker, where he had to contend with ſimilar difficulties, on account of his attachment to the Arminian doctrines. In the year 1710, however, he was admitted to the profeſſion of the miniſtry, and appointed to a church at Bleſwyck, in the neighbourhood of Rotterdam. In the following year he appeared as one of the deputies at the conference held at the Hague, before the ſtates of the province, between ſix anti-remonſtrant and ſix remonſtrant miniſters, where he diſtinguiſhed himſelf by his defence of the opinions of his party. In 1712 he was choſen profeſſor of divinity at Leyden, in the room of Gomarus, who ſurrendered that office. In this ſituation he conducted himſelf with ſingular prudence, as well as ability, ſo that he lived on terms of amity with Polyander, his colleague, who belonged to the party of Gomariſts. The controverſy concerning predeſtination was at this time the occaſion of great animoſity; and Epiſcopius, and his friends, were objects of enmity and perſecution to the deluded populace. Their condition was rendered more perilous by the partiſans of Maurice, prince of Orange, by whom they were calumniated, not only as heretics in their theological ſentiments, but as enemies to the proteſtant religion, and to the United Provinces. At length Maurice and the Gomariſts, of whom he was the head, ſucceeded in obtaining a decree of the States for convening a national ſynod; but the Arminians remonſtrated againſt the meeting of ſuch a ſynod, becauſe they well know that it would be compoſed of their inveterate enemies, who on this occaſion would appear both as their accuſers and their judges. However, it met at Dort in the year 1618, (See *Synod* of DORT,) and the buſineſs of the ſeſſions was conducted as Epiſcopius and his party apprehended. The ruling members were invincible, and required implicit ſubmiſſion to their deciſions. It was in vain that Epiſcopius and his brethren demurred and remonſtrated againſt their proceedings. They were expelled from the ſynod, and their cauſe was tried during their abſence. The reſult was a ſentence, which charged them with peſtilential errors, and with being corrupters of the true religion. This ſentence was followed by their excommunication, a deprivation of their offices, eccleſiaſtical and civil, a prohibition to exerciſe their miniſtry, and beſides fines and impriſonment, baniſhment from the territories of the republic. Accordingly Epiſcopius, as well as ſeveral of his adherents, retired to Antwerp, where he drew up various publications in defence of his oppreſſed party, ſome of which are, "A Confeſſion of Faith," expreſſed for the moſt part in words and phraſes of ſcripture: a treatiſe, entitled "Antidotum adverſus Synodi Dordracenæ Canones," and two letters, addreſſed to Wadingus, a Jeſuit, who wiſhed to ſeduce him into his church, one on the rule of faith, and the other upon the worſhip of images. In 1609, Epiſcopius withdrew into France, and endeavoured to confirm and comfort his brethren, as well as to diffuſe the opinions for which he ſuffered, both by his correſpondence and publications. In 1626, after the death of prince Maurice, and the acceſſion of prince Frederick Henry, he returned to his native country, and enjoyed the benefits of toleration and tranquillity. The place of his ſettlement was Rotterdam, where he exerciſed his miniſtry for about 8 years, and compoſed ſeveral pieces of a theological

logical and controverfial nature, which were publifhed during his life and after his death. The Arminians, having remained for fome years unmolefted, eftablifhed a college at Amfterdam, of which Epifcopius was the firft theological profeffor, and this appointment occafioned his removal to Amfterdam in the year 1634. In the honourable and diligent difcharge of the duties of this office, he continued till his death, which happened in 1643. Epifcopius was a man of folid and extenfive learning; a cool and accurate judgment, a lively genius, and commanding powers of cloquence. His controverfial pieces, though occafionally intermixed with unbecoming ardour and bitternefs, are generally diftinguifhed by a fpirit of candour and moderation. His character was highly exemplary. His fentiments coincided with thofe of Arminius, which he reduced into a fyftematic form, and recommended by the graces of compofition. His works, confifting of commentaries, theological inftitutions, controverfial treatifes, &c. form two volumes in folio; which were edited by Peter Curcellæus, who has prefixed an account of the author. A larger life of him was publifhed by Philip â Limborch, the fon of his brother's daughter, written in the Dutch language, of which a Latin verfion appeared at Amfterdam in 1701. 8vo. Bayle. Mofheim. Moreri. Gen. Biog.

EPISCOPUS PUERORUM, *bifhop of the boys*, a ludicrous kind of office, formerly exercifed in churches, in that called the feaft of fools, or the feaft of the kalends. See *Boy* BISHOP.

EPISEMASIA, from επισημαινω, *I fignify*, in *Medicine*, is the very time that a difeafe firft feizes a perfon, and is properly called fignificatio. Blancard.

EPISODE, Επεισοδιον, from επι, *upon*, and εισοδος, *entry*, is commonly conceived to be a feparate incident, ftory, or action, which an hiftorian, or poet, inferts, and connects with his principal action; to furnifh out the work with a greater diverfity of events; though, in ftrictnefs, all the particular incidents whereof the action or narration is compofed, are called epifodes.

EPISODE, in *Dramatic Poetry*, was the fecond part of the ancient tragedy.

The origin and ufe of epifodes is defcribed by M. Hedelin, and F. Boffu. Tragedy, in its original, being only a hymn fung in honour of Bacchus, by feveral perfons, who made a kind of chorus, or concert of mufic, with dancing, and the like; to diverfify the reprefentation a little, and divert the audience, they determined at length to divide the finging of the chorus into feveral parts, and to have fomething rehearfed in the intervals.

At firft, a fingle perfon, or actor, was introduced, then two, then more; and what the actors thus rehearfed, or entertained the audience with, being fomething foreign, or additional to, or befide, the fong of the chorus, and no neceffary part thereof, was called επεισοδιον, *epifode*.

And hence tragedy came to confift of four parts, the prologue, epifode, exode, and chorus. The prologue was all that preceded the firft entrance of the chorus, and concluded with the firft interlude, or choral ode, between the acts. The epifode, all that was interpofed between the fingings of the chorus, and extended in general from the firft to the laft of the interludes. The exode, all that was rehearfed after the chorus had done finging, or comprehended all that was faid after the laft interlude. And the chorus, was the grex, or company, that fung the hymn. See each of thefe articles.

And as this recitation of the actors was in feveral parts, and inferted in feveral places, it might either be confidered together as a fingle epifode, confifting of feveral parts; or each part might be called a diftinct epifode.

Thefe feveral epifodes in the fame tragedy might either be taken from fo many different fubjects, or from the fame fubject divided into a proper number of recitations, or incidents.

To confider only the firft occafion, and inftitution of thefe foreign or additional pieces, it appears no ways neceffary, that they fhould be taken from one and the fame fubject; three or four recitations of different actions, no wife related, or connected to each other, would eafe the actors, and amufe the people, in the intervals of the chorus, as well as if they were all fo many parts of the fame action. By degrees, what was at firft only an addition to the tragedy, became the principal part thereof. Then the feveral pieces, or epifodes, began to be confidered as one fingle body which was not to have parts, or members of different nature, and independent of each other.

The beft poets took the thing in this light, and drew all their epifodes from the fame action; which practice was fo fully eftablifhed in Ariftotle's time, that he lays it down as a rule. Thofe tragedies wherein this unity and connexion were not obferved, he called epifodic pieces. See TRAGEDY.

EPISODE, in *Epic Poetry*. The term epifode, by being tranfplanted from the ftage to the epopœia, did not change its nature. All the difference Ariftotle makes between the tragic and epic epifodes, is, that the latter are more ample than the former.

Ariftotle ufes the word in three different fenfes: the firft taken from the enumeration already made of the parts of the tragedy, *viz.* prologue, chorus, epifode, and exode; whence it follows, that in tragedy, every thing is epifode that is none of the other parts; fo that as, among us, there are tragedies without either prologue, chorus, or epilogue, the tragic epifode includes the whole tragedy; confequently the epic epifode muft be the whole poem, in like manner; all there is to retrench from it being the propofition and invocation, which ftand in lieu of the prologue. In this fenfe, the epopœia and tragedy have each only one epifode; and if the parts or accidents be ill connected together, the poem will be epifodic and defective.

But farther, as all that was fung in the tragedy was called the chorus, in the fingular number, yet this fingularity did by no means prevent every part or divifion of the fame from being called a chorus, without making feveral choruffes; fo it was with the epifode; each incident, and part of the fable and action, is not only a part of the epifode, but it is an epifode itfelf.

The term epifode, therefore, in this fenfe, fignifies every part of the action expreffed in the plan, or firft draught of the fable; as the abfence and wanderings of Ulyffes, the diforders in his family, and his prefence, which retrieved and fet all to rights again.

Ariftotle furnifhes us with a third kind of epifode; in fhewing that what is contained and expreffed in the firft plan of the fable is proper, and that all the reft is epifode.

By *proper* he means what is abfolutely neceffary; and by epifode, what in one fenfe is neceffary, and in another not; fo that the poet is at liberty to ufe, or let it alone.

Thus, Homer, having made the firft draught of the fable of his Odyffey, was not at liberty either to make Ulyffes abfent from his country, or not. His abfence was effential; and therefore Ariftotle ranks it among the things he calls *proper*. But he does not beftow that appellation on the adventures of Antiphates, Circe, the Sirens, Scylla, Charybdis,

Charybdis, &c. The poet was at liberty to have left thefe alone, and to have chofen others in their room; fo that they are epifodes diftinct from the firft action, to which they are not immediately neceffary.

The third fenfe of the word epifode comes to the fecond: all the difference between them is, that what we call epifode in the fecond fenfe, is the ground or plan of the epifode in the third; and that the third adds to the fecond certain circumftances which are only probable, and not neceffary, as the places, princes, and people, among whom Ulyffes was caft by Neptune.

It muft be added, that in an epifode in the third fenfe, the incident, or epifode in the firft fenfe, whereon it is grounded, is to be extended and amplified; otherwife, an effential part of the action and fable does not become an epifode.

Laftly, it is in this third fenfe that we are to underftand that precept of Ariftotle, not to make the epifodes till after the names of the perfons have been chofen. Homer would not have fpoken of the fleets and fhips as he has done, if, in lieu of the names of Achilles, Agamemnon, and Iliad, he had chofen thofe of Adraftus, Capaneus, and Thebaid.

Upon the whole, the term epifode, in the epic poem, as ufed by the father of the critics, Ariftotle, does not fignify any foreign or accidental adventure; but the whole narration of the poet, or a neceffary and effential part of the action and fubject, amplified with probable circumftances.

Thus Ariftotle enjoins that the epifode be not added to the action, or fetched from elfewhere; but that it be a part of the action; and never ufes the word *adding*, in fpeaking of epifodes, though it occurred fo naturally to his interpreters, that they have generally ufed it in their tranflations and comments. He does not fay, that after laying the plan and choofing the names, the poet is to add the epifodes; but ufes the derivative of the word epifode, ἐπισοδεῖν, as if in Englifh we fhould fay epifodify his action.

From what has been faid, we may venture to define epifodes to be neceffary parts of the action, extended and filled up with probable circumftances. Now an epifode is only a part of an action, and not a whole action; and this part of the action, which is the bafe or ground of the epifode, muft not, when epifodified, retain any thing of the fimplicity which it had when firft expreffed in general, in the plan of the fable.

The fubject of a poem may be lengthened two ways; either by the poet's making ufe of a great many of his epifodes; or by his amplifying and giving a greater extent to every one. By this latter method, chiefly, it is, that the epic poets lengthen their poems much beyond the dramatic. It muft be added, that there are certain parts of an action, which of themfelves do not naturally prefent or afford more than one epifode; fuch as the death of Hector, of Turnus, or the like: whereas there are other parts of the fable more copious and fertile, and which oblige the poet to make diverfe epifodes on each, though laid down in the firft plan with as much fimplicity as the reft: fuch are the battles of the Trojans and Grecians, the abfence of Ulyffes; the wanderings of Æneas, &c. For Ulyffes's abfence fo many years from his own country, required his prefence elfewhere; and the defign of the fable was to throw him into feveral dangers, and different countries. Now each peril, and each new country, furnifhed an epifode, which the poet might ufe if he pleafed.

The refult of the whole is, that epifodes are not actions, but parts of actions; that they are not added to the action and matter of the poem, but make the action and matter themfelves; that of courfe they are not to be fetched from elfewhere, but raifed from the ground or bafis of the action; that they are not united and connected with the action, but with one another; that all the parts of an action are not fo many epifodes, but only fuch as are amplified, and attended with particular circumftances; and laftly, that their union with each other is neceffary in the ground of the epifode, and probable in the circumftances.

Epifodes, fays Dr. Blair, (Lectures, vol. iii.), as the term is now underftood, are certain actions, or incidents, introduced into the narration, connected with the principal action, yet not of fuch importance as to deftroy, if they had been omitted, the main fubject of the poem. Of this nature are the interview of Hector with Andromache, in the Iliad; the ftory of Cacus, and that of Nifus and Euryalus in the Æneid; the Adventures of Tancred with Erminia and Clorinda, in the Jerufalem; and the profpect of his defcendants exhibited to Adam, in the laft books of Paradife Loft. Such epifodes as thefe, are not only permitted to the epic poet; but, provided that they be properly executed, are great ornaments to his work. The rules that ferve to regulate them are fuch as follow: they muft be naturally introduced, and have a fufficient connection with the fubject of the poem; they muft feem to be inferior parts belonging to it, and not mere appendages annexed to it. In the next place, epifodes ought to prefent to us objects of a different kind, from thofe which go before, and thofe which follow, in the courfe of the poem. For epifodes are introduced into an epic compofition, principally for the fake of variety. Laftly, as an epifode is a profeffed embellifhment, it ought to be particularly elegant and well-finifhed; and, accordingly, it is, for the moft part, in pieces of this kind, that poets put forth their ftrength. The epifodes of Taribezus and Ariana, in Glover's Leonidas; and of the death of Hercules, in the Epigoniad, are the two greateft beauties in thefe poems. With regard to epifodes in didactic poetry; fee DIDACTIC *Poetry*.

EPISODIC, in *Poetry*. A fable is faid to be epifodic, when it is fwelled with unneceffary incidents; and its epifodes are not neceffarily, nor properly, connected with each other.

Ariftotle lays it down, that thofe tragedies are moft defective, whofe epifodes have no connection, or dependence on each other, which he calls epifodic, *q. d.* fuperabundant in epifodes; becaufe fo many little epifodes can never compofe one whole one, but neceffarily remain in a vicious plurality.

If an epifode be ufed, the names and circumftances whereof are unneceffary, and whofe ground and fubject make no part of the action, that is, of the matter of the poem, fuch an epifode renders the fable epifodic. This irregularity is difcovered, when one may take away a whole epifode, without fubftituting any thing in its room; and yet leave no chafm, or defect, in the poem. The hiftory of Hypfipule, in Statius's Thebaid, affords an inftance of thefe faulty epifodes. If the whole ftory of that illuftrious nurfe were retrenched, the fequel of the principal action would be the better for it. Nor would any body imagine he had forgot any thing, or that there was any member of his action wanting. Boffu, and Arift. Poet. cap. 9.

EPISPASTIC, from ἐπι and σπάω, *I draw*, in *Medicine*, a term denoting the quality of thofe fubftances, which, when applied to the fkin, draw the humours to the part, or excite inflammation and vefication in it. The word, therefore, is nearly fynonymous with veficatory, or bliftering. See BLISTER.

EPISPHÆRIA, from επι and σφαιρα, *a sphere*, in *Anatomy*, are windings and turnings in the outer fubftance of the brain, that the fanguiferous veffels may pafs more fecurely.

EPISTÆBE, in *Botany*, a name given to the cufcuta or dodder, found growing on the plant ftæbe of the ancient Greeks. See Epiphæos.

EPISTAPHYLINUS, in *Anatomy*, a name under which the azygos uvulæ mufcle has been defcribed. It will be found, in different writers, under the names of ftaphylinus, columellæ mufculus teres, mufculus uvulæ, or mufcle de la luette. It is defcribed in the article Deglutition.

EPISTATES, Επιςατες, derived from επι, *over*, and ιςημι, *I ftand*, in *Antiquity*, a perfon who has the command and direction of an affair, or of a people.

The term is of confiderable ufe, in fpeaking of the government of Athens, where the epiftates was the fenator in command for that day, or whofe turn it was to prefide that day. The conftitution was this: the ten tribes of Athens formed by Clifthenes, elected every year by lot, each of them, fifty fenators, which made a fenate of five hundred. Every tribe had the precedence in its turn, and furrendered it again fucceffively to another. The fifty fenators in office were called prytanes; the particular place where they affembled, prytaneum, and the term, or duration of their office, *viz.* thirty-five days, prytanea. During thefe thirty-five days, ten of the fifty prytanes prefided weekly, under the name of proedri; and of thefe proedri there was one to prefide each day of the week, under the title of epiftates.

No perfon was allowed to hold his office more than once in his whole life, left he fhould acquire too much the tafte of dominion: the fenators of all the other tribes ftill voted, according to the order the lot had given them; but the prytanes laid the bufinefs before them, and the epiftates took their votes and opinions.

It muft be added, that of the ten proedri, of each week, there were but feven that would prefide each his day in the quality of epiftates; the ten proedri elected the feven prytanes.

EPISTAXIS, from επιςαζω, *inftillo*, in *Surgery*, hemorrhage from the nofe.

When bleeding from the nofe takes place in fuch a degree as to be dangerous, or likely to bring on exceffive debility, the further effufion of blood may be ftopped in the following manner. Roll a confiderable piece of lint round the end of a probe; wet it completely through with a ftrong folution of the zincum vitriolatum; introduce it into the noftril, and prefs it as ftrongly as poffible againft the part whence the blood iffues. As foon as the blood ceafes to flow, we may conclude that the preffure acts on the bleeding point. This plan generally fucceeds.

When the blood, however, flows from fome point which lies very deeply in the noftril, it might be found impracticable to make preffure exactly on the bleeding veffels. At all events, we may then pafs a piece of catgut through the noftril, and bring it out of the mouth, from the fauces, by means of a pair of common forceps. A tent of lint may next be faftened to the ligature, and drawn backward through the mouth into the nofe, fo as completely to ftop up the pofterior opening of the noftril. The front aperture may be eafily filled with a proper doffil of lint. In this manner, it is clear that no further hemorrhage can happen, as the blood cannot poffibly find its way outward.

EPISTEMONARCH, derived from επιςημη, *knowledge*, and αρχη, *command*, a dignitary, in the *Ancient Greek Church*, appointed to watch over the actions of the church, and to infpect or fuperintend every thing relating to the faith, in quality of a cenfor. His office anfwered pretty much to that of magifter facri palatii at Rome.

EPISTHOTONOS, from επισθω, *forwards*, and τεινω, *to extend*, in *Surgery*, a fpecies of tetanus, in which the body is bent forwards. See Tetanus.

EPISTITES, from επιςημι, *I keep off*, in *Natural Hiftory*, the name of a ftone, defcribed by the writers of the middle ages, as being of a beautiful red, and fhining very elegantly. It was renowned for its many magical virtues, according to the idle tradition of thefe times; they faid it drove away all noxious animals, and kept off ftorms from the place where any one was who had it about him.

EPISTLE, a letter miffive.

The word is formed of επιςελλω, *I fend.*

The term epiftle is now fcarcely ufed, but for letters wrote in verfe, and letters dedicatory.

In fpeaking of letters written by moderns, or rather in the modern languages, we never ufe the word epiftle. Thus, we fay, the letters, not epiftles of the cardinal D'Offat, of Voiture, of Balzac, of Howel, of Pope, &c.: but thofe wrote by the ancients, or rather in the ancient language, we call epiftles; as the epiftles, not letters in Cicero, Pliny, Seneca. The epiftles of St. Paul, St. Peter, St. John, &c. to the Romans, Corinthians, &c.

A Table of St. Paul's Epiftles, in the order of time, with the places where, and the times when they were written.

Epiftles.	Places.		A. D.
1 Theffalonians 2 Theffalonians	Corinth		52
Galatians	Corinth, or Ephefus	Near the end of or the beginning of	52 53
1 Corinthians	Ephefus	The beginning of	56
1 Timothy	Macedonia		56
Titus	Macedonia, or near it	Before the end of	56
2 Corinthians	Macedonia	About October	57
Romans	Corinth	About February	58
Ephefians	Rome	About April	61
2 Timothy	Rome	About May	61
Philippians	Rome	Before the end of	62
Coloffians	Rome	Before the end of	62
Philemon	Rome	Before the end of	62
Hebrews	Rome, or Italy	In the fpring of	63

A Table of the Seven Catholic Epiftles, fo called becaufe they were written to Chriftians in general, and the Revelation, with the places where, and the times when they were written.

Epiftles.	Places.		A. D.
The Epiftle of St. James	Judea	61 or beginning of	62
The 2 Epiftles of St. Peter	Rome		64
St. John's 1ft Epiftle	Ephefus	About	80
His 2d and 3d Epiftles	Ephefus	Between	80 and 90
The Epiftle of St. Jude	Unknown		60 or 65
The Revelation of St. John	Patmos, or Ephefus		95 or 96

See Lardner's Credibility of the Gofpel Hiftory, vol. xvi. and vol. xvii.

Learned writers are not abfolutely agreed as to the dates of thefe feveral epiftles, nor the places whence they were written. It would lead us too far to examine and produce the various authorities and arguments that have been ufed for fettling thefe particulars: we fhall only mention that Dr. Doddridge dates the 1ft Epiftle to the Corinthians about the year 57; and the 2d Epiftle in 58; thofe to the Ephefians, Philippians, Coloffians, and Philemon, in 63; the 1ft to Timothy, in 58 or 65; the 2d to Timothy, in 66 or 67; the Epiftle to Titus, between St. Paul's firft and fecond imprifonment at Rome; the Epiftle of St. James, in 60 or 61; the 1ft of Peter in 61; the 2d, in 67; that of St. Jude, fome time after the 2d of Peter, according to Dr. Mills, in the year 90. As to the general defign of thefe feveral epiftles, it is obferved by Dr. Doddridge, who is defervedly efteemed an excellent and ufeful expofitor, that the Epiftle to the Romans is intended to fix in the minds of the Chriftians, to whom it is addreffed, a juft fenfe of the excellency of the gofpel, and to engage them to act in a manner agreeable to their profeffion of it: the Epiftles to the Corinthians are defigned to refolve fome important queries propofed by them, and to correct the various criminal irregularities and diforders, of which they were guilty: the principal defign of the Epiftle to the Galatians was to affert and vindicate the apoftle's authority and doctrine, and to confirm the churches of Galatia in the faith of Chrift, efpecially wih refpect to the important point of juftification; to expofe the errors that were introduced among them, and to revive thofe principles of Chriftianity which he had already taught them. In the Epiftle to the Ephefians, that apoftle endeavours to eftablifh them in the faith; and to this end to give them more exalted views of the divine love and the excellence of Chrift; to fhew them that they were now, though Gentiles, made partakers of equal privileges with the Jews; to encourage them, by his own example and concern for their welfare; and to engage them to the practice of duties becoming their Chriftian character. The Epiftle to the Philippians is defigned to comfort them under the concern they felt on his account; to check a party-fpirit that had broke out among them, and to promote union and affection; to guard them againft the feduction of judaizing teachers; to fupport them under their trials, and to infpire them with an ambition of excelling in ornamental and diftinguifhed attainments. The Epiftle to the Coloffians is defigned to excite them to a temper and conduct worthy of their facred character, and to fecure them from the influence of thofe Pagan fophifts or Jewifh bigots, who endeavoured to feduce them from the purity of the Chriftian faith. The two Epiftles to the Theffalonians are intended to confirm them in their adherence to the Chriftian faith, and to engage them, from the fufferings they had already endured, and the extraordinary character they had hitherto maintained, to make great advances, and to excel ftill more in religion and virtue; and alfo to rectify fome erroneous apprehenfions they entertained about the coming of Chrift, and to direct them in the proper exercife of Chriftian difcipline The firft Epiftle of Timothy was partly intended to direct him in managing the affairs of the church, and choofing proper perfons for the various offices it required; and partly to caution him againft the influence of judaizing teachers, to urge him to pay a conftant regard to the interefts of practical religion, and to animate him to diligence, fidelity, and zeal. The fecond epiftle prepares Timothy for the fufferings that awaited him, forewarns him of the apoftacy that was beginning to appear in the church, and animates him to the perfevering difcharge of every part of the minifterial office. The Epiftle to Titus contains a variety of prudent inftructions and cautions. The defign of the Epiftle to the Hebrews was to confirm the Jewifh Chriftians in the faith and practice of the gofpel, which they might be in danger of deferting through the infinuation or ill-treatment of their perfecutors. St. James, in his epiftle, aims to correct thefe errors both in doctrine and practice into which the Jewifh Chriftians had fallen, which might otherwife have produced fatal confequences; and then to eftablifh the faith, and animate the hope of fincere believers under their prefent and approaching fufferings. The Epiftles of St. Peter are defigned to induce the Chriftian converts in various parts of the world to maintain a conduct inoffenfive and amiable; to fupport them under their trials, and to encourage their conftancy, notwithftanding the artifices of falfe teachers, and the perfecution of their moft inveterate enemies. The leading defign of St. John in his firft epiftle, is to evince the vanity of faith feparate from morality; to infpire the minds of Chriftians with mutual charity, and to guard them againft the fnares and efforts of Antichrift, and of all who were endued with his fpirit. The Epiftle of Jude defcribes the characters of the falfe teachers, reprefents the divine judgments which fuch perfons had reafon to expect, and thus cautions Chriftians againft being perverted by them. See Doddridge's Fam. Expofitor, vol. iv. v. and vi. in the general introduction prefixed to each epiftle. See alfo an account of the writers of thefe epiftles, and of the churches to which they were addreffed.

Epistle, *Poëtical*, a fpecies of didactic poetry, the fubjects of which are the manners and characters that occur in ordinary life, and that require to be treated with fomewhat of the eafe and freedom of converfation. When thefe epiftles are employed on moral and critical fubjects, they feldom rife into a higher ftrain of poetry than *fatires*, which fee. Many other fubjects may be difcuffed in the form of an epiftle; fuch as love poetry, or elegiac; fpecimens of which occur in Ovid's "Epiftolæ Heroidum," and his "Epiftolæ de Ponto." As thefe works are defigned to be merely fentimental, and their merit confifts in being proper expreffions of the paffion or fentiment which forms the fubject, they may affume any tone of poetry that is fuited to it. But didactic epiftles feldom admit of much elevation. The poet, commonly reftricting himfelf to obfervations on authors, or on life and characters, and not intending to compofe a formal treatife, or to confine himfelf ftrictly to regular method, gives fcope to his genius on fome particular theme, which, at the time, has prompted him to write. Much of the grace of this kind of writing confifts in a fpirited concifenefs, which gives to fuch compofition an edge and livelinefs, that ftrike the fancy and keep attention awake. Much of their merit depends alfo on juft and happy reprefentations of characters. Unfupported by thofe high beauties of defcriptive and poetical language, which adorn other compofitions, the reader expects them to entertain him with lively paintings of men and manners; and therefore in thefe a certain fprightlinefs and turn of wit find their proper place, and contribute to the beauty and effect. Of this kind of poetry Mr. Pope's ethical epiftles furnifh an almoft perfect model. In thefe his wit difcovers itfelf to fuch a degree as to give a proper feafoning to grave reflections. His paintings of characters are natural and lively; and, never was any writer fo happy in that concife fpirited ftyle, which gives animation to fatires and epiftles. His rhyme likewife adds to the ftyle an elevation which otherwife it could not have poffeffed, while at the fame time he manages it fo artfully, that it never appears in the leaft to incumber him, but, on the contrary, ferves to increafe the livelinefs of his manner. In this fpecies of writing, eafe and elegance are the diftinguifhing characters; nothing, therefore, fhould be forced or unnatural, laboured or affected, but every part of the compofition fhould manifeft an eafy, polite, and unconftrained freedom.

EPISTOLARES, among the Romans, under-fecreta- ries

ries to the "magifter fcrinii epiftolarum," or fecretary who wrote the emperor's leters. They were thirty-four in number. See MAGISTER.

EPISTOLARY, a term ufed in the phrafe epiftolary ftyle. As the matter of an epiftle is the fame with that of converfation, it fhould not differ in the manner of expreffion; and, therefore, all pomp and ftudy of language are not only needlefs but very improper: the moft plain and eafy way of conveying our thoughts muft certainly be beft, as being moft natural. Purity in the choice of words, and juftnefs of conftruction, joined with perfpicuity, are the chief properties of this ftyle: to which purpofe Cicero obferves, "that in writing letters we make ufe of common words and expreffions." (Ad Fam. lib. ix. cap. 21.) And Seneca fays, "I would have my letters be like my difcourfes, when we either fit or walk together, unftudied and eafy." (Ep. 75. ad Lucill.)

The firft and fundamental requifite in epiftolary writing is to be natural and fimple, for a ftiff and laboured manner is as bad in a letter as in converfation. This does not banifh fprightlinefs and wit. Thefe are graceful in letters as well as in converfation; when they flow eafily, and without being ftudied; when employed fo as to feafon, and not to clog. A perfon, who either in converfation or in letters affects to fhine and fparkle always, will not pleafe long. The ftyle of letters fhould be neat and correct, but not too highly polifhed. Nicety about words betrays ftudy; and on this account mufical periods, and appearances of number and harmony in arrangement, fhould be carefully avoided in letters. Thofe that are written with the greateft facility are commonly the beft. Neverthelefs, it fhould be remembered, that the eafe and fimplicity of epiftolary writing are not to be underftood as importing entire carelefsnefs. In writing to the moft intimate friend, a certain degree of attention, both to the fubject and the ftyle, is requifite and becoming. The firft requifite both in converfation and correfpondence, is to regard all the proper decorums, which our own character, and that of others demand. An imprudent expreffion in converfation may be forgotten and pafs away; but with the pen in hand, we fhould remember the well-known adage, "Litera fcripta manet."

As the fubjects of epiftles are various, they will neceffarily acquire fome variety in the manner of expreffion. If the fubject be weighty and momentous, the language fhould be ftrong and folemn; in things of a lower nature, more free and eafy; and upon lighter matters, jocofe and pleafant. In exhortations, it ought to be lively and vigorous; in confolations, kind and compaffionate; and in advifing, grave and ferious. In narratives, it fhould be clear and diftinct; in requefts, modeft; in commendations, friendly, without adulation; in profperity, chearful; and mournful, in adverfity. In a word, the ftyle ought to be accommodated to the particular nature of the fubject about which it is converfant. Although there fhould be nothing very confiderable in the fubject; yet if the fpirit and turn of the correfpondence be agreeable, if the letters be written in a fprightly manner, and with native grace and eafe, they may ftill be entertaining, more efpecially if there be any thing to intereft us in the characters of thofe who write them. As letters from one friend to another make the neareft approach to converfation, we may expect to fee more of character difplayed in thefe than in other productions, which are ftudied for public view. We are pleafed with beholding a writer fo fituated as to allow him to be at his eafe, and to give occafional vent to the overflowings of his heart. Befides, the different character of the perfon, to whom the letter is written, requires a like difference in the modes of expreffion. Superiors fhould be addreffed with refpect; inferiors, with courtefy; and equals, with civility. Old men and young, the grave and facetious, courtiers and philofophers, friends and ftrangers, require fome variety in the mode of addrefs. The epiftles of Cicero, the ftyle of which is plain and fimple, and yet pleafant and engaging, furnifh a proper model in this refpect. They are the moft valuable collection of letters in any language, as they are letters of real bufinefs, written to the greateft men of the age, compofed with purity and elegance, but without the leaft affectation; and, what adds greatly to their merit, written without any intention of being publifhed to the world. Pliny's letters are elegant and polite; and exhibit a very pleafing and amiable view of the author; but, according to the vulgar phrafe, they fmell too much of the lamp. They are too elegant and fine: and the author feems to be cafting an eye towards the public, when he is appearing to write only to his friends. His ftyle abounds fo much with turns and quibbles upon the found of words, as to render it more ftiff and affected than agrees with converfation, or than a man of fenfe would choofe to ufe in difcourfe, if it were in his power. This, indeed, was owing to the age in which he lived, at which time the Roman eloquence was funk into puns, and an affectation of wit; for Pliny was otherwife a man of fine fenfe and great learning. We need not here recommend Melmoth's tranflation of the letters of Cicero and Pliny. The moft diftinguifhed collection of letters in the Englifh language is that of Mr. Pope, Dean Swift, and their friends; publifhed partly in Mr. Pope's works, and partly in thofe of Dean Swift. Many letters in this collection are written with eafe and a beautiful fimplicity. Thofe of Dr. Arbuthnot deferve this commendation. Dean Swift's are unaffected. Several of lord Bolingbroke's and of bifhop Atterbury's letters are mafterly. Mr. Pope's are too artificial. Among the French in the laft age, Balzac and Voiture were the two moft celebrated epiftolary writers. Balzac's periods are fwelling, and his ftyle pompous; fo that his reputation foon declined. Voiture continued for a long time a favourite author. His compofition is extremely fparkling; he manifefts much wit, and trifles agreeably. His only fault is, that he is too open and profeffed a wit, to be thoroughly agreeable as a letter-writer. The letters of Madam de Sevigné are now efteemed the moft accomplifhed model of a familiar correfpondence. Trifling as are their fubjects, and overloaded as they are with compliments, they fhew fuch perpetual fprightlinefs, they contain fuch eafy and varied narration, and fo many ftrokes of the moft lively and beautiful painting, perfectly free from any affectation, that they are juftly entitled to high praife. The letters of lady Mary Wortley Montague poffefs much of the French eafe and vivacity, and retain more the character of agreeable epiftolary ftyle, than perhaps any letters which have appeared in the Englifh language. Ward's Orat. vol. ii. p. 213, &c. Blair's Lect. vol. iii. Lect. 37. See STYLE.

EPISTOLARY is fometimes alfo applied to authors who have wrote epiftles or letters. The principal epiftolary authors are Sidonius Apollinaris, Tully, the younger Pliny, Seneca the philofopher, Petrarch, Politian, Bufbequius, Erafmus, Lipfius, Muretus, Afcham, Milton, Petau, Launoi, Sarau, Balzac, Voiture, fir W. Temple, Lyttelton, &c. &c. See the preceding Article.

EPISTOMIA, in *Anatomy*, are the utmoft gapings and meetings of veffels.

EPISTOMIUM, Επιϛομιον, from επι, *upon*, and ϛομα, *mouth*, in *Hydraulics*, a plug or inftrument, by the application whereof

whereof the orifice of a veffel may be opened and fhut again at pleafure.

EPISTROPHE, Επιστροφη, in *Rhetoric*, a figure wherein that which is fuppofed of one thing is ftrongly affirmed of another, and the repetition of the fame word occurs at the end of each member or fentence.

"Since concord was loft, friendfhip was loft, fidelity was loft, liberty was loft, all was loft." Auct. ad Herenn. lib. iv. cap. 13. See alfo 2 Cor. xi. 22.

EPISTROPHEUS, in *Anatomy*, from επι, *upon*, and στρεφω, *I turn*, a name given to the fecond vertebra of the neck, round a particular procefs of which the firft vertebra turns. See SPINE.

EPISTYLE, Επιστυλιον, from επι, *upon*, and στυλος, *column*, in the *Ancient Architecture*, a term ufed by the Greeks for what we call architrave, *viz.* a maffive ftone, or a piece of wood, laid immediately over the capital of a column.

The epiftyle is the firft or loweft member of the entablature.

EPITAPH, Επιταφιον, from επι, *upon*, and ταφος, *fepulchre*; a monumental infcription, in honour or memory of a perfon defunct; or an infcription engraven or cut on a tomb, to mark the time of a perfon's deceafe, his name, family, and ufually fome eloge of his virtues or good qualities.

At Sparta, epitaphs were only allowed to people who died in battle. Boxhornius has made a collection of epitaphs, not very ample, but exceedingly well chofen. F. Labbe has likewife given a collection of the like kind in French, intitled, "Trefor des Epitaphes." Camden, Weaver, and Toldervy, have done fomething in the fame way with our Englifh epitaphs.

In epitaphs, the dead perfon is fometimes introduced by way of profopopœia, fpeaking to the living; of which we have a fine inftance, worthy the Auguftan age, wherein the dead wife thus befpeaks her furviving hufband.

"Immatura peri: fed tu, felicior, annos
Vive tuos, conjux optime, vive meos."

The French have a proverb, "Menteur comme une epitaphe; He lies like an epitaph;" an allufion to the eloges ordinarily contained therein, which are not always over-juft.

EPITAPH, is alfo applied to certain eloges, either in profe or in verfe, compofed without any intent to be engraven on tombs.

The elegance of an epitaph confifts in a nervous and expreffive brevity, and it is fometimes clofed with an epigrammatic point. It is obferved by Dr. Johnfon, in his life of Pope, that the difficulty of writing an epitaph confifts, in giving a particular and appropriate praife. This, he fays, is not always to be performed, whatever be the diligence or ability of the writer; for the greater part of mankind have no character at all, or little that diftinguifhes them from others equally good or bad; and, therefore, nothing can be faid of them, which may not with equal propriety be applied to a thoufand more.

In the Anthologies, or collections of epigrams, we have abundance of epitaphs, fome of them ludicrous and fatirical, others grave. For a fpecimen, we fhall here add a very beautiful one, compofed by Mr. Cowley, on himfelf, to be put in a little country-houfe, whither he retreated from the court and town to fpend his laft days.

"Hic, O viator, fub lare parvulo,
Couleius hic eft conditus, hic jacet
Defunctus humani laboris
Sorte, fupervacuaque vita;
Non indecora pauperie nitens,
Et non inerti nobilis otio,
Vanoque dilectis popello,
Divitiis, animofus hoftis.
Poffis ut illum dicere mortuum,
En terra jam nunc quantula fufficit
Exempta fit curis, viator,
Terra fit illa levis, precare.
Hinc fparge flores, fparge breves rofas;
Nam vita gaudet mortua floribus;
Herbifque odoratis corona
Vatis adhuc cinerem calentem."

The following epitaphs, befides many others, are worth recording. That of Alexander:

"Sufficit huic tumulus, cui non fufficeret orbis."

That of Newton:

"Ifaacum Newton
Quem immortalem
Teftantur Tempus, Natura, Cœlum,
Mortalem hoc marmor
Fatetur."

That of Dryden:

"Dryden."

Similar to which is that which the Italians have annexed to the tomb of Taffo:

"Les os du Taffe."

The following epitaph on the fifter of fir Philip Sidney, the countefs of Pembroke, and faid to be written by the famous Ben Jonfon, is diftinguifhed by its admirable conclufion:

"Underneath this noble marble hearfe
Lies the fubject of all verfe,
Sidney's fifter, Pembroke's mother:
Death, ere thou haft kill'd another
Fair, and learn'd, and good as fhe,
Time fhall throw a dart at thee."

The following alfo by the fame author is well known, and has been much admired:

"Underneath this ftone doth lie
As much virtue as could die;
Which, when alive, did vigour give
To as much beauty as could live."

Another epitaph, by Dr. Samuel Johnfon, on a celebrated mufician, deferves to be recorded, as it is equalled by few, and furpaffed by none.

"Philips! whofe touch harmonious could remove
The pangs of guilty pow'r and haplefs love,
Reft here, diftreft by poverty no more;
Find here that calm thou gav'ft fo oft before;
Sleep undifturb'd within this peaceful fhrine,
Till angels wake thee with a note like thine."

The following epitaphs are fpecimens of the fatirical or ludicrous kind:

Prior on himfelf, ridiculing the folly of thofe who value themfelves on their pedigree.

"Nobles and heralds, by your leave,
Here lie the bones of Matthew Prior,
The fon of Adam and of Eve;
Let Bourbon or Naffau go higher."

On a Miser.

" Reader, beware of immod'rate love of pelf;
Here lies the worst of thieves, who robb'd himself."

A similar epitaph by Dr. Swift.

" Beneath this verdant hillock lies
Damer, the wealthy and the wise.
His heirs, that he might safely rest,
Have put his carcase in a chest;
The very chest, in which, they say,
His other self, his money, lay.
And if his heirs continue kind
To that dear self he left behind,
I dare believe that four in five
Will think his better half alive."

We shall here subjoin the epitaph of the ingenious and laborious author of the Cyclopædia, from his tomb in the cloisters of Westminster Abbey, on the north side, written by himself:

" Multis pervulgatus,
Paucis notus;
Qui vitam inter lucem et umbram,
Nec eruditus, nec idiota,
Literis deditus transegit; set ut homo
Qui humana nihil a se alienum putat,
Vita simul et laboribus functus,
Hic requiescere voluit
Ephraim Chambers,
R. S. S.
Obiit 15 Maij, 1740."

In English thus:

" Heard of by many,
Known to few;
Who led a life between fame and obscurity;
Neither abounding nor deficient in learning;
Devoted to study; but as a man
Who thinks himself bound to all offices of humanity;
Having finished his life and labour together,
Here desires to rest.
Ephraim Chambers."

We shall close this article with some pertinent remarks on epitaphs, by an anonymous writer in the " Olla Podrida." The perusal of epitaphs is not to be considered as a light and frivolous amusement. If such only be the object of attention, as have been noticed with our applause, it is unquestionably an introduction to pleasing knowledge, and an incentive to moral improvement. What biography is to history, an epitaph is to biography. It is a sketch which marks the great outlines of character, and excites curiosity to view the portraits as painted in the pages of history. It is likewise an epitome of a sermon, which teaches the most useful truths in the most comprehensive form. Monumental inscriptions remind us, that time is on the wing, that every rank and age must fall a prey to his depredations; that the moments of life are too precious to be squandered away on trifles; that religion is the only support against the horrors of death, and the only guide to the joys of eternity.

EPITASIS, formed of επιτεινω, *intendo*, *I heighten*, in the *Ancient Poetry*, denoted the second part or division of a dramatic poem, wherein the plot or action proposed and entered upon in the first part or protasis was carried on, heightened, warmed, and worked up, till it arrives at its state or height called the catastasis.

This division is laid aside in the modern drama; in lieu whereof our plays are divided into acts. See Act.

The epitasis might ordinarily take up about our second or third act.

Epitasis, in *Medicine*, denotes the increase or growth and heightening of a disease; or the beginning of a paroxysm, particularly in a fever.

EPITHALAMIUM, Επιθαλαμιον, formed of επι, and θαλαμος, *bride-chamber*, in *Poetry*, a nuptial-song, or a composition, usually in verse, on occasion of a marriage between two persons of eminence.

The topics it chiefly insists on are the praises of matrimony, and of the married couple, with the pomp and order of the marriage solemnity: it concludes with prayers to the gods for their prosperity, their happy offspring, &c. This kind of poetry is very ancient: the 44th Psalm, and the book of Canticles have been considered as specimens of the epithalamium. Stesichorus, who flourished in the forty-second Olympiad, has been usually esteemed the inventor of the epithalamium among the Greeks, though it is known that Hesiod composed the epithalamium of Thetis and Peleus, a work now lost; but a fragment of which is preserved by an ancient scholiast. Catullus exceeded all antiquity in his epithalamiums, and the cavalier Marino all the moderns.

Among the Greeks, the epithalamium was sung by young men and maids at the door of the bed-chamber of the married pair in the evening and morning. The former sort were called επιθαλαμια κοιμητικα, and the latter εγερτικα.

EPITHEM, Epithema, from επι, *upon*, and τιθημι, *pono*, *I put*, in *Pharmacy*, a kind of fomentation or remedy, of a spirituous or aromatic kind, applied externally to the regions of the heart, liver, &c. to strengthen and comfort the same, or to correct some intemperature thereof.

There are principally three kinds of these external applications, the liquid, the solid, and the soft or poultice kind. See Cataplasm and Fomentation.

Epithem, *Volatile*, *epithema volatile*, a form of medicine prescribed in the late London Pharmacopœia, and ordered to be made of equal weights of common turpentine and spirit of sal armoniac. The turpentine is to be kept continually stirring in a mortar, and the spirit gradually dropt in till the whole is reduced to a white mass.

The spirit of sal armoniac used in this mixture must not be that made in the common way, with the addition of quick-lime, but with the alkali salt. Pemberton's Lond. Disp. p. 377.

EPITHE'SIS, from επι and τιθημι, *to lay upon*, an old term in *Surgery*, the meaning of which was the straightening of deformed limbs by mechanical contrivances.

EPITHET, Επιθετον, a noun adjective, expressing some quality of a substantive to which it is joined.

The word is formed of επι, *upon*, and θεσις, *positio*, *putting*. As a fruitful vine, a stately pile, an echoing vault, &c.

Epithets are of great use and conveniency among poets and orators, who supply in epithets what they want in other requisites. Card. Perron even blames Homer on the head of epithets, observing, that he frequently hooks in epithets without any sense or significancy at all, to help out his measures; and that he equips every hero with an epithet, not according to the exigence of the case, but the measure of the verse.

Epithet, is also used for a surname, or a person's second appellation.

Epithets were anciently bestowed very frankly, either on account of excellencies or defects of the body or mind; kings themselves were not exempted from them. Hence those thofe epithets fo frequent in hiftory, as Edward Long-fhanks, Richard Cœur de Leon, Edmund Iron-fide, Richard Crook-back, John Lack-land, &c.

Nor have the French ufed their kings any better; witnefs their Charles the Simple, Louis the Lazy, faineant (Ludovicus nihil faciens) Pepin the Short, Louis the Stammerer, le begue.

EPITHRICADIA, in *Antiquity*, a feftival in honour of Apollo.

EPITHYME. See DODDER, and EPITHEOS.

EPITOME, an abridgment, or a reduction of the principal matters of a larger book into a little compafs. See ABRIDGMENT.

The word is Greck, επιτομη, formed of επιτεμνειν, *refecare, to retrench, abridge*, or *cut off.*

The epitome of Baronius's Annals is done by De Sponde (Spondanus). Bernier has given an epitome of the philofophy of Gaffendus.

It is a popular objection againft the epitomizing of authors, that it frequently occafions the lofs of the originals. Thus the lofs of the hiftorian Trogus Pompeius is attributed to his epitomizer Juftin, and the lofs of a great part of Livy to Luc. Florus. See LIVY.

"Epitomes," fays the learned Bacon, "are the moths and corruptions of hiftory, that have fretted and corroded the found bodies of many excellent hiftories, and wrought them into bafe and unprofitable dregs."

EPITRITES, from επι, and τριτος, *third*, in *Profody*, a foot confifting of four fyllables, three long, and one fhort.

Grammarians reckon four fpecies of epitrites; the firft, confifting of an iambus and fpondee, as fălūtāntēs; the fecond, of a trochee and fpondee, as cōncĭtātī; the third, of a fpondee and an iambus, as cōmmūnĭcāns; and the fourth, of a fpondee and trochec, as īncāntārĕ.

EPITRITES, among the *Greek Muficians*, denoted a ratio, called alfo the fefquitertial ratio, the fame with that of three to four. See FOURTH.

EPITROCHASMUS, in *Rhetoric*, a figure wherein we flightly pafs over feveral things of great moment, by only mentioning them in general. Such is the faying of Cæfar, *Veni, vidi, vici.*

EPITROPE. See CONCESSION. This is one of the figures of fentences, which grants one thing to obtain another more advantageous. It is either real or feigned; and either the whole of a thing, or only a part is granted. Nothing more confounds an adverfary, than to grant him his whole argument, and at the fame time either to fhew that it is nothing to the purpofe, or to offer fomething elfe, which may invalidate it. Of the ufe of this figure we have examples in Cicero's defence of Ligarius, who was accufed by Tubero for having joined with Pompey in the civil war between him and Cæfar, (cap. 1.); and in the affair of Rofcius, where the proof depended upon circumftances; and when Cicero, who defended him, inquires what reafon could be alledged for his committing fo black a crime, as to kill his father, (cap. 27.) Cicero has alfo given us an example of a feigned or ironical conceffion in his defence of Flaccus (cap. 38.); when interceding for him on account of his former good fervices, in the time of Catiline's confpiracy, he fays in the way of irony, if fuch things are to be overlooked, "let us appeafe the ghofts of Lentulus and Cethegus; let us recall thofe who are in exile, and let us be punifhed for our too great affection and love for our country." To thefe feigned conceffions we may refer fuch modes of reafoning, by which the orator both juftifies a charge brought againft him, upon the fuppofition of its being true; and alfo proves that the charge itfelf is falfe. Thus Cicero, in his defence of Milo, reprefents the taking off of Clodius, with which Milo was accufed, as a glorious action; after he has fhewn that Milo's fervants did it without the knowledge of their mafter. (Cap. 10. and 27.)

EPITROPUS, a kind of judge, or rather an arbitrator, which the Greek Chriftians under the dominion of the Turks elect in the feveral cities, to terminate the differences that arife among them, and avoid carrying them before the Turkifh magiftrates. See ARBITRATOR.

There are feveral epitropi in each city. M. Spon, in his Travels, obferves, that at Athens there are eight taken out of the feveral parifhes, and called vecchiardi, *i. e.* old men. But Athens is not the only place where there are epitropi; they are in all the iflands of the Archipelago.

Some Latin authors of the fixth century call epitropi thofe who more anciently were called villici, and fince vidames.

In times ftill earlier, the Greeks ufed the term επιτροπος, in the fame fenfe as the Latins did *procurator, viz.* for a commiffioner or intendant.

Thus the commiffioners of provifions in the Perfian army are called by Herodotus and Xenophon epitropi. In the New Teftament, επιτροπος denotes the fteward of a houfehold, rendered in the vulgate procurator.

EPIZEUXIS, in *Rhetoric*, a figure where the fame word is repeated with vehemence in the fame fenfe, without any others intervening, and fuited to exprefs anger, furprife, forrow, and feveral other paffions: thus *age, age*; *adefte, adefte*; and that of Virgil, *nunc, nunc infurgite remis*, are inftances of it. Thus alfo, when Cicero would exprefs his indignation againft Antony for having been the chief inftrument in bringing on the civil war, he fays to him: "You, you, Antony, pufhed Cæfar upon the civil war." (Philip. ii. c. 22.) Thus he tells Catiline in his firft invective againft him; "You live, and live, not to lay afide, but to purfue your wicked defign." (Ibid. cap. 2.) See Matthew xxiii. 37. The ufe of this figure fhews the earneftnefs of the fpeaker and the great concern of his mind about what he fays, and has a natural tendency to excite the attention of the audience.

EPIZOOTIC STRATA, or *Mountains*, in *Geology*, are fuch as contain remains of animals, which a very large portion of all thofe upon the furface of the earth feem to do, although their reliquiæ are by no means equally numerous in all ftrata, probably owing to their not being preferved in every inftance, fo that their remains or impreffions can be now traced.

EPIZOOTY, a denomination given to an epidemical or contagious diftemper among horned cattle. M. de Saive, apothecary to the prince bifhop of Liege, has given the following inftructions for the prevention and cure of this diforder. As foon as any fymptoms of the diftemper are perceived, about $1\frac{1}{2}$ pint of blood fhould be taken from the beaft, unlefs he has been ill a day or two, in which cafe he fhould not be blooded; but in both cafes the following draught fhould be given, *viz.* N° 1. an ounce of the beft Venice treacle diffolved in a pint of vinegar, after which the back-bone and the whole hide muft be well rubbed with a dry hair cloth, to heat the hide and promote perfpiration. No drink fhould be given him but a white drink compofed of (N°. 2.) a handful or two of rye-meal in a pailful of clean water; and if the beaft fhould want food, mix up fome crumbs of rye bread with fome of this white drink, and give it him. The animal's mouth muft be wafhed twice a day with a cloth dipped in a mixture of (N°. 3.) equal quantity of vinegar and water, with a fpoon-

ful

ful of honey to a pint of it. If on the fecond day the beaft has not dunged, a clyfter compofed of (N°. 4.) a pint of water in which bran has been boiled, two fpoonfuls of falt, and a fmall glafs of vinegar muft be given and repeated every day till the evacuations are natural and regular. Befides the above remedies, the following cordial mixture (N°. 5.) *viz.* a pint of clear water, the fame quantity of vinegar, four fpoonfuls of honey or fyrup, and two glaffes of brandy, muft be given four times a day to facilitate and keep up perfpiration; taking particular care to repeat the friction as above directed. If the beaft fhould ftill continue low and heavy, the draught (N°. 1.) muft be repeated, unlefs he fhould be found to be hot and thirfty, in which cafe only the drink (N°. 2.) fhould be ufed. On the fourth day, if he feems more lively and free from heat, purge him with (N°. 6.); two ounces of falts and one ounce of common falt, diffolved in a pint of lukewarm water, with two fpoonfuls of honey. If this does not procure four or five evacuations, repeat the clyfter the fame day.

This mode of treatment muft be continued without intermiffion till the beaft begins to eat; then he muft have only the white drink (N° 2) and a little good fodder, or fome rye-bread dipped in ftale beer, moderately fweetened with honey or fyrup. The exterior treatment confifts in the application of fetons in the beginning of the diftemper, at the bottom of the dewlap, and of cauteries towards the horns, between which fome weight, *e.g.* a ftone of a pound weight or more, wrapped up in a cloth, muft be fixed in order to keep it fteady. This is neceffary to keep the head warm. But above all, the friction muft be carefully attended to, for determining the critical efforts of nature. It would be proper alfo to evaporate vinegar in the cowhoufe, &c. and if it could be done without rifk, blowing of a few grains of gunpowder in them twice a day would be a very ufeful fumigation. If, notwithftanding thefe aids, the beaft be not perfectly cured in ten or twelve days, they muft be continued without bleeding, unlefs the inflammation be very confiderable; but if, after all, the diftemper does not give way, the beaft muft be killed, buried very deep, and well covered with earth and turf, for the purpofe of preventing the exhalation of the putrid vapours and the fpread of the infection. The principal prefervatives from infection confift in wafhing the racks, troughs, &c. and the hide of the beaft every day, with plenty of water; and inftead of expenfive aromatic fumigations fometimes recommended, the ufe of fires made with the branches of green wood, with pitch thrown on it to quicken the flames and perfume the air. Common falt given in fmall quantities every day to horned cattle, is reckoned an excellent prefervative, particularly in a learned differtation on the contagious diftempers among horned cattle, by M. de Limborg, M.D. F.R.S. Letters, &c. on Agriculture of the Bath, &c. Society, vol. i.

EPLOYE', in *Heraldry.* An eagle eployé is what in Englifh we more ufually call an eagle difplayed, or a fpread eagle. See Displayed.

EPNEUMATOSIS, from πνευματόω, *I breathe,* in *Medicine,* the fame with expiration.

EPOBOLIA, in *Antiquity,* a fine laid upon thofe that could not prove the indictment they had brought againft their adverfaries.

It was fo called, becaufe they were obliged to pay the fixth part of the value of the thing they contended for, *viz.* an obolus out of every drachm. Some of thefe fums were depofited in all law-fuits, a very few excepted, before the trial could proceed. Potter. Archæol. Græc. lib. i. cap. 21. tom. i. p. 117.

EPOCH, in *Aftronomy,* is the mean longitude of a planet for the commencement of a given year. It is one of the principal elements of the elliptic motion. (See Element and Elliptic *Motion.*) When two obfervations of a planet are made in the mean diftances, that is, at three and nine figns of mean anomaly, it is then practicable to correct, by two fuch obfervations, both the epoch and equation of the centre. If the latter is exact, there will be no other difference between the calculation and obfervation than the epoch of the mean motion, fince the place of the aphelion does not influence the longitudes taken at the mean diftances; the error will, therefore, be equal in the two obfervations, for we fuppofe the mean motion known exactly. Thus, if the errors of the tables are found equal at three and nine figns of anomaly, it is a proof that the equation of the centre is exact, and that the error lies wholly in the epoch being improperly affumed.

EPOCHA, in *Chronology,* a term or fixed point of time, whence the fucceeding years are numbered or accounted.

The word is ἐποχη, q. d. *inhibitio, repreffio,* formed of ἐπεχειν, *to fuftain, ftop,* becaufe the epocha defines or limits a certain fpace of time. For the difference between epocha and era; fee Æra.

Different epochas obtain in different nations; and no wonder; for there being no aftronomical confideration to render one preferable to another, their conftitution is purely arbitrary. That principally regarded among Chriftians is, the epocha of the Nativity or Incarnation of Jefus Chrift; that of the Mahometans, the Hegira; that of the Jews, &c. the Creation of the World; that of the ancient Greeks, the Olympiads: that of the Romans, the Building of the City; that of the ancient Perfians and Affyrians, the epocha of Nabonaffar, &c.

The doctrine and ufe of epochas are of very great extent in chronology.

To reduce the years of one epocha to thofe of another, *i. e.* to find what year of one correfponds to a given year of another; a period of years has been invented, which, commencing before all the known epochas, is, as it were, a common receptacle of them all, called the Julian period. To this period all the epochas are reduced, *i. e.* the year of this period whereon each epocha commences is determined. All that remains, therefore, is, to add the given year of one epocha to the year of the period correfponding with its rife; and from the fame to fubtract the year of the fame period correfponding to the other epocha; the remainder is the year of that other epocha.

Epocha *of Chrift,* or *of our Lord,* is the vulgar epocha throughout Europe, commencing from the fuppofed time of our Saviour's nativity, December 25, or rather according to the ufual account, from his circumcifion, that is, from the firft of January.

Now, the year of the Julian period, wherein Chrift was born and circumcifed, is ufually computed to be the 4713th; confequently, the firft year of the era of Chrift correfponds to the year 4714 of the Julian period.

Hence, 1. If to any given year of Chrift you add 4713, the fum will be the year of the Julian period correfponding thereto, *E. gr.* If to the year 1809 be added 4713, the fum 6522 is that year of the Julian period.

2. On the contrary, fubtracting 4713 from any given year of the Julian period, the remainder is the current year of Chrift. *E. gr.* from the year of the Julian period 6522, fubtracting 4713, the remainder is the year of Chrift 1809.

In effect, the epocha of our Lord ferves not only for the computation

computation of the years elapfed fince the epocha commenced, but even of thofe before it.

Now, to find the year of the Julian period correfponding to a given year before Chrift, fubtract the given year from 4713, the remainder is the correfpondent year required. Thus, *e. gr.* the year before Chrift 752, is the year 3961 of the Julian period. On the contrary, fubtracting the year of the Julian period from 4713, the remainder is the year before Chrift.

The author of the vulgar epocha, or way of computing from Chrift, is an abbot of Rome, one DIONYSIUS *Exiguus*, (which fee,) by nation a Scythian, who flourifhed under Juftinian about the year 507, or, according to others, 527, though this Dionyfius borrowed the hint from Panodorus, an Egyptian monk. Till his time, the generality of Chriftians computed their years either from the building of Rome, or according to the order of the emperors and confuls, and by other ways in ufe with the people among whom they lived.

This diverfity occafioning a great diftraction between the churches of the Eaft and Weft; Dionyfius, to compofe the fame, firft propofed a new form of the year, with a new general era, which in a few years time was generally admitted.

Dionyfius began his account from the conception or incarnation, by us popularly called Lady-day, or the Annunciation; which method obtained in the dominions of Great Britain till the year 1752, before which time the Dionyfian and Englifh epocha was the fame; but in that year the Gregorian calendar having been admitted by act of parliament, they now reckon from the firft of January, as they do in the other countries of Europe, except in the court of Rome, where the epocha of the incarnation ftill obtains for the date of their bulls.

It muft be added, that this epocha of Dionyfius is charged with a miftake: the common opinion is, that it places our Saviour's nativity a year too late; or that he was born the winter preceding the time prefcribed by Dionyfius for his conception.

But the truth is, the fault lies on Bede, who mifinterpreted Dionyfius, and whofe interpretation we follow, as has been fhewn by Petavius from Dionyfius's own epiftles; for Dionyfius began his cycle from the year 4712, but his epocha from the year 4713, wherein the vulgar era fuppofes Chrift to have been incarnate.

The year, therefore, which, according to the vulgar epocha, is the firft year of Chrift, according to Dionyfius's era is the fecond; fo that the year which we call 1809, fhould, in juftice, be 1810, though fome chronologers, inftead of one year, will have the error two.

Others fuppofe that the Dionyfian era is four years too late; which fuppofition is confirmed by confidering that our Saviour was born before the death of Herod the Great; and during the reign of Auguftus (Matth. ii. 1. 22. Luke, ii. 1.) and according to the teftimony of Jofephus, (lib. xvii. cap. 18.) there was an eclipfe of the moon in the time of Herod's laft illnefs; which eclipfe appears to have happened in the year of the Julian period 4710, March 13, at Jerufalem. Now, as our Saviour muft have been born fome months before Herod's death, fince in the interval he was carried into Egypt, the lateft time in which we can fix the true era of his birth is about the end of the 4709th year of the Julian period.

In order to afcertain the true year of our Saviour's birth, it is neceffary to fix the precife time of Herod's death. The chief opinions concerning the time of this event are three. Some think he died a little before the paffover of A. U. 750, Julian year 42; others on Nov. 25 in that year; and others, a fhort time before the paffover A. U. 751. We learn from Jofephus, (De Bell. lib. ii. c. 1. Antiq. l. xvii. c. 9.) whofe authority we cannot reject in deciding this queftion, that Herod died but a fhort time before one of the Jewifh paffovers. That Herod died a fhort time before the paffover A. U. 750, Julian year 42, is argued in this manner. His diftemper had made great progrefs before the pulling down of the golden eagle at the temple. The Jewifh rabbies excited their fcholars to this action. News being brought that Herod was *dying* (Jof. de Bell. l. i. c. 33. § 1.) or *dead* (Jof. Ant. l. xvii. c. 6. § 3.) thefe rabbies were taken up and carried to Jericho, where Herod was, in a very infirm ftate, and where they were tried and burnt to death. On that very night there was an eclipfe of the moon, which, as we have already mentioned, happened March 13th A. U. 750. From this time Herod grew worfe and worfe; fo that he could not live long. The paffover of this year happened on the 11th of April; and the interval between the 13th of March and 11th of April would have been fufficient for every thing that Jofephus has related concerning Herod's illnefs; the fettling of his affairs, the execution of Antipater, Herod's death and funeral, which are the occurrences between the eclipfe and Archelaus's coming to Jerufalem at the paffover.

Befides, from circumftances related by Jofephus concerning Archelaus, one would be apt to conclude, that he reigned nine years complete, and that the 10th year was current when he was banifhed. Dio (l. lv. p. 567.) places Archelaus's banifhment in the 759th year of Rome. If Herod did not die, as fome imagine, till the beginning of A. U. 751, the 9th year of Archelaus's reign could not be completed in the 759th year of Rome. But if Herod be fuppofed to have died in the beginning of A. U. 760, Jofephus and Dio agree. Moreover, Jofephus fays, that Cyrenius feized Archelaus's eftate, and finifhed the affeffment in Judea in the 37th year after the defeat of Antony at Actium by Cæfar Auguftus. The victory at Actium was obtained Sept. 2, A. U. 723; therefore the 37th year from it begins Sept. 2, A. U. 759, and ends Sept. 2, 760. Suppofing then that Herod died in the beginning of A. U. 750, there is in this particular alfo a very good harmony between Jofephus and Dio. Befides, Jofephus informs us (Ant. l. xiv. c. 29.) that Herod was appointed king by the Roman fenate A. U. 714. *i. e.* 40 years before the vulgar era. The fame hiftorian obferves, that he died in the 37th year of this reign, and 34th after the death of Antigonus, *viz.* in the 42d Julian year (Antiq. l. xvii. 10.) If to 713 we add 37, the fum will be 750, the year of Rome in which this prince died.

The opinion, adopted by other learned men, that Herod died a fhort time before the paffover A. U. 751, labours under feveral great difficulties, which are pointed out by Dr. Lardner (ubi infra). Upon the whole it appears, that Herod did not die before the year 750, nor furvive the year 751, and that he died a fhort time before the Jewifh paffover of one of thefe years. It follows, that if Herod died in 750, he died three years and nine months before the vulgar Chriftian era, which commences January 1, A. U. 754; if at the time above-mentioned, in the year 751, then he died about two years and nine months before the faid era. "Which is the truth," fays Dr. Lardner, with his ufual diffidence and modefty, "I am not able to determine." Accordingly he fays, that "if Herod died in March A. U. 750, I fhould be inclined to place the nativity of Jefus in September or October, A. U. 748; if Herod died in March 751, then the nativity of Jefus might

very

very well be placed in September or October 749." The birth of Jesus must be dated about a year and five or six months before the death of Herod, *i. e.* before the latter end of the year of Rome 748 or 749, *i. e.* 4708 or 4709 of the Julian period; but for reasons already assigned, the latter date is the most probable.

We shall here add, that an objection has been urged against the 15th year of the reign of Tiberius, compared with the age of Jesus at his baptism. (Luke, iii. 1, 2. 23.) If Jesus, it is said, was born above a year, much more, if above two years before Herod's death, then the age of 30 years, here ascribed to him at his baptism, is absolutely inconsistent with the notes of time mentioned at the commencement of John the Baptist's ministry; even allowing, that *the word of God came to John* in the very beginning of the *15th year of Tiberius*, and that Jesus was baptized a few months after. Dr. Lardner observes, that the true meaning of these words, *Jesus himself began to be about* 30 *years of age*, is not that he then *entered* the 30th year of his age, but that Jesus was about 30 years of age when he began his ministry. This, he says, is now the general opinion of learned men; so the Greek word of this text is used by St. Luke in other places. The objection is thus stated: Augustus died, and Tiberius succeeded him the 19th of August, A. U. 767, Julian year 59, A. D. 14. Therefore the 15th of Tiberius began the 19th Aug. A. U. 781, A. D. 28. Herod died before the passover, in A. U. 751, Jul. year 43. If then John the Baptist began to preach in the beginning of the 15th of Tiberius, in the latter end of A. U. 781, and Jesus be supposed to have been baptized by John a few months after, on the 6th of January of the year following, *viz.* A. U. 782, Jesus must have been in the 32d year of his life, if Herod died in the spring, *viz.* A. U. 751, and if Jesus was born the 25th of December preceding, *viz.* A. U. 750. But if Herod died A. U. 750, and Jesus was born the 25th December before, *viz.* A. U. 749, then he would be at his baptism in the 33d year of his age. But it may be made to appear in several ways, that Jesus was born above a year, probably above two years before Herod died. Dr. Lardner has stated this objection in its full force; and detailed several circumstances that tend to obviate it. From some of them he infers, that there is no necessity of placing the birth of Jesus above a year and six months before the death of Herod, as we have already stated. As it is most probable that Herod died A. U. 750, we may be disposed, from other circumstances alleged by this accurate and impartial writer, to place the nativity of Jesus in September or October A. U. 748. The latter part of the summer, or the autumn season, seems to be the most likely time of the year for the birth of Jesus; nor is there any particular reason that should determine us to the 25th of December. The very depth of winter was not a very proper season for a survey and assessment, when people are to enter themselves according to their tribes or families; the autumn, when harvest and vintage are over, would be a time of general leisure. When Jesus was born in Bethlehem, *there were in the same country shepherds abiding in the field, keeping watch over their flocks by night,* (Luke, ii. 8.) This circumstance is not very favourable to the supposition, that Jesus was born the 25th of December; and we are at liberty to place it in autumn, a more likely season. (See CHRISTMAS.) It is not improbable then, that Jesus might be born some time between the middle of August and the middle of November. Cyrenius, we may suppose, came into Judea at the time, or soon after the time, that Varus became governor of Syria (before Sept. A. U. 748), and published the decree of Augustus, requiring all people to enter themselves, their dependents, and estates. This assessment could well be made in a country of such small extent as Judea in two or three months; and the short time appointed for this work may be inferred from the peculiar circumstances of Cyrenius, who wished to hasten back to Rome, and also from St. Luke's history of it. Upon the whole, we may conclude, that about a year and six or seven months before the death of Herod, soon after the arrival of Varus in the province of Syria, in August or September A. U. 748 or 749, Julian year 40 or 41, Cyrenius (or some other person of eminence) came into Judea, an assessment was made there, and in the time of it, Jesus was born at Bethlehem, in the month of September or October. In order, however, to settle satisfactorily the *15th year of the reign of Tiberius*, we should consider that the commencement of his reign may be computed from a different period than that of his sole empire, after the death of Augustus. In fact, it appears, that there were two different dates of the beginning of Tiberius's reign; one from the time of his being made colleague with Augustus, and the other from his sole empire, after the death of Augustus. Many learned writers are of opinion, that St. Luke intends the former of these two computations, referring to a period two years before the death of Augustus, *viz.* in A. U. 765, when Piso was præfect of Rome, Tiberius being prince. Archbishop Usher and Prideaux place the beginning of this government of Tiberius in this year. This epoch of Tiberius's empire was followed for some time by some persons, in the provinces at least; but it is not so certain, when this pro-consular empire began, whether about two years, or about three years before Augustus died. If Tiberius's proconsular empire began about three years before Augustus died, on the 28th of August A. U. 764, A. D. 11, then this 15th of Tiberius's reign (according to this computation of it) began August 28th, A. U. 778, A. D. 25. Supposing that John the Baptist began his ministry November following, in the same year, and that Jesus was baptized by him the 6th of Jan. following, in A. U. 779, A. D. 26; then upon the supposition that Jesus was born in Sept. A. U. 748, he would be at his baptism 30 years of age, and some months more. If Tiberius's proconsular empire commenced about two years before the death of Augustus, in A. U. 765, A. D. 12, then the 15th year of the reign of Tiberius began in A. U. 779, A. D. 26. And supposing that John the Baptist began his ministry in November of that year, and that Jesus was baptized by him the 6th of January following, A. U. 780, A. D. 27, then, upon the supposition that Jesus was born in September, A. U. 749, he would be at the time of his baptism 30 years of age, and some months more; or, if born A. U. 748, he would be somewhat more than 31 years of age. Again, if John the Baptist began his ministry in the 15th of Tiberius, A. U. 778, A. D. 25, according to the first statement, but did not baptize Jesus till the 6th of January, A. U. 780, A. D. 27, after he had preached somewhat above a year, then Jesus would be at his baptism 30 years of age and odd months, if he was born A. U. 749; 31 years of age and some odd months, if born the latter end of the year 748. Such will be the result, if we take those dates of these events, which appear most favourable to St. Luke; since it is not absolutely certain when Herod died, or when Tiberius's proconsular empire began. But if we allow on each hand the dates least favourable to St. Luke's numbers, *viz.* that Jesus was born A. U. 748, and that he was not baptized till January A. U. 780, A. D. 27; yet even then Jesus would be little more than 31 years of age; at which time a person

perſon may be ſaid very properly to be ABOUT *thirty years of age*.

The queſtion of our Lord's nativity and age at his baptiſm is amply diſcuſſed, and the difficulties which it involves accurately and impartially examined, by Dr. Lardner in his "Credibility, &c." See his Works, vol. i. See alſo Playfair's Syſtem of Chronology, p. 49, &c.

Learned men have differed in opinion concerning the preciſe time of the death of Chriſt. Some have referred this event to the 29th year of the vulgar era; others to the 31ſt; and not a few to the 33d. Playfair (with whom Blair agrees) inclines to adopt the laſt of theſe dates, for the following reaſons. 1. There is no other year beſides the 33d of the vulgar era, 78th Julian year, 4746th of the Julian period, A. U. 786, to which this event can be properly referred; for Jeſus Chriſt went to eat the paſſover with his diſciples on the evening of the 14th of the firſt month, and was crucified on the day following, *viz.* on Friday, April 3d, the 16th day of the paſchal moon, according to the true, and the 15th, according to the Jewiſh computation. 2. The 70 weeks of Daniel, which began in the 20th year of Artaxerxes Longimanus, and ended in J. P. 4746, when Meſſiah was cut off. 3. Phlegon, the freedman of Adrian, and eſteemed as an exact computer of the Olympiads, obſerved "that in the 4th year of the 202d Olympiad, there was a miraculous darkneſs; for at the ſixth hour of the day came on night, inſomuch that the ſtars of heaven were ſeen. At the ſame time, there was alſo a great earthquake in Bithynia, which threw down part of the city of Nice." (Compare this account with Matth. xxvii. 45. and Luke, xxiii. 45.) The 4th year of the 202d Olympiad anſwers to the firſt ſix months of the 33d year of our vulgar era, and to the 19th of the reign of Tiberius. Concerning the teſtimony of Phlegon; ſee PHLEGON. 4. When Chriſt ſuffered, Pontius Pilate was governor of Paleſtine (Tacit. l. xv. Joſeph. Antiq. l. xviii. c. 5.); Herod Antipas was tetrarch of Galilee (Luke, xxiii. 6. Joſeph. Antiq. l. xix. c. 7.); and Caiaphas was high-prieſt among the Jews (John, xi. 49. Luke, iii. 2. and Acts, iv. 6.) (See CAIAPHAS.) From theſe and other characters it appears, ſays Playfair, that Jeſus Chriſt lived about 36 years, 3 months, 9 days, and 15 hours, if we reckon (according to the generally received opinion concerning the month and day of his nativity) from midnight of December 25th, of the 42d Julian year commencing, to April 3d and 3 in the afternoon, of the 78th Julian year. His reſurrection took place on Sunday April 5th, and his aſcenſion on Thurſday May 14th.

To the vulgar era of our Lord's nativity, as a ſure fixed point, chronologers have been accuſtomed to reduce all the other epochas, though there is not one of them but what is controverted; ſo much uncertainty there is in the doctrine of time. We ſhall exhibit them as reduced to the Julian period.

EPOCHA *of the Creation, Orbis Conditi*, according to the computation of the Jews, called alſo the Jewiſh epocha, is the year of the Julian period 953, anſwering to the year before Chriſt 3761, and commencing on the ſeventh day of October. Hence ſubtracting 952 years from any given year of the Julian period, the remainder is the year of the Jewiſh epocha correſponding to it. Thus, *e. gr.* the year 1809 being the 6522d year of the Julian period, it is the 5570th year of the Jewiſh epocha, or ſince the creation of the world.

This epocha is ſtill in uſe among the Jews.

The EPOCHA *of the Creation*, uſed by the Greek hiſtorians, is the year before the Julian period, 787, anſwering to the year before Chriſt 5500.

Hence, to any given year of the Julian period, adding 787, the ſum gives the year of this epocha. *E. gr.* 1809 being the 6522d year of the Julian period, 7309 is that year of this epocha, or the year of the world, according to this computation.

The author of this epocha is Julius Africanus, who collected it from the hiſtorians: but when it came to be admitted into civil uſe, 8 years were added to it, that ſo every year thereof divided by 15 might exhibit the indiction, which the eaſtern emperors uſed in their charters and diplomas.

The epocha of the creation uſed by the latter Greeks and Ruſſians is the year 795 before the Julian period, or the year 5508 before Chriſt, commencing from the firſt day of September. Though the Ruſſians, having lately admitted the Julian calendar, begin their year from the firſt of January.

Hence, adding 795 to the year of the Julian period, the ſum gives the year of this epocha. Thus, *e. gr.* the Julian period of the year 1809 being 6522, that year of this epocha, *i. e.* the years from the creation on this footing are 7317. Again, from that year 7317 ſubtracting 5508, the remainder is the year of the common era 1809. This era was uſed by the emperors of the Eaſt in their diplomata, &c. and thence alſo called the "civil era of the Greeks." In reality, it is the ſame with the epocha of the Conſtantinopolitan period; whence ſome call it the "epocha of the period of Conſtantinople."

The Alexandrian EPOCHA *of the Creation* is the year 780 before the Julian period, anſwering to the year before Chriſt 5493, and commencing on the 29th day of Auguſt.

Hence, adding 5493 to the year of Chriſt 1809, the ſum 7302 gives that year of this epocha, or years elapſed ſince the creation, according to this computation.

This epocha was firſt concerted by Panodorus, a monk of Egypt, to facilitate the computation of Eaſter; whence ſome call it the "Greek eccleſiaſtical epocha."

The Euſebian EPOCHA *of the Creation*, is the year of the Julian period 486, anſwering to the year before Chriſt 4228, and commencing in autumn.

Hence, ſubtracting 486 from the year 6522 of the Julian period, or adding 4228 to the year of Chriſt 1809, the reſult 6036 will be that year of this epocha.

This epocha is uſed in Euſebius's Chronicon, and the Roman Martyrology.

The EPOCHA *of the Creation*, according to Mr. Bedford and Mr. Kennedy, is the year of the Julian period 706, anſwering to the year before Chriſt 4007.

The EPOCHA *of the Creation*, according to archbiſhop Uſher, adopted in Blair's tables, is the year of the Julian period 710, correſponding to the year before Chriſt 4004; but it muſt be allowed, that all the epochs of the creation are uncertain. See Strauchius's Brev. Chron. by Sault. p. 152, &c. See chronological table under the article CHRONOLOGY.

EPOCHA *of the Univerſal Deluge*, in the year of the creation 1656, and according to the different methods of computation; ſee the table under CHRONOLOGY, and ANTEDILUVIAN.

EPOCH *of the Olympiads*, is the year of the Julian period 3938, anſwering to the year 776 before Chriſt, commencing at the full moon next the ſummer ſolſtice, and each Olympiad containing four years.

This epocha is very famous in ancient hiſtory; it was uſed principally by the Greeks, and had its origin from the Olympic games, which were celebrated at the beginning of every

every fifth year. See the table above cited, and Olympic *Games*.

Epocha *of the Building of Rome*, or *Urbis Conditæ, U. C.* is the year of the Julian period 3961, according to Varro; or 3962, according to the Fasti Capitolini, answering to the years before Christ 753 or 752, and beginning on the 20th of April. Hence, if the years of this epocha be fewer than 754, subtracting them from 754 or 753, you have the year before Christ; and, on the contrary, if they be more than 754, you must subtract 754 to have the year of Christ, and add the year of Christ to 754 to have the year of this epocha, or the time since the building of Rome. Thus, *e. gr.* the year 1809, according to Varro, is the year of Rome 2563.

The sentiments of the earliest Roman writers, with respect to this epoch, are various; Polybius refers it to the year B. C. 751. Cato, whose opinion is adopted by Solinus, Eusebius, Dionysius Halic. &c. places it one year earlier. Fabius Pictor, who flourished in the time of the first Punic war, and who is styled by Dion. Hal. an accurate writer, brings it down to the 29th year of the olympiads, *i. e.* 747 B. C. Diodorus Siculus adopts this opinion. Sir Isaac Newton, on the testimony of some later Roman writers, observes that Rome was built in the 15th age after the destruction of Troy, that is, after the 14 kings who reigned in Alba. Allowing 21 years to the reign of every king, and computing from the year B. C. 904, when he supposes Troy to have been taken, he brings forward this epoch to the 38th olympiad, *i. e.* 627 B. C. The date of Varro has been adopted by the Roman emperors in their proclamations, by Plutarch, Tacitus, Dion, Gellius, Censorinus, Onuphrius, Baronius, and by most modern chronologers.

Epocha *of Nabonassar*, is the year of the Julian period 3967, answering to the year before Christ 747, commencing the 26th day of February of the Julian year at mid-day. The solar cycle was 19, the lunar 15, and the cycle of indiction 7.

This era takes it denomination from its institutor Nabonassar king of Babylon, and is that used by Hipparchus, by Ptolemy in his Astronomical Observations, by Censorinus, and others.

This epoch is of singular service in chronology, as it serves to connect and adjust all other epochas. The form of this era, which included a period of 424 Egyptian years from the commencement of Nabonassar's reign to the death of Alexander the Great, and which was thence carried down to the reign of Antoninus Pius, is singular. Every year consists of 365 days, and is divided into 12 months. Every month contains 30 days; five intercalary days are added to these months, and the sum composes the quantity of the Nabonassarean year. In every four Julian years, the corresponding four years of this era were evidently deficient by one day; therefore the beginning of the Nabonassarean years must have moved retrogradely; and in the space of 1460 Julian years, must have gone through every day of the year. Whence it appears, that 1460 Julian are equal to 1461 Nabonassarean years. If the first year of the era of Nabonassar began on Wednesday, Feb. 26th, the second and third years must have begun on the same day; because these two years contain 365 days each in the Julian, as well as in the Egyptian calendars. The following year, *i. e.* 744 B. C. being a bissextile, one day was added to the Julian year, consequently the Nabonassarean year began on Feb. 25th in this and the three succeeding years. In the year 740 B. C. it began on February the 24th; in 736 B. C. on February the 23d, &c. The first day of any year of the Nabonassarean era may be found by the following general rule.

Divide the given year by 4 (because in 4 years the Nabonassarean year anticipates the Julian by one day), and the quotient will be the number of days of anticipation, or of the omitted leap-days. If the quotient be less than 57 (the number of days from January 1st to February 26th), let it be subtracted. If the quotient exceeds 57, subtract it from 422, *i. e.* from 57 + the number of days in one Julian year, and the remainder will be the day of the Julian year, reckoned from January 1st, which is the Thoth, or first day of the year following the given one; (Thoth being the name of the month, which in the first year of this era corresponded to Feb. 26th of the Julian year.) From the day found, subtract 1, and the remainder will be the number of the day required.

E. G. On what day of the Julian year did the Thoth of the Nab. era 230 fall? Divide 230 by 4, and the quotient 57, subtracted from 422, leaves a remainder of 365. This shews that the Thoth of N. E. 231st falls on December 31st, or on the 365th day of the Julian year: subtract 1, and the remainder 364, or December 30th, will be the day required.

Epocha, or *Era of Constantinople*, is supposed to have commenced before the creation of the world; for the 5509th year of it answers to the 1st of the vulgar Christian era. It was adopted by the Greek church and empire, all the public acts of which are still dated by it; and the Muscovites computed by it until the reign of Peter the Great. Those who reckon by it make use of civil and ecclesiastical years. The former begin with the month of September, and the latter, sometimes with the 21st of March, and sometimes with the 1st of April.

Epoch *of New Rome*, or *Constantinople*, is usually computed from the time of the consecration of the city. Accordingly the first year of this era was the 25th of the reign of Constantine, A. M. 5838, as the modern Greeks estimate the era of the creation, Julian period 5043. Thus directed, the consecration of the city is fixed in the 330th year of the vulgar era, on the 11th of May.

Epocha, *Dioclesian*, or *Epocha of Martyrs*, is the year of the Julian period 4997, answering to the year of Christ 284, called the "era of martyrs," from the great number of Christians who suffered martyrdom under the reign of that emperor.

The Abyssinians, among whom it is still used in all ecclesiastical computations, call it the "year of grace;" though they do not reckon their years in a continued series from this epocha. But when the Dionysian period of 534 years is expired, they begin their computation afresh from 1, 2, &c.

Epocha *of the Hegira*, or *Mahometan Epocha*, is the year of the Julian period 5335, answering to the year of Christ 622. It commences on Friday the 16th of July, the day of Mahomet's flight from Mecca to Medina.

This epocha is used by the Turks and Arabs, and even all who profess the Mahometan faith. It was first introduced by Omar, the third emperor of the Turks. The astronomers Alfraganus, Albategnius, Alphonsus, and Ulugh Beigh, refer Mahomet's flight to the 15th of July; but all the people who use the epocha agree to fix it on the 16th. See Hegira.

Epocha *of the Seleucidæ*, which is used by the Macedonians, is the year of the Julian period 4402, answering to the year before Christ 312. This is reckoned from the time when Seleucus, one of the generals of Alexander's army, took Babylon and ascended the Asiatic throne.

This era is ſometimes called the Grecian era, and the era of Principalities, in reference to the diviſion of Alexander's empire. The Arabians ſtyle it "Tarik Dhilcarnaim," *i. e.* the era of Contracts, and the Greeks denominate it the Horned era. Thoſe who uſe it reckon ſometimes by Nabonaſſarean years, and ſometimes by Julian, compoſed of Roman months, to which Syrian names have been affixed. Its commencement has been variouſly ſtated, ſome date it on Tueſday March 13th. The Greeks in Syria reckon from a month correſponding to our September. Albategni, and others, reckon from the 1ſt of October. In the firſt book of Maccabees the year is ſaid to have began in Niſan, or the firſt month of ſpring; but in the ſecond book, and in other Jewiſh hiſtories, its beginning is dated in Tizri, which is the firſt month of autumn. See SELEUCIDÆ.

EPOCHA, *Perſian*, or *Yezdegerdic*, is the year of the Julian period 5345, anſwering to the year of Chriſt 632, and commencing on the 16th of June.

This epocha is taken from the death of Yezdegerdis, the laſt king of Perſia, ſlain in battle by the Saracens. See *Perſian* CALENDAR.

EPOCHA, or *Era of the Perſian Monarchy*, is referred by almoſt all ancient hiſtorians to the 1ſt year of the 55th olympiad, *i. e.* 560 B. C. Of this opinion are Diodorus Siculus, Thallus, Caſtor, Polybius, Phlegon, and Euſebius. From the beginning of the Nabonaſſarean era to the firſt year of the reign of Cyrus over Babylon, Ptolemy reckons 209 years. If this number be ſubtracted from 747, the remainder 538 will be the Babylonian epoch of Cyrus; and the monarchy ſtood, according to Agathias, from the firſt year of Cyrus 228 years. That this was its duration is evident from a paſſage of Plutarch (in Vit. Alex.) which mentions an eclipſe of the moon that happened 11 days before the laſt battle between Darius and Alexander, in the month Boedromion. This eclipſe is found, by calculation, to have coincided with the 446th olympic year, Sept. 20. If, therefore, the difference be computed between the 550th olympiad, *i. e.* the 217th olympian year, when the Perſian empire began, and the 446th, when it ended, it will appear to have flouriſhed 228 or 229 years.

EPOCHA, *Gelalæan*, called alſo *Royal Epocha*, and *Epocha of the Sultans*, began in the year of the Julian period 5787, A.D. 1074, on the 14th day of March, at the time of the equinox, and was eſtabliſhed for the convenience of finding the vernal equinox, at which time the Perſians celebrated their great feaſt, called *Neuruz*. See *Perſian* CALENDAR.

EPOCHA *of the eſtabliſhment of the Roman Conſular dignity*. The republican form of government in Rome owed its origin to the tyranny of Tarquin the ſeventh king; in conſequence of which the ſovereign authority was divided, and two magiſtrates were elected under the denomination of conſuls. The conſular dignity was conferred on Brutus and Collatinus, 244 years after the building of the city. The names of the conſuls were regiſtered in the calendars until A. D. 541; and in the 15th year of Juſtinian the order was aboliſhed. See CONSUL.

EPOCHA, *Julian*, or *Epocha of Julian years*, is the year of the Julian period 4668, anſwering to the year before Chriſt 46.

This epocha had its origin from the year of the reformation of the calendar under Julius Cæſar, called the "year of confuſion."

EPOCHA, *Gregorian*. See GREGORIAN.

EPOCHA, *Spaniſh*, is the year of the Julian period 4676, anſwering to the year before Chriſt 38.

This era commenced at the time of the ſecond diviſion of the Roman provinces among the Triumviri, and is reckoned from the 1ſt of January in the year 38 B. C. ſo that the firſt year of the Chriſtian coincides with the 39th year of the Spaniſh era. The moſt famous ſynods of Spain and Africa have been diſtinguiſhed and deſcribed according to the computation of this era; but by a decree of the council of Tarragon, A. D. 1180, the Chriſtian era was ſubſtituted in its room, though it continued in uſe till the year 1383. The Portugueſe were the laſt people who computed by this era, and they gave it up A. D. 1415 or 1422. See ÆRA.

EPOCHA, *Actiac*, or *Actian*, is the year of the Julian period 4684, anſwering to the year before Chriſt 30, commencing in Egypt on the 29th day of Auguſt, and on the 1ſt of September among the Greeks of Antioch; but among the Romans on the 1ſt of January in the year of Rome 724.

EPOCHA *of the Reformation*. See REFORMATION.

For other epochas or eras, and the dates of remarkable events, ſee the table under CHRONOLOGY.

EPOCHETEUSIS, from ἐποχετεύω, *I draw through a canal*, of ὀχετός, *canal*, a word uſed by Hippocrates, and others of the old writers in *Medicine*, to expreſs the derivation of the blood, or juices, from one part to another.

EPODE, Ἐπῳδός, in *Lyric Poetry*, the third or laſt part of the ode; the ancient ode, or ſong being divided into ſtrophe, antiſtrophe, and epode.

According to its moſt common acceptation, it ſignified a number of Lyric verſes of different conſtruction, compriſed in a ſingle ſtanza; and it was ſung by the prieſts, ſtanding ſtill before the altar, after all the turns and returns of the ſtrophe and antiſtrophe. The invention of epodes is aſcribed to Archilochus.

The epode was not confined to any preciſe number, or kind of verſes, as the ſtrophe and antiſtrophe were: but when the ode contained ſeveral epodes, ſtrophes, &c. they were all alike.

As the word epode, then, properly ſignifies the end of the ſong; and as in odes, what they called the epode finiſhed the ſinging, it became cuſtomary, as M. Dacier ſhews, for any little verſe which, being put after another, cloſed the period, and finiſhed the ſenſe which had been ſuſpended in the firſt verſe, to be called epode, ἐπῳδός.

And hence it is, that the ſixth book of Horace's Odes is entitled "Liber Epodon, Book of epodes," becauſe the verſes thereof are all alternately long and ſhort; and the ſhort one, generally, though not always, cloſes the ſenſe of the long one. The name of epode was likewiſe given to a ſmall Lyric poem, compoſed of trimeters or iambics, of ſix feet, and dimeters of four feet alternately. Of this kind were the epodes of Archilochus, mentioned by Plutarch. But the ſignification of the word is extended ſtill farther; epode being become a general name for all kinds of ſhort verſes, that follow one or more long ones; and in this ſenſe, a pentameter is an epode, after an hexameter, which in reſpect thereof is a pro-ode.

EPODOS, from ἐπί, and ᾠδή, *ſong*, in *Medicine*, a word uſed to expreſs the curing of diſeaſes by incantation.

EPOICODOMESIS, from ἐποικοδομέω, *I build upon*, in *Rhetoric*, is ſometimes uſed for what is otherwiſe called climax.

EPOISSES, in *Geography*, a ſmall town of France, in the department of the Côte d'Or, 9 miles W. of Semur.

EPOMIS, Ἐπωμίς, in *Anatomy*, the upper part of the ſhoulder, reaching up to the neck.

The word is Greek, ἐπωμίς, which primarily ſignifies a ſhort cloak or mantle made to cover the ſhoulders.

Some authors apply the word epomis to the upper part of the

the os humeri; but the ancient Greek phyficians only ufe it for the mufcular, or flefhy part, placed as above mentioned. See Deltoides.

EPOMPHALION, from επι, *upon*, and ομφαλος, *navel*, any medicine which purges, on being applied to the navel.

EPOPOEIA, Εποποιια, in *Poetry*, the hiftory, action, or fable, that makes the fubject of an epic poem.

The word is derived from the Greek επος, *carmen*, *verfe*, and ποιεω, *facio*, *I make*.

In the common ufe of the word, however, epopoeia is the fame with epos, or epic poem itfelf: in which fenfe it is defined a difcourfe invented with art, or a fable agreeably imitated from fome important action, and related in verfe, in a probable and furprifing manner; with a view to form the manners, &c. See Epic *Poem*.

EPOPS, in *Ornithology*, a name by which fome of the ancient writers have called the bird we call the upupa, or hoopoe. See Upupa, of which it is a fpecies.

EPORA, in *Ancient Geography*, a town of Spain, 28 miles from Caftulon, according to the Itinerary of Antonine. Pliny calls it Ripepora. It is thought to be *Montoro* in the diocefe of Cordova. M. D'Anville places it on the river Bœtis, in Bœtica, N. E. of Corduba.

EPOREDIA, Ivrée a town of Gallia Tranfpadana, fituated towards the weft, on the Doria Major.

EPOTIDES, in the *Ancient Ship-Building*, two large thick pieces of wood on each fide of the prow of a galley, which refembled two ears, whence they had their name.

The epotides were chiefly defigned to ward off the blows of the roftra of the enemies' veffels.

EPPHA, or Epha, in *Ancient Geography*, a country of Arabia, in the vicinity of the Midianites.

EPPING, in *Geography*, a market town in the hundred of Waltham, in the county of Effex, England, is irregularly built, and confifts of two parts or affemblages of houfes; one round the church, called Epping Upland; the other, nearly a mile and a half fouth-eaft from the church, called Epping Street. The latter is by far the largeft, and confifts of one wide ftreet, nearly a mile in length, fituated on the high road from London to Newmarket, on a ridge of hills extending to a confiderable diftance north and fouth. Here a market is held on Fridays: the chief commodities expofed for fale, are butter and poultry, which are chiefly purchafed for the ufe of the metropolis. At the weft end of the ftreet is a fmall new chapel: and near the middle are the fhambles. The inns and public houfes are numerous. Epping is 17 miles from London; contains, in both divifions, 315 houfes, inhabited by 1726 perfons; it has two annual fairs.

Epping *Foreft*, is an extenfive tract of good woodland, deriving its prefent name from the town, but was formerly called Waltham Foreft, and in very remote ages the Foreft of Effex. Since it obtained the latter appellation, it has, however, been greatly curtailed, many thoufand acres having been grubbed up, and the land cultivated. This foreft is under the jurifdiction of a lord warden and four verderers: the wardenfhip is hereditary in the family of fir James Tilney Long, bart.: the verderers are elected by the freeholders of the county, and retain their offices during life. The foreft rights are as various as the tenures of the different manors that furround it. In this foreft, though fo near to London, wild ftags are yet found; and a ftag is annually turned out on Eafter Monday, under an eftablifhment patronized by the principal merchants of the city. The hunt is well fupported: the kennel for the hounds, and the building belonging to the hunt, have been lately erected at the expence of feveral thoufand pounds.

At a fmall diftance to the fouth-eaft is Hainault Foreft, famous through many centuries for a venerable tree, called Fairlop Oak, which is remarkable for its fize, and alfo for an annual fair held on the firft Friday in July under its branches, which overfpread an area nearly 300 feet in circumference: the ftem, which is rough and irregular, meafures 36 feet in girth. Morant's Hiftory of Effex. Beauties of England and Wales, vol. v.

Epping, a town of Germany, in the archduchy of Auftria; 4 miles S. of Aigen.

Epping, a poft town of America, in Rockingham county, New Hampfhire, taken from the N. W. part of Exeter, and incorporated, in 1741. It contains 1121 inhabitants, and lies 6 miles N. W. of Exeter and 23 W. of Portfmouth.

EPPINGEN, a fmall town of the kingdom of Bavaria, in the palatinate on the river Elfatz, 21 miles N. E. of Philipfburg, and 18 miles N.W. of Heilbrun. N. lat. 49° 12'.

EPROUVETTE, is a machine, of which there are feveral varieties, ufed for proving the ftrength of gun-powder. The principle of this invention, in whatever form it may be applied, is to afcertain how far a certain meafure or weight of gun-powder is capable of overcoming the refiftance either of a certain weight, or of a fpring, whofe preffure againft the explofion is computed. The former is evidently the moft regular, and, confequently, the beft adapted to military purpofes, wherein the ftrength of the powder is often of the greateft moment, not only on account of the advantages gained by the greateft concentration of force, but becaufe in the mortar and howitzer practice it is neceffary to have a very accurate knowledge of the powers of expanfion in the powder when ignited; by which means fhells may be thrown, with the greateft precifion, to any intended diftance; whence the explofion takes the greateft poffible effect.

In our arfenals, an eight inch mortar is ordinarily employed as an eprouvette: being charged with two ounces of powder, and an iron ball of fixty-four pounds, the latter fhould be projected at leaft 150 feet; the elevation of the piece being 45°, and the bed being placed perfectly horizontal. We confider this to be a fair ftandard; though fome powder made from the beft materials, and frefh from the mill will fometimes exceed even 180 feet; while, on the other hand, weak powder, that is, fuch as has not been kept very dry, or that has been re-ftored, will rarely make a range equal to 120, and generally not exceeding even 110 feet.

The above mode of proof relates to cannon-powder; that intended for the ufe of mufketry is afcertained by an eprouvette of a different defcription; namely, a mufket barrel, of which the interior is highly polifhed. This fhould, with a charge of only four drachms, impel a fteel ball through fifteen wet elm boards, each a quarter of an inch in thicknefs, and placed at ¾ of an inch afunder; the firft being 39 feet and 10 inches diftant from the muzzle of the barrel. We muft confefs this exact number of inches in the diftance, appears to be more faftidious than neceffary, for we are apt to believe, that, in experiments of this nature, the odd two inches, neceffary to complete the fortieth foot, would by no means derange the procefs.

The French eprouvette for cannon powder comes very clofe to our's, they ufing a brafs ball of 60lb. (French weight) whofe diameter is 7 inches and 9 points, or ¾ of a line, (French meafure) with one line of windage, (or fpace between the fhot and the fides of the bore.) The chamber holds precifely three ounces; which quantity of their beft powder will throw the ball full 180 yards; their re-ftored powder throwing it about 160 yards. But Monf. Lombard's bard's experiments give a refult of 250 yards, with the powder now manufactured at the French mills; the eprouvette being always elevated to 45°.

Fine powder is fometimes tried by means of a fmall machine refembling a piftol, of which the barrel is very fubftantial, and the bore not more than the eighth of an inch in diameter. Over the barrel is a circular plate, acted upon ftrongly by a fpring, which offers confiderable refiftance to the revolution caufed therein, by the action of the powder on a projection which fhuts down clofe upon the muzzle. The bore being filled with powder, and the wheel, or plate, turned fo that its projection clofes the muzzle, the explofion will, in proportion to its force, throw up the projection, and caufe the wheel to revolve: the power of the powder is fuppofed to be afcertained by means of figures on the circumference, which indicate how much the wheel has been thrown round.

But fuch a machine cannot poffibly give a correct ftandard; it being fo fubject to variation; as is alfo that contrivance which caufes the powder to act underneath the hammer of a piftol lock. The pan being filled, the powder fhould have force enough to throw the hammer back. We need not comment on the uncertainty of fuch an eftimate.

EPSOM, or Ebbesham, in *Geography*, a parifh and formerly a market town in the hundred of Copthorpe, Surrey, England, is fifteen miles S.E. from London. In the year 1800 it contained 414 houfes, and 2404 inhabitants. The houfes are difpofed chiefly on two fides of a long wide ftreet, or public road, and are fituated on the weft fide of Banftead Downs. Thefe are diftinguifhed for their fine fweet verdure, which is moftly grazed by fheep; and the Banftead mutton is much efteemed for its flavour. On thefe downs are annual horfe-races, which are much frequented by gamblers and fharpers, from the metropolis. The church, above a mile from the centre of the village, was ferved for many years by the late Rev. Jonathan Boucher, who died here in the year 1804. A large old feat near the church, called *Durdans*, was originally built by George, the firft earl of Berkley, with the materials brought from the palace of Nonfuch, when that celebrated royal manfion was taken down. The firft houfe being deftroyed by fire, another was erected, and fubfequently poffeffed by the earl of Guildford. Several other fpacious feats, and pleafant villas, are found in the vicinity of Epfom, among which are Woodcote Park, the late lord Baltimore's; and Pit's-place, which receives its name from being fituated within the excavation of a chalk pit. It is a fingular and curious place.

Epsom, a poft town of America, in Rockingham County, New Hampfhire, E. of Pembroke, adjoining, 10 miles E. of Concord, and 45 N. W. of Portfmouth. It was incorporated in 1727, and in 1800 contained 1034 inhabitants.

Epsom *Salt and Water*. This fo much celebrated falt was firft extracted from the purgative mineral fpring at Epfom in Surrey, which had long been celebrated for its medicinal qualities, by Dr. Nehemiah Grew in 1675, who publifhed a treatife concerning it (De Natura Salis Cathartici Amari.) Dr. Grew gave it the appropriate name of fal catharticus amarus, or bitter purging falt; which is ftill retained, together with the names of Epfom falt, magnefia vitriolata, or fulphat of magnefia of modern chemical nomenclature; which fee for the chemical properties of this falt.

The original Epfom falt, or that which was procured by the evaporation of the Epfom water, was fold in London at a very high price. Afterwards it was prepared, very extenfively, by chemifts of the name of Moult, about the year 1700, by evaporating the water of fome fprings at the foot of Shooter's-hill; which were found to refemble that at Epfom. Soon after it was difcovered, as appears by Haukwitz, a celebrated trading chemift in London, that the fame falt could be procured from the bittern of fea-water; and in a few years the fecret tranfpired, and the fame was prepared from fea-water at Portfmouth, Lymington, and at Newcaftle; by which the falt from the Shooter's-hill fprings was underfold, and the works were abandoned. Epfom falt was for a long time only prepared in this country, and the continent was fupplied from hence; on which account it became known in Europe under the name of Epfom, or Englifh falt; but Bergman afterwards difcovered the fame in the Sedlitz or Seydfchutz waters in Bohemia, whence the name Sedlitz falt was added to its other appellations.

A confiderable confufion prevailed for a long time between this falt and Glauber's Sal Mirabile (fulphat of foda,) the acid of both being the fame, and the medicinal ufes of each, and comparative dofes, not materially differing. In fact it appears, that fometimes the true Glauber's falt was made fmall grained, by ftirring it as it began to cryftallize; and fometimes the true Epfom falt was made large grained to imitate Glauber's; and each was occafionally paffed off for the other as either happened to be in moft requeft. This kind of fraud indeed is ftill practifed pretty extenfively on parts of the continent where the Epfom falt is not eafily procured. Some chemical difference between the two falts was very foon afcertained. Dr. Grew gives it as characteriftic of the Epfom falt, that it coagulates with an alkali; but the nature of the earth that forms this coagulum, was not fully underftood till the refearches of Black and Bergman proved it to be the earth magnefia.

Epfom falt is a highly and juftly efteemed purgative medicine, and is in very conftant ufe. The tafte is falt and bitter, attended, however, with a peculiar flavour approaching to fweetnefs. Notwithftanding its naufeous tafte, it is often found to remain on the ftomach when rhubarb and moft other medicines are rejected, and in general it operates fpeedily, effectually, and without griping or debilitating. The ufual dofe for an adult is from half an ounce to an ounce; but it fhould be pretty largely diluted in gruel, broth, or any mucilaginous liquor.

EPSTEIN, in *Geography*, a fmall town of Germany, formerly in the Landgraviate of Heffe Darmftadt, but fince the peace of Luneville, in the territory of the princes of Naffau Dietz. It is fituated at no great diftance from the confluence of the Rhine and Mayn, 18 miles N.W. of Francfort on the Mayn; and is chiefly remarkable for fome good iron mines in its neighbourhood.

EPTACTIS, in *Natural Hiftory*, a name given by Linkius, and fome other authors, to a fpecies of ftar-fifh, of the aftrophyte kind, whofe rays, or branches, at their firft going out from the body, are only feven in number; but which very foon fpread into more. See Star-*fifh*.

EPTAMERIDES, in *Mufic*, a name given by M. Sauveur to one of the intervals of his fyftem, inferted in the Mem. de l'Acad. des. Sc. for 1701.

This author begins by dividing the octave into 43 parts or merides, then each of thefe into 7 eptamerides, fo that the octave entire comprehends 301 eptamerides, which he ftill fubdivides. (See Decameride.) The word is formed of επτα, *feven*, and of μερις, *a part*. In Sauveur's fubdivifion the octave is $= 23\frac{10}{301}\Sigma + \frac{21}{301}f + \frac{53}{301}m$: and its common logarithm is = .9989999.0035. or .9990000.0000 according to the affumption of M. Sauveur, wherein the octave = .6990000.0000 and its reciprocal .3010, &c.

EPTE, in *Geography*, a fmall river of France in the

 department

department of the Eure, which has its source near Bernay, and falls into the Seine below Vernon.

EPULÆ. See Entertainments.

EPULARES, in *Antiquity*, an epithet given to those who were admitted to the sacred epulæ or entertainments, it being unlawful for any to be present at them who were not pure and chaste.

EPU'LIS, (from ἐπι, *upon*, and ουλα, *the gums*,) in *Surgery*, a tubercle on the gums. There are two kinds; one of a benign nature, and free from pain; the other more malignant, being very troublesome, and occasionally becoming, according to the descriptions of surgical writers, of a cancerous quality. Some of the excrescences are represented as having a narrow pedicle, while others are connected with the gum by means of a broad base.

The best plan of treatment consists in extirpating an epulis, as soon as the nature of the case manifests itself. The object may be accomplished either with caustic, or the knife. The latter mode is that, to which we should generally give the preference, because attended with the greatest degree of certainty, and not more pain.

Some writers advise us to tie the excrescence, when its neck is narrow. However, in such a case, the knife, or a pair of scissars, might also be very conveniently employed.

EPULO, in *Antiquity*, the name of a minister of sacrifice among the Romans.

The pontifices, not being able to attend all the sacrifices performed at Rome, to so many gods as were adored by that people, appointed three ministers, whom they called epulones, because they conferred on them the care and management of the epulæ, feasts in the solemn games and festivals.

To them belonged the ordering and serving the sacred banquet offered on such occasions to Jupiter, &c. They wore a gown bordered with purple, like the pontifices, their number was at length augmented from three to seven, and afterwards by Cæsar to ten.

Their first establishment was in the year of Rome 558, under the consulate of L. Furius Purpureo, and M. Claudius Marcellus.

EPULO'TICS, (from ἐπουλοω *to cicatrize*), in *Surgery*, topical applications, which dispose wounds and ulcers to heal.

EPULUM, in *Antiquity*, *banquet*, a holy feast prepared for the gods.

The statues of the gods were commonly laid upon a bed, and served in the epula, as if they had been very hungry; to perform which was the function of the ministers of sacrifice, hence called epulones.

EPWORTH, in *Geography*, a market town in Lindsey division of Lincolnshire, England, is situated 158 miles from London: it is built in a straggling irregular manner; and contains, according to the late population return, 275 houses, and 1434 inhabitants, who are chiefly employed in spinning hemp and flax, of which great quantities are grown here, and in the manufacture of sacking and bagging, which is the chief trade of the town. A weekly market is held on Thursdays, and two fairs annually. Quantities of large oaks, firs and other trees, some of which appear to have been burnt, and others cut down, are frequently found here three feet beneath the surface of the earth. The rectory of Epworth was held by the Rev. Samuel Wesley, the father of the distinguished leaders of the Arminian Methodists, John and Charles Wesley.

EQUABLE Motion, is that whereby the moveable body proceeds with the same continued velocity; neither accelerated nor retarded.

Equable *Pulse*. See Pulse.

Equable *Style*. See Style.

EQUABONA, in *Ancient Geography*, a town of Spain, in Lusitania, according to the Itinerary of Antonine, situated on the left side, and at the mouth of the Tagus, not far from the sea.

EQUAL, a term of relation between two or more things of the same magnitude, quantity, or quality.

Wolfius defines equals to be those things which may be substituted for each other, without any alteration of their quantity. It is an axiom in geometry, that two things which are equal to the same third, are also equal to each other. And again, if to or from equals you add or subtract equals, the sum or remainder will be equal.

Equal *Altitudes*, in *Practical Astronomy*. One of the most practicable and certain methods of determining the time, and thus ascertaining the error of a clock or chronometer, is by observing equal altitudes of the sun, or of a fixed star. For this purpose all that is necessary is to observe the instant the sun or star is at any altitude towards the east, before the meridian passage; and the instant must likewise be marked when the same object attains exactly the same altitude towards the west, after the meridian passage: the mean between the above quantities will be the instant marked by the clock at the moment the sun or star was on the meridian. The preceding operation, however, supposes, that the declination of the object has not varied during the elapsed interval, but this with the sun seldom happens. The observation, therefore, must be corrected by a table, or by a direct calculation.

Let P (*Plate* XII. *Astronomy*, *fig.* 106.) be the elevated pole, Z the zenith, S the sun, S B an arc parallel to the horizon H O, so that the points B and S have the same altitude; P S the polar distance of the sun in the morning, P B its polar distance in the evening (supposed to have become less). When the sun in the afternoon arrives at the point B, whose altitude suppose 20°, the same as the morning, the hour angle Z P B, or the distance of the sun, and its hour angle from the meridian P Z, will be greater than the morning hour angle Z P S. We have, therefore, two triangles, Z P S, Z P B, which have each the side P Z common, and the sides Z S, Z B, each equal to 70°, since they are the complements of the altitudes, 20° in each case. The sides P S, P B, differ by a quantity which is equal to the change of the sun's declination in the interval between the two observations. If the two triangles be resolved separately, the two hour angles will be found different: the half of this difference is the correction, which must be applied to the middle point of time to obtain the exact instant of the sun's passage over the meridian. This correction is given in the annexed table, which is taken from the last edition of La Lande's Astronomy. It is calculated from the following differential analogy.

$$\frac{\delta x}{30}\left(\frac{\text{tang. latitude}}{\text{sin. hour-angle}} \pm \frac{\text{tang. dec. } \odot}{\text{tang. hour-angle}}\right)$$

TABLE

☞ Multiply the Tangent by the Latitude, and if it is South, change the Signs.

EQUAL-*Altitude Inſtrument*, is an inſtrument uſed in *Aſtronomy* for aſcertaining the exact time at any place, by means of equal altitudes of any heavenly body, as obſerved ſucceſſively at the oppoſite ſides of the meridian. Formerly, the inſtrument uſed excluſively for this purpoſe was a refracting teleſcope of conſiderable length, attached to a vertical axis of motion, placed truly perpendicular to the horizon by means of a plumb-line or ſpirit-level, ſo that when the teleſcope had a given elevation, it might be fixed at that elevation, and deſcribe a parallel of altitude as the vertical axis turned round; which method was equally ſimple and accurate, as it required no graduated circles for reading either horizontal or vertical angles; but then its utility was limited to the ſingle operation of determining the inſtant when any celeſtial body on the weſtern ſide of the meridian had the ſame altitude that it had at a given inſtant on the eaſtern ſide, and hence the intermediate inſtant when the ſaid body was on the meridian, provided its declination had not ſenſibly altered during the interval. But in the preſent improved ſtate of aſtronomical and nautical inſtruments, almoſt any of them will meaſure equal altitudes with great preciſion, and at the ſame time indicate the quantity of the altitudes obſerved, ſo that an inſtrument to take equal altitudes only is no longer a deſideratum, and its origin and conſtruction may now be conſidered as matter of curioſity, or as a link in the hiſtorical chain of aſtronomical inſtruments, but yet at the time was a link of great importance. When ſir Iſaac Newton preſented to the obſervatory at Trinity college, Cambridge, an excellent pendulum clock for the uſe of the profeſſor, it became a matter of great importance to have the ready means of adjuſting the rate of the clock to exact time; profeſſor Cotes, therefore, contrived an equal-altitude inſtrument, which was made at very little expence, and which yet fully anſwered its purpoſe. This inſtrument is deſcribed in Dr. Robert Smith's Optics, and alſo another, which is an improvement on it, as being at that time in the poſſeſſion of the earl of Ilay. As we preſume it will not be unacceptable to our readers to ſee how an inſtrument, that does not indicate any meaſure, will yet determine equal altitudes with accuracy, we ſhall give in ſucceſſion brief deſcriptions of the two inſtruments we have already named, accompanied by correſponding figures.

Profeſſor Cotes' Equal-altitude Inſtrument.—*Fig.* 3. of *Plate* XVII. of *Aſtronomical Inſtruments*, is a repreſentation of Mr. Cotes' equal-altitude inſtrument, as applied in taking an obſervation. A B is a ſtrong wooden axis in a vertical poſition about ſix feet long, and having the extreme ends of well-tempered ſteel; the ſuperior end A has a cylindrical pivot, and the lower end a conical one, both reſting in adjuſtable pieces of metal, that are not neceſſary to be deſcribed; two ſtrong bars, C D and D E, are firmly attached to the axis, ſo as to form a right angle where they are united at D; in like manner two other bars are fixed together and to the axis, namely, G F and F E, making a right angle at F; and below theſe a thick pin Y paſſes quite through the axis. Near the top at T is a piece of tapped wire ſcrewing into the axis, and ſupporting a plumb-line T V, which falls at the point of a fine needle inſerted a little out of the centre of the thick pin Y; ſo that by turning this wooden pin round, the needle point may be brought into contact with the line whenever it does not touch it: the bar C D has half a dozen tapering pins or pegs turned round, inſerted into holes at equal diſtances, or nearly ſo, and the bar E F has one ſuch pin. The pin at F ſupports the lower end of the teleſcope P Q, and the upper or object end hangs by one of the ſix pins on the arm C D, as the elevation in any obſervation may require; the piece I L K M, that carries the peg N, by which the teleſcope hangs, being made faſt to its tube. The teleſcope, not being an achromatic at that time, was five feet long, and therefore required the axis of motion to be at leaſt ſix feet. When the pivots of the axis were nicely adjuſted with reſpect to eaſt and weſt, and alſo to north and ſouth, which was known by the plumb-line hanging in apparent contact with the needle point, during the whole of an entire revolution, then the object-end of the teleſcope deſcribed an exact parallel to the horizon, or parallel of altitude, and whatever bodies appeared in the centre of the eye-glaſs, which we ſuppoſe to have been a ſingle one, had all equal apparent altitudes.

The Earl of Ilay's Equal-altitude Inſtrument.—The inſtrument ſaid to have been in the poſſeſſion of the earl of Ilay, is repreſented by *fig.* 4. of *Plate* XVII. We know not who was the maker, otherwiſe we ſhould have given his name in preference. The axis *a b* is of ſteel ſquared, thirty inches long; the upper end of it, *a*, bears a ſextantal arch *c d*, fixed at *a* immoveably; the teleſcope N is thirty inches long alſo, and is moveable together with its graduated ſemi-circle round the ſame point *a* as a centre of motion: this ſemi-circle may be fixed to the ſextantal arch at any elevation of the teleſcope, by the finger-nuts *c* and *d*, paſſing through the circular aperture of the ſemi-circle, and ſcrewing into the ſextantal arch. Immediately under the ſemi-circle is a ſpirit-level *l m*, with ſcrews of adjuſtment, and at *e* under it, the axis, for a ſhort way down, is cylindrical, about an inch in diameter, and well-poliſhed. The lower end of the axis is conical, and the eye-piece of the teleſcope has in its focus five vertical wires at equal diſtances, parallel to each other, and two parallel croſs wires, as repreſented in *fig.* 5. When the inſtrument here deſcribed is uſed, its axis is let down into a ſtand of the ſhape of a long hollow parallelopiped, wanting two ſides. Its other ſides *f*, *g*, are a couple of braſs plates, equal in length to the part *b e* of the axis, and are ſcrewed together edgeways, but the centre of the upper ſquare end piece *h*, four inches ſquare, is a round hole, juſt large enough to receive without touching it, and over this hole is fixed another plate with a triangular hole, concentric, one of the ſides of which triangle is moveable by an adjuſtment ſcrew, to make the cylinder bear alike on all ſides: on the lower ſquare, or baſe *i*, lies another adjuſtable piece, with a fine conical hole to bear the point *b* of the axis, and to adjuſt the axis vertical by means of its ſcrews, as pointed out by the level. The frame, thus furniſhed with the inſtrument, is then firmly faſtened to a ſolid pillar K, by means of a niche made in it to receive the braſs plates. The axis is known to be truly perpendicular when the bubble of the level will remain in the middle of the tube during every part of an entire revolution of the axis. If the axis of this inſtrument were to be placed parallel to the earth's axis, and in the true meridian, its conſtruction is equally adapted for an equatorial teleſcope, in which caſe the ſemi-circle would in every ſituation be a ſecondary to the equator, or would meaſure declinations. The croſs wires in the teleſcope are very uſeful for taking five pairs of obſervations, from which a mean may be taken with greater accuracy than one pair of obſervations alone would give, and in cloudy weather will afford five chances of ſeeing the body at the proper inſtants of required altitude. For the methods of applying the corrections for equal altitudes, and of aſcertaining the exact time as deduced from the obſervations, the reader is requeſted to conſult our article CHRONOMETER, where the requiſite problems are exemplified. It is ſcarcely neceſſary to add, that a common Hadley's ſextant or octant is a good

inſtrument

inſtrument for taking equal altitudes, provided the obſerver have a good artificial horizon, when his obſervations are taken on the land; the imperfection of the graduations being of no importance, except when the exact meaſure is wanted for other purpoſes.

Equal *Angles*, are thoſe whoſe containing lines are inclined alike to each other; or which are meaſured by ſimilar arches of their circles.

Equal *Arches*. See Arch.

Equal *Arithmetical Ratios*, are thoſe wherein the difference of the two leſs terms is equal to the difference of the two greater. See Ratio.

Equal *Circles*, are thoſe whoſe diameters are equal. See Circle.

Equal *Curvatures*, are ſuch as have the ſame or equal radii of curvature. See Curvature.

Equal *Figures*, are thoſe whoſe areas are equal, whether the figures be ſimilar or not.

The ſegments of a ſphere, or circle, are of an equal concavity, or convexity, when they have the ſame ratio, or proportion to the diameters of the ſpheres, or circles, whereof they are parts.

Equal *Geometrical Ratios*, are thoſe whoſe leaſt terms are ſimilar, aliquot, or aliquant parts of the greater.

Equal *Hours*. See Hour.

Equal *Hyperbolas*, are thoſe, all whoſe ordinates to their indeterminate axes, are equal to each other; taken at equal diſtances from their vertices.

Equal *Solids*, are thoſe which comprehend, or contain, each as much as the other; or whoſe ſolidities, or capacities, are equal. See Solid.

Equal *Beating*, in *Muſic*, is ſaid of ſuch tempered concords as beat equally quick, or make the ſame number of *wa, wa, wa, wa's*, in a given ſpace of time, when ſounding. The firſt who mentions, or makes any uſe of equal-beating concords, is Dr. Robert Smith, who obſerves, (Harmonics, p. 188.) "if ſeveral imperfect conſonances of the ſame name, as Vths, for inſtance, (by which the whole ſcale is uſually tuned,) beat equally quick, they are not equally harmonious, or tempered; to make them ſo, the higher in the ſcale ought to beat as much quicker than the lower, as their baſes vibrate quicker (prop. xi. cor. 2.); that is, if a Vth be a minor tone higher than another, it ſhould beat quicker, in the ratio of 10 to 9, or (if a major tone) 9 to 8 nearly; if a IIId higher, in the ratio of 5 to 4; if a Vth higher, in the ratio of 3 to 2; if an VIIIth higher, of 2 to 1, &c.

In ſchol. 2. to prop. xx., the doctor gives a table of beats to be made in fifteen ſeconds of time, by four ſucceſſive 5ths above C reſpectively, in order to form a ſyſtem for the common inſtruments with twelve notes in an octave, wherein every IIId ſhall beat ſharp, as faſt as the Vth to the ſame baſe beats flat: let it be obſerved, however, that this will not be the caſe in the IIIds or Vths affected by the beating notes, or reſulting 5th, after this method has been purſued through eleven 5ths.

In the ſame table we have the number of beats for the above ſucceſſion of 5ths, ſo calculated, that the Vths and VIths to the ſame baſs may beat equally quick, the former flat, and the latter ſharp; which will give the notes of the doctor's ſyſtem of equal harmony in three octaves, as far as the ſame can be applied on a defective or douzeave inſtrument. At page 220, mention is made of another equal-beating ſyſtem, wherein the IIIds and the VIths to the ſame baſs beat equally quick, and which is ſaid to approach ſo near to the ſyſtem of equal harmony, as not to need a particular table.

In the directions given by earl Stanhope, pages 13 and 14, of his ſtereotype "Principles of the Science of Tuning," for adjuſting his two ſucceſſive biequal 3ds, and three ſucceſſive triequal quints; his lordſhip directs that theſe ſhall be made to beat equally quick reſpectively; and falls into the miſtake of ſuppoſing that this would produce the equal temperament of thoſe IIIds and the Vths reſpectively, that he had previouſly calculated for them, by mean proportionals, for his monochord ſyſtem, contrary to the demonſtrations of Dr. Smith above; and in a printed "Letter to the Duke of Cumberland reſpecting the Stanhope Temperament," this error being perſiſted in, after it had been pointed out by Mr. Farey in the Philoſophical Magazine, vol. xxvii. p. 203, it becomes neceſſary for us to point out (as could not be done under Biequal *Third*, in our work), that the ratios $\frac{4}{5}$, $\frac{12}{19}$, and $\frac{1}{2}$, exactly repreſent the notes E, ♭A and *c* reſpectively, when the two ſucceſſive 3ds (which his lordſhip calls biequal) E, ♭A and ♭A *c*, whoſe ratios are $\frac{15}{19}$ and $\frac{19}{24}$, make an equal number of beats in a ſecond of time; and this number of beats, when C makes 240 complete vibrations in 1″, is exactly ten times in a ſecond. Thus we ſee, that there are three different intervals, called by his lordſhip biequal thirds, whoſe ratios are $\frac{19}{24}$, $\frac{\sqrt{10}}{4}$, and $\frac{15}{19}$, and their common logarithms are .8985423.5924, .8979400.0867, and .8973376.5811 reſpectively, or in the new notation $206.228\ \Sigma + 4f + 18\ m$, $207.5\ \Sigma + 4f + 18\ m$, and $208.772\ \Sigma + 4f + 18\ m$ nearly reſpectively: and there are, indeed, others which ariſe from the new inſtructions which his lordſhip gives in the letter to the duke of Cumberland above referred to, for tuning equally-tempered concords by means of the *abſence* of "beating between the two beatings;" which new ſpecies of equal beating is conſidered in the Philoſophical Magazine, vol. xxxiii. p. 297, and is ſhewn to produce other intervals than the above, and which yet come under the appellation of biequal thirds, as defined by earl Stanhope.

Equal *Harmony*, has been applied by Dr. Robert Smith to the different concords V, VI, and III, (or their complements 4th, 3d, and 6th,) when they are ſo tempered, as to be equally harmonious or pleaſant to the ear, as tempered concords; and the reſult of his laborious calculations for forming a ſyſtem, wherein every concord within the compaſs of *three* octaves ſhall be equally and the moſt harmonious, (Harmonics, p. 140.) is, that each V, VI, and III, are to be tempered $\frac{-5}{18}$, $\frac{+3}{18}$, and $\frac{-2}{18}$ parts of a major comma reſpectively: or, in a ſyſtem of four octaves of equally harmonious concords, theſe temperaments are to be $\frac{-11}{40}$, $\frac{+7}{40}$, and $\frac{-4}{40}$ parts of a comma for the V, VI, and III, reſpectively. But it is to be obſerved, that theſe temperaments are applicable only to inſtruments with 21 ſtrings, or pipes, in each octave, and not to the common piano-fortes, organs, &c. in uſe, with only 12 ſtrings, or pipes, of different pitches within the compaſs of an octave.

The term equal harmony has been, as we think, improperly applied by Mr. Emerſon, and others, to the *iſotonic* or *equal temperament* ſyſtem of intervals (which ſee); it being obſervable that Dr. Smith's deſign is to effect an equal harmony among the different concords, and the equal temperament makes an equal harmony among the different keys, which are in effect very different ſyſtems, and ought not to bear the ſame name.

Equal harmony alſo denotes the tuning by perfect 5ths without temperament, making all the keys participate equally

equally of the imperfection of the ſcale on keyed inſtruments. By this method of tuning, the thirds will, at firſt, ſeem very harſh and crude; but by a little uſe the ear will accommodate itſelf to the evil, and indulge the abbé Rouſſier, or his manes, with the *triple progreſſion*, by which Pythagoras formed the ſcale, and by which the Chineſe, in the moſt remote antiquity, according to Pere Amiot, produced the few ſounds with which their imperfect ſcale is furniſhed. See TEMPERAMENT and TRIPLE *Progreſſion*.

EQUAL *Temperament*, is a ſyſtem of twelve intervals within an octave, all equal to each other; each of which has the ratio of $\frac{1}{\sqrt[12]{2}} = 51\,\Sigma + f + 4\tfrac{5}{12}\,m$, (ſee Philoſophical Magazine, vol. xxix. p. 347.) the common logarithm of each of ſuch mean ſemitones being = .9749141.6703. This ſyſtem is often called the iſotonic, and ſometimes that of Merſennus, by M. Couperin, M. Marpurg, Mr. Emerſon, Mr. Cavallo, Mr. Davis, and others, who have written in its favour. Dr. Robert Smith, who diſapproves of this ſyſtem, ſtates the temperaments of its V and 4th, its VI and 3d, and its III and 6th, to be $\frac{1}{10}$, $\frac{7}{10}$, and $\frac{6}{10}$ parts of a major comma reſpectively (Harmonics, p. 167.), but theſe are incorrect, and ought to have been $\frac{1}{11}$, $\frac{7}{11}$, and $\frac{6}{11}$ of a comma, the temperaments of theſe concords, very nearly, as ſtated in the firſt column of Tab. II. page 158, of the ſame work. Mr. Emerſon, in his "Algebra," prob. ccii. calculates the beats which the concords in this ſyſtem make, in the octave above the G of the baſs cliff, and ſtates theſe at − 15, + 11, + 1½, − 1, − 18, and + 13 in one ſecond of time, made by the 3d, III, 4th, V, 6th, and VI reſpectively, the flat temperaments being marked — and the ſharp ones +.

The equal temperament of Mr. Farey, (Philoſophical Magazine, vol. xxviii. p. 65, and xxx. p. 6.) differs only in an inſenſible degree from the above, his half note being $51\,\Sigma + f + 5\,m$ between the notes C and ♭D, ♭E and E, F and ♭G, G and ♭A, and ♭B and B; and $51\,\Sigma + f + 4\,m$ between the notes ♭D and D, D and ♭E, E and F, ♭G and G, ♭A and A, A and ♭B, and B, &c.; yet this very ſlight variation enables an organ tuner to tune the twelve notes of this ſyſtem, by help of certain combinations of perfect Vths, 4ths, and IIIds! In this method of obtaining an equal temperament, the ſucceſſive 5ths C G, G D, D A, A E, E B, B ♭G, G ♭D, and D ♭A, are to be tuned upwards, each by aſcending (on a ſpare range of pipes or different ſtop to the one intended to be tuned) five ſucceſſive perfect 4ths, and from the higheſt note of theſe deſcending two perfect 5ths and one major 3d, which laſt or loweſt note is to be transferred to the G of the ſtop intended to be tuned. From this ſame note, G, five 4ths up, and two V + III down, are to be tuned to get D, and ſo on to ♭A. The remaining 5ths *c* F, F ♭B, and ♭B ♭E, are to be tuned downwards, by deſcending from *c* five ſucceſſive 4ths, and thence aſcending two Vths and a IIId to obtain F, from which note, repeating the ſame proceſs until the note ♭E is obtained; when, if the operations have been carefully performed, and *no beats* ſuffered to remain in any of the perfect 4ths, 5ths, 3ds, or uniſons, or in the octave C *c*, &c. the reſulting 5th, or that between the beating notes ♭A and ♭E, will be found, but in an almoſt inſenſible degree flatter than all the other fifths in the ſcale; the difference being only *m*, or leſs than $\frac{1}{1400}$th part of a major comma! between this V and each of the other eleven Vths: this being $357\,\Sigma + 7\,f + 30\,m$, and each of the others $375\,\Sigma + 7\,f + 31\,m$. The logarithm of the firſt or largeſt of the half-notes in this ſyſtem is = .9749119.1920, and of the ſmalleſt .9749157.7262. See TEMPERAMENT.

EQUAL, in *Optics*. We ſay, that things ſeen under equal angles are equal. Equal parts of the ſame interval, or magnitude, if unequally diſtant from the eye, appear unequal. Equal objects, and at equal diſtances, only the one placed directly, and the other obliquely, ſeem unequal; and that placed directly, the bigger.

Maſonry by EQUAL *Courſes*. See MASONRY.

EQUALITY, in *Algebra*, is a compariſon of two quantities, that are equal both really and repreſentatively, *i. e.* which are ſo both in effect and letters.

A compariſon of two quantities equal in effect, but unequal in letters, to render them equal, is called an *equation*, which ſee.

EQUALITY is uſually denoted by two parallel lines, as =: thus 2 + 2 = 4, *i. e.* 2 plus 2 are equal to 4. This character was firſt introduced by Robert Recorde. Des Cartes, and ſome after him, in lieu thereof, uſe ∝: thus, 2 + 2 ∝ 4; ſo *z* − y ∝ b + c, ſignifies that *z* minus y is equal to b plus c.

From an equation we arrive at an equality, by changing an unknown letter into another, whereby the two members of the equation, *i. e.* the two quantities compared together, and connected by the ſign of equality, are rendered equal. Thus, in the equation a a x = b c d; ſuppoſing $x = \frac{bcd}{aa}$, we change *x* into $\frac{bcd}{aa}$, and by this ſubſtitution arrive at the equality bcd = bcd.

In the ſolution of a numerical problem, which is to be rendered rational, if there be only one power to be equalled to a ſquare, or other higher power, it is called ſimple equality.

Where there are two powers to be equalled, each to a ſquare, it is called double equality, &c.

Diophantus hath given us a method for double equalities, and F. de Billy, another for triple equalities, in his Diophantus Redivivus.

EQUALITY, in *Aſtronomy*. *Circle of* EQUALITY, or the *equant*. See CIRCLE and EQUANT.

EQUALITY denotes the exact agreement of two or more things in reſpect of quantity. Thus, figures are equal which may occupy the ſame ſpace, by the fluxion or tranſpoſition of their parts. See on this ſubject an elaborate diſſertation by Dr. Barrow, in the 11th and 12th of his Mathematical Lectures.

EQUALITY, *ratio*, or *proportion of*, in *Geometry*, is that between two equal numbers, or quantities.

Proportion of EQUALITY *evenly ranged*, or *ex æquo ordinata*, is that in which two terms in a rank, or ſeries, are proportional to as many terms in another ſeries, compared to each other in the ſame order, *i. e.* the firſt of one rank to the firſt of another; the ſecond to the ſecond, &c.

Proportion of EQUALITY *evenly diſturbed*, called alſo *ex æquo perturbata*, is that in which more than two terms of one rank are proportional to as many terms of another compared to each other, in a different and interrupted order; *viz.* the firſt of one rank to the ſecond of another; the ſecond to the third, &c.

EQUALITY, *Union of*. See UNION.

EQUALITY, in *Law*, the law delights in equality; ſo that when a charge is laid upon one, and divers ought to bear it, he ſhall have relief againſt the reſt. 2 Rep. 25.

EQUANIMITY, in *Ethics*, denotes an even, uniform temper of mind, amidſt all the varieties and revolutions of time and chance. This virtue, together with prudence, forms the character which Horace gives of Ariſtippus:

"Omnis

"Omnis Ariſtippum decuit color & ſtatus & res."

EQUANT, or ÆQUANT, in *Aſtronomy*, a circle, formerly imagined by aſtronomers, in the plane of the deferent, or eccentric; for regulating and adjuſting certain motions of the planets, and reducing them more eaſily to a calculus. See APOGEE, CIRCLE, DEFERENT, and EXCENTRIC.

EQUATED ANOMALY. See ANOMALY and ELLIPTIC *Motion*.

EQUATED *Bodies*. On Gunter's ſector there are ſometimes placed two lines, anſwering to one another, and called the lines of equated bodies: they lie between the lines of ſolids, and ſuperficies, and are noted with the letters D, I, C, S, O, T, for dodecahedron, icoſihedron, cube, ſphere, octahedron, and tetrahedron.

The uſes of theſe lines are, 1. When the diameter of the ſphere is given, to find the ſides of the five regular bodies, ſeverally equal to that ſphere. 2. From the ſide of any of the bodies being given, to find the diameter of the ſphere, and the ſides of the other bodies, which ſhall be equal ſeverally to the firſt body given.

If the ſphere be firſt given, take its diameter, and apply it over in the ſector in the points S, S: if any of the bodies be firſt given, apply the ſide of it over in its proper points; ſo the parallels taken from between the points of the other bodies ſhall be the ſides of thoſe bodies, equal ſeverally to the firſt body given.

EQUATION, in *Algebra*, is when two equal quantities, differently expreſſed, are compared together, by means of the ſign $=$ placed between them.

Thus, $9 - 4 = 5$, is an equation expreſſing the equality of $9 - 4$ and 5; and $a + b - c = d$, is an equation denoting that the difference between the ſum of $a + b$, and c, is equal to d; the quantities between which the ſign $=$ is placed being called the two ſides of the equation.

It is ſometimes cuſtomary, however, to place all the quantities on one ſide of the equation, and to make them equal to 0, or zero, on the other ſide; as $a - b = c$, or $a + b - c = 0$, &c. which is only ſetting down the difference of two equal quantities and putting it equal to 0.

The *terms* of an equation, are the ſeveral quantities or parts of which it is compoſed: thus, in the equation $a + b = c$, the terms are a, b, and c; and the ſenſe or meaning of the expreſſion is, that ſome quantity repreſented by c, is equal to the ſum of two others, repreſented by a and b.

When a quantity ſtands alone, on one ſide of an equation, the terms on the other ſide are ſaid to be a *value* of that quantity. Thus, in the equation $x = a - b$, the difference of the two numbers repreſented by a and b is called the value of x.

Equations are alſo diſtinguiſhed by the denominations of *ſimple* and *compound*, or, as they are frequently called, *ſimple* and *affected*; which latter term, however, it would be better to diſcard, as being leſs natural and appropriate than that of *compound*.

A ſimple equation, is that which contains only one power of the unknown quantity; as $x + a = b$, or $a x^2 + b = c$, or $2 x^3 + 3 a^3 = 4 b$, &c. where x denotes the unknown quantity, and the other letters or figures ſuch quantities as are known.

A compound equation, is that which contains two or more powers of the unknown quantity; as $x^2 + a x = b$, or $x^3 + a x^2 - b x = c$, &c.

Equations are likewiſe divided into different *orders*, according to the higheſt power of the unknown quantity contained in any one of their terms; as *quadratic*, *cubic*, *biquadratic*, &c. thus,

A quadratic equation, is that in which the unknown quantity riſes to two dimenſions, or that contains both the unknown quantity and its ſquare; as $x^2 + 10 x = 30$, or $a x^2 + b x = c$.

A cubic equation, is that in which the unknown quantity is of three dimenſions, or that riſes to the cube or third power; as $x^3 - 3 x = 1$, or $x^3 + 2 x^2 = 4$, or $a x^3 + b x^2 + c x = d$.

A biquadratic equation, is that in which the unknown quantity is of 4 dimenſions, or that riſes to the fourth power; as $x^4 + 2 x = 5$, or $x^4 + 3 x^2 = 10$, or $x^4 + 4 x^2 + 7 x = 50$, or $a x^4 + b x^3 + c x^2 + d x = e$. And ſo on, for the 5th, 6th and other higher order of equations; which are all denominated according to the higheſt power of the unknown quantity contained in any one of their terms.

The root of an equation, is that quantity, whether poſitive, negative, or even imaginary, that when ſubſtituted for the unknown quantity, will make both ſides of the equation vaniſh, or become equal to 0.

Thus, in the equation $x^2 - 6 x = 72$, either $+ 12$ or $- 6$ is a root, or value, of the unknown *quantity*; for if each of theſe numbers be ſeparately ſubſtituted for x, they will be found to ſatisfy the conditions of the equation.

In the reſolution of an equation, containing only one unknown quantity, ſeveral previous operations are often required to be performed, in order to adapt it to the rule to which it belongs; the greater part of which may be performed by means of a few ſelf-evident and obvious principles; namely, that if equal quantities be added to, or ſubtracted from, equal quantities, the ſums or remainders will be equal; if equal quantities be multiplied or divided by the ſame quantity the products or quotients will be equal; or if equal quantities be raiſed to the ſame power, or have the ſame root extracted, the reſults will ſtill be equal.

From theſe ſimple conſiderations are derived the following rules, which will equally apply to equations of all orders, and are alone ſufficient for the reſolution of ſimple equations.

Rule 1.—Any quantity may be tranſpoſed from one ſide of the equation to the other by changing its ſign.

$$\begin{aligned} &\text{Thus, if } x - 5 = 8 \\ &\text{Then } x = 8 + 5 \\ &\text{Or } x = 13 \\ &\text{And if } 4 x - 8 = 3 x + 7 \\ &\text{Then } 4 x - 3 x = 7 + 8 \\ &\text{Or } x = 15 \end{aligned}$$

From this rule it alſo follows that if any quantity be found on each ſide of the equation, with the ſame ſign, it may be left out of both. And that the ſigns of all the terms of an equation may be changed into the contrary ones, without affecting the truth of the equation.

$$\begin{aligned} &\text{Thus, if } x + 2 = 7 + 2 \\ &\text{Then } \quad x = 7 \\ &\text{And if } a - x = b - c \\ &\text{Then } x - a = c - b \\ &\text{Or } x = a + c - b \end{aligned}$$

Rule 2.—If the unknown quantity, in an equation, be multiplied by any quantity, that quantity may be taken away, by dividing all the reſt of the terms by it.

$$\begin{aligned} &\text{Thus, if } 7 x = 49 \\ &\text{Then } x = \frac{49}{7} = 7 \\ &\text{And if } a x = b - c \\ &\text{Then } x = \frac{b - c}{a} \end{aligned}$$

Rule 3.—If any term of an equation be a fraction, its denominator

nominator may be taken away, by multiplying all the reft of the terms by it.

$$\text{Thus, if } \frac{x}{2} = 3$$
$$\text{Then } x = 6$$
$$\text{And if } \frac{x}{a} - b = c$$
$$\text{Then } x - ab = ac$$
$$\text{Or } x = a(b + c)$$

Or the denominators may be taken away from feveral terms of an equation, by one operation, if all the terms be multiplied by any number which is a multiple of each of the denominators.

$$\text{Thus, if } \frac{x}{2} + \frac{x}{3} + \frac{x}{4} = 6$$

Then, if all the terms be multiplied by 12, which is a multiple of 2, 3 and 4,

$$\text{We fhall have } 6x + 4x + 3x = 72$$
$$\text{And } 13x = 72$$
$$\text{Or } x = \frac{72}{13} = 5\frac{7}{13}$$

It alfo appears, from this rule, that if each of the terms of an equation be either multiplied or divided by the fame quantity, that quantity may be left out of them all.

$$\text{Thus, if } ax = ab + ac$$
$$\text{Then } x = b + c$$
$$\text{And if } \frac{x}{a} + \frac{b}{a} = \frac{c}{a}$$
$$\text{Then } x + b = c$$
$$\text{Or } x = c - b$$

4. If the unknown quantity, in any equation, be in the form of a furd, let it be made to ftand alone on one fide of the equation, and the remaining terms on the other; then involve each fide to a power denoted by the index of the furd, and the quantity will thus be rendered free from any furd expreffion.

If, for example, $\sqrt{x} + 2 = 5$

Then, by tranfpofition, $\sqrt{x} = 5 - 2 = 3$

And, by fquaring both fides, $x = 9$

In like manner, if $\sqrt{x^2 + a} - x = b$

Then, by tranfpofition, $\sqrt{x^2 + a} = b + x$

And by fquaring $x^2 + a = b^2 + 2bx + x^2$

And by leaving out x^2 on each fide $a = b^2 + 2bx$

Or $a - b^2 = 2bx$

Or $x = \dfrac{a - b^2}{2b}$

5. Any analogy, or proportion, may be converted into an equation, by making the product of the two extremes equal to that of the two means.

$$\text{Thus, if } 3x : 16 :: 5 : 7$$
$$\text{Then } 3x \times 7 = 16 \times 5$$
$$\text{Or } 21x = 80$$
$$\text{Or } x = \frac{80}{21} = 3\frac{17}{21}$$

Having thus fhewn the manner in which a fimple equation, containing only one unknown quantity, may be folved, it will be proper, in the next place, to explain the methods by which two or more equations of this kind may be reduced to a fingle one, and thence refolved by fome of the foregoing rules; obferving, in this cafe, that there muft always be the fame number of equations as there are unknown quantities, otherwife the queftion will admit of a variety of anfwers.

The principal methods, made ufe of for this purpofe, as far as regards the refolution of two fimple equations, are the three following:

1. Obferve which of the unknown quantities is the leaft involved, and find its value in each of the two equations by the methods already explained.

This being done, let the values, thus found, be put equal to each other; and there will arife a new equation, with only one unknown quantity in it, the value of which may be found as before.

As an example in this cafe, let it be required to determine x and y from the two following equations.

$$2x + 3y = 23$$
$$5x - 2y = 10$$

$$\text{Then, from the 1ft equation } x = \frac{23 - 3y}{2}$$
$$\text{And from the 2d, } x = \frac{10 + 2y}{5}$$

Hence, if thefe two values be put equal to each other,

$$\text{We fhall have } \frac{10 + 2y}{5} = \frac{23 - 3y}{2}$$
$$\text{Or } 20 + 4y = 115 - 15y$$
$$\text{Therefore } 15y + 4y = 115 - 20$$
$$\text{Or } 19y = 95$$
$$\text{And confequently } y = \frac{95}{19} = 5$$
$$\text{And } x = \frac{10 + 2y}{5} = \frac{10 + 10}{5} = \frac{20}{5} = 4$$

2. Confider which of the unknown quantities you would firft exterminate, and find its value in that equation where it is the leaft involved.

Then fubftitute this value for its equal in the other equation, and there will arife a new equation, with only one unknown quantity in it, the value of which may be found as before.

Thus, taking the fame example as in the former rule,

$$2x + 3y = 23$$
$$5x - 2y = 10$$
$$\text{Then, from the 1ft equation, } x = \frac{23 - 3y}{2}$$

And, if this value be fubftituted for x in the 2d equation, we fhall have

$$5\left(\frac{23 - 3y}{2}\right) - 2y = 10$$
$$\text{Or } 115 - 15y - 4y = 20$$
$$\text{And confequently } 115 - 20 = 15y + 4y$$
$$\text{Or } y = \frac{95}{19} = 5$$
$$\text{And } x = \frac{23 - 3y}{2} = \frac{23 - 15}{2} = \frac{8}{2} = 4$$

3. Let the given equations be multiplied or divided by fuch numbers or quantities as will make the term which contains one of the unknown quantities the fame in both equations.

Then, by adding or fubtracting the two equations, as occafion may require, there will arife a new equation with only one unknown quantity in it, which may be refolved as before.

Thus, taking the fame example as in the two former methods.

$$2x + 3y = 23$$
$$5x - 2y = 10$$

Then, to exterminate x, let the firft equation be multiplied by 5, and the 2d by 2, and we fhall have

$10x$

$$10x + 15y = 115$$
$$10x - 4y = 20$$

And fubtracting the latter of thefe two equations from the former, the refult will be

$$19y = 95$$

And confequently $y = \frac{95}{19} = 5$

And if this be fubftituted for y in the laft of the two given equations, we fhall have

$$5x - 2 \times 5 = 10$$
$$\text{Or } 5x = 10 + 10 = 20$$
$$\text{Or } x = \frac{20}{5} = 4$$

As another example of this third method, which is commonly more eafy and expeditious in practice than either of the other two,

Let there be given $\left\{\begin{matrix} ax + by = c \\ dx + fy = g \end{matrix}\right\}$ to find x and y

Then, in order to exterminate y, let the firft equation be multiplied by f, and the fecond by b, and we fhall have

$$afx + bfy = cf$$
$$bdx + bfy = bg$$

And by taking the difference of thefe two equations, there will arife

$$afx - bdx = cf - bg$$
$$\text{Or } (af - bd)\,x = cf - bg$$
$$\text{And confequently } x = \frac{cf - bg}{af - bd}$$

In like manner, if the firft of the two given equations be multiplied by d, and the fecond by a, we fhall have

$$adx + bdy = cd$$
$$adx + afy = ag$$

And, the difference of thefe equations being taken as before, will give

$$bdy - afy = cd - ag$$
$$\text{Or } (bd - af) = cd - ag$$
$$\text{And confequently } y = \frac{cd - ag}{bd - af}$$

In which cafe, x and y are here found in general terms: and confequently the folution will hold true, whatever numbers may be fubftituted for a, b, c, d, e, f, and g.

If it be required to exterminate three unknown quantities, or to reduce the three fimple equations containing them to a fingle one, it may be done as follows:

Find the value of one of the three unknown quantities in each of the three fimple equations containing it; then compare the firft of thefe values with the fecond, and the fecond with the third, and there will arife two new equations, containing only two unknown quantities, the values of which may be found by either of the former rules.

Let there be given, for example, the three following equations, to find x, y, and z.

$$x + y + z = 53$$
$$x + 2y + 3z = 105$$
$$x + 3y + 4z = 134$$

Then, if x be exterminated in each of thefe equations, we fhall have,

$$x = 53 - y - z$$
$$x = 105 - 2y - 3z$$
$$x = 134 - 3y - 4z$$

And by comparing the firft of thefe with each of the other two, there will arife the two following equations:

$$53 - y - z = 105 - 2y - 3z$$
$$53 - y - z = 134 - 3y - 4z$$

From which, by tranfpofition, and the rules of addition and fubtraction, we fhall readily find,

$$y = 52 - 2z$$
$$y = \frac{81 - 3z}{2}$$

And confequently, by equating thefe two values of y, we fhall obtain,

$$\frac{81 - 3z}{2} = 52 - 2z$$
$$\text{Or } 81 - 3z = 104 - 4z$$
$$\text{Or } 4z - 3z = 104 - 81 = 23$$
$$\text{Hence } z = 23$$
$$y = 52 - 2z = 52 - 46 = 6$$
$$x = 53 - y - z = 53 - 6 - 23 = 24$$

And if the three following equations be propofed, in general terms,

$$ax + by + cz = d$$
$$a'x + b'y + c'z = d'$$
$$a''x + b''y + c''z = d''$$

Then the values of x, y, and z, found in a fimilar manner, will be as below:

$$z = \frac{ab'd'' - ad'b'' + da'b'' - bad'' + bd'a'' - db'a''}{ab'c'' - acb'' + ca'b'' - ba'c'' + bc'a'' - cb'a''}$$

$$y = \frac{ad'c'' - ac'd'' + ca'd'' - da'c'' + dc'a'' - cd'a''}{ab'c'' - ac'b'' + ca'b'' - ba'c'' + bc'a'' - cb'a''}$$

$$x = \frac{db'c'' - dc'b'' + cdb'' - bd'c'' + bc'd'' - cb'd''}{ab'c'' - ac'b'' + ca'b'' - ba'c'' + bc'a'' - cb'a''}$$

Where, if any numbers whatever be fubftituted in the place of the literal coefficients, the equation will hold: and in a manner analogous to this, we may exterminate four or more unknown quantities in general terms; and thence, by fubftitution, determine their values in any numeral equations that may be propofed.

Having thus fufficiently fhewn the method of folving fimple equations, it will next be proper to proceed to the refolution of quadratic equations, or thofe of the fecond power, which, omitting the fimple cafe $x^2 = a$, and confining ourfelves only to fuch as are compound, may always be reduced to one of the three following forms:

1. $x^2 + ax = b$
2. $x^2 - ax = b$
3. $x^2 - ax = -b$

Where the value of the unknown quantity x, in each of the equations, taken according to the order in which they ftand, may be exhibited as below:

1. $x = -\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}$
2. $x = +\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}$
3. $x = +\frac{a}{2} \pm \sqrt{\frac{a^2}{4} - b}$

Or the general equation $ax^2 \pm bx = \pm c$, which comprehends all the three cafes above-mentioned, may be refolved by means of the following rule:

Tranfpofe all the terms that involve the unknown quantity to one fide of the equation, and the known quantities to the other; obferving to arrange them fo, that the term which contains the fquare of the unknown quantity may be pofitive, and ftand firft in the equation.

Then, if the fquare of the unknown quantity have any coefficient prefixed to it, let all the reft of the terms be divided by it, fo that the coefficient of the fquare of the unknown quantity may be 1.

This

This being done, add the ſquare of half the coefficient of the unknown quantity itſelf to both ſides of the equation, and the ſide which involves the unknown quantity will now be a complete ſquare.

Laſtly, extract the ſquare root of both ſides of the equation, by which means it will be reduced to a ſimple one; and if the unknown quantity be made to ſtand alone, on one ſide of the equation, and the known terms on the other, its value will be determined as was required.

Note. The ſquare root of the firſt ſide of the equation is always equal to the ſum or difference of the unknown quantity, and half the coefficient of the ſecond term, according as that term is + or —.

It may alſo be obſerved, that all equations, in which there are two terms involving the unknown quantity, and which have the index of the one juſt double that of the other, are ſolved like quadratics, by completing the ſquare.

Thus, $x^4 - ax^2 = b$, or $x^{2n} - ax^n = b$, are the ſame as quadratics; their roots being as below.

$$x = \sqrt{\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}},\quad x = \sqrt[n]{\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}}$$

As an illuſtration of the rule for quadratics given above, the following ſimple examples in numbers will be found ſufficient.

1. Given $x^2 + 4x = 140$, to find x.

Here $x^2 + 4x + 4 = 140 + 4 = 144$, by completing the ſquare.

And $\sqrt{x^2 + 4x + 4} = \sqrt{144}$, by extracting the root.

Or, which is the ſame thing, $x + 2 = 12$.

And conſequently $x = 12 - 2 = 10$.

2. Given $x^2 - 6x + 8 = 80$, to find x.

Here $x^2 - 6x = 80 - 8 = 72$, by tranſpoſition.

Then $x^2 - 6x + 9 = 72 + 9 = 81$, by completing the ſquare.

And $x - 3 = \sqrt{81} = 9$, by extracting the root.

Whence $x = 9 + 3 = 12$.

3. Given $2x^2 + 8x - 20 = 70$, to find x.

Here $2x^2 + 8x = 70 + 20 = 90$, by tranſpoſition.

Then $x^2 + 4x = 45$, by dividing by 2.

And $x^2 + 4x + 4 = 45 + 4 = 49$, by completing the ſquare.

Whence $x + 2 = \sqrt{49} = 7$, by extracting the root.

And conſequently $x = 7 - 2 = 5$.

4. Given $\frac{x^2}{2} - \frac{x}{3} + 20\frac{1}{2} = 42\frac{2}{3}$.

Here $\frac{x^2}{2} - \frac{x}{3} = 42\frac{2}{3} - 20\frac{1}{2} = 22\frac{1}{6}$, by tranſpoſition.

And $x^2 - \frac{2}{3}x = 44\frac{1}{3}$, by dividing by $\frac{1}{2}$, or multiplying by 2.

Whence $x^2 - \frac{2}{3}x + \frac{1}{9} = 44\frac{1}{3} + \frac{1}{9} = 44\frac{4}{9} = \frac{400}{9}$, by completing the ſquare.

And $x - \frac{1}{3} = \sqrt{\frac{400}{9}} = \frac{20}{3}$.

Therefore $x = \frac{20}{3} + \frac{1}{3} = \frac{21}{3} = 7$.

It muſt here, however, be obſerved, that ſince the ſquare root of any quantity may be either poſitive (+) or negative (—), it follows that all quadratic equations will admit of two ſolutions. Thus, the ſquare root of a^2 (or $\sqrt{a^2}$) is either $+a$ or $-a$; for $(+a) \times (+a)$ or $(-a \times -a)$ are each equal to a^2, by the rules for the ſigns in multiplication. So, in like manner, if there be given $x^2 + ax = b$, where $x + \frac{a}{2}$ is found $= \sqrt{b + \frac{1}{4}a^2}$, the root may be $+\sqrt{b + \frac{1}{4}a^2}$, or $-\sqrt{b + \frac{1}{4}a^2}$, ſince either of them being multiplied by itſelf will produce $b + \frac{1}{4}a^2$. And this ambiguity is uſually expreſſed by writing the uncertain ſign $\pm$ before $\sqrt{b + \frac{1}{4}a^2}$, by which means we have $x = \pm\sqrt{b + \frac{1}{4}a^2} - \frac{1}{2}a$; and the ſame mode of reaſoning is equally applicable to any literal or numeral quadratic equation whatever. Thus, in the firſt numeral equation above, $x^2 + 4x = 140$, it has been found that $x + 2 = \sqrt{144} = 12$; but if the uncertain ſign $\pm$ be put before $\sqrt{144}$, it will become $x + 2 = \pm\sqrt{144} = +12$ or -12; and conſequently $x = +12 - 2 = 10$ or $-12 - 2 = -14$, which are the two roots of the equation $x^2 + 4x = 140$, as will be found by ſubſtituting either of them for x; the reſult in both caſes being 144.

In addition to this, it may be ſtill farther remarked, that a quadratic equation may be propoſed of ſuch a form, or have its coefficients ſo related to each other, that the value of the unknown quantity can only be exhibited by means of the ſquare root of a negative quantity, which, it is plain, cannot be determined; as there is no quantity, either poſitive or negative, which being multiplied by itſelf produces ſuch a form of expreſſion. If, for example, the value of x were required from the equation $x^2 + 13 = 4x$, or $x^2 - 4x = -13$, we ſhould find $x = 2 \pm \sqrt{-9}$; and as it is here neceſſary to extract the ſquare root of -9, which cannot be determined, the queſtion is ſhewn to be impoſſible, or to involve a contradiction.

But although imaginary expreſſions of this kind are of no other uſe in the reſolution of quadratic equations, than to ſhew that a particular problem cannot be ſolved, they muſt not, on this account, be altogether rejected; as they are well known to be of the greateſt uſe in many mathematical inveſtigations, particularly in ſome of the higher branches of the ſcience, where no other mode of reaſoning could be ſo ſucceſsfully or advantageouſly employed.

Thus, if e be made to repreſent the number of which the hyperbolic logarithm is 1, it is well known, as a theorem in trigonometry, that

$$\text{Coſ. } x = \frac{e^{x\sqrt{-1}} + e^{-x\sqrt{-1}}}{2}$$

$$\text{Sin. } x = \frac{e^{x\sqrt{-1}} - e^{-x\sqrt{-1}}}{2\sqrt{-1}}$$

Where the ſine and coſine of any arc x is exhibited in a very commodious manner, by means of imaginary exponential expreſſions; which formulæ, though objected to, and ridiculed by certain writers, are conſidered, by the celebrated Lagrange (Leçons, ſur des Fonct. Analytiques) as one of the fineſt analytical diſcoveries of the eighteenth century.

Having thus ſufficiently explained the nature of quadratic equations, it will be neceſſary, before we proceed to the reſolution of cubics and thoſe of higher dimenſions, to ſhew how the ſecond term of any equation may be taken away, in order to fit it for a ſolution; which is done as follows:

Divide the coefficient of the ſecond term of the propoſed equation by the exponent of the firſt term, and add the quotient, with its ſign changed, to ſome new unknown quantity: then if this ſum be ſubſtituted for the unknown quantity in the propoſed equation, a new equation will ariſe, which will want the ſecond term, as required.

For example, let the quadratic equation $x^2 - 8x + 15 = 0$, be that of which it is required to take away its ſecond term.

Then ſince $\frac{8}{2} = 4$, if x be put $= y + 4$, we ſhall have,

$x^2 =$

$$x^2 = y^2 + 8y + 16$$
$$-8x = \quad -8y - 32$$
$$+15 = \quad +15$$

Whence $y^2 - 1 = 0$, the equation required.

From which it appears, that any quadratic equation may be ſolved without completing the ſquare, by only taking away the ſecond term; for ſince in the above reduced equation $y = \sqrt{1} = 1$, we ſhall have $x = y + 4 = 1 + 4 = 5$.

Again, let the equation $x^3 - 9x^2 + 26x - 34 = 0$ be given, to exterminate the ſecond term.

Then ſince $\frac{9}{3} = 3$, if x be put $= y + 3$, we ſhall have,

$$x^3 = y^3 + 9y^2 + 27y + 27$$
$$-9x^2 = \quad -9y^2 - 54y - 81$$
$$+26x = \quad +26y + 78$$
$$-34 = \quad -34$$

Whence $y^3 - y - 10 = 0$, or $y^3 - y = 10$, the equation required.

In like manner, let the following literal equations of the fourth power $x^4 + px^3 + qx^2 + rx + s = 0$ be given, to exterminate the ſecond term.

Then, by putting $x = y - \frac{p}{4}$, we ſhall have,

$$x^4 = y^4 - py^3 + \frac{3p^2}{8}y^2 - \frac{p^3}{16}y + \frac{p^4}{256}$$
$$px^3 = \quad + py^3 - \frac{3p^2}{4}y^2 + \frac{3p^3}{16}y - \frac{p^3}{64}$$
$$qx^2 = \quad + qy^2 - \frac{pq}{2}y + \frac{qp^2}{16}$$
$$rx = \quad + ry - \frac{rp}{4}$$
$$s = \quad + s$$

Hence $y^4 + \frac{8q - 3p^2}{8}y^2 + \frac{8r - 4pq + p^2}{8}y + \frac{256s - 64rp + 16qp^2 - 4p^3 + p^4}{256} = 0$, the reduced equation required. And the ſame method of ſolution may be applied to the taking away the ſecond term of any equation whatever.

Another ſpecies of transformation, of uſe in reducing equations to their ſimpleſt form, is that of converting ſuch of the terms as have fractional coefficients into others that ſhall be integral; which is done by ſubſtituting a new unknown quantity, divided by the product of all the denominators, inſtead of the unknown quantity in the equation; and then, by proper reductions, the equation will be found to have the form required.

Thus, let $x^4 + \frac{p}{a}x^3 + \frac{q}{b}x^2 + \frac{r}{c}x + \frac{s}{d} = 0$, be the given equation.

Then, if x be aſſumed $= \frac{y}{abcd}$, we ſhall have, by ſubſtitution,

$$\frac{y^4}{a^4b^4c^4d^4} + \frac{py^3}{a^4b^3c^3d^3} + \frac{qy^2}{a^2b^3c^2d^2} + \frac{ry}{abc^2d} + \frac{s}{d} = 0.$$

And by multiplying the whole equation by $a^4b^4c^4d^4$ it will become

$y^4 + bcdpy^3 + a^2bc^2d^2qy^2 + a^3b^3c^2d^3ry + a^4b^4c^4d^3 = 0$, which is of the form required.

This preparation being made, it will now be proper to proceed to the ſolution of *cubic equations*, or thoſe of which the higheſt power is of three dimenſions; all of which, when expreſſed in general terms, are of the form

$$x^3 \pm px^2 \pm qx \pm r = 0.$$

Or, if the ſecond term be taken away, by means of the above-mentioned rule, any equation of this kind may be exhibited under the form

$$x^3 \pm px = \pm q$$

And, in this caſe, the value of the unknown quantity x, according to the rule uſually aſcribed to Cardan, is as follows:

$$x = \sqrt[3]{\tfrac{1}{2}q + \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}} + \sqrt{\tfrac{1}{2}q - \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}}$$

Or

$$x = \sqrt[3]{\tfrac{1}{2}q + \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}} - \frac{\tfrac{1}{3}p}{\sqrt[3]{\tfrac{1}{2}q + \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}}}$$

the values of p and q being always ſuppoſed to be taken with the ſign $+$ or -1 according as they are found in the given equation.

The rule may be demonſtrated thus:

Let the equation, whoſe root is to be determined, be

$$x^3 + px = q$$

Then if x be aſſumed $= y + z$, we ſhall have, by ſubſtitution,

$$x^3 = y^3 + 3yz(y + z) + z^3$$
$$px = \quad p(y + z)$$

Or $x^3 + px = y^3 + 3yz + p \times \overline{y + z} + z^3 = q$

And if, in this laſt equation, $3yz$ be taken $= -p$, we ſhall have the two following equations for determining the values of y and z: *viz.*

$$3yz = -p$$
$$y^3 + z^3 = q$$

Where, ſince in the firſt of them, $z = -\frac{p}{3y}$, if this value be ſubſtituted in the ſecond, it will become

$$y^3 - \frac{p^3}{27y^3} = q$$

Or by multiplying by y^3, and then tranſpoſing the terms,

$$y^6 - qy^3 = (\tfrac{1}{3}p)^3$$

And as this equation is now in the form of a quadratic, on account of the index of the higheſt term being double that of the ſecond, we ſhall have, by the rule already given for that purpoſe, and by ſimple equations.

$$y = \sqrt[3]{\tfrac{1}{2}q \pm \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}}$$
$$z = \frac{\tfrac{1}{3}p}{\sqrt[3]{\tfrac{1}{2}q \pm \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}}}$$

Whence $x = y + z = \sqrt[3]{\tfrac{1}{2}q \pm \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}} - \frac{\tfrac{1}{3}p}{\sqrt[3]{\tfrac{1}{2}q \pm \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}}}$

as was to be ſhewn.

As a practical application of the rule, let there be given the equation $x^3 + 6x = 20$, to find the value of x.

Thus, if p be put $= 6$, and $q = 20$, the analytical expreſſion will become

$$\sqrt[3]{10 + \sqrt{100 + 8}} - \frac{2}{\sqrt[3]{10 + \sqrt{100 + 8}}} = \sqrt[3]{10 + \sqrt{108}} - \frac{2}{\sqrt[3]{10 + \sqrt{108}}}$$

$$= \sqrt[3]{10 + 10.3923} - \frac{2}{\sqrt[3]{10 + 10.3923}} = \sqrt[3]{20.3923} - \frac{2}{\sqrt[3]{20.3923}}$$

$$= 2.732$$

$= 2.732 - \frac{2}{2.732} = 2.732 - .732 = 2$, which is the required value of x.

It happens, however, that the value of the unknown quantity is here only found by approximation; but this, when the root is a whole number, may always be avoided, for ſince in the preſent inſtance, $\sqrt[3]{10 + \sqrt{108}} = 1 + \sqrt{3}$, as may be proved by raiſing it to the third power, if this be ſubſtituted in its proper place, in the above expreſſions, we ſhall have $\sqrt[3]{10 + \sqrt{108}} - \frac{2}{\sqrt[3]{10 + \sqrt{108}}} = 1 + \sqrt{3}$

$$- \frac{2}{1+\sqrt{3}} = \frac{(1+\sqrt{3})^2 - 2}{1+\sqrt{3}} = \frac{1 + 2\sqrt{3} + 3 - 2}{1+\sqrt{3}}$$

$= \frac{2 + 2\sqrt{3}}{1+\sqrt{3}} = 2$, as before.

Again, as a ſecond example, let there be given $x^3 - 6x = -q$, to find the value of x.

Here $p = -6$ and $q = -q$

Then, by ſubſtituting theſe values in the above formula, we have

$$x = \sqrt[3]{-4\tfrac{1}{4} + \sqrt{20\tfrac{1}{2} - 8}} - \frac{-2}{\sqrt[3]{-4\tfrac{1}{4} + \sqrt{20\tfrac{1}{2} - 8}}}$$

$$= \sqrt[3]{-4\tfrac{1}{2} + 3\tfrac{1}{2}} + \frac{2}{\sqrt[3]{-4\tfrac{1}{2} + 3\tfrac{1}{2}}} = \sqrt[3]{-1} + \frac{2}{\sqrt[3]{-1}}$$

$= -1 + \frac{2}{-1} = -1 - 2 = -3$, the required value of x.

But as a quadratic equation has been ſhewn to have two roots, or values, of the unknown quantity, ſo, in like manner, it may be proved that the unknown quantity, in a cubic equation, has three values or roots, each of which will be found to anſwer the conditions of the queſtion.

Thus, in the firſt equation $x^3 + 6x - 20 = 0$, given above, where x has been found $= 2$, or $x - 2 = 0$, if $x^3 + 6x - 20 = 0$ be divided by $x - 2$, we ſhall have $x^2 + 2x + 10 = 0$, or $x^2 + 2x = -10$, the roots of which equation, found according to the rule for quadratics, are $-1 + 3\sqrt{-1}$, and $-1 - 3\sqrt{-1}$, each of which, as well as the former root 2, are values of the unknown quantity, as will be found by ſubſtituting them for x in the given equation.

It muſt be obſerved, however, that neither the formula of Cardan, nor any other that has yet been diſcovered, will be found ſufficient to determine the numerical value of the unknown quantity in every cubic equation that can be propoſed; for when the coefficient of the ſecond term of the equation is negative, and the cube of $\frac{1}{3}$ of it is greater than the ſquare of half the abſolute term, the expreſſion for the root becomes imaginary; and therefore no intelligible reſult can be derived from it.

Thus, if the equation propoſed, were $x^3 - 3x = 1$, the analytical expreſſion, when converted into numbers, will become $x = \sqrt[3]{\tfrac{1}{2} + \sqrt{\tfrac{1}{4} - 1}} - \frac{1}{\sqrt[3]{\tfrac{1}{2} + \sqrt{\tfrac{1}{4} - 1}}} =$

$\sqrt[3]{\tfrac{1}{2} + \tfrac{1}{2}\sqrt{-3}} - \frac{1}{\sqrt[3]{\tfrac{1}{2} - \tfrac{1}{2}\sqrt{-3}}}$, the value of which cannot be determined either in integers, fractions, or rational ſurds; although, by ſubſtituting it for x in the given equation, the terms will all vaniſh as they ought; and conſequently, in a certain ſenſe, it may be ſaid to be a root of the equation.

This defective ſtate of Cardan's formula, or that in which it fails as a general rule, has commonly been called the *irreducible caſe of cubic equations*; and notwithſtanding the reiterated efforts of the moſt celebrated analiſts in Europe, from the time when the want of generality in the rule was firſt obſerved, to the preſent day, no remedy has been found for this defect, except by a method of ſolution which is derived from the triſection of an angle, or by converting the expreſſion into an infinite ſeries; in which latter caſe that part of the quantity which is imaginary diſappears, and by that means enables us to compute the root to any degree of exactneſs. For it is to be remarked, that although the unknown quantity cannot be determined from the formula itſelf, yet all the three roots are, in this caſe, real, and can be found, at leaſt approximately, by either of the two methods laſt-mentioned.

Leaving this part of the ſubject, for the preſent, we ſhall next proceed to *biquadratic equations*, or thoſe of the fourth power; any one of which, when the ſecond term is taken away, may be repreſented, in general terms, by $x^4 + ax^2 + bx + c = 0$; and the rule for the reſolution of any equation of this form, is as follows:

Find the value of y in the cubic equation $y^3 - \frac{a^2 + 12c}{3}y = b^2 + \frac{2a}{27}(a^2 - 36c)$, by the rule before given for this purpoſe; and let the root, thus determined, be denoted by v.

Then find each of the values of x in the two following quadratic equations,

$$x^2 + (\sqrt{v - \tfrac{2}{3}a})x = -[\tfrac{1}{2}a + \tfrac{1}{2}(v - \tfrac{2}{3}a)] + \frac{b}{2\sqrt{v - \tfrac{2}{3}a}}$$

$$x^2 - (\sqrt{v - \tfrac{2}{3}a})x = -[\tfrac{1}{2}a + \tfrac{1}{2}(v - \tfrac{2}{3}a)] - \frac{b}{2\sqrt{v - \tfrac{2}{3}a}}$$

And the values of x, thus found, will be the four roots of the biquadratic equation $x^4 + ax^2 + bx + c = 0$, as was required.

The rule, which is here given in a more commodious form than that of Des Cartes, may be readily demonſtrated, by making the given equation $x^4 + ax^2 + bx + c = 0$, equal to the product of two quadratic equations, and then equating the coefficients of the homologous terms. Thus, if $x^2 + px + q$ be multiplied by $x^2 - px + r$, and the product thence ariſing put $= 0$, we ſhall have $x^4 + (r + q - p^2)x^2 + p(r - q)x + rq = 0$.

Hence $r + q - p^2 = a$, $p(r - q) = b$, and $rq = c$; and conſequently $2r = a + p^2 + \frac{b}{p}$, and $2q = a + p^2 - \frac{b}{p}$.

And if theſe values be ſubſtituted in the equation $rq = c$, or its equal $4rq = 4c$, we ſhall obtain, after proper reduction, the equation $p^6 + 2ap^4 + (a^2 - 4c)p^2 = b^2$.

Or, by putting $p^2 = y - \frac{2}{3}a$, and ſubſtituting it in the latter equation, we ſhall have for the reſult the cubic equation $y^3 - \frac{a^2 + 12c}{3}y = b^2 + \frac{2a}{27}(a^2 - 36c)$, which is that given in the rule.

Hence, if the value, or root of y, in this equation, be put $= v$, we ſhall have, from the equations given above, $p = \sqrt{v - \tfrac{2}{3}a}$, $q = \tfrac{1}{2}a + \tfrac{1}{2}(v - \tfrac{2}{3}a) - \frac{b}{2\sqrt{v - \tfrac{2}{3}a}}$, and $r = \tfrac{1}{2}a + \tfrac{1}{2}(v - \tfrac{2}{3}a) + 2\sqrt{v - \tfrac{2}{3}a}$. And by

ſubſtituting

ſubſtituting theſe values in the two quadratic equations $x^2 + px + q = 0$, and $x^2 - px + r = 0$, they will become $x^2 + (\sqrt{v - \frac{2}{3}a})\, x = -\frac{1}{2}a - \frac{1}{2}(v - \frac{2}{3}a) + \frac{b}{2\sqrt{v - \frac{2}{3}a}}$, and $x^2 - (\sqrt{v - \frac{2}{3}a})\, x = -\frac{1}{2}a - \frac{1}{2}(v - \frac{2}{3}a) - \frac{b}{2\sqrt{v - \frac{2}{3}a}}$; the roots of which equations will be the 4 roots of the propoſed biquadratic equation $x^4 + ax^2 + bx + c = 0$. As a practical example for the exerciſe of this rule, let there be given $x^4 - 6x^2 - 16x + 21 = 0$, to find the 4 values of x.

Then, if the numbers -6, -16, and 21 be ſubſtituted in the place of a, b, c, in the cubic equation $y^3 - \frac{a^2 + 12c}{3} y = b^2 + \frac{2a}{27}(a^2 - 36c)$, it will become $y^3 - \frac{36 + 252}{3} y = 256 - \frac{12}{27}(36 - 756)$, or $y^3 - 96y = 576$, where the value of y, as determined by the preceding rule for cubic equations, will be found $= 12$.

Hence, if 12 be put for v, -6 for a, and -16 for b, in the two quadratic equations,

$$x^2 + (\sqrt{v - \tfrac{2}{3}a})\, x = -\tfrac{1}{2}a - \tfrac{1}{2}(v - \tfrac{2}{3}a) + \frac{b}{2\sqrt{v - \frac{2}{3}a}}$$

$$x^2 - (\sqrt{v - \tfrac{2}{3}a})\, x = -\tfrac{1}{2}a - \tfrac{1}{2}(v - \tfrac{2}{3}a) - \frac{b}{2\sqrt{v - \frac{2}{3}a}}$$

they will become,

$$x^2 + (\sqrt{12 + 4})\, x = 3 - 8 - 2 = -7$$
$$x^2 - (\sqrt{12 + 4})\, x = 3 - 8 + 2 = -3$$

Or,

$$x^2 + 4x + 7 = 0$$
$$x^2 - 4x + 3 = 0$$

In the firſt of which $x = -2 + \sqrt{-3}$, or, $-2 - \sqrt{-3}$. And in the ſecond, $x = 3$ or 1, which are the roots of the given equation $x^4 - 6x^2 - 16x + 21 = 0$; there being always as many values of the unknown quantity, in any equation, as there are units in the index of its higheſt power; as will be ſhewn in a ſucceeding part of this article.

But before we proceed to any enquiries of this kind it will be proper to obſerve, that no general rule has hitherto been found for reſolving equations of the 5th, 6th, or other higher orders, notwithſtanding the numerous attempts that have been made for this purpoſe; ſo that in this reſpect we have not been able to advance a ſingle ſtep beyond what had been done by Louis Ferrari, Bombelli, and others in the early part of the 17th century, who were all acquainted with the method of reſolving biquadratic equations; which is ſtill the boundary that the moſt ſkilful analiſts, aſſiſted by all the advantages of a more comprehenſive and commodious calculus, have not been able to paſs.

But although no general reſolution has hitherto been given of equations higher than thoſe of the 4th power, there are, notwithſtanding, ſome particular equations, of all orders, which, on account of certain relations ſubſiſting between the coefficients of their different terms, may be reſolved by the rules which have been given for thoſe of the firſt four orders.

This is particularly the caſe with what have been uſually called *reciprocal equations*, which are ſuch that the coefficients of the terms form the ſame numerical ſeries, whether taken in a direct or an inverted order; or that remain the ſame when the reciprocal of the unknown quantity, or $\frac{1}{x}$ is ſubſtituted for x.

Thus, for example, the equations $x^5 + px^4 + qx^3 + qx^2 + px + 1 = 0$, $x^4 + px^3 + qx^2 + px + 1 = 0$, &c. which are of this kind, may always be transformed into others of a degree denoted by half the exponent of the higheſt power of the unknown quantity, if it be an even number, or by half the exponent diminiſhed by 1, if it be an odd number.

Thus, let the laſt of the two equations given above, $x^4 + px^3 + qx^2 + px + 1 = 0$, be taken in the form $x^2 + \frac{1}{x^2} + p(x + \frac{1}{x}) + q = 0$, to which it can be readily reduced; then if $x + \frac{1}{x}$ be put $= z$, we ſhall have $x^2 + 2 + \frac{1}{x^2} = z^2$, or $x^2 + \frac{1}{x^2} = z^2 - 2$; and if this be ſubſtituted in the original equation $x^4 + px^3 + qx^2 + px + 1 = 0$, it will become $z^2 + pz = 2 - q$. And ſince $x + \frac{1}{x} = z$, we ſhall have $x^2 - zx + 1 = 0$. Hence, if the two roots of the equation $z^2 + pz = 2 - q$, be denoted by r and r', we ſhall have the two following equations $x^2 - rx + 1 = 0$, and $x^2 - r'x + 1 = 0$; the roots of which will be the four roots of the given biquadratic equation $x^4 + px^3 + qx^2 + px + 1 = 0$.

And in a ſimilar way may any other equation of this kind be reſolved, when the index of the greateſt power of the unknown quantity is an even number.

And if the index of the unknown quantity be an odd number, as in the equation $x^5 + px^4 + qx^3 + qx^2 + px + 1 = 0$, it is obvious from inſpection only, that -1 is a root of the equation; and, conſequently, if $x^5 + px^4 + qx^3 + qx^2 + px + 1 = 0$, be divided by $x + 1$, it will be reduced to the form $x^4 + (p - 1)x^3 - (p - q - 1)x^2 + (p - 1)x + 1 = 0$, which is another reciprocal equation, a degree lower than the former; and having the index of its higheſt power an even number, it is conſequently reſolvible in the manner above explained.

Alſo, when two or more roots of any equation are equal to each other, the equation may always be reduced to another of an inferior degree, and the roots, by that means, determined.

Thus, if the cubic equation $x^3 - px^2 + qx - r = 0$, has two equal roots, each of them will be $x = \frac{pq - 9r}{p^2 - 6q}$.

For, let the three roots be denoted by a, a and b; then by the compoſition of equations we ſhall have $x^3 - (2a + b)x^2 + (a^2 + 2ab)x - a^2 b = 0$; where $2a + b = p$, $a^2 + 2ab = q$, and $a^2 b = r$; and if theſe values be ſubſtituted in the above form, it will become $x = \frac{pq - 9r}{p^2 - 6q} = \frac{2a^3 + 4a^2 b + a^2 b + 2ab^2 - 9a^2 b}{8a^2 + 8ab + 2b^2 - 6a^2 - 12ab} = \frac{2a^3 - 4a^2 b + 2ab^2}{2a^2 - 4ab + 2b^2} = a$, as was to be ſhewn.

Thus, let the equation $x^3 + 5x^2 - 32x + 36 = 0$, which has two equal roots, be the one propoſed to be reſolved.

Then ſince $p = -5$, $q = -32$, and $r = -36$, if theſe values be ſubſtituted in the formulæ $x = \frac{pq - 9r}{p^2 - 6q}$, it will become $x = \frac{-5 \times -32 - 9 \times -36}{2 \times 25 - 6 \times -32} = \frac{160 + 324}{50 + 192} = \frac{484}{242} = 2$, which is one of the equal roots of the equation.

And

And in a ſimilar manner may the equal roots of equations of the higher orders be determined; but though the ſubject conſidered as a branch of analyſis is highly curious, and on that account has been far more completely and ſcientifically inveſtigated than in the caſe here given, its practical importance is too trifling to render any farther elucidation of it neceſſary, in an article ſo confined as the preſent. The ſame may alſo be ſaid of the method uſually given for determining the roots of an equation by means of the diviſors of its laſt term, and other ſimilar proceſſes, which are moſtly tentative, and only adapted to the finding ſuch roots of the equation as are rational, and for that reaſon readily diſcovered by a few trials.

It remains, therefore, only to ſhew how the roots of any numeral equation whatever may be determined by approximation; for which purpoſe, it will be ſufficient to give the rule firſt employed by Newton and Ralphſon, which, though attended with ſome defects, is as commodious, when conſidered as a general method of ready and eaſy application, as any one that has yet been propoſed. The rule is as follows.

Find, by trial, a number nearly equal to the root required, which call r; and let z be put equal to the difference between r and the true root x.

Then, inſtead of x in the given equation, ſubſtitute its equal $r \pm z$, and there will ariſe a new equation, affected only with z, and known quantities.

This done, reject all thoſe terms in which there are two or more dimenſions of z, and the value of z will then be found by means of a ſimple equation.

And if the value of z, thus found, be added to, or ſubtracted from, that of r, according as r was aſſumed too great or too little, it will give the root required *nearly*.

And if this root ſhould not be thought ſufficiently near the truth, the operation muſt be repeated, by ſubſtituting the laſt reſult inſtead of r, in the equation exhibiting the value of z; by which a ſecond correction of the root will be obtained more accurate than the former, and ſo on to any degree of exactneſs required.

As a practical example, for the illuſtration of the rule, let there be given the equation $x^3 + x^2 + x = 90$, to find the value of x by approximation.

Here it is ſoon found, by a few trials, that the root is ſomething greater than 4.

Let, therefore, $4 = r$, and $r + z = x$, then,

$$x^3 = r^3 + 3r^2z + 3rz^2 + z^3$$
$$x^2 = r^2 + 2rz + z^2$$
$$x = r + z$$

And conſequently by rejecting the terms $z^3 + 3rz^2 + z^2$, we ſhall have $r^3 + 3r^2 z + r^2 + 2rz + r + z = 90$;

$$\text{or, } z = \frac{90 - r^3 - r^2 - r}{3r^2 + 2r + 1} = \frac{90 - 64 - 16 - 4}{48 + 8 + 1} = \frac{6}{57} = .10,$$

and $x = 4 + .10 = 4.1$, nearly.

And again, if 4.1 be ſubſtituted in the place of r, in the laſt equation, we ſhall have.

$$z = \frac{90 - r^3 - r^2 - r}{3r^2 + 2r + 1} = \frac{90 - 68.921 - 16.81 - 4.1}{50.43 + 8.2 + 1} = \frac{78.121}{59.63}$$

$= .00283$; and $x = 4.1 + .00283 = 4.10283$.

And by proceeding in this manner, the root may be obtained to any degree of accuracy required.

The chief defect in this rule is, that it does not ſhew the progreſs made in the approximation at each operation, and that when the roots are ſmall and ſome of them nearly equal to each other, they may be paſſed over, by this method of operating, without their being perceived; both of which circumſtances have been particularly noticed by Lagrange, who has given an improved method of approximation in his excellent work on the "Réſolution des Equations Numériques," to which we muſt refer the reader, as being but little ſuſceptible of that kind of conciſe elucidation which neceſſarily belongs to an article like the preſent.

It, therefore, only remains to give ſome account of the general theory of equations; in which it will be firſt neceſſary to ſhew, that every equation, of any order whatever, has as many roots as there are units in the index of the higheſt power of the unknown quantity in that equation.

For this purpoſe, let us take the general equation $x^n + Px^{n-1} + Qx^{n-2} \ldots\ldots + Tx + U = 0$, to which all others can be readily reduced: then if a root of this equation be denoted by a, the firſt ſide of it will be diviſible by $x - a$.

For, ſince $x^n + Px^{n-1} + Qx^{n-2} \ldots + Tx + U = 0$:

And $a^n + Pa^{n-1} + Qa^{n-2} \ldots + Ta + U = 0$.

Therefore, by ſubſtraction, $(x^n - a^n) + P(x^{n-1} - a^{n-1}) + Q(x^{n-2} - a^{n-2}) \ldots T(x - a) = 0$.

But any expreſſion of the form $(x^n - a^n)$, where n denotes any whole poſitive number, is $= (x - a) \times (x^{n-1} + ax^{n-2} + a^2x^{n-3} \ldots a^{n-2}x + a^{n-1})$, as may be readily proved by multiplication. Whence, if the quantities $x^n - a^n$, $x^{n-1} - a^{n-1}$, $x^{n-2} - a^{n-2}$, &c. be each divided by $x - a$, we ſhall have

$$\begin{array}{rrrl}
x^{n-1} + a\,x^{n-2} & + a^2x^{n-3} & \ldots\ldots & + a^{n-1} \\
x^{n-2} & + a\,x^{n-3} & \ldots\ldots & + a^{n-2} \\
 & + \;\; x^{n-3} & \ldots\ldots & + a^{n-3} \\
 & & \ldots\ldots\ldots\ldots & \\
 & & & + 1
\end{array}$$

Or, if the ſame expreſſions be arranged according to the powers of x, they will become

$$\begin{array}{rrrl}
x^{n-1} + a\,x^{n-2} & + a^2x^{n-3} & \ldots\ldots & + \;\; a^{n-1} \\
+ Px^{n-2} & + Pa\,x^{n-1} & \ldots\ldots & + Pa^{n-2} \\
 & + Qx^{n-1} & \ldots\ldots & + Qa^{n-3} \\
 & \ldots\ldots\ldots\ldots & & \\
 & & & + T
\end{array}$$

Where, by putting $P' = a + P$, $Q' = a^2 + aP + Q$, &c. we ſhall have $x^n + Px^{n-1} + Qx^{n-2} \ldots + Tx + U = (x - a) \times (x^{n-1} + P'x^{n-2} + Q'x^{n-3}, \text{ \&c.}) = 0$.

And if b be ſuppoſed to be a root of the equation $x^{n-1} + P'x^{n-2} + Q'x^{n-3}$, &c. $= 0$, the former of theſe will become $x^n + Px^{n-1} + Qx^{n-2}$, &c. $= (x - a) \times (x - b) \times (x^{n-2} + P''x^{n-3} + Q''x^{n-4}, \text{ \&c.})$; which latter equation may be ſhewn to have a ſimilar factor, $x - c$; and by proceeding in the ſame manner, the original equation may be decompoſed into as many factors, $x - a$, $x - b$, $x - c$, $\ldots\ldots\ldots x - l$, as there are units in the exponent n of its higheſt term.

Hence, by conſidering equations as formed by the product of certain factors, $x - a$, $x - b$, $x - c$, &c. we are enabled to diſcover a number of relations which ſubſiſt between its roots and coefficients.

Thus ſuppoſing a, b, c, d to be the roots of the biquadratic equation $x^4 + px^3 + qx^2 + rx + s = 0$, if this be repeſented by its factors $(x - a) \times (x - b) \times (x - c) \times (x - d) = 0$, we ſhall have, by multiplying them together, $x^4 - (a + b + c + d)x^3 + (ab + ac + ad + bc + bd + cd)x^2 - (abc + abd + acd + bcd)x + abcd = 0$; and by proceeding in the ſame manner, a ſimilar reſult may be obtained for any equation whatever.

Hence, from the bare inſpection of this equation, the following conſequences are readily derived.

1. The coefficient of the ſecond term of any equation, taken with a contrary ſign, is equal to the ſum of all the roots of that equation.

2. The coefficient of the third term is equal to the ſum

ſum of the products of all the roots, multiplied together, two by two.

3. The coefficient of the fourth term, taken with a contrary ſign, is equal to the ſum of the products, of all the roots, multiplied together, three by three; and ſo on to the laſt term, which is equal to the product of all the roots with contrary ſigns.

From this it alſo follows, that in an equation wanting its ſecond term, there muſt be both poſitive and negative roots, and that the ſum of the former is equal to that of the latter.

And in the ſame way, a number of other properties of the various orders of equations may be derived, which will be found of great uſe, not only with reſpect to their reſolution, but as furniſhing the materials for a complete inveſtigation of this curious and intereſting branch of analyſis.

We ſhall only farther add, that beſides the ſimple factors into which any equation may be decompoſed, it may likewiſe be produced by multiplying together factors of any degree, provided the ſum of their dimenſions be equal to that of the propoſed equation.

For the application of the principles and rules, illuſtrated in the preceding article, to the ſolution of arithmetical, geometrical, and other queſtions and problems, we refer to Reduction of *Equations*, Application of *Algebra*, &c.

Equation, in *Aſtronomy*, is a term uſed to expreſs the correction, or quantity, to be added to or ſubtracted from the mean poſition of a heavenly body, to obtain the true; it alſo, in a more general ſenſe, implies the correction ariſing from any erroneous ſuppoſition whatever. *E. g.* The time of noon, determined by taking equal altitudes of the ſun, is firſt obtained by ſuppoſing the ſun's declination conſtant during the whole interval, which falſe ſuppoſition is corrected by an appropriate equation. Moſt of the principal equations will be found under their different articles, in the various tables to which they belong.

Equations, *Conſtruction of.* See Construction *of Equations*.

Equations, *Converſion of.* See Conversion *of Equations*.

Equations, *Abſolute, adfected* or *affected, differential, eminential, exponential, fluential, fluxional, literal, numeral*, and *tranſcendental*. See the adjectives.

Equation *of a Curve*, is an equation ſhewing the nature of a curve, by expreſſing the relation between any abſciſs and its correſponding ordinate, or elſe the relation of their fluxions, &c. Thus, the equation for the circle is $ax - x^2 = y^2$, where a is its diameter, x any abſciſs or part of that diameter, and y the ordinate at that part of the diameter; and the equation denotes, that whatever be the abſciſs expreſſed by x, the ſquare of its correſponding ordinate will be $ax - x^2$. Thus alſo the equation for the ellipſe is $\frac{p}{a} \times \overline{ax - x^2} = y^2$; for the hyperbola $\frac{p}{a} \times \overline{ax + x^2} = y^2$; and for the parabola $px = y^2$; in all which a is an axis, and p the parameter. This method of expreſſing the nature of curves by algebraical equations was firſt introduced by Des Cartes, who, by thus connecting together the two ſciences of algebra and geometry, made them naturally ſubſervient and auxiliary to each other, and thus laid the foundation of the moſt conſiderable improvements that have been made in every branch of them ſince that time. See Application of *Algebra*, &c. See alſo Curve.

Equation *of Payments*, in *Arithmetic*, is the method of reducing ſeveral debts payable at different times, and bearing no intereſt till after the term of payment of a ſingle debt or payment, to be diſcharged at once, without loſs either to debtor or creditor, allowing ſimple intereſt; or, it is the method of finding the equated term at which theſe ſeveral debts ſhould be paid in one ſum. Cocker, Hatton, Kerſey, ſir Samuel Moreland, and Ward, have given rules for this purpoſe, which Mr. Malcolm has examined and found to be erroneous; and though the error reſulting from any of the rules which they have propoſed is not very conſiderable, the following proceſs furniſhes one more accurate.

Let the debt firſt payable be called	d	The laſt payable debt	D
The diſtance of the term of payment	t	The diſtance of the term	T

The diſtance of the equated time x
The rate of intereſt, or 1 year's intereſt of 1*l.* r
The diſtance of the time t and x is $x - t$
The diſtance of the time T and x is $T - x$ } for x lies between them.

Then the intereſt of d for the time $x - t$ is $dr \times \overline{x - t}$, or $drx - drt$, dr being one year's intereſt of d; and $\frac{DTr - Drx}{1 + \overline{Tr - rx}}$ is the diſcount of D for the time $T - x$, becauſe $Tr - rx$ is the intereſt of 1*l.* for that time, which is conſequently the diſcount of $1 + Tr - rx$ for the ſame time; conſequently, from the nature of the queſtion, we ſhall have $drx - drt = \frac{DTr - Drx}{1 + Tr - rx}$; which being reduced, gives $\overline{T + t + \frac{D + d}{dr}} \times x - x^2 = \frac{DT + dt}{dr} + Tt$. Then make $T + t + \frac{D + d}{dr} = a$, and $\frac{DT + dt}{dr} + Tt = s$, and $ax - x^2 = s$; and reſolving this quadratic equation, $x = \frac{a}{2} \pm \sqrt{\frac{a}{4} - s}$.

E. gr. Suppoſe 100*l.* payable one year hence, and 105*l.* payable three years hence; what is the equated time, allowing ſimple intereſt at 5 *per cent. per annum?*

Here $\begin{matrix} d = 100 \\ t = 1 \end{matrix} \left\{ \begin{matrix} D = 105 \\ T = 3 \end{matrix} \right\}$ $r = .05$.

Then $D + d = 205$, $dr = 5$, and $\frac{D + d}{dr} = \frac{205}{5} = 41$.

And $T + t + \frac{D + d}{dr}$, or $a = 4 + 41 = 45$.

And s or $\frac{DT + dt}{dr} + Tt = \frac{315 + 100}{5} + 3 = 83 + 3 = 86$. Conſequently,

$x = \frac{45}{2} \pm \sqrt{\frac{2025}{4} - 86} = \frac{45}{2} \pm \sqrt{506.25 - 86} = 22.5 \pm \sqrt{420.25} = 22.5 \pm 20.5 = 43$ or 2: but 43 cannot be the true anſwer by the conditions of the queſtion, ſince it is greater than the diſtance of the laſt term in the queſtion; and therefore 2 is the anſwer required.

If there are more debts than two you muſt firſt find an equated time for the two that are firſt payable; then conſider their ſum as a debt payable at that equated time, and find another equated time for that debt and the next of the given debts, &c. See Malcolm's Arithm. book vi. § 5, or p. 616—621.

Equation *of the Centre.* This is the firſt and moſt conſiderable of all the equations that are applied to the mean motion of a planet. It ariſes immediately from the nature of the ellipſe. If the orbit of a planet was perfectly circular

circular it would have no equation of the centre; and a ſpherical body, revolving round a centre of force in an elliptic orbit, undiſturbed by the motion of other bodies, would require no other equation to correct its mean motion than the equation of the centre.

The neceſſity of applying this equation to the motion of the ſun, in its apparent orbit, was known to the early aſtronomers; for, in fact, no very accurate obſervations were neceſſary to ſhew that the ſun did not perform equal parts of its annual motion in equal portions of time. When, by means of gnomons, the length of the year and the obliquity of the ecliptic were pretty well eſtabliſhed, it muſt have been eaſy, with the ſame inſtrument, to have obſerved the declination of the ſun every day, and from thence to have computed its longitude. The firſt aſtronomers who undertook this examination muſt naturally have expected to find a regular increaſe in the ſun's longitude for every day in the year; but when they found that in the courſe of three months the obſerved longitude differed near two degrees from that which they had computed, it became then evident, that if the ſun's orbit was circular, and its motion uniform, at leaſt the earth was not placed in the centre of it.

This difference, which we now call the equation of the centre, was named by the ancient aſtronomers προσθαφαιρεσις, from προσθεσις, *addition*, and αφαιρεσις, *ſubtraction*, becauſe this equation is ſometimes additive and ſometimes ſubtractive, a name almoſt applicable to all equations, but applied to the equation of the orbit as the moſt conſiderable of all. Hipparchus was acquainted with this unequality in the motion of the ſun, which had not long been diſcovered before his time. He obſerved, that from the equinox of ſpring to the ſummer ſolſtice, there was an interval of $94\frac{1}{2}$ days, and from the ſolſtice to the next equinox $92\frac{1}{2}$ days; that is, two days leſs, notwithſtanding theſe points were equally 90° from each other. The motion of the ſun in two days is 1° 58′, which is nearly the quantity of the greateſt equation. To explain this difference, and to aſſign the exact proportion to every day in the year, the ancient aſtronomers either placed the earth out of the centre, at a ſufficient diſtance to produce the greateſt equation, or imagined an epicycle to revolve upon the circular orbit, on whoſe circumference the ſun was ſuppoſed to move. Theſe ſuppoſitions would give the ſun's longitude near enough the truth to ſatiſfy the imperfect obſervations of thoſe days, and when ſimilar unequalities were obſerved in the moon and planets, new cycles and epicyles were invented to explain them. But theſe contrivances, however ingenious, had very little pretenſion to be claſſed as theories or hypotheſes, capable of giving a ſatiſfactory explanation of the cauſes of theſe phenomena. An ingenious mechanic may make a clock, that ſhall repreſent all the inequalities of ſolar time, and by a proper application of ſome very ſimple principles in practical mechanics, we may repreſent the moſt complicated ſyſtem of motions; yet theſe machines would give us no inſtructions as to the original motions which they imitated; and in proportion as they became complicated, ſhould we be the leſs inclined to ſuppoſe any reſemblance between their mechaniſm, and that of the motions they repreſented.

Nevertheleſs, in the ſimple caſe that we are now conſidering, had obſervation accurately agreed with the ſuppoſition, there would have been no reaſon for not admitting it; it would have reſted on the ſame ground as Kepler's elliptic hypotheſis, before Newton had demonſtrated how obviouſly it is derived from one general law of nature.

For the method of calculating the greateſt equation of excentric orbits, we refer the reader to De la Lande's Aſtronomy, vol. ii.

We ſhall here only explain the nature of this equation in an orbit perfectly elliptical. The equation of the orbit of a planet is evidently nothing at the apſides; beginning to reckon from the aphelion it augments rapidly; as the true or real motion being there the ſloweſt, differs moſt from the mean motion, it continues to increaſe, but leſs and leſs rapidly, till the planet has arrived at ſome point about three ſigns, and ſomething more from the aphelion, at which point the true and mean motions are equal. At this time the equation is the greateſt, it begins then ſlowly to diminiſh, and the diminution becomes more and more rapid, as it approaches the perihelion, at which time the real motion exceeds the mean motion by the greateſt quantity. When it arrives at the aphelion the equation is again nothing. In the ſame manner it increaſes again to a maximum, and then diminiſhes till its return to the aphelion, where it is again nothing. The equation is ſubtractive in the firſt ſix ſigns from the mean motion, and additive in the others.

The greateſt equation may be derived directly from obſervation; or if the excentricity be known it may be computed, and at the ſame time the degree of anomaly in which it happens. For this purpoſe it is ſufficient to find the point M (*Plate* XII. *Aſtronomy*, *fig.* 107.) where the planet is at its mean diſtance. For it is evident, that the moment the planet arrives at the point where its angular velocity D F M is equal to its mean velocity, the mean longitude will ceaſe to gain upon the true longitude, but their difference will be a maximum; becauſe till that moment the real velocity, which was leaſt, had continually cauſed the mean velocity to accelerate upon the true, but from the moment they are equal, the real velocity begins to accelerate upon the mean, and to regain the quantity which it had before loſt: from this time the true and mean place approach each other, and the equation begins to diminiſh. Thus the problem conſiſts in finding the point M, and the true anomaly A F M of the planet, at the moment that its true velocity is equal to the mean angular velocity.

Take F M a mean proportional between the two ſemi-axes of the orbit. With the focus F as a centre, and diſtance F M, deſcribe a circle M N, which circle will have a ſurface equal to the ellipſe. Suppoſe a body to deſcribe uniformly this circle in the ſame time in which the planet deſcribes its ellipſe, its angular velocity will always be equal to the mean angular velocity of the planet in the ellipſe; and the area deſcribed in the circle will be always equal to the area deſcribed in the ellipſe, becauſe the planet always deſcribes equal areas in equal times. For example, if the planet deſcribes in one day an area D F R $=\frac{1}{365}$ th part of the elliptic ſurface, the area E F O, deſcribed in the circle, will likewiſe be the $\frac{1}{365}$th part of the area of the circle; and the real velocity of the planet, or the angle D F R, will be equal to the mean velocity in M, that is, to the angle E F O; for there are two equal ſectors having the ſame length E M, the ſame ſurface, and conſequently the ſame angle. Beſides the equal triangles M E D, M R O, which are the one without, and the other within the circle, ſhew that the elliptic ſector is preciſely equal to the circular ſector, that has the ſame angle in F. Therefore to find the point of the mean velocity, we muſt find at what degree the interſection of the ellipſe correſponds with the circle equal to it in ſurface. From the point M let the ſtraight line M B be drawn to the other focus of the ellipſe, then in the triangle B E M three ſides will be known; namely, B F, which is the double of the excentricity, F M, which is the mean proportional between the two ſemi-axes, and B M, which is the difference between

4 FM,

F M, and the greater axis, becauſe the two lines E M and M B are together equal to the greater axis. By reſolving this triangle the angle F may be found, which will be the true anomaly of the planet, at the time of its greateſt equation.

In the caſe of the greateſt equation, the reſolution of the above triangle gives the following rule. From the aphelion diſtance take ſeparately the mean proportional of the two ſemi-axes, and the third ſide B M (difference between the greater axis and the mean). Take the logarithms of theſe differences, and ſubtract the leaſt from the greateſt; from this difference take the difference of the logarithms of the aphelion and perihelion diſtances; the half of the remainder is the logarithmic tangent of half the true anomaly. By the method of coſines take the logarithms of the aphelion diſtance, and of the difference of the ſide B M; add the complements of the logarithms of B E and F M, the half of the ſum is the logarithmic coſine of half the true anomaly. If the angle is ſmall, this method of the coſines is leſs exact; but when the angle is large, it is preferable to the other, being ſomewhat ſhorter.

Having thus deſcribed the method of calculating the greateſt equation, we have now to conſider the manner of obſerving it.

From the inſtant a planet departs from its aphelion A, to the time it arrives at the point M of its greateſt equation, its real velocity is leſs than its mean velocity; therefore, the true anomaly is leſs than the mean anomaly, and differs from it more and more. When the planet has paſſed the point P, or its perihelion, and arrives at the point G, having about nine ſigns of anomaly, its true diſtance A F G from the aphelion is in the ſame manner leſs than its mean diſtance, by a quantity equal to the greateſt equation. If we obſerve two true longitudes of the planet in G and M, they will differ from each other by the angle G F M, which is the ſum of two true anomalies: but the ſum of two mean anomalies will be greater by the double of the equation, ſince each true diſtance is leſs than the mean diſtance by the whole of the equation. It is eaſy to calculate the ſum of two mean anomalies without knowing the place of the aphelion A, becauſe the ſum of two mean anomalies is equal to the mean motion of the planet for this interval of time, which is found by taking its proportion of the whole revolution: thus, the exceſs of the mean motion, calculated over the true diſtance obſerved, will be double the greateſt equation, provided the two obſervations are made in M and G, the times that the mean velocities equal the true. It will, on the contrary, be the true or obſerved motion that will exceed the mean, if the obſervations are taken on each ſide the perihelion. To determine the time and the obſervations moſt ſuitable to this inveſtigation, an obſerver, who ſhould be ſuppoſed to have no previous knowledge of the ſituation of the orbit, muſt begin by collecting a great number of obſerved poſitions, and compare them two and two together, and obſerve how much the obſerved motion differs from the mean for each interval: in this manner the greateſt of the obſerved diſtances will be found double the greateſt equation; but if this compariſon is made with a ſingle obſervation, then the greateſt difference additive and the greateſt ſubtractive, added together, will give double the equation. But ſince at preſent we know very nearly the place of the apſides, and of the mean diſtances of all the planets, we can immediately ſelect the obſervations that are made about the time of the greateſt equation.

Example.—The 7th October, 1751, the place of the ſun obſerved by La Caille, was, after three ſucceſſive obſervations - - - - and the 28th March, 1752:

vations - - - -	6	13	47′	13″.7
And the 28th March, 1752 - -	0	8	9	25.5
The difference is - - -	5	24	22	11.8
The mean motion calculated for this interval is - - - - -	5	20	31	43.2
Difference, or double the equation -	0	3	50	28.6
The half is the equation required -	0	1	55	14.3

This would be exactly the greateſt equation, if the obſervations had been made exactly at the moment of the greateſt equation; but having calculated by the tables theſe equations, it was found that 18″.6 muſt be added to have the greateſt equation, which will make the above quantity $1^\circ\ 55'\ 33''$.

With reſpect to this 18″.6 it may be remarked, that an error of ſeveral minutes in the equation of the tables would have produced no ſenſible alteration in this correction, as the error would be the ſame for the given day as for the greateſt of all which happened extremely near it.

As it is extremely rare to meet with two obſervations which are preciſely ſituated in the two points M and G of the mean time, ſo it is not eaſy to find by the firſt calculation the exact value of the equation; but after having found it very nearly, and likewiſe the place of the apſide, the equation may be calculated for the times of obſervation, and likewiſe the greateſt equation; by the method explained above, it may be then ſeen how much the equation derived from the obſervations ſhould differ from the greateſt. It was by this means that La Caille, in the preceding example, found the above correction 18″.6. The greateſt equation of the ſun is that which may be obſerved the moſt frequently, and with the greateſt eaſe. A perſon ſtudying aſtronomy, and deſirous of making himſelf converſant with the methods by which all theſe elements of the planetary motions have been obtained, may deduce them himſelf from the Nautical Almanac, or other ſimilar publications; he may regard the longitudes and latitudes of the planets there found as ſo many obſervations, and by computing from them, the original elements ſhould be found, from which the tables themſelves were calculated. If the minutes and ſeconds be omitted, or the neareſt half or quarter of a degree only taken, they will repreſent the obſervations of the early aſtronomers, and it will then be ſeen what very imperfect theories were ſufficient to explain ſuch inaccurate obſervations.

Theſe methods of finding the greateſt equation cannot be applied to Mercury, as we never can obſerve its heliocentric longitude but when on the ſun's diſc. Its elongation, and that of Venus, is found by obſerving the greateſt digreſſion when the planet is in the apſides. For a farther account of this method conſult De la Lande's Aſtronomy.

Caſſini employed the tranſits of Mercury obſerved in 1661, 1690, and 1697, and found the greateſt equation $24^\circ\ 3'$. De la Lande, from the tranſits of 1740, 1743, and 1753, found $23^\circ\ 27'\ 51'$. But theſe obſervations are not well ſuited, as the three points of the orbit are not diſpoſed at diſtances ſufficiently great. The equation of the centre does not remain for ever the ſame; by compariſon with ancient obſervations the equation of the earth's orbit appears to have undergone a diminution, and the theory of attraction explains the cauſe, and aſſigned the quantity more correctly than can be obtained by obſervation. La Place makes the diminution for the earth's orbit $0^\circ.0058$ decimals in a century;

tury; this phenomenon fuppofes a correfponding diminution in the excentricity, for if the excentricity was nothing, the equation would be nothing. The correfponding diminution of the excentricity is 0.000045553, the femi-axis major being taken as unity.

This is nearly equal to 1548 French leagues in a century, or 40 Englifh miles in a year. Thus, fractions which appear infenfible in the heavens, become confiderable when compared with our known meafures. If this diminution was always progreffive, the folar ellipfe would in time be changed into the circumference of a circle, and in the end, the excentricity decreafing always, the earth, after a great number of ages, would fall into the fun; but the theory of attraction indicates that the variation in the equation of the orbit and excentricity are periodic, and that after having diminifhed for a certain period, they will again increafe and take the fame values they had before, and will thus ofcillate within narrow limits; but the periods of thefe ofcillations are ftill unknown, and thus the fyftem might be eternally maintained, except fome exterior and unknown caufe fhall come to change the fyftem of the world, and new-modify its laws.

EQUATION, *Secular, of the Mean Motion of the Moon.* The motion of the moon, and its elements, do not remain conftant, but undergo progreffive alterations, which would foon render the tables inaccurate, if we were obliged to improve merely by comparifon with recent obfervations. The only method of avoiding this inconvenience is to calculate the elements of the lunar motion for different periods very remote from each other, to deduce the variations they have undergone, and then to inveftigate the laws proper to reprefent them.

We may apply thefe confiderations to the mean and fecular motion of the moon, which has been determined with great exactnefs by modern obfervations, and which ferves as a bafis for all the other refults, and compare it with ancient obfervations, to fee if it is the fame, or if it has materially changed. The method of making this comparifon confifts in confidering the ancient obfervations of the moon as fo many obferved longitudes; the place of the moon is then calculated by the tables for this diftant epoch, and the refult compared with the obfervation.

The moft ancient eclipfe upon record may be taken as an example. It was obferved by the Chaldeans 721 years before the Chriftian era, and recorded by Ptolemy. The obfervation was made at Babylon the 19th March: the moon began to be eclipfed about an hour after its rifing. At the middle of the eclipfe the longitude of the moon was equal to that of the fun; this latter is eafy to calculate by the folar tables; thus the longitude of the moon is given at the period of the eclipfe. Now, if the place of the moon be calculated by the tables for this epoch, it will be found lefs advanced in its orbit, than it muft have been by the obfervation: the difference is about one degree and a half; and as this is too great an error to be attributed to the inaccuracy of the tables, we muft conclude that the motion of the moon is now accelerated: fo that in referring it to a diftant period, we throw it too far back in its orbit, which diminifhes its longitude.

And this refult acquires additional confirmation, by making fimilar comparifons with obfervations made at intermediate periods; for if the motion of the moon is really accelerated, we fhould ftill find the longitude calculated by the tables too fmall, though the error fhould be lefs as the interval is fmaller; and this appears to be the cafe by a fimilar comparifon with an eclipfe obferved at Cairo by Ibn-junis, an Arabian aftronomer of the 10th century.

This coincidence leaves no doubt as to the reality of the phenomenon; and it appears certain, that the motion of the moon has accelerated from the time of the Chaldeans to the Arabians, and from that time to the prefent. To reprefent this acceleration, a third term, proportional to the time, muft be added to the fecular motion of the moon, and another leffer term proportional to the cube; this, together, is what is called the fecular equation of the moon. According to La Place, (Mecanique celefte, vol. iii. p. 273.) if n be the number of centuries elapfed fince 1750, the formula for the correction will be $31''.424757\, n^2 + 0''.05721742\, n^3$. Thefe feconds are according to the decimal divifion.

But we are not to infer that this acceleration will always be increafing, or that the preceding formula will always reprefent it; the theory of attraction, in making known the caufe, has fhewn that it is periodic, and connected with the variations of the excentricity of the terreftrial orbit. See EXCENTRICITY, and EQUATION *of the Centre.*

This acceleration, after increafing to a certain limit, will be changed into a retardation, but the extent of this period is very confiderable; and the interval, which feparates us from the moft ancient obfervations, has yet only developed an extremely fmall part of this revolution. The inequalities which will refult in the motion of the moon will amount at leaft to a 40th part of the circumference of her orbit. Pofterity, who will obferve thefe great phenomena, may remark, and not without gratitude, that the geometricians of the prefent age have forefeen, calculated, and prepared for their fucceffors the means of judging of the paft and future ftate of the fyftem of the world, with the fame certainty as in the age in which they lived.

It was the celebrated Dr. Halley who firft difcovered the effects of this acceleration; and La Place, by a moft profound

found analyſis, has explained both the cauſe and the law. The obſerver and the geometrician are each entitled to admiration. If the reſult of the latter is more ſatisfactory and uſeful to ſcience, it muſt be confeſſed, that it was a proof of no ſmall ſagacity in the former to be the firſt to doubt of the uniformity of the mean motions which had been admitted as an eſtabliſhed principle for above two thouſand years.

Equations, *Secular, which affect the Elements of the Orbit of the Moon.* The motion of the lunar perigee is not uniform, but ſubject to a ſecular equation analogous to that of the mean motion, and depending on the ſame cauſe. The compariſon of ancient obſervations with the modern leaves no doubt of this fact; but it is to the theory of attraction that we are indebted for the diſcovery. This equation is equal to that of the mean motion, multiplied by the coefficient — 3.00052, that is to ſay, that if k repreſent the ſecular equation of the mean motion, the term — 3.00052 k muſt be added to the mean longitude of the perigee, calculated from the duration of a tropical revolution. Mec. celeſte, vol. iii. p. 247.

The motion of the nodes is likewiſe ſubject to a ſimilar inequality, and the equation has the ſame ſign as that of the perigee, it is equal to the equation of the mean motion multiplied by — 0.735452, that is, to the mean longitude of the node add — 0.735452 k. Theſe reſults are confirmed by obſervation.

It appears from this, that the ſecular equation diminiſhes the longitude of the perigee and of the nodes when it augments the mean motion of the node, and reciprocally; hence the motion of the perigee and of the nodes becomes ſlower, when that of the moon is accelerated, and on the contrary is accelerated when that of the moon is retarded. Moreover, theſe inequalities are connected together by very ſimple analogies, ſince they are repreſented by the numbers 1; 3.00052; — 0.735452.

The anomaliſtic revolution, depending at the ſame time on the motion of the moon and of the perigee, is likewiſe modified by the ſecular variation. It is the ſame with all the quantities which depend on the apogee, and on the nodes.

The theory of attraction indicates, that the diſtance of the moon from the earth, the excentricity, and the inclination to the orbit, are equally ſubject to ſecular equations, which are connected with that of the mean motion. But hitherto their effect is ſcarcely perceptible; nevertheleſs, in the courſe of ages, it will become neceſſary to attend to them, and they have been calculated in advance. The expreſſion for the greater axis of the orbit contains no inequality of this kind. This likewiſe is the reſult of theory. The cauſe of all theſe extremely curious facts has been explained by La Place, who was led to them by the diſcovery of the original cauſe which produced the ſecular equation of the moon. For the ſecular equations of the other celeſtial bodies, ſee their reſpective names, and Secular.

Equation-*Clock*, in *Horology*, is a clock contrived ſo as to indicate both *mean* and *equated* ſolar time, and conſequently their difference, which at any inſtant is the *equation of time.* Various contrivances have been invented to anſwer this purpoſe by ingenious men, who at one time were ſeized with a rage for inventing ſuch uſeleſs appendages of the clock, but the dictatorial power of faſhion has nearly baniſhed ſuch ſuperfluities, that are now conſidered as mere matters of curioſity. For a deſcription of a clock of this ſort by Enderlin, ſee our article Clock, and *Plate* XXIV. of *Horology.*

Equation-*Mechaniſm*, in a planetarium or orrery, is a mechanical contrivance for repreſenting the alternate accelerations and retardations of motion in the requiſite parts of the reſpective orbits of the different planets, which contrivance has been variouſly effected by different ingenious men. If the motions of the heavenly bodies had been in concentric circles, and perfectly equable in every point of their orbits, the conſtruction of a common planetarium would have been well calculated to exhibit all the phenomena in a natural and exact manner, provided the trains of wheelwork were accurately calculated for the reſpective periods, and the length of the arms proportional to the reſpective diſtances; but as all the planets that have conſiderable excentricity, and conſequently conſiderable equations of the centre alternately *plus* and *minus*, have their motions conſtantly varying in angular velocity, a common planetarium, without equation-mechaniſm, is a very imperfect machine, and by no means competent to ſolve any of the phenomena, in a particular way, that depend on the relative velocities; for when the heliocentric motions are improperly repreſented, the geocentric appearances depending on them are deranged, and no dependance can be placed in the *times* pointed out of the apparent conjunctions, oppoſitions, ſtations, retrogradations, longitude, or latitude of any of the heavenly bodies. For inſtance Mercury, which planet performs its period through the ecliptic in ſomewhat leſs than 88 days, inſtead of continuing 44 days in each half of its orbit, at oppoſite ſides of the conjugate axis, as it does reſpectively in thoſe at each ſide of the tranſverſe axis, continues about $55\frac{1}{2}$ days in the aphelion portion, and only $32\frac{1}{2}$ in the perihelion portion, ſo that the times of conjunction with the earth or other planet, even allowing the motion of that planet to be equable, would from this cauſe alone become very irregular, exceeding or falling ſhort of the mean ſynodic period by many days, according to circumſtances. It is evident, therefore, that the variations of velocity depending on the equation of the centre of both orbits of two planets, one received from the other, require to be taken into conſideration, and allowed for in the conſtruction of any mechaniſm that profeſſes to be accurate in the repreſentation of planetary motion.

Contrivances by Mr. Huygens.—The earlieſt attempt that we have met with, to produce the requiſite inequalities of planetary motion by mechaniſm, is that of Mr. Huygens, the Dutch mathematician and philoſopher, which he has deſcribed in his Latin treatiſe on the conſtruction of his *Automaton*, or ſelf-moving planetarium; he has availed himſelf of two different applications of the ſame principle, that are reſpectively applicable to different degrees of inequality of motion, that the excentricity of an orbit may require; his account and demonſtration of both which methods we ſhall give in a free tranſlation from his own words, which will probably be intereſting to thoſe who cannot read the original, particularly as there has been no notice taken of them by any writer, or inſtrument-maker, except perhaps Rowley, during the laſt century.

"It remains now," ſays our very ingenious author, "that we explain how the true anomalies may be repreſented by wheelwork; for this purpoſe let A N P, *fig.* 1. of *Plate* III. of *Planetary Machines*, be the orbit of a planet, the centre of which is C with the ſun at S, and let the point E be taken any where in the line S C, ſo that the excentricity S C may be to the radius C A, as C E is to E D; with which radius and centre E let the circle D M be deſcribed. Now let it be underſtood, that upon the centre of the circle A L there be fixed immoveably the contrate wheel D M with equal teeth, which therefore will neceſſarily revolve round the point C as a centre; let it be alſo ſuppoſed that the arbor of the long pinion K H be directed to C, and turned equally with its teeth adapted to thoſe of the wheel D M, which will agree ſufficiently, although on account of the excentricity of this wheel it will not always have the pinion at right angles; by this motion, I ſay, a planet will be be carried unequably in its orbit, and in ſuch a manner that its motion will very nearly correſpond to Kepler's hypotheſis, For having taken in the circle D M, deſcribed from the point E, any arc D O, let the teeth of that arc paſs over to the line C D by turning the pinion K H, and the line C O will coincide with the line C A D, but not ſo that the point O may fall on the point D, but within at R, becauſe C D, which is equal to both C E and E O, is greater than C O : now whatever may be the angle O C D, ſuch will be that over which the line C A D has moved round the centre C; therefore if we make the angle D C T equal to the angle D C O, C T will be the right line into which C A D will have advanced, ſo that the planet will have proceeded from A to the point N, where the right line C T cuts the circumference of the circle A N deſcribed from the centre C. But the circle D M, having its centre E advanced to F by making F T equal to E D, will have the ſame ſituation as the circle T R : and it appears that on account of the equality of the angles O C D and D C T, the arc D M, which the right line C T cuts in the circumference of O D M, is equal to the arc D O; ſo that M and E being joined, the angle M E D will be equal to D E O. If, therefore, the arc A L be made to contain as many degrees as the arc D M, and C F be joined, this line will be parallel to E M.

"In the triangles C E M and S E L, therefore, the angles L C S and M E C will be equal, and the ſubtending ſides proportional; for by conſtruction S C is to C L, as C E is to E M, C L being equal to C A, and E M to E D. Alſo the angles M C E and L S C are equal, and conſequently the lines C M and S L are parallel.

"Now by this rotation of the circles D M and A L, the planet placed in A will be moved through the circle A L, very nearly according to Kepler's hypotheſis, as may be thus ſhewn. Let the planet be ſuppoſed to have moved from A to N, the ſpace or area N S A will be equal to its mean anomaly; but ſeeing the lines S L and C N are parallel, the triangles N S C and C L N will be equal, at leaſt their difference will be inſenſible; the ſpace or area, therefore, C L A, and conſequently the arc A L, will anſwer to the mean anomaly when the planet has advanced from A to N. If, however, we make A Q P the elliptic orbit of Kepler, the planet will be in Q, where the perpendicular N Q falling on A P cuts the ellipſe A Q P, and not in N; but the ellipſes are ſo like circles, that the variation in a machine is imperceptible, N will, therefore, be the true place of the planet correſponding to the mean motion A L, which arc is equal to D O or D M.

"Again, if the pinion be placed in any other point, as at G, equally diſtant from the centre C, to which the arbor is directed, and the point D, which is the moſt diſtant from the centre C, in the wheel O D M, be placed under the pinion, the planet being again at its aphelion A, it appears that the ſame angles are formed round the centre C by an equable motion of the pinion placed in G as in D. Wherefore in whatever ſituation the pinion be placed, the motion of the planet will be unequable, notwithſtanding the teeth of the wheel D M are made equal among themſelves, provided the pinion that points to the centre C have its teeth made long enough to act with all the teeth of the wheel which come ſucceſſively to it at different diſtances from the centre C, and provided that the planet be put to its aphelion point of its orbit, when the longeſt line, or radius, drawn from C to D M, is in contact with the pinion.

"But ſince in our machine (automaton) all the pinions are placed on one common arbor, it cannot be placed properly towards the centres of more than two planets; we muſt, therefore, conſider how the ſame effect can be produced by *unequal teeth:* for this end let us ſuppoſe the circle D M divided into the equal parts D *a*, *a b*, *b* M, and M *g*, and right lines be drawn to them from the point C, theſe lines C *a*, C *b*, C M, C *g*, will divide A N L, the orbit of the planet, into the unequal parts A *d*, *de*, *e* N, N *f*. By this method as many unequal teeth may be determined in the circle A N L, as there are equal ones in the circle D M. If now the pinion be applied to theſe teeth, cut into the ſame number as in the former caſe, they will work together pretty well, though ſome are too large and others too ſmall for the pinion, and the wheel A N will move unequably as the wheel D M did before, which has been proved to be according to the hypotheſis of Kepler."

This is a faithful tranſlation of Mr. Huygens' account and demonſtration of his two methods of repreſenting the irregularities of a planet's motion in its orbit, concerning which we have to obſerve, that, though both of them manifeſt great ingenuity as to the originality of the projects, yet they fall ſhort of producing ſeparately that full effect which he attributes to them, and which he ſeems to have credited; whereas the truth is, that inſtead of effecting the *whole* equation of the centre, the methods juſt deſcribed effect each only *one half* thereof; for agreeably to Kepler's theory, which ſuppoſes equal areas in equal times, biſhop Ward has proved that *double the excentricity* of a planet's orbit ſubtends very nearly its greateſt equation, and that, according to his elliptic hypotheſis, which is an excellent approximation to the truth, if the angular velocity of a planet round one focus of the ellipſe be uniformly equable, its angular velocity, as ſeen from the other focus, will be ſo unequable, that one will repreſent the mean and the other the true or equated anomaly very nearly; but the diſtance between the two foci of any ellipſe is its excentricity laid off both ways from the centre, or *doubled;* whereas the method of Mr. Huygens' propoſes the excentricity to be taken only *once*, ſo that he has demonſtrated rightly enough, but from wrong data; for if he had made the diſtance C E equal to double the excentricity, then the whole of the equation would have been very nearly repreſented. The demonſtration which Mr. Olinthus Gregory of Woolwich, then of Cambridge, has given in the 2d vol. of Mr. Nicholſon's Philoſophical Journal of the 8vo. ſeries, to which we beg leave to refer, has proved with great perſpicuity what the Rev. W. Pearſon of Parſon's Green had before aſſerted, that "the excentricity of any planet's orbit is very nearly equal to the ſine of one half only of its greateſt equation." It may be conſidered as a ſingular circumſtance that a man of Mr. Huygens' genius and mathematical ſkill, whoſe whole life was devoted to the ſciences, ſhould not diſcover that the methods which he ſo ingeniouſly deviſed to exhibit a planet's equated motion, produced but one half of the grand equation; and equally ſingular, perhaps, may it be conſidered, that no one before the writer of this article has detected the deficiency. When both theſe methods of conſtructing a planetary wheel are *united*, the full effect will be produced; or either of them may be united with any other contrivance that produces only one half the equation.

Mr. Roemer's Contrivance.—The next contrivance that we have met with, for repreſenting planetary motion, is that of Roemer, who was mathematician to the king of France in the time of Mr. Huygens; this contrivance is detailed in Mr. Nicholſon's Journal, vol. 4. of the 4to. ſeries, by a correſpondent, who tranſlated his account from the French of "Machines and Inventions approved by the Royal Academy of Sciences for 1699," and who, in our opinion, ſpeaks better of it than it deſerves. The plan propoſed might anſwer for one planet only, but is not applicable to a number of planets at the ſame time, for the planetary wheel propoſed is is intended to be fo thick as to conftitute the fruftum of a cone, on the furface of which a diagonal elliptical line is to be drawn round it, from the fmaller to the larger diameter and back again, in which line the teeth are to be formed, after they have been laid down by a pair of dividers from a diagram previoufly made ; fo that, fetting afide the tedioufnefs of making fuch a wheel by the mechanical manipulation defcribed ; there could not be a number of thefe wheels brought into action by any of the ufual arrangements of wheelwork, feeing the pinions that are to act with them muft neceffarily be conical alfo, and be the drivers in every cafe, which the requifite calculations of the trains in planetary machines will not always admit, where the extreme ratios of relative velocity are fo widely different from each other. This plan, therefore, of exhibiting unequable motion in a planetarium, or orrery, muft be confidered among thofe projects of ingenuity which are more plaufible in theory than ferviceable in practice, and no doubt was abandoned for the reafons that have been here ftated ; which are our reafons for paffing over it without further notice.

Dr. Defaguliers' Contrivance.—The next mechanifm in the order of time, as far as we know, was Dr. Defaguliers' elliptic pulleys, or oval wheels with grooves at the circumference, and an endlefs cat-gut furrounding them, as defcribed under our article COMETARIUM. This was certainly a fcientific contrivance, and admits of application where the excentricity of the orbit is great ; for the excentricity and fhape of the pulleys may be made exactly fimilar to the excentricity and fhape of the orbit to be reprefented. The principal objection to the adoption of this invention in a planetarium, is the liability of the catgut to contract and elongate with the variations of moifture in a room, and confequently to be fometimes too tight for the pulleys, and fometimes too loofe, fo as not to perform their office of giving motion to the elliptic plates. We have feen the elliptic plates with their edges cut into teeth, which is a great improvement in the contrivance ; and where the excentricity is not very great, a pair of excentric circular wheels will act together very well, to anfwer the fame purpofe, as we fhall have occafion to fhew prefently.

Mr. Adam Walker's Contrivance.—Another method of exhibiting planetary motion we have witneffed in the philofophical lectures of Mr. Walker, fenior, which, if we recollect perfectly, was effected thus : A wooden board was fhapen nearly into the form of an epicycloid, and had equal teeth cut on its circumference by hand, with an arm fixed faft to one of its extremities, that carried the ftem of a planet, or of a ball to reprefent a planet ; then a pinion was fixed on the furface of an inclined plane, down which the epicycloidal wheel was fuffered to flide by its own weight, in a detached ftate, till its teeth came in action with the teeth of the pinion ; and a motion given to the pinion by a handle, made the wheel, thus circumftanced, to revolve with unequal velocities, accordingly as its central point was near to, or removed from, the pinion, during its revolution in this fliding ftate ; thus were not only the accelerations and retardations of motion alternately exhibited, but alfo the variations of diftance, as they regarded the fun's ball fixed in the focus of an elliptical board, placed over this mechanifm, and divided into twelve triangular areas, fo that the planetary body was feen to move through the twelve fectors, coloured alternately white and black, in a manner correfponding to the fame number of revolutions of the pinion ; and to perform apparently equal areas in equal times. It is hardly neceffary to obferve on this contrivance, that, however convenient it might be to illuftrate in a general way the nature of planetary motion to an audience, it is obvious that detached wheels acting thus at liberty cannot be introduced into any machine that gives motion to a fyftem of bodies, where their apfides crofs one another in various directions, and would require as many inclined planes as there are planets to be reprefented ; likewife the planetary arms would require to be attached to *wheels* in every inftance, though the calculations of the ratios of velocity might, and, according to the general conftructions, would require in fome inftances *pinions* to be the laft movers ; all which difficulties in practice are infurmountable. The *fhape* of the planetary wheel, we have underftood, was not determined geometrically, nor yet by calculation, but by a repetition of manual rectifications of the figure till it was found to correfpond with the areas previoufly delineated.

Mr. Jofeph Prieftley's Contrivance.—When Dr. Birbeck was appointed profeffor to fucceed the late Dr. Garnet, at Anderfon's Univerfity in Glafgow, his friend, Mr. Jofeph Prieftley of Bradford, contrived an orrery, which was made for him by a watch-maker at Halifax, of the name of Thomas Lifter, which orrery the doctor has lately brought with him to London, on quitting the faid profefforfhip. It was finifhed in the year 1801, and will be defcribed in its proper place with the other planetary machines. The inequalities of motion in this machine are produced by two feparate methods ; the two fuperior planets Saturn and Jupiter have their equations effected by inequalities made in the teeth of the laft moving wheels ; but the others have their equations, with the exception of the earth, produced by a contrivance which is at the fame time novel, fimple, and accurate enough for mechanical reprefentation. The inventor has been kind enough to comply with our requeft of his giving us an account of his mode of producing unequable motion by mechanifm, which account we fhall prefent to our readers in his own words. The figure to which he refers, is *fig.* 2. of *Plate* III. of *Planetary Machines*.

Let A P B, fays Mr. Prieftley, be the orbit of the planet, O its centre, and S and F the two foci ; in the former of which the fun is fuppofed to be placed. On the other focus F, as a centre, defcribe a circle D E p.

Let P be any given place of the planet in its orbit ; draw Fp, cutting the circle D Ep in p. Now, agreeably to the hypothefis of Ward, it will be,

As the periodical time of the planet,
Is to the time of its paffing from A to P ;
So is 360 degrees,
To the angle E Fp.

Hence, if a point p be made to revolve equably in the circle D E p, defcribed on the lower focus F of the orbit, performing one revolution in the periodical time of the planet ; and if, at any given time, the point be found at p, then a line drawn from the focus F through p, will cut the orbit of the planet in P, its place at the fame time.

There are different ways of adopting this hypothefis in machinery. The firft I fhall mention, will immediately occur to any one viewing the figure. Let a wire, fomething longer than F B, be made to revolve equably round F, in the time reprefenting one revolution of the planet. On this wire let a ftud P be made to flide freely, and confined to move in the orbit A P B ; then the motion of the ftud will, very nearly, reprefent that of the planet.

In the conftruction of an orrery, where each planet will require a feparate arm Fp, moveable on its peculiar centre, with the flider P confined to its own orbit, it may not be eafy to contrive the whole fo as to prevent one part of the machinery from interfering with another ; nor can this method be conveniently ufed, where the wheels carrying the arms

arms are rims. The following construction has been found to answer the intention, and the motion to be very free and regular.

Let E p D be the toothed rim moving equably, the time of a revolution representing that of the planet. This rim may have any convenient diameter, not differing greatly from the orbit. Upon this rim, or on any projection attached to it, is fixed a pin C, round which one end of a bar C P moves; on the other end of the bar is fixed a perpendicular wire, or stem P, which carries the planet. This stem is confined to move in the orbit A P B; and, during its revolution, is made to rise and fall, so as to shew the inclination of the orbit to the ecliptic. The bar C P may be made of any convenient length; and the pin C should be so situated, that when P is at p, the bar becomes a tangent to the circle E p B. This is necessary, that the end P, in its vibrations on C, may be always found, as nearly as possible, in the line F p; and on this account, the length of the bar should be as great as circumstances will conveniently admit.

Contrivances by the Rev. William Pearson.—Some time previously to the year 1796, the Rev. William Pearson, who lived at that time in the city of Lincoln, had read the accounts of Mr. Benjamin Martin's and Mr. James Ferguson's planetary mechanism with such attention, as enabled him to discover many imperfections in them, which it appeared to him might be avoided, and among the rest that defect which arises from equable motion and unvarying distance. On entering into a correspondence with one of the instrument-makers in London, he found that the modern machines owed their origin chiefly to one or the other of the above-named authors, and that little or no improvement had been made in the accuracy of their representations since their time. In consequence of this information, and unacquainted with the contrivances we have just described, except that of Dr. Desaguliers, described by Mr. Ferguson, he turned his mind towards the subject with a view of devising some improvements in this kind of machinery, which required an union of mechanical skill, with a knowledge of the science of astronomy, to enable him to strike out original plans for the accomplishment of his purpose. His first object was to render the trains of wheel-work as nearly as possible such as would produce the true periods of the different planets in their orbits, in doing which he found no difficulty after he had adopted a direct and unerring system of calculation, which became easy and familiar by practice; but this part of his pursuit is not the object of our present article: the next object of his attention was to devise the mechanical means of exhibiting planetary motion, both with regard to variable velocity and variable distance; different methods presented themselves in succession at different times, some of which he afterwards found had been tried before by others, but the first project that promised to be really subservient to his purpose was that which was represented in *fig.* 3. of *Plate* III. of *Planetary Machines*, and which was made for the arm of Mercury, in an orrery constructed under his direction, by a clock-maker at Lincoln. The contrivance had three objects in view, the variable distances, the variable velocities, and the latitudes of the planets, or deviation from the ecliptic, two of which purposes it answered most completely, and the third in a certain degree, besides preserving, fourthly, the parallelism of the planet's axis in every part of its orbit. It occurred to the contriver of the mechanism in question, before he had ever seen Mr. Adams's "Geometrical and Graphical Essays," and before he had heard of "Suardi's Geometric Pen," that if a small arm were by any means made to revolve in a retrograde direction, when placed at the distant end of the long arm, or radius vector of any planet, during the time that the radius vector itself revolved just once by a direct motion round the sun in the centre, the curve traced by a pencil placed at the remote end of the small arm would be *an excentric circle;* and also that there would be an alternate acceleration and retardation of angular velocity in the pencil with respect to the sun, or central point round which the radius vector might be carried; which velocity would be the quickest when the pencil was in its nearest situation, and slowest when most remote; because in the former case, the compound motion would be the sum of two motions, both in the same direction, and in the latter the difference of two motions in contrary directions. This idea, having at the moment of its occurrence made a strong impression on the mind of the inventor, excited in him much impatience to have it brought to the practical test of an experiment; the small frame, shewn in *fig.* 3, was roughly put together, and the equal wheels A, B, and C, were included, so that A was fast to the arbor S, but B and C revolved on their arbors in the frame; the arbor of the latter, however, was left long enough for its pivot to protrude downwards, and to receive a crank-piece P, bearing a short pencil: the stem or arbor S, having its conical point at S fixed on a sheet of paper, was then held fast by a milled nut above it, to prevent its revolving, and the frame was carried round while the three small wheels, with equal numbers of teeth, were connected together; the consequence was, as had been expected, that the pencil traced a circle of a diameter equal to twice the distance of the arbors A and C from each other, but the centre of the circle was found to be at G instead of S, just the length of the short arm or crank-piece P, from the point S, from which the excentric circle was described. This fact determined at once that the frame and short arm ought to be to each other in length as the mean distance is to the excentricity of the orbit of any planet thus to be described, and, as orbits with but little excentricity are very nearly *excentric circles*, a circle thus described cannot be discriminated in a machine from an ellipse of the same excentricity.

Before we proceed to describe the mechanism resulting from the principle of a little arm revolving backwards on the end of the radius vector of any planet just once in each revolution of the planet, let us illustrate the principle itself more clearly. Suppose the line A C, in *fig.* 4. of *Plate* III. to represent the length of the frame or radius vector S C, and also the short arm C A, representing the excentricity or distance from the centre to the focus of the orbit, to be both directed into one right line S A, before any motion be communicated to the frame; then as the teeth of the three wheels A, B, and C, of equal numbers of teeth, are connected together, and the wheel A is at rest, the wheel B will have a motion in the same direction as the frame, and the wheel C will have its motion in a contrary direction, but of the same velocity; conceive the centre of the wheel C to be carried along the circumference of the concentric circle C O I E, the space of the quadrant C O, this wheel C by means of its connection with the wheel A, through the medium of wheel B, will in the same time have made a quarter of a revolution, and the remote end of the small arm attached to this wheel will be at N, at right angles to the radius vector, after having passed along the quadrant A N, of the excentric circle A N P E, of which the point G is the invisible centre, and during the whole continuance of these two equal but contrary motions of the radius vector and short arm, through these quadrants respectively, the latter will have preserved itself parallel to its original situation A C; again, while the radius vector is moving through the three remaining quadrants of the concentric circle

circle from O to I E and C, successively, the remote end of the small arm will describe the three corresponding quadrants of the excentric circle from N to P, M, and A, in equal portions of time, and its parallelism will still be preserved throughout the whole circle, as seen in the figure. Thus, while the centre of the wheel C describes the concentric circle C O I E round the point S with an equable motion, the remote end of the small arm, supposed to carry a planetary body, will describe the excentric circle A N P M, during the whole of which time the motion of the planet will be equable as it respects the point G or centre, but unequable as it respects the point S out of the centre, where the sun is supposed to be placed: for conceive lines like S N to be drawn from S to the planet in different parts of the circle A N P M, or orbit, and they will intersect the circle C O I E *behind* the remote end of the radius vector in one half of a revolution, and *before* it in the other, and the angle at S, subtended by the short arm in any situation, will express the *equation of the centre* in that point of the orbit, which equation, therefore, is *additive* to the mean motion of the radius vector in one six signs of anomaly, and *subtractive* from it in the other six. The nature of the alternate retardation and acceleration of motion produced by this mechanism round the point S, and also the variation of distance, may be easily apprehended by attending to the successive retrograde and direct motions of the arm in each revolution of the radius vector; from A to N these move in opposite directions, and the difference of their velocities, as viewed from S, is equal to the quantity of retardation in any particular point of this quadrant; at N the difference is nothing, in which situation of the arm the equations would be a *maximum* if the arm were perpendicular to the line S N, *i. e.* if S N were a tangent, to the circle of which the arm O N is radius; but this will not happen till the radius vector has advanced beyond the space of an exact quadrant, and the arm has come to *n*, where the angle subtended at S by the arm will be the greatest possible.

The distance of this point, where the equation is a maximum from 90° of mean anomaly, will evidently depend on the relative proportions in length of the radius vector and short arm, or which is the same thing, of the mean distance and excentricity of the planet to be represented. From *n* to P, through the remainder of the first semi-circle, the radius vector and arm will both move in the same direction, and will cause an acceleration which will be greatest at P, the perihelion point, where they will both be again in a right line, shortened by double the whole length of the short arm, as compared with the original situation at the aphelion point. From the perihelion to the point of greatest equation at the opposite side of the orbit, the motions of the radius vector and arm continue to be in the same direction, but through the last quadrant and a small portion of the third, the directions are again opposite till the planet arrives at the aphelion point A, where it has undergone all its changes of velocity and distance, and where it commences the same alternation of slow and quick motions that were before exhibited.

Thus, if S be considered as the sun, A the place of the aphelion of any planet, P its perihelion, *m* and *n*, in the small circle of the arm, the places of mean motion, the concentric circle C O I E the ecliptic, and the excentric one A N P M the planet's orbit, it is evident that both the excentricity, and also a *certain equation* of the centre of a planet's orbit, may be very conveniently represented by the same apparatus that has long been used for no other purpose but that of preserving the parallelism of its axis.

But still the main question is not disposed of; *viz.* what portion of the equation, considered as an arc of the orbit, will a line equal to the excentricity subtend? The analogy for resolving this query is as follows:

As the mean distance, or radius vector, of the planet,
Is to radius,
So is the excentricity, or short arm,
To the sine of the greatest angle at S subtended by the short arm.

This angle, taken in degrees and minutes, we find is invariably, as nearly as may be, *one-half of the greatest equation*, as has been already mentioned.

It will now have occurred to the reader, probably, that, if a line equal to the excentricity subtends one-half the equation of the centre of a planet, *double* the excentricity will be the measure of a short arm that will subtend the *whole* equation; this is nearly true as to the question of the equation alone, but then the distances and excentricity of the orbit, on which the geocentric appearances depend, would be greatly out of proportion; and what is gained in the heliocentric apparent places would be lost in the geocentric appearance in the system. To keep all the desiderata within their due bounds, and to make the elements of the orbit accord with both heliocentric and geocentric appearances in the mechanical representation, an additional contrivance was superadded, which supplied the defect of the revolving short arm without deranging materially the effect of its operation; the last wheel of the train, which carries the radius vector round in the due period, had its teeth so unequally cut as to represent the second half of the equation, by causing an alternate acceleration and retardation in the revolution of the radius vector itself, so that the total effect produced by these two contrivances acting together was very nearly agreeable to the real motion of the planet itself in its own orbit. But we have said, that the latitude of the planet was represented by the same contrivance that shews the distances and one-half of the equation. This was done by placing the stem of the planet in a square socket, at the remote end of the small arm, in so detached a way, that it was at liberty to rest on the plane of an inclined plate, carried by the radius vector, to represent the inclination of the orbit, and to receive the circular scale of latitudes pointed to by the end of the stem as it travelled up and down the said plane in its retrograde revolution.

The little frame we have had occasion to mention might do very well as a piece of mechanism for a radius vector, where the length is small, but where the planet is represented as moving at a considerable distance from the sun, the mechanism contained in *fig.* 3. of *Plate* IV. is better adapted, where A B is the radius vector proportional to the mean distance, and embracing fast the upper extremity of the tube of the wheel with unequal teeth; C is a contrate wheel of any number of teeth made fast to a surrounding tube that has no motion; the horizontal arbor D has two pinions of equal numbers, no matter what, one of which, E, is connected with the fixed wheel C, and the other, F, is connected with a second contrate wheel G, which is every way like the wheel C, except that its position is inverted for the sake of making its direction of motion retrograde; the lower pivot of wheel G rests in a cock H, attached to the end of the radius vector, and its upper pivot ascending above the same carries the short arm that supports the stem of the planet; lastly, I is the inclined plate with a scale of latitudes, on which the end of the stem rests, and by which it is made to ascend through one portion of its orbit, after which its own weight brings it gradually down again. The inclined plate is so placed that the nodes may fall at their

 respective

refpective diftances from the aphelion point; and all the changes of place arifing from the combined caufes of varying diftance, varying velocity, and inclination of the orbit, are duly reprefented.

A fimilar combination of mechanical contrivances was afterwards, in the year 1802, adopted by Mr. Pearfon, when he contrived and fuperintended the conftruction of the large planetarium at the houfe of the Royal Inftitution in Albemarle ftreet, London; though the means are fomewhat different. The plane of the inftrument was defired by Dr. Thomas Young, at that time the lecturer, to be vertical inftead of horizontal, which afforded the means of making the fhort arms, reprefenting the refpective excentricities revolve backwards by a weight fufpended to each, inftead of the wheel-work which we have defcribed: the inequalities among the teeth of the tubed wheels in this inftrument effect one half of the equation, and the retrograde revolutions of the little arms produce the other, and make all the planets revolve according to equated motion, while the ftems round which the faid fhort arms revolve are, agreeably to Dr. Young's fuggeftion, fo bent, as to reprefent alfo the inclination of the orbits, and confequent heliocentric latitudes, for eftimating which the ecliptic plate is put exactly in the plane paffing through the centre of the fun, or coincident with the plane of the earth's orbit, The fmall divided plates carried by the ends of the radii vectores indicate both the equations and heliocentric latitudes; which obfervations we make here, becaufe the conftruction of the inftrument has never yet been publicly explained, except perhaps partially in the lectures, and becaufe the ufes of the different parts, not being obvious by mere infpection, are as yet but little underftood. For a more particular defcription of this inftrument, fee our article PLANETARIUM.

But we are not to take for granted, becaufe one half of the greateft equation will be thus reprefented at the point of mean diftance by a radius vector and fhort arm, that are to each other as the mean diftance to the excentricity, that therefore half the equation will be equally well reprefented in every other part of the orbit of a planet. Let us examine this matter more particularly, and bring it to the teft of actual calculation. Let the line S H, *fig.* 5. of *Plate* III. be the radius vector of Mercury, and H A the fhort arm reprefenting the excentricity, which are to each other very nearly as 5 to 1; then when the planet is at A, its greateft diftance from S, the fun, it is obvious from what has been faid, that its angular velocity, as it refpects S, muft be flower than if it were at P, or any other part of the line S A; conceive now the point H, round which the little arm revolves, to move forwards fo far that the planet may fall back by means of the arm to the point a; then if a line were drawn from S to a, the equation or angle at S would be fubtended by $a\ b$, the fine of the angle A H a to radius A H, which line confequently is perpendicular to the radius vector at the point b; the diftance b H is the cofine of the fame angle, and we have S H + H b for the bafe of a right-angled triangle, and $b\ a$ for the perpendicular of the fame, to determine the angle at S or femi-equation, which is one of the fimple cafes in plane trigonometry, where the bafe is ufed as radius, and the perpendicular as tangent of the required angle. For example, the mean diftance of Mercury, as given by La Lande, is 38710, and its excentricity 7955.4, the mean diftance of the earth being 100000; then if, agreeably to this ratio, we take the fmall arm reprefenting the excentricity at unity, the radius vector muft be 4.86587; for as 7955.4 : 38710 :: 1 : 4.86587; let the point a now be taken equal to 30° from A, and from the tables of natural fines we have $a\ b = .5000000$ and S H + H b = 4.86587 + .8660254 = 5.7318954, hence

As log. 57319	Ar. co.	.2417014
Log. 5000		.6989700
Tang. of ½ equation 4° 59′ 7″		.9406714

In the fame manner one half of the equation, correfponding to any other point c in the quadrant A Q, may be found where H d is the cofine to be added to the radius vector, and $c\ d$ the fine which conftitutes the fubtenfe of the required angle at S. In the fecond quadrant from Q to P the radius vector minus the cofine becomes the bafe of the triangle at any point e or g, but the fines at thofe points are the perpendiculars $e\ f$ and $g\ h$, as in the laft quadrant, fo that the bafe of the triangles fucceffively taken is conftantly fhortening from the aphelion to the perihelion points of the orbit, whilft the perpendiculars are increafing in the firft quadrant, and then decreafing in an inverted order in the fecond, which circumftance makes the equation greater in a given quantity of mean motion near the perihelion than near the aphelion, as the Newtonian theory requires. That a due eftimate may be had of the effect produced by this mechanifm in every part of Mercury's orbit, we fhall fubjoin a fmall table containing the data and refult of correfponding calculations for every ten degrees of mean motion; and parallel to the femi-equations fo obtained, we fhall put a parallel column of half the equations taken from the beft tables as publifhed by La Lande, from which it will be feen that the errors, which at moft are a fmall portion of the whole equation, are in excefs from the aphelion or 0° to 102° of mean anomaly, and in defect from 102° to about 258°, then from 258° to 360° or 0° again in excefs, which deviations from the truth are agreeable to the deviations arifing from the approximation called the "elliptic hypothefis," which Buliald proved from four obferved places of the planet Mars, as obferved by Tycho Brahe, makes the computed places more *backward* than the true ones in the firft and third quadrants of mean motion, and more *forward* in the fecond and fourth.

TABLE.

Dift. from the A-phelion	Bafe Line.	Perpendicular.	Dift. from the A-phelion	Correfponding Semi-Equations by Mechanifm.	Semi-Equations by La Lande.
°			°	° ′ ″	° ′ ″

150	399984	50000	210	7 8 30	7 27 35
160	392618	34202	200	4 58 2	5 15 24
170	38816	17365	190	2 23 42	2 43 13
180	386587	00000	180	0 0 0	0 0 0

In examining the preceding table it may be feen that the place of mean motion, or point where the equation is a maximum, falls, according to the mechanifm, fomewhere between 100° and 110°, which, in La Lande's tables, is at 105°; let us try where it will fall exactly by the mechanical reprefentation.

The point B, where the line S B is a tangent to the fmall circle, is the place of the planet's greateft equation, and this point will be found beyond the firft quadrant, a quantity equal to the angle Q H B, or, which is the fame thing, H S B, or greateft femi-equation; for as S H Q and S B H are both right-angled, and have the angle at S common to both, the third angle, H Q S, is equal to the third angle B H S, and, confequently, the fupplemental angle Q H B is equal to the fupplemental angle H S Q, or greateft femi-equation. *Q. E. D.*

But the greateft femi-equation by the mechanifm when computed is $11° 51' 34''$, therefore the place of mean motion falls at $90° + 11° 51' 34''$, or at $101° 51' 34''$, which point is fhort of 105° by a quantity upwards of 3°. This want of exact coincidence is, however, of little or no moment in the mechanical reprefentation of the orbit, becaufe the quantity of the greateft equation is nearly ftationary for many degrees both before and after the exact point of mean motion. The reprefentation will be ftill more accurate where the orbits have lefs excentricity, than that of Mercury, which is the cafe with all the other planets, except two out of the four newly difcovered ones, *viz.* Pallas and Juno.

As we have had frequent occafion in this article to fpeak of a wheel with unequal teeth, made for the purpofe of effecting alternate accelerations and retardations of angular motion, and have alfo feen the theory explained by Mr. Huygens, it may be proper to fay a few words here about the practical method of cutting fuch a wheel. This operation may be done by three different methods; firft, the divided circle of the plate, to be ufed with the engine, may have the divifions laid down unequally by Huygens' mode of transferring equal divifions from an excentric circle to a concentric one, as already explained; and then the teeth may be cut in the ordinary way from thefe unequal fpaces, when punched or drilled into dividing holes; or, fecondly, an equally divided circle of the engine plate may be ufed, and the increments and decrements, previoufly calculated, may be given at each tooth by the micrometer fcrew of fuch an engine as either Hindley's or Rehé's; or, thirdly, which is the readieft method, the wheel to be cut may have a hole drilled in the excentric point, and be placed thereby on the arbor of the engine, till all the teeth are marked with flight notches by the cutter, adjufted for diftance at each cutting, and then the hole in the centre muft be ufed for completing the teeth in their proper direction; for when the cutter is put into the notches fucceffively, it will cut the teeth towards the centre without any guidance of the index or alidade; and this method is practicable with any common engine without a micrometer fcrew for taking and giving fmall portions, as deductions from or additions to a mean tooth. For the wheels with unequal teeth in the large planetarium of the Royal Inftitution, in Albemarle ftreet, London, the firft method was ufed by the maker, M'Culloch, under the direction of the contriver both of the machine itfelf, and of the method ufed of rendering the teeth of certain wheels gradually unequal round each feparate femicircle, agreeably to the planetary motions to be produced thereby in the planets themfelves; but in an accurate and elegant machine fince made (by Fidler) for himfelf, the laft method was ufed with fuccefs for the large wheel that produces the fun's, or rather earth's annual equation.

Another, and that a very recently contrived method of exhibiting the equations of all the planetary orbits at the fame time, together with their variable diftances, by very fimple mechanifm, has been adopted by Mr. Pearfon in the machine we have juft mentioned, as made by Fidler, under his own direction; this method has the advantage of fhewing alfo the mean motions, and is well calculated for illuftrating the irregularities of motion on which the various phenomena of the heavenly bodies depend, as well as for fhewing the exact times at which they occur, and the countries to which they will be vifible. For a defcription of the machine itfelf we refer the reader to the articles Planetarium and Orrery, and fatisfy ourfelves in this place with an account of the principle by means of which the equations of the centre are effected. *Fig.* 1. of *Plate* IV. of *Planetary Machines*, which is illuftrative of the principle in queftion, is derived from *fig.* 4. of *Plate* III. which has been explained, but has the addition of a third diminutive arm at the end of the longer arm placed at the extremity of the radius vector; we have feen that one arm, equal in length to the excentricity of the orbit to be reprefented, will, by its retrograde revolution, give the diftances and one half of the equation, very nearly, in every part of the orbit, and we have feen that if the faid arm were made equal to twice the excentricity it would give the whole equation near enough, but would not give the diftances truly; now the introduction of the additional arm is to make the apparent place of the planet fulfil both thefe conditions, which it does in a furprizing manner. Let S J, in *fig.* 2, be a radius vector, revolving equably round the point S, in *fig.* 1, in which cafe the extreme end J will defcribe the concentric circle J K O L Q R T V; let J *a* be a fhort arm equal in length to the excentricity once and a half taken, which arm is made to revolve in a backward direction by means of the faft grooved circle *d*, of the catgut *e f*, and of the pulley *g* of the fame diameter as *d*, which mechanifm anfwers as well as that in *fig.* 3, before defcribed, and is fimpler: over the pulley *g* is fixed faft to a ftem, borne by the radius vector, round which the pulley turns, another grooved circular piece J, round which the gut *h i* goes, and embraces alfo a diminutive pulley *a* of half the fize of J, fo that whilft the radius vector and arm J *a* go each once round in contrary directions, the third or little arm *a* A, which is equal in length to only one half the excentricity, goes twice round in the fame direction, in which the radius vector moves, and thus carries a planet at its extremity round the point S, in which the fun is placed, very nearly agreeably to the laws of planetary motion, with regard both to angular velocity and diftance in every part of the orbit. To render the effect thus produced more intelligible, conceive two pins made faft in the line J A, *fig.* 1, confidered as one line equal to twice the excentricity of the orbit to the radius S J, and let one of them be at C, the middle of the line, and the other at A, the extremity; then if this line preferves its parallelifm all round the orbit, by a retrograde motion given to it by the catgut *e f* and pulley *g*, *fig.* 2, the pin C being at the diftance of the excentricity S G from the end J of the radius vector, will defcribe the excentric orbit 1, 2, 3, I, 4, 5, 6, of the planet, while the pin at A will have the proper velocity as feen from S, but will move in the circle A B D E P F M H, which is too excentric to become the true orbit; but if the point A of the additional fmall arm be put to C when the motion begins, and has the planetary body placed on its extremity, then it will move in the fame excentric

2 circle

circle as the firft pin C, but with the apparent angular veloci ty of the fecond pin A as feen from the other focus W, and very nearly fo as feen from the fun at S: for conceive the radius S J to have moved to K, the pin A will be found at B, on account of the angle B K *b* being equal to the angle J S K, which is here 45°, but the planet has moved a quadrant to 1, and is found in the circle defcribed by the pin C, or middle circle; but, viewed from W, according to the elliptic hypothefis, is feen in the line W B, as though it had been actually at B in the outermoft circle; again, when the radius vector has completed a quadrant and is in the fituation S O, the firft pin is at N, the fecond at D, and the planet at 2, in the line W D as before, and the additional arm has now defcribed a femicircle: here the equation D S O is fubtended by double the excentricity very nearly: when J is advanced 135° to L, the additional arm has moved $\frac{3}{4}$ of a circle, and is found at 3, ftill in the middle circle, and alfo in the line W E, extended: and when S Q is the fituation of the radius vector the planet is at I, the perihelion point of the middle circle, and alfo in the line W P, extended as before. In like manner in the other femicircle of mean anomaly, when the extreme end of the radius vector is fucceffively at the points R, T, and V, the planet will be found at the points 4, 5, and 6, and alfo in the lines W F, W M, and W H, refpectively, ftill moving in the middle circle, till it arrives at the aphelion point C, from which it originally fet out. When the pulleys are made to produce this effect very nicely, the band or gut, that embraces two pulleys of different diameters, will affect the ratio of 1 : 2 in practice, and will require the fmaller pulley to be fomewhat lefs in diameter than what the exact proportion requires in theory. The radius vector has a flit in its remote end, with a thumb-fcrew under it, to fix the pulley at a greater or lefs diftance, as the tenfion of the gut may require, and the whole contrivance being fimple, fteady in its motion, and light in its conftruction, as well as having a tendency to prevent the radius vector from bending downwards, is far preferable, in every point of view, to any contrivance we have before feen for anfwering the fame purpofe. The mechanical reprefentation of the orbit bears the fame analogy to the elliptic hypothefis, that an excentric circle does to an ellipfe of the fame excentricity, and in the orbits of the planets thefe figures are fo nearly alike, that they may be fubftituted for each other, without fenfible error; and we may add, that the equation produced by only one arm, equal to twice the excentricity, is by no means fo accurate as the *equation doubled*, that is, produced from an arm equal to the exact excentricity, becaufe the tangents of different angles do not increafe by equal quantities.

Befides the preceding methods of producing the equation of a planet's orbit, our author has contrived to indicate the quantity thereof in any point of the orbit, as well as the latitude alfo, as feen from the fun; this is done by means of a hand fixed under the revolving pulley J, travelling over a divided and filvered plate, fixed faft in the fituation of the dotted circle, on the end of the radius vector, concentric with the pulley, which plate not only fhews the equation and latitude at any time, but is of ufe in placing the arms in their proper fituations by the latitudes taken from the Ephemeris or Nautical Almanac.

Thefe are all the methods that have fallen within our notice, of effecting the grand equation of a planet's orbit, as applied to an orrery, or planetarium; but there remain yet two pieces of mechanifm, contrived by our prefent inventor, that are well calculated to explain in a lecture-room the equation of an individual planet, as detached from the fyftem, which we fhall briefly defcribe, as being contrivances equally novel and competent to their purpofe. The firft is reprefented by *figs*. 4 and 5 of our laft plate, the former being a fection of the wheel-work, and the latter a fketch of a part of the vifible part of the inftrument. AB is a little frame, containing four wheels, *a*, *b*, *c*, and *d*; *a* and *b* are equal in diameter, and of fimilar numbers of teeth, *a* fixed on the arbor of the handle *e*, and *b* on a tubed arbor *f*, that carries the index *g*, feen in *fig*. 5 of the fhape of a T, with a point touching the circle *k*, which is an ecliptic circle; fo that whatever velocity is given by the handle to the wheel *a* in an equable manner, the fame is communicated, by the medium of the wheel *b*, to the index *g*, which therefore moves according to mean motion in the ecliptic circle K. The wheels *c* and *d* are excentric, and have alfo fimilar diameters and numbers of teeth, but are placed to act fo, that the longeft radius of one always acts with the fhorteft of the other, and thus produce the fame effect as Dr. Defaguliers' elliptic grooved plates with the endlefs catgut. The excentricity of the wheels bears the fame proportion to their common radius, that the excentricity of the planet's orbit does to its mean diftance: wheel *c* is fixed faft to the fame arbor of the handle as wheel *a* is, but wheel *d* has a feparate arbor, which goes with the tube of wheel *b*, and carries the hand *i*, and on its upper end a ball to reprefent the fun. The fectoral arc of the index *g* is graduated, for Mercury for inftance, into 24° each way from the middle, to which the hand *i* muft be put when the index points to that part of the ecliptic circle in which the aphelion point of the planet is; then as the handle is turned the index fhews the mean motion in the ecliptic, which may have a fecond circle divided into figns of mean anomaly, beginning at the aphelion point, and as the motion proceeds the hand *i* falls back, till at the end of three figns and a half of mean anomaly it is found near the extremity of the fectoral arc, at *g*; at the perihelion point the hand is again in the middle; and at eight and a half figns of mean anomaly it will be in its prefent fituation again, at its greateft equation, at the oppofite end of the fectoral piece; and laftly, at the aphelion point the hand will be again found in the middle, which is the zero of both the pofitive and negative equations, which are refpectively marked + and − on the oppofite ends of the graduated fectoral arc. Thus, the index *g* fhews the mean motion, the hand *i* the equated motion, and the graduated portion of the index has the quantity of the equation plus or minus, fhewn by the hand *i* in every part of the orbit, while a line drawn from S, the fun, over the point of the hand *i* to the ecliptic K, fhews the equated or true heliocentric place of the planet. The other inftrument for explaining the nature of the mean and equated anomaly of a detached planet, and of its equation, which is their difference, is fimply a mechanical conftruction of the elliptic hypothefis of bifhop Ward, and is reprefented by *fig*. 6. of the fame plate. S G W is an elliptic plate of wood or metal, defcribed from the foci S and W, the fmall circle at S is divided into an ecliptic circle with a flender ftem in the centre bearing a ball to reprefent the fun, and the other fimilar circle at W is divided into as many fpaces as there are days or weeks in the period of the planet; of which 88^d are proper for Mercury; the bar *a* G is concealed under the dotted line, and turns on the vertical ftem of the ftand that fupports the elliptical plate at G, by means of a piece of brafs tube fixed at its end; on the bar *a* a fliding piece *b* is inferted, that bears a fmall pulley *c*, and a planet in the angular point behind it, on a ftem as high as that of the fun; this fliding piece has two rollers, bearing againft the edge of the elliptical plate, to facilitate the motion of the bar round the plate, which is produced by

 hand;

hand; an endlefs gut or filk cord S W c draws the fliding piece clofe to the faid plate, and caufes the pulley and planet to defcribe the proper ellipfe for the orbit. According to the elliptic hypothefis, if the angle c W A be the meafure of the mean anomaly, the angle at the fun in the other focus, *viz.* c S A, will always be the equated anomaly, and the fmall angle S c W will, in every fituation, be the equation of the centre, as being the fupplement of the fum of the other two angles, that is, the external angle c W A, that reprefents the mean anomaly, is equal to the fum of both the internal angles of the triangle at S and c, as being refpectively the fupplement of the other internal angle at W; but the internal angle at S is the equated anomaly; therefore the angle c W A $- \angle c$ S W is the angle c, or equation during the firft fix figns of mean anomaly; in the other fix figns the angle reprefenting the mean anomaly at W will be fmaller than the angle at S, reprefenting equated anomaly, therefore the equation, or difference between them, which has been fubtractive, becomes now additive; and the hypothefis, thus mechanically conftructed, affords the ready means of explaining the particulars of planetary motion, for which purpofe equal fectoral arcs are laid down on the plate alternately black and white, which the thread S c moves over in equal arcs of the circle W, moved over by the thread W c; which are equal portions of time; and when the circle W is divided into days or weeks, and the circle S into figns of longitude, and alfo into figns of anomaly, the fame refults will follow as from the preceding mechanifm, as nearly as may be, while, at the fame time, all the variations of diftance, as well as of the equation, will be faithfully exhibited. Both thefe contrivances may be conftructed fo as to be ufed either horizontally or vertically, and on any fcale of magnitude that the audience of a lecture room may require.

Equation *of Time*. Having, under the article Day, explained the origin of the difference between folar and mean time, we have now only to explain the method by which this difference is calculated.

To effect this, it is neceffary to know precifely the motion of the fun, and the dimenfions of its orbit: we may then calculate the arc which it defcribes every day in the year parallel to the equator. If this real and variable motion be compared with its mean motion, the difference will be the equation of time.

If we imagine two meridians, drawn through the two extremities of the arc of the ecliptic, which the fun defcribes in one day, the arc of the equator, which they intercept, is the difference between the folar and a fidereal day; for when the rotation of the celeftial fphere is terminated, this fmall arc of the equator muft traverfe the meridian before the centre of the fun can arrive there. Now as this arc is not always of the fame length, the folar days are not all equal.

Nor would they be fo, even if the fun defcribed every day an equal arc of the ecliptic, for thefe arcs take fucceffively different inclinations relatively to the equator. At the moment of the equinoxes, they cut this plane at an angle equal to the obliquity of the ecliptic, and at the period of the folftices they are parallel to it. The meridians drawn through the extremities of thefe diurnal arcs are more feparated at the folftices than if they contained the fame arc at the time of the equinoxes; and, as it is this feparation of the two meridians which meafures the fucceffive retardations of the fun, thefe are unequal, and lefs at the equinoxes than at the folftices. The daily variation of the motion of the fun in its orbit is another fource of inequality, as it augments and diminifhes the diurnal arc of the ecliptic, and this produces a correfponding variation in the arcs of of the equator contained between the above-mentioned meridians.

Thus the inequality in the folar days arifes from two diftinct caufes, the obliquity of the ecliptic, and the unequal motion of the fun in its orbit. As thefe two caufes each produce their feparate effect, they muft be both deftroyed, to render the folar days equal, that is, the motion of the fun muft become uniform, and the ecliptic muft coincide with the equator.

To calculate the value of the equation of time, we muft calculate the arc which the fun defcribes each day on the ecliptic, and project it on the equator, and from this deduct the mean diurnal motion: the difference will give the equation of time for that day.

To reprefent thefe refults geometrically, we may fuppofe an artificial fun to move in the manner defcribed under the article Day, the mean day is the interval between two fucceffive returns of this fictitious fun, and the mean noon the inftant of its paffage over the meridian; and the mean equinox is the inftant of its paffage through the equinoctial point. It is obtained by a fimple proportion, when the longitude of the perigee is known, and the epoch when the true fun is in the apfides, the time which elapfes between two confecutive returns to the mean equinox, forms the mean tropical year, and which is equal to $365,^{d} 242250$.

To calculate the place of the mean fun on the equator for a given inftant, it is fufficient to calculate the mean longitude, and this, reduced to the equator, is the mean right afcenfion of the fun.

The projection of the true fun on the equator may either be determined from obfervation, or from calculating its right afcenfion. The difference between their right afcenfions, reduced into time, in the proportion of 24^{h} to 360°, indicates the interval between the paffage of the true and mean fun, and is the required equation of time: it is fometimes additive, and fometimes fubtractive, and has the remarkable property of becoming zero four times in a year.

To underftand the reafon of this phenomenon, let us imagine (*fig.* 108.) two funs, S^2 and S, to fet out at the fame time from the equinox, both moving with an uniform motion; the one, S^2, in the ecliptic, the other, S^3, in the equator, and let the motion of each be referred to the latter place. S^3 will at firft advance upon the meridian of S^2, but afterwards this latter will approach it, and they will arrive together at the folftice; after this the meridian of S^2 will advance upon that of S^3, till the fecond equinox, where they will arrive together. The fame circumftances will occur in the other half of the orbit, and thus the two funs will coincide together four times in the year, namely, at the equinoxes and folftices.

But, in reality, the mean fun does not fet out at the fame time as the true fun; they will not, therefore, meet at the fame points; the unequal motion of the fun changes this difference, but thefe two caufes united only change the epoch of the coincidences; their number remains the fame.

Let us confider the motion of the two funs, S^2, and S^3, fuppofed to fet out together from the autumnal equinox, and proceeding towards the perigee. The true fun, S^1, which defcribes the ecliptic, being referred by its meridian to the plane of the equator, will then be found behind the others, for it is preceded by S^2 till the perigee; let us now confider the motion of the other two. Till the moment of the folftice, S^3 precedes S, and S^2 precedes S^1, their order is therefore S^1, S^2, S^3. At the folftice S^2 joins S^3, and afterwards paffes it; their order is then S^2, S^3, S^1, but at the perigee S coincides with S^2, and afterwards precedes it: to do this S and S^3 muft meet in the interval. The order then becomes S^1, S^3,

S^2, S^1; thus between the winter folftice and the perigee the true fun S^1, referred to the equator, meets the mean fun S^3, and the equation becomes zero. From the perigee to the vernal equinox S^1 precedes S^2, and S^2 precedes S^3; they none of them meet therefore in this interval. At the equinox S^3 joins S^1, and their order becomes S^2, S^3, S^1; but S^3 cannot remain long between the two others, for at every quadrant the feparation of S^3 and S^2 increafes to $2^\circ\ 24'\ 24.''4$, as appears by calculation; but the diftance of S^1, S^2 never exceeds $1^\circ\ 55'\ 27''$, which is the greateft equation of the centre, and as, in the prefent fituation of the folar orbit, this takes place near the equinoxes, the arc which correfponds to it on the equator is ftill lefs than it. It is evident, therefore, after the vernal equinox, and before the fummer folftice, there muft be fome moment when the mean fun S^3 arrives upon the meridian of S^1, when the equation is again zero. From that point to the fummer folftice the order is as follows, S^2, S^1, S^3: at the folftice S^2 joins S^1, and afterwards paffes it. But S^1 precedes S^3 as far as the apogee, confequently the meridian of S^1 joins the mean fun S^3, before the folftice, and the equation becomes zero for the third time.

From the folftice to the apogee, the order of the three funs is as follows, S^3, S^2, S^1; at the apogee S^2 joins S^1, and afterwards precedes it till the perigee, the order thus becoming S^3, S^1, S^2; but at the autumnal equinox S^3 joins S^2, and confequently meets in this interval the meridian of S^1, and the equation becomes zero for the fourth time.

The order of the three funs then becomes S^1, S^2, S^3, and the fame appearances are re-produced in the fame order as before.

Hence it appears, that in confequence of the obliquity of the ecliptic, combined with the unequal motion of the fun, the equation of time becomes zero four times a year, *viz.* once between the winter folftice and the perigee, twice between the vernal equinox and the fummer folftice, and for the laft time between the apogee and the autumnal equinox. The epochs of thefe phenomena evidently vary with the pofition of the greater axis of the folar orbit; at prefent they happen about the 24th December, 15th April, 15th June, and the 31ft of Auguft. If the equator coincided with the ecliptic, that part of the equation of time depending on their inclination would difappear, and the mean motion would only differ from the true by the equation of the centre, and mean and true time would agree twice a year when the fun is in the apfides.

Dr. Mafkelyne has invented a rule for computing the equation of time, in which all the three caufes are confidered; it was inveftigated in the following manner.

Let A P L Q (*Plate* XII. *fig.* 109.) be the ecliptic, A L Q the equator, A the firft point of Aries, P the point where the fun's apparent motion is floweft, S any place of the fun; draw S v perpendicular to the equator, and take $An = AP$. When the fun begins to move from P, fuppofe a ftar to begin to move from n, with the fun's mean motion in right afcenfion or longitude, *viz.* at the rate of $59'\ 8''$ in a day; and when n paffes the meridian, let the clock be adjufted to 12; take $nm = Ps$, and when the ftar comes to m, if the fun moved uniformly with his mean motion he would be found at s, but at that time let S be the place of the fun. Let the fun S, and confequently v, be on the meridian; and then as m is the place of the imaginary ftar at that inftant, mv muft be the equation of time. The fun's mean place is at S, and as $An = AP$, and $nm = Ps$, we have $Am = APs$; confequently $mv = Av - Am = Av - APs$. Let A be the mean equinox, or the point where it would have been if it had moved with its mean velocity, and draw Az perpendicular to A Q: then $Am = Az + xm = Aa \times$ cofine $zAa + zm$: or becaufe the cofine of zAa, the obliquity of the ecliptic $23^\circ\ 28'' = \frac{11}{12}$ very nearly, $Am = \frac{11}{12}Aa + xm$: hence $mv = Av - zm - \frac{11}{12}Aa$. Here Av is the fun's true right afcenfion; zm the mean right afcenfion, or mean longitude; and $\frac{11}{12}Aa$ (*viz.* Ax) is the equation of the equinoxes in right afcenfion; therefore the equation of time is equal to "the difference of the fun's true right afcenfion, and his mean longitude corrected by the equation of the equinoxes in right afcenfion."

When Am is lefs than Av, mean or true time precedes apparent; when it is greater, apparent time precedes mean: that is, when the fun's true right afcenfion is greater than his mean longitude, corrected as above fhewn, we muft add the equation of time to the apparent to obtain the mean time; and when it is lefs we muft fubtract. To convert mean time into apparent, we muft fubtract in the former cafe, and add in the latter.

Tables of the equation of time are computed by this rule for the ufe of aftronomers; they are either calculated for the noon of each day, as given in the Nautical and fome other Almanacs, or for every degree of the fun's place in the ecliptic, as is done in the annexed tables.

Strahan and Prefton,

Equation, *lunar* and *folar*, in *Chronology*. See Metempsosis.

EQUATOR, or Æquator, in *Aftronomy* and *Geography*, a great circle of the fphere, equally diftant from the two poles of the world, or having the fame poles with thofe of the world.

Such is the circle D A (*Plate* XII. *Aftron. fig.* 109.) its poles being P and Q. It is called the equator, becaufe when the fun is in it the days and nights are equal; whence alfo it is called the *equinoctial*; and when drawn on maps and planifpheres, the *equinoctial line*, or fimply the *line*. Every point of the equator is a quadrant's diftance from the poles of the world; whence it follows, that the equator divides the fphere into two hemifpheres, in one of which is the northern, and in the other the fouthern pole.

By the paffages or tranfits of arcs of the equator over the meridian, equal or mean time is eftimated; hence we have frequent occafion for the converfion of degrees of the equator into time; and again, for the re-converfion of parts of time into degrees or parts of the equator.

For the performance whereof, we fubjoin the following table; wherein are exhibited the arcs of the equator, which pafs the meridian in the feveral hours, minutes, &c. of equated or mean time.

Converfion of the Parts of the Equator into Time, and *vice verfâ*.

Deg. of Equat.	Hours.	Min.	Hours.	Deg. of Equat.	Hour. Min.	Deg. of Equat.	′
Min.	Min.	Sec.	Min. ′	Min. ′	Sec.	Min. ′	″
Sec.	Sec.	Third	Sec. ″	Sec. ″	Third.	Sec. ″	‴
Third.	Third.	Fourth.	Th. ‴	Th. ‴	Fourth.	Th. ‴	⁗
1	0	4	1	15	1	0	15
2	0	8	2	30	2	0	30
3	0	12	3	45	3	0	45
4	0	16	4	60	4	1	0
5	0	20	5	75	5	1	15
10	0	40	6	90	6	1	30
15	1	0	9	135	10	2	30
30	2	0	12	180	20	5	0
60	4	0	15	225	30	7	30
90	6	0	18	270	40	10	0
180	12	0	21	315	50	12	30
360	24	0	24	360	60	15	0

The conftruction of this table is very eafy; for the equator being divided into 360 degrees, and revolving always in 24 hours, any point of it moves through 15° in one hour, and in one minute through the 60th part of 15°, or 15′ of a degree, and in one fecond through 15″ of a degree, &c. and therefore nothing more is neceffary befides fimple addition, in order to have the number of degrees, minutes, and feconds, which it defcribes in any given time.

The ufe of the table is obvious; fuppofe, *e.gr.* it were required to turn 19° 13′ 7″ of the equator into time: againft 15 deg. in the firft column we have 1ʰ 0′ 00″; againft 4 deg. we have 16′ 0″; againft 10 minutes, 40″; againft 3 minutes, 12″ 0‴; againft 5 feconds, we have 0′ 20‴; and againft 2 feconds, 8‴; which, added together, give 1ʰ 16′ 52″ 28‴.

Again, fuppofe it were required to find how many degrees, minutes, &c. of the equator anfwer to 23 hours 25 min. 17 fec. and 9 thirds. Againft 21ʰ in the fourth column of the table, you have 315; and againft 2 hours, 30; againft 20′, 5°; againft 5′, 1° 15′; againft 10 fec. 2′ 30″; againft 5 fec. 1′ 15″ 0‴; againft 2 fec. 30″ 0‴; againft 6 thirds, 1″ 30‴; and againft 3 thirds, 45‴; which, added together, give 351° 19′ 17″ 15‴. See Equinoctial.

Equator, *elevation* or *altitude of the*. See Elevation *of the equator*.

Equator *of the Sun*, or *Solar Equator*. The fun revolves from eaft to weft on an axis inclined to the ecliptic, and the plane, paffing through the centre of the fun perpendicular to this axis, is called the plane of the fun's equator. It cuts the plane of the ecliptic in a ftraight line, called the line of the nodes of this equator; and the nodes themfelves are the points where this line, produced each way, meets the celeftial fphere.

To determine the pofition of the axis of rotation in fpace, it is neceffary to determine the inclination of the folar equator to the ecliptic, and the angle which the line of nodes makes with fome fixed line in the plane of the ecliptic, for example, with the line of the equinoxes. This angle is called the longitude of the nodes of the folar equator, and is thus determined: when the pofition of a fpot on the difc of the fun has been obferved, and its latitude and longitude determined, the direction of the vifual rays drawn to the fpot at the moment of obfervation is known. The longitude of the fun at the fame inftant is likewife known, its diftance from the earth, and its apparent diameter.

The interfection, therefore, of its furface with this ray, is found by a fimple geometrical procefs. Three fimilar obfervations of the fame fpot determine three points upon the furface of the fun, and thefe three fpots are fituated on the fame circumference of fome circle parallel to the folar equator, and the pofition of a plane is known when it paffes through three given points. The plane of this circle defcribed by the fpot will, therefore, be known by thefe obfervations, by which the pofition of the folar equator may be determined.

To determine the fucceffive pofitions of the fpots on the furface of the fun, fuppofed fpherical, we may imagine the three rectangular co-ordinates or axes paffing through the centre of the fun, and continuing parallel to each other during the whole annual revolution. The firft of thefe axes is perpendicular to the ecliptic, the two others are fituated in this plane, one parallel to the line of the equinoxes, the other perpendicular to it. Latitudes and longitudes, reckoned relative to thefe axes from the centre of the fun, are called heliocentric, and they may evidently be found by trigonometric methods, if we can determine their analogous longitudes and latitudes meafured in the fame manner from the centre of the earth, and which are called geocentric.

By methods of this kind it has been found that the folar equator is inclined to the ecliptic about 7°. It continues conftantly parallel to itfelf, the points of this equator, as they are raifed by the rotatory motion of the fun above the plane of the ecliptic, traverfe this plane in a point which, feen from the centre of the fun, was, in 1750, 85°. This was then the heliocentric longitude of the folar equator. Since that time it has undergone no variation except what arifes from the motion of the equinoctial points.

EQUATORIAL Instrument, is an inftrument made ufe of in *Practical Aftronomy*. When a fimple telefcope, mounted on a ftand, is elevated to view any heavenly body at the moment of its meridian paffage, the obferved body appears to pafs horizontally acrofs the field of view, but in any

any other ſituation to the eaſt or weſt of the meridian, the apparent paſſage of any heavenly body through the field of view, is in an oblique direction, and the more ſo, the greater the declination towards the viſible pole, and alſo the greater the diſtance from the meridian line. Hence the motion of the ſimple teleſcope, which moves in a parallel of altitude, or circle parallel to the horizon, when turned round in a ſtate of elevation on its vertical axis, will never coincide with the motion of a heavenly body, that moves either in the equator, or in a circle parallel to it; unleſs indeed the obſerver could ſtand at one of the poles, in which caſe the equator would become the horizon, and circles of altitude would be alſo circles of declination. But no obſerver can be ſo circumſtanced. He may, however, incline the axis of motion of his teleſcope, ſo as to be placed in the meridian, and exactly parallel to the earth's axis, and then, when the field of view is directed to take in any heavenly body, the motion of ſuch inclined axis, or the motion of the teleſcope round ſuch axis, ſuppoſing the axis to be fixed, will attend the ſaid body during the remainder of its path above the horizon. Accordingly we find Chriſtopher Scheiner uſing a teleſcope mounted on a polar axis in the year 1620, which time was ſoon after Galileo had invented the ſimple dioptric teleſcope, and though John Muller, or Regiomontanus, had contrived and deſcribed his torquet, a kind of portable equatorial, in the year 1544, and alſo Tycho Brahe had given the name of *equatoriæ* to ſome of his inſtruments about thirty years afterwards, yet the idea of Scheiner's polar axis no doubt ſuggeſted to the modern inſtrument-makers the beſt principle on which an equatorial inſtrument, as well as equatorial ſector, and equatorial ſtands, ought to be conſtructed. Scheiner's contrivance was competent to the following of a ſtar or other heavenly body through its diurnal arc, but had no appendages by which to aſcertain the place of the obſerved body, as to right aſcenſion, declination, diſtance from the meridian, &c. neither would the teleſcope be directed to a body inviſible to the naked eye for want of ſuch appendages.

Mr. Henry Hindley, an eminent clock-maker at York, was probably the firſt man who contrived and attached the different adjuſtable circles as companions to the teleſcope. Mr. Smeaton, in his paper on the "Graduation of Aſtronomical Inſtruments," read before the Royal Society of London, on November 17, 1785, has informed us, that Hindley contrived an inſtrument of the equatorial kind ſo early as the year 1741, which was ſent up to London to be ſold in the year 1748. This inſtrument had the equatorial plate, quadrant of latitude, and declination ſemi-circle indented at the circumference, and moved by worm-ſcrews, containing fifteen threads each, all in action together, which ſcrews at the ſame time meaſured as micrometer ſcrews, the angular motions, and, as it ſeems, without other graduations. The teleſcope was of the refracting kind, and inverted the object viewed. "It ſtaid with me," ſays Mr. Smeaton, "two years, in which time I ſhewed it to all my mechanical and philoſophical friends, amongſt whom was Mr. Short, who afterwards publiſhed, in the Philoſophical Tranſactions, an account of a portable obſervatory, but without claiming any particular merit from the contrivance. However, the model of it differs from Hindley's equatorial only in the following articles: he added an azimuth circle and compaſs at the bottom; he omitted the endleſs ſcrews, placing verniers in their ſtead, and at the top a reflecting teleſcope inſtead of a refractor. This inſtrument of Hindley's being afterwards returned to him unſold, I pointed out the principal deficiencies that I found therein; *viz.* that in putting the inſtrument into different poſitions, the ſpringing of the materials was ſuch, as in ſome poſitions to amount to conſiderable errors. This remained with him in the ſame ſtate till the year of the firſt tranſit of Venus in 1761, when it was ſold to —— Conſtable, eſq. of Burton Conſtable in Holderneſs. Mr. Hindley, to remedy the evil above-mentioned, applied balances to the different movements. He ſoon after completed one, *de novo*, upon this improved plan, for his Grace the late duke of Norfolk." The next, in point of time, to Mr. Hindley, was Mr. Short, who placed his reflecting teleſcope over a ſyſtem of graduated circles, and who has generally been conſidered as the firſt contriver of the equatorial inſtrument, though it appears evident from Mr. Smeaton's account, that Hindley's inſtrument was prior to his. Mr. Short publiſhed his account in the Tranſactions of the Royal Society, not in the year 1789, as ſtated by a typographical error under our article CIRCLE, but in 1749, in vol. xlvi. N° 493. About the year 1770 a rage for making equatorial inſtruments generally prevailed, and numberleſs were the modifications that makers of every deſcription produced, but the chief improvers of the inſtrument at that period were Nairne, Ramſden, and Dollond, who married Ramſden's ſiſter, all of whom, ſoon after the year juſt ſpecified, improved on the original portable inſtrument, chiefly by introducing the improved dioptric in place of the heavy catoptric teleſcopes, and by uſing the beſt divided circles, together with the moſt accurate adjuſtments, balancing of the parts, and nicely divided verniers. Mr. Ramſden, to ſecure the advantages of his ſhare of the improvements, took out a patent for his inſtrument, including the refraction apparatus, and hanging level in the year 1775.

Still, however, the equatorial inſtrument had its ſcale of magnitude adapted only for portability, and its circles conſequently were not capable of meaſuring with that degree of accuracy that celeſtial obſervations demand, to be of real uſe in the preſent improved ſtate of aſtronomy; and it remained for Mr. Edward Troughton to conſtruct an equatorial inſtrument ſufficiently large to be placed in an obſervatory, for the purpoſe of making uſeful obſervations. This ingenious artiſt contrived many commodious modifications of the inſtrument under our preſent conſideration, but we mean to confine our notice to two of the principal of them, both worthy of future imitation; one as a moveable, though not very portable inſtrument, and the other as a fixed one. The firſt was made to go to Coimbra, in Portugal, where it has had the ill fate to be ſhut up in the dark, though it was finiſhed ſo long ago as the year 1788; the latter is now in uſe under the direction of Dr. Hamilton, at Armagh, in Ireland, and is that with which the Armagh obſervations were made; of theſe Mr. Pond, the lecturer on aſtronomy at the Royal Inſtitution, availed himſelf when he compoſed his famous catalogue of declinations of ſome of the principal ſtars, which we noticed under our article CIRCLE, and which is inſerted in the article DECLINATION. This inſtrument was made in the year 1796; about three years after ſir George Shuckburgh's large equatorial inſtrument was deſcribed in the Philoſophical Tranſactions of London, as an inſtrument on a large ſcale, carefully made under Mr. Ramſden's direction by Mr. Berge, who has ſince become his ſucceſſor. The principal modern authors who have deſcribed the different equatorial inſtruments, are Mr. Short, Mr. Benjamin Martin, Mr. Nairne, Mr. Dollond, the Hon. Stuart M'Kenzie, profeſſor Vince, and ſir George Shuckburgh; at one time it was our intention to deſcribe one or two only of the different conſtructions of this inſtrument, and to have noticed the differences of the others; but to do juſtice to the ſubject, and to ſhow more clearly the progreſſive progreffive improvements in the art of conftructing aftronomical inftruments of this defcription, we have determined to give drawings and correfponding defcriptions, in fucceffion, of each inftrument that appears to poffefs any claim to originality. Of courfe we muft avail ourfelves of the refpective defcriptions that have been publifhed of the various inftruments that have been before defcribed, but our detail will be a condenfed one, and interfperfed with original remarks, tending to affift the reader in forming his opinion of their refpective merits; and where no defcription has been previoufly given, as is the cafe with Mr. Troughton's inftruments, and a neat portable one by his nephew, Mr. Farer, we fhall fupply the accounts from original and authentic fources, preferving, as we proceed, that order of time in which the feveral inftruments were conftructed, except in the inftance of Mr. Farer's, which being portable, we have thought it better to place immediately after the portable ones of older date, by way of contraft, than to give it a place after the larger and more complete inftruments.

Portable Equatorial Inftrument by Mr. James Short.—We have already faid that Mr. Short's equatorial inftrument, called by him the equatorial telefcope, or portable obfervatory, was the firft inftrument probably made in England that could be confidered as a well arranged affemblage of graduated circles for afcertaining the various data of a heavenly body's place, out of the meridian, by a fingle obfervation. Mr. Ben. Martin has given a brief defcription of this inftrument, together with its ufes, in appendix II. of his Philofophia Brittannica, the fubftance of which, not being in every one's hands, we think may be acceptable to our readers, particularly as its perufal will afford the beft means of contrafting the more improved inftruments with the original model, and, confequently, of tracing the progrefs that the art of making inftruments of this kind has made within the period of our own recollection. *Fig.* 1. of *Plate* XI. of *Aftronomical Inftruments*, exhibits a perfpective view of all the effential parts of Mr. Short's inftrument, which is compofed of four graduated circles, two of them entire, and two of them about three-fourths of a circle, together with a four-footed ftand, a variety of fupporting pillars, levels, wheels, and endlefs fcrews, axes of motion, and a reflecting telefcope furmounted over the whole. A, A, are two horizontal plates one over the other, and reprefenting the horizon of the place of obfervation; thefe plates reft on four pillars of the pedeftal, that contains a magnetic box and needle, and that is fupported by the four adjuftment fcrews B, B, B, B, the lower plate being faft to the pillars, and the upper one, that carries two fpirit levels on its plane at right angles to each other, being moveable by a rod or handle C, the fcrew on which takes into the teeth cut on the edge of this upper horizontal plate. This moveable plate is divided into 360°, and a vernier borne by the under plate reads to the accuracy of every *three minutes*. Another fet of four pillars, inferted into the moveable horizontal plate, fupports the vertical circle D D, or rather portion of a circle, which is divided into twice 90°, and fomewhat more at each fide, and is called the meridian circle; its vernier, placed on the upper horizontal circle, reads alfo every three minutes of fpace. The handle or rod E moves this circle in like manner as the rod C moves the horizontal circle defcribed. On the upper or mutilated part of the meridian circle D D, are placed two other plates, the upper one moveable on the under one, like the horizontal plates, and the vernier carried by the under one. It does not appear from the drawing or account whether the axis of motion rotates or is fixed. The upper or moveable plate, marked F F, is divided into hours and ten-minute fpaces, and thefe again are fubdivided by the vernier into fingle minutes of time. This plate, which is called the equatorial plate, has a third fet of pillars inferted into it, and is moveable by the rod G, like the other moveable plates; the pillars fupport a fourth circle, or rather mutilated circle H H, on the upper part of which the telefcope L L is mounted, as feen in the drawing. This uppermoft circle is called the circle of declination or horary circle, and is divided into twice 90°; it is alfo moveable by the rod or handle K, like the reft of the moveable circles; and has every three minutes of fpace, by its vernier, placed on the plane of the equatorial circle. The telefcope is of the Gregorian conftruction, with a great fpeculum of 18 inches focal length. In making the adjuftments of this inftrument for obfervation, the horizontal plates A, A, are firft levelled by the joint aid of the two levels and fcrews of adjuftment that bear the whole fabrick; this adjuftment is not perfect till the bubbles of the levels will remain ftationary, in the middle of their tube, while the upper plate is carried quite round the fubjacent one. In the next place the meridian circle D D is turned by its handle E, till the equatorial plates are parallel to the equator; that is, till they are raifed equal to the complement of the latitude of the place of obfervation, and the inftrument is faid to be fit for making obfervations; of courfe the placing of the circles relatively to each other, in regard to perpendicularity, and of the line of collimation of the telefcope in regard to the points zero in the declination circle, are fuppofed to be immoveably adjufted by the maker, fo as to require no future rectification. As it will be of fome importance to the developement of the progreffive improvements of the different equatorial inftruments, to confine ourfelves to the ufes that this inftrument by Mr. Short was applied to, we cannot do better than confine ourfelves to the words of one of the early defcriptions of its practical application.

"*To find the Hour of the Day, and Meridian of the Place.*—Firft, find, from aftronomical tables, the fun's declination for the day, and for that particular time of the day; then fet the declination-femicircle to the declination of the fun, taking particular notice whether it is north or fouth, and fet the declination-femicircle accordingly.

"You then turn about the horizontal handle, and the equatorial handle, both at the fame time, till you find the fun precifely concentrical with the field of the telefcope. If you have a clock or watch at hand, mark the inftant of time; and by looking upon the equatorial plate and vernier, you will find the hour and minute of the day, which comparing with the time fhewn by the clock or watch, fhews how much either of them differs from the fun. In this manner you find the hour of the day.

"Now, in order to find the meridian of the place, and, confequently, to have a mark by which you may always know your meridian again, you firft move the equatorial plate, by means of the equatorial handle, till the meridian of the plate or hour-line of 12 is in the middle of the vernier; and then, by turning about the declination-handle till the telefcope comes down to the horizon, you obferve the place or point which is then in the middle of the field of the telefcope; and a fuppofed line, drawn from the centre of this field to that point in the horizon, is your meridian line. The beft time of the day for making this obfervation for finding your meridian is about three hours before noon, or as much after noon. The meridian of the place may be found by this method fo exact, that it will not differ at any time from the true meridian above 10″ of time, and if a proper allowance be made for the refraction at the time of obfervation, it may be found much more exact. This line

line thus found will be of ufe to fave trouble afterwards; and is, indeed, the foundation of all aftronomical obfervations.

"*To find a Star or Planet in the Day-Time, even at Noon-Day.*—The inftrument remaining as rectified in the laft experiment, you fet the declination-femicircle to the declination of the ftar or planet you want to fee; and then you fet the equatorial plate to the right afcenfion of the ftar or planet at that time, and, looking through the telefcope, you will fee the ftar or planet; and after you have once got it into the field, you cannot lofe it: for, as the diurnal motion of a ftar is parallel to the equator, by your moving the equatorial handle fo as to follow it, you will at any time, while it is above the horizon, recover it, if it be gone out of the field.

"The eafieft method for feeing a ftar or planet in the day-time is this: your inftrument being adjufted as before directed, you bring the telefcope down fo as to look directly at your meridian mark; and then you fet it to the declination, and right afcenfion, as before-mentioned.

"By this inftrument moft of the ftars of the firft and fecond magnitude have been feen even at mid-day, and the fun fhining bright; as alfo Mercury, Venus, and Jupiter: Saturn, and Mars are not fo eafy to be feen, upon account of the faintnefs of their light, except indeed when the fun is but a few hours above the horizon.

"And in the fame manner in the night-time, when you can fee a ftar, planet, or any new phenomenon, fuch as a comet, you may find its declination and right afcenfion immediately, by turning about the equatorial handle, and declination handle, till you fee the ftar, planet, or phenomenon; and then looking upon the equatorial plate, you find its right afcenfion in time; and you find upon the declination-femicircle its declination in degrees and minutes.

"In order to have the other ufes of this inftrument, you muft make the equatorial plates become parallel to the horizontal plates; and then this inftrument becomes an equal altitude inftrument, a tranfit inftrument, a theodolite, a quadrant, an azimuth inftrument, and a level. The manner of applying it to thefe different purpofes is too obvious to need any explanation.

"As there is alfo a box with a magnetic needle faftened in the lower plate of this inftrument, by it you may adjuft the inftrument nearly in the meridian; and by it likewife you may find the variation of the needle; if you fet the horizontal meridian, and the equatorial meridian, in the middle of their verniers, and direct your telefcope to your meridian mark, you obferve how many degrees from the meridian of the box the needle points at: and this diftance or difference is the variation of the needle."

Thefe are the ufes to which Mr. Short's inftrument, before us, was principally applied, and had the circles been divided with verniers fubdividing the divifions more minutely, it would have been fomething more than an aftronomical play-thing, to which it cannot be confidered as any thing fuperior, when it comes to be contrafted with one of the moft improved kind, even of thofe that are equally portable. We cannot difmifs our notice, however, of the prefent inftrument, without remarking further, that the manner in which the two pairs of plates A A, and F F, move over each other refpectively, is by no means calculated to preferve a fteady undeviating motion, for want of a fufficient length in the axis of motion. This is the principal objection we expreffed to Dr. Wollafton's circle made by Mr. Cary, and if the doctor borrowed his notion of fuch a pofition of his circles from Mr. Short, he copied one of the worft properties that this artift's inftrument poffeffes.

This equatorial inftrument has obtained the name of univerfal, from the circumftance of its being applicable to ufe in any latitude; which name is equally due to its fucceffors.

Portable Equatorial Inftrument by Mr. Ed. Nairne.—The imperfections of the preceding inftrument were attempted to be removed by Mr. Nairne, whofe conftruction introduced a long axis of motion for the horizontal circle, thereby effecting a fteadinefs in its performance, and placed the telefcope on the axis of the declination-femicircle to obtain a lefs encumbered elevation of the telefcope; but ftill the circles were not graduated fo minutely as to render them of real ufe in practical aftronomy. A brief account of this inftrument is contained in vol. lxi. part i. of the Philofophical Tranfactions of London, and was read before the Society on Feb. 7, 1771. Its fubftance is this:—

The inftrument confifts of the following parts, *Plate* XII. *fig.* 1. of *Aftronomical Inftruments*, a mahogany triangular ftand A A A, and three adjufting fcrews B, B, B, a moveable azimuth circle C, which is divided into degrees, and by a vernier index into every fix minutes; above this azimuth circle is the horizontal plate D, to the under part of which is faftened the vertical conical axis E; on the middle of the upper furface of the horizontal plate is placed a ground glafs level F, by which the plate D is fet parallel, and the pillar E perpendicular to the horizon; from this plate rife perpendicularly two quadrants G, G, one of which is divided for the latitude into half degrees, and has a vernier index to three minutes; the equatorial plate H, with its hour circle, is fupported by the two quadrants G, G, its axis of motion, which is placed near the hours XII, XII, paffes through the centres of the quadrants, and carries the index I, pointing to the divided quadrant; the equatorial plate is divided into half degrees, and has a vernier index fhewing every three minutes of right afcenfion, or 12 feconds of time: it is figured to fhew both degrees and time. To prevent mifapprehenfion it may be right to remark that the hours XII, XII, ought properly to have been placed according to the meridian line; but they are here placed otherwife for the convenience of better feeing the meridian diftance fhewn by the vernier. On the upper part of the equatorial plate is the plate K; upon this plate K are fixed the two fupporters M, M, which fupport the axis N, *under* which is faftened the femicircle of declination O, divided into half degrees with a vernier fubdividing it into every three minutes. On the *upper* part of this axis is fixed an achromatic telefcope P, which magnifies about 50 times; to the eye-end of this telefcope is applied a fmall reflecting fpeculum, making an angle of 45° with the axis of the telefcope, whereby objects that are in the zenith or in any other altitude may be obferved without putting the body in an inconvenient pofition. To the under part of the axis N is faftened a brafs arm carrying the weight Q, which counterbalances the telefcope, and brafs-work annexed to it; whilft the weights R, R, counterbalance in like manner the whole of the inftrument that is moveable on the equatorial axis, fo that whatever pofition the inftrument is put in it will there remain, being perfectly balanced. The four motions of this inftrument may, when required, be moved extremely flowly, by means of the indented edges of the circles and femicircles, and the fcrews or worms of the handles S, T, V, and W, for the horizontal circle, the motion for latitude, the equatorial and declination motions refpectively. The adjuftments and ufes of this inftrument are fo fimilar to thofe of its predeceffor, both in kind and extent, that it would be fuperfluous to particularize them again. In this account it is not ftated whether the axis of motion of the equatorial circle is prolonged,

longed, but as the height to which it is elevated above the horizon circle feems to admit of it, and as the axis of this is elongated, we are difpofed to believe that a fimilar advantage belonged to the former; otherwife it would not have that ftability that is neceffary in this part of the inftrument for making the moft effential motion fteady enough to be depended on. How far the mahogany legs were firm and fteady enough for the purpofe of affording a motionlefs pedeftal is not faid; but the want of accuracy, or rather the want of minutenefs in the divifions and fubdivifions of the graduated circles, quadrant, and femicircle, made this confideration of lefs importance than it would have been in an inftrument poffeffing greater powers. We have been informed, from credible authority, that Mr. W. Ludlam, of St. John's college, Cambridge, was the principal contriver of Mr. Nairne's conftruction.

Ramfden's portable equatorial inftrument.—The principal parts of this inftrument, fays profeffor Vince, (Treatife on Prac. Aftr.) are, the azimuth circle G H, the equatorial, or hour circle E F, and the declination circle C D; (fee *Plate* XI. *fig.* 2. of *Aftronomical Inftruments*,) to this latter there is fixed a telefcope A B, having under it a rod *m n*, paffing through two pieces π, ρ, in one of which, as π, are two fcrews acting on the rod againft each other, in order to adjuft the rod perpendicular to the axis on which the declination circle turns. The azimuth circle G H lies on a brafs plate *t u*, fupported by three feet, refting on the fcrews X, Y, Z, and on this plate it turns about an axis T, by means of a fcrew S; upon this circle are placed two fpirit levels *c d*, *a b*, at right angles to each other, fupported at each end by a fcrew, by which they may be adjufted; the circle is divided into twice 180°, and has a vernier V fixed on the plate *t u*, by which the degrees are fubdivided into minutes or half minutes, according to the fize of the inftrument; and by means of the fcrew I the circle may be fixed to the plate *t u*. K K is a polar axis moveable about a centre L, fuftained by two fupporters *q*, *i*, refting on two pieces W, V, firmly connected to the plane of the circle G H; the lower end of this axis has an arc fixed to it, which runs againft an arc *z y*, attached to G H, and to which it may be fixed by a key at *e*; and in this fituation, if you apply the key to Q, it gives a motion to the axis, by which you may very accurately adjuft the telefcope to an object. To the centre L, and perpendicular to the polar axis, are fixed two ftrong pieces of brafs, one of which is here reprefented by *x*, and the other is on the other fide of the axis; thefe fupport a circle $\alpha\ \beta\ \gamma\ \delta$; on the top of the polar axis, and perpendicular to it, is placed a brafs plate, moveable about a pivot on the top of the axis; to this are fixed four pieces, two of which are reprefented by *f*, *g*; thefe are connected to the hour circle E F, lying on $\alpha\ \beta\ \gamma\ \delta$, and carry it about; upon $\alpha\ \beta\ \gamma\ \delta$, at W, is fixed a vernier to the circle E F, which circle is divided into twice twelve hours. The declination circle C D is fupported by its centre, on an axis refting on two fupporters *h*, *k*, on one fide, and two others of the like kind on the other; thefe reft upon the brafs piece on the top of the polar axis, and may be adjufted by two pair of fcrews at the feet of the two fupporters, to fet the plane of the declination circle perpendicular to the hour circle, which, by the maker, is placed perpendicular to the polar axis. This circle is divided from zero both ways to a little more than 90°, and a vernier is placed at R to fubdivide, as at V. A fmall quadrant is fixed to the eye-piece of the telefcope, which turns round upon the piece, carrying two wires perpendicular to each other, for the parallel of declination and hour circle. The eye-piece carries two crofs wires to reprefent the circle of altitude and a parallel to the horizon. The quadrant has two radii *l*, *o*, perpendicular to each other, and move together; the former has a round or circular fpirit level upon it, fo that by turning about the eye-glafs and the quadrant till the bubble refts in the middle, the plane of the quadrant becomes perpendicular to the horizon; and the vernier on the latter fhews the altitude to which the telefcope is directed, and the correfponding refraction; and in this pofition the circle of altitude is perpendicular to the horizon. At P is a fmall micrometer circle, called the refraction circle, (with a fixed index,) moveable by a finger fcrew; this circle is divided into half minutes, and one revolution is equal to 3′ 18″; when moved it raifes or depreffes the centre of the crofs wires in a circle of altitude.

After this general defcription of the parts of the inftrument, let us confider what motions it is capable of, and what the circles may be made to reprefent, before we proceed to its adjuftments. And firft, the azimuth circle G H, being fet parallel to the horizon, will reprefent the horizon; fecondly, if the polar axis K K be inclined to the horizon at an angle equal to the latitude of the place, the equatorial circle E H will be inclined to the horizon in an angle equal to the inclination of the equator to the horizon; therefore, if we turn about the azimuth circle, and confequently the equatorial circle, the latter may be made to coincide with the equator; thirdly, if the declination circle be fet perpendicular to the equatorial, then the confequences muft be, that if the line of collimation be adjufted parallel to the plane of the declination circle, or perpendicular to its axis, and alfo parallel to the equatorial circle E F, when zero on the declination circle coincides with zero on the vernier R, then the telefcope is directed to the equator in the heavens, and by turning about the declination circle the line of collimation will defcribe a fecondary to the equator; and by fetting the declination circle to the declination of any body in the heavens, if we turn about the circle E F, and confequently the circle C D with the telefcope, on the brafs plate, on the top of the polar axis (which is kept fixed,) the equatorial circle, moving in its own plane perpendicular to the polar axis, muft continue to coincide with the equator, and, confequently, the telefcope will defcribe a parallel to the equator, and therefore muft bring the body into the field of view. Thefe being the motions of the parts of the inftrument, we may now proceed to defcribe the neceffary adjuftments for them.

Adjuftments.—1. *To adjuft the azimuth circle parallel to the horizon.*—Turn it till one of its levels becomes parallel to a line joining two of the fcrews at the feet, as X, Z, and then adjuft that level with one of them; turn the circle half round, and if the bubble be not in the middle, adjuft it half way, by one of the above-mentioned fcrews, and half way by the fcrew at one end of the level; repeat this operation till the bubble ftands right in both thefe pofitions; then turn the circle at right angles to thefe pofitions, and, if neceffary, fet the bubble right by the other fcrew Y at the foot, and the adjuftment is made. If you previoufly adjuft the other level by one of the fcrews at the end, then the circle may be adjufted horizontal by them, without turning it.

2. *To adjuft the level* r s *parallel to the rod* m n.—Set the polar axis, as near as you can, perpendicular to the horizon, and turn about the declination circle C D by a pinion for that purpofe, until the bubble of the level *r f* ftands in the middle; reverfe the level, and if the bubble do not ftand in the middle, adjuft it half way by the fcrew at S, under one

one end of the level, and half way by turning the declination circle; and repeat the operation till the bubble ſtands in the middle in both poſitions.

3. *To adjuſt the rod* m n *perpendicular to the axis on which the declination circle turns.*—Set the polar axis as near as you can parallel, and conſequently the equatorial circle perpendicular to the horizon; ſet the declination circle to zero, and turn the hour circle till the bubble ſtands right; then ſet the declination circle to 90°, and adjuſt the bubble by the polar axis: then turn the declination circle to the oppoſite 90°, and if the level be not right, correct half the error by the polar axis, and the other half by the two ſcrews in the piece π, releaſing one and ſcrewing up the other; repeat this operation till the bubble ſtands right in both poſitions, and the adjuſtment is made. For theſe two adjuſtments tend, the former to ſet the axis of the declination circle, on the axis about which the rod revolves, perpendicular to the horizon: and the other to ſet the rod *m n* parallel to the horizon, and conſequently perpendicular to that axis; when, therefore, the bubble thus continues right, both circumſtances muſt have taken place.

4. *To ſet the axis of the declination circle perpendicular to the polar axis.*—The inſtrument remaining as in the laſt adjuſtment, that is, the declination circle at 90° and the bubble right, turn the equatorial circle half round, and if the bubble be not right, correct half the error by the polar axis, and the other half by the two pair of ſcrews at the feet of the two ſupporters *h, k;* and repeat this operation till the bubble is right in both poſitions, and the adjuſtment is completed. For the former adjuſtment tends to ſet the axis of the declination circle perpendicular to the horizon, and the latter to ſet it parallel to the equatorial circle, or perpendicular to the polar axis; conſequently, when the bubble is right in both the above poſitions both circumſtances muſt take place, that is, the polar axis muſt be parallel to the horizon, and the axis of the declination circle perpendicular to it. And as this adjuſtment is made by the level, which is horizontal when the axis of the declination circle is thus adjuſted perpendicular to the horizon, and which is previouſly adjuſted parallel to the rod, they muſt both be perpendicular to the axis, about which they turn; and, conſequently, they move in a plane paſſing through the polar axis, or perpendicular to the equatorial circle. Hence, alſo, the declination circle, being perpendicular to its own axis, becomes perpendicular to the equatorial circle.

5. *To make the centre of the croſs wires cut the ſame object whilſt you turn round the eye-glaſs by the pinion of the refraction apparatus.*—Set the index on the refraction circle to the beginning of the diviſions, and turn round the eye-glaſs, and if the centre of the wires do not continue to cut the ſame object, correct it by four ſmall ſcrews (which you will find by unſcrewing the neareſt end of the eye-tube which contains the firſt eye-glaſs), the two oppoſite at a time, and repeat the correction till the centre continues to cut the ſame object.

6. *To make the line of collimation deſcribe a great circle perpendicular to the equatorial circle.*—Set the declination circle to 90°, and the equatorial circle to VI, and bring the bubble to the middle by the polar axis. Then note ſome object covered by the centre of the croſs wires, repreſenting the parallel of declination and hour circle, and turn the equatorial circle half round, and if the ſame object be not now covered by the centre of the wires, move, if neceſſary, the declination circle in its own plane, until it is in the ſame vertical circle with the object, and then bring the centre half way to it by the upper and lower of the four ſmall ſcrews which move theſe wires, and turn the declination circle back through half the ſpace it was moved, and you get a new object now covered by the centre of the wires; repeat this operation till the ſame object be covered in both theſe poſitions; then ſet the hour circle to XII, and bring the bubble to the middle by the declination circle, and if the centre do not now cover the ſame object, bring it to the object by the other two ſcrews, and the line of collimation is adjuſted parallel to the level, or to the rod *m n*, and, conſequently, it muſt be perpendicular to the axis of the declination circle. Hence as that circle is turned about in its own place, the line of collimation muſt deſcribe a ſecondary to the equator. The line of collimation for the centre of the croſs wires being thus adjuſted, it is, at the ſame time, in the centre of motion, on which the wires parallel and perpendicular to the horizon turn; hence, when the index of the refraction circle is ſet to the beginning of the diviſions, the interſections of the two ſets of wires coincide. The adjuſtment of the wire parallel to the equatorial circle may be examined by the paſſage of a ſtar through the teleſcope, (all the other adjuſtments being previouſly made, and the equatorial circle adjuſted to coincide with the equator in the heavens, and the declination circle ſet to the ſtar's declination;) for if the ſtar do not run upon the wire, it muſt be adjuſted till it does: or it may be done thus. Set the equatorial circle to XII, and having directed the line of collimation to ſome ſmall well defined object, turn the declination circle in its own plane, and obſerve whether the perpendicular wire continue to cut the ſame object as it paſſes through the field of view; if not, adjuſt till it does.

7. *To adjuſt the verniers of the equatorial and declination circles.*—Elevate the equatorial circle to an angle of about 45°, as moſt proper for this purpoſe, and ſet the declination circle to zero, and turn the equatorial circle in its own plane till the bubble ſtands right; then turn the equatorial circle half round, and if the bubble do not ſtand right, adjuſt half by moving the equatorial, and half by moving the declination circle; and repeat this operation till the bubble ſtands right in both poſitions, then, by moving the verniers, ſet zero on the vernier belonging to the equatorial circle to VI, and zero on the vernier belonging to the declination circle to zero, and the verniers are adjuſted. Thus the inſtrument is ready for obſervation, except that the azimuth circle is not adjuſted to ſhew azimuths, which will be done when we come to ſhew the methods of making obſervations.

The method here uſed ariſes out of the two diſtinguiſhing features of the inſtrument under our conſideration; namely, the poſition of the level near the teleſcope, and the want of graduations on the latitude arch, or arch for giving the polar axis its due inclination.

But the Hon. Mr. M'Kenzie's method appears to us more ſimple, as well as more intelligible, for elevating the equatorial circle to the co-latitude of the place, thus; "lower the teleſcope as many degrees, minutes, and ſeconds below zero, on the declination-ſemicircle, as the complement of your latitude is; then elevate the polar axis till the bubble be horizontal, and the equatorial circle will be elevated to the co-latitude of the place, as required; after which the level may be made to ſtand true in oppoſite poſitions, and the verniers be placed to zero, as above directed.

Mr. Atwood, in his Syllabus, has given another method of making this adjuſtment, which profeſſor Vince acknowledges to have the advantage over his in point of both eaſe and accuracy, the ſubſtance of which is as follows:

 Having

Having ſet the declination circle to 90° in either quadrant, direct the point of interſection of the croſs-wires to coincide with ſome diſtant object as a mark; turn the equatorial circle in its own plane 180°, and if the interſection does not now coincide with the diſtant mark, correct half the error in declination by moving the declination circle in its own plane, and half the error in right aſcenſion by the feet ſcrews of the ſupporters that adjuſt the axis of the declination circle; now if theſe adjuſtments be accurately made, the interſection will coincide with any diſtant mark, choſen anew, when the equatorial circle has been turned 180°; but if the coincidence is not perfect, the ſame adjuſtments muſt be repeated till the condition is fulfilled. The line of collimation being now directed to coincide with the diſtant mark, ſet the vernier of the declination circle to 90°, and turn this circle 180° in its own plane, turn alſo the azimuth circle, ſo that the line of collimation may be again directed to the ſaid diſtant mark, then turn the equatorial circle about in its own plane 180°, and if the diſtant mark be not now covered by the interſection, the quantity of deviation ſhews double the total error of dividing the two ſemi-circles of the declination circle, and alſo its excentricity, which errors cannot be allowed for by adjuſtment. The error in right aſcenſion, now diſcovered, muſt ariſe from the plane of the declination circle not being quite perpendicular to the equatorial, and alſo from the line of collimation not being exactly parallel to the plane of the declination circle; therefore correct $\frac{1}{4}$th of the error by the ſcrews of the declination axis, and $\frac{1}{4}$th by moving the line of collimation perpendicular to the plane of the declination circle: if the firſt trial of theſe adjuſtments be not attended with complete ſucceſs, when the diſtant mark is again examined in reverſed poſitions they muſt be repeated till they are correct. Hence it is manifeſt, when the above adjuſtments are properly made, 1ſt, that the line of collimation is parallel to the plane of the declination circle; 2dly, that the plane of the declination circle is perpendicular to the plane of the equatorial; 3dly, that the errors of diviſion are at the oppoſite points 90°, if any are diſcovered in the declination circle, and, 4thly, that when the declination circle is ſet to 90°, the line of collimation is perpendicular to the plane of the equatorial circle, or, when it is ſet to zero, it is parallel to it.

The azimuth circle being adjuſted horizontal, and the declination circle put to 90°, make the vertical wire parallel to it, turning the equatorial and azimuth circles in their reſpective planes; direct the point of interſection to a diſtant mark near the horizon, and move the azimuth and declination circles each in their own planes to 180°, ſo that the ſaid mark may appear ſomewhere in the vertical wire, and if there is an error in altitude, let the line of collimation biſect it, by moving the polar axis, and it will then be horizontal. Let this new biſected point or mark in the horizon be noted; then the declination circle being put to zero, turn the azimuth circle 90°, ſo as to bring the new mark upon the croſs wire, and direct the interſection to it by turning the equatorial circle in its own plane, and the declination is in that ſituation parallel to the horizon. The inſtrument remaining as before, turn the equatorial and azimuth circles in their reſpective planes 180°, and if each circle be accurately divided, the teleſcope muſt evidently be brought into a poſition exactly parallel to its former one, and therefore the interſection of the wires will again coincide with the new mark in the horizon. Otherwiſe the quantity each of thoſe circles muſt be moved further or back, will ſhew their reſpective errors of excentricity and alſo of diviſion. Laſtly, the declination circle being at zero, and the line of collimation or interſection made to coincide with the horizontal mark, by moving the equatorial and azimuth circles, ſet the equatorial vernier to VI, and the adjuſtment is finiſhed; for the line of collimation being parallel to the horizon and to the plane of the declination circle when the vernier ſtands at VI, that plane, by revolving about the polar axis, muſt be perpendicular to the horizon when the vernier ſtands at XII, which is the thing required.

Methods of making Obſervations.

1. *To take the altitude of a body above the horizon.*—Set XII on the equatorial circle to zero on its vernier, and the plane of the declination circle is then perpendicular to the horizon; make, therefore, the line of collimation horizontal, by bringing the bubble to the middle of the level in the teleſcope, and obſerve what point of the declination circle ſtands againſt zero in its vernier, and then by moving the declination and azimuth circles in their own planes, bring the body to the centre of the croſs wires, and obſerve again what point of the declination circle ſtands againſt zero, and the arc intercepted between theſe two points gives the apparent altitude. If the declination circle had been ſet to zero, and the line of collimation been adjuſted horizontal by moving the polar axis, then, when the body had been brought to the centre of the croſs wires, the declination circle would have ſhewn its altitude at once. For Mr. Atwood's indirect methods of taking an altitude, ſee pages 163, 164, and 165 of Vince's "Treatiſe on Practical Aſtronomy."

2. *To meaſure very ſmall vertical angles.*—Let the elevation of the equatorial circle be a, the polar diſtance of the teleſcope (either more or leſs than 90°) be b, and ſet XII (correſponding to noon) on the equatorial circle to zero; then if that circle deſcribes an angle whoſe verſed ſine is v, and the line of collimation be brought (by moving the azimuth circle) back to the ſame vertical, it will have been depreſſed through a vertical arc equal to $\frac{v \times si.a \times si.b}{si.b - a}$, radius being unity. Or, if $b = 90°$, the depreſſion $= v \times \tan. a$. Hence if, for example, it ſhould be required to find the angle which the horizontal wire of the teleſcope ſubtends, ſelect ſome well defined diſtant object, ſet the declination circle to zero, and XII on the equatorial to zero, and elevate the equatorial ſo as to bring the object into the field of view, and make the upper edge of the wire coincide with it, then move the equatorial and azimuth circles in their own planes till the lower edge coincide with it, and read off the equatorial arc. *Ex.* If the elevation of the equatorial be 41° 3′, and the arc denoted by the equatorial vernier be 57′, the angle required = vec. ſin. $57' \times \tan. 41° 3' = 24'' 6'''$. Hence alſo the diameter of a planet may be meaſured. When the planet comes to the meridian (the two circles being fixed as before) alter the elevation of the equatorial circle, and bring the upper edge of the horizontal wire to be a tangent to the upper limb of the planet (or the apparent lower limb), and then by turning the azimuth and equatorial circles in their own planes, bring the lower edge of the wire to be a tangent to the lower limb of the planet (or the apparent upper limb), and the rule gives the ſum of the diameters of the planet and wire, from which ſubtract the diameter of the wire, and you get the diameter of the planet.

3. *To find the latitude of a place.*—Take the altitude of the ſun's upper or lower limb a little before noon, and continue your obſervation till he riſes no longer, and you get

 his

his apparent meridian altitude; with which and his declination you may find the latitude by the common rule.

4. *To incline the equatorial circle so as to make any angle with the horizon.*—Set the declination-circle (in the southern quadrant) to the given angle, and XII on the equatorial circle to zero on its vernier; then bring the line of collimation horizontal by moving the polar axis till the bubble in the level on the telescope stands in the middle, and the equatorial circle stands at the proper angle.

5. *To determine the position of the meridian.*—Elevate by the last article the equatorial circle, to make an angle with the horizon equal to the co-latitude of the place, and set the declination-circle to the declination of any known star, then turn the equatorial and azimuth-circles in their own planes till the star is brought to the centre of the cross wires, and correct the position of these circles on account of refraction, by the small quadrant and apparatus at the eye-piece of the telescope, and the equatorial circle will then coincide with the equator in the heavens, and the vernier will shew how far, in time, the star is from the meridian; and hence, if we turn the equatorial circle till XII stands at zero on the vernier, the plane of the declination-circle will coincide with the meridian. Hence, if we direct the telescope to the horizon, the point which the centre of the wires will cut is the south point of the horizon, and may serve for a meridian mark. If the point of the arc of the azimuth-circle lying against zero on its vernier be noted, the error in its position will be known; and if this be very small, so that by moving the vernier till zero on it may be brought to zero on the arc, it may be adjusted to shew azimuths. The position of the vernier of the azimuth-circle may also be verified thus. The equatorial-circle being set parallel to the horizon, and XII set to zero on its vernier, turn the azimuth-circle, and by moving the declination-circle, bring a star on the east side of the meridian to the centre of the cross wires, and note the azimuth, then turn the azimuth-circle (the telescope remaining fixed) and do the same when the body comes to the west side; and if the azimuths at both observations be the same, the vernier is adjusted right; if not, half their difference is the error. The instrument being set upon a moveable plane, if the points on which the three screws at the feet rest be marked, it will then always be easy to set the azimuth-circle very nearly in its proper position.

6. *To determine the apparent time of the day.*—Proceed as in the last article, only take the sun instead of a star, and bring its centre to the centre of the cross wires, and correct for refraction, and the arc intercepted between XII and zero on the vernier shews the distance of the sun, in time, from the meridian, or from apparent noon.

7. *To find a star or planet in the day-time.*—Elevate the equatorial-circle to make an angle equal to the co-latitude, and adjust it to coincide with the equator in the heavens, and set the declination-circle to the declination of the body. Find by the usual way the distance of the star from the meridian at the time required, and reduce it to siderial time; then turn the equatorial-circle in its own plane, east or west, as the star lies, till the arc between XII and zero on the vernier be equal to that time, and the star will be in the field of view. By this means Jupiter, Venus, and fixed stars of the first magnitude, may be observed in the day-time.

8. *To find the right ascension and declination of a star.*—Elevate the equatorial-circle to the co-latitude of the place, and previously set it to coincide with the equator in the heavens, and set XII on the equatorial-circle to zero on its vernier. After this set the declination-circle to the sun's declination, and take the time of its transit; then set the declination-circle to the star's declination and take the time of its transit, and the difference of the times will give the difference of their right ascensions; and the star's transit being taken at the intersection of the wires, the declination-circle (corrected for refraction) will give its declination. Thus also you may compare two stars, or the moon and a star. Or it may be done at any time, if you move the declination and equatorial-circles in their own planes till the star is brought to the centre of the cross wires, and correct the position of these circles on account of refraction, and the declination-circle will give you the declination required; and the vernier of the equatorial-circle will give you the star's distance, in time, from the meridian, or your clock will give you the sun's distance, the difference of which times gives the difference of their right ascensions, and, therefore, knowing the sun's right ascension, you have the right ascension of the star.

9. *To find the longitude.*—The equatorial-circle being set to coincide with the equator in the heavens, and XII to zero on its vernier, take the time of the transit of the moon's limb, and also of a proper star as near as possible to the moon's parallel, and the longitude may be determined therefrom by the lunar method, in the usual way.

10. *To measure horizontal angles.*—Adjust the equatorial-circle parallel to the azimuth-circle; and having directed the line of collimation to one of the objects, move the equatorial-circle in its own plane, and also the declination-circle, if necessary, and bring the line of collimation to the other, and the arc through which the equatorial-circle has moved gives the angle required.

As an appendage to this account, by professor Vince, of Ramsden's portable equatorial instrument, we think it may be acceptable to our readers to have the Hon. S. M'Kenzie's account of Mr. Ramsden's new refraction apparatus much improved, which was published in his anonymous pamphlet, (dated in the year 1791, a year after the professor's treatise was published), together with the explication of the principles on which the apparatus was constructed.—"Refraction or parallax," says our author, "by changing the apparent altitude of a planet, may also change its apparent right ascension and declination; see *fig.* 2. of *Plate* XII. (of *Astron. Inst.*) where H O represents the horizon; E Q, part of the equator; P, the pole of the equator; Z, the zenith; P E H, the meridian; Z V, an arc of a vertical drawn through I, the *apparent* place, and F, the *true* place of the planet; P A, a circle of declination, or hour-circle, drawn through the true place F; and P B, a circle of declination or hour-circle drawn through the apparent place I. The error in altitude from F to I alters the right ascension of the planet as much as the arc of the equator A B, or its parallel F C, amounts to. It also alters its declination from A F to B L, that is, from C to I. If a planet be in the meridian at L, the error, in declination from L to K, will be the same as the error in altitude; but there will be no error in right ascension, because the same circle of declination P E H, (perpendicular to the horizon,) passes through the apparent place K, and the true place L. In like manner, if by the construction of an instrument you have a vertical circle Z V, perpendicular to the horizon, it will pass through the apparent place I and the true place F, and there will be no error in right ascension; and if by the same instrument the error in altitude from F to I be determined, the true place F is found, and consequently there will be no error in declination. With Mr. Ramsden's new refraction apparatus you have just such a vertical circle as will appear from what follows.

In the focus of the telescope of the equatorial two *fixed* wires

wires are placed at right angles to each other; one, E Q, (ſee *fig.* 4.) repreſents part of a parallel of the equator; the other, P A, part of a meridian, or hour-circle. There are alſo two moveable croſs wires at right angles to each other; one, H O, repreſents a portion of a parallel to the horizon; the other, Z V, a portion of a vertical circle. Theſe moveable wires have a motion round the axis of the teleſcope, by turning a pinion.

A ſmall quadrant (ſee *Plate* XI. *fig.* 2. and alſo *Plate* XII. *fig.* 2.) is fixed on the part that carries the moveable wires, with diviſions on each ſide; one expreſſing the degree of altitude of the object viewed, the other expreſſing the minutes and ſeconds of error occaſioned by refraction, correſponding to that degree of altitude. To the index of this quadrant is fixed a ſmall circular level, which being adjuſted by its own pinion, gives the altitude; while by another pinion it aſcertains the perpendicularity of one of the moveable wires, which gives the vertical circle above-mentioned, whereby the true right aſcenſion may be determined, free from all error ariſing from refraction or parallax. Hence, in taking the moon's right aſcenſion with an equatorial inſtrument, fitted with this refraction apparatus, in order to determine longitudes at land, there is no occaſion to attend to her parallax, as the difference of her right aſcenſion, cauſed by parallax or refraction, will only depreſs or elevate her on the ſame vertical circle, but will not change her right aſcenſion from one hour-circle to another. In this refraction apparatus the centre of the fixed wires always remains in the line of collimation; whereas by the former conſtruction, on raiſing or depreſſing that centre, it was moved out of that line; and as it was very difficult to replace it exactly, an error in the obſervation was liable thereby to be produced. In all obſervations made with this refraction apparatus, firſt adjuſt the circular-level, then ſet the centre of the moveable wires, by the micrometer ſcrew, to the refraction correſponding to the altitude of the object viewed, as given by the ſmall quadrant; and let one of the moveable wires be ſet always perpendicular. Since copying the preceding extract from Mr. M'Kenzie's pamphlet, we have been aſſured that it was publiſhed previouſly to profeſſor Vince's treatiſe, and that the date 1791 is a typographical error for 1771; accordingly, we learn from Mr. Dollond, that Ramſden's inſtrument preceded his, but our inquiries to obtain the *preciſe time* of its origin have not been ſucceſsful. The two different ſizes of Ramſden's portable inſtrument were according to the following table of dimenſions.

	Rad. in In.	Limb divided to	Vernier of 30 gives	Divided to parts	By vernier into
Azim. or horizontal circle,	5.1	15′	0° 30″	45th of in.	1350th

Vertical ſemicircle for declination or latitude,	5.5	15	30″	42d ditto	1260
	2.75	30	1′	41st ditto	1230

Portable Equatorial Inſtrument by Meſſrs. P. and J. Dollond.—Mr. Dollond informs us that his father contrived the inſtrument, which now comes under our notice, in or about the year 1775, and the readineſs with which he communicated all the particulars we wiſhed for reſpecting it deſerves our grateful acknowledgment. This inſtrument, ſays the author, (in his quarto pamphlet,) which of all others is the moſt amuſing to lovers of aſtronomy, is now rendered, by the following improvements, greatly ſuperior to any hitherto produced. As the whole weight does not exceed thirty pounds, it may be ſaid to be truly portable, yet, by the ſteadineſs of all the parts, and the perfection of the achromatic teleſcope, the obſervations may be made to a very great exactneſs. The focal length of the achromatic object-glaſs is about 17 inches; it is compoſed of three glaſſes, and admits of an aperture of two inches. The tube being made as thin as poſſible, is eaſily balanced by the weight A, which is fixed in the ſemi-circle B B; (ſee *fig.* 3. of *Plate* XI.) then again all the parts above the horizontal axis (the end of which is ſeen as C) are balanced by the ſquare weight D. By means of theſe balances the centre of gravity is preſerved over the centre of the inſtrument in every poſition, and the different parts prevented from being ſtrained when the inſtrument is put into any oblique poſition, which may be required in its various uſes. This alſo tends to keep the teleſcope ſteady, which is of the greateſt advantage in making an obſervation. Beſides theſe very eſſential improvements, every part has been reduced to the moſt ſimple ſtate; and ſeveral, which in other inſtruments of this kind, were found ſuperfluous, have been entirely rejected.

The inſtrument is ſupported by three feet E, E, E; the ſcrews *a*, *a*, *a*, are to raiſe or depreſs the feet, in order to bring the plate G G into an horizontal poſition, which is determined by two ſpirit-levels *b*, *b*, that are fixed on it at right angles to one another. If theſe levels are well adjuſted, the plate will be horizontal when the air-bubbles come into the middle of the glaſs tubes. As this plate repreſents the horizon of the place, it is called the horizontal plate: it is divided into half-degrees, and by a vernier *c* of thirty diviſions is ſubdivided to every minute. This index is made to move round the centre of the horizontal plate in order to ſet it to zero, or point o, when that point is found to be in the plane of the meridian. The plate is moved round by turning the handle *d*. The worm-ſcrew, which works in the part *e*, may be eaſily diſengaged from the plate, when any conſiderable quantity is required to be moved at once. Preſs the handle *d* outwards, and the worm will be diſengaged. The plate F F is called the equatorial plate, as it repreſents the plane of the equator; it turns on the horizontal axis C, ſo that it may be inclined according to the latitude of the place, which is ſhewn on the latitude arch *f f*, that paſſes through the ſquare weight D: this arch is divided into 90°, and by the vernier is ſubdivided into every minute. The tube *g* is fixed to the horizontal axis, cloſe under the centre of the equatorial plate. An axis is fixed to the middle of the plate, which paſſes through the tube *g*, into a centre fixed in the ſquare weight; this axis tends greatly to ſecure the equatorial plate from ſwinging, when put into different inclinations, or when the teleſcope is turned into any oblique poſition.

The horizontal axis is made parallel to the horizontal plate by turning the ſcrew *h*, which will raiſe or depreſs that end of it. When the equatorial plate is inclined nearly to the latitude of the place, the clamp *i* may be tightened by the ſcrew at the ſide; then, by turning the finger-ſcrew *k*, it may be adjuſted to the greateſt exactneſs: the vernier *l* may be adjuſted, (in caſe any error ſhould be found,) by the ſmall ſcrews at *m*.

The equatorial plate is divided into twice XII hours; theſe

these are fubdivided into every two minutes of time, and by the vernier n again fubdivided to every four feconds. This plate is moved round by turning the handle O. The worm-fcrew which works in the edge may be difengaged from the plate, by preffing the handle O outwards.

Above this plate is the femi-circle B B, which is called the declination femi-circle; this is divided into twice 90°, and fubdivided as the other circles are; it is fixed to the axis H, which may be made parallel to the horizontal axis by the fcrew p, in the fame manner as the horizontal axis is made parallel to the horizontal plate. On this declination femi-circle the telefcope I I is fupported, and being balanced by the weight A, is moved with the greateft eafe, by means of the pinion fixed at q, which is turned with the fingers at r.

To fet the line of collimation of the telefcope at right angles to the axis H, the wires in the eye-tube s may be moved in an horizontal direction by the fcrews, which will be difcovered when the part of the eye-tube t is taken off; this piece carries the eye-glafs, and is made to flide on the part that contains the wires, that diftinct vifion may be obtained by eyes of different convexities. There are four eye-tubes, intended for different purpofes, producing magnifying powers from 40 to 60, and an eye-piece with a diagonal fpeculum is fometimes added for gaining a convenient view of ftars near the zenith. There is a combination of lenfes to the number of four in one of thefe eye-tubes, and the enlargement of the field of view thereby affords a pleafing view of the heavens. Befides thefe, there is a fliding piece containing fmoaked glaffes to guard the eyes of the obferver from the fun's rays, which glaffes are fmoaked but faintly at one end, and have the fhade of darknefs gradually increafed towards the other to fuit all ftates of illumination. There is alfo a femi-ring fitted by friction to the tube of the telefcope, near the object end, which bears an arm holding a fmall diagonal reflector to direct the light of a lamp or candle into the tube fo as to enlighten the crofs wires contained in one of the eye-tubes.

The compafs box, placed on one fide of the horizontal plate, is ufeful in afcertaining nearly the meridian line, and alfo in detecting the variation of the magnetic needle at any time. Thefe were the original parts compofing the inftrument before us; and the inftrument viewed as a whole piece of mechanifm prefents a fightly compact figure, but the circumftance of the declination-femicircle, not allowing the telefcope to reach as high as the pole, is an objection in the conftruction of this inftrument, which, we are obliged to confefs, renders it of lefs value in our eftimation than it otherwife would have been. When the inftrument is to be adjufted for obfervation, the horizontal plate is levelled by the levels in the firft place, and then the equatorial plate is made parallel to the equator itfelf, by moving the fquare weight along the arc $f f$ till the vernier l marks the latitude of the place. The directions given for the ufes of Mr. Short's inftrument will equally apply here as far as they go, but as this inftrument profeffes greater accuracy in the readings than that and Nairne's, it ufes are more extenfive; for it will ferve occafionally for an equal altitude inftrument, a tranfit inftrument, a quadrant or fextant, an azimuth circle, a theodolite, and a level.

When this inftrument is to be ufed for obferving equal altitudes, bring zero on the equatorial plate to zero on the vernier z, by the handle O, and zero on the vernier l to 90° on the latitude arch, taking care that the clamp i is made faft by the fcrew at the fide; adjuft the horizontal plate very nicely by the two levels and feet fcrews, then by turning the handles d and r bring the telefcope to the fun for the morning obfervations: in the afternoon fet again the horizontal plate level, and the declination-femicircle to the degree and minute fhewn at the correfponding morning obfervation; then bring the telefcope to the fun by turning the handle d only. In this manner feveral correfponding altitudes may be obferved on the fame day, and the inftrument ufed in the mean time for other purpofes. For the methods of making equal altitudes ferviceable in the practice of nautical aftronomy, fee problems X, XI, XII, and XIII, in our article CHRONOMETER.

To convert this equatorial into a tranfit inftrument, bring zero on the vernier l to 90° on the latitude arch, and fix the clamp i; level the horizontal plate, and bring the telefcope to the meridian mark, fuppofed to be afcertained, by turning the handles d and r: turn now the handle r alone, and it will raife the telefcope in the plane of the meridian, fo that when the fun or ftars are feen to pafs the vertical wire, they will then be upon the meridian, and the time may be noted accordingly. This application fuppofes of courfe the axes of the declination-circle perfectly parallel to the horizon plate, and alfo the line of collimation perfectly parallel to the fame plate, but at right angles to the former, when the vernier is at zero. Thefe verifications, however, we think, demand the levels to be applied nearer to the telefcope than on the horizon plate only.

When the inftrument is in the pofition juft defcribed, let the moveable vernier c be put to zero on the horizontal plate and be made faft, then turn the handles d and r to bring any celeftial object into the field of view of the telefcope, and its azimuth will be fhewn on the horizontal plate, while at the fame time its altitude will be indicated on the declination femi-circle.

When ufed as a theodolite, let this inftrument have its horizontal plate levelled as before; then bring zero on the equatorial plate to zero on the vernier z, and alfo zero on the vernier l to 90° on the arc of latitude, and fix the clamp i. Turn the horizontal plate and declination-femicircle, fo as to gain a view of the object whence the angle is to be meafured; then bring the telefcope to the fecond object, by moving the equatorial plate and declination-femicircle without the horizontal plate, and this laft plate will then fhew the meafure of the faid angle; and if there is any elevation or depreffion of the latter object compared with the firft, the declination-femicircle will point it out. The bearings, alfo, will be fhewn by the compafs, as in the common theodolite.

When zero on the femicircle is brought to zero on the vernier y, the inftrument then becomes a level; fo that by turning the equatorial plate round, an obferver may fee what objects are level with the telefcope. For this purpofe alfo, our opinion is, that the level would be much better applied parallel to the telefcope, on the declination-femicircle itfelf.

The late Mr. John Dollond had invented his object-glafs micrometer previoufly to his arrangement of the circles and other parts of his equatorial inftrument, feeing Dr. Mafkelyne gave a paper on it to the Royal Society, which was read Dec. 12, 1771, which micrometer was fometimes made an appendage to his equatorial; but as this addition is not peculiar to the inftrument in queftion, but may be applied to any other aftronomical inftrument, or even a common telefcope, we will defcribe it hereafter, under our article EQUATORIAL *Micrometer*. We muft not, however, omit a notice of the refraction apparatus belonging to the equatorial inftrument, as made by the Dollonds, an account of which was read before the Royal Society on March 4, 1779, as drawn up by Mr. Peter Dollond, and prefented by the

the aftronomer royal. *Fig.* 3. of *Plate* XII. of *Aftronomical Inftruments*, is a reprefentation of this apparatus, detached from the object end of a telefcope. The account itfelf, being fhort, will admit of being tranfcribed.

"The refraction of the atmofphere," fays the author, "occafions the ftars or planets to appear higher above the horizon than they really are; therefore a correction for this refraction fhould be made in a vertical direction to the horizon. The equatorial inftrument is fo conftructed, that the correction cannot be made by the arches or circles which compofe it, when the ftar, &c. is in any other vertical arch, except that of the meridian; becaufe the declination arch is never in a vertical pofition but when the telefcope is in the plane of the meridian.

"To correct this error, a method of moving the eye tube, which contains the wires of the telefcope in a vertical direction to the horizon, has been practifed: but as the eye-tube is obliged to be turned round, in order to move it in that direction in the different oblique pofitions of the inftrument, the wires are thereby put out of their proper fituation in every other pofition of the inftrument, except when it is in the plane of the meridian; for the equatorial wire fhould always be parallel to the equator, that the ftar in paffing over the field of the telefcope may move along with it, otherwife we cannot judge whether the telefcope be fet to the proper declination, except at the inftant the ftar is brought to the interfection of the wires, which is only a momentary obfervation.

"The method I have now put in practice for correcting the refraction of the atmofphere, is, by applying two lenfes before the object-glafs of the telefcope; one of them convex, and the other concave; both ground on fpheres of the fame radius, which in thofe I have made is thirty feet. The convex lens is round, of the fame diameter as the object glafs of the telefcope, and fixed into a brafs frame, or apparatus, which fits on to the end of the telefcope. The concave lens is of the fame width, but nearly two inches longer than it is wide, and is fixed in an oblong frame, which is made to flide on the frame that the other lens is fixed into, and clofe to it. Thefe two lenfes being wrought on fpheres of the fame radius, the refraction of the one will be exactly deftroyed by that of the other, and the focal length of the object-glafs will not be altered by their being applied before it: and if the centres of thefe two lenfes coincide with each other, and alfo with that of the object-glafs, the image of any object formed in the telefcope will not be moved or fuffer any change in its pofition. But if one of the lenfes be moved on the other, in the direction of a vertical arch, fo as to feparate its centre from that of the other lens, it will occafion a refraction, and the image will change its altitude in the telefcope. The quantity of the refraction will be always in proportion to the motion of the lens, fo that by a fcale of equal parts applied to the brafs frame, the lens may be fet to occafion a refraction equal to the refraction of the atmofphere in any altitude. If the concave lens be moved downwards, that is, towards the horizon, its refraction will then be in a contrary direction to that of the atmofphere, and the ftar will appear in the telefcope as if no refraction had taken place.

"There is a fmall circular fpirit level fixed on one fide of the apparatus, which ferves to fet it in fuch a pofition, that the centres of the two lenfes may be in the plane of a vertical arch. This level is alfo ufed for adjufting a fmall quadrant, which is fixed to it, and divided into degrees, to fhew the elevation of the telefcope when directed to the ftar; then the quantity of refraction anfwering to that altitude may be found by the common tables, and the concave lens fet accordingly, by means of the fcale at the fide, which is divided into half minutes, and, if required, by ufing a vernier, may be divided into feconds.

"It muft be obferved, that when a ftar or planet is but a few degrees above the horizon, the refraction of the atmofphere occafions it to be confiderably coloured. The refraction of the lens acting in a contrary direction would exactly correct that colour, if the diffipation of the rays of light were the fame in glafs as in air; but as it is greater in glafs than in air, the colours occafioned by the refraction of the atmofphere will be rather more than corrected by thofe occafioned by the refraction of the lens. We may conclude this defcription with the fubjoined references to *fig.* 3. of *Plate* XII. which is a view of this apparatus:

"A A, the circular brafs tube which fits on to the end of the telefcope.

"B B, the oblong concave lens, in its frame, which flides over the fixed convex lens.

"C, the circular fpirit level, which fhews when the oblong lens is in a vertical arch.

"D, the quadrant to which the fpirit level is fixed, for fhewing the angular elevation of the telefcope.

"E, the milled head fixed to a pinion, by which the whole apparatus is turned round on the end of the telefcope, in order to fet the oblong lens in a vertical arch.

"F, another pinion for fetting the quadrant to the angular elevation of the telefcope. By means of thefe two pinions the air bubble muft be brought to the middle of the level.

"*a a*, is the fcale, with divifions anfwering to minutes and half minutes of the refraction occafioned by the concave lens."

The beft portable equatorial inftrument of the Dollonds, with a 17 inches achromatic telefcope, is marked in their catalogue at 84*l.*; and their achromatic object-glafs micrometer of the new conftruction, at 21*l.*

Were we to be guided by a fimple comparifon of this inftrument and its refraction apparatus with Ramfden's, and to infer from thence which of the two was prior in point of time, we fhould be induced to place this before the other for obvious reafons, deduced from their comparative conftructions, particularly the fituation of the levels and refraction apparatus, and total elevation of the telefcope, but, on minute inquiry, we found that Ramfden's was the firft, and we can only account for the preference we are difpofed to give it, from the circumftance of his having a patent, that precluded the latter, though his brother-in-law, from adopting his conftruction. If there is any real comparative advantage in Dollond's, now that his achromatic telefcopes are generally made, it is that which arifes from the graduation of the latitude quadrant, and the lightnefs of the whole inftrument; Ramfden's weighing 59 pounds, and Dollond's only 30.

Portable equatorial inftrument by Fayrer.—We have already faid that Mr. Fayrer of White Lion ftreet, Pentonville, has the poffeffion of a large engine for cutting clock wheels, &c. the property of his uncle Troughton, which we have defcribed under our article CUTTING-*engine* as originally made by Rehe: this artift, during fome of his hours not occupied by his engine, makes mathematical and philofophical inftruments, and among others he has lately conftructed a portable equatorial inftrument for Mr. Lowe of Iflington, which, we think, merits a place in our collection, as being not only an original one, but as poffeffing advantages likely to recommend it to public attention. This portable inftrument differs from its predeceffors chiefly in thefe refpects; it has no azimuth circle fixed in a permanently horizontal pofition; it has its equatorial circle divided into degrees and

and alfo into time, with two verniers reading at oppofite points, one vernier reads to the accuracy of 30″ of fpace, and the other to 2″ of time; this circle has a long axis paffing through a tube, like Troughton's large Coimbra inftrument hereafter defcribed, from which probably this part of the conftruction was taken; it may, therefore, be placed in a horizontal direction by its axis being placed firmly vertical, in which fituation it becomes an azimuth circle; the telefcope is fixed on the end of the axis of the declination circle, which idea correfponds with, and may have been borrowed from, Nairne's conftruction; this pofition allows any elevation of the telefcope that may be required, and keeps the obferver's eye at a diftance from the other parts of the inftrument, but injures the uniformity of the appearance of the inftrument as a whole; the levels are applied, one on the common axis of the telefcope and declination circle, and the other at right angles thereto, as a chord to the declination circle; and laftly, the declination circle is complete, with oppofite verniers reading, like the other oppofite verniers, to an accuracy of twenty or thirty feconds, according to the dimenfions of the graduated circles, when nicely divided on Troughton's dividing engine. From fuch conftruction it is eafy to perceive, that this little inftrument poffeffes the advantage of having its telefcope reverfed as well as its circles with refpect to the oppofite verniers, which property greatly enfures the accuracy of the adjuftments. After thefe previous remarks it will fuffice to give a brief detail of the parts of this inftrument as reprefented in *fig.* 4. of *Plate* XI. *of Aftronomical Inftruments.*

A, A, A, are three adjuftment fcrews for levelling the circular ftand to which the feet are faftened; B, B, are a pair of triangular frames fixed firmly to the faid circular ftand, and fupporting the pivots of the horizontal axis, round which the tube C, attached to the axis, moves; at the fummit of the more vifible triangular frame B is an adjuftable or fliding part Y, like that of a tranfit inftrument, by which the telefcope may be adjufted into the meridian, when previoufly placed nearly fo by the feet. The graduated circle D, which may be either an equatorial or azimuth circle, accordingly as its axis is inclined or vertical, has a fteel axis nicely fitted to revolve in the tube C, in any pofition of this tube with refpect to the horizon; but the double vernier bar is faft to the inferior end of the tube, as may be feen in the figure: the pofterior pivot of the horizontal axis, borne by the triangular bars B, B, projects, and has firmly attached to it the quadrantal piece E, partly hidden from fight in our view of the inftrument; this quadrantal piece is graduated, and reads by a vernier as minutely as the other circles; it ferves to fet the equatorial axis parallel to the earth's axis, in which fituation it may be clamped faft, as well as in a vertical, or indeed any other pofition, by a clamping fcrew out of fight in the prefent pofition applying to the quadrantal arch; F F is the declination circle, with its horizontal axis refting on a pair of vertical fupports, carried by the upper end of the polar axis, that paffes through the tube C, fo that, when the telefcope, attached to the axis of the declination circle, has any horizontal or rather oblique motion the circle D moves with it, and indicates the diftance moved along the equator, or in a circle parallel to it, when the polar axis is properly adjufted and clamped faft. The double vernier bar is on the pofterior plane of the declination circle, and may therefore be viewed after an obfervation without danger of altering the pofition of the telefcope. The level on the declination axis may be conveniently adjufted by turning the circle D half round, and by making the bubble keep the middle of the tube in both fituations, which may be done, partly by the fcrews A, A, A, and partly by the fcrews of rectification of the level itfelf; and zero of the declination circle may be put to zero on the verniers when the circle D is truly placed in an horizontal pofition, in which fituation alfo zero of the quadrant E muft coincide with zero on its vernier. Under thefe circumftances the levels will be competent to effect all that is required, and in the beft way; and the inftrument will poffefs all the various powers afcribed to a portable equatorial inftrument when converted into the other inftruments.

Univerfal equatorial inftrument by Mr. Ed. Troughton.— The equatorial inftruments we have hitherto defcribed are all, properly fpeaking, portable, and confequently of a fize not profeffing great accuracy in their readings. We now come to an inftrument of larger dimenfions, and one having its parts fo arranged and adjufted, as to entitle it to rank among the firft clafs of inftruments employed in modern obfervatories. It is of the univerfal kind, and may be called moveable (in oppofition to fixed) rather than portable, as it ftands feven feet high, and is therefore too bulky to be carried by one man. It was finifhed in the year 1788 for the late Mr. J. H. Magellan, and fent by him to the univerfity of Coimbra in Portugal, where we have faid it has been unfortunately fhut up in the dark. *Plate* XIV. of *Aftronomical Inftruments*, exhibits a perfpective drawing, fhewing all the principal parts of this excellent inftrument in its equatorial pofition, which we propofe to defcribe in the order of their afcent from the ground.

It will not be neceffary to give any letters of reference to this inftrument, as it is prefumed the reader, who has made himfelf acquainted with the component parts of the preceding inftruments, cannot be at a lofs to accompany us in our defcription of the prefent inftrument without the aid of alphabetical references. The bafis is of mahogany, confifting at the inferior part of a ftrong tripod, and at the fuperior of a circular table; thefe are connected by three pieces diverging from the table downwards, and connected by diagonal croffing bars: this frame work is ftill further united by three vertical pillars near the centre, one of which is omitted in the drawing, in order to expofe to view a more effential part. Immediately above the table, and parallel to it, is a very ftrong azimuth circle of brafs, 24 inches in diameter; this circle, however, is not in contact with the table, but refts on its conical axis, that paffes through a collar of brafs, attached to the centre of the table, and is fupported on its conical point on a ftud faft to the centre of the tripod. This length of bearing, like that of Mr. Nairne's defcending axis, keeps the azimuth circle fteady in the horizontal line both in motion and at reft, which is a circumftance of the utmoft importance. The tripod is furnifhed with three ftrong feet fcrews for the adjuftment of the azimuth circle into a true horizontal pofition; and three handles, with each a Hook's joint, are attached refpectively to thofe fcrews, that the adjuftments may be made with the body in an upright pofition. or nearly fo. The apparatus for quick or flow motion is fcrewed faft to the table, and clamps to the azimuth or horizontal circle. Two oppofite verniers, reading to the accuracy of 10″, are attached to the edge of the table, but in fuch a way that they are of ready adjuftment to an exact bifection of the circle, in cafe the wood work of the table and frame fhould alter its figure by warping in the leaft degree; otherwife the wooden frame, as a pedeftal, would have been objectionable. Upon the plane of the faid azimuth plate are erected two vertical fupporters of frame work, fomewhat refembling the appearance of two chair backs; which fupporters confequently have a motion in azimuth whenever the circle is turned round; they are 19 inches apart from each other, and an horizontal axis of this length binds them together at their upper extremities; the

the poſterior ſupporter has an adjuſtment apparatus for bringing the axis perfectly horizontal, which apparatus is hidden in the drawing behind the ſaid ſupporter. At the middle of the horizontal axis called alſo the axis of latitude, is a cubical part ſimilar to that in the axis of a tranſit inſtrument; to this the long braſs ſocket or tube, that embraces the polar ſteel axis, is made faſt, and is ſet exactly at right angles thereto by conſtruction. The polar axis, that paſſes down through this ſocket, has the equatorial or hour circle attached firmly to it, at right angles alſo by conſtruction, at its inferior end; and to its ſuperior end above the axis of latitude, is fixed a ſmall platform, of the ſhape of a parallelogram, to ſupport the ſuperſtructure not yet deſcribed. Any additional weight may be fixed to the lower end of the polar axis, that the ſuperincumbent materials may require to form an exact equipoiſe in any poſition; the ſiderial time, depending on the horary angles, is read by oppoſite verniers, fixed to the inferior end of the long polar ſocket; one of which only can be ſeen in the figure of the inſtrument, as it ſtands in the drawing: the equatorial circle is divided, ſo that a ſingle ſecond of time is diſtinctly read by the verniers; and if the application of three verniers had been thought of when this inſtrument was conſtructed, the inequality of the diviſions would have been corrected thereby ſtill more perfectly, as well as the excentricity of the circle, if any exiſts; which obſervation will equally apply to the azimuth and declination circles. Two quadrants are made faſt to the pivots of the axis of latitude, or horizontal axis already deſcribed, having their poſition juſt within the vertical ſupporters of the ſaid axis, and conſequently move with it, when it has any motion: theſe quadrants are divided, one of them agreeably to the uſual diviſions of the circle, and the other by particular deſire into 96 equal parts with its ſubdiviſions, and the two verniers are reſpectively placed on the contiguous ſupporters of the axis; the uſe of the quadrants is to fix the elevation or inclination of the polar axis agreeably to the latitude of the place of obſervation; that is, parallel to the axis of the earth; which poſition requires to be well verified when the inſtrument is uſed. Between the feet of the ſupporters, and at right angles to each other, are placed, on the plane of the azimuth circle, two nicely ground ſpirit levels, one of which is about half viſible, and the other ſtill leſs, which ſerve to place this circle perfectly horizontal in every direction, by the aid of the feet ſcrews: and near the centre of the ſame circle may be ſeen an apparatus for adjuſting and fixing the polar axis in any given degree of inclination from a horizontal to a vertical poſition, which it does with equal convenience, accuracy, and ſteadineſs: the lower end of this apparatus may be ſcrewed to any pair of the parallel holes made in the plate, farther from, or nearer to, the centre, as the quantity of inclination may require; while the upper end is attached to a broad ring embracing the ſocket of the polar axis; and about the middle is an adjuſtment ſcrew, juſt above a Hook's joint, that allows the ſcrew to act freely in any poſition of this apparatus. The ring that embraces the long ſocket of the polar axis will ſlide along it till the ſtem of the ſaid apparatus, into which the ſcrew acts, ſtands at right angles to the polar axis, in which ſituation its poſition will be firm and ſteady, as the axis can have no lateral or vibratory motion, by reaſon of its union with the axis of latitude. From this deſcription of the apparatus in queſtion it is eaſy to perceive that the nearer the polar axis approaches to a vertical ſituation, the farther from the centre of the azimuth plate muſt the fixing ſcrews be inſerted, and *vice verſâ;* alſo the lower towards the equatorial circle muſt the ſliding ring be, that embraces the ſocket; as well as the ſteadier the axis ſo fixed. Again, upon the platform on the ſuperior end of the polar axis, already noticed, are erected a ſecond pair of ſupporters, at the diſtance of 15 inches from each other at the bottom, and bound together at the ſame diſtance at top by the axis of the declination, which conſequently is 15 inches long; theſe ſupporters, which partake of any motion given to the equatorial circle, bear the declination or meridian circle, and teleſcope ſurmounted over all. At the upper end of one of theſe laſt named ſupporters is an adjuſtment for ſetting the declination axis at right angles to the polar axis, which is a very eſſential adjuſtment; the apparatus for producing quick or ſlow motion is faſt to the platform, the milled nuts of which apparatus may be ſeen under the declination circle; alſo the oppoſite verniers for reading off the angles of declination are attached to the ſaid platform, and both faces of the circle are divided, like the quadrants, one according to common uſage, and the other into 384 diviſions with their ſubdiviſions, which, at the time of the conſtruction, were conſidered by Mr. Magellan as the beſt check on the accuracy of the verniers that read off to 10″. The elevated ſituation of the teleſcope, which is $3\frac{1}{2}$ feet long, is ſufficiently explained by the drawing, where ſome of the ſupporters are ſeen attached to the declination axis, and ſome to the circle itſelf; this elevation was given, that the eye-tube might keep clear of the ſupporters and other parts of the mechaniſm, when a ſtar or planet is followed along the equator, or other circle parallel thereto; and as the declination circle is complete, the teleſcope will riſe to any degree of elevation that may be required, while the circle will meaſure that elevation. As a tangent to the upper edge of the circle, and parallel to the line of collimation of the teleſcope, is a very ſenſible ſpirit level with proper adjuſtment ſcrews: and on the upper ſide of the tube of the teleſcope are mounted two microſcopes, the uſe of which is to obſerve the coincidence of a fine plumb-line with points made on the tube, when placed in a vertical poſition for the purpoſe of levelling the declination axis; and indeed many of the adjuſtments of this inſtrument may be verified both by the plumb-line and levels. There are various eye-pieces to anſwer different purpoſes, both with and without diagonal reflectors for high altitudes, which it is not neceſſary to deſcribe here minutely, as they form no diſtinguiſhing feature of the inſtrument. Laſtly, the refraction apparatus placed at the eye end of the teleſcope, as made by Ramſden, was an appendage of this inſtrument, and by moving the adjuſtable croſs wire in the focus of the eye glaſs a quantity equal to the refraction or refraction and parallax taken together, rendered the calculations from the tables unneceſſary, by converting mechanically the apparent into the true altitude of any obſerved body. The reading of the ſubdiviſions of a circle by means of a microſcopic micrometer had not been adopted at the period this beautiful and uſeful inſtrument was conſtructed, otherwiſe its powers would have been made more extenſive than they now are by the verniers alone.

It is hardly neceſſary to add, that the powers of this univerſal inſtrument, as far as they go, may be readily and conveniently applied to almoſt all the purpoſes of practical aſtronomy, as well as of land-ſurveying and levelling; ſeeing it has all the properties aſcribed to the preceding inſtruments, but in a degree approaching nearer to perfection. This is the only inſtrument of the conſtruction here deſcribed that ever was made on ſo large a ſcale, but three or four others of an inferior ſize have ſince been made on the ſame.

fame plan, that, as portable inftruments, can hardly be furpaffed unlefs by the adoption of triple verniers, which are of recent origin.

Adjuftments.—1. In the firft place, the *telefcope* muft have its wire-plate turned round into fuch a pofition, that the middle vertical wire will coincide with a diftant mark throughout the whole field of view, as the telefcope is elevated or depreffed, and then the object-glafs muft be flided in or out, till a ftar of the fecond magnitude is feen as diftinctly as poffible, to prevent parallax at the wires.

2. In the next place, make the *azimuth circle horizontal* by means of two levels, adjufting one half of the error, produced by turning the circle half round, by means of the feet-fcrews, and the other half by the levels, as with the preceding inftruments.

3. Make the *polar axis perpendicular;* clamp it nearly fo, and turn the declination circle round till the bubble ftands in the middle of its level, now turn the upper part half round on the polar axis, and, if there is an error, correct one-half of it by the apparatus acting on the polar axis, at the azimuth plate, and the other half by turning round the declination axis by the flow motion. When the error has difappeared by a repetition of this procefs, turn the declination circle round the polar axis juft fix hours, and bring the bubble to the middle by the adjuftment at the top of one of the fupporters of the latitude axis: when this is done the azimuth and equatorial circles will be parallel to each other, and their axes perpendicular to the horizon; and, of courfe, the level near the telefcope will keep its bubble at the middle, as well as the other levels, while either or both of thefe circles revolve. Here the verniers of the latitude-quadrants may be fet to their refpective zeros.

4. The declination axis muft be fet *level*, or at right angles to the polar axis. In order to do this, fet the telefcope perpendicular by fixing the declination circle with its vernier at 90°, and put on the plumb-line; by the motion of one of the points, which is *adjuftable*, and alfo by the proper motion of the plumb-line; make the latter bifect both the points under the microfcopes; reverfe now the telefcope by turning the declination circle to the oppofite 90°, fufpend the plumb-line from the contrary end of the telefcope, and by the proper motion of the line make it bifect the *fixed* point; then half the error that appears at the adjuftable point muft be corrected by that adjuftment, and the other half by that at the top of the fupporter of the declination axis.

5. The line of collimation of the telefcope muft next be adjufted, both as it regards the right afcenfion and declination. In order to do this, let the upper end of the polar axis, and the object-end of the telefcope, be pointed to fome fixed object a little above the horizon, the declination circle being firft put with 90° to the zero of its vernier, the hour index placed at XII, and the telefcope above the polar axis; bring now the centre of the crofs-wires to the object fixed on, by raifing or lowering the polar axis in conjunction with a motion in azimuth, and read off the degrees, minutes, and feconds fhewn by the verniers of the azimuth circle and quadrants refpectively; in the next place, fet the polar axis nearly vertical, and place the hour circle at the oppofite XII, and point the polar axis, as before, to the faid fixed object, the telefcope being now below it; move the inftrument as before, by a compound motion of the polar axis and azimuth circle till the interfection of the middle wires coincides with the object before fixed on and ufed, and read off, as before, the degrees, minutes, and feconds both on the azimuth circle and quadrants: in this fituation of things, fet the azimuth circle to the *mean* of the two obferved azimuths by taking half their fum, and alfo the polar axis to the *mean* of the two obferved altitudes or inclinations of the polar axis; in this pofition of the inftrument, let the telefcope be carefully moved by altering the fcrews that faften it to the circle, until the vertical central wire coincides with the original object, and the adjuftment for right afcenfion is finifhed. Again, move the telefcope, by altering it in declination, till the horizontal wire cuts the fame object, and adjuft the verniers of the declination-circle to the points 90° and 96 parts refpectively on its oppofite planes. If, however, the object is not a very diftant one, the above directed adjuftment in declination will not be quite correct, becaufe the telefcope ftands *higher*, when *above* the pole than it is *below;* confequently, when this adjuftment is made by means of a near object, two marks fhould be ufed on that object, the diftance between which muft be double the meafure from the centre of the declination axis, to the line of collimation of the telefcope; otherwife a fmall angle will be formed at the object, by the two lines of fight, which angle will be fubtended by the double diftance in queftion; but when the object is at an infinite diftance this fmall fubtenfe is reduced in effect to nothing, and the fame mark therefore will do in both the pofitions of the telefcope.

6. To adjuft the hour index let the point 90° of the azimuth circle be turned to an object of fmall altitude; let the polar axis be made horizontal; and the telefcope be fet to 0° of declination: in this pofition the hour circle becomes vertical, and the altitude of the object may be taken by it, which muft be read off in time from VI hours: turn now the inftrument half round in azimuth, and make the telefcope look towards the object by turning round the polar axis; take another altitude in this pofition, and read off what is indicated from the oppofite VI hours, and the mean of thefe two altitudes is the exact place where the adjuftable index muft have its zero placed to be in its true pofition.

The apparatus for correcting the horary angle on account of refraction confifts of a fmall quadrant and level for taking altitudes, which are moveable round the axis of vifion, and therefore determine very readily the elevation of the telefcope in any given pofition; alfo the eye-piece and wires of the telefcope being moveable by means of a nice micrometer fcrew, may be fet with great accuracy to the refraction correfponding to the altitude of the obferved body as determined by the fmall quadrant and level.

The chief advantages refulting from the conftruction of the equatorial inftrument juft defcribed, are, firft, that it affords a firm fupport to a very long, and, therefore, powerful telefcope; and, fecondly, that the great range of polar diftance beyond 90° of declination renders an obfervation with the telefcope below the polar axis unneceffary.

As the rules we gave for ufing Ramfden's portable inftrument, as extracted from profeffor Vince's treatife, are not exemplified by actual obfervations, and as rules, however plain, are not always underftood without the illuftration of appropriate examples, we cannot finifh our account of the prefent inftrument better than by fubjoining to the rules given by the Hon. Mr. M'Kenzie his examples given at full length, when adapted to our purpofe, by which the reader will be led to have an idea of the practical application of the obfervations to the various purpofes of aftronomy. The rules were originally written as directions for the ufe of Ramfden's inftrument, but after our account of the adjuftments,

ments, they are equally applicable to the inſtrument under our immediate conſideration.

Obſervation 1. *To find the latitude of the place by the ſun, or any known fixed ſtar.*—The inſtrument being perfectly adjuſted in all its parts according to the directions given,—

Make the polar axis perpendicular to the horizon, and when the ſun approaches his meridian altitude, elevate the teleſcope to that altitude, and adjuſt the refraction apparatus as above directed: then follow the ſun by moving both the equatorial and declination circles (if neceſſary), and keeping the refraction piece always adjuſted till he is at his greateſt altitude; the vernier of the declination circle will then give you his meridian altitude; from which ſubtract his declination, if it be north, or add it if it be ſouth, the remainder if north, and the ſum if ſouth, is the height of the equator, that is, the complement of your latitude, which being ſubtracted from 90°, gives your latitude.

Example.

Sun's declination ſuppoſed - -	6°	57′	37″	North.
Meridian altitude of his centre obſerved	45	6	29	
Subtract his declination -	6	57	37	
Height of the equator or co-latitude	38	8	52	
Which ſubtracted from -	90	0	0	
Gives your latitude -	51	51	8	

If inſtead of obſerving the altitude of the centre, you obſerve that of the upper or lower limb of the ſun, you muſt allow for the ſemi-diameter of the ſun, which allowance you find in the Nautical Almanac. Alſo, if the refraction apparatus were not uſed, the tables for refraction and parallax in altitude muſt be uſed to reduce the apparent to the true altitude.

Obſervation 2. *To find the meridian by one obſervation only.*—Elevate the equatorial (or hour) circle to the co-latitude of the place, ſet the declination circle to the ſun's declination for the day and hour required; and adjuſt the refraction apparatus, then move the azimuth and hour circles both at the ſame time (either in the ſame or a contrary direction) till you bring the centre of the moveable wires (the vertical being truly perpendicular) exactly to cover the apparent centre of the ſun; that done, the centre of the fixed wires will be in the true centre of the ſun, the index of the hour circle will then give the apparent or ſolar time at the inſtant of obſervation. Thus you get the time though the ſun be at a diſtance from the meridian. Then turn the hour circle till the index points preciſely at 12 o'clock, and lower the teleſcope to the horizon to obſerve ſome mark in the centre of the teleſcope, and that is your meridian found by one obſervation only.

The beſt time for finding the meridian is, when the ſun is three hours diſtant from the meridian on either ſide of it.

Obſerve, that when you have once a true meridian fixed, you need make no uſe of the refraction apparatus in any obſervation, except to ſet one of the moveable wires perpendicular.

The meridian and ſolar time may be found in like manner by a fixed ſtar, whoſe declination and right aſcenſion are known.

Obſervation 3. *To obſerve a ſtar or planet in broad daylight, at any time when it is above the horizon.*—The table of right aſcenſions, declinations, &c. of Dr. Maſkelyne's 36 principal fixed ſtars, under the articles Chronometer and Declination, gives you the times of their tranſits over the meridian in ſiderial time.

Elevate the equatorial circle to the co-latitude of the place, and ſet the vernier of the declination-circle to the ſtar's declination, then adjuſt the refraction piece; look into the table for the time of its meridian tranſit or right aſcenſion; then take the time of the ſaid tranſit from the time of your obſervation as given by the ſiderial clock, borrowing 24 hours if neceſſary; this difference is the hour to which you muſt ſet the hour index of the equatorial circle, and the ſtar will then appear in the teleſcope.

Example 1.—Let it be required to place the teleſcope of the equatorial inſtrument to obſerve Capella on Sept. 30th 1809, exactly at 9h 0m 0 by a ſiderial clock well regulated?

Declin. of Capella from Tab. III. under Chronometer, 1806 -	45°	47′	5.″88	North.
3¾ years of annual variation add from ditto - - -	0	0	17.14	
True declination -	45	47	23.02	North.
Right aſcenſion or ſiderial time of tranſit from ditto, 1806 -	5h	2m	22.s62	
3¾ years annual variation add -	0	0	16.55	
True time of tranſit -	5	2	39.17	
Which ſubtract from ſiderial time of obſervation - - -	9	0	00.00	
And there remains the interval ſince the tranſit for the index to be put to	3	57	20.83	

Note, if the clock ſhews ſolar time, it muſt be converted into ſiderial time by problem VI. under our article Chronometer, and then the work may be done as here directed.

Example 2.—Let it be required to find Arcturus on April 1ſt, 1810, when the ſiderial time is 10h 30m?

Declin. of Arcturus 1806 -	20°	11′	59.″41	North.
4¼ years annual variation ſubtract	0	1	19.85	
True declination -	20	10	39.56	North.
Right aſcenſion or ſiderial time of tranſit - - -	14h	6m	48.s83	
4¼ years annual variation add -	0	0	11.59	
True time of tranſit -	14	7	0.42	
Which take from the time of obſervation, borrowing 24h - -	34	30	0.00	
The remainder is the place of the index	20	22	59.58	

In this obſervation Mr. M'Kenzie uſed a table of meridian paſſages given in ſolar time, which required the acceleration of ſiderial or ſolar time to be uſed; but as the principal catalogues give the paſſages in ſiderial time, we have adapted his rule thereto.

Obſervation 4. *To find the right aſcenſion and declination of a planet, comet, or fixed ſtar.*—The equatorial circle being elevated, as before, to the complement of the latitude of the place, move the declination and equatorial circles till the planet or comet is in, or near the centre of the field of the teleſcope, then adjuſt the refraction piece, and bring the centre of the moveable wires to cover the planet, the vernier of the declination circle will then give you the declination of the planet, and the vernier of the equatorial circle will give you the hour of the planet, &c.; then your regulator or clock will give you the sun's time or hour of the day. Take the difference between the sun's time and the planet's time; and if the planet's time be less than the sun's time, add that difference to the sun's right ascension at the time of observation, (which you find in the Nautical Almanac,) the sum (rejecting 24 hours, if it exceeds that number) is the right ascension of the planet, &c. Again, if the planet's time exceeds the sun's time, subtract the difference from the sun's right ascension; the remainder (adding 24 hours to the sun's right ascension, if necessary,) is the right ascension of the planet, &c.

Example 1.

Observed a star whose time by the equatorial circle is	2^h	18^m	3^s	P.M.
Sun's time as given by the regulator, *viz.*	9	44	40	P.M.
Difference between the two	7	26	37	
As the star's time is less than the sun's, add that difference to the sun's right ascension	20	57	9	
Reject 24 hours from	28	23	46	
Right ascension of the star is	4	23	46	

Its declination (by the vernier of the declination circle) is 16° 2′ 50″ north.

Example 2.

Observed a star whose time by the equatorial circle is 10^h A.M. (that is, astronomically)	22^h	0^m	0^s
Sun's time as given by the regulator, *viz.* 5° 55′ 4″ A.M. (that is, astronomically)	17	55	4
Difference between the two	4	4	56
As the star's time exceeds the sun's, subtract that difference from the sun's right ascension	10	38	58
Remains the right ascension of the star	6	34	2

Its declination (by the vernier of the declination circle) is 16° 25′ 1″ south.

Observation 4. *To find the longitude at land by the right ascension of the moon.*

Observed the centre of the moon on the moveable wire set vertical, either in or out of the meridian; time given by the equatorial or hour circle, suppose	2^h	28′	2″
Sun's apparent time by the regulator	6	0	0
Difference between those times	3	31	58
Add that difference to the sun's right ascension at 6 hours (because the moon's time is less than the sun's time, for had it been greater, the difference must have been subtracted)	8	25	27
And you have the moon's right ascension at the place of observation at 6 hours	11	57	25

Another method of making the above observation.—The centre of the moon being observed in the same manner at six hours P.M. as before directed, let the instrument remain in the same position it was in (only altering the declination) till a known star comes to the vertical wire, which will happen (suppose) in one hour after, *viz.* at 7 hours, then subtract that one hour of difference in time of transits, with the addition of 9″ 86dec for the acceleration corresponding to one hour, that is, subtract 1^h 0′ 9″ 86dec from the AR of the star, supposed to be 12^h 57′ 35″, the remainder is the moon's AR at six hours P.M. at the place of observation.

Star's right ascension	12^h	57′	35″
Difference in siderial time, (see CHRONOMETER, Tab. I.)	1	0	9.86
Moon's right ascension at 6 hours P. M. at the place of observation.	11	57	25.14

Then find, by the Nautical Almanac, at what time at Greenwich the moon has the same right ascension as that now observed.

Moon's right ascension at Greenwich at noon is	11^h	43′	20″
Ditto at midnight	12	10	36
Difference in those 12 hours	0	27	16
Moon's right ascension at Greenwich at noon	11^h	43′	20″
Moon's right ascension at 6 hours, at the place of observation	11	57	25
Difference between them	0	14	5

Proportion for finding the time at Greenwich.

As 27^m 16^s : 14^m 5^s : : 12^h : 6^h 12^m 0^s

So that the time at Greenwich, when the moon has 11^h 57′ 25″ of right ascension, is 6^h 12^m 0,′ that is, 12^m later than at the place of observation, which is therefore 12^m of longitude west from Greenwich.

Sir George Shuckburgh's fixed equatorial instrument.—A B, C D, E F, G H, (*Plate.* XV. *of Astronomical Instruments,*) are four columns, says sir George Shuckburgh, composed of hollow brass tubes 3½ inches in diameter, and five feet ten inches long; these, with two others, one of which appears in part at I K, and the other partially hidden behind E F, are firmly fixed, at their upper ends, to a circle of bell metal B D F H, and, at their lower end, to an inverted truncated hollow cone, L L L, of brass, in height two feet, and in diameter, at the base A G, one foot nine inches. The cross pieces, or tubes P, P, as likewise O, O, and O, O, serve to connect the columns more strongly together, and prevent their bending. These several parts constitute the principal axis of the instrument, the lower end of which terminates in a steel point or cone, resting in a hollow conoid of bell metal, in such manner that the apex of the former does not reach to the bottom of the latter, but the place of bearing, or of friction, is (it may be) about two tenths of an inch from the extremity of the cone; the other end of this axis finishes in a cylindrical pivot N, of about 1¼ inch long, and one inch in diameter, turning in a Y of bell metal. The entire length of this axis is eight feet four inches, the lower end being supported by an iron frame 3, 4, 5, 6, 7, 8, which is firmly fixed below the floor, into brick-work, and by means of two iron bars, one of which is seen at 28, and the other on the opposite side, not visible in the drawing, is kept

kept fecure from any motion, eaftward or weftward; the lower part of this frame, to about one foot high, is inclofed by a mahogany box or cafe 9, 10, the top of which is entirely covered up, and ferves as a die or bafe to this end of the inftrument. The other extremity of this long axis, *viz.* the pivot N, refts upon the ftrong iron fupport 29, 30, 31, ftanding 10 feet above the floor, made of maffive pieces of caft iron, $2\frac{1}{2}$ inches wide, and $\frac{1}{2}$ an inch thick, and held firmly by bolts and nuts as in the figure: 32, and 33, are the places where two iron bars, nearly at right angles to each other, and at $\frac{1}{2}$ right angles to the meridian, are fcrewed, to connect this upright fupport with the walls of the building, and going through the bricks, are held faft by iron collars and nuts on the outfide of the wall; thefe bars, or braces, not in the figure, refift any tendency from the weight or preffure of the inftrument, to pufh the fupporter 29, 30, and 31, out of its upright pofition; and being at right angles to each other, ferve to keep it fteady with refpect to any lateral force that may accidentally be applied. The lower part is continued below the floor, and firmly fixed with mortar and lead into the brick work of an arch. The bottom is fhut up in a box or plinth of mahogany, 34, 35, as has been mentioned in the defcription of the frame fupporting the other end of the axis at 9, 10. Near the lower end of the principal axis L N, are inferted 10 concentric brafs cones, or radii, *a a*, *b b*, *c c*, *d d*, *e e*, carrying on their extremities a graduated brafs circle, of $49\frac{1}{2}$ inches dimeter, at right angles to the principal axis already defcribed; this circle has two fets of divifions, one of points, and one of lines, each into degrees, and every ten minutes, and the intermediate minutes and feconds are read off by the microfcopes W and X, with a moveable wire, and micrometer fcrew, fuch as has been defcribed in general Roy's account of his inftrument for meafuring horizontal angles. (See Philofophical Tranfactions, vol. lxxx. p. 145.) The circle juft mentioned, is inclofed by a circular frame, or rail of mahogany, 14, 15, which is fupported by ten baluftérs, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, (17 and 24 being concealed) and ferves to protect the brafs circle from any accidental injury in paffing by it, without depriving it of expofure to the general temperature of the room. It at the fame time affords means of fupport to a fmall lamp, 13, which, by reflection from the perforated fpeculum at the bottom of the microfcopes, to be feen in that marked X, throws light upon the divifions by night: 26, 26, and 27, are iron rods that, by being attached to the wooden cafe, 9, 10, give fteadinefs to the upright baluftérs, and the circular frame that they fupport: 1 and 2 are large ftout brafs cones firmly fixed into the frame, 3, 4, 5, 6, 7, 8, before mentioned, and whofe ufe is to carry the microfcopes W, X. Any degree of pliancy or flexure in thefe cones would be readily difcernible in the microfcopes, and extremely detrimental to the obfervations; they are therefore made as ftiff as poffible: δ is a plane forming the upper fide of the frame, 3, 4, 5, 6, &c. and confifting of three plates, two moveable in grooves; and one fixed, furnifhed with fuitable fcrews, one giving the extremity of the axis a motion upward or downward, and the other a motion to the right or left. This latter is procured by a rod paffing through the cone, 2, one end fcrewing into the plate below L, near the centre, and the other turned by an occafional handle fixed on, near X, the former motion, *viz.* of elevating or depreffing the axis, is procured by a handle fixed on to a fcrew near ε: Q R is another circle of the fame dimenfions with the former, graduated in the fame manner, and held together by eight conical radii, *f f*, *g g*, *h h*, *i i*, firmly fcrewed to a circular centre-piece, which ferves as a bafe to a large conical axis, two feet three inches long, one fide of which is feen at U, and its exterior extremity near V, with its fliding plate and fcrews for adjuftment. Clofe behind the graduated circle, and at right angles to this axis paffing through it, lies the telefcope T S, $5\frac{1}{2}$ feet long. This circle is likewife furnifhed with two microfcopes and micrometers, as in the equatorial circle, one of which is feen at full length at Y, and Z, the eye-tube being at Y, and the object-glafs, with the perforated fpeculum, to throw light at Z; the other microfcope, on the oppofite fide of the circle, is not fo prominent in the drawing, being fomewhat fore-fhortened at Z. Near T, α, α, α, α, α, is an hexagonal lozenge, compofed of fix brafs rulers, firmly fixed to the columns A, B, and E, F, and fupporting the lower end of the microfcopes, as the pieces $\beta\,\beta$, $\beta\,\beta$, in like manner fuftain the upper end. By thefe means, the wire in the field of the microfcopes becomes a fixed immoveable index, and after proper adjuftment, an exact diameter of the circle, whilft the telefcope, together with the circle, turns round the conical axis beforementioned. At P is a fpirit level, paffing through the centre plate of the conical axis at right angles to the telefcope, fupported by a cock at each end, one of which appears at *k*; this cock is placed on the cone U, and by means of a fmall-toothed wheel and pinion, the level is made to revolve round its own axis, fo that the fame fide of the level may readily be brought uppermoft, whatever pofition the circle be put into; it is alfo furnifhed with all neceffary adjufting fcrews. It will readily be feen, that a telefcope thus fitted up, will have all the properties of a tranfit inftrument, while the graduated circle will poffefs thofe of a meridian quadrant. For this purpofe *l m* is a ftout brafs tube, inclofing a ftiff iron rod, turning upon two fine fteel points, adjufted by proper fcrews, parallel to the line of fight of the telefcope: this rod is attached to a fpirit level of great fenfibility, lying below it, which, with the rod, turns round upon the fteel points juft mentioned, and is in fact a hanging level of the beft conftruction. At the eye-end of the telefcope S is a peculiar apparatus, to correct the effects of refraction and parallax, when an obfervation is made out of the meridian: it is compofed of two levels, a fmall quadrant of altitude *n o*, and a femicircle divided with its vernier to every 5′ on the breech plate of the telefcope, the exterior eye-tube having a circular motion by a wheel and pinion at *o*, independent of the tube that carries the crofs wires; by this means the angle of the horary and vertical circles may at any time be found, together with the altitude of the object, and then by the refolution of two right-angled triangles the refraction and parallax in right afcenfion and declination will be obtained: *t*, *u*, are two handles to a Hook's joint at *x x*, which turning an endlefs fcrew at *w w*, give a gradual motion to the telefcope in right afcenfion or declination; and this motion can at any time be reftrained by a clamp at *q*: 11, 12, (the latter not feen,) are two fupporters to the clamp and endlefs fcrew. The handles *t*, *u*, are hung on to any part of the inftrument by means of the line and wire *v*, *v*, and are thus kept within the obferver's reach. Near *r* and *s* are two microfcopes, placed on oppofite fides of the circle Q R, and at right angles to the line of fight of the telefcope, but are hidden by the columns in our figure; they are of ufe only when the plumb-line, fufpended from the roof of the obfervatory, is ufed in preference to the level *l m* above defcribed, either for adjufting the inftrument, or obferving a meridian altitude, in which cafe the line muft bifect the centres of both microfcopes: *y*, and *z*, are thin perforated brafs plates, attached to the cover that goes on the object-glafs, and by occafionally turning them over it, change the aperture to $\frac{1}{2}$ or $\frac{1}{4}$. The crofs wires, of which there are

three

three vertical and one horizontal, within the eye-tube S, have all the requifite adjuftments by fcrews, &c. as in a common tranfit inftrument, and are enlightened at night by a lamp fixed near to one end of the declination axis U, *viz.* that oppofite the end V; but this part of the apparatus is hidden behind the axis and the telefcope, except the weight *i*, which is a counterpoife. This lamp throws a light through the conical axis, which is perforated at that end on purpofe, on a fpeculum in the centre of the telefcope, placed at $\frac{1}{2}$ right angles to the axis of the object-glafs, and from thence reflected to the crofs wires. This fpeculum, which is an elliptical diaphragm, is perforated to permit all the rays from the object-glafs to pafs unobftructed to the eye. The contrivance has been mentioned by Mr. Vince (Practical Aftronomy, p. 80.) From what has been already defcribed, it muft now be evident that if the principal, or polar axis, as it has been called, L N, be elevated to the latitude, and adjufted to the meridian of the place, if the line of fight of the telefcope be at right angles to the axis V U, and this latter at right angles to the polar axis L N, the brafs circle 14 and 15 will correfpond with the equator in the heavens, and the circle Q R will become an horary circle; that is, if the centre of the wires in the field of the telefcope be directed to any celeftial object, on Q R will be had its declination, and on 14 and 15 its diftance from the meridian, from whence, by knowing the hour, the right afcenfion will be obtained, and confequently its true place in the heavens.

Befides the preceding parts of this expenfive inftrument, there are fome neceffary appendages, as a ftool marked 36, and fome others defcribed in the original account, with references to the accompanying plates, a minute detail of all which would lengthen this article too much; we will therefore briefly enumerate them, and refer the more curious reader to the Tranfactions themfelves for the particulars. The appendages are, 1ft, a lamp to illuminate the crofs-wires; 2dly, the refraction-piece hereafter defcribed; 3dly, the plumb-line; 4thly, the moveable roof of the obfervatory; 5thly, a regulator or fiderial clock which indicates degrees, minutes, and feconds of fpace on the equator; and, 6thly, the meridian mark, confifting of a fmall adjuftable light-houfe, placed on a brick pier at the diftance of 2970 feet, which can be feen as well by night as day.

After a very rigorous examination of the two divided circles of this inftrument, it feems that the greateft error, including both the inequalities of the divifions and the excentricity, never amounts to more than 2″ in either of them, and the author calculates that an obfervation of right afcenfion, taken *out of* the meridian, may be depended on to the accuracy of 5″, allowing an error of 2″ for counting the beat of the clock, 1″ for the deviation of the meridian mark, and $\frac{1}{2}$″ for the error in reading the microfcope; but that the error in polar diftance may amount to 7″, including all the errors of the inftrument, of the adjuftments, and of the readings. This inftrument, it will have been obferved, has no azimuth circle, like moft of the portable inftruments, but if its axis were fixed perfectly vertical, its equatorial circle would then become an azimuth circle, and the inftrument altogether would greatly refemble Piazzi's great circular inftrument made by Ramfden. From what we apprehend alfo from fir George Shuckburgh's account of the variablenefs of the errors of adjuftment, in different degrees of temperature, we are difpofed to attribute much of the imperfection of this inftrument, in this refpect, to the metallic fupport of the upper pivot of the polar axis, which fupport muft naturally elongate and contract its dimenfions alternately, by changes of temperature; and as it is compofed of various parts differently placed, it affords no data for afcertaining by calculation either the quantity or direction of deviation from the truth. Before we proceed to the adjuftments of this inftrument, it may be proper to defcribe the refraction apparatus which is attached to it, and which is neceffary to be underftood in ufing the appended tables. *Fig.* 2. of *Plate* XI. exhibits a perfpective view of this apparatus on a larger fcale than is exhibited in *fig.* 1. where "A B is a portion of the telefcope; C the eye-tube; *a b c* a divided femicircle, *d* its vernier fixed to A B, fhewing the angle of the horary and vertical circles; *e* a fmall fpirit-level, attached to the plate on which this femicircle is engraved, and moving with it by means of the fcrew *f*, which turns a pinion, that works in a toothed wheel, that turns the whole plate, together with the exterior eye-tube round its centre, but without moving the tube that carries the crofs-wires. From hence it may be underftood, that by turning the fcrew *f* till the level *e* ftands true, the index *d*, which reprefents a point in the horary circle, will mark how much the divifion zero, which reprefents the vertical, is inclined thereto: *l k* is a fmall quadrant of altitude, that, by means of the level *g*, and fcrew and pinion *h*, turning on a centre at *m*, gives the elevation above the horizon of any object in the field of the telefcope: *i* is a fmall aperture through which a key is fixed on, to give a lateral motion to the wires to adjuft them; and near *f* is another fcrew, to adjuft them parallel to the equator and declination-circle."

This apparatus, it will be feen, has not the refraction-circle, or micrometer and divided nut, to elevate or deprefs the horizontal wire, a quantity correfponding to the data thereby determined, in order to convert the apparent to the true place of a heavenly body; it therefore indifpenfably requires the aid of fuch tables as we have fubjoined to our prefent article; but Ramfden's portable inftrument defcribed by the Hon. S. M'Kenzie, and by profeffor Vince, whofe accounts we have adopted, has the addition of the micrometer feen in miniature at P, in the figure of that inftrument. To that inftrument, therefore, as well as to Dollond's, the tables are otherwife unneceffary, than as they ferve as a check on the accuracy of the mechanical contrivances in queftion.

Adjuftments.— The three principal adjuftments, according to fir George Shuckburgh's account, are, 1ft, to adjuft the level P *k* parallel to the declination axis U V; 2dly, to adjuft this axis at right angles to the line of collimation of the telefcope; and, 3dly, to make this axis at right angles to the polar axis. The polar axis is placed nearly in the meridian, by means of a meridian mark previoufly verified, and elevated pretty nearly to the latitude of the place. This is to be done more accurately afterwards, by the fliding plates and fcrews at the bottom of the polar axis. The axis of the declination-circle is then brought nearly horizontal, by its proper level, *viz.* is turned round about the polar axis, till the bubble of the level ftands true between the indexes; the inftrument is then turned half round about the polar axis, = 180°, fhewn by the microfcope W. If the bubble then ftand true it requires no correction, but if it do not, correct half the error, by moving the equatorial circle by its handle *t*, and the other half by the (invifible) capftan fcrew, which we will call *a*, or end-fcrew; then turn the inftrument back again to its firft pofition, and fee if the level ftands true; if not, repeat this operation till it does, correcting one half of the error by the equatorial handle, and the other half by the fcrew *a*. The declination-axis will then be parallel to the level, and both of them to the horizon. It muft be remarked that in this operation it will be neceffary to move the declination-circle round its own axis a little, in order to bring the fame fide of the level uppermoft;

permoft; but this in no degree affects the refult, for the imaginary line, round which this axis revolves, is what is meant all along by the axis, and is the line to which the parallelifm of the level is referred.

The declination axis remaining in an horizontal pofition, with the level above the axis, as in the *fig.* turn the declination-circle 180°, *viz.* till the level become below the axis; then, by means of the pinion for this purpofe, reftore the tube of the level to an upright pofition, and fee if the bubble ftand true; if not, correct ½ the error by the fide fcrew, and the other ½ by *a*, the end fcrew. Now turn the declination-circle 90° each way from its laft fituation, and repeat the examination of the bubble, and correct as before, ½ by the fide fcrew, at the oppofite end of the tube, at right angles to the other fide fcrew; and ½ by the end fcrew, near the fide fcrew in queftion; and if after all thefe corrections in every part of an entire revolution of the declination-circle round its axis, and of the level round its axis, the bubble ftand true, it follows that the axis of the declination-circle, and of the level, are in every direction parallel to each other, both of them to the tangent of curvature, in the middle of the level, and all three to the horizon. This adjuftment is therefore complete.

It remains to be feen whether the line of fight of the telefcope be at right angles to the declination-axis, and the latter to the polar axis.

Take the error of the collimation of the telefcope in right afcenfion, by a ftar in the equator, *viz.* let the tranfit of a ftar on the equator over the affumed meridian be obferved with the declination-circle turned towards the eaft, and alfo towards the weft. If there be any difference in thefe obfervations, it will denote double the error of collimation in right afcenfion, and half of it will be the deviation of the line of fight from a line at right angles, to the axis of the declination-circle, and is correfpondent to a fimilar adjuftment of a tranfit inftrument. The amount of this error being thus afcertained, let it be corrected by the fcrews, at the eye-end of the telefcope, that move the wires to the eaft and weft. The declination-axis, by means of its level being reftored to an horizontal pofition, let the centre wire of the telefcope, (by which is always underftood the line of collimation,) be brought to bifect the meridian mark, by means of the fliding plate, and adjufting fcrew, below the polar axis; the telefcope will then become a complete tranfit inftrument; for, by the firft operation, the declination axis is made parallel to the level and its axis, and both to the horizon; by the fecond, the line of fight is put at right angles to this axis; and, thirdly, it is adjufted to the meridian.

Now, let the error of collimation in right afcenfion in the fame manner be obferved with any ftar out of the equator, by a circumpolar ftar, (the nearer the pole the better,) fuppofe the pole ftar. If any difference in minutes and feconds of a great circle, as afcertained by the micrometer, fhould be noticed in its paffage with the circle eaft or weft, halve that difference, and it will be equal to the angle that the plane of the declination circle makes with the polar axis, if the obferved ftar were actually in the pole; if not, divide it by the fine of its declination, and the true angle of the plane of this circle, (or of the line of collimation,) with the polar axis will be had. Again, if this operation be repeated with any other ftars, and the error fo found be divided by the fine of their declination, the error of the plane of the declination circle at the pole, *viz.* its greateft error, or angle with the polar axis, will be had. And note, if thefe obfervations are made with ftars on each fide of the equator, thefe quantities will be had in oppofite directions. Finally, the fame may be done by two land objects, one to the north, and the other to the fouth, the north and fouth meridian marks, for inftance, proper confideration being had to their declination; by this means the error will be thrown in contrary fenfes or doubled, and from a variety of fuch refults a very correct mean quantity may ultimately be deduced; and when found muft be corrected by the fcrews at one end of the declination axis.

It has now been feen, that, 1ft, the level and its axis are parallel to the axis of the declination circle: 2dly, the line of fight is at right angles to this axis, and parallel to the polar axis; and, confequently, the declination axis is at right angles to the polar axis: 3dly, the polar axis parallel to that of the earth. Thefe are the chief requifites in the adjuftment of this inftrument. Thofe that remain are fecondary, and we fhall take them in the following order: 1ft, the adjuftment of the crofs wires to the focus of the telefcope: 2dly, the hanging level: 3dly, the line of collimation north and fouth, as well as eaftward and weftward; 4thly, the index wires in the microfcopes: 5thly, the refraction apparatus; and, 6thly, the power and fcale of the microfcopes.

Firft, *the crofs wires.* Let the eye-tube be adjufted to diftinct vifion for parallel rays by fome diftant object, fuch as Jupiter, Saturn, or Venus, by day-light; that done, obferve, while one limb of either of thefe planets appears running along the equatorial wire, whether any motion of the eye, upwards or downwards before the eye-glafs, alters the relative place of the image and the wire; if a motion of the eye upwards moves the planet in the *fame* direction, the wires are too near the eye-glafs, and muft be pufhed in; and *vice verfâ*, till the image becomes fixed upon the wire, whatever be the motion of the eye. When this point is obtained, the eye ftop, with its wires, muft then be fixed, for that is their true place, *viz.* the correct focal point of the object-glafs; and whatever indiftinctnefs may be found from the diverfity of eyes of different obfervers, muft be corrected by the motion of the eye-glafs only. Another point to be fecured is the permanency, as far as may be, in the pofition of the object-glafs; for if this be not correctly centered, which is very rarely the cafe, and, indeed, never to be expected, that is, if its axis be not concentric with the axis of the cell, in which it is fixed, any motion of this latter, by fcrewing or unfcrewing it, may not only change the place of the focus to which the wires are adjufted, but will neceffarily move the line of collimation both in right afcenfion and declination. To obviate this, therefore, two correfponding marks fhould be made with a graver, both upon the cell into which the glafs is burnifhed, and alfo upon the tube of the telefcope into which the cell is fcrewed, or otherwife inferted, that in cafe the object-glafs fhould ever be taken out to clean it, &c. it may be reftored very nearly, if not exactly, to its former pofition.

The eye-glafs, object-glafs, and wires being thus fettled in their refpective places to each other, it will not be an improper time to meafure the interval between the wires, which cannot be too accurately done, being of fuch conftant ufe; this may be either, 1ft, by obferving the paffage of a ftar in the equator, and making proper allowances for the rate of the clock, or by a ftar out of the equator, and making proper allowances for the declination in the proportion of the radius to the cofine, or, 2dly, by means of the equatorial circle, and a fixed land object; and here the quantity muft be diminifhed in the fame ratio as the radius to the fine of the polar diftance. We have made ufe of both methods as a confirmation of each other, and find the interval, which is equal in the three wires of my telefcope, to be $7' \, 34''.5 = 30''.3$ fiderial time; and thefe three

three wires divide the diameter of the field very nearly into four equal parts.

Second and third adjuſtments: *the hanging level.* By means of its proper handle *u*, move the declination circle about its axis, till the bubble of the hanging level *l m* reſts true between the indexes; there fix it by the clamp *w*, reverſe the level by taking it out of its pivots, and turning it end for end; if the bubble now ſtand true, the level is adjuſted; if not, correct $\frac{1}{2}$ the error by the declination handle, and the other $\frac{1}{2}$ by the ſmall ſcrew at the bottom of the level; then reverſe the level and repeat this operation till it does. The level, or rather a tangent to its curvature at its middle, will be parallel to the axis on which it ſwings, and both will be horizontal. At this time look through the teleſcope, and ſee what land object is covered by the horizontal wire; now invert the teleſcope by turning it 180° round the declination axis, and 180° round the polar, and bringing the level true, it will then point to nearly the ſame place; and if exactly the ſame object as before be now covered by the horizontal wire, the axis of the level is adjuſted parallel to the line of collimation in a vertical direction, if not, correct half the error by the little capſtan ſcrew at the bottom of the cock, or arm, that ſupports one end of the axis of the level, and the other half by the declination handle; invert the teleſcope, and repeat the operation, till the ſame object is covered in both poſitions, and the level is found true, then will the level and its axis be parallel to the line of collimation, and the object covered by the wire may be concluded to be in the horizon.

Fourth. *The index wires of the microſcopes.*—The line of collimation, with reſpect to eaſt and weſt, has been already adjuſted as above. Let then the declination axis, by its level, be reſtored to an horizontal poſition; at this time adjuſt the index wires in the two equatorial microſcopes W, X, to biſect the two oppoſite diviſions 360° and 180°, then will theſe wires be rectified to their proper place. That being done, bring 90°, or the diviſion that repreſents the equator on the declination circle, under its reſpective microſcope, and turn the whole inſtrument one quarter round on the polar axis, *viz.* till 90° on the equatorial circle be biſected by the micrometer; and, if at this time the bubble of the hanging level appear true, the index wire of the declination microſcope is correct; if not, correct $\frac{1}{2}$ the error by the declination handle *u*, and $\frac{1}{2}$ by the little ſcrews at the ſide of the hanging level, then reverſe the teleſcope, *viz.* turn it till 270° on the equatorial circle come under the micrometer wire, and if the level then reſt true the adjuſtment is complete; if not, repeat the operation, as before, till it does; then by its proper ſcrew bring the index wire of the declination micrometers to biſect the points 90° and 90°. The indexes of both circles will be then adjuſted, and the axis of the hanging level brought parallel to the line of collimation, with reſpect to eaſt and weſt, as well as with reſpect to north or ſouth. Note, this paralleliſm of the axis of the level, to the line of collimation in a direction eaſt and weſt, does not appear to be a very important rectification, but on ſome occaſions may have its uſe.

Fifth. *The refraction piece.*—After what has been done, this apparatus will be adjuſted. Bring the teleſcope, by means of its two levels P *k*, and *l m*, to point to the horizon, and in the meridian; then by the two points, *f*, *h*, *Plate* XI. *fig.* 2, of the refraction piece, bring its two levels *e* and *g* to reſt true; move the nonius *d*, of the little ſemicircle of the horary and vertical angles, *a*, *b*, *c*, to the middle of the diviſions, or 0°, 0′, and alſo that of the little quadrant of altitude, *l k*, to 0°, 0′, and this part is adjuſted.

Sixth. *The microſcopes.*—The magnifying power and ſcale of the microſcopes is all that remains to be conſidered. The magnifying power of a compound microſcope, as is well known, depends on the proportion between the diſtance of the object, and of its image from the object-glaſs, together with the proportion between the focus of the eye-glaſs and the ordinary focus of the eye looking at a ſmall object (ſuppoſe) of $\frac{1}{50}$th. or $\frac{1}{10}$th inch. Theſe two ratios compounded give the power of the microſcope. The former is called magnifying by diſtance, and is a material part in the conſtruction of theſe microſcopes; the ſcale of the micrometer being regulated by this part of the magnifying power. For example, let the diſtance of the object from the glaſs be = 1, and the diſtance of its image = 4, its power will be 4; and conſequently the ſcale of the micrometer or motion of its ſcrew, to anſwer to 10′, (ſuppoſe) muſt be 4 times as great as the ſpace occupied by 10′, on the limb of the circle; and if the radius of the circle be two feet, an arc of 10′ will be equal to 0.07 inch nearly on the limb, and = 0.28 inch on the ſcale, *viz.* = to the ſame arc on a circle of 8 feet radius: and if each revolution of the micrometer ſcrew be intended to deſcribe 1′, the ſcrew muſt contain about 35 threads in an inch. But as it would be difficult to adjuſt the ſcrew exactly to the ſcale, the advantage of the conſtruction of theſe micrometers is, the ſcale may at any time be adjuſted to the ſcrew; for let the interval between any two neareſt diviſions = 10′ on the limb, be meaſured by the ſcrew, and, ſuppoſe, inſtead of being = 10′ or 600″, it appears only = 570″; it is evident that the ſcale is bigger than it ſhould be, or, which is the ſame thing, that the image is leſs by $\frac{30}{600}$ or $\frac{1}{20}$. In this caſe, increaſe the diſtance between the micrometer wires and the object-glaſs = $\frac{1}{20}$, by unſcrewing or drawing out the tube that carries the micrometer and eye-glaſſes, and the ſcale is adjuſted. It will, at the ſame time, however, be right to re-adjuſt the object-glaſs of the microſcope to diſtinct viſion, by the ſcrew of the cell that contains it, until the image and the wires have no relative change of place by any motion of the eye. This will again occaſion ſome ſmall alteration in the ſcale, and muſt be corrected by repeated trials, and the ſcale adapted to the diviſions on the arc; and if the moveable wire of the microſcope be now brought to coincide exactly with the fixed one, and the moveable index brought to zero on the ſcrew-head, the micrometer is completely adjuſted. This having been done with all the microſcopes, and the oppoſite ones being made to agree, each with the other, in ſuch manner that the fixed wires may become a correct diameter, the whole inſtrument will have been completely adjuſted.

Before taking an obſervation of right aſcenſion and declination, the teleſcope muſt be adjuſted to the meridian mark, ſo as that the centre wire may exactly biſect it, in which ſituation care muſt be taken to make the index wires of the equatorial micrometers biſect the points of 360° and 180°, by means of the adjuſting ſcrew of the polar axis; and when an obſervation is made out of the meridian the altitude and angle of the horary and vertical circles muſt be taken by the refraction apparatus; then with theſe arguments, the refraction and parallax, in north polar diſtance, and in right aſcenſion, may be found by inſpection in the ſubjoined tables, by which any obſervation may be readily reduced to the meridian.

In this account of ſir George Shuckburgh, the reader may have obſerved, that the *order* of the adjuſtments propoſed is not that which is beſt in practice; as ſome of the *leading* adjuſtments muſt neceſſarily be deranged by the ſubſequent ones as he has deſcribed them, and indeed ſo as to

 render

tender new adjuftments neceffary; but we were unwilling to transform the baronet's directions that have met with the approbation of the Royal Society, though we cannot difmifs the account without this remark for the reader's confideration; *viz.* the rectification of the telefcope, levels, &c. ought certainly to *precede* the adjuftments of the circles, that depend on *their* accuracy of pofition.

The Armagh equatorial inftrument by Mr. Ed. Troughton.— The inftrument which now claims our attention is reprefented in *Plate* XVI. of *Aftronomical Inftruments*, and, though fimilar to its predeceffor fhewn in *Plate* XV, as to its ufe and properties, yet forms a ftriking contraft with it, in regard to compactnefs and beauty; too evident a contraft indeed to be overlooked at the firft glance of comparative infpection. The arrangement of its principal parts is fo novel, and at the fame time fo natural, as well as the connection of its fmaller ones effected with fuch fymmetrical precifion, that the mind is ftruck with the contemplation of it, and fpontaneoufly confiders it as an inftrument of a fuperior order, that feems to place at a diftance every other individual of its kindred: we therefore feel a peculiar pleafure in concluding our article with the account of an inftrument, which, though it comes laft, ought in our eftimation to ftand firft, as a model for future imitation. As the different component parts of the equatorial inftrument are now become familiar to the reader, who has perufed the preceding defcriptions, we fhall fatisfy ourfelves with a brief detail, unaccompanied by alphabetical references to the drawing, which prefents a perfpective view of all the leading features.

The horary or equatorial circle, without centre or radii, occupies the middle part of the inftrument; and is held in its proper place by eight conical tubes of brafs, four above and four below, which converge refpectively towards the upper and lower poles, and which ftand at the diftance of a quadrant from each other. A ftrong and light frame is thus formed of the fhape of two fimilar cones joining their bafes at the horary circle, and connected near their fummits by two pieces of metal that terminate each with a hollow cylinder of about two inches diameter; this frame is further braced by crofs connecting tubes, as well as by fide braces, or props, in the manner fufficiently explained by the figure; and the whole frame, thus firmly united, fupplies the place of a revolving axis, and carries the horary circle round with it, when it is made to turn on its cylindrical pivots. On thefe pivots the horary circle was finally turned true, after the frame was united and made faft in all its parts, fo that the excentricity of the circle, if it had any previoufly, was done away, by being turned on its own pivots. The inferior end of the polar axis or frame is fupported by a folid ftone, about 30 inches above the floor, with which it has no connection to produce unfteadinefs; this ftone is capped by an apparatus of ftrong brafs work, in which is produced the adjuftment for bringing the inftrument into the plane of the meridian, as well as that for giving the polar axis its proper elevation. This lower end of the axis terminates in a hemifpherical button of hardened and finely polifhed fteel, which preffes endwife againft a plane of agate, and is kept centrical by two rollers that form an angle to receive it on the lower part of the apparatus; all which contrivances may be readily conceived without more minute defcription. The fupport for the elevated pole confifts principally of a ftone pier, reaching from the ground to the centre of the inftrument; but on it is firmly fixed a ftrong frame of wrought iron, fo conftructed as to turn its edges towards the telefcope hereafter defcribed, in every direction; otherwife it would obftruct the field of view in elevations below the upper pole. The upper gudgeon is received between two rollers fimilar to thofe below, except that thefe are perforated, as well as the gudgeons, in order that as little light as poffible may be intercepted when the telefcope is pointed to the pole. At about fix feet diftance from each other, in the eaft and weft line, upon the fame folid foundation that fupports the bearing ftone and pier, are firmly fixed two pillars of ftone, each nearly three feet high; and on the tops of thefe are placed faft two ftrong cones of brafs to fupport the microfcopes for reading off the horary angles. The length of thefe two cones of brafs is fo proportioned as to correfpond to the effective length of one half of the frame, or polar axis, in its inclined ftate, in all changes of temperature, by which means the microfcopes preferve their relative fituations at the horary circle. This circle is divided into 5′ fpaces, or fpaces of 20 feconds of time, upon its extreme or exterior edge, which was made broad for this purpofe, and the heads of the equatorial micrometers are fo divided as to fubdivide the faid fpaces into tenths of a fecond of time. The axes of the microfcopes of courfe are horizontal. At the tops of the conical parts of the pillars are adjuftments for moving the microfcopes; one with refpect to perpendicular height, another with refpect to the diftance of the exterior edges of the horary circle, and a third along its plane. An apparatus alfo for quick or flow motion is attached to each of the cones in queftion, by means of which the inftrument may be fecurely fixed, either in the meridian, or in any other given pofition, as it regards the meridian. The declination circle likewife occupies the middle of the frame, and has its centre precifely in the fame point that is the centre alfo of the horary circle, thefe two circles being concentric, but having their planes exactly at right angles to each other, after the manner of the meridian and equatorial circles of a common ring-dial, when put into a ftate for ufe. The declination circle is double, or compofed of two complete circles united in feveral places by connecting pillars, and having each eight radii alfo connected in the fame manner, after being inferted into the common axis, which is of the fhape of a double cone. The telefcope paffes through the bafes of the united cones of the axis, and has an aperture of $2\frac{3}{4}$ inches, confequently the connecting pillars are long enough to admit fuch a telefcope between the united circles, in which fituation it is not very eafily diftinguifhable in the figure. Its eye-piece, however, is difcernible juft under the declination circle. It is 44 inches long, and revolves within the horary circle; confequently requires a diagonal or reflecting eye-piece when directed to the equator, in which fituation the aperture admits light enough, notwithftanding the interpofition of the horary circle. When the elevation is great, the head of the obferver muft neceffarily be admitted between two out of the four lower conical pillars of the frame, which circumftance points out the fcale of magnitude on which an inftrument of this conftruction ought to be made, to be ufeful at all degrees of elevation of the telefcope. The telefcope has various magnifying powers, which may be ufed according to circumftances. Two oppofite quadrantal arcs of the horary circle have chord-bars parallel to each other, at the middle points of both which are fockets for the gudgeons of the declination axis to work in as their fupports; which bearings made the braces of the frame and horary circle effentially neceffary to give ftrength and firmnefs to the whole. The declination axis, which is about three feet long, has an adjuftment at one end for fetting it at right angles to the polar axis, and carries alfo a very fenfible fpirit-level parallel to itfelf; with another of which the

the telefcope is likewife furnifhed, which it cannot be neceffary to particularize further, after our former defcriptions of fpirit-levels, except that in thofe the adjuftment fcrews had divided heads, whereas in thefe there are divided fcales of ivory, by means of which the half differences can be accurately eftimated to the *fraction of a fecond*. The declination circle is divided into fpaces of 5′, which are again fubdivided by the microfcopic micrometers into minutes and fingle feconds. One of thefe microfcopes is feen above the horary circle and the other below, but both are fupported by it, and point horizontally to oppofite points of the declination circle, as one of the others is feen at the top of one of the pillars pointing to the exterior edge of the horary circle. The apparatus for quick or flow motion, to govern the declination circle, is attached to the lower part of the frame, or polar axis, as reprefented in the figure. The excellence of this inftrument has been fully eftablifhed in public eftimation, by the ufe that has been made by Mr. Pond of the Armagh obfervations, taken with it in 1797, when he formed his catalogue of fome of the principal ftars, as we have already ftated; in which catalogue (fee our article DECLINATION,) it will be feen that the accuracy of its meafures accord very nearly with the refults derived from an average of the beft modern inftruments: and we may add, that the coincidence would doubtlefs have been ftill more remarkable, had not the divifions, which are by dots, been injured by an accident. An intenfe froft, to which the inftrument was expofed at the top of the maker's houfe, covered it with black fpots, and corroded its furface fo as almoft to obliterate the dividing points, which were neceffarily enlarged by hand, and of courfe might be altered a little by this manual operation, however carefully performed. The divifions of the other circle met alfo with an accident at the other fide of the water, which, though of a different nature, has rendered the divifions lefs correct than they were at firft. Befides which, two other circumftances ought alfo to be named as drawbacks in this inftrument, when compared with the circular inftruments with which it has been contrafted, namely, its verifications were not made with a plumb-line; and its polar pofition may be confidered as fomewhat unfavourable for taking declinations with the utmoft nicety; but notwithftanding all thefe deductions, the accurate performance of the inftrument has ftood the teft of a rigid comparifon with the inftruments of three modern obfervatories.

Adjuftments.—1. Turn the *wire-plate* round, if neceffary, fo as to make the middle vertical wire continue, throughout the whole field of view, on fome diftant and well defined point, while the telefcope is elevated or depreffed as it turns on the axis of the declination circle, to which the wire will in that cafe be perpendicular.

2. Slide the *object-glafs* of the telefcope in or out, while you view a ftar of the fecond magnitude, until the parallax of the wires is taken off, that is, until the vifion is as diftinct as poffible.

3. To adjuft the *level* of the *declination axis*. By the motion round the polar axis bring the bubble of the level to the middle of the tube, and in this fituation make its fcales or indices to coincide with both its ends; turn the level, end for end, and if it now ftand in the middle, as before, the axis is level; if not, alter one half of the deviation from the truth by a flight motion round the polar axis, and the other half by the fcrews of the level itfelf; and repeat thefe rectifications till the bubble will ftand always in the middle of the tube when its ends are reverfed. But the bubble of a hanging level may alfo require a lateral adjuftment; to examine it in this refpect, turn it round on its own axis a little, and if the bubble has a tendency to go to either end of the tube it muft be rectified by the fide fcrews till this tendency is removed, and then if the bubble will yet bear reverfing, the level is properly adjufted.

4. To adjuft the *pivot holes* of the level *parallel* to the *axis* of the declination-circle, and the *axis horizontal;* bring the bubble of the level to the indices on the tube, with the level above the axis, by moving the inftrument round the polar axis; then turn the declination-circle half round till the level is under its axis, and if the bubble now fettles to the middle, as pointed out by the indices, the level is right; if not, alter one half of the error by turning the polar axis round, and the other half by the two fcrews that govern the pivot-hole; in the next place turn the telefcope 90° round the declination-axis, and by the fcrews that govern the other pivot-hole, bring the bubble to the indices, and the axis will be horizontal, as well as the pivot-holes parallel to it in all directions; for when the level itfelf is adjufted, as above directed, it is evident that if the bubble keeps its place at the indices during a revolution of the declination-circle, the axis itfelf muft neceffarily be horizontal.

5. To fet the *declination-axis* at *right angles* to the *polar axis*, we may ufe the level itfelf inftead of the declination-axis, after it has been fet parallel thereto as juft directed; for this purpofe, bring the bubble to the indices by moving round the polar axis, and bifect oppofite points of the equatorial circle by the two wires of the microfcopes; turn the inftrument exactly half round by the help of the microfcopes fo adjufted, and if the bubble now fettles to the indices, the two axes are at right angles to each other; if not, alter one half of the error by the flow motion of the polar axis, effected by the equatorial tangent fcrew, and the other half by the two fcrews at one end of the declination-axis adapted for this purpofe.

6. To fet the *line of collimation* true in *right afcenfion*, let the bubble be brought to the middle of the tube, or to the indices as in the laft adjuftment, and look at any well-defined fmall object near the horizon, as bifected by the middle vertical wire; then having noted this mark, turn the inftrument half round the polar axis, as indicated either by the level or equatorial microfcopes, which are now adjufted to do the fame thing; and when the telefcope is turned back round the declination-axis, note if the fame object or mark be interfected as before, if not, alter one half of the deviation by the equatorial tangent fcrew, and the other half by moving the wires of the eye-piece in the telefcope; thus when the fame mark is bifected by the middle vertical wire, in reverfed pofitions of the telefcope, the line of collimation will be right with refpect to right afcenfion.

7. To place the *indices* of the declination-circle to read *polar diftances* truly. Before we defcribe this adjuftment, it may be proper to remark, that the microfcopes themfelves of this circle have each three feparate adjuftments, the firft, that which alters the power by altering the diftance of the object lens, fo as to make one minute on the circle equal to a revolution of the micrometer fcrew; the fecond, that which produces diftinct vifion by varying the diftance of the entire microfcope from the divifions of the circle; and the third, that which places zero on the fcale of minutes to agree with zero on the declination-circle, and alfo zero on the fcale of feconds, to agree with zero on the fcale of minutes, as effected by the head of the micrometer being made to turn independently of the fcrew. Thefe minor adjuftments being underftood, point the telefcope to any diftant land object, and let the middle horizontal wire bifect it, and read off the polar diftances fhewn by the indices, and take half their fum; make

the ſame obſervation when the inſtrument is turned half round the polar axis, and take another mean of the angles now ſhewn by the oppoſite indices; ſubtract the former mean from 180°, and add the difference to the latter mean, and *half of this ſum* is the angular diſtance from the pole of the inſtrument, to which quantity the indices muſt be put within the exactneſs of a minute or ſo, as this proceſs muſt hitherto be conſidered as an approximation only: repeat the operation we have deſcribed of obtaining two means of polar diſtances more accurately by uſing the ſcales of minutes and ſeconds; thus, read off by the indices the quantity to the diviſion next below the ſub-diviſions to be meaſured by the ſcales; then turn the micrometer head till the wire of the microſcope biſects the next following point, taking care to count the notches paſſed over as minutes, and the ſeconds and parts on the micrometer ſcale to be added to the quantity given by the indices alone; and the *ſupplement* of the mean of the two meaſures by the microſcopes, added to the mean read off in the ſame way, when turned half round the polar axis, being divided by two, will give the *true* angle from the pole of the inſtrument; and the ſcale of minutes, as well as ſcale of ſeconds on the micrometer head, muſt be finally adjuſted thereto.

8. To place the *declination-level parallel to the line of collimation* of the teleſcope, bring the declination-axis level, or nearly ſo, and let the bubble of the declination-level be brought to the middle of its tube, by the motion round the polar axis, and let the indices be put to its ends; turn the level a ſmall quantity round its own axis, and try if the bubble has any tendency to either end; if it has, adjuſt it laterally by the ſcrews that move one of its pivots ſideways, till it is right in this reſpect; now reverſe the level, and if the bubble does not ſtand in the middle, alter one half the error by moving the teleſcope in declination, by means of its ſcrew for ſlow motion, and the other half by the ſcrews that govern the pivots of the level, and the level itſelf will then be adjuſted. In this ſituation of things look for ſome object in the centre of the field of the teleſcope, and note it; turn the inſtrument half round the polar axis, and as much round the declination-axis as to bring the teleſcope exactly to the ſame object again; if the bubble now ſtands in the middle, the adjuſtment is right, but if otherwiſe, one half of the error muſt be altered by the motion of the teleſcope in declination, and the other half by altering the pivot-hole of the level. Laſtly, turn the inſtrument the ſpace of *ſix hours* round the polar axis, and adjuſt the other pivot hole till the bubble ſtands in the middle of its tube, and the adjuſtments are all complete, provided the polar axis of the inſtrument be exactly parallel to the axis of the earth, which we have all along taken for granted, and which may be effected by its own adjuſtments as pointed out by an obſervation of a circum-polar ſtar, agreeably to our directions given under our article EQUATORIAL *Sector*.

Refraction in Right Ascension × Sec. of Declination.

This correction is — on the East, and + on the West side of the Meridian.

N° I. TABLE of the Effect of Refraction in North Polar Distance—*continued.*

This correction is always +

Angle of the Vertical with the Horary Circle.	Degrees of Altitude. 32°	34°	36°	38°	40°	42°	44°	46°	48°	50°	52°	54°	56°	58°	60°	Angle of the Vertical with the Horary circle.

Explication and Ufe of the Tables.

The three firft tables are particularly calculated for the ufe of a large equatorial inftrument, for the purpofe of clearing obfervations made with it from the effects of refraction and parallax, when neither Dollond's refraction apparatus is ufed, nor the micrometer circle of Ramfden's for adjufting the wire ufed in taking altitudes; but the four laft are adapted more peculiarly for portable inftruments. They are copied from fir George Shuckburgh's account in the Philofophical Tranfactions, and, being adapted for all latitudes, are a fuitable appendage to the defcriptions we have given of the different inftruments.

Table I. gives the correction of the refraction in north polar diftance, by entering it with the altitude at the top, and the angle of the horary and vertical circles on the left hand fide; and in the common point of meeting is found a quantity in feconds and decimal parts, that is in all cafes to be *added* to the *apparent* polar diftance to give the *true*; but if it be entered with the angle of the horary and vertical circle in the right hand column, it will give the refraction in right afcenfion, by multiplying the quantity here found by the fecant of the declination to be found in Tab. IV., which is a readier operation than dividing by the cofine, and amounts to the fame thing.

Table II. gives the effect of the fun's parallax in right afcenfion and north polar diftance, and is to be entered with the fame arguments as Tab. I.; and the parallax in right afcenfion is to be multiplied by the fecant of the declination as before; the fun's horizontal parallax being affumed = 8.″6.

Table III. is a fimilar table, only calculated to an horizontal parallax of 10″; fo that whatever be the parallax of the fun or planets, this correction may readily be found, almoft by infpection, *viz.* by multiplying the tabular number by the exact quantity of parallax of the body obferved, and cutting off the decimal quantity.

Table IV. contains the natural fecants to each degree, extracted from Sherwin's tables, to be ready for the operations required above.

Table V. gives the correction of the *time*; *viz.* of the fun or ftar's diftance from the meridian, as afcertained by a portable inftrument not previoufly adjufted to the meridian; this quantity alfo is to be multiplied by the fecant of the declination.

Table VI. gives the correction of the meridian line in minutes and decimals, which may be near enough for portable inftruments; but the quantity here found muft be multiplied by the fecant of the altitude.

Table VII. (like Table I.) is adapted to feconds of *time*, and gives the refraction in right afcenfion in terms fuited to fuch inftruments as have the equatorial circle divided into hours and minutes.

Table VIII., in like manner, gives the refraction in declination. The arguments are the fame in all the tables.

Thefe tables were conftructed by fir G.S. in the year 1774, for his own ufe, and were founded on the principles explained by the Hon. S. M'Kenzie in *fig.* 4. of *Plate* XIII., where I F is a portion of a vertical circle = the refraction in altitude; C F a parallel to the equator; I C a portion of an horary circle = the refraction in declination, found by Tab. I and Tab. VIII., the angle C I F, the angle of the horary and vertical circle; C F the refraction in right afcenfion, found by Tab. I. and Tab. VII.; D I (a parallel to the horizon) the correction of the meridian, found by Tab. VI.; and D F the correction of the time, found by Tab. V; and as I F will hardly ever be found to exceed 30′, thefe triangles have been confidered all as plane; making due allowance, in the proportion of the fine to the radius, for the diftances of the arcs D I, F C, and D F, from their refpective poles, which has been noticed at the foot of each table. The refraction in altitude was taken from Mayer's Tables, 1770, London; which is calculated for a denfity of the air expreffed by 29.6 inches of the barometer, and 50° of Fahrenheit's thermometer.

Equatorial *Micrometer*, is an apparatus applied to a telefcope, that has an equatorial motion, for the purpofe of meafuring fmall differences of right afcenfion and declination of any two heavenly bodies, that pafs either fucceffively, or at the fame time nearly, through the field of view, fo as to be both vifible at the fame elevation of the telefcope. This method requires no graduated circles with verniers or compound microfcopes, and yet is capable of great accuracy within certain limits of difference between the relative fituations of the bodies to be compared together; and if the right afcenfion and declination of one of the two obferved bodies be previoufly known with fufficient accuracy, the place of the other can be determined therefrom by the obferved differences. The common wire micrometer has been long in ufe as an appendage to the eye-piece of a telefcope, and was ufed by Dr. Bradley in making aftronomical obfervations, his manner of doing which was communicated to the Royal Society in the year 1772 (vol. lxii.) by Dr. Mafkelyne; but as the telefcopes then in ufe were from ten to fifteen feet long, for want of the achromatic object-glaffes, an equatorial motion was given, not from one centre, but by means of fupporters at each end of the wooden tubes, fo contrived as to be manageable both in altitude and azimuth; which apparatus is ftill preferved at the Royal Obfervatory. The wires of the micrometer have been adapted differently by different makers, fome making only one moveable, and fome more; but they all agreed in placing them in the focus of the eye-piece of the telefcope. It is not, however, our intention to enter into a detail in this place of all the different conftructions of the micrometer, as applied to various purpofes, but to confine ourfelves to a notice of thofe that have been more particularly applied to telefcopes having an equatorial motion. For the other conftructions, we refer to the article Micrometer.

Soon after the difcovery of the properties of the achromatic object-glafs of a telefcope had reduced the length of the aftronomical telefcope to a portable fize, without diminifhing either its power or fize of its field of view, not only were equatorial inftruments contrived of various conftructions, as we have already defcribed, but equatorial ftands for fimple telefcopes were invented, and continue to be in ufe with the beft telefcopes to the prefent day. To thefe telefcopes the micrometers are a very neceffary and ufeful appendage, inafmuch as they render it capable of being applied with advantage in afcertaining the right afcenfion and declination of a comet, planet, or other body out of the meridian, when they happen to be near enough to a known body to admit of being taken into the fame field of view without altering the elevation. Though the wire micrometer was firft invented, as applied to the focus of the eye-piece, and continues to be ufed in many inftruments, yet fince the invention of the achromatic object-glafs, Dollond's object-glafs micrometer has by fome aftronomers been preferred, or at leaft deemed equally ufeful, particularly when the crofs wires are alfo ufed in conjunction, as defcribed by Dr. Mafkelyne in his paper on this fubject read to the Royal Society of London on Dec. 12, 1771, which was the year after Smeaton finifhed his wire micrometer, that had been begun about forty years before. If we give an an account of thefe two kinds of micrometers in fucceffion, the reader will perceive the varieties that may arife from them by flight deviations of conftruction. We will begin with Smeaton's, as being of prior origin.

We are not aware that Mr. Smeaton has left behind him any perfpective drawing of his equatorial micrometer, though we have heard that there is an undefcribed fketch of one among his papers, at prefent in the poffeffion of Mr. Lloyd; but there is a fection of one accompanying his paper read to the Royal Society of London on June 7, 1787, which is fufficient for explaining the principle of its application. *Fig.* 3. of *Plate* XIII. of *Aftronomical Inftruments*, is the faid fection, as viewed from the eye-end of the telefcope. "This micrometer," fays the author, "is furnifhed with five horary wires, denominated in their order, *a*, A, B, C, D, (B being the middle horary wire,) and the two declination wires are denominated A, B, each moveable by a feparate and independent micrometer-fcrew, from the outfide of the field to the centre, and a little beyond it; fo that each wire can be moved into the place of the other, when at or near the centre." The field of view was only 1° 17′, and the magnifying power as low as 20, with an eye glafs of 1¾ inch focus, and a double object-glafs of 34½ focal length; notwithftanding the author calculates that a difference of only 2½″ may be read by fuch apparatus, which he concluded was near enough for any inftrument to read out of the meridian. In the conftruction of the ftand every thing was done to enfure ftability of pofition at any given elevation, and the fruftum of an hexagonal ftone was ufed as a pedeftal, detached from the floor of the obfervatory. With an apparatus fo fteady, it was not neceffary to confine the obfervations to two bodies, to be compared, whofe difference of right afcenfion was only a few minutes, but even hours could be admitted of for the interval of the fucceffive tranfits, provided the difference of the declinations did not exceed the interval between the two adjuftable crofs wires. The difference of the right afcenfions was eafily afcertained by a regulator or chronometer, meafuring the interval between the tranfits, and the diftance between the bodies as meafured by the interval between the crofs wires, gave the difference of the declinations. The firft trial of the fteadinefs and accuracy of this apparatus was made with Saturn and γ Capricorni, from which it was found that the ftar had the fame right afcenfion and declination, determined on two feparate evenings, at the diftance of 48 hours, though the inftrument had not been touched during the interval. But the principal obfervations noticed in the memoir, are thofe relating to the elongation of Mercury, as taken from Sep. 23, to Oct. 13, 1786, the refult of which was, that at $5^h\ 22^m\ 35^s$ mean time on Sep. 23, A.M. Mercury's right afcenfion, deduced from a comparifon with α Orionis, was 163° 59′ 21″, and his declination north 7° 44′ 25″. For the particulars of the calculations and the tables of the obfervations, fee the Phil. Tranf. of 1787. Alfo for the manner in which a fimple telefcope may be made to move in an equatorial direction, fee our article EQUATORIAL *Stand* of a telefcope.

The object-glafs micrometer of Dollond, of his moft improved conftruction, is reprefented by *fig.* 4. of *Plate* XII. agreeably to a drawing given in Mr. Dollond's pamphlet that accompanies his equatorial inftrument. By the improvement, fays the author, this micrometer has received, it is rendered capable of being applied to telefcopes of fmall aperture; the focal length of the object-glafs being confiderably increafed, the fcale by which the angles are meafured is much enlarged. By this increafe in the focal length of the object-glafs of the micrometer, the perfection of the telefcope is lefs injured; but the greateft advantage that is derived from the improvement, is the length of the fegments, which admit of the whole aperture of the telefcope, even in meafuring the largeft diameters of the fun or moon, and the object retains the fame brightnefs in meafuring the largeft angles as in meafuring the fmalleft.

Notwithftanding thefe feveral advantages, the inftrument is greatly reduced in fize, as will appear by infpecting the figure reprefenting the micrometer on the end of the telefcope; the defcription of which is as follows:—

a and *b* are two long fegments of an achromatic object-glafs, divided into feparate pieces by a diametrical line, and fitted into feparate frames, fo that by fliding one or both the fegments, they may be made to form in effect either one object-glafs or two, it being the property of half a well ground glafs to give as diftinct an image as the whole would do; the fegment *a* is moved by turning the milled head *c*, and the fegment *b* is moved by turning the handle *d*. When an obfervation is to be made, it is generally known what number of minutes the angle will contain nearly; fuppofe, for example, the diameter of the fun were to be meafured, which is known to be about 32′; move the fegment *a* till the index *e* comes to 32 on the fcale *ff*, then looking through the telefcope, move the fegment *b*, by turning the handle *a* till the circumferences of the two images, formed refpectively by the two fegments, are brought to touch one another externally, and the quantity that the fegments have moved will be meafured by the fcale *gg*, and vernier *h*, by which an inch is divided into five hundred parts: the greateft exactnefs is required in this fcale, as the angle is abfolutely to be determined by the meafure taken with it; the fcale *ff* being only of ufe to fet the fegment *a*, fo that in meafuring the angle by moving the fegment *b*, they may be both moved nearly the fame quantity.

The handle *i* is to turn the micrometer round, to bring the line dividing the two fegments of the object-glafs into the plane paffing through the two objects, whofe diftance is to be meafured. It is neceffary, in making obfervations with the micrometer, that the telefcope, when the micrometer is on, be adjufted to the *moft perfect vifion* of the object to be obferved, as a fmall error in this refpect may occafion a confiderable difference in the obfervation. To find if there is any error in the adjuftment of the micrometer fcale *gg*, turn the handle *d*, fo as to make the two images perfectly unite, and the number fhewn by the fcale and vernier will be the error of adjuftment, if there is any; this error may either be allowed for in the obfervations, or be corrected by the vernier fcrews at *k*. The object proper to be ufed for adjufting the focus of the telefcope with the micrometer on, may be any of the celeftial bodies, or fome diftant well defined land object; but for adjufting the micrometer fcale, the object may be nearer, fuch as a printed paper at two or three hundred feet diftance, provided the focus be firft well adjufted to this object. A table is ufually given with the micrometer, which fhews the number of minutes and feconds anfwering to the divifions on the fcale. When the micrometer is on the end of the tube of the telefcope, it is neceffary that the fcrew at the centre of motion be tight, otherwife, which is better, that there be a counterpoife at the eye-end to preferve the equilibrium in any elevation. Alfo, as the object-glafs of the micrometer is concave, the common focus of the object-glafs of the telefcope end of it is lengthened, which circumftance requires the tube of the eye-glafs

to

to be longer than when the telefcope is ufed without the micrometer.

The properties peculiarly afcribable to the two kinds of micrometers we have defcribed are, that the one at the focus of the eye-glafs is adapted for meafuring the differences of right afcenfions and declinations of two bodies, one of which has its plane known; but the one placed at the object end of the telefcope is calculated, by means of its graduated fcale, to meafure abfolute fmall diftances; and the accuracy of its fcale may be brought to the teft by a comparifon with a known interval between two ftars or other diftant bodies. Dr. Mafkelyne, in the paper we have already noticed, has however fhewn how, by the addition of two crofs-wires in the focus, the differences of right afcenfions and declinations may alfo be meafured by Dollond's micrometer, thus: "Suppofe it be required to meafure the difference of right afcenfion and declination of two ftars, whofe difference of declination does not exceed the extent of the fcale of the micrometer, and the diftance of the meridians paffing through the ftars does not exceed the femi-diameter of the field of view, turn the wires about till the weftern ftar runs exactly along the crofs-wire by the diurnal motion; then feparate the two fegments of the divided object-glafs to a convenient diftance, and turn the micrometer about, by means of its proper handle, till the two images of the fame ftar, formed by the two fegments of the object-glafs, pafs the horary or vertical wire at the fame inftant. Laftly, partly by the feet-fcrews of the ftand, and partly by the handle that feparates the fegment, caufe the fouthermoft image of the northermoft ftar, and the northermoft image of the fouthermoft ftar to appear both upon and run along the crofs or horizontal wire: the numbers ftanding upon the fcale of the micrometer will then fhew the difference of declination of the faid ftars; and if the times be noted when they pafs fucceffively the horary or vertical wire, the difference of the two times will give the difference of their right afcenfions alfo." (See Phil. Tranf. vol. lxi. article xlix.) It was one of Dollond's object-glafs micrometers, attached to an 18 inch reflecting telefcope by Short, and another attached to a two feet reflector, that lieutenant (afterwards captain) J. Cook, of the Endeavour, and Mr. Charles Green, formerly affiftant at the Royal Obfervatory, ufed in obferving the tranfit of Venus over the fun's difc on June 3, 1769, in King George's ifland, or Otaheite, in the South fea, as recorded in the fame volume of the Philofophical Tranfactions.

For an account of the hiftory of the micrometer, and its various conftructions by different artifts and ingenious men, fee the article MICROMETER.

EQUATORIAL *Sector*, an inftrument fometimes ufed in *Practical Aftronomy*. This inftrument was invented by Mr. George Graham, F. R. S. for meafuring greater differences of right afcenfion and declination of a heavenly body, as compared with another body, than the equatorial micrometer alone will give, and may be made of any convenient dimenfions. One of thefe inftruments made by Mr. Graham, is yet preferved at the Royal Obfervatory at Greenwich, and is occafionally employed to determine the right afcenfions and declinations of a comet or other body out of the meridian, for doing which it is ftill found to be ferviceable. Doctor Robert Smith has defcribed the principle and conftruction of Graham's fector, in the year 1738, and Mr. B. Martin copied the account verbatim in his magazine, from one or other of which authors the different dictionaries have their defcription tranfcribed.

Graham's Equatorial Sector.—In juftice to the contriver of the equatorial fector, we propofe to defcribe it agreeably to its original conftruction; but as we have caufed the different parts of the drawings, as given by Dr. Smith, to be thrown into one perfpective inftrument, it becomes neceffary to vary the detail accordingly. *Fig.* 1. of *Plate* XIII. (of *Aftron. Inftr.*) is a perfpective view of the principal parts of the fector lying in its inclined ftand or bed, which we have fuppofed to be firmly fixed to a floping pedeftal, exactly parallel to the earth's axis. This inclined bed, A B, is a ftrong brazen plate or bar, turned up at the ends in a perpendicular direction at C and D; the lower end C has a fcrew, entering it from below, ftrong enough to bear the inferior end of the fector's axis E F G, the conical hole made in the end of the latter at E, refting on the conical point of the former; the upper end D has a flit in it, into which the axis is demitted at the cylindrical part F, below the circular plate H attached to the axis. The whole length of the axis is 18 inches, of which the fquare part E F is 12. On the pofterior part of the bent end D of the inclined fupporting plate A B, is a clamp I, turning on two pivots, fo that it may be elevated or depreffed without turning round in an equatorial direction; this clamp fixes the circular plate H, in any given place on its edge from turning round, but adapts itfelf to the plate, fo as to prefs equally on both furfaces, by means of its vertical motion on pivots; confequently the axis E F G, to which the plate H is attached, may have a motion like the polar axis of the earth when wanted, and may be firmly fixed by the clamp acting on its plate in any given fituation. At the fuperior end G of the axis is fixed another circular brazen plate K L on one of the flat fides of the fquared axis, and having a motion round a pin with fcrews and a tightening collar; on this plate a crofs of brafs is fcrewed faft, compofed of four bars at right angles to each other, two of which bars conftitute an inverted cock, on the bent parts of this the long radial bar M N is fixed, which is made ftrong by an edge-bar on its under fide. Whenever, therefore, the circular plate K L moves round its central pin at G, the radial bar, carried by it, partakes of its motion, and *vice verfâ*; this plate has alfo a clamp O, fimilar to the clamp I in every refpect, by which it may be made fteady in any given fituation. The length of the radial bar is $2\frac{1}{2}$ feet, and its breadth at M and N $1\frac{1}{2}$ and 2 inches refpectively: at N is a fmall arch of a circle, 6 inches long and $1\frac{1}{2}$ broad, graduated into 10°, and fubdivided into quarters, that read and are figured both ways. Upon this radial bar is mounted a telefcope P, of $2\frac{1}{2}$ feet in length, moveable on the point M, as an axis of motion, near the object-end, and having a vernier near the eye-end with 16 quarters of a degree divided into fifteen equal parts, fo as to read off exact minutes. This vernier is moved by the nut of an endlefs fcrew Q, that is adapted as an apparatus for faft or flow motion, in the ufual way. The diameters of the two circular plates are each 5 inches, and the plates are ftrong enough to hold the telefcope in any given pofition that an obferved body may require.

The polar axis E F G of this inftrument muft be placed *truly* in the meridian and parallel to the earth's axis, which may be done by bringing the telefcope parallel to the axis itfelf, and, after fixing it, by following a circumpolar ftar therewith, and noting the apparent path as it refpects the interfection of the crofs-wires of the telefcope: the deviation above or below the crofs-wire will point out the error of elevation of the axis, and the difference in the times of the ftar's paffage through the two femicircles, eaft and weft refpectively, will difcover the deviation from the meridian line;

line; then half these errors may be corrected by the screws that fix the inclined bar A B to the pedestal, and the other half by altering the position of the telescope, till, after several successive trials, the star will accompany the intersection of the wires through its entire circle. It is necessary, however, that the polar axis be placed, by means of a small quadrant or other such contrivance, very nearly in its proper degree of elevation, as well as nearly in the meridian on the pedestal previously to the adjustment by a circumpolar star. It is also necessary that the line of collimation of the telescope be parallel to the plane of the sector, as well as the latter at right angles to the circular plate H, which represents the equator; the former may have its truth examined by a distant plumb-line suspended in a vertical position; for if the intersection of the cross-wires of the telescope will pass along this line, when the plane of the sector is vertical, and when the telescope derives its motion from the screw of the vernier alone, it may be concluded that the line of collimation is parallel to the plane of the sector; but the plane of the sector itself must be previously set right, as it regards the equatorial plate H, by the screws that fix it to the inverted cock of the cross, attached to the circular plate K L. From a consideration of this instrument, as we have described it, it is obvious, that, provided the telescope, thus having a polar motion and bearing a graduated sector, be made perfectly steady, and placed in the true direction of an hour circle in the heavens, the difference of declination of any two bodies in the celestial regions, that does not exceed the extent of the sector's limb, may be measured to the accuracy of a minute of space, and that whether the two bodies pass the telescope together or successively, provided the elevation of the telescope does not vary in the mean time; and also the difference of right ascension of any two bodies, similarly situated, may be had by noting the difference of siderial time, (by a regulator,) of their passages over the horary wire; provided the situation of the sector itself does not alter while the telescope is raised or depressed; but much of the accuraryof the results will depend on the steadiness of the parts that are clamped. Were the equatorial sector to be constructed at this time, the reading by a microscopic micrometer would greatly enlarge the powers of this instrument.

"But however well adapted this instrument may be to the purposes for which it was intended," says professor Vince (Treatise on Pract. Astron. p. 141, and sec. 7.) "yet it will not conveniently admit of a large telescope; Dr. Maskelyne, therefore, thought of a construction which would admit of one of a larger size, and which has, besides, several other advantages in respect to the adjustments, as will be evident when we come to describe them. The instrument was made by Mr. Sisson, the construction of which we will first describe, and then proceed to its adjustments."

Equatorial sector by Mr. Jonathan Sisson.—A B, in *fig.* 1. of *Plate* XVII. (of *Astron. Inst.*) is a polar axis, H I a circle fixed upon, and at a small distance from it, on the centre of which is an axis, about which the telescope C D turns, carrying the indices *a*, *b*, each having a vernier which subdivides to minutes, and the circle is graduated to shew north polar distances; this, which is called the cross axis, goes through A B into a fixed case E on the other side, and is moveable by a screw *q* in order to fix it perpendicular to the polar axis: L M is an arc of 22° fixed upon A B, and concentric with H I; *v w* is a vernier whose arm K may be screwed to the axis on which the telescope turns, and consequently in that case will turn with it, but if the screws be released, the telescope will turn without it. N O P Q is a brass frame, the two ends of which, O N, P Q, consist of two pieces, one of which goes over the arc L M, and the other under, so that by means of two screws at *y* and *x* to press them together, the frame may be fixed to the arc, in which case the screw *c d*, passing through a nut at *s* on the arm K, will move the vernier *v w*; V is a brass circle graduated on the edge, and moveable with the screw *c d*, against which is fixed a piece of brass *r* as an index; W is a piece of brass fixed on an immoveable piece of wood, on which is another piece not seen to receive the end of the axis B, and in which it turns, and this piece is moveable east or west by a screw of adjustment; the end turns in a brass socket *e f*, moveable by a screw T in order to alter the inclination of the axis A B, and thence adjust it to the latitude; R S is an equatorial circle fixed perpendicular to A B, having a vernier *m n*; this circle is divided into 24 hours, and each hour into minutes, and the vernier subdivides into seconds.

The adjustments are three; first, to set A B parallel to the earth's axis; secondly, to adjust the line of collimation parallel to the circle H I; thirdly, to adjust the cross axis perpendicular to the polar axis. The first adjustment consists of two parts, to set the axis at the proper angle, and to place it in the plane of the meridian. Now to adjust the axis to an angle equal to the latitude of the place, the instrument is supposed to be at first fixed as nearly as possible to the true angle, and then the error is to be corrected by adjustment; to do which, turn about the polar axis until the circle H I becomes perpendicular to the horizon, and direct the horizontal wire of the telescope to the pole star, or any other whose polar distance is known, when it comes above or below the pole; then turn the axis half round (which is shewn on the equatorial circle); in which case the circle becomes perpendicular to the horizon again; then if the axis be at the proper angle, it is manifest that the telescope is now directed to a point as much below or above the pole as it was above or below before, that is, to the polar distance of the star increased or diminished by the refraction of the star at the first observation; hence, if we turn the telescope till the star be again observed at the same wire, the indices *a*, *b*, will have moved over twice the refraction, supposing the star to be so near to the pole, that the refraction may be considered the same both above and below; for if the star be first observed above, its apparent place is above the true, and therefore if the telescope and star revolve about the axis till they come below, the telescope is now directed to a point below the true place by the refraction, and as the apparent place is now above the true place by refraction, the telescope is directed to a point distant from the apparent place of the star by twice the refraction; but if it do not move over twice that distance, then half the difference is the error of the angle of the elevation of the axis; move the telescope therefore through twice the distance which the indices *a* or *b* will shew, then turn the telescope, and bring it half way to the star, and by the screw T bring the star to the wire, and the axis is adjusted to an angle equal to the latitude of the place; in the same manner we determine whether the axis be in the plane of the meridian, by observing the star in the equator, either in the east or west, and then turning the axis half round, if the axis be rightly adjusted to the meridian, the telescope must be moved 180° in order to bring the star to the same wire; hence if the telescope do describe 180° the axis is right; if not, half the difference is the error; move, therefore, the telescope through 180°, and then by turning it bring it half way to the star, and by the screw at top out of sight bring

bring it the other half, and the polar axis is truly adjusted. Secondly, to adjust the line of collimation parallel to the circle H I. Observe a star in the equator, and note the time of its transit over the middle wire of the telescope by a clock, adjust it to siderial time, and note also the time shewn by the vernier *m n* on the hour circle R S; turn the polar axis half way round according to the order of the figures on the hour circle R S, and the vernier shews a difference of 12 hours; now as the line of collimation is first directed to the equator, it must be perpendicular to the polar axis, and therefore by turning the polar axis about, it must continue to be directed to the equator, whether or not it be parallel to the plane of the circle H I; and if this could be done, and the telescope turned about, and the observation repeated without loss of time, the star would appear on the same wire, provided the line of collimation were parallel to the plane of the circle H I, for then the line of collimation in the second observation being parallel to what it was in the first, it must be directed to the same point in the heavens, the telescope being turned half round; but as this operation will take up some time, the polar axis must be turned a little more than half round in order to bring the star to the same wire, and the vernier would point out the same difference of times as the clock shews in the interval of the observations; but if these differences of times shewn by the clock and the hour circle be not equal, the line of collimation is not parallel to the plane of the circle, and half that inequality of times is the error, which must be corrected by the adjustment for that purpose. Thirdly, to adjust the cross axis perpendicular to the polar axis, or to the line of collimation. By the last adjustment, the line of collimation was made to move in a plane; therefore, if that plane be adjusted to the polar axis, the line of collimation will describe a secondary to the equator. On this supposition, if we take a star of any declination, and note the time of its transit over the middle wire by the clock, and also the hour on the hour circle; then turn the polar axis half round, and observe again as in the last position, and the differences of the times of the two observations shewn by the clock, and on the hour circle diminished by 12, must be equal; but if the line of collimation do not describe a secondary, the differences will not be equal. To correct, therefore, this error, let E Q, *fig.* 2. *Plate* XVII. be the equator, E P Q a great circle passing through the pole P, E F Q the great circle described by the line of collimation, and let the telescope be directed to a star at *b*, and let *d b y* be a portion of its parallel, take $a d = a b$, and draw the secondaries P *d m*, P *b c*. Now it is manifest, that if we turn the polar axis half round, the plane E F Q will then lie as much on the contrary side of E P Q; and, therefore, when the telescope is directed to the star's parallel, it will cut it at *d*, and half *m* C, or E *c*, is the error of right ascension. Note the time on the hour circle, and continue to turn (in the present instance) the polar axis until the star, now at *x*, on account of its motion, be again brought to the middle wire, and note again the time on the hour circle, and we have the difference *m r* shewn by the hour circle, from which subtract the time *c r*, shewn by the clock between the observations, and we have *m* C, the half of which is E *c*. Now the star being on the middle wire, move the polar axis so as to cause the hour circle to move through an arc *rs* equal to E *c*, and by the screw *q*, *fig.* 1, alter the position of the cross axis, and consequently of the plane E F Q till the star appears again on the same wire, moving, if necessary, the telescope on the circle H I to bring the star into the field; and then as $y x = a b$, the line of collimation would have been corrected so as to make it pass through P, and the adjustment would have been truly made, provided the star had not moved in the time of this last operation. Correct again, therefore, and you will get the line of collimation to describe a secondary to the equator, when the telescope is moved on the circle H I. Thus the instrument is adjusted for use.

To find any object in the heavens, whose right ascension and declination are known.—Find its distance, at the time required, from the meridian in the usual way, and reduce it to siderial time, and turn about the polar axis, that way the object lies from the meridian, until the hour circle points out that distance of the telescope from it; then turn the telescope till the indices *a*, *b*, shew the polar distance, and the object will be in the field of view. By this means we direct the telescope to a comet, or any other body whose place is known, which is invisible to the naked eye.

To find the true place of a body, and trace out its path in the heavens.—Screw the index K to the cross axis of the telescope; bring the body upon the wire parallel to the equator, and take the time of its transit over the middle wire perpendicular to it, and note the degrees on the arc L M, pointed out by the vernier *v w*; then if there be any known fixed star near its parallel, move the telescope on the circle H I (the polar axis remaining fixed) to the star's parallel, wait till the star enters the field of view, and make it run along the same wire as the body did, and take the time of its transit at the middle wire, and the difference of these times will give the difference of their right ascensions, and the difference of the arcs on L M, pointed out by the vernier *v w* at the times of the transits, gives the difference of their declinations; hence the right ascension and declination of the body is known. Continue these observations as long as the body is visible, and you will get its path in the heavens. The utility and convenience of this method is, that we can at any time determine the place of a body without waiting for its coming to the meridian; where, besides the inconvenience of waiting, an observation might be hindered by the badness of the weather, or the body might come to the meridian in the day-time, when it could not be seen.

An instrument, somewhat similar in construction, but with considerable improvements, was begun by Mr. Bird in the last year of his life, or the year preceding, for the observatory at Oxford, and was finished by Mr. Troughton (the senior) about the year 1773, by order of Mr. Bird's executors. We regret that we have not had the means, in due time, of obtaining a perspective drawing of this instrument, that we might have gratified our readers with a description of it.

Equatorial *Stand* of a telescope is a contrivance for making a common telescope follow a celestial body in its apparent path along, or parallel to, the equator; and answers the purpose of a polar axis of motion, while it adds but little to the expence of a simple stand for horizontal and vertical motions only. The thing required to be done to a common stand, was to give the horizontal motion an equatorial direction, and then the vertical motion, of itself, becomes a motion in declination, or in an horary circle, as well out of, as in the meridian. Various methods have been devised of effecting this purpose in the simplest way; but the contrivance invented by Mr. Smeaton, usually called Smeaton's Block, and which has all the advantages of cheapness, stability and simplicity, has been preferred to all others, and in our opinion merits a place in our collection of astronomical instruments.

Fig. 5. of *Plate* XIII. of *Astron. Inst.* is a representation of an equatorial stand of Smeaton's construction, in which the

the three legs are of mahogany, well braced together, and ſhortened at the lower extremities for the purpoſe of bringing them within the plate. The part *a b*, at the top of the legs, in the ſhape of a blunt wedge, is of mahogany, and is faſt to the legs; the other ſimilar part *c d*, above it, is alſo mahogany, and ſloped exactly like the part *a b*; the two parts taken together are called the *block*, the lower half of which is fixed, and the upper moveable on a ſtrong cylindrical piece of braſs fixed to the piece *c d*, at right angles to the line of ſection, or plane of contact, and paſſing through the piece *a b* ſo as to be fixed, when neceſſary, by a finger ſcrew below the block, and within the junction of the three legs. The plane of contact of the two halves of the block is ſo ſloped as to make an angle exactly equal to one half of the co-latitude of the place of obſervation, with a horizontal line, in which the under-face of the block is ſuppoſed to be by its poſition; but as the upper half of the block is exactly ſimilar to the under one, its face, when in the preſent equatorial poſition, makes an angle with the horizon equal to the whole co-latitude of the place; *i. e.* when in the meridian, is coincident with the plane of the equator. When the part *c d* is turned half round, ſo that the point *d* may coincide with the point *a*, and the point *c* with the point *b*, the ſlopes of the two halves of the block are then reverſed, and the face of *c d* becomes horizontal: hence it appears that a motion of the half block *c d* round its axis of motion, will carry any teleſcope *g*, or other body, placed on it parallel to its face, in the direction of the equator, provided it be placed in the meridian of the place when it has the greateſt elevation. Accordingly an axis of motion of a ſmall graduated equatorial circle *e* is attached perpendicularly to the face of the half block *c d*, round which the ſaid circle is moveable; and over this circle is mounted a graduated ſemicircle of declination *f*, or of altitudes, when the block is in its horizontal poſition, to which the teleſcope is made faſt. The circle *e* is divided into half degrees, or two minutes of time, and is ſubdivided by a vernier into $\frac{1}{30}$th of this quantity, that is, into minutes of ſpace, and four ſeconds of time; the declination-ſemicircle is alſo ſubdivided into minutes of ſpace by a vernier; and by enlarging the radii the ſubdiviſions might be rendered ſtill more minute; but the uſe of theſe graduations is merely to *find* a ſtar or planet, by its right aſcenſion and declination, to which purpoſe the inſtrument is quite competent. Mr. Troughton informs us, that he has made this ſtand an univerſal one ſometimes, by dividing the block diagonally by an angle of 45°, in which caſe it would take any degree of elevation from a horizontal to a vertical poſition, and one of the half blocks, being graduated into 360°, was read by a vernier fixed to the other, ſo as to aſcertain any given quantity of elevation; but as the conſtruction of the inſtrument does not admit of great accuracy in its adjuſtments and motions, he conſidered ſuch addition rather as curious than really uſeful in aſtronomy. Still, however, when the teleſcope is fitted up with the beſt micrometer for meaſuring the difference of right aſcenſions and declinations, and when the ſtand is made very ſteady, the inſtrument may be very ſerviceable in an obſervatory, and is often made a part of its furniture.

The ſliding tubes *h* are ſometimes ſuperadded to brace the eye-end of the teleſcope, and are found to anſwer a good purpoſe, when well made, and fitted to any pair of the legs that may happen to be turned towards this end of the teleſcope. Both the equatorial circle *e* and ſemicircle *f* have the uſual apparatus for quick or ſlow motion; and when the block is in the horizontal poſition. the teleſcope may be fixed, by the finger ſcrew under the block, to be conveniently uſed for viewing terreſtrial objects; in which poſition the inſtrument makes no contemptible theodolite, as well as equal-altitude inſtrument, when a level is added.

EQUEA, in *Geography*, a town of Africa, on the Gold coaſt.

EQUERY, or Ecury, a grand ſtable or lodge for horſes, furniſhed with all the conveniences thereof; as ſtalls, manger, rack, &c.

The word is formed from the French, *eſcurie*, which ſignifies the ſame thing. Some again derive *eſcurie* from the Latin, *ſcuria*, which not only denotes a place for beaſts to be put up in, but alſo a grange or barn. But a more probable derivation is from *equile*, a ſtable for horſes, of *equus*, horſe.

Some hold that the word ſtable, in propriety, relates only to bullocks, cows, ſheep, hogs, &c. and equery, to horſes, mules, &c.

A ſimple equery is that provided for one row of horſes; a double equery that provided for two, with a paſſage in the middle, or two paſſages; the horſes being placed head to head, as in the little equery at Verſailles.

Under equery are ſometimes alſo comprehended the lodgings and apartments of the equeries, grooms, pages, &c.

Equery, *eſcuyer*, is alſo an officer who has the care and management of the horſes of a king or prince.

EQUERIES, or Equerries, popularly called *querries*, are particularly uſed amongſt us for offices of the king's ſtables, under the maſter of the horſe, five in number, who, when his majeſty goes abroad, ride in the leading-coach, are in waiting, one at a time, monthly, and have a table with the gentlemen-uſhers during the time, and a ſalary of 300*l.* a year each: that of the firſt equerry and clerk-martial being 500*l.*

They uſed to ride on horſeback by the coach ſide when the king travelled: but that being more expenſive to them than neceſſary to the ſovereign, it has been diſcontinued.

Equeries *of the crown ſtable*, have that appellation, as being employed in managing and breaking the ſaddle-horſes, and preparing them for the king's riding.

The equerry of the crown ſtable has an annual ſalary of 200*l.* and is, or always ſhould be, in cloſe waiting at court; and when his majeſty rides holds the ſtirrup, while the maſter of the horſe, or one of the equerries in his abſence, aſſiſts in mounting him; and when his majeſty rides, they uſually attend him. To the eſtabliſhment of the queen's houſhold belong two equerries with a ſalary of 220*l.* each. There are alſo two belonging to the prince of Wales's houſhold. Officers under the ſame denomination form a part of the eſtabliſhed houſholds of the royal dukes, &c.

EQUES Auratus, is uſed to ſignify a knight bachelor, called *auratus*, q. d. *gilt*, becauſe anciently none but knights might gild or beautify their armour, or other habiliments of war, with gold.

In law this term is not uſed, but inſtead of it *miles*, and ſometimes *chevalier*.

EQUESTRIA, among the Romans, a place in the theatre where the equites or knights ſat.

EQUESTRIS, Equestrian, formed of the Latin, *eques*, knight, horſeman, of *equus*, horſe, a term chiefly uſed in the phraſe equeſtrian ſtatue, which ſignifies a ſtatue repreſenting a perſon mounted on horſeback.

The Fortuna equeſtris, in ancient Rome, was a ſtatue of the goddeſs on horſeback. We ſometimes alſo ſay, *equeſtrian* column, which ſee.

Equestrian *cohort*, in *Antiquity*. See Cohors *equitata*.

Equestrian *games*, *ludi equeſtres*, among the Romans, horſe-races, of which there were five kinds, the prodromus, or or plain horſe-race, the chariot race, the decurſory race, about funeral piles, the ludi ſevirales, and the ludi neptunales.

Equestrian *order*, among the Romans, ſignified the order of the knights or equites.

EQUI, in *Ancient Geography*, a ſmall town of Africa Propria, near a lake in the vicinity of Utica. According to Diodorus Siculus it was taken by Agathocles.

EQUIANGULAR, in *Geometry*, is applied to figures whoſe angles are all equal; ſuch are the ſquare, and all regular figures.

All equilateral triangles are alſo equiangular.

An equilateral figure inſcribed in a circle is always equiangular; but an equiangular figure inſcribed in a circle is not always equilateral, except when it has an odd number of ſides. If the number of the ſides be even, then they may be either all equal, or elſe half of them will always be equal to each other, and the other half to each other; the equals being placed alternately. See Hutton's Math. Miſc. p. 272.

Equiangular is alſo applied to any two figures of the ſame kind, when each angle of the one is equal to a correſponding angle in the other, whether each figure, ſeparately conſidered, be an equiangular figure or not, that is, having all its angles equal to each other. Thus, two triangles are equiangular to each other, if, *e. g.* one angle in each be of 30°, a ſecond angle in each of 50°, and the third angle of each equal to 100°.

Equiangular triangles have not their like ſides neceſſarily equal, but proportional to each other; and ſuch triangles are always ſimilar to each other.

EQUICRURAL Triangle, is what we more uſually call an iſoſceles triangle.

EQUICULUS, Equuleus, or *Equus minor*, in *Aſtronomy*, a conſtellation of the northern hemiſphere. See Equuleus.

EQUIDIFFERENT, in *Arithmetic*. If in a ſeries of three quantities there be the ſame difference between the firſt and ſecond as between the ſecond and third, they are ſaid to be continually equidifferent; but, if in a ſeries of four quantities, there be the ſame difference between the firſt and ſecond as between the third and fourth, they are ſaid to be diſcretely equidifferent.

Thus, 3, 6, 7, and 10, are diſcretely equidifferent, and 3, 6, and 9, continually equidifferent.

EQUIDISTANT, in *Geometry*, a term of relation between two things which are every where at an equal or the ſame diſtance from each other. Thus, parallel lines are ſaid to be equidiſtant, as they neither approach nor recede.

EQUILATERAL, of *æquus*, equal, and *latus*, ſide, is applied to any figure whoſe ſides are all equal. Thus, an equilateral triangle is that whoſe ſides are of equal length. In an equilateral triangle all the angles are likewiſe equal. See Equiangular.

All regular polygons and regular bodies are equilateral. See Polygon, Regular, &c.

Equilateral *Hyperbola*, is that in which the conjugate axes, and every pair of conjugate diameters, are equal to each other. The aſymptotes are alſo at right angles to each other, and each of them forms a right angle with the axis. Such an hyperbola is alſo equal to its oppoſite hyperbola, and likewiſe to its conjugate hyperbola, ſo that all the four conjugate hyperbolas are mutually equal to each other.

Hence, as the parameter is a third proportional to the conjugate axes, they are all mutually equal; conſequently, if in the equation for the hyperbola $y^2 = \frac{p}{t} \times \overline{tx + x^2}$, or $= \frac{c^2}{t^2} \times \overline{tx + x^2}$, in which t is the tranſverſe axis, c the conjugate, p the parameter, x the abſciſs, and y the ordinate, t, c, and p being made equal, the equation for the equilateral hyperbola becomes $y^2 = tx + x^2$; differing from that of the circle merely in the ſign of the term x^2, which in the circle is $-$. See Hyperbola.

EQUILIBRIUM, or Equipoise, in *Mechanics*, means an equality of forces acting in oppoſite directions, ſo that they mutually balance each other. Thus, the ſcales of a balance are ſaid to be in equilibrio, when neither of them preponderates, in conſequence of which the beam of the balance remains perfectly horizontal. But, it muſt not be imagined, that the equality of weights alone determines the equilibrium of mechaniſms in general; for that is only the caſe when the velocities and directions are equal, as in the above-mentioned caſe of the balance, where the two arms of the beam being equal, the weights in the ſcales have equal velocities, ſuppoſing that the balance is made to vibrate, and move in vertical directions. Therefore, it has been ſaid above, that the equilibrium takes place, when the *forces*, which act in oppoſite directions, are equal; for the forces are eſtimated from the weight of the bodies, their velocities, and directions conjointly. Thus, in the common mechanical powers, the equilibrium takes place, when the power is to the weight as the velocity of the weight is to the velocity of the power. The equlibrium of ſolids forms a conſiderable part of the ſcience of ſtatics, and the equilibrium of fluids forms a conſiderable part of hydroſtatics.

Equilibrium is alſo uſed figuratively on other occaſions. A painter muſt take care to obſerve the equilibrium of his figures, *i. e.* diſpoſe them well on their centre of gravity, that they may not ſeem ill-ſupported, or ready to tumble. Thus, *e. gr.* if one arm be moved forward, the other muſt be proportionably backward to poiſe the figure.

In a picture there ſhould always be an equilibrium between one part and another; that is, the objects are to be diſtributed ſo as to balance and contraſt each other; and not too many, *e. gr.* be crowded on one ſide, and the other be left bare.

EQUIMULTIPLE, in *Arithmetic* and *Geometry*, is applied to ſimple magnitudes when multiplied equally, *i. e.* by equal quantities or multipliers.

Thus, taking A as many times as B, or multiplying them equally, there will ſtill remain the ſame ratio between the magnitudes thus multiplied, as between the primitive magnitudes before multiplication.

Now thoſe magnitudes, thus equally multiplied, are called equimultiples of the original ones A and B; whence we ſay, that equimultiples have the ſame ratio as the ſimple quantities. In arithmetic, we generally uſe the term equimultiples for numbers which contain equally or an equal number of times their ſubmultiples.

Thus 12 and 6 are equimultiples of their ſubmultiples 4 and 2, inaſmuch as each of them contains its ſubmultiple three times.

EQUINA Sella. See Sella.

EQUINOCTIAL, in *Aſtronomy*, a great circle of the ſphere, under which the equator moves in its diurnal motion.

The equinoctial is conceived by ſuppoſing a ſemidiameter of the ſphere produced through a point of the equator, and there, by the rotation of the ſphere about its axis, deſcribing a circle on the immoveable ſurface of the primum mobile.

The

The poles of this circle are the poles of the world. The ſphere is divided by it into two equal parts, the northern and ſouthern. It interſects the horizon of any place in the eaſt and weſt points; and at the meridian its elevation above the horizon is equal to the co-latitude of the place.

Whenever the ſun, in his progreſs through the ecliptic, comes to this circle, it makes equal days and nights all around the globe; as he then riſes due eaſt and ſets due weſt, which he never does at any other time of the year. And hence the denomination from *æquus* and *nox*, night, *quia æquat diem nocti*. All the ſtars that are under this circle, or that have no declination, do alſo riſe due eaſt and ſet due weſt.

The equinoctial, then, is the circle which the ſun deſcribes, or appears to deſcribe, at the time of the equinoxes: that is, when the length of the day is every where equal to that of night, which happens twice a year. (See Equinox.) From this circle is the declination in the heavens or latitude of places on the earth counted in degrees of the meridian. Upon this circle is reckoned the longitude, 180° weſt and 180° eaſt, in all 360°. Hence, 1° of longitude anſwers to 4′ of time; 15′ to 1′ of time; and 1′ to 4 ſeconds of time, &c.

The ſhadows of thoſe who live under this circle are caſt to the ſouthward of them for one-half of the year, and to the northward of them during the other half; and twice in a year, *viz.* at the equinoxes, the ſun at noon caſts no ſhadow, being in their zenith.

Equinoctial *colure*, is that paſſing through the equinoctial points. See Colure.

Equinoctial *dial*, is that whoſe plane lies parallel to the equinoctial. See Dial.

Equinoctial *hours*, *line*, *orient*. See the ſubſtantives.

Equinoctial *points*, are the two points wherein the equator and ecliptic interſect each other: the one, being in the firſt point of Aries, is called the vernal point, or equinox; and the other, in the firſt point of Libra, the autumnal point, or equinox.

The equinoctial points, and, indeed, all the other points of the ecliptic, are found, by obſervation, to be continually moving backwards, or in antecedentia, *i. e.* towards the weſt. This retrograde motion is called the *Preceſſion of the equinoxes*; which ſee.

EQUINOX, in *Aſtronomy*, the time when the ſun enters one of the equinoctial points.

The equinoxes happen when the ſun is in the equinoctial circle, of conſequence the days are equal to the nights throughout the world, which is the caſe twice a year, *viz.* about the 21ſt of March, and the 22d of September, the firſt of which is the vernal, and the ſecond the autumnal equinox.

As the ſun's motion is unequal, that is, ſometimes ſwifter and ſometimes ſlower (from the cauſes already explained under the article Equation), it comes to paſs, that there are about eight days more from the vernal to the autumnal equinox than from the autumnal to the vernal, the ſun ſpending ſo much more time in travelling through the northern than the ſouthern ſigns.

According to the obſervations of M. Caſſini, the ſun is $186^d\ 14^h\ 53'$ in the northern ſigns, and only $178^d\ 14^h\ 56'$ in the ſouthern. The difference of which is $7^d\ 23^h\ 57'$.

The ſun, continually advancing forwards in the ecliptic and gaining a degree every day, makes no ſtay in the equinoctial points, but the moment he arrives in them he alſo leaves them.

Of courſe, therefore, though the day the ſun enters the equinoctial point is called the equinox, as being reputed equal to the night; yet it is not preciſely ſo, unleſs the ſun enter the equator at mid-day: for if the ſun riſing, ſhould enter the vernal equinox at ſetting, he will have departed from it, and have got northwards about 12′; conſequently, that day will be ſomewhat longer than 12 hours, and the night proportionably ſhorter.

The time of the equinoxes, *i. e.* the moment in which the ſun enters the equator, is found by obſervation, the latitude of the place of the obſervation being given.

Thus, in the equinoctial day, or near it, take the juſt meridian altitude of the ſun; if this be equal to the altitude of the equator, or the complement of the latitude, the ſun is that very moment in the equator: if it be not equal, the difference is the ſun's declination. The next day obſerve the meridian altitude as before, and find his declination; if the declination be of different kinds, *viz.* the one north and the other ſouth, the equinox has happened in the interval of time between them; otherwiſe, the ſun has not entered the equinoctial, or had paſſed it at firſt. From theſe obſervations a trigonometrical calculus gives the time of the equinox.

Thus, let D G (*Plate* XII. *Aſtronomy, fig.* 110.) repreſent the equator, A C the ecliptic, E the equinoctial point; the points A, B, C, the places of the ſun at the times of obſervation; the arcs A D, B F, C G, the correſponding declinations; in the right-angled ſpherical triangles C E G, B E F, the obliquity of the ecliptic, and the declinations are known; whence may eaſily be found E C, E B; then B C, the ſum or difference of E C, E B is the ecliptic arc deſcribed in 24 hours: then ſay as B C : B E :: 24 hours for B C : time for B E; and this time ſhews the diſtance of the equinox from the time of the middle obſervation.

EQUINUS Barbatus, a kind of comet. See Hippeus.

Equinus *ellipticus* and *quadrangularis*. See Hippeus.

Equinus *venter*. See Venter *equi*.

EQUIP, *To*, in *Naval Language*, a term borrowed from the French marine, and frequently applied to the buſineſs of fitting a ſhip for ſea, or arming her for war. See Fitting-out.

EQUIPAGE, in *Navigation*. See Crew and Fitting-out.

Equipage, *Camp*. Under this term we confine ourſelves entirely to what relates to the tents generally in uſe; remarking, that ſuch as ſuit admirably for a cold climate, would be found totally unſerviceable in higher latitudes, where the air, confined in a ſmall ſpace, under a vertical ſun, while probably not a leaf is in motion, could not fail to be unfit for reſpiration. Therefore, we ſhall give the regulation ſizes of tents, both according to the home ſervice, and to what is found neceſſary for troops employed in the Eaſt Indies.

Home Service, *Laboratory Tent*, with mallets, poles, pins, &c. ſhould weigh 3 cwt. 24lb.; and ought to be ſuſtained on poles of $14\frac{1}{2}$ feet each in length; the ridge pole ſhould be 18 feet. Some of theſe are made with half-walls; that is, their flies, or canopies, do not come within three feet of the ground, but are there faſtened to a half-wall, or curtain, which being laced or hooked to the interior of the fly, hangs perpendicularly to the ground, to which it is ſecured by wooden pins, or pegs.

India Service, *Laboratory Tent*.—This claſs of tents is nearly ſimilar, but they have commonly extra flies, ſtanding at about a yard diſtant from the inner ſhell, which are ſometimes well

well foaked in oil, or flightly with tar, at leaft fufficiently to throw off rain. This occafions them to be extremely ponderous; the poles being fome feet longer, and the fpread of canvas confiderably greater; the average weight of a laboratory tent may here be taken at nearly half a ton. Such a weight could only be conveyed on an elephant, or on a cart, (the latter being far too dilatory for moft fituations,) were it not that the fly, the fhell, and the walls, are all made to feparate. By this means two camels may conveniently bear one of thefe tents.

Home Service, Bell Tent, fhould, according to the new conftruction, have a pole of 9 feet long, and form a circular fpread of 14 feet in diameter, fo as to give fhelter to twelve men. Since it has been found neceffary to reduce the quantity of baggage attached to our armies, little or no ufe is made of any tents that are inadequate to the fhelter of a certain number of perfons; confequently thofe bell tents, which were called "Bells of Arms," have in a manner ceafed to be known in our arfenals, they being totally incompetent to any effential fervice. The modern bell tent is, therefore, to be confidered as a medium between the bells of arms, and the private tents formerly in ufe; they are extremely portable, and, in proportion to their weight, which ought not to exceed 45lb. are far more ferviceable; as they cover twelve men better than the common infantry tents, that weighed 27lb., did five. The facility with which a tent, having only a pole, is raifed, or ftruck, the great fafety it infures from prefenting no flat fide to the wind, and the paucity of pins, &c. requifite for its ufe, give it a very confiderable claim to preference.

Indian Service, Bell Tents, are made of very ftout canvas, fupported on poles of about 7 feet in length, and overlapping in their front, for the purpofe of keeping the arms they contain perfectly dry. The mufquets, &c. are filed round the pole of a bell tent by means of two fticks, about 18 inches in length, paffing at right angles to each other, and to the pole alfo, through two holes made in the latter. Thefe, which may be drawn at pleafure, form a crofs, in the four divifions of which the arms of the company are filed. Average weight, when dry, 1 cwt.; when wet, 1 cwt. 1 qr. 14lb.

Home Service, Common Infantry (or Private) Tents, which are now lefs ufed than formerly, require two ftandard poles, each 6 feet in length, and a ridge pole of 7 feet. They fhould weigh *in toto* 27lb., and be capable of covering five men. It is obvious, that a tent of this defcription muft be lefs fafe, and lefs comfortable to its inhabitants, than the bell tent now fubftituted

Indian Service, Private Tents, ftand upon two poles, each 9 feet long, and have a ridge pole of 8 feet. Thefe tents are made of very ftrong canvas, and are fometimes lined feparately; whereby they are rendered tolerably cool. They fhould be capable of fheltering twelve men commodioufly; but in hot weather not more than eight ought to be allotted to one tent. Confiderable relief is afforded by the walls of thefe tents; which are generally about 30 inches high. The average weight of one, complete, may be about 2 cwt. 1 qr. when dry; but when wet, it will perhaps exceed 4 cwt.

Home Service, Officer's Marquee, fhould have two ftandard poles, each 8 feet high, and a ridge pole of 7 feet: the total weight about 130lb. This kind of tent has walls about 4 feet in height, and is generally furnifhed with a feparate lining throughout.

Indian Service, Marquees, are upon a very different conftruction. The proportions are as follows; *viz.*

	Length.	Breadth.	Ridge Poles.	Standard Poles.
Captain's marquee on two poles lined throughout with gingham, and having walls of 5 ft. 6 in.	23 feet.	15 feet.	10 feet.	12 feet.
Subaltern's tent on 1 pole	14 feet.	14 feet.	——	11 feet.

Thefe proportions may feem very great, but they are found to be actually neceffary in that climate. The total weight of a captain's marquee may be eftimated, when dry, at 4 cwt.; when wet, at $6\frac{1}{2}$ cwt. A fubaltern's marquee, when dry, $3\frac{1}{2}$ cwt.; and when wet, 5 cwt.

With refpect to the larger claffes of tents, fuch as are ufed by our colonels and general officers, they approach fomewhat towards the conftruction of what, in the Indian fervice, are called field officers' fleeping tents, which generally have from 12 to 14 feet between two poles of 14 feet in height. They are chiefly compofed of ftrong fhells made of Ruffia-duck, with flies of canvas, and are ordinarily lined with perpet. The weight of fuch a tent may be computed at 5 cwt. when dry; and when wet at $7\frac{1}{2}$ cwt. State tents may meafure about 18 feet in the ridge, and have ftandards of full 16 feet in height. Their poles are generally made in two pieces, joining in their centres by means of a cylinder of iron; on the fame principle as the fliding ferrils in ladies' parafols.

We have thus given fome infight into the proportions between the tents appropriated to the feveral claffes, fo far as they could tend to inftruct the reader; who will, of courfe, underftand, that in proportion as the ftandards of a tent are lengthened, fo will the feveral flopes of the fly be lengthened in a fuitable ratio. The ordinary computation is, that the direct depth of the flope ought to be two-thirds the length of the poles where a full wall is to be attached; four-fifths where a half-wall is to be furnifhed; and that the pole fhould be one-quarter, or even a third, lefs in length than the direct flope of the fly is deep, if no walls whatever are to be added. The climate will indicate the neceffity for more or lefs fteepnefs in the flope; for if little rain falls, lefs declivity will anfwer; whereas, if, as in India, the rains are abundant and heavy, fuch a flope muft be given as may infure that the interior fhould remain dry.

It is of the utmoft importance, that all camp equipage fhould be made not only conformably to a particular pattern, thereby to preferve uniformity of appearance; but, as nearly as practicable, of the fame kind of materials, and of a given weight; fo that a very correct eftimate may be formed both of the bulk and gravity of the whole, when about to be conveyed either by land or by water. Befides, it is expedient, that the camp-colourmen, batmen, &c. fhould have a perfect underftanding of this branch of military economy, and have the whole of the tents handed to them, when about to be laden, or conveyed, packed in a regular manner; fo as to occupy as little fpace as poffible; otherwife they never can ftow to advantage, fo as to be fafe, and to afford as much fpace as can be fpared for other articles.

Equipage, in the *Military Art,* denotes all forts of utenfils, artillery, &c. neceffary for commencing and profecuting with eafe and fuccefs any military operations.

EQUIPOLLENCE, in *Logic,* is when there is an equivalence between any two or more terms or propofitions; *i. e.* when they fignify one and the fame thing, though they exprefs it differently. Such propofitions, &c. are faid to be equipollent.

EQUIPPE', in *Heraldry*, expreffes a cavalier equipped, *i. e.* armed at all points.

EQUIRIA, in *Antiquity*, a feftival inftituted by Romulus, and celebrated on the 27th of February, in honour of Mars, at which there were horfe-races.

EQUISELIS, in *Natural Hiftory*, the name of a large fly, of the fize of a hornet, but having only two wings and no fting: it otherwife much refembles the common hornet in fhape. This fly is found only in Macedonia. We have alfo in England flies which nearly refemble the hornet, wafp, and bee, but in their wanting ftings and having only two wings.

Equiselis, in *Ichthyology*, a name ufed by fome authors for a fea-fifh, caught on the Spanifh fhores, and fuppofed by many to be the fame with the *Dorado*, or *Coryphæna*, with the forked tail of Artedi. See Coryphæna.

EQUISETUM, in *Botany*, from *equus*, a horfe, and *feta*, a ftrong hair or briftle. Horfetail. Plin. Hift. Nat. lib. 26. cap 13. Linn. Gen. 559. Schreb. 753. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 1102. Hedwig. Theor. 33. t. 1, 2. Juff. 17. Clafs and order, *Cryptogamia Filices*. Linn. *Cryptogamia Mifcellaneæ*. Schreb. Nat. Ord. *Filices fpicatæ*.

Gen. Ch. *Fructifications* in an ovate-oblong terminal catkin, compofed of whorled, ftalked fcales. Each fcale peltate, fomewhat orbicular, but with many fides, bearing on its under fide from four to feven tubular, angular, obtufe fheaths, parallel to and furrounding the ftalk of two valves, burfting internally, containing numerous florets. *Stam.* Filaments four, coiled up round the germen, in a fpiral manner, while moift, divaricated when dry; anthers terminal, fimple, fpatulate. *Pift.* Germen globofe, wrapped up in the ftamens; ftyle none; ftigma obfolete, acute. *Seeds* globofe, deciduous, accompanied by the ftamens.

Eff. Ch. Catkin with peltate fcales, fructifying on their infide. Partial involucrums tubular, of two valves. Seeds numerous, naked, furrounded by four fpiral ftamens.

Many different opinions have exifted concerning the fructification of this genus, but Hedwig's, as above given, feems to us the moft fatisfactory. In the artificial claffification we retain it among the ferns, to which it is clofely allied in natural affinity, though of itfelf a moft natural and diftinct genus; nor do we think Schreber's order, entitled *Mifcellaneæ*, leffens in any degree the difficulties refpecting this tribe.

Seven fpecies of *Equifetum* are found in Britain, and two or three foreign ones are imperfectly known befides.

E. *fylvaticum*, Engl. Bot. t. 1874, known by its compound drooping branches, is one of the pretticft. It occurs chiefly in mountainous countries, in moift, fhady fpots.

E. *hyemale*, Engl. Bot. t. 915, called Shave-grafs or Dutch rufh, is remarkable for the callous roughnefs of the ribs of its naked ftem, which renders it ufeful in polifhing wood, ivory, and even brafs. Being rare in England, it has for thefe purpofes been imported from Holland. Profeffor Davy has detected a large proportion of flinty earth in the cuticle, to which its hardnefs and afperity are owing.

E. *variegatum*, Engl. Bot. t. 1987, found on the fandy fea-coaft of Scotland, by Mr. G. Don, and a native alfo of Sweden, Denmark, Switzerland, &c. is a fmaller fpecies, nearly related to the laft, and having a fimilar roughnefs.

Equisetum, in *Natural Hiftory*, is the name by which fome writers have denominated certain foffil plants, (phytolithii,) which are found bearing fome faint refemblance to the recent plant called horfe-tail. Mr. William Martin, after defcribing an organic remain of this kind in his "Petrificata Derbienfia," fays, "there are other plants with ftellate leaves, to which it might with as much propriety be referred: hippuris, afperiala, and galium, for inftance," and he continues, "we may here obferve, that little has yet been done with refpect to difcriminating the original genera of foffil plants: thofe parts indeed, on which fuch difcrimination *muft* be founded, are rarely, if ever, vifible in the petrified ftate. The characteriftic diftinctions of the fpecies are frequently attainable, if ftudioufly fought after, by a diligent and careful comparifon of various fpecimens; and the habit or general appearance of the foffil often leads to the knowledge of the natural clafs and order of the recent plant: but its genus, for the moft part, remains undetermined or doubtful." The great importance of the organic remains or *reliquia* in tracing and identifying the ftrata, according to the new difcoveries of Mr. Smith and his pupils, will, it is hoped, ere long, induce naturalifts ferioufly to turn their attention to this neglected branch of fcience.

EQUISONANCE, in *Mufic*, a name by which the ancients diftinguifhed octaves from other concords. Octaves being the only *paraphoni*, or concords, when doubled above or below. This is a diftinction which would be as ufeful in modern mufic as in the ancient. All other concords, doubled, become difcords.

EQUITANTIA, Folia, in *Botany*, is applied to leaves fo folded at the bafe, as to embrace each other in two ranks. See Leaf.

EQUITATA Cohors, in *Antiquity*. See Cohors *Equitata*.

EQUITY, Æquitas, denotes juftice or right, mitigated and tempered by the confideration of particular circumftances; or a correction and abatement of the feverity of fome law; or a temperament, which, without being unjuft, abates the rigour of fome juft law.

Equity, as Grotius defines it, is the correction of that, wherein the law (by reafon of its univerfality) is deficient. For fince in law all cafes cannot be forefeen or expreffed, it is neceffary, that when the general decrees of the law come to be applied to particular cafes, there fhould be fomewhere a power vefted of defining thofe circumftances, which (had they been forefeen) the legiflator himfelf would have expreffed. And thefe are the cafes which, according to Grotius, "lex non exacté definit, fed arbitrio boni viri permittit."

This is what the Greeks call ἐπιείκεια. The utmoft feverity of a good law is frequently contrary to juftice; it fhould always have equity for its rule and guide. "Summum jus, fæpe fumma injuria."

The foundation of equity is not that there is any miftake in the law, but that the law was laid down univerfally, becaufe all circumftances could not be confidered or taken in under one law.

For an inftance, fuppofe it an exprefs law, that the city being now befet with an enemy, the gates be all fhut; and fuppofe it fall out that the enemy is then in purfuit after fome of the citizens by whom it is defended, fo that it would be highly prejudicial thereto not to open for them the gates; equity here decrees the gates to be opened, contrary to the exprefs words of the law.

As equity depends, effentially, upon the particular circumftances of each individual cafe, there can be no eftablifhed rules and fixed precepts of equity laid down, without deftroying its very effence, and reducing it to a pofitive law. And, on the other hand, the liberty of confidering all cafes in an equitable light, muft not be indulged too

 far;

far; leſt we thereby deſtroy all law, and leave the deciſion of every queſtion entirely in the breaſt of the judge. And law, without equity, though hard and diſagreeable, is much more deſirable for the public good, than equity without law; which would make every judge a legiſlator, and introduce infinite confuſion, as there would then be almoſt as many different rules of action laid down in our courts, as there are differences of capacity and ſentiment in the human mind.

Equity is of two kinds, and thoſe of contrary effects; the one abridges, and takes from the letter of the law; and the other enlarges, and adds to it.

The firſt is defined the correction of a law, made generally in that part wherein it fails; as ſuppoſe a ſtatute made, "that whoſoever does ſuch a thing ſhall be a felon, or ſuffer death:" yet if a mad-man, or an infant, who hath no diſcretion, do the ſame, he ſhall neither be a felon nor ſuffer death.

The other is defined an extenſion of the words of the law to caſes which are not expreſſed, which yet come under the ſame reaſon: ſo that when one thing is enacted, all other things which are of the like degree are ſo too.

Thus, the ſtatute which ordains, that in action of debt againſt executors, he who appears by diſtreſs ſhall anſwer, extends by equity to adminiſtrators; and ſuch of them as ſhall appear firſt by diſtreſs, ſhall anſwer by the equity of the ſaid act, "quia ſunt in æquali genere."

Equity is alſo uſed for the virtue of juſtice. See Justice.

Equity, in our *Laws*, &c. is alſo frequently uſed for the Court *of Chancery*, (which ſee,) where controverſies are ſuppoſed to be determined according to the exact rules of equity and conſcience, by mitigating the rigour of the common law.

"Æquitas ſequitur legem," is an old maxim in law; but, from the great increaſe of ſuits in chancery, ſome have thought fit to give it this conſtruction, that in all caſes after a man has been at law, he muſt go to equity.

Judge Blackſtone has given a brief, but comprehenſive view of the nature of equity, as it is now underſtood and practiſed in our ſeveral courts of judicature. Equity, he ſays, in its true and genuine meaning, is the ſoul and ſpirit of all law; *poſitive* law is conſtrued, and *rational* law is made by it. In this, equity is ſynonymous to juſtice: in that, to the true ſenſe and ſound interpretation of the rule. But the very terms of a court of *equity*, and a court of *law*, as contraſted to each other, are apt to confound and miſlead us; as if the one judged without equity, and the other was not bound by any law. Whereas every definition or illuſtration to be met with, which now draws a line between the two juriſdictions, by ſetting law and equity in oppoſition to each other, will be found either totally erroneous, or erroneous to a certain degree. Thus, in the *firſt* place, it is ſaid, that it is the buſineſs of a court of equity in England to abate the rigour of the common law; but no ſuch power is contended for. The learned judge ſpecifies various caſes of poſitive law, in which the court of equity can give no relief, and in which theſe, as well as the courts of law, muſt ſay with Ulpian, "hoc quidem perquam durum eſt, ſed ita lex ſcripta eſt." Again it is ſaid, that a court of equity determines according to the ſpirit of the rule, and not according to the ſtrictneſs of the letter: but ſo alſo does a court of law. Both, for inſtance, are equally bound, and equally profeſs, to interpret ſtatutes according to the true intent of the legiſlature. In general laws, all caſes cannot be foreſeen; or, if foreſeen, cannot be expreſſed: ſome occur that will fall within the meaning, though not within the words of the legiſlator; and others, which may fall within the letter, may be contrary to his meaning, though not expreſsly excepted. Theſe caſes, thus out of the letter, are often ſaid to be within the equity of an act of parliament; and ſo caſes within the letter are frequently out of the equity. Here by equity we mean nothing but the ſound interpretation of the law; though the words of the law itſelf may be too general, too ſpecial, or otherwiſe inaccurate or defective. Theſe are the caſes to which Grotius refers in the paſſage cited above. But there is not a ſingle rule of interpreting laws, whether equitably or ſtrictly, that is not equally uſed by the judges in the courts both of law and equity: the conſtruction muſt in both be the ſame, or, if they differ, it is only as one court of law may alſo happen to differ from another, each endeavours to fix and adopt the true ſenſe of the law in queſtion: neither can enlarge, diminiſh, or alter that ſenſe in a ſingle tittle.

It has been further ſaid, that *fraud*, *accident*, and *truſt*, are the proper and peculiar objects of a court of equity. But every kind of *fraud* is equally cognizable, and equally adverted to, in a court of law. Many *accidents* are alſo ſupplied in a court of law. And, although a technical *truſt*, created by the limitation of a ſecond uſe, was forced into the courts of equity; and this ſpecies of truſts, extended by inference and conſtruction, has ever ſince remained as a kind of *peculium* in theſe courts; yet there are other truſts which are cognizable in a court of law. Moreover, it has been ſaid that a court of equity is not bound by rules or precedents, but acts from the opinion of the judge, founded on the circumſtances of every particular caſe. Whereas the ſyſtem of our courts of equity is a laboured, connected ſyſtem, governed by eſtabliſhed rules, and bound down by precedents, from which they do not depart, although the reaſon of ſome of them may perhaps be liable to objection.

In ſhort, if a court of equity in England did really act, as many ingenious writers have ſuppoſed it (from theory) to do, it would riſe above all law, either common or ſtatute, and be a moſt arbitrary legiſlator in every particular caſe. Formerly, indeed, our courts of equity arrogated to themſelves ſuch an unlimited authority as hath totally been diſclaimed by their ſucceſſors for more than a century paſt. But the ſyſtems of juriſprudence, in our courts, both of law and equity, are now equally artificial ſyſtems, founded in the ſame principles of juſtice and poſitive law; but varied by different uſages in the forms and mode of their proceedings; the one being originally derived (though much reformed and improved) from the feudal cuſtoms, as they prevailed in different ages in the Saxon and Norman judicatures; the other (but with equal improvements) from the imperial and pontifical formularies, introduced by their clerical chancellors.

The ſuggeſtion indeed of every bill, to give juriſdiction to the courts of equity (copied from thoſe early times) is, that the complainant hath no remedy at the common law. But he, who ſhould from thence conclude, that no caſe is judged of in equity, when the law might have given relief, and, at the ſame time, caſts his eye on the extent and variety of the caſes in our equity reports, muſt think the law a dead letter indeed. The rules of property, rules of evidence, and rules of interpretation, in both courts, are, or ſhould be, exactly the ſame; both ought to adopt the beſt, or muſt ceaſe to be courts of juſtice. Neither a court of equity nor of law can vary men's wills or agreements, or (in other words) make wills or agreements for them. Both are to underſtand them truly, and therefore both of them uniformly.

uniformly. The rules of decifion are in both courts equally appofite to the fubjects of which they take cognizance. Such then being the parity of law and reafon which governs both fpecies of courts, it may be afked what conftitutes their effential difference? It principally confifts in the different modes of adminiftering juftice in each; in the mode of proof, the mode of trial, and the mode of relief. Upon thefe, and upon two other accidental grounds of jurifdiction, which were formerly driven into thefe courts by narrow decifions of the courts of law, *viz.* the true conftruction of fecurities for money lent, and the form and effect of a truft or fecond ufe; upon thefe main pillars hath been gradually erected that ftructure of jurifprudence which prevails in our courts of equity, and is inwardly bottomed upon the fame fubftantial foundations as the whole fyftem of law. As to the mode of proof, when facts, or their leading circumftances, reft only in the knowledge of the party, a court of equity applies itfelf to his confcience, and purges him upon oath with regard to the truth of the tranfaction; and, that being once difcovered, the judgment is the fame in equity as it would have been at law. But, for want of this difcovery at law, the courts of equity have acquired a concurrent jurifdiction with every other court in all matters of account. From this compulfive difcovery upon oath, the courts of equity have acquired a jurifdiction over all matters of fraud. As to the mode of trial, this is by interrogations adminiftered to the witneffes, upon which their depofitions are taken in writing, wherever they happen to refide. With refpect to the mode of relief, the want of a more fpecific remedy, than can be obtained in the courts of law, gives a concurrent jurifdiction to a court of equity in a great variety of cafes. Thus it is in executory agreements, and in various kinds of frauds, &c. The true conftruction of fecurities for money lent is another fountain of jurifdiction in courts of equity. The form of a truft, or fecond ufe, gives the courts of equity an exclufive jurifdiction as to the fubject-matter of all fettlements and devifes in that form, and of all the law terms created in the prefent complicated mode of conveyancing. This is a very ample fource of jurifdiction. Blackft. Com. vol. iii.

Equity *of redemption*, on mortgages, is that right which a mortgagor has of redeeming his eftate upon payment of the money borrowed. This enables a mortgagor to call on the mortgagee who has poffeffion of his eftate to deliver it back, and account for the rents and profits received, on payment of his whole debt and intereft; thereby turning the *mortuum* into a kind of *vivum vadium*. But on the other hand, the mortgagee may either compel the fale of the eftate in order to get the whole of his money immediately, or elfe call upon the mortgagor to redeem his eftate prefently, or, in default thereof, to be for ever foreclofed from redeeming the fame, that is, to lofe his equity of redemption without poffibility of recall. And alfo in fome cafes of fraudulent mortgages, (ftat. 4 & 5 W. & M. c. 16.) the fraudulent mortgagor forfeits all equity of redemption whatfoever. This is done by proceedings in the court of chancery. But the chancery cannot fhorten the time of payment of the mortgage money, where it is limited by exprefs covenant, though it may lengthen it; and then upon non-payment, the practice is to foreclofe the equity of redemption of the mortgagor. 2 Vent. 364.

To foreclofe the equity, a bill in chancery is exhibited, to which an anfwer is put in, and a decree being obtained, a mafter in chancery is to certify what is due for principal, intereft, and cofts, which are to be prefixed by the decree, whereupon the premifes are to be re-conveyed to the mortgagor; or, in default of payment, the mortgagor is ordered to be foreclofed from all equity of redemption, and to convey the premifes abfolutely to the mortgagee. Law of Securities, p. 129. 133.

By ftat. 7 Geo. II. cap. 20, after payment or tender by the mortgagor of principal, intereft, and cofts, the mortgagee can maintain no ejectment, but may be compelled to re-affign his fecurities.

Equity, in *Mythology*, fometimes confounded with Juftice, a goddefs among the Greeks and Romans, reprefented with a fword in one hand and a balance in the other.

EQUIVALENT, is underftood of fomething that is equal in value, force, or effect, to another.

Equivalence is of various kinds, in propofitions, in terms, and in things.

Equivalent *propofitions*. See Equipollence.

Equivalent *terms*, are where feveral words that differ in found have yet one and the fame fignification; as "every body was there," and "nobody was abfent," *nihil non*, and *omne*.

Equivalent *things*, are either moral, phyfical, or ftatical. Moral, as when we fay that the commanding or advifing a murder is a guilt equivalent to that of the murderer. Phyfical, as when a man who has the ftrength of two men is faid to be equivalent to two men. Statical, whereby a lefs weight becomes of equal force with a greater, by having its diftance from the centre increafed.

EQUIVOCAL, Equivocum, denotes a word or expreffion that is dubious and ambiguous, or that may have feveral fenfes, one true and another falfe.

Equivocal terms anfwer to what are otherwife called *homonyma*, or homonymous terms.

Such is the word *emperor*, which is both the name of a dignity, the proper name of a perfon, and the name of a plant. So alfo the Latin *gallus*, which ftands indifferently for a cock and a Frenchman.

In thefe cafes, one word denotes two or more different ideas, or different forts of objects: whence that common definition of equivocals in the fchools, "quorum nomen eft commune ratio vero effentiæ fecundum illud nomen diverfa." Philofophers diftinguifh equivocals into active and paffive; or æquivoca æquivocantia, and æquivocata.

Æquivoca æquivocantia, or thofe that denominate and fignify things, are words common to feveral things in a very different fignification, *i.e.* to feveral things which have a fimilar effence correfpondent to the fimilar denominations. *E. gr.* The word *taurus*, which ftands for a fign, a mountain, and an animal; and in one fignifies a lowing animal; in another, a heap of ftones and earth; and in the third, a conftellation or fyftem of ftars.

Æquivoca æquivocata, or thofe that are called or denominated, are the things fignified by ambiguous names, *e. gr.* a fign, a mountain, and an animal; which laft fpecies of equivocals alone Ariftotle feems to have had in view in his definition, which agrees to thefe, and thefe only.

Equivocal *action and caufe*. See Action and Cause.

Equivocal *generation*, is a method whereby animals and plants are fuppofed to be produced, not by the ufual way of coition between male and female, but by fome fuppofed plaftic power or virtue in the fun, &c.

Thus, infects, maggots, flies, fpiders, frogs, &c. have ufually been fuppofed to be produced by the heat of the fun warming, agitating, and impregnating the duft, earth, mud, and putrified parts of animals.

This method of generation, which we alfo call *fpontaneous*, was commonly afferted and believed among the ancient philofophers; but the moderns, from more and better obfervations, unanimoufly reject it, and hold that all animals,

animals, nay, and vegetables too, are univocally produced; that is, from parent animals, and vegetables of the fame fpecies and denomination.

It were a thing, one would imagine, fufficient to difcredit the Ariftotelian, or rather the Egyptian doctrine of equivocal generation, to find flies, frogs, lice, &c. to be male and female, and accordingly to ingender, lay eggs, &c.

The doctrine of equivocal generation we call an *Egyptian doctrine*, as having, in all probability, had its rife in Egypt, to folve the hypothefis of the original production of men, and other animals, out of the earth, by the help of the fun's heat.

To prove which, the Egyptians, as Diodorus Siculus obferves, produce this obfervation, that about Thebes, when the earth is moiftened by the Nile, and afterwards impregnated by the intenfe heat of the folar rays, an innumerable fwarm of mice come forth: whence he infers, that all kinds of animals might equally have arifen out of the earth at the beginning of things; and from thefe bifhop Stillingfleet takes the other writers and adherents to the doctrine of equivocal generation, Mela, Pliny, Ovid, &c. to have borrowed the hypothefis without inquiring into its truth. Derham's Phyf. Theol. lib. iv. cap. 15. See GENERATION.

EQUIVOCATION, ÆQUIVOCATIO, the ufing a term or expreffion that has a double fignification.

Equivocations are expedients to fave telling the truth, and yet without telling a falfity. The fathers are great patrons of equivocations and mental refervations, holding, that the ufe of fuch fhifts and ambiguities is in many cafes allowable.

St. Auguftine, particularly, is reproached with endeavouring to vindicate Ifaac for faving his wife from a crime by an equivocation; "tacuit aliquid veri, & non dixit aliquid falfi." To advance a dubious propofition, knowing it will be underftood in a fenfe different from that you give it in your mind, is an equivocation, and a breach of good faith and fincerity.

In moral theology, it is ftrictly underftood of a term or phrafe with two different fignifications, the common and obvious, the other more unufual and remote; the latter of which being underftood by the fpeaker, but the former by the hearers, they conceive fomething different from one another.

Of this we have an inftance in St. John, chap. xi. where our Saviour is reprefented as faying, "Lazarus fleepeth," for the difciples who took the word fleeping in the ufual fignification, concluded that Lazarus, whom they had been told, was fick, began to take reft, and would foon recover; but Jefus, ufing the word in a lefs direct and ufual fignification, meant that Lazarus was dead.

When the equivoque confifts of feveral words, it is properly called an *amphibology*, (which fee,) of which we have an inftance in St. John, chap. ii. "Deftroy this temple," fays Jefus, fpeaking to the Jews, "and I will raife it again in three days."

The lawfulnefs of the ufe of equivocations has been greatly difputed among the modern cafuifts; many grave authors deny that it is allowable to ufe them on any occafion whatever. Their reafon is, that an equivoque is to all intents and purpofes the fame thing with a lie.

EQUIVOQUE, L', in *Mufic*, is when a fharp, by extraneous modulation, becomes a flat, and *è contra*. As the chord of D♭ becoming the chord of C♯ with a fharp 3d, &c. See MODULATION, and EXTRANEOUS.

EQUULEUS, or ECULEUS, in *Antiquity*, a kind of rack, or engine of torture, ufed for extorting the truth; at firft chiefly on flaves, but afterwards turned againft the Chriftians.

The patient's arms and legs being faftened on the equuleus with cords, he was hoifted aloft, and extended, in fuch manner that all his bones were diflocated. In this ftate, red-hot plates were applied to his body, and he was alfo goaded in the fides with an iron-forked inftrument, called *ungula*.

The equuleus was of wood, and had holes at certain diftances, with a fcrew, by which the criminal was ftretched to the third, fometimes to the fourth or the fifth hole: at intervals, the fcrew was flackened again, by which he had fome refpite; but then he was tormented with queftions.

The equuleus in more ancient times was conftructed in the form of a horfe; the criminal was laid on his back, and his arms were turned under the breaft of the equuleus, his hands were bound, and his feet ftretched out towards his tail. A rope faftened to the feet was made to pafs over a fmaller pulley between the hind-legs of the equuleus, and made to coil over another larger pulley fixed under the belly by means of a handle, which the executioner turned round till all the bones, &c. were diflocated. See a learned differtation on the form and ufe of this inftrument, by Dr. Ward, in the Phil. Tranf. vol. viii. part iv. p. 32, &c.

Hieronymus Magius, when a prifoner among the Turks, wrote an exprefs treatife "De Equuleo;" and another of Bells, merely as it is faid from his memory, without any affiftance of books. Sigonius had another treatife on the fame fubject.

EQUULEUS, *Equiculus*, and *Equus minor*, *equi fectio*, the *Horfe's Head*, in *Aftronomy*, a conftellation of the northern hemifphere, whofe ftars in Ptolemy's Catalogue are 4, in Tycho's 4, in Hevelius's 6, and in Mr. Flamfteed's 10. See CONSTELLATION.

EQUULEUS, in *Arts* and *Manufactures*. See HORSE.

EQUUS, in *Zoology*, a genus of the Belluæ order. The fore-teeth in the upper jaw are fix, erect, and parallel; the lower fix, and more prominent; tufks folitary, included, remote; teats two, inguinal.

Species.

CABALLUS. Tail with long flowing hair. *Equus cauda undique fetofa*, Linn. *Equus auriculus brevibus erectis, juba longa*, Briff. Ἵππος. Ariftot. Ælian, &c. *Equus, equa, equiferus*, Pliny. Gefn. Aldr. &c. *Cheval*, Buff. *Rofs*, Gefn. *Horfe*.

FERUS. α. *equus ferus*, Haffelq. *Wilde Pferde*, Gmel. Pallas. *Tarpany*, Rytfchk. Orenb. *Wild horfes*, Bell.

DOMESTICUS. β. *equus domefticus*. *Domeftic horfe*.

This generous animal is cultivated in moft parts of the earth, and is found in a wild ftate in the deferts of Great Tartary, in the fouthern parts of Siberia, the banks of the river Don, and other parts of Afia and Africa. See HORSE.

HEMIONUS. Longitudinal dorfal ftripe without humeral tranfverfe band; tail hairy at the tip only. *Equus hemionus*, Pallas Nov. Comm. Petrop. v. 19. Gmel. *Czigitai*, Buff.

This curious animal, defcribed by Pallas in the Tranfactions of the Royal Academy of Peterfburgh, is fuppofed by that naturalift to be the hemionos of Ariftotle, and which appears, if this conjecture be correct, to have remained almoft unnoticed from the time of Pliny, who mentions it as a native of Cappadocia.

The

The *Czigitai*, or, as more commonly called, *Dſhiggetéi* in the Mongolian language, is a native of the deſert regions between the rivers Onon and Argun, in the ſouthern parts of Siberia, and eſpecially thoſe of Gobi, which extend even to the confines of China and Thibet. The name *Dſhiggetéi* ſignifies *Great Ears*, and is given to this ſpecies of wild horſe, becauſe its ears exceed in proportion the ſize of thoſe of the common kind. They are, nevertheleſs, ſtraighter and better formed than thoſe of the mule, to which the whole conformation of the animal bears much ſimilitude. His ſtature is that of a mule of the common dimenſions: the length being more than five feet, and his weight from four to five hundred pounds. The head is large, with an appearance of heavineſs, and the front flattened: the eyes moderate, with aſh-coloured irides. The mouth is furniſhed with thirty-four teeth. The neck is ſlender, and compreſſed with a ſoft, ſhort, erect mane, and on the fore-top a tuft of downy hair about two inches in length. The body is rather long; the breaſt large and protuberant; the back ſomewhat concave or depreſſed, with the flanks and poſterior part thin, as in the mule. The limbs are long and ſlender, with an oval callus within the fore legs; the hoofs like thoſe of the aſs; and the tail, which is two feet in length, correſponding with that of the cow, in being naked for half its length, and having the tip hairy.

During ſummer the prevailing colour of this animal is yellowiſh brown, with the upper part of the head and inner part of the limbs tawny, and ſometimes the inſide of the hind thighs and belly are ſaid to be whitiſh. The noſe is white; the mane and tail blackiſh; and the back marked with a line of cheſnut or deep black, extending from the mane to the tail. The dorſal line is rather dilated on the loins, and becomes narrower towards the tail. The ſummer coat is much ſmoother than that which it aſſumes in winter, for the hair during the latter ſeaſon is longer, and changes to a deeper or more ruddy hue, inclining at the tips to grey.

Theſe animals are of a ſocial diſpoſition among themſelves, living together in troops of twenty or thirty, or ſometimes an hundred. They prefer the open plains, abounding in ſalt marſhes; and never approach the foreſts nor mountainous ſituations. Each of thoſe troops is placed under the guidance of a leader, who is conſtantly on the watch while the reſt of the herd is at reſt, or feeding; and who, in caſe of danger, gives the ſignal of alarm, by leaping and looking ſteadfaſtly at the object which excites his fears. This vigilant leader is often killed, becauſe he is ſtationed at ſome diſtance from the herd, and oftentimes approaches ſtill nearer to the hunters, in order to watch them attentively; and when he falls the herd does not diſperſe till many of them are killed. When alarmed and put to flight the beſt horſes could not overtake them; their ſwiftneſs ſurpaſſes that even of the antelopes. They have the ſenſes of ſight and ſmell in exquiſite perfection In their manners they are naturally timid, but when cloſely preſſed by an enemy are very fierce, and defend themſelves both with their teeth and feet. Their neigh is more ſhrill than that of a horſe. The pregnant females are with young from Auguſt till the following ſpring, when each produces a foal, or rarely two.

The Czigitais would form an excellent race of ſmall horſes, could they be reduced to a ſtate of domeſtication, but ſuch is the untractableneſs of their diſpoſition, that the difficulties of training them for this purpoſe appear unſurmountable. The people of the vaſt deſerts which they inhabit purſue them only for the ſake of their fleſh and ſkin, the former of which they eſteem a delicacy.

Asinus. Tail briſtly at the extremity; a black croſs on the ſhoulders. Linn. The Aſs.

This animal is deſcribed at length under the article Asinus.

Zebra. Body pale buff, with perpendicular fuſcous bands; limbs tranſverſely ſtriped with fuſcous. *Equus zebra, faſciis fuſcis verſicolor*, Linn. *Equus indicus*, Jonſt. *Equus braſilienſis*, Jacob. *Zecora*, Ludolf. *Aſne de beauté extraordinaire*, Thevenot. *Indianiſch Maulthier*, Geſn.

The zebra is one of the moſt beautiful quadrupeds known; uniting to the grace of the horſe, and ſwiftneſs of the ſtag, a peculiar combination of colours, that renders its appearance admirable. This animal is rather larger than the common aſs, and bears ſome reſemblance to the mule. The head is of moderate ſize, and well formed, the ears long, the legs delicate, the body graceful, and the beauty of its ſhape heightened by the ſmoothneſs of the ſkin. The colour is either milk white, or faintly tinged with brown, or pale ferruginous, and the whole animal adorned with alternate pale and fuſcous bands diſpoſed with ſuch amazing regularity as to have rather the appearance of art than nature. The ſtripes run in a tranſverſe direction both on the body and limbs. The head is ſtriped with fine bands of black and whitiſh, forming a centre in the forehead. The neck is adorned with ſtripes of the ſame, running in the ſame direction as thoſe on the back, all which point perpendicularly towards the belly. The thighs and legs are faſciated tranſverſely with fuſcous. The tail is of moderate length, round, rather ſlender, marked with blackiſh bands, and terminated by a thick tuft of browniſh hair. The colours in the male are remarkably vivid, being ſometimes of a fine yellow or yellowiſh, with the ſtripes nearly black, the female is almoſt white, with the ſtripes brown.

Theſe animals are found in the hotter regions of Africa, from Ethiopia to the Cape of Good Hope; and are in particular met with in great plenty in the extenſive ſolitary mountainous waſtes of the latter tract of country. They live in large herds, and poſſeſs much of the manners both of the horſe and the aſs, are exceſſively ſwift and vigilant, and prefer ſubſiſting on the hard and dry herbage their ſterile haunts afford, to deſcending into the more fertile and more frequented plains. The diſpoſition of the zebra is more unmanageable than that either of the horſe or aſs; and even ſuch as have been taken when very young have evinced the ſame invincible degree of paſſion for liberty, when grown up, as thoſe caught at an age of maturity. The Dutch have taken great pains to train them for domeſtic purpoſes, but with little ſucceſs, and which is the more to be regretted as the domeſtication of theſe animals would be of eſſential utility to the colony. This is teſtified from the actual obſervations of many travellers.

The zebra, tranſported into the temperate climates of Europe, have been known to produce young; but their offſpring degenerates. It has been known to couple with the Arabian horſe, and to give birth to a ſmall mule not very unlike the hybrid creature formed between the horſe and aſs. According to Sparrmann, the zebra is hunted by the Hottentots for the ſake of its fleſh, which they deem excellent; but, in reality, it is in no reſpect ſuperior to that of the horſe. Le Vaillant deſcribes the manners of theſe animals: the cry of the zebra, according to this writer, is very ſingular.

Quagga. Above cheſnut faſciated with fuſcous, ſides ſpotted; belly, legs, and thighs white. *Equus quagga*, Gmel. *Opeagha*, or *quagga*, of the Hottentots. Maſſon's Travels, Phil. Tranſ.

The quagga approaches ſo nearly in reſemblance to the zebra, as to have remained till very lately confounded with it, and from various circumſtances to be conſidered as the female. This animal is inferior in ſize to the zebra. The prevailing

prevailing colour reddifh brown, and the upper part is marked with bands of black, but one of the principal differences confifts in the belly, legs, and thighs being white, and deftitute of bands, as are alfo the flanks and buttocks. There is an obvious diftinction between the two fexes of this animal, the colours of the male being far more vivid than thofe of the female.

The more folitary regions in the fouthern parts of Africa are the haunts of this beautiful animal. They are of a focial difpofition, and in a ftate of wildnefs, herd in troops of a hundred or more together; and it is obferved that though they inhabit the fame deferts as the zebra they never affociate with that fpecies. The quagga, unlike the zebra, is of a tractable nature: in fize it is fmaller, but ftronger, and in proportion more robuft. The attempts of the colonifts of the Cape to reduce this animal to a ftate of fervitude, like the horfe, has been attended with fome fuccefs; an inftance of this is mentioned by Sparrmann. Quagga, opeagha, and alfo *cwah*, or *kwah*, are the names by which the Hottentots diftinguifh this animal; its cry refembles the barking of a dog, in which founds, fimilar to the latter words, are frequently repeated. Its flefh, which refembles that of the zebra, is eaten by the natives.

Appendix.

Bifulcus. Hoofs cloven. Gmel. *Guémul*, or *Huémul*, Molina. Hift. Chili.

The cloven-footed, or Chilefe horfe, is an animal of very ambiguous character, and which, if our fufpicions be well founded, will be removed from the equus tribe whenever naturalifts become better acquainted with this fuppofed fpecies than they appear to be at prefent. The animal feems to have been unknown till obferved by Wallis in the ftraits of Magellan. Molina, in his "Storia Naturale del Chili," defcribes it as a horfe, under the title of *Guémul* or *Huémul*, and, as later writers depend on the authority of Molina for their defcription of this anomalous animal, it may not be amifs to repeat the particular information his account affords us. The guemul is defcribed by him as refembling in different refpects both the horfe and the afs; it bears an affinity to both, but cannot appertain to either; the divifion of the hoofs alone being fufficient to remove it from thefe apparently congenerous animals. In point of ftature and appearance, the texture of the hair, and colour, the guemul, according to Molina, refembles the afs. The form and difpofition of the teeth correfpond with thofe of the horfe. The ears are not long, as in the afs; they are fhort, ftraight, and pointed, as in the horfe; neither is the back or fhoulders of the guemul marked with the black ftripe by which the afs is ufually diftinguifhed. The head is better formed than that of the afs, the cheft more elegant, and the tail and buttocks more graceful. The internal conformation affords the moft obvious diverfity; and the voice, dependant, in a material degree, on this interior organization, rather refembles the neighing of the horfe than the bray of the afs. Gmelin is not correct in his tranflation from Molina, when he defcribes the "ftructura interna," &c. as correfponding with that of the afs; this point may be thought material to the developement of the true character of the animal, and fhould be therefore mentioned; and the more efpecially fince the fame miftake prevails in all the Englifh defcriptions of this cloven-footed, or Chilefe horfe, that we have feen.

Molina fpeaks of the guemul as an animal of a vicious nature, wild, and of furprizing velocity. It inhabits the heights of the moft inacceffible mountainous regions of the Andes of Chili; and it is faid, befides, to be found in other Alpine tracts of South America.

The information upon which this animal is defcribed appears to be not fufficiently explicit. We think the guemul ought not to be retained with the horfe or equus tribe. Perhaps it is of the camelus tribe, or that, with ftill more propriety, it ought to be allowed to conftitute a new genus. An ingenious writer obferves, that "if only a fingle fpecimen of this animal had been defcribed, we might have hefitated as to admitting it otherwife than as an accidental variety." We could have wifhed the other authorities alluded to had been adduced. The continental naturalifts offer argument and fpeculation dependant on the defcription given by Molina only; any farther information would therefore prove acceptable. In the Gmelinian "Syftema Naturæ" this animal is claffed as a horfe. Sonnini confiders it as allied to the lama, or camelus glama, and camelus vicugna. According to the character "pedes ungula indivifa," eftablifhed by Linnæus for the equus genus, nothing can be more abfurd than a cloven-footed horfe. Its affinity to the camel appears rather more evident, or, as before intimated, if it be not of that tribe, it is not improbable that it may conftitute a new genus.

Equus *Marinus*, in *Ornithology*, the *Fulmar* of Pennant and Latham, and the Procellaria *Glacialis* of other writers, which fee.

Equus *Marinus*, in *Zoology*, a name given by fome to an animal very different from the hippopotamus, or riverhorfe, and more ufually known by the name of the *Morfe*. See Trichechus *Rofmarus*.

ERA, in *Chronology*. See Æra.

Era, in *Geography*, a river of Tufcany, which runs into the Arno; 14 miles above Pifa.

ERABA, a town of Perfia, fituated on the eaftern bank of the river that anfwers to the Arabius of Alexander and Nearchus.

ERACLISSA, in *Botany*, fo named by Forfkall, from the Greek village near which he gathered it, is according to Juffieu, no other than *Andrachne telephioides* of Linnæus. See Forfk. Fl. Ægyptiaco-Arab. 208.

ERACTUM, in *Ancient Geography*, a town of European Sarmatia, in the country of the Baftarnæ, according to Ptolemy. It has been thought to be the modern *Row*, a fmall town of Podolia.

ERADICATIVE, in *Medicine*. See Radical.

ERÆ, in *Ancient Geography*, a fmall maritime, fortified town of Afia Minor, in Ionia, according to Strabo, who fays that it was either founded or poffeffed by the Teians.

ERAGE, a town of Africa, in the Pentapolis, according to Ptolemy.

ERAGISA, Rajik, a town of Syria, in the Cyrrhaftii territory, upon the banks of the Euphrates, according to Ptolemy, fituated S. S. E. of Hierapolis.

ERAGROSTIS, in *Botany*, from ἔρος, *love*, and ἄγρωστις, *grafs*, the name of an elegant grafs, *Poa Eragroftis* of Linnæus, called in Latin *Gramen Amoris*, and in French *Amourettes*. See Sm. Fl. Græc. Sib. t. 73, where the Linnæan *Briza Eragroftis* is given as a fynonym.

ERANA, in *Ancient Geography*, a borough of Afia, in Cilicia; being the chief place of mount Amanus, upon which it was fituated, on the fame fide with the altars of Alexander. Cicero fays it refembled a town rather than a village.

ERANARCHA, formed of ἔρανος, *alms*, *contribution*, and ἀρχὴ, *command*, a public officer among the ancient Greeks, whofe bufinefs was to prefide over and direct the alms given, and provifions made for the poor.

The eranarcha was properly the adminiftrator or fteward of the poor: when any perfon was reduced to poverty, taken captive, or had a daughter to marry, which he could not effect for want of money, &c. this officer called an affembly of friends and neighbours, and taxed each, according to his means and eftate, to contribute towards his relief. This is what we learn from Cornelius Nepos, in his life of Epaminondas.

ERANG, in *Geography*, a town of the ifland of Ceram.

ERANGELIA, in *Botany*, (Ηϱαγγελια, the herald of fpring), a name given by Renealm in his Specimen Hiftoriæ Plantarum, 97, to the Snow-drop. See GALANTHUS.

ERANNA, in *Ancient Geography*, a town of the Peloponnefus, in Triphylia, a province of the Elide. Strabo calls it *Erana*, and places it between Cypariffia and Pylus.

ERANNOBOAS, or ERRANOBOAS, a river of India, according to Arrian; fituated within the Ganges, into which it difcharged itfelf near the town of Palibothra. This river was of the third degree of magnitude among the Indian rivers, and inferior to none but the Ganges and Indus. Major Rennell cannot apply the name Erranoboas to any particular river. Pliny certainly fays, that the Jomanes (Jumnah) entered the Ganges by Palibothra, between Methora and Clifobara (otherwife Caryfobora and Cyrifoborea): but it is equally true, that in another place he mentions the conflux of the Ganges and Jomanes, and in the very next article fays that Palibothra is fituated 425 miles below that very point of conflux. Strabo does not give the name of the adjoining river. See PALIBOTHRA.

ERANTHEMUM, in *Botany*, from ερα, *the earth*, and ανθος, *a flower*, according to Linnæus (Phil. Bot. 177.) who is the author of the name; but fuch a derivation is, in the prefent inftance, wholly deftitute of any appropriate meaning. We fhould have fuppofed it rather from ερος, love, on account of the beauty of the flower, which might well juftify fuch a denomination; and it is not impoffible that Linnæus might have had this idea in his mind when he wrote the Flora Zeylanica, but forgot it when compofing his Philofophia Botanica. Linn. Fl. Zeyl. 6. Diff. Nov. Gen. Pl. 1. Am. Acad. v. 1. 384. Gen. Pl. ed. 4. 418. ed. 6. 11. Schreb. 15. Willd. Sp. Pl. v. 1. 51. Mart. Mill. Dict. v. 2. Juff. 110.

Gen. Ch. *Cal.* Perianth five-cleft, tubular, very narrow, erect, fhort, pointed, permanent. *Cor.* of one petal, funnel-fhaped; tube very long and thread-fhaped; limb deeply five-cleft, (occafionally four-cleft), flat, its fegments obovate. *Stam.* Filaments two, very fhort, in the mouth of the corolla; anthers nearly ovate, compreffed, projecting beyond the tube. *Pift.* Germen ovate, minute; ftyle thread-fhaped, reaching to the top of the ftamens; ftigma fimple. *Peric.* and *feeds* not known. Linnæus adds, that he had feen only a fingle fpecimen, (which by the mark †, was a dried one), and therefore he left the genus to the attentive examination of other botanifts.

Eff. Ch. Corolla five-cleft; tube thread-fhaped. Anthers projecting beyond the tube. Stigma fimple. Fruit ....

Such are the characters given by Linnæus, and copied by Schreber, but the plant whence they were taken being no other than a *Jufticia*, very near, if not the fame with *J. pulchella*, Roxb. Corom. t. 177, *Eranthemum* falls to the ground. Linnæus indeed, in his own Gen. Pl. has made the following manufcript corrections: that the two upper fegments of the calyx are the fhorteft; fegments of the corolla not obovate but oblong, two of them joined together; anthers within the mouth of the tube.—Whence thefe corrections were taken we have no knowledge; probably from fome of the plants he fubfequently referred to *Eranthemum*, for he certainly never again faw the fpecimen he originally defcribed from Herman's herbarium, nor had he in his own any thing to illuftrate the fubject. In the Species Plantarum one fpecies only is mentioned, by the name of *E. capenfe*, faid to grow in Ethiopia, and to have the habit of a *Chironia*; yet he comprehends under it the plant of his Flora Zeylanica, which, as we have faid, is a *Jufticia*, and with this laft the fynonyms of Herman's Paradifus, Amman and Ray have certainly no connection. In the thirteenth and fourteenth editions of the Syftema Vegetabilium *Selago dubia* of Sp. Pl. having but two ftamens and its fruit not afcertained, is called *Eranthemum anguftifolium*; while another fpecies, called *parvifolium*, is adopted from Bergius, along with a fynonym of Commelin, who figures it with four ftamens and all the afpect of a *Selago*; indeed Linnæus, in his own copy of Bergius, has expreffed a fufpicion of its being fuch. *E. falfoloides*, from Teneriffe, the only fuppofed fpecies befides, is defcribed in the Suppl. Pl. but wholly unknown to us. How far the above, and other fpiked fpecies of *Selago*, may conftitute a genus by themfelves, as Juffieu fufpects, we muft leave in doubt; but if fo, they cannot have any thing to do with the name or the above generic characters of *Eranthemum*. S.

ERANUSA, in *Ancient Geography*, a fmall town of Italy, placed by Pliny near the promontory of Lavinium.

ERARIUM. See ÆRARIUM.

ERAS, in *Ancient Geography*, a town of Afia Minor, in Ionia, in the vicinity of Ephefus, according to Thucydides.

ERASED, in *Heraldry*, expreffes any thing that feems violently torn off from its proper place. It is ufed in contradiftinction to couped, which fignifies a thing clean cut off. The family of Card bears ermine, a demy lion rampant erafed, azure, &c.

ERASINUS, in *Ancient Geography*, a river of the Peloponnefus, in Arcadia, according to Strabo, who fays that this river had its mouth near Bura, in the gulf of Corinth.—Alfo, a river of Greece, in Eretria. Strabo.—Alfo, a river of Greece, in Attica, near Brauron. Strabo.—Alfo, a river of Afia Minor, in Lycia.—Alfo, a river of the Argolide, towards the S. E. of Cenchrea, which formed a confluence with the Phryxus.

ERASISTRATUS, in *Biography*, a phyfician of great reputation among the ancients, but of whofe parentage and birth-place, as well as of the æra in which he flourifhed, different accounts have been tranfmitted to us by different writers. It appears moft probable, however, that he was born at Julis, in the ifle of Cea or Ceos, (and not in Cos, the birth-place of Hippocrates, as has been afferted,) that he was the moft diftinguifhed pupil of Chryfippus, the Cnidian phyfician, and had attained a high character in his profeffion in the 123d olympiad. His fame acquired him the notice and efteem of Seleucus Nicanor, king of Syria, at whofe court he is faid to have evinced his fagacity in the following manner. Antiochus, the king's fon, was feized with a fevere malady, and the moft ingenious phyficians of the time were unable to difcover the caufe of it; until Erafiftratus, obferving the prince moft attentively, remarked, that whenever Stratonice, his father's fecond wife, entered his apartment, he became confiderably agitated, a blufh fuffufed his countenance, his voice grew more feeble, and his pulfe quickened:—whence the phyfician decided that his diforder was the effect of a concealed paffion for Stratonice. In order to inform the king of this delicate affair, he ftated that

Antiochus's difeafe was the refult of a paffion, the more unfortunate as it could not be gratified. The king, furprifed at the impracticability of gratifying the inclinations of his fon, demanded eagerly who was the object of his love. "My wife," replied Erafiftratus, promptly. Seleucus having urged him ftrongly not to occafion the death of his fon, by refufing to give up his wife, Erafiftratus inquired, if he would give up Stratonice to fave his fon's life, were fhe the object of his affection; with which the king expreffed his ready compliance, and Erafiftratus avowed that this would be the only means of preferving the life of Antiochus. Seleucus immediately declared him king of the provinces in Upper Afia, and gave him Stratonice in marriage, although fhe had already had one child.

The great character of Erafiftratus, however, is founded upon more folid ground than this anecdote difplays. He may be confidered as the father of anatomical fcience, at leaft conjointly with Herophilus. It feems to be clearly eftablifhed, that, before the time of thefe phyficians, no one had dared to diffect human bodies; anatomical examinations had been confined exclufively to the bodies of brutes. Human bodies had, indeed, been opened for the purpofe of embalming, among the Egyptians, but no anatomical inquiry had refulted from that practice. The Ptolemies, efpecially Soter and Philadelphus, being defirous that the arts fhould be cultivated, and having furmounted the prejudices of the age, granted the bodies of malefactors to the phyficians for diffection, of which opportunity Erafiftratus and Herophilus availed themfelves largely, and made feveral important difcoveries. To what extent thefe difcoveries were carried, it is not eafy to afcertain, fince the works of thefe phyficians are loft; and what we learn refpecting them is chiefly through the medium of Galen, who deeming Erafiftratus in fome fort a rival of his idol, Hippocrates, feldom quotes him but to confute him. It is afferted by Celfus (De Medicinâ, Præfat.), that the monarchs above-mentioned took the condemned criminals from prifon, and gave them up to Erafiftratus and Herophilus, who diffected them alive, in order to obtain a more accurate knowledge of the vital motions. (See Empiric.) It has been doubted, however, whether they were guilty of this barbarous practice, in confequence of their adoption of the opinion of Praxagoras, that the veins only received blood, and the arteries, and left ventricle, air; fince, if they had opened the living body, they muft have had ocular demonftration of the exiftence of blood in the latter: and this imputation is fuppofed to have been thrown upon them in a fabulous age; juft as Medea is faid to have boiled living men, becaufe fhe was the firft who practifed warm bathing. (See Eloy Dict. Hift.) It would appear, however, from the ftatement of Galen, that the evidence of their fenfes, upon this fubject, was contravened by this fort of fubterfuge: "as foon as the left ventricle of the heart is opened," they obferved, "the air is diffipated, and the ventricle is inftantaneoufly filled with blood." (Galen, an fanguis fit naturâ in arteriis.)

Erafiftratus and Herophilus were the firft who diffected the human brain accurately; according to the fragments preferved by Galen, Erafiftratus defcribed the brain minutely, its convolutions, the divifion of cerebrum and cerebellum, its cavities or ventricles, with their paffages of communication, and the origin of the nerves; and he inferred that the brain was the common fenforium, or fource of all the vital actions and fenfations, which were effected through the medium of the nerves. (Galen, De Hippoc. et Platon. decret. lib. vii. cap. 3.) He alfo examined minutely the ftructure of the heart and of the great veffels, and was the firft to point out the valvular apparatus, and its peculiar form in each of the cavities of that vifcus. (Loc. cit lib. i. cap. 10. and lib. vi. cap. 6.) He affirmed that the veins divided in the liver, for the purpofe of fecreting the bile; and knew that the urine was fecreted by the kidnies.

His phyfiology, in general, was not, however, very profound, and his pathology neceffarily imperfect; although he attempted to explain the caufes of difeafes from his knowledge of the ftructure of the body. The function of refpiration ferved, in his opinion, merely to fill the arteries with air. "The thorax being dilated," he faid, "the lungs expand at the fame time, and receive air: this air paffed to the extremities of the divifions of the trachea, and from them into the extremities of the pulmonary artery, whence it is pumped into the heart, by the dilatation of that organ, in order to be diftributed to all parts of the body, by the great artery." He attributed digeftion to attrition produced by the coats of the ftomach; but he did not attempt to explain the particular manner in which the ftomach accomplifhed fuch attrition.

The hypothefis, by which Erafiftratus attempted to explain the origin of inflammation, refembled, in its leading feature, that modern fuppofition, which, fanctioned by the name of Boerhaave, was generally received in the medical world for a long feries of years. (See Error *loci.*) He maintained, as we have already ftated, that the great vein (*vena cava*) was the refervoir of blood, and the great artery (*aorta*) the refervoir of air. "Thefe refervoirs are divided and fubdivided," he affirmed, "until they arrive at the furface, where the ramifications become fo minute, that the blood cannot pafs farther. Here the mouths or extremities of the arteries and veins clofe to each other, but the blood continues within its proper bounds, and does not enter the arterial or air-veffels, fo that the body continues in the natural ftate. But when any caufe of violence occurs to difturb this regularity, the blood is infinuated into the arteries, and hence the origin of difeafes. Among the caufes of difturbance juft alluded to, too great abundance of blood is the principal; for by it the coats of the veins are preternaturally dilated, and their extremities, which are ordinarily impervious, open, and admit of the paffage of the blood into the arteries. This transfufed blood becomes an impediment to the courfe and motion of the arterial fpirit or air, which is fent from the heart; and if the oppofition of the two matters is direct, or if the blood be arrefted near a vital part, a *fever* is produced; but if the air repel the blood, fo that it pafs not farther than the extremity of the artery, *inflammation* of that part is the confequence." (Galen, de venâ fect. adverf. Erafiftratum.)

The practice of Erafiftratus, like that of his mafter Chryfippus, was extremely fimple. He did not employ bloodletting, nor purgatives; confidering the former as hazardous in the operation, and debilitating in its effects, and the latter as not bringing away the proper humours of the body, but humours in a fort of corrupted ftate. He fometimes employed glyfters, but thefe of the mildeft qualities. All thefe remedies operated, in his opinion, by reducing plethora, which might be effected more fafely and naturally by fafting, or abftinence in diet, efpecially when aided by exercife. He advifed his patients, therefore, to ufe fuch articles of diet as contained little nutriment, as melons, cucumbers, and vegetables in general. He was exceedingly averfe from the employment of compound medicines, and efpecially of the mixture of mineral, vegetable, and animal fubftances; and he exclaimed againft the ufe of the antidotes of the phyficians of his day, in which fimplicity was altogether fhunned.

From the fragments of his writings to be found in Galen and

and Cælius Aurelianus, it would appear, that Erafiftratus wrote an accurate treatife on the dropfy, in which he difapproves of the operation of tapping; and that he had left other books on the following fubjects:—*viz.* on the Difeafes of the Abdomen, on the Prefervation of Health, on wholefome Things, on Fevers, and Wounds, on Habit, on Palfy, and on Gout.

Having lived to extreme old age, and fuffering feverely from the pains of an ulcer in the foot, Erafiftratus is faid to have terminated his exiftence by fwallowing the juice of cicuta, or hemlock. See Le Clerc, Hift. de la Medicine, Eloy, Dict. Hift. Cælius Aurel.

ERASMUS, Desiderius, a man of great celebrity in the republic of letters, was born at Rotterdam on the 28th of October, 1467. He was the natural fon of Gerard, a native of Tergou, by Margaret the daughter of a phyfician, whom he intended to marry, but being deceived by a report of her death, he entered into the church, and on this account Erafmus has been called, by way of reproach, the fon of a prieft, though his father was not in orders at the time of his birth. When Erafmus was about nine years old he was fent to fchool at Deventer, where he made very confiderable progrefs in learning, and was particularly diftinguifhed by the excellence of his memory. His mother, who followed him to Deventer, to watch over his health, died of the plague when he was about 13 years of age. He was now left an orphan, and his guardians, forgetful of the facred truft repofed in them, forced him into the church with a view of embezzling his property. Erafmus refifted their importunity for a confiderable time, but at length, when he was nineteen years old, he entered among the regular canons in the monaftery of Stein, near Tergou. He was of a delicate conftitution, and his health was not fufficiently robuft for the life of a monk. His temper and fentiments were likewife averfe from the habits of the profeffion; he accordingly, with the leave of his fuperiors, accepted, in his 23d year, an invitation to refide with the archbifhop of Cambray; but finding the patronage of that prelate not equal to his expectations, he went to Paris and ftudied in the college of Montaigne. Here he fupported himfelf by giving private lectures to thofe who were lefs advanced in their learning than himfelf. His neceffities required great exertion, and thus he acquired habits of induftry which raifed him to the higheft pitch of literary excellence. Some of his pupils at Paris were the fons of Englifhmen of confiderable confequence, by whofe liberality and earneft requeft he vifited their country, and contracted many valuable friendfhips. This was in the year 1497; from England he went to Italy, continued a year or more at Bologna, from thence to Venice, where he publifhed his Adagia; afterwards to Padua, and at laft he vifited the capital, Rome, where his reputation was very high, and where he might have fettled to great advantage, had he not determined, at the entreaties of his friends, and by the exprefs invitation of Henry VIII. to return to England. Henry, while prince, had contracted a friendfhip and high refpect for Erafmus, and in a few months after he fucceeded to the crown, we find Erafmus at the court of London high in favour with the monarch, with Wolfey, with the archbifhop of Canterbury, and with other perfons of diftinction.

At firft he lived with fir Thomas More, under whofe roof he wrote his "Moriæ Encomium," or "Praife of Folly," a witty and fatirical compofition. He afterwards went to Cambridge, and read lectures to the ftudents in Greek and theology. For this he was remunerated with a living and many valuable prefents, though not of fo fubftantial a nature as to fatisfy his expectations. He wifhed for an independency, and not being able to fecure that in England, he went over to Flanders in 1514, and was fhortly after created nominal counfellor to prince Charles of Auftria, with a ftipend. Soon after this he paid a vifit to Bafil, where he formed an intimacy with fome valuable friends, which induced him to fpend his latter days in that place. At Bafil he publifhed, in the year 1516, his New Teftament, in Greek and Latin, which was received with the utmoft eagernefs by all thofe whofe minds were turned to theological purfuits. It was dedicated to Leo X. In the courfe of the fame year, his edition of St. Jerome, a favourite author, made its appearance, which he infcribed to his generous patron, archbifhop Warham. Erafmus was ever inimical to that fyftem of war which in his time, as in ours, was but too much in fafhion among the ambitious rulers of mankind; he publifhed, in 1517, a work entitled "Querela Pacis, undique gentium ejectæ profligatæque," which is written with much ftrength of reafoning and true eloquence. By his contemporaries he was charged with maintaining the unlawfulnefs of war on all and every occafion: this, however, was a calumny invented by his enemies, of whom he had many, for, in the work alluded to, he exprefsly fays he is fpeaking only of wars undertaken on trifling and unjuftifiable occafions. "I think," fays he, "very differently of wars, which are ftrictly and purely defenfive, fuch as with an honeft and affectionate zeal for the country, repel the violence of invaders, and at the hazard of life, preferve the public tranquillity." He was aware of the horrors and atrocities of a ftate of warfare, and thought almoft any facrifice might be made by wife princes to prevent it. He undertook to vindicate the caufe of peace, whom he makes the fpeaker on this occafion. But the arguments which he puts into her mouth, and the perfuafive eloquence with which fhe addreffes the fovereign princes of thofe dark times, as they are fometimes called, would fcarcely be borne by the monarchs of Europe in this enlightened age. His defcriptions are vivid, and his reflections but too juft: "Exuruntur vici, vaftantur agri, diripiuntur templa, trucidantur immeriti cives, dum princeps interim otiofus ludit aleam, dum faltitat, dum delectat fe morionibus, dum venatur, dum amat, dum potat. O Brutorum genus jam olim extinctum! O fulmen Jovis aut cæcum aut obtufum." To whom this is particularly applied it does not appear, but the "Querela Pacis" was occafioned by the following remarkable circumftance:

It was a favourite project at this period to affemble a congrefs of kings at Cambray, confifting of the emperor of Germany, the kings of France, England, and the Low Countries; "of which," fays the author, "I am a native. They were to enter into mutual and indiffoluble engagements to preferve peace with each other, and throughout Europe. This momentous bufinefs was very much promoted by William a Ciervia, and by one, who feemed to have been born to advance the happinefs of his country, and of human nature, John Sylvagius, chancellor of Burgundy. But certain perfons, who get nothing by peace, and a great deal by war, threw obftacles in the way which prevented this truly kingly purpofe from being carried into execution. After this great difappointment, I fat down and wrote, by defire of Sylvagius, my Querela Pacis." This work was dedicated to Philip of Burgundy, bifhop of Utrecht, who was likewife a zealous promoter of peace, and who, fo far from being offended with the free fentiments of the book, thanked the author, and even preffed him to accept a living, as a remuneration, which he civilly refufed. Erafmus fought no preferment, though, fays his biographer, he merited the higheft: he fought the happinefs of his fellow creatures, and felt himfelf abundantly rewarded by his own confcience,

and

and their approbation. The bishop, however, in token of his high esteem, sent him a most beautiful ring, set with a sapphire, which his own brother, his predecessor, in the bishopric, had constantly worn, and which he desired Erasmus to wear for his sake.

The commencement of the reformation, under Luther, was a circumstance of considerable importance in the life of Erasmus. He had shewn himself inimical to the superstitions of the times, he had arraigned the principles and practices of the monks, and had done much to undermine the whole system of popery, and to expose the various frauds which had been attached to its observance by avaricious and licentious priests; yet he was not prepared to join the reformers as such, his zeal was not sufficient to enable him to endure persecution: he did not wish to break openly from the church, nor was he quite satisfied with the doctrines of the reformers, and still less was he disposed to coalesce with the rudeness, vulgarity, and contempt of polite literature which characterized some of that class of people. It has also been said that he was very desirous of being noticed by the great, that he had habituated himself to that degree of indulgence, which would render the prospect of poverty and imprisonment absolutely insupportable to his mind. His income likewise arose almost entirely from pensions which he received from crowned heads, prelates, and men of consequence belonging to the Catholic persuasion, which he would unquestionably have lost had he gone over to the opposite side. These are the reasons which have been assigned why Erasmus did not come boldly forward in defence of the reformation; but with these deductions there is enough in his character to challenge the admiration and gratitude of the friends to liberty and the human race. He was ever the undaunted advocate of free enquiry, and perpetually waged war against the ignorance and bigotry that characterized the age in which he lived. On these accounts he was, in the first years of the reformation, highly regarded by Luther, and it was owing to some unadvised, and, probably, unwarranted attacks made upon Erasmus, about the year 1520, by the zealous reformers, that he was driven to enlist among the defenders of the church of Rome.

In the year 1522, he published his "Colloquies," which, though apparently intended for young persons, were generally read, and are supposed to have been very efficacious in promoting the principles of the reformation. As soon as their tendency was discovered, the clergy attempted to stop their sale, but it was then too late; more than twenty thousand copies of them were disposed of in Paris, besides a number of editions which were printed and sold in other places.

In 1524, Erasmus published his treatise, "De Libero Arbitrio," which was an avowed attack upon Luther's opinion concerning predestination, but the author, in his zeal, spoke against reformers in general; Luther replied, and had unquestionably the best of the argument: in some passages he seemed to commiserate the case of his antagonist, and to regret the necessity that he was under of exposing him. "We saw," says he, "that the Lord had not conferred upon you the discernment, the courage, and the resolution to join us in opposing those monsters, and therefore we dared not to exact from you that which greatly surpasses your strength and capacity." He then refers to the motives of worldly interest by which Erasmus had suffered himself to be swayed from the path of rectitude. The controversy increased in violence, and much unjustifiable acrimony proceeded from the pens of the disputants. Under the article REFORMATION we shall have occasion to enter more at large into this subject, and also into the controversy between Erasmus and Melancthon.

Another antagonist with whom our author had to contend was Julius Cæsar Scaliger, who had put himself at the head of those who were so fastidious in the use of pure Latin as to reject every word not to be found in the works of Cicero, and who on that account had assumed the title of "Ciceronians." Erasmus, superior to this pedantry, employed new words for new ideas, and in justification of his conduct published, in 1528, a dialogue entitled "Ciceronianus," in which he attacked the sect both with argument and ridicule. Scaliger wrote against him with all the malignity that human wit and learning could devise, and he was backed in his scurrility by others of the Ciceronians less able in the warfare, but not less inveterate than their master. The nature of this controversy is fairly exhibited in the notes on the life of Erasmus by Bayle.

Erasmus, wearied, perhaps, by disputation, published, in a short time after his "Ciceronianus" had made its appearance, a treatise of much ability and learning, entitled "De Recta Latini Græcique sermonis Pronunciatione." In the year 1529, Erasmus left Basil for Friburg, in order to shew his attachment to the church which had for some years been losing ground in Basil, and so completely had the reformed religion gained an ascendancy there at this period, that all the images were taken from the town-house and other public places and burnt, which was supposed to have been the means of putting an end to the differences among the common people. Erasmus was now advancing in life, and seemed, more than ever, fearful of being thought friendly to the reformation, and to shew his zeal for the opposite system he wrote and published an epistle against some "who falsely call themselves Evangelists," and as they, from his former works, had produced his authority against persecution, he began to maintain that there were certain cases in which they might lawfully be punished capitally as blasphemers and seditious persons. Such were the unworthy steps to which he was led by an anxiety to keep on good terms with his patrons and protectors.

In 1535 he returned to Basil, and so highly was he esteemed by the church of Rome, that there was an intention to give him a place in the college of cardinals; but it was too late for him to accept of the high honour. His health rapidly declined, and on July 12, 1536, he died of a dysentery at the age of sixty-nine. He was buried with great funeral pomp in the cathedral church of Basil, where his tomb still remains. By his will he left legacies to several friends, and the residue of his property he devoted to charitable purposes. In person he was below the middle size, well-shaped, of a fair complexion, with a chearful countenance, a low voice, and agreeable elocution. He had assumed the name of Erasmus in conformity with the pedantic taste then prevailing among men of letters of taking names of Greek or Latin etymology; he translated his name of "Gerard," signifying "Amiable," into the equivalent ones of "Desiderius" in Latin, and "Erasmus" in Greek, making use of both, but the latter was his common and perpetual appellation.

Erasmus was a voluminous writer; and his works were published in nine volumes folio. They consist of numerous translations from the Greek; of grammatical and philological pieces; of poems, declamations, and orations; of a collection of adages and apophthegms; of works in divinity on various topics, moral, didactic, and controversial; of a version of the New Testament, paraphrases of the gospels and the epistles, and commentaries on some other parts of scripture; and of apologies, epistles to correspondents, &c. A new and handsome edition of his works was published in Holland by Le Clerc in eleven volumes folio,

1703.

1703. Dr. Jortin, the biographer of Erafmus, fpeaking of his Latin ftyle, fays, it "is that of a man who had a ftrong memory, a natural eloquence, a lively fancy, and a ready invention, who compofed with great facility and rapidity, and who did not care for the trouble of revifing and correcting; who had fpent all his days in reading, writing, and talking Latin; for he feems to have had no turn for modern languages, and perhaps he had almoft forgotten his mother-tongue. His ftyle, therefore, is always unaffected, eafy, copious, fluent, and clear; but not always perfectly pure and ftrictly claffical."

No one contributed fo much as Erafmus to throw difcredit upon the barbarifm and ignorance of the fchools, or to make literature agreeable, and connect it with good fenfe and folid criticifm. He was a great public benefactor; and therefore he is juftly regarded as one of the principal glories of his age and country. His memory is equally honoured at the place of his birth and of his death. Several of his relics are preferved at the latter place, and at the former, the houfe in which he was born, is marked with an infcription, and his ftatue decorates the great fquare. Jortin's life of Erafmus. Bayle. Complaint of Peace. 1802.

Erasmus, in *Geography*, a mountain of the ifland of Ceylon; 30 miles N.W. of Trincomaly.

ERASTIANS, in *Ecclefiaftical Hiftory*, a religious fect or faction, which arofe in England during the time of the civil wars, thus called from their leader, Thomas Eraftus, a German divine of the fixteenth century, whofe diftinguifhing doctrine was, that the church had no right to difcipline, that is, no regular power to excommunicate, exclude, cenfure, abfolve, decree, or the like.

According to the founder of this fect, the paftoral office was only perfuafive, like a profeffor of the fciences over his ftudents, without any power of the keys annexed. The Lord's fupper and other ordinances of the gofpel were to be free and open to all. The minifter might diffuade the vicious and unqualified from the communion, but might not refufe it, or inflict any kind of cenfure; the punifhment of all offences, either of a civil or religious nature, being referved to the magiftrate. The pretended advantage of this fcheme was, that it avoided erecting *imperium in imperio*, or two different powers in the fame civil government; it effectually deftroyed all that fpiritual jurifdiction and coercive power over the confciences of men, which had been challenged by popes, prelates, prefbyteries, &c. and made the government of the church "a creature of the ftate." Moft of our firft reformers adopted thefe fentiments fo far as to maintain, that no one form of church government is prefcribed in fcripture as a rule for future ages, as Cranmer, Redmayn, Cox, &c. and archbifhop Whitgift, in his controverfy with Cartwright, delivers the fame opinion. The Eraftians formed a party in the Affembly of Divines in 1643, and the chief leaders of it were Dr. Lightfoot, Mr. Colman, Mr. Selden, and Mr. Whitlock; and in the houfe of commons there were, befides Selden and Whitlock, Oliver St. John, efq., fir Thomas Widdrington, John Crew, efq., fir John Hipfley, and others of diftinguifhed reputation. In the affembly, the Eraftians did not except againft the prefbyterian government as a "political inftitution," proper to be eftablifhed by the civil magiftrate, but they were againft the claim of a "divine right." Accordingly the claufe of divine right was loft in the houfe of commons. Neales's Hift. Purit vol. ii. 4to.

ERASTUS, Thomas, in *Biography*, a phyfician, was born, in 1523, at Auggenen, a village in the diftrict of Badenweiller, in Switzerland. He ftudied at Bafil, where he was feized with the plague in 1542, and narrowly efcaped death. He fuffered a long and tedious convalefcence, which, together with his poverty, threw an almoft infurmountable impediment in the way of his ftudies; but he fortunately found a generous protector, who opened the door of the fciences to him, and furnifhed him with the means of travelling to Italy. He took up his refidence at Bologna, where his proficiency in the ftudy of philofophy and medicine was fuch, that he obtained the honour of the degree of doctor of thefe two fciences. Finding himfelf in a fhort time holding a diftinguifhed fituation among the men of learning, he followed the cuftom of the times by changing his name; giving a Greek turn to his original name, which was Lieber, (beloved,) he called himfelf Eraftus. Under this appellation he became a teacher of medicine at Heidelberg, where he obtained confiderable reputation; and in 1581 he was called to fill the medical chair in the univerfity of Bafil. But this honourable fituation he did not long enjoy; he died on the 1ft of January, 1583.

He left many works behind him, of which fome were printed during his life, and others have been publifhed fince his death; their contents, however, are not particularly interefting; the following is a lift of their titles and editions. "Difputationum de Medicina nova Phillippi Paracelfi," p. i. Bafil, 1572, p. ii. ibid. 1572, p. iii. ibid. 1572, p. iv. et ultima, ibid. 1573, all in 4to. In thefe volumes he refutes the doctrines which Paracelfus had previoufly taught at Bafil, and had committed to writing. 2. "De Caufa Morbor. Continente," 4to. 1572. 3. "De Occult. Pharmacor. Poteftatibus," 4to; ibid. 1574; Francofurti, 1611. 4. "Difputat. de Auro Potabili." 4to. Bafil, 1578, 1594. 5. "De Putredine Liber," 4to. ibid. 1580; Lipfiæ, 1590. 6. "Epiftola de Aftrologia Divinatrice," 4to. Bafil, 1580. 7. "De Pinguedinis in Animalibus Generatione et Concretione," 4to. Heidelbergæ, 1580. 8. "Comitis Montani, Vicentini, novi Medicorum cenforis, quinque Librorum de Morbis nuper Editorum Viva Anatome," 4to. Bafil, 1581. 9. ERATO, from ερανω, *I love*, in *Mythology*, the name of one of the nine Mufes who prefided over love-poetry. "By Erato," fays Callimachus in his epigram on the nine Mufes, "the pious hymn was made." To this Mufe fome have afcribed the invention of the lyre and lute; but particularly the pfaltery or long lyre of nine ftrings; and fhe is reprefented with a garland of myrtles and rofes, holding a lyre in one hand, and a bow in the other, and at her fide a Cupid with his torch. In the portraits of Apollo and the Mufes, dug out of Herculaneum, Erato is exhibited holding a plectrum or bow in her right hand, and feeming to play with the fingers of her left. The pfaltery, or lyre, is more than twice the length of that in the hand of Terpfichore. (See Muses.) There is alfo a Nereid of the fame name.

ERATONOS, in *Ancient Geography*, iflands of the Arabic gulf. Pliny defignates their aridity by the epithet *Sitientes*.

ERATOSTHENES, in *Biography*, an eminent Greek mathematician, philofopher, and chronologift, was born at Cyrene in the fecond year of the 126th olympiad, or 275 B. C. He was educated under Arifto, the philofopher of Chios, and Callimachus, the poet; and he himfelf had feveral difciples who were eminent, and among the number was Ariftophanes of Byzantium, one of the moft celebrated grammarians of his time. Such was the fame of Eratofthenes as a man of extenfive erudition, that he was denominated πενταθλος, *i. e.* victorious in five contefts, alluding to to the five prizes of the Olympic games, and expreffing his pre-eminence in all kinds of literary purfuits. He was alfo ftyled the cofmographer and father of chronology, the meafurer of the univerfe, and the fecond Plato. On the invitation of Ptolemy Euergetes, he removed from Athens to Egypt, and fucceeded Zenodotus in the office of librarian to the famous library at Alexandria. This office he retained under three fucceffive princes, difcharging his truft with fingular honour, and acquiring high reputation for literature and fcience by his writings and difcoveries. Availing himfelf of the multitude of hiftorical memoirs, which the library furnifhed, he was both prompted and enabled to determine the dates of many diftinct facts, by laying down certain chronological canons, for which fee CHRONOLOGY. He alfo employed his eminent abilities and learning, with equal fuccefs, in reducing geography to a regular fyftem, and laying its foundation upon clear and folid principles. He likewife firft introduced into his map a regular parallel of latitude, which was a geographical outline traced over certain places, whofe longeft day was obferved to be exactly of the fame length. He began it from the ftraits of Gibraltar, and it thence paffed through the Sicilian fea, and near the fouthern extremities of Peloponnefus, and was continued through the ifland of Rhodes and the bay of Iffus, and then entering Cilicia, and fo croffing the Euphrates and Tigris, was extended to the mountains of India. By means of this line he endeavoured to rectify the errors in the ancient geographical map, fuppofed to be that of Anaximander. In drawing this parallel, he was regulated by obferving when the longeft day confifted of $14\frac{1}{2}$ hours, which Hipparchus afterwards determined to be the latitude of 36°. The running of this parallel through Rhodes was a happy thought of Eratofthenes, becaufe it not only encouraged him to trace upon his map other parallels at certain intervals from his firft, fuch as one through Alexandria, another through Syene, and another through Meroe, but he undertook to trace at right angles to thefe a meridian paffing through Rhodes and Alexandria down to Syene and Meroe. His progreffion this way enlarged his ideas with regard to the fciences of geography and aftronomy, and induced him to attempt a more arduous tafk, which was that of determining the circumference of the globe by an actual meafurement of one of its great circles, making his computation upon the whole by uniting certain accurate obfervations made in the heavens with a correfponding diftance carefully furveyed, and taken upon a meridian of the earth. The fegment of the meridian which he fixed upon for this purpofe, was that between Alexandria and Syene, the diftance of which was meafured, and found to be 5000 ftadia, and the angle of the fhadow upon the fcaphia, or fun-dial, which was obferved at Alexandria, was equal to the 50th part of the circle; for at Syene there was no fhadow from the gnomon at the mid-day of the fummer-folftice; and that this might be more accurately taken, they dug a deep well, which being perpendicular, was completely illuminated at the bottom, when the fun was vertical. The fubftance of this account was taken from Cleomedes, who feems to have extracted it from Eratofthenes's original work, entitled Μετρησεις. (See Fabr. Bell. Græc. vol. ii. p. 477.) And it is publifhed as fuch at the end of the Oxford edition of Aratus in 1672, though under the title of Μετρον της γης περιφερειας. By this account Eratofthenes made the circumference of the earth amount only to 250,000 ftadia, whereas a multitude of original authors, (fuch are Strabo, Geminus, Vitruvius, Macrobius, Pliny, Capella, and Cenforinus,) have uniformly given the numbers to be 252,000. In order to reconcile thefe differences, Dr. Murdoch (Enquiries concerning Meafures of length, prefixed to Bufching's Geography, vol. i.) has ingenioufly fuppofed, that inftead of 7° 12′, the difference of latitude was 7° $8\frac{1}{2}$′, which was the $\frac{1}{50}\frac{2}{5}$th of the circumference, which would bring the calculation to 252,000 ftadia, and that Cleomedes neglected the fmall fractional part of the denominator; but that the principal miftake was in meafuring the diftance, and finding it to be 5000 ftadia. Eratofthenes, by making the circumference to be 250,000 ftadia, allowed 700 ftadia to a degree, which, by the reduction of 8 ftadia to a Roman mile of 5000 feet, amounted to $87\frac{1}{2}$′ Roman miles to each degree. We fhall return from this digreffion, after obferving, that the map of Eratofthenes appears to have contained little more than the ftates of Greece, and the dominions of the fucceffors of Alexander, digefted from preceding furveys. He had feen indeed, and has quoted the voyages of Pytheas into the great Atlantic ocean, which gave him fome faint idea of the weftern parts of Europe: but they were fo imperfect, that they could not be realized into the outline of a chart. Strabo tells us that he was extremely ignorant of Spain, Gaul, Germany, and Britain, as well as of the Gæti and Baftarni; he was equally ignorant of Italy, the coafts of the Adriatic, of Pontus, and of all the countries towards the north. And he mentions in another paffage, that Eratofthenes had made the diftance from Epidamnus, or Dyrrhachium, on the Adriatic, to the bay of Thermæ on the Ægean fea, quite acrofs Epirus, to be only 900 ftadia, when it was really above 2000 ftadia; and in another inftance he had enlarged the diftance from Carthage to Alexandria to be 15,000 ftadia, whereas it amounted to no more than 9000 ftadia.

Eratofthenes alfo obferved the obliquity of the ecliptic, which, in the year 230 B. C. he makes 23° 51′ 20″. (See ECLIPTIC.) In an epiftle to king Ptolemy he gave a folution of the problem for the duplication of the cube; and he invented a convenient method of difcovering the primary numbers, that is, fuch as have no common meafure but unity, which has been called the fieve of Eratofthenes. He wrote alfo numerous treatifes in grammar, aftronomy, hiftory, and geography, together with dialogues on the philofophical fects, and poems. Fragments merely of his different pieces have reached our times, fome of which were publifhed at Oxford in 1672, with brief annotations, in 8vo. Thefe fragments were alfo printed in the Uranologium of Petavius at Paris in 1630, and afterwards at Amfterdam in 1703. The moft valuable remnant of his works is his "Catalogue of the kings of Thebes in Egypt, from Menes, who firft peopled Egypt after the deluge, to the time of the Trojan war." This contains a feries of 38 kings in a direct line of fucceffion, taken not only from the records in the Alexandrian library, but from the facred archives in Diofpolis, or Thebes itfelf, and probably intended for fupplying the defects, and correcting the errors of Manetho's dynafties. This has been ufed by fome of our ableft chronologers as an authority for fettling the Egyptian chronology. Eratofthenes died at the advanced age of 80 or 81, having, as fome authors report, ftarved himfelf to death, becaufe he was unable to bear the depreffion of fpirits occafioned by the decay of his fight. Suidas. Voff. de Hift. Græc. Fab. Bib. Græc. Moreri. Anc. Un. Hift. Gen. Biog.

ERBACH, in *Geography*, a fmall town of Germany, in the circle of Franconia, anciently called Erdtpach, with an old caftle, belonging to the counts of Erbach, who, before the diffolution of the German empire, had two voices at the diet of Ratifbon, in the college of the imperial counts of Franconia. The whole county is about 25 miles in length, and 20 miles in breadth; its population does not exceed the number

number of 30,000 individuals. It is a mountainous country, but tolerably fertile, and producing both corn and wine; of the latter, that of Schonberg, near the Bergftraffe, is reckoned the beft.

ERBAT, a town of Afiatic Turkey, in the province of Diarbekir; 58 miles S.E. from Diarbek.

ERBAZ, a town of Afiatic Turkey, in the province of Natolia; 36 miles W.S.W. from Degnizlu.

ERBITA, in *Ancient Geography*, a town of Sicily, written Herbita by Cicero. It is thought to be the modern *Nicofia*.

ERBLSPACH, or Erlsbach, in *Geography*, a town of Germany, in Lower Bavaria; 34 miles E.S.E. from Ingolftadt.

ERCABUM, in *Ancient Geography*, a town of European Sarmatia. Ptolemy.

ERCE', in *Geography*, a town of France, in the department of the Ille and Vilaine, and diftrict of Bain; 5 miles E. from Bain.

ERCEUS, of ἑρκος, *feptum*, in *Mythology*, the name by which thofe who were appointed to guard the walls of a city invoked Jupiter. This appellation, fometimes written *Herfæus*, was given to Jupiter, becaufe his altars, efpecially in the houfes of princes, ftood under the open air in places inclofed with walls.

ERCHEE, in *Geography*, a town of Perfia, in the province of Adirbeitzan; 60 miles E.N.E. of Tauris.

ERCILLA Y ZUNIGA, Don Alonzo de, in *Biography*, an eminent Spanifh poet, was born at Madrid in 1533. His father, defcended from a noble family, purfued the profeffion of the law, but dying while Alonzo was an infant, the child and his mother were received into the houfehold of Ifabella, wife of Charles V. Alonzo, as foon as his years permitted, was made page to the infant don Philip, whom he attended in his progrefs through the Low Countries, and part of Germany and Italy. He afterwards accompanied the fame prince to England, to celebrate his marriage with queen Mary. During their ftay here intelligence was received of a revolt in Chili, upon which troops were immediately fent off, with whom Ercilla embarked and proceeded to Lima. His duty required him perfonally to engage in a fubfequent war with the Araucanians, whofe courage and love of liberty he admired, and even applauded, though he was under the neceffity of ufing all his efforts in fubduing them. The intervals of warfare he employed in recording, in heroic verfe, the interefting fcenes to which he was witnefs. After he had efcaped the dangers of the expedition, he had nearly loft his life at a tournament exhibited in honour of the acceffion of Philip II. During the fête a difpute arofe between Ercilla and another gentleman; fwords were drawn, and many joined in the conflict, which being conftrued into a plan of mutiny by the governor, he haftily, and without examining into the matter, condemned the principal difputants to be beheaded. Ercilla was led to the fcaffold, and his innocence was demonftrated but juft in time to fave him from an ignominious death. He returned to Spain with his health very much impaired, in his twenty-ninth year; but after a very fhort ftay at home, he commenced a tour through various parts of Europe; but with what particular view has never been afcertained. In 1570 he married, and was made gentleman of the bed-chamber to the emperor Rodolph II. Ten years after this, he was found refiding at Madrid, in retirement and poverty. The king whom he had ferved, and to whom he dedicated his poem "Araucana," made him no requital for his fervices, and little more is known of him, than the mention made by a contemporary of his being engaged, in 1596, in celebrating the victories of the marquis of Santa Cruz, in a poem that has never been publifhed.

The "Araucana" is an hiftorical poem, containing a narrative of real events, interfperfed with fabulous circumftances. It contains 37 cantos, is formed on no regular plan, but is an unconnected feries of adventures. The verfe is faid to be flowing and fpirited, though fometimes it is profaic and infipid. Mr. Hayley, in his Effay on Epic Poetry, has taken pains to make Ercilla known to the Englifh reader, by tranflations of felect parts, and an analyfis of the whole poem. Gen. Biog. Hayley on Epic Poetry.

ERCTA, in *Ancient Geography*, a mountain of Sicily, near mount Erix. Diod. Sic. Polybius.

ERCYNA, a river of Greece, in Bœotia, not far from the cave of Trophonius.

ERDENI-TCHAO, in *Geography*, a town of Chinefe Tartary, in the country of the Eluths; 680 miles N.W of Pekin.

ERDER, a town of Germany, in the circle of Weftphalia, and country of Lippe; 12 miles N.N.E. from Lemgow.

ERDMANSDORF, a town of Germany, in the circle of Upper Saxony, and circle of Erzgeburgh; 5 miles E. of Chemnitz.

EREBENNUS, ἐρεβεννός, a name given by Galen and fome other of the Greek writers, as a diftinctive epithet for the black chamæleon thiftle, which was efteemed poifonous, and was by this word diftinguifhed from the ægleus, or αἰγληις, or white chamæleon, which was an efculent plant, and ufed by fome as an antidote. It has happened, however, that the white chamæleon thiftle has been by fome called a poifon, as well as the black; but this is only owing to a miftake of Pliny, in fuppofing the effects of birdlime to have been attributed to this plant, becaufe of its yielding a vifcous, but fafe gum, at its root. It was called by fome *ixias chamæleon*. See Ixias.

EREBINTHUS, in *Botany*, (ἐρέβινθος, an ancient Greek name for fome kind of vetch or legume), was applied by Mitchel to a fuppofed new genus of his own, which is the *Galega virginiana* of Linnæus. The latter in his Sp. Pl. inaccurately quotes Mich. Gen. which fhould mean Micheli, and profeffor Martyn, under his *Galega*, fp. 4, has Mant. Gen. both which would be unintelligible without an explanation

EREBUS, Ερεβος, from ערב, *night*, in *Mythology*, a term denoting darknefs. According to Hefiod, Chaos engendered Erebus and Night, from whofe mixture was born æther and the day. Ariftophanes, ridiculing fome ancient fyftem of theogony, in his comedy of the Birds, introduces one of his actors as faying, that in the beginning were the Chaos, the black Erebus, and the vaft Tartarus; but as yet there was neither earth, nor air, nor heavens. Night, with her fable wings, laid the firft egg in the womb of Erebus, whence fprung, after fome time, beneficent love, adorned with golden wings. From the union of love with chaos, arofe men and animals. This was alfo the name of part of the inferi among the ancients: they had a peculiar expiation for thofe who were detained in Erebus.

Erebus was properly the gloomy region, and diftinguifhed both from Tartarus, the place of torment, and Elyfium, the region of blifs: according to the account given of it by Virgil, it forms the third grand divifion of the invifible world beyond the Styx, and comprehends feveral particular diftricts, as the limbus infantum, or receptacle for infants; the limbus for thofe who have been put to death without caufe; that for thofe who have deftroyed themfelves; the fields of mourning, full of dark groves and woods, inhabited by those who died for love; and beyond these, an open champaign country for departed warriors. Æn. lib. vi. p. 427. &c.

EREC, or Erech, in *Ancient Geography*, a town of Chaldæa, which is mentioned in the book of Genesis (ch. x. v. 10.) as one of the places in which Nimrod began to establish his kingdom. This was probably the Aracca, placed by Ptolemy in Susiana, on the river Tigris, below its confluence with the Euphrates. Ammianus calls it Arecha. From this city the Arectæan fields, which abound with Naphta, and sometimes take fire, derive their name.

"Ardet Arectæis aut unda per hospita campis."
Tibull.

Erec, a province of Asia, which extended on both sides along the common bed of the Tigris and Euphrates, from their junction to the sea.

ERECT Flowers, in *Botany*, are such as grow upright, without hanging or reclining the head. See Flower.

Erect *leaf*, *erectum folium*. See Leaf.

Erect, in *Fortification*. The defences of a face, in fortification, are said to be erect when the several works bear directly and regularly upon the approaches, in such manner as to tend uniformly towards the capital, from which they are drawn respectively. Thus, when the two bastions which defend a curtain are equal and similar, and the raveline, with all its dependencies, stands evenly upon the line, or capital, of that face, without obliquity, or curve, the whole of such defences are said to be erect. It will be readily understood, that in every regular fortification the whole of the defences will be of this description: and that in all irregular fortifications there will probably be a mixture of erect and of oblique defence. The latter is by no means to be considered a defect; since innumerable cases might occur in which the prolongation, or the curtailment of any particular part, such, for instance, as the face or flank of a bastion, might be indispensably necessary, either to make way for some natural advantage, or to prevent that kind of weakness which might otherwise be entailed by the proximity of some height, whence enfilading might be successfully practised. When, therefore, the two bastions are dissimilar, or when they are unequal, so as to render the flanked angle of either less distant on the capital, if a line of defence were to be drawn upon, and formed from, the two extremities of such unequal bastions, the raveline must either stand a little obliquely, or the bastions must be unequally protected by it. This kind of obliquity is extremely rare, and is often neglected where great accession of strength might otherwise, by its adoption, be given to weak parts: it is peculiarly appropriate to fortresses, of which only one or two faces are understood to be subject to approach.

Erect *Vision*, in *Optics*. See Vision.

Erect, *direct*, and *declining*, &c. *dials*, &c. See Dial.

ERECTHEUS, in *Biography*, is reckoned the 6th king of Athens, from Cecrops its founder, and is supposed to have succeeded his father Pandion about the year 1397 B. C. Some have referred to this reign the arrival of Ceres in Attica, after the rape of her daughter Proserpine, who taught the cultivation of corn, about the year 1383 B. C. and the institution of the Eleusinian mysteries. Erectheus reigned 50 years, and was slain in a battle with the Eleusians.

ERECTHIA, in *Ancient Geography*, a municipal place of Greece, in Attica, belonging to the Egeid tribe, and deriving its name from king Erectheus. It was the native place of the orator Isocrates.

ERECTION, the act of raising or elevating a thing in a right line.

The erecting of a perpendicular on a line given, is a popular problem in geometry. See Perpendicular.

The term erection is also used figuratively; as the erection of a marquisate into a duchy; bishoprics can only be erected by the king.

Erection, in *Physiology*, is the change in the state of the male penis, by which that organ is rendered capable of entering the vagina of the female, for the purposes of sexual intercourse. See Generation.

ERECTOR, in *Anatomy*, a name given to two muscles supposed to possess the power of bringing the organs with which they are connected into an erect state. They are the erector penis of the male, and erector clitoridis of the female subject. See Generation.

ERECTUM, Folium, in *Botany*. See Leaf.

ERECTUS, Caulis, an upright stem. See Caulis, *n.* 6.

EREGEM, in *Geography*, a town of Flanders; 10 miles S.W. of Bruges.

EREGMOS, from ερεικω, *I break*, a word used by the ancients to express a bean decorticated and broken into small pieces, in order to be boiled in ptisans; and also applied indifferently to all the leguminous fruits broken in the same manner.

EREKLI, in *Geography*, a town of Asiatic Turkey, in the province of Caramania; 60 miles E. of Cogni.

EREMEGIKE, a town of Asia, in Thibet; 25 miles S. of Tourfan.

EREMIT. See Hermit.

ERES, or Eris, in *Geography*, a town of Persia, in the province of Schirvan, on the borders of Armenia; 80 miles S.W. of Derbend, and 120 S.E. of Teflis.

ERESIA, in *Botany*, a name given by Plumier to a new American genus, Nov. Gen. 8. t. 25, in honour of the Grecian botanist Theophrastus Eresius; but Linnæus, and all succeeding writers, have, with the greatest possible propriety, called the plant *Theophrasta*, whch see.

ERESMA, in *Geography*, a river of Spain, which runs into the Duero, between Simancas and Tordesillas.

ERESOS, in *Ancient Geography*, a town of the island of Lesbos, which was the native place of Theophrastus.

ERESUS, or Ebusus, a town of the island of Ebusus, founded by a colony of Carthaginians. Its harbour was commodious, its walls very large, and its houses well built.

ERETENUS, a river of Italy, in Venetia, famous, according to Ælian, for its excellent eels, and supposed to be the present Retona.

ERETHISMUS, (from ερεθιζω, to *irritate*, or *excite*). Medical writers extend the general meaning of this term to every kind of irritation which has a tendency to weaken and destroy the vital powers.

In this article we intend to take particular notice of a dangerous affection of the constitution, well known among surgeons by the name of the *mercurial* erethismus.

Mr. Pearson acquaints us, that on his first succeeding to the situation of surgeon to the Lock hospital, he had occasion to remark, that almost every year one, and sometimes two instances of sudden death occurred among the patients of that charity. No cause could be assigned for these events, but the subjects were commonly observed to be men who had either nearly, or completely finished a course of mercury. Messrs. Bromfield and Williams, on being consulted by Mr. Pearson, concerning these extraordinary cases, confessed themselves ignorant of the cause, mode of prevention, and treatment, and explained, that they had never been able to detect any diseased appearances in the bodies of such persons as had died in this sudden and unexpected manner.

Mr.

Mr. Pearſon at length aſcertained, that theſe unfortunate accidents were to be aſcribed to mercury acting as a poiſon on the ſyſtem, quite unconnected with its operation as a remedy; and that its deleterious qualities were neither in proportion to the inflammation in the mouth, nor to the actual quantity of mercury abſorbed into the conſtitution. The diſordered ſtate of the ſyſtem, implied by the mercurial erethiſmus, comes on after a long employment of mercury, and tends to a fatal termination. According to Mr. Pearſon, it is characterized by great depreſſion of ſtrength, a ſenſe of anxiety about the præcordia, irregular action of the heart, frequent ſighing, partial or univerſal trembling, a ſmall, quick, and ſometimes an intermitting pulſe, occaſional vomiting, a pale contracted countenance, a ſenſe of coldneſs; but the tongue is ſeldom furred, and the vital and natural functions are not much diſordered.

Mr. Pearſon obſerves, that when theſe, or the greater part of theſe ſymptoms are preſent, a ſudden and violent exertion of the animal power will ſometimes prove fatal. Walking haſtily acroſs the ward; riſing up ſuddenly in the bed to take food; or ſlightly ſtruggling with ſome of the other patients, are circumſtances noticed by the above gentleman as having commonly preceded the ſudden death of ſuch perſons as have died of the mercurial erethiſmus.

In order to avert the perilous effects of this peculiar affection, Mr. Pearſon ſtates, that the employment of mercury is, at all events, to be diſcontinued, whatever may be the ſtage, extent, or violence of the venereal ſymptoms. Every conſideration muſt yield to the great object of extricating the patient from a ſtate of impending deſtruction; nor would a perſeverance in the uſe of mercury, under theſe circumſtances, be of any avail, in regard even to the ſyphilitic complaints.

The patient ſhould be expoſed to a dry, cool air, without being ſubjected to any more fatigue than can be avoided. Mr. Pearſon contends, that ſitting in a room with a window open is not ſufficient, but that the patient ſhould go into a field or garden, and live as much as poſſible in the open air, till the above ſymptoms have diſappeared. This plan ſhould be conjoined with a generous diet. In this way patients have often been ſufficiently relieved in the ſhort ſpace of ten or fourteen days, to re commence the employment of mercury, and to bear its exhibition effectually, without any bad conſequences.

The gradual approach of the mercurial erethiſmus is commonly indicated (according to Mr. Pearſon's account) by paleneſs of the countenance, a ſtate of general inquietude, and frequent ſighing: the reſpiration becomes quicker, ſometimes accompanied with a ſenſe of conſtriction acroſs the cheſt; the pulſe is ſmall, frequent, and often intermitting, and there is a ſenſe of fluttering about the præcordia. In this early ſtage the further progreſs of the mercurial erethiſmus may be frequently prevented by the exhibition of the camphor mixture with large doſes of the volatile alkali, the employment of mercury being at the ſame time ſuſpended. Alſo, when the ſtomach is not oppreſſed by ſarſaparilla, this medicine is productive of infinite benefit to perſons afflicted with the mercurial erethiſmus. See Pearſon on the "Effects of various Articles of the Materia Medica in the cure of Lues Venerea," edit. 2. p. 155 to 159.

ERETRIA, in *Ancient Geography*, a town of Greece, in the Phthiotide, a country of Theſſaly.

Eretria, a town of the iſland of Eubœa, ſituated on the ſea-coaſt at ſome diſtance to the ſouth-eaſt of Chalcis, oppoſite to the mouth of the Oropus, which, on the continent, ſeparates the limits of Bœotia from thoſe of Attica. This town was probably built by the Athenians, as Strabo ſays, before, but according to Herodotus, after the war of Troy. It was for a long time a conſiderable place, and remained in a flouriſhing ſtate under the reign of Darius, ſon of Hyſtaſpes. It was deſtroyed by the Perſians in the war of Greece, but was afterwards rebuilt, became very rich, and ſubſiſted in the time of Strabo. It was amply furniſhed with pictures, ſtatues, and ſuch ornaments. We cannot trace any remains, except a perſuaſion that it exiſted in a place called by the modern Greeks *Gravelainas*.

Eretria *terra*, *Eretrian earth*, in the *Materia Medica*, the name of a very peculiar kind of alkaline bole, dug in the Negropont, near the ancient Eretria, and once in great uſe as an aſtringent and a ſudorific.

The ancient writers in medicine all mention the Eretrian earth, and Dioſcorides and Galen deſcribe two kinds of it, a grey and white. The grey is what is properly diſtinguiſhed by this name, being an earth of a different kind from all the other boles. The white, though the ancients ſeem not to have obſerved it, yet was plainly, from their own deſcriptions, the ſame with the white bole armenic, though found in a different place. Hill's Hiſt. of Foſſ. p. 5.

The grey or genuine Eretrian earth is a fine and pure greyiſh white earth, moderately heavy, naturally of a ſmooth ſurface, of a friable texture, eaſily crumbling to pieces between the fingers, but not ſtaining the ſkin in handling; it ſticks firmly to the tongue, but melts to a butter-like ſubſtance in the mouth; it burns to a perfect ſnow-white, and effervеſces violently with aqua-fortis. But what abundantly diſtinguiſhes it from all other earths is, that if a little be wetted, and drawn over a plate of braſs or copper, ſo as to mark a line, the mark will in a little time appear blueiſh. This is recorded of it ſo early as in the writings of Dioſcorides, and experiment proves it to be true. It ſeems plainly to be owing to an alkaline quality in the earth; this it plainly manifeſts by its fermenting ſo ſtrongly with acids; and it is as well known that alkalines draw a blue tincture from copper.

The ancients all eſteemed it a great medicine, and were particularly careful in their way of preparing it for uſe, by frequent waſhing. It is now unknown in the ſhops, but its highly alkaline quality, in which it is ſo much ſuperior to all the earths in uſe, might make it worth the bringing into uſe again; and it may ſtill be had in its old place, in almoſt any quantities.

ERETRIAC School, in the *Hiſtory of Philoſophy*. See Eliac *School*.

ERETRUM, in *Ancient Geography*, a town of Italy, in the country of the Sabines, N. E. of Rome, and S. W. of Cures. Strabo preciſely marks its ſituation, when he ſays that it was on the Via Salaris, and that the Via Nomentana terminated there. It was at a ſmall diſtance from the Tiber, near the 18th mile ſtone, according to the tables of Antonine and Peutinger.

EREUATIS, a town of Aſia Minor, in Lycia.

EREUM, a town in the iſland of Sardinia.

EREWASH-Canal, in *Geography*, is the parliamentary name of an important line of canal navigation, which nearly divides the counties of Derby and Nottingham for about twelve miles, of which an account has been given under our article Canal, to this it may be neceſſary to add, that by the act of the 29th George III. for Cromford canal, the tolls on this canal for all articles, except coals and coke, were lowered to one-half of thoſe mentioned in the original act, it being provided that no ſupplies of water to the canal ſhould be taken for the uſe of the Cromford canal, except at thirty feet below the ſummit level of this. Upon this canal the very important experiment was tried, at Ilkerton common, of ſuffering the coal-owners to work their coal under the canal inſtead of paying large ſums in order to have the ſame left, as the act had provided, and a great length has been thus excavated and the ground ſettled, with only a trifling and temporary inconvenience to the canal, in raiſing the banks; on the Nottingham canal the ſame was alſo ſucceſsfully tried, even under the locks, on the recommendation of Mr. Thomas Walker; ſee *Nottingham canal.* A rail-way branch conducts from the head of this canal to Beggarlea and another to Old Brinſley collieries in Nottinghamſhire; and another, conſtructed in 1808, to the new collieries in Cotmanbury-wood in Derbyſhire.

EREZE'E, a ſmall town of France, in the department of the Sambre and Meuſe, chief place of a canton in the diſtrict of Marche, with a population of 640 individuals. Its canton has a territorial extent of 272½ kiliometres, 13 communes, and 4519 inhabitants.

ERFA, a town of the iſland of Corſica; 25 miles N.N.W. of Baſtia.

ERFURT, or Erfort, anciently called *Erpes*, or *Erpisfurt*, a very old town of Germany, in Thuringia, on the river Gera, 60 miles N. by E. of Coburg. N. lat. 51° 6′. It appears to have been founded in the beginning of the fifth century. The emperor Lewis held a diet at Erfurt in the year 852. The emperor Henry I. did the ſame in 935, and Rudolph I. in 1289. The laſt diet of the empire held at Erfurt was that of the year 1566. Erfurt was not an immediate free imperial city, but it enjoyed ſeveral conſiderable lordſhips and immunities, firſt under the protection of the landgraves of Thuringia, then of the princes of Brunſwick, and laſtly, from the year 1483, of the electoral houſe of Saxony: but the archbiſhops of Mentz claiming the ſovereignty over Erfurt, it was at laſt agreed, in 1667, that they ſhould keep a governor in the city, on the expreſs condition that the Proteſtant doctrine and worſhip ſhould be reſpected. The profeſſors' chairs of the univerſity, which had been eſtabliſhed in 1392, were allowed to be filled half with Roman Catholic and half with Proteſtant teachers. In 1754 an academy of ſciences was founded, to which were ſubſequently added a botanical garden, an anatomical theatre, an aſtronomical obſervatory, a riding ſchool, and a ſociety of natural hiſtory. The beſt public libraries are thoſe of the Jeſuits, of the Scottiſh convent, and of the Lutheran miniſtry, which contained ſome valuable ancient manuſcripts of the Hebrew bible.

The moſt remarkable public building at Erfurt is its cathedral church, which is reported to have been built in the year 752. Its celebrated great bell weighs 275 cwt. In more ſuperſtitious times, pilgrims uſed to flock to Erfurt from all parts of Germany on a particular day, to dance the *dance of Death* (den Todtentantz.)

At the peace of Luneville, in 1801, the city of Erfurt, its territory and dependencies, and all the rights of ſovereignty poſſeſſed by the eccleſiaſtical elector of Mentz, or Mayence, were ceded to the king of Pruſſia, as part of the indemnities to which this monarch was entitled for his loſſes on the right ſhore of the Rhine. The population of Erfurt and its territory, together with the Eichsfeld, was, in 1802, reckoned at 121,200 individuals, and in the territory of Erfurt in particular, incluſive of the town, there were 3517 individuals to the German ſquare mile. The city of Erfurt, without the garriſon, contained 16,500 inhabitants.

But Pruſſia having declared war againſt France in 1806, Erfurt was one of the firſt towns which ſurrendered to the French after the unfortunate battle of Jena or Auerſtädt, in October 1806. The fort of Peterſberg, which protects the city, and which had always been conſidered as very ſtrong, did not even attempt a defence. At the peace of Tilſit, in 1807, Pruſſia was ſtripped of all the new acquiſitions and old poſſeſſions beyond the Elbe; and Erfurt, by the conqueror's decree of the 18th of Auguſt, 1807, was to form part of the new kingdom of Weſtphalia. But the French emperor having had a conference with the emperor Alexander I. of Ruſſia at Erfurt in the month of October, 1808, this city was again transferred, by way of compliment, to the Ruſſian emperor's brother-in-law, the preſent duke of Saxe-Weimar, who is a member of the Confederation of the Rhine. There is at Erfurt a conſiderable manufacture of ribbands, which employs above 500 individuals.

ERGALIA, of ἐργον, *opus*, a word uſed by the *Alchemiſts*, to expreſs that part of their treatiſes which explains the inſtruments employed in their operations.

ERGANE, in *Mythology*, the *Inventreſs*, an epithet of Minerva, becauſe to her was aſcribed the invention of ſeveral arts; ſince, beſides that of the art of war, Lucian aſcribes to her that of architecture; the art of ſpinning, of making cloth, tapeſtry, ſilk and woollen ſtuffs, is alſo aſcribed to her by the ancients. She was alſo reckoned the firſt who taught man to plant and cultivate the olive. She is likewiſe honoured with the invention of chariots, and of the uſe of trumpets and the flute, &c.

ERGASIMA, a name given by Dioſcorides and other of the ancients to a very foul and coarſe kind of myrrh.

ERGASTERIUM, a word uſed by the writers in *Chemiſtry*, ſometimes to expreſs the whole elaboratory, and ſometimes that part of a furnace on which the bottom of the retort, copel, or crucible, is to reſt in an operation.

ERGASTINÆ, Εργαστιναι, in *Antiquity*, a ſelect number of virgins employed in weaving Minerva's peplos or robe, which was carried in proceſſion at the Athenian feſtival Panathanæa. See Peplos, and Panathanea.

ERGASTULUM, among the *Ancients*, a houſe of correction, or workhouſe, where ſlaves, by the private authority of their maſters, were confined, and kept at hard labour for ſome offence. It was likewiſe called ſophroniſterium.

ERGATIA, Εργατια, in *Antiquity*, a Laconian feſtival, in honour of Hercules.

ERGAVIA, in *Ancient Geography*, a town of Spain, in the Tarragonenſis. Ptol.

ERGAVICA, a town of Hither Spain, S. of Bilbilis. This appears to have been a conſiderable place when it was taken by Gracchus in his campaign. Several medals were ſtruck here, which repreſented Auguſtus and Tiberius, with an ox upon the reverſe.

ERGENE, in *Geography*, a river of European Turkey, which runs into the Mariza, near Demotica, in Romania.

ERGERS, a river of France, which runs into the Ill, about two miles eaſt from Griſpoltheim, in the department of the Lower Rhine.

ERGETIUM, in *Ancient Geography*, a town of Sicily. Ptol. and Steph. Byz.

ERGINUS, a river of Thrace, in the vicinity of the Athyras, which ran before Sarpedon.

ERGITIUM, a town of Italy, in that part of Magna Græcia called Apulia, ſituated on the Appian way, between Teanum N.W. and Sipontum S. E.

ERGOT, in the *Manege*, is a ſtub, like a piece of ſoft horn, about the bigneſs of a cheſnut, placed behind and below the paſtern joint, and commonly hidden under the tuft of the fetlock. To diſ-ergot, or take it out, is to cleave it to the quick with an inciſion-knife, in order to pull up a bladder full of water that lies covered with the ergot. This operation is ſcarcely practiſed at Paris, but in Holland

land is frequently performed upon all four legs, with intent to prevent watery fores and foul ulcers.

Ergot, in *Agriculture*, is a vegetable difeafe which affects different forts of grain, and other crops, fhewing itfelf, according to the author of Phytologia, by the feeds growing out into large horns, having a black appearance without, as in fea-cale, rye, and in carex. It very often attacks the rye in France, and occafionally in this country in fuch feafons as are very moift; the grain in thefe cafes becoming confiderably elongated, being either ftraight or crooked, containing a black meal along with the white; and is afferted to have the appearance of being pierced or perforated by infects, which are believed by fome to be the caufe of the affection. It has frequently other different appellations, fuch as clavus, or the fpur, and horn feed. No certain remedy or method of preventing it has, we believe, been yet difcovered. See next article.

Ergot, in *Medicine*, a term originally applied, as we have feen, to a peculiar difeafe of corn, efpecially of rye, from the refemblance of the grains thus affected, to the fpur of a cock: and, by metonymy, ufed to denote a difeafe in the human body, occafioned by taking this difeafed, or *ergoted* rye as food.

The earlieft account of this difeafe of rye, and of its pernicious influence on the human body, with which we are acquainted, is contained in a letter from M. Dodart to the editor of the Journal des Savans, publifhed in March, 1676. (See vol. iv. part ii. p. 79.) The facts were communicated a few years before by the phyficians and furgeons of Sologne, in which diftrict the difeafe had been very prevalent. The grains of rye, affected by the ergot, according to M. Dodart, are of a blackifh colour externally, but white within, and when dry, they are harder and of a more compact fubftance than the natural grains, and have no bad tafte. They are confiderably longer than the other grains, fome of them being fourteen or fifteen lines in length, and two in breadth; and feven or eight of them are fometimes feen in one ear. They are obvioufly not foreign fubftances engendered between the grains of rye, M. Dodart adds, but the true grains, furrounded with their proper coats, in which the place of the germ is difcernible. Thefe grains were called *ergots*, *fpurs*, in Sologne; in Gaftinois, where they alfo were known, they were termed *bled cornu*. In various other places this difeafed rye has been called fecale cornutum, or corniculatum, fecale luxurians, clavus fecalinus, mater fecalis, or *mutterkorn*, (by the Germans), &c. It is ftated by Tiffot, on the authority of Haller, that the ergot affects rye only, or two or three other Alpine plants of the grafs-kind. (See Philof. Tranfact. vol. lv. for 1765, p. 110. A minute defcription of the ergot was publifhed by C. N. Langius in 1717, the fubftance of which may be found in the Acta Eruditorum for 1718, p. 309.)

The learned Tiffot, in his letter to fir George Baker, juft referred to, ftates that there are two other difeafes which affect rye and wheat, and which have been confounded with each other, as well as with the ergot, or fecale cornutum, *viz.* the *rubigo*, or mildew, and the *uftilago*, *brulure*, or blight; the former being characterized by the appearance of a reddifh yellow powder, of a glutinous nature, adhering to the ftalk and head of the corn; and the latter by a blacknefs and degeneration of the corn. (See Fontana on this fubject, and fir Jof. Banks on the difeafes of corn.)

The ergot was particularly obferved in rye in wet feafons, and more efpecially when a wet fpring was fucceeded by exceffive heat. M. Dodart remarks that the bread, which was made of ergoted rye, did not differ from ordinary bread in point of tafte; that this rye was moft particularly pernicious when new; but that its effects were not obferved until it had been eaten for a confiderable time. M. Noël affirms that it lofes its deleterious qualities altogether after being kept a few months in fheaf. (See a letter in Quefnay's Traité de la Gangrène, feche, p. 407, Paris, 1749.) And writers in general agree in ftating, that the difeafe, which the ergoted rye induces, is prevalent only at the conclufion of harveft, and ceafes before the commencement of winter; and that it was chiefly obferved among the poor, who were unable to procure wheaten bread in thofe feafons of humidity and fcarcity. (See Muller in Comment. Lipfiæ, anno 1752, p. 634, &c.)

The fymptoms of the ergot in the human body are defcribed fomewhat differently by different writers; but they coincide in reprefenting a dry gangrene, and ultimately death, as the ordinary refults of the difeafe. It commences with a laffitude and debility, but with little interruption to the functions in general. A degree of torpor in the lower extremities is then obferved, accompanied, according to fome of the writers, with a fenfe of prickling, and of the creeping of infects (formicatio) upon the fkin; a flight degree of fwelling, but without inflammation, enfues, often accompanied by the moft excruciating pains, and with a fenfe of burning heat; foon fucceeded by that of extreme cold; the fkin of the feet and legs becomes fhrivelled, and of a dark hue, as if dried in fmoke, afterwards black and deftitute of feeling; in fact the limb dies, or is gangrenous, but in a dry ftate, which has been compared to that of a mummy. By degrees the dead parts feparate from the living, as if they had been deftroyed by cauftic. In this mutilated condition, deprived of one, fometimes of both legs, more rarely of the hands or arms, fome individuals have furvived for months, or even years.

Befides this fpontaneous gangrene of the limbs, another fpecies of difeafe has been afcribed to the ufe of *ergoted* rye by Hoffmann, Tiffot, and fome other writers; but with what juftice or propriety may perhaps admit of a queftion. The difeafe alluded to was a febrile difeafe, faid to be of a contagious and malignant nature, and to be accompanied and principally characterized by various fpafmodic and convulfive fymptoms, by which, or by a general epilepfy, the patients were frequently carried off. This difeafe is faid to have been epidemic in Heffia, Weftphalia, and other parts of Germany, at feveral different periods, in the 16th and 17th centuries; and a defcription of it by the profeffors of the univerfity of Marpurg, in the year 1597, is generally referred to, as the firft complete account of the difeafes. But in that account, of which a tranflation is given by Gregorius Horftius, no allufion whatever is made to the ergot, or fecale cornutum; bad bread is mentioned only among other forts of crude and unwholefome aliment, to which the difeafe (occurring in a time of dearth) is there afcribed. The whole of what is faid refpecting the exciting caufes of that epidemic is contained in the compafs of thefe few lines. "Caufas hujus affectus quod attinet, ex ægrotantium relatione fcire licet, quod externa caufa communiter in alimento, ad nutriendum minus idoneo et improportionato, confiftat, dum pauperes rebus ad vitam neceffariis deftituti, panem impurum et male coctum longo tempore, in fummâ famis urgentiâ, devorant, interdum etiam poma acerba et auftera, fungofque et fimilia deglutientes, fefe eduliis crudis, immaturis, et aftringentibus ingurgitant, de quorum depravatâ concoctione cruditates obortæ, &c." (See Greg. Horft. Opera, vol. ii. lib. viii. obf. xxii.) A fimilar ftatement, refpecting the origin of this epidemic, is given by Sennertus in his chapter, "De febre Malignâ cum Spafmo," probably

upon

upon the authority of the Marpurg profeffors. The difeafe he fuppofed to be excited by a malignant vapour or humour, vellicating the brain and nerves. " Malignus autem ille vapor et humor ortum habuit ex victu pravo, dum, ob annonæ caritatem, panem non bonum, fructus corruptioni obnoxios, fungos, et id genus alia, ad explendam famem, pauperes devorabant. Ex quo victu pravo vitiofos humores in corpore colligi neceffe eft, &c." (Sennert. de Febribus, lib. iv. cap. 16.) The difeafe, therefore, is obvioufly confidered by the original writers as originating from defect of nutritious food, and the ergot is not in any way alluded to. The fymptoms of this fever, which was called by the Germans *die kriebel kranckheit, oder ziehende feuche*, the convulfive peftilence, are thus briefly enumerated by Hoffmann. " The difeafe in its commencement occupies the limbs and the extremities of the hands and feet, in which a fenfe of formication is felt. In fome inftances it begins with ficknefs and vomiting. Then follow violent fpafmodic contractions of the fingers and toes, which at length alfo attack the knees, fhoulders, elbows, and even the face, eyes, and lips, accompanied by an intolerable pain, and fometimes with a fenfe of extreme coldnefs, fometimes with that of a burning heat. Thefe fymptoms return at ftated periods, and fometimes continue for feveral weeks. As the pains diminifh, the patients fall into a ftate of drowfinefs and torpor, often into an alienation of mind, and are affected with giddinefs and deafnefs, the limbs remaining ftiff, and deftitute of the power of motion. In the extremities of the limbs large veficles, filled with ferum, often appear, and fometimes other tumours, which pafs into a gangrenous condition, but by a very flow progrefs, by which ultimately even the bones have been gradually deftroyed. A ftate of general convulfion, or epilepfy, occafionally fupervenes, and proves fatal, efpecially in children." (Hoffmann. Med. Rat. vol. ii. par. ii. cap. 9. § xvi.) A more detailed account of the fymptoms is given by Sennertus, loc. cit. Dr. Cullen has followed Linnæus and Vogel in denominating this difeafe *Raphania;* (See Amœn. Academ. vol. vi.) but queftions whether it be the fame difeafe as the *Necrofis uftilaginea*, by which term Sauvages has defignated the ergot. (See Cullen Nofol. Meth. gen. 52. Sauvage Nofol. Meth. clafs x. gen. 39.) There is, in fact, much confufion in the accounts of authors upon this fubject; and it feems probable that the true effects of the ergoted rye are to be found only in the dry gangrene, and not in the epidemic fevers, which have been afcribed to it.

It was long ago known that corrupted corn was poifonous to the animal body. Galen remarked, that the feeds of colium temulentum mixed with wheat, or the degenerated grain, called black wheat, would produce fever, head-ache, delirium, and gangrenous ulcers. (De Aliment. facultat. lib. i. cap. 37.) Moft of the writers on the fubject, from M. Dodart downwards, have ftated, that the ergoted rye, when given to fowls, hogs, and other animals, as food, produces the fame fymptoms as in man, and deftroys life. More lately the Abbé Teffier made a feries of experiments upon this fubject, and has given a minute defcription of the ergot in rye. He found that by feeding or cramming turkies and other animals with this difeafed rye, he could produce in all of them the dry gangrene and death. (See Memoires de la Soc. Roy. de Medecine for 1776, p. 303. Hift. de l'Acad. des Sciences for 1710. Acta Erudit. Lipf. 170 et 1752. Saviard Obf. Chirurg. The Treatife of M. Teffier, &c.

The dry gangrene occurs from other caufes than the ergoted rye. An account of a whole family confifting of eight perfons, who were feized and mutilated or deftroyed by gangrene of the lower extremities, preceded by pain and fome fwelling, at Wattifham in Suffolk, is given in the Philof. Tranf. vol. lii. part ii. The ftate of the family, three months after the commencement of the difeafe, is thus reprefented: " 1. Mary, the mother, æt. 40. The right foot off at the ancle; the left leg mortified, a mere bone, but not off. 2. Mary, æt. 15. One leg off below the knee; the other perfectly fphacelated; but not yet off. 3. Elizabeth, ætat 13. Both legs off below the knees. 4. Sarah, æt. 10. One foot off at the ancle. 5. Robert, ætat. 8. Both legs off below the knee. 6. Edward, ætat 4. Both feet off at the ancles. 7. An infant, four months old, dead." The father alfo fuffered flightly in the fingers. Although the fymptoms were exactly thofe of the ergot, yet, in this cafe no rye was eaten, nor could any other circumftance in the diet or economy of the family be difcovered, to which the gangrene could be attributed. See Gangrene.

ERIACH, in *Antiquity*, the name of a recompenfe affigned by the Irifh Brehon law, in cafe of murder, to the friends, or to the child or wife of him that was flain, as a kind of compofition between the murderer and his profecutors.

ERIAMBO, in *Geography*, a river of Ruffia, which runs into the Oby; 30 miles above Obdorokoi.

ERIANTHUS, in *Botany*, from ἐριον, *wool*, and ἀνθος, *a flower*, Michaux Fl. Boreali-Amer. v. 1. 54. A genus of graffes eftablifhed by Michaux, in its character very near *Saccharum*, but more naturally allied to *Andropogon*, to which, if the character of that genus were reformed, Michaux himfelf fufpects the prefent might be referred. *Andropogon* indeed feems to require a thorough inveftigation, and probably a divifion into more than two genera.

ERIBANUM, in *Ancient Geography*, a town of Italy, in Campania, upon the Vulturnus. Polybius.

ERIBŒA, a town of Macedonia, in the country of the Parthæans. Ptol.—Alfo, a mountain of Macedonia, in the fame country.—Alfo, a town of Afia, in Bithynia.

ERIBOLUM, the port of Nicomedia, a town of Bithynia.

ERIC, king of Denmark, in *Biography*. There were feveral princes of this name, though but few of them have any claim to notice in this place. Eric the Firft was poffeffed of fo many virtues that he was furnamed the " Good." A mufician, celebrated for his great fkill on the harp, afferted that he could deprive his hearers of their underftanding by the powers of his inftrument. Eric challenged him to the trial, and in the paroxyfm of phrenzy into which the performer threw the monarch, he killed four of his guards. Grieved at what he had done, he made all the recompenfe he was able to the relations of the deceafed, and to do penance for the bloody deed, he determined to undertake a pilgrimage to the Holy Land. His fubjects remonftrated againft his defign, but he was not to be diffuaded from his purpofe, fet out on his journey, and died at the ifle of Cyprus. This event took place in the year 1107.

Eric X., king of Sweden and Norway, as well as of Denmark, the fon of Wratiflaus VII. duke of Pomerania, was declared fucceffor to the crowns of Denmark and Norway in the year 1388, by his great aunt, queen Margaret; and when, in 1396, fhe annexed the crown of Sweden to her dominions, Eric was, by the treaty of the " Union of Calmar," declared fucceffor to that alfo. This celebrated treaty confifted of three articles 1. " That the three kingdoms of Denmark, Sweden, and Norway, fhould thence forward have but one king, who fhould be chofen alternately by each of them, and approved in a general affembly. 2. That the monarch fhould divide his refidence equally between the three

three kingdoms, and appropriate the revenues of each to its particular exigencies. 3. That each kingdom ſhould retain its own laws, cuſtoms, ſenate and privileges; and that the ſubjects of the one ſhould not be elevated to offices of profit or power in another." Theſe conditions ſeemed, at firſt ſight, to have been dictated by wiſdom, but they proved to be the ſource of wars that continued to rage during a whole century between the three kingdoms. On the death of the queen in 1412, Eric ſucceeded without oppoſition to the three united crowns. He had married the daughter of Henry IV. king of England, with whom he had a large portion, and thus might be regarded as one of the moſt potent kings of his time. Eric was ſoon involved in a war with the princes of Holſtein, which for ſome time was carried on with doubtful ſucceſs, but in 1424 the whole of South Jutland, including Sleſwick and Gottorp, was adjudged to the Daniſh crown. This award, which was made by the emperor Sigiſmund, at Buda, determined Eric upon a pilgrimage to the Holy Land. During the expedition, he was made captive, and obliged to pay a large ranſom for his liberty. His abſence from home was attended with other evils. From his acceſſion he had diſpleaſed the Swedes by refuſing to call a general diet for the confirmation of their liberties, which excited much diſcontent, that at length broke out into open rebellion. In 1435 he met the Swediſh diet at Stockholm, and agreed to a full redreſs of grievances. His promiſes, however, were of little avail to his people, who, after enduring much from his miſconduct, depoſed him in 1439, and choſe, in his ſtead, his nephew Chriſtopher of Bavaria. For ten years he made many attempts to regain his ſituation, but without ſucceſs. After this he employed himſelf in compiling a hiſtory of Denmark from the public regiſters, comprizing the period from the commencement of the monarchy to 1288. He afterwards repaired to the iſle of Rugen, where he died in 1459. Eric poſſeſſed quick natural parts, and was a lover of learning; but he was ambitious, deſpotic, irreſolute, and inſincere, qualities which led him into many difficulties, and which rendered his reign truly diſaſtrous. Univer Hiſt.

Eric XIV., king of Sweden, ſon of Guſtavus Vaſa, aſcended the throne of Sweden in 1560, at the age of twenty-ſeven, and was poſſeſſed of all the accompliſhments proper to his elevated ſituation. He ſpoke the modern languages, danced gracefully, ſhewed animation in all his actions, and was eloquent and polite. But he ſuffered himſelf to be hurried away with guſts of paſſion, which ſometimes obliterated every trace of reaſon, and rendered him furious. His father, who had witneſſed theſe fits of rage, had once formed the deſign of excluding him from the throne, and of conferring the crown on his ſecond ſon. For the ſame reaſon he refuſed to permit him to viſit England to pay his court to the princeſs (afterwards queen) Elizabeth: but negotiated the buſineſs by means of his ambaſſador and ſecond ſon John. Eric, however, almoſt immediately after his acceſſion, determined to obtain an interview with Elizabeth, and ſet ſail with a large fleet and ſplendid train, but the veſſels being overtaken by a violent ſtorm, were driven back upon his own coaſt, where he ſuffered ſhipwreck, and for a time relinquiſhed his matrimonial project. He next ſent propoſals of marriage to Mary queen of Scotland, and almoſt before he could obtain any anſwer, ſolicited from the emperor the hand of the princeſs of Lorraine, daughter of Chriſtian II. with whom he was enamoured by the deſcription of ſome of his courtiers. He received a favourable anſwer, but in the mean time he had changed his mind in favour of Elizabeth. His political conduct was as capricious as his amours, and involved him in continual quarrels with his neighbours, and a confederacy was formed againſt him by Muſcovy, Poland, Denmark, and Lubeck. His brother John, who had married Catharine, daughter of the king of Poland, fell under his ſuſpicion, and was driven to an open rupture. John was cited to Stockholm, to vindicate his conduct, and refuſing to appear, an army was ſent into Finland with orders to ſeize him and his wife, and to bring them to the capital. He was immediately thrown into priſon, accompanied by his wife, who voluntarily choſe to ſhare in his ſufferings. It is ſaid that the king went frequently to the priſon with the deſign of murdering his brother, but that on ſeeing him he felt his heart ſo moved with pity, as to prevent him from ſtriking the fatal blow. Sometimes with tears in his eyes he would confeſs the ſanguinary deſign which had prompted his viſit, and added, "I know that the crown of Sweden is intended for you, and I requeſt that, when you are in poſſeſſion of it, you will pardon my errors." This circumſtance ſtrongly diſplays the violence of contending paſſions in the mind of Eric, and has been brought to prove his inſanity.

The early years of his reign were ſpent in wars chiefly with Denmark, carried on with vigour on the part of Eric, though without any permanent advantage. Domeſtic troubles at length withdrew his attention from foreign wars, and his capricious conduct deſtroyed all reſpect for him in the breaſts of his ſubjects. Diſappointed in his matrimonial projects, he entertained a number of concubines, one of whom, a peaſant's daughter, gained ſuch an aſcendancy over him that he married her. He was under the influence of his miniſters and domeſtics of mean rank, who frequently excited his jealouſies of the great families. He entertained a particular hatred of the Stures, an illuſtrious family, deſcended from the ancient regents. Eric had taken one of them into favour, though he had, on a former occaſion, diſgraced him, and made him contemptible in the eyes of the populace. He now ſent him in the quality of embaſſador to Stralſund, but he became once more the object of the king's abhorrence, who conceived that he was conſpiring againſt his life and crown. The king took pains to convince the ſtates that Sture carried on dangerous intrigues at Stralſund, and he ſuborned witneſſes to accuſe him of treaſonable deſigns. An infamous favourite, named Peerſon, perſuaded Eric to extirpate the whole family; ſentence of death was accordingly pronounced againſt thoſe unfortunate men, together with twenty-ſix nobles, who were the pretended accomplices of a conſpiracy laid to their charge. A public trial was afterwards allowed them, in which the Stures were able to vindicate their cauſe ſo completely, and to prove their innocence ſo undeniably, that the king himſelf apologized to them for their detention and long impriſonment: nevertheleſs, in a very ſhort time, he ſtabbed Nils Sture with his own hand. The unfortunate man drew the dagger from his breaſt, and preſented it to the monarch, who, with the moſt ſavage barbarity, ordered his guards to accompliſh that which he had failed to perform himſelf. The reſt of the priſoners were alſo cruelly murdered at the ſame time. No ſooner was this bloody ſcene over than Eric felt the pangs of a wounded conſcience. He grew frantic, and, as if purſued by the avenging furies, fled into the woods, where he wandered for many days like a wild beaſt, refuſing to take food or repoſe. On his return he endeavoured to compenſate for his cruelty, by beſtowing large ſums upon the friends and relations of the victims; and by giving up Peerſon to the hands of juſtice, who was condemned but not executed. Being threatened by the king of Denmark, Eric ſet at liberty his brother John, to whom and to his other brother he propoſed aſſigning lands

in

in Livonia, in lieu of thofe left them by their father Guftavus. Shortly after he formed a defign of putting them to death, and of conciliating the friendfhip of the czar of Mufcovy, by delivering him the wife of duke John, to whom that prince had paid his addreffes before her marriage. His intentions were difcovered in time to defeat the purpofe, and the brothers began to raife forces in their own defence. Eric made a ftand, and an accommodation was effected, but by the treaty he bound himfelf to give up Peerfon, his favourite, who, being put to the torture, confeffed a plot contrived by himfelf and the king, of pillaging Stockholm, burning part of the fhips in the harbour, and proceeding with the reft loaded with fpoil to Narva. The dukes now felt themfelves juftified in breaking the treaty, and they obliged Eric to capitulate in the citadel. He was put under confinement, folemnly depofed by the ftates, and duke John elected in his ftead. His children were declared incapable of fucceffion, and himfelf was condemned to perpetual imprifonment. His keepers were appointed from among the relations of thofe whom he had cruelly maffacred, and who did not fail to fubject him to various infults and indignities, and not unfrequently to the evils of cold and hunger. After nine years imprifonment, he finifhed a wretched life in 1578, in confequence, it was fuppofed, of a dofe of poifon adminiftered by order of his brother John, who dreaded the poffibility of his being liberated, and again fet upon the throne. Eric was not deficient in talents; and he poffeffed great perfonal bravery: under his conduct the Swedifh troops repeatedly diftinguifhed themfelves in contending with and overcoming the Danifh armies, and it has been thought that he would never have fubmitted to the hard conditions which Denmark at length impofed on his fucceffor. (See JOHN.) Univer. Hift.

ERICA, in *Botany*, ερεικη of Diofcorides, the fame name, varioufly corrupted, being applied to the feveral fpecies of this genus among the modern Greeks at prefent, according to Dr. Sibthorp. See Prod. Fl. Græc. 256, 257.—Heath or Ling.—Linn. Gen. 192. Schreb. 258. Willd. Sp. Pl. v. 2. 356. Ait. Hort. Kew. v. 2. 14. Sm. Fl. Brit. 417. Mart. Mill. Dict. v. 2. Juff. 160. Gærtn. t. 63. Tourn. t. 373. Clafs and order, *Octandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Ericæ*, Juff.

Gen. Ch. *Cal.* Perianth of four ovate-oblong, permanent, upright, often coloured leaves. *Cor.* of one petal, permanent, four-cleft, regular, with an ovate or cylindrical tube, more or lefs inflated. *Stam.* Filaments eight, capillary, equal, inferted into the receptacle; anthers cloven at the fummit, opening by two pores, by which they laterally cohere while young. *Pift.* Germen fuperior, roundifh; ftyle thread-fhaped, ftraight, longer than the ftamens; ftigma capitate, in four or eight lobes. *Peric.* Capfule roundifh, fmaller than the calyx, which covers it, of four cells and four valves. *Seeds* numerous, affixed to the columella.

Eff. Ch. Calyx of four leaves. Corolla four-cleft. Stamens inferted into the receptacle. Anthers with two pores. Capfule fuperior, of four cells. Seeds numerous.

Obf. Some fpecies appear to have a double calyx, but the lowermoft was by Linnæus latterly efteemed rather of the nature of bracteas. The fhape of the corolla is extremely different in different fpecies, its tube being in fome globular, in others ovate, in others again cylindrical and much elongated; fometimes dilated at the orifice, fometimes contracted, in fome inftances curved. The anthers, either included within the tube or projecting beyond it, are in fome fimply cloven at the top, without any appendage at the bafe; in fome this latter part bears a pair of briftles, in others a pair of notched leaflets, termed a creft, which, as Mr. Salifbury remarks, originate rather from the filament than from the anther.

This extenfive and moft elegant genus is confined to Europe and the fouthern part of Africa, the country about the Cape of Good Hope being, of all others, moft abundant in Heaths, whence the green-houfes of Britain are continually fupplied with new fpecies or varieties, to the great profit of nurferymen, fome of whom find it worth while to keep a collector refident there. No *Erica* is found in America, in New Holland, nor fcarcely in the Torrid Zone. The habit of the whole genus is fhrubby, very rarely arborefcent, with fmall, oppofite or whorled, ufually narrow, leaves, and bracteated ftalked flowers, whofe colours partake of all the moft exquifite tints of red, purple, yellow or orange, occafionally variegated with green or white. Some are entirely white, but the anthers are commonly dark brown or purplifh.

It is difficult to guefs at the number of the real fpecies of *Erica*. Willdenow has 137, fome of which are duplicates. Our gardeners reckon about 300, many of which are merely varieties, but there are feveral others only known hitherto in a dried ftate, and probably not a few yet remain to be difcovered in the wilds of fouthern Africa.

The greater part bloffom with us in the fpring, but many at various feafons. They are for the moft part inodorous, though a few of them are delightfully fragrant. They commonly keep well in an herbarium, provided they are dried fuddenly, fo as not to throw off their leaves during the procefs.

Few good figures of this genus, except of the European kinds, are found in the older botanical works, but many appear to great advantage in the more recent works of Ventenat, Wendland, Curtis's Botanical Magazine continued by Dr. Sims, and efpecially in a folio publication by Mr. Andrews, entirely devoted to the fubject, as well as an octavo one, equally ufeful, by the fame artift. The moft fuperb of all, however, are two thin fafciculi, publifhed by Mr. Aiton, of coloured plates by Mr. Frederick Bauer, but unhappily without any defcriptions or even fpecific characters.

In the fcientific definition of the fpecies of *Erica* much yet remains to be done. The labours even of Linnæus and Thunberg are very far from perfection. Mr. Salifbury, who has paid much attention to the fubject, has given an arrangement of 246 fpecies, according to their natural affinities, in the fixth volume of the Linnæan Society's Tranfactions, with often expreffive, if not claffical, fpecific characters, but with an unlicenfed change, and frequent perverfion, of names. This writer includes the Linnæan genus *Blæria*, like Thunberg, under his *Erica*, while he excludes *E. vulgaris* as a genus, by the name of *Calluna*, and feparates a few fpecies (which have an irregular calyx, and flefhy fruit, with three cells and three feeds) into another genus, named, from its large ftigma, *Salaxis*. To him we are indebted for remarking that the corolla of *Erica* is permanent, which is not the cafe in *Andromeda* and *Menziefia*, and that the anthers are united laterally to each other by their pores before they difcharge the pollen. He alfo confiders all true *Ericæ* as having the partitions of the fruit originating from the centre of each valve.

Linnæus and his followers diftribute the fpecies of this genus into three principal fections by the ftructure of the anthers; firft, anthers ariftated or furnifhed with a pair of briftles at their bafe; fecondly, anthers crefted, as above defcribed; thirdly, anthers fimple, or deftitute of any of thofe appendages. The latter are fubdivided into fuch as have the

the anthers included within the corolla, and such as have them projecting beyond its border. All these sections are moreover separated into subordinate ones by the situation of the leaves, whether opposite, or in three, four, or more rows, or scattered, of which last *E. glutinosa* is perhaps the only example. All these characters, however combined, unfortunately prove but artificial, separating species naturally allied to or resembling each other; nor are some of them, derived from the crusted anthers, or number of leaves, constant or invariable, even in the same species. Still, as no natural subdivisions have yet been suggested, we may be glad of artificial and imperfect ones in so vast a genus. Mr. Salisbury, though he disposes the species in order, according to what he conceives to be their natural affinity or resemblance, especially in the form and proportion of the corolla, has not attempted to define or characterize many subdivisions of the genus. As, however, it is very instructive to contemplate the species of such a genus in this light, and as this writer's is the only attempt of the kind, we shall give examples of each of his subdivisions in the order in which he places them. It is necessary to premise that these subdivisions are considered as having in general no peculiar connection, and that one or more species often come between two of them, almost equally distinct from both and from each other. Thus, in the very beginning, *E. scoparia*, (E. coris folio quarta; Clus. Hist. v. 1. 42. f. 3.) ;—and *E. spiculifolia*, (Sm. Fl. Græc. Sib. t. 353. Prod. v. 1. 257.) ; stand as distinct from each other, and from three species immediately following them, among which are *absinthoides* of Linnæus ;—and *setacea*, Andrews, t. 62.—Next come *planifolia*, Linn. (Pluk. t. 347. f. 1.) and *oxycoccifolia* of Mr. Salisbury, agreeing in their ovate dilated leaves, in which they are very unlike their neighbours. Then again *strigosa*, Ait. Hort. Kew. v. 2. 17 ;—and *sicæfolia*, Salisb. (rather *sicifolia*), a new species, each stand separate, as not immediately allied to any other.—We shall, in separate paragraphs, mention one or more species of Mr. Salisbury's subdivisions, noticing likewise the separate anomalous species, and introducing two or three new ones, to the best of our judgment, according to their several affinities. Many still unsettled remain in every collection.

After *sicifolia* follows an assemblage of eight species. Among these is *E. pubescens*, Linn. Sp. Pl. ed. 2. 506, *pallida* of Mr. Salisbury, thus characterized by him.—Leaves three in a whorl. Anthers crested, included. Flowers terminal. Leaves linear. Sides of the calyx doubled back. Corolla two lines long, downy on both sides. Crests short.—Also *E. urceolaris*, Berg. Cap. 107. Ait. and Bau. Ic. t. 16. (*pentaphylla*, Linn.)

Then 13 species with little or no affinity to each other, among which are *arborea* (E. coris folio prima ; Clus. Hist. v. 1. 41.); and *Thunbergii*, Linn. Suppl. 220, Curt. Mag. t. 1214, a most beautiful species, conspicuous for its globose white tube and large deep-orange limb, very rare at present in the gardens.

Next appears a collection of eight, among which is *melanthera* ; another of three, including *capitata* and *bruniades* (Andr. t. 61.); and a third of 18, amongst which are *sexfaria*, Ait. and Bau. Ic. t. 11, with *nigrita* of Linn. and Thunberg, so called from its conspicuous dark anthers, elegantly contrasted with the white corolla and calyx. This last Mr. Salisbury is pleased to denominate *volutæflora*. These three subdivisions he indicates as not so distinct or dissimilar as most.

The following section comprises five new species of Mr. Salisbury's, named by him *fabrilis*, *dianthifolia*, *brevifolia*, *chlamydiflora*, and *selaginifolia*. They have all crested included anthers, and terminal flowers.

His *pannosa*, with a woolly corolla, stands alone.

Then follow 15 species, mostly *Blæria* according to Linnæus, having but four stamens ; see Blæria. Nor can we much object to the union of these two genera, except that in so vast a tribe, we may be glad of even so slight a circumstance as number to make a genus, when there is moreover such a difference in habit as this very arrangement of Mr. Salisbury's implies. If indeed a few species of *Erica*, here and there in the different natural subdivisions, were tetrandrous, nobody would think of separating them for such a reason.

E. nudiflora, Linn. Mant. 2. 229. Sm. Plant. Ic. t. 57, (accompanied by two others) follows. Mr. Salisbury exults in having discovered its bracteas, which escaped Linnæus, Dryander, and the author of the present article, who in this instance readily submits to his correction. They are in the form of two or three excessively minute woolly scales, near the base of each flower-stalk.

The next five, or rather we would say seven, uniting two of Mr. Salisbury's sections, are *herbacea*, Linn. Sp. Pl. 501, Curt. Mag. t. 11, not at all different from *carnea*, Sp. Pl. 504 ; (this, according to Dr. Sibthorp, is the genuine ερεικη of Dioscorides, extremely common every where in Greece);—*mediterranea*, Linn. Mant. 2. 229, Curt. Mag. t. 471 ;—*multiflora*, Sp. Pl. 503, (Garidel. t. 32.), another beautiful native of the south of Europe, long confounded with *vagans* ;—*manipuliflora*, Salisb. (Sm. Fl. Græc. Sibth. t. 352.);—*vagans*, Linn. Mant. 2. 230, (Engl. Bot. t. 3.) common on all the heaths of Cornwall, either with red, flesh-coloured, or white flowers ;—*umbellata*, Linn. Sp. Pl. 501, (Ait. and Bau. Ic. t. 5.) ;—and lastly *nutans*, Wendland. Eric. fasc. 3. 5.—The native country of this last we know not, nor have we seen Wendland's publication. The rest of this very natural assemblage grow in Europe only.

Filiformis and *turgida*, Salisb. we have not ascertained to our satisfaction.

Nine species, very naturally allied, having excessively long anthers, projecting from an elongated tubular corolla, are placed next. Among these are *E. Plukenetii* ; *Petiveri* ; *Banksii*, Andr. t. 26 ; *Sebana*, Dryand. in Ait. and Bau. Ic. t. 10 ; &c. mostly familiar to collectors.

Nine more comprehend *imbricata*, Linn. Sp. Pl. 503 ;—and *flexuosa*, Andr. Eric. t. 33 ;—with *leucanthera*, Linn. Suppl. 223 ;—and *milleflora*, Berg. Cap. 96, which last name is well retained by Mr. Salisbury, in preference to the inaccurate one, *paniculata*, given by Linnæus.

An assemblage of six more contains the beautiful *baccans* Linn. Mant. 2. 233. Curt. Mag. t. 358, a good specimen of the rest.

Five following ones are supposed to be little, if at all, related. Among them are the beautiful *glauca*, Andr. t. 47. Curt. Mag. t. 580 ; in the same section with which the *elegans*, ibid. t. 966, should be inserted. The flowers of the latter are larger, and differently coloured, but they closely agree in structure with those of *glauca*.—*E. Monsoniæ*, Dryand. in Ait. and Bau. Ic. t. 7, (E. Monsoniana ; Linn. Suppl. 223.), one of the most magnificent of all, is placed by Mr. Salisbury, with a sign of incomplete affinity, after *glauca*.—*E. halicacaba*, Linn. Sp. Pl. 507, Ait. and Bau. Ic. t. 2, follows alone. Its corolla is of a pale uniform yellowish green.

Ten species, with a long tubular corolla and short included anthers, are needlessly, we think, divided into three parcels. These are mostly handsome flowers, very frequently to be seen in gardens. Among them are *versicolor*, Andr. t. 12, which

which comprehends as a variety his *coſtata*, t. 46;—*diſcolor* of the ſame author, t. 3;—*cruenta*, Ait. and Bau. Ie. t. 13;—*abietina*, Linn. Sp. Pl. 506, (*E. Patterſonia* of Andr. t. 7, and the gardeners), remarkable for its thick-ſet leaves and crowded golden bloſſoms, as well as its pulpy ſeed-veſſel;—and *concinna*, Ait. Hort. Kew. v. 2. 23, miſtaken by Andrews, t. 64, for *abietina*. For this laſt (*concinna*) Mr. Saliſbury has, in our opinion with advantage, adopted the name *paludoſa* from Hermann, which indicates its place of growth, and conſequently its requiſite treatment in a garden.

E. pyramidalis, Ait. Hort. Kew. v. 3. 491. Curt. Mag. t. 366, with two others unknown to us, conſtitute the next ſubdiviſion.

Then follow 12 fine plants, needleſsly, we again preſume, divided into two parcels. Among them are *tubiflora; curviflora; conſpicua*, Ait. Hort. Kew. v. 2. 22. Ait. and Bau. Ie. t. 12; and *ſordida*, Andr. t. 56; with ſeveral often confounded with theſe, (for it is rather an indiſtinct and perhaps variable tribe,) all which contribute much to adorn our green-houſes, and are in general eaſily cultivated.

E. faſcicularis, Linn. Suppl. 219. Ait. and Bau. Ic. t. 6; and *E. Maſſoni*, Linn. Suppl. 221. Curt. Mag. t. 356; occupy a ſection by themſelves. Theſe are two of the moſt highly prized of the whole genus. The flowers of both are tipped with green.

The 12 next are, in general, ſcarcely leſs ſplendid, witneſs *pharetriformis*, Saliſb. (exſurgens, Andr. t. 13.);—*grandiflora*, Linn. Suppl. 223. Curt. Mag. t. 189;—and *longifolia*, remarkable for its tremulous leaves and the variation of colour in its flowers, inſtances of which are diſplayed in Andrews, t. 8, t. 20, and t. 33; likewiſe in Curt. Mag. t. 402. The deep ſcarlet is juſtly the moſt admired variety.—We cannot but think *pinea*, Andr. t. 57, muſt be a diſtinct ſpecies.

To theſe are nearly allied the next five, comprehending *ſeſſiliſl ra*, Linn. Suppl. 222, (*ſpicata*, Thunb. Diſſ. 43. t. 4. Andr. t. 6);—*alveiflora*, Saliſb. called in the gardens *gelida*, which name aptly expreſſes the cool aſpect of its ſnow-white corolla tipped with pea-green, and ſurely ought to have been retained;—and *mammoſa*, Linn. Mant. 2. 234. Andr. t. 58. (abietina, Schneev. Ic. t. 23.); of which a beautiful ſcarlet variety is moſt common with us, called *ſpecioſa* in Schneevooght, t. 3, and *verticillata* by Andrews, t. 21.

Of Mr. Saliſbury's *brachialis*, a ſolitary ſpecies, we have only ſeen a doubtful ſpecimen.

Four ſpecies follow, among which are *E. Sparmanni*, Linn. Fil. Suppl. 219. Stockh. Tranſ. for 1778. t. 2; and the noble *cerinthoides*, Linn. Sp. Pl. 505. Curt. Mag. t. 220.

E. cernua, Montin Nov. Act. Upſ. v. 2. 292. t. 9. f. 3. Linn. Suppl. 222, ſtands alone; as does Mr. Saliſbury's *doliiformis*, (*mammoſa*, Thunb. Diſſ. de Ericâ, ed. Saliſb. 42. f. 21.)

E. auſtralis, Linn. Mant. 231, not uncommon in gardens;—and *ciliaris*, Linn. Sp. Pl. 503. Curt. Mag. t. 484. follow next. Theſe are both European ſpecies, and are immediately followed by two others, our elegant Engliſh *E. Tetralix*, Curt. Lond. faſc. 1. t. 21. Engl. Bot. t. 1014, (a name changed by Mr. Saliſbury to *botuliformis*, ſauſage-ſhaped);—and his *multicaulis*, the *ſtricta* of Donn and Willdenow, native of Corſica.

Next comes by itſelf our common Britiſh *cinerea*, Curt. Lond. faſc. 1. t. 25. Engl. Bot. t. 1015, more happily, but without any neceſſity, altered to *mutabilus*.

E. regerminans, Linn. Mant. 2. 232, only known in the Linnæan herbarium;—and *pulchella*, Andr. t. 51, occupy two ſeparate ſections.

A very diſtinct and natural aſſemblage of four ſpecies next occurs, in which are *empetrifolia*, Linn. Sp. Pl. 507, known by its hairy corolla;—and *malleolaris*, Saliſb. (*empetrifolia*, Curt. Mag. t. 447.)

The four next ſeem ſcarcely to be ſeparable from them, if we may judge by *viſcaria*, Linn. Mant. 2. 321. Andr. t. 55, the only one of the four with which we are acquainted.

A difficult family of ſeven ſpecies, with a hoary habit, and ſmall turgid downy flowers, is placed next, of which *tardiflora*, Saliſb. (*pubeſcens*, Curt. Mag. t. 480.);—and *hirtiflora*, Curt. Mag. t. 481, are examples. Both are diſtinct from, though nearly allied to, the real *pubeſcens* of Bergius and Linnæus, as well as from his *parviflora*.

A ſomewhat ſimilar tribe, but ſmooth, and with larger more bell-ſhaped flowers, contains ten ſpecies. Amongſt them is *margaritacea*, Ait. Hort. Kew. v. 2. 20. Andr. t. 54, very pretty when laden with its pearly bloſſoms.

E. Bergiana, Linn. Mant. 2. 235, remarkable for its reflexed calyx, with two others, come next, and lead inſenſibly to the following ſection.

This comprehends *pilulifera*, Linn. Sp. Pl. 407;—*obliqua*, Thunb. Diſſ. 44. Ait. and Bau. Ie. t. 3;—and *phyſodes*, Linn. Sp. Pl. 506. Curt. Mag. t. 443; with four more.

E. cernua, Andr. t. 48, ſtands alone, but between it and *phyſodes* we would introduce a new ſpecies, communicated by Mr. G. Hibbert among the reſt of his dried ſpecimens of this genus from the Cape, and by Meſſrs. Lee and Kennedy from their garden, where it firſt bloſſomed in 1808. We would name it

E. roſaria. Leaves in four rows, obtuſe, recurved, toothed. Anthers ſimple, included, with long pores. Corolla ovate, viſcid. The leaves reſemble thoſe of *phyſodes*, but are more diſtant and recurved. Flowers about the ends of the branches, on moſtly axillary, long, viſcid ſtalks, with two or three oblong, pellucid, concave bracteas towards their middle; the flowers droop a little, and are remarkable for their fragrant ſcent, reſembling ottar of roſes. The calyx-leaves are like the bracteas, and about one-third as long as the corolla, which is of a pale ſtraw-colour, ovate, inflated, viſcid, its ſegments obtuſe, crenate, but little ſpreading. Stamens about the length of the calyx; their filaments purple at the ſummit, without any ereſt or appendages; anthers brown, oblong, with pores two-thirds of their length. Germen turbinate, furrowed, ſmooth; ſtyle twice as long as the ſtamens; ſtigma capitate, dark coloured.

E. pulchella, Saliſb. a new ſpecies, ſtands alone, the author being unacquainted with its affinity to any other.

Two others, unknown to us, occupy a ſection with *glutinoſa*, Berg. Cap. 98. Ait. and Bau. Ic. t. 17. (*Andromeda droſeroides*, Linn. Mant. 2. 239.) This is a beautiful plant, with all the habit of an *Erica*, nor any thing but an occaſional luxuriance of number in the parts of the flower to make it an *Andromeda*.

A very ſplendid and diſtinct aſſemblage follows, of ſix ſpecies, diſtinguiſhable by their large flowers, with a long tube, always contracted at its mouth, and more or leſs inflated below. The border is ſpreading and ornamental. Among theſe are *retorta*, Linn. Suppl. 220. Curt. Mag. t. 362, firſt found at the Cape by Maſſon, not by Thunberg;—*ampullacea*, Curt. Mag. t. 303;—and *Aitonia*, Curt. Mag. t. 429. This laſt varies a little in the ſize and hue of its border, but ſo ſtrikingly reſembles the Catalonian Jaſmine, that we long ago named it *jaſminea*, nor is there any occaſion for the uncouth preciſion of *jaſminiflora*.—We have ſtill ſome of this tribe, which appear to be nondeſcripts.

Ten

Ten ſpecies with flowers of a ſomewhat ſimilar form but ſmaller, and more ſlender needle-ſhaped leaves, conſtitute the next parcel. To this belongs *faſtigiata*, Linn. Mant. 66, of which there are ſeveral elegant varieties, named *E. Humea*, &c. in the gardens. Alſo *E. Muſcari*, Andr. t. 1. ſmelling like the Muſky Hyacinth, which it imitates in colour;—and *comoſa*, Linn. Mant. 234, Ait. and Bau. Ic. t. 18.

A tribe more ſplendid in general, of nine ſpecies, ſucceeds. To theſe belong *inflata*, Thunb. Diſſ. 41. t. 2;—*ventricoſa*, ibid. 27. t. 1. Curt. Mag. t. 350;—*lutea*, Linn. Mant. 234. Andr. t. 11;—*articularis*, Linn. Mant. 65. Curt. Mag. t. 423;—and *taxifolia*, Ait. and Bau. Ic. t. 19.

Two ſpecies, indicated as nearly related to the laſt, cloſe Mr. Saliſbury's liſt of 246 in all. Theſe are *tetragona*, Thunb. Diſſ. 14. t. 4;—and *albens*, Linn. Mant. 231. Curt. Mag. t. 440.

We truſt, that thoſe who may have occaſion to deſcribe new heaths in future, will, as far as they are competent, keep the above arrangement in view, as they will find it very inſtructive, however they may differ from Mr. Saliſbury in principles of nomenclature. To this ſubject we have ſcarcely found it neceſſary to advert, except occaſionally, and we rather paſs over in ſilence what we cannot approve. This botaniſt rejects all names of perſons as applied to the ſpecies of any genus. Mr. Dryander once began a more uſeful reformation in ſuch names of *Erica*, making thoſe which commemorate a writer on the ſubject end in *ana*, as *Sebana*; thoſe which apply to a collector only, in the genitive caſe, as *Maſſoni*. The greateſt and moſt correct information is ſtill to be expected from this able botaniſt, in the intended new edition of Mr. Aiton's *Hortus Kewenſis*, where the genus of *Erica* muſt always make a pri cipal figure. S.

Erica, in *Gardening*, comprehends plants of the evergreen, flowery, ſhrubby kind; moſtly exotics; of which the ſpecies moſt in cultivation, according to Martyn, are: the croſs-leaved heath (E. tetralix); the fine-leaved heath (E. cinerea); the double-anthered heath (E. didyma); the tree heath (E. arborea); the Spaniſh heath (E. auſtralis); the many-flowered heath (E. multiflora); the Mediterranean heath (E. Mediterranea); the yellow heath (E. lutea); the purple-ſtalked heath (E. halicacaba); the bladder-flowered heath (E. monſoncana); the mucous heath (E. mucoſa); the hairy-flowered heath (E. urceolaris); the marum-leaved heath (E. marifolia); the bloody-flowered heath (E. cruenta); the ſlender-branched heath (E. rumentacea); the bluſh-flowered heath (E. perſoluta); the three-flowered heath (E. triflora); the arbutus-flowered heath (E. baccans); the ſlender-twigged heath (E. corifolia); the crow berry-leaved heath (E. nipetrifolia); the woolly heath (E. capitata.); the tube-flowered heath (E. tubiflora); the long-tubed yellow heath (E. conſpicua); the honey-wort-flowered heath (E. cerinthioides); the tufted-flowered heath (E. comoſa); the tall downy heath (E. Maſſoni); the ſmooth-twigged pencil-flowered heath (E. Plukenetii); the downy twigged pencil-flowered heath (E. Petiveri); the early-flowered dwarf heath (E. herbacea); and the great flowered heath (E. grandiflora). But there are many other ſpecies equally deſerving of cultivation.

Concerning the firſt of theſe ſpecies, it is obſerved by the editor of Miller's dictionary, that it is not inferior to many of the foreign heaths in the beauty and delicacy of its flowers. It is diſtinguiſhed from the other Britiſh heaths not only by the flowers growing in a kind of pendulous cluſter on the tops of the ſtalks, but by the leaves growing in fours, and forming a ſort of croſs.

The whole of the different ſpecies of heaths which are mentioned above, are plants of conſiderable beauty and elegance, but moſtly tender and delicate in their habits of growth.

Method of Culture.—Theſe very elegant plants muſt be treated in different methods, according to their nature and habits of growth.

The firſt three Britiſh ſorts are capable of being propagated by ſowing the ſeeds either in the places where they are to remain, or in pots filled with peaty earth, in either the autumn or ſpring ſeaſons; but this is a tedious method of practice. The better method is, therefore, to take them up from the places where they grow naturally, in the early autumn, with good balls of earth about their roots, planting them again immediately where they are to grow and remain for ornament.

They are found to ſucceed beſt where the ſoil is of the peaty or moory kind, and where it has not been enriched by manure; and as they protrude their roots chiefly near the top, it ſhould be as little dug about them as poſſible, the ſurface only being kept clean and free from rubbiſh.

And the four following ſorts may be increaſed in the ſame manner as the above; but the beſt practice is by layers, cuttings, or ſlips, which ſhould be laid down or planted out in pots filled with boggy earth either in the early ſpring or the latter end of ſummer, plunging them in a moderate hot-bed, and giving them proper ſhade and water. When they have taken full root, they ſhould be carefully removed with balls of earth about them into ſeparate pots, being replaced in the hot-bed till they become well eſtabliſhed when they will be capable of bearing the open air in mild weather when the ſeaſon is ſuitable.

All the other ſpecies may be increaſed either by cuttings or layers, but moſt of them by the former. The cuttings ſhould be made from the beſt young ſhoots, and be planted in the ſpring ſeaſon in pots filled with a compoſition of light boggy and loamy earth, being placed in the hot-bed, and covered with bell-glaſſes, and duely ſhaded from the ſun, ſlight waterings being given when neceſſary; the layers are beſt laid down in the autumn, being managed in the ſame way as the cuttings. When the plants have become perfectly rooted, they ſhould be removed into ſeparate pots filled with the ſame ſort of mould, being then put in the dry ſtove or green-houſe, where ſome of them require to be conſtantly placed.

But the ninth, twentieth, and twenty-ſixth ſpecies muſt be raiſed by layers, as they have not yet been increaſed by planting their cuttings in the manner directed above.

Where ſeeds are made uſe of in producing theſe plants, they ſhould be ſown in pots filled with the above ſort of earth in the early ſpring, and plunged in the hot-bed of the ſtove. When the plants have acquired a few inches growth, they ſhould be removed into ſingle pots with a little earth about their roots, and be replunged in the hot-bed in the ſtove, being preſerved in it, or the warmeſt part of the green-houſe, during the winter ſeaſon, and whenever the weather is bad.

The firſt three ſorts afford an agreeable variety in the borders and clumps, as they continue long in flower. The four following kinds are likewiſe hardy, and afford variety among other potted plants in the open air during the ſummer months.

All the other ſpecies are more tender, but produce as agreeable an effect among the ſtove and green-houſe collection, from the great beauty and continuance of the flowers in many of the ſorts.

Erica *marina*, *ſea-heath*, a name given by many authors to to a very beautiful zoophyte of the fucus kind, called by Mr. Ray and fome others the fucus ericæ folio.

Erica, in *Ichthyology*, a name given by Gaza and fome others, as the interpretation of the chalchis of Ariftotle, that is, as the name of the common herring.

ERICÆ, in *Botany*, the third natural order in the ninth clafs of the fyftem of Juffieu, fo named from the genus *Erica* which makes a part of it. This order confifts of fuch dicotyledonous monopetalous plants as have perigynous ftamens, and the following diftinguifhing characters. *Calyx* of one leaf, permanent, fometimes fuperior, more frequently inferior and deeply divided. *Corolla* of one petal, fometimes deeply divided, inferted either into the upper part of the calyx, more commonly into its lower part, or into a gland at its bafe; moftly withering and permanent. *Stamens* of a definite number, diftinct, inferted into the fame part, or rarely originating from the lower part of the corolla; anthers moftly with two horns at the bafe. *Germen* fuperior, or rarely inferior; ftyle folitary; ftigma generally fimple. *Fruit* either fuperior or inferior, with many cells and many feeds, either pulpy, or more generally dry with many valves, fixed by their bafes to the central axis, the partitions originating from the middle of each valve. *Seeds* generally minute. *Stem* fhrubby, of a more or lefs elevation, or herbaceous. *Leaves* alternate, or oppofite, or whorled.

This order is in a great meafure analogous to the Linnæan *Bicornes*, exclufive of the *Rhododendra* of Juffieu, which differ from his *Ericæ* chiefly in having the partitions of the capfule formed of the inflexed margins of its valves, and not originating longitudinally from their centre. Ventenat retains the name of *Bicornes* for the *Ericæ*.

The *Ericæ* are divided by Juffieu into two fections, 1. *Germen* fuperior, confifting of *Cyrilla*, Linn. (which being of the fame genus as *Itea*, and having the capfule of the *Rhododendra*, is to be removed thither); *Blæria*; *Erica*; *Andromeda*; *Arbutus*; *Clethra*; *Pyrola*; *Epigæa* (removed by Ventenat to *Rhododendra*); *Epacris* (omitted by Ventenat); *Gaultheria*; and *Broffæa* (likewife omitted by Ventenat, a very uncertain plant).

2. Germen wholly or partly inferior, *Argophyllum*, Forft. and Linn. fil.; *Mæfa*, Forfk; and *Vaccinium*.

A third fection contains two genera allied to *Ericæ*, or fuppofed to be fo, *Empetrum* and *Hudfonia*.

ERICALE, from ηρ, the *fpring*, and καλη, *beautiful*, a name given by Renealm in his Specimen Hift. Plant. 75. t. 68. to the *Gentiana verna*, a moft elegant vernal plant. Linnæus erroneoufly prints it *Ericoila*.

ERICERUM, a name given by Aetius and other authors to a fort of collyrium, ufed in weakneffes of the eyes, in which the herb erica or heath was an ingredient.

ERICEYRA, in *Geography*, a town of Portugal, in the province of Eftremadura, on the fea-coaft; 20 miles N. W. of Lifbon.

ERICHTHONIUS, in *Aftronomy*, a conftellation, the fame as Auriga.

ERICOILA, in *Botany*. See Ericale.

ERICU, a name given in Rheede's Hortus Malabaricus, v. 2. 53. to the *Afclepias gigantea*. It is corrupted from the Sanfcrit name *Roey*.

ERICUSA, in *Ancient Geography*, one of the feven Æolian iflands, now *Alicuda*.

ERIDANUS, in *Aftronomy*, a conftellation of the fouthern hemifphere, in form of a river.

The ftars in the conftellation Eridanus, in Ptolemy's Catalogue, are 34; in Tycho's, 19; in the Britifh Catalogue, 84. See Constellation.

Eridanus, in *Ancient Geography*, a river of Italy, in Cifalpine Gaul, now the Po, which fee. Virgil defcribes it as the largeft river of Italy, calling it the king of rivers:

"Fluviorum rex Eridanus."

—Alfo, a fmall river of Greece, in Attica, which purfuing its courfe to the W. of Athens, united with the Iliffus below that city.—Alfo, a river of Celtica, near the Pyrenées.

ERIE, Fort, in *Geography*, a ftrong fortification in the townfhip of Bertie, Upper Canada, fituated on the N. fhore of lake Erie, at its eaftern extremity, and the W. bank of Niagara river; 27 miles S. by E. from Niagara fort, 18 above the carrying place of the Falls of Niagara, and 45 from fort Chippeway. This is a fmall ftockaded fort, fomewhat fimilar to that at Chippeway; and adjoining it are extenfive ftores as at Chippeway, and about half a dozen miferable little dwellings. It has a barrack for troops and a block houfe; and a company of foldiers is quartered here for the purpofe of tranfporting the public ftores. The lake narrows here into the Detroit ftrait, which carries the waters over the great falls of Niagara. The new fort is projected on a fmall height in the rear of the prefent garrifon. The harbour is capable of accommodating veffels of any fize, which lie oppofite to the fort, at the diftance of about 100 yards from the fhore, expofed to the violence of the wefterly winds; but the anchorage is good, and they ride in perfect fafety. The little fort, with the furrounding huts built on the rocky fhore, the veffels lying off at anchor before it, the rich woods, the diftant hills on the oppofite fide of the lake, and the vaft lake itfelf, extending to the fartheft part of the horizon, altogether form an interefting and beautiful fcene. N. lat. 42° 53′ 17″. W. long. 78° 20′ 30″.

Erie, *Lake*, called alfo *Eric*, *Erige*, or *Erike*, or the lake of the Cat, is a lake of the fourth magnitude in North America, through which runs the line between the United States and Upper Canada. Detroit river on the weft brings the waters of the great lakes with which lake Erie has a communication on the north-weft; and Niagara river on the eaft forms its communication with the waters of lake Ontario and the river St. Lawrence. It is fituated between 41° and 43° N. lat. and between 78° 48′ and 83° W. long. It is of an elliptical form, being about 300 miles in length, and about 90, at the wideft part, in breadth. The depth of water in this lake is not more than 20 fathoms, and in calm weather veffels may fecurely ride at anchor in any part of it; but when ftormy, the anchorage in an open part of the lake is not fafe, the fands at the bottom not being firm, and the anchors being apt to lofe their hold. At this time the water becomes turbid, by the wafhing up of the yellow fand from the bottom of the lake; but in calm weather it is clear, and of a deep greenifh colour. The northern fhore of the lake is very rocky, which is alfo the cafe with the fhores of the iflands, of which there are feveral clufters towards the weftern extremity of the lake; but along moft parts of the fouthern fhore there is a fine gravelly beach. The height of the land bordering the lake is very unequal; in fome places long ranges of fteep mountains rife from the very edge of the water; in others, the fhores are fo flat and fo low, that when the lake is raifed a little above its ufual level, in confequence of a ftrong gale of wind fetting in towards the fhore, the country is deluged for miles. To the very great infularity of the height of the land on both fides of it, is attributed the frequency of ftorms on this lake; the coaft, however, on both fides, is generally favourable for the paffage of batteaux and canoes. A peninfula, called Longpoint, runs upwards of eighteen miles into

the

the lake, and being compofed of fand, is convenient for hauling boats upon it, when the lake is too rough for failing and rowing. Towards the fouth fide, however, on both fides of the lake, it would be impoffible to land, on account of the perpendicular height of the rocks. There is a great deficiency of good harbours along the fhores of this lake: on its northern fide there are but two places which afford fhelter to veffels drawing more than feven feet water, *viz.* Long Point, and Point Abineau, and thefe afford only a partial fhelter. On the fouthern fhore, the firft harbour you come to in going from fort Erie is that of Prefqu'tele, which is fituated at the diftance from that fort of about fix miles, and where veffels drawing eight feet water may ride in perfect fafety. Beyond this, about midway between the eaftern and weftern extremities of the lake, there is another harbour, capable of containing fmall veffels at the mouth of Cayahega river, and another at the mouth of Sandufky river, which falls into the lake within the N. W. territory of the States. Britifh fhips feldom ufe thefe harbours, but trade almoft folely between fort Eric and Detroit river, and in cafe of contrary winds, they return to fort Erie, if bound to Detroit river; or to fome of the bays amidft the clufters of iflands fituated towards the weftern extremity of the lake, if bound to fort Erie. The navigation of this lake is very uncertain; and veffels are often detained, at a confiderable expence to paffengers, in fome of the harbours. Lakes Huron and Michigan afford communication with lake Erie, by veffels of eight feet draught. There are portages into the waters of this lake from the Wabafh, Great Miami, Mufkingam, and Alleghany, from two to fixteen miles. The iflands at the weftern end of the lake, of various fizes, lie very clofe to each other, and exhibit a very pleafing fcenery; the largeft of them are not more than fourteen miles in circumference, and many of them are very fmall. The largeft iflands produce a variety of fine timber, amongft which are found oaks, hiccary trees, and red cedars, which latter, being large, are fent for even from the Britifh fettlements on Detroit river, at the diftance of forty miles. Lake Erie has a great variety of fine fifh, fuch as fturgeon, eel, white fifh, trout, perch, &c. Amongft the woods are found racoons and fquirrels, and alfo bears, in the winter feafon, when the lake is frozen between the main land and the iflands. All the iflands are dreadfully infefted with ferpents, and on fome of them rattlefnakes are fo numerous, that in the height of fummer it is dangerous to land. Two kinds of rattlefnakes are found in this part of the country; the one is of a deep brown colour, clouded with yellow, about thirty inches in length, which frequents marfhes and low meadows, and does great mifchief among cattle: the other fort is of a greenifh yellow colour, clouded with brown, and nearly twice the fize of the former. Many different kinds of ferpents, befides rattlefnakes, are found on the iflands in lake Erie. The ponds and marfhes in the interior parts of thefe iflands abound with ducks and other wild fowl, and the fhores fwarm with gulls; among the woods are a few fmall birds, remarkable neither for their fong nor plumage. Weld's Travels, vol. ii.

Erie, a county of Pennfylvania, on the fouth fide of lake Erie, containing 639,400 acres, and 1468 inhabitants. Its chief town is Erie.

ERIEUX, a river of France, which runs into the Rhone, at Beauchaftal.

ERIFFS, a name given to canary birds when about two years old. See Canary *Bird*.

ERIGENA, John Scotus, in *Biography*, who flourifhed in the ninth century, was probably born in Ayrfhire Scotland, though fome writers make him a native of Herefordfhire, in England, and others fuppofe his birth-place to be Ireland. He poffeffed an ardent thirft for literature, and fpared no pains in rendering himfelf accomplifhed in the learning of the Eaft, and from the extent of his erudition he obtained the name of "Scotus the Wife." He ftudied fome years at Athens, and became very converfant in Greek philofophy. Upon his return, he accepted an invitation from Charles the Bald of France, and lived for feveral years in habits of intimacy and familiarity with his royal patron, who affigned to him the direction of the univerfity of Paris. To the fovereign he was not only an inftructor in literature and fcience, but an advifer in the affairs of government. The high rank which he obtained excited much jealoufy, particularly among the bigotted priefts, who accufed him of maintaining heretical opinions. In the year 824, the Greek emperor, Michael the Stammerer, fent to the Weftern emperor, Lewis the Pious, a copy of the treatifes of the fuppofed Dionyfius the Areopagite, which had long been held in great veneration among the Greek Chriftians. Dionyfius was fuppofed to be the firft Chriftian teacher in France, and, on that account, the work in queftion was deemed of great value, and the king, who was unable to read the original Greek, employed Erigena to tranflate it into the Latin language. Unfortunately this was performed without licence from the pope, who, when he found the tranflation eagerly read, infifted that the French king fhould not only banifh Erigena from Paris, but fhould fend him to Rome. Charles refufed to act in this ungenerous manner, neverthelefs, it was deemed advifable, that Erigena fhould leave the capital of France, and in a fhort time after he took refuge in England. This tranflation of Dionyfius's treatifes is faid to have caufed the revival of the knowledge of the Alexandrian Platonifm in the Weft, and to have laid the foundation of the myftical fyftem of theology which afterwards fo generally prevailed. Of the original works of Erigena, the principal was his treatife "On the Divifion of Nature, or the Nature of Things," which was publifhed from the author's MS. by Dr. Thomas Gale, at Oxford, in 1681, under the title of "Joannis Scoti Erigena de Divifione Naturæ, Libri quinque, diu defiderati." Erigena was employed by our great king Alfred in the reftoration of learning at Oxford, where he was appointed profeffor of mathematics and aftronomy. In this fituation he remained only about three years, when fome differences that took place in the univerfity obliged him to retire to the abbey of Malmfbury in Wiltfhire, where he opened a fchool. Here, it is afferted, by moft writers, that he was murdered by his own fcholars, either on account of his harfhnefs and undue feverity; or at the inftigation of the monks, who hated Erigena as being a heretic, and much more learned than themfelves. The particular time and place of his death have been the fubjects of fome difpute. Certain writers contend that his death took place about the year 864 or 866, and others, who are generally followed, make it in 883. Some fay he died in England, and others, among whom is Dr. Henry, think that it happened in France. He was certainly a very extraordinary man for the times in which he lived, and after his deceafe his name was, for a confiderable time, to be found in the lift of the faints of the Romifh church, till it was ftruck out of the calendar, by Baronius, on account of the heterodoxy of his opinions concerning tranfubftantiation. Biog. Brit. Enfield's Hift. Phil.

ERIGENS Penis. See Erector.

ERIGERON, in *Botany*, ἠριγέρων of the ancient Greeks, from ἦρ, *the fpring*, and γέρων, *an old man*, becaufe it is hoary in the fpring. Linn. Gen. 422. Schreb. 553. Willd. Sp.

Pl. v. 3. 1952. Sm. Fl. Brit. 876. Mart. Mill. Dict. v. 2. Juff. 180. Gærtn. t. 170. Clafs and order, *Syngenefia Polygamia-fuperflua.* Nat. Ord. *Compofitæ difcoideæ,* Linn. *Corymbiferæ,* Juff.

Gen. Ch. *Common calyx* oblong, cylindrical, imbricated; fcales awl-fhaped, erect, gradually longer, nearly equal in breadth. *Cor.* compound, radiated; *florets* of the difk all perfect, tubular, funnel-fhaped, with an equal five-cleft limb; thofe of the radius female, ligulate, linear, awl-fhaped, erect, for the moft part entire. *Stam.* (in the tubular florets) Filaments five, capillary, very fhort; anthers forming a cylindrical tube. *Pift.* (in the tubular florets) Germen minute, crowned with hairs longer than its own corolla; ftyle thread-fhaped, the length of the hairs; ftigmas two, oblong, revolute: the female or ligulate florets differ in having their corolla about as long as the hairs, and very flender ftigmas. *Peric.* none, except the clofed permanent calyx. *Seeds,* in the florets of the difk as well as of the radius oblong, fmall. *Down* long, capillary. *Recept.* naked, flat.

Obf. Dillenius obferves that the innermoft or central florets of the difk are generally males. One fpecies has thofe of the radius deftitute of a corolla.

Eff. Ch. Receptacle naked. Down fimple. Florets of the radius linear, very narrow, numerous. Calyx imbricated.

This genus comprehends feveral plants called *Conyza, Virga-aurea, After,* and *Senecio* by former writers, but is a very natural one, characterized by the erect very narrow florets of its radius, ufually coloured blue or white. The lateft edition of Linnæus has 22 fpecies, Willdenow 32. Three are natives of Britain.

1 E. *canadenfe,* Engl. Bot. t. 2019. " Stem hairy, panicled. Leaves lanceolate; the lower ones toothed."—To all appearance perfectly wild in Glamorganfhire, (Mr. Middleton), though fuppofed by Ray to have come over from North America, where it abounds. It is an annual plant, of mean appearance, with innumerable fmall flowers, whofe radius is white or pale red, their difk yellow.

2. E. *acre.* Engl. Bot. t. 1158. Curt. Lond. fafc. 1. t. 60. " Stem racemofe. Stalks moftly fingle-flowered. Leaves lanceolate or tongue-fhaped, feffile."—Common on a dry gravelly or chalky foil, flowering in July and Auguft. The flowers are larger and fewer than in the former; their radius blue. Root biennial.

3. E. *alpinum.* Engl. Bot. t. 464. " Stems almoft fingle-flowered. Calyx flightly hairy. Radius fpreading."—Found in moift parts of the highland mountains of Scotland, flowering in July. This has feldom more than one flower on a ftem, which is much larger than in E. *acre,* with a longifh blue radius, which fpreads more than is confiftent with the generic character, and, perhaps, might authorize the removal of this fpecies to *After,* where Linnæus originally placed its near ally E. *uniflorum,* Fl. Lapp. n. 307. t. 9. f 3.

ERIGONUS, in *Ancient Geography,* a river of Macedonia, which, according to Livy, ran from Illyria through Pæonia into the Axius; called *Erigon* by Strabo and Ptolemy.

ERINACEA, in *Botany,* Tourn. Inft. 646, fee Anthyllis, fp. 15. Tournefort eftablifhed it as a genus, (diftinct from his *Genifta-Spartium,* which confifts of *Ulex* and the prickly *Geniftæ,*) merely becaufe the bufh is all over armed with prominent ftrong fpines, like a hedge-hog.

ERINACEUS, a name given by Dillenius and Micheli to a genus of *Fungi.* Linnæus, perceiving the inconvenience and abfurdity of adopting a generic denomination, already univerfally appropriated to an animal, changed it to *Hydnum.*

Erinaceus, in *Zoology,* a genus of the Feræ order, the hedge-hog of Englifh authors. This tribe is diftinguifhed principally by the teeth. The fore-teeth in the upper jaw are two, and diftant, in the lower two approximate; the tufks in the upper jaw five each fide, in the lower three; grinders four each fide above and beneath; body above covered with fpines.

Species.

Europæus. Ears rounded; noftrils crefted. Linn. Fn. Suec. *Erinaceus auriculis erectis,* Briff. *Echinus terreftris,* Gefn. *Igel,* Knorr. *Heriffon,* Buff. *Common hedge-hog.*

The common hedge-hog, or as it is fometimes called erroneoufly the European hedge-hog, appears to be a native of the temperate parts of Afia, and to be found in Madagafcar as well as Europe. It lives in thickets and bufhes, forming a neft of mofs, grafs, or leaves, of large fize. When difturbed it rolls itfelf up into a globular form, prefenting on every part a formidable armament of fpines, and this is indeed its principal means of defence; upon being immerfed in cold water it expands, and fwims with perfect facility. During the winter it is fuppofed to remain in a ftate of torpidity.

Vegetables of various kinds, as the roots of plants, or fruits, reptiles, fmall birds and infects, conftitute the principal food of this animal; the Calmucs tame and keep it in their dwellings like the cat; and in this refpect they become ufeful, as they deftroy the cockroaches, and other obnoxious infects. They produce from three to five young at a birth. The flefh is very indifferent, yet is fpoken of among the old writers as an article of food, with inftructions for roafting or otherwife preparing it for the table.

The hedge hog is confidered as an inoffenfive animal, notwithftanding the vulgar fuppofition, that it fucks the teats of cattle by night, and occafions ulcerations in thofe tender parts with the irritation of their prickles. The animal has a mufky fmell. Length ten inches.

Inauris. Without external ears. Linn. Seba. *Guiana hedge-hog.*

Length eight inches. Inhabits South America. The head is thick, fhort; fpines cinereous tinged with yellow; hair foft, whitifh chefnut over the eyes; tail fhort; claws long and crooked. Defcribed on the authority of Seba.

Auritus. Ears oval, long. *Auriculis ovalibus longis, naribus criftatus,* Pallas. Nov. C. Pet. *Siberian hedge-hog.*

Inhabits the lower parts of the Volga and Ural and extends from thence to the eaftern parts beyond the lake Baikal. Its form refembles that of the common hedge-hog, but is fmaller, the eyes larger, wifkers difpofed in four rows; the feet longer, more flender; tail fhorter, conic, annulated, and nearly bald. The female is faid to breed twice a year, and to produce from four to feven each time.

Malaccensis. Ears pendulous. Briff. *Hyftrix brachyura,* Linn. *Porcus aculeatus, f. Hyftrix malaccenfis,* Seba. *Malacca hedge-hog.*

Extremely allied in its general appearance to the porcupine, and referred to the hedge-hog tribe chiefly on account of the number and arrangement of the teeth. Its fize is fuppofed to be equal to that of the common porcupine. This animal is faid to inhabit Afia, and to produce the precious ftone called Piedra del Porco, the imaginary virtues of which are fo highly extolled in the old materia medica.

Setosus. Ears fhorter; top and hind head and fhoulders befet with fpines; tail very fhort and fpinous. *Erinaceus*

ceus setosus, Gmel. Schreber. *Tendrac*, Buff. *Petit tendrac de Madagascar*. Sonner. *Asiatic hedge-hog*.

Native of India and Madagascar; length six inches; wallows in the mire, and grunts like a hog, and forms burrows. Remains torpid for six months, during which the hair falls off.

Ecaudatus. No tail; snout very long and acute. Schreber. *Tanrec, et le jeune tanrec*, Buff. *Madagascar hedge-hog*.

Inhabits India and Madagascar. In habit resembles the former, but is larger, measuring in length eight inches. The mouth and eyes are small; ears rounded and longer than in the setosus; the spines black, and covering the whole back and sides; hair yellowish and feet tawny.

The two last mentioned animals are considered by Pennant as the same species, on the presumption that the former is the adult state, the other in a less advanced stage of growth. Dr. Shaw seems inclined to adopt this supposition. There, nevertheless, appears in our mind no plausible reason for such conjecture, unless the descriptions be defective in the most essential particular; for, if one has a tail and the other none, they must be distinct. That the animal described by Buffon had not obtained its full growth is rendered extremely probable by the explanation afforded, but the production of a tail cannot be supposed to depend on the age of the animal. The tanrec feeds on fruits, and remains torpid during about three months of the year.

ERINÆI, in *Ancient Geography*, a people of Asiatic Sarmatia. Ptolemy.

ERINDES, a river of Asia, towards Hyrcania or Sparta, according to Tacitus.

ERINEUS, one of the four cities of Doris, situate on the most northern verge of the kingdom, near the foot of the hills which part Doris from Macedonia.—Also, a port of the sea of the Peloponnesus, in Achaia, between Ægium and the promontory Rhium. Pliny.—Also, a river of Sicily, according to Thucydides, called *Orinos* by Ptolemy.

ERINGO. See Eryngo.

ERINNA, in *Biography*, a Greek poetess, mentioned by different writers as a native of Lesbos, of Teios, of Rhodes, and of Tenos in Laconia, is supposed to have been contemporary with Sappho, about the year 600 B.C. but she is placed by the Chronicle of Eusebius 250 years later. She was celebrated in ancient Greece, and several epigrams were written upon her, one of which speaks of her as inferior to Sappho in lyrics, and superior in hexameters. Some fragments are extant in her name, which are inserted in the "Carmina Novem Poetarum Fœminarum." Antw. 1568. Voss. Poet. Græc.

ERINUS, in *Botany*, a name adopted by Linnæus from Dioscorides, the etymology of which is unknown. Neither is his ερινος the same with the Linnæan plant, but rather, we presume to think, something which has hitherto eluded the sagacity of commentators. His description accords in some points with *Samolus Valerandi*.—Linn. Gen. 318. Schreb. 4:7. Willd. Sp. Pl. v. 3. 332. Mart. Mill. Dict. v. 2. Juss. 100. Gærtn. t. 55.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personatæ*, Linn. *Pediculares*, Juss.

Gen. Ch. *Cal.* Perianth in five deep, lanceolate, erect, nearly equal, permanent segments. *Cor.* of one petal, unequal; tube cylindrical, somewhat ovate, the length of the calyx, reflexed; limb flat, in five deep, nearly equal, inversely heart-shaped segments. *Stam.* Filaments four, very short, within the tube of the corolla; two of them (the uppermost) a little longer than the others; anthers small. *Pist.* Germen nearly ovate; style very short; stigma capitate. *Peric.* Capsule ovate, invested with the calyx, of two cells and two valves, the latter cloven half way down when ripe; partition double. *Seeds* numerous, small. *Recept.* compressed.

Ess. Ch. Calyx of five leaves. Limb of the corolla in five, nearly equal, notched segments. Capsule of two cells. Seeds numerous.

Obs. By an unaccountable error in the Ess. Char. in all the editions of Linnæus the upper lip is said to be very short and reflexed, though the whole limb of the corolla is justly described as (nearly) equally five-cleft. Willdenow copies this, though the Hortus Kewensis had corrected it.

E. *alpinus* is the best-known species. "Flowers racemose. Leaves spatulate."—Linn. Sp. Pl. 878. Curt. Mag. t. 310. Native of the alps of Switzerland, and the Pyrenæan mountains, flowering in the middle of summer. It forms tufts, with several dwarf stems, bearing numerous purple flowers, and is a very ornamental plant for rock-work, requiring protection against severe frost and excessive moisture, like most alpine rock plants. It is increased by parting the roots, or by seed.

E. *africanus*. "Flowers axillary, sessile. Leaves lanceolate, slightly toothed."—Linn. Sp. Pl. 878. (Lychnidea villosa, foliis ex alis floriferis, &c.; Burm. Afr. t. 50. f. 1.) Native of the Cape of Good Hope. This has a taller, more branched stem, more oblong leaves, and axillary flowers, of what colour we know not, with a very long slender curved tube. It has not yet appeared in our gardens.

E. capensis. "Flowers spiked. Leaves linear, toothed."—Linn. Mant. 252, excluding Burman's synonym. Gathered by Sparmann in sandy ground at the Cape of Good Hope. This is also a stranger to our gardens. The flowers are said to be yellow and very fragrant. In the dried plant they are black. The tube is an inch and half long; the segments of the limb deeply cloven, the lobes dilated, obtuse and divaricated.

E. *fragrans*. "Leaves lanceolate-oblong, toothed. Segments of the limb undivided."—Ait. H. Kew. v. 2. 357. (Selago Lychnidea; Linn. Sp. Pl. 877. Lychnidea villosa, foliis oblongis, &c. Burm. Afr. t. 49. f. 4.) Native of the Cape, rarely seen in our green-houses. The flowers are yellow or brownish, and fragrant.

E. *tristis*. "Leaves oblong, cut, toothed. Segments of the limb slightly cloven."—Linn Suppl. 287.—Found by Thunberg at the Cape. The flowers are said to be sweet-scented, and of a dull colour.

E. *peruvianus* and *laciniatus* of Linnæus, are both nearly related to *Verbena Aubletia*, and the former at least seems to be the very same species.

ERIOCALIA, from εριον, *wool*, and καλια, *a nest*, in allusion to the singularly woolly involucrum in the midst of which the flowers are seated as in a bird's nest. Sm. Exot. Bot. v. 2. 37. Intr. to Bot. 373. (Actinotus; Labillard. Nov. Holl. 67.) Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*.

Gen. Ch. *Umbel* simple, of many short rays. *Invol.* of many lanceolate, equal, undivided, coloured leaves, longer than the rays of the umbel, and densely clothed with wool. *Cal.* Perianth superior, in five deep, equal, concave, sometimes coloured, externally hairy, permanent leaves. *Cor.* none. *Stam.* Filaments five, about as long as the calyx, equal, awl-shaped; anthers roundish, of two lobes. *Pist.* Germen inferior, obovate, compressed, furrowed, very hairy; styles two, capillary, spreading, longer than the stamens; stigmas simple. *Peric.* Fruit ovate, obtuse, compressed, furrowed, hairy, crowned with the calyx and styles. *Seed.* solitary?

Ess. Ch. Umbel simple. Involucrum of many lanceolate,

late, equal, woolly, coloured leaves, longer than the umbel. Fruit compressed, hairy. Petals none. Many flowers abortive.

This New Holland genus bears the most striking analogy to the European *Astrantia*, from which it differs in its woolly, not smooth, involucrum, but more essentially in having no petals, and in its hairy, not muricated, fruit. M. Labillardiere had, unknown to us, previously named it *Actinotus*, but that name being already long ago occupied in mineralogy, is untenable in botany.

The only species known are two.

1. E. *major*. Sm. Exot. Bot. v. 2. 37. t. 78. (Actinotus helianthi; Labill. Nov. Holl. 67. t. 92.) "Segments of the leaves bluntish, flat, woolly on both sides. Flower-stalks somewhat corymbose."—Native of the sandy country about Port Jackson, New South Wales, as well as of the west coast of New Holland, flowering in October. The *root* appears to be annual; it is woody and branching. *Stem* solitary, about two feet high, erect, leafy, round, woolly, but little branched except at the upper part, where the long flower-stalks, more or less numerous, grow in a corymbose form. *Leaves* alternate, stalked, three-cleft, lobed and pinnatifid; their segments spreading, linear, entire, flat, a little dilated upward, and bluntish; clothed with dense wool, whiter beneath. *Stipulas* none. *Flowers* terminal, large and ornamental, all over white with a green or rufous tinge. *Involucrum* of eight or ten spreading leaves, each an inch or more in length, peculiarly soft and pliable, like velvet. *Flowers* very numerous, forming a convex compact sort of disk, those of the circumference males. *Calyx* whitish, so as to resemble petals. No aromatic or pungent flavour is perceptible in any part of the plant.

2. *E. minor*. Sm. Exot. Bot. v. 2. 39. t. 79. "Segments of the leaves acute, revolute; smoothish above; silky beneath. Flower-stalks scattered."—Found near Port Jackson, in a sandy or gravelly soil, flowering in March.—Much smaller than the last, and bearing the same analogy to it that *Astrantia minor*, Sm. Exot. Bot. t. 77, does to the *major*, t. 76.—*Root* woody, branched, perhaps perennial. *Stem* a foot or two high, much branched, leafy, round, clothed with close-pressed hairs. *Leaves* on long foot-stalks, divided into three or five deep, spreading, dilated, acute, revolute, pinnatifid or three-cleft lobes; green, smooth, or slightly hairy, above; densely clothed with white silky hairs beneath. *Flowers* on long, solitary, terminal, naked stalks, scarcely a quarter so large as in the other. *Calyx* green, and not coloured. *Involucrum* almost naked underneath; hairy, somewhat silky, white or reddish above. This species is likewise without any peculiar flavour.

ERIOCAULON, from ἐριον, *wool*, and καυλος, *a stem*, because of the woolly or hairy stalk, which however is rarely the case. Linn. Gen. 40. Schreb. 56. Willd. Sp. Pl. v. 1. 485. Sm. Fl. Brit. 1009. Juss. 44. Gærtn. t. 83.—Class and order, *Monoecia Triandria*, Smith. (*Triandria Trigynia*, Linn.) Nat. Ord. *Junci*, Juss.

Gen. Ch. *Common calyx* globose, depressed, imbricated, many-flowered; its scales lanceolate or obovate, obtuse, scariose, equal, permanent; perianth inferior, of two or three obtuse, permanent, muricated leaves. *Male flowers* several, in the middle of the disk. *Cor.* funnel-shaped; tube about as long as the calyx; limb in two deep, obtuse, muricated lobes. *Stam.* Filaments three or four, equal, inserted into the tube of the corolla, and rather longer than the limb; anthers vertical, roundish, of two lobes. *Pist.* Germen obsolete; style capillary, cloven; stigmas blunt. *Female flowers* several, in the circumference, between the calyx-scales. *Cor.* inferior, of two oblong, concave, obtuse petals, muricated at the upper part externally. *Stam.* none. *Pist.* Germen superior, of two or three lobes; style thread-shaped, shorter than the corolla, cloven; stigmas two or three, acute. *Peric.* Capsule roundish, of two or three lobes, with as many cells and valves. *Seeds* solitary.

Eff. Ch. Common calyx of many leaves, many-flowered; perianth superior, of two or three leaves. Male flowers central. Corolla of one petal, cloven. Female fl. in the margin. Corolla of two petals. Stigmas two or three. Capsule of two or three cells. Seeds solitary.

The characters of this genus were so ill defined in the works of Linnæus, that Hudson conceived our British *Eriocaulon*, confounded by Linnæus with his *decangulare*, must be a distinct genus, and he therefore called it *Nasmythia*, in honour of sir James Nasmyth, baronet; see Fl. Angl. ed. 2. 414. As however no genus can be more natural and distinct than *Eriocaulon*, and the fault appears to have been entirely in the descriptions of authors, its characters are now reformed. The above description is made from the only British species, *E. septangulare*, With. 184. Sm. Fl. Brit. 1010. Engl. Bot. t. 733.—"Stalk with seven angles. Leaves sharp-pointed, with an internal network of cells. Male flowers with four stamens." It grows in several lakes in the isle of Skye very abundantly, and was found in September 1801 by Dr. Wade, decorating the edges of all the lakes in Cunnamara, in the county of Galway, Ireland. The *root* is perennial, consisting of abundance of simple, white, shining fibres, composed internally of a series of cells, frequently interrupted by transverse partitions, which is the general structure of the whole herb. *Stalk* a span high, solitary, upright, simple, naked, twisted, with seven angles and as many intermediate furrows, smooth, (so that in this instance the generic name does not well apply), invested with a tubular sheath at the base. *Leaves* numerous, radical, sword-shaped, smooth, taper-pointed, about two inches long. *Head* of flowers terminal, solitary, hemispherical, about three lines broad, prettily variegated with dark purple and white, the calyx and anthers being of the former colour, as well as a few spots on the white corolla. The snow-white club-shaped protuberances, with which the extreme parts of the calyx and corolla are muricated, give the whole an elegant feathery aspect.

Linnæus knew about five species of *Eriocaulon*, but very imperfectly, and he was cautious of adopting Dr. Hope's accurate generic description of the above plant, published in the Philosophical Transactions, v. 59. 243. t. 12, lest it should not accord with every species. As far as subsequent examination of the several exotic ones has gone, it is found to confirm the account here given. Willdenow enumerates eight species in all; Lamarck describes 12 in his Encyclopedie, v. 3. 274—277, and figures 4, rather imperfectly, in his t. 50. This last author is, nevertheless, the best we have on the subject, though Willdenow hesitated to follow him, and Vahl, in his Sp. Pl. v. 2. 210, removes his *E. spadiceum*, perhaps rightly enough, to *Schoenus*.

Authors are very much confused in their accounts of the native countries of several species. The *repens* of Lamarck was gathered by Thierry de Menonville in Hispaniola, not by Commerson in the isle de Bourbon. *E. spadiceum* of the same author was found by Smeathman at Sierra Leone, from whom we have it in plenty, and whom Lamarck rightly quotes; yet Vahl mentions St. Domingo (Hispaniola) a its native country, on the authority of Lamarck's herbarium, without naming Smeathman.

The following 6 species we believe are hitherto entirely nondescript. They will probably appear, with others, more fully illustrated hereafter from the pen of Mr. R. Brown,

Brown, when he has time to resume the study of this genus, of which we believe he has ascertained about 30 species. In the mean while, to secure his specific names and our own thus far, we shall attempt definitions of what we have determined from actual observation.

E. *pygmæum*, Soland. MSS.—Stalks aggregate, five-angled. Leaves and sheaths rough; the latter longest. Head globose. Calyx-scales obovate, pointed.—Native of New Holland. *Herb. Linn. fil.* The *stalks* are about two inches high. *Leaves* about half an inch long, being rather shorter than the sheaths of the stalks, which is unusual. *Heads* brownish.

E. *scariosum*.—Stalks aggregate, five-angled. Leaves and sheaths smooth, of equal length. Head globose. Calyx-scales obovate, acute.—Communicated from New South Wales in 1792, by John White, M. D.—*Stalks* five or six inches high. *Heads* of a silvery white, scarcely so large as a pea, being about twice as big as the former.

E. *stupeum*.—Stalk nearly solitary, five-angled. Leaves and sheaths of equal length, densely woolly at the base. Head hemispherical. Calyx-scales obovate, acute. Gathered by Sonnerat at the Isle de Bourbon. *Stalk* sometimes above a span high. *Leaves* spreading, involute when dry, smooth, or nearly so, but enveloped at their base, as well as the sheath of the stalk, by a dense integument of silky wool. *Head* much like that of *E. septangulare*.

E. *latifolium*.—Stalks somewhat aggregate, cylindrical, furrowed. Leaves smooth, taller than the stems. Head hemispherical. Outer calyx-scales rounded, obtuse; inner lanceolate, acute.—Gathered at Sierra Leone by Dr. Afzelius. The very long and broad flat *leaves*, a span in length, are remarkable. The *sheaths* are also large, about half as long as the stalk. *Head* smaller than in the last, variegated with brown and white.

E. *fistulosum*. Brown MSS.—Stalks aggregate, cylindrical, striated. Leaves smooth, twice as long as the sheaths. Head hemispherical. Inner calyx-scales obovate, pointed.—Native of New Holland.—*Stalks* a span high. *Leaves* about half as long, or more, taper-pointed, smooth, rather turgid. *Heads* small, brownish.

E. *depressum*. Brown MSS.—Stalks aggregate, cylindrical, furrowed. Leaves smooth, as tall as the stalks. Head flattened. Calyx-scales wedge-shaped, obtuse. Native of New Holland. *Stalks* about two inches high. *Heads* hemispherical beneath, nearly flat at the top, dark purplish brown.

We have in our descriptions substituted the word stalk (*scapus* or *pedunculus*) for stem, as being more correct. S.

ERIOCEPHALUS, so named by Dillenius from ἐριον, *wool*, and κεφαλη, *the head*, in allusion to the remarkably woolly appearance, singular in the tribe to which it belongs, which this plant makes when in seed. Linn. Gen. 450. Schreb. 586. Willd. Sp. Pl. v. 3. 2384. Mart. Mill. Dict. v. 2. Juss. 186. Gærtn. t. 168.—Class and order, *Syngenesia Polygamia-necessaria*. Nat. Ord. *Compositæ nucamentaceæ*, Linn. *Corymbiferæ*, Juss.

Gen. Ch. *Common calyx* erect, of ten ovate, equal, cohering scales; the five outermost keeled, the inner ones flat. *Cor.* compound, radiated; the perfect florets doubly numerous, constituting the disk; female ones five, making the radius: that of the perfect florets funnel-shaped, with a five-cleft spreading border; of the radius flat, inversely heart-shaped, with three terminal lobes. *Stam.* in the perfect florets, Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* in the perfect florets, Germen obsolete; style simple; stigma cloven, acute: in the female ones, Germen ovate, naked; style simple; stigma pointed, inflexed. *Peric.* none, except the scarcely altered calyx. *Seeds* in the disk none; in the radius obovate, naked. *Recept.* flat, woolly, and the elongated wool which separates the two rows of calyx-scales, is moreover introduced between the perfect and female florets.

Obs. A small compressed body adheres to the base of each scale of the calyx.

Eff. Ch. Receptacle woolly. Seed-down none. Calyx of ten equal leaves. Florets of the radius five, inversely heart-shaped.

The species are two, both shrubs natives of the Cape of Good Hope, and to be met with, though rarely, in our green-houses.

1. E. *africanus*. Linn. Sp. Pl. 1310. Ait. Hort. Kew. v. 3. 278. Curt. Mag. t. 833. (E. sempervirens, foliis fasciculatis & digitatis; Dill. Elth. v. 1. 132. t. 110. f. 134). "Leaves lobed or undivided. Flowers corymbose."—The *leaves* are fasciculated, fleshy, and nearly cylindrical, hoary and glaucous, mostly undivided, sometimes with two or three lobes or notches. *Flowers* resembling many species of Yarrow, *Achillea*, having broad white radiant florets, and a small purple and yellow disk. The *seeds* are enveloped in the long soft hairs of the receptacle which come forth after the flowering is past. It is propagated by cuttings, and flowers from January to March.

2. E. *racemosus*. Linn. Sp. Pl. 1311. Ait. Hort. Kew. v. 3. 279.—"Leaves linear, flat, undivided. Flowers racemose."—The *leaves* are shorter, flatter, and less fasciculated than in the former. *Flowers* in long clusters or rather spikes. *Wool* of the receptacle very long.—Dr. Sims in Curt. Mag. justly refers Gærtner's synonym to the foregoing species, not to this.

ERIOGONUM, from ἐριον, *wool*, and γονυ, *a joint*, in allusion to the woollinefs of the habit, and the jointed structure of the stem. Michaux Fl. Boreali-Amer. v. 1. 246. Class and order, *Enneandria Trigynia*. Nat. Ord. *Holoraceæ*, Linn. *Polygoneæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in six deep, obovate, coloured, spreading segments, of which the three innermost are somewhat the largest. *Cor.* none. *Stam.* Filaments nine, occasionally eight or ten, rather longer than the calyx and inserted into its base, hairy in their lower part; anthers roundish, versatile, incumbent. *Pist.* Germen superior, oblong, triangular, with three furrows; styles three, the length of the stamens; stigmas simple, obtuse. *Peric.* Capsule triangular, membranous, not bursting. *Seed* solitary, triangular, sharp at each end, black; with a snow-white, small, farinaceous albumen, and large flat cotyledons.

Eff. Ch. Calyx inferior, coloured, in six deep segments, permanent. Capsule membranous. Seed solitary, triangular. Stigmas simple.

This genus in its parts of fructification very nearly approaches *Polygonum*, but the above characters are sufficient to distinguish it, and the habit, more especially the absence of stipulas, renders it totally distinct. We are possessed of three species, one of which only has been hitherto mentioned.

1. E. *tomentosum*. Michaux as above, t. 24. (Chrysosplenium? oppositifolium; Walter Fl. Carolin. 140.) Calyx woolly, stem-leaves whorled, sessile.—We have been acquainted with this plant ever since November, 1793, when a root brought by Mr. John Fraser from Carolina, flowered for the first time in his garden at Chelsea. It was drawn by Mr. Sowerby, but the figure remains unpublished. Michaux in the mean while has named and described this genus as above, giving an indifferent plate of the only species known to him, which, he says, grows in the dryest fir woods of Carolina

Carolina and Georgia, and which is the very fame as Mr. Frafer's, in whofe herbarium we have feen a fpecimen from Mr. Walter, who named it, with a mark of doubt, *Chryfofplenium oppofitifolium*, not being furnifhed with fufficient materials to judge how far he was correct or not. Michaux has given a fpecific character, a perilous attempt, and indeed an abfurd one, for a folitary fpecies, as it can only by accident ferve to contraft that fpecies with others as yet unknown. The *Root* is perennial, rather woody, ftem a foot or more in height, erect, round, woolly, rufty-coloured, leafy, branched and forked, many-flowered. *Leaves* nearly entire, fomewhat undulated; green, fcattered with loofe, deciduous, rufty down above; denfely woolly and whitifh, with rufty veins, beneath: the *radical* ones cluftered, obovate, two inches in length, on broadifh woolly footftalks about half as long, fpreading: *ftem-leaves* in numerous rather diftant whorls, three or four in a whorl, feffile, fcarcely an inch long, unequal, pointed. *Stipulas* none. *Bracteas* either terminal or from the forks of the ftem, folitary, feffile, cup-fhaped, bluntly toothed, woolly, containing eight, ten, or more inodorous *flowers* on fimple, flender, woolly *ftalks*, each joined in the middle, and fwelling upwards. Segments of the *calyx* elliptical, broad, obtufe, white at the edge, green clothed with rufty wool at the back. The bafe of the *ftamens*, and fummit of the *flower-ftalks*, are tinged with purple. *Fruit* covered by the clofed internal fegments of the calyx, become contracted at their bafe, and a little undulated.

2. E. *parvifolium*. Calyx naked. Stem-leaves ftalked, alternate, ovate, revolute.—Gathered in California by Mr. Archibald Menzies. The *ftem* is fhrubby, branched, leafy, with a deciduous, nearly fmooth bark. *Leaves* alternate or cluftered, about a quarter of an inch long, ovate, obtufe, revolute, almoft if not quite entire; fmooth and fhining above; denfely clothed with rufty wool beneath. *Footftalks* half as long as the leaves, very woolly, dilated at their bafe, but not quite embracing the ftem. *Flowers* very numerous, in denfe, globular, woolly tufts, one terminating each branch, and furmounted by another, on an elongation of the fame branch, two inches above it. *Flower-ftalks* fmooth. *Calyx* fmooth, or very flightly downy at the back, its fegments oblong, obtufe, keeled, entire, not wavy. We have not feen the radical leaves, nor been able to inveftigate the *bracteas*. The round tufts of very copious flowers, and the ftalked fcattered fmall leaves, at once diftinguifh this fpecies.

3. E. *latifolium*. Calyx naked. Stem-leaves ftalked, alternate, heart-fhaped, undulated. Foot-ftalks embracing the ftem.—Gathered in California by Mr. Menzies, with the laft. *Stem* fhrubby. *Branches* round, woolly, leafy. *Leaves* alternate, two inches long, heart-fhaped, bluntifh, undulated and crifped at the edge; covered with a web of deciduous white down above; very woolly and white beneath. *Footftalks* as long as the leaves, woolly, fheathing the ftem with their dilated bafes. Some leaves are cluftered about the end of each branch. *Flowers* not larger than in E. *parvifolium*, and, as in that fpecies, very numerous in globofe woolly tufts, terminating elongated, naked, woolly branches. Segments of the *calyx* obovate, keeled, fomewhat undulated.

The addition of thefe two fpecies confirms the very natural genus of *Eriogonum*, which in the Linnæan fyftem fhould immediately follow *Rheum*. Probably more fpecies are to be found in the unexplored wilds of North America. Thofe we have defcribed would all certainly bear the climate of Britain, and though not fplendid plants, are worthy of cultivation for their fingularity. Their qualities cannot be fuppofed different from *Polygonum* and *Atraphaxis*. S.

ERIOPHORUM, from ἐριον, *wool*, and φερω, *to bear*, alluding to the woolly or cottony tufts borne by the plant when in feed. Cotton-grafs.—Linn. Gen. 30. Schreb. 41. Willd. Sp. Pl. v. 1. 312. Sm. Fl. Brit. 58. Juff. 27. Gærtn. t. 2. Clafs and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoideæ*, Juff.

Gen. Ch. *Spike*, or rather *Catkin*, imbricated every way: fcales ovate-oblong, flat, flightly inflexed, pointed, membranous, loofe, feparating the flowers. *Cor.* none. *Stam.* Filaments three, capillary, anthers erect, oblong. *Pift.* Germen fuperior, very fmall; ftyle thread-fhaped, the length of the calyx-fcale; ftigmas three, longer than the ftyle, reflexed. *Peric.* none. *Seed* triangular, pointed, furrounded at the bafe with numerous hairs longer than the fpike.

Eff. Ch. Glumes chaffy, imbricated every way. Corolla none. Seed one, invefted with very long hairs.

Six fpecies are defcribed by Willdenow, four of which are found in Britain, *viz. E. vaginatum*, Engl. Bot. t. 873; *polyftachion*, t. 563; *anguftifolium*, t. 564, long confounded with the laft; and *alpinum*, t. 311. The exotic fpecies are, *E. virginicum*, Linn. Sp. Pl. 77; and *cyperinum*, ibid; both natives of North America. The latter has browner and fhorter hairs to the feed than any other, fo as to have nothing of their ftriking appearance. The whole genus grows in a turfy foil, generally in wet places, to which the firft fpecies is an occafional exception, being fometimes found on dry mountainous heaths. Some German botanifts have lately diftinguifhed from the *vaginatum*, one which they name *E. Scheuchzeri*. This is *Eriophorum*, n. 1332 β. Hall. Hift. v. 2. 175. (Juncus alpinus, capitulo tomentofo majori; Scheuchz. Prod. 27. t. 7. f. 2.) It has creeping *roots*, folitary *ftems*, not half fo tall, but much ftouter than thofe of *vaginatum*, with a much lefs remarkable fheath. The *leaves* alfo are very fhort; the hairs of the *feed* very denfe and remarkably delicate. It grows in the moft elevated marfhy paftures of the Alps, or about the boggy borders of Alpine lakes, as mentioned by Scheuchzer, and is undoubtedly a diftinct fpecies.

ERIOPHORUS, Bulbus, the *Woolly Bulb*, βολβος ἐριοφορος of Theophraftus, book vii. chap. 13, who mentions it as "growing on the fhore, and having between its outer coats and the inner part, which is eatable, a woolly fubftance, of which various garments are woven." Pliny obferves, that Theophraftus does not inform us in what country this is practifed. Dodonæus, among the moderns firft inftituted an inquiry into this bulb, Hift. Stirp. 692, giving a figure, communicated by a friend of whofe fidelity he is very unwilling to doubt, of a plant hitherto unfeen by any other mortal. It has fcaly bulbs, more refembling tuberous roots invefted with the permanent bafes of the foliage; long fword-fhaped leaves: and large folitary flowers, unlike every thing known in the vegetable world, being formed of five denfely fhaggy ovate fpreading petals, and a fixth ftanding upright in the place of the ftamens and piftils. This cut has always been judged fictitious, and, if true, it would not anfwer to the defcription of Theophraftus. Dodonæus, moreover, figures the *Scilla hyacinthoides* as one kind of *Bulbus eriophorus*, and refers to Clufius, who, in his Hift. Plant. 173, gives *Scilla peruviana* for another. Both thefe bulbs, and, indeed, fome others, have, in fact, a woollinefs about their upper part when the coats are torn afunder, apparently confifting of their large and tenacious fpiral-coated fap-veffels; but the quantity or quality of this wool is not, in any inftance that has come under our infpection, by any means adequate to the ufes mentioned in Theophraftus.

ERIOSPERMUM, from ἔριον, *wool*, and σπέρμα, *feed*. Jacq. Coll. v. 5. 72. Willd. Sp. Pl. v. 2. 110. Clafs and order, *Hexandria Monogynia*. Nat. Ord. *Coronariæ*, Linn. *Afphodeli*, Juff.

Gen. Ch. *Cal.* none. *Cor.* bell-fhaped, permanent, of fix ovate, equal, keeled petals, three of which are exterior and moft expanded. *Stam.* Filaments fix, fhorter than the corolla, awl-fhaped, uniform, dilated at the bafe, fmooth; anthers incumbent, oval, two-lobed. *Pift.* Germen fuperior; ovate, with fix ribs; ftyle erect, angular, as long as the ftamens; ftigma fimple, obtufe. *Peric.* Capfule of three cells and three valves; partitions from the centre of each valve. *Seeds* feveral, affixed to the lower part of each partition, roundifh, invefted with long prominent woolly hairs.

Eff. Ch. Corolla of fix petals, bell-fhaped, permanent. Filaments broad at the bafe. Capfule of three cells. Seeds invefted with wool.

This genus, than which none can be more natural, either with refpect to character or habit, was eftablifhed by Jacquin in the fifth or fupplemental volume of his Collectanea, upon the *Ornithogalum capenfe* of Linnæus and Thunberg, with two other fpecies. They all agree in their tuberous root; radical, ftalked, folitary, elliptic-oblong, entire, involute leaves; and tall, naked, racemofe, many-flowered ftalks. The flowers are fmall; petals white with reddifh, brown, or greenifh keels.—They are all delineated in Jacquin's Icones Plant. Rarior. v. 2, as follows.

1. E. *latifolium*, t. 420. (Ornithogalum capenfe; Linn. Sp. Pl. 441. Commel. Hort. v. 2. t. 88.) Leaves broadly elliptical, fomewhat heart-fhaped, recurved.—The *leaves* are of a dark fhining green. Partial *flower-ftalks* two inches long. *Petals* with a rofe-coloured rib.

2. E. *lancifolium*, t. 421. Leaves ovato-lanceolate, acute, erect.—The upper fide of the *leaves* is reprefented glaucous by Jacquin, their backs of a grafs green. Partial *flower-ftalks* but an inch long. *Petals* with a brownifh rib.

3. E. *parvifolium*, t. 422. Leaves elliptical, obtufe, erect, flat. The *leaves* of this are glaucous, reticulated, and much fmaller than in either of the former, being but from an inch and half to two inches long. *Petals* with a green rib. *Partial-ftalks* an inch long, fpreading.

All thefe fpecies are natives of the Cape of Good Hope. We fufpect that Bengal and the coaft of Guinea may afford one or two more, but we are not furnifhed with materials fufficient to afcertain them completely.

ERIOSTEMON, from ἔριον, *wool*, and στήμων, *a ftamen*, alluding to the fringed filaments. Sm. Tranf. of Linn. Soc. v. 4. 221. Clafs and order, *Decandria Monogynia*. Nat. Ord. *Rutaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, in five deep fegments, nearly equal, permanent. *Cor.* Petals five, ovate, feffile, regular and equal, fomewhat fpreading, moftly five times as long as the calyx, fometimes rough, inferted under a glandular nectary, which furrounds the bafe of the germen. *Stam.* Filaments 10, awl-fhaped, flattened, clothed or fringed with fine fpreading hairs; anthers on terminal ftalks, roundifh with a fmall point, two-lobed, incumbent, fmooth. *Pift.* Germen of five lobes, fuperior, ftanding on the nectary, each lobe fomewhat ovate, triangular, acute, foon fpreading; ftyle central, from the bafe of the germen, erect, cylindrical, elongated after flowering, fmooth; ftigma capitate, with five notches. *Peric.* Capfules five, connected by their bafe, ovate, compreffed, coriaceous, of two valves, enclofing an elaftic, cartilaginous, bivalve arillus. *Seeds* folitary, kidney-fhaped, brown, fmooth.

Eff. Ch. Calyx in five deep fegments. Petals five, feffile. Stamens flat, fringed. Anthers ftalked, terminal. Style from the bafe of the germen. Capfules five, combined, feated on a glandular nectary. Seeds enclofed in an arillus.

Obf. Some fpecies have a four-cleft flower, with but eight ftamens, and others have five of their 10 ftamens imperfect and abortive.—This genus differs from *Boronia*, Sm. Tracts on Nat. Hift. 287. t. 4—7, in having the anthers upon terminal footftalks, and the ftyle from the bafe of the germen; not to mention the flowers being generally five-cleft and decandrous, and the leaves ufually alternate. From *Corræa* and *Crowea*, fee vol. 10, its differences are evident from the characters there given of thofe genera. We are happy here to mention that the long-defired *Corræa rubra* flowered, for the firft time in Europe, at Meffrs. Lee and Kennedy's, Hammerfmith, in June 1809.

The fpecies of *Erioftemon* in our poffeffion are fix.

1. E. *falicifolia*. Willow-leaved Erioftemon.—Leaves linear-lanceolate, flat, ftraight, naked on both fides. Branches fmooth. Flowers lateral. Gathered near Port Jackfon, New South Wales, by John White, M.D. who communicated dried fpecimens to us in 1791, but it has not yet appeared in the gardens. This is a very handfome flowering fhrub, with numerous, alternate, wand-like, leafy, fmooth, angular *branches*, having indeed much of the habit of *Crowea faligna*. *Leaves* alternate, from one to two inches long, but little fpreading, linear-lanceolate, entire, bluntifh with a fmall point, thick and coriaceous, naked and fmooth on both fides, befprinkled with glandular dots, fcarcely veiny, but marked with an obfolete central rib; their bafe tapering down into a fhort flat *footftalk*. *Stipulas* none. *Flowers* pink, refembling thofe of *Crowea faligna*, on fhort, fimple, folitary, axillary, angular, downy, bracteated ftalks. *Bracteas* imbricated, roundifh, obtufe, concave, pale, downy, fringed. Segments of the *calyx* much refembling the bracteas, about a line long, imbricated at their bafe. *Petals* alternate with them, and five or fix times as long, obovate, fpreading, bluntifh, clothed with fhort, denfe, fcurfy pubefcence, efpecially on the outfide. *Filaments* about one-third as long as the corolla, red, all clothed from the bafe with denfe, white, fpreading hairs, and terminated by a naked, club-fhaped, obtufe, red ftalk, which in the five innermoft alternate ones is much longer, thicker, and more glandular, than in the reft, rendering thofe ftamens confpicuoufly the longeft; anthers at the top of each ftalk, incumbent, uniform, all fertile, ovate, of two cells, burfting longitudinally on their inner fide, tipped with a fmall, pale, reflexed fcale or creft. *Style* fhorter than the ftamens.

2. E. *buxifolia*. Box-leaved Erioftemon.—Leaves elliptical, keeled, revolute, with a recurved point. Branches hairy, round. Flowers lateral.—Gathered near Port Jackfon, by Dr. White. Of this we have two very diftinct varieties, for confidering the Proteus-like nature of the leaves in New Holland plants, in which alone thefe differ, we dare not call them diftinct fpecies. In one the *leaves* are obovate, narrow at the bafe, bluntly crenate and glandular at the edges; in the other they are broadly elliptical, heart-fhaped, and embracing the ftem at their bafe, generally even and entire at their edges, though occafionally furnifhed, in the very fame manner, with blunt glandular teeth. In both the *branches* are round, clothed with fhort prominent hairs. *Leaves* numerous, fcattered, fcarcely half an inch long, coriaceous, nearly fmooth, keeled, with a fharp recurved point, and a thick, flightly revolute, margin. *Flowers* towards the ends of the branches, axillary, folitary. *Stalks* rather fhorter than the leaves, thickened upwards, flightly

ſlightly hairy, with ſeveral minute, crowded, roundiſh, ſmooth *bracteas* a little above their baſe. *Calyx* much reſembling the bracteas. *Petals* whitiſh or roſe-coloured, almoſt as large as in the former, but ſmooth or very ſlightly downy; more ſpreading and recurved. *Filaments* minutely fringed, their terminal ſtalks awl-ſhaped, bearing a few long ſcattered hairs; anthers much like the former but ſhorter, and with a ſhorter broader point. *Germen* ſmooth, with very pointed lobes; ſtyle ſhorter than the ſtamens.

3. E. *ſalſolifolia*. Saltwort-leaved Erioſtemon.—Leaves crowded, linear, obtuſe; flattened above; convex beneath; rough-edged, ſtraight. Flowers terminal.—Gathered by Dr. White near Port Jackſon, with the laſt. It ſeems a more humble ſhrub than either of the foregoing, and has angular *branches*, all over ſcarred where former leaves have ſtood; ſlightly hairy when very young. *Leaves* very numerous, ſomewhat imbricated, half an inch or leſs in length, fleſhy, linear inclining to obovate, obtuſe, flattiſh above, convex beneath, more or leſs rough-edged, and ſometimes otherwiſe pubeſcent, dotted with ſcattered glandular points, which in the dried leaves are prominent tubercles. The baſe tapers down into a very ſhort broad *footſtalk*, articulated with a decurrent prominence of the branch. *Flowers* few, terminal at the top of each branch, on ſhort, ſimple, ſmooth ſtalks, which are minutely bracteated at their baſe. Segments of the *calyx* ſhort, broad and acute. *Petals* recurved, downy, pale red with a darker keel. *Filaments* ſmooth at the baſe, their upper part, and terminal ſtalks, denſely clothed with long, upright, white hairs, almoſt concealing the anthers, which are oblong, with a very minute point or creſt. *Germen* ſmooth, with obtuſe lobes.—The ſtamens in theſe three ſpecies would afford beautiful ſpecific differences, were not thoſe of the leaves more commodious and obvious.

4. E. *uniflora*. Single-flowered Erioſtemon.—Leaves ſcattered, elliptic-lanceolate, ſmooth; paler beneath. Flowers ſolitary, terminal, on ſhort ſtalks. Five of the ſtamens abortive. (Dioſma uniflora; Linn. Sp. Pl. 287. Ait. Hort. Kew. v. 1. 276. Mart. Mill. Dict. v. 2. n. 17. Curt. Mag. t. 273. Schrad. Sert. Hannov. 16. t. 8.)—Native of the Cape of Good Hope, from whence it was ſent to the Kew garden, in 1775, by Mr. F. Maſſon, and is now not unfrequent in collections, being much eſteemed for its beautiful flowers, produced abundantly in the ſpring and early part of ſummer. This is a ſhrub from one to two feet high, much branched, ſtrongly, but not agreeably, aromatic in all its parts. *Branches* leafy, nearly ſmooth. *Leaves* ſcattered, on ſhort, rather hairy, *footſtalks*, elliptic-oblong, often nearly linear, obtuſe, very glandular, paler beneath, very obſcurely crenate, and ſomewhat fringed, varying in length from half an inch to an inch. *Flowers* ſolitary at the end of each branch, but from the number of the ſhort branches they ſometimes appear cymoſe. *Stalks* much ſhorter than the leaves, ſwelling upwards, downy, without bracteas. Segments of the *calyx* near half an inch long, lanceolate, purpliſh, fringed. *Petals* twice as long as the calyx, obovate, pointed, of a ſhining varniſhed white, like porcelain, or often bluſh-coloured above; purpliſh beneath. *Stamens* about the length of the calyx, their filaments all fringed; five of them ſhort, bearing large heart-ſhaped anthers, with greeniſh glandular tips; five much longer and more ſlender, each terminating in a ſmall round ſtalked gland, without any anther, varying in ſize and ſhape. *Germen* globular, clothed with numerous ſtalked nectariferous glands; ſtyle and ſtigma like the other ſpecies. Curtis and Schrader have well deſcribed this plant, but neither of them was ſufficiently acquainted with the real ſpecies of *Dioſma*, now numerous in our gardens, to diſcover that it was generically diſtinct, and that the curious nectary, eſſential to *Dioſma*, was wanting. Schrader endeavours to make his deſcription of that part agree with the generic character, but in vain, and his accuracy would ſoon have diſcovered the truth, had he ſeen a real *Dioſma*. The *Hænkæa* of Schmidt in Uſter's Annals, faſc. 6. 117, to which Schrader refers, agrees in generic characters with *Dioſma barbigera* of Linnæus, and not with our *Erioſtemon*.

5. E. *marginata*. Bordered Erioſtemon.—Leaves ſcattered, lanceolate, paler beneath. Flower-ſtalks axillary, twice as long as the leaves, corymboſe. Five of the ſtamens abortive. (Dioſma marginata; Linn. Suppl. 155.) Native of the Cape of Good Hope, raiſed by Meſſrs. Lee and Kennedy, with whom it flowered in June 1809. It agrees very much in habit with the laſt, but has a more pleaſant ſmell, like ſaſſafras or myrrh, when rubbed, and differs very eſſentially in the great length of its *flower-ſtalks*, which are not terminal, but ſpring from the boſoms of ſeveral of the uppermoſt leaves, and riſing above the ſummit of the branch, make a ſort of corymbus. A pair of lanceolate *bracteas* grow either near the top of each ſtalk, or towards its middle, or in our garden ſpecimens, near the baſe. Their preciſe ſituation ſeems not characteriſtic of any ſpecific difference. The ſegments of the *calyx* vary in breadth, and are often fringed, ſometimes ſmooth. *Petals* moſtly notched at the extremity, but otherwiſe like thoſe of *E. uniflora*, as are alſo the *ſtamens*. The *leaves* vary greatly in length and breadth. Their membranous margin, whence the name is taken, is often very conſpicuous in the dried plant, but we cannot perceive it in the living one, nor even in our garden ſpecimens when dried, ſtill we would not preſume to change a name founded in truth, though not always applicable; otherwiſe *pedunculata* would be a more eligible one. Our remarks on this ſpecies are made from various ſpecimens named and unnamed in the Linnæan herbarium, which vary greatly in the hairineſs or ſmoothneſs of their branches and leaves, as well as the form and breadth of the calyx, but we can find no poſitive ſpecific diſtinction among them. The leaves in ſome are nearly oppoſite, but never conſtantly ſo. We know, from frequent obſervation, that the laſt ſpecies is extremely variable, and are perſuaded that this is ſubject to equal differences. The infloreſcence, however, of each is ſo conſtant, that they can never be confounded together.

6. E. *paradoxa*. Various-leaved Erioſtemon.—Leaves lanceolate, revolute, downy beneath; ſimple, ternate, or pinnate. Flowers lateral, four-cleft. Stamens eight. Sent from Port Jackſon, New South Wales, by Dr. White.—*Stem* ſhrubby, with numerous, oppoſite, round, rough, leafy *branches*. *Leaves* an inch, more or leſs, in length, lanceolate, obtuſe, entire, ſomewhat revolute; ſmooth and naked above; clothed with denſe, white, entangled or ſtarry pubeſcence beneath. In one variety they are ſimple, almoſt perfectly oppoſite, on ſhort footſtalks; in another ſmaller, ternate, ſeſſile on one common winged ſtalk, which is about half the length of the lateral pair; in a third they are as large as in the firſt, and are either ternate or conſiſt of two pair and an odd one, all ſeſſile on a ſimilar, but longer, winged ſtalk. The pinnate and the ternate kinds are unqueſtionably but varieties of each other, nor can we think the firſt a diſtinct ſpecies, however paradoxical our opinion may ſeem. The *flowers* of all are exactly alike. *Flower-ſtalks* copious, axillary, ſolitary, ſhorter than the leaves, ſimple, ſingle-flowered, angular, clothed with ruſty ſtarry ſcales or pubeſcence. *Bracteas* two, towards the middle of each ſtalk, obovate, ruſty, ſmall. *Calyx* downy and ruſty,

 quadrangular

quadrangular at the bafe, its four fegments ovate, broad, keeled. *Petals* four, thrice as long as the calyx, elliptical, keeled, rofe-coloured, fmoothifh above, downy beneath. *Filaments* eight, all nearly equal, rather fhorter than the calyx, red, thick, obtufe, glandular, fringed in their lower part; anthers fhort and roundifh, each on a fhort, flender, white, terminal ftalk, their white tip or creft very minute. *Germen* reddifh, with four blunt lobes.—We have hefitated whether to refer this plant to *Boronia*, with which genus it agrees beft in habit, and number of parts in the fructification, but the infertion of the anthers and of the ftyle have always appeared to us rather like *Eriostemon*. We have never feen it alive. Future obfervations on the living plant may correct our prefent determination. It appears to be one of the pretty tieft fhrubs that New South Wales affords, and would be a welcome acquifition for the Englifh confervatories. S.

ERIOX, or Erox, in *Ichthyology*, a fpecies of Salmo, called by Pennant, Willughby, and Ray the *Grey*. See Salmo.

ERISANA, in *Ancient Geography*, a town of Spain, in Lufitania.

ERISKAY, in *Geography*, one of the weftern iflands of Scotland, feparated from South Vift by a narrow ftrait, called "Erifkay Sound;" about five miles in circumference.

ERISMA, in *Botany*, according to the author of the name, is derived from ερειδω, *to prop*, or *fupport*, and not from εριζω, *to difpute*, or *contend*. Rudge Pl. Guian. 7. Clafs and order, *Monandria Monogynia*. Nat. Ord. uncertain.

Gen. Ch. *Cal.* Perianth of one leaf, permanent, downy on both fides, in four deep unequal fegments, one of which is much the longeft, irregular, obtufe, behind the larger petal; the reft fharper, and half-lanceolate. *Cor.* Petals two, oppofite, unequal, emarginate, the uppermoft united with the calyx betwixt its leffer fegments, broad, roundifh; its bafe ending in a horn-like, blunt *nectary*, the length of the petal, downy externally, like the calyx; the lowermoft thrice as long as the other, and broader, inferted into the receptacle behind the perfect filament. *Stam.* Filaments five; one of them fertile, as long as the upper petal, incurved, inferted into the receptacle; the other four very fhort, abortive; anther arrow-fhaped, narrow. *Pift.* Germen inferior, oblong, of one cell; ftyle thread-fhaped, as long as the filament, afcending; ftigma blunt. *Peric.* unknown. Rudiments of *feeds* two, oblong.

Eff. Ch. Calyx in four deep unequal fegments. Petals two, unequal; the uppermoft united with the calyx, fpurred at its bafe; the lowermoft inferted into the receptacle. Fruit with two feeds.

E. *floribunda*. Rudge t. 1. Native of Guiana. A tree or fhrub with round *branches*, when young clothed with ftarry down of a brown colour. *Leaves* large, nearly oppofite, elliptical or obovate, obtufely pointed, entire, fmooth, with numerous parallel veins. *Stipulas* fmall, deciduous. *Panicles* large, terminal. *Bracteas* in pairs, very unequal, downy, the fmalleft about a line long, the other four lines long, broad and ovate. The *flowers* are very fmall, and concealed by the *bracteas*. Of their colour or properties we have no account.

ERISMATOLITHUS, in *Natural Hiftory*, and *Mineralogy*, is the name of a genus in the animal order of remains (*reliquia*, or relics) of a former race of beings, which inhabited the earth or its waters, and includes the *fulciments* or plant-like fupports which certain animals fabricated for their fupport and habitation, and which are preferved in a foffil ftate. According to Mr. William Martin (Outlines of the Knowledge of extraneous Foffils, p. 193.) the effential characters or diagnoftics of the permanent fpecies in this genus are to be fought in various parts of the *reliquium*, e. g. "In reliquia of cellular fulciments, the ftirp exhibiting the internal form or ftructure of the cells: in reliquia of folid fulciments, the ftirp exhibiting its external form." The temporary fpecies of this genus are to comprife fuch cellular fulciments as do not fhew the ftructure of their cells, and fuch folid imperfect fpecimens as are not reducible to known fpecies. The foffil corals, corallines, fponges, &c. rank under this genus. See Reliquia.

ERISTALIS, the name of a ftone, mentioned by Pliny and the ancients, and of which a very memorable quality is recorded by them, which is, that though it was naturally white, it would occafionally turn red.

ERISTICI, from ερις, *difpute*, in *Botany*, fuch authors as have attempted the ftudy of that fcience in a philofophical way, and have been publicly engaged in difputes about the true foundation of its feveral diftinctions, &c.

ERITHACE, a name given by the ancients to the yellow matter collected on the hinder legs of the bees after their excurfions in fearch of the materials for their hives; we ufually efteem this to be real wax, and the French call it *cire*, brute, or rough-wax; it is certain, however, that though the matter of which wax is to be formed is contained in this fubftance, yet the Dutch and fome other nations have the moft juft idea of it, in calling it *pain des abeilles*, or the food of the bees.

This fubftance is only the farina of flowers, and no experiment has been able to feparate real wax from it. The moft probable opinion concerning it is, that it ferves the bees as food, and that after this it is converted in their bowels into the fubftance called wax.

ERITHALIS, in *Botany*, Εριθαλις is an ancient name of fome plant now unknown, derived from εριθαλης, *highly verdant*, or *beautifully leafy*. Browne adopted it for the prefent genus, and was followed by Jacquin and Linnæus.—Browne Jam. 165. Jacq. Amer. 72. Linn. Gen. 95. Schreb. 130. Willd. Sp. Pl. v. 1. 996. Mart. Mill. Dict. v. 2. Juff. 206. Gærtn. t. 26. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juff.

Gen. Ch. *Cal.* Perianth fuperior, of one leaf, cup-fhaped, with five teeth, permanent. *Cor.* of one petal, deeply five-cleft; tube very fhort; fegments of the limb long, lanceolate, recurved. *Stam.* Filaments five, awl-fhaped, fpreading, fcarcely fo long as the corolla; anthers oblong. *Pift.* Germen inferior, roundifh; ftyle thread-fhaped, compreffed in the upper part, the length of the ftamens; ftigma acute. *Peric.* Berry globofe, crowned with the bafe of the calyx, of ten cells, (fometimes but eight, *Gærtner.*) *Seeds* fmall, folitary, pendulous.

Eff. Ch. Corolla in five deep recurved fegments. Calyx cup-fhaped. Berry inferior, of ten cells. Seeds folitary.

The fpecies are,

1. E. *fruticofa*. Linn. Sp. Pl. 251. (E. odorifera; Jacq. Amer. 72. t. 173. f. 25. E. fruticulofa; Brown. Jam. 165. t. 17. f. 3. Sambucus ligno duro odoratiffimo; Plum. Ic. 247. t. 249. f. 2.)—Leaves obtufe. Flower-ftalks all cymofe, many-flowered.—Native of Jamaica, and other Weft Indian iflands, growing near the fea-fide, and very various in height and luxuriance, according to its fituation. *Stem* fhrubby, with round, fmooth *branches*, leafy towards their extremities. *Leaves* oppofite, ftalked, obovate, entire, about two inches long, various in breadth, obtufe, fmooth and fhining. *Flowers* white, fmelling (according to Jacquin) like the common lilac, growing many together, in long-ftalked, axillary, cymofe panicles, about the ends of the branches, but they are not terminal as Willdenow defcribes them. *Berries* purple, the fize of a pea.—Jacquin

defcribes

defcribes another fpecies or variety, he is doubtful which, with inodorous flowers, whiter berries, and a more humble diffufe ftem, growing on barren maritime rocks in the ifland of Curaçao. This we have never feen.

2. E. *polygama*. Forft. Prod. 17.—Leaves acute. Male flowers cymofe; perfect ones folitary.—Gathered by Forfter in the Society Iflands.—That writer refers to the *Timonius*, Rumph. Amb. v. 3. 216. t. 140, as a narrower-leaved variety of his plant. This is, indeed, to all appearance, an *Erithalis*. Rumphius informs us that it grows in graffy open hilly places in Amboyna, and the neighbouring iflands.

The *ftem* is the height of a man. *Leaves* four or five inches long, and as broad as two fingers, acute at each end. *Flowers* of a dirty white. *Berries* yellowifh-black, eaten by ftarlings and other birds. The *roots* are ufed by the natives to chew, along with a flight mixture of cloves, nutmegs and ginger, in their maritime excurfions, in which they fuffer much from cold and other inconveniencies.

ERITRI, in *Geography*, a town of Afiatic Turkey, in the province of Natolia; 36 miles W. of Smyrna.

ERITZKA, a town of Ruffia, in the government of Irkutfch; 20 miles E. of Kirenfk.

ERIVAN, called *Perfian Armenia*, *Greater Armenia*, and *Eaftern Armenia*, a province of Perfia, about 200 leagues in length, and 60 in breadth. See ARMENIA.

ERIVAN, *Irvan*, or *Irivan*, a city of Afia, and capital of Greater Armenia, or Erivan; fituated in a plain, furrounded with mountains, and watered by two fmall rivers; large, dirty, and ill built, and but indifferently peopled: the ramparts are of earth; the fortrefs is encompaffed with a wall of bricks, in which are a palace for the governor, and 800 houfes, inhabited only by Perfians; the Armenians have fhops there, but muft not remain during the night. The churches are fmall, and half buried in the ground, refembling catacombs; in the town and its environs they reckon 28 convents for devotees of both fexes, but they are poorly endowed.

ERIX, or ERYX, in *Ancient Geography*, a mountain of Sicily, fituated towards the weftern part, near the fea. Solinus fays, that it was confecrated to Venus. Polybius places it between Drepana and Palermo. According to Apollodorus, this mountain derived its name from a fon of Venus, called *Erix*. It is now called "Monte St. Giuliano," or "Monte di Trapani."—Alfo, a town of Sicily, now "Trapani del Monte," fituated on the fummit of mount Eryx, difficult of accefs, and famous for a temple of Venus, called Erycina. Polybius and Strabo mention this town. Minos decorated this temple with fuperb fculpture, and enriched it with fuch noble offerings, as have claimed for him the honour of being its founder. The victims offered themfelves voluntarily at the altar. The moft beautiful women in the world were the prieftefles, and the Roman fenators, laying afide their characteriftic feverity, came hither to indulge in pleafure with the beauteous Sicilian females, perfuaded they fhould thus make their offerings acceptable to the goddefs, and render her propitious. In the time of Strabo the town and temple were much decayed. It is faid that Eryx was deftroyed by Hamilcar, who in the firft Punic war, A. U. C. 493, removed its inhabitants to Drepanum, which he had built not long before. Nothing now remains but a paltry village, and fome foundations of a temple.

ERIZZO, SEBASTIAN, in *Biography*, a noble Venetian, was particularly diftinguifhed for his knowledge of the medallic fcience. He publifhed, in 1559, in Italian, "A Difcourfe upon Ancient Medals," which has been highly efteemed for its erudition. He contended for the difference between the medals and coins of the ancients. Erizzo was the author of a treatife on "Logic;" a tranflation of "Plato's Dialogues;" a difcourfe on "Civil Governments," and fome other pieces. He died in 1585. Gen. Biog.

ERKELENS, or EREKELENS, probably *Herculanum*, in *Geography*, in the days of the Romans, is an ancient town of France, in the department of the Roer, chief place of a canton, in the diftrict of Créveldt, with a population of 1340 individuals. It is at a diftance of about three miles from the river Roer, 15 miles north of Juliers; its ancient fortifications were demolifhed by the French in 1674. The canton contains 48 communes, and 17,853 inhabitants.

ERLA, a fmall town of the kingdom of Saxony, in the circle of the Ertzgebirge, at the foot of the mountain called Rothenberg, remarkable for a rich mine of excellent iron, the beft of the whole of this mountainous diftrict. Its iron works are celebrated for cafting the beft ovens and frying-pans in Saxony; there is alfo a manufactory of cannon-balls. There was anciently a fmall town of the fame name in Ruffia, in the government of Riga, not far from Dorpat; but it is now in ruins.

ERLACH, in French *Cerlier*, a fmall town of Switzerland, in the canton of Berne, at a diftance of about three quarters of an Englifh mile from the upper part of the beautiful lake of Bienne, is fituated on the declivity of the Julimont, or Julius' mountain, for it is proved beyond contradiction that Julius Cæfar eftablifhed upon this hill one of his ftrong entrenched camps. This elevation is alfo called Jolimont, pretty mount, from the beauty of the profpect, which can be no where more varied, or more interefting, on account of the number of picturefque contrafts which it affords. Travellers who wifh to vifit the famous ifland of St. Pierre, in the lake of Bienne, generally take a boat at Erlach. It has an ancient caftle, which gave the title of barons to the illuftrious Swifs family of the Erlachs, who, from the time of the intrepid Ulrich of Erlach, have held fuch a diftinguifhed place in the annals of their country.

ERLANG, or ERLANGEN, a handfome town of Germany, in the circle of Franconia, in that part of the margraviate of Anfpach Baireuth which was called the principality of Culmbach, on the river Rednitz, 18 miles N.W. of Nuremberg, and 30 miles S. of Bamberg. N. lat. 49° 38′. Until the peace of Tilfit, concluded in July 1807, between France and Pruffia, this town, and the whole margraviate of Anfpach Baireuth, belonged to the kings of Pruffia, to whom it had been ceded by the laft margrave, in 1792: but it is now at the difpofal of the French emperor.

Erlang is divided into the old and new town; the latter is alfo called Chriftian Erlang, from the name of its founder, the margrave Chriftian Erneft, who built it in the year 1686 to accommodate feveral families of Proteftant French refugees. The ftreets of both towns are regular and fpacious: there are two handfome fquares, and fome fine churches. The principal manufactures eftablifhed by the French refugees were thofe of hofiery and of hats, which are ftill flourifhing. In 1742 the univerfity of Baireuth was alfo removed to Erlang.

ERLAU, in Latin *Eger*, or *Agria*, a town of Upper Hungary, in the diftrict of Heves, near which there is a fine hot mineral fpring, which is ufed for bathing. It is the fee of a bifhop, and the feat of an univerfity, the buildings of which are very fine: the profeffors are well accommodated, the lecturing rooms very good, and the chapel, library, and public hall extremely elegant. The fee of Erlau is one of the

the richeſt in the kingdom. The town is in general ill built, the only good houſes are thoſe of the canons of the cathedral. There is, however, a Turkiſh tower in good condition. The only remarkable manufactures are thoſe of wax and of leather. The neighbourhood of Erlau is famous for an excellent ſort of Hungary wine, little inferior to the beſt Burgundy.

ERLEBACH, a river of Germany, which riſes in the duchy of Stiria; 6 miles below Ips.

ERLEBACH, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz, on the Main; 3 miles N.N.W. of Clingenberg.

ERLENBACH, a town of Germany, in the circle of Franconia, and county of Wertheim; 10 miles N.N.E. of Wertheim.

ERMELAND, or ERMLAND, in Latin *Varmia*, one of the four ſubdiviſions of that part of the kingdom of Pruſſia which is called Eaſtern Pruſſia. In ancient times, two-thirds of this country belonged to the biſhops of Ermeland, who were princes of the German empire, and one-third to the chapter of the cathedral church of Frauenburg. The biſhop enjoys ſtill a very conſiderable income.

Ermeland is particularly remarkable for its hemp and flax, and its linen yarn, great quantities of which three articles are annually exported to England in time of peace. The principal towns are Frauenburg, the ſee of the biſhop; Braunſberg, the chief city, which alone exports yarn to nearly the annual amount of two millions of guilders; Heilſberg, Allenſtein, Röſſel, Wormdit, &c.

ERMENEK, a town of Aſiatic Turkey, in the province of Caramania; 63 miles S. of Cogni.

ERMENONVILLE, a ſmall town of France, in the department of the Oiſe, chiefly remarkable for its beautiful park, and a caſtle, which derives ſome celebrity from having belonged to the handſome Gabrielle, miſtreſs of king Henry IV. of France. But Ermenonville is become far more famous in modern times, for having been the laſt retreat of the eloquent and miſanthropic Jean Jaques Rouſſeau, who died here on the 2d of July 1778, and to whom a handſome monument has been erected in a ſmall iſland called the iſland of poplars, which is in the middle of a fine lake. This monument is remarkable for the beautiful ſimplicity of its inſcription.

"Ici repoſe l'homme de la nature et de la vérité."

"Here repoſes the man of nature and of truth."

ERMESIA, a name given to a compoſition uſed among the ancients, and famous for its effects in making people beget handſome children. It conſiſted of honey, myrrh, ſaffron, and palm-wine, all beaten together. This maſs was to be taken mixed in milk. The women took it as well as the men, and many had great faith as to its effects.

ERMIJA, in *Geography*, a town of Spain, in the province of Biſcay; 16 miles E.S.E. of Bilbao.

ERMIL, a town of Ruſſia, in the government of Tamboo; 44 miles S. of Tamboo.

ERMIN, or ERMINE, in *Heraldry*, denotes a white field or fur, powdered or interſperſed with black ſpots, called powdering. See FUR.

It is ſuppoſed to repreſent the ſkin of an animal of the ſame denomination. In effect, there is no animal whoſe ſkin naturally correſponds to the herald's ermin.

The animal is milk white; and ſo far is it from having ſpots, that tradition reports, that it will rather die, or be taken, than ſully its whiteneſs. Whence its ſymbolical uſe.

But white ſkins having for many ages been uſed for the linings of the robes of magiſtrates and great men; the furriers at length, to add to their beauty, uſed to ſew bits of the black tails of thoſe creatures upon the white ſkins to render them the more conſpicuous. Which alteration was introduced into armoury.

The ſable ſpots in ermin are not of any determinate number, but they may be a greater or leſs, at the pleaſure of the painter or furrier

ERMIN, an order of knights, inſtituted in 1450 by Francis I. duke of Bretagne, and formerly ſubſiſting in France. The collar of this order was of gold, compoſed of ears of corn in ſaltier; at the end of which hung the ermin, with this inſcription, *a ma vie*. But the order expired when the dukedom of Bretagne was annexed to the crown of France.

ERMINE', a croſs erminé is a croſs compoſed of four ermine ſpots.

It muſt be obſerved, that the colours in ſuch arms are not to be expreſſed, becauſe neither the croſs nor the arms can be of any colour but a white and black.

Colombiere blazons it quatre queues d'ermine en croix. The editor of Guillim deſcribes it thus; a croſs of four ermines; or, more properly, four ermine ſpots in croſs. It is the coat of Hurſton in Cheſhire.

ERMINE, *timbre of*. See TIMBRE.

ERMINE, in *Zoology*. See MUSTELA *Erminea*.

ERMINES is uſed by ſome Engliſh writers for the reverſe of ermine, *i. e.* for white ſpots on a black field; but on what foundation nobody can tell; for the French, from whom we have our heraldry, have no ſuch term; but call this black powdered with white contre-ermine; as denoting the counter, or reverſe of ermine, which is white powdered with black.

ERMINEUM ANIMAL, *ſtoat*, or *ermine*, the creature whoſe ſkin is the ermine, ſo much eſteemed as a fine fur.

This creature is properly a ſpecies of weaſel, and is called by Mr. Ray, and other authors, muſtela candida, the white weaſel, and by Linnæus muſtela erminea. It is in all reſpects like the common weaſel, and is all over of a pure ſnow white, except the tip of the tail, which is of as beautiful a black, and it has a little yellowiſh grey about the eyes, and a mark or ſpot of the ſame colour on the head, another on the ſhoulders, and a third near the tail. Its colour is, however, very different in degree and elegance, according to the ſeaſon of the year. It is frequent about rivers, and in meadows, in thoſe countries which produce it, and feeds on moles, mice, and other ſmall animals. The ſkins and tails are a very valuable article of commerce in Norway, Lapland, and Ruſſia, and other cold countries, where they are found in prodigious numbers, and regularly change their colour in winter, becoming white. In Siberia, they burrow in the fields, and are taken in traps, baited with fleſh. In Norway they are ſhot with blunt arrows, or taken in traps. The ſtoat is ſometimes found white in Great Britain, and called the white weaſel. See MUSTELA.

ERMINITES ſhould ſeem a diminutive of ermines, and naturally to ſignify little ermines; but it is otherwiſe. Erminites expreſſes a white field powdered with black; only that every ſpot has a little red hair therein.

Some authors uſe the word erminites for a yellow field powdered with black, which the French expreſs much better by, or, ſemée d'ermines de ſable.

ERMINOIS expreſſes an or field, with ſable powdering.

ERMS, in *Geography*, a river of Germany, which runs into the Danube, four miles S. W. of Nurtlingen, in the circle of Swabia.

ERMSLEBEN, a town of Germany, in the circle of Lower

Lower Saxony, and principality of Halberſtadt; 14 miles S. E. of Halberſtadt.

ERNANI, a town of Spain, in the province of Guipulcoa; 5 miles S. of Sebaſtian.

ERNATIA, a town of Aſiatic Turkey, in the province of Natolia; 16 miles N. W. of Satalia.

ERNE, the name of a river in Ireland, which riſes near the boundaries of the counties of Longford and Cavan, and paſſes through loughs Gawnah and Oughter in the latter county. From the laſt of theſe lakes it continues a northern direction till it flows into lough Erne, a little below Belturbet. The ſuperfluous waters of this lake are diſcharged by a rapid current of about ſeven miles, which is alſo called Erne, and which falls into the bay of Donegal, below Ballyſhannon.

ERNE-*Lough*, a lake of the county of Fermanagh, Ireland, which is ſuppoſed to occupy above 45,000 acres. It conſiſts properly of two lakes connected by a broad winding channel of about ſix miles. The upper lake is nine miles long, and from one and a half to five wide; the lower lake extends in length about ten miles, and in breadth from two to eight. Both theſe lakes are full of iſlands, being ſaid to contain from three to four hundred, the number varying according to the ſeaſon, being more numerous in winter than in ſummer, on account of the greater height of the water. Some of theſe iſlands are large and inhabited, and many of them well wooded, ſo that the variety of intereſting proſpects afforded by them and the neighbouring coaſt is aſtoniſhing, and far ſurpaſſes the power of deſcription. A canal to open the navigation from the lough to the ſea has been projected, and would be attended with great advantage to the whole of Fermanagh and Cavan. It is alſo probable that a conſiderable part of the lake might be drained, and notwithſtanding its beauty, it is a pity that ſo many acres ſhould be unprofitable.

ERNEE, a ſmall town of France, in the department of Mayenne, chief place of a canton, in the diſtrict of Mayenne, with a population of 4740 individuals. It is ſituated on the river Ernée, 15 miles W. of Mayenne. The canton contains 6 communes and 15,053 inhabitants, on a territorial extent of 232 kiliometres and a half.

ERNES, in our *Old Writers*, ſignify the looſe ſcattered ears of corn that are left on the ground, after the binding or cocking of it.

It is derived from the old Teutonic *ernde*, harveſt; *ernden*, to cut or mow corn. Hence ern is, in ſome places, to glean.

ERNEST, in *Biography*. See MANSFELD.

ERNEST *Town*, in *Geography*, a townſhip of Upper Canada, in the midland diſtrict, the fineſt above Kingſton, ſheltered from lake Ontario by Amherſt iſland, which lies in its front.

ERNESTI, JOHN AUGUSTUS, in *Biography*, was born in Auguſt, 1707, at Tennſtadt, where his father was ſuperintendant. He ſtudied at Pforta, and ſoon diſplayed uncommon talents; he afterwards applied himſelf to the ſtudy of theology at Leipſic, and took his degree of M. A. in the year 1730. In 1734, having been elected rector of Thomas's ſchool in the room of Geſner, ancient literature, and thoſe branches of knowledge connected with it, became the principal objects of his purſuit. The ſucceſsful application of his talents in this department of knowledge cauſed him to be choſen, in 1742, extraordinary profeſſor of ancient literature, in 1756 he was elected public profeſſor of eloquence, and in 1758, he was made doctor and profeſſor of theology. He died in the year 1781, having, till within the laſt two or three years, been inceſſantly engaged in the laborious diſcharge of his public duties. For twenty years and more he paſſed the greater part of each day in inſtructing others, yet he found ample time for the publication of many original works, and for editing various ancient authors. Among the latter may be mentioned, 1ſt, the Memorabilia of Xenophon, which has been frequently republiſhed in this and other countries. 2d, Ciceronis Opera omnia cum clave, in 6 vols. The Clavis has been publiſhed ſeparately. Erneſti, in preparing this work for the preſs, employed the beſt and oldeſt editions of Cicero, as well as ſeveral MSS.; he examined critically the text of Gruter, corrected in it a great many faults, and in his ſhort notes, he has in various places illuſtrated, and in others reſtored the original. He alſo gave the world new editions with notes of Suetonius, Tacitus, Homer, &c. He publiſhed Ariſtophanis Nubes, cum ſcholiis antiquis et Prefat; Hederici Lexicon, multis vocabulorum millibus auctum; a New Theological Library, in 11 volumes; and "Inſtitutio interpretis Novi Teſtamenti," which has paſſed through ſeveral editions. Alberti of Leyden was ſo much delighted with this, that he called it "The Golden Work." A new edition of it was publiſhed in Holland within a few months after it was printed at Leipzic. The extenſive talents and ſober judgment of Erneſti enabled him not only to embrace every department of literature, but to examine and illuſtrate many of its obſcurities and difficulties. He poſſeſſed a ready and retentive memory, and, above all, an honeſt and upright heart. "Though," ſays his biographer, "the ſerioufneſs of his countenance beſpoke a character hoſtile to every kind of levity, and born for labours that require great vigour and exertion, he was a friend to chearfulneſs, and his company, on account of his eaſy behaviour and good humour, which was often heightened by Ciceronian wit, but confined within the boundaries of virtue and decency, made his converſation much ſought after, and highly agreeable." Gen. Biog.

ERNODEA, in *Botany*, from ἐρνώδης, *branched*, ſo that it ought rather to be written *Hernodea*. Swartz. Prod. 29. Fl. Ind. Occ. v. 1. 223. Schreb. 788. Willd. Sp. Pl. v. 1. 611. Mart. Mill. Dict. v. 2. Sm. Prod. Fl. Græc. Sibth. v. 1. 98. Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Rubiaceæ*.

Gen. Ch. *Cal.* Perianth ſmall, ſuperior, in four deep, upright, acute, equal, permanent ſegments. *Cor.* of one petal, ſalver-ſhaped; tube elongated, quadrangular; limb in four deep, lanceolate, recurved ſegments. *Stam.* Filaments four, inſerted into the tube towards the middle, awl-ſhaped, longer than the tube; anthers erect. *Piſt.* Germen ſquare, inferior; ſtyle thread-ſhaped, about as long as, or longer than the ſtamens; ſtigma obtuſe, notched. *Peric.* Berry roundiſh, crowned with the calyx, having a furrow at each ſide, and conſiſting of two cells. *Seeds* ſolitary, hemiſpherical, ſtriated.

Eſſ. Ch. Corolla of one petal, ſalver-ſhaped. Calyx in four deep ſegments. Style ſimple. Berry inferior, of two cells. Seeds ſolitary.

1. E. *littoralis*. Swartz. Fl. Ind. Occ. v. 1. 224. t. 4. Vahl. Symb. v. 2. 28. (Thymelæa humilior, foliis acutis atrovirentibus; Sloane Jam. v. 2. 93. t. 189. f. 1, 2.)—Stem ſquare, ſmooth. Leaves nearly ſeſſile, acute, with a ſpinous point. Gathered by Sloane, Browne, and Swartz, in Jamaica. The latter informs us that it grows in gravelly places by the ſhore, or on calcareous rocks. *Root* perennial. *Stems* procumbent, creeping, rather woody, with numerous, long, creeping or pendulous *branches*, which are ſtraight, ſquare, ſmooth, ſomewhat jointed, not much divided, but bearing numerous, alternate, ſhort, leafy, ſimple, lateral branches. *Leaves* crowded, oppoſite, croſſing each other

other in pairs, nearly feffile, about an inch or more in length, elliptic-lanceolate, acute at both ends, entire, very fmooth, ribbed, rigid, of a dark green, tipped with a fpinous point. *Stipulas* united with a ftem between the very fhort footftalks, each crowned with three briftles, the middle one longeft. *Flowers* axillary, folitary, feffile, yellowifh. Many of them, according to Dr. Swartz, have no piftils.

*2. E. *montana*. Sm. Fl. Græc. Sib. v. 2. t. 143, unpublifhed. Prod. n. 343. (Afperula calabrica; Linn. Suppl. 120. Willd. Sp. Pl. v. 1. 577. L'Herit. Stirp. v. 1. 65. t. 32. Rubeola cretica fœtidiffima frutefcens myrtifolia, flore magno fuaverubente; Tourn. Cor. 5.)—Stem round, downy. Leaves ftalked, blunt, pointlefs.—Native of mountainous places in Crete, Sicily, and the fouth of Italy. Much fmaller than the laft, except in its *flowers*, which are larger, clustered about the ends of the branches, and of a fine rofe-colour. The *ftems* are much branched, woody, decumbent. *Leaves* on fhort ftalks, oppofite, about half an inch long, elliptic-lanceolate, bluntifh at both ends, entire, revolute, without any terminal fpine, much more pliable than in the former; dark green above; pale beneath; roughifh occafionally. When bruifed they have a very difagreeable ftercoraceous fmell. *Stipulas* with a fimple lanceolate point. *Branches* more or lefs downy when young.—Authors have greatly differed about the genus of this plant. By the older ones it has been taken for a *Rubia*, a *Valeriana*, a *Thymelæa*, and a *Nerium* or *Oleander*; by modern writers it has been referred to *Afperula*, *Sherardia* and *Pavetta*. We hope to be nearer the truth than our predeceffors; at leaft its technical generic characters agree well with Swartz's *Ernodea*, nor do we find any great difcordance in the habit.—This beautiful plant emulates the *Daphne Cneorum* in colour and general afpect, and would be fcarcely lefs admired in our gardens, to which it is, as yet, a ftranger.

ERNSPACH, in *Geography*, a town of Germany, in the circle of Franconia, and principality of Hohenloe; fix miles N. of Okringen.

ERNSTEIN, a caftellated town of Germany, in the circle of the Lower Rhine, and electorate of Cologne; eight miles E. of Lintz.

ERNSTHOFEN, a town of Germany, in the circle of the Upper Rhine, and principality of Heffe Darmftadt; 10 miles S. of Darmftadt.

ERNSTTHAL, a fmall town of the kingdom of Saxony, in the county of Schonburg, clofe by Hohnftein, at the foot of a mountain called the Pfaffenberg, with a population of about 2000 individuals. It has a few cotton and linen manufactories.—Alfo, a fmall town of Germany, in the duchy of Saxe-Coburg, which has a confiderable glafs manufactory; in the fpace of thirteen weeks, or three calendar months, they make 216,000 glaffes, 1000 of which ufed to be fold, in 1788, for $3\frac{1}{2}$ rix dollars, or not quite twelve fhillings fterling.

ERODINUM, a word ufed by fome of the enthufiaftic writers in alchemy, to fignify the prognoftic, good or bad, of any operation.

ERODIUM, in *Botany*, from ερωδιος, *a heron*, becaufe the fruit refembles the head and beak of that bird. For a fimilar reafon it is called in Englifh Stork's-bill. L'Heritier. Geraniolog. unpublifhed. Ait. Hort. Kew. v. 2. 414. Sm. Fl. Brit. 727. Willd. Sp. Pl. v. 3. 625. Sibth. Oxon. 211. (Geranium; Linn. Gen. 350. Schreb. 458. Juff. 268. Gærtn. t. 79, *mofchatum.*) Clafs and order, *Monadelphia Pentandria*. Nat Ord. *Gruinales*, Linn. *Gerania*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of five ovate, pointed, concave, permanent leaves. *Cor.* Petals five, obovate, fpreading, rather longer than the calyx, generally more or lefs irregular. *Nectary* of five glands between the petals. *Stam.* Filaments 10, awl-fhaped, united by their bafe into a fort of cup; five of them fertile, nearly as long as the petals; the alternate five fhorter and barren; anthers five, oblong, verfatile. *Pift.* Germen fuperior, with five furrows, beaked; ftyle central, awl-fhaped, fpirally furrowed, as long as the ftamens, permanent; ftigmas five, reflexed. *Peric.* Capfules five, aggregate, membranous, obovate, vertical, feparating at their infide, fharp-pointed at their bafe, each tipped at its fummit with a long, linear, flat, pointed, rigid awn, hairy on its infide, and at length fpirally twifted, adhering by its point to the fummit of the ftyle. *Seeds* one or two, erect, ovate-oblong.

Eff. Ch. Calyx of five leaves. Petals five. Nectariferous glands five. Barren filaments five. Fruit beaked, of five aggregate capfules, each tipped with a long fpiral awn, bearded on the infide.

Linnæus in his Genera Plantarum had long ago indicated a divifion of his genus *Geranium* into feveral natural fections, diftinguifhable by characters in their fructification and inflorefcence. The late learned botanift Monf. L'Heritier, purfuing the idea, divided that genus into three, each of them as naturally and diftinctly defined as any in the whole fyftem, and although the convulfions of his country, and his own premature death, prevented his publifhing an elaborate work on the fubject, he had fortunately conferred by letter with the intelligent editors of the Hortus Kewenfis, and with the writer of the prefent article, fo that his intention has been carried into effect, both in that work and the Flora Britannica. Of thefe three genera *Geranium* with its 10 fertile ftamens, regular flower, and recurved naked awns, confifts of what are ufually called European Geraniums, bearing but one or two flowers on a ftalk; *Pelargonium* with its feven fertile ftamens, irregular flower, tubular nectary, and fpiral bearded awns, comprehends what are generally called Cape Geraniums; while the prefent genus is made up of the Linnæan *Gerania cicutaria*.

Three fpecies of *Erodium* are natives of Britain,

1. E. *cicutarium*. Engl. Bot. t. 1768. Hemlock Stork's-bill. (Geranium cicutarium; Linn. Sp. Pl. 951. Curt. Lond. fafc. 1. t. 51.) "Flower-ftalks many-flowered. Leaves pinnate; leaflets feffile, pinnatifid, cut." Common in wafte ground. In fandy places near the fea its petals are generally white, or their ufual rofe-colour is elegantly diverfied with a green fpot on two or three of them. The *herb* is fetid, proftrate and annual, with finely divided leaves.

2. E. *mofchatum*, Engl. Bot. t. 902. Mufky Stork's-bill. (Geranium mofchatum; Linn. Sp. Pl. 951.) "Flower-ftalks many-flowered. Leaves pinnate; leaflets nearly feffile, elliptical, unequally cut." Wild in the mountainous paftures of Yorkfhire and Weftmoreland, but in other places it is ufually the outcaft of gardens, where it has often been cultivated for the fake of the ftrong mufky fcent of its herbage. The *flowers* are fmaller and lefs ornamental than thofe of the preceding; *leaves* larger, paler, and more vifcid.

3. E. *maritimum*, Engl. Bot. t. 646. Sea Stork's-bill. (Geranium maritimum; Linn. Sp. Pl. 951.) "Flower-ftalks barely three-flowered. Leaves heart-fhaped, cut, crenate, rough Stems depreffed." Native of fandy fea-fhores in various places, flowering all fummer long. When brought into a garden it becomes wonderfully luxuriant. The *root* is perennial. *Petals* white or reddifh, for the moft part much fmaller than the calyx leaves.

Willdenow has 34 fpecies of this genus in all. Moft of them

them abound in the warmer countries of Europe, and the northern part of Africa, and feveral are cultivated with us for ornament, as *E. gruinum*; (Geranium creticum; Ger. em. 943), a hardy annual with large blue flowers; *E. hymenodes*; Andr. Repof. t. 413, which requires a greenhoufe, and is perennial. Three fpecies are natives of the Cape of Good Hope, *viz.* the moft beautiful *E. incarnatum*, Ait. H. Kew. v. 2.415. Curt. Mag. t. 261. (Geranium incarnatum; Linn. Suppl. 306.) This is a tender greenhoufe plant, and therefore not very common, but worthy of all attention for the delicate hues, and eye-like pencilling, of its bloffoms. The other two Cape fpecies are *arduinum*, (Geranium arduinum; Linn. Sp. Pl. 952.) very little known to botanifts, and never introduced into the gardens of Europe; and *ribifolium*, Jac. Ic. Rar. v. 3. t. 509.) an inconfpicuous flower, not much likely to excite the attention of cultivators.

ERODIUS, in *Entomology*, a genus of the Coleopterous kind, eftablifhed by Fabricius. Thefe infects are generically diftinguifhed by the following character: the antennæ moniliform; feelers four; jaws horny, truncated, and bifid; lip horny and emarginate. This is the Fabrician definition, to which may be added that the body is roundifh, gibbous, and emarginate; thorax tranfverfe; wing-cafes clofely united, and longer than the abdomen.

Species.

Testudinarius. Black; wing-cafes rough, the fides covered with whitifh duft. Fabr.

An infect of large fize, found at the Cape of Good Hope; the wing-cafes are very gibbous, with fmall raifed dots.

Gibbus. Black; wing-cafes with three raifed lines. Fabr. Remarkable for the gibbofity of its form, and the obtufity of the wing-cafes; it is of moderate fize; and has the anterior fhanks armed with a ftrong tooth in the middle and at the tip. The fpecies inhabits Arabia.

Planus. Black; wing-cafes with a fingle raifed line. Fabr.

Native of the fame country as the former. The anterior fhanks not armed with a fpine.

Minutus. Black; wing-cafes perfectly fmooth. Fabr. Small thorax with two impreffed dots on the back; legs unarmed. Inhabits the eaftern parts of the world.

Muricatus. Gibbous, black; wing-cafes muricate. Fabr.

A fpecies defcribed in the Fabrician Suppl. Ent. from the cabinet of Lund. It is a native of the Cape of Good Hope; in fize and appearance refembles E. gibbus. The head and thorax fmooth.

EROPHEEVO, in *Geography*, a town of Ruffia, in the government of Irkutfch; 60 miles N. of Balaganfkoi.

EROS, of ερως, *love*, in *Mythology*, one of the two chiefs over all the other cupids, being the caufe of love. See Anteros.

EROSION, in books of *Surgery*, we often find this expreffion ufed fynonymoufly with the term ulceration.

Erosion, in *Geology*, according to Mr. Kirwan, (Geol. Eff. 230 and 285,) denotes a folution or melting of the fofter calcareous particles by water, by which he accounts for the formation of the vaft caverns and grottos to be found in the Derbyfhire lime-ftone rocks, and thofe of other countries. M. de Sauffure, in his Agenda (Journal. des Mines, N° 20.) directs the attention of geological travellers to the fides of valleys (§ 12.) to fearch for the veftiges of the erofion of water: by which we might underftand a mechanical fweeping or wafhing away of ftrata, as well as a folution or melting as above.

EROSUM Folium, among *Botanifts*. See Leaf.

EROTESIS, Ερωτησις, in *Rhetoric*, the fame figure with *Interrogation*. Every interrogation or queftion is not figurative; but it becomes figurative, when the fame thing may be expreffed in a direct manner; but the putting it by way of queftion gives it much greater life and fpirit. As when Cicero fays, (in Catal. i. c. 1.) "Cataline, how long will you abufe our patience? Do not you perceive your defigns are difcovered?" He might have faid, "You abufe our patience a long while; you muft be fenfible your defigns are difcovered." But it is evident how much this latter mode of expreffion falls fhort of the force and vehemence of the former. Thus alfo, when Medea fays, "I could fave; and do you afk, if I can deftroy?" Had fhe merely faid, "I could fave, and I can deftroy," the fentence would have been flat, and very unfit to exprefs the rage and fury in which the poet there reprefents her. (Quint. Inft. Orat. l. viii. c. 5.) This figure is fuited to exprefs moft paffions and emotions of the mind, as anger, difdain, fear, defire, &c. It ferves alfo to prefs and bear down an adverfary. This figure likewife diverfifies a difcourfe, and gives it a beautiful variety, by altering the form of expreffion, provided it be neither too frequent, nor continued too long. Befides, the warm and eager manner in which it is expreffed enlivens the hearers, and quickens their attention.

EROTEUM, in *Botany*, perhaps from ερωτάω, *to queftion*, in allufion to its doubtful nature at firft fight, being very like *Thea* till the fruit is inveftigated. Swartz. Prod. 5. The author, however, being himfelf, as it feems, diffatisfied with this name, has, in his Fl. Ind. Occ. v. 1.971, changed it to Freziera, which fee.

EROTIA, Ερωτια, a feftival among the Greeks, in honour of Cupid, being celebrated every fifth year with fports and games.

EROTIANUS, in *Biography*, the author of a gloffary, containing an explanation of all the words ufed in the writings of Hippocrates, lived in the firft century of the Chriftian era, in the reign of Nero, and dedicated his work to Andromachus of Crete, who was phyfician to that emperor. It was printed at Venice, in 1566, in 4to. with the notes of Barth. Euftachius, under the title of "Vocum, quæ apud Hippocratem, collectio, et ejus operum in feptem fectiones diftributio." The gloffary of Erotain was alfo annexed to the edition of Hippocrates, publifhed by Foefius at Geneva, in 1657. Haller. Bibl. Med. Eloy.

EROTIC, derived from ερως, *love*; whence ερωτικος, is applied to any thing which has a relation to the paffion of love.

In *Medicine*, we particularly ufe the phrafe delirium eroticum, for a kind of melancholy contracted through excefs of love.

Though, among the feveral fpecies of pulfes, there be no amorous pulfe, that is, no pulfe peculiar to that paffion; yet we can certainly difcover where the diforder is erotic, by the beating of the pulfe, which, in that cafe, is changeable, unequal, turbulent, and irregular. Speak to the patient of the perfon he loves, and his pulfe inftantly changes, becoming higher and quicker; and the minute you change the converfation, the pulfe is loft again, and is difturbed anew.

EROTIDIA, ερωτιδια, the fame with erotia.

EROTOMANIA, in *Medicine*, a term ufed by fome writers to denote that modification of infanity, of which the paffion of love is the origin, and in which the love of a particular individual conftitutes the predominant idea. Sauvages treats of this form of derangement under the name of *melancholia amatoria*; (fee his Nofol. Meth. Clafs viii. Gen. xix. Spec. 2.) Sennertus under that of *amor* *infanus*, &c. The word is derived from ἔρως, *love*, and μανια, *mania*, madnefs.

This difeafe is diftinguifhed from fatyriafis and nymphomania, if indeed fuch maladies have any exiftence, inafmuch as the patient, fo far from being urged by libidinous defires, contemplates the object of his affection with reverence and diftant admiration, as if fhe were a divinity; he would fpend his days in doing homage to her perfections, and deems food, fleep, and the affairs of the world of little comparative moment. As a remedy for this fpecies of infanity, low and light diet has been recommended. Ovid has advifed the performance of a long journey, during which a conftant change of fcene, and the abfence of all objects, with which the recollection of the individual beloved, might tend to reftore the mind to its ufual condition: conftant occupation of body or mind, "qui vis fanari, res age, tutus eris;" and the admonitions of the wife in regard to the lofs of health, fortune, and character, which muft attend fuch hallucination, have alfo been fuggefted. The former part of the advice may be fometimes beneficial, but thofe who are moft experienced in the treatment of the infane, well know how little benefit is produced by reafoning with madmen. See Melancholy.

EROTYLOS, in *Natural Hiftory*, the name of a ftone, of which we have no defcription left us, but which the ancients are faid to have ufed in divination.

EROTYLUS, in *Entomology*, a genus of Coleoptera in the Fabrician fyftem, allied, and in fome degree confounded, with the two Linnæan genera Chryfomela and Coccinella, and arranged by Gmelin under that of Cryptocephalus. The antennæ are filiform; feelers four and unequal, the anterior longer and hatchet-fhaped; jaws horny and bifid; lip horny, fhort, dilated at the lip, truncated, and fomewhat emarginate; body fuboval. The transformations of thefe infects are unknown, in the perfect ftate they are found generally on flowers. Three of the fpecies are defcribed by Linnæus, the remainder principally by Fabricius.

Species.

Giganteus. Oval, black; wing-cafes with numerous fulvous dots. Fabr. *Chryfomela gigantea*, Linn. *Coccinella gigantea*, Sulz. Native of India.

Cancellatus. Black; wing cafes yellow, reticulated with black. Fabr. Large and roundifh; inhabits Brazil.

Histrio. Deep black; wing-cafes barred with black and yellow, a fcarlet fpot at the bafe and tip. Fabr.

A fpecies of large fize, an inhabitant of Cayenne.

Lugubris. Teftaceous; antennæ and fhanks black. Fabr. Native of America.

Gibbosus. Black; wing-cafes yellowifh with black dots; band in the middle and at the end black. Fabr. *Chryfomela gibb fa*, Linn. *Coccinella*, Gronov.

An infect of confiderable magnitude, the wing-cafes of which are remarkably gibbous, and the thorax impreffed on each fide; it is a native of South America.

6-Fasciatus. Oval, black; wing-cafes with fix waved fulvous bands, the anterior one interrupted. Fabr.

Inhabits Cayenne.

Notatus. Black; wing-cafes with a yellow band in the middle fpotted with black, and marked with red at the bafe. Fabr. Native of South America.

Concatenus. Black; wing-cafes reticulated with yellow and black, and marked with two black bands. Fabr. Mant. Inf. Country unknown; the body large.

5-Punctatus. Oval; wing-cafes black with five red dots. Fabr. Inhabits America.

Punctatissimus. Black; wing-cafes yellow with numerous black dots. Fabr.

Defcribed from the Hunterian cabinet: an American fpecies.

Varius. Black; wing-cafes punctured, fpotted with fulvous in the middle. Fabr. Inhabits Surinam.

Gemmatus. Black; wing-cafes with numerous fulvous dots; thorax variolous. Fabr.

An infect of moderate fize, found in Cayenne.

Macrocheiros. Black; wing-cafes with alternate black and yellow bands; fore legs very long. Fabr.

Native of India.

Abdominalis. Black; wing-cafes yellow with four waved black bands and a diftinct black dot. Fabr.

A Brafilian fpecies, in fize refembling E. fafciatus, and having the abdomen yellow with two lines of black dots.

Fasciatus. Black; wing-cafes with three yellowifh bands. Fabr.

From the Bankfian cabinet: the native place unknown: fize moderate.

Zebra. Yellowifh; head, bafe of the thorax, and three bands on the wing-cafes with the legs black. Fabr. Mant.

Alternans. Black; wing-cafes with two yellow bands, the anterior one dotted with black. Fabr.

Surinamensis. Black; wing-cafes red and immaculate. Fabr. Native of Surinam.

Limbatus. Oblong, black; margin of the thorax and border of the wing-cafes yellow. Fabr.

South American fpecies; head yellowifh with a black frontal fpot; thorax fmooth with a broad finnate lateral margin.

Nebulosus. Black; thorax, and wing-cafes varied with ferruginous. Fabr.

Inhabits the fame country as the preceding.

Dilatatus. Oblong, black; thorax and wing-cafes ferruginous. Fabr.

Native of the Cape of Good Hope. The antennæ are brown, at the bafe ferruginous; wing-cafes fmooth, and much broader than the body.

Morio. Oblong, black, and immaculate. Fabr.

This, and the four following fpecies, are natives of New Holland. Thefe are defcribed by Fabricius from the Bankfian cabinet, and are reprefented in the volume of "Donovan's General Illuftration of Entomology, devoted to the Infects of the Auftralafian regions."

Smaragdulus. Oblong, black; wing-cafes ftriated and green.

Amethystinus. Oblong, black; thorax and wing-cafes blue; refembles the laft; front retufe; wing-cafes with punctured ftriæ.

Bicolor. Oblong, black; bronzed above.

Cupreus. Oblong, black; thorax and wing-cafes coppery.

Rufipes. Oblong, black; legs pitchy. Fabr. Mant. Inhabits Kiel.

Flavipes. Oblong, gloffy green; antennæ and legs yellowifh. Native of Jamaica, in the Bankfian cabinet.

EROWA, the name of a kind of nettle which grows in the mountains at Otaheite in the South Sea, with which the inhabitants make fifhing lines, which ferve to hold the ftrongeft and moft active fifh, and are much ftronger than our filk lines of twice the thicknefs.

ERPACH, in *Geography*. See Erbach.

ERPENIUS, Thomas, in *Biography*, was born at Gorcum, in Holland, in the year 1584. His parents, natives of Bois-le-Duc, were, on account of their converfion to the Proteftant religion, obliged to withdraw from that place, to one more favourable to the rights of private judgment. They provided their fon with a good education in the rudiments of learning, and when they difcovered in him a propenfity pensity for literary pursuits they sent him to Leyden, where he felt so diffident of succeeding in his studies, that for some time he determined to relinquish them. Fortunately his desire for knowledge overcame his modesty, and he applied himself with so much diligence, that he obtained the highest praise of his different tutors, and excited their surprize at his extraordinary progress. He excelled in metaphysics, but his fame with posterity is built on the skill which he acquired in the oriental languages. After availing himself of all the advantages which the university of Leyden afforded, he travelled for farther improvement in foreign countries. In England he became acquainted with Bedell, who was celebrated for his knowledge in Hebrew and rabbinical learning. In France he improved himself in his knowledge of the Arabic tongue; and in Italy he improved his acquaintance with the Hebrew language, by conversing with some learned Jews, and made himself master of the Persian, Turkish, and Ethiopic tongues. After spending several years in foreign countries, Erpenius returned to Holland, where he was elected professor of the oriental languages in the university of Leyden. This was in the year 1612, and very shortly after his appointment he set up a press for the printing of works in the Eastern literature. In the year 1620 he was sent by the States General on different journies into France, to engage Peter du Moulin, or Andrew Rivet, to undertake the theological professorship at Leyden. After this he was appointed oriental interpreter to the States, and was employed to translate the letters addressed to them from Asia and Africa, and to write such as were sent by them to the sovereigns in those parts of the world. He was frequently invited into Spain by the sovereign of that country, to explain certain inscriptions in the Arabic language on the Moorish buildings and monuments in that country, and the emperor of Morocco is said to have been highly pleased with the purity and beauty of his style, and to have exhibited his letters as objects of real curiosity. He died in the year 1624, when he was only 48 years of age. His works are numerous, and have given him a high reputation among the learned. They are enumerated by Moreri, and other biographical writers, and we are informed that he projected an edition of the Koran, with a Latin version and notes, likewise an Arabic grammar and lexicon, which his death prevented him from executing. Gerard-Jean Vossius pronounced over him a funeral oration. Moreri.

ERPIS, or Herpis, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana. Ptolemy.

ERRA, in *Geography*, a town of Portugal, in the province of Estremadura, on a river of the same name; 22 miles S.E. of Santarem.—Also, a river, which runs into the Latas, 12 miles E. of Salvateira, in the province of Estremadura.

ERRABARI, a town of Egypt; 10 miles N.W. of Cairo.

ERRAINE, a town of Egypt; two miles E. of Tahta.

ERRANT, in *Law*, the same with itinerant; the term is attributed to judges who go the circuit; and to bailiffs at large.

Errants, *knight*. See Knight.

ERRATA, a list usually placed at the beginning or end of a book, containing the faults that have escaped in the impression, and, sometimes, even in the composition of the work.

Lindenberg has an express dissertation on typographical errors, "De Erroribus Typographycis;" in which he observes, that there is no book exempt from them, not even the sacred books. He sets himself to enquire into all the causes thereof; and proposes means to prevent them, but he advances nothing on that article but what is either common, or impracticable.

ERRATIC, in *Astronomy*, an epithet applied to the planets, which are called erratic, or wandering stars, in contradistinction to the fixed stars.

Erratic *fevers*, in *Medicine*, a term used to express such fevers as, according to the language of medical writers, observe no regular type, that is, are not determinate either in their attacks, or in their general period. They are thus called by way of distinction from the typic fevers, which are regular in both. See Fever.

Erratic *winds*. See Wind.

ERRHINE, in the *Materia Medica*, from ἐν, *in*, and ῥὶν, *the nose*, is a term applied to those substances which are introduced into the nose, for the purpose of exciting a discharge from the passages. When they excite sneezing, the medicines of this class have been called ptarmica, and sternutatories; and, from the discharge which they occasion, they have been termed apophlegmatica, and, in barbarous Latin, caput-purgia.

Errhines, by stimulating the exhalent vessels and the mucous follicles of the Schneiderian membrane, which lines the internal surface of the nose, and the cavities adjoining it, excite those vessels and follicles to pour out their fluids more copiously than usual. The discharge is sometimes of a mucous, and sometimes of a thinner fluid; it is often attended with sneezing, but sometimes is procured without. This, however, implies no difference in the operation, except as to the stronger or weaker irritation of the medicine employed. For although when sneezing is excited a larger evacuation is often produced, yet the effects of errhines are not altogether proportional to the sensible irritation which they occasion. See Alston, Mat. Med. vol. i sect. 8.

The evacuation produced by these medicines consists not merely in emptying the mucous follicles of the lining membrane of the nose of their contents, but in augmenting the secretion: whence, agreeably to the laws of the circulation, a greater afflux of fluids to those parts is necessarily occasioned, and therefore a diminution of the fluids in the neighbouring vessels. In this way Dr. Cullen explains the fact, that errhines often give relief to rheumatic pains in the neighbouring parts, especially to the tooth-ach, as well as to some forms of head-ach, pains of the ear, and ophthalmia. "How far their effects may extend," he says, "cannot be exactly determined; but it is probable that they may operate more or less on the whole vessels of the head, as even a branch of the carotid passes into the nose: and independent of this, it is not improbable that our errhines may have been of use in preventing apoplexy and palsy; which at least is to be attended to so far, that whenever any approach to these diseases is suspected, the drying up of the mucous discharge should be attended to, and, if possible, restored." Cullen's Mat. Med. vol. ii. p. 436.

The nicotiana, or tobacco, as it is commonly prepared for persons who amuse themselves by snuffing, may be conveniently employed, with people unaccustomed to it, as an errhine; but repetition soon diminishes its power, and renders it useless. It produces a different degree of discharge in different people, even of those who use it habitually; and Dr. Cullen states, from his own experience, "that whenever the discharge has been considerable, the laying aside snuffing, and therefore suspending that discharge, may have very bad effects."

The article most commonly employed as an errhine, is the *Asarum asarabacca*, snuffed up the nose every evening, for a short time, in the quantity of three grains. Quincy observes, ferves, that its pungency is not immediately felt upon taking, but after fome time it makes the nofe run very much. In larger quantities it fometimes brings blood, and even occafions a fwelling of the whole head. This laft effect, however, has been oftener produced by the *Euphorbium*, a ftill more acrid errhine. Dr. Cullen, fpeaking of thefe fevere effects, fays, "I have feen fome inftances of megrims, ophthalmias, and particularly tooth-achs, cured by the violent operation of errhines; but I never thought it fafe to imitate the practice." The *white hellebore*, in very fmall quantity, is alfo an acrid errhine.

ERRIFF, in *Geography*, a province of Africa, in the country of Fez. See RIF.

ERRIPSIS, from ῥιπτω, *I precipitate*, in *Medicine*, is ufed in different fenfes, fometimes for a weaknefs of the whole body, fometimes only of fome one part. When applied to the whole body, it expreffes that utter dejection and proftration of ftrength which makes a man fall down like a dead carcafs; and, when applied to the eyes, it expreffes fuch a debility, as renders it impoffible to keep them open.

ERROAD, in *Geography*, a town of India, in the country of Coimbatore; 39 miles E.S.E. of Damicotta, and 48 N.E. of Coimbatore.

ERROL, a fmall uninhabited town of America on lake Umbagog, on the north-eafternmoft fettled part of Grafton county, in New Hampfhire, incorporated in 1774.

ERROMANGO, an ifland in the Southern Pacific ocean, being one of thofe called the "New Hebrides," 18 leagues from Sandwich ifland, and 24 or 25 leagues in circuit. The middle of it lies in S. lat. 18° 54'. E. long. 169° 19', and it is of a good height. Captain Cook anchored in a bay of this ifland; and he found that although the behaviour of the inhabitants was at firft friendly, their real intentions were very different. They were armed with clubs, fpears, darts, bows and arrows, and feemed determined to employ them in a hoftile manner. On this account it became neceffary for the captain to give orders to his men to fire upon the affailants. At length they were fo terrified as to withdraw and make no farther appearance. Thofe iflanders, it was obferved, feemed to be of a different race from thofe of Mallicollo, and they fpoke a different language. They are of a middle fize, with a good fhape, and tolerable features. Their colour is very dark, and their afpect is not improved by their cuftom of painting their faces, fome with a black, and others with a red pigment. Their hair is curly and crifp, and fomewhat woolly. The few women, who were feen and who appeared to be ugly, wore a kind of petticoat, made either of palm leaves, or of a fimilar plant; but the men, like thofe of Mallicollo, were almoft entirely naked. On account of the treacherous behaviour of the inhabitants of Erromango, captain Cook called a promontory, or peninfula, near which the fkirmifh happened, "Traitor's Head." This is in the N.E. point of the ifland, and is fituated in S. lat. 18° 43', and E. long. 169° 28'.

ERRONAN, or FOOTOONA, the moft eaftern ifland of all the Hebrides, appeared to captain Cook to be about five leagues in circuit, of a confiderable height, and flat at top. On the N.E. fide is a little peak feemingly disjoined from the ifle; but which was thought to be connected by low land. It is diftant in the direction of N. by E. ½ E. 11 leagues from Port Refolution in the ifland of Tanna.

ERROR, a miftake of the mind in giving affent to a thing, or propofition, which is not true. See FALLACY.

Some philofophers define error an act of the mind, whereby things that fhould be joined are feparated; or, things that fhould be feparated, are joined; or a wrong judgment, difagreeing with the things whereon it is paffed.

Error ftands in oppofition to truth, which confifts in an agreement between the propofition and the thing whereof it is affirmed or denied.

However, a bare failure, or non-attainment of truth, does not conftitute error; that being common both to ignorance and doubting.

Error only ftands diftinguifhed from *falfhood*, in that the former is in the mind, and the latter only in the propofition.

The great origin of all error, *i. e.* of believing that to be true which is falfe, is a liberty, or power, in the human mind, of giving its affent to ideas, to propofitions, that are obfcure, as if they were perfpicuous and plain.

Particular caufes of error are, inadvertency, ignorance, impatience, intereft, authority, education, &c. See FAITH, PROBABILITY, OPINION.

Againft all which, there is this one general rule or caution laid down by F. Malebranche and others; *viz.* never to give our full affent to any propofition, unlefs the evidence for it be fo ftrong, as that we can no longer withhold it, without incurring the fecret reproaches of our own reafon.

Mr. Locke reduces the caufes of all our errors to thefe four; *viz.* 1. Want of proofs. 2. Want of ability to ufe them. 3. Want of will to ufe them. And, 4. Wrong meafures of probability.

F. Malebranche confiders five occafional caufes of error, or rather of five different kinds of errors, accommodated to the different manners we have of perceiving things. 1. Errors of fenfe. 2. Of the imagination. 3. Of the underftanding. 4. Of our inclinations. And, 5. Of the paffions. See SENSE, IMAGINATION, UNDERSTANDING, INCLINATION, and PASSION.

ERRORS, *popular.* See POPULAR.

ERROR, in *Law*, generally denotes a fault, or overfight, either in pleading, or in procefs; upon either of which is brought a writ, by way of remedy, called a *writ of error;* in Latin, *de errore corrigendo.*

A writ of error lies for fome fuppofed miftake in the proceedings of a court of record; for, to amend errors in a bafe court, not of record, a writ of "falfe judgment" lies. The writ of error only lies upon matter of law arifing upon the face of the proceedings; fo that no evidence is required to fubftantiate or fupport it; there being no method of reverfing an error in the determination of *facts*, but by an attaint, or a new trial, to correct the miftakes of the former verdict. A writ of error may be brought for notorious miftakes in the judgment or other parts of the record; as where a man is found guilty of perjury, and receives the judgment of felony, or for other lefs palpable errors, fuch as any irregularity, omiffion, or want of form in the procefs of outlawry, or proclamations; the want of a proper *addition* to the defendant's name, according to the ftatute of additions; for not properly naming the fheriff, or other officer of the court, or not duly defcribing where his county or court was held; for laying an offence committed in the time of the late king, to be done againft the peace of the prefent; and for many other fimilar caufes, which (though allowed out of tendernefs to life and liberty) are not much to the credit or advancement of the national juftice. Thefe writs of error to reverfe judgments in cafe of mifdemeanors are not to be allowed of courfe, but on fufficient probable caufe fhewn to the attorney-general; and then they are underftood to be grantable of common right, and "ex debito juftitiæ." But writs of error to reverfe attainders in capital cafes are only allowed "ex gratia;" and not without exprefs warrant under the king's fign manual, or at leaft by the confent of the attorney-general. 1 Vern. 170. 175.

If a writ of error be brought to reverſe any judgment of an inferior court of record, where the damages are leſs than ten pounds; or, if it is brought to reverſe the judgment of any ſuperior court after verdict, he that brings the writ, or that is plaintiff in error, muſt (except in ſome peculiar caſes) find ſubſtantial pledges of proſecution, or bail (ſtat. 3 Jac. I. c. 8. 13 Car. II. c. 2. 16 and 17 Car. II. c. 8. 19 Geo. III. c. 70.): to prevent delays by frivolous pretences to appeal; and for ſecuring payment of coſts and damages, which are now payable by the vanquiſhed party in all, except a few particular inſtances, by virtue of the ſeveral ſtatutes here recited. 3 Hen. VII. c. 10. 13 Car. II. c. 2. 8 and 9 W. III. c. 11. 4 and 5 Ann. c. 16.

A writ of error lies from the inferior courts of record in England into the king's bench, and not into the common-pleas. (Finch. L. 480. Dyer 250.) Alſo from the king's bench in Ireland to the king's bench in England. It likewiſe may be brought from the common pleas at Weſtminſter to the king's bench; and then from the king's bench the cauſe is removable to the houſe of lords. From proceedings on the law ſide of the exchequer a writ of error lies into the court of exchequer chamber, before the lord chancellor, lord treaſurer, and the judges of the court of king's bench and common pleas; and from thence it lies to the houſe of peers. From proceedings in the king's bench in debt, detinue, covenant, account, caſe, ejectment, or treſpaſs, originally begun there by bill (except when the king is party) it lies to the exchequer chamber, before the juſtices of the common pleas, and barons of the exchequer; and from thence alſo to the houſe of lords (ſtat. 27 Eliz. c. 8.); but when the proceedings in the king's bench do not firſt commence therein by bill, but by original writ ſued out of chancery, this takes the caſe out of the general rule laid down by the ſtatute (1 Roll. Rep. 264. 1 Sid. 424. 1 Saund. 346. Carth. 180. Comb. 295.); ſo that the writ of error then lies, without any intermediate ſtage of appeal, directly to the houſe of lords, the dernier reſort for the ultimate deciſion of every civil action. Each court of appeal, in their reſpective ſtages, may, upon hearing the matter of law in which the error is aſſigned, reverſe or affirm the judgment of the inferior courts; but none of them are final, ſave only the houſe of peers, to whoſe judicial deciſions all other tribunals muſt therefore ſubmit, and conform their own. Blackſt. Com. book iii.

Error, *to aſſign.* See Assign.

Errors, *Clerk of the.* See Clerk.

Error *loci*, literally *error of place*, a doctrine of conſiderable importance in the theory of diſeaſes, taught by the celebrated Boerhaave. It was deemed the principal cauſe of thoſe obſtructions to the circulation of the blood, on which inflammation, in all its varieties, was ſuppoſed to depend. "The parts of a fluid," ſays Boerhaave, "become unable to paſs by error of place (per errorem loci), when a corpuſcle ruſhes into the dilated mouth at the baſis of a conical canal, and cannot paſs through the narrow end of it." (Aphoriſm 118.) This doctrine is founded upon theſe three circumſtances; the ſeries of particles, of which the blood is compoſed; the ſeries of progreſſively diminiſhing veſſels; and the conical form of theſe veſſels: and it is thus explained by the comment of Van Swieten.

The largeſt particles in the blood are the red globules, which are to be found naturally in the larger veſſels only. Now the extremities of the arteries carrying red blood, tranſmit the red globules ſingly, according to the obſervations made with microſcopes on the pellucid parts of living animals. The finer parts of the blood are conveyed into the ſmaller lateral veſſels, and the red vein receives the red blood only. The veſſel of the next magnitude receives all the fluids except the red globules, and retaining the larger particles only, (*viz.* the ſerous globules) tranſmits the remaining thinner liquids into the ſtill ſmaller veſſels, that ariſe from the ſerous artery. This law obtains, then, in all the decreaſing ſeries of veſſels. The red arteries can receive and tranſmit all the humours; the ſerous arteries exclude the red part of the blood, but tranſmit the ſerous globules, and every other thinner fluid, and ſo on. Now, ſhould the diameter of a lateral veſſel ariſing from a larger one be by any means increaſed, for example, the aperture of a ſerous artery, which ariſes from a red one, a red globule might be able to enter its orifice when thus dilated; but as a conical canal always grows narrower, it will ſhortly ſtick faſt, and be by no means able to paſs through its extremity, and conſequently will cauſe an obſtruction, as the bulk of the particle to be carried through exceeds the capacity of the tranſmitting veſſel.

This error loci of the fluids was conſidered as the proximate cauſe of inflammation by Boerhaave, and his commentator illuſtrates the dilatation and diſtention of the lymphatic and ſerous veſſels by the red blood in the caſe of inflammations of the eye; in which the veſſels of the ſurface of the eye, which are naturally tranſparent, become red, and viſible, ſometimes even giving a red colour to the whole of the ſurface. See Van Swieten, Comment. ad Aph. 118—378, &c.

ERRUCA, in *Ancient Geography*, a town of Italy, belonging to the Volſii, according to Diodorus Siculus.

ERSE, in *Geography*, a river of Germany, in the circle of Lower Saxony, which runs into the Fuhſe; 8 miles S. of Zelle.

ERSH, in *Agriculture*, is a term ſignifying land in the ſtate of ſtubble after the grain has been taken off. Hence we have pea, bean, and different ſorts of grain erſhes.

Ersh-*Crop*, is ſuch a crop as is grown after ſome of theſe ſorts of ſtubbles have been turned down by the plough.

ERSTEIN, in *Geography*, a ſmall town of France, in the department of the Lower Rhine, chief place of a canton in the diſtrict of Barr, with a population of 2344 individuals. The canton contains 14 communes and 8991 inhabitants, on a territorial extent of $137\frac{1}{2}$ kiliometres.

ERTA, a town of Aſia, in Parthia.

ERTHOLM, a ſmall iſland, about three leagues from the coaſt of Schoonem, and half a league from Bornholm. It belongs to the Danes; and till of late was garriſoned only with 50 men: the force has been ſince augmented to 500. This iſland may be eaſily captured and retained by that power, which, during the interval of naval operations in the Baltic, has the ſuperior fleet.

ERTO del Ferro, a town of Italy, in the kingdom of Naples, and province of Calabria Citra; 10 miles W. of Umbriatico.

ERTZGEBIRGE, or rather Ertzgeburge, (arch-mountainous country,) is the fifth of the ſeven circles into which that part of the kingdom of Saxony, which is called Saxony Proper, or formerly Electoral Saxony, is divided. As late as the tenth century this whole extenſive tract of mountainous country was nothing but an impervious foreſt, called Miriquido, or Miriquidvi, few ſpots of which began to be cleared in 1004. It is bounded to the north by the circles of Miſnia, or Meiſſen and Leipzick, and by the principality of Altenburg, to the weſt by the ſame principality, the circles of Neuſtadt and Voigtland, and the dominions of the princes of Reuſs; to the ſouth and eaſt by the kingdom of Bohemia. Its principal rivers are the Zſchopau, the Flöhe, the Pöhl, the Preſnitz, and the Schwartzwaſſer.

The

The territorial extent of the Ertzgebirge is 121 German ſquare miles, and its population, in 1785, amounted to 405,600 individuals, which gives 3352 $\frac{1}{11}$ inhabitants to the German ſquare mile. It produces corn, potatoes, vegetables of all ſorts, and excellent flax, and has ſeveral manufactories, but chiefly thoſe which work upon minerals and metals.

The circle of the Ertzgebirge is remarkable for its numerous and valuable mines, which, in 1789, employed 12,867 miners, and, in 1788, yielded in ſilver only 50,618 marks. The aggregate of all the metals produced the ſum of 700,64 dollars. Amalgamation, or application of mercury to extract the ſilver from the ore, was firſt introduced in the Saxon mines in the year 1787.

Freyberg is the chief place of the Ertzgebirge, and the firſt town in Europe for the ſtudy of mineralogy. See FREYBERG.

The whole circle of the Ertzgebirge contains 61 towns and 723 villages. It is ſubdivided into 13 diſtricts, *viz.* Freyberg, Auguſtuſburg, Chemnitz, Roſſen, Frauenſtein, Altenberg, Lauterſtein, Wolkenſtein, Annaberg, Grünhayn, Schwartzenberg, Weiſenburg, and Zwickau.

ERTZICA, a town of Aſia Minor, in Cappadocia, commonly called *Arzingham.*

ERUBRUS, a river of Gaul, thought by M. D'Anville to be the Rouver, which runs into the Moſelle, a little below Treves.

ERUCA, in *Zoology.* See CATERPILLAR.

ERUCA *marina griſeo fuſca.* See APHRODITA.

ERUCAGO, in *Botany,* Tourn. Inſt. 232. t. 103, ſee BUNIAS, ſpec. 3.

ERUCTATION, BELCHING, the ſame as ructation.

ERUDITION, denotes learning or knowledge; and chiefly that of hiſtory and antiquity, of languages and of books, which is the reſult of hard ſtudy, and extenſive reading. The Scaligers were men of deep erudition: the writings of M. Launoy, a prieſt of the Oratory, are full of erudition.

Mr. Locke ſays, it is of more uſe to fill the head with reflections than with points of erudition. If the mind be not juſt and right, ignorance is better than erudition, which only produces confuſion and obſcurity. M. Balzac calls a heap of ill choſen erudition the luggage of antiquity.

ERVEDEIRA, in *Geography,* a town of Portugal, in the province of Eſtremadura; 12 miles N.N.W. of Leiria.

ERVILIA, in *Botany,* an ancient name for a kind of vetch or pea. See PISUM OCHRUS, alſo ERVUM.

ERUPA, in *Ancient Geography,* a town of Arabia Deſerta. Ptolemy.

ERUPTION, in general, a burſting forth, or excluſion of ſomething which was before covered, or concealed.

The eruption of volcanos, or burning mountains, is frequently the effect and iſſue of earthquakes. See EARTHQUAKE, VOLCANO, &c. For an account of the eruptions of mount Ætna and Veſuvius, ſee ÆTNA and VESUVIUS.

ERUPTION, in *Medicine,* denotes the appearance of various ſpots and diſcolourations of the ſkin, whether puſtules, pimples, raſhes, &c.: thus, we ſpeak of an eruption of ſmall-pox, or of meaſles; and, by a figure of ſpeech, theſe puſtules, raſhes, &c. are often denominated eruptions, or cutaneous eruptions.

ERUPTION *in Infants.* See INFANTS.

ERUPTIVE DISEASES, a term nearly ſynonymous with CUTANEOUS *Diſeaſes,* (which ſee). Eruptive fevers are theſe febrile diſeaſes which are accompanied by an eruption of ſpots or tumours on the ſkin, by which they are principally characterized: ſuch as ſmall-pox, meaſles, chicken-pox, cow-pox, ſcarlet fever, eryſipelas, ſhingles, &c.

ERVUM, in *Botany,* an ancient Latin name of unknown derivation. Tare. Linn. Gen. 376. Schreb. 498. Willd. Sp. Pl. v. 3. 1112. Sm. Fl. Brit. 775. Juſſ. 360. Claſs and order, *Diadelphia Decandria.* Nat. Ord. *Papilionaceæ,* Linn. *Leguminoſæ,* Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, tubular, erect, cloven half-way down into five acute ſegments, all of equal breadth, but the lowermoſt is rather the longeſt. *Cor.* papilionaceous, twice as long as the calyx: ſtandard obovate, nearly entire, aſcending, with a broad claw, compreſſed and keeled at the back; wings two, oblong, obtuſe, half-heart-ſhaped, ſhorter than the ſtandard, with narrow claws; keel as long as the wings, of two conjoined compreſſed petals, with ſeparate claws. *Stam.* Filaments in two ſets, one compoſed of nine, the other ſolitary; anthers roundiſh, two-lobed, erect. *Piſt.* Germen ſuperior, oblong, compreſſed, horizontal; ſtyle ſimple, aſcending, forming a right angle with the germen, and about half as long; ſtigma capitate, obtuſe, hairy all over. *Peric.* Legume oblong, obtuſe, compreſſed, rigid, knotty from the prominent ſeeds, of one cell, and two pointed, ſpirally-elaſtic valves. *Seeds* from two to four, occaſionally more, roundiſh, ſomewhat compreſſed.

Eſſ. Ch. Stigma capitate, hairy all over.

The genus *Ervum* in Linnæus is a heterogeneous aſſemblage, difficult to be accounted for. *E. Lens,* the ſpecies from which his generic character ſeems to have been principally taken, is moſt completely a *Cicer,* under which head it ſhould have been deſcribed in our eighth volume. *E. ſolonienſe* is not only a true *Vicia,* but the very ſame plant with *Vicia lathyroides,* Linn. Sp. Pl. 1040. See Engl. Bot. t. 30. *E. monanthos* and *Ervilia,* having the ſtyle hairy on the upper ſide, appear to us to belong to *Lathyrus.* Thus none of the Linnæan *Erva* remain, except our two Britiſh ſpecies, and theſe are not only very peculiar in habit, but according to the analogy of the tribe to which they belong, their ſtigma affords an excellent eſſential character, not to be found in any other *diadelphous* flower. All this was firſt explained in the Flora Britannica, by the author of the preſent article, and Willdenow has adopted it in every point, except that he retains the old erroneous character, "calyx deeply five-cleft," in addition to that derived from the ſtigma, and alſo makes *E. Ervilia* a *Vicia.* He moreover adopts a ſuppoſed new ſpecies from Deſfontaines, making three in all.

1. E. *tetraſpermum.* Smooth-podded Tare. Linn. Sp. Pl. 1039. Curt. Lond. faſc. 1. t. 55. Engl. Bot. t. 1223. Stalks moſtly two-flowered. Pods ſmooth, many-ſeeded.—A troubleſome weed in cultivated land throughout Europe, flowering in June and July. *Root* annual, fibrous. *Stem* weak, climbing, branched, ſquare, hairy. *Leaflets* numerous, alternate, linear-oblong, obtuſe, hairy beneath, their common ſtalk ending in a branched tendril. *Flower-ſtalks* axillary, ſolitary, ſlender, as long as the leaves without their tendril, each bearing two (ſometimes ſolitary,) little drooping flowers of a pale blue veined with dark purple. *Calyx* hairy. *Pods* half an inch long, pendulous, oblong or obovate, ſmooth. *Seeds* four; occaſionally from five to ſeven in a variety found in Huntingdonſhire and at Algiers, which we have in vain tried to make a diſtinct ſpecies.

2. E *vicioides.* Vetch-like Tare Desfont. Atlant. v. 2. 168. t. 198. Willd. Sp. Pl. v. 3. 1112.—Stalks many-flowered. Pods ſilky, two-ſeeded. Leaflets obovate, entire. Gathered by Deſfontaines in hedges at Algiers. It appears to be very nearly related to the following, from which it

chiefly differs in being rather larger, and in having more rounded and not emarginate *leaflets*. Nothing however is more variable than the termination of the leaflets in *Vicia* and its allies. The *pods* are called filky, which is perhaps equally applicable to *E. hirfutum*. All things confidered, we much doubt of the permanency of this fpecies, which we, like Willdenow, adopt entirely from the excellent work of Desfontaines. We tolerate, but cannot approve the mixture of Greek and Latin in the name *vicioides*, which if the fpecies fhould remain, ought to be made *viciæformis*.

3. E. *hirfutum*. Hairy-podded Tare. Linn. Sp. Pl. 1039. Curt. Lond. fafc. 1. t. 54. Engl. Bot. t. 970.—Stalks many-flowered. Pods hairy, two-feeded. Leaflets emarginate.—A pernicious weed in cornfields and paftures throughout Europe. It much refembles the firft fpecies, but the *ftem* is ufually fmoother, the ends of the *leaflets* more abrupt and notched, the *flowers* and *pods* more numerous on each ftalk. The moft effential difference confifts in the fhorter, fomewhat rhomboid, hairy *pods*, with only two feeds.—Mr. Curtis obferves that he has "in wet feafons feen whole fields of corn overpowered and totally deftroyed by this plant, which is ftronger and more prolific than *E. tetrafpermum*." He does not, however, fuggeft any remedy. Thefe weeds are too minute and inconfpicuous when young to be eradicated, and when they have fixed their tendrils upon the crop, they can no longer be feparated without "rooting up alfo the wheat with them." S.

Ervum *Orientale*. See Sophora.

ERVY, in *Geography*, a fmall town of France, in the department of the Aube, chief place of a canton in the diftrict of Troyes, with a population of 1975 individuals. It is 9 miles S. of St. Florentin, and has fome manufactures of linen-cloth. The canton contains 14 communes and 11,199 inhabitants, on a territorial extent of 222½ kiliometres.

ERWASH, a river of England, which rifes in the county of Nottingham, and almoft in its whole courfe feparates that county from Derbyfhire, and falls into the Trent, 4 miles S. W. of Nottingham. See Erewash.

ERWITE, a town of Germany, in the circle of the Lower Rhine, and duchy of Weftphalia; 5 miles S. of Lippftadt.

ERXLEBEN, John Christian Polycarp, in *Biography*, was born in June, 1744, at Quedlingburg, where his father was dean of St. Nicholas's church. He ftudied medicine at Gottingen, where he took the degree of mafter of arts in 1765, and fhortly after gave lectures on natural hiftory and the veterinary fcience. Having publifhed his introductory lectures, he undertook, at the expence of the Hanoverian government, a tour through France, Holland, Denmark, and a great part of Germany, in the courfe of which he acquired much practical knowledge in the veterinary art. On his return he lectured on the feveral fciences connected with natural hiftory, and natural and experimental philofophy. In 1774, and the following years, he was elected a member of moft of the learned focieties on the continent. He died in Auguft, 1777, when he had but juft attained his thirty-third year. Erxleben publifhed many works which were highly efteemed, among thefe are "Principles of Natural Hiftory;" "Principles of Natural Philofophy;" "An Introduction to the Veterinary Art." Gen. Biog.

ERYANNOS, in *Ancient Geography*, a river of Afia Minor, in the Troade, which had its fource in mount Ida.

ERYBIUM, a town of Greece, in the Doride, fituated, according to Diodorus Siculus, at the foot of mount Parnaffus.

ERYCEIRA, Francis de Meneses, *Count of*, in *Biography*, born at Lifbon in 1614, was brought up to the ufe of arms, and obtained fome important offices under government; but in the midft of his ufual occupations he cultivated literature, and publifhed a number of works, particularly hiftories of Tangier and Portugal; and the life of John I. king of Portugal.

Eryceira, Francis-Xavier de Meneses, was grandfon of the preceding, and, like him, united a literary with an active and military life. He was born at Lifbon in 1672, and rofe to eminence in the ftate. He was chofen member of various learned focieties. From his anceftor he inherited a well chofen and extenfive library, to which he made many great additions. He is faid to have been the author of more than a hundred different works, of thefe, however, but few feem entitled to notice. The beft known are, "Memoirs on the Value of the Monies of Portugal," 4to. 1738; "Reflection on Academical Studies;" "Parallels on Illuftrious Men and Women;" and "A Tranflation of the Henriade." He died in the year 1743. Nouv. Dict. Hift.

ERYCINA, in *Mythology*, a furname given to Venus, from Erix, a mountain in Sicily, where fhe had a temple. Venus Erycina had alfo a temple at Rome, which was deemed very ancient even in the time of Thucydides. See Erix.

ERYMANTHUS, in *Ancient Geography*, a mountain or foreft of the Peloponnefus, in Arcadia, E. of a river of the fame name, which had its fource towards the north, on the confines of the Elide and of Arcadia, in mount Lampie. The wood of Erymanthus was full of boars, which made great defolation in the country. Hercules was employed to give chafe to them, which he did with fuch fuccefs, that he flew with his own hands the largeft of them. See Hercules.—Alfo, a town of the Peloponnefus, in Arcadia, called *Phegia* and *Pfophis*, according to Paufanias.

ERYMI, a people of Scythia, on this fide of the Imaus. Ptolemy.

ERYMNÆ, a town of Afia Minor, in Lycia. Steph. Byz.—Alfo, a town of Greece, in Theffaly; placed by Pliny in Magnefia.

ERYNGIUM, in *Botany*, ἠρυγγιον of Diofcorides, the derivation of which is unknown. Eryngo or Sea Holly. Linn. Gen. 127. Schreb. 177. Willd. Sp. Pl. v. 1. 1356. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 288. Juff. 226. Gærtn. t. 20. Clafs and order, *Pentandria Digynia*. Nat. Ord. *Umbelliferæ*.

Gen. Ch. *Common Receptacle* conical. *Flowers* all fertile, feffile, with fcales between them. *Involucrum* of the whole receptacle of many leaves, flat, fpreading beyond the flowers. *Cal.* Perianth fuperior, of five upright, acute leaves, feffile on the germen, fhorter than the corolla. *Cor.* in the aggregate uniform, roundifh. Petals five, equal, oblong, with a linear longitudinal ftricture, their points bent in, fo as nearly to reach the bafe. *Stam.* Filaments five, capillary, ftraight, projecting far above the corolla; anthers oblong, verfatile. *Pift.* Germen inferior, briftly; ftyles two, thread-fhaped, a little fpreading, fomewhat fhorter than the filaments; ftigmas fimple. *Peric.* Fruit ovate, feparable perpendicularly into two parts. *Seeds* oblong, cylindrical; in fome fpecies remaining fhut up in the cruft of the pericarp, in others deciduous from it.

Eff. Ch. Involucrum of many leaves. Flowers in little denfe heads. Common receptacle conical, fcaly. Seeds briftly.

A moft fingular and very natural genus, having the habit and afpect of a thiftle, the herbage rigid, thorny, either

either more or lefs tinged with vivid blue, or pallid and whitifh; while the fructification is exactly that of an umbelliferous plant, though the inflorefcence is capitate. Willdenow has eleven fpecies, but they and their fynonyms require a thorough inveftigation. Two are natives of Britain, *viz. E. maritimum*, Engl. Bot. t. 718, (in which plate we are forry to remark that the petals are drawn reflexed inftead of inflexed, an error that till now efcaped us.)—This is frequent on fandy fea fhores throughout Europe, flowering in July and Auguft. The long creeping perennial *roots* are aromatic and fomewhat acrid; they are efteemed ftimulant and reftorative, and are fometimes fold candied. The herbage is glaucous variegated with a permanent blue. *Leaves* rounded, plaited, lobed, with fpinous teeth. *Flowers* blue, in denfe terminal heads, encompaffed with a large leafy involucrum. *Scales* of the receptacle three-cleft. The other Britifh fpecies is *E. campeftre*, Engl. Bot. t. 57, found very rarely in England, though common on the continent. Its *leaves* are much more narrowly divided than the firft, and pinnatifid. *Flowers* greenifh-white, with narrow involucral leaves and undivided fcales. This appears to be the true ηρυγγιον of Diofcorides.

Among the exotic kinds *E. amethyftinum*, Linn. Sp. Pl. 337, a native of Styria; *E. alpinum*, ibid. Curt. Mag. t. 922, from the Swifs alps; and *E. planum*, Jacq. Auftr. t. 391; are all hardy perennials, frequently cultivated for ornament. The *alpinum* is indeed peculiarly handfome, on account of its many-leaved, finely divided, blue involucrum.

The following five fpecies are not in Willdenow.

E. *cyaneum*. Sm. Prod. Fl. Græc. Sibth. v. 1. 175. Fl. Græc. v. 3. t. 258. unpublifhed. "Radical leaves in five deep pinnatifid fegments. Stem much branched and divaricated. Involucrum of about five leaves."—Common in Greece and the iflands of the Archipelago. The *root* is perennial *Stem* 12 or 18 inches high, of a fine blue, as well as the involucrums and foliage, many-flowered and divaricated. *Leaves* fmall, in linear, narrow, pinnatifid fegments. Heads of *flowers* fmall, blue, with prominent, confpicuous, white anthers. This moft refembles *E. triquetrum*, Vahl. Symb. v. 2. 46, in habit, but the flowers and involucrum are very different.

E. *multifidum*, ibid. Fl. Græc. v. 3. t. 259.—"Leaves doubly pinnatifid, fomewhat lyrate; radiated at the extremity. Stem corymbofe. Involucrum pinnatifid."—Gathered by Dr. Sibthorp in the Morea. Taller than the laft, with a bright blue *ftem* and *flowers*. The finely pinnatifid *leaves* give it the afpect of an *Echinops*. This is prefumed to be Eryngium creticum erectum, folio multifido, caule et ramis amethyftinis; Tourn. Cor. 23.

E. *parviflorum*, ibid. (E. foliis laciniatis, capitulis florum exiguis et denfe congeftis; Tourn. Cor. 23.) "Leaves bipinnatifid. Stem corymbofe. Involucrum three-cleft or fimple, four times as long as the head." Of this no figure is extant, nor is it known where Dr. Sibthorp gathered the fpecimens found in his herbarium. The *root* is perennial. *Herb* whitifh. *Stem* denfely clothed with leaves, and bearing numerous flowers at the fummit. *Leaves* twice or thrice pinnatifid, their fegments narrow and divaricated. Heads of *flowers* very fmall, with large involucra, generally of five leaves, which are either undivided or three-cleft.

E. *purpuratum*. Leaves all pinnatifid, their lower part fringed with capillary teeth. Stem nearly fimple, with few flowers. Involucrum of about feven undivided leaves.—Gathered near Tangier by the late M. Brouffonet and the Abbè Durand, who feverally fent fpecimens to Dr. Smith. *Root* perennial. *Stems* a fpan high, round, furrowed, leafy, fcarcely branched, but bearing about three dark-blue heads of *flowers*, with very fpinous calyces. *Leaves* all nearly alike, pinnatifid, with decurrent, fometimes lobed, fegments; their lower part clafping the ftem, pectinated, fringed with fine long capillary teeth. Great part of the ftem, and the upper fide of each leaf of the involucrum, are tinged with a rich deep blueifh purple, hardly equalled in any other of the genus.

E. *carthamoides*. Leaves oblong, toothed, undivided, heart-fhaped and clafping the ftem at their bafe. Stem nearly fimple, with few flowers. Involucrum of feveral ovate leaves. Gathered by M. Brouffonet in the neighbourhood of Algiers, flowering in June. *Stem* a foot high, ftrong, round, leafy, fometimes purplifh, fimple, except at the fummit, where it bears from three to five large heads of blueifh *flowers*, whofe involucrum confifts of feveral large, ovate, purplifh, fpinous-toothed leaves, much refembling thofe of a *Carthamus*. The radical and ftem-*leaves* are all fimple, oblong, wavy, with large fpinous teeth, veiny and pale-green.

ERYNGO, in the *Materia Medica*. The root of eryngium is attenuant and deobftruent, and is therefore efteemed a good hepatic, uterine, and nephritic. Its whole virtue, it is to be obferved, confifts in the external or cortical part. Their virtues, however, appear to be but weak; and they are now fcarcely otherwife ufed than as made into a fweetmeat.

The London college directs it to be candied in the following manner: boil the roots till the rind will eafily peel off; when peeled, flice them through the middle, and the pith being taken out, wafh them three or four times in cold water; then for every pound of roots thus prepared, take two pounds of double-refined fugar; diffolve the fugar in water, fet it on a fire, and as foon as it begins to boil, put in the roots, and continue the boiling till they become foft.

Thefe candied roots are an ingredient in artificial affes milk, which is thus made: take of candied eryngo root one ounce, pearl barley half an ounce, liquorice root three drams; boil them in two pints of water to one pint, to which add a pint of new milk from the cow; boil them gently together, then ftrain the liquor for ufe, of which half a pint fhould be drunk three times a day.

ERYNNIS, *q. d.* ερις νȣ, *contentio mentis*, or becaufe, as Paufanias remarks, ἐρινύειν fignifies to fall into a fury, or *Furious*, a name given to Ceres by the Sicilians.

ERYSIBE, in *Botany*, ερυσιβη, *ruft, or the mildew of corn*, from its rufty panicle. Roxb. Pl. Coromand. v. 2. 31. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Sapotæ*, Juff.

Gen. Ch. *Cal.* Perianth in five deep, roundifh, concave, permanent fegments. *Cor.* of one petal, falver-fhaped, the length of the calyx; tube cylindrical, pervious; limb the length of the tube, in 10 roundifh fegments, fpreading. *Stam.* Filaments five, very fhort, inferted into the lower part of the tube; anthers erect, ovate, fhorter than the tube. *Pift.* Germen fuperior, ovate; ftyle none; ftigma five-lobed. *Peric.* Berry oval, of one cell. *Seed* folitary, large.

Eff. Ch. Corolla falver-fhaped; limb in ten equal fegments. Style none. Stigma five-cleft. Berry fuperior, with one feed.

E. *paniculata*. Roxb. Coromand. t. 159. The only known fpecies, a native of the mountain forefts of India, from whence Dr. Roxburgh fent us fpecimens in 1789. A very large climbing fhrub. *Branches* alternate, leafy, round, clothed when young with copious rufty down. *Leaves* alternate, three or four inches long, fpreading and deflexed,

deflexed, elliptic-oblong, pointed, entire, veiny; smooth and shining above; paler and opaque beneath. *Footstalks* half an inch long, angular, rusty. *Stipulas* none. *Panicles* many-flowered, terminal, erect, much branched, about a span long, their stalks, small oblong scattered bracteas, and the calyx, all densely clothed with rusty down. Tube of the *corolla* greenish; limb yellow, about three lines in diameter. *Berry* the size of a small cherry, black, pulpy, containing one large seed.

Of the uses or qualities of this plant or its fruit we have no account. From its botanical affinity to *Chrysophyllum*, *Achras*, &c. it may certainly be eaten with safety. The flowers are not inelegant.

ERYSIMA, in *Ancient Geography*, a town of Asia, in Cappadocia.

ERYSIMUM, in *Botany*, ερυσιμον of Theophrastus and Dioscorides, about the etymology of which there is much controversy among the learned, but, as often happens in such controversies, nothing satisfactory. Hedge-mustard. Linn. Gen. 339. Schreb. 442. Willd. Sp. Pl. v. 3. 509. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 706. Juss. 239. Tournef. t. 111. Gærtn. t. 143. Class and order, *Tetradynamia Siliquosa*. Nat. Ord. *Siliquosæ*, Linn. *Cruciferæ*, Juss.

Gen. Ch. *Cal.* Perianth of four ovate-oblong, coloured, parallel, cohering, deciduous leaves. *Cor.* cruciform, of four oblong, flat, very obtuse petals, whose claws are the length of the calyx and erect. Nectary a gland betwixt each of the shorter filaments and the germen. *Stam.* Filaments six, the length of the calyx; of which two opposite ones are shorter than the rest; anthers simple. *Pist.* Germen superior, linear, square, the length of the stamens; style very short; stigma small, capitate, permanent. *Peric.* Pod long, linear, straight, exactly square, of two cells and two valves. *Seeds* numerous, small, roundish.

Eff. Ch. Pod straight, columnar, exactly square. Calyx-leaves cohering. Stigma capitate.

Willdenow has 14 species, of which five are British.

1. E. *officinale*. Linn. Sp. Pl. 922. Curt. Lond. fasc. 5. t. 50. Engl. Bot. t. 735. "Pods close-pressed to the main stalk. Leaves runcinate." Common in waste ground and about hedges. This is usually taken for the ερυσιμον of Dioscorides, whose description, more full than usual with that writer, is very applicable to it. Dr. Sibthorp, however, decidedly considered *Sisymbium polyceratium* as the plant Dioscorides meant, and this, perhaps, will be found to accord still better with his description, which compares the horn-like pods to fænugreek. See its figure in Matthiolus, Ed. Valgr. fol. v. 1. 524. The ερυσιμον of Theophrastus is supposed to be a still different plant, as he reckons it among the various kinds of grain.

In this and similar cases, therefore, though the Linnæan generic name is adopted from ancient writers, it does not follow that their plant is of the same genus, which matter is frequently impossible to be ascertained. It is sufficient that such names are established by common consent amongst systematical botanists, from whom they acquire a new stamp of authority; nor ought they to be changed, whatever new light may be thrown upon them by future commentators. We study by the arrangements of Linnæus or Jussieu, not by those of Theophrastus or Dioscorides. It is only in case any species requires to be separated from an established genus, that we are glad to recur to its ancient appellation for a generic name; as in the cases of *Cyamus*, Sm. Exot Bot. v. 1. 59. t. 31, 32 (see CYAMUS); and *Nuphar*, Prod. Fl. Græc. v. 1. 361.

2. E. *Barbarea*. Linn. Sp. Pl. 922. Engl. Bot. t. 443. "Lower leaves lyrate; their terminal lobe rounded: upper ones obovate, toothed."—Common in waste ground, either dry or wet, flowering most in the spring. Its numerous *flowers* of a full yellow, often seen double in gardens, and its dark shining broad *leaves* easily distinguish it. The whole plant has a nauseous, bitter, slimy flavour.

3. E. *præcox*. Sm. Fl. Brit. 707. Engl. Bot. t. 1129. "Lower leaves lyrate: upper ones pinnatifid, their segments linear, oblong, and entire."—Found in Devonshire by the Rev. Dr. Beeke. The narrow lobes of the *stem-leaves*, smaller *flowers*, and much longer *pods*, distinguish this from the last, with which we believe Linnæus confounded it. The distinction is highly important, as we are convinced the present is the very same with the American Cress, as it is called, or rather Winter Cress, of the gardens, an agreeable and wholesome pungent herb for sallads, &c.

4. E. *Alliaria*. Linn. Sp. Pl. 922. Curt. Lond. fasc. 2. t. 48. Engl. Bot. t. 796. "Leaves heart-shaped."—Common under hedges in the spring, and known by its broad toothed *leaves*, white *flowers*, and strong scent of garlick when bruised.

5. E. *cheiranthoides*. Linn. Sp. Pl. 923. Engl. Bot. t. 942. Jacq. Austr. t. 23.—"Leaves lanceolate, slightly toothed. Pods erect. Flower-stalks when in fruit spreading."—Not rare in Osier-grounds, Turnip fields, and other cultivated ground, where the soil is gravelly or sandy, flowering in July. This resembles the yellow stock or wall-flower in habit and *leaves*, but the small *flowers* and square *pods* at once distinguish it.

The exotic species are not quite so well ascertained as ours. Ehrhart and Roth have taken pains to elucidate them, and the result is given by Willdenow. We know not that any of them is worthy of the attention of the cultivator except for botanical curiosity.—They are all either annual or biennial, perfectly hardy in our climate, and bear narrow lanceolate leaves, with small yellow flowers. As weeds their copious seeds render them rather troublesome.

ERYSIPELAS, from ερυω, *to draw*, and πελας, *near*, from the disposition of the affection to draw the adjacent parts into the same state; or from ερυθρος, *red*, and μελας, *black*, a dark red.) The generality of surgical authors have considered erysipelas as a species of inflammation, and every reflection induces us to entertain the same opinion, notwithstanding the opposite sentiment of one of the lecturers on surgery in this metropolis. The immortal Celsus has observed: "notæ verò inflammationis sunt quatuor; rubor, et tumor, cum calore et dolore," lib. 3. cap. 10. According to this definition, erysipelas is certainly an inflammation, although the degree of swelling is not so great, nor the pain exactly of the same kind, as in cases of phlegmon, or common inflammation.

With many distinguished surgical authors, we regard erysipelas as a particular kind of inflammation, most frequently affecting the small vessels on the surface of the body. It is, as Mr. Hunter describes, more commonly a cutaneous inflammation, than one situated in deeper parts; although it is probable, that, in some constitutions, every inflammation, wherever it exists, will be of this kind. However, there can be no doubt of the fact laid down by this accurate observer, *viz.* that the skin appears to be the most susceptible of erysipelas, because this affection will spread over a prodigious extent of the surface of the body, while (at least, in common instances) the cellular membrane underneath remains free from disorder. (See Hunter on Inflammation, p. 270.)

Mr. Hunter taught surgeons, that one of the uses of the adhesions, adhefions, which form in cafes of common inflammation, is to circumfcribe and bound the matter, in the event of fuppuration taking place. Now, in eryfipelas, the extravafation in the place affected is not fo confiderable as in phlegmon, nor is it of that kind, which produces adhefions among the inflamed parts. Indeed, fince eryfipelas feldom ends in fuppuration, fuch adhefions, according to Mr. Hunter's view of the fubject, would in general be unneceffary. Perhaps, alfo, the circumftance of there being no adhefions in eryfipelatous cafes, may account for the terrible diffufion of mifchief, which always happens, when abfceffes do occafionally take place. Then, we know, that the matter makes its way extenfively through the cellular fubftance, in every direction under the fkin, under fafciæ, and between the mufcles, producing, wherever it goes, what has been often named a gangrenous fuppuration. When eryfipelas is of an unmixed kind, it has not the dark red colour which common inflammations have, but a lighter red, with a yellow tinge, which is particularly obfervable towards the termination of the diforder. The fwelling which occurs is unattended with any remarkable induration, and forms a very inconfiderable prominence. The fkin of the inflamed part has a fhining appearance, and, on being touched with the finger, turns white at the fpot where the preffure is made; but the bright red colour immediately afterwards returns. The pain is ufually of a burning, fhooting defcription, and the patient frequently complains of a fort of itching, which is found to be particularly annoying. The fwelling, which happens in cafes of eryfipelas, is not only not fo hard and elevated as that which arifes in examples of phlegmonous inflammation, it is at the fame time not fo clearly circumfcribed.

Another remarkable feature of eryfipelas, is the manner in which this inflammation often changes its fituation, by getting well on one fide, while it is fpreading in fome other direction. The great celerity with which the affection fpreads, and the large furface which it in a very little while covers, may alfo be fet down among its moft ftriking peculiarities.

When the affection is intimately dependent on the ftate of the conftitution, we very often fee all the local fymptoms recede in one place, and the difeafe make its attack in fome other part of the body. Such inftances are not unfrequently mentioned by writers as *metaftafes*, juft as if it were a real fact, that, when the eryfipelatous fymptoms get well on one leg, and the other leg becomes affected in a fimilar way, thefe events happen, in confequence of the firft identical difeafe actually moving from one limb to the other. From this abfurd doctrine originates all the cant about the danger of ufing fuch applications as are likely to repel the inflammation. The truth is, that the fecond attack of the eryfipelas is not at all connected with the termination of the firft; but arifes from fome different, and probably inexplicable caufe, juft as encyfted tumours will often form, one after another, in various parts of the body, as regularly as they are cut out. In this latter inftance, no one is abfurd enough even to fufpect that the growth of one tumour is the effect of a previous one being cured.

In true eryfipelas, there is no throbbing of the part affected, as in cafes of phlegmon; and when eryfipelatous inflammation runs along the fkin, the affection has a determinate edge, and does not lofe itfelf gradually and infenfibly in the furrounding parts, as common inflammation does.

The alteration which the fkin undergoes in eryfipelas confifts in its feeling at the part affected lefs pliable than in the natural ftate, and a little thickened.

Such are the ordinary local fymptoms of eryfipelas. They are fubject, however, to fome variety, depending on the mildnefs or violence of the attack, and on the circumftance of the diforder being either fimple, or complicated with another affection; for inftance, œdema, phlegmon, &c.

With refpect to violence, eryfipelas may be very properly divided into three degrees. In the firft, or mildeft form of the complaint, the eryfipelas makes its appearance, without any preceding illnefs, or with only a flight indifpofition of fhort duration, and confifting of laffitude, difturbed fleep, lofs of appetite, &c. Thefe complaints very foon go off, when the eryfipelas comes out, which happens in about a couple of days. For two days more the local fymptoms remain the fame, and then the eryfipelas turns pale and yellow, gradually difappearing altogether, with a detachment of the cuticle. During the whole courfe of the diforder there is no fever of any confequence; but a little while before the rednefs occurs the pulfe is fometimes rather difturbed.

In the fecond, or more fevere degree of the diforder, the patient is troubled, about two days before the eryfipelas makes its appearance, with an unufual proftration of ftrength, heavinefs in all his limbs, head-ach, lofs of appetite, naufea, and even actual vomiting, complaints in the ftomach, &c. Befides thefe inconveniencies, the patient is affected with a fever, and all its ufual fymptoms. After a couple of days, commonly on the third day from the commencement of all indifpofition, the eryfipelas comes out, attended with a gentle fweat, and a moderate increafe in the fecretion of urine, after which circumftances the fever, with all its attendant fymptoms, goes off. The reft of the progrefs of the cafe is fimilar to what we have related, as happening in the firft, or mildeft attack of eryfipelas.

In the third, or moft violent degree of the diforder, particularly in thofe cafes in which eryfipelas makes its attack on the face, the patient is affected with fevere febrile fymptoms, head-ach, lofs of fleep, delirium, ficknefs, &c. Thefe complaints do not diminifh, as in the milder cafes of eryfipelas, when the local rednefs, heat, &c. take place on the third day; but continue with unabated vehemence, until the eryfipelas itfelf fubfides. The laft defirable event commonly happens, according to Richter, on the eleventh day, accompanied with an increafe in the fecretions from the fkin and kidnies.

The moft dangerous cafes of eryfipelas are thofe in which the face is affected. Of this form of the diforder, the celebrated Cullen has left us a matchlefs defcription, which we think is highly deferving of infertion in this Cyclopædia. The eryfipelas of the face, (fays this interefting author,) comes on with a cold fhivering, and other fymptoms of pyrexia. The hot ftage of this is frequently attended with a confufion of head and fome degree of delirium; and almoft always with drowfinefs, or perhaps coma. The pulfe is always frequent, and commonly full and hard.

When thefe fymptoms have continued for one, two, or at moft three days, there appears on fome part of the face a rednefs, fuch as that of erythema. This rednefs at firft is of no great extent; but, gradually fpreads from the part it firft occupied, to other parts of the face, commonly till it has affected the whole; and frequently from the face it fpreads over the hairy fcalp, or defcends on fome part of the neck. As the rednefs fpreads it commonly difappears, or, at leaft decreafes in the parts it had before occupied. All the parts upon which the rednefs appears are at the fame time affected with fome fwelling, which continues for fome time after the rednefs has abated. The whole face becomes confiderably turgid; and the eye-lids are often fo much fwelled, as entirely to fhut up the eyes.

To

To continue Dr. Cullen's account: when the rednefs and fwelling have proceeded for fome time, there commonly arife, fooner or later, blifters of a larger or fmaller fize on feveral parts of the face; thefe contain a thin yellowifh, or almoft a colourlefs liquor, which fooner or later runs out. The furface of the fkin in the bliftered places fometimes becomes livid and blackifh, but this livor feldom goes deeper than the furface, or difcovers any degree of gangrene affecting the fkin. On the parts of the face not affected with blifters the cuticle fuffers, towards the end of the difeafe, a confiderable defquamation.

Sometimes the tumours of the eye-lids end in a fuppuration.

The inflammation coming upon the face does not produce any remiffion of the fever which had before prevailed; and fometimes the fever increafes with the increafing and fpreading inflammation.

The inflammation ufually continues for eight or ten days; and, for the fame time, the fever and fymptoms attending it alfo continue.

In the progrefs of the inflammation, the delirium and coma attending it fometimes go on increafing, and the patient dies apoplectic, on the feventh, ninth, or eleventh day of the difeafe. In fuch cafes, it has been commonly fuppofed that the difeafe is tranflated from the external to the internal parts. But, Dr. Cullen obferves, that he never met with any inftance in which it did not appear to him, that the affection of the brain was merely a communication of the external affection, as this continued increafing at the fame time with the internal.

When the fatal event does not take place, the inflammation, after having affected a part, commonly the whole of the face, and, perhaps, the other external parts of the head, ceafes. With the inflammation the fever alfo ceafes; and, (fays Cullen,) without any evident crifis, the patient returns to his ordinary ftate of health.

The fame diftinguifhed writer reprefents the difeafe as being not commonly contagious; but he conceived it poffible that it might fometimes be communicated from one perfon to another; and, he adds, that perfons who have once laboured under the diforder are liable to returns of it.

According to Cullen, the event of the difeafe may be forefeen from the ftate of the fymptoms which denote more or lefs affection of the brain. If neither delirium nor coma comes on, the difeafe is feldom attended with any danger; but when thefe fymptoms appear early in the difeafe, and are in a confiderable degree, the utmoft danger is to be apprehended.

We have already remarked that, in cafes of eryfipelas, fuppuration does not frequently happen; but that when it does, owing to the matter not being confined by the adhefive inflammation, very bad confequences follow. Wherever the matter fpreads, it occafions under the fkin an extenfive floughing of the fafciæ, tendons, and cellular fubftance, all which kind of mifchief may take place, while the fkin itfelf, which is very vafcular and highly organized, remains unimpaired in its texture. This combination of fuppuration and mortification is more likely to happen when the eryfipelatous inflammation extends to a greater depth than common, fo as to affect the cellular membrane. In this ftate, as Mr. Hunter has well defcribed, air, matter, and floughs, are all produced together under the fkin, and, on handling the part, a ftrange feel is communicated, neither like that of a fluctuation, or a crepitation. Mr. John Pearfon very whimfically, we will not fay unaptly, compares the fenfation with that excited by a quagmire or morafs. Frequently, the practitioner may obferve in fome opening, made either by ulceration or the lancet, a fmall black floughy point, and, on taking hold of it with a pair of forceps, and drawing it out, he finds, to his great furprife, that a whole mortified tendon, of confiderable length, follows his inftrument.

Eryfipelas is to be met with more frequently in fummer than winter, and more commonly in hofpitals than other places. Wounds of the head, oftener than any other kind of accident, give rife to the diforder.

Eryfipelas has fometimes been obferved on the fkin of new-born infants. Several inftances of this kind are mentioned in the Medical Communications, as having occurred in the Britifh Lying-in-Hofpital. In one of thefe examples, the child was born with its whole face fwelled and inflamed, the left fide being affected with a true eryfipelas. There was alfo an inflammation on the legs, feet, and left hand. On each tibia, there appeared an oblong flough, of a dark brown colour, almoft livid; the one on the left leg was exceedingly large. The cure was attempted by employing embrocations, emollient poultices, and fomentations, and applying camphorated fpirit of wine. This child appears to have fwallowed the decoction of bark with great eafe, as it took four ounces of it every day from the very time of birth. In three days the fwelling of the face and other parts had confiderably fubfided; but, on the third day, a vefication began to form on the left cheek, and another juft above the eye-brow, on the fame fide. Thefe vefications increafed in number and fize, efpecially on the legs, where they extended over the whole limb. Some confectio cardiaca was added to the decoction of bark, and pledgets, dipped in oil of turpentine, were put on all the parts affected, previoufly to the application of the poultice. The vefications began to break on the fixth day, and a fanies to iffue from them; yellow floughs alfo now made their appearance in different parts. The child feemed much debilitated, and, for the laft three or four days, had taken eight ounces of the decoction of bark, with one dram of the confectio cardiaca every twenty-four hours. The pledgets, applied to the fores, were dipped in a digeftive ointment, with oil of turpentine, and fome cataplafm e cymino. Under this mode of treatment, the floughs were foon detached, and the child recovered, though not without the lofs of the little finger, two joints of the ring finger, and one of the middle one.

The diftemper, which we have juft been defcribing, for fome time proved extremely fatal, none of the infants recovering who were attacked. However, bark is ftated to have acted quite as a fpecific remedy for the difeafe, as foon as it was tried, and almoft all the children are faid to have got well who took this medicine. Mortification always took place in fuch fubjects as died; and the danger was regularly obferved to be the greateft in the inftances in which the genitals were the parts firft attacked. The difeafe was alfo noticed to affect the children of weakly women, and of fuch as were addicted to drinking fpirits.

To return, however, to our account of the common forms of eryfipelas, we have to apprife the reader, that the term "St. Anthony's fire," which is fo frequently mentioned by all forts of perfons, is ftrictly applied by medical writers and practitioners to that fpecies of the affection in which veficles arife upon the furface of the fkin; while other inftances, not accompanied with vefications, are named *fimple* eryfipelas.

The divifion of the fubject, however, cannot be properly comprehended under thefe two varieties; and the generality of authors have found it neceffary to obferve other diftinctions.

Mr.

Mr. Pearſon, in his Principles of Surgery, has noticed the following ſpecies of the complaint:

1. The acute eryſipelas.
2. The œdematoſe eryſipelas.
3. The malignant, or gangrenous eryſipelas.

Each of theſe ſpecies may be an idiopathic, or ſymptomatic diſeaſe.

Mr. Pearſon remarks, that the acute eryſipelas is moſt commonly ſeen in thoſe of a ſanguine and choleric temperament; it is generally ſudden in its attack, and uſually affects the face. Febrile ſymptoms are often preſent immediately after the acceſſion of the diſeaſe; but they gradually diminiſh as the eryſipelas becomes more diſtinctly formed. Conſiderable heat, and great uneaſineſs, take place in the part affected; the ſkin is alſo of a brighter ſcarlet colour than in the other ſpecies. If puſtules appear, they are diſtinct; but ſometimes there are no veſications on the ſurface.

Suppuration very rarely occurs in this kind of eryſipelas, and the violence of the diſeaſe commonly ſubſides in three or four days; the part then grows yellowiſh, and throws off furfuraceous ſcales. The diſeaſe terminates about the tenth day. A tenderneſs of the hairy ſcalp will often continue for a conſiderable time after the diſeaſe has diſappeared.

The acute eryſipelas, as we have already obſerved, is ſometimes an idiopathic affection; frequently it is ſymptomatic, or, in other words, the conſequence of a wound, eſpecially one of the head. Perſons who have once been attacked with the acute eryſipelas, in a ſpontaneous manner, are particularly liable to ſuffer again from future attacks of the ſame diſorder.

Mr. Pearſon ſtates, that the œdematoſe eryſipelas is not, in general, ſo ſudden in its attack, nor ſo ſevere on its acceſſion, as the acute eryſipelas. The diſeaſe increaſes gradually, is more diffuſed, and is attended with leſs burning pain. If febrile ſymptoms ſhould ariſe, they never run high, nor are they of long duration; moſt commonly the ſtrength is depreſſed, attended with a ſoft, frequent, perhaps, irregular pulſe. In this ſpecies of eryſipelas no conſtitutional relief is derived from the appearance of the local affection: on the contrary, the danger increaſes with the progreſs of the external diſeaſe.

When the face is the ſeat of the œdematoſe eryſipelas the whole countenance has a bloated appearance. The red colour of the ſkin is mingled with yellow or brown, and the complaint is attended with ſhiverings, vomiting, and more or leſs diſturbance of the functions of the brain. Mr. Pearſon further remarks, that the veſications are often ſmall and numerous, and, that when they have been expoſed for a few days to the air, the countenance becomes covered with a dark-coloured cruſt, very much reſembling the appearance which ariſes in the confluent ſmall-pox. Though the face is very much ſwelled, it is not firm to the touch, and eaſily yields to preſſure.

The œdematoſe eryſipelas is deemed highly dangerous. Patients often die, in a delirious or comatoſe ſtate, about the ſeventh day, ſometimes a little later.

It is common to ſee many people afflicted with this ſpecies of eryſipelas about the ſame time. Mr. Pearſon informs us, that, in hoſpitals, he has ſeen ſeveral perſons ſucceſſively attacked with the complaint in the ſame ward. Some conjectures have been entertained of the diſorder being contagious.

All ages and conſtitutions may be affected with the œdematoſe eryſipelas. However, ſubjects weakened by age, or intemperance, are moſt frequently attacked. Dropſical patients, children, and new-born infants, are alſo ſeen affected with the complaint.

According to Mr. Pearſon, the œdematoſe eryſipelas, when ſymptomatic, is much leſs dangerous than when idiopathic; but, ſays this author, whenever the face is conſiderably affected, the diſeaſe is always to be regarded as a ſerious one, whatever be the remote cauſe. On the limbs it is ſeldom dangerous, or very afflicting, unleſs treated in an improper way. Mr. Pearſon mentions his having ſeen the œdematoſe eryſipelas make its firſt appearance upon the face, and, by a gradual and regular progreſſion, proceed downward to the extremities, ſucceſſively appearing upon an inferior portion of the body, as it diſappeared from a ſuperior part. Each renewed acceſſion of the complaint was leſs and leſs ſevere, as it receded to a greater diſtance from the part that was primarily affected.

The malignant, or gangrenous eryſipelas, makes its firſt appearance ſomewhat like the œdematoſe form of the diſorder. Its progreſs, however, is much quicker. Phlyctenæ, with a livid baſe, ſoon occur on the ſkin, together with gangrenous ſymptoms. The diſeaſe, at a very early period, becomes attended with a ſtate of the conſtitution, reſembling that which exiſts in putrid fevers.

The gangrenous eryſipelas moſtly occurs on the face, neck, breaſt, and ſhoulders: the danger of the diſeaſe depends very much on the ſtate of the conſtitution.

When an eryſipelatous inflammation, particularly one of the legs has been cured, a degree of œdema will frequently continue about the lower part of the limb for ſome time afterwards.

Eryſipelatous inflammation differs from phlegmon in the following reſpects. The ſwelling is leſs prominent; and is never diſtinctly circumſcribed. The ſkin often has the appearance of being ſcorched, or burnt. The redneſs is quite circumſcribed, has a very determinate edge, is frequently tinged with yellow, and, on being touched with the end of the finger, a white ſpot is produced for a ſhort time in the place where the preſſure was made. The pain is not of the lancinating, throbbing kind, which attends phlegmonous inflammation; but is ſuch as cauſes a ſenſation of a great heat and burning in the part, together with a violent degree of itching. The part affected does not preſent the feel of, what ſurgeons underſtand by, tenſion; but only ſeems to the touch as if the ſkin were a little thickened. Except in the acute eryſipelas, there is no hardneſs of the pulſe, as in caſes of phlegmon, and inſtead of being attended, as the latter affection, with rather an increaſe of ſtrength, eryſipelas is almoſt always accompanied with more or leſs debility.

With reſpect to the cauſes of eryſipelas our knowledge is very imperfect, and every obſervation on this ſubject muſt be received with doubt. We do not mean to ſtate, that the remote cauſes are not very often ſufficiently obvious. We frequently have occaſion to remark, in the practice of ſurgery, that certain punctured wounds, and injuries of the external parts of the head give riſe to eryſipelas. Indeed, we may ſtate, as a general remark, that the ſame claſs of irritations, termed *remote* cauſes, which in one conſtitution would occaſion phlegmonous inflammation, in another would excite eryſipelas. What is far more difficult of inveſtigation, is the cauſe why eryſipelas ſhould take place rather than common inflammation; in other words, the exact particularity, to which the origin of eryſipelatous inflammation is to be aſcribed, is involved in much more obſcurity. Sometimes even the remote cauſe cannot be diſcovered, the affection having the appearance of originating in a ſpontaneous manner.

It

It was one of the ancient doctrines, eftablifhed by Galen, and maintained down to the prefent time, that what is underftood by a bilous habit is particularly fubject to eryfipelatous inflammation. Many parts of the writings of the celebrated Pott, the experienced Richter, and other noted modern writers, evince their belief in this opinion.

Weak and irritable conftitutions appear to us to be moft fubject to eryfipelas; while ftrong, plethoric perfons moft frequently undergo common phlegmonous inflammation. We think, that there is every reafon to believe, that, in general, eryfipelas is intimately dependant on the ftate of the conftitution, or on fome peculiarity of temperament. This opinion is fomewhat confirmed by the fact, that while perfons, who lead drunken, intemperate lives, are particularly often afflicted with eryfipelatous inflammation, in confequence of local injuries, other people, who lead more regular lives, generally have phlegmonous inflammation after fimilar injuries.

It muft be admitted, however, that eryfipelas occafionally makes its appearance in conftitutions with which we can find no evident fault. Indeed, Hunter feems to have confiderable reafon for his inference, that the affection may, in fome inftances, be altogether independent of conftitutional caufes, fince it is the common courfe of the difeafe to be actually getting well on one fide as faft as it is fpreading on another.

If we can fometimes affign particular circumftances, which operate as caufes conducive to eryfipelas, it is all that we can hope to do. To trace the proximate caufe in every example which prefents itfelf, is far beyond our pretenfions; neither do we believe that it is to be done by the powers of human refearch. We might adopt the language of Cullen, and talk of eryfipelas depending "on a matter generated within the body, and thrown out, in confequence of fever, upon the furface of the body." We might alfo join Mr. Pearfon in reprefenting eryfipelas as being fometimes the "critical termination of another difeafe, fuch as obftructed menftruation, quartan ague, fupprcffed fuppuration, fpafmodic and convulfive difeafes." However, we fhould fhew juft as much devotion for truth, were we to offer any other wild, vague fuppofitions, unfupported by rational evidence.

Lefs afpiring in our attempts, we fhall only aim at pointing out circumftances which feem to act as caufes, conducive to the diforder, in fome inftances. If many women of temperate lives, and young children, are occafionally affected with eryfipelas, as they undoubtedly are, the fact only proves, that there are other caufes befides intemperance which may be concerned in giving rife to the complaint. The fources of the difeafe muft, we believe, on fome occafions, be regarded as among the myfterious and inacceffible fecrets of nature. When drunkennefs and other kinds of intemperance are affigned as caufes conducive to eryfipelas, it is not meant that they are exclufively fo. There are, probably, hundreds of other caufes in exiftence, though we may not be able to detect them.

With regard to women of temperate regular lives, and to children being occafionally affected with eryfipelatous inflammation, the fact cannot be called in queftion. But, ftill, no experienced man will contend that fuch fubjects are attacked with eryfipelas, on meeting with local injuries, half fo frequently as perfons with conftitutions impaired by any kind of intemperance, habits, or modes of life.

Richter and fome other writers, have defcribed eryfipelas as depending very much on a fuppreffed ftate of the perfpiration; but we are inclined to think that they have afcribed the importance of a caufe to a mere effect of the fever, with which eryfipelas is connected.

Treatment of the acute, or phlegmonous eryfipelas.—This fpecies of the difeafe being commonly attended with a full, and frequently a hard pulfe; the blood drawn fhewing upon its furface the buffy coat to be feen in all inflammatory complaints; and laftly, the fwelling of the eyelids, frequently ending in fuppuration; there can be no doubt, that the affection fhould be treated very much in the fame manner as phlegmonous inflammation. Blood-letting, cooling purgatives, and every part of the antiphlogiftic regimen, are advifed by Cullen, who affirms, that his experience had confirmed the fitnefs of this method of cure.

The evacuations of blood-letting and purging are to be employed, more or lefs, according to the urgency of the fymptoms, particularly the febrile ones, and thofe which mark an affection of the brain.

Although Mr. Pearfon mentions general and topical bleeding as being indicated in the treatment of the acute eryfipelas, yet he obferves, that cafes very rarely occur in large towns where bleeding is at all admiffible, and a repetition of the operation can very feldom be proper.

Profeffor Richter ftrongly praifes the good effect of emetics on eryfipelas; but fome other writers, probably in a ftrain of ignorance, or prejudice, reprefent fuch medicines as having fometimes occafioned fatal confequences.

Another indication is to promote a gentle degree of perfpiration. For this purpofe, we may exhibit fmall dofes of the antimonium tartarifatum, or the pulvis ipecacuanha comp., æther vitriolicum; faline draughts with volatile alkali, &c.

Opium and camphor are alfo proper remedies for allaying irritation.

Whoever has been in the habit of confulting the writings of feveral celebrated medical authors, will perceive that they place great reliance in bark, as a medicine tending very powerfully to check and cure eryfipelatous inflammations. When we mention Mr. John Hunter among fuch authors, our readers will be inclined, perhaps, to fufpect that there muft be fome foundation for the repute into which this medicine has rifen for the complaints under confideration. However, we muft confefs our own belief, that bark gained credit for its good effects on eryfipelas entirely in confequence of the general enthufiafm which once depicted it as a cure for almoft every difeafe of the human frame. The fentiment is corroborated, if not confirmed, by the fact, that the beft modern practitioners feem now to confider bark no longer of eminent fervice in cafes of acute eryfipelas.

With refpect to local applications, in thefe inftances, feveral kinds have been ufed by different practitioners. Cold aftringent lotions, oily fubftances, rubefacients, farinaceous, or earthy powders, and emollient poultices, have all been tried. As far as our experience extends, the lotio aquæ lithargyri acetati is as good an application as can be made to a part affected with the acute fpecies of eryfipelas. However, it becomes us to apprife the reader, that the majority of medical writers beftow the greateft praife on the employment of dry mealy powders, fuch as flour, ftarch, &c. for topical remedies, with which the inflamed part is to be covered.

Mr. Pearfon, ftrangely enough, fpeaks in favour of rubefacients, as if the fkin were not already reddened enough by the difeafe; but referves his higheft recommendations for mild warm poultices. Let the furgeon, however, confider the ill confequences and terrible mifchief which always occur when fuppuration fupervenes, and let him beware of the injudicious plan of promoting the latter event.

Treatment of the œdematofe eryfipelas.—In this cafe topical bleeding may be practifed; but venefection is hardly ever allowable. The bowels ſhould be kept open with ſaline purgatives of the mildeſt deſcription, and a gentle perſpiration ought to be excited, by means of ſmall doſes of tartariſed antimony, the pulvis ipecacuanha comp., &c. For the purpoſe of appeaſing pain and irritation, the practitioner may preſcribe camphor, opium, æther, &c.

When the patient's conſtitution is in a debilitated condition, tonics are indicated, together with the moſt nouriſhing food. Bark, wine, porter, brandy, the confectio aromatica, may now be found of the utmoſt ſervice.

Treatment of the malignant or gangrenous eryſipelas.—Little need be ſaid here on this ſubject, as the mode of treatment is the ſame as that of mortification in general. See GANGRENE.

The grand objects are; to ſupport the patient's ſtrength; to cover the parts affected with emollient poultices; to foment them two or three times a day with a decoction of poppy-heads; to make depending openings for the eſcape of the matter and ſloughs; and remove the dead parts, as ſoon as it can be done without occaſioning the leaſt irritation and pain.

We have frequently ſeen the gangrenous miſchief ſo extenſive in theſe caſes, that amputation of the limb was the only means of ſaving the patient from deſtruction. See Richter's Anfangſgründe der Wundarzneykunſt. Band i. Von der Roſe. Pearſon's Principles of Surgery. Cullen's Firſt Lines of the Practice of Phyſic. Cooper's Firſt Lines of the Practice of Surgery.

ERYSIPHE, in *Agriculture*, a term applied by ſome to that vegetable diſeaſe generally known by the name of mildew. See MILDEW.

ERYSTHIA, in *Ancient Geography*, a town of the iſland of Cyprus. Steph. Byz.

ERYTHEIA, an iſland of Iberia, in the ocean. According to Strabo, it was ſeparated from the continent by a large ſtrait of a ſtadium, or, according to Pliny, of 100 paces. It was near Gades. Its name was derived from the Phœnicians, who, having inhabited the banks of the Erythrean ſea, came to ſettle here. It was alſo called *Aprodiſias*, or the iſle of Venus, and the iſle of Juno. See GADES.

ERYTHE'MA, in *Surgery*, (from ερυθος, *red.*) The celebrated Cullen diſtinguiſhed two claſſes of eryſipelatous inflammations. When the diſeaſe was an affection of the ſkin alone, and very little of the whole ſyſtem, or when the affection of the ſyſtem was only ſymptomatical of the external inflammation, he called the diſeaſe *erythema;* but when the external inflammation was an exanthema, and ſymptomatical of an affection of the whole ſyſtem, he named the diſeaſe *eryſipelas*, which ſee.

"An Erythema, Roſe, or St. Anthony's Fire, (ſays Dr. Cullen) is an inflammatory affection of the ſkin, with hardly any evident ſwelling; of a mixed, and not very bright red colour, readily diſappearing upon preſſure, but quickly returning again; the redneſs of no regular circumſcription, but ſpreading unequally, and continuing almoſt conſtantly to ſpread upon the neighbouring part; with a pain like to that from burning; producing bliſters, ſometimes of a ſmall, ſometimes of a larger ſize, and always ending in a deſquamation of the ſcarf-ſkin, ſometimes in gangrene."

We need not enlarge on the ſubject of erythema, in the ſenſe of an eryſipelas not originating from a conſtitutional affection, as every uſeful information, concerning eryſipelatous inflammations in general, is to be found in the article ERYSIPELAS.

The chief object which we have in view in the preſent part of this work is to deſcribe a particular affection of the ſkin, named, in conſequence of its being occaſioned by the uſe of mercury, the *mercurial erythema*, or *eczema*.

It was perhaps, for the firſt time, diſtinctly noticed and deſcribed by Mr. Benjamin Bell in his Treatiſe on the Venereal Diſeaſe. "It is not an uncommon effect of mercury (ſays this author) to excite an eruption upon the ſurface of the body. In ſome, this appears as a miliary raſh, ſomewhat reſembling meaſles; while in others it is conſiderably elevated, and ſeems to be produced by a ſerous effuſion between the cutis and ſcarf-ſkin. In ſome the eruption is partial, being confined to particular ſpots; while in others it prevails generally over the whole body.

"This eruption, or efflorescence, is not attended with pain; but the heat and itchineſs which accompany it are, in ſome inſtances, ſo diſtreſsful, that it keeps the patient at all times very uneaſy, and deprives him entirely of reſt.

"The remedies, (obſerves Mr. B. Bell) which I have found to anſwer the beſt, are the internal uſe of opiates, conjoined with the application of flour or ſtarch-powder to the parts affected. The ſkin is kept ſufficiently cool and eaſy by one or the other of theſe powders being from time to time freely applied to the eruption; and, by a proper exhibition of opiates we ſecure reſt during the night. In ſome inſtances, however, we are obliged to avoid the uſe of opiates; for although they may anſwer the purpoſe of procuring ſleep, they tend evidently to increaſe the heat and itchineſs of the eruption. We find, indeed, that, in ſome conſtitutions, opium excites an uneaſy itchy ſenſation over the whole body, even where an eruption has previouſly taken place: and it is, perhaps, with ſuch patients only, that it cannot be employed in the treatment of this eruption.

"The eruption to which I allude, (adds Mr. Bell,) appears to ariſe entirely from the effect of mercury upon the ſyſtem; but it does not ſeem to depend upon any particular preparation of the remedy. It takes place indiſcrimately from all of them; and not more readily from unction than from thoſe preparations that are uſed internally." See a Treatiſe on Gonorrhæa Virulenta and Lues Venerea; by B. Bell, vol. ii. p. 228.

Since this gentleman publiſhed the foregoing work, the mercurial erythema has excited conſiderable attention, and ſeveral writers, *viz.* Drs. Moriarty, M'Mullin, and Spens, and Meſſrs. Alley and Pearſon, have endeavoured to render our knowledge of the ſubject more extenſive.

Dr. M'Mullin judiciouſly obſerves, that eruptions of various kinds are very common ſymptoms of ſyphilis, but a very unuſual effect of mercury. Hence, until the real nature of the mercurial erythema was aſcertained, whenever the affection occurred in patients undergoing a mercurial courſe for ſyphilitic complaints, it was naturally enough conſidered as an anomalous form of lues venerea. The mercury was conſequently puſhed to a greater extent, in proportion to the violence of the ſymptoms, and from the cauſe of the diſeaſe being thus unconſciouſly applied for its removal, it could not fail to be aggravated, and hurried on to a fatal termination. At length, the obſervation of this fact, and of another truth, that a ſimilar eruption did ſometimes appear in patients who were uſing mercury for other complaints, and in whom no ſuſpicion of ſyphilis could be entertained, led to the important diſcovery that the eruption was entirely an effect of mercury, and not at all connected with the original diſeaſe.

Dr. M'Mullin imputes the firſt explanation of the nature of the mercurial erythema to Drs. Moriarty and Spens, and Mr. George Alley, all which writers publiſhed in the courſe of the ſame year, *viz.* 1804. However, the paſſage which we have quoted above, from Mr. B. Bell's work on the

the venereal difeafe, clearly evinces that though the above gentlemen have undoubtedly great merit in having increaf.d our information concerning the difeafe, yet the latter writer had noticed the affection before them. Indeed, Dr. Spens has had the liberality to make this acknowledgment himfelf.

According to Dr. M'Mullin, the different appearances which this difeafe affumes, from its feverity and duration, may be beft underftood by defcribing it as confifting of three diftinct ftages. The firft ftage, fays this gentleman, commences with languor, laffitude, and cold fhiverings. Thefe fymptoms are fucceeded by increafed temperature of the body, quick pulfe, naufea, head-ach, and thirft. The patient is troubled with a dry cough, and complains of difficult refpiration, anxiety, and fenfe of ftricture about the præcordia. The tongue is ufually moift, and covered with a white glutinous flime. It fometimes appears clean and of a bright red colour in the centre, while the margins remain foul. The fkin feels unufually hot and itchy, with a fenfe of prickling, not unlike the fenfation experienced from the application of nettles. The belly is generally coftive; but a diarrhœa is often produced by very flight caufes.

To continue Dr. M'Mullin's defcription: on the firft, or fecond day, an eruption moft commonly appears, the colour of which is either dark or bright red. The papulæ are at firft diftinct and elevated, very much like thofe which occur in rubeola. Sometimes, but not often, the eruption appears like urticaria, and in fuch inftances the difeafe is obferved to be very mild. The papulæ very fpeedily run together in fuch a manner as to form a fuffufed rednefs, which difappears on preffure. In moft cafes, it firft begins on the fcrotum, infide of the thighs, fore-arm, or where mercurial frictions have been made, and the fkin of the parts affected becomes confiderably fwollen. Inftances have alfo been feen in which an eruption of a purplifh colour, and accompanied by papulæ, has fuddenly diffufed itfelf over the whole body. (See Moriarty on Lepra Mercurialis.) Dr. M'Mullin remarks, however, that the latter form of the affection may be confidered as uncommon. In every inftance which Dr. M'Mullin has feen the eruption was at firft confined to a few places, and thence gradually extended, until the different portions of the eruption had united. The papulæ were alfo rough to the feel. But, in fuch cafes as refemble urticaria, many minute veficles, interfperfed among the papulæ, and containing a ferous fluid, make their appearance from the very firft. Contrary to what happens in moft difeafes, accompanied with cutaneous affections, the febrile fymptoms are much aggravated, and continue to increafe, after the eruption is complete. The pulfe in general beats from 120 to 130 in a minute, the thirft continues urgent, and the patient, who is extremely reftlefs, feldom enjoys quiet fleep. Dr. M'Mullin further informs us, that when the eruption has continued in this manner, for a certain period, the cuticle begins to peel off in thin, whitifh, fcurfy exfoliations, not unlike thofe obferved in rubeola. This defquamation firft begins where the eruption made its earlieft appearance. and in this order fpreads to other parts. About this period the fauces become fore, the tongue fwells, and the eyes appear fomewhat inflamed.

The duration of this ftage is very various; fometimes it continues from ten to fourteen days, and in other cafes it terminates in half that time. When the difeafe has appeared in its mildeft form, the patient recovers immediately after this defquamation, a new cuticle having formed underneath. When the difeafe is fevere, however, he has only experienced the fmalleft part of his fufferings, and the fkin now affumes a new appearance, which Dr. M'Mullin has confidered as the fecond ftage.

This author reprefents the fkin as appearing at this period as if ftudded with innumerable minute veficles, which are filled with a pellucid fluid. Thefe veficles (he obferves) may be expected, if the patient, at the clofe of the firft ftage, fhould complain of increafed itching, and a fenfe of a burning heat in the parts, from which the cuticular exfoliations have fallen. The veficles fometimes remain for a day or two; but in general they are burft immediately after their formation, by the patient rubbing the parts, in order to relieve the troublefome itching which he fuffers. A ferous acrimonious fluid is difcharged. which poffeffes fo difagreeable an odour, that it induces naufea in the patient himfelf, and thofe who approach his bed-fide. The fmell is faid to be fo peculiar, that it can be eafily recognifed by any perfon who has once perceived it. Dr. M'Mullin ftates, that this fluid is poured out moft copioufly from the fcrotum, groin, infide of the thighs, or wherever the fkin forms folds, and febaceous glands are moft numerous. The ferous difcharge from the veficles forms, with the cuticle, incruftations, which Dr. M'Mullin regards as the criterion of the third or laft ftage.

The fame writer obferves, that the crufts are generally very large, and when detached retain the figure of the parts from which they have fallen. Their colour is in general reddifh, but it fometimes appears dark and dirty. Dr. M'Mullin conceives, that this period of the difeafe might be termed, with much propriety, the ftage of *decruftation*, in order to diftinguifh it more fully from the *defquamation*, which has been already noticed. When the ftage of decruftation appears, the fauces become more affected, the eyes intolerant of light, and the tarfi tender, inflamed, and fometimes turned inward. The crufts formed on the face, as in other parts of the body, before falling off, break fo as to leave cracks and fiffures, which horridly deform the countenance; and in confequence of the great fwelling of the face the eye-lids are alfo completely clofed. The back and hairy fcalp are faid to be the parts moft backward in becoming affected, and, according to Dr. M'Mullin's account, they even fometimes efcape entirely in very fevere cafes.

In this ftage of the mercurial erythema the patient is under the neceffity of avoiding every kind of motion, on account of the pain which it occafions, and which he compares with fuch a fenfation as one may fancy would be produced by a cracking of the flefh. The crufts alfo fall off in fuch abundance, that the bed feems as if ftrewed with the cones of hops.

While the eruption is only making its appearance in one place, it may have attained its moft advanced form in another part, fo that all the different ftages of the difeafe may be prefent at one time, in the fame individual.

Typhus prevails throughout the whole courfe of the complaint; but, what is curious, the appetite continues in moft cafes unimpaired, and fometimes is even voracious.

Dr. M'Mullin alfo remarks, that when the catarrhal fymptoms have continued during the progrefs of the complaint, they are particularly aggravated in the advanced ftage of the cafe. The anxiety and pain in the breaft are likewife ftated to be very fevere, attended with cough and bloody expectoration, the patient invariably feeling languid and dejected. The pulfe becomes frequent, feeble, and irregular; the tongue black and parched; and, at length, diarrhœa, delirium, convulfions, gangrene of the furface of the body, and death, enfue.

The

The mild form of the diſeaſe only goes through the firſt ſtage, and ends, as we have already deſcribed, in a ſlight deſquamation, after a few days. When the affection is ſevere, however, it is often protracted more than two months, every ſtage of the eruption continuing proportionably longer; and when, in this manner, it has run its courſe, it repeatedly breaks out on the new ſurface, and paſſes through the ſame ſtages.

For the preceding hiſtory of the ſymptoms of the mercurial erythema, we feel ourſelves highly indebted to Dr. M'Mullin. See Edinburgh Medical and Surgical Journal, vol. ii. p. 25, &c.

With the exception of one caſe, which Dr. Rutter has inſerted in the eighteenth number of the journal juſt now mentioned, we have no inſtance recorded, in which the preſent diſorder originated, without the patient being under the influence of mercury. Whether Dr. Rutter's example is to be conſidered as the ſame identical diſeaſe as the one which we have been deſcribing, we ſhall not undertake to inveſtigate. We ſhall only obſerve, that ſince it is very poſſible to miſtake other complaints for the real mercurial erythema, we do not conſider one ſolitary fact, reſting on the judgment of an individual, who might differ in opinion concerning the nature of the diſeaſe, with the next medical practitioner conſulted, a ſufficient ground for implicitly believing, that ſuch a diſeaſe as the mercurial erythema can be produced quite independently of the uſe of mercury.

In certain habits, every preparation of mercury, and every form of employing this medicine, ſeem capable of bringing on the diſeaſe. As the complaint was firſt taken notice of in patients who were afflicted with ſyphilis, it was ſuppoſed to be an anomalous form of the venereal diſeaſe. But, at laſt, the repeated appearance of the eruption in perſons exempt from all ſuſpicion of having any ſyphilitic ſymptoms, made ſurgeons convinced, that what is now commonly named the mercurial erythema had nothing venereal in its nature. However, ſince few out of the great number of patients, continually employing mercury, are afflicted with this erythema, medical writers have attempted a further explanation of the difficult ſubject of cauſes, by ſtating, that the mercurial erythema only takes place in ſuch patients as have a certain undeſcribable peculiarity of conſtitution. The contemplative reader will at once perceive, that this is a vague and an unphiloſophical mode of accounting for the production of the diſeaſe, as the ſame ſorry kind of explanation may be generally adopted in regard to every diſorder, the immediate cauſe of which is totally unknown. Is it not a greater mark of prudence and good ſenſe to confeſs our ignorance, under theſe circumſtances, than to offer ſtatements, wiſhing them to be conſidered as explanatory, while they do not convey any information whatever on the ſubject?

It has been ſuppoſed by ſome, among whom is Dr. Gregory of Edinburgh, that the application of cold to the body, while under the influence of mercury, is abſolutely eſſential to the production of the diſorder under conſideration.

Notwithſtanding there can be no reaſonable doubt that the mercurial erythema is commonly excited by the uſe of mercury in ſome form or another, yet it appears from what Mr. Pearſon has ſtated, that the diſeaſe is not always exaſperated by a perſeverance in the employment of the medicine. On ſome particular occaſions, when this gentleman judged it to be of great moment to continue the mercurial frictions, the eruption neither ſpread univerſally, nor was it materially increaſed. The patients, however, did not get rid of the raſh till the mercury was diſcontinued.

We have already noticed the opinion of Dr. Gregory and ſome other practitioners, that expoſure of the body to cold, at a time when the ſyſtem is under the influence of mercury, is abſolutely neceſſary for the production of the mercurial erythema. Mr. Pearſon ſeems to entertain a very different ſentiment; for, he obſerves, that he is not aware of any other cauſe, than the action of mercury on a particular kind of conſtitution being concerned. He acquaints us, that he has ſeen this cutaneous diſeaſe occur in private practice as well as the Lock hoſpital, where the ſtricteſt attention has been paid to the temperature of the apartment, to regimen, and to perſonal cleanlineſs. He has had no reaſon to believe that any one ſeaſon of the year is more conducive to the diſeaſe than another; and he ſtates that free expoſure to the air, either in winter or ſummer, has not the leaſt perceptible effect in exciting the eruption.

Mr. Pearſon, as a general rule, recommends the employment of mercury to be immediately left off on the firſt appearance of the eruption; and though he ſeems to admit that the affection may be relieved by remedies, yet he is doubtful whether any plan of treatment has the power of interrupting its regular courſe, or abridging its duration. Mr. Pearſon would by no means wiſh to inſinuate, however, that the patient may not derive conſiderable benefit from medical aſſiſtance; his ſufferings (he owns) may be greatly mitigated; many inconveniences may be remedied; his ſtrength may be ſupported; and, in ſhort, (ſays Mr. Pearſon,) he may be ſo conducted through the diſeaſe, that his general ſtate of health ſhall not ſuffer any material or permanent injury.

It is not enough to diſcontinue the employment of mercury. In large hoſpitals, and particularly ſuch as are appropriated to venereal caſes, the patient ſhould be immediately removed from thoſe wards which may have their atmoſphere vitiated by the breathing of perſons charged in general with mercury.

In the early ſtage of the mercurial erythema, Mr. Pearſon recommends ſmall doſes, of antimonial powder, with ſaline draughts, or elſe the ammonia acetata. A gentle purgative ſhould be given every three or four days, and opium is proper for appeaſing the pain and irritation, and procuring ſleep. Sometimes, ſays Mr. Pearſon, opium mixed with camphor, or Hoffman's anodyne liquor, will have a better effect than when adminiſtered alone. When the diſcharge is no longer ichorous, and the tumefaction is ſubſiding, the ſame ſurgeon preſcribes the liberal exhibition of ſarſaparilla and bark. He has alſo thought, that the general ſenſe of uneaſineſs has been leſſened by the vitriolic acid, which proves at the ſame time grateful and refreſhing.

The diet ſhould be of a light and nouriſhing quality; but no fermenting liquors can be prudently allowed till the deſquamation of the cuticle is ſomewhat advanced.

In order to diminiſh the pain ariſing from the irritation of the ſkin, the warm bath may be uſed as often as the patient's ſtrength will permit. His linen and ſheets, which are ſoon rendered hard and ſtiff by the diſcharge, ſhould be very frequently changed. Mr. Pearſon is alſo in the habit of covering every part, where excoriations occur, with a ſoft mild cerate, made of litharge plaſter, yellow wax, and olive oil. This application is to be thickly ſpread on rollers, by which means it may be conveniently put wherever it is needed. The dreſſing ſhould be changed twice a day.

Dr. M'Mullin has noticed, that, though in the early ſtage of the mercurial erythema, diaphoretics are indicated, yet the bowels are ſo irritable, that ſuch medicines can ſcarcely be employed. For the ſame reaſon, he recommends

mends us to be very cautious in giving mineral acids, ripe fruits, &c. This gentleman approves of the patient being kept in rather a warm temperature, and in a place where he can derive the advantage of a quick circulation of air. The bowels being weak, Dr. M'Mullin advifes us only to employ the mildeft purgatives, when medicines of this clafs are required.

With regard to the topical treatment, the latter gentleman fays, that folutions of fulphate of zinc, and acetite of lead, fulphur ointment, and the decoction of oak-bark, have all been tried, but without any particular good, and he feems to prefer fprinkling the parts with powdered ftarch. To allay the cough and forenefs of the fauces, he advifes mucilaginous mixtures, containing a fmall proportion of opium.

When the incruftations become general, the fever always affumes more of the typhoid type. In this ftage bark has been ufually prefcribed, with a view of fupporting the ftrength; but Dr. M'Mullin remarks, that this medicine can never be given in fufficient quantity, owing to its affecting the ftomach, or occafioning diarrhœa. In fome inftances, he obferves, the cold infufion, conjoined with aromatics, has been beft retained, and a little opium may be added to the dofes. Opium, which this gentleman defcribes as improper in the firft ftage, may now be taken without any rifk of unpleafant confequences. He ftates, that wine is the beft remedy in this ftage of the difeafe. Porter and diluted fpirit are alfo proper, and the thirft muft be affuaged with whey, light broths, and nourifhing drinks of every kind. Owing to there being now a large extent of the fkin in an excoriated ftate, the patient cannot at this time generally bear warm bathing, which often brings on a ftate of fyncope, and all that can be done is to wafh the parts, in the moft tender manner, with tepid water.

For the ophthalmia tarfi, the unguentum zinci vitriolati is recommended, and the linimentum aquæ calcis is faid to relieve moft effectually the pain which makes the patient feel as if his flefh were cracking.

We fhall conclude this article with advifing the reader, who wifhes to be perfectly acquainted with the fubject of mercurial erythema, to confult B. Bell's Treatife on Gonorrhœa Virulenta and Lues Venerea, vol. ii. p. 228. Pearfon on the Effects of various Articles in the Cure of Lues Venerea. Edit. 2. p. 166. An Effay on a Peculiar Eruptive Difeafe arifing from the Exhibition of Mercury, by G. Alley, Dublin, 1804. A Defcription of the Mercurial Lepra, by Dr. Moriarty, Dublin, 1804. Hiftory of Three Cafes of Erythema Mercuriale, by Dr. Spens, in Edinb. Med. and Surgical Journal, vol. i. p. 7. Effay on Erythema Mercuriale, by Dr. M'Mullin, in Edinb. Med. and Surgical Journal, vol. ii. p. 25. Cafe of Erythema not occafioned by Mercury, by John Rutter, M. D. in Edinb. Med. and Surgical Journal. vol. v. p. 143.

ERYTHRÆ, in *Ancient Geography*, a town of Greece, in Bœotia. Pliny. It was fituated near mount Citheron, according to Euripides. Some authors place it in the territory of Platæa, to the eaft of this town.—Alfo, a town of Greece, in Theffaly, fituated upon the river Erypæus, according to Strabo.—Alfo, a town of Greece, in Œtolia, near Eupalium.—Alfo, a town in the ifle of Cyprus, called Paphos.—Alfo, one of the twelve towns of Afia Minor, in Ionia, according to Pliny Strabo fays, that it gave name to the Erythræan Sibyl. He fays alfo, that it had a port, called Cyffus, in which were four ifles called Hippi. This town was built by Nilæus, the fon of Codrus. In the town was a temple of Hercules, one of the moft ftately edifices in all Afia. Erythræ took part, on all occafions, with the Romans, who rewarded its fidelity with ample privileges, and confiderably enlarged its territory. It is now a village, named Erethri.—Alfo, a town of Africa, in Libya.

ERYTHRÆA, in *Botany*, ερυθραια, *red*, a name given by Renealm to the *Chironia Centaurium*, (Gentiana *Centaurium* of Linnæus), on account of its red colour, unufual in the Gentian tribe. This writer controverts the univerfally received opinion of its being the κενταυριον μικρον of Diofcorides, becaufe the latter is faid to prefer watery fituations. But neither this, nor indeed any other of his arguments, is of much weight; for the *Chironia Centaurium* often occurs in low and wet places, and according to Dr. Sibthorp is very frequent throughout Greece. *Chironia fpicata*, which Diofcorides would hardly diftinguifh from it always grows in marfhy fpots, and is found on the coafts of Greece, as may alfo *Chironia pulchella*, though fcarcely diftinguifhed by any body from the common kind when Dr. Sibthorp vifited that country, and therefore not noted by him.

ERYTHRÆAN Sea, in *Ancient Geography*, is the ancient name of the *Red Sea*. Indeed, the ancients gave this name to the whole expanfe of water that extends from the coaft of Ethiopia to the ifland of Taprobana. This appellation was probably derived from Edom or Efau, whofe defcendants were called Idumæans, and inhabited the northern part of Arabia. The Idumæans navigated upon the Red fea and the Perfian gulf, and alfo upon the Indian fea, and the oriental name Idumæan fignified red. Whence the fea of the Idumæans was called the Red fea, and the Erythræan fea.

Erythræan *Sibyl*. See Sibyl.

ERYTHREAN, an appellation given to Hercules, from a temple which he had at Erythres, in Arcadia.

ERYTHRINA, in *Botany*, from ερυθρος, *red*, on account of the fcarlet flowers, whence alfo it is called Coral-tree. Linn. Gen. 365. Schreb. 486. Willd. Sp. Pl. v. 3. 912. Mart. Mill. Dict. v. 2. Juff. 356. (Corallodendron; Tournef. t. 446.) Clafs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminofæ*, Juff.

Gen. Ch. *Cal.* Perianth of one leaf, entire, tubular; its margin more or lefs two-lobed; its bafe on the lower fide furnifhed with a honey-bearing pore. *Cor.* papilionaceous, generally of five petals; ftandard much the longeft, lanceolate, afcending, its fides bent downwards; wings minute, fomewhat ovate, fcarcely longer than the calyx, and hardly reaching beyond the claw of the ftandard; keel ftraightifh, ufually about the length of the wings, fometimes longer, of two petals either feparate or united, notched at the end. *Stam.* Filaments ten, unequal, united below into a tube, flit at the upper edge, a little incurved, half as long as the ftandard, one of them occafionally feparate; anthers ten, oblong. *Pift.* Germen fuperior, ftalked, awl-fhaped, tapering into an awl-fhaped ftyle, as long as the ftamens; ftigma terminal, fimple. *Peric.* Legume very long, protuberant from the feeds, pointed, of one cell. *Seeds* feveral, kidney-fhaped.

Eff. Ch. Calyx two-lobed, ftandard much longer than the keel. Wings minute. Legume cylindrical, with many convex feeds.

Obf. *E. herbacea* has the tenth ftamen feparate; which is alfo the cafe with *E. Crifta-galli*, whofe keel moreover has its petals united into one, and is much longer than in the generality of the fpecies.

The fpecies of this fplendid genus are, for the moft part, natives of very hot climates in the Eaft or Weft Indies, and amount in Willdenow, who has paid particular attention to them, and defcribed two new ones, to twelve.

E. *herbacea*, Linn. Sp. Pl. 992. Trew. Ehret. t. 58. found in in Carolina, will ſupport our winters in a green-houſe, nor does its ſtem always die down to the root. The *flowers* form long and very handſome ſpikes, being of a moſt vivid though deep ſcarlet, with purpliſh ſtalks and calyx. *Seeds* ſcarlet with a black eye.

E. *Corallodendrum*, Linn. Sp. Pl. 992, brought from the Weſt Indies, requires a ſtove. It has an arboreſcent prickly *ſtem*, with *flowers* much like the former.

E. *mitis*, Jacq. Hort. Schoenbr. v. 2. 47. t. 216, is another ſimilar ſpecies in its *flowers*, but deſtitute of prickles. It was ſent to the Imperial garden from the Caraccas.

E. *Criſta-galli*, Linn. Mant. 99. Sm. Exot. Bot. v. 2. 69. t. 95, is perhaps one of the moſt ſtately of the whole. This is ſaid to be a native of Braſil, but was raiſed in the Liverpool garden from ſeeds brought from the Eaſt Indies, probably from the garden at Calcutta. It was in 1805 but a ſlender prickly ſhrub about ſix feet high, with ternate prickly-ribbed *leaves*. *Flowers* in large terminal cluſters, of a rich unpoliſhed deep ſcarlet, their ſtandards much broader, and keels much longer, than is uſual in this genus; the wings very ſmall and three-lobed, of a greeniſh white. Tenth *filament* ſeparate to the very baſe.

E. *ſpecioſa*, Andr. Repoſ. t. 443, a plant we have never ſeen, flowered in the garden of A. B. Lambert, eſq., and though ſuppoſed to be a native of South America, is ſaid to be perfectly hardy, and to ſtrike very freely from cuttings. Whether it be comprehended under any of Willdenow's ſpecies, we are not at all certain. The *ſtem* is prickly, thick and ſtrong. *Leaflets* very broad, with prickly ribs. *Flowers* ſcarlet, in very denſe ſpikes. *Wings* half as long as the ſtandard, which is narrow like the firſt ſpecies; keel not half ſo long as the wings. If theſe circumſtances are conſtant, the generic character will require correction.

ERYTHRINUS, in *Ichthyology*, a ſpecies of Sparus and alſo of Salmo, which ſee reſpectively.

ERYTHROCEANEUS, in *Ornithology*, the red and blue maccaw, with a wedge-like tail, and the ſides of the head naked and rough. See Psittacus.

ERYTHRODANUM, in the *Materia Medica*, a name by which ſome authors have called the rubia tinctorum, or madder.

ERYTHROIDES, in *Anatomy*, from ερυθρος, *red*, and ειδος, *form*, a name given by ſome anatomiſts to the firſt proper covering of the teſticles. It is not now admitted that theſe bodies are covered by any thing except the fibres of the cremaſter and cellular ſubſtance of the ſcrotum, to which, perhaps, the above-mentioned name may have been applied.

ERYTHRONIUM, in *Botany*, from ερυθρος, *red*, in alluſion either to the colour of the flower, or to the more unuſual blood-like ſtain in the leaves. Dog's-tooth Violet. Linn. Gen. 165. Schreb. 220. Willd. Sp. Pl. v. 2. 96. Mart. Mill. Dict. v. 2. Juſſ. 48. (Dens canis; Tournef. t. 202.) Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Liliа*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* Petals ſix, regular, lanceolate, pointed, lying over one another alternately towards the baſe, ſpreading gradually, reflexed from about the middle; three of them external, three internal. Nectary two ſcars, or little ſcales, at the baſe of each of the inner petals. *Stam.* Filaments ſix, uniform, awl-ſhaped, ſhort; anthers oblong, erect, as long as the filaments. *Piſt.* Germen ſuperior, roundiſh or oblong, with three angles; ſtyle ſimple, ſhorter than the corolla, taper at the baſe, and a little bent at that part, otherwiſe ſtraight; ſtigmas three, ſpreading, ſomewhat cylindrical, furrowed, or notched. *Peric.* Capſule nearly globular, contracted at the baſe, of three cells and three valves. *Seeds* numerous, ovate, pointed.

Eſſ. Ch. Corolla bell-ſhaped, of ſix reflexed petals. Nectary two ſcars at the baſe of the three inner ones. Capſule globoſe, contracted at the bottom. Seeds ovate.

1. E. *Dens canis*. Linn. Sp. 437. Jacq. Auſtr. v. 5. 31. append. t. 9. Curt. Mag. t. 5. Leaves with a blunt flat point. Style cylindrical. Germen globoſe, obtuſe. Native of mountainous places in Italy, Switzerland, Carniola, Styria, Carinthia and Tartary, flowering in the ſpring. In our gardens it is a hardy perennial, diſtinguiſhed by its elliptical radical *leaves*, very various in breadth, elegantly ſtained with purple, and its ſolitary drooping crimſon or whitiſh *flower*, with pendulous dark purple anthers. No remains of the herbage are to be ſeen after the end of June. Lobel and ſeveral botaniſts of his time preſumed this to be the real σατυριον of Dioſcorides, nor does it ill accord with the deſcription, though Dr. Sibthorp ſeems not to have met with the plant in Greece. It cannot, however, be made to agree with the σατυριον ερυθρονιον of the ſame author, though the latter appellation ſeems to have given riſe to its preſent generic name. The old authors made two ſpecies on account of the various dimenſions of the leaves, which Linnæus reduced to one, but he very improperly made a third variety of the following ſpecies.

2. E. *flavum*. (E. americanum; Curt. Mag. t. 1113. E. Dens canis γ; Linn. Sp. Pl. 437.) Leaves involute at the point. Style club-ſhaped. Native of the colder parts of North America. It flowered in April 1808, in the gardens of Mr. Loddiges at Hackney, and Mr. Saliſbury at Brompton, and was firſt well determined by Mr. Gawler in Curtis's Mag. The leaves reſemble the former, except in having a hooded termination, from the involute edges of the point. *Flower* deep yellow ſpotted with red. *Anthers* and pollen yellow. *Style* very thick in the upper half. *Germen* obovate.

3. E. *revolutum*. Leaves flat-pointed? Style cylindrical. Germen elliptic-oblong, acute.—Gathered by Mr. A. Menzies on the weſt coaſt of North America. The *leaves* are broadly elliptical, and in our ſpecimens appear pale, and ſcarcely ſpotted. *Petals* purpliſh, very much rolled back, as in the Martagon Lily. *Stamens* with unuſually long taper-pointed filaments, and pale or yellowiſh, not dark purple, anthers. *Germen* elliptic-lanceolate, pointed. *Style* contracted at the baſe, but otherwiſe pretty exactly cylindrical, with much longer ſtigmas than either of the foregoing.—The whole plant alſo is larger, and appears to us unqueſtionably diſtinct. The diſcovery of this ſpecies in America renders the original name of the laſt ſo exceptionable, that we hope we may be pardoned for changing it before it is adopted in any regular ſynoptical work, otherwiſe it would be too late. S.

ERYTHROPHTHALMUS, in *Ichthyology*. See Cyprinus.

ERYTHRORHIZA, in *Botany*, ερυθρα ριζα, *a red root*; Michaux Fl. Boreali-Amer. v. 2. 36. t. 36, is *Galax aphylla*, which ſee.

ERYTHROXYLUM, ερυθρον ξυλον, *red wood*. Brown. Jam. 278. Linn. Gen. 228. Schreb. 307. Willd. Sp. Pl. v. 2. 746. Mart. Mill. Dict. v. 2. Juſſ. 253. Claſs and order, *Decandria Trigynia*. Nat. Ord. *Trihilatæ*, Linn. *Malpighiæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, turbinate, very ſmall, withering, in five ovate acute ſegments. *Cor.* Petals five, ovate, concave, ſpreading. Nectary an upright, coloured, notched ſcale, attached to the baſe of each petal. *Stam.* Filaments 10, the length of the corolla, connected at the baſe by an abrupt

abrupt membrane; anthers heart-ſhaped. *Piſt.* Germen ovate, ſuperior; ſtyles three, thread-ſhaped, diſtant, the length of the ſtamens; ſtigmas thickiſh and obtuſe. *Peric.* Drupa ovate, of one cell. *Seed.* Nut oblong, with four obtuſe angles.

Eſſ. Ch. Calyx turbinate. Petals five, each with a notched nectariferous ſcale at its baſe. Stamens connected at their baſe. Drupa of one cell.

This genus, founded by Browne, conſiſts of two ſpecies only in his work. 1. *E. areolatum*, Linn. Sp. Pl. 612. Brown. Jam. t. 38. f. 2. and t. 14. f. 3. (E. carthaginenſe; Jacq. Amer. 134. t. 87. f. 1.) This is called, in Jamaica, Red Wood, or Iron Wood, and is ſaid to be excellent for the ſize of the tree, which is not above five or ſix inches in diameter. The *leaves* are obovate, two inches long, marked with two lines at the back, which circumſcribe the part that was expoſed before each leaf expanded. *Flowers* ſtarry, white, fragrant, on ſimple, cluſtered, lateral ſtalks.

2. The ſecond ſpecies of Browne has been neglected by following authors, probably as a variety of the firſt. He deſcribes it as different in its manner of growth, with ſmaller rounder *leaves*.

Cavanilles and Lamarck have much increaſed the number of ſpecies, ſo that they now amount in Willdenow's work to 12, all except the above unknown to Linnæus. They are natives either of South America, Madagaſcar, or the iſlands of Mauritius and Bourbon, and were chiefly gathered by Commerſon. The French call many of them Bois d'huile. The wood is, in ſome inſtances, ſaid to have a very ſtrong and diſagreeable ſmell while burning.

ERYX, in *Ancient Geography*. See Erix.

Eryx, in *Zoology*, a ſpecies of Anguis, being the *Anguis dorſo trilineato* of Boddaert, above cinereous, with three black lines, and light blueiſh beneath. It is found in England, and in America.

ERZ, or Erzi, in the *Botanical Writings of the Ancients*, a word uſed originally by the Hebrews, and by them made the name of the cedar.

ERZEN, in *Geography*, a town of Germany, in the circle of Lower Saxony, and principality of Calenberg, ſeated on the Humme; 7 miles S.W. of Hameln.

ERZERUM, or Arzerum, a city of Aſiatic Turkey, and capital of a pachalic to which it gives name, and is a part of Armenia, ſituated near the head of the Euphrates, at the foot of a chain of mountains which are uſually covered with ſnow till the latter end of ſpring. The town is ſurrounded with a double wall, and defended with ſome ſquare towers; the houſes are mean, and none of them large. The ſuburbs are inhabited by Chriſtians. Of the inhabitants, they count 18,000 Turks, of whom two-thirds are Janizaries; 6000 Armenians, who have an archbiſhop, and two churches; and 400 Greeks, who have a biſhop, and one mean church. The Greeks are moſtly employed in the manufacture of copper, brought from ſome mines three days journey from the city; this, and the manufacture of the ſkin of a ſpecies of martin, are the only articles of their commerce. Erzerum is the ſtaple of the merchandize of India, eſpecially when the Arabians infeſt the environs of Aleppo and Bagdad. This merchandize conſiſts of ſilk from Perſia, cotton, painted linens, ſpices, rhubarb from Bucharia, madder from Perſia, zedoary, &c. This town was one of the laſt which was taken from the Greek emperors by the Arabians; 250 miles N.N.E. of Aleppo, and 510 E. of Conſtantinople.

ERZGEBIRG. See Ertzgebirge.

ESAPHE, from εσαφαω, *I feel with the fingers*, a word uſed by Hippocrates, to expreſs the touching of the mouth of the uterus, in order to diſcover its ſtate of diſeaſe.

ESAU, in *Biography*, the ſon of Iſaac and Rebecca, and the twin-brother of Jacob, whom he ſucceeded at his birth, was born in the year 1836 B.C. At his birth he was covered with hair, indicating great bodily ſtrength, by which he was fitted for the kind of life to which he afterwards devoted himſelf. As he was fond of hunting, he ſupplied his father with a variety of delicious food, and became his favourite. Jacob, however, was the favourite of his mother, and by means of a circumſtance mentioned in his hiſtory, ſupplanted Eſau of his birth-right, which he conſented to barter for a meſs of red pottage, that had been prepared for their father, during his abſence. Hence he and his poſterity derived the appellation of Edom, ſignifying red. At the age of 40 years Eſau diſtreſſed his parents by marrying two wives out of idolatrous Canaanitiſh families, with which the poſterity of Abraham were prohibited from forming any connection. In proceſs of time, he regained his father's favour, and as death approached, Iſaac determined to confer his laſt prophetic benediction on Eſau, as his firſt-born ſon and heir. The artifice of his mother, however, counteracted his purpoſe; and ſhe contrived to impoſe upon Iſaac, and to obtain the father's parental bleſſing for her ſon Jacob. Eſau was indignant on account of the treatment of his brother; and determined to kill him as ſoon as their father ſhould die.

Rebecca again interpoſed, and ſent Jacob away to her brother Laban, with whom he might be ſecure from the threatened vengeance of his brother. During the period of ſeparation, which laſted ſeveral years, Eſau married a wife of the family of Iſhmael, and removing to mount Seir, acquired great power and wealth. When Jacob returned, after long abſence, to his father's country, with a numerous family, and large flocks and herds, he dreaded his brother's diſpleaſure; and though they had an amicable and affectionate interview, he entertained ſuſpicion of remaining reſentment, and inſtead of complying with the wiſhes of his brother, who was deſirous that he would ſettle in his neighbourhood, he dwelt in Shechem. After their father's death they lived in peace and amity; but as their poſſeſſions enlarged, and there was not ſufficient room for them in the land in which they were ſtrangers, Eſau returned to mount Seir, where his poſterity multiplied under the denomination of Edomites. (See Edom.) The time of his death is not mentioned, but biſhop Cumberland thinks it probable that he died about the ſame time with his brother Jacob, at the age of about 147 years. Geneſis, ch. xxv—xxxvi.

Esau, in *Geography*, a mountain of Arabia, in the country of Yemen, 4 miles N. of Udden.

ESAULOVO, a town of Ruſſian Siberia, in the government of Kolivan; 36 miles E.S.E. of Kraſanoiarſk.

ESBONITÆ, in *Ancient Geography*, a people of Arabia Petræa, who took their name from the capital, which was ſeated in the mountains over-againſt Jericho.

ESBUS. See Heshbon.

ESCACENA, in *Geography*, a town of Spain, in the country of Seville; 20 miles W. of Seville.

ESCAILLON, a river of France, which runs into the Scheldt, about two miles above Valenciennes.

ESCALA, La, a town of Spain, in the province of Catalonia, on the coaſt of the Mediterranean; 22 miles E. of Gerona.

ESCALADE, or Scalade, in the *Military Art*, a furious attack of a wall or a rampart; carried on with ladders, to paſs the ditch, or mount the rampart; without proceeding in form, breaking ground, or carrying on regular works to ſecure the men.

When the troops are prepared to paſs the ditch, either with the affiftance of boards, hurdles, and fafcines, when it is muddy, or with fmall boats of tin, or bafkets covered with fkins, or oil-cloth when it is deep, and filled with water, a party muft be placed on the counterfcarp, oppofite to the landing-place, ready to fire at the garrifon if they are alarmed, and oppofe the mounting on the rampart. If the ditch is dry, the ladders are fixed in fome place fartheft diftant from the centry; and as foon as they get upon the rampart, they put themfelves in order to receive the enemy; if the centry fhould be furprifed, and filently overcome, the detachment haftens to break open the gate, and to let in the reft of the party. If the ditch is wet, the rampart high, and provided with a revetement, it will be difficult to furprife the town in this way; but if there is no revetement, the troops may hide themfelves along the outfide of the rampart till all are over. Since the invention and ufe of gun-powder, and the walls of cities have been flanked, they are feldom taken by efcalade.

ESCALANA, in *Geography*, a town of Spain, in Old Caftile; 14 miles N.N.E. of Segovia.

ESCALANTE, a town of Spain, in the province of Bifcay; 15 miles E. of Santander.

ESCALAON, a town of Portugal, in the province of Beira; 16 miles N. of Almeida.

ESCALLION, in *Botany*. See Scallion.

ESCALLONIA, fo called by the younger Linnæus, at the recommendation of Mutis, in honour of a learned Spaniard named Efcallon, the pupil of Mutis in botany, mathematics and philofophy, and his infeparable companion during his abode in New Spain. This gentleman difcovered the fhrub in queftion, as well as a vaft number of new or rare plants befides, in his various journeys through New Granada, moft of which were, by Mutis or himfelf, communicated to Linnæus or his fon. A very fine plant was originally chofen by Mutis for the above purpofe, of which a fpecimen and drawing were fent to Linnæus; but it proved, on a careful examination, to be a *Loranthus*, and remains undefcribed in the Linnæan herbarium. —Linn. Suppl. 21. Schreb. 152. Willd. Sp. Pl. v. 1. 1149. Mart. Mill. Dict. v. 2. Juff. 321. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Onagræ*, Juff.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, hemifpherical, with five large, fpreading, ovate, acute, permanent teeth. *Cor.* Petals five, equal, inferted into the calyx, tongue-fhaped or obovate, obtufe, a little diftant from each other, longer than the calyx-teeth. *Stam.* Filaments five, equal, erect, awl-fhaped, inferted into the calyx between the petals, oppofite to its teeth and about the fame length; anthers incumbent. *Pift.* Germen half invefted with the calyx, globular; ftyle cylindrical, ftraight, the length of the ftamens; ftigma capitate, umbilicate. *Peric.* Berry roundifh, of two cells, crowned with the calyx-teeth. *Seeds* very numerous, minute.

Eff. Ch. Berry of two cells, with many feeds. Calyx encompaffing the fruit. Stigma capitate. Petals five, inferted into the calyx.

1. E. *myrtilloides*. Linn. Suppl. 156. Sm. Pl. Ic. t. 30. —Leaves finely ferrated, minutely pointed, veiny beneath. Flowers folitary.—Gathered in New Granada by Efcallon. —*Stem* fhrubby, branched, flightly angular, with a fmooth deciduous bark. *Young branches* numerous, alternate, fhort, fimple, leafy, each terminated by a folitary, ftalked, terminal *flower*. *Leaves* alternate, fpreading, about three-quarters of an inch long, obovate, obtufe with a minute point, minutely ferrated, efpecially towards the end, fmooth, deciduous; with no perceptible veins on the upper fide; paler and veiny beneath; the bafe tapering down into a fhort, often fringed, *footftalk*, each of whofe edges unites at their bafe with a glandular toothed angle or rib in the branch. *Stipulas* none. *Flower-ftalks* angular and glandular. *Petals* about thrice as long as the calyx-teeth, apparently white, erect, their extremities reflexed. *Berry* black? the fize of a large pea, or bigger, crowned with the calyx and bafe of the ftyle.

2. E. *ferrata*. Sm. Pl. Ic. t. 31.—Leaves ferrated, fomewhat abrupt, fmooth and without veins at the back. Flowers folitary.—Gathered about the ftraits of Magellan, by Commerfon; in Staten land, (not Terra del Fuego,) by Mr. Archibald Menzies.—A humble branched fmooth *fhrub*, with fomething of the afpect of a *Vaccinium*. *Branches* alternate, fomewhat zig-zag, angular, with a pale fmooth bark; thofe of the prefent feafon green, leafy, ftraighter, each bearing a folitary, terminal, ftalked flower. *Leaves* deciduous, alternate, obovate, obtufe, often abrupt or retufe, with a minute central point or tooth, equally ferrated or fomewhat crenate, very fmooth; flightly veiny above; pale and deftitute of lateral veins beneath, though furnifhed like the former with a ftrong central rib. *Footftalks* fmooth and entire, as are the angles of the branches. *Stipulas* none. *Flower-ftalk* fmooth. *Petals* white, fpreading, not recurved. Top of the *germen* violet. All the parts of fructification, except the petals, are but one-third the fize of the former. The little *berries*, crowned with the permanent ftyle, appear to remain through the winter, and their upper part, above the calyx-teeth, eafily feparates like a lid as they ripen, expofing the pulp full of fmall feeds, with its tranfverfe partition.

3. E. *glandulofa*. Leaves double ferrated, acute, glandular at the back like the branches. Flowers fomewhat corymbofe.—Gathered in Chili by Mr. A. Menzies.—*Branches* wand-like, roundifh, leafy, when young clothed with abundance of prominent glandular tubercles. *Leaves* alternate, when full grown near an inch and half long, obovate, pointed, ftrongly and doubly ferrated; fmooth or flightly downy above; veiny, and rough with innumerable prominent refinous glands, beneath; tapering at the bafe into a fhortifh glandular *footftalk*. Each leaf is accompanied by an axillary tuft of fmaller ones, the rudiments of future branches. *Stipulas* none. *Flower-ftalks* feveral about the tops of the branches, axillary and terminal, fimple or fubdivided, each about an inch long, angular, glandular like the branches, as is alfo the bafe of the calyx. *Bracteas* few, at the bafe or fubdivifion of each ftalk, linear, glandular. *Calyx* about the fize of the laft. *Petals* more like the former, and fomewhat longer, with rounded, reflexed extremities. *Style* furrowed, furrounded at its bafe with an annular lobed gland or nectary, of which we can find no traces in the other fpecies. *Germen* of two cells. The *fruit* we have not feen. S.

ESCALONA, in *Geography*, a fmall, tolerably built, walled town of Spain, in the province of New Caftile, with feveral fuburbs, feated on an eminence defended by a caftle, in a fruitful fpot watered by the Alberche, 20 miles N.W. of Toledo, and 32 S.W. of Madrid. It has four churches, and two convents.

ESCALOP *Foffil Shells*, in *Conchology*, are defcribed by Da Cofta (Conchol. p. 247.) as found in the lime-ftone quarries at Thame in Oxfordfhire; Mr. Walcot, in his "Petrifactions found near Bath," has alfo defcribed a fimilar kind of fhell, as found in the clay on the fide of the road between Claverton-Down and village, and in the free-ftone at the quarries near King's Down; and another kind found in a flaty loam at the limeftone quarry near the Crefcent in Bath.

ESCAMBIA, one of the moſt conſiderable rivers that fall into the bay of Penſacola, in Weſt Florida, diſcharges itſelf near the head of the north branch, about 12 or 15 miles from Penſacola, through ſeveral marſhes and channels which have a number of iſlands between them, that are overflowed when the water is high. The courſe of this river from an unknown ſource is very winding. The lands on each ſide are, in general, rich, low, or ſwampy, or well adapted for the culture of rice or corn. The numerous rivulets that fall into this river from the high country about it may be led over every part of the rice lands, at any ſeaſon of the year. The iſlands at the mouth of the river, of which ſome are conſiderable in extent, are not inferior for rice to any in America.

ESCAMBIO, from the Spaniſh *cambier*, to change, was anciently a licence granted any one for making a remittance, or giving a bill of exchange to another, beyond ſea.

For, by ſtat. 5 Rich. II. no perſon might exchange, or return money beyond ſea, without the king's licence

ESCAMUS, in *Ancient Geography*, a river of Mœſia, which has its ſource in mount Hæmus.

ESCAPE, Fire. See Fire-Escape.

Escape, in *Law*, an evaſion out of ſome lawful reſtraint, either by violence or ſtealth.

Eſcapes are either *voluntary*, or *negligent*.

Voluntary, are ſuch as are, by the expreſs conſent of the keeper to whoſe cuſtody, in civil actions, the debtor has been committed; after which, he can never retake his priſoner again, (3 Rep. 52. 1 Sid. 330.) though the plaintiff may retake him at any time, (ſtat. 8 or 9 W. III. c. 27.); but the ſheriff muſt anſwer for the debt.

Negligent eſcapes are where the priſoner eſcapes without his keeper's knowledge or conſent; and then upon freſh purſuit the defendant may be retaken, and the ſheriff ſhall be excuſed, if he has him again before any action brought againſt himſelf for the eſcape. (F. N. B. 130.) A reſcue of a priſoner in *execution*, (which ſee,) either going to gaol or in gaol, or a breach of priſon will not excuſe the ſheriff from being guilty of and anſwering for the eſcape; for he ought to have ſufficient force to keep him, ſince he may command the power of the county (Cro. Jac. 419.)

An eſcape of a perſon arreſted upon criminal proceſs, by eluding the vigilance of his keepers before he is put in hold, is an offence againſt public juſtice; and the party himſelf is puniſhable by fine or impriſonment. (2 Hawk. P. C. c. 122.) But the officer permitting ſuch eſcape, either by negligence or connivance, is much more culpable than the priſoner. Officers, therefore, who, after arreſt, *negligently* permit a felon to eſcape, are puniſhable by fine (1 Hal. P. C. 600.); but *voluntary* eſcapes, by conſent and connivance of the officer, are a much more ſerious offence; for it is generally agreed that ſuch eſcapes amount to the ſame kind of offence, and are puniſhable in the ſame degree, as the offence of which the priſoner is guilty, and for which he is in cuſtody, whether treaſon, felony, or treſpaſs; and this, whether he was actually committed to gaol, or only under a bare arreſt. (1 Hal. P. C. 590. 2 Hawk. P. C. 134.) But the officer cannot be thus puniſhed, till the original delinquent hath actually received judgment or been attainted, upon verdict, confeſſion, or outlawry, of the crime for which he was ſo committed or arreſted; otherwiſe it might happen, that the officer might be puniſhed for treaſon or felony, and the perſon arreſted, and eſcaping, might turn out to be an innocent man. But before the conviction of the principal party, the officer thus neglecting his duty may be fined and impriſoned for a miſdemeanor. (1 Hal. P. C. 588, 9. 2 Hawk. P. C. 134, 5.). See Rescue.

Escape *warrant*. If any perſon committed or charged in cuſtody in the king's bench, or Fleet priſon, in execution, or on meſne proceſs, &c. go at large; on oath thereof before a judge of the court where the action was brought, an eſcape warrant ſhall be granted, directed to all ſheriffs, &c. throughout England, to retake the priſoner, and commit him to gaol when taken, there to remain until the debt is ſatisfied; and a perſon may be taken on a Sunday upon an eſcape warrant. Stat. 1 Anne, cap. 6.

ESCAPEMENT, in *Horology*, is an ingenious mechanical contrivance for tranſmitting, in a modified way, and at equidiſtant intervals of time, the maintaining power of a clock or watch to the regulator, whether balance or pendulum, in order to reſtore that loſs of motion in every vibration or oſcillation, which neceſſarily ariſes from the friction of the acting parts, and the reſiſtance of the air in every machine. It has been ſaid, under the article Clock, that the maintaining power, whether conſiſting of a weight or ſpring, when ſuffered to expend itſelf unreſtrained, would make the wheel-work run on with an increaſing velocity, until the obſtacles to motion, ſuch as the friction in the teeth and at the pivots, the reſiſtance of the air, &c. fixed the maximum of velocity with which it could expend itſelf; at which period the friction and reſiſtance would jointly operate as a regulator, whilſt they and the maintaining power remained unaltered, and the machine ſo circumſtanced would greatly reſemble a common kitchen-jack; and if an index were inſerted on the arbor of the firſt or ſlowly moving wheel, it would indicate ſuch portions of time as the ratio between the maintaining power and the regulating friction and reſiſtance of the air taken together would produce; but it is obvious, that every alteration produced in the friction by wear, foulneſs, &c. or in the denſity of the air by the ſtate of the atmoſphere, would affect the indication ſo much, as to render it extremely irregular; hence the balance and the pendulum were ſucceſſively invented and applied to regulate the indication of time by their iſochronous vibrations; but then as both theſe regulators have alternate motions backwards and forwards, they could neither of them be applied *immediately* to check a wheel that moves continually in one direction, without the intervention of ſome contrivance, connected both with the wheel and regulator, which ſhould convert a direct circular motion into a motion changing its direction by perpetual alternations. To deviſe and execute a piece of mechaniſm that ſhould perform ſuch an office ſteadily and accurately, required much ſcience as well as mechanical ſkill, and the invention once executed was denominated an *eſcapement*, or by contraction among the workmen *'ſcapement*, becauſe it ſuffers a tooth of the wheel, with which it acts, to *eſcape*, or paſs on, at ſuch intervals of time as are meaſured by the regulator, which wheel is therefore alſo called the *eſcapement wheel*.

From this ſhort account of the origin and office of an eſcapement, the reader will perceive, that the accuracy of its conſtruction conſtitutes one of the moſt eſſential conſiderations in an horometrical machine, it being an indiſpenſable condition, that the ſucceſſive impulſes taken from the maintaining power through the medium of the wheel-work, and given to the regulator, ſhould be ſo modified, as to diſturb as little as poſſible the natural iſochroniſm of the regulator, or, if it do diſturb it, that it ſhould ſomehow compenſate that diſturbance. Hence it becomes neceſſary, that the workman, or mechanician, ſhould be fully acquainted with the theory of the natural iſochroniſm of his propoſed regulator, when he undertakes to deſign and execute his eſcapement; he muſt not only know how much of the

 maintain-

maintaining power will be fufficient to balance the lofs fuftained in the natural length of a vibration, by reafon of friction and the refiftance of a ftandard medium, but he muft confider and indeed afcertain, by theory or experiment, or both, at what part of the arc of vibration the power muft be applied; likewife how long the impulfion fhall continue to act, and whether that action ought to be uniform, increafing, or decreafing in its intenfity. Thefe and fimilar confiderations have produced, as might be expected, a great variety of conftructions of an efcapement, both with regard to their external fhape and *modus operandi*. As a good efcapement is of the utmoft importance in the ufeful art of clock-making, and as we have no author in the Englifh language who has given us the different conftructions in hiftorical order, together with fuch remarks as may enable the reader to judge of their refpective excellence, we will devote fome time to the detail of both the theory and practical conftruction of fuch different efcapements as feem to merit a general notice.

But before we enter upon our defcription and examination of different efcapements of clocks and watches, as the reader has not yet had an opportunity of perufing the article PENDULUM, and as all efcapements derive their fhape and manner of action from the relation they bear either to the laws of its motion, or to thofe of a moving balance, it will contribute greatly to his better underftanding the fubject, if we premife firft fome of the chief circumftances which relate to the theory of a free pendulum, and to the influence that any external impulfe will have on it when applied to become the regulator of a clock; and fecondly, if we explain the theory of a balance's motion, which we have purpofely referved for this place by reafon of its intimate connection with the efcapement.

1. In *fig.* 1. of *Plate* XXXI. of *Horology*, let C D reprefent a *free pendulum*, or pendulum that has no weight but what is collected at the centre of ofcillation or point D, and let the arc D B reprefent a femi-vibration round the point C, taken as the centre of motion or point of fufpenfion, at which we will fuppofe there is no friction, then if the refiftance of the air and rigidity of the ftring or rod were not to interfere, when the pendulum was once removed from its natural or perpendicular fituation C D to B, and fuffered to defcend again by the fole force of gravity, it would acquire fuch a velocity at its loweft point D, by means of the accelerating force of gravity, as would, under thefe circumftances, carry it up an equal femi-vibration or arc D G, the increments of accelerated motion being equal in the arc B D to the decrements of retarded motion in the equal arc D G, the fame reafoning would apply in the returning vibration from G to B; the velocity acquired at D by the defcent from G to D would carry the pendulum again up to B, and the confequence would be, under fuch *unnatural* circumftances, if they could be effected, that there would be a perpetual alternation of vibrations of the fame length, which would confequently be ifochronal with refpect to each other, fo long as the pendulum remained of the fame length; and fuch a pendulum would of itfelf be a perfect time-meafurer, and would only want a regifter to indicate the number of its vibrations, to make it a complete regulator or chronometer: but the fact is, the friction and rigidity at the point of fufpenfion cannot by human art be entirely annihilated, though ingenuity can greatly diminifh it; nor can the obftacle to free motion arifing from the refiftance of the air be removed, or even rendered uniform; hence it is found that when a pendulum is drawn afide from its point of reft, every fucceeding vibration, after motion has commenced, is fomewhat fhorter than the preceding one, until after fome hours have been fpent in alternate vibrations continually fhortening, the pendulum finds its original point of reft; the time expended in doing this is longer in proportion to the diminution of friction, the air and other circumftances remaining unchanged. Ferdinand Berthoud, the famous French clock-maker, made fome experiments to afcertain this fact, and conftructed the knife-edge fufpenfion of a fecond's pendulum, with a heavy lenticular ball, fo free from friction, that an arc of vibration of 10° was not reduced to $15'$ till $29^h\,46^m$ had elapfed; but notwithftanding every attempt to reduce the friction, the pendulum came to reft at laft. From this fhort view of the tendency of a pendulum to come to reft after it has had a motion communicated to it, we clearly perceive the neceffity of making fome auxiliary additions to the natural force of gravity, in order that the pendulum may keep up the length of its original vibration in every fucceeding one, notwithftanding the obftructions which continually oppofe the operation of gravity; thefe auxiliary additions to the motion, produced by gravity only, conftitute the operation of the maintaining power, modified by the wheel-work and efcapement, in every pendulum clock; and hence arifes a *difturbance* in the *theory* of the free pendulum, which makes fuch a theory no farther of ufe in clock-work, than as it affords certain laws and a fcale of forces, fuch as the mechanician may labour to imitate, by modifying the joint agency of his *auxiliary additions* and of the operation of gravity, fo that they fhall act in concert; which imitation is to be effected principally, as to its *mode*, by the efcapement, the maintaining power being concerned only as to the *quantity* of any additional power to be applied in aid of gravity.—Now, if we fuppofe the pendulum at the fituation B, or extremity of its arc, and draw A B perpendicular to the vertical line C D, and B E = C B perpendicular to the line A B, or, which is the fame thing, parallel to the line C D; alfo, if we draw B F a tangent to the arc at the point B, and from the point E demit the line E F upon it, to form a right angle at F, in which cafe the line F E will be parallel to the line C B, B E will reprefent the force of gravity, which, by the refolution of forces, is equivalent to B F and F E; but F E is perpendicular to the tangent, or is in the direction C B of the radius, and therefore can neither accelerate nor retard the motion, whilft B F, being in the direction of the tangent, or perpendicular to the radius, is wholly employed in accelerating or retarding the pendulum's motion: hence, the line B E : B F : : the force of gravity : the accelerating force; but from the fimilar triangles B E F, C B A, B E is = C B, and B F = B A, therefore, by fubftitution, C B : B A : : force of gravity : accelerating force, and confequently the accelerating force $= \frac{\text{gravity} \times \text{B A}}{\text{C B}}$, in which expreffion gravity and the radius C B are invariable, therefore the accelerating force varies as the fine B A of the arc of vibration. From this law of variation of the accelerating force of a body moving in a circular arc, it follows, that the longer arcs require longer times than the fhorter arcs in the proportion of 34 : 29, as Huygens has demonftrated; for the fine does not increafe fo faft as the arc, which it ought to do, to make the vibrations of the fame pendulum in different arcs ifochronal: if, however, the body could be made to move along the chord or ftraight line B D, inftead of the arc B D, then the vibrations of different lengths would be ifochronal, becaufe two fimilar bodies will run down each a feparate chord of different lengths to the loweft point of the fame circle in the fame time, namely, in the time that each would take in falling

through

through the whole diameter of the circle, and the acquired velocity of each, at the loweſt point, would be in proportion to the length of its chord. But the mechanician has not attempted to make his pendulum vibrate in chord lines, which probably is impracticable, but has invented another curve, called the cycloid, generated by a point in a circle revolving on a ſtraight line, which curve poſſeſſes this peculiar property, that the accelerating forces, which a body acquires by moving along it, are exactly proportionable to the *arcs*, (ſee CYCLOID,) ſo that a pendulum vibrating in this kind of curve, will perform its long and ſhort vibrations in the ſame time. This property of the cycloid was firſt diſcovered by the celebrated Huygens, who owed much of his celebrity to it, and adopted a contrivance for making a pendulum move in ſuch a curve, which will be deſcribed under our article PENDULUM, and alſo the reaſons will be given why it was laid aſide in the practice of clock-making. It may be proper, however, to remark here, that with a pendulum vibrating in the arc of a cycloid, with all its weight collected in the ball, and its length rendered invariable, if ſuch a pendulum could be made, it would, notwithſtanding, be of conſequence what the nature of the eſcapement were, becauſe though the variations in the *arcs*, ariſing from varied gravity alone, would not affect the *times* of the ſucceſſive vibrations, yet, when *additional force* is applied in aid of gravity, by means of the maintaining power and eſcapement, the uniform law of acceleration juſt deſcribed would be partially diſturbed by ſuch addition, though the diſturbance would be leſs perceptible than in circular arcs of conſiderable extent.

When, however, a pendulum vibrates in a ſmall arc, it is demonſtrable that ſuch an arc differs very little from a cycloidal arc near its loweſt point, nay almoſt coincides with it; it is alſo found from experience, that a heavy ball is leſs diſturbed by the requiſite additional force, communicated by the maintaining power, than a light one, as might be inferred from theory; on which two accounts the prevailing practice among clock-makers is, to make ſuch eſcapements for a pendulum as require but ſhort vibrations, and, in order to gain momentum, to append a heavy ball; and it has been diſcovered, and is now indeed an acknowledged fact, that a regulator with an exact compenſation for the effects of variable temperature in its pendulum, and that vibrates by means of a good eſcapement in ſmall arcs, with a heavy lenticular ball, goes with a degree of accuracy beyond what Huygens durſt even hope for from his cycloidal contrivance; in effecting which, theory and practice were found to be greatly at variance.

But the cycloidal theory, which, conſidered as a theory, is not only ingenious, but illuſtrative of the principal circumſtances which relate to the motion of a pendulum, will furniſh us with a conciſe and clear notion how the natural arc and time of a vibration will be altered by an acceſſion of external force to the force of gravity, without ſome knowledge of which alteration no mechanician can proceed on ſcientific principles in the conſtruction of an eſcapement.

Suppoſing now the pendulum in *fig.* 2, ſimilar to that in the preceding figure, and the arc to be ſo ſmall as nearly to coincide with the cycloidal curve, let the arc G B be unbent into the ſtraight line h H, and with the ſemi-arc D H, as a radius, deſcribe the ſemi-circle H L h; ſet the line A B from H to M, and from h to m perpendicular to the line h H, and join m M, which line will paſs through the centre D; from any other points I and K in the ſemi-arc or radius, draw the lines I N and K O parallel to H M, and alſo the correſponding ones $i\ n$ and $k\ o$ parallel to $h\ m$, and we ſhall obtain the following relations of the properties of the pendulum's motion, *viz.*

1ſt. The forces of gravity urging the pendulum towards D from B, at the points I and K of the ſemi-vibration, will be repreſented by, and proportional to, the ordinates I N and K O of the ſtraight line M D m; and the correſponding ordinates $i\ n$ and $k\ o$ will repreſent, and be proportional to, the retarding forces of the ſame gravity, at the points i and k of the other ſemi-vibration, and *vice verſâ* in each half of the returning vibration.

2dly. The velocities acquired by the uniform action of gravity at the points I K and $i\ k$, will be reſpectively proportional to the ordinates I P, K Q, and $i\ p$, $k\ q$, of the ſemi-circle H L h; hence the velocity of the pendulum at the loweſt point D, is to its velocity at any other point of the arc I, as D L (= D H, or whole ſemi-arc) is to I P.

3dly. The times of the pendulums vibrating through the portions H I, I K, K D, &c. of its arc, will be repreſented by, and proportional to their correſponding arcs H P, P Q, Q L, &c. reſpectively in the ſemi-circle H L h; which proportions will be equally applicable in the aſcending portions of the arc D k, $k\ i$, and $i\ h$, which will alſo be moved through in times proportional to the arcs L q, $q\ p$, and $p\ h$, reſpectively; if the pendulum is projected from the loweſt point D with the initial velocity D L, this velocity will be reduced at the point k to $k\ q$, at i to $i\ p$, and at h to nothing, whence the pendulum will return, and the operation of gravity will begin to be reverſed.

4thly. If one pendulum deſcribe the arc repreſented by H D h, and another deſcribe the arc K D k, (ſtill ſuppoſing them to be cycloidal or very nearly ſo,) they will deſcribe them in equal times, but their velocities at D, or greateſt velocities, will be reſpectively proportional to H D and K D, or length of their ſemi-arcs; that is, while a pendulum, projected with the initial velocity D L, from the loweſt point, aſcends to the point h, or extremity of its ſemi-vibration, another ſimilar pendulum, projected with the initial velocity R D, will aſcend to the point k, or extremity of its arc, D R being = D k, and the ſame will be true in the deſcent, where the increments of motion exactly balance the aſcending decrements.

5thly. The areas M H I N, M H K O, &c. are proportional to the ſquares of the velocities acquired in moving down the arcs H I, H K, &c. or to the diminution of the ſquares of the velocities effected by the retardation of gravity in the returning or aſcending ſemi-vibration.

From a due examination of the relations exhibited in the preceding illuſtration of the principles of a pendulum's motion, the reader will readily perceive that there is a certain length of the arc of every vibration, whether performed in a circle or cycloidal curve, which correſponds to its maximum of velocity, or velocity at the loweſt point; which length, in large circular arcs, is determined by the greateſt chord line, but in cycloidal curves, or *ſmall* circular arcs, is the whole arc itſelf: he will alſo underſtand how, when the weight of a pendulum is given, its accelerating action in any given point of the arc may be appreciated; from which and ſimilar conſiderations he will be able to form ſomething like an eſtimate of the effect that will be produced in the above natural relations by the application of an external force of an aſcertained quantity, acting in a given manner: for inſtance, let us ſuppoſe that a maintaining power is applied to keep up the vibrations of a pendulum, as in our laſt figure; that the quantum of power to be added to gravity be to its accelerating force at H or h, as $h\ m$ is to $m\ r$, which we will ſuppoſe to be a number of grains to ſome number of ounces; and that this additional

power

power is applied through the agency of an escapement, which so modifies it, that its action is exerted but a short time, and at the extremity of the arc: the rough conjecture which the reader would be apt to form would be, that as the two forces began to act in concert, a pendulum actuated by them would obey a compound scale of forces, differing in quantity but not in quality from the simple scale of gravity, and that therefore little or no alteration would take place in the time of its vibration; let us see what would be the result according to our theory; from the point *m* of the line *h m*, of the greatest acceleration or retardation, as the case may be, set off *m r* equal to its representative, for so many grains of augmenting or retarding force, and then *h r* will be the whole force urging the pendulum towards D: do the same for every point of *h* D, and we get a new scale of forces represented by the dotted line *r s t* D, and the space *m* D *r*, contained between the two scales D *m* and D *r*, will represent the addition made to the square of the velocity in moving over *h* D by the joint action of gravity and of the maintaining power. Then if we make the area D *u v* equal to the area D *h m*, by leaving out as much space parallel to the perpendicular *h m*, as we take in beyond the hypothenuse *m* D, the point *u* will limit the excursion or extent of the returning, as well as of every succeeding vibration, because the area of the triangle D *u v* is proportional to the square of the velocity, and *u* is therefore the point where the initial velocity D L will be extinguished. Lastly, if the arc *h w* of the semi-circle be bisected, its half will very nearly represent the contraction effected in the time of the outward semi-vibration, agreeably both to theory and practice; and in a similar manner might be estimated the effect to be produced on a natural vibration, or vibration from simple gravity, by any accession of external force differently applied: in the instance we have given, a temporary impulsion would evidently make a greater derangement when given at the extremity of the arc, than if it had been given at I, and greater at I than at K, and consequently the least derangement would have arisen if the impulsion had been given at the lowest point D, which is worthy of recollection; though the fact is, that most of the escapements, that are not of the detached kind, continue to act for a sensible time, and, after all, the thing principally aimed at in modern practice is, to construct all the parts of an horological machine so, that the arc of vibration may vary as little as possible under the different influences that affect the pendulum's motion; for then, whatever the length of the arc be, whilst there is no variation in it, the vibrations will be isochronal, whatever be the nature of the curve; but completely to effect so desirable a purpose can hardly be expected under all the combinations of variable resistances arising from friction, oil, air, &c., however detached the escapements may be, *i.e.* however small the continuance of each of their impulsions. Hence, certain ingenious artists have attempted such a compound scale of forces, consisting of gravity and maintaining power conjointly, as shall render even circular vibrations of different lengths isochronal among themselves, when they shall happen to vary in length, which plan would certainly make the best compensation for the effects of variable resistances, if such plan could be completely executed at pleasure; and the compound scale of forces to do this, must be to the scale of gravity alone, as the *arc* of semi-vibration is to the *sine* of the same in every point of the excursions. For in *fig.* 1, if B F be supposed equal to the semi-arc B D, then B E, the whole compound force at the point B, will be greater than C B or force of gravity alone, and will be to it, by similar triangles, as B F (= B D) is to the sine A B, as has been demonstrated; therefore the whole compound force at any point B of either semi-vibration should be to the force of gravity alone in that point, as the arc D B is to the sine A B, which compound scale consequently will demand a certain limited variation, or scale, in the auxiliary force derived from the maintaining power through the modifying medium of the escapement.

2. When a balance was first applied as a regulating power, it possessed no natural property, like the pendulum, of perpetuating its own oscillations, but had its motion produced by an artificial force acting alternately on its opposite pallets, and derived entirely from the maintaining power at certain intervals; so that to perform all the oscillations in equal times, the action of the force applied was required to be the same in mode, quantity, and duration, in each oscillation, which conditions could not be fulfilled by reason of the constant changes that took place in the friction of the works, and in the density and consequent resistance of the air; a simple balance therefore was no otherwise better than a continued fly, except that its alternate oscillations prevented the acceleration of motion that would ensue, if there were no such frequent checks as the balance experiences at each alternate impulse of the pallets. Dr. Hooke's invention of a regulating spring, to be to the natural balance what gravity is to a pendulum, was an important one, to which all the excellence of an ordinary watch may have its origin imputed, and without which the compensations for different temperatures in the best chronometers would not be of any utility. The discovery of a *spring's force* being *as its tension*, or distance moved from the point of rest, *(ut tensio sic vis,)* was the first step towards a theory of motion by which the balance and its regulating spring, taken conjointly, may have their effect estimated, and by which such a balance with the best compensation and escapement now vies in accuracy even with the pendulum itself.—George Atwood, esq. of Cambridge, has published an excellent memoir in the Philosophical Transactions of London, vol. 84, part i. 1794, intitled "Investigations founded on the Theory of motion, for determining the times of Vibration of Watch Balances," from which we beg leave to extract so much as falls within our purpose in this place.

"Let P M N S, *fig.* 3. of our last plate, represent the circumference of a watch balance, which vibrates by the action of a spiral (or helical) spring, on an axis passing through the centre C. Let O D B E be the circumference of a concentric circle, considered as fixed, to which the motion of the balance may be referred. In the circumference of this circle let any point O be assumed, and when the balance is in its quiescent position, suppose a line to be drawn through C and O, intersecting the circumference of the balance in the point A; the radius C A will be an index, by which the position of the balance, and its motion through any different arcs of vibration, will be truly defined. In the sequel, the motion of the balance, and the motion of the index C A, will be used indifferently, as terms conveying the same meaning. Since the balance is in its quiescent position when the index C A is directed to the fixed point O, on this account O is called the point of quiescence of the balance, or balance spring, indicating the position when the balance is not impelled by the spring's elastic force either in one direction or the other. If the balance should be turned through any angle O C B, the spiral spring being wound through the same angle, endeavours by its elastic force to restore itself, and when at liberty, impels the balance through the arc B O with an accelerated velocity, till it arrives at the position O, where the force of acceleration ceases; with the velo-

city

-city acquired at O, the balance proceeds in its vibration, defcribing the arc O E with a retarded motion. The elaftic forces of the fpring at equal diftances, on the oppofite fides of the point O, are affumed to be equal; it is alfo affumed that the effects of friction, and other irregular refiftances, which retard the motion of the balance, are compenfated by the maintaining power, fo that the time of defcribing the firft arc of vibration B O, by an accelerated motion, fhall be equal to the time of defcribing the latter arc O E, by a retarded motion, and that the entire arc of vibration B O E is bifected by the point O.

To render the conftruction of *fig.* 3. more diftinct, the fixed circle O D B E is reprefented to be at a fmall diftance from the circumference of the balance, but is to be confidered as coincident with it, fo that the arc B O, fubtending the angle B C O, may be of the fame length with an arc of the circumference of the balance, which fubtends the fame angle B C O: on this principle C O or C A may be taken indifferently as the radius of the balance.

The determination of the time in which the balance vibrates, from the theory of motion, requires the following particulars to be known, *viz.*

Firft. The fpring's elaftic force, which impels the circumference of the balance, when it is at a given angular diftance O D, (*fig.* 3.) from the quiefcent point O:

Secondly. The law or ratio obferved in the variation of the fpring's force, while the balance is impelled from the extremity of the femi-arc B, to the point of quiefcence O, where all acceleration ceafes.

Thirdly. The weight of the balance, including the parts which vibrate with it.

Fourthly. The radius of the balance C O, and the diftance of the centre of gyration from the axis of motion C G.

Fifthly. The length of the femi-arc B O.

Suppofe the plane of the balance to be placed vertically, and let a weight P, (*fig.* 4.) be applied by means of a line fufpended freely from the circumference at T, to counterpoife the elaftic force of the fpring when the balance is wound through an angle from quiefcence O C D. This weight P (the weight of the line being allowed for,) will be the force of the fpiral (or other) fpring, which impels the circumference of the balance, either at reft or in motion, when at the angular diftance O D from the quiefcent pofition. It appears from many experiments (of Berthoud) that the weights neceffary to counterpoife a fmall fpring's elaftic force, when the balance is wound to the feveral diftances from the quiefcent point, reprefented by the arcs O G, O H, O I, &c. *fig.* 4, are nearly in the ratio of thofe feveral arcs. It alfo appears, that the fhape, the length, and number of turns of the fpiral, may be fo adjufted to each other, that the forces of elafticity fhall be counterpoifed by weights, which are in the precife ratio of the angular diftances from the quiefcent pofition, or, as it is fometimes expreffed, in the ratio of the fpring's tenfions; at leaft as nearly as can be afcertained by experiment: this law of elaftic force is affumed in the fubfequent inveftigation.

The pofition of the centre of gyration may be always determined when the figure of the vibrating body is regular, by calculating the fum of the products, which arife from multiplying each particle into the fquare of its diftance from the axis of motion, and dividing the fum by the weight of the vibrating body; the fquare root of the refult will be the diftance of the centre of gyration from the axis of motion. When the figure of a vibrating body is irregular, recourfe muft be had to experimental methods, in order to determine the pofition of the centre of gyration. See Atwood's treatife "On the Rectilinear Motion and Rotation of Bodies."

Let the radius of the balance C A or C O $= r$, *fig.* 3, the femi-arc B O $= b$; let the fpring's elaftic force, acting on the circumference of the balance, when wound to any given angle O C D, from the quiefcent pofition, be P, and let the arc O D $= a$; the weight of the balance and the parts which vibrate with it $=$ W; the diftance of the centre of gyration from the axis of motion C G $= g$. Thefe notations being premifed, the refiftance of inertia, by which the mafs contained in the balance oppofes the communication of motion to the circumference, is $\frac{Wg^2}{r^2}$, and confequently the force which accelerates the circumference at the angular diftance O C D from the quiefcent pofition is $\frac{Pr^2}{Wg^2}$. This quantity remaining invariably the fame, while the balance defcribes the arc of vibration B O E, may be denoted by the letter F, fo that $F = \frac{Pr^2}{Wg^2}$; fuppofe the radius C A commencing a vibration from the point B to have defcribed the arc B H, and let O H $= x$, fince the force which accelerates the circumference at the angular diftance from quiefcence O D $=$ F, and the forces of acceleration are fuppofed to vary in the proportion of the angular diftances from the quiefcent point O, the force which accelerates the circumference of the balance at the point H will be $= \frac{Fx}{a}$; let u be the fpace through which a body falls freely from reft by the acceleration of gravity, to acquire the velocity of the circumference at the point H; the principles of acceleration give this equation $\dot{u} = \frac{-Fx\dot{x}}{a}$; (Newtonii Princip. vol. i. prop. xxxix.) and taking the fluents while x decreafes from b to x, $u = \frac{F \times \overline{b^2 - x^2}}{2a}$: if therefore l is made $=$ 193 inches, being the fpace which bodies falling freely from reft by the force of gravity near the earth's furface defcribe in one fecond of time, the velocity of the circumference, when the extremity A of the index C A has arrived at the point H, will be $= \sqrt{\frac{2lF}{a}} \times \sqrt{b^2 - x^2}$. Let t reprefent the time in which the circumference defcribes the arc B H; then will $\dot{t} = \sqrt{\frac{a}{2lF}} \times \frac{-\dot{x}}{\sqrt{b^2 - x^2}}$; and $t = \sqrt{\frac{a}{2lF}} \times$ a circular arc, of which the cofine $= \frac{x}{b}$ to radius $= 1$, which is the time of defcribing the arc B H expreffed in parts of a fecond; when $x = o$, that is, when the circumference has defcribed the entire femi-arc B O, the circular arc of which the cofine $= \frac{x}{b}$ is a quadrant of a circle to radius $= 1$. Let $p = 3.14159$, &c. the time t of defcribing the femi-arc $BO = \sqrt{\frac{a}{2lF}} \times \frac{p}{2} = \sqrt{\frac{p^2 a}{8lF}}$.

In this expreffion for the time of a femi-vibration, the letter a denotes the length of the arc O D (*fig.* 3.); if this arc fhould be expreffed by a number of degrees $c°$, a will then $= \frac{prc°}{180°}$; and this quantity being fubftituted for

a, the

a, the time of a ſemi-vibration will be $t = \sqrt{\frac{p^3 r c^\circ}{8\,l\,F \times 180^\circ}}$; if inſtead of F, its value $\frac{P r^2}{W g^2}$ is ſubſtituted in the equation $t = \sqrt{\frac{p^3 r c^\circ}{8\,l\,F \times 180^\circ}}$, the time of a ſemi-vibration will be $t = \sqrt{\frac{W p^3 g^2 c^\circ}{8 P r l \times 180^\circ}}$.

Let the given arc c° be $= 90^\circ$; in this caſe $t = \sqrt{\frac{W p^3 g^2}{16\, P r l}}$. Theſe are expreſſions for the time of a ſemi-vibration, whatever may be the figure of the balance, the other conditions remaining the ſame as they have been above ſtated. If the balance ſhould be a cylindrical plate, it is known that the diſtance of the centre of gyration from the axis is to the radius as 1 to $\sqrt{2}$; wherefore in this caſe $g^2 = \frac{r^2}{2}$; and the time of a ſemi-vibration, or $t = \sqrt{\frac{W p^3 r}{32\, P\, l}}$."

Agreeably to this expreſſion, Mr. Atwood wiſhed to try the practical reſults of a chronometer made by Kendal, to prove how far his theory agrees with practice, and aſſuming the centre of gyration to be the ſame as if the balance were a cylindrical plate, he obtained from Mr. Earnſhaw the following data, *viz.*

W, the weight of the balance and vibrating parts $= 42$ grains.

P, the force at the circumference of the balance, which counterpoiſes the force of the ſpring when wound to the diſtance of $90^\circ = 24$ grains.

r, the radius of the balance $= 1.125$ inches.

l, the ſpace deſcribed in one ſecond of time by bodies which deſcend freely from reſt by the acceleration of gravity $= 193$ inches.

p, the circumference of a circle to radius $1 = 3.14159$, &c.

The balance, when adjuſted to mean time, made juſt five vibrations in a ſecond; the actual time of a ſemi-vibration is therefore 0.1000.

Then t, the time of a ſemi-vibration by the theory, will be $= \sqrt{\frac{42 \times 3.14159^3 \times 1.125}{32 \times 24 \times 193}} = 0.0994$ parts of a ſecond; hence $(0.1000 - 0.0994) = 0.0006$ is the difference between the actual time and the time by calculation from the theory; and the near coincidence of the two reſults proves that the ſuppoſition of the centre of gyration being nearly as in a cylindrical plate, is near the truth.

"It is obſervable," ſays our author, "that the ſemi-arc of vibration B O $= b$, does not enter into theſe expreſſions for the time of a ſemi-vibration; if, therefore, inſtead of the ſemi-arc B O, an arc of any other length L O, terminating in the point of quieſcence, (*fig.* 3.) ſhould be ſubſtituted in the preceding inveſtigation, the time of deſcribing L O would be ſtill $= \sqrt{\frac{a p^2}{8\, l\, F}}$, or, $\sqrt{\frac{p^3 r c^\circ}{8\, l\, F \times 180^\circ}}$, equal to the time of deſcribing the other ſemi-arc B O; conſequently, whether the balance vibrates in the largeſt or ſmalleſt arcs, the times of vibration will be the ſame. From the preceding inveſtigations it appears, continues our author, that when the force by which the circumference of the balance is accelerated at the given angular diſtance c° from the quieſcent poſition is $=$ F, the time of a ſemi-vibration $t = \sqrt{\frac{p^3 r c^\circ}{8\, l\, F \times 180^\circ}}$; and converſely, when the time of a ſemi-vibration is $= t$, the force which accelerates the circumference at the given angular diſtance c° from the quieſcent poſition, that is, $F = \sqrt{\frac{p^3 r c^\circ}{8\, l\, t^2 \times 180^\circ}}$.

"Since time-keepers are uſually adjuſted to mean time when the balance makes five vibrations in a ſecond, the time of a ſemi-vibration will, in this caſe, be $= \frac{1}{10}$th part of a ſecond; the ſubſtitution of $\frac{1}{10}$th for t being made in the preceding equation, the force which accelerates the circumference of the balance, when at any given angular diſtance c° from the quieſcent poſition, will be determined for all time-keepers adjuſted to mean time, in which the balances make five vibrations in a ſecond. Suppoſe the given angle $c^\circ = 90^\circ$, then making $c^\circ = 90^\circ$, $p = 3.14159$, &c. $l = 193$, $t = \frac{1}{10}$, the accelerative force at the angular diſtance from quieſcence 90° or $F = \frac{p^3 r\, 90^\circ}{8\, l\, t^2 \times 180^\circ} = r \times 1.00408926$. We have therefore arrived at the following concluſion; if the radius of the balance is equal to one inch, and the time-keeper is adjuſted to mean time when the balance makes juſt five vibrations in a ſecond, the force which accelerates the circumference of the balance at the diſtance of 90° from the quieſcent poſition is $= 1.00408926$, the accelerative force of gravity being $= 1$. And if the radius of the balance is greater or leſs than one inch, the force by which the circumference is accelerated at the diſtance of 90° from quieſcence will be greater or leſs than 1.00408926 in proportion to the radii.

"According to the principles aſſumed in the preceding ſolution, the ſpring's elaſtic force is ſuppoſed to vary in the proportion of the angular diſtances from the quieſcent poſition, and on this condition the vibrations are ſhewn to be iſochronous, whether they are performed in longer or ſhorter arcs; but if the ſpring's elaſtic force at different diſtances from quieſcence ſhould not be preciſely in the ratio here aſſumed, the longer and ſhorter arcs may be deſcribed in times differing in any proportions of inequality. If, for inſtance, the ſpring's force, inſtead of varying in the ratio of the aforeſaid diſtances, ſhould vary in the $\frac{999}{1000}$dth power or $\frac{1001}{1000}$dth power of the diſtances, it does not appear from the preceding ſolution what alteration in the daily rate would be cauſed by this change in the law of the force's variation, when the ſemi-arc of vibration is increaſed or diminiſhed by a given arc. To aſcertain this point fully, other reſearches will be neceſſary, by which it may be known, what alteration of the daily rate of a time-keeper is occaſioned by a given increaſe or diminution of the arc of vibration, when the ſpring's elaſtic force varies in a ratio of the diſtances from the quieſcent poſition, the general index or exponent of which is any number or fraction n.

"The force which accelerates the balance being aſſumed in that power of the diſtances, the exponent of which is n, let B O $= b$, (*fig.* 5.) be the ſemi-arc of vibration when the time-keeper is adjuſted to mean time; let D O $= a$; the accelerating force on the circumference at the diſtance from quieſcence O D $=$ F; ſuppoſe the circumference to have deſcribed the arc B H from the extremity of the arc B; and let H O $= x$: then the force by which the circumference is accelerated when at the angular diſtance from the quieſcent poſition O H $= \frac{F x^n}{a^n}$; let u be the ſpace through which a body falls freely from reſt by the acceleration of gravity, to acquire the velocity of the circumference when it has deſcribed the arc B H; the principles of acceleration gave this equation $\dot{u} = \frac{-F x^n \dot{x}}{a^n}$: taking the flu-

ents

ents while x decreafes from b to x, $u = \frac{Fb^{n+1} - Fx^{n+1}}{\overline{n+1} \times a^n}$, and l being 193 inches, the velocity acquired by the circumference, after defcribing B H, will be $= \sqrt{\frac{4lF}{\overline{n+1} \times a^n}} \times \sqrt{b^{n+1} - x^{n+1}}$; let T be the time of defcribing the arc BH; wherefore $\dot{T} = \sqrt{\frac{\overline{n+1} \times a^n}{4lF}} \times \frac{-\dot{x}}{\sqrt{b^{n+1} - x^{n+1}}}$. The time of defcribing the arc B H will be the fluent of this fluxion, while x decreafes from b to x, and the time of defcribing the femi-arc B O will be the entire fluent of $\sqrt{\frac{\overline{n+1} \times a^n}{4lF}} \times \frac{-\dot{x}}{\sqrt{b^{n+1} - x^{n+1}}}$, while x decreafes from b to o. Now let the balance commence its vibration from any other point I, (*fig.* 5.) and let $IO = c$; fuppofe the circumference to have defcribed the arc I K, and make $OK = y$; let t be the time of defcribing the arc I K; then by proceeding in the fame manner as in the former cafe, it is found that $\dot{t} = \sqrt{\frac{\overline{n+1} \times a^n}{4lF}} \times \frac{-\dot{y}}{\sqrt{c^{n+1} - y^{n+1}}}$; and the time of defcribing the femi-arc I O will be the entire fluent of this fluxion, while y decreafes from c to o. Although the fluents of the fluxions $\frac{-\dot{x}}{\sqrt{b^{n+1} - x^{n+1}}}$, and $\frac{-\dot{y}}{\sqrt{c^{n+1} - y^{n+1}}}$, cannot be expreffed in general terms, yet the exact proportion of the faid fluents may be affigned, which will be the proportion of the times in which the balance vibrates in the two femi-arcs B O, I O; the multiplying quantity $\frac{\sqrt{\overline{n+1} \times a^n}}{4lF}$ being common to both fluxions; and fince the entire fluent of $\frac{-\dot{x}}{\sqrt{b^{n+1} - x^{n+1}}}$ is to the entire fluent of $\frac{-\dot{y}}{\sqrt{c^{n+1} - y^{n+1}}}$ as $b^{\frac{1-n}{2}}$ is to $c^{\frac{1-n}{2}}$, it follows that the time of a femi-vibration in the arc B O is to the time of a femi-vibration in the arc I O as $b^{\frac{1-n}{2}}$ to $c^{\frac{1-n}{2}}$, or as 1 to $\left(\frac{IO}{BO}\right)^{\frac{1-n}{2}}$.

Suppofe a watch to be adjufted to mean time when the femi-arc of the balance's vibration is $=$ B O, (*fig.* 5.) and let this femi-arc be afterwards diminifhed to I O; the time fhewn by the watch in any given portion of mean time t, when the femi-arc of vibration is I O, will be $= t \times \left(\frac{BO}{IO}\right)^{\frac{1-n}{2}}$; and if t is put $= 24^h$, the alteration of the daily rate, in confequence of the diminution of the femi-arc of vibration from BO to IO, will be $24^h \times \overline{\left(\frac{BO}{IO}\right)^{\frac{1-n}{2}} - 1}$. To apply this propofition, let a cafe be affumed; fuppofe a watch to be regulated to mean time, when the femi-arc of vibration is 135°, and let this femi-arc be diminifhed 8°, fo as to become 127°; let the ratio of the fpring's elaftic force deviate from that of the diftances from the quiefcent pofition by a fmall difference of $\frac{1}{1000}$dth power of the diftances, inftead of in the entire ratio of the faid diftances from the quiefcent pofition. The alteration in the daily rate of the watch will be obtained from the preceding theorem, by making the following fubftitutions; $BO = 135°$, $IO = 127°$, $n = \frac{999}{1000}$, the alteration of the daily rate $= 24^h \times \left(\frac{135}{127}\right)^{\frac{1}{2000}} - 1 = + 2''.62.$"

From this theory of the balance and balance fpring it is evident, that when there is a very minute alteration in the law of the force's variation, amounting to no more than $\frac{1}{1000}$dth part of the entire ratio of the diftances, an acceleration is caufed in the daily rate of more than $2\frac{1}{2}''$, when the diminution of the femi-arc is only 8°, and as this alteration in the force is lefs, probably, than can be detected by actual meafurement of the force by mechanical means, it is very probable that a much greater acceleration or retardation of the rate, than in the example before us, may occur from the fame caufe, which can only be corrected by a correfponding alteration either in the length or ftrength of the balance fpring, or both, as the cafe may require, and the beft way of detecting the law of force by which the fpring acts at different diftances from the quiefcent pofition, is by increafing or diminifhing the maintaining power, fo as to render the arc of vibration unequal in fucceffive trials for a limited time. The neceffary conclufion, from fuch trials with different maintaining powers, will be, that when an acceleration of the daily rate accompanies a diminution of the arc of vibration, the elaftic force of the fpring ufed varies in a lefs ratio than that of the diftances from the quiefcent pofition; but on the contrary, when a retardation takes place under the fame circumftances, the faid elaftic force varies in a higher ratio than that of the diftances from the point of quiefcence. We here fuppofe the fame efcapement to be ufed in all the trials, and that the impulfe given to the balance is no more than fufficient to overcome the inertia of the balance and the refiftance it meets with from friction and the denfity of the air; but as there is generally an overplus of power communicated to the balance to guard againft ftopping by the acceffion of dirt or thickening of the oil, this fuperfluous power has fuch an influence on the balance and its fpring when in motion, as to produce a compound law of varying forces, fomewhat different from the fimple law derived folely from the elafticity of the fpring, and the more this compound law varies from the fimple law derived from the fpring's elafticity, the greater will be the difcrepancy between the theory and performance of a watch balance. The bufinefs of a good efcapement of a watch or balance clock is to keep the balance in continual motion with as little interference as poffible with the fimple law of its natural varying forces, which it has been fhewn are in proportion to the diftances from the point of quiefcence.

After thefe remarks on the laws by which a pendulum and a balance together with its fpring become the regulators of an horological machine, the reader will be able to form an opinion, founded on fcientific principles, on the merits or demerits of the different efcapements that are fucceffively defcribed, not only in this article, but in the articles CHRONOMETER and CLOCK, which have been already publifhed.

Henry Sully, who was an ingenious clock and watch maker about the beginning of the 18th century, wrote a hiftory of the efcapements of his time down to the year 1727, which Julien le Roy added to Sully's "Regle Artificielle du Temps," in the fecond edition, publifhed at Paris, 1737, from which Berthoud has extracted his account of feveral efcapements in his "Hiftoire de la Mefure du Temps," and which we mean to avail ourfelves of in a certain degree in our fubjoined defcriptions.

The

The different efcapements of clocks and watches may be divided into four claffes; *viz;*

1. Thofe with a *recoil*, or which produce a backward motion of the efcapement wheel and fecond's hand in fome parts of the vibration; (echappement a recul.)

2dly. Thofe that have the *dead-beat*, or that allow the efcapement wheel and hand to reft while the whole vibration is made; (echappement a repos.)

3dly. *Detached*, or *free* efcapements, which act on the balance or pendulum an almoft infenfible time, and fuffer the vibration to be performed almoft without connection with the pallets; (echappement a vibrations libres.)

4thly. *Detached*, or *free* efcapements with a *remontoir*, or auxiliary fpring frequently wound up by the maintaining power, to equalife the arcs of vibration; (echappement a vibrations libres et a remontoir d'égalité d'arcs.)

The moft ancient efcapement in ufe at this time, and probably the firft that was ever contrived, is the *crown-wheel efcapement* at prefent employed in our table-clocks and common watches; we know not who was the original inventor, but find mention made of it by Leonard de Vinci, who died in the year 1513; and Venturi thinks that the horological machines of Wallingford and Dondi, early in the fourteenth century, had the fame, as we have feen, under our article Clock, that Henry de Wyck's clock had in the year 1364. The idea of converting a rotatory into a vibratory motion, and the means adapted to effect this purpofe mechanically are equally ingenious; as an effort of genius this thought is much to be admired. We have already given a general defcription of the connection that the efcapement-wheel has with a train of wheel-work on one fide of it, and with the balance on the other, under our article juft referred to, but as the balance had no rim, and was without the *regulating*, or, as it is fometimes called, the *pendulum fpring*, we think it right to give a feparate drawing and defcription of this efcapement, as made at prefent, together with fome remarks on its properties.

1. *Crown-wheel efcapement.*—In *Plate* XXXI. of *Horology*, *fig.* 6. reprefents the crown-wheel and balance in connection, which may be in either a horizontal or vertical pofition, and is in fact fometimes in one pofition and fometimes in the other in a common watch agreeably to the different pofitions of the body of the wearer; and it is eafy to conceive that a fhort pendulum might be fubftituted for the balance when the crown-wheel moves horizontally in a fixed pofition, and the axis of the balance is placed horizontally, which is the cafe in moft of the portable clocks. The name of crown-wheel is taken, no doubt, from the refemblance it has to an old fafhioned *royal diadem;* but when applied to a watch it is frequently called fimply the *balance-wheel*, from its connection with the *balance:* this wheel and the balance, including the pallets and regulating fpring, may be confidered as conftituting the *efcapement*, the action of all which may be underftood from the following fhort account.

Suppofe the pinion *a*, on the arbor *a b* of the balance-wheel or crown wheel *c d*, to be actuated by the main-fpring, or weight which forms the maintaining power, by means of the train, in the direction *c f d e*, while the pallets *e* and *f*, attached to the axis of the balance *g h*, and ftanding at right angles to each other, or very nearly fo, are long enough to fall in the way of the ends of the floped teeth of the wheel, when turned round an angle of 45°, fo as to point in oppofite directions, as in the figure; then a tooth of the wheel below, for inftance, meets with the pallet *f*, fuppofed to be at reft, and drives it before it a certain fpace, till the end of the tooth *efcapes;* in the mean time the balance attached to the axis of the pallets moves in the direction *h k g*, and winds up the fmall fpiral fpring *i*, one end of which is faft to the axis and the other to a ftud on the plate of the frame, in this operation the fpring oppofes the momentum given to the balance by this pufh of the pallet *f*, and prevents the balance from going quite round before the pallet *e* meets with another tooth at the oppofite end of the wheel's diameter; here this pallet receives a pufh which carries the balance back again, having as yet but fmall momentum, in the direction *h l g*, and aids the fpring, which now unbends itfelf till it comes to its quiefcent pofition, but beyond that point is unwound, partly by the pufh from the maintaining power on the pallet *e*, and partly by the acquired momentum of the moving balance, particularly when this pallet has efcaped; at length pallet *f* again meets with the fucceeding tooth, and is carried *backward* by it, in the direction the balance is now moving in, till the maintaining power and force of the unwound fpring together overcome the momentum of the balance; during which time the *recoil* of the fecond's hand is apparent, when put on the pivot of the arbor *a b*; at length the wheel brings the pallet *f* back again till it efcapes, and the fame procefs takes place with pallet *e* that has been defcribed with refpect to pallet *f*, and thus two contrary excurfions, or ofcillations of the balance, take place before one tooth has completely efcaped, which is the reafon why there muft be always an odd number of teeth in this wheel, that a fpace at one fide of the wheel may always be oppofite to a tooth at the other, in order that one pallet may be out of action while the other is in action. The fame account will apply to the vibrations of a fhort pendulum fubftituted for the balance, when this efcapement is ufed. This efcapement, which is of the firft clafs, is evidently calculated to derange the natural law of the fpring's varying force, which, we have feen, is in theory in proportion to the diftances from the quiefcent pofition; for as the action of the maintaining power continues to prefs on the pallets, either with or againft the balance's motion, during a large portion of each vibration, this extraneous force acting along with the elaftic force of the fpring makes a new law compounded of the two forces, which may or may not be a regular law, as modified by circumftances, that are to be taken into confideration; for inftance, the relative forces of the maintaining power and of the regulating fpring, the uniformity of each force feparately confidered, the ratio between the radius of the pallet-wheel and length of the pallets, the weight and diameter of the balance, the angle of action in the efcapement relatively to the whole arc of vibration, the adjuftment of the length and ftrength of the fpring for ifochronifm, and of its quiefcent place to the pofition of the pallets, together with the friction and inertia of the acting parts, as well as refiftance of the air to the moving balance muft all enter into the account, which complex data render all calculations founded in theory very inadequate to their purpofe of determining the practical refults independently of experimental trials, which are neceffarily adopted by the workmen in finifhing the adjuftments. The bad effect of an almoft conftant force on the balance, as derived from the maintaining power, is evident by the application of the key to the fufee-arbor of a watch, and by urging it in a direction contrary to that of winding up, for the additional force thus given to the maintaining power, will very fenfibly accelerate the beats of the watch, and leffen the arc of vibration; hence any inequality occafioned in the maintaining power, by the acceffion of dirt, or by want of perfect compenfation in the fufee of the varying force of the main-fpring, &c. will alter the daily rate very materially, though the me-

 chanical

chanical adjuftments at the balance may, in the firft inftance, have produced jointly a law of varying forces in the regulating mechanifm that fhall approximate near enough to the ifochronous law of the balance fpring, while the arcs of vibration remain unaltered. It is of the utmoft importance, therefore, when a crown-wheel efcapement is ufed in any watch, that, whenever a new main-fpring is put in, the fufee fhould alfo be altered, fo as to become as perfect a compenfator as poffible for that *identical fpring*, which, we believe, is feldom, if ever, attended to in practice. This efcapement ufually has a pin in the rim of the balance that may catch a notch on each fide of the cock beyond the extremities of the longeft vibrations, called the *banking*, to prevent the derangement of the balance and of its regulating fpring by any fhake or accident.

2. *Efcapement à pirouette by Huygens.*—About the year 1675, when Huygens was contriving the beft conftruction he could devife of a marine time-piece, he naturally dwelt upon the portability of the balance, as affording the likelieft plan of accomplifhing his purpofe, but he was aware that the balance vibrating in fhort arcs was not comparable in point of fteadinefs to a pendulum, as a regulating principle, feeing it is too much under the controul of the maintaining power, when ufed with the crown-wheel efcapement, the only one at that time known. The balance under fuch ftrong influence, and that a variable influence, had the property of putting itfelf into motion when in a ftate of reft: Huygens, therefore, made fuch additions to the balance and efcapement then in ufe, as produced much longer vibrations than had been before witneffed, and introduced an additional wheel and pinion between the pallet-wheel and the balance to effect this object; thus, in *fig.* 7. of our laft plate, is a fide view of a fmall frame containing the mechanifm of Huygens' efcapement, confifting of two wheels, one pinion, a pair of pallets, and a balance with the fpiral fpring, together with the requifite cocks to bear the pivots of the arbors; *a b* is the crown-wheel or pallet-wheel of the ufual fhape and number of teeth, placed in a vertical pofition, like the contrate wheel of a common watch or table clock; *c d* is a contrate wheel placed horizontally, like the pallet-wheel of a common watch, having two pallets *e*, *f*, as ufual on its arbor, at right angles to each other, and acting exactly as we have explained above; the contrate wheel *c d* drives a pinion *g* on the axis of the balance *h*, under which, as ufual, is the fpiral fpring *i*; the action of this efcapement differs from that of its predeceffor only, inafmuch as the contrate wheel impels the pinion feveral times round at each impulfe of one of the pallets, thereby occafioning feveral revolutions of the balance itfelf at each ofcillation; and Sully fays, that when the fpring is not ufed he has feen the ofcillations performed in the fpace of two feconds, and with a fpring in one, in imitation of a feconds' pendulum clock, to which this efcapement is not applicable. The influence, however, of the maintaining power muft have been exerted on the balance in this conftruction alfo, during at leaft one of its revolutions, and the extraneous force interfering with the law of the fpring's varying forces would produce a compound fcale of forces, in which, as in the former inftance, one would be nearly conftant while it acted, and the other varying; befides, the friction in the teeth of the wheel and pinion, however well executed of the refpective fizes and fhapes, would produce checks that would be unfavourable to the fteady ofcillations of the balance, we therefore are not furprifed to find that this efcapement, which was of the firft clafs, was foon difcontinued.

3. *Efcapement with two balances by Dr. Hooke, and by Du Tertre.*—Dr. Hooke, fays Sully, produced a balance in the year 1675, which he had invented in 1658, with two balances engaging each other by means of teeth cut in their edges, and one of them having a fpiral fpring on its verge or axis; but Berthoud attributes the invention of this efcapement with two balances, without the fpring, to a German artift on the authority of Thiout (Traité d'Horlogerie de Thiout) where there is a drawing of the efcapement in queftion; J. B. Du Tertre afterwards made fome additions, which we have given in *fig.* 8. of *Plate* XXXI., and of which the following is a defcription, *viz.*; A and B are two balances acting together, like wheels with equal numbers of teeth, and having on one of the croffes of each a pallet, at *a* and *b* refpectively; at equal diftances from the axes of thefe balances is the arbor of the laft wheel of the train, bearing two ftars with each five radii, one numbered 1, 2, 3, &c. which is fmaller than the other, lying the lower in pofition, and the other marked *d e f*, &c. with radii long enough to reach almoft to the centres of motion of the balances, which they can pafs only when the femi-circular parts that are cut away are prefented to them; but at other times they reft againft the central femi-circular pieces that remain uncut: the radii of the fmall ftar reach far enough to fall on the pallets *a* and *b* fucceffively, which they impel alternately, and give motion to both balances at the fame time; but the efcape takes place by means of the radii of the large ftar, that reft fucceffively againft the femi-circular portions of metal not cut away, above the centres of the balances refpectively. The three axes ftand in the angles of an ifofceles triangle, and have their upper pivots fupported by three feparate cocks, placed over the upper plate of the frame, the lower pivots of the balances refting on the upper plate, but the arbor of the two ftars paffing acrofs the frame to take the laft wheel. The action is thus; radius 1 of the fmall ftar has parted with the pallet *a* of balance B, and the long radius *d* is efcaping; prefently radius 4 will fall on the pallet *b* of balance A, and impel it in a direction from 4 to 5, the balance B at the fame time moving in a contrary direction; this impulfe will continue till the radius 4 falls from the pallet, foon after which the long radius *g* will fall on the femicircular central piece of balance A, and ftop the further motion of the two ftars, which move together on the fame arbor, and the balances will go on in their vibrations till the fpring under balance B brings them back again, fo as to prefent the cut half of the central piece of balance A to the point *g* of the long radius, which, being impelled by the train, now efcapes; the ftars go on till radius 4 of the fmall ftar meets with the pallet *a* of balance B, the motion of which it now oppofes, and is itfelf brought back, fo as to make a recoil of the hands till it has ftopped the motion of the balances, which now begin each another ofcillation: this radius 4 efcapes the pallet *a*, and the long radius *g* falls on the femi-circular piece, at the centre of balance B, as it did before on that of balance A; the ofcillation continues forward again till the fpring brings it back, when another following radius of the fmall ftar falls again on the pallet *b* of balance A, as before, and drives it; foon after which a fucceeding long radius falls on its femi-circular central piece, and refts till at the return of the ofcillation it can efcape; thus an alternation of ofcillations is produced by the fhort radii acting alternately on the two balances, while the long radii fufpend the impulfes by refting on the femi-circular parts of the centres of the balances, during the latter portion of each excurfion. This efcapement was evidently of the firft clafs, like its predeceffors, and though it avoided the jerk ufually given to one balance by the ftroke of the pallet, yet was fubject to the friction arifing from the action of the teeth, like the preceding

ing one; it had, however, a capability of making the angle of action and angle of the balance's motion before the eſcape in any ratio to each other, by altering the lengths or number of the radii reſpectively, as well as the diſtance of the pallets from the centres of motion; it had alſo the good property of preventing an increaſe in the maintaining power from affecting the balances in the ſame proportion, by the long lever preſſing againſt the ſemi-circular central part of the balances alternately, during the latter part of the excurſion of the balances, ſo as to check any acceſſion of momentum occaſioned by an acceſſion of maintaining power: the law of this preſſure, however, might be modified by changing the figure of the ſemi-circular piece into a ſpiral ſhape, ſo that the preſſure might bear a proportion to the angular diſtances of the balances from the ſpring's quieſcent poſition. The friction in both caſes, it muſt be admitted, would be detrimental to the performance. The banking, we preſume, in this eſcapement, was the ſame as in an ordinary watch, as no remark is made thereon. The invention, it appears, muſt be attributed to three ſucceſſive artiſts; firſt the German, whoever he was, invented the eſcapement without the balance ſpring, and with the ſmall ſtar only, in which ſtate it would act under the controul of the main-ſpring, without the regulating ſpring: ſecondly, the regulating ſpring was added by Dr. Hooke, and, thirdly, the large ſtar was introduced by Jean Baptiſte Du Tertre, about the year 1724, which addition completed the eſcapement as given in our drawing, which in its preſent ſtate will not act without a regulating ſpring. Of courſe this laſt addition followed Tompion's and De Baufre's eſcapements hereafter deſcribed, from which probably the idea of the large ſtar preſſing on the circular part of the axis of motion was derived. Each addition was evidently an improvement on the original German eſcapement as deſcribed by Thiout; but the number of pivots in motion, and the increaſed friction occaſioned by the preſſure of the ſemi-cylindrical pieces at the centres of the balances, were obſtacles too powerful to be overcome in this conſtruction.

4. *Firſt dead beat eſcapement by Tompion.*—The ingenious Tompion of London was probably the firſt watch-maker who contrived an eſcapement without recoil, or eſcapement of the ſecond claſs, called a *dead-beat* eſcapement from the circumſtance of the ſecond's hand remaining motionleſs, or, as it were, dead, during the motion of the balance after the eſcape. Sully ſays that he ſucceeded in effecting this about the year 1695. In this eſcapement, of which *fig.* 7. of *Plate* XXXV. is a plan, the balance verge carried a cylindrical piece of metal *a b c*, terminating with a pallet *c*, with a notch cut between *a* and *c* to allow the eſcape of each ſucceſſive tooth of the balance wheel. This wheel had its plane parallel to the planes of the plates of the frame, and its teeth bent at the end, and ſo diſtant, that the cylindrical piece and pallet could revolve between any two of them. When the cylindrical part of the pallet preſented its notch to a contiguous tooth of the eſcapement wheel, it received a puſh therefrom, which put the balance in motion, and the next ſucceeding tooth falling on the circular or cylindrical portion of the pallet, now in motion in the direction *c b a*, reſted againſt it without recoil till the balance ſpring had brought the notch back again, when it eſcaped in its turn by giving its puſh, and a third tooth fell on the cylindrical part of the pallet, and in like manner remained motionleſs till the notch came back again and allowed the eſcape: thus one eſcape took place at every alternate vibration, and the contrivance was admirably calculated to prevent the bad effect on the balance of any change in the impulſes derived from the main-ſpring; but the friction on the back of the pallets when large, and at the balance pivots occaſioned by the preſſure of the reſting teeth, conſtituted the ſame objection in practice as applied to Du Tertre's modification of the eſcapement with two balances. This eſcapement, however, was the archetype of all the ſucceeding dead-beat eſcapements, and therefore is deſerving of the notice we have given it.

5. *Cylinder eſcapement in diamond by De Baufre.*—A native of Geneva of the name of Facio had applied rubies to the pivot holes of a watch about the year 1700, and went into partnerſhip with De Baufre, a French watchmaker, eſtabliſhed in London; the latter artiſt finding the advantage of applying the poliſhed ſurfaces of the precious ſtones for diminiſhing friction at the parts of action, contrived a new eſcapement about 1704, of which the pallets were of diamond. Sully ſays that a watch of De Baufre, with the diamond pallets, was put into his hands by ſir Iſaac Newton, who had found its accuracy of performance admirable. The following account will be intelligible, we preſume, to any artiſt who underſtands the mechaniſm of a watch. The balance had two pallets on its verge conſiſting of a ſemi-cylindrical diamond, and the eſcapement wheels, of which there were two, were vertical, with their common arbor at right angles to the verge of the balance; *i. e.* with their planes parallel to the verge: theſe wheels, which were ſimilar, were placed one oppoſite the other on contrary ſides of the verge in ſuch way, that a tooth of one fell in the middle of the ſpace of the other, and *vice verſâ*; the pallets were $\frac{1}{24}$th of an inch thick, and two and a half twelfths in diameter, and the diſtance between the ends of the teeth of the double eſcapement wheel about $\frac{1}{12}$th of an inch, or twice as much as the thickneſs of the pallets; the pallets had their planes parallel to the plane of the balance, and had their ſemi-circle ſloped in an angle of about 45° at the ends for the pallets to ſlide over, after preſſing on their planes alternately during the reſpective oſcillations. We will endeavour to explain the action, as we comprehend it to have been by a verbal deſcription. Let the leading pallet be called *a*, and the following pallet *b*; and let the balance be ſuppoſed in motion with a tooth of the eſcapement wheel reſting on the plane of the diamond; when the ſloped end of pallet *a* arrives at the ſaid tooth, the tooth falls off, accelerating the balance by its ſliding motion, and goes on till an oppoſite tooth of the other wheel falls on the plane of the diamond in motion; this tooth reſts without recoil, as did the former one, till the ſloped end of the pallet *b* comes to it, when it falls off in its turn, and gives motion to the balance, which has thus its ſpring wound up by the momentum of the balance ſufficiently far to bring the balance back again after every impulſe; and thus an alternation of vibrations is continually maintained while the force of the mainſpring laſts. This eſcapement is alſo of the ſecond claſs, or of the dead-beat kind, but is ſubject to the conſtant friction of its immediate predeceſſors, though this friction is greatly diminiſhed by the ſubſtitution of the diamond for metallic pallets, and by the buſhing of the pivot holes with rubies; it poſſeſſed all the good properties of Tompion's eſcapement juſt deſcribed. (See Machines and Inventions approuveés, &c. vol. vii. p. 137.) Larcum Kendal uſed two crown wheels in a ſimilar manner, which W. Howell improved by adding a forked detent to make the eſcapement detached, which was rewarded by the Adelphi Society, in 1792. See their Tranſactions, vol. x. p. 216.

6. *Sully's modification of De Baufre's eſcapement.*—The praiſe which ſir Iſaac Newton beſtowed on De Baufre's new watch induced H. Sully to beſtow much attention on it, and in the year 1721 he adopted an alteration in it, which made only one wheel neceſſary for the eſcape at both oſcillations;

lations; but Berthoud has expreffed an opinion that his alteration conftituted no real improvement, but made the adjuftment of the pallets more difficult. Sully having applied his modification of the efcapement in queftion both to a pendulum clock and a marine time-piece, prefented two memoirs on its conftruction to the Royal Academy of Sciences in the years 1723 and 1724; which are alfo printed in his defcription of marine time-pieces, publifhed in 1726. *Fig.* 1. of *Plate* XXXII. of *Horology*, reprefents a fide view of this efcapement, where A is the efcapement wheel, B the contratc wheel between it and the balance C, which has a pinion only on its verge, that is actuated by the contrate wheel; the pallets 1, 2, are two circular pieces of agate, placed at the diftance from one another of one fpacc of the efcapement wheel nearly; thefe pallets have each an inclined or floped end, like De Baufre's, thc flopes alfo being at thc contrary ends of each; the intention of this modification is not only to make one wheel A perform the whole bufinefs of the efcapes, but to produce long vibrations of the balance, even beyond a complete circle. The action was thus; on giving motion to the balance C, fuppofe the tooth *b* to reft on the plane of the pallet or agate 1, it foon meets with the end flope, and falls off till it meets with the pallet 2 below, on which it refts, after having given a pufh to the pallet during the act of fliding off; the balance goes on, till the fpring, now wound up, brings it back, there being in the mean time no recoil, by reafon of the arbor of the contrate wheel being alfo the axis of the pallets, and at right angles thereto; the tooth *b* now finds, after the return of the balance, the floped end of pallet 2, and efcapes entirely; but at the fame inftant tooth *c*, which follows, falls on the plane of pallet 1, and is then in the fame fituation we at firft found *b* in, therefore the fame action is repeated with this, and every fucceeding tooth, till the power of the main-fpring is exhaufted. This modification of De Baufre's efcapement is confequently of the fecond clafs alfo, and enables us to comprehend more clearly the action of the original one, which had its double efcapement-wheel placed with refpect to the balance verge, as the prefent one has its fingle one, with refpect to the arbor of the contrate wheel. The effect produced muft have been nearly the fame on the pallets, though the vibrations of the original balance muft neceffarily have been fhorter than of the latter, but then it had not the friction in the wheel-work between the pallets and balances.

7. *Efcapement with two cylindrical pallets.*—In the year 1727 Julien le Roy fhewed Sully fome watches juft brought from England into France, which had each two cylindrical pallets with notches cut in them like Tompion's fingle pallet, which kind of efcapement feems to have differed from his, only in having an efcape at every vibration, and in having the old crown-wheel as an efcapement wheel; but as we have not been able to trace the inventor of this efcapement, we muft confider it as a lineal defcendant from Tompion's, and therefore as a variety of Englifh extraction. Its utility has been, however, evinced by the circumftance of Julien le Roy's having adopted it as a favourite, and ufed it in fome of his productions: it had the property of converting the recoil of the crown-wheel into a dead-beat.

8. *Cylinder or horizontal efcapement of Graham.*—We are not informed in what particular year Mr. Geo. Graham, the celebrated watch and clock-maker, invented the efcapement with a cylinder, called alfo the horizontal efcapement, from its wheel being in an horizontal pofition, but it appears that Julien le Roy introduced this conftruction into France in the year 1728, when wonderful properties were attributed to it, but particularly the property of compenfating all the inequalities of the maintaining power, which at that time was the great defideratum among watch-makers. The contrivance bears a great analogy to Tompion's efcapement, and was probably originally derived from his, which, however, does not leffen the merit of the contrivance, as it requires as much ingenuity to improve an exifting inftrument, frequently, as to invent a new onc. *Fig.* 2. of *Plate* XXXII. is a perfpective view of Graham's horizontal efcapement, in which A is thc efcapement-wheel, B the balancc, and C the hollow cylinder fixed on the verge of the balance; each tooth of the wheel, which may have any convenient number of teeth, is formed of a triangular inclined plane or wedge, fupported by a ftem projecting perpendicularly from the plane of the wheel at its circumference; the length of the wedge of each tooth is juft a diameter of the internal part of the cylinder, fo that the cylinder may revolve round the wedge when the balance is in motion; in this fituation the anterior point of the wedge juft touches the cylinder's interior furface, but the pofterior point of the fame is free, fo as not to touch and ftick faft in the cylinder, but to give it a pufh on the edge when the contact ceafes; the diftance between the teeth is alfo great enough to allow the exterior portion of the cylinder to come between them, when the efcape has taken place, and while the balance continues its ofcillation. The action is performed in the following manner; fuppofe the wedge to be juft efcaping from the hollow part of the cylinder, and to be giving its impulfe to the edge of the cylinder which it quits, the balance goes on and winds up the fpring, as ufual, at the fame time prefents its exterior face, or convex furface to the point of the fucceeding tooth or wedge; this point falls on the faid convex furface and refts there, without recoil, till the ofcillation is finifhed, at the return of the balance, by means of the fpring now wound up, the hollow or concavc part of the cylinder comes to the point of this following wedge, and being rounded at this end, admits it eafily into its concavity, at which inftant the other edge of the cylinder receives a fecond impulfe in a contrary direction; the balance now makes another ofcillation, and the point of the wedge refts againft the interior face of the cylinder, as it did before on the exterior, without recoil, and in both fituations of reft the wedge has no other effect on the balance than that of retarding it by its preffure againft the circular furface; the fecond tooth is now in the fame fituation as we found the firft, and prefently in its turn gives another pufh at leaving the cylinder altogether, and leaves the third wedge to perform the fame office by firft refting on the back of the cylinder, then entering it, and laftly giving its parting impulfe to the fecond edge of the faid cylinder, as the two wedges that preceded had fucceffively done before. At one period this efcapement was in high eftimation in England, as well as on the continent, and even now the common watches that are conftructed with this efcapement will fetch greater prices than thofe with the ordinary crown-wheel efcapement, but the detached efcapements of the beft chronometers are now held in much higher eftimation than either. We have feen that the hollow cylinder, though conftituting but one pallet, in effect performs the office of two pallets, and permits but one tooth or wedge to efcape entirely at two ofcillations, during one of which the point refts at the outfide, and during the other at the infide of the cylinder, while the two edges of the cylinder perform the part of feparate pallets on receiving feparate impulfes in contrary directions, it is, therefore, of importance in this, as indeed in all efcapements with a regulating fpring, that the quiefcent pofition be duly adjufted to render both ofcillations precifely fimilar in extent and duration at each fide, otherwife the performance will be a fpecies of hobbling, and the compound law of motion,

 derived

derived from the spring's action and impulses on the pallets conjointly, will be far from regular; consequently not likely to be an isochronal law. Berthoud has described a cylinder escapement with two balances connected by two pinions, but it did not prove successful.

9. *French escapement a Virgule.*— The French escapement known by the appellation of *a virgule*, from the pallet's resemblance of a *comma*, is represented by *fig*. 6 of *Plate* XXXV. A, B, C, are three teeth of the balance wheel, placed very obliquely compared to a true radial line, and carry each a pin at their extreme ends, standing vertically like the supports of Graham's wedges for his cylindrical escapement; the pallet B A has its centre of motion at *c*, the centre of both the concave and convex portion, exactly over the verge of the balance; this centre is in the circumference of the circle that passes through the points or pins of the teeth; the pallet, which is of hardened and polished steel, has its plane parallel to that of the wheel, and is supported between *f* and *e* by a crank piece put over the verge, which cannot be admitted as high as the pallet; this end *a o*, which connects the convex and concave portions, is a portion of an equi-angular spiral, and the part *b d* of the pallet is called the *horn*, probably from its resemblance of the beak of a bird; the inferior face *b* A may be straight like the dotted line, or curved, at the option of the maker, and the superior part *f* A may be of any shape: the convex part *a e f* contains about 100°. The length of the pallet from *a* to *d* is such, that when the pin at B presses against the curved part at *a*, the point *d* of the horn will just miss the pin at A of the preceding tooth, and the height at which the pallet stands is such as to make it pass over the rim of the wheel, but not over the pins at the ends of the teeth. When the balance is at rest, and has its spring in equilibrio, the point *d* of the horn is at the point *i*, about 30° from *d*; but the present position is that which the pallet has when the tooth A has just escaped from the point *d* of the horn. To explain the action, on a supposition that the tooth A has just escaped, the succeeding pin B has just fallen on the point *a*, joining the spiral and convex portions of the pallet, and the balance has just received its impulse from tooth A as it passed from *b* to *d* along the inferior face of the horn; it, therefore, proceeds in its motion in the direction *d g h* of the dotted circle, while the point B slides on the convex side *e f*, and is detained without recoil; when the point *d* of the horn has arrived as far as *h*, more than 90° from A, the momentum of the balance is exhausted, and the balance returns; the point *d* comes to about the point *i* before the pin of tooth B comes to *o*, and enters the concave part of the pallet, where it slides till the point arrives about *k*, where the momentum of the balance spring is again exhausted; the balance returns again, and when the point *d* comes to *i*, the pin of tooth B escapes the concave part at *b*, and slides along the inferior face of the horn, at the same time giving it a push till it escapes entirely, and is in the situation of tooth A, where the process began; in the same manner the following tooth C, and every succeeding tooth in its turn, will fall on the convex side of the pallet, return and enter the concave side, and then finally escape. We must observe, however, that the pallet opposes the motion of the balance as it passes along the small spiral part from *a* to *o*, which may be so proportioned as to be a counterbalance to the impulse previously given to the balance by the leading tooth, in case the friction on the back of the cylindrical part is not competent to retard the balance's impulse sufficiently. The effect produced by this escapement must be very similar to that produced by Graham's cylindrical escapement, but has this advantage, that the inclined plane formed on every wedge of Graham's construction is transferred to the pallet, and serves for all the pins to slide on in succession, thereby removing the difficulty of forming all the wedges alike in size and shape. Besides, the convex and concave sides of the pallet may be reduced to any dimensions, provided the acting tooth may not slide at once from the spiral to the horn, and allow the train to run down, which may be the case if the parts of action be small, and there be much play in the pivot holes of the wheel and balance. The construction is a compound of Tompion's and Graham's watch escapements, to both of which it has certain points of resemblance. In 1752, Le Paute altered this escapement, by putting pins for teeth in both planes of the wheel, as he did in Amant's escapement *a cheville*, which addition gave it some advantages.

10. *Escapement with one pallet and one detent by Thiout.*— Thiout, a French clock-maker of considerable eminence, published a work in 1741, entitled "Traité de l'Horlogerie Mechanique et Practique, approuvé par l'Academic Royale des Sciences," 2 vols. 4to. in which he has described an escapement of a watch that has been mistaken sometimes for a real detached escapement, and considered as the first that has been made of such a construction, though the inventor himself did not consider it as such, as is evident from his own description. This escapement is given in *fig*. 8. of *Plate* XXXII., and to use the author's own account, "it is an escapement of a watch in which half of the vibrations *seem* independent of the train of wheels, while they are performed. The detent B stops the escapement wheel, the balance bringing back the pallet A, the detent recedes, to leave the wheel free to strike the pallet; and so on. This escapement could not perform without a spiral spring." — It hence appears, that the pallet A is on the verge of the balance, but that the detent B is on a separate arbor, while they are connected by the tail of the pallet entering the slit in the remote end of the detent, so that the balance is never disengaged from the detent, and therefore cannot be considered as of the detached class. When the balance moves in a direction from A to B the pallet gets out of the teeth, but the detent falls in, and *vice versâ*. The curves of the claw of the detent appear to have been drawn from the centre of its motion, and therefore we are disposed to think that there would be no recoil in the escapement wheel.

11. *The anchor escapement by Clement, or Dr. Hooke.*—While these improvements were going on in watch escapements, an equal attention was paid to the contrivance of new clock-escapements. Huygens had placed the pallets of the crown-wheel escapement at an angle of about 60° instead of 90°, as they were made for a watch, in order that they might be accommodated to the short vibrations of a pendulum, or rather, perhaps, to the vibrations of some length performed in a cycloidal curve, by means of his cycloidal cheeks near the point of suspension; but still the arc of action on the pallets was too long to allow practice and theory to coincide, as to the performance of long and short arcs of vibration in the same time. The preference that seemed due to short arcs, when circular, suggested the propriety of contriving an escapement that would admit of very short arcs of vibration. This was first effected about the year 1680 according to Smith's account, by Clement, who was a clock-maker in London; but Dr. Hooke has disputed the priority of the invention, and has affirmed that he exhibited a pendulum with what is now known by the name of the *anchor* escapement, to the Royal Society of London, in the year 1666, soon after the great fire of that year. We will not endeavour to settle the point that relates to priority of invention, but proceed to describe the contrivance itself, which has continued, and is likely to continue, to be of permanent

use

ufe in ordinary clocks. *Fig.* 3. of our laft named plate is the reprefentation of the anchor efcapement, as it is commonly conftructed for a pendulum clock that fwings feconds, which pendulum, in conjunction with the anchor efcapement, gained the appellation of the *Royal pendulum.* The efcapement, or fwing-wheel A, has ufually thirty teeth, when a vibration is performed exactly in a fecond, in which cafe a fecond's hand is ufually inferted on its elongated pivot, to indicate feconds; but if no attention is intended to be fhewn to the indication of feconds, the train may be made to admit of any other convenient number of teeth; B C is the anchor and pallets, taking its name from a refemblance to a fhip's anchor, that may be obferved in its fhape; the diftance from its centre of motion *a* to that of the wheel *b* is determined by the number of teeth that the pallets take in between them, it being effential to the freedom of action that two lines, drawn from the two centres of motion *a* and *b*, fhould conftitute a right angle at each of the two points of action, as feen included by the dotted lines, meeting at the ends of the acting teeth *d* and *e*: in the pallets which we have made to include nine teeth, the centre of the pallet's motion falls at the point *a*, but if they were made to include eleven teeth the faid point would fall above at *h*; and if they included fewer than nine the point for the centre of motion would fall below *a*: in general ten or twelve are contained between the pallets of a fecond's pendulum, but this muft depend on the arc that the pendulum is intended to vibrate; for the more teeth are taken in, the greater is the diftance of the two centres of motion, and confequently the fmaller the angle or arc of action on the pallets. If a circle *f g* be defcribed by a radius equal to half the diftance of the centres of motion *a b*, round the point *a*, the two faces of the pallets B and C ufually lie in the tangent lines *e i* and *d g* of that circle, which lines are the guides for making the flopes. The action of the efcapement before us may be explained thus; fuppofe the tooth *d*, feen refting on the flope of pallet C, to be urging this pallet outwards from the centre of the wheel, by which a motive force is applied to the moving pendulum through the medium of the crutch; prefently it efcapes, and pallet B is brought inwards towards *b*, fo as juft to avoid the tooth *e*; the wheel is now at liberty to move, and goes on, by the force of the maintaining power, till the fucceeding tooth *k* falls on the floped face of pallet B, which is now urged outwards, and endeavours to give a contrary motion to the pendulum; but the momentum of the moving pendulum is too powerful for its impulfe, and carries the tooth *k* back again till the momentum is expended, at which inftant a recoil of the wheel and fecond's hand placed on its arbor take place; prefently the pendulum returns, and the tooth *k* now pufhes it on, and efcapes; the pallet C is now brought back, fo that the tooth following *d* falls on its floped face, and in its turn experiences a recoil till the pendulum returns, when it pufhes on and efcapes; then another tooth next after *k* falls on the face of B, and experiences the fame recoil and fubfequent power of efcaping that the others did; and thus the alternate vibrations of the pendulum are perpetuated as long as the maintaining power continues. The effect of this efcapement on the pendulum is fimilar to that of the crown-wheel efcapement on the balance; the pendulum is either accelerated or retarded in every part of its vibration, except during the almoft infenfible inftant of the drop of the fucceeding tooth, when one has efcaped; but as the momentum of a heavy pendulum in motion is greatly exceeding that of a balance in motion, the bad effect is fmaller in degree. When an additional weight is added to the weight conftituting the maintaining power, the arc of vibration is increafed, whence one might be led to expect a retardation in the time of a vibration, the arcs being circular; but the fact is, that the vibration is accelerated very fenfibly by means of the pendulum being both accelerated in its defcent and oppofed in its afcent, and the pendulum comes fooner back than gravity alone would bring it. Here then the compound law of motion differs from the fimple law of gravity, but not in the ratio of the arcs to the fines of the angle of vibration; for if the compound law were to the fimple law of gravity as the *arcs* are to their *fines*, the vibrations would be ifochronal, whatever their extent might be. It is hardly neceffary to add that this efcapement is one of the firft clafs.

12. *Graham's dead-beat.*—The dead-beat efcapement, as originally contrived by Graham, is a modification of the anchor efcapement we have juft defcribed, from which it differs only by taking off a part of the flope of each pallet, and by making the pads, that is, the back of one pallet and interior part of the other, portions of circles defcribed from the anchor's centre of motion, fo that when the point of a tooth refts on thofe parts, while the pendulum is finifhing a vibration, no recoil takes place, but the wheel continues motionlefs, or, as it were, *dead*. *Fig.* 4. of the fame plate gives the figure of the dead-beat efcapement-wheel and pallets, where we have reprefented the wheel, as we did the wheel of recoil, with only four inftead of fix radii, that there might be more fpace for our geometrical lines. In this conftruction, as in the preceding one, the diftance of the centres of motion *a*, *b*, is determined by the tangent lines meeting the radii at the points of the acting teeth; when this diftance is an exact diameter of the efcapement wheel, we find that the pallets take in juft ten teeth out of thirty, which is the cafe in the figure before us, but when twelve teeth are taken in, the centre of the anchor's motion falls at *h*, juft a diameter and a half from the centre of the wheel; and this is Berthoud's rule for giving the diftance *a b* without any reference to the tangent and radius; for he has found that the arcs of action on the flopes of the pallets *a m n*, and *a o p*, are each only one degree, but that if fewer teeth than twelve were included between the pallets, the anchor would be fhorter, and the arcs of action proportionally longer. This rule might be a good one with a given maintaining power, that is, where the whole arc of vibration is of a given extent, but it does not follow that one degree for the arc of action before the efcape is the beft in all cafes where the motive powers vary. We are of opinion that experiments might be inftituted to afcertain this important point, by applying various weights fucceffively, firft with pallets that have twelve teeth included, and then with fuch as have eleven, ten, &c. but the experiment could not go beyond 14 teeth, becaufe when half the wheel is included the tangent becomes a vertical line, parallel to the line of diftance *a b*, and therefore this diftance becomes *infinite*. There is probably a certain maintaining power that is beft for a certain angle of action, with a pendulum of a given weight, but that does not feem to have been afcertained either by calculation or experiment hitherto. The thing to be aimed at is, to make the compound law of the pendulum's motion fuch that the varying forces may accelerate or retard it in proportion to the arcs of diftance from the loweft point, which is the cafe with the fimple law of gravity, as it regards the *fines* of the faid arcs. We have put the fame letters of reference to our prefent figure as to *fig.* 3, that the reader may the more eafily comprehend the correfpondence between them, and to prevent the neceffity of further minute defcription of the parts; the flopes of the pallets being determined by the fame tangent lines *e i*, and *d g*, as before. We fhall, therefore, confine the remainder of

of our defcription to the features that differ, and to the mode of action depending thereon. The circle B C, paffing the points of the firft and eleventh teeth, including the ten fpaces between the pallets, forms the interior faces of the faid pallets B and C, and the exterior portions B *e* and C *d* are formed by a concentric circle of larger radius. Thefe circles are defcribed from the point *a*, or centre of the anchor's motion, therefore a tooth refting at any time againft any one of thofe circular portions remains without recoil; the diftance between the faid circles is fomewhat lefs than one-half of the fpace contained between the extreme ends of any two contiguous teeth, and the nearer it is to one-half of a fpace, the fmaller will be the drop after an efcape, or, as the workmen fay, the clofer the pallets will be laid. The teeth are fomewhat varied in fhape from the inclined teeth of the recoil efcapement, a portion of the flope at the bottom being cut away, that the end of the pallet may enter the fpace, when the pendulum vibrates beyond the arc of action, without coming in contact with the metal of the wheel, which would make the pendulum rebound, and difturb the regularity of the vibration. Thefe obfervations being premifed, the reader will now be prepared to comprehend the action. The tooth at *e* has juft paffed the flope of pallet B, and is efcaping, after having given its ftroke or impulfe gradually, in fliding along the flope from *e* to its prefent fituation; the pallet B is now going from the centre of the wheel's motion *b*, and the pallet C is come back from its excurfion, in time to allow the tooth *b* to fall on its inner circular part, near the angular point of the flope; the pendulum goes on in its vibration till its gravity overcomes its momentum, during which time, the pallet B is no longer in contact with the wheel, but the pallet C enters the fpace between *b* and *d*, and the point of the tooth *b* refts on the inner circle of the pallet; prefently the pendulum returns, the point of tooth *b* flides back again till the flope *b d* prefents itfelf, when urged by the maintaining power, it efcapes after having made its pufh to the pallet C, which now continues its motion outwards, and confequently pallet B falls in the way of the tooth *k*, which follows, but which refts on the exterior circle B *e* of this pallet, till the pendulum returns as before; it then meets the flope at *e*, and, giving its pufh to the pallet, efcapes, as its preceding tooth had done; and thus the vibrations are alternately aided in future, while, as has been feen, one tooth only completely efcapes at the interval of two vibrations: which is the reafon why a wheel of 30 teeth is proper for the indication of 60 vibrations of a fecond's pendulum. When the wheel is made of hardened fteel, and the pallets of ruby or agate, the friction is greatly diminifhed, and will admit a fhort angle of action, or diminution of power.

13. *Modification of the dead beat by Grignon.*—When we gave the "Hiftory of the fucceffive Improvements in Clocks," under our article CLOCK, we faid that the fenior Thomas Grignon, of Covent Garden, London, improved the dead-beat efcapement of Graham, and prefented a clock to the Society of Arts in 1759, which remains in one of their rooms to this day, that has got this improved efcapement, the peculiar property of which is faid to be, that it performed alike with *four* and with *twelve* pounds fufpended as a maintaining power; if this is a fact, the efcapement muft have the property, fo much defired in all efcapements, of rendering all the arcs of vibration ifochronal. We have been favoured with a manufcript account of this efcapement, and of its principle of conftruction. It will be doing but juftice to the memory of departed genius, if we give the author's own figures, demonftration, and account of his improvement, as he has left it in his own hand-writing. *Fig.* 5. *of Plate* XXXII. is the *fcheme*, and *fig.* 6. the *demonftration*, as the author himfelf has intitled the figures, the latter of which has no letters of reference, but is fufficiently intelligible in conjunction with the other. "It appears from the fcheme," fays the author, "that the diftance of the centre of the pallets from the centre of the fwing wheel in that machine (at the Adelphi) is *one whole diameter* of the wheel, which has this peculiar excellence, that the triangles formed at the ends of the pallets, by drawing the tangents for the flopements are *equal*; (nor indeed can they ever be equal, continues he, where the diftance is more or lefs than *one whole* diameter of the fwing wheel,) and, on the contrary, where that diftance is duly obferved, all the triangles will ever be equal; for then all the interfections, made by drawing the two tangents to the circle of the pallets, will fall exactly alike, (*fig.* 6.) interfecting the intermediate circle, as may be feen by the figure, confequently the tangent lines, together with the chord of the fwing wheel form a rectangled triangle, the upper angle of which, by altering the flopement only, changes its place in the circumference of the circle, the fame chord always continuing its bafe. For a farther demonftration of which, fee 21ft propofition of the the 3d book of Euclid.

"Again, when the diftance is duly obferved, we fhall find that one of the lines for the flopement of the pallets will be the hypothenufe, and the other the perpendicular of rectangled triangles, whofe bafes are equal to 120°, the halves of which muft be 60°. That they are rectangled triangles may be eafily proved; for if the bafe be 120°, and perpendicular 60°, the hypothenufe muft be 180°. See 1ft Prop. of the 12th book of Euclid."

In another manufcript paper, Mr. Grignon fays, "that the teeth of the fwing wheel have an equal effort, when they act upon the flopements or faces of the two levers or pallets, may be thus demonftrated.

"Draw the lines A, A, upon the faces or flopements of the pallets or levers *a*, *a*, now thefe are the lines of direction; let fall the perpendiculars B, B, from the centre of motion of the pallets C; now, I fay, that if you meafure the lengths of thefe perpendiculars, they give you the efforts of the arms of the levers or pallets D C, D C; for by the 9th prop. of Mr. De la Hire's Treatife of Mechanics, the efforts of a weight or power are not to be meafured by the length of the arms of the levers, but by perpendiculars drawn from the hypomochlion upon the lines of direction of the weight or power. That thefe levers are equal is thus proved; for, taking C for your centre, defcribe the circle E E E; now if the perpendiculars B, B, are both radii of the circle E E E, they muft, of confequence, be equal, which is what was to be proved. Again, that the faces or flopements of the pallets or levers are equal may alfo be thus proved: *a* A, *a* A, are the lines of direction of the action of the teeth, and being both tangents of the fame circle E E E are confequently equal."

The remarks that have occurred to us on contemplating Mr. Grignon's *fcheme*, as he has called it, are, firft, that his diftance between the centres of motion require *ten teeth* out of thirty to be taken in by his pallets, as we have fhewn in our laft article; fecondly, the circle E E E is defcribed with lefs than half the diftance of the centres, and is yet made the circle to which the tangents are drawn, that form the flopes, the reafon of which he has explained, the radius C B of this circle, it appears, muft be determined by a line *a* A, drawn parallel to the line of diftance, which muft be a tangent to the faid circle, and which affords an eafy and practicable mode of drawing the flopes agreeably to this conftruction; thirdly, if the flopes thus formed by tangents drawn

drawn to a diminiſhed circle have the iſochronal property, they are worthy of future imitation, under the circumſtance particularly of ten teeth being included between the pallets; and laſtly, we obſerve, that the *ſame circle* forms the *exterior* curve of one pallet, and the *interior* one of the other, which is not the caſe with Graham's pallets, but which certainly makes the friction alike on both pallets, ſeeing the circular ſurfaces rubbed by the points of the wheel's teeth are at equal diſtances from their common centre of motion. Theſe conſiderations are all in favour of Mr. Grignon's modification of the dead-beat eſcapement, as each excurſion of the pendulum muſt be influenced by ſimilar circumſtances, and if moreover it poſſeſſes the iſochronal property attributed to it, it is ſomewhat remarkable, that the Adelphi ſociety have been labouring to reward inferior eſcapements in great variety, while one of the beſt *dead-beat* eſcapements is beating *dead* to the ſociety, having *eſcaped* their notice, while performing its functions within their own walls.

14. *Mr. Bennett's modification of the dead-beat.*—Mr. J. Bennett of Norwich has publiſhed an account of what he conſiders an improved method of deſcribing the curves and faces of Graham's dead-beat pallets (ſee Nicholſon's Jour. vol. xv. 8vo.) which account we think deſerves a place here in common with Grignon's method.

Draw the line A B (*fig.* 7. *Plate* XXXII.) ſays the author, on which deſcribe the circle B, the ſize of the intended ſwing wheel; then, according to the number of teeth the pallets are intended to eſcape over ſay, as 60 (the double of the number of the wheel's teeth) is to 360°, ſo is double the number intended and one more to that proportion; thus, ſuppoſe the number intended to eſcape over nine, the double of which is 18, to which add one, and there are 19; then ſay,

As 60 : 360° : : 19 : 114°; the half of 114°, which is the whole arc included, is 57°; then on the circle already drawn ſet off on each ſide of the line A B 57°, from which points draw lines to the centre of the circle; then on theſe points where the circle is croſſed erect perpendiculars, which will interſect at the centre of the pallet's motion in the line A: from this point as a centre draw the arc C C, to cut the points where the radial lines cut the circle; the arc thus drawn deſcribes the receiving and leaving pads of the pallets. The inclination or inclined plane of each pallet muſt form an angle of 60° with the ſaid radial lines; thus from the points of interſection, near E and G, draw the ſmall ſemicircles D and G with any radius, and ſet off 60° from *f* to *g* on the ſemi-circle D, and from *h* to *m* on the ſemi-circle G, then will lines drawn from the centres of the ſemi-circles, through the points *g* and *m* reſpectively, give the proper direction of the ſlopes of the pallets' faces.

This conſtruction is very ſimilar to Grignon's, though differently projected: the centre of motion A is determined in the uſual way, and the odd unit given to double the number of teeth included is an allowance for the breadth of the pallet, to have as little drop as poſſible; the ſlope of the pallet G is parallel to the line A B, in Grignon's conſtruction, but is not quite ſo here, for the difference of the angles at the oppoſite ſides of the radial line is $60° - 57° = 3°$, which is what theſe lines want of being parallel, which quantity of deviation ſeems to conſtitute the principal difference between the two conſtructions; if the radial line of pallet G had been drawn to the lower point of the pallet, ſo as to have made the angle at the centre 60°, and the teeth included had been exactly ten, then the two methods would have coincided, and the point A of the pallets' motion would have been an exact diameter of the wheel from its centre. We conceive that the effects of the two conſtructions may be ſo nearly alike, that their difference in practice may be almoſt imperceptible. If there is any difference, varying the maintaining power conſiderably in different trials will detect it, by rendering the alterations in the rates perceptible from the compariſons. Otherwiſe the alternate angles might each have been 57°, inſtead of one of them being 60°.

15. *Iſochronal eſcapement for a pendulum.*—So long ago as about the year 1720 Saurin, Julien le Roy, and Enderlin, wrote memoirs on the nature of the curve that was neceſſary to give to the pallets of an anchor, inſtead of the concentric circles, in order that the ſwing wheel may have juſt ſo much recoil only, as will render all vibrations, performed in arcs of different extent, iſochronal; and ſince their time Berthoud in France, Reid in Edinburgh, Melville and others in London, have put in practice a method of conſtructing pallets founded upon the ſame principle. We think it not improbable, however, but that the Scotch and Engliſh artiſts have borrowed their contrivance from the French author, who publiſhed his conſtruction in his "Eſſai ſur l'Horlogerie" in the year 1786, before which time we do not find any traces of an iſochronal eſcapement except Grignon's juſt deſcribed, and Smeaton's, which follows. The conſtruction of the eſcapement in queſtion differs from the dead-beat only in one particular, which is, that the circular portions of the pallets, which in the dead beat are concentric, deſcribed from the centre of the pallet's motion, in the iſochronal eſcapement are *excentric*, with reſpect to each other, thoſe curves on which the ends of the teeth of the ſwing wheel reſt being deſcribed from points out of the centre of motion. Berthoud had made ſeveral experiments with different eſcapements, and different maintaining powers, from which he found that the ſame addition to the power which accelerated the vibrations of the pendulum, when a recoil eſcapement was uſed, retarded the ſame when a dead-beat eſcapement was ſubſtituted; hence he concluded that there muſt be a medium between much recoil and no recoil, which would make the pendulum vibrate in the ſame time in all arcs, or, which is the ſame thing, with any addition or diminution of the maintaining power; he therefore fixed, after various trials, on a conſtruction producing but a *ſmall recoil*, which anſwered his moſt ſanguine expectations, and which we ſhall be happy to deſcribe here, particularly as it promiſes to anſwer a better purpoſe than the common dead-beat, which has been long in high eſtimation; and as it has not, we believe, been deſcribed by any Engliſh author. *Fig.* 1. of *Plate* XXXIII. is a plan of Berthoud's iſochronal eſcapement, where A, as before, is the ſwing-wheel, B and C the pallets of the anchor, and *a* the centre of their motion; the diſtance of the centres *a*, *b*, alſo, as before, depending on the number of teeth taken in by the pallets; the angles *m a n* and *o a p*, are the angles of action by which Berthoud has given his ſlopes of the pallets without the tangent lines *e i*, and *d g*, but we have thought it right to ſhew how they may be given both ways. Berthoud's method of ſloping to ſuit any angle previouſly given is more extenſive in its application, but the quantity and direction of the impulſe will vary as the angles *m a n*, and *o a p*, vary; whereas the method of ſloping by the tangent lines can only vary by varying the circle *f g*; as Grignon has propoſed: in our plan we have taken the circle's diameter equal to the diſtance *a b* of the centres for the ſake of uniformity of plan, that the reader may ſee how the pallets, ſo formed, differ in ſhape from the dead-beat pallets. The exterior portion of the circle *d* C, of pallet C, is deſcribed with the extent *a d* from the centre *a*, but the interior portion *b* 4 is deſcribed with the ſame extent from a point 5

below

below the centre; the difficulty confifts in determining the true fituation of this excentric point 5; Berthoud's rule, founded on the refult of experiments, is this; having determined the breadth of the pallets, equal to fomewhat lefs than half a fpace of the fwing-wheel, defcribe from *b*, in the line *a p*, the concentric dotted circle 1, 2, 3, &c. fet the diftance between the two concentric circles, or breadth of the pallet, *three times* over along the inner curve to 1, 2, and 3, then in a direction from 3 towards *a* fet the fame *once* to 4; in the next place, with the extent *a b* find the point 5 by interfection from the points *b* and 4, and this point 5 is the excentric point defired, from which the curve *b* 4 is defcribed with the extent *a b* as before, which is the interior curve to be fubftituted for the concentric curve 1, 2, 3 of the dead-beat efcapement; and it is evident that while the pendulum is in motion inwards, with a tooth refting on this excentric curve, the wheel muft have a certain recoil. Again, the exterior curve of excentricity, of pallet B, is thus defcribed; the curve 1, 2, 3, &c. is defcribed, from the point of the tooth that is in the line *a m*, and the points therein are taken as before at the diftance from each other of the breadth of the pallet, or at fomewhat lefs than half a fpace of the wheel; the point 4 is here fet outwards in the direction from *a* to 3; then with the extent *a e* the excentric point 6 is determined by interfection from *e* and 4, which point is above the centre; laftly, with the extent *a e*, as before, defcribe the excentric curve *e* 4 from the point 6, which being fubftituted for the concentric circle 1, 2, and 3, will produce a fimilar recoil in the pallet B, as the curve *b* 4 produces in pallet C. The inner curve of pallet B having no action, like the outer curve of pallet C, may be defcribed from *a*, or be a ftraight line. The writer of this article has a half-fecond's pendulum clock with this efcapement, and Troughton's tubular pendulum, which goes admirably with any power that will keep it in motion.

16. *Smeaton's efcapement of the turret-clock at Greenwich.*—The efcapement which Mr. Smeaton contrived for the turret clock at Greenwich refembles the ifochronal efcapement, which we have juft defcribed, in a certain degree, and was, no doubt, intended to anfwer the fame purpofe. *Fig.* 2. of *Plate* XXXIII. contains the plan of this efcapement, in which A B is the radius of the efcapement wheel; B C a tangent line at $3\frac{3}{4}$ teeth from the vertex, drawn from C, the centre of the pallet's motion; B D E is a circle defcribed from the centre C through the points B and E, which are each $3\frac{3}{4}$ teeth from the vertex; F G is a line drawn parallel to the vertical line A C at the diftance from the vertex of $3\frac{1}{2}$ teeth, and cutting the circle B D E in the point G; then G C B is half of the angle of vibration, and fetting off the arc B H = B G, G C H will be the whole angle of vibration. Draw the line C H cutting F G in I, and through the point G of this pallet from the centre A defcribe a circle that may cut the radius A K in the point K; this will be the point of the other pallet; the line E C being alfo a tangent to the wheel at $3\frac{3}{4}$ teeth from the vertex. Now fetting off K L on the circular arc = G H, the angle of vibration K C L will be equal to the other angle of vibration G C H, and if through the point L the line C L be produced, and L M be fet off = I H, then will the wheel move equally forward, by a fimilar motion of each pallet. Again, with the radius K C, upon K as a centre, defcribe the arc C N, and alfo with the fame radius from the point M defcribe the interfecting arc O P; then from Q, the point of interfection with the radius unaltered, defcribe the curve through the two points K and M to R, which curve will give the working face of the pallet that will produce a fmall recoil nearly equal to that produced by the plane G I; in this conftruction the depth of the teeth is equal to a fpace contained between two contiguous teeth, and the acting fide of the tooth is a portion of a circle defcribed from the bottom of the floped fide of the *fifth tooth* inclufive. The circle to which the flope of the tooth is a tangent is $\frac{1}{6}$th of the diameter of the wheel. When the fwing-wheel has a greater number of teeth than 30, $7\frac{1}{2}$ teeth are ftill contained between the pallets, and the centre of their motion is determined, as in the former conftructions, by a tangent line drawn from the point of the acting tooth. The two ends of the anchor may be made more apparently equal in length by letting the pallet K efcape over $3\frac{1}{4}$ teeth and the pallet G over $4\frac{1}{4}$, in which cafe the arc B D will be of a greater radius than the arc N D. The fteel pallets or end-pieces are fixed by fcrews that allow an adjuftment for diftance or depth of the pallets, fo that they may be detached, newly formed, and replaced, at any time after they have been in ufe.

17. *Efcapement with two levers by De Bethune.*—Thiout fays that De Bethune was the firft contriver of the clock efcapement with two detached levers, and that the origin of this conftruction was derived from the efcapement of Dr. Hooke, or of a German artift, with two balances, which we have defcribed. Thiout made the firft of his in the year 1727, and fays that from that time the efcapement with two levers became common among clock makers in France. *Fig.* 3. of our laft plate is a reprefentation of this efcapement as made for a pendulum; where A and B are the two levers placed faft on each a feparate arbor included within the frame; to the lever B is attached the crutch or fork that communicates with the pendulum not feen, and the fork C which is vifible in the figure; the lever A has a bar of metal D faft to it, that carries the roller E, of a diameter equal to the aperture of the fork C; and the ends of thefe levers conftitute the pallets placed at the diftance from each other of five out of thirty teeth of the fwing wheel. During the action of this efcapement, when one of the levers is acted on by a tooth, the roller and fork are raifed up, and the other lever becomes a detent to the wheel; then when at the next vibration the other lever is acted upon, the roller and fork are depreffed, and the firft lever in its turn becomes a detent; and thus the vibrations are alternately affifted while the maintaining power continues to actuate the fwing wheel. This efcapement has a recoil, and Julien le Roy difcovered (Memoire fur l'Horlogerie par M. le Roy, fils ainé de Julien le Roy, 1750) that when the levers are each the exact length of the radius of the fwing wheel, it poffeffes the ifochronal property, that is, all arcs of vibration will be performed with it in the fame time. We are not aware that this efcapement was ever made in England.

18. *Dead-beat efcapement for a pendulum by Amant, (a cheville)*—*Fig.* 4. of the fame plate fhews the plan of an efcapement by Amant, formerly a clock-maker at Paris, that has an efcapement wheel without teeth, but with pins or pegs inferted in a concentric circle in the plane of the wheel, as appears in the figure; the pallets A and B are both faft to the verge or arbor of the crutch, in the ufual way, and are brought fo nearly together that the fame pin that flides along the floped face of one pallet B immediately falls on the inner circle of the other pallet A, and continues without recoil till the pendulum has made its vibration; at the return of the pendulum the pin meets with the floped face of pallet A and efcapes; then the next pin falls on the interior circle of pallet B, and remains without recoil till the pendulum returns from its vibration, when it flides down the flope and gives a pufh to the pallet as the firft one did before; thus the two pallets are alternately actuated by the fame pin before

 its

its final efcape, and fixty vibrations are made during one revolution of the plate with thirty pins. The flopes appear to ftand at right angles to each other, but it is not faid, in the account we have feen, how either of the flopes ought to be drawn geometrically. This is the kind of efcapement at prefent ufed in the large turret clock at Hampton Court, and we have feen many other clocks in England with a fimilar efcapement, which, we have no doubt, may perform as well as with the ordinary dead-beat efcapement as originally conftructed by Graham, provided the drop from the firft to the fecond pallet, which muft neceffarily be equal to the thicknefs of the pin, do not produce a jerk that may affect the vibrating pendulum.

19. *Dead-beat efcapement (a cheville) by J. A. le Paute.*—In Le Paute's "Traité d'Horlogerie," publifhed at Paris in 1755, is an account of a dead-beat efcapement as made by him for a clock, which differs from our laft by Amant only in its mode of pofition, and which therefore requires no figure for its defcription; the levers of the two pallets open like a pair of dividers to any extent, but are not in the fame plane, one of the levers being over the anterior plane of the pin wheel, and the other over the pofterior plane; hence two fets of pins are neceffary, one on each plane; but the action is the fame as we have defcribed it in Amant's efcapement, which it probably excels inafmuch as the drop may here be made as little as poffible, becaufe the fame pin is not required to pafs between the ends of the pallets in efcaping; but one pin acts only with one pallet before it efcapes; there are confequently fixty pins in all, thirty on each plane of the wheel.

The fame author alfo publifhed an account of a watch efcapement with pins (a cheville) which the reader will find defcribed at page 198 of the fame treatife.

It is eafy to conceive, after what we have faid about the ifochronal pallets, that both Amant's and Le Paute's efcapements, and indeed all the dead-beat efcapements, may be made to have a little recoil, fo as to become of the ifochronal kind, provided the acting concentric circles of the pallets were made in a certain degree excentric; that is, if they were defcribed from points out of the centre of motion of the pallets themfelves. The only difficulty is in determining the fituation of thofe points under different circumftances, which we think is a fair object for future experiments.

20. *Harrifon's clock efcapement.*—The efcapements which we have hitherto defcribed require oil on the pallets, to diminifh the friction of the parts that rub againft one another in action; but the efcapement we are now going to defcribe as the invention of the ingenious Harrifon requires no oil, on account of his conftruction being free from rubbing at the time of the pallets' action. *Fig.* 5. of *Plate* XXXIII. exhibits the fhape of Harrifon's efcapement. G D O is a portion of the fwing wheel, moving round M as a centre: A is the verge or arbor of the crutch that communicates with the rod of the pendulum; to this are attached the pallets, each confifting of a long and a fhort lever with a joint at the place of union; the fhort lever A B is faft to the arbor or axis of motion, and carries the longer lever B C which has a claw or hook *a* C, and a flender fpring is fo applied as to keep thefe two levers nearly at right angles to each other; at right angles to A B is alfo the other fhort lever A E faft likewife to the axis of motion, and bearing the longer lever E F, as A B bears the lever B C; the joints are at B and E, and a fimilar fmall fpring holds the levers AE and E F in like manner at right angles to each other, when not otherwife acted on. The lever E F has not only a claw, like the other long lever, but a heel to it, or projecting part *f*. The action of this contrivance may be thus explained; fuppofe the tooth D urging the pallet or claw C, while the pendulum is moving towards the right hand in its excurfion; this preffure of the tooth produces a tendency in the lever B C to move round, but the joint at B yields, and opens the angle A B C a little; during this motion round A, the fhort lever A E is lowered a little, and with it the long lever E F, which we will call the detent; its claw F therefore falls in the way of the tooth G, which now drops on the back part of the claw, and is inferted into a notch under the projecting heel *f*; the further motion of the pendulum, and confequent depreffion of the fhort lever A E, carry the end of the tooth G back again till the vibration is finifhed, and produce a recoil. At the moment when the tooth begins to have a recoil, the tooth D at the pallet or claw C is withdrawn and efcapes; the flender fpring of the lever B C, which had been bent from its quiefcent ftate, now refumes its original fituation, and throws out the lever B C, till its angle formed at B is again nearly a right angle; in the mean time the wheel is detained by the heel of the detent E F, in which fituation it oppofes the vibration through the medium of the two levers E F and E A, which are attached to the crutch of the pendulum. The vibration being finifhed, the pendulum returns towards the left, and the wheel is at liberty to advance again; the preffure of the tooth G on the claw of the detent now affifts the vibration through the arc of efcapement or arc of action, and caufes the pallet C to approach the wheel, till the tooth following D falls on it and experiences a recoil in its turn. This recoil fets the detent F at liberty from the preffure of the tooth G, which now flies back by means of its flender fpring to its rectangular fituation, as it regards the fmall lever A E: prefently this vibration terminates and the pendulum returns, while the tooth following D aids its vibration by pulling forwards the pallet C, when the procefs of making two fucceffive vibrations is gone through, and the fame operation is repeated. The reader will have obferved in this account that the tooth and pallet, or tooth and detent, do not *flide* on one another, but give each other a *direct pufh*, or pull, the bufinefs of the fmall fprings being to remove them from contact by one fudden leap, where rubbing is altogether avoided, which contrivance fuperfedes the neceffity of having oil applied to the pallets, and is certainly an ingenious contrivance, as well as ufeful in practice. It muft be obferved, however, that the recoil, fuch as it is, takes place at the extremities of the vibration, when the momentum of the pendulum is almoft exhaufted, and is therefore the moft unfavourable part of the vibration to occur in; notwithftanding which difadvantage the efcapement has performed as well as any other that had preceded, perhaps as well as any that has followed it, as the regulator to which it was applied has feldom if ever been excelled in fteadinefs and accuracy of performance for fourteen years of uninterrupted fucceffion. The imperfection arifing from the recoil taking place at the extremities of the vibrations feems to have been compenfated by the immenfe momentum of the pendulum that this efcapement admitted of with a comparatively fmall maintaining power, while the abfence of friction and of oil gave it the advantage of permanently uniform action. Of courfe the pendulum was of the grid-iron form, that compenfated the effects of varying temperature, and allowed the efcapement to have its merit appreciated. The report of the performance of Harrifon's regulator with the efcapement in queftion was, that it did not vary *one fecond* per day from any preceding or following day for the fpace of fourteen years, and that the aggregate of the variations from true mean time did not amount to half a minute.

Haley alfo conftructed clock pallets that required no oil,

but

but as none of them have fallen under our notice, we pretend not to ſay how they differed from Harriſon's.

21. *Eſcapement by Alex. Cumming for a clock.*—Mr. Cumming publiſhed his elements of clock and watch-making in the year 1766, in which, among other matters, he deſcribes a conſtruction of an eſcapement of his contrivance, that removes the friction and influence of oil not only during the time of reſt of the pallets, but alſo during the motion of the ſwing wheel, ſo far as they can influence the vibrations of the pendulum; and alſo obviates all the irregularities that can poſſibly ariſe from the maintaining power as tranſmitted through the train. *Fig.* 6. of *Plate* XXXIII. exhibits as much of this eſcapement as is neceſſary for explaining its general action, but thoſe readers who wiſh to ſee all the minutiæ of the conſtruction, as repreſented by different plates of ſections, muſt have recourſe to the book itſelf, as the complexity of the parts repreſented in various points of view demands more minute repreſentation than our plan admits of. Our figure is a copy of plate 5 of the author, in which A B C is the eſcapement or ſwing-wheel; D E the pallets ſeparately moveable on the axis of motion, and having each a little ball or weight H and I reſpectively ſupported by horizontal arms; each pallet with its attached weight is ſeparately moveable from the other round its reſpective axis of motion, ſo that when one is raiſed by the wheel the other remains at reſt; F and G are two detents firmly attached together, like the ordinary pallets of a common dead-beat or recoil eſcapement, and are fixed to a cylinder of braſs P P, that ſurrounds the two axes of motion of the pallets, which are in the ſame ſtraight line but ſeparated from each other at the middle of the cylinder, where is a partition that bears the interior pivot of one axis and the exterior one of the other; the crutch of the pendulum is alſo faſt to the cylinder; ſo that the two detents and crutch move together along with the cylinder, without the motion of either pallet; and each pallet can move ſeparately without the detents and crutch. M is a load to counterpoiſe the detents and crutch in any poſition given them; and *n o* are two pins carried by the pendulum that project far enough to fall alternately in the way of the arms that carry the balls H, I, as the pendulum vibrates.

To explain the action of this eſcapement, let us ſuppoſe the pallets D and E, the detents G and F, the crutch L, and pins *n* and *o*, together with the balls H and I to be exactly as repreſented in the figure, where the lever of the detent G is hid behind the lever of the pallet E, but may be conceived to be parallel to it, the pallet D having been previouſly lifted from its quieſcent poſition, where its point reſted on the rim near the foot of tooth A; then if we conceive the pendulum moving from right to left with the ball I urging the pin *o* attached to an arc fixed to the pendulum, or crutch of the pendulum, the vibration is aided by the gravity alone of this ball. The arc, that bears the pins *n* and *o*, has a contrivance not ſeen in the figure for unlocking the detents at the moment when either of the pins bears againſt its ball, which contrivance it will be ſufficient for our purpoſe to call Z. Conceive now the pin *n* brought into contact with the arm of ball D by the moving pendulum, the detent F is unlocked, and the tooth A of the wheel quits the end of pallet D; the ball H now acts by its gravity on pin *n*, and deſcends, at the ſame time aiding the returning vibration, while the pallet D, united to the arm of ball H, deſcends alſo towards the wheel; but as ſoon as the pendulum firſt began its original vibration, the pin *o* was withdrawn from the preſſure of the ball I, by means of the attached pallet E falling on the tooth C of the wheel, ſo that all the latter part of the vibration was free; this preſſure of pallet E on the tooth C diminiſhed the preſſure of tooth A on the detent F at the inſtant of the unlocking, which we have mentioned; the wheel now in motion by the action of the maintaining power, (through the medium of the train,) goes on till the tooth C, acting on the pallet E, raiſes it outwards, together with its attached ball I, till the detent G ſtops the wheel's motion, when all the parts are at reſt till the pendulum nearly finiſhes its returning vibration, and then its pin *o*, meeting with the elevated arm of ball I, preſſes againſt it and concludes the vibration; at the moment this preſſure is felt the contrivance Z unlocks the detent G, and allows the tooth C to eſcape; in the mean time the ball I by its gravity urges the pendulum for a ſhort time, while the tooth following A, meeting with pallet D, raiſes it and the ball H a ſecond time, the tooth following C comes in the way of pallet E, and ſtops the further action of the ball I on the pendulum, which now vibrates, as before, free, till its pin *n* again meets with the arm of ball H, when the ſame proceſs is repeated; and thus the weights H and I are alternately raiſed by the wheel, and then alternately act for a ſhort time on the pendulum, at the beginning of each vibration, ſo that gravity alone is properly ſpeaking the maintaining power of the pendulum, and whatever may be the maintaining power of the train, it never affects the motion of the pendulum; but only raiſes the balls, that afterwards act on the pendulum by their gravity alternately exerted from a ſtate of reſt. Thus, whatever may be the effects of oil, duſt, friction, wear, &c. on the action of the train of wheel-work, as it has no immediate connection with the pendulum, except during the ſmall inſtant of unlocking the detents, theſe effects are almoſt entirely avoided, as they regard the pendulum or regulating part of the motions. The greateſt objection in theory to this conſtruction is, that the additional gravity commences inſtantaneouſly, and alſo ceaſes inſtantaneouſly, and at a part of the vibration where the inſtantaneous exertion of extraneous force of any ſort is the leaſt favourable for aiding the ſimple gravity of the pendulum's ball, which conſideration is analogous to the obſervation we had occaſion to make on Harriſon's eſcapement; but, like his, the eſcapement before us has ſtood the teſt of practical experience, notwithſtanding its complexity, in his majeſty's private obſervatory. If, however, this eſcapement is not *better* than any of the other eſcapements, the number of its adjuſtments, and variety of its parts, conſtitute a practical objection to its general adoption; and we believe no proof has been given of its being preferable to Harriſon's, or even to the common dead-beat or iſochronal eſcapements, except that the works of the clock that has this eſcapement may not require to be ſo often cleaned. This eſcapement leaving the pendulum free or detached from the wheel-work during the greateſt part of each vibration, is of the third claſs of eſcapements.

22. *Eſcapement by Mudge for a clock.*—The clock eſcapement contrived by Mr. Mudge to detach the pendulum from the train, ſo as to allow it to have nearly a free vibration maintained by gravity alone, may be conſidered as a ſimplification of Cumming's eſcapement juſt deſcribed, from which its principal difference is, that each of his two ſeparate pallets act alſo as detents; the mode of action and effect produced are very ſimilar in both. Mr. Mudge's eſcapement is repreſented by *fig.* 7. of our laſt plate, in which L M is a portion of the ſwing wheel; G A and G B are two levers ſeparately moveable round one common axis of motion, and have each a pallet at the lower extremities; theſe pallets are formed like the common recoil pallets, except that each has a claw at the loweſt point, that prevents the eſcape of the ſliding tooth when acting thereon: the pallet G A has a lever, which

which may be called its tail-piece G O, attached to it, and alfo a fmall metallic ball u furmounted on a pin over the pallet, which may be eafily changed for one of a different weight; the pallet G B has a fimilar tail-piece I O, with a fimilar ball v over its pallet B; and the dark circular fpot at N is the end of a ftiff pin projecting from the pendulum, or its crutch, far enough to fall in the way of the tail-pieces alternately, as the pendulum vibrates. After having perufed our account of the action of the preceding efcapement, the reader will anticipate the explanation we have to offer of this mechanifm. Suppofe the wheel to be urged by the train in its proper direction from I towards M, and an impulfe given to the pendulum, to produce a motion in it in a contrary direction; the pin N keeps pace with the pendulum towards L, while the tooth at L is locked in the claw of pallet A, (which it is fuppofed to have raifed fo as to bring the tail-piece G O out of its vertical direction,) and at length meets with this tail-piece, to which it gives a pufh, at the extremity of the vibration, fufficiently ftrong to drive the pallet A from its locked tooth L, when the wheel is at liberty to proceed, till the tooth near pallet B raifes it and its furmounted ball v until the claw detains the further motion; in the mean time the returning vibration commences, and the ball u urges the pendulum, by means of its tail-piece G O being in contact with the pin N; when, however, the tail-piece has gained its vertical fituation, the pallet A meeting with the rim of the wheel ftops; the pendulum now finifhes its vibration in a detached ftate, having gained an acceffion of force by the impulfe from the ball u downwards, which has been greater than the refiftance it met with in moving upwards at the inftant of unlocking: the tail-piece I O is now in the fituation of I P, by reafon of the ball v being elevated by the wheel, therefore when the pin N of the pendulum arrives at I P, which is at the other extremity nearly of the returning vibration, its ftroke drives the pallet B in its turn from the locked tooth near M, which now efcapes; the wheel is again at liberty to proceed till the tooth behind L has raifed the pallet A a fecond time, when it is again locked; the pendulum begins another vibration, aided by the ball v, till its tail-piece refumes its vertical pofition, and then the pendulum is again detached, after being a fecond time urged down a longer arc than it was oppofed up; and thus the vibrations are maintained by the excefs of the downward pufh over the refiftance upwards at every new vibration, which excefs, derived from gravity alone, is in fact the maintaining power of the pendulum. This efcapement is alfo of the third clafs, and being more fimple in its conftruction than its predeceffor and parent, perhaps we may add, is better adapted for practice. The external force derived from the gravity of the balls in aid of the pendulum's gravity is here alfo both applied and withdrawn fuddenly, as well as at the moft unfavourable parts of the vibration, as was the cafe with Cumming's efcapement; but it poffeffes the fame advantages of detachment from the train.

23. *Detached efcapement by Peter le Roy in* 1748.—We have deviated a little from the regular order of time, in having noticed the detached clock-efcapements before thofe that were previoufly applied to the balance, in order that the fucceffion of improvements made in clock-efcapements might not be interrupted by an intermixture with watch-efcapements. We now go back again to the year 1748, when Peter, the eldeft fon of Julien le Roy, invented an efcapement for a balance that vibrated a confiderable portion of its total arc without any connection whatever with the efcapement wheel, and which therefore may be confidered as the father of the third clafs of efcapements, and the origin of the fubfequent more recent improvements in the efcapement of chronometers. *Fig.* 8. *of Plate* XXXIII. will afford us the means of explaining this efcapement, a model of which was prefented to the Academy of Sciences at Paris in the year 1748, previoufly to which year, no detached efcapement had been made public, though Du Tertre is faid to have invented one, and even to have made it at the time; but as the invention, or at leaft the conftruction, was kept a fecret, it did not derogate from the merit of Peter le Roy's contrivance, which muft be confidered as original. G H is the efcapement wheel of the contrate kind, actuated by a pinion on its arbor, receiving the force of the maintaining power; its profile is feen contiguous to it, at $g\ h$; T V is the balance, the verge of which has a fpiral fpring attached to it at the interior end in the ufual way; a curved pallet A E is faft to the verge under the balance, and the femi-circular piece C I is affixed to the fame above the balance, but under the fpiral fpring; the end C of this piece is rounded, and fo fituated, that a line drawn from it to the centre of the balance would form with the curve A E an angle of about 80°. An angular lever Q P X, turning on pivots under a little cock on the plate at C, is fo proportioned, that the branch P Q will reach the pallet, while the other branch P X with a concave end will reach to a tooth G in the balance wheel, when not refting on a pin K, to which in its quiefcent ftate it is kept by the fpring R M, made faft to the plate on the other fide at R. Suppofe now, the regulating fpring moved from its ftate of natural reft, and the balance to move with it through a certain arc of vibration, more or lefs, till the rounded end C of the femi-circular piece falls on the branch P Q of the angular lever near Q, and pufhes it from its fituation, at the fame time bringing the concave end of branch P X into the way of a tooth G of the wheel; when the acting tooth, which we will call D, efcapes the pallet A E; the wheel is then at liberty till its tooth G falls on the concave end of the branch P X, which may be called the detent, becaufe it now *detains* the wheel from moving further under exifting circumftances. The balance is now perfectly free from all contact of the acting part of the branch P Q, and continues its vibration, after having received a pufh from tooth D on its pallet: prefently its velocity is deftroyed by the tenfion of the regulating fpring, the re-action of which now makes it return with an accelerated motion, when the pallet comes into contact with the efcapement wheel at the tooth following D, which now experiences a recoil for about half of a fpace in the wheel: the branch P X, or detent, is relieved by this partial recoil, and obeys its fpring R M, which takes it back again to its ftate of reft at the pin K; when the wheel, having ftopped the balance, fends it off again with a new impulfe, by ftriking the pallet in a contrary direction, when the fame operation of the angular lever is repeated, and the vibrations are maintained as in other efcapements. It muft be remarked of this efcapement, that it does not allow the balance to be detached for an entire vibration, but oppofes the balance back from the point where it gave its forward pufh, thereby producing a certain recoil, which, fo far as this is a leading confideration, would entitle us to rank the efcapement among thofe of the firft clafs, but inafmuch as the balance vibrates in a detached or free ftate in the remaining portion of its vibration, we may place this efcapement with propriety at the head, in point of time of the third clafs.

24. *Peter le Roy's fecond or improved detached efcapement.*—Some time after Peter le Roy had completed his firft detached efcapement, and had confidered its principal defects, he fet about contriving another, lefs liable to objections, in which he fucceeded in a very confiderable degree; when in the

the year 1766 he presented a time-piece to the Academy of Sciences, which was afterwards tried at sea by the French government, with his improved escapement, which we shall now describe. *Figs*. 1, 2, and 3, of *Plate* XXXIV. exhibit sufficient of Peter le Roy's improved escapement to enable our readers to form a complete idea of its construction; the leading feature of which is to give the balance one temporary push that shall maintain its motion for two successive vibrations, one forwards and the other back, and that this push may be given at a moment of the balance's vibration that is most favourable for avoiding a derangement of the law of the spring's forces. *Fig*. 1. is a view of the balance-wheel, which has six radial levers for teeth, but no rim, that it may be as light as possible, the ends of which levers are bent downwards, that is, in an opposite direction to those on the horizontal wheel with Graham's cylinder escapement; the connection of this horizontal balance-wheel with the train is by means of the pinion on the opposite end of its arbor; *fig*. 2. is the arbor of the detents, on which there are three levers, one double one for locking, and two single ones for unlocking, all clearly shewn in the figure; *fig*. 3. shews the wheel, detents, unlocking levers, and balance in their relative situations, and in one of the acting positions. A is a portion of the balance, on the plane of which is screwed a pallet *p*, so as to fall in the way of one of the levers of the balance-wheel. The same letters denote the same parts in *fig*. 3. as in *figs*. 1 and 2, which therefore explain themselves. The action may be explained thus: suppose one of the levers of the balance-wheel to be detained by the claw of the detent D, while the balance put in motion is vibrating in the direction from *i* to A; when the force of the balance spring, not seen, overcomes the momentum of the balance, it returns by means of the spring's force, which is now at its greatest tension, or distance from the point of quiescence; the direction of the balance, we have said, is now from A towards *i*; in this return a pin at *i*, situated in the superior plane of the balance, strikes the end of the lever H F of the detent arbor, unlocks by this stroke the detent D from the claw of the wheel's radial bar or tooth, and at the same instant directs the other end H *e* of the double detent into the way of a succeeding radial bar of the wheel K *r*, which now rests on this end of the detent; this part of the action is called by the inventor the *preparation*, the vibration goes on to finish, and the spring brings the balance back; at a certain part of this vibration the balance receives its stroke from the radial bar K, which impels the pallet *p*, screwed on the balance itself, in this manner; a pin, situated like the former pin at *i*, but placed on the inferior plane of the balance, out of sight, and a little farther from the balance's centre than the former pin, strikes the end of the short lever H *c*, and unlocks the radial bar of the wheel, that has been resting against the opposite end of the detent D, and that now runs on to D, which is in the way to catch it; during this short period the wheel is free, the pallet *p* of the balance being at that instant in the situation F, the point K of the radial bar K *r* of the wheel pursues the pallet and makes its stroke on it, about the time when the balance-spring, as we suppose, is at its quiescent point, and therefore when the balance is moving with its most accelerated velocity; the stroke is of short duration on that account, as well as on account of the short distance the wheel has to run before it is again detained by the detent D: the backward vibration is made as before, and the same process is repeated of two lockings and unlockings at each stroke of the wheel on the balance. The stroke, however, which the balance receives, has more force than both the strokes that its pins give in the acts of unlocking, and therefore the difference of these contrary strokes constitutes the real maintaining power of the balance, which was of the thermometrical kind, with alcohol and quicksilver, as described under our article COMPENSATION-*balance*. The step made towards perfection, when this escapement was devised, was very long, and the principal objection to it in practice is, that it has too many pivots that require oil, as well other parts that come successively in contact during the action, which therefore are not sufficiently free from friction and consequent wear. It may be necessary to add, that to prevent the detent's being displaced by any jerk, a long tail-piece behind it is contiguous to a circular appendage of the balance, seen from *i* to F, against which it falls, but only when any derangement of the detent accidentally takes place, and thus reinstates it. The stroke is given to the balance not only when its velocity is greatest and least liable to be deranged, but the pallet that receives it, being removed from the centre of the balance, requires but a comparatively small impulse in this situation; besides, the spring, which the inventor considered as not desirable, for holding the angular lever to its place of locking, is here entirely dispensed with. This was considered as an improvement at the time, but subsequent experience has proved the utility of spring detents, which are now in universal use in the best English chronometers.

25. *Detached escapement by F. Berthoud.*—Ferdinand Berthoud, one of the members of the National Institute of France, and the author of various works on horology, has contrived different escapements for clocks and watches at different times, and has written more on the subject than any other author, but it will not come within our plan to detail here all the alterations that have presented themselves to him; we shall satisfy ourselves with describing a few of those which he has himself selected as most worthy of public notice in his last publication; "Histoire de la Mesure du Temps." Others may be seen in his "Traité des Horloges Marines;" or in the "Supplement" to that work. The first that we mean to describe is contained in *fig*. 4. of *Plate* XXXIV., which is a perspective view of all the parts necessary to be seen: A represents the verge of the balance, to which is affixed by two screws the circle of escapement B as a pallet; C is the escapement wheel, *a b c* the detent, which has at *b* a claw to catch a tooth of the wheel, when it suspends its motion, during the period of the balance's free vibration; the portion *a b* of the detent is a flexible spring, that yields first at the point *a*; this, therefore, is the *spring of the detent*; the other part *b c* properly forms the detent, which has a claw rounded at the end *c*; another slender spring *b e* lies cross-wise near the said end, and is held fast to the circle B by a screw and fixing-piece *f*; this second spring carries a pin *d* near its extreme end, which acting on the end of the detent, disengages the locked tooth of the wheel, when the balance vibrates in a direction from B towards A; at that instant the succeeding tooth of the wheel acts on the notch or pallet part of the circular piece B at *h*, and transmits an accession of force to the balance, which now vibrates in free space; at the balance's return, the pin *d* of the small spring *d e*, borne by the balance's circular piece B, applies itself to the end of the detent, so as to slide past it without disturbing its position with regard to the claw, against which the next tooth is now resting; when the balance has finished this second vibration it returns, the pin *d* again pushes aside the detent, and unlocks the wheel, which now gives another push at *h*, and the same operation is resumed that we have been describing. Thus two vibrations are performed at once unlocking, and at one stroke of the wheel on the notch of the circular pallet piece. The small spring *b e* may be

be called the lifting fpring, in oppofition to the detent fpring, or fpring detent ; and to give a clear idea how it detaches the claw of the detent in paffing forwards, but not in paffing back again, it may be neceffary to obferve, that this lifting-fpring has a pin in the circular piece B, againft which it refts, to prevent its laying too much hold on the back floping part of the detent's extremity ; but it is at liberty to yield in the contrary direction towards the verge of the balance ; and as the fpring is very flender, and has its yielding point or centre of motion at the remote end *e*, it gives way to the detent in the direction that pufhes the detent againft the tooth of the wheel, which becomes a prop to fteady it ; but when the impulfe is in a contrary direction, the detent, having no fuch prop, and its end being at that fide fuited to receive the blow of the pin without its fliding, itfelf yields and withdraws its claw from the wheel, which is then unlocked. The fpring of the detent is alfo confined from rebounding too far by a pin *g* fixed in the plate. Here we have an inftance of a retrograde ftep in the improvement of efcapements, the fpring which Peter le Roy laboured to reject in his fecond conftruction is here refumed with an additional fpring, and the adoption of the *fpring-detent* has become general in the fubfequent conftructions. Berthoud began his detached efcapements in the year 1754.

26. *Another modification of a detached efcapement by Berthoud.*—The efcapement which Berthoud employed in fome of his watches, particularly N° 60, was confidered by him to be more fure in its action than the preceding one, as well as more eafy of conftruction ; *fig.* 5. of the fame plate reprefents the plan of one of thefe efcapements, where L is the efcapement wheel ; *m* the circle of efcapement carried on the verge of the balance ; *p o r* the detent, the claw of which at *r* fufpends the motion of the wheel ; the verge carries above the circle *m* a fmall tube made faft by friction, and to this tube is made faft a projecting forked claw, in which a pin is adjufted to act on the detent and raife it. The pin, which we will call *s*, in turning in one direction, acts on the part *p* of the detent, and withdraws the claw *r* from the wheel ; this is now at liberty to impel the circle *m* by its notch and with it the balance ; the flender fpring *u* brings back the claw of the detent, and the vibration goes on ; at its return the pin meets with the end of the detent-fpring fixed on an arm at *t*, this fpring yields to the retrograde motion of the balance. The balance at its return makes its pin (of the fork) urge the fpring *p* againft a pin *s* in the arm *n* of the detent ; this arm turning on its centre of motion, withdraws the claw of the detent from the wheel, which now acts again on the notch of the circle *m*, as before. The pin *q* ferves as a ftop to the detent, and the arm *k* of *precaution* is to lock the wheel when the balance is difmounted.

27. *Another efcapement without a fpring by Berthoud.*—*Fig.* 6. of the laft plate is a view of an efcapement by Berthoud, in which he has difpenfed with fprings altogether. The action of the wheel A is tranfmitted to the balance, as before, by the notch of the circular piece B on the verge ; the prefent pofition of the parts is for the moment when the detent allows the wheel to begin its action on the notch of B. The detent C has two arms, with each a claw *a* and *b*, the faces of which are circular ; the claw *a* ferves to fufpend the action of the wheel after its ftroke is made ; but the claw *b* receives the tooth of the wheel when the balance in its return makes the tooth at *a* to efcape. Thefe effects are produced by two levers C *d*, C *e*, forming the fork that moves the detent C : this fork is fixed on the centre C of the detent, and its levers lie one above the other. The lever C *d*, which is contiguous to the detent, correfponds to the fmall femi-circular piece *d e*, placed on the circle of efcapement B ; this femi-circle is notched by lines, one of which tends to the centre ; this fide of the notch unlocks the wheel by its action on the arm C *d* whenever the balance retrogrades from the firft vibration of the pair ; during this effect the wheel advances but a fhort way, juft fufficient to unlock the claw *a*, and to fuffer the balance to proceed in its retrogradation. The balance, having finifhed in a detached ftate this fecond vibration, returns, when the femicircle *f g*, placed over the other femi-circle, and notched in like manner, prefents its acting fide to the upper arm *f* C of the fork, and unlocks the tooth at claw *b* ; at this moment another tooth, catching the notch at *c* of the circular piece B, gives it another impulfe, and confequently puts the balance in a ftate of renewed force, and the procefs already defcribed is renewed, while the femi-circular pieces *d e* and *f g* on the verge alternately ferve to keep the arms C *d* and C *e* of the fork in a firm pofition to enfure the defired effects of the efcapement. It is eafy to perceive that there muft be much friction in this efcapement, and that the femicircular pieces on the verge of the balance, if not fomehow counterpoifed, muft affect the rate of going in different pofitions of the time-piece.

28. *Detached efcapement with a detent and fpring by Berthoud.*—*Fig.* 7. of the fame plate is the plan of another of Berthoud's efcapements with a detent and fpring, and that which we underftand has been moft copied by others. It was ufed in the author's marine time-piece N° 9. A is the circle of efcapement ; C the wheel ; *a b d* the detent with three arms ; the arm *a* fufpends the motion of the wheel while the balance ofcillates in a free ftate ; the fpring *d* ferves to bring the detent *a* back again as foon as the pallet *c* has ceafed to act on the arm *b* ; at that moment one of the teeth of the wheel impels the circle by acting on the roller *h*, and communicates its force to the balance ; this having finifhed its ofcillation returns, and in the return the pallet *c* meets with the end *b* of the detent, which turns the pallet back towards B, the centre of the circle, till it has paffed without unlocking the wheel ; its fpring *b* brings the pallet back again to its original ftate of reft on the pin at *c*, the ofcillation ceafes, and in the return of the balance the pallet *c* again meets with the arm *b* of the detent, which it turns afide, the tooth being no prop to it in this direction ; the unlocking therefore takes place ; the wheel's motion is refumed, and a new impulfe is given to the moving balance. Here the detents are arms or levers acted on by a feparate fpring, as is alfo the pallet, confequently there ftill remain pivots that require oil, though we are difpofed to confider this as the beft of Berthoud's watch efcapements ; perhaps equal to any of the Englifh conftructions.

29. *Ifochronal efcapement of a watch by F. Berthoud.*—Among the other contrivances of Berthoud is an efcapement for a watch with ifochronal pallets, fimilar to thofe applied to a pendulum which we have defcribed above, but the mode of applying them is different. In *fig.* 8. of our laft plate, A is the efcapement wheel ; B the anchor with the ifochronal pallets producing a fmall recoil, and formed in the manner before defcribed, (fee *fig.* 1. of *Plate* XXXIII.) C D the balance ; *a* a pinion on the verge above the wheel, that is actuated by a fectoral toothed piece *b*, attached to the anchor of the pallets, and moving with it round the common centre of motion of it and the pallets at E ; the intention of this conftruction is to produce a long ofcillation of the balance compared to the motion of the wheel and toothed fectoral piece, and to render all the ofcillations, however long or fhort, of equal duration, the arcs of action being large in proportion to the whole ofcillations. This conftruction may

may have given rife to that which is now known by the name of the Liverpool efcapement, which fo greatly refembles it, that they may be confidered as the fame thing. We obtained a watch by Litherland of Liverpool, with a view of giving a feparate defcription and drawing, but we found that the only difference is, that the pallets are placed a little on one fide of the wheel, inftead of the three pivots being in one ftraight line, and that the centre of the pallet's motion is between the verge and pallets requiring a counterpoife behind: a further defcription is therefore unneceffary.

30. *Modern efcapements of Englifh chronometers.*—If we had not already anticipated our defcriptions of the modern efcapements for chronometers, as they are now made in England, we fhould have given them a place here; but as we have been very minute in our account of the efcapements of Meffrs. Mudge, Arnold, the Brockbanks, and Earnfhaw, under our article CHRONOMETER, and have given drawings of them in our *Plates* XIII. XIV. and XV., it would be fuperfluous to enter into a fecond detail of the fame here, and therefore we pafs over them by a fimple reference to the article already named.

It may not be improper to mention here, that Mr. John Watkin, of Weft Smithfield, has propofed an alteration in the fituation of the pallets in the modern fpring detent efcapement, for which he received thirty guineas as a premium from the Adelphi Society, in the year 1804. His alteration confifts in bringing the pallets into a fituation between the centre and circumference of the wheel, and making the wheel a contrate one with the teeth upwards. (See the Tranfactions of the Society, vol. xxiii. p. 375.)

31. *Mudge's forked efcapement.*—Mr. Mudge contrived another detached efcapement befides the one we have referred to as already defcribed, which we fhall now notice, though he did not feem to place fo much value on it as Emery, Margetts, and others have done after him; we fhall not be able to make the reader comprehend the conftruction without two figures: *fig.* 1. of *Plate* XXXV. is the plan of this efcapement, and *fig.* 2. a profile or fide view of the frame that contains the mechanifm: A is the efcapement wheel, B the anchor of the pallets, which are of Graham's dead-beat kind adapted to a watch, and which give the neceffary force to the balance for maintaining its motion; *a* is the centre of motion of the anchor, nearer to the wheel than to the balance; *b* is the forked part of the anchor, the two prongs of which appear in *fig.* 1. to be clofe together in the fame plane, but *fig.* 2. fhews that they are one above the other. The pallets are on the verge of the balance, and are of the cylindrical fort, one above the other, fo as to fall in the way of the two prongs alternately, pallet 1 is urged by *b*, and pallet 2 by the other prong in its turn; the time of action of the prongs on the two pallets is very fhort, and the blows are made alternately one in each vibration; the remainder of the vibration is perfectly free, the wheel being in the intervals refting on the circular portions or pads of the anchor's pallets, which may in this cafe be confidered as detents and pallets alternately. A timepiece by Emery with this efcapement performed with wonderful accuracy, though the detachment continues only for a portion of one vibration before the balance has its force renewed, which confequently might be fuppofed to have its motion more difturbed than if the impulfe had been given at each alternate vibration. The queen's watch by Mudge with this efcapement had a flight recoil, which kept one of the prongs preffing gently againft the cylinder of the verge to fteady the fork. The performance was excellent.

32. *Margetts' modification of Mudge's forked efcapement.*—The late ingenious Margetts adopted Mr. Mudge's efcapement, which we have juft defcribed, for his chronometers that indicated both folar and fiderial time, but made fome alterations with the fork. *Fig.* 3. of the fame plate fhews the plan and profile of Margetts' modification, where A is the wheel; *a b* the anchor moveable at *a*; *b* the fork where the prongs are in the fame plane; *c* a piece of fteel carrying a pin *e* under its extreme end that ftrikes the prongs of the fork *b* alternately, one at each ofcillation of the balance *g*, which ftrokes unlock the wheel; *h* and *i* are two banking fcrews, the points of which act as ftops to the anchor at oppofite fides of the centre of motion, and keep the fork in its place to be caught by the pin *e*, one or other of them at each vibration; *d* is a circular piece of metal, under the pallet piece *c*, that has a notch in it bounded by ftraight lines going towards its centre; and *f* is a pin carried under the anchor, as feen in the figure, the end of which gives the circular piece *d* a pufh, by acting on its notched fide at each unlocking of the wheel, thereby aiding the vibration: the pin *f* is always at the notch when the pin *e* is in the fork, therefore the notch in *d* and the pin in *c* are always placed in the fame vertical line over one another, and as they move together on the verge will always remain fo, while the pin *f* and fork *b* are alfo together on the anchor. The writer of the prefent article has a chronometer by Margetts with this efcapement, which acts very well when ftationary, but when carried in the pocket the pin is apt to catch the outfide of the prong, when any jerk has fent the anchor back during the balance's excurfion.

33. *Modification of Mudge's forked efcapement by R. Robin of Paris.*—R. Robin, a watch-maker of Paris, publifhed a memoir in 1794, containing an account of a free efcapement, which he confidered as new, but which we confider as another modification of Mr. Mudge's forked efcapement, though we allow that in theory it appears to be an improvement. *Fig.* 4. of the fame plate is a plan of this efcapement, in which the wheel reftores the exhaufted force of the balance once only in two vibrations, which circumftance conftitutes the improvement; to effect this, pallets G *a*, and G *b*, acting as detents, are made of unequal length from G, the centre of their motion, and the fork, which is feen feparately at *e*, as well as the tooth or pallet *d* and lever *f*, are concealed under B, the circular piece carried by the balance; the fork *e* is faft to the end of one of the pallets *a*, inftead of forming an anchor with the pallets, but this fhape makes no difference in the action; the lever *f* is alfo faft to the fame underneath the fork; but the tooth *d*, which acts with the fork, is faft to the verge under B, as we have already faid. We have given three pofitions of the circular part B and pallets, to fhew more clearly the nature of the action, as fome of the acting parts are concealed. One of the claws *a* of the pallets being removed, the wheel A efcapes, and acts on the notch of the piece B, thereby aiding the balance; the claw *b* receives another tooth and holds it as a detent, and the balance finifhes its ofcillation; at its return it unlocks the tooth at *b*, which is the longer pallet, and the wheel runs on a very fhort way till a leading tooth falls on the pallet *a*, and the balance vibrates without a new pufh; at its return the tooth at *a* is unlocked, and its efcaping tooth gives the notch of B another pufh, which ferves for other two vibrations; but if the two ends of the pallets G *b*, and G *a*, had been of equal lengths, the efcapement would have acted in the ufual way, and would have given its pufh at each ofcillation. The manner in which this effect is produced, however, does not yet appear evident: the lever *f*, which is faft to the end *a* of the pallet or detent G *a*, refts in a groove made in a circular collet on the verge, and holds the fork *e* from going on one fide, like as the banking

 fcrews

fcrews do in Margetts' efcapement, then the tooth d, faft to the balance, ftrikes the two prongs of the forks alternately, one at each vibration, which ftrokes make two unlockings during the time that one pufh is made to the balance by a tooth; becaufe the faid tooth previoufly made two fteps forward, one long and one fhort, before it efcaped to make its pufh. We have not been informed how this modification performed, but we fee no reafon to doubt its competency, while we fee much reafon to admire the ingenuity of the application of two detents of unequal length, formed like the pallets of the anchor efcapement, which detents we have named pallets on that account.

34. *Prior's modification of Mudge's forked efcapement.*—In the year 1798 Mr. John Prior received 30 guineas as a premium from the Society for the Encouragement of Arts at the Adelphi, for his invention of what he confidered a new detached efcapement; but its fork differs from Mudge's principally in its having a roller for a pallet borne by an arbor carried by the balance itfelf; the wheel of efcapement, together with its acting pallets, were fimilar to Le Paute's improvement on Amant's wheel, and therefore had nothing original in it. The reader who wifhes to fee the account and drawings of this efcapement, compofed as it is of Mudge's and Le Paute's contrivances, which notwithftanding the author might not have feen or known, may find it in the 16th vol. of the Tranfactions of the Society juft named, and alfo in the 2d vol. of Nicholfon's Journal, 4to. ed. p. 363 and 364, where the editor has remarked that Mr. Crofthwaite of Dublin had made a pendulum clock with fimilar pallets in 1788, which was defcribed in the Memoirs of the Irifh Acad. vol. ii.

Prior junior has very recently been rewarded by the fame fociety for another efcapement contrived by him for a clock, but the account of it is not yet publifhed in their Tranfactions, and therefore cannot with propriety be given here.

35. *Duplex efcapement.*—We are not informed who was the original contriver of the efcapement known by the name of *Duplex* efcapement, a name probably taken from the circumftance of its having a wheel with *two* fets of teeth neceffary for the efcaping; neither are we aware of its date: but the efteem in which it is held by thofe who have tried it, entitle it to a place in our collection. *Fig.* 5. of *Plate* XXXV. exhibits on a large fcale enough of the acting parts to enable us to convey an idea of its action. A B is a part of the efcapement wheel, having teeth a, b, c, &c. at the periphery, intended for detaining the wheel while it ofcillates beyond the angle of action. An agate cylinder $d\,e\,f$, placed on the verge of the balance, acts with thefe teeth to produce the defired effect. This cylindrical agate has a notch d, which paffes by the tooth at D, that is fuppofed to reft on the cylindrical furface, when the motion is in the direction $d\,e\,f$; but when the motion of the cylinder is in the contrary direction $f\,e\,d$, the tooth at D falls into the notch and accompanies it, preffing on one of its fides till the notch comes into the fituation d: the tooth, then at the fituation of b, efcapes from the notch, and a fucceeding tooth falls on the convex furface of the cylinder at D. The other fet of teeth are erect on the plane of the wheel's rim, and are ftrong and fquared at the fides; they ftand a little fhort of the middle of the fpaces between the pointed teeth on the edge of the wheel, but confift of the fame number; they are to be feen at h, i, &c. denoted by darkened parallelograms: above the fmall cylinder we have named as being made of agate, is a larger one E F G without a notch, and placed high enough on the verge to go over the edge of the wheel's rim; this bears a pallet of ruby or fapphire G, long enough to fall in the way of the fquare vertical teeth, when they happen to be near the line joining the centres of motion of the balance and wheel, but fhort enough to avoid touching the teeth when not near that line. The larger cylinder is fo placed with refpect to the fmall one, that when the tooth b has juft efcaped from the notch, the pallet G has juft paffed the fquare tooth h, which was at A, while D refted on the fmall cylinder, but is moved from A to h, while D moves to b. The wheel is now free, and the tooth h exerts its force, derived from the main-fpring, in the moft direct way on the pallet G, and urges it forward till another tooth on the edge falls on the convex part of the fmall cylinder $d\,e\,f$, and the fame action that has been defcribed is refumed. The angle of action in this efcapement depends partly on the length of the pallet G, and partly on the diameter of the fmall agate cylinder, and advance of tooth D into the notch; for when a horizontal tooth on the edge falls on the faid fmall cylinder, the motion of the wheel is arrefted, and the vertical fquare tooth ceafes to impel the pallet G fo far as it otherwife would have done. This efcapement requires very little oil on the fmall agate cylinder, and none at all on the pallet G, which receives a direct pufh without friction, and its excellence is confidered as at leaft equal to that of Graham's horizontal or cylindrical efcapement.

36. *Free efcapement under the pendulum.*—The clock efcapements which we have before defcribed fuppofe a connection with the upper end of the pendulum, which is the moft common connection, but there are efcapements that give their impulfe at the inferior end, one of which is reprefented by *fig.* 8. of *Plate* XXXV. which we fhall now defcribe, though we know not who was its original contriver. The part A B D C is made faft to the rod of the pendulum, and vibrates therewith; at B is a joint on which the lever B C is moveable; fo that when the end C meets with any refiftance the lever mounts upwards at this end, but cannot fall below a horizontal line; it terminates in a claw with both an interior and exterior flope or inclined plane; D is a pallet of agate or other polifhed ftone, with a flat face next the end C of the lever, and made faft into the vertical part A D; F G H I is a two-armed detent, moveable round H as a centre, but kept in its prefent pofition againft the ftop or pin K, by means of the weight G, when not otherwife acted on. In the prefent pofition the arm H I, which forms the detent, detains the tooth I of a vertical wheel of efcapement, while the pendulum is fuppofed to be vibrating clear of all the teeth. Let us fuppofe the end C of the horizontal lever, moving with the pendulum, to be approaching the end F of the fecond arm of the detent; prefently it gives the end F a blow, the lever C flies up, flides over the inclined face of F, and returns into its horizontal pofition; when the vibration terminates, the pendulum returns by virtue of its gravity, and the interior face of claw C catches the exterior one of the arm F, and gives it a pull fufficient to draw the end of H I from the tooth I; the wheel is then at liberty to run on till the tooth E, moving fafter than the pendulum, overtakes the pallet D, and gives it a direct pufh forwards; this pufh aids the claw C to get over the claw of F, and the weight G replaces the arm H I to catch the following tooth M, which prevents the further impulfe of the wheel on the pallet D, and fuffers the pendulum to finifh its vibration in free fpace; at the return of the pendulum the fame operation is repeated, and the pendulum continues to receive one pufh at every two vibrations, and that when the pendulum is in its vertical pofition, or moving with its greateft velocity, which we have faid is the moft favourable point of the arc. The arc of action, before the pallet is quitted, depends greatly on the

the radius of the wheel compared to the length of the pendulum, when the number of teeth is limited. The pendulum, however, ought to be of the compensating kind, otherwise an increase in the length of the rod will derange the action of the claw C, with the claw F, as well as of the tooth on the pallet D, in all the extremes of atmospheric temperature. The maintaining power of the train that actuates the wheel E M may be either a spring or weight, as the mechanist may think proper. Berthoud has proposed this construction of a free escapement for a half-second's pendulum in his "Histoire de la Mesure du Temps," tome i. p. 214; but he does not clearly say that it was of his own contrivance; on examining his drawings, since our observations were written on this escapement, we find that this author proposed a compensation pendulum to be used with it; and he proposes such a combination of parts as a proper model for an astronomical clock to vibrate half-seconds. Mr. Nicholson, who has also described the same escapement as one he has noticed in England, does not venture to ascribe its invention to any particular artist.

37. *Detached escapement of a clock by Berthoud.*—Among the numerous contrivances of F. Berthoud in clock-work, we frequently find this author applying the same contrivance to answer different purposes; for instance, when he had hit upon an isochronal escapement for a clock, he adapted it soon after, as we have seen, to a watch; and in the instance before us, he has converted a free or detached escapement of a watch into a clock escapement, which we shall here describe, not knowing the exact date of the application. *Fig.* 1. of *Plate* XXXVI. is a representation of an escapement of the third class adapted to a half second's pendulum, as described by Berthoud himself. F is the escapement wheel, and *a*, *b*, the detents of escapement, (formed like the pallets of the dead-beat escapement of Graham,) the action of the wheel F is transmitted to the pendulum by means of the notch made in the circular portion of the escapement piece A B, thus; the detent has two claws, *a* and *b*, formed by portions of a circle, at the holding parts. The claw *a* serves to suspend the action of the wheel, when it has communicated its motion to the notch of the escapement piece, which this does again to the pendulum, by means of the lever C, which it carries, and of the roller D, corresponding to the pendulum. The claw *b* serves to receive, and to detain the wheel, when the pendulum returns. These effects are produced by two levers *d c*, *e c*, fixed on the centre *c* of the detent; but one of them more distant from the plane than the other. These two levers form a fork that corresponds to the circle of escapement *b g*. The lever *d e*, which is nearest to the detent, answers to one portion of the circle *g*, carried by the circle of the escapement D. This part *g* presents a straight line to the fork *d*, which being acted on, detaches the claw *a* of the detent, and, consequently, sets the wheel at liberty. The notch *f* presents itself, and the tooth of the wheel acts on the notch, and restores to the pendulum the force that it had lost. The wheel having finished its action on the notch *f*, a tooth presents itself to the claw *b*, and the pendulum finishes its vibration in a free manner, at its return, the portion of the circle *g*, which is most elevated, meets with the arm *e* of the fork, and disengages the claw *d*; the tooth that was here detained now escapes, and runs on a short space before another tooth drops on the claw *a*, and the process is repeated. We have not seen this escapement in England.

38. *Escapement by Mr. Nicholson.*—Some time in the year 1784, Mr. Nicholson says (Phil. Jour. vol. ii. 4to. p. 59.) that he contrived a clock escapement to go without oil, and which is of the dead-beat kind; it was constructed in the year 1798, and when the account was written had been going freely for a year or more. His account is this, *fig.* 2. of *Plate* XXXVI. "is a sketch, in which G H represents a steel wheel; D and E are pallets of agate, with flat polished faces. The pallet D is fixed to the lever D C, which is confined to its present situation by the loaded branch or arm C B resting on the stop *k*. The lever E C is also kept in its situation by the loaded arm C A resting upon I. A pin N proceeds from the pendulum rod to its situation between the levers. The centre of motion of the pendulum is in the continuation of the axis of the pallets. Suppose the vibrations to be begun; the pin N in its progress will lift the pallet D towards L, while part of the weight B will be supported by the tooth of the wheel which will follow, and at last escape and suffer the opposite tooth F to fall on the pallet E. But in its return, or descent, the pendulum will be acted on by the whole weight B, and, consequently, its vibration will be kept up. When the pin N raises the pallet E, a similar effect will take place on the side of the perpendicular towards M, and thus the process will go on as long as the wheel G H retains any force." In this escapement, the two weights are not raised entirely by the action of the wheel, but are chiefly lifted by the pendulum itself; therefore though the vibration is made during the repose of the wheel, in a state detached from the train, yet the pendulum is not detached from the weights, and, consequently, the compound law of forces by which the pendulum is maintained consists of the action of the pendulum's gravity, of the action of the ball's gravity, which acts in concert with the other, and of a short action of the wheel on the agate pallet; this compound action differs from Mudge's and Cumming's in this respect, that their weights are raised by the wheel entirely without opposing the pendulum, otherwise than by the short stroke made at unlocking.

39. *Crank escapement by Simon Goodrich.*—In the year 1799 the Adelphi Society rewarded Mr. Goodrich for his contrivance of a crank escapement, which is exhibited in *figs.* 3. and 4. of *Plate* XXXVI. of which *fig.* 3. is a front view, and *fig.* 4. a side view of the same, where the same letters of reference apply to both. A A A A is the back plate of a clock frame; B the crank fixed to the end of C the arbor of the last pinion of the train; D, D, are two small wire chains, composed of two links only attached to the crank B, by means of two collets, with great liberty of play. These chains are fastened to E, E, two small springs screwed to F F F, a bar that goes across, and is fastened in the middle to G G, the crutch of the pendulum. I, I, are two screws going through the bar F; the ends of which being made to act against the springs E, E, serve to adjust them to a proper distance and degree of strength, and by that means easily to put the pendulum into proper beat. In *fig.* 3. the pendulum is partly represented by dotted lines, in order to shew the crank, &c. The advantages attributed to this construction are, simplicity of construction and consequent cheapness; total silence during the escape; uniformity of action on the pendulum; durability and certainty of continuance; and the power of acting without oil. These properties may recommend the escapement before us, but as its influence on the pendulum is constant, it is but ill calculated to counteract any irregularities in the maintaining power as transmitted and varied by the train under different circumstances of wear, dirt, and friction. The originality of the contrivance is that of a rotatory motion converted into a vibratory one, which Soumille had done very nearly in the same way in the year 1746. (See Machines et Inventions approuvées par l'Academie Royal des Sciences; tome xiii. p. 325.) As there is no escapement wheel, a

 further

further explanation is unneceſſary to every one who has ſeen a treadle in action; but it may be neceſſary to remark that an additional wheel and pinion muſt be requiſite in the train where the laſt pinion revolves more frequently than in other eſcapements.

40. *Eſcapement without a verge on the pallets by Ed. Maſſey.*—Mr. Maſſey's eſcapement without a verge was one of two eſcapements which together gained him twenty guineas from the Adelphi Society in 1803; the other, being of the 4th claſs, will be deſcribed in another place. *Fig.* 5. of *Plate* XXXVI. is a plan of this eſcapement, which is of a novel conſtruction, borrowed probably from the ſpring detent eſcapement of the modern chronometers, and adapted to a clock, where the pendulum is free, during a large portion of its vibration. The pendulum rod is ſeen at *a*, ſuſpended by a piece of watch ſpring in the uſual way, but without a crutch and verge; *b* is the ſwing wheel with its teeth ſhaped like the dead-beat kind, except that they are rounded at the end; this wheel is not within the frame as uſual, but on the outſide of the back plate; *c* and *d* are the arms of the pallets *f* and *g* reſpectively; theſe arms are attached to the frame, and are adjuſtable for the included angle by the ſcrews *h* and *i*, which preſs againſt the upper ends of the arms, that open like a pair of tongs, and are kept open by a ſlender ſpring *e* forced into notches at the ends. A croſs bar *k*, carried by the pendulum, gives alternate ſtrokes to the two pins fixed in the pallets *f* and *g*, at the time of unlocking. In the figure the pendulum is ſuppoſed to be in motion with the pin of pallet *g* reſting againſt the croſs bar *k*, which bar it impels on the returning vibration, and aids the pendulum, while the inclined plane of pallet *f* is raiſed by the wheel to give its ſtroke, when unlocked, in a contrary direction. Thus the pallets are raiſed partly by the wheel and partly by the pendulum, as is the caſe with Mr. Nicholſon's pallets; for the ſpring in this caſe performs the ſame office that the weight does in that; but in this eſcapement the inclined planes muſt require oil, which is not neceſſary in the other, where the wheel acts by a direct puſh without any ſliding motion. The inventor tells us, that a more than uſually large maintaining power is neceſſary when this eſcapement is adopted, which indeed muſt be the caſe with all detached eſcapements, where the duration of the impulſe is ſhort.

The reader may have obſerved that we have not yet noticed in this article the fourth claſs of eſcapements which act by the aid of *remontoirs*; this omiſſion has been intentional, not only for the purpoſe of avoiding the further enlargement of the article, but that we may give the hiſtory of the invention of the *remontoir*, and of its modifications by the different ingenious men, who have preferred its uſe to that of a detached eſcapement without ſuch additional aid. We have already had occaſion to ſpeak of Harriſon's and Mudge's auxiliary ſprings, or remontoirs, under our article CHRONOMETER, and it will ſuffice, for our preſent purpoſe, to name here that Huygens, Leibnitz, Gaudron, Haley, Breguet, De Lafons, Maſſey, Mendam, Antis, and others have taken a part in bringing the remontoir into notice, as we ſhall have occaſion to relate more particularly under the article REMONTOIR.

ESCARAY, in *Geography*, a town of Spain, in Old Caſtile; 5 miles S. of Calzada.

ESCARIGO, a town of Portugal, in the province of Beira; 12 miles N.W. of Penna Macor.

ESCARPE, or SCARP, in *Military Affairs*, relates to the exterior ſlope of each defence, while on the other hand the interior ſlope of every excavation beyond or facing the eſcarpe is deſignated the counter-ſcarp. It may be neceſſary to remark, that, in ſtrictneſs, the term is not applicable, except where ſome talus or ſlope is given to the exterior, though it is in very general and indiſcriminate uſe. Originally, when the ſides of hills, &c. were to be defended, it was found neceſſary to remove all ſuch maſſes as might afford cover to an approaching enemy, or enable them to aſcend to the aſſault; each rugged exuberance being in ſuch caſes adequate to the ſteps of a ladder, and offering a footing to the aſſailants.

To avoid this facility of attack, it became cuſtomary to chip away the prominent parts, and to render the ſurface inacceſſible; this was effected by eſcarping it, (from the French verb *eſcarper*, to cut ſteep or ſloping,) in ſuch manner as to render it impoſſible for any one to aſcend without the aid of ladders, &c.; giving at the ſame time a direct line of fire to the defenders, and enabling them to roll down ſtones, &c. with prodigious effect, upon ſuch as ſhould have the temerity to aſſault.

Latterly, however, the term has been applied to the exterior face of the works, whether the wall, or revetement, be inclined or perpendicular. Nor does the corruption ſtop here; for many are in the habit of calling the berm the eſcarpe, and of confounding the covert-way with the counter-ſcarp: whereas neither the eſcarpe nor the counter-ſcarp have any thing to do with the terre-pleine, or level ground; but are applicable ſolely to the inclined faces of the ditch and ramparts reſpectively.

It is true that modern engineers, who often allow their phraſeology to follow cuſtom rather than etymology, make little, if any, diſtinction between ſuch revetements as are inclined, and ſuch as are perpendicular: not that many opportunities exiſt for indulgence in this error; there being very few walls or revetements intended for military works, and eſpecially for the faces of parts ſubject to be battered, which have not a talus equal to at leaſt one-ſixth of their reſpective heights.

In ſome fortreſſes leſs reliance is placed on the artillery mounted upon the ſeveral works than upon the advantages afforded by the inclination of the eſcarpe. Thus, where a fort or redoubt is built upon a conical mound of rock, of which the interior may be excavated for lodging the defenders and their ſupplies, if the face of the cone be every where eſcarped to an angle of about 40°, or more, from the horizon, a very moderate perpendicular, ſay to the depth of ſeven feet, around the ſummit, will prevent any aſſailants, however numerous, from carrying the place by ſtorm; provided that perpendicular be properly manned and ſupplied with large ſtones, perhaps from twenty to a hundred pounds weight, which being rolled down the eſcarpe, invariably precipitate all who may be in the line of their deſcent; ſuch a defence is not to be overcome ſo long as vigilance is maintained, and a ſupply of ſtones is at hand.

In India, (as well as in other parts of the world,) ſmall forts are often eſcarped on this principle; there the ſtones held in preparation for defence, all along the interior of the parapet, are deſignated "Mut-wallahs," (*i. e.* drunken men,) in alluſion to the manner in which they roll, and in which thoſe whom they overſet are tumbled down to the plain below.

ESCARS, in *Geography*, a ſmall town of France, in the department of the Upper Vienne; 15 miles S.W. of Limoges, which, before the French revolution of 1789, conferred the title of count on the lords of the manor.

ESCARTELE', in *Heraldry*, quartered, or quarterly. See QUARTERING.

ESCATALENS, in *Geography*, a ſmall town of France, in the department of the Lot; 6 miles W. of Montauban.

ESCATARI, a ſmall iſland about 5 leagues N. of Louiſbourg, in the iſland of Cape Breton.

ESCATRON, a ſmall town of Spain, in the province of Aragon, above the confluence of the Martin and Ebro, nearly oppoſite to Rueda, between Saragoſſa and Mequinenza.

ESCAUT, The, more generally known in England by its Flemiſh or Dutch appellation of the *Scheldt*, or *Schelde*, was formerly a river of Auſtrian Flanders, and is now a river of France, which gives its name to one of the northern departments. It has its ſource in the department of the Somme, near Beaurevoir, a few miles to the north of Saint Quentin, a town of the department of the Aiſne; runs by Beauvoiſi, Catelet, Homécourt, Crévecœur, Cambray, Houdain, Bouchain, Neuville, Denain, Valenciennes, Fraine, and Condé, where it becomes navigable, after having received the Aiſne; it then flows to Mortagne, where it receives the Scarpe; from thence it goes on to Tournay, Gand, and Antwerp, where it is 701 mètres, or 360 fathoms wide, and 10 metres, or 30 feet deep at low water; the tide at high water riſes 15 feet. After having paſſed Antwerp, the Eſcaut branches out into two channels; the eaſtern one paſſes by Bergen-op-Zoom, the weſt channel, called the Upper Eſcaut, loſes itſelf between the iſlands of Zealand into the North ſea, near Fleſſingue or Fluſhing. From Antwerp to this place its courſe is 74 miles; it widens gradually, and has pretty nearly the ſame depth every where; but its bed is obſtructed by ſand-banks, which render its navigation difficult and dangerous.

The Eſcaut has a communication with the river Somme by means of a canal, part of which is under ground.

Escaut, *the department of the*, is the ninth department of the firſt region or United Countries (pays réunis) of France, and derives its name from the river Eſcaut (Schelde) which traverſes it from ſouth to north. It is compoſed of part of Auſtrian Flanders; its chief place is Gand. The limits of the department of the Eſcaut are to the north, the kingdom of Holland; to the eaſt, the departments of the Dyle and of the two Nethes, from which it is ſeparated by the Eſcaut; to the ſouth, the department of Jemmapes, and to the weſt, that of the Lys. Its principal rivers are the Eſcaut, the Lys, the Durenn, the Liévre, the Dender, &c.

There are ſeveral canals in this department; that which goes from Gand to Bruges, and from Bruges to Oſtend, is the moſt important. Another towards the north opens a communication between Rodenherpen and Sao-de-Gand; a third one, near Morbeck, communicates by one of its branches with Axel, and by the other with Hulſt. There are alſo ſeveral leſſer canals for the purpoſes of irrigation, or of draining low marſhy grounds.

The ſoil is in general fertile, and produces all ſorts of corn and vegetables, chiefly hemp, flax, and hops. It abounds in game. Domeſtic fowls and ſweet water fiſh are plentiful. The chief manufactures are thoſe of linen yarn, linen cloth, cobalt, Pruſſian blue, ribbands, woollen cloth, earthenware, glaſs, writing paper. There are alſo ſeveral paper mills, ſugar-houſes, ſalt-works, and bleaching grounds.

The territorial extent of the department of the Eſcaut is $2888\frac{1}{2}$ ſquare kiliometres, or $159\frac{3}{4}$ ſquare leagues; its population 595,258, or 3720 inhabitants to the ſquare league. The whole department is divided into four diſtricts, Gand, Audenaërd, Termonde, and l'Ecluſe; 41 cantons, and 338 communes. The average contribution of every individual to the expences of the ſtate is about 9*s.* 2*d.* ſterling annually. Herbin Statiſtique de la France.

Escaut *and Meuſe, the department of the*, in Dutch the department of the Schelde and Maas, is one of the new diviſions of the kingdom of Holland, and is reported to compriſe the weſtern part of the ancient Dutch Brabant, Zealand, and the iſlands of the Maas or Meuſe. Middleburg is its chief place.

ESCH, a town of the duchy of Luxembourg, on the Sour; 7 miles W. of Dierich.

Esch, in *Ichthyology*, a name given by Hildegard and others to the fiſh we call the grayling, or umber, and the generality of authors, the thymallus. It is of the coregonous kind, and is diſtinguiſhed by Artedi by the upper jaw being longer, and the back fin containing twenty-three bones. The Germans call it *aſch*, and the Italians *temello*. See Salmo *Thymallus*.

ESCHALLOT, *Cepa Aſcalonica*, in *Botany*, a ſpecies of onion, cultivated in gardens for its uſe in cookery, and nearly reſembling the Welch onion. See Cepa.

ESCHAR. This term, in *Surgery*, implies a portion of fleſh, deadened by the application either of actual fire or cauſtic ſubſtances. In caſes of violent burns we frequently ſee eſchars produced; and whenever we wiſh to make a common iſſue, for the relief of any ſuch diſeaſe as a white-ſwelling, a caries of the vertebræ, &c. we cannot accompliſh our object better, than by forming an eſchar with the kali purum cum calce vivâ. The ſeparation of an eſchar, or its detachment from the living parts, is a work of nature, being chiefly effected by the action of the abſorbent veſſels, which remove the particles of matter, connecting the dead and living parts together, ſo as to looſen the eſchar, and allow it to be taken away, without pain, bleeding, &c.

ESCHARA, in *Natural Hiſtory*, the name of a ſpecies of coralline, &c. the characters of which are theſe: they are of a ſtony or coral-like hardneſs, and reſemble a woven cloth in their texture; and the microſcope ſhews us that they conſiſt of arrangements of very ſmall cells, whoſe ſurfaces appear much in that form. (See Millepora.) For other ſpecies, ſee Flustra and Madrepora.

ESCHAROPEPA, a word uſed by the old writers in *Medicine*, to expreſs a coarſe kind of barley-meal, which had been torrified over the fire.

ESCHAROTICS, in *Surgery*, are certain ſubſtances and applications which, when put on any part of the body, occaſion an eſchar, or ſlough. Although the ſtrict meaning of the word eſcharotic is the ſame as that of *cauſtic*, yet, modern practitioners uſually underſtand by the firſt term ſome application that is milder in its action, than ſuch ſubſtances as are denominated cauſtics. By the latter, a ſurgeon generally means the kali purum, with or without quicklime, or the argentum nitratum, antimonium muriatum, &c. But by eſcharotics he commonly implies applications like the cuprum vitriolatum, hydrargyrus præcipitatus ruber, &c.

The chief uſe of eſcharotics, in the practice of ſurgery, is to deſtroy excreſcences, funguſes, and high exuberant granulations. When mixed with ointment, ſo as to have their action weakened, they are alſo ſometimes employed for ſtimulating ſores, which are of an indolent nature.

ESCHATON, in *Muſic*, the difference between the dieſis enharmonica and the hyperoche; that is, what remains, after taking the difference between the ſemi-tone minor and dieſis enharmonica, from the latter. Henfling, in Miſc. Berolin. vol. i. p. 279, 280.

Thus the difference between the ſemi-tone minor and the enharmonic dieſis is $\frac{25}{24} : \frac{128}{125} = \frac{3125}{3072}$, and this taken from

from the diesis, is $\frac{128}{125} : \frac{3125}{3072} = \frac{393216}{390625} = 6\Sigma - f + m$, and is the *major residual*; which see. This interval is about $\frac{53}{100}$ of a comma, as will easily appear by logarithms. Mr. Hensling has taken notice of this interval. He calls it eschaton, from its being the least and the last interval that occurs in his system.

The word is Greek, εσχατον. See INTERVAL.

ESCHATON of Dr. Callcott's MSS., is an interval whose ratio is $\frac{16,677,181, \&c.}{16,777,216, \&c.} = 5\,\Sigma + 2\,f$, and is the *greater residual*, which see.

ESCHE, in *Geography*, a town of Switzerland, in the canton of Uri; eight miles S.E. of Altorff.

ESCHEAT, ESCHET, or *Echet*, formed from the French *eschoir*, or *échoir, to happen*, in *Law*, denotes an obstruction of the course of descent, and a consequent determination of the tenure, by some unforeseen contingency; in which case the land naturally results back, by a kind of reversion, to the original grantor or lord of the fee. (1 Feud. 86. Co. Litt. 13.) This was one of the fruits and consequences of feodal tenure: and is incident to tenure in socage, as well as to tenure in knight-service; except only in gavel kind lands, which are subject to no escheats for felony, though they are to escheats for want of heirs.

The civilians call such escheats, or forfeitures, *bona caduca*; and in the same sense, as we say the fee is escheated, they say *feudum aperitur*.

The word *escheata* sometimes also signifies a lawful inheritance descending on the heir. But then it is usually distinguished by the addition of *recta*; as *recta escheata*.

ESCHEAT is also used for the place or circuit within which the king, or other lord, hath escheats of his tenants.

ESCHEAT is also sometimes used for a writ, lying where the tenant having estate of fee-simple, in any lands or tenements holden of a superior lord, dies seised without heir, general or special: in which case the lord brings this writ against him that possesses the lands, after the death of his tenant; and thereby recovers the same in lieu of his services.

ESCHEATOR, an officer who anciently took care of the king's escheats in the county, and certified them into the exchequer, or chancery.

He was appointed by the lord treasurer; held his office only for one year; nor could any person be escheator above once in three years. But this office, having its chief dependence on the court of wards, is now out of date.

ESCHEFELD, in *Geography*, a small town of Saxony, near Wolfftitz, in the circle of Leipzick, remarkable for its quarries of beautiful jasper, known by the name of Bandstein von Gnandstein.

ESCHEL, in *Mineralogy*, a term used by the smalt-workers, to express a sort of grey substance resembling ashes, which is usually mixed with the smalt when in fusion. This is carefully separated from it before it is powdered for use, otherwise it would debase the colour. Phil. Trans. N° 396.

ESCHELLON, or EÇHELLON, in the military acceptation, is a term borrowed from the French language, in which it signifies a ladder; alluding to the regular and parallel gradations of any series of lines, more or less inclined from any given base line. Thus if we suppose in *fig.* 1. *Plate* I. *Tactics*, the line A B to be divided into any given number of equal parts, as 1, 2, 3, 4, 5, 6, and suppose the left end of each division to be moveable on a pivot, the other end swinging round at pleasure, we shall find that those several divisions are capable of being moved forward, at the assumed angles from the base line A B.

Now it is necessary to be well understood, that, according to the military step, the number of files from any given pivot will determine the number of paces to be taken to make a wheel, corresponding with a right angle: thus when the 8th file from the pivot makes eight paces in wheeling, the whole of the division performing such evolution will make a wheel equal to the quarter of a circle, because all distances from the centre must invariably correspond with the quarter of a circle, of which such distances are respectively radius.

But the eçhellon movements are never understood to amount to the quarter of a circle; that being considered a full wheel, changing from line into column: yet the eçhellon is itself a species of column, disposeable with equal promptitude either to flank or front; thus affording peculiar advantage, while it gives at the same time a parallel movement of a line, broken for the moment, into small portions, towards any object obliquely situated towards either flank; in front or rear. These important advantages have not been overlooked by modern tacticians, who have amply availed themselves of the mutability thus afforded: consequently we find the eçhellon adopted in the existing code of evolutions, on an unlimited scale.

It being ascertained that the eighth file, by moving forwards eight paces in a regular curve on the given pivot, makes a wheel of one quarter of a circle; it is obvious, that any intermediate part, of which one pace is the multiple, may be wheeled, by taking the desired number of paces; thus, four paces will make an octave, or the eighth part of a circle, which is the most frequent declination from the base line; two paces will give the sixteenth of a circle, or the fourth part of a quadrant; and thus of any number.

Let us suppose it requisite to change the front of a battalion to a new position, forming, as nearly as the eye could estimate, an angle of 75° from the base line A B. Now, as each step of the eighth file gives a change of front equal to about eleven degrees, it is obvious, that seven ordinary paces will rather exceed the given angle; therefore, if very great precision should be indispensable, the eighth file should make six long, and one short pace, which would throw the whole battalion into eçhellon at such an angle as would allow the several divisions to march with a full front to their positions in the new line. This is a most important object; because it admits the utmost freedom of individual movement, and avoids that oblique tendency which must be resorted to whenever such full frontage cannot be preserved.

Eçhellon may be formed towards either flank; whether to the rear or to the front; the open column may be readily formed by wheeling so as to complete the quarter of a circle, including the original portion, and adding it to the supplement: both wheels being in the same direction. Thus if only the eighth of a circle was wheeled into eçhellon, another wheel, of another eighth, will be needful to bring the corps into open column.

To form the line from eçhellon; either a back wheel may be made equal to the wheel forward: thus, if a battalion has broken into eçhellon by wheeling an octave *to* the right, it will, by wheeling *back* an octave *on* the right of divisions, be instantly formed into line. In this instance the right flank gives the point d'appui. But if the left is to give it, there the whole of the divisions must wheel *forward* on their left pivots, as many degrees as were included in the original wheel to the right. If the first wheel was only the

16th

16th part of a circle to the right, the complementary wheel to the left muft be equal to only one fixteenth. In faying this, it is neceffary to be underftood, that all the divifions are fuppofed to be of equal ftrength; otherwife it will be indifpenfably neceffary that the refpective pivots, which are to guide the alignement, be properly dreffed; that is, cover correctly, before any wheel is made under their guidance.

Eçhellon divifions do not always move with a full front towards that point on which the wheel is made; on the contrary, it is often expedient to wheel to the right, when the new front is towards the left. This is done for the purpofe of giving the flanks of the divifions a proper direction, that they may refpectively march by files, towards their ftations in the new line; and is particularly neceffary in broken ground, as well as in countries covered with wood. The feveral leaders of files muft, in this cafe, be extremely correct in maintaining their original direction; attending to their feveral pivot-men, if fuch be in fight: where that guide cannot be afforded, the greateft care muft be taken to obferve any two diftant objects that may be in the given direction; fo as to proceed, as nearly as poffible, to the appointed fpot.

From the foregoing it will be collected, that, while *direct* changes of front are made by full wheels (*i. e.* the quarter of a circle,) to either right or left, oblique changes are effected by means of a due degree of parallelifm, produced in confequence of wheeling in any proportion lefs than the quarter of a circle. Therefore, as the code of regulations now in ufe for the movements of battalions properly inculcates, the eçhellon pofition and movements are not only neceffary and applicable to the immediate attacks and retreats of great bodies; but alfo to the previous oblique or direct changes of fituation, which a battalion, or a more confiderable corps, already formed in line, may be compelled to make, to the front or the rear, or on a particular fixed divifion of the line.

When a battalion marches in eçhellon its route muft be on the reverfe principles of Marquois's parallel rule, which confifts of a fcale, having a triangular piece fliding at liberty along its edge, as fhewn in *fig.* 2. In that the inclined plane A B even follows a line not perpendicular to its front, and this is the main diftinction between the eçhellon movement and the oblique-ftep; the former may continue for any diftance, rather giving eafe, than proving unufually fatiguing, to the men; whereas the oblique-ftep is peculiarly diftreffing, if kept up for a length of time; while it befides poffeffes the great difadvantage of gaining but little ground. In the above figure the line A B may proceed the whole length of C D, without gaining ground towards its oppofite, or exterior flank B; becaufe it is, in a manner, fixed by the inner flank A, which may be faid to run in a groove on the line B C; whereas if we applied the eçhellon movement to the line A B, that is perpendicular to its own front, its courfe would be according to A E, B F, and ground would be gained to its right, as well as to its front, in exact proportion to the angle D A B; if that be fmall, there will be a greater tendency to the front of the line C D, than towards its left flank, and *vice verfâ*; ever carrying in mind, that fo foon as the wheel amounts to a quarter of a circle, the term eçhellon is annulled.

We fhall here exhibit the ufe of an eçhellon movement as applicable to the reinforcing of a line advancing at the *debouchure* of a *detroit*; where, in confequence of the regular expanfion, it becomes neceffary to keep adding to either, or perhaps to both flanks, in order to prevent the enemy from penetrating; fo as to attack the rear. It may be expedient to obferve that not only companies, but whole battalions, may form in eçhellon; and that it is an evolution fuited equally to cavalry and to infantry. When a park of artillery has to flank an enemy, in a pofition where the proper line cannot be affumed, fo as to bring the feveral guns to a line perpendicular to the direction of their fire, they muft then, properly fpeaking, be individually in eçhellon. Thus when guns are mounted in *barbet*, (*i. e.* where there are no embrafures, the muzzles traverfing over the parapet,) whenever the object does not bear at right angles with the face of the battery, each gun is obliqued, and the fhots fired from the whole would reprefent the movements of divifions thrown into eçhellon. *Fig.* 3. fhews a line forming as the army iffues from a detroit, the feveral battalions compofing it being allowed to reinforce the centre until due fpace be gained for the whole to wheel into eçhellon. Now it will be feen, that each battalion formed in column, in by files, fucceffively affumes a pofition perpendicular to that line; but, that when fpace admits, the wheel is made, whereby each divifion is directed towards the poft it will occupy on the flank, as the expanfion takes place. Here S S is the line, and O P the battalion deftined to cover the right flank; its feveral divifions, being thrown into eçhellon, muft in their progrefs fall into their refpective pofts, at the new pofition *a a* one after the other, filling up the augmenting fpace with celerity and exactnefs. It is, however, to be underftood, that each, as it approaches its fituation in line, muft accelerate or retard its pace according to circumftances; fince it cannot be expected that the ground will expand with perfect regularity.

In cafe of an attack, in which the enemy may fucceed in getting round the flank, thofe divifions clofe to that flank muft wheel back into line; leaving to two or three of the rear divifions to join on their flank in the direction of the eçhellon front; thus forming a re-entering angle, effectually cutting off the enemy's progrefs, and fubjecting him to a concentrated fire; as fhewn by the dotted pofitions at E. The dotted lines emanating from the feveral eçhellons fhew their direction when marching: their prolongation would fhew how they would fall in on the flank, fo as gradually to extend the front; compleating the new line *a a*. When neceffary, the fame operation is performed towards the left.

It has been obferved that the eighth file gives a determinate meafurement, in regard to the wheel of divifions into eçhellon; it is therefore expedient, when the given direction is afcertained, to caufe the eighth file to ftep out the required diftance, (fay four paces for the eighth of a circle,) obferving, that his advance muft be on a wheeling principle: that is to fay, curved; the pivot being confidered as the centre, and the diftance between that and the eighth file being radius. Each divifion thus fending forth its eighth file, the whole are ordered to wheel until thofe files are reftored to their places in their divifions: during the wheel of the divifions, each muft neceffarily remain motionlefs; that all may drefs by them; fo as to give a true parallel throughout the line of eçhellon.

ESCHENAU, in *Geography*, a town of Germany, in the archduchy of Auftria; eight miles S. of St. Polten.

ESCHENBACH, a town of Germany, in the circle of Bavaria, and Upper Palatinate; 34 miles E.N.E. of Nuremberg.

ESCHENBERGA, a fmall town of Germany, in the duchy of Saxe Gotha, with a population of 504 inhabitants, remarkable for its trade in madder. It was anciently of more importance.

ESCHERSHEIM, a town of Germany, in the circle of the Upper Rhine, and county of Hanau-Munzenberg; 10 miles

10 miles W. of Hanau, and 3 N.N.W. of Francfort on the Main.

ESCHEVIN, or Echevin, *Scabinus*, in the French and Dutch *Polity*, a magiſtrate elected by the inhabitants of a city to take care of their common concerns, the good order, conveniency, and decoration of the city, &c.

At Paris there is a prevot and four eſchevins; in moſt other cities a maire, or mayor, and eſchevins. In Languedoc, Provence, and Dauphiné, they are called *conſuls*; at Thoulouſe *capitouls*; and *jurats* at Bourdeaux.

Anciently, the eſchevins were the aſſeſſors and counſellors of the comites, or judges of cities; on which account they were called, in ſome places, *pairs*, *pares*; they even took cognizance of petty cauſes themſelves.

Du-Cange obſerves, that the judges, and their aſſeſſors, who were choſen by the inhabitants, were called *ſcabini*, eſchevins, and their college, *ſcabinagium*, or *eſchivinage*. He adds, that ſome authors call them *paciarii*, becauſe their office and juriſdiction extended to the ſecuring peace in their city and banlieue, called *pax villæ*.

In Holland, the *ſcabins*, or eſchevins, judge of all civil affairs at firſt hand. They alſo take cognizance of criminal matters; and if the criminal confeſs himſelf guilty, they can ſee their ſentence executed without appeal. They can even give torture. The number is not the ſame in all cities; at Amſterdam there are nine, at Rotterdam ſeven, &c.

ESCHLBERG, in *Geography*, a town of Germany, in the archduchy of Auſtria; 14 miles S.W. of Freuſtadt.

ESCHLKAMP, a town of Germany, in Lower Bavaria; 3 miles E. of Furth.

ESCHRAKITES, or Esrakites, a ſect of philoſophers, among the Mahometans, who adhere to the doctrines and opinions of Plato.

The word is derived from the Arabic שרק, *ſchraka*, which in the fourth conjugation אשרק, *aſchraka*, ſignifies *to ſhine*, *glitter like the ſun*; ſo that Eſchrakite ſeems to import *illumined*.

The Eſchrakites, or Mahometan Platoniſts, place their higheſt good and happineſs in the contemplation of the Divine Majeſty; deſpiſing the groſs imaginations of the Alcoran touching Paradiſe. See Mahometanism.

They are very careful in avoiding all vice; they preſerve an equal and eaſy temper, love muſic, and divert themſelves with compoſing little poems, or ſpiritual ſongs. The ſheics, or prieſts, and the chief among the preachers of the imperial moſques, are Eſchrakites.

ESCHWEGE, in *Geography*, a ſmall town of Germany, in the landgraviate of Heſſe Caſſel, which now forms part of the new kingdom of Weſtphalia. It is ſituated on the Werra, 33 miles E. of Caſſel, near a lofty hill called the Meiſner, which has ſome coal-mines. Eſchwege is a place of high antiquity.

ESCHWEILLER, a ſmall town of France, in the department of the Roer, chief place of a canton, in the diſtrict of Aix-la-Chapelle, with a population of 1713 individuals. The canton has 18,588 inhabitants, diſperſed in 28 communes.

ESCHYLUS. See Æschylus.

ESCHYNOMENOUS Plants. See Æschynomenous.

ESCLAIRCISSEMENT, or Eclaircissement, a French term, which we find retained in ſome late Engliſh writers; it properly ſignifies the act, or effect, of clearing a thing, or rendering it more bright and tranſparent; being formed from the verb *eſclaircir*, to clear, &c.

It is chiefly uſed in a figurative ſenſe, for an explanation of an obſcurity or difficulty. The eſclairciſement of difficult paſſages in the bible, is to be ſought for from ſimilar paſſages, or paſſages of the like kind occurring in other places.

ESCLAME, in the *Manege*, an obſolete French word, formerly uſed to ſignify a light-bellied horſe.

ESCLATTE', in *Heraldry*, is applied to a thing violently broken. Thus a bend or rather partition, eſclatté, is repreſented torn, or broken off, like a ſhield ſhattered with the ſtroke of a battle-ax.

ESCOBAR, Anthony, ſurnamed *De Mendoza*, in *Biography*, a Spaniſh Jeſuit, who flouriſhed in the beginning and middle of the ſeventeenth century. The opinions which he maintained have been cenſured by more modern writers; and the principles of his morality have been expoſed by Paſchal in his "Lettres Provinciales," and by other authors of leſs note. He left behind him many works, among which are "Theologia Moralis;" "Commentaria in Vetus et Novum Teſtamentum;" and "Examen y Pratica de Confeſſores." Moreri.

ESCOL, in *Ancient Geography*, a valley or torrent of Paleſtine, in the ſouthern part of the tribe of Judah; mentioned in the book of Numbers.

ESCORT, in *Military Affairs*, ſignifies that guard granted, either under military authority, or of military perſons, for the ſafe conveyance of perſons, property, &c. from one place to another. This may be ſaid to diſtinguiſh an eſcort from a convoy; the latter being generally applicable to ſuch extenſive affairs as relate rather to the guarding of ſupplies, &c. on their way to an army, or to a fortreſs. The extent of an eſcort is uſually proportioned either to the dignity of the perſon attended, if it be meant as a compliment; or, if of treaſure, according to the ſum, and the dangers lying in the way. In ſome caſes, eſcorts are taken only from particular corps; as, for inſtance, thoſe which attend upon his majeſty, which are ſelected from certain regiments only, unleſs on extraordinary occaſions. When an eſcort is employed on ſuch an occaſion, its commander is uſually placed under the orders of the perſon to be guarded; but when treaſure, priſoners, &c. are in queſtion, the commander is in every reſpect paramount; he being reſponſible for the ſafe arrival, and the delivery, of whatever is under his charge. Such is the ſtrictneſs with which the reſponſibility of an eſcort is upheld, that a few years back, when a deſerter who was under charge of a guard made an attempt to abſcond, one of the party fired at him, but unhappily miſſing the fugitive, killed an unfortunate paſſenger in the ſame ſtreet; the man who fired was conſidered to have done no more than his duty. We naturally view ſuch an occurrence with much concern, and commiſerate the ſufferer; but when we contemplate what might have been the ſituation of the ſoldier, had he omitted to do his beſt towards preventing the eſcape, though we cannot exactly applaud his conduct, we muſt aſſuredly ſee much in extenuation of the manſlaughter.

When travelling any diſtance, and that ſpeed is eſſential, it is uſual to relieve the eſcorts, when convenient, at certain ſtages. In ſuch caſe, it behoves the commander of each party to be very careful in examining every matter previous to taking charge. If there be treaſure, or other valuables, &c. under ſeal, the impreſſions ſhould be minutely inſpected; and if the articles, or packages, be numerous, but more eſpecially if ſubject to damage, he ſhould cauſe the whole to be counted, and aſcertain, in the preſence of the perſons from whom he receives them, the exact ſtate and appearance, noting every point worthy of obſervation in the way-bill, and exclusively giving a receipt, in which all casualties or deficiencies should be fully described. This inspection should always be made in the presence of others of his own party, and it would not be amiss were he to cause them to attest the condition in which the articles should be, at the time of his receiving charge. Should any accident take place while under his own protection, the hour, the place, and the cause, ought to be in like manner noted, so soon as possible, under the certificate of credible persons on the spot; or at least of some of his own party. By such precautions much imputation will be avoided; while at the same time a character for correctness, and for assiduity, will be gained.

ESCOT, L', in *Geography*, a small town of France, in the department of the Lower Pyrenées; 6 miles S. of Oleron, remarkable for a cooling mineral spring.

ESCOUADE, or SQUAD, is usually the third or fourth part of a company of foot; so divided for mounting guards, and for the more convenient relieving of one another. It is equivalent to a brigade of a troop of horse. See BRIGADE.

ESCROL, or SCROLL, in *Heraldry*, a long slip, as it were, of parchment, or paper, wherein a motto is placed.

Leigh observes, that no person, under the degree of a knight, might, long after king Henry V. place his crest on a wreath, as is now usually done, but only on an escrol.

ESCROW, in *Law*, a deed delivered to a third person, to be the deed of the party making it upon a future condition when such thing is performed; and then it is to be delivered to the party to whom made. It is to be delivered to a stranger, mentioning the condition; and has relation to the first delivery. 2 Roll. Abr. 25, 26. 1 Inst. 31. See DEED.

ESCU, or ECU, the French crown, of sixty sols, or three livres. The escu was thus called, because the escutcheon, or arms of France, which they call escu, was struck thereon. See COIN.

ESCU, *Emaux de l'*. See EMAUX.

ESCUAGE, or SCUTAGE, an ancient kind of knight's service, called also "service of the shield;" the tenant holding by which was obliged to follow his lord to the Scottish or Welsh wars, at his own expence. But personal attendance being inconvenient, the tenants compounded for it by a pecuniary satisfaction, which was levied by assessments at a certain rate for every knight's fee; and thus it became a pecuniary in lieu of a military service. The first instance that occurs was in 5 Hen. II. on account of his expedition to Toulouse; it afterwards became more general and oppressive; so that king John was obliged to consent, by his Magna Charta, that no scutage should be imposed without consent of parliament; but the clause was omitted in the charter of Hen. III. which directs, that it should be taken as it is used to be in the time of Henry II. or in a reasonable and moderate manner. However, it was afterwards enacted by stat. 25 Edw. I. cap. 5 and 6. and many subsequent statutes, that the king should take no aids or tasks but by the common assent of the realm; and it appears that scutages were the ground work of all succeeding subsidies, and of the land-tax of later times. Blackst. Com. vol. ii. p. 74.

ESCUAGE was also a reasonable aid, demanded by the lord of his tenants, who held of him by knight's service. See AID.

"Concesserunt domino regi ad maritandum filiam suam de omnibus qui tenent de domino rege in capite de singulis scutis 20 solidos solvendos." Matt. Paris, anno 1242.

ESCULAPIUS. See ÆSCULAPIUS.

ESCULENT, in *Gardening*, is a term frequently applied to such roots or plants as are replete with nutritious matter, and consequently proper for being eaten as a food. Carrots, parsnips, turnips, cabbages, and various others of a similar nature, are of this kind.

ESCULUS, in *Botany*, a name given by many authors to the phagus, or sweet oak, called also the esculent oak.

ESCULUS, or *Æsculus*. See ÆSCULUS.

ESCURA, in *Geography*, a province of the empire of Morocco, called by Leo Africanus *Ascora*, which, together with that of Ramna, formerly composed only one government. It has been divided to keep the people of these countries, so near to the mountains, more easily in subjection. Ramna and Escura have the province of Morocco to the south, that of Duquella to the west, the river Morbeya to the north, and mount Atlas to the east.

ESCURIAL, by the Spaniards written *Escorial*, a term that denotes the place of residence of the kings of Spain. Escurial originally signifies a little village in Spain, situated in the kingdom of New Castile, 22 miles to the N.W. of Madrid, on the side of a chain of mountains, called by some the Carpetane, or Carpentanian mountains, and by others the Pyreneans, as being the branch of the Pyrenean ridge, and environed by wood-lands and green fields. Here king Philip II. built a stately monastery of the order of St. Jerom, held by the Spaniards for one of the wonders of the world, and called the Escurial. It was begun in 1557, and finished in about twenty-two years, at the expence of six millions of piastres.

Fa. Francisco de los Padros, in a description thereof, intitled "Description breve del Monasterio de S. Lorenzo el real del Escorial, &c." assures us it was built by that prince in memory of the battle of St. Quintin, gained on the day of St. Laurence, Lorenzo, a famous Spanish saint, and at his intercession; accordingly the plan of the work resembles a gridiron, the instrument of the saint's martyrdom.

The king and queen have their apartments there; the rest being possessed by the monks. Whence many of the great transactions of that court are dated from the Escurial.

This superb palace is a long square, 740 by 580 Spanish feet, besides 460 for what may be termed the handle of the gridiron. The height of the roof is 60 feet; and at every angle is a square tower, 200 feet high. In the west front there are 200 windows, and 366 in the east.

The Escurial has a very fine church, the dome of which is 330 feet, supported by four rows of pillars, and paved with black marble, containing 40 chapels, and 48 altars. To this church Philip IV. annexed a beautiful mausoleum, called the Pantheon, or Rotondo, built on the plan of that temple at Rome, 36 feet in diameter, and incrusted with marble; in which the kings and queens of Spain, who leave any posterity, are interred; the rest being laid in another vault of the same church, together with the infantas, and other princes.

The palace possesses every convenience and ornament that can render a place agreeable in so hot a climate; such as an extensive park, groves, fountains, cascades, grottos, &c. The adjacent country contains specimens of all the mineral substances, stones, earths and vegetables, which are found in other parts of the kingdom. The library belonging to this palace is said to consist of 30,000 volumes, contained in two magnificent apartments, each 194 Spanish, or somewhat more than 182 English feet in length. In the lower room are chiefly printed books; and in this is deposited the famous

famous MS. of the four gofpels, written in gold letters, faid to be a work of the 11th century. Over thefe are collected 4300 MSS., of which 567 are Greek, 67 Hebrew, 1800 Arabic, the latter of which are well defcribed in a catalogue publifhed by Cafiri. In the middle of the lower room is a temple, with a great variety of figures, containing 1448 ounces of filver, and 43 of gold, befides rich gems. In every part of the convent of the Efcurial, are feen the works of the beft mafters, and fome of them moft capital performances. The beft of the pictures are collected in five principal apartments; the great ftaircafe is beautiful, adorned with frefco-paintings of the battle of St. Quintin, by Luca Jordano. The fituation of the Efcurial, as a refidence, is not pleafant: expofed, as it is, to the full ftroke of the meridian fun, and raifed up near to regions covered with eternal fnow; without fhelter and deftitute of fhade, it has no local charms at any feafon of the year. (Townfend's Travels, vol. 2.) Part of this fuperb palace was burnt in 1671.

ESCUROLLES, in *Geography*, a fmall town of France, in the department of the Allier, chief-place of a canton, in the diftrict of Gannat, with a population of 1042 individuals. It is 6 miles N. of Gannat. The canton contains 15 communes, and 11,408 inhabitants, on a territorial extent of 237½ kiliometres.

ESCUTCHEON, or SCUTCHEON, in *Heraldry*, the field or coat, wherein the bearing, or arms, of any perfon are reprefented.

The word efcutcheon is formed of the French *efcuffon*, and that from the Latin *fcutum*, fhield; which was the place arms were originally borne on, before ever they came on banners; and ftill, wherever they are placed, it is on fomething reprefenting the form of a fhield. The Latin *fcutum*, no doubt, came originally from the Greek, σκυτος, *leather*, wherewith the fhields were ufually covered. See SHIELD.

The efcutcheon is of a fquare figure, excepting the bottom part, which is ufually a little rounded, ending in a point in the middle.

Till within a few hundred years, the efcutcheons of the French and Englifh were triangular; thofe of the Spaniards are ftill quite round at bottom, without any point; thofe of the Italians are oval; and thofe of the Germans in form of a catoozes.

The ancient efcutcheons were generally couched, or inclined; and they only began to place them upright, when crowns, &c. were put over them by way of creft.

In France *efcuffon*, efcutcheon, was formerly reftrained to a fhield, or coat, pointed at bottom; by which it was diftinguifhed from the efcu, which was quite fquare, and was only allowed to be borne by the counts and vifcounts. Thofe of the inferior quality were confined to the efcuffon or pointed efcu.

The feveral parts or points of the efcutcheon have their proper names: the point A, for inftance, is the dexter chief point; B the middle chief; and C the finifter chief point; D is the honour point; E the feffe point; F the nombril point; G the dexter-bafe; H the middle; and I the finifter bafe point. See *Plate* of *Heraldry*.

The dexter fide of the efcutcheon anfwers to the left hand, and the finifter fide to the right hand of the perfon that looks on it.

The efcutcheon is differently denominated, according to its divifions. It is called dextered, when the perpendicular line that divides it is to the right of a third part of the efcutcheon; finiftered, when on the left; tierced in pale, when this line is double, and divides the whole efcutcheon into three equal parts; paled, when increafed to the number of fix, eight, or ten. A horizontal line makes the chief, when at one third part from the top; the plein, when at a third from the bottom; and when double, in the middle at an equal diftance from both extremes, it makes the feffe, and the tierced in feffe: when it is multiplied, it denominates it feffed; when there are eight or ten equal fpaces burrelle. A diagonal from the dexter point of the chief to the finifter of the bafe, makes it tranché; the contrary doublé; if it be double at equal diftances the firft makes bandé, and the tierce in bend; and the other barre, or tierce in bar; increafing the number of the firft makes bandé, and cotticé; and increafing that of the fecond barré, and traverfe.

ESCUTCHEON *of pretence*, is an inefcutcheon, or little efcutcheon, which a man who has married an heirefs, and has iffue by her, may bear over his own coat of arms, and in it the arms of his wife; and, in this cafe, the furviving iffue will bear both coats quarterly.

ESCUTCHEON, in *Sea Language*, a name fometimes given to the compartment for the names or arms of the owner, or of the perfon whofe title the veffel affumes. It is ufually fixed on the middle of the fhip's ftern; and is more peculiar to the French, and other foreigners, than to Englifh-built veffels. Falconer.

ESCUTCHEON, *Secret*, is a contrivance to be placed before a lock, which clofes up, and conceals the key-hole, and renders it inacceffible for any perfon except the owner, who is acquainted with the fecret.

The marquis of Worcefter appears to have invented fome fecret efcutcheons, for in his "Century of Inventions," publifhed in 1663, at N° 72, after having fpoken of three kinds of locks invented by him, fays, "an efcutcheon to be placed before any of thefe locks with thefe properties:

"The owner, though a woman, may with her delicate hand vary the ways of coming to open the lock ten million times beyond the knowledge of the fmith that made it, or of me who invented it."

Many attempts have been made to form a machine equal in its properties to the defcription here given; and from thence, it is probable, arofe the kind of padlocks which have been long made in this country, in great numbers, which having feveral letters on different rings, can only be opened when a certain fet of thofe letters is arranged in one order; but this was in no degree equal to the end propofed; for befides the workman who made it, being at all times informed of the pofition the letters muft be in, and, confequently enabled to open it, the letters and rings admitting of no variation of place, at the will of the owner; referving, at the fame time, a power of opening the locks; whenever the proper arrangement became known, the fecret was divulged, and all fecurity at an end; but by the improvement lately made by Mr. Marfhall (for which the Society of Arts rewarded him with ten guineas,) the letters or figures allowing an almoft infinite variety of changes, the owner may, in one minute, alter the fecret in fuch a manner, that even the maker would be as unlikely to open it, as he would be of gaining the higheft prize in a lottery, by the chance of a fingle ticket. Thus this kind of efcutcheon is infinitely more fecure than any hitherto in ufe, efpecially as the alteration of the letters may be made every day for years, without recurring to their firft ftate; and as the owner may at one time chufe to truft a friend, or a domeftic with the fecret, fo that they might have recourfe to his valuables, &c. he may alfo at another time wifh to exclude them from that privilege, which this contrivance renders very eafy to be done. As this improvement relates only

to

to the efcutcheon, it is obvious that every attempt to pick the lock it covers, or to open it by means of falfe keys, is prevented; a circumftance of no fmall importance, when locks of a curious conftruction, and when a number of fine wards are made ufe of.

The efcutcheon for which the bounty was given is referved in the repofitory of the fociety for the infpection of the public.

Figs. 2, 3, 4, 5, 6, 7, 8, and 9, *Plate* XII. *Mifcellany*, reprefent this contrivance: *fig.* 3. is a view from behind the machine, fuppofing it to be firft removed from the door. *Fig.* 2. is an elevation of the machine, as it appears upon the door; A B C D is a brafs box, faftened over the key hole; it has a fquare hole through it, covered by a fmall door E; this door is kept fhut by a pin fixed into a fmall lever *a*, *fig.* 3, which enters a projection from the fide of the door, and thus prevents it being open, unlefs the lever is firft drawn back; a fpring *b* is applied behind the lever to force it outward, and another at E always preffes againft the door, and acts to throw it open as foon as the lever *a* is drawn back, which is accomplifhed by means of a pin, which comes through a groove in the plate; this pin is faftened in a fquare bar F, *figs.* 2 and 5. (fhewn feparately in *fig.* 4.) on the front of the plate. The fmall perfpective, *fig.* 8. reprefents two brafs cocks *d*, *d*, which fupport the ends of a cylindric wire *g*, in which is a groove for the bar F to flide backwards and forwards; thefe cocks are fcrewed to the plate within-fide, as fhewn at *d d*, *figs.* 2, 3, and 5, and come through an opening in the Plate; fo that the bar F is in front of the plate; the wire *g* is the common axis for five fmall rollers *a*, *e*, *f*, *m*, *o*, the ftructure of one of thefe is explained by *figs.* 5, 6, 7, and 9; *h* is a circular piece of brafs which fits upon the centric wire: this, as is fhewn in the fections, *figs.* 5 and 9, is thicker at the outfide than the middle; and the front view, *figs.* 6, 7, fhew how a recefs is cut, communicating with the centre hole; now when the five rollers are turned round upon the central wire *g*, fo that the receffes are all brought into the front, the projecting teeth *x*, *x*, of the flider F will meet with no obftruction, and may be drawn back fo as to open the efcutcheon; but when any of the rollers are turned round, fo that the thin parts near the centre are brought between the teeth of the flider, then the flider cannot be withdrawn. The pofition of the roller, when the flider is at liberty, is known by bringing five of the letters which are engraven on the outfide of the rollers uppermoft, and it is in thefe letters that the fecret confifts. But to render the combination of letters variable, the letters are not engraved upon the outfide of the rollers themfelves, but upon a thin brafs hoop *e*, which is fitted on round the roller; a fpring *n* is faftened to the roller, and preffing upon the infide of the hoop caufes fuch a friction, that they go together in general; but when the fecret is to be changed, the flider F muft be drawn partly back, fo that its teeth *x* come in the way of the thin parts of the rollers, and they cannot, therefore, be turned round; the outfide hoop *l* is then forced round upon the infide one, and a frefh letter brought oppofite the recefs; by this operation the fecret is altered, and the efcutcheon cannot be opened till the fame combination is produced. Each roller has four letters upon it, in all twenty letters, and the combinations which they are capable of are fo numerous, that the chance is ftrongly againft any perfon not acquainted with the fecret opening it.

ESCUTCHEON-*grafting*. See GRAFTING.

ESDEN, in *Geography*, a town of Germany, in the kingdom of Weftphalia, and bifhopric of Liege; 3 miles S.S.W. of Stecklim.

ESDRAELON, or ESDRELA, in *Ancient Geography*, a village of Paleftine, in the tribe of Iffachar, the fame as Jezreel, 10 miles from Scythopolis, according to the old Itinerary. (Jofh. xix. 18.) It gave name to a plain, which extended eaft and weft from Scythopolis to mount Carmel; called likewife the "Great Plain," the "Valley of Jezreel," and the "Plain of Efdrela,"

ESDRAS, See EZRA. We have four books of fcripture under the name of Efdras; of which, only the two firft are acknowledged as canonical; and they were formerly reckoned by the Hebrews as one, according to St. Jerom. The firft of thefe is allowed to be the work of Ezra; for he relates events of which he was witnefs, and often fpeaks in the firft perfon. Some, however, have fuppofed that the fix firft chapters were compofed by a more ancient writer; and they allege, that the author of thefe chapters was at Jerufalem in the time of Darius the fon of Hyftafpes. (Ch. v. 4.) From this paffage it is inferred that the writer was then at Jerufalem; but Ezra did not come thither till the reign of Artaxerxes, as appears by the beginning of the 7th chapter. To this argument it is replied, that Ezra fpeaks in the name of the Jews, and that it is ufual for hiftorians of a country to fpeak in the firft perfon in the name of their own nation, although the hiftorians themfelves had no participation in the events which they record. Another difficulty occurs in explaining the genealogy and number of thofe who returned from Babylon to Jerufalem under Nehemiah, mentioned in the fecond chapter, and related in the fame manner, though with fome additions and alterations in the 9th chapter of Nehemiah. Some fuppofe that Nehemiah tranfcribed this out of the book of Ezra, adding the names of thofe perfons who came to Jerufalem in the fecond return from the captivity. Others, on the contrary, imagine that Ezra copied the paffage from Nehemiah, fince mention is made in it of Nehemiah. Others pretend that the genealogy of Ezra was afterwards corrected from that of Nehemiah. However, none of thefe conjectures are reconcileable with the differences that occur in the two genealogies. But after all, there is no neceffity for fuppofing that one of thefe authors tranfcribed from the other, for they might both of them have written thefe genealogies: Ezra having furvived the fecond tranfmigration made under Nehemiah, and not having written his book till the latter end of his life. The fecond book under the name of Ezra, is attributed to Nehemiah; though fome inconfiderable particulars have been added to it, which cannot belong to Nehemiah: fuch as the mention of the high-prieft Jaddua, and king Darius. (Neh. xii. 22.) This Jaddua is Jaddus, in whofe time Alexander the Great came to Jerufalem; and Darius is Darius Codomannus, overcome by Alexander 100 years after Nehemiah. The firft of thefe two books contains the hiftory of the deliverance of the Jews from the captivity of Babylon, and of their re-fettlement in Judea, from the firft year of Cyrus to the 20th of Artaxerxes Longimanus; and the fecond begins at the 20th year of the fame prince, to the reign of Darius Nothus. The chronology of this fpace of time depends on the duration of the reigns of the kings of Perfia.

The third book, under the name of Efdras, is thought by the Greeks to be canonical. Its author is not known, but he is fuppofed to have been an Hellenift Jew. The book is the fame in fubftance as the firft of Efdras, but interpolated; and in different parts of it we have a fummary repetition of the two laft chapters of the fecond book of Chronicles, as well as of the books of Ezra and Nehemiah. Againft its authority there are feveral material objections, for which we refer to Arnald's excellent Commentary on the Apocrypha. p. 122.

3 U 2 The

The fourth book of Efdras is written with fufficient art, as if Efdras himfelf had compofed it; but the marks of falfhood are difcernible in it. Neither the Synagogues, nor the Greek or Latin church ever unanimoufly received it as canonical; though fome of the fathers have cited it, and the Latin church has borrowed fome words out of it. It is not now extant in Greek; and it never was in Hebrew. It feems moft probable that the author was a Jew, converted to Chriftianity, who, in hopes of converting others, compofed this work under the name of a writer, for whom the Jews had the higheft efteem. And there feems good reafon for concluding that the author lived in the times of the firft heathen perfecutions, from many paffages encouraging faith, and a fpirit of conftancy under perfecution.

ESEBON, a name given, by fome of the chemical writers, to common fea falt.

ESENS, in *Geography*, a town of Germany, in the kingdom of Weftphalia, and county of Eaft Frifeland; 24 miles N.N.E. of Emden.

ESFARAIN, a town of Perfia, in the province of Chorafan; 80 miles E. of Afterabat.

ESGUEVA, a river of Spain, which runs into the Pifuerga, at Valladolid.

ESGUEYRA, or Esgueria, a town of Portugal, in the province of Beira, containing about 1600 inhabitants; 8 miles S. of Aveiro.

ESH, in *Rural Economy*, a term provincially employed to denote the afh-tree.

ESHANESS, in *Geography*, a cape on the weft coaft of Main-land, the largeft of the Shetland iflands. N. lat. 60° 38'. Long. 1° 7' E. of Edinburgh.

ESHCOL. See Escol.

ESHTAOL, in *Ancient Geography*, a town of Paleftine, in the tribe of Dan, which belonged firft to Judah. According to Eufebius it was 10 miles diftant from Eleutheropolis, towards Nicopolis.

ESHTEMOTH, a city in the fouth of Judah, which, according to Eufebius, was a large town in the diftrict of Eleutheropolis, north of that city. It was ceded to the priefts. 1 Chron. vi. 57.

ESI, in *Geography*, a town of Italy, in the ftate of the church, and marquifate of Ancona; 11 miles S.S.W. of Ancona.

ESK, South and North, rivers of Scotland, which defcend from the Benakinnan mountains on the north border of Angus. The former runs S.E. and E. by Cortachie, Tannadyce, Brechin, and falls into the German ocean below Montrofe, to which town it is navigable from the tide-way in the German ocean. (See Canal). The direction of the latter is E. and S.E. through a narrow valley, till it reaches the ftrath lying between the Grampians and the fea. In the lower part of its courfe it forms the common boundary of Angus and Kincardine.

Esk, a river in Cumberland, which is navigable from the Solway firth up to the town of Longton.

ESKARMAKRUN, a town of Perfia, in the province of Chufiftan; 90 miles S. of Sufa.

ESKE, a river in the Eaft Riding of Yorkfhire, which is navigable only from the fea up to Whitby-bridge. See Canal.

Eske, a river in Cumberland, which is navigable from the fea near Ravenglafs to Mulcafter. Near to Ravenglafs it is joined by the Irt river.

ESKER, a river of European Turkey, which runs into the Danube; 20 miles W. of Nicopolis.

ESKI-Baba, a town of European Turkey, in Romania; 30 miles S.E. of Adrianople.

ESKIER, a town of Arabia, in the country of Yemen; 60 miles N. of Aden.

ESKIJALFA, a town of Perfian Armenia, in the country of E. van; 120 miles S. E. of Erivan.

ESKI-HISAR, a town of Afiatic Turkey, in the province of Natolia; 16 miles W. of Mogla.

ESKI-HISSAR, a town of Afiatic Turkey, in the province of Natolia, formerly Laodicea, now almoft a heap of ruins; 8 miles N. of Degnizlu.

ESKIMAUX, or Esquimaux. See Esquimaux and Labrador.

Eskimaux *Bay*, a bay on the fouth-coaft of Labrador. N. lat. 51° 30'. W. long 57° 50'.

Eskimaux *Iflands*, a clufter of fmall iflands in the gulf of St. Lawrence, near the fouth-coaft of Labrador. N. lat. 50° 15'. W. long. 63'.

ESKISADRA, a town of European Turker, in the province of Romania; 48 miles E of Filippopoli.

ESKISHEHR, a town of Afiatic Turkey, in the province of Natolia, on the river Sakharia; 116 miles S.E. of Conftantinople. N. lat. 39° 48'. E. long. 32° 58'.

ESLA, a river of Spain, which runs into the Duero, between Zamora and Miranda de Duero.

ESLINGEN, a town of Germany, in the circle of Suabia, which, till the peace of Luneville, was a free imperial city. It now belongs to the king of Wirtemberg, and is fituated on the Necker, 30 miles N. E. of Tubingen, and 6 miles S. E. of Stutgard.

ESMONA, or Azemona, in *Ancient Geography*, a town of Arabia Petræa, which was one of the ftations of the Ifraelites in the Defert. The book of Jofhua afcribes it to the tribe of Juda, fo that it is probably the fame with *Efem*.

ESMOUTIER, in *Geography*, a fmall town of France, in the department of the Upper Vienne; 21 miles E. of Limoges.

ESNA, in *Ancient Geography*, a town of Paleftine, in the tribe of Juda. Jofh. ch. 15.

ESNECY, *Æfnecia*, *dignitas primogeniti*, in *Law*, a private prerogative, allowed to the eldeft coparcener, where an eftate has defcended to daughters for want of heirs male, to chufe firft after the inheritance is divided. Fleta, lib. v. cap. 10. "Jus efneciæ *is* jus primogenituræ," in which fenfe it may be extended to the eldeft fon, and his iffue, holding firft. In the ftatute of Marlbridge, cap. 9. it is called "initia pars hereditatis."

ESNEH, Esné, or *Afna*, in *Geography*, one of the moft important towns in Upper Egypt, feated on the left of the Nile, in N. lat. 25°. E. long. 49° 15'. This town is governed by an Arabian prince and by a Cachef, dependent on the Bey of Girgé. The Mahometans have feveral mofques here, and the Copts a church, that is ferved by two priefts. According to the defcriptionof Abulfeda, which correfponds in a great degree to its prefent ftate, Efné is remarkable for its public baths and its commerce: it is built on the weftward of the Nile, between Affouan and Cous, but nearer to the latter. The Copts are faid to be its founders. The well-cultivated territory abounds in grain and palm-trees. Situated on the edge of a rich country it is fhaded by groves of orange-trees loaded with fruits and flowers, and immediately furrounded with gardens amply ftocked with fruit-trees. It prefents to view feveral ancient monuments conftructed by the Copts, and fuperb ruins. This town, formerly called *Latopolis*, revered Minerva and the fifh *Latus*. (Strabo, l. 17.) It contains within its boundary an antique temple, enclofed on three fides by thick walls. Six large fluted columns, crowned by a capital, ornamented with the palm leaf, form the façade of it; eighteen others fupport the roof; which is compofed of large fquares of marble; the building is furrounded by a frieze, and innumerable hieroglyphics cover its exterior afpects. Thofe of the infide, executed with greater care, mark the progrefs made by the Egyptians in fculpture. Thefe hieroglyphics contain, among other fubjects, a zodiac and large figures of men with crocodiles' heads; the capitals, though all different, have a very fine effect; and as an additional proof that the Egyptians borrowed nothing from other people, it is remarked, that they have taken all the ornaments, of which thefe capitals are compofed, from the productions of their own country, fuch as the lotus, the palm-tree, the vine, the rufh, &c. The portico of this temple is reprefented by M. Denon, (Travels in Egypt, vols. 2. and 3.) as the moft perfect monument of ancient architecture. Denon has given a plan and elevation of this portico, and delineated the varieties of its capitals, and part of the fculptures on the cieling; but he was furprifed that, after all his refearch, he could find no reprefentation of the fifh *latus*, from whofe name the town was called *Latopolis*. At prefent this temple is foiled by the ordure of the cattle kept there by the Turks, who convert the moft beautiful monuments of ancient Egypt into ftables. About a league to the weft of Efné is another temple, on the walls of which is carved in feveral places a woman feated, reprefenting an Egyptian deity called "Neith," to whom the ancient Greeks gave the name of Minerva. The columns of this temple, as fome have conjectured, gave to the Greeks the idea of the Corinthian order; the capitals being ornamented with a foliage very much refembling the Acanthus. Several animals painted on the cieling have preferved their colours. To the fouth of Efné are feen the ruins of a monaftery founded by St. Helena, and near it the burying place of the martyrs, adorned with tombs crowned by cupolas, fupported by arcades. The inhabitants of Efné having revolted againft the perfecution of Dioclefian, this emperor deftroyed the town, and put them to the fword. This place, confecrated by religion, is become a celebrated pilgrimage among the Copts, who repair hither from the moft diftant provinces of the kingdom. In the chain of mountains, which ftretches to the eaftward of the Nile, and nearly oppofite to Efné, are quarries of a foft ftone, called "Baram," which hardens in the fire, and is ufed in the manufacture of kitchen utenfils. Savary's Letters, &c. vol. ii.

ESOCHE, from ἐσω, *within*, and ἐχω, *to have*, in *Surgery*, a tubercle within the anus.

ESOPUS. See Kingston.

ESOTERIC. See Exoteric.

ESOX, in *Ichthyology*, a genus of the abdominal kind, diftinguifhed by the following effential particulars. The head flattifh above; mouth and throat large; jaws toothed, unequal, the upper one flat, lower punctated; tongue broad, loofe; palate fmooth; eyes round, moderate fize, and lateral; noftrils double, near the eyes; gill-covers large, aperture ample, with from feven to twelve rays; body elongated, covered with hard fcales; above convex, and compreffed at the fides; lateral line ftraight, neareft the back, and fcarcely vifible; dorfal and anal fin very fhort, and generally placed oppofite.

Species.

Lucius. Snout depreffed; jaws nearly equal. Linn. Fn. Suec. Art. Gen. Rondel. *Brochet*, Bell. *Pike*, Penn. Donov. Brit. Fifhes.

The pike is an inhabitant of moft of the lakes of Europe, and the north of Afia, and alfo of many of the larger rivers in Lapland, Siberia, and countries adjacent. It grows to a confiderable fize, thofe of four or five feet in length not being uncommon in the northern regions, and fometimes even they attain to the length of eight feet or more. The pike is highly prolific, and from its extreme voracity as well as cunning, is called the wolf, or the fox of fifhes; it fubfifts on fifhes, on frogs, ferpents, and other reptiles, and on the young of fwans and other aquatic fowl, and is reputed fo undaunted in its attacks that it will even contend with the otter for its prey. This fifh fpawns in fpring between the months of February and May. The colours vary in brightnefs at different feafons; in general the upper part is olivaceous green, with the back nearly black, and the whole fpotted with yellow, whitifh, or orange, according to the health of the fifh. The belly white, and the fins beautifully variegated with vivid colours and fpots of blackifh purple. The jaws contain a formidable armament of teeth difpofed in longitudinal rows. The longevity of the pike is well known to be very great; but what credit ought to be repofed in the affurances of fome writers, that it lives to the age of two or three hundred years, muft remain for others to determine. Their multiplication is immenfe; in the northern parts of Ruffia, and in Siberia, where they are taken in the greateft plenty, they conftitute an article of commercial importance, being prepared by means of falting and drying, for exportation.

Viridis. Green; lower jaw longer, fcales thin. Gmel.

This is regarded by Bofc as a variety only of the common pike, (Efox lucius,) the accuracy of which opinion appears rather uncertain, as we may perhaps be unacquainted with the fpecies or fifh intended by Gmelin; the reference of the latter author to the Acus maxima fquamofa viridis for the fame fifh is fuppofed to be incorrect.

Sphyræna. Dorfal fins two, the firft fpinous. Linn. Arted. *Sea pike or Spit-fifh*, Charlt.

There is fome remote refemblance between this fifh and the common pike, from which among other particulars it is diftinguifhed by having the lower jaw advanced, the body more flender, the tail furcated, and the back furnifhed with two dorfal fins inftead of one. The rays of the firft dorfal fin are fpinous, and are defcribed both by Linnæus and Artedi as five in number, but according to Bloch thefe amount to only four. The fifh is blueifh above, beneath white; the pectoral, ventral, and anal fins red. It grows to the length of two feet, and inhabits the Atlantic and American feas The flefh is in efteem.

The Barracauda pike of Shaw's Gen. Zool. defcribed after Catefby, appears very clofely allied to the preceding, if it be not the fame; the character "brown, elongated, whitifh beneath, with two dorfal fins and forked tail," differs from that fifh only in having the upper part brown inftead of blueifh. It is found in the Weft Indies, and grows to the length of eight or ten feet.

Becuna. Silvery-blueifh, marked on each fide by a row of deep-blue fpots, with two dorfal fins, and forked tail. Shaw. Gen. Zool. *Sphyræna becuna*, Cepede.

This accords fo nearly with the Efox fphyræna that we cannot fupprefs our fufpicions of its being the fame. The only authority on which it is defcribed is a drawing by Plumier; this, indeed, reprefents a fifh of fomewhat more elongated form, in which the fides are marked with a feries of blue fpots not obfervable in the former. If it prove diftinct it is certainly very analogous. It is defcribed as a native of the American feas.

Aureo-viridis. Body golden-green, with two dorfal fins, a fpine before the firft; lower jaw longer. *Sphyræna aureo-viridis*, Cepede. *Gold-green pike*.

Defcribed and figured by Cepede from the drawings of Plumier; the body is deep, as in the fparus, the head fharp pointed;

pointed; fcales middle fized; tail forked and lunated. The fpecies inhabits the American feas.

Vulpes. Dorfal fin in the middle of the back; the gill membrane three-rayed. Gmel. *Vulpes bahamenfis*, Catefby. *Fox pike.*

Refembles the common pike, but is more flender in proportion towards the tail, the colour brown above, beneath paler. Native of Carolina and the Weft Indies.

Synodus. Dorfal fin in the middle of the back: gill membrane five rayed. Gmel. *Synodus*, Catefby.

Clofely allied to the former, and inhabits the fame feas, and according to Cepede the Mediterranean alfo. The body is marked with dufky bands; abdomen filvery; fins ftriped with black.

Hepsetus. Lateral line filvery. Gmel. *Argentina pinna dorfali pinnæ ani oppofita*, Linn. Amœn. Acad. *Piquitinga*, Marcgr. Inhabits America.

Marginatus. Dorfal and anal fins oppofite; lateral line filvery; lower jaw fix times as long as the upper. Forfk. Fr. Arab.

This and the preceding are fuppofed to be the fame. The latter is defcribed by Forfkal as an inhabitant of the Red fea; its length about a fpan and a half; the body linear, tapering each fide, and covered with broad lax, entire fcales, the colour brown above, beneath white; the anal fin fmall, triangular, glaucous, and yellow without; dorfal yellow externally; tail bilobate, the upper lobe pale yellow, the pofterior edge brown.

Chinensis. Head flender, lower jaw longer; eyes large and protuberant. *Sphyræna chinenfis*, Cepede.

Slightly defcribed by Cepede from the manufcripts of Commerfon as a native of the Indian feas. The general colour is faid to be green with a filvery hue, and the fcales of the middle fize.

Chilensis. Jaws equal; lateral line blue. Molina. *Chili pike.*

Native of the Chilefe feas. Length from two to three feet; body round, covered with bony angular deciduous fcales, above golden, beneath filvery; flefh white, and excellent.

Argenteus. Brown variegated with yellowifh characters. Gmel. Forfter, &c. *Silver pike.*

Inhabits frefh waters of New Zealand and other iflands of the fouthern ocean.

Brasiliensis. Lower jaw very long; body ferpentine. Linn. Muf. Ad. Fr.

Thefe are feveral figures of this fifh in different authors, moft of which are defective in one particular or other. Nieuhoff omits the anal and ventral fins, Valentyn and Renard conftitute two fpecies of the fame fifh; and in other reprefentations the dorfal fin is omitted. Linnæus erroneoufly refers to the Timucu of the Brafilians as being fynonymous; the fifh fo named by thefe people has both the jaws elongated, and ending in a point, and is fuppofed to be the fpecies Belone. Gmelin adopts the fame mifreference. The length of this fifh is from twelve to fifteen inches; the upper part of the body green, beneath yellow, and the back marked with about fix broad and equidiftant bands of fufcous. The fpecies inhabits the Brafils, and is efteemed a delicacy for the table.

Gymnocephalus. Jaws equal; gill-covers very obtufe; head naked. Linn. *Naked-headed pike.*

Native of India, according to Linnæus, who fpeaks of it as being the fize of the fand launce.

Malabaricus. Two canine teeth in each jaw; gill-membrane with five rays. Bloch.

Found in the rivers of Malabar. The length is about twelve inches: its form fomewhat refembling that of the common pike. The colour above greenifh-blue, beneath yellow; fins yellow; at the bafe purplifh, and marked with feveral diftinct bands of brown. The lower jaw is rather longer than the upper, and the tail is rounded.

Chirocentrus. Breaft armed on each fide by a fpine over the ventral fin; lower jaw longer. Cepede.

Defcribed from the manufcripts of Commerfon. Its form refembles in fome refpects that of the common pike. The fpine is faid to be ftrong, and flightly curved; its length about two-thirds that of the fin, of which it appears to be the firft ray.

Belone. Each jaw long and fubulate. Gmel. *Sea pike, gar-fifh, or fea needle*, Penn. Donov. Brit. Fifhes.

Length from eighteen inches to three or four feet, of a very flender eel like form, with long projecting fnout, the back fine green; belly filvery. It is a common fpecies in all the European feas; migrating annually in large fhoals from the depths of the ocean to the fhore. They appear on our coafts in the fpring, commonly announcing the arrival of the mackarel, but remain with us for a much fhorter period than that fifh. They depofit their fpawn clofe to the fhore among the rocks and fea weeds, where the young are hatched, and after a certain time retire. We have feen the fry of this fifh on our coafts during the fummer months. As an article of food the gar-fifh is held in far lefs eftimation than the mackarel, to which its flavour in fome degree approaches. By many people the flefh is confidered unwholefome, and even poifonous; arifing, no doubt, from the fingular circumftance of the bone becoming of a fine grafs green colour in boiling. This fpecies grows to the length of eight feet. Donov. Brit. Fifhes.

Saurus. Jaws fubulate, and flighty curving upwards, lower one longeft; above and beneath fpurious fins near to the tail. *Maxillis fubulatis fuafcendentibus, inferiore longiore, caudam verfus fupra infraque pinnulis fpuriis.* Donov. Brit. Fifhes. *Saurus*, Rondel. *Skipper*, Ray. *The faury*, Penn. &c.

The obfcurity that prevailed refpecting this curious fifh till within a very recent period, induced us to enter on the details of its general defcription with rather more than ordinary minutenefs: the writer of this article has already treated at fome length on the Efox faurus in his work on Britifh fifhes lately publifhed, and conceives a repetition of the following obfervations fubmitted on that occafion may not prove altogether unacceptable.

Our countryman Ray appears to be the firft writer who defcribes this rare and curious fpecies of efox as a native of Britain; he fpeaks of it as a Cornifh fifh, under the provincial name of fkipper. Rondeletius and Gefner previoufly mention it as a fcarce kind among the fifhes of the Mediterranean. In 1769 the fame fifh was again introduced to notice by Mr. Pennant in his tour of Scotland, and afterwards in his Britifh Zoology, wherein we are informed, that vaft numbers of them were thrown afhore on the fands of Leith, near Edinburgh, after a great ftorm in November, 17'8. In the fummer of 1800 a fingle fpecimen was taken near the ifle of Portland, in Dorfetfhire, after a hard ftorm; an account of which, accompanied with a figure of the fifh in its natural fize, is given by the Rev. Mr. Rackett, in the third volume of the Linnæan Tranfactions. "This fifh (Mr. Rackett obferves) appears to be rare on the Dorfet coaft. Of the fifhermen in this part, only one was acquainted with it, and called it a fkipper, the name under which, according to Ray, it was known in his time on the coaft of Cornwall. This writer adds that the fpecies has not been noticed by Linnæus, Gmelin, nor Bloch; and that Pennant

nant has given a very indifferent figure of it in his Tour in Scotland, and has made ufe of the fame plate in his Britifh Zoology." See Linn. Tranf. 3. p. 60.

It is altogether fingular that this fifh has no place in either edition of the Linnæan Syftema, not even that by Gmelin; it is inferted by Dr. Turton in his tranflation on the authority of Pennant. The length of this fpecies is about eighteen inches: the body of a long and flender form; not like that of an eel, as writers defcribe, but agreeing precifely with that of the common gar-fifh (Efox belone). The fnout is fubulate, fine, toothlefs, and curving upwards. The jaws are of unequal length, the lower being longeft, and bending upwards at the tip, in which refpect it differs from the figures of Mr. Pennant and Mr. Raekett, in both which the jaws appear ftraight and of equal length. Neither do the jaws, when clofed, exhibit that remarkable hiatus or gaping fhewn in thofe two reprefentations; there is a kind of flexuofity in the fhape of the mouth, when open, which might excite fuch an idea, but upon gently clofing it the curvature in the form of one jaw will be found to correfpond with the future of the other; fo that the character "maxillis medio hiantibus," affigned to it, is by no means applicable. Dr. Shaw mentions in the Gen. Zool. that "in a fpecimen figured in the work of Cepede, the jaws are reprefented upwards, contrary to what has hitherto been obferved; the fpecimens figured in the work of Mr. Pennant, as well as that of Rondeletius, and the drawing by Mr. Rackett, have the jaws ftraight." This is certainly true, and it is therefore to be prefumed that the examples from whence the figures of the latter mentioned writers have been taken muft have fuftained injury, or been mifreprefented; for it is clear Cepede is right in reprefenting the jaws curving upwards: it is indeed evident, from the comparative fhortnefs of the jaws in the figure by Pennant and others, they could not be perfect, the beak in the fifh itfelf being nearly twice the length delineated by either. Dr. Shaw has alfo been apparently mifled to the perfuafion that the fkin of this fifh is reticulated by fine fins decuffating each other at equal diftances, which is not by any means the natural appearance of the fifh, and the figure in the Britifh Zoology is ftill more erroneous, as it appears entirely fmooth, and deftitute of fcales.

Some mifunderftanding feems to prevail likewife as to the colour of the fifh. Mr. Pennant defcribes it as having the back dufky, and the belly bright and filvery, in which particulars he is followed by Dr. Shaw, who remarks that the colour of the whole animal is dufky above, and filvery beneath, with dufky or blueifh brown back. This is not, however, correct, the true colour of the back of the fifh is a moft lovely azure blue, changeable to green, and gloffed with purple and yellow, and the lower parts filvery. The body has a fmooth appearance, the fcales with which it is covered being thin and glabrous: the lower part of the body from the gills to the tail is marked with a longitudinal carina or keel, which terminates at the latter part in a fomewhat protuberant manner.

The fpecies may be readily diftinguifhed by the pinnules or fpurious fins on the body near the tail, in which particular it agrees with the fcomber or mackarel genus; thefe have been varioufly mifreprefented; in the fifh itfelf they amount altogether to twelve in number, five of which are difpofed above and feven beneath; and it is alfo neceffary to add that they are perfectly detached from each other. The flefh, in point of flavour, refembles that of the mackarel.

Osseus. Upper jaw longer; fcales bony. Linn. *Efox maxilla fuperiore cauda quadrata*, Arted.

Native of North America and Afia, and has been found in Europe. (Donov. Brit. Fifhes.) The fpecies is from two to three feet in length, and is covered with rhombic fcales.

Cepedianus. Snout long, jaws fpatulate; fcales bony. *Le pifofleus fpatula*, Cepede. *Efox cepedianus*, Shaw.

The principal difference between the two laft mentioned fifhes feems to confift in the fnout being fhorter in proportion in E. cepedianus than the other. There is likewife another pike of the fame bony fcale kind, which has the jaws rather fhorter than either, and bears the name of Leverianus. We are not entirely fatisfied that the three laft mentioned differ fpecifically from each other.

No fmall degree of uncertainty feems to prevail throughout this tribe of fifhes independently of thofe laft adverted to; the fpecies fynodus, hepfetus, vulpes, and marginatus, appear to be imperfectly underftood: barracuda, viridis, and becuna, are perhaps more doubtful, as are alfo chirocentrus, and chinenfis; and it will have been obferved that the true characters of the fpecies faurus were not till lately afcertained.

The viper-mouthed pike (Efox ftomias), and vipera marina of Catefby, is diftinguifhed by having four of the teeth much larger than the reft: this is a very extraordinary fifh, and ought, in our opinion, to conftitute a new genus.

ESPADACINTA, in *Geography*, a town of Portugal, in the province of Tras-los-Montes, fituated on the Duero, and borders of Spain; 34 miles S.W. of Miranda de Duero, and 28 N. of Almeida.

ESPAGNAC, John-Baptist-Joseph de Sahuguet-Damarzil, Baron d', in *Biography*, a military writer, was born in the year 1713 at Brive la-Gaillarde. At the age of nineteen he entered the army, and became celebrated for great fkill and prowefs. In 1742 he was aid-de-camp in the war of Bavaria, and was afterwards employed by marfhal Saxe as aid-major general and colonel of a regiment of grenadiers. In 1780 he was raifed to the rank of lieutenant-general, and died at Paris in 1783. As an author he attained a good fhare of celebrity by his "Campaigns of the King in 1745—48," which were publifhed in four octavo volumes. He publifhed alfo "Effays on the Science of War," 3 vols. 8vo. "An Effay on the great Operations in War," in 4 vols. 8vo; "A Supplement to the Reveries of Marfhal Saxe," in 2 vols. 8vo. 1773. He likewife drew up "The Hiftory of Marfhal Saxe," in 3 vols. 4to. in which are detailed plans of his battles and marches, together with thofe particulars of the life of that general, as render it a work of confiderable intereft to literary as well as to military men." Nouv. Dict. Hift.

Espagnac, in *Geography*, a fmall town of France, in the department of the Lozere; 12 miles S. of Mende.

ESPAGNE, John d', in *Biography*, a French proteftant divine in the feventeenth century, was born at Dauphiné, and became minifter of the French church in London, an office which he fuftained during the reigns of James I. and Charles I. He publifhed feveral fmall tracts, which were afterwards collected and publifhed at Geneva and the Hague, in three and in two volumes 12mo. about the year 1670. He alfo publifhed a work, which he dedicated to Charles I., entitled "Erreurs Populaires en points Generaux qui concernent l'Intelligence de la Religion." Of this and of fome other of his pieces Bayle fpeaks in terms of commendation. Moreri. Bayle.

Espagne, in *Geography*. See Epaigne.

ESPAGNET, John d', in *Biography*, who flourifhed in the 17th century, was prefident of the parliament of Bourdeaux. As a literary character he publifhed a work entitled "Enchiridion Phyficæ Reftitutæ," which was afterwards

wards tranflated into French under the title of "La Philofophie des Anciens retablie en fa Pureté." This may be regarded as the firft book that appeared in France, in which there is a complete fyftem of phyfics contrary to that of Ariftotle; though the author pretended that he had merely re-eftablifhed the ancient philofophy. He publifhed alfo a work concerning the philofoper's ftone, entitled "Arcanum Hermeticæ Philofophiæ Opus." Alfo an old MS. entitled "Le Rozier des Guerres," found at Nerac in the king's clofet, and attributed, though erroneoufly, to the pen of Lewis XI. To this work he added a treatife of his own, upon the education of a prince. In publifhing the "Rozier des Guerres," he followed the original with the utmoft exactnefs, becaufe, fays he, "this little tract feemed to me fo good, that I would not embellifh or difguife it, but have left it in its native fimplicity: and though the language of it is not in ufe in this age, yet it may be underftood, being fo full of good fenfe and meaning, that with all its jargon it may filence the affected language of the court and bar. I have alfo carefully preferved the fpelling, becaufe in adding or diminifhing a letter, a word is often changed, and of old made new." Bayle.

ESPAIN, Saint, in *Geography*, a fmall town of France, in the department of Indre and Loire; 15 miles S.E. of Chinon.

ESPALIER Trees, in *Gardening*, are fuch fruit trees of low growth as are trained to treillages or framed woodworks made for the purpofe, in ranges, fo as to conftitute a fort of hedge. They are ufually planted in fingle rows along the borders, on the fides of the principal walks, in the main divifions of the garden, affording fhelter to other plants as well as ornament to fuch parts.

The forts of fruit trees moftly employed in this way are thofe of the apple, pear, and plum kinds; but many others may be managed in this method where variety is wanted; as the quince, cherry, almond, apricot, mulberry, and filbert. And it is neceffary, with a view to beauty and uniformity, to manage them in fuch a manner as to have them that are nearly of the fame growth in the fame range or line of planting.

The forts of apples moft adapted to this ufe are thofe of the golden and other pippin kinds, the nonpareil, rennet, and ruffet; but many others may be cultivated in this way.

In the pear kind, the jargonelle, blanquette, bergamot, burre du Roy, &c: the melting pears being always better in this way than thofe of the breaking kind. On ftrong moift foils thofe grafted on quince ftocks are the beft, but on dry ones thofe on free ftocks.

Trees intended for this ufe fhould be grafted or budded within a few inches of the furface of the ground, that branches may be thrown out regularly from the bottom upwards, to furnifh and fill the treillage; and the more effectually to accomplifh the purpofe, the firft fhoots from the grafts, &c. fhould be cut off, or headed down within a few inches of the grafts, in the fpring feafon, when they have had one year's growth. The branches or fhoots thus produced, whether the trees are in the nurfery, or planted out as efpaliers, fhould, in the latter part of the fummer, or beginning of autumn, be trained both ways laterally in their advancing growth, to ftakes put down for the purpofe, or the efpalier frames. In this way the trees acquire a proper form, thofe in the nurfery being thus trained and kept for fale. A fecond heading down in the upper branches may likewife be practifed when neceffary, in order to fill up the middle, and completely cover the frames.

When thefe trees have been thus trained for three or four years in the nurfery-ground, they are generally in a proper fituation for being planted out as efpaliers in the borders or other parts along the fides of the walks in the garden or pleafure ground, a fufficient breadth being allowed for the borders according to the fize or extent of fuch grounds, as fix, eight, ten, or more feet.

Befides this, there is another method fometimes practifed in forming efpalier trees, which is that of, after heading the firft fhoots down as above, training the fide-fhoots horizontally in the direction of the frames, and the middle one upright, forming the lateral fhoots, which it throws out horizontally on each fide; and, if they are not thrown off fufficiently low, heading the upright one down, by which lateral branches will be fent off, fo as to range with regularity at the diftance of fix or feven inches, one above another, on each fide, from the bottom to the top. In this way the trees have a very neat appearance.

In planting the trees out, when they are of the apple or pear kind, on dwarf ftocks, the diftance in the rows fhould be fifteen, eighteen, or twenty feet; and when on free ftocks, not lefs than twenty or thirty; and for free growing trees confiderably more. For plums, the diftance fhould be eighteen feet or more; and for cherries, apricots, almonds, and mulberries, it fhould never be lefs than fifteen. Confiderably lefs diftance will, however, be fufficient for filberts, efpecially in the poorer forts of foil.

When thefe trees have been planted, it is the ufual practice to put fticks down in a line to train them to for the two or three firft years; but it has a much neater appearance to have the treillage fixed down to train them to at once.

Frames for this ufe are made in different ways, according to the tafte of the perfon who has them; but the moft ufual forts are thofe conftructed of three or four inch fquare pieces of oak timber for the pofts, with rails of deal carried from poft to poft, at the diftance of every ten or twelve inches from the bottom to the top. Between thefe rails thin upright pieces are again fometimes fixed at the fame diftances, for particular purpofes. The whole fhould be well painted over in oil fome time before the trees are to be trained to it. This laft is performed either by tying the branches to the trellis by ofier twigs, woollen-yarn, or other fimilar fubftances, or by nailing them in the manner of wall-trees. In whichever way it is done, the greateft exactnefs and regularity fhould be obferved in laying in and directing the fhoots, that they may have a neat regular appearance. The manner of performing the future pruning and managing of thefe trees will be explained when we come to fpeak of the nature of pruning in general. See Pruning *of Fruit Trees*.

Thefe forts of trees are chiefly advantageous in admitting the branches to produce fruit fpurs on both fides, which is not the cafe with wall-trees; in taking up but little room in the garden; in not being fo injurious to the crops that are near them; in affording fruit of a finer flavour, from the more free admiffion of air and fun, and in the fruit not being fo liable to be blown down and injured as in other cafes.

ESPALION, in *Geography*, a fmall town of France, in the department of the Aveyron, chief place of a diftrict of the fame name, with a population of 2622 inhabitants. It is fituated on the river Lot, 18 miles N.E. of Rhodez, and has fome manufactures of coarfe woollen cloth. The canton has a territorial extent of 167½ kiliometres, 12 communes, and a population of 9139 individuals.

As chief place of a diftrict, Efpalion has a fub-prefect, a court of juftice, and a regifter office. Corn, wine, and madders, grow in its neighbourhood, and the whole diftrict contains 9 cantons, 101 communes, and 58,855 inhabitants, on a territorial extent of 1630 kiliometres.

ESPAMISCACK,

ESPAMISCACK, a lake of Lower Canada; 74 leagues N.E. of Quebec. N. lat 50°. W. long. 68°.

ESPAQUE, a town of Perfia, in the province of Segeftan; 54 miles S.W. of Kin.

ESPARCET, in *Agriculture*, a name fometimes given to faintfoin. See SAINTFOIN.

ESPARRAGOSA, in *Geography*, a town of Spain, in the province of Eftremadura; 35 miles E.S.E. of Merida.

ESPARRAGUERA, a town of Spain, in the province of Catalonia; 15 miles N.N.W. of Barcelona.

ESPARZA, a town of Spain, in Navarre; 22 miles E. of Pamplona.—Alfo, a town of North America, in Mexico, and province of Cofta-Rica.

ESPEJA, a town of Spain, in the province of Cordova; 17 miles N.N.E. of Montilla.

ESPELETTE, a fmall town of France, in the department of the Lower Pyrenées, chief place of a canton in the diftrict of Bayonne, with a population of 1200 individuals. Its canton has a territorial extent of $237\frac{1}{2}$ kiliometres, 7 communes, and 7861 inhabitants.

ESPEN, ZEGER BERNARD VAN, in *Biography*, was born at Louvain in the year 1646. After going through the ufual courfe of ftudies at the univerfity, with much credit to his talents and diligence, he was admitted to prieft's orders in the year 1673, and had, within two years of this time, the degree of doctor of laws conferred upon him. From this period till the year 1702, he lived in the college of pope Adrian VI., where he performed the duties of profeffor, and applied himfelf to the ftudy of thofe works which have rendered his name illuftrious. He obtained fo much refpect by his various writings that he was confulted from every quarter: by the tribunals of juftice, by the bifhops, and by feveral fovereign princes. His principal work was entitled "Jus Ecclefiafticum Univerfum." Befides this, he is well known for other treatifes, "De peculiaritate et Simonia;" "De Officiis Canonicorum;" "Tractatus Hiftorico-Canonicus in Canones;" "De promulgatione Legum Ecclefiafticarum," and many others, all of which were collected and publifhed in 4 vols. folio, in 1753, at Paris. When he was in his 65th year, he was deprived of fight by a cataract, which was not removed for two years; during this time, however, he neither loft his cheerfulnefs, nor remitted his application. His manner of living was at all times frugal, and very fimple, his temper was benevolent, modeft, and humble. He was eminent for piety towards God, and for his candour and good-will towards men. He neverthelefs had made himfelf enemies, by the integrity and independence of his mind; fome of whom, to render Efpen obnoxious to the ruling powers, had forged a treatife, containing fome things very offenfive, in a religious and political point of view, which they attributed to him; but he luckily detected the impofture, and punifhed the agents. On other accounts, he met with fevere and unmerited perfecution, and in one inftance, after a variety of proceffes, fentence was pronounced againft him, without any declaration refpecting the definitive judgment of the court. Under thefe circumftances, believing that it was intended to put him under an arreft, he withdrew to Maeftricht, and afterwards to Amersfort, in the province of Utrecht, where he died in 1728, in the 83d year of his age. He left behind him, which was afterwards publifhed, a learned treatife, entitled "Commentarius in Canones Juris Veteris ac Novi," and other differtations, which are faid to contain difcuffions on fome of the moft important points in moral philofophy, as well as the canon and civil laws. Moreri.

ESPENCE, CLAUDE DE, was born at Chalons fur Marne in the year 1511. He received his education at different colleges in Paris, to the principal of which he was chofen rector at a very early age. When he was about thirty years old, he took his doctor's degree, foon after which he was invited by the cardinal of Lorrain to refide in his houfe, to manage the ecclefiaftical concerns of which he had the care. In the year 1544 he accompanied the cardinal on an embaffy to Flanders, to negociate a treaty of peace between Francis I. and the emperor Charles V. He was afterwards felected by the king to affift at the ecclefiaftical conference, to confider the queftions proper to be propofed for difcuffion at the council of Trent; and in 1547 he was deputed by Henry II. to attend the council of Trent, which was then transferred to Bologne. Some years afterwards he was employed in negociating at Rome in favour of the French court, where his talents, as a diplomatic minifter, produced fuch an impreffion in his favour, that the pope, Paul IV. wifhed to attach him to his interefts by making him cardinal. He declined the intended honour, and having finifhed the bufinefs on which he was fent to Rome, he returned to his native country, where he appeared with high reputation at a meeting of the States at Orleans in the year 1560. In the following year he was appointed a member of the conference at Poiffy, where he attached himfelf to the Calvinifts, which was highly difagreeable to the Catholic divines, by whom he was likewife fufpected of being the author of a treatife on Image Worfhip, which occafioned him fome trouble with the faculty. After this, he paffed his life in retirement, devoted to his ftudies, till he died at Paris in the year 1571. His works are chiefly theological; the moft important are his "Commentaries on the Epiftles of St. Paul to Timothy and Titus;" in thefe, feveral queftions relative to hierarchy and ecclefiaftical difcipline are difcuffed. Moft of his treatifes were written in the Latin language, in the knowledge of which he was fuppofed to excel his contemporaries. He was one of the moft learned, judicious, and moderate ecclefiaftics of his time. He was very converfant in the canons and difcipline of the church; and not lefs celebrated for his knowledge of profane literature. He was attached to the Catholic religion, but was a decided enemy to every fpecies of perfecution and intolerance. Moreri.

ESPER, JOHN FREDERIC, was born at Droffenfeld, in Bayreuth, in 1732. He ftudied very diligently at Erlangen, where he applied himfelf chiefly to theological purfuits, but at the fame time made himfelf well acquainted with natural hiftory and botany, of which he afterwards became a teacher. He died of a fever in July 1781, leaving behind him a confiderable reputation as a naturalift, particularly in that department which relates to the zoolites in the principality of Bayreuth. In this place are a number of large fubterranean caverns, partly infulated, and partly connected with each other, which contain immenfe numbers of bones of various animals, thrown together in heaps to a confiderable height, and covered with the earth arifing from decompofed animal bodies. The entrance to thefe caverns is highly picturefque, but almoft as foon as a perfon enters them he is furrounded by darknefs, and the paffage becomes ftill more difficult and narrow, till the eye at laft is ftruck by the immenfe extent of an awful arch, which on every fide prefents fiffures and clefts, ftrewed with the fragments of once living bodies, which excite the idea of a repofitory of the dead. With the aid of an ingenious apothecary of Erlangen, Efper undertook an examination and defcription of thefe curiofities, and publifhed the refult of his labours under the following title; "An accurate Defcription of the Zoolites of Unknown Animals, &c." This was publifhed at Nuremberg, in the year 1774, in folio, with fourteen illuminated plates. Efper was author likewife of various papers in the Tranfactions of the Friendly Society of the Searchers into Nature: and he wrote an account of "A Method of determining the Orbits of Comets, and other Celeftial Bodies without Inftruments, or Mathematical Calculations." Gen. Biog.

ESPERAZA, in *Geography*, a town of France, in the department of the Aude, and diftrict of Quillan; $2\frac{1}{2}$ leagues S. of Limoux.

ESPERNAY. See Epernay.

ESPERNON, a fmall town of France, in the department of Eure and Loire, on the river Guefle; 15 miles N.E. of Chartres, and 6 miles E. of Maintenon.

ESPESEL, a town of France, in the department of the Aude, and diftrict of Quillan; $2\frac{1}{2}$ leagues S.W. of Quillan.

ESPHLASIS, (from εσφλαομαι, *to recede inwards*,) in *Surgery*, a receffion of a part of the body inwards, in confequence of fome violent outward force.

ESPIERRE, a town of Savoy, in the county of Maurienne, on the river Arc; $3\frac{1}{2}$ miles S. of Argentina.

ESPIERS, in *Geography*, a town of Flanders; 8 miles N. of Tournay.

ESPINAL. See Epinal.

ESPINAR, a town of Spain, in Old Caftile; 18 miles S.S.W. of Segovia.

ESPINHAL, a town of Portugal, in the province of Beira; 18 miles S E. of Coimbra.

ESPINOSA de los Monteros, a fmall town of Spain, in Old Caftile; fituated in a pleafant valley, watered by the river Trueva, among the mountains of Burgos, about 15 leagues N.W. of Miranda, in the north corner of the province.

Espinosa, a town of Spain, in New Caftile; 44 miles S.W. of Toledo.

ESPIRITU Santo, the largeft and moft wefterly of the New Hebrides iflands, in the South Pacific ocean, about 57 miles in length, and 30 in breadth.—Alfo, a province of Brafil, which is chiefly productive of fugar.—Alfo, a town of Brafil, feated in a fertile country on the fea-coaft, with a fmall caftle and harbour. S. lat. 20° 10'. W. long. 41°.—Alfo, a river of Brafil, which runs into the Atlantic.—Alfo, a town on the fouth coaft of the ifland of Cuba; 55 miles S. W. of Bayamo.—Alfo, a bay on the weft coaft of Eaft Florida. N. lat. 27° 36'. W. long. 82° 54'. It has a good harbour and fafe anchorage; but the land about the fea-coaft is very low. Several low, fandy iflands and marfhes, covered with Mangrove bufhes, lie before the main land. This bay abounds in the fummer with fifh, which may be taken with a feine, in quantity fufficient to load a fhip, if the climate would admit of curing them, in a few days.—Alfo, a lake towards the extremity of the peninfula of Eaft Florida, fouth from the chain of lakes which communicate with St. John's river.

Espiritu *Santo, Ilhas del*, iflands fituated on the S. W. of Providence in the Weft Indies. See Andros *iflands*.

ESPLANADE, in *Fortification*, called alfo the glacis; a part which ferves the counterfcarp, or covert way, for a parapet; being a declivity, or flope of earth, commencing from the top of the counterfcarp, and lofing itfelf, infenfibly, in the level of the champagne.

Esplanade alfo fignifies the ground which has been levelled from the glacis of the counterfcarp to the firft houfes; or the vacant fpace between the works and the houfes of the town.

The term is alfo applied, in the general, to any piece of ground which is rendered flat, or level, and which before had fome eminence that incommoded the place.

ESPLEES, Expletiæ, from *expleo*, in *Law*, the products which ground or land, &c. yield; as the hay of the meadows, the herbage of the pafture, corn of the arable, rents, fervices, &c. and of an advowfon, the taking of tithes in grofs by the parfon; of wood, the felling of wood; of an orchard, the fruit growing there; of a mill, the taking of toll, &c. Thefe and fuch like iffues are termed efplees. And it is obferved, that in a writ of right of land, advowfon, &c. the demandant ought to allege in his count, that he or his anceftors took the efplees of the thing in demand; otherwife the pleading will not be good.

Sometimes this word hath been applied to the farm, or land, &c. themfelves. "Dominus E. habebit omnia expletias & proficua de corona emergentia." Plac. Parl. 30 Ed. I.

ESPOSENDA, in *Geography*, a town of Spain, in the province of Galicia; 12 miles S. W. of Orenfe.

ESPOSENDE, a fmall port town of Portugal, in the province of Entre Minho, at the mouth of the Cavado, three leagues S. of Viana. Its fhallow harbour is flightly protected by a fort, 22 miles N. of Oporto.

ESPRIT, James, in *Biography*, was born at Befiers in the year 1611. Having paffed through his initiatory ftudies, to which he had applied himfelf with great diligence, he was introduced to the duke de la Rochefoucault, who brought him acquainted with the chancellor Seguier, who not only allowed him a penfion from his own private purfe, but procured for him a penfion of two thoufand livres, on an abbey and a brevet of counfellor of ftate. Through fome fecret enemies he incurred the difpleafure of the chancellor, and withdrew to the feminary of St. Magloire, where he became acquainted with the prince of Conti, and at that time had ferious thoughts of entering the church. This prince was fo charmed with the converfation of M. Efprit, that he gave him handfome apartments in his own hotel, and a penfion of a thoufand crowns. In a fhort time afterwards Efprit gave up all thoughts of the ecclefiaftical life, and determined to marry. On this occafion he received fome handfome prefents from the prince, to whom he became fo much attached that he followed him, in 1766, to his government of Languedoc, and became his moft confidential friend and advifer. After the death of his patron, he devoted the whole of his time to the education of that prince's children. He himfelf died at the place where he was born in 1678. As a literary man he left behind him "Paraphrafes on fome of the Pfalms;" and a treatife, entitled "La Fauffeté des Vertus humain," in two volumes, which was publifhed the fame year in which he died, and which was intended as a commentary on the maxims of his firft patron the duke de la Rochefoucault, to fhew the fallacy of the virtues that are merely human, and the reality of Chriftian virtues. By the abbé Olivet and others he is fuppofed to have been the tranflator of Pliny's panegyric on Trajan. Efprit was a member of the French academy, and in its infancy was confidered as one of its fhining ornaments. Moreri.

Esprit, *Saint*, in *Geography*, a fmall town of France, in the department of the Landes, chief place of a canton in the diftrict of Dax, with only 589 inhabitants. Its canton has a population of 10,161 individuals, difperfed in eight communes, on a territorial extent of $147\frac{1}{2}$ kiliometres.

ESPOUSALS, Sponsalia, in *Law*, a contract or mutual promife between a man and a woman to marry each other. Marriage or matrimony is faid to be an efpoufal de prefenti.

ESPRONCEDA,

ESPRONCEDA, in *Geography*, a town of Spain, in Navarre; 11 miles W.S.W. of Eftella.

ESQUADRILLE. See QUADRILLE.

ESQUADRON. See SQUADRON.

ESQUERDES, in *Geography*, a town of France, in the department of the ftraits of Calais, and diftrict of St. Omer; one league S. of St. Omer.

ESQUIAVINE, in the *Manege*, an old French word fignifying a long and fevere chaftifement of a horfe in training him.

ESQUILIÆ, or ESQUILINUS MONS, in *Ancient Geography*, one of the feven mountains on which Rome was feated, where was anciently one of the gates of the city, now the gate of St. Laurence, to whofe magnificent church it leads. This gate feems to have been anciently called "Libitinenfis," on account of the dead bodies that were carried through it, in order to their being interred in the "Campus Efquilinus," which was the general buryingplace of the common people. The name of Efquilinus was varied, for facility of pronunciation, from Exquilinus, a corruption of Excubinus, *ab Excubiis*, from the watch that Romulus kept in this place. It was taken in by Servius Tullius, who had his royal feat upon this hill. Varro will have the Efquiliæ to be two hills. To the eaft, it has the city walls; to the fouth, the via Labicana; to the weft, the valley lying between Mons Cœlius and Mons Palatinus; to the north, Mons Viminalis; and is in compafs between three and four miles. It is now called "Il Monte de Santa Maria Maggiore." One of the 14 regions or wards, inftituted by Auguftus, was denominated "Efquilina." It contained 15 ftreets, eight luci, fix temples, five ædes, 75 public baths, 18 granaries, 22 mills, and 180 great houfes; and its circuit was 15,950 feet.

ESQUIMAUX, the inhabitants of the coafts of Labrador and Hudfon's bay, who differ, in feveral characteriftic marks, from the inland inhabitants of North America. That the Greenlanders and the Efquimaux agree in every circumftance of cuftoms, and manners, and language, which are demonftrations of an original identity of nation, was difcovered near half a century ago. Crantz, in his "Hiftory of Greenland," (vol. i. p. 262.) informs us, that the Moravian brethren, who, with the confent and furtherance of fir Hugh Pallifer, then governor of Newfoundland, vifited the Efquimaux, or the Labrador coaft, found that their language, and that of the Greenlanders, do not differ fo much as that of the high and low Dutch. Mr. Hearne, in 1772, traced this unhappy race farther back, towards that part of the globe, from whence they had originally coafted along in their fkin-boats, having met with fome of them at the mouth of the Copper-mine river, in the latitude of 72°, and near 500 leagues farther weft than Pickerfgill's moft wefterly ftation in Davis's ftrait. Their being the fame tribe, who now actually inhabit the iflands and coafts on the weft fide of North America, oppofite to Kamtfchatka, is a difcovery, the completion of which was referved for captain Cook. The reader of his third voyage will find them at Norton found, and at Oonalafhka, and Prince William's found; that is, near 1500 leagues diftant from their ftations in Greenland, and on the Labrador coaft. And left fimilitude of manners fhould be thought to deceive us, a table exhibiting proofs of affinity of language, drawn up by captain Cook and inferted in the appendix to the work juft cited, will remove every doubt from the mind of the moft fcrupulous inquirer after truth. See *New* BRITAIN and LABRADOR.

ESQUIMAUX *Bay*. See ESKIMAUX.

ESQUINANCY, in *Medicine*, from the French *efquinancie*; whence our more common term *quinfy*. See CYNANCHE.

ESQUIRE, a title of diftinction, next below that of knight, and above that of a fimple gentleman.

The origin, both of the name, and the thing, efquire, is very obfcure. The Englifh denomination is confeffedly borrowed from the French, *efcuyer*; and that from the Latin *fcutum*, fhield, as fome will have it; or, as others, from *fcutarius*, or *fcutiger*, fhield-bearer; or from *fcuria*, ftable; or from *equifo*, groom. So many different opinions of the formation of the word have given rife to as many about the primitive office of efquires; unlefs, perhaps, the latter hath given occafion to the former. Pafquier, in his Recherches, liv. ii. chap. 15. maintains the title of efquire, *efcuyer*, *fcutarius*, to be very ancient. From the time of the declenfion of the Roman empire, he obferves, there were two extraordinary kinds of foldiery in the Roman army: the one called *gentiles*, and the other *fcutarii*.

Ammian. Marcellin. lib. xiv. cap. 7. and lib. xvi. cap. 4. fpeaks of thefe *fcutarii* as men of redoubted prowefs, and even deemed invincible: it is added, that Julian the Apoftate fet a mighty value on thofe troops, when he was among the Gauls; and hence, probably, it was, that the Gauls, or perhaps only the Franks, finding the braveft among the Roman forces were called *gentiles*, and *fcutarii*, gave the like names to the boldeft and braveft among themfelves; fuch, according to that curious antiquary, is the original of efquires.

Efquire, however, afterwards came to be ufed in a fomewhat different fenfe; *viz.* for a gentleman who attended a knight in the wars, and on other military occafions; bearing his fhield, *fcutum*, before him (whence he was called *fcutarius*, *fcutiger*, or *fcutifer*), as alfo his lance, and other weapons; whence his other Latin appellation, ufual among us, *armiger*, q. d. *armour-bearer*. And hence likewife it is, that, in all our ancient romances, the hero is conftantly attended by a gentle and trufty *'fquire*.

After all, the moft probable derivation of *efcuyer* is not from *efcu*, *fcutum*, as is the common opinion; but from *equus*, horfe; the primitive efquires being no other than what the Latins call *equifons*, who had the care and intendance of the equerries, or ftables, only.

Be this as it will, the title efquire, *armiger*, as now eftablifhed among us, is next below that of knight, *eques*. They who bear this title are all younger fons of noblemen, and the eldeft fons of fuch younger fons; the eldeft fons of knights, and their eldeft fons fucceffively; both which fpecies of efquires fir Henry Spelman entitles *armigeri natalitii*; the four efquires of the king's body, now difufed, and efquires created by the king, by putting about their necks a collar of SS's, and beftowing on them a pair of filver fpurs, letters patent, or other inveftiture, and their eldeft fons. Laftly, divers others, in the fuperior public offices, are reputed efquires, or equal to efquires; as fheriffs of counties, ferjeants at law, juftices of peace, mayors of towns, counfellors at law, lieutenant-colonels, majors, captains, &c. during the time of their commiffion. Laftly, the heads of fome ancient families are likewife efquires by prefcription. To thefe may be added the efquires of knights of the Bath, each of whom conftitutes three at his inftallation; and all foreign, nay Irifh peers; for not only thefe, but the eldeft fons of peers of Great Britain, though frequently titular lords, are only efquires by the law, and muft be fo named in all legal proceedings. See GENTLEMAN.

ESQUISSE, in the French *Painting*, a term fignifying the firft flight fketch or draught of a picture; the firft

 thought

thought of a defign drawn haftily with a crayon; or in colours, on paper, canvas, or the like, in order to be finifhed, and painted, or engraven afterwards.

He had not the trouble of making a finifhed and correct defign, but went to work upon the efquiffe.

The word is formed of the Italian *fchizzo*, a fplafh; becaufe an efquiffe of a painting only reprefents, as it were, fplafhes, or dabs, of colours.

ESQUIVO. See Essequibo.

ESRAKITES. See Eschrakites.

ESS, in *Agriculture*, a term made ufe of in fome places to fignify afhes.

ESSA, in *Ancient Geography*, a town of Paleftine, on the other fide of Jordan, according to Jofephus, who fays that it was taken by Alexander, king of the Jews.

ESSACHORDO. See Hexachord.

ESSÆANS. See Esseni.

ESSAORE, in *Geography*, a town of Egypt; three miles S.S.E. of Achmim.

ESSARS, Les, a town of France, in the department of La Vendée, and diftrict of La Roche-fur-Yon; 3 leagues N.E. of La Roche.

ESSART, or Assart. See Assart.

Du-Cange derives the word from fome of the barbarous Latin words, exartus, exartum, effartum, affartum, fartum, and fartus; which all fignify a foreft cut down, or dug up; though Spelman choofes to deduce it from the Latin *exertum*, torn up, or unrooted. Others from *farrire*, to weed; and others, laftly, from *exaro*, I plow; whence *exarare;* and, by contraction, *exartum*. In our ancient law-books, "exartum facere in fylva," is to effart a place in a foreft. To effart, is to grub up, or extirpate bufhes, trees, old roots, ftumps, or the like; in order to fit the ground for tillage.

Essarts, *Les*, in *Geography*, a fmall town of France, in the department of La Vendée, chief place of a canton in the diftrict of Montaign, with a population of 2089 individuals, 24 miles W. of Mauléon. Its canton contains 9 communes, and 9043 inhabitants, on a territorial extent of 242½ kiliometres.

ESSATUM, a word ufed by fome of the chemical writers to exprefs the medicinal power or fanative property refiding in fimple medicines.

ESSAY, a trial, or experiment, to prove whether a thing be of the requifite quality or goodnefs.

The word is French, *effai;* which fome authors derive farther from the Latin *examen*.

Essay is alfo ufed for an attempt, or tentative, to learn whether or not a thing will fucceed.

Effays of machines fhould be made in large; it is not enough that they fucceed in little.

Essay, in *Monafteries*, is particularly ufed for a trial which a perfon makes of the monaftic life, in a fecular habit.

This effay is of one, two, and, in fome monafteries, of three months. The effay is not reckoned in the noviciate. See Probation.

Essay, or *Affay*, or fimply *Say*, in *Coinage*. See Assay.

Essay, in matters of learning, is a peculiar kind of compofition; whofe character is to be free, eafy, and natural; not tied to ftrict order, or method, nor worked up, and finifhed like a formal fyftem.

The matter of an effay is fuppofed to confift principally of fudden and occafional reflections, which are to be wrote much at the rate, and in the manner, a man thinks; fometimes leaving the fubject, and then returning again, as the thoughts happen to arife in the mind.

At leaft, this has hitherto been the practice; and Montagne, who has acquired no fmall reputation by this way of writing, feldom keeps many lines to the fubject he propofes; though it is our opinion, that lord Bacon, in many of his works, is a better pattern in the effay kind. Mr. Locke, however, and a few other authors, ufe effay in a ftricter fenfe: the Effay of Human Underftanding, every body knows, is a regular, artful, and laboured work; though perhaps fo called to guard againft too fevere ftrictures, by pleading the title.

Essay-*hatch*, is the miners term for a little trench or hole, which they dig to fearch for fhoad, or ore. See Tin.

Essay-*mafter*. See Mint, and Assay.

ESSE, in the *School Philofophy*, is ufed in the fame fenfe with effence; principally for that which is actual, or actually exifting.

The word is pure Latin; being the infinitive of the verb *fum*, I am; whence *effe*, to be.

From effe arifes *effatum*, a barbarous term, now almoft obfolete, fignifying that which is ended with effence, or nature; or affected with the virtue, or efficacy, of another. Some diftinguifh effe into *real* and *intentional;* and, again, into *effatum* and *volitum*.

ESSEDARIUS, among the Romans, a gladiator, who fought in a car or chariot. See Hift. Acad. Infcrip. vol. ii. p. 376. feq.

ESSEL, or Ebstel, in *Geography*, a town of Germany, in the circle of Weftphalia, and county of Verden; 2 miles N. of Verden.

ESSEN, a fmall town of Germany, in the circle of Weftphalia, remarkable for its manufactures, chiefly of fwords and fire arms; but more particularly for a rich abbey, which, until the peace of Luneville in 1801, was a free imperial abbey. It was fecularized, and its poffeffions, together with the town and its territory, were given to Pruffia as an indemnity for her loffes on the right fhore of the Rhine. After the peace of Tilfit in 1807, when Pruffia loft all her dominions beyond the Elbe, Effen was added to the grand duchy of Berg and Cleves, which now belongs to the eldeft fon of the king of Holland. There are other towns of this name in the circle of Weftphalia.

ESSENBACK, a town of Denmark, in Jutland; 4 miles from Randers.

ESSENBERG, a town of Germany, in the circle of Weftphalia, and county of Meurs, near the Rhine; 3 miles E. of Meurs.

ESSENCE, a term much ufed among the fchoolmen; and denoting what the Platonifts called the idea of a fpecies. The word *effentia* is faid to have been made by Cicero; but his authority could not give it currency, until long after his time. It came at laft to be ufed, and the fchoolmen fell into much the fame opinions concerning effences, as the Platonifts held concerning ideas. The effences of things were held by many to be uncreated, eternal, and immutable. Mr. Locke diftinguifhes two kinds of effence, the real and the nominal. By the former he means the conftitution of an individual, which makes it to be what it is. This effence moft begin and end with the individual to which it belongs. It is not therefore a Platonic idea. But the latter or nominal effence, fo called by Mr. Locke, is the conftitution of a fpecies, or that which makes an individual to be of fuch a fpecies; and this is nothing but that combination of attributes which is fignified by the name of the fpecies, and which we conceive without regard to exiftence. The effence of a fpecies is, therefore, what

what the Platonifts called the idea of the fpecies. The nominal effence depends on the real effence; thus, the nominal effence of gold, is that complex idea which the word gold reprefents; *e. gr.* a body, yellow, heavy, malleable, fufible, and fixed; but its real effenec is the conftitntion of its infenfible parts, on whieh thofe qualities, and all its other properties depend; whieh is wholly unknown to us.

In philofophy, the effence of a thing is defined to be, that whereby a thing is diftinguifhed from every other thing. The Cartefians hold the effence of matter to confift in extenfion; and, on that principle, deny that there is any fuch thing as mere fpace, or vacuity; but the hypothefis is falfe, as will be fhewn under the articles MATTER, SPACE, VACUITY, PLENUM, &c.

Gaffendus, and moft of the corpufcular philofophers, hold the effence of matter to confift in folidity, or impenetrability, refiftance, or, more adequately, in a folid impenetrability refifting the touch; which it muft be allowed, of all the properties of matter, feems to have the faireft title to it.

The fchool philofophers give us two fignifications of the word effence; the firft denotes the whole effential perfection of a being, and, confequently, its entity, with all its intrinfie, or effential, and neceffary attributes, taken together; in which fenfe, effence may be defined to be, all that whereby a thing is, and what it is. In which cafe the effence of a thing is to the thing itfelf, what humanity, *e. gr.* is to man.

The fecond fignification of effence is, that whereby it denotes the principal, and moft intimate, of all the attributes of a thing; or that which agrees to every fuch thing, and fuch alone, and that always, and in fuch manner, as that the mind, with all its attention, cannot perceive any thing prior thereto; by which, effence is diftinguifhed from the effential attributes, *i. e.* from fuch as flow from its effence, or firft attribute. Thus, the effence of the human mind is commonly fuppofed to confift in the power of thinking; becaufe all its other perfections feem to pre-fuppofe this; but this pre-fuppofes none. And thus the powers of underftanding, doubting, affenting, willing, &c. do all flow from the power of thinking; and cannot exift without it, though this may without any of them.

It muft be allowed, however, that the effential properties of a thing do fo clofely cohere, nay, and inhere, in the effence itfelf, that it is fcarcely poffible to diftinguifh the one from the other. Hence, what fome urge, that, fetting afide all the attributes and properties of a thing, and what remains is its effence, is a mere chimera. For fet afide, *e. gr.* from the mind, the powers of underftanding and willing, with the reft of its attributes, and what will there remain to call its effence?

It is greatly difputed, in the fchools, whether the effences of created things be eternal? or whether the effences, as well as their exiftence, had their origin in time? The Cartefians hold, that the effences of things depend abfolutely on the free concurring will of God.

ESSENCE, *Effential oil, Effential falt.* The effence of a vegetable, according to the old chemifts, was, that one of its proximate elements, in which refided the quality of tafte or odour, which peculiarly diftinguifhed it from other vegetables, and rendered it efpecially applicable to pharmaceutical purpofes. Thus the fragrance of orange peel, of pepper-mint, of cinnamon, was found by experience to be feparable from the other parts of the vegetable, by means of diftillation, &c.; the refult of this procefs was a fmall portion of highly fragrant oil, in which was contained the entire odour that had been naturally difperfed through the whole mafs: hence the oil thus procured obtained the name of "effential oil." Again, moft four vegetables, as forrel, lemons, &c. owe this quality to the prefence of an acid, which, when feparated from the other vegetable principles, affumes a cryftalline appearanee, and was known by the name of their effential falt. The fame appellation was alfo given to all thofe vegetable principles which, when pure, are capable of cryftallizing, whether they were acid to the tafte or not. Thus fugar was ranked among the effential falts. The term, however, is at prefent obfolete. Effential oil ftill retains its place in chemical nomenclature, and we refer the reader to the article OILS, *effential,* for a particular account of their fpecies and properties.

ESSENCE *of Rofes.* See ROSES.

ESSENCE, *Ward's.* See WARD'S *Medicines.*

ESSENCE *of Wine,* a term ufed by Paracelfus, and fome of the German chemifts fince his time, to exprefs what is called fometimes the philofophical fpirit of wine, or the fpirit of wine of the ancients. It is not a diftilled fpirit like what we call fpirit of wine, but approaches more to what Stahl has greatly recommended to the world, under the name of concentrated wine, or wine whofe ftrength has been reduced to a fmaller compafs, by feparating its aqueous parts only by freezing. Stahl recommends the immediately expofing of wine to the frofty air on this occafion; but the procefs ordered by Paracelfus for the preparation of this liquor is more tedious. He orders that the fineft and beft flavoured wine be chofen; that it be put into a glafs, filling it up three parts in four: and the neck being then fealed hermetically, it is to be put into horfe-dung for three months, and then expofed to the frofty air for a month, after which the ice is to be thrown away, and the liquid part, which is the effence, preferved. Shaw's Chemical Effays.

ESSENDO *Quietum de Tollonio,* in *Law,* a writ to be quit of toll, and lies for citizens and burgeffes of any city or town that by charter or prefcription ought to be exempted from toll, where the fame is exempted of them. Reg. Orig. 258.

ESSENEUX, in *Geography,* a town of the Netherlands, in the duchy of Limburg, fituated on the Ourt; 9 miles S. E. of Liege.

ESSENI, ESSENES, or *Effæans,* an ancient fect among the Jews.

As to the etymology of the name, critics have been much divided. Philo derives it from οσιος, *holy*; Epiphanius from ישי, *Jifhai, Jeffe,* the father of David; Salmafius from a city called *Effa,* mentioned by Jofephus; whence he apprehends the fect firft fprung; Godwin derives it from the Syriac word אסא, *afa,* whieh fignifies *to heal*; becaufe Philo calls one branch of the Effenes Therapeutæ; and Serrarius enumerates at leaft a dozen different etymologies. Philo in Tract. Omnis probus Liber. Oper. p. 678. Colon. Allobr. 1613. Epiphan. Hæref. xix. lib. i. Salmaf. Plin. exercit. in Solin. cap. 35. Serrar. Trihæres. Jud. lib. iii. cap. 1. p. 106. 110. edit. Trigland. 1703. The principal ancient writers, who give any confiderable account of the Effenes, are Jofephus, Philo, and Pliny. Jof. de Bell. Jud. lib. ii. cap. i. cap. 8. & 12. and Antiq. lib. cxiii. cap. 9. 13. 19. lib. xviii. cap. 1. & cap. 2. & alibi. Philo, ubi fupra, & De Vita contemplativa, p. 688. ed. col. Allobr.

As to the origin of this fect, Pliny afferts, without mentioning his authority, that it had fubfifted for feveral thoufand years. The moft probable opinion is, that this fect was formed by Jewifh exiles, a little before the time of the Maccabees, who were forced to fly from the perfecution of their enemies into caves and deferts. The firft Effenes we read of are mentioned in the fourth book of Maccabees, under the name

name of Hasdanim, and by Josephus; both which accounts agree that they were already settled in Judæa, in the time of Jonathan, the brother and successor of Judas Maccabæus, about a hundred and fifty years before Christ. Josephus states that their number in Judæa was about four thousand, meaning, as Dr. Lardner (Works, v. i. p. 128.) suggests, those of them, that entirely rejected marriage. Philo says, that in Syria and Palestine there were about 4000 of them, but he makes the number in Egypt much greater. Philo says, that they sacrificed no living creatures, and that they shunned cities. Josephus says that they sent presents to the temple, but offered no sacrifice there. They seem therefore not to have exposed themselves much to public view, nor would they admit a man of another sect into the apartments in which they lived. Some have expressed their surprise, that no mention should be made of this sect in the New Testament. This proceeded, as some imagine, from their retired mode of living, by reason of which they never came under our Saviour's observation, as the Pharisees and Sadducees often did. Others suppose, that, being very honest and sincere, without guile or hypocrisy, they gave no reason for that reproof and censure, which the others very justly merited. It should be considered that it was the design of the evangelists to write the history of our Saviour's ministry, and not that of the Jewish sects. Prideaux observes, that almost all that is peculiar in this sect is condemned by Christ and his apostles. Prid. Conn. vol. iii. p. 384. However, it has been supposed, that they are referred to by the apostle Paul in his epistle to the Colossians, ch. ii. 18. 21. 23.

Josephus, making mention of the several sects among his countrymen, distinguishes three; *viz.* the Pharisees, Sadducees, and Esseni; which last he prefers to the two former, as to their manner of life. He assures us, farther, that they were Jews, by original; from which it should appear, that St. Epiphanius was mistaken in ranking them among the Samaritans.

In effect, the Esseni appear to have been true Pythagorean philosophers, in every thing that related to their manner of living; for they greatly affected solitude and retirement; and avoided all conversation with women, to devote themselves more entirely to the contemplative life. Grotius will have the Esseni the same with the ancient חסידים, *Hasidim*, or *Hasidæi*; thus called, according to Philo, from their singular piety, humility, and devotion. Among these, Gale observes, it was, that the Hebrew philosophers chiefly flourished. Porphyry is very prolix in his praises of the Esseni: Ειϛι τοινυν οι Εσσαιοι Ιȣδαιοι μην το γενος φιλαλληλον, &c. He represents them as despisers of pleasures, riches, glory, and delicacy; and strenuous retainers to continency, austerity, study, &c. He adds, they decline marriages, and adopt and educate other people's children in the principles of religion and philosophy; they are all on a level, hold every thing in common, neither buy nor sell, &c. By long habit, they arrived at such a degree of patience, that Porphyry assures us, flames and tortures had not the least effect on them. They scorned to intreat their tormentors; nor ever shed a tear; but would smile under all their agonies, &c. As to their learning, Philo Judæus, in his treatise, That every good Man is free, tells us, that they despised logic, as useless to the acquiring of virtue; physics they left to the sophists and disputants, as judging it to transcend the human faculties; and applied themselves wholly to morality. Porph. de Abstin. lib. iv. § 11. seq. Gale Philos. Gener. lib. i. cap. i. § 11.

Both Josephus and Philo give a surprising account of their austere way of life, which the curious reader may see at large in Prideaux's Conn. ubi supra. Their houses were mean; their cloaths made of wool, without any dye; they never changed their cloaths or shoes till they were quite worn out; their food was plain and coarse, and their drink water; they neglected all bodily ornaments, and would by no means anoint themselves with oil, according to the fashion of those times. They lived in sodalities, and had all their goods in common; their morals were very exact and pure, and they kept the Sabbath more strictly than any of the Jews. Before any of them were admitted to the common table, they bound themselves by a solemn oath to observe the rules of the society, which were very strict and exemplary.

Some have said that the Essenes, as well as the Pythagoreans, prohibited oaths; that they used only inanimate sacrifices, and that they not only worshipped towards the rising sun, but worshipped the sun itself. But it has been urged, that neither of these charges seem to be well founded; or at least, that it is difficult to reconcile them with their known veneration for the writings of Moses, and other instances of their conduct. Pliny, and others on his authority, have asserted, that they wholly declined marriage; and Pliny (lib. v. cap. 17.) with more wit than justice, says, that for several thousand of years, this people is perpetually propagated without any being born among them, so fruitful and prolific unto them is the repentance of others. But Josephus informs us (De Bell. Jud. lib. ii. cap. 1.) that there is one sort of Essenes, who agreed with the others, except in the article of marriage. For they reckoned, that those that do not marry cut off a great part from the number of the living, and that thus the whole race of mankind would soon be extinguished. Accordingly they made choice of those women, who, after three years trial, were found fit to bear children, and never cohabited with them after they were known to be with child; consulting the propagation of their species, and not their own gratification in this business.

With respect to the religious opinions of the Essenes, they believed the existence of angels, the immortality of the soul, and a future state of rewards and punishments, but denied the resurrection of the body. They maintained, that fate governs all things, and that nothing happens to man but by its appointment.

The Esseni seem to have been, among the Jews, what the most retired and austere monks are, or were, among the Christians: which was what gave them their denomination of Ιȣδαικοι ασκηται, *Jewish ascetics*.

Many Catholic writers have even deduced the origin of monks from them; building, principally, on what Philo relates of them, who divides them into two branches, or sects; the one who married, and the other who lived in celibacy.

Josephus seems likewise to have had an eye to these two sorts of Esseni. Serrarius, who has wrote very amply on the subject, follows Philo in making two classes of Esseni. The first are those whom he calls *Practici*, and who lived in community; the second, those called *Theoretici*, who lived in solitude, and led a life of pure contemplation. He adds, that Josephus only makes mention of the first; omitting the contemplative kind, whom Philo calls *Therapeutæ*, and who were principally found in Egypt. See THERAPEUTÆ.

Eusebius holds, that the Esseni, called *Therapeutæ*, were real Christians, or Jews converted by St. Mark, who had embraced this kind of life. Scaliger, on the contrary, maintains, that these Therapeutæ were no Christians, but real Esseni, who made profession of Judaism; however, he he allows of the two kinds of Eſſeni above-mentioned. But Valeſius, in his notes on Euſebius, abſolutely rejects any ſuch diſtinction: he denies that the Therapeutæ were any real Eſſeni; and that chiefly on the authority of Philo himſelf, who never calls them Eſſeni, and who places the Eſſeni in Judæa and Paleſtine; whereas the Therapeutæ were ſpread throughout Greece, Egypt, and other countries.

Some traces of the Eſſenes are found under the emperor Trajan, and under Juſtinian; but they were much degenerated from their primitive purity both of doctrine and manners; and the ſect about that time became extinct. Though the Therapeutæ, as well as the Eſſenes, were ſtrictly Jews, and not Chriſtians, it is not impoſſible, that ſome of them, becoming Chriſtians, might ſtill affect their former recluſe way of living; and being imitated by others, laid the foundation of monkery among Chriſtians.

ESSENIAS, Andrew, in *Biography*, a learned Dutch divine, was born at Bommel in the year 1618. He was educated chiefly at Utrecht, was admitted to the exercise of the miniſtry in the year 1639, and in the following year took the degree of M. A. He obtained ſome preferment, and took his doctor's degree in the year 1645. Soon after this, he was choſen paſtor of the principal church at Utrecht, and in 1653 was appointed profeſſor of theology at that univerſity. He died in 1677, leaving behind him many works, that were very highly eſteemed by his contemporaries. He was what the world has uſually denominated an orthodox divine, and wrote againſt Crellius, and others among the Unitarians. One of his largeſt publications was "A Syſtem of Divinity," in 2 vols. His moſt popular piece was entitled "A ſhort View of Theological Controverſies, with an Index to Scripture Paſſages." This has gone through many editions. Moreri.

ESSENTIA Dulcis, in *Chemiſtry*, a name given by Kunkel, and ſome others of the German authors, to a menſtruum, of which they relate wonderful effects; but the preparation of which ſeems hitherto a ſecret. They ſay this menſtruum has nothing acid or corroſive in it, but that it approaches to the nature of ſpirit of wine, yet that it is capable of diſſolving the moſt denſe metals, and of converting any of them into a pure white ſalt, which has all their virtues, but nothing of that vitrolic acrimony, which they have when prepared in the common way. The ſalts of mercury and of gold thus prepared have great praiſes beſtowed on them, and are ſaid to cure epilepſies, the venereal diſeaſe, and many other diſtempers, without any violence or danger. Kunkel, De Salis Metal. See Metal.

ESSENTIAL, ſomething that is neceſſary to conſtitute a thing, or that has ſuch a connection with the nature and reaſon of a thing, that it is found, or ſuppoſed, wherever the thing itſelf is.

Thus, it is eſſential to God to be juſt. Mr. Locke has laboured to overturn that great principle of the Carteſians, that thinking is eſſential to the ſoul.

The heart, brain, and ſpinal marrow, are parts ordinarily ſuppoſed eſſential to life, or without which life cannot be; yet we have inſtances, in hiſtory, of children being found, and alive, without almoſt any of thoſe parts. See Brain, &c.

Essential *characters*, in *Natural Hiſtory*, or *Diagnoſtics*, are ſuch particulars as mark or diſtinguiſh a plant or animal from all others in the ſame genus or order. Mr. William Martin, in his "Outlines of the Knowledge of Extraneous Foſſils," p. 189, ſtates the principles under five heads, which ſhould direct the choice of parts of a foſſil animal or plant, to be conſidered as its diagnoſtic or eſſential characters. See Reliquia.

Essential *oils*. See Oils.

Essential *properties*, are ſuch as neceſſarily depend on and are connected with, the nature and eſſence of any thing, ſo as to be inſeparable from it; in diſtinction from *accidental*.

Essential *ſalts*, are thoſe prepared from decoctions, or thoſe which are found cryſtallized in the juices and infuſions of plants; in contradiſtinction to thoſe made by incineration. See Salt.

Essential *Fever*, *Form*, *Mode*, *Part*, *Perfection*. See the ſubſtantives.

ESSEQUEBO, or Esquivo, in *Geography*, one of the four provinces into which the Dutch poſſeſſions in Guiana are divided; the other three being Surinam, which is the chief ſettlement, Berbiſche or Berbiz, and Demerara. This ſettlement derives its name from that of the large river on which it is ſituated, and which at its diſcharge into the Atlantic is 3 leagues wide. The productions of this country are ſugar, coffee, and cotton. See Guiana, Surinam, Berbische, and Demerara.

ESSERA, a river of Spain, which runs into the Cinca, in Arragon.

ESSERA, Essere, or *Sere*, in *Medicine*, a generic denomination, uſed by the Arabian phyſicians, and compriſing ſeveral popular eruptions, and raſhes, which appear on the ſkin: eſpecially the eruption of the ſummer ſeaſon, in warm climates, which has been termed the Prickly-*heat*, the Nettle-*raſh*, the Prurigo of Dr. Willan's claſſification; &c. See theſe articles. See alſo Willan on Cutaneous Diſeaſes, genus Lichen.

ESSERUM, in *Geography*, a ſmall town of Denmark, in the iſland of Zealand, in the diſtrict of Cronburg, and the herred of Holboe. Before the Reformation it was remarkable for a rich monaſtery of Bernardines, founded in 1150, in an extremely pleaſant country, watered by lakes abounding in fiſh. But Eſſerum is now much more intereſting for a royal ſtud of horſes, and for having conſtantly flocks of the moſt renowned foreign ſheep, Spaniſh and others, which are diſtributed among the farmers to improve the Daniſh breed. In the beginning of the year 1800, there were at Eſſerum 652 choice ſheep, of which 223 ewes, and 33 rams, were Spaniſh of the beſt Merino breed. Catteau Tableau des Etats Danois, vol. ii. p. 147.

ESSES, in *Military Language*, are fixed to draught chains, made in the form of an S; one end of which is faſtened to the chain, and the other to hook to the horſe's harneſſes, or to a ſtaple; they ſerve likewiſe to lengthen and piece chains together.

ESSEX, in *Geography*, the name of one of the Engliſh counties, which has for its boundaries the German ocean and river Thames to the eaſt and ſouth; the counties of Suffolk and Cambridge to the north; and thoſe of Middleſex and Hertfordſhire on the weſt. The area of land thus encompaſſed meaſures about ſixty miles in length from eaſt to weſt, by fifty from north to ſouth: its circumference being about 225 miles. It is divided into 20 parts, of which fourteen are hundreds, five half hundreds, and one a royal liberty. Theſe are ſubdivided into about 400 pariſhes and townſhips, and twenty-five towns; containing, according to the late official report, 39,398 houſes, and 226,437 inhabitants. When the Romans invaded Britain, this diſtrict, with that now denominated Middleſex, were inhabited by a claſs or tribe of the Britons, called Trinobantes, or Trinovantes, who poſſeſſed, according to Cæſar, and ſome other ancient writers,

ters, two confiderable cities or fortified towns; one, the fite of modern London; and the other, that of Colchefter in this county. This tribe was the firft to fubmit to and become vaffals to the Romans, who, to keep them in fubordination, eftablifhed five military ftations within this diftrict. Thefe were Durolitum, Cæfaromagus, Canonium, Camalodunum, and Ad Anfam. Thefe ftations were all feated on the road which formed the fifth Iter from Londinium to Venta Iceno-rum, Caftor in Norfolk. Camalodunum was unqueftionably the principal ftation in Effex, and though its fite has been much contefted by different writers, an attentive examination of the feveral places affigned, combined with a knowledge of the antiquities difcovered in the vicinity of each, will admit little doubt of Colchefter being the real fituation. Effex formed a feparate and diftinct kingdom during a certain period of the Saxon Heptarchy, and was called Eaft-Seaxa; but the times of its eftablifhment and termination are not precifely authenticated. Turner ftates that this diftrict, and Eaft Anglia, were originally occupied by the Saxons at nearly the fame period; and that Erkenwin was the firft king of the former; commencing his reign in 527, and dying in 587.

By the Domefday book it appears, that ninety land-owners of this county were deprived of their lands by the Conqueror, during whofe reign the whole civil and ecclefiaftical eftablifhment of the kingdom, and of each county, underwent very confiderable changes. Effex was now governed and tyrannized over by Norman barons, who conftructed caftles on their eftates to fecure themfelves, and to awe their dependant vaffals. In the civil wars between the houfes of York and Lancafter, and in thofe of Charles's time, this county fuffered greatly from the interference of the De Vere's in the former, and during the long fiege of Colchefter in the latter. Formerly there were twelve caftles, or fortified buildings in this county; two of which, Landguard fort, and Tilbury fort, were denominated royal caftles, as built for national fecurity: the others were baronial refidences, *viz.* Colchefter, Hadleigh, Canfield, Hedingham, Clavering, Raleigh, Ongar, Plefhy, Stanftead-Montfichet, and Walden. Thefe formidable fortreffes, though once the pride of the nobility, and the terror of the peafantry, are moftly rafed to the ground; the only parts remaining being their high keeps and wide foffes. At Colchefter, Hadleigh, Hedingham, and Walden, fome parts of the walls ftill remain. Effex compofes part of that tract of country on the eaftern fide of England which forms the largeft connected fpace of level ground in the whole ifland; not one lofty eminence or rocky ridge being found in feveral contiguous counties. The furface of Effex is not, however, totally flat, having many gentle hills and dales; and towards the north-weft, whence moft of the rivers proceed, the country rifes, and prefents a continued inequality of furface. The moft level tracts are thofe of the fouthern and eaftern hundreds. The fea-coaft is broken into a feries of iflets and peninfulas, deeply cut in by arms of the fea, and exhibiting evident tokens of the force and effects of that reftlefs element. Extenfive falt marfhes border moft of the coaft, the greater part of which is protected by embankments. The banks of the Thames, and the lower part near the fea, are likewife low and marfhy. This county lies under a proverbial imputation of being particularly unhealthy; but this character can only apply to a fmall part of it; as the middle and northern diftricts are juftly noted for a dry foil, and a wholefome clear air. That part known by the name of the hundreds of Effex, bordering on the fouth coaft, from its low and marfhy fituation, and expofure to the eafterly winds and fea fogs, is certainly inimical to health, and many intermitting fevers proceed from thefe caufes.'

The principal productions of this county are wheat, barley, oats, beans, peas, turnips, tares, rape, muftard, ryegrafs, and trefoil. Many diftricts on the eaft fide are extremely productive: wheat is not unfrequently found to rife to a load an acre; oats, (particularly the Poland,) to eleven or twelve quarters; beans and other corn in proportion. Among the more rare plants cultivated in Effex, are thofe of coriander, teafel, and carraway; many acres are alfo appropriated to the produce of hops, and various horticultural plants and roots. The latter are confined to the vicinity of large towns, and to the lands adjoining to the metropolis. Almoft every fpecies of foil is to be found within the limits of Effex, from the moft ftubborn to the mildeft loam. The north-weft fide is characterized by a chalky fubftratum; but the eaft and fouth fides abound with marfhy and boggy land, having abundance of gravel intermixed. Of wafte lands and forefts, Meffrs. Griggs (in their "General View of the Agriculture of Effex,") computed the county to contain fifteen thoufand acres; the greater part of which, they obferve, is capable of producing corn. Since their report, however, many diftricts have been inclofed and cultivated. Though Effex is not highly celebrated for its dairies, yet thofe in the parifh of Epping and its vicinity are famous for the richnefs of their cream and butter. The butter is moftly fent to London, where it bears a high character and price. Few counties have lefs minerals than Effex; which is alfo nearly exempt from quarries, or any mafs of rocks. In confequence, the houfes are almoft wholly built with brick; and many of them are fingular and curious fpecimens of brick-architecture. In conftructing the caftles, the monaftic buildings, and many of the old manfion-houfes, the builders have endeavoured to render them not only durable monuments of their fkill, but alfo examples of their tafte, difplayed by a variety of ornaments in the cornices, doors, pilafters, and particularly in the chimnies. Some mineral waters rife in the county, but few have obtained much repute; that of Tilbury is occafionally reforted to, and found to be impregnated with fome earthy and muriatic falts.

The principal rivers, properly belonging to this county, are the Colne, the Blackwater or Pant, the Clelmer, the Crouch, the Ingerbourn, the Roding, and the Cam. Befides thefe, Effex partakes of other rivers, which ferve as natural boundaries, and irrigate and fertilize its land: thefe are the Thames, the Lee, or Lea, the Stort, and the Stour.

In the early periods of our hiftory, it is reafonably prefumed, that the whole, or the greater part of Effex, was one extenfive foreft. During the Britifh and Roman governments, many parts muft have been cleared for ftations, roads, and cultivation: yet in the time of king Stephen it appears that the principal portion of the county was either foreft, or fubject to foreft laws. In his reign, however, a large tract in the north-eaft part of the county was difafforefted, and cultivated; and the remaining part, north of Stane-ftreet, was difafforefted by king John. Henry the Third, in the twelfth year of his reign, directed perambulations to be taken of Waltham foreft, in order to afcertain its extent and value; and about the fame time had large tracts cleared for the plough. This judicious plan was purfued by Edward the Firft, in the twenty-fixth and twenty-eighth years of his reign: yet much foreft land ftill remained; and Paul, vifcount Bayning, with many other gentlemen of the county, purchafed of the crown, and difafforefted

feveral

feveral parts of it. Thefe proceedings, combined with the more equitable decifions of fubfequent monarchs, occafioned the forefts to contract their boundaries, and be lefs injurious to the public. While the forefts continued in the crown, and were under the local government of arbitrary forefters and ftewards, the fubject, whofe eftate was contiguous, fuffered repeated oppreffions. The grievance was partly redreffed in the perilous reign of king John, when the barons compulfively procured from that monarch the "Charter of Forefts," by which many of thefe royal diftricts were difafforefted, and ftripped of their oppreffive privileges; while more lenient regulations were adopted in the government of thofe that remained. The forefts of Epping and Hainault ftill retain the name, and fupport a few deer, &c. The office of chief forefter for Effex was deemed highly honorary, and was generally beftowed on fome illuftrious perfon. The ftewardfhip was alfo an office of great confequence, and was ufually enjoyed by fome of the nobility. It continued in the De Veres, earls of Oxford, for many generations, but was taken from them by Edward the Fourth, on account of their adherence to the Lancaftrian party. On the acceffion of Henry the Seventh, it was reftored by grant to John, earl of Oxford. The fteward had power to fubftitute a lieutenant, one riding forefter, and three yeomen-forefters, in the three bailiwicks of the foreft. He alfo had many lucrative privileges, and was keeper of Havering at Bower, and of the houfe and park there.

Previous to the diffolution, Effex contained forty-feven religious houfes: of thefe, two were mitred abbies; fix common abbies; twenty-two priories; three nunneries; three colleges; two præceptories of templars; and nine hofpitals.

Effex is included in the diocefe of London, and contains three archdeaconries and fifteen deaneries; it returns eight members to parliament, *viz.* two for the county, two for Malden, two for Harwich, and two for Colchefter; it is in the home circuit; pays twenty-four parts of the land-tax, and fupplies 960 men for the militia.

Essex, one of the moft populous and beft cultivated counties in Maffachufetts, in the United States of America; bounded N. by North Hampfhire, E. and S. by the ocean, and the town of Chelfea in the county of Suffolk, and W. by Middlefex county; 38 miles long and 25 broad; of a triangular fhape, Chelfea being the acute point. It is fubdivided into 22 townfhips, containing 7644 houfes, and 61,196 inhabitants, about 135 to each fquare mile. The firft fettlement in Maffachufetts proper was made in Salem, the capital of this county, in 1628, and it was made a fhire in 1643, being one of the three into which the colony was divided. Effex county pays about ⅟₇th part of the ftate-tax, elects fix fenators for the government of the commonwealth, and two reprefentatives in the legiflature of the United States. The principal towns are Salem, Newbury-port, Gloucefter, Marblehead, Beverly, Newbury, and Ipfwich; and in it are two academies, one at Byefield, and another at Andover. The face of the county is agreeably variegated with hills, vales, plains, and woods; the land is generally fruitful, but more fuited to the culture of barley than moft other parts of the ftate; it has quarries of marble and limeftone, and the coaft is indented with a number of good harbours. The north part of Effex county is interfected by Merrimack river; and between it and the North Hampfhire line is a ftrip of land three miles wide, divided into the towns of Methuen, Haverhill, Almfbury, and Salifbury, containing 1429 inhabitants. The chief ifland on the coaft of this county is Plum ifland.

Essex, a county in Upper Canada, bounded on the E. by the county of Suffolk, on the S. by lake Erie, on the W. by the river D'Etroit to Maifonville's mill, thence by a line running parallel to the river D'Etroit and lake St. Clair, at the diftance of four miles, till it meets the river Thames, and thence up the faid river, to the N.W. boundary of the county of Suffolk. This county fends one reprefentative to the provincial parliament.

Essex, a county in Virginia, bounded E. and N.E. by Rappahannock river, which divides it from Richmond county; about 55 miles in length and 12 in breadth, and containing 3741 free inhabitants, and 5767 flaves.

Essex, a county in New Jerfey, fituated in the eaftern part of the ftate, and feparated from Staten ifland by Newark bay. It is about 25 miles in length and 16 in breadth, and has three townfhips, *viz.* Newark, Elizabeth-town, and Acquackanack, containing 22,269 inhabitants, of whom 1521 are flaves. The foil is fertile, and its productions find a ready fale in the city of New-York. This county comprehends feven Prefbyterian churches, three for Epifcopalians, one for Anabaptifts, and two for Dutch Calvinifts.

Essex, a county of New-York, having on the north Clinton county, on the fouth Wafhington county, and on the eaft lake Champlain, which feparates it from Vermont.

Essex, a county in Vermont, bounded N. by Canada, and E. by Connecticut river, containing 1429 inhabitants.

Essex, a townfhip in Chittenden county, in Vermont, containing 729 inhabitants, and lying between Jericho on the S.E. and Colchefter on the N.W.

Essex *Valley Mountains*, mountains of the ifland of Jamaica; 10 miles S.S.E. of Lacovia.

ESSEY, a town of France, in the department of Orne, and diftrict of Alençon; 3 leagues N.E. of Alençon.

ESSLISORS. See Elisors.

ESSOIGN, or Essoin, in *Law*, an excufe for him who, being fummoned to appear and anfwer to an action real, or to perform fuit to a court baron, &c. cannot attend, becaufe of fome legitimate hindrance.

The word is formed of the French *effoine*, or *exoine*; and that from the barbarous Latin *effonia*, or *exonia*, which fignifies the fame.

The caufes that ferve to effoin, are various; yet they may be reduced to five heads. The firft is, *effoin de ultra mare*, when the party is beyond fea; by which the defendant fhall have 40 days: the fecond, *de Terra Sancta*, when on an expedition in the Holy Land, and the defendant fhall have a year and a day; the third, *de malo veniendi*, when he is infirm of body, and cannot come; which is alfo called the common effoin; the fourth, *effoin de malo lecti*, when the defendant is fick a-bed, and may by writ be viewed by four knights; the fifth, *de fervitio regis*, when he is in the king's fervice. Befides thefe, there are feveral other excufes to fave a default in real actions, as conftraint of enemies, floods of water, &c. 2 Co. Inft. 125.

Essoign *day of term*, is the firft day of that term when the court fits to take effoigns, or excufes, for fuch as do not appear according to the fummons of the writ; *e. g.* the octave of St. Hilary, or the eighth day inclufive after the feaft of that faint; which falling on the 13th of January, the octave, therefore, or firft day of Hilary term, is the 20th of January. But the perfon fummoned hath three days grace beyond the return of the writ, in which to make his appearance; and if he appear on the fourth day inclufive, the *quarto die poft*, it is fufficient.

Essoign *de malo villæ*, is when the defendant is in court the firft day, but gone without pleading; and being afterwards furprifed with ficknefs, &c. cannot attend, but fends two effoigners, who openly proteft in court that he he is detained by ficknefs in fuch a village, that he cannot come *pro lucrari et pro perdere;* and this will be admitted: for it lieth on the plaintiff to prove, whether the effoign is true or not.

Essoigns, *Clerk of the.* See Clerk.

ESSOMMES, in *Geography*, a fmall town of France, in the department of the Aifne, on the river Marne; 3 miles S.W of Château Thierry.

ESSONE, a river of France, in the department of Seine and Oife, which has its fource near Pithiviers in the foreft of Orleans, flows by Ferté Alais, receives the Juine near Saint Vrain, 3 miles above Villeroi, and falls into the Seine near Corbeil. It has lately been rendered navigable.

ESSONNE, a fmall town of France, in the department of Seine and Oife, near the river Effone, 24 miles S. of Paris, and 24 miles N. of Fontainbleau, remarkable for its manufactures of gunpowder and of writing paper.

ESSORANT, from the French *efforer*, to air, in order to dry, in *Heraldry*, a term ufed to exprefs a bird ftanding on the ground with the wings expanded, as if it had been wet, and were drying itfelf.

ESSOYES, in *Geography*, a fmall town of France, in the department of the Aube, chief place of a canton in the diftrict of Bar-fur-Seine, with a population of 1585 individuals, 15 miles S.W of Bar-fur-Aube. Its canton contains 21 communes, and 11,655 inhabitants, on a territorial extent of 375 kiliometres.

ESTABLISHMENT *of Dower*, in *Law*, is the affurance or fettlement of dower made to the wife by the hufband on marriage; and *affignment of dower* fignifies the fetting it out by the heir afterwards, according to the eftablifhment. See Dower.

Establishment *of Religion.* See Religion.

ESTACHE, is ufed in our *Old Writers*, for a bridge or ftank of ftone and timber.

ESTAFFLISCHEN, in *Geography*, a town of Poland, in the palatinate of Kalifh; 14 miles N.E. of Kalifh.

ESTAFORT, a town of France, in the department of the Lot and Garonne, and diftrict of Agen; 3 leagues S. of Agen.

ESTAGEL, a town of France, in the department of the Eaftern Pyrenées; 3½ leagues N.W. of Perpignan.

ESTAGNAC, a fmall town of France, in the department of the Charente; 33 miles E. of Angoulême.

ESTAIN. See Etain.

ESTAING, a fmall town of France, in the department of the Aveyron, chief place of a canton in the diftrict of Efpalion, with a population of 1075 individuals. It is fituated 18 miles N. of Rhodéz. Its canton contains 12 communes and 6700 inhabitants on a territorial extent of 195 kiliometres.

ESTAIRE, a fmall town of France, in the department of the North, on the river Lys, between Merville and Armentiéres; 15 miles W. of Lille.

ESTAMBOLIC, or Istambol-Antir, a town of Arabia, in the fheriffal of Mecca, near the coaft of the Red fea; 180 miles N.N.W. of Medina.

ESTAMPES. See Etampes.

ESTANDARD. See Standard.

ESTANFORDE, in *Geography*, a town of Flanders; 12 miles S.W. of Ypres.

ESTAPA, or Istapo, a town of North America, in Mexico, and province of Tabafco, fituated on a river of the fame name; 10 miles S.W. of Villa Hermofa.

ESTAPLES. See Etaples.

ESTAPO, a ftrong town of America, in New Spain, inhabited by Spaniards and native Americans, fituated at the mouth of the river Tlaluc. N. lat. 17° 30'. W. long. 103° 5'.

ESTARREJA, a town of Portugal, in the province of Beira; 18 miles S. of Oporto.

ESTATE, in *Law*, the title or intereft which a man hath in lands or tenements, &c. An eftate in lands, tenements, and hereditaments, fignifies (fays judge Blackftone) fuch intereft as the tenant hath therein; fo that if a man grants all *his eftate* in Dale to A. and his heirs, every thing that he can poffibly grant fhall pafs thereby. (Co. Litt. 345.) It is called in Latin *ftatus*, fignifying the condition or circumftance in which the owner ftands with regard to his property. For afcertaining this with accuracy, eftates may be confidered in a three-fold view: firft, with regard to the *quantity of intereft* which the tenant has in the tenement; fecondly, with regard to the *time* at which that quantity of intereft is to be enjoyed; and, thirdly, with regard to the *number* and *connexions* of the tenants.

I. The *quantity of intereft* which the tenant has in the tenement is meafured by its duration and extent. Thus, either his right of poffeffion is to fubfift for an uncertain period, during his own life, or the life of another man; to determine at his own deceafe, or to remain to his defcendants after him; or, it is circumfcribed within a certain number of years, months, or days; or, laftly, it is infinite and unlimited, being vefted in him and his reprefentatives for ever. This occafions the primary divifion of eftates, into fuch as are *freehold*, and fuch as are *lefs than freehold.* See Freehold.

Eftates of freehold, underftood as they are defined under that article, are either eftates *of inheritance*, or eftates *not of inheritance.* The former are again divided into inheritances *abfolute* or fee-fimple, and inheritances *limited*, one fpecies of which is ufually denominated fee-tail. See Fee, Fee-simple, and Fee-tail.

Of eftates of freehold, not of inheritance, but *for life* only, fome are *conventional*, or exprefsly created by the acts of the parties; others are merely *legal*, or created by conftruction and operation of law. As to eftates for life, exprefsly created by deed or grant; fee Life-estate. As to the eftate of tenant in tail after poffibility of iffue extinct; fee Tail and Fee-tail. As to tenant by courtefy, and tenant in dower; fee Tenant and Dower.

Of eftates that are lefs than freehold, there are three forts; *viz.* 1. Eftates for years; 2. Eftates at will; 3. Eftates by fufferance. For the two former, fee Lease; and for the latter, fee Sufferance.

Befides the feveral divifions of eftates above enumerated, in point of intereft, there is another fpecies which is called an eftate *upon condition;* being fuch whofe exiftence depends upon the happening or not happening of fome uncertain event, whereby the eftate may be either originally created, or enlarged, or finally defeated. (Co. Litt. 201.) Eftates upon condition are of two forts: 1. Eftates upon condition *implied;* 2. Eftates upon condition *expreffed:* under which laft may be included, 3. Eftates held in *vadio, gage*, or *pledge;* 4. Eftates by *ftatute-merchant* or *ftatute-ftaple;* 5. Eftates held by *elegit.* See thefe feveral articles.

II. Eftates, with regard to the *time of their enjoyment*, when the actual receipt of the rents and profits commences, may be confidered either in *poffeffion* or in *expectancy;* as to eftates in poffeffion, fometimes called eftates *executed*, whereby a prefent intereft paffes to and refides in the tenant, not depending on any fubfequent circumftance or contingency, as in the cafe of eftates *executory;* all thofe above-mentioned are of this kind; but the doctrine of eftates in expectancy contains, fays Blackftone, fome of the niceft and moft moſt abſtruſe learning in the Engliſh law. Of expectancies there are two ſorts; one created by the act of the parties, called a *remainder*; the other by act of law, and called a *reverſion*. See REMAINDER and REVERSION. See alſo EXECUTORY *Deviſe* and LIMITATION.

III. Eſtates conſidered with reſpect to the *number and connexions* of their owners, or the tenants who occupy them, whatever be their quantity or length of duration, and whether they be in actual poſſeſſion or expectancy, may be held in four different ways: *viz.* in *ſeveralty*, in *joint-tenancy*, in *coparcenary*, and in *common*. See SEVERALTY, JOINT-TENANCY, COPARCENARY and PARCENERS, and TENANTS *in common*.

With regard to the title to eſtates and the different modes of tenure; ſee TITLE and TENURE.

Eſtates are acquired divers ways, *viz.* by deſcent from a father to the ſon, &c. conveyance or grant from one man to another; by gift or purchaſe, deed, or will; and a fee-ſimple is the largeſt eſtate that can be in law. 1 Litt. 541.

Eſtates are real, of lands, &c. or perſonal, of goods and chattels; otherwiſe diſtinguiſhed into freeholds that deſcend to the heir, and chattels, which go to the executors. The word eſtate, generally, in deeds, grants, and conveyances, comprehends the whole, in which the party hath an intereſt or property; and will paſs the ſame. 3 Mod. 46.

ESTATE, *additions of*. See ADDITION.

ESTATE, *baſe*. See BASE.

ESTATE, *que*. See QUE *eſtate*.

ESTATE, or ſimple *State*, denotes alſo the empire, kingdom, provinces, or extent of lands under the government of any ſovereign.

The eſtates of the grand ſeignor, of the king of Spain, &c. are very extenſive; thoſe of the king of France were before the revolution compact, and well peopled. Italy was formerly cantoned out into a great number of petty ſtates. We ſay, miniſters of eſtate, ſecretaries of ſtate, &c.

ESTATE, or *State*, is alſo generally applied in the ſame ſenſe with claſs or order; thus, the lay part of his majeſty's ſubjects, or ſuch of the people as are not comprehended under the denomination of clergy, may be divided into three diſtinct eſtates or ſtates, the civil, the maritime, and the military. See each term.

ESTATE is more particularly applied to the ſeveral ranks or claſſes of a people aſſembled together, for concerting meaſures, reforming public abuſes, or compoſing the diſturbances of a ſtate. In England, the three eſtates, *viz.* king, lords, and commons, meet ordinarily in parliament. See PARLIAMENT.

ESTATES *General*. } See STATES *General*, &c.
ESTATES *of Holland*. }

ESTAVAYER, in *Geography*, a ſmall town of Switzerland, in the canton of Fribourg, pleaſantly ſituated on the eaſtern ſhore of the lake of Neufchatel, N. lat. 46° 46′.

ESTE, a town of Italy, in the Paduan; 11 miles S.S.W. of Padua.

ESTELLA, a handſome manufacturing town of Spain, in Navarre, with an univerſity in its neighbourhood, founded A.D. 1565. It contains ſeveral churches and convents, and 4500 inhabitants, defended by a caſtle, ſituated in a plain, watered by the rivers Ega and Ureder; 6 leagues S.W. of Pampeluna. The environs of this place are agreeable and fertile.

ESTELMUR, a town of Aſiatic Turkey, in the province of Caramania; 120 miles S. of Cogni.

ESTENIDE. See EKSENIDE.

ESTEPA, a town of Spain, in the province of Seville, or, according to ſome geographers, in that of Granada, celebrated for its olives and oil; 15 miles S. of Ecija.

ESTEPONA, a ſmall fiſhing town of Spain, ſituated near the coaſt in the province of Granada, between Gibraltar and Marbella. Its territory furniſhes abundance of wine.

ESTERLING, or EASTERLING. See STERLING.

ESTERNAY, in *Geography*, a ſmall town of France, in the department of the Marne, chief place of a canton in the diſtrict of Epernay, with a population of 835 individuals. Its canton has 23 communes and 6498 inhabitants, upon a territorial extent of 325 kiliometres.

ESTETE', in *Heraldry*, is uſed by the French to ſignify a beaſt whoſe head has been, as it were, torn off by force, and, conſequently, the neck left rough and rugged; in contradiſtinction to deffait, or decapité, where the neck is left ſmooth, as if the head had been cut off.

ESTEVE, M. in *Biography*, a writer on the theory of muſic, or rather of ſound or harmonics. He has attacked the demonſtration of the principles of harmony by Rameau, in which M. Laborde allows him to have reaſon on his ſide: however, as he does not build his ſcale by the triple progreſſion of Pythagoras, in the way which the abbé Rouſſier preſcribes, and without which ſeries of perfect fifth he thinks there never was nor ever can be any muſic fit to be heard, M. Eſteve has not been honoured with the ſeal of Meſſrs. Laborde and Rouſſier's approbation. He has, however, explained the cauſe of more and leſs perfection in concords, from the coincidences of vibration, which has been known ever ſince the time of Galileo, (ſee BASSE *fondamentale*), but never ſo clearly explained in France.

ESTHER, a canonical book of the Old Teſtament: denominated from a celebrated Jewiſh captive of that name, in Perſia, whoſe beauty preferred her to the bed of Ahaſuerus (ſuppoſed by ſome to have been Darius Hyſtaſpis, by others Xerxes, but probably Artaxerxes Longimanus, though Jacob. Capellus makes him to be Ochus, called in Perſia Achaſch-Veroſh), and the throne of Perſia; and who, in that quality, ſaved her countrymen, the Jews, from the death to which Ahaſuerus had doomed them, by the counſels of his favourite Haman; who wiſhed thus to be revenged on Mordecai for withholding from him that reſpect to which he conceived himſelf entitled. Mordecai informed the queen of the danger to which her nation was expoſed; and induced her to wait upon the king, and invite him and Haman to a ſumptuous banquet which ſhe had prepared. Haman was puffed up with this high honour, and thought himſelf ſure of accompliſhing his ample ſcheme of vengeance. During the interval, the king chanced to read the public records, which reminded him of Mordecai's having diſcovered a conſpiracy that had been formed againſt him. Determined to diſtinguiſh him by ſome ſignal token of favour, he ordered Haman to conduct Mordecai in triumph through the city. The queen having diſcovered to Ahaſuerus, that ſhe belonged to the Jewiſh nation, intreated juſtice againſt Haman on behalf of her people, for the deſtruction of whom he had obtained the king's decree. Ahaſuerus ordered Haman to be hanged on the gallows which he had erected for the execution of Mordecai; revoked the decree iſſued forth againſt the Jews, and granted another, by which he permitted them to avenge themſelves on their enemies on the day appointed. After the death of Haman, the king beſtowed his eſtates upon Mordecai, and admitting him into his confidence, as the acknowledged uncle of the queen, advanced him to a ſtation of high office and truſt in his court. The hiſtory of this tranſaction makes the ſubject of the book of Eſther. Eſther was of the tribe of of Benjamin, and a defcendant from one of thofe families, which had been carried into captivity by Nebuchadnezzar, king of Babylon, and afterwards fettled in the city of Shufhan. She was the niece of Mordecai, and her Jewifh name was "Hadaffeh."

The critics are divided about the author of this book: St. Epiphanius, St. Auguftine, and Ifidore, attribute it to Ezra; but Eufebius will have it to be of a later date. Some afcribe it to Joachim, high prieft of the Jews, and grandfon of Jofedek; others will have it compofed by an affembly, or fynagogue, of the Jews, to whom Mordecai wrote letters, informing them of what happened. Efth. ix. 29.

But the generality of interpreters, Hebrew, Greek, Latin, &c. afcribe the book to Mordecai himfelf; Elias Levita, in his Maff. Hamum. pref. 3. mentions this opinion as unqueftionable.

It is chiefly founded on that paffage, chap. ix. ver. 20. where it is faid, that "Mordecai wrote thefe things, and fent letters unto all the Jews, that were in all the provinces, &c." It is alfo fuppofed that queen Efther herfelf might have fome fhare therein: it being expreffed in the fame chapter, ver 29. that Efther and Mordecai wrote a fecond letter, by the king's authority, to ordain the folemnizing a yearly feaft, called *purim*, that is, *day of lots*, in commemoration of the Jews being delivered from the lots, or fortes, whereby they had been condemned.

Some will have this book to be deuterocanonical, or apocryphal; others contend for its being canonical, as far as chap. x. ver. 3. inclufive; and all the reft deuterocanonical. Of this fentiment are, St. Jerome, De Lyra, Dionyfius the Carthufian, Cajetan, and others. The council of Trent turned the fcale for its being canonical throughout; fo that the matter is determined for the Catholic countries.

But the Proteftants retain the old opinion, and only admit it as far as the third verfe of the tenth chapter; the reft, to the end of the fixteenth chapter, is thrown among the apocryphal books. See Canon and Apocrypha.

Esther *Town*, in *Geography*, a town of America, in the county of Lancafter, and ftate of Pennfylvania, fituated on the eaft bank of the Sufquehannah river, a little N. of Harrifburg.

ESTHIO'MENOS, (from ἐσθίω, *to eat*,) in *Surgery*, the difeafe called herpes exedens. Alfo any obftinate ulcer, which continues to eat away the parts.

ESTHONIA, in *Geography*, is the ancient name of the Ruffian government of Reval, on the fouthern coaft of the gulf of Finland, over-againft Finland Proper. In the year 1386 Efthonia was fold to the Teutonic order, and formed a part of Livonia; with which, after a feparation of a hundred years, when it was under the dominion of Sweden, it was united to the Ruffian territory.

Not only the government of Reval, but alfo the greater part of Livonia, or five circles of the government of Riga, are inhabited by Efthonians. In the former they probably amount to 180,000, in the latter to 257,000 individuals. The language, manners, complexion, dwellings, and hufbandry of the Efthonians prove their relationfhip to the Finns, who are one of the moft far fpread nations of the globe, extending from the fhores of the Baltic to the remoteft confines of Afia. In the Ruffian annals, where they act a confiderable part, as they, in common with the Novgorodian Slavi, founded the Ruffian ftate, the Efthonians are called *Tfchudes*. Tooke's View of the Ruffian Empire, vol. i.

ESTIÆA, Ἑστιεια, in *Antiquity*, folemn facrifices to Vefta, called in Greek ἑστια, of which it was unlawful to carry any away, or communicate any part to any befide the worfhippers. Potter, Archæol. Græc. lib. ii. cap. 20. tom. i. p. 396.

ESTIATORES, Ἑστιατορες, among the Athenians, perfons appointed by lot to provide an entertainment for the whole tribe. Befides thofe appointed by lot to this office, others voluntarily undertook it to ingratiate themfelves. Potter, Archæol. Græc. lib. i. cap. 15. tom. i. p. 86.

ESTIMIONE, in *Natural Hiftory*, a name by which fome call the *harmefion*.

ESTISSAC, in *Geography*, a fmall town of France, in the department of the Aube, chief place of a canton in the diftrict of Troyes, with a population of 1255 individuals. Its canton has 6089 inhabitants, difperfed in 10 communes, on a territorial extent of 200 kiliometres.—Alfo, a fmall town of France, in the department of the Dordogne, 18 miles N. E. of Bourdeaux.

ESTIVAL, a town of France, in the department of the Vofges, and diftrict of St. Diey; 2 leagues N. of St. Diey.

Estival *occident*. See Occident.

Estival *orient*. See Orient.

Estival *folftice*. See Æstival, and Solstice.

ESTIVAREILLES, in *Geography*, a town of France, in the department of the Allier, and diftrict of Montluçon; 5 miles N. of Montluçon.

ESTIUS, William, in *Biography*, a learned Dutch divine, was born at Gorcum in Holland in the year 1542. He received the early part of his education at Utrecht, and finifhed his ftudies in philofophy and theology at Louvain, where he afterwards became an inftructor. In 1580 he was admitted to the degree of doctor in divinity, and was fucceffively chofen profeffor of theology, in the univerfity of Douay; fuperior of that feminary, and afterwards its chancellor. He died in 1613 at the age of 71, while he was in the difcharge of the various duties of his laborious office at Douay, highly efteemed on account of his modefty, piety, and active virtues. He had ever been indefatigable in his ftudies, and zealous in promoting the interefts of thofe committed to his care. As an author his principal works are, "Commentarii in omnes S. Pauli et VII. Catholicas Apoftolorum Epiftolas," in two volumes folio. "Annotationes in præcipua ac difficiliora S. Scripturæ Loca." Another work is mentioned with much applaufe, it is a difcourfe "Contra Avaritiæ Scientiæ," intended to expofe thofe who lock up their learning in their clofets, and refufe to communicate it to the public by ufeful writings, or to individuals by well-timed and feafonable advice. The writings of Eftius are recommended by Du Pin as exceedingly ufeful to young theologians in their enquiries after truth. Moreri.

ESTOILE'. A crofs eftoilé is a ftar with only four long rays, in manner of a crofs; and accordingly broad in the centre, and terminating in fharp points.

ESTOILLE, Peter de l', in *Biography*, who flourifhed towards the clofe of the fixteenth century, was educated to the profeffion of the law, and became grand audiencer of the chancellery of Paris. He died in 1611, and after his death was publifhed from his manufcripts "A Journal of the reign of Henry III." which has paffed through many editions; of thefe the laft was edited by the Abbé Lenglet du Frefnoi in 5 vols. 8vo. The fame learned editor gave to the public "L'Eftoille's Journal of the reign of Henry IV." in four volumes, 8vo. This, as well as the other work, is enriched by fome curious pieces not to be found in the preceding editions. The ftyle and manner of thefe journals poffefs much fimplicity, exhibiting the air of truth,

truth, and affording a lively and accurate picture of the times. Moreri.

Estoille, Claude de l', fon of the preceding, was a poet, and admitted a member of the French academy in the year 1632. He was patronized as a dramatic writer by Richlieu, but his pieces were not well received by the public, though he is allowed to have had a talent at verfification, and a thorough knowledge of the rules of the ftage. He was a rigid cenfor of his own performances, and of thofe of others, and is faid to have occafioned the death of a young author by the feverity of his criticifm on a comedy put into his hands. He died in 1652 about 50 years of age. He had obtained, and richly deferved, the character of an honourable and truly independent man. In the earlier part of life, though ill provided for with refpect to fortune, he chofe to quit the capital with a wife whom he loved, rather than fubmit to the meanneffes which men of letters are too much inclined to practife in courting the opulent. Moreri.

ESTOPPEL, formed of the French *eftouper*, *oppilare*, *obftipare*, to ftop, or block up, in *Law*, an impediment, or bar of action, arifing from a man's own act, or deed; againft which a man is forbidden, by law, to fpeak, though it be to fay the truth. See Bar.

Goddard defines an eftoppel to be any bar, or hindrance, to one to plead the truth; and extends it not only to the impediment given by his own act, but by another's alfo. There are three kinds of eftoppel; *viz.* by matter of record, by matter in writing, and by matter in pais.

ESTOVERS, is ufed by Bracton, (l. iii. tr. 2. c. 18.) for that fuftenance which a man, committed for felony, is to have out of his lands, or goods, for himfelf and his family, during imprifonment.

In ftat. 6 Edw. 1. it is ufed for an allowance in meat, or cloaths. In fome manors the tenants have common of eftovers; that is, neceffary botes, or allowances, out of the lord's wood; in which laft fenfe, eftovers comprehends houfe-bote, hay-bote, and plow bote; fo that if a man have in his grants thefe general words, "de rationabili eftoverio in bofcis, &c." he may thereby claim all three.

Eftovers is alfo ufed for alimony, which if the hufband refufes to pay, there is, befides the ordinary procefs of excommunication, a writ at common law, "de eftoveriis habendis," in order to recover it.

ESTOURMELLES, in *Geography*, a town of France, in the department of the North, and diftrict of Cambray; 1½ league E. of Cambray.

ESTOUTEVILLE, a fmall town of France, in the department of the Lower Seine, 12 miles N. of Caudebec.—Alfo, a fmall town of France, in the fame department, 15 miles N. of Rouen.

ESTRAC, in the *Manege*, fignifies a horfe that is light bodied, lank-bellied, thin flanked, and narrow-chefted. See Belly.

ESTRADE, a French term, literally fignifying a public road, or highway. Hence the military phrafe, *battre l'eftrade*, to beat the eftrade, that is, to fend fcouts, or horfemen to get intelligence, to learn the difpofitions of the enemy, and inform the general of every thing likely to fall in the way. An army never marches without fending batteurs d'eftrade on every fide.

The word is formed of the Italian *ftrada*, ftreet, or road; which is derived from the Latin *ftrata*, a paved ftreet. Some derive it from *eftradiots*, who were cavaliers anciently employed in beating the eftrade.

Estrade is alfo ufed for a little elevation of the floor of a room, frequently encompaffed with an alcove, or rail, for placing a bed in; and fometimes, as in Turkey, only covered with fine carpets, for receiving vifitors of diftinction.

ESTRADES, Godfrey *Count of*, in *Biography*, was at an early age defigned for the profeffion of arms, and ferved under prince Maurice in Holland, with whom he acted as agent of the French court, and afterwards attained the high honour of marfhal of France. He was highly efteemed as a diplomatic character, and in the year 1661 went to England as embaffador extraordinary, where he maintained with fpirit the precedence of the crown of France to that of Spain. In the following year he went to Holland in the fame character, and concluded the peace of Breda. He was intrufted with the important negociation for a general peace at Nimeguen, and acquitted himfelf to the fatisfaction of all concerned. He fuftained with high reputation various other diplomatic characters, and in 1685 was nominated governor to the duke de Chartres, but died within a few months, at the age of feventy-nine. The count left behind him an abundance of MSS. concerning the different negociations in which he had been engaged: from thefe, which confifted of twenty-two volumes folio, a collection was publifhed in 1709, entitled "Letters, Memoirs, and Negociations of the Count d' Eftrades." An improved edition was publifhed in 1743 at the Hague, in 9 vols. 12mo.

ESTRANGEL, Estrangelus, in the Syriac *Grammar*. Eftrangel character, is a particular fpecies, or form, of Syriac letter; ferving as the majufcule letters in that language.

Abraham Ecchellenfis takes the eftrangel character for the true ancient Chaldee characters; and it is certain the Abyffinians, who call themfelves Chaldeans, ftill occafionally ufe the eftrangel character, if we may credit Hottinger, in his Thefaur. Philol. p. 286. Bifhop Walton, in his Prolegomena, gives us an eftrangel alphabet.

ESTRAPADE, in the *Manege*, is the defence of a horfe that will not obey, but to get rid of his rider, rifes much before, and while his forehand is yet in the air, yerks furioufly with his hind legs, ftriking higher than his head was before; and during his countertime goes back rather than advances.

ESTRAY, or Stray, fignifies any tame beaft, or fheep, oxen, fwine, and horfes, or fwans, found within a lordfhip, and not owned by any man; in which cafe being cried, according to law, in the church, and two market-towns adjoining, if it be not claimed by the owner, within a year and a day, it becomes the lord's of the foil where found. If the owner claims it within the year and day, he muft pay the charges of finding, keeping, and proclaiming; and he may feize it, without telling the marks, or proving his property, which may be done at the trial if contefted. If the beaft ftray within the year to another lordfhip, the firft lord cannot retake it. An eftray muft be fed and kept, uninjured, and without labour, till it is reclaimed, or the limited time expires.

ESTREAT, Extractum, in *Law*, is ufed for the true copy, or duplicate, of fome original writing, efpecially of amercements, or penalties, fet down in the rolls of a court, to be levied by the bailiff, or other officer, on every offender. Juftices, commiffioners, &c. are to deliver their eftreats into the exchequer yearly, after Michaelmas; and fines to have writs, which fhall be entered in the eftreat, in order as they are entered in the chancery rolls, &c. ftats. 51 Hen. III. ftat. 5. 16 Edw. II. All forfeited recognizances are to be firft eftreated in the exchequer by fheriffs of counties; on which procefs iffues to levy the fame to the ufe of the king. Stat. 22 and 33 Car. II. cap. 22.

Sheriffs'

Sheriffs' eſtreats muſt be in two parts, indented and ſealed by the ſheriff, and two juſtices of peace; who are to view them, and one of them is to remain with the ſheriff, and the other with the juſtices. Stat. 11 Hen. VII. c. 15. The eſtreats of fines, at the quarter-ſeſſions, are to be made by the juſtices; and to be double, one of which is to be delivered to the ſheriff by indenture. Stat. 14 R. II. c. 2. Fines, poſt-fines, forfeitures, &c. muſt be eſtreated into the exchequer twice a year, on pain of 50*l.* And officers are to deliver in their returns of eſtreats upon oath. Stat. 22 & 23 Car. II. c. 22. 4 and 5 W. & M. c. 24. It is the courſe of the court of B. R. to ſend the eſtreats into the exchequer twice a year, *viz.* on the laſt day of the two iſſuable terms; but in extraordinary caſes there may be a rule to eſtreat them ſooner. 1 Salk. 45.

Estreats, *Clerk of the.* See Clerk.

ESTREES, Francis-Annibal D', in *Biography*, was born in 1573, and educated for the church, in which he had the biſhopric of Noyon conferred upon him by Henry IV. at a very early age. When he was only twenty-one he reſigned his eccleſiaſtical preferment, on account of the death of his elder brother, and aſſumed the profeſſion of arms, in which he became diſtinguiſhed under the title of the marquis De Coevres. He was embaſſador extraordinary to Switzerland and the princes of Italy, in 1614. He was created marſhal of France in 1626, and in 1630 ſuccoured the duke of Mantua, who was beſieged in his capital. In 1636 he was deputed embaſſador extraordinary to Rome, a character in which he well ſupported the honour and intereſts of his crown in oppoſition to pope Urban VIII., with whom, and the nephews of the haughty pontiff, he was continually involved in quarrels. He was recalled by his own ſovereign, which he conſidered as an affront, and refuſed to appear at court, to give an account of his conduct. He died at Paris in 1670, at the great age of ninety-eight years, highly reſpected by his countrymen. At the deſire of cardinal Richelieu, he drew up "Memoirs of the Regency of Mary de Medicis," which was publiſhed at Paris in 12mo. in the year 1660. "A relation of the Siege of Mantua, in 1620," and "An Account of the Conclave, in which Pope Gregory XV. was choſen in 1621," have alſo been given to the public from his papers. Moreri.

Estrees, Cæsar d', ſon of the preceding, was born in 1628, and being brought up to the church, he was raiſed to the biſhopric of Laon in 1653. He was created cardinal by Clement X. in 1671; and at the death of that pontiff entered the conclave, and managed ſo as to put off the election five weeks, till the arrival of the other French cardinals. He was ſent into Bavaria to negociate the marriage of the dauphin in 1677, and afterwards went to Rome, on other important and difficult buſineſs. He ſupported the rights of the crown, and of the Gallican church in oppoſition to pope Innocent XI., whom he prevented from publiſhing any act infringing on both. He reſided many years at Rome, the ſole reſident on the part of France, and exerted much influence at the election of ſucceeding popes. On his return to France he was rewarded with the rich abbey of St. Germain des Pres, where he died in 1714, in his eighty-ſeventh year, greatly regretted, &c. leaving behind him a high character as a politician. Moreri.

Estrees-*Saint-Denis*, in *Geography*, a ſmall town of France, in the department of the Oiſe, chief place of a canton, in the diſtrict of Compiègne, with a population of 1040 individuals. The canton has a territorial extent of 150 kiliometres, with 20 communes, and 10,325 inhabitants.

ESTREMADURA, *i. e. Extrema Durii*, a province of Portugal, bounded on the north by Beira, on the eaſt and ſouth by Beira and Alentejo, on the weſt by the ocean; lying between 38° and 40° N. lat. and obliquely between 7° 10′ and 9° 30′ W. long.; being 140 miles from north to ſouth, and 70 in breadth; containing 5,440 ſquare miles, 8 juriſdictions, 400 pariſhes, and 350,760 inhabitants. Several diſtricts of this province are abundantly fertile, yielding grain, wine, oil, and fruits. The whole country is covered with flowers, and the bees produce a great quantity of honey. The manufacture of ſalt affords one of the chief articles of commerce. The principal towns are Liſbon, Leiria, Abrantes, Pombal, Alcobaca, Setuval. Thomar, Santarem, Alanquer, Torres Vedras, Cintra, and Caſcaes; and the chief rivers are the Tagus, or Tajo, and the Sador or Sado, ſometimes called Cadaon and Caldas.

Estremadura, a province of Spain, bounded on the N. by Leon; on the E. by New Caſtile; on the S. by Andaluſia; and on the W. by Portugal; lying between 38° and 40° N. lat.; and between 7° 10′ and 4° 40′ W. long.: being 140 miles from north to ſouth, and 90 — 1.0 from weſt to eaſt. This province was formerly a part of Portugal, but being ſeparated from that country, it is ſometimes called Eſtremadura of Caſtile. It is traverſed by the rivers Guadiana and Tajo, which divide it into three equal parts. Interſected by ridges of hills, it abounds in grain, fruits, and excellent paſtures; but good water is ſcarce, and the air in ſummer is exceedingly hot, inſupportable to ſtrangers, but to the natives not inſalubrious. The principal commerce conſiſts of cattle and fine wool; and the hills are covered with oaks, the acorns of which feed large herds of ſwine, that are black. The inhabitants are in general inclined to corpulency; and are conſidered as humane, affable, ſincere, ſtout, and brave. The principal towns are Badajoz, Placentia, Coria, Albuquerque, Caceres, Truxillo, Merida, Montejo, Xeres de los Cavalleros, Ellerena, and Zafra; and the chief rivers are the Guadiana, the Tajo, and the Alagon.

ESTREMERA, a town of Spain, in New Caſtile; 27 miles S.E. of Madrid.

ESTREMOZ, a fortified ill-built town of Portugal, in the province of Alentejo, containing three churches, ſix convents, two hoſpitals, and 6500 inhabitants; pleaſantly ſituated on a riſing ground in a fertile country; 7 leagues N.E of the capital; and famous on account of a victory gained by the Portugueſe over the Caſtilians, in the year 1663. In its vicinity there is excellent marble. The country on the weſt ſide of the town is pleaſant and well cultivated, abounding in orange gardens and laurels; but at ſome diſtance no traces of cultivation appear. This town has a manufacture of beautiful earthenware.

ESTREPAGNI. See Etrepagny.

ESTREPEMENT, in *Law*, an impoveriſhing or making of land barren, by continual plowing and ſowing, without due manuring, reſt, and other huſbandry.

The word is derived from the French *eſtropier*, to maim; or the Latin *extirpare*, to extirpate, root up.

Estrepement is alſo uſed for any waſte, or ſpoil, made by the tenant for life, upon lands or woods, to the prejudice of him in reverſion; as the cutting down of trees, or lopping them farther than the law allows, &c.

Estrepement is alſo a writ which lies in two caſes: the one, by the ſtat. of Glouceſter, 6 E. I. c. 13, when a man having an action depending, as a formedon, writ of right, or the like, ſues to inhibit the tenant from making waſte during the ſuit.

The other is for the demandant, who is adjudged to recover ſeiſin of the land in queſtion; and before execution,

 for

for fear of waſte to be made till he can get poſſeſſion, ſues out his writ.

ESTRICH, or Oestrich, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz on the Rhine; 14 miles W. of Mentz.

ESTUCUA, a town of Mexico, in the province of Mechoachan; 58 miles W. of Mechoachan.

ESULA, or Æsulum, in *Ancient Geography*, a town of Italy, ſituated on a mountain, near the Tiber.

Esula, or *Æſula*, in *Botany*, a word ſaid to be of Arabian origin. See Euphorbia *Eſula*, and Apocynum *Venetum*.

ESULÆ Radix, in the *Materia Medica*, the name of a root of a plant of the ſpurge kind, ſometimes uſed in medicine. The root conſiſting of a cortical part, and an inner ſticky one, the bark only is uſed; and ſuch ſhould be choſen as is new dried, and of a reddiſh colour without and within, and ſuch as, when held in the mouth, affords a very diſagreeable taſte, with great acrimony. It is a very violent purge, and has been ſaid to have performed cures in dropſical caſes, when more gentle medicines have proved ineffectual. It is a good method to macerate it a day or two in vinegar before it is uſed.

ESURIS, in *Ancient Geography*, a town of Spain, ſuppoſed to be *Xeres*.

ESUS, or Hesus, in *Mythology*, a deity among the Gauls, to which they ſacrificed after victory whatſoever came alive into their poſſeſſion. They ſometimes ſprinkled the altars of this deity with the blood of their women and children.

ESZEK, in *Geography*, a town of Sclavonia, with a wooden bridge, built by the Turks over the Drave; 48 miles W.N.W. of Peter-Waradin, and 80 N.W. of Belgrade.

ETABLES, a town of France, in the department of the North Coaſts, and diſtrict of St. Brieuc; 2½ leagues N. of St. Brieuc.

ETAIN, or Estain, a ſmall town of France, in the department of the Meuſe, chief place of a canton in the diſtrict of Verdun, 18 miles N.E. of Verdun. It has a population of 2300 individuals, and its canton compriſes 30 communes, with 7125 inhabitants, on a territorial extent of 247½ kiliometres.

ETALLE, a ſmall town of France, in the department of the Forêts, chief place of a canton in the diſtrict of Neufchâteau, with a population of 1080 individuals. Its canton has a territorial extent of 280 kiliometres, and 13 communes, with 9013 inhabitants.

ETAMPES, a ſmall town of France, in the department of Seine and Oiſe, chief place of a diſtrict of the ſame name, with a population of 7786 individuals. It is ſituated on the left bank of the river Juine, at the confluence of two other rivulets, 36 miles E. of Chartres, ; 45 miles N. by E. of Orleans; and 40 miles S. of Paris. N. lat. 48° 25′. The canton contains 14,187 inhabitants, diſperſed in 15 communes, on a territorial extent of 192½ kiliometres.

As chief place of a diſtrict, Etampes has a ſub-prefect, a court of juſtice, and a regiſter office. There are ſome manufactures of hoſiery, woollen, and cotton yarn, and leather. The ſtockings, in particular, are known in the French trade by the name of ſtockings of Beauce, or Bas de Beauce, from the village where the beſt are made.

The ſoil of the diſtrict of Etampes is ſandy: it produces, however, ſome wheat, rye, barley, oats, and hemp. There are a few vineyards and ſome artificial meadows. The diſtrict contains 6 cantons, 111 communes, 1372½ kiliometres, and 58,890 inhabitants.

ETANGS, Les, a town of France, in the department of the Moſelle, and diſtrict of Boulay; 2½ leagues E.N.E. of Metz.

ETAPLES, or Estaples, a ſmall town of France, in the department of the Pas de Calais, chief place of a canton in the diſtrict of Montreuil, with a population of 1360 individuals. It is ſituated at the mouth of the river Canche, which forms a ſmall harbour, 12 miles N.E. of Boulogne, 168 miles N. of Paris. N. lat. 50° 30′ 44″. The canton contains 19 communes, and 7807 inhabitants, on a territorial extent of 232½ kiliometres.

ETAPPE, in *War*, an allowance of proviſions and forage made to the ſoldiers upon march through a kingdom, or province, to or from winter quarters.

Hence, he that contracts with the country, or territory, for furniſhing the troops in their march, is called etappier.

ETARRY, in *Geography*, a town of Hindooſtan, in the country of Bahar; 34 miles S.W. of Arrah.

ETAULIERS, a town of France, in the department of the Gironde, and diſtrict of Bourg; ſeven miles N. of Blaye.

ETASAGGAH, a town of Hindooſtan, in Bahar; 35 miles S.E. of Bahar.

ETAVERAM, a town of Hindooſtan, in the Carnatic; 10 miles E. of Coilpetta.

ETAYA, a circar of Hindooſtan, in the Soubah of Agra, bounded on the N. by Rohilla; on the E. by the circar of Pattan, Canoge an Corah, and on the S.W. by Jumna. Etaya is the capital.

Etaya, a town of Hindooſtan, in the country of Agra, on the N.E. ſide of the Jumnah, 52 miles S.E. of Agra. N. lat. 26° 45′. E. long. 79° 17′.

ETCH, in *Agriculture*, a term ſignifying the ſame thing as erſh. See Ersh.

ETCHAUK, in *Geography*, a town of Bengal, 22 miles N. of Ramgur.

ETCHING, in the *Polite Arts*, an important branch of that ſpecies of engraving which is performed with the view of delivering impreſſions on paper, by means of the rolling-preſs, is the ſuperaddition of the chemical proceſs of corroſion, to the art of drawing through etching-varniſh, (or etching-*ground*, as it is more frequently termed,) on plates of metal; though it has ſometimes been ſucceſsfully performed on other ſubſtances, and particularly on glaſs.

Etching is moſt frequently performed on plates of copper; and (though aqua-tinta be a ſpecies of etching, for which ſee Aqua-tinta) the means commonly employed, are lines drawn with a ſtylus, or ſteel-point, termed an etching-*needle*, which are afterwards corroded by aqua-fortis.

The etching-needle reſembles the dry point (ſee the article Dry-point) in all reſpects, excepting the ſuperior ſharpneſs of the latter, and that it need not be quite ſo long as dry-points are at the firſt. Of theſe needles, the artiſt ſhould provide himſelf with three or four, for etching finer or coarſer lines, of various dimenſions and different degrees of bluntneſs; that for the fineſt or moſt delicate lines being little leſs ſharp than the dry-point. That he may with certainty etch lines of ſimilar ſtrength and depth, where ſuch are required, as in covering a ſurface of an even tint, the extreme point of his needle ſhould be very delicately and gradually rounded off on a leathern ſtrop ſupplied with crocus-martis, or putty-powder.

The practitioner in etching ſhould, moreover, provide himſelf with a ſoft and large camel's-hair bruſh, wherewith occaſionally to ſweep the duſt, and eraſed etching ground, from the ſurface of his work: and an etching-board of from three to ſix inches in breadth, bevelled to an edge on one ſide, ſupported at the ends by ſmall bars of wood about one-third of an inch in thickneſs, and of ſufficient ſpan to ſtand as a bridge over the varniſhed plate, and prevent the engraver's hand from touching and marring his work, ſhould alſo be provided,

provided, and the copper-plate, being previoufly prepared, as fee COPPER-PLATE, he may proceed to lay his etching-ground in the following manner.

The plate is put upon a German ftove, or chafing-difh, and heated over the fire; or, if fmall, is held with a hand-vice, the polifhed fide being upwards, and heated with the flame of paper burning under it; when hot, it is rubbed over with etching varnifh (fuch as is defcribed in the fequel of this article) wrapped up in taffety, which fhould be gently paffed from one fide to the other in a right line, fo as to form feveral rows, till the plate is every where moderately covered; then with a *dabber*, formed of cotton, tied up in Perfian filk, let every part of the plate be beat gently, while the varnifh is in a fluid ftate; and in order to give it a fine grain, and that the varnifh may be equally fpread over the furface of the plate, continue to beat it with the dabber, after the plate is taken from the fire, till it attains a fomewhat harder confiftence in cooling; but the ufe of the dabber fhould be difcontinued long before the varnifh is cold, left it fhould be made to rife from the plate.

When the plate is thus uniformly and thinly covered with the varnifh, it muft be blackened whilft it is yet warm by a piece of flambeau, or of a large wax-candle, or taper, twifted together, till fix or more flames unite in one, which affords a copious fmoke; difpatch is of importance, that the varnifh may not grow cold during the operation, which fhould be performed, if poffible, at one heating of the plate, for repeated melting of the varnifh does it much damage. Large plates may be fufpended from the ceiling of a room by four cords and iron rings, with the varnifhed fide downwards, for the greater convenience of being blackened. Care fhould be taken that the flambeau or candles be kept at a proper diftance from the plate, that the wick may not touch and burn, or otherwife impair the varnifh. The varnifh may be made white, if that colour is preferred to black, by grinding white lead in water, and putting it into a glazed earthen difh, with a little good glue diffolved, and melting the whole together. This mixture is fpread with a brufh or pencil of hog's hairs thinly and evenly on the varnifh laid on the plate and fmoothed. The colour is then left to dry; if it fixes with difficulty on the varnifh, the compofition fhould be mixed with a drop or two of ox-gall.

When the copper-plate is thus varnifhed, and is quite cold, it remains to transfer from paper to the varnifhed plate, the tracing, or outline of the defign. If the outline be reduced from an oil or water-colour picture or other original of larger dimenfions than the intended etching, and be executed with lead pencil or red chalk upon drawing or writing paper, the method moft in ufe among Englifh engravers, is, to take the varnifhed plate and outline to the rolling-prefs printers, and (fuffering the latter to lie between wetted paper for a quarter of an hour or fo, that it may become fufficiently damp for the lead or chalk to be in a certain degree liquified, while the paper is fufficiently foftened to do no injury to the etching ground,) to pafs it through the prefs, the upper roller thereof being fupplied with blankets in the fame quantity, and the prefs adjufted to about the fame degree of preffure, as for printing. If this be carefully performed, the outline will appear at once transferred, and reverfed on to, the furface of the etching-ground, and the artift have nothing to do but to proceed with his etching. By thefe means the trouble both of retracing and *reverfing* (*i. e.* of changing the right hand view of his picture round to the left, and *vice verfâ*, the left to the right, as it would appear if reflected in a looking-glafs,) is faved to the engraver. The method formerly ufed,—which muft ever be ufed where no rolling prefs is at hand, and which is ftill believed to be generally practifed in the other countries of Europe—is, either to trace the outline of the defign on tranfparent paper, that by fimply turning the paper it may be feen in reverfe, or ufing thin drawing paper for the purpofe, to render it tranfparent afterwards by means of oil or varnifh. When this is thoroughly dry, a piece of fan, or other very thin, paper, of the fize of the outline to be traced, muft be evenly rubbed over on one fide with powdered red chalk or black lead, and interpofed between the outline and varnifhed plate, with the chalked or leaded fide downward, and both outline and tracing paper being ftretched tight over the varnifhed plate, and faftened by means of fmall bits of wax placed along the margin, a blunt etching-needle muft be carefully paffed over the feveral outlines with a moderate degree of preffure, which will occafion fo much of the powdered lead or chalk to adhere to the fmoked etching ground, as, when the papers are removed, will exhibit the outline or tracing of the whole defign in all its correctnefs.

Having proceeded through thefe introductory mechanical preparations, which require care and fome knowledge of drawing, the engraver's tafk as an artift, or man of tafte or genius, properly begins. Who fhall prefcribe laws to genius?—He may now exercife the knowledge he has previoufly ftored, and call forth his inventive powers. The forms of his objects muft now be feverally drawn, with fuch tafte and feeling as he may poffefs; and his fhadows, demi-tints, and lights, excepting fuch as he may prefer to leave to be executed by the graver or dry point, be hatched, by employing lines more clofe or more open, and preffing on his needles more lightly or more ftrongly, as a fkilful mufician preffes on the keys of his harpfichord, and as the feveral parts of his work may demand, varying his line with the nature of his object.

The characteriftic, or local advantage of etching, for certain purpofes, over lines cut with the graver, confifts in the unlimited freedom of which this mode of art is fufceptible. The etching-needle, meeting little refiftance from the varnifh, glides along the furface of the plate, and eafily takes any turn that the tafte of the artift may direct, or his hand accomplifh; and hence its peculiar adaptation to the expreffion of that clafs of objects which artifts term picturefque, fuch as trees, rocks, ruins, cottages, the fhaggy hair of animals, broken ground, or other rough and irregular furfaces.

It has formerly been much difputed among the curious, whether Germany or Italy had the honour of giving birth to the invention of etching, and with the view of afcertaining this point, the dates of the impreffions from the earlieft etchings by Albert Durer and Parmegiano have been affiduoufly fought for and compared. The writer of the prefent article conceives that fome portion, at leaft, of this difcuffion and refearch, might have been fpared, had the difputants reflected that etching, originally Etzen, is not an Italian but a German word, and how very unlikely it is that an Italian invention fhould have been denominated by a German word.

Although this art afforded means analogous to the objects themfelves, of drawing and characterifing all thofe objects, of which wildnefs and freedom, communicated by fpontaneous perception and feeling, is the foul, yet engraving with the graver had been previoufly invented, and in the beginning of the fixteenth century impreffions from fuch engravings had called forth the admiration of the tafteful. For thefe reafons, and from the prevalence of thofe habits, and prejudices of tafte and education, which hang like dark veils about the faculties of man, the extent and variety of energy of which etching was capable were not perceived, and

and probably are not even yet perceived; the means of engraving, or manual operation of the graver, was miftaken for the end; and hence a falfe criterion of merit obtained confiderable influence; connoiffeurs gravely put on their critical fpectacles in order to fee in what degree, and how dexteroufly, the etcher had imitated the clear and clean-cut lines of the graver; juft as the early printers with the letter prefs, merely endeavoured to imitate M.S. miffals and bibles, without perceiving the fuperior degree of perfection of which printing was fufceptible. The Sadelers, Le Boffe, and others run into this egregrious miftake, and the latter, who wrote a treatife on the art of engraving, lays it down as a principle, that the perfection of this mode of engraving confifts in the clofe fimilitude of etching to the work done by the graving-tool.

That the efforts of the moft tafteful, bold, and inventive among the engravers of our own country, have largely contributed to difpel thefe prejudices, will be feen towards the clofe of this article. At prefent we proceed with our account of the procefs of etching.

The forms of the feveral objects of which any given etching may confift, being drawn with requifite knowledge and care, and the chiarofcuro, and expreffion of the textures of the feveral fubftances introduced into the compofition, hatched with the degrees of tafte and truth, which the ability of the artift may enable him to difplay, the bufinefs of corrofion, which is technically called *Biting-in*, begins. For this purpofe a border of fuch wax as is of a moderate degree of hardnefs when cold, and of a moderate degree of tenacity whilft warm, muft be applied round the margin of the plate, in the form of a little wall or rampart, about an inch, or three quarters of an inch in height. This wax may be compofed of bees' wax, either tempered with common pitch, or with Venice turpentine and tallow, and at one of the corners a gutter, or fpout, fhould be formed for pouring the aquafortis conveniently off the plate. The plate being thus bordered, it is ufual further to fortify or fecure the work againft the egrefs of the aquafortis whilft biting, by turpentine-varnifh thickened with lamp-black, and applied with a hair pencil on the margin of the plate, and under the infide edge of the rampart of wax. This varnifh or compofition (which is called *ftop-ground*) being fufficiently dry, the aquafortis may be poured on the plate.

We are now arrived at a part of the procefs where experience, combined with chemical knowledge, is the only practical guide on which any thing like found reliance may be placed. Yet a few general rules may not be difpenfed with. The aquafortis may either be pure nitrous acid, diluted with pure water in the proportions of four or five parts water to one of nitrous acid for the more delicate parts of the etching, or it may be the double aquafortis of the fhops diluted with pure water in the proportions of two to one, or fometimes of equal parts, according to the degree of ftrength or delicacy of the fainteft parts of the work. Of aquafortis thus diluted, but which muft be gradually ftrengthened as the work proceeds, let a fufficient quantity be employed to rife, when poured on the plate, about half an inch above its furface. If all things have been rightly conducted, it will now be feen that the menftruum will foon exert its action in thofe lines or hatches where the artift has preffed hardeft on his etching-needle, and will gradually begin to corrode the more delicate lines. It may here be proper to obferve that a feather, or camel's hair brufh, fhould be ufed during the biting, to burft the fmall bubbles of fixed air which are liberated from the copper, and cleanfe away from the lines the verdigreafe which is generated during the operation of the aquafortis: by thus moving the aquafortis to and fro on the plate, it will exert its action uniformly over the whole etching.

In about a quarter of an hour, or when the effects of the aquafortis have become vifible in the more tender parts, it may be poured off, the plate wafhed with clean water, and dried by expofure to the air, funfhine, or (which is now more common, becaufe more expeditious) by the operation of a pair of bellows. After trial made by taking off a fmall portion of the etching-ground with the fcraper, or a fmall piece of pointed charcoal, fuch parts of the etching as are believed to be fufficiently corroded, muft be painted over carefully, or *ftopped-out*, with the compofition of lamp-black and turpentine varnifh which is mentioned above; and when this is dry, the aquafortis muft be re-applied, and the biting proceeded with in the fame manner, till the ftronger parts are judged to be fufficiently corroded, the aquafortis being ftrengthened from time to time according to the judgment of the operator.

To bite-in a large plate will fometimes occupy feveral days, for great judgment and nicety of obfervation are required in gradating the chiarofcuro, and confiderable care muft be exerted in the ftopping-out. It need fcarcely be mentioned, that the operator fhould be as cautious as the neceffary degree of attention to his work will allow, not to inhale the fumes which arife from the mingled copper and aquafortis, which become more and more deleterious, as the biting advances.

When the ftrongeft parts are believed to be fufficiently corroded, and the plate is thoroughly wafhed with water, it may be again placed on the chafing difh, or German ftove, till it be fufficiently warm for the border of wax to be removed, after which, and while it is yet warm, the varnifh may be diluted by the application of a fmall quantity of oil of turpentine or of olives, and wiped off with a rag; when, if the biting-in hath been fuccefsfully accomplifhed, the etching is complete, and in fome cafes the plate is finifhed; though in moft cafes it happens that the engraver's tafte and judgment direct him purpofely to leave certain parts to be finifhed with the dry point and graver.

For an account of the early progrefs of the art of etching, the reader is referred to our account of the GERMAN and ITALIAN *fchools* of engraving. Its more recent improvements have taken place in England. In etching trees, which no other mode of engraving can adequately exprefs, Vivares and Pouncy have difplayed an art of characterizing the fpecies of tree which it was their object to reprefent, and at the fame time of fuggefting in the varying ftyles of their foliage, thofe maffes or countlefs numbers of leaves which are feen in nature itfelf. Their etchings of trees are decidedly fuperior to thofe which have been produced on the continent, unlefs we might except the trees of Waterlo and Kobell, and have rarely been equalled by thofe of the engravers of our own ifland.

He who would fee the moft perfect fpecimens which have been produced of this fpecies of art, fhould look at aquafortis proofs (not the finifhed engravings) which Vivares has produced after Claude, Patel, and Gainfborough; and thofe which Pouncy has etched after Wilfon, Hearne, and Farington. In looking at the former, he will fee with furprife how much Vivares has attained of the peculiar beauty, feeling, and delicacy of Claude's pencil, although he could only have been acquainted with certain pictures:—the larger Colonna Claude for example, from which he has produced a moft exquifite etching—through the medium of chalk drawings, and thofe not very good. It is not lefs worthy of admiration, at leaft of high approbation, to obferve how truly Pouncy has characterized the painting of Wilfon, in his

his etchings of "Athens in Profperity," and "Athens in Ruin," which are alfo executed from chalk drawings copied from the originals of Wilfon in the library of the late Mr. Willett.

In rocks and cottage fubjects Browne has fcarcely been lefs fuccefsful, as may be feen in the aquafortis proofs of the beft of his large plates after Both, Salvator Rofa, and Du Sart. In the rocks of his "St. John preaching," after Salvator Rofa, he is perhaps fomewhat extravagant, and out of harmony with his own figures and foliage, though vigorous and characteriftically rugged; but in "the Cottagers," and "the Jocund Peafants," after Du Sart, he is unrivalled; the feveral textures of the old plafter walls, old planks, thatch, broken ground, rough coated animals, (though thefe are probably etched by Woollett,) and even the flufh which trickles down the hog-trough, are etched with the trueft feeling of nature and Du Sart.

In etching ruins, as well as more perfect architectural fubjects, Piranefi the Roman led the way, and Rooker the elder fuccefsfully followed. Thefe artifts more than perhaps any other, except Mr. Lowry, fhewed the affinity, or fufceptibility of picturefque union, which fubfifts in fine art, between freedom of handling and geometrical precifion; as may be feen with pleafure in the antiquities of Rome and Pæftum, which Piranefi etched from his own drawings; (the original and very mafterly drawings of the temples at Pæftum being preferved in the collection of Mr. C. Lambert of the Temple F. A. S.) in the fix large views of London, which Rooker etched after the drawings of P. Sandby and himfelf; and among numerous other works from the hand of Mr. Lowry, in the plate of the weft door of the cathedral of Carrara from the drawing of Flaxman, as well as in various other plates of architectural and mechanical fubjects, by which this work is illuftrated and adorned, and which confift almoft entirely of etching.

With the view of etching fubjects of this kind with fuperior accuracy and facility, Mr. Lowry, about twenty years fince, invented and began to conftruct feveral inftruments or machines, which it is within the knowledge of the writer of this article have been much employed on the engravings which are fpoken of above. The firft was "for etching fucceffive lines either equidiftant, or in juft graduation from being wide apart to the neareft approximation, *ad infinitum*; the compafs of the inftrument being commenfurate with the poffible demands of the art. The fecond, which is more recently conftructed, is for ftriking elliptical, parabolical, and hyperbolical curves, and, in general, all thofe lines which geometricians call mechanical curves, from the dimenfions of the point of a needle, to an extent of five feet."

Within the laft feven years he has conftructed other machinery for facilitating particular operations in etching, and enfuring precifion in defcribing arches of circles of every poffible radius; lines converging to points at all diftances; various kinds of fpiral lines, and the cogs and fmaller teeth of wheel work; of the feveral ufes and fuperior powers of which machinery, numerous examples may be feen in what has already appeared of this Cyclopædia.

Of thefe inventions it may be truly faid that they combine elegance with utility, and are of high value if only confidered as auxiliaries of the imitative part of this branch of engraving; but as the auxiliaries of chemical, agricultural, and mechanical fcience, they are of incalculable advantage. The accuracy of their operation, as far as human fenfe, aided by the magnifying powers of glaffes, enables us to fay fo, is perfect; and it is not neceffary here to infift on the advantages that muft refult to the whole cycle of fcience, from mathematical accuracy. A hope may be indulged that before the completion of thefe volumes, Mr. Lowry may be induced to favour the public with plates, and particular defcriptions of his various apparatus.

It now remains to defcribe the compofition of the feveral kinds of etching-ground, which have been ufed by different engravers from time to time.

Of etching grounds there are three principal kinds, *viz.* common etching ground, hard ground, and foft ground.

The hard ground was formerly much ufed, being better accommodated to the intention of imitating the engraving with the tool; but the former has now wholly fuperfeded the ufe of the other, as it gives a power of expreffion incompatible with the greater inflexibility of the hard varnifh, which confines the lines and hatches to fuch a famenefs and regularity as give a ftiffnefs of manner, and coldnefs of effect to the work.

There are various directions for preparing the *common* etching-varnifh, which is by far the moft in ufe and the moft worthy of being fo. Le Boffe recommends the following: take of virgin wax, very white and clean, and of grains of maftic very clear and pure, each one ounce; and of calcined afphaltum, half an ounce: grind the maftic and afphaltum feparately, very fmall, and melt the wax over the fire in an earthen pot well glazed. When the wax is thoroughly melted, and very hot, fprinkle the maftic into it gradually that it may melt, and ftir the mixture that the ingredients may incorporate. Then fprinkle the afphaltum into the mixture, ftirring the whole compofition over the fire till the afphaltum be entirely melted: take the pot from the fire, and let the mixture cool; and pour the varnifh into clean warm water, and by working it with the hand, form it into a roll of about an inch in diameter, or into fmall balls, which may be wrapt up in taffety and kept for ufe. The quantity of wax fhould be increafed in winter, in order to attemper the varnifh to the exifting ftate of the atmofphere.

The following varnifh is ufed by many of the engravers at Paris: take of virgin wax, and afphaltum, of each one ounce; half an ounce of black pitch; and a quarter of an ounce of Burgundy pitch: the afphaltum muft be pounded in a mortar, and the wax melted over a flow fire in a pot of glazed earthen-ware, and the reft of the ingredients added by little and little, ftirring the mixture till the whole be well melted and incorporated. Then throw the whole mafs into a veffel of clean warm water, and proceed as before.

Mr. Lowry's recipe for common etching ground is as follows:—To two ounces of afphaltum add one of Burgundy-pitch, and an ounce and a half of white virgin wax. The afphaltum muft firft be finely powdered, and then melted in the glazed earthen veffel over a moderate fire, before the Burgundy pitch is put in: the wax muft be added laft, when the whole compofition muft be well ftirred, and then poured into warm water, to be further incorporated by means of the hands, and made up into balls for ufe.

The *hard* varnifh, which was ufed by Callott and other engravers of the continent, and which was commonly called the Florence varnifh, was prepared in the following manner. Take four ounces of fat oil, very clear, and made of good linfeed oil, like that ufed by painters. Heat it in a new pot of glazed earthen ware, and afterward put to it four ounces of grains of maftic well powdered, and ftir the mixture brifkly till the whole be well melted together, then filter the whole through a piece of fine linen into a glafs bottle with a long neck, that can be ftopt very fecurely, and keep it for ufe.

In laying this varnifh on the plate, it may be fpread evenly with the dabber and fmoked, as before directed, but after

after it is so spread, there remains to dry or harden it over the fire, for which purpose it will be proper to prepare a charcoal fire which shall emit no sparks; it should be contained in a coal-pan or chafing-dish, somewhat larger than the plate, which should be placed over it for the space of from eight to twelve minutes, every precaution being used to prevent dust from approaching the plate. Whilst in this situation the varnish will soon begin to smoke, and when this smoking is observed to decrease, the plate must be removed from the fire, and touched at the side or on the margin with a little piece of hard wood. If the varnish be easily raised by the touch, it is yet too soft, and the plate must be again placed over the fire as before: after a short time it must again be tried with the stick, and if the stick adhere to the varnish so as to require some slight effort to draw it away, the plate must from that instant be left to cool. If on the first trial the stick adhere strongly to the varnish, water must be immediately thrown on the back of the plate, to cool it as quickly as possible, lest a longer continuance of the heat render it too hard, or burn the varnish. When the plate is cold, the artist may proceed with the tracing and etching, as before directed.

The *soft* ground or varnish is prepared simply by mixing common etching ground with animal oil, in proportion of more or less according to the existing state of the atmosphere; a much smaller portion of the oleaginous ingredient being admissible in summer than in winter. If common tallow be used for the purpose, the salt which it may contain should first be precipitated, by dropping the melted tallow into water, and afterward skimming it from the top; but Mr. Gilpin recommends veal suet, and it is probably to be preferred.

The method of using soft ground is as follows. Over a plate thinly covered with this sort of varnish, and smoked as in the case of the common etching ground, the artist cautiously spreads a sheet of very thin paper, which it is best to spread in a damp state, and to fasten with strong paste by the edges, which should be folded over for the purpose on the back of the plate: the paper will thus, when dry, be stretched tight and flat over the surface of the varnish.

All is now ready for the reception of the etching, which is performed simply by making a hatched drawing of the intended subject with a black lead pencil on this paper. Great care must be taken during the etching that nothing but the pencil touch the paper, and for this purpose such a bridge must be employed on which to rest the hand of the artist, as is before recommended. When the drawing is complete, the paper must be carefully removed from the surface of the plate, which must be surrounded with a rampart of wax, and the aquafortis applied as before directed. This is the whole of the process of etching in soft ground. As much of the varnish as it was necessary to remove, in order to admit the aquafortis to the copper, will be found to have adhered to the back of the paper on which the artist has been drawing, which, presuming the plate to be judiciously *bit-in*, will exhibit the exact archetype of the impressions which the etchings will produce.

It remains to be said of etching in soft ground, that the stippling with the graver, which it is sometimes found necessary to add in certain parts, after the plate is bit-in, does not incorporate so thoroughly with the sketchy looseness and chalky texture of the etching, but that a judicious eye will always discover the junction, and a delicate taste will dwell on it with the same kind of dissatisfaction that we regard a modern repair of a fine old picture that has been damaged; and further, that though it be a mode of art extremely well calculated to imitate a painter's sketch or drawing in black-lead or chalk, it is by no means capable of producing a complete abstract of a finished picture.

There are certain local energies peculiar to every branch of engraving. He who should endeavour in mezzotinto or the chalk manner to rival the playful freedom and characteristic taste which is displayed by Vivares in his etchings of trees, would find himself as much mistaken in his aims as he who by etching through soft ground, or on *stone* (for which see Etching *on Stone*,) should attempt to render the delicate blandishments, so as to produce a complete abstract of the full harmony, of the finished works of Correggio or Claude. On the other hand, either of these modes of etching is far more capable of producing a faithful transcript of a drawing hatched with chalk or lead-pencil, than the powers of the graver and aquafortis united on copper, and of multiplying such drawings, certainly affords the most efficient means.

It may not be superfluous to add that it is not the painter's sketches that it is most desirable to multiply, but his finished performances; we wish most to see the mercury of his active imagination amalgamated with the sterling gold of his cultivated understanding; and we justly value an art of engraving as it is capable of rendering or reproducing the pure forms into which this rich mass may be moulded.

Etching *on Stone*. A method of etching on calcareous substances, which may be termed a chemical art of multiplying hatched drawings, has also been recently discovered in England, or recently imported from Germany; and some very spirited sketchy etchings have been executed in this way by the president West, and Messrs Fuseli, Cosway, Barry, and some other members of the Royal Academy. Messrs. Corbould, Stubbs, and C. Heath are also among those who have successfully practised this new art.

The materials were supplied by a gentleman not now in England: the knowledge of the exact proportions of the ingredients of which they consisted, was not imparted to those who made use of them, neither is it believed to have been imparted to any one else; but the materials themselves being known, the proportions may presumptively be ascertained by a little experience.

The stone was of a species resembling that fine-grained stone of a yellowish colour, which is found in large quantities in the neighbourhood of Bath, and is called Bath stone. The etchings were of two kinds; those performed with a crayon, and those performed with pen and ink. The crayon was a mixture of white wax and lamp-black, with a small quantity of shell-lac. The ink consisted of shell-lac, borax, and water, and the stones which received the crayons were ground to a surface somewhat less smooth than those which were prepared for the reception of the ink.

The method of etching is merely *drawing* on the stone with these materials. The mystery, or secret—which any chemist would easily develope—resides in the manner of printing these drawings, and is simply as follows.

The ink is to be prepared as printer's ink is commonly prepared, namely, ground up with oil, and the paper which is to receive the impression must be damped in the usual manner. The etched stone is then to be wetted by immersion in water; when it is taken out, and while it is still wet, the ink being carefully applied on its surface, without violent friction, by means of a printer's ball (such as is used in letter-press printing) will be found to adhere only where the stone has been hatched by the artist, with the crayon or ink, the antipathy of oil to water effectually preventing it from sticking any where else. The paper is now to be placed as in letter-press printing, and a pressure, which need not be very violent,

violent, applied either by means of a roller paſſed over the back of the paper or otherwiſe: a blanket or finer woollen cloth, being interpoſed between the roller and paper.

ETCHING *on Glaſs*, is performed in the following manner: Lay a thin coat of white wax (as etching ground is laid) on the plate of glaſs. On this the drawing muſt be traced in the uſual way. When the ſubject is etched, a border or wall of wax of a very even height muſt be put around: take then ſome fluor ſpar powdered to about the fineneſs of oatmeal, and ſtrew it *evenly* over the etching, and on this pour a mixture of equal quantities of ſulphuric acid and water, till the whole is about the conſiſtence of thick cream: a cover of metal or wood muſt then be laid over, and fitted cloſe on the border of wax, to keep in the fumes of the acid, the eſcape of which would ſo weaken the liquor that it would not act on the glaſs, and would beſides be very hurtful to the lungs.

If the ſubject be to be etched with care, and high finiſhing be required, the acid mixture muſt be taken off occaſionally, and the plate, after being well waſhed and dried, muſt have the parts that are bit-in enough, ſtopped-out, as in common etchings, when the mixture muſt be again put on, and cloſed down as before; and this muſt be repeated till the ſeveral gradations of ſhade are believed to be ſufficiently corroded.

Etchings on glaſs are printed by means of the rolling preſs, and it need ſcarcely be added that much care is requiſite on the part of the printer, leſt the plates of glaſs ſhould ſplit in paſſing through the preſs.

ETEA, or ETIA, in *Ancient Geography*, a ſmall town of the iſle of Crete.

ETELENT, in *Geography*, a town of Aſiatic Turkey, in the Arabian Irak, ſituated on the Tigris; 66 miles N.N.W. of Baſſora.

ETENDUE, *Fr.* in *Muſic*. See COMPASS.

ETEON, in *Ancient Geography*, a town of Greece, in Bœotia.

ETEONOS, a town of Greece, in Eubœa.

ETERNAL FLOWER, in *Botany*. See XERANTHEMUM.

ETERNITY, duration which is conceived incommenſurable with time, and excluſive of beginning, progreſs, ending, &c. See GOD.

Authors are much at a loſs for a proper and juſt definition of eternity: that of Boethius, De Conſol. Philoſ. lib. v. part 6. *viz.* " Interminabilis vitæ tota ſimul et perfecta poſſeſſio, *i. e.* a perfect poſſeſſion of a whole endleſs exiſtence altogether," though retained by S. Thomas and others, is faulty in divers reſpects.

Cenſorinus, De Die Natal. defines eternity by infinite duration, that is, duration which has always been, and always will be. Others more fully deſcribe it by a duration that exiſts altogether without any flux or ſucceſſion of parts prior or poſterior to each other; where the word duration, taken abſtractedly, imports no more than the perſeverance of a thing in its exiſtence, the τὸ *durare* being here oppoſed to the *τὸ ceſſare, in exiſtendo.*

But ſoften the word duration how you will, it is ſcarcely conceivable but by conceiving a quantity thereof, nor a quantity without conceiving a ſucceſſion. Others, therefore, define eternity by a *perpetuum nunc*, a perpetual now, or a *nunc ſemper ſtans*, an everſtanding now; but neither are theſe unexceptionable, the words *perpetuum* and *ſemper ſtans* importing an obſcure ſort of duration. See DURATION.

ETERNITY, in *Mythology*, a divinity among the Romans, who had neither temples nor altars. They repreſented it under the figure of a woman, who held the ſun in one hand and the moon in the other: her ſymbols were a phœnix, globe, and elephant.

ETERNOZ, in *Geography*, a town of France, in the department of Doubs, and diſtrict of Quingey; 2½ leagues S.E. of Quingey.

ETESIÆ, or ETESIAN *Winds*, are ſuch as blow at ſtated times of the year, from what part ſoever of the compaſs they come. They are ſo called from the Greek word ἔτος, *year*, being yearly or anniverſary winds, ſuch as our ſeamen call monſoons and trade-winds, which, in ſome parts of the world, continue conſtantly blowing for certain ſtated ſeaſons of the year. Thus the north winds, which, during the dog-days, conſtantly blow upon the coaſts of Egypt, and hinder all ſhips from ſailing out of Alexandria for that ſeaſon, are called eteſiæ in Cæſar's Commentaries. In other authors, the weſt and eaſt winds are called eteſiæ, when they continue blowing for certain ſeaſons of the year. Vide Salmaſ. Exercit. in Solin. p. 421.

Cellarius endeavours to prove that thoſe winds are properly eteſian which blow from that part of the horizon which is between the north and weſt about the time of the ſolſtice. Geog. Antiq. lib. i. cap. 8. See MONSOON and WIND.

ETETA, in *Ancient Geography*, a town of Upper Myſia, according to Ptolemy; called Ægeta in the Itinerary of Antonine.

ETFU, or EDFOU, in *Geography*, a village of Upper Egypt, ſituated near the Nile, above Eſneh, built on the ruins of the great city of Apollo, or Apollinopolis Magna, and now governed by an Arab ſcheik. It poſſeſſes an ancient temple, covered with hieroglyphics, among which, ſays Savary, we diſtinguiſh men with falcons' heads. Its inhabitants were enemies of the crocodile. The extent, majeſty, and preſervation of this edifice, ſays Denon, who has given a view of it, " ſurpaſſed all that I had ſeen in Egypt, or elſewhere; it made an impreſſion on me as vaſt as its own gigantic dimenſions. This building is a long ſuite of pyramidal gates, of courts decorated with galleries, of porticoes, and of covered naves, conſtructed, not with common ſtones, but entire rocks." " The excellent preſervation of this ancient edifice forms a wonderful contraſt with the grey ruins of modern habitations built within its vaſt incloſure; a part of the population of this village is contained in huts built in the courts, and around the fragments of the temple; which, like ſwallows' neſts in our houſes, defile them without concealing or injuring their general appearance." Below Etfu, the cultivated country becomes very narrow, ſo that there is only a quarter of a league in breadth between the deſert and the river.

ETHAM, in *Ancient Geography*, a town of Egypt, ſituated in the deſert, which gave name to the lower part of the Red ſea, oppoſite to Magdalum. It was the third ſtation of the Iſraelites in their eſcape from Egypt.

ETHELBERT, in *Biography*, king of Kent, ſucceeded to the throne about the year 560. He began his reign with a reſolution to revive the reputation of his family, which had been ſinking in the ſcale of monarchy; with this view he made war upon the king of Weſſex, by whom he was twice defeated, though he was afterwards triumphant, and acquired the complete aſcendancy over Weſſex and the other ſtates, except Northumberland, and reduced them to the condition of his tributaries or dependants. In the reign of Ethelbert, Chriſtianity was introduced into England. The king had married Bertha, daughter of the king of Paris, who being a Chriſtian, had ſtipulated for the free exerciſe exercife of her religion, and had carried over in her train a French bifhop. So exemplary in every refpect were her life and conduct, that fhe infpired the king and his court with a high refpect for her perfon, and for the religion by which fhe appeared to be influenced. The pope, taking advantage of this circumftance, fent a miffion of forty monks, at the head of whom was Auguftine, to preach the gofpel in the ifland. They landed in Kent in 597, and were well and hofpitably received by Ethelbert, who affigned them habitations in the ifle of Thanet. A conference was held, and the king took time to confider of the new doctrines propounded to him; and in the mean while gave them full liberty to preach to his fubjects. Numbers were converted, and at length the king fubmitted to a public baptifm. Chriftianity proved the means of promoting knowledge and civilization in this ifland; and the king, with the confent of his ftates, enacted a body of laws, which was the firft written code promulgated by the northern conquerors. Ethelbert died in the year 616, and left his crown, after a reign of 50 years, to his fon Edbald. Hume's Hift of Eng.

Ethelbert, king of England, was fon of Ethelwolf, and fucceeded to the government of the eaftern part of the kingdom in 857, and in three years afterwards he became fole king. He died in 866, but had, in the courfe of his reign, fhewn a confiderable fhare of vigour in defending his dominions from the inroads of the Danes, who at that period were cruel enemies to this country, and continued to ravage one part as they were repulfed from another. Hume.

ETHELEUM, in *Geography*, a river of Afia, which feparated between the Troade and Myfia.

ETHELING, or Ætheling. See Atheling.

ETHELRED I., in *Biography*, king of England, fon of Ethelwolf, fucceeded his brother in the year 866. The reign of this monarch was fhort but full of troubles. The Danes had already gained an afcendancy over the kingdom, and feemed now to threaten it with entire conqueft. The enterprifing Alfred united his fkill to the power which his brother the king was able to call forth; they purfued the invaders from place to place, and drove them from the centre of Mercia. The Mercians, carelefs of their liberties, or jealous of the fuperiority which victory was likely to give to the monarch, refufed to co-operate with him, and Ethelred was under the neceffity of oppofing the Danes with his Weft Saxons alone. With thefe he was generally fuccefsful, till large reinforcements were fent to fupport the invaders, which enabled them to make a ftand againft the natives. The actions fought were frequently very bloody, and in one of them Ethelred was wounded. He died in 871, leaving his crown to the immortal Alfred; of whom we have already fpoken. Hume's Hift.

Ethelred II. king of England, was fon of Edgar, and brother to Edward the Martyr, whom he fucceeded to the crown in the year 978. He was at this period a minor, and from his want of capacity and vigour in the affairs of government he was, in his riper years, characterized by the epithet of "The Unready." No man, however, ftood more in need of exertion and enterprife, for the Danes, who had for feveral years forborne all depredations, renewed their attacks with the utmoft fury; and meeting with little oppofition, they became more bold, till, at length, in the year 993, under Sweyn king of Denmark, and Olave king of Norway, they made a formal invafion of the country. At firft nothing feemed to oppofe the rapidity of their progrefs: and they laid fiege to London, which was valiantly and fuccefsfully defended by the citizens. A miftaken policy in behalf of the Englifh induced them to purchafe the departure of the invaders, who, in 997 and 998, returned in large bodies, laid wafte the fouthern parts of the kingdom, and demanded a ftill larger bribe than they had before received. To ftrengthen himfelf by a foreign connection, Ethelred married, in 1001, Emma, fifter to Richard II. duke of Normandy. In the following year a dreadful maffacre took place, on the fame day throughout England, of all the Danes fettled in the kingdom. The Englifh in this inftance were the willing inftruments in the hands of the king to execute his bloody orders. They fpared neither age nor fex; even a fifter of the Danifh fovereign, who had married an earl, and had conformed to the Chriftian profeffion, was barbaroufly murdered, having already witneffed the death of her hufband and infant children. Such revenge, fays the hiftorian, added nothing to the ftrength of the nation, but rendered its enemies more implacable. In 1003, Sweyn again invaded the ifland, and carried defolation all along the Weftern coaft. On a fubfequent occafion the bold invader obliged the nobles to fwear allegiance to him as king of England, while Ethelred, in 1013, fled into Normandy with his family. Sweyn maintained his power only a year, when death put an end to his reign, and Ethelred was recalled by his loyal fubjects. He refumed the government, but had not learned that wifdom which his misfortunes were calculated to teach; he fubmitted to Canute the fon of Sweyn, whofe valour and activity he was unable to refift. Ethelred died in 1016, after an inglorious reign of thirty-five years. Hume.

ETHELWOLF, king of England, fucceeded his father Egbert in the year 838. Little ambitious of government, one of his firft acts was to give his eldeft fon, Athelftan, the fovereignty over Effex, Kent, and Suffex. His whole reign was molefted by the incurfions of the Danes, and about the year 851 they became fo formidable as to threaten the total fubverfion of the government. The natives were not inactive, but oppofed the enemy with the utmoft vigour; neverthelefs they took up their winter-quarters in England, and before they returned, burnt Canterbury and London. In the midft of thefe dangers the king, excited by a fpirit of devotion, made a pilgrimage to Rome, where he remained about a year, being accompanied by Alfred, who was afterwards king. During his abfence he left his eldeft fon Athelftan as regent, who foon after died, and thus afforded an opportunity to his ambitious brother of feizing the reins of government with an intention of dethroning his father. To avoid the evil confequences of civil war the king, without hefitation, ceded the weftern part of his dominions to his fon. After this, influenced, in all probability, by the intriguing monks, he fummoned the eftates of the whole kingdom, and folemnly conferred upon the clergy the tithes of all the produce of the lands. This act of piety, as it was denominated, was confidered as the moft effectual meafure for refifting the Danes. Ethelwolf died in 857. Hume.

ETHER, in *Chemiftry*, is a light, odorant, inflammable liquid, produced by the action of certain of the acids upon alcohol. The acids that have actually been employed for this purpofe are the fulphuric, the nitric, the muriatic, the acetic, and the fluoric; whence originate as many fpecies, or perhaps varieties of ether, all of which we fhall defcribe in due order.

§ 1. *Sulphuric ether.*—The method of preparing this fubftance is firft mentioned in the Difpenfatory of Valerius Cordus, publifhed about the year 1540; it was alfo known to Bafil Valentine, Paracelfus, and Boyle: it had, however, attracted the notice of chemifts only in a very imperfect degree, before it was defcribed by Froben, a German, in the Philofophical

Philofophical Tranfactions for 1730. Since that period the preparation and properties of fulphuric ether have been carefully inveftigated by many able chemifts, efpecially Scheele, Dollfufs, Macquer, Pelletier, Vauquclin and Fourcroy.

The mode of obtaining ether in the fmall way is as follows. Take a tubulated glafs retort, of the capacity of about fix quarts, lengthen its beak by an adopter, and pafs the other end of the adopter into a two-neck quilled balloon receiver; fix another adopter into the oppofite neck of the balloon, and join to this a common quilled balloon receiver, placed in fuch a pofition that the quill, inftead of pointing directly downwards, as in the firft receiver, fhall flant gently upwards; then lute all the junctures with linfeed meal or common pafte, except that of the retort to the firft adopter; fix alfo a 24 ounce vial to the quill of the firft receiver, and loofely clofe the quill of the fecond with a cork or plug of moift paper. The lute being moderately dry and hard, withdraw the retort, and pour in through the tubulure 40 ounces by weight of rectified alcohol, and 32 ounces of the ftrongeft fulphuric acid. Replace the retort with its contents, being careful to fhake it as little as poffible, and let it remain for 12 hours or more, during which the acid and alcohol will gradually act on each other, producing a confiderable degree of heat. Afterwards withdraw the retort, and mix together its contents as accurately as poffible, by communicating to them a gentle circular motion; this being finifhed, replace the retort, and carefully clofe by lute its junction with the adopter, and leave the whole in this ftate till the contents of the retort have acquired a reddifh-brown colour, which will take place in a day or two. Now proceed to diftillation, by placing a pot of lighted charcoal beneath the retort, obferving to heat it very gradually. The firft impreffion of the fire drives off a little highly dephlegmated alcohol, but as foon as the mixture begins to boil, the ether itfelf paffes over and condenfes on the fides of the receiver in large ftreaks. It is now effentially requifite to keep the receiver as cool as poffible, by the application of ice or of wet cloths wrung out in cold water and frequently renewed; and if this is properly attended to, by far the greater part of the ether will be condenfed in the firft receiver, whence it will flow into the vial beneath; a little, however, will pafs through the fecond adopter into the fecond receiver, where it muft be condenfed by the fame means as have already been recommended. The contents of the retort are to be kept moderately boiling, till fulphurous acid gas begins to pafs through the quill of the fecond receiver, which may be known at once by its ftrong fuffocating odour. As foon as this is perceived, the fire is to be withdrawn, and the vial is to be detached from the receiver, and its contents poured into a ground-ftoppered bottle; being then replaced as before, the procefs of diftillation is to be re-commenced till about fix or feven ounces of a coloured liquid are produced, after which the operation is to be ftopped. The original mixture of fulphuric acid and alcohol is thus divided into three feparate products; namely, the refidue in the retort, and the products of the fecond and firft diftillations. In the retort is a black thickifh matter, fmelling ftrongly of fulphurous and acetous acids, and intenfely four to the tafte. If diluted with an equal bulk of warm water and filtered through pounded glafs or clean white fand, it will be feparated from the carbonaceous matter with which it was loaded, and by fubfequent boiling the fulphurous and acetous acids will be driven off, leaving behind fulphuric acid in a confiderable degree of concentration, and applicable to a variety of ufeful purpofes. The product of the fecond diftillation confifts of two diftinct liquids, the heavieft of which is acidulous water, and the lighter an impure ether, called *oil of wine*, which may be feparated from the water by inverting the vial that contains them in warm water; a little of the ether is in confequence converted into elaftic vapour, which forces out of the vial the lower and heavier fluid. The product of the firft diftillation is impure ether, in quantity about $17\frac{1}{2}$ ounces. Thus from 32 ounces of fulphuric acid and 40 ounces of alcohol there are procured about $17\frac{1}{2}$ ounces of impure ether, and three ounces of oil of wine; and the fulphuric acid that may be recovered, taking into confideration its quantity and denfity, amounts to about 46 per cent. of that originally employed.

Ether, when frefh diftilled, is contaminated by fulphurous and acetous acids and a little coloured oil, in confequence of which it is neceffary to purify it by rectification. This is generally done by adding to the ether fucceffive portions of cauftic potafh or foda diffolved in water, and fhaking together the two fluids in a well clofed bottle, after each addition of alkali, till the fulphurous odour is totally deftroyed; the contents of the bottle are then to be poured into a retort, and by the application of a gentle heat, never amounting to ebullition, the ether will pafs into the receiver in a ftate of great purity, leaving behind a watery faline liquor covered by a thin film of brownifh-yellow oil. Scheele recommends that the alkali employed in rectification fhould be diffolved in alcohol inftead of water; the advantage of which is that no fpontaneous feparation of the liquors takes place, and therefore the fulphurous and acetous acids are neutralized and feparated with greater certainty. Diftillation at a gentle heat will readily feparate the ether from the other ingredients. A ftill cheaper and very effectual method of rectifying ether is the following, firft employed by Mr. Woulfe. "Fill three-fourths of a bottle with the impure ether, add a little water and a portion of flacked lime; agitate the bottle with violence, and keep it for fome time in cold water, before taking out the cork; if the fmell of the fulphurous acid be not removed, add a little more lime and agitate a fecond time. Decant off the ether into a receiver, and diftil it off." Another very cheap and ingenious procefs was invented by Pelletier. It confifts in adding to the impure ether a little finely pulverized black oxyd of manganefe. The mixture being corked up in a bottle, is to be well fhaken four or five times a day for the fpace of a week, at the end of which time the fulphurous acid will have been converted into fulphuric, and will have combined with the manganefe, from which the ether may be poured off without the neceffity of diftillation.

By any of the above methods ether is rectified fufficiently for any purpofes to which it is ufually applied; but if the greateft poffible degree of purity is required, there fhould be added to the rectified ether fucceffive portions of dry pulverized muriat of lime, till it ceafes to be diffolved; from this mixture, by diftillation with a very gentle heat, and keeping at the fame time the receiver quite cold by the application of ice, an ether may be procured, probably entirely free from alcohol and water, and of the fpecific gravity of 0.65.

Rectified ether exhibits the following properties. It is a tranfparent colourlefs liquor, of a peculiar and to moft perfons an agreeably fragrant odour, and a hot penetrating, and fomewhat fuffocating tafte. Its ufual fpecific gravity, according to Lavoifier, is $=0.758$. It is volatilizable at a lower temperature, and more rapidly than any other liquid; a confiderable proportion being loft, efpecially in hot weather, by merely pouring it from one vial into another; hence the veffels in which it is kept ought to be very exactly clofed, and for further fecurity are often kept inverted in cold water.

water.

water. It boils at 98° Fahr. under the ufual atmofpherical preffure, and at 20° in vacuo.

Owing to the extraordinary rapidity with which ether evaporates, it poffeffes a very great power of refrigeration. This is made obvious to the feeling by pouring a little into the palm of the hand; it is almoft inftantly volatilized, and the hand becomes painfully cold. So alfo if fome fine tow is wrapped about the bulb of a fmall thermometer, and the blaft from a pair of double bellows is let upon it, after it has been well foaked in ether, the mercury in the thermometer will, in the fpace of a minute or lefs, be lowered to 0° Fahr. Ether, notwithftanding its ready volatility, is capable of being congealed at a low temperature. If a fmall matrafs filled with this fluid is cooled down to —25° Fahr. by a mixture of fnow and muriat of lime, the liquor becomes gradually filled with brilliant tranfparent cryftalline laminæ, refembling benzoic acid or oxymuriat of potafh; and prefently, efpecially at a fomewhat lower temperature, the whole is congealed into a white almoft inodorous mafs. Ether is remarkably inflammable, taking fire inftantly on the near approach of an ignited body; it burns with a large white flame and a little fmoke, and is refolved into water, carbonic acid, and a minute quantity of charcoal. When paffed through a red-hot earthenware tube, it is entirely decompofed, and a large production of carburetted hydrogen takes place. Ether remarkably increafes the bulk of any of the permanent gaffes to which it was added, as was firft obferved by Dr. Prieftley. A fmall quantity of this fluid being mixed with oxygen confined over mercury, exactly doubled its bulk, nor could any additional quantity occafion a further dilatation. Nearly the fame effect took place with atmofpheric air, azot, hydrogen, nitrous gas, and carbonic acid; but by a flight agitation in water the ether was abforbed, and the gas refumed its former dimenfions without any alteration of its original properties. If oxygen gas thus diluted by ether is fet fire to, it burns rapidly, but does not explode; but if one part of this mixture is added to three parts of oxygen, the application of an ignited body, or of the electric fpark, caufes a violent explofion, the products of which are water and $2\frac{1}{2}$ parts of carbonic acid. Hence it appears that one part of ether requires 6.8 of oxygen for its faturation, and that the proportion of carbon to hydrogen in fulphuric ether is nearly as 5 to 1.

Water and ether appear to combine with each other in two different proportions. If equal parts of thefe fluids are fhaken together in a graduated tube, the ether will be found to have diminifhed in bulk about $\frac{2}{10}$, and the water to have enlarged in nearly the fame proportion; the lower fluid confifts of water faturated with ether, and the upper fluid is ether combined with a little water. The ether in this ftate is faid to be *wafhed*, and acquires in confequence fome properties which pure ether does not poffefs; in particular, it is now capable of diffolving caoutchouc with great eafe, whereas this fubftance is acted on by pure ether only in a very imperfect manner. Phofphorus is foluble in ether, but the folution is not luminous. When ether is boiled with phofphorus, it often depofits cryftals by cooling; agitation with water produces no change in this liquid, but the addition of a little alcohol caufes an immediate turbidnefs, whence the fophiftication of ether by alcohol may be detected by the addition of a few drops of phofphorized ether. The fixed alkalies feem incapable of uniting with ether, but ammoniacal gas is abforbed by it very copioufly. The fame may be obferved of nitrous gas; but neither of thefe combinations has hitherto been fubmitted to an accurate examination. Sulphuric acid acts on ether with confiderable energy, efpecially if affifted by a gentle heat; it is converted into a brownifh oily fluid, much heavier than ether, called oil of wine, and at a higher temperature is changed into olefiant gas. With regard to the action of oxymuriatic acid on ether, a curious experiment is related by Mr. Cruickfhank. "If we fill a bottle of the capacity of three or four pints with the pure oxymuriatic acid gas, taking care to expel the water as completely as poffible, and then throw into it about a drachm or half a drachm of good ether, covering its mouth immediately with a piece of light wood or paper, in a few feconds white vapour will be perceived, moving circularly in the bottle; this will foon be followed by an explofion, accompanied by flame, at the fame time a very confiderable quantity of carbon will be depofited, and the bottle will be found to contain carbonic acid gas." Nitric acid excites a confiderable effervefcence in ether, and feems to convert it into oil of wine. The effential oils are foluble in ether, and it combines with alcohol in almoft all proportions.

Concerning the theory of etherification, much has been written, and many experiments have been made by able chemifts, without, however, obtaining the fatisfaction that could be wifhed. According to Macquer, ether is a fubftance intermediate between alcohol and oil, and alcohol approaches to the ftate of oil precifely in proportion as it parts with its water of compofition. But though it is true that the production of water accompanies the converfion of alchohol into ether, and of ether into oil of wine, yet this is by no means the only phenomenon, fo that the theory of Macquer is, at beft, imperfect, fince the depofition of charcoal, and the generation of acetous acid, are not at all accounted for. According to Pelletier, Chaptal, and others, the whole procefs of etherification confifts in a transfer of oxygen from the fulphuric acid to the alcohol: the difengagement of fulphurous acid accompanies the production of ether, and therefore fhews that the fulphuric acid is deoxygenated: the oxygen, thus feparated, does not come over in the ftate of gas, and therefore muft be combined with the alcohol forming ether. But in reply, it may be obferved, that this mode of explanation accounts for only a few of the phenomena, and that the preparation of ether, if carefully managed, may be carried on without the difengagement of any fulphurous acid. The moft elaborate enquiry into this intricate fubject was undertaken by Vauquelin and Fourcroy, which we fhall now proceed to detail, though it is by no means fo complete and fatisfactory as to preclude the neceffity of further refearches. The facts and obfervations by which this theory is fupported are the following.

If one part of alcohol and two of fulphuric acid are mixed together, the temperature rifes to about 200° Fahr.; the mafs immediately acquires a deep brownifh-red colour, which deepens into black in a few days after, and at the fame time exhales a vapour manifeftly ethereous.

Equal parts of concentrated fulphuric acid and rectified alcohol acquire on mixture a temperature of 190° Fahr.; bubbles of gas are extricated, the liquor becomes turbid and opalefcent, and at the end of a few days acquires a deep red colour. The whole being then transferred to a diftillatory pneumatic apparatus, and being heated to 107° Fahr., ebullition takes place, and ether paffes over into the recipient; if the operation is carefully conducted no elaftic fluid is difengaged, and the vapour, when condenfed, is found to be only water and ether. When the liquor thus obtained amounts to about half of the alcohol employed, fulphurous acid begins to be manifeft, and, in a fhort time, the production of ether ceafes, and is fucceeded by oil of wine, accompanied by acetous acid. The contents of the retort being kept boiling, and becoming more and more concentrated as the

the diftillation proceeds, are conftantly acquiring a higher temperature; when this amounts to about 234° Fahr., olefiant gas begins to come over, and continues till the oil of wine ceafes to flow. At this period carbonic acid gas firft makes its appearance, and water and fulphurous acid ftill continue to be produced, the refidue in the retort being in the mean time reduced to little elfe than fulphuric acid thickened by charcoal.

From thefe facts the able chemifts who obferved them have concluded,

1. That the fpontaneous action of alcohol and fulphuric acid, when this latter is confiderably in excefs, is fufficient for the formation of ether without the affiftance of any extraneous heat, and that by duly proportioning the two fubftances, the alcohol might be wholly decompofed and made to yield all the ether of which it is capable when treated in the ufual manner.

2. That the formation of ether is not owing to the affinity of the oxygen of the fulphuric acid, for the hydrogen and carbon of the alcohol, becaufe in the preparation of ether no fulphurous acid gas is evolved till the production of ether has almoft ceafed. It muft therefore be the entire attraction of the acid for one or more of the elements of the alcohol that determines its decompofition: now fince water is formed during the whole procefs, and, fince the attraction of fulphuric acid for this fubftance is very powerful, it appears likely that this is the caufe that deftroys the equilibrium of the affinities by which the elementary particles of alcohol are retained in combination, and induces the oxygen and hydrogen to unite and form water. Hence it might at firft fight be fuppofed that ether differs from alcohol in containing a fmaller proportion of oxygen and hydrogen. This however will not be found to be the cafe, when we advert to the depofition of charcoal, which, equally with the production of water, accompanies the formation of ether: now the amount of charcoal depofited is greater in proportion to that which is left, than the hydrogen of the water compared to what remains in the ether; therefore this latter fluid, though compofed of the fame elements as alcohol, differs from it in containing a fmaller proportion of carbon compared with the hydrogen. During the progrefs of diftillation the heat to which the materials in the retort are expofed is conftantly increafing, and (the affinity of the acid and alcohol alfo augmenting) the acid itfelf is at length decompofed, fulphurous acid is generated, and the excefs of oxygen deprives the alcohol of part of its hydrogen whence refults the oil of wine, differing from ether in containing a larger proportion of carbon; and in confirmation of this, it may be obferved, that the charcoal depofited during the production of oil of wine is not fo abundant as during the generation of ether.

Hence as (according to the authors of the above hypothefis) no decompofition of the fulphuric acid takes place during the formation of ether, the agency of the acid is partly that of detaining the alcohol in a temperature more than fufficient for the volatilization of this fluid when uncombined, and partly that of affifting the caloric to decompofe the alcohol in confequence of its own powerful affinity for water.

A circumftance, however, firft remarked by Scheele, but which has hitherto failed to obtain the notice to which it is fo well entitled, fufficiently proves that in the formation of ether the acid employed acts a much more important part than is affigned to it in the theory of Vauquelin and Fourcroy. The admirable chemift above-mentioned ftates that if fulphuric ether be duly rectified by agitation with cauftic alkali and fubfequent diftillation, it occafions no precipitate with barytic falts; but if to the ether thus purified there be added nitric acid, a copious precipitate is then produced by any of the foluble falts of barytes, indicating the prefence of fulphuric acid. This fact ftrikingly points out that a portion of the bafe of the acid in a more or lefs deoxygenated ftate actually combines with the alcohol to compofe ether. A like fact refpecting muriatic ether is alfo mentioned by Scheele, namely, that though this ether, when rectified, occafions no decompofition of nitrated filver, yet the watery refidue, after combuftion of the ether, occafions a copious precipitate of muriated filver when mixed with the nitrat of this metal.

§ 2. *Nitrous ether.*—Although nitrous ether appears to have been known to Bafil Valentine and Kunkel, yet the mode of its preparation being kept a fecret, it foon ceafed to be attended to by chemifts, till in the year 1740 it was re-difcovered by Duhamel, and afterwards was more particularly defcribed by Navier, Sebaftiani and others. It was prepared by Navier in the following manner. Put 12 ounces of rectified alcohol into a ftrong bottle, and add to it gradually and at intervals 8 ounces of ftrong nitric acid; after each portion of acid the liquors are to be well mixed by agitation, and the bottle is to be kept clofe corked and immerfed up to its neck in ice and water; when the whole of the acid has been added, the bottle is to be well corked and further fecured by a leathern cap. A ftratum of ether rifes by degrees to the furface of the liquor, and after five or fix days the cork is to be pierced by a needle in order to let out the nitrous gas formed during the procefs: this gas having efcaped, the cork is to be drawn, and the whole contents of the bottle being poured into a feparatory funnel, the ether is thus procured unmixed with the heavier fluid on which it floats. This is, however, a very rude way of proceeding, and is attended with the utmoft rifk to the apparatus, the ether obtained alfo is in fmall quantity, and very impure. In order to prevent the violent and rapid action of the concentrated acid on the alcohol, which is the chief difficulty in the preparation of nitrous ether, Dr. Black propofed to interpofe a thin ftratum of pure water, and Fifcher on the fame principle made ufe of a little weak fpirit of nitre for the fame purpofe. M. Dolfufs, from a careful repetition of the latter procefs, obtained the following refult. Upon two ounces of very ftrong nitric acid he poured gently fix drachms of the fame very much diluted, and upon this three ounces of rectified alcohol. The bottle was loofely corked and fuffered to ftand undifturbed for three days; at this time the lower liquor appeared perfectly homogeneous with a ftratum of ether floating above it. The whole being put into a retort and fubjected to a gentle heat, there were obtained two ounces and a drachm of very pure ether unmixed with any acid, and the refidue in the retort confifted of weak acetous acid mixed with oxalic acid, nearly the whole of the nitrous acid having been decompofed.

The laft mode by which nitrous ether may be prepared, that we fhall mention, and which on the whole appears to be the beft, confifts in mixing together alcohol and fulphuric acid, and pouring the liquor upon pulverized nitre; the fulphuric acid difengages the nitre, which immediately re-acts on the alcohol, and ether is the refult. The able chemift whom we have already mentioned has fhewn the excellence of this method by the following experiment. Having put into a retort four ounces of perfectly dry and pulverized nitre, he added to it a mixture confifting of two ounces of concentrated fulphuric acid, and four ounces of alcohol. The whole being fubmitted to diftillation, there came over firft fix drachms of dulcified fpirit of nitre, and then three ounces of a liquor from which by fubfequent rectification were procured two ounces of pure ether.

Nitrous

Nitrous ether, when recently made, contains in loofe combination a confiderable quantity of nitrous gas, which in fome degree modifies its properties, and renders it peculiarly liable to burft the bottles in which it is kept, efpecially in warm weather. This lofs and trouble, however, may be avoided by rectifying the ether, which is beft done in the following way. Pour into a ftrong vial fo as to fill it two thirds, one part of ether and four parts of pump-water, and agitate it cautioufly at firft, frequently removing the thumb from the mouth of the vial in order to afford a free paffage to the difengaged nitrous gas: when no more of this gas is given out add a quantity of dry pearlafh equal in weight to the ether, and fhake the whole well together; then put the mixture into a tubulated retort and proceed to diftillation, taking care that the temperature does not exceed 120° Fahr.; the ether will pafs into the receiver quite pure, and may be kept for any length of time in ftrong well clofed bottles, with no more rifk of accidents than fulphuric ether is fubject to.

Nitrous ether refembles fulphuric ether in moft of its properties; it has, however, a dilute yellow colour, and a fomewhat different odour and flavour; this appears to be owing to the prefence of a little refinous matter, from which it can never be entirely freed; by repeated diftillations from frefh parcels of dry white fugar, as Deyeux has obferved, this impurity may, in great part, be feparated, and in proportion as this takes place the ether becomes more and more analogous to that prepared by fulphuric acid.

Nitrous ether appears capable of uniting with nitrous gas in two proportions; when the ether is in excefs it forms nitrous ether in the ftate in which it appears previous to rectification; when the nitrous gas exceeds the ether it forms a permanently elaftic fluid that has obtained the name of *etherized nitrous gas*. The preparation of this differs only in the rapidity with which the nitrous acid and alcohol are made to act on each other: when the combination takes place very flowly much ether and little etherized gas are the refult, but when the contrary is the cafe, thefe two products are formed in an inverfe proportion. If equal parts of alcohol and ftrong nitrous acid are mixed together at the common atmofpheric temperature, or at a higher heat in proportion as the acid is diluted, a very rapid and copious effervefcence takes place, a little ether is condenfed in the receiver, and a large quantity of gas paffes through the conducting tube, the firft portions of which are etherized nitrous gas, and the latter common nitrous gas. What remains in the retort is acetic acid with a little oxalic acid. The properties of etherized nitrous gas (according to Van Diemen and his affociates, to whom we are inbebted for its difcovery) are the following. It has a difagreeable ethereal odour, exactly refembling that of olefiant gas when treated with oxymuriatic acid. By the application of flame it takes fire and burns with a yellowifh lambent flame like alcohol; after the combuftion has ceafed, the veffel in which it was carried on contains a vapour of fingular pungency. Water abforbs this gas, but requires a confiderable time to effect this, except agitation is had recourfe to, refembling, in this refpect, carbonic acid. Alcohol produces the fame effect as water, and takes up the gas not only more rapidly, but alfo in larger proportion. A folution of cauftic potafh alfo diffolves it, but with confiderable difficulty, and on the addition of fulphuric or muriatic acids the etherized gas is again fet at liberty unaltered in any of its properties. Ammonia, whether liquid or in the gafeous ftate, is incapable of contracting any union with it; the fame is the cafe with oxygen gas at the common temperature, but a mixture of the two airs, when inflamed, produces a moft violent explofion; fulphuric acid immediately decompofes this gas, by abforbing the ether, the nitrous gas retaining its elaftic ftate. Sulphurous acid produces the fame effect, only it requires fome days for this purpofe. If fulphuric acid, previoufly diluted with an equal weight of water, is placed in contact with this gas over mercury, its action is greatly retarded, the diminution of volume in the inclofed air takes place much more flowly, and even after fome days a portion of ether is retained by the nitrous gas, which in confequence acquires the property of enlarging the flame of a taper that is immerfed in it, in the fame manner as nitrous oxyd does. Nitrous acid, according to the degree of its concentration, abforbs either wholly or in part, the ethereous portions of the gas, and the fame may be obferved of muriatic acid.

Etherized nitrous gas, when paffed through a red-hot tube, depofits a little oil, and by fubfequent wafhing in lime-water is freed from fome carbonic acid; the refidue is nitrous gas, mixed or combined with common carburetted hydrogen, and is not acted on by the fulphuric, nitric, or muriatic acids, by cauftic potafh or alcohol. The addition of oxygen gas produces red vapours, the nitrous gas is converted into acid, and the gafeous refidue is carburetted hydrogen.

§ 3 *Muriatic ether*.—After chemifts had fhewn the production of ether by means of the fulphuric and nitric acids, it was natural to attempt its preparation by the muriatic acid. But this latter, in its ufual ftate of dilution with water, has no action on alcohol, and therefore the various modes that were firft practifed to obtain muriatic ether entirely failed. A few chemifts were faid to have fucceeded by employing fimple muriatic acid, but in a more concentrated and dry ftate than the common liquid acid; the procefs, however, was both difficult and doubtful, and muriatic ether can hardly be faid to have been known till Rouelle difcovered that it might be prepared by diftilling together alcohol and the fmoking liquor of Libavius, which is a concentrated muriat of tin in its higheft ftate of oxydation. The marquis de Courtanvaux, having repeated the procefs of Rouelle with great care, propofes the following as the beft method of making the fubftance in queftion. Mix together in a retort three parts of the fuming muriat of tin and one of alcohol; a confiderable degree of heat is immediately excited, and a white fuffocating vapour arifes, which, however, foon difappears on agitating the mixture. As foon as an ethereous odour is perceived, let two balloon receivers be luted on, and kept as cool as poffible; then by the application of a gentle heat to the retort there comes over firft a little dephlegmated alcohol, which is fucceeded by the ether: by an increafe of temperature a few drops of coloured oil are produced, and there arifes, partly in the form of a foft butter and partly in that of a denfe brown liquid, a quantity of fmoking muriat of tin, part of the metallic oxyd remaining in the retort as a grey powder. When the ether thus procured is mixed with pearlafh, a copious effervefcence and precipitation take place, owing to the decompofition of fome muriat of tin contained in the ether; after which, by diftillation at a gentle heat, the ether arifes in a ftate of great purity, amounting to half the impure product of the firft diftillation.

Several other of the metallic muriats have been found to be equally efficacious with the liquor of Libavius; the corrofive muriats of antimony and of arfenic, the muriats of bifmuth and zinc, and the red muriat of iron, have in particular been ufed with fuccefs in the preparation of muriatic ether. Scheele.

Scheele, the difcoverer of oxymuriatic acid, was induced to try the effect of this in the preparation of muriatic ether. For this purpofe he put three ounces of alcohol into a receiver,

receiver, with which was connected a retort holding two ounces of common salt, upon which was poured an equal weight of sulphuric acid; the muriatic acid thus disengaged passed into the receiver, where it combined with the alcohol; and this, when saturated with acid, was transferred to another retort, containing three ounces of black oxyd of manganese in fine powder; the mixture instantly assumed a green colour, and presently after became so hot as to boil. When the ebullition had ceased, there was found in the receiver a liquor, from which, on mixture with water, a quantity of ether immediately separated. The same method is recommended by Van Mons, except that he employs only one fourth of the manganese used by Scheele, and performs the second distillation in a Woulfe's apparatus, the bottles of which contain a solution of caustic potash, by which the acid is prevented from re-acting on the ether.

Another mode of applying oxymuriatic acid to the preparation of ether, first practised by Scheele, is mentioned by Pelletier, and deserves to be repeated, as being perhaps the most expeditious and economical of any. He introduced into a large tubulated retort a mixture of eight ounces of manganese, and 16 ounces of decrepitated common salt, upon which he poured a mixture of 12 ounces of sulphuric acid, and eight ounces of alcohol. From this mass ten ounces were drawn off by distillation at a gentle heat, which, by subsequent rectification, yielded four ounces of ether.

It deserves to be remarked, that the ether prepared by oxymuriatic acid generally deposits, during its rectification with potash, a considerable quantity of a clear aromatic and bitter oil, which sinks in drops to the bottom of the vessel; the ether also, according to Dollfuss, at least before rectification, is compleatly miscible with water when shaken with it for some time. The preparation of ether, by means of simple muriatic acid, is not easy, and was readily supposed to be impossible by some of the leaders of the modern school of French chemists, because it contradicted one of their early theories on the process of etherification; yet Beaumé, a chemist of great experience and unquestioned veracity, had affirmed, that he had obtained a small quantity of ether, by mixing together alcohol and muriatic acid, both of them in the state of vapour. The practicability of this method appears also to be established beyond doubt by the following formula of M. Basse. Keep a quantity of common salt in fusion for about an hour, in order to drive off all the water of crystallization, then pulverize it, and put 40 parts into a tubulated retort, connected with a Woulfe's apparatus, in the first bottle of which are to be poured 20 parts of most highly rectified alcohol; then add to the salt in the retort 20 parts of the strongest sulphuric acid, and proceed to distillation by a gentle heat, keeping the bottle holding the alcohol as cool as possible. When the alcohol is saturated with acid, transfer it to a retort, and distil over about one half of it; agitate this portion with an alkaline ley, and the ether will presently separate and float on the surface, whence it may be obtained by decantation or distillation. The quantity of ether from the above materials amounts to about five parts.

Muriatic ether has a striking resemblance to that prepared by sulphuric acid; its specific gravity, however, is greater, amounting, according to Hermbstadt, to 0.84; its taste also has a peculiar astringency like alum, and when burning it exhales a strong acrid odour, somewhat resembling that of sulphurous acid.

§ 4. *Fluoric ether.*—All that we know of this substance is derived from the discoveries of Scheele. He first impregnated rectified alcohol with fluoric acid gas, by distilling pulverized fluor spar with sulphuric acid, and placing alcohol in the receiver; the smoking spirit thus obtained was distilled with a gentle heat, but no sign of ether made its appearance. Another portion of the acidulated spirit was then mixed with black oxyd of manganese, and by subsequent distillation an ethereous fluid came over, from which, by subsequent rectification, a little ether was obtained of a very agreeable odour, resembling nitrous ether.

§ 5. *Acetic ether.*—Acetic ether was first discovered by the Count de Lauraguais; the method of its preparation was by distilling together equal parts of alcohol and acetic acid. Scheele, Porner, Bergman, and other chemists, repeated this process ineffectually, and hence were induced to suspect some error. In consequence of these doubts, Pelletier entered into a careful examination of the subject, and has both shewn the reason of the failure of Scheele, and has given the proper method by which to succeed. He distilled together equal parts of alcohol and acetic acid, and drew off a little more than half; this liquor was acidulous, and had an ethereal odour, but no true ether could be made to separate. He then mixed together 12 ounces of strong radical vinegar, and the same quantity of alcohol, and distilled over one half of it at a boiling temperature; this product he poured back into the retort and recommenced the distillation; the produce of this and of a third distillation were in like manner recohobated, and having distilled the whole again for the fourth time, he finally obtained 12 ounces of an ethereous fluid; with this he mixed a quantity of carbonated potash, sufficient to saturate the acid which it contained, and then submitted it to gentle distillation. The first six ounces that came over were pure acetous ether, the next four ounces also contained ether, but not so pure as the former. It is remarkable that during the cohobations a considerable absorption of air took place.

Scheele obtained acetous ether in a much more compendious manner, by mixing together acetat of potash, or of lead, or of copper, with alcohol, and then adding as much sulphuric acid as was requisite to decompose the acetous salt, and distilling the mixture at a low heat. The produce being shaken with water, the ether rises to the surface and may be poured off. From 16 parts acetat of lead, six parts strong sulphuric acid, and nine parts of water, Bucholz obtained six parts rectified ether.

Acetic ether always retains the odour of the acid by which it is formed; it is not so volatile as the ethers procured by the mineral acids; it burns with a lambent blue flame, like alcohol; it is soluble in a little more than twice its bulk of water, and is decomposable into acetous acid by repeated distillations at a very gentle heat.

Various other acids have been distilled with alcohol for the purpose of procuring ether, but with little or no success. Oxalic acid, with an equal weight of alcohol, yielded Bergman a watery somewhat etherized alcohol. Benzoic acid and alcohol, according to Scheele, afford no ether, but when a little common muriatic acid is added to the mixture, an ethereous liquor comes over, of which part floats on water and part sinks in the same fluid. The ether, or the lighter portion, has the odour of benzoic acid, burns with a clear flame and smoke, and is about equal in volatility to acetic ether. The phosphoric, boracic, tartarous, citric and succinic acids, were found by the same able chemist to be incapable of producing ether, either by their own action on alcohol, or when mixed with oxyd of manganese or muriatic acid.

Ether, in *Ancient Geography*, a town of Palestine, in the tribe of Juda, which afterwards was assigned to the tribe of Simeon.

ETHEREAL Oil. See Oil, *volatile* or *essential.*

ETHEREGE, George, in *Biography*, chiefly known as a writer of comedy, was born in the vicinity of London about the year 1636. Little is known of his early years, but it is supposed he was educated at Cambridge; spent some time in foreign travel, and afterwards entered himself at one of the inns of court. His talents were but ill adapted to the laborious profession of the law; he was fond of gay and polite company, and became a writer for the stage. In 1664, his first comedy, entitled "The Comical Revenge, or Love in a Tub," was presented to the town, and well received. The author was immediately enrolled among the wits of the age. His next piece is thought to have been entitled to more praise for wit than for morality. It is entitled "She would if she could;" its licentious tendency was justly reprobated by the "Spectator," who says he knew of but one author who had professedly written a play upon the desire of multiplying our species, and that is the polite sir George Etherege in the play of "She would if she could:" "Other poets," he adds, "have here and there given an intimation, that there is this design under all the disguises and affectations which a lady may put on, but no author except this has made sure work of it, and put the imaginations of his audience upon this one purpose, from the beginning to the end of the comedy." His next piece was not produced till the year 1676; it was entitled "The man of the mode, or sir Fopling Flutter," and dedicated to the second duchess of York, Mary of Modena. It was very popular, and regarded as a true model of polite comedy; one of its principal characters was said to be a representative of the earl of Rochester, the finished fine gentleman and man of pleasure. Etherege lived a dissipated life, and in a few years injured his fortune and constitution. With a view of maintaining his rank in society, he paid his addresses to a lady of considerable fortune, who refused to marry him, unless he could procure the honour of knighthood. This he readily obtained, and upon the accession of James II. he was sent out envoy to Ratisbon, where he resided some time, and from whence he wrote letters which are favourable specimens of his talent for easy pleasantry. He died soon after the revolution, but the account of the time and manner of his death has been differently related. By some he is supposed to have died in his native country soon after his return from France, whither he had been on public business, and by others it is said, that it happened at Ratisbon by a fall down stairs. Besides the comedies already mentioned, Etherege was author of many smaller poems. His letters to the duke of Buckingham are in the Biographia Britannica, to which the reader is referred.

ETHERINGTON'S Bay, in *Geography*, a bay on the north-west coast of the island of St. Vincent; a little to the north of Chateau Belair bay.

ETHESIUS Lapis, a name given by some authors to the chrysolite.

ETHICAL GOOD, Ethical *possible.* See the respective articles.

ETHICS, Ἐθικη, the doctrine of manners, or the science of moral philosophy. See Philosophy and Morality.

The word is formed of ηθος, *mores*, *manners*, because the scope or object thereof is to form the manners.

Gale makes ethics only the first part or branch of moral philosophy, *viz.* that which regards private persons, or in a private capacity.

By manners or morals is here meant a way, or manner, of living confirmed by custom or habit, or certain habitudes of doing, or actions which are often repeated, which, if they be according to right reason, the morals or manners are said to be good, otherwise, evil and vicious.

Hence the object of ethics is the exercise of right reason in all our affairs, actions, and relations; or it is a man himself considered as dirigible, and to be conducted according to reason: and the end of ethics is to make him good and happy: so that if a man conducted himself according to right reason in all the circumstances of his actions, affairs, and relations, he would arrive at the highest pitch of moral perfection and beatitude.

Whence ethics may be defined a right manner of thinking in order to attain to human felicity, or a science whereby man is directed to conduct his will, and the actions thereof, so as to live well and happily. See Will.

The principal, nay, the only topics thereof, are happiness and manners, whence arise two parts or branches of ethics; the first on moral happiness, considered as the end; and the second on moral virtues or good manners, as the means to arrive at that end.

ETHICOPROSCOPTÆ, formed of ηθος, *manners*, and προσκοπτω, *offendo*, *I offend*, in *Antiquity*, the name of a sect. Damascenus, in his Treatise of Heresies, tells us, that the denomination of Ethicoproscoptæ was given to such as erred in matters of morality and things relating to practice that were to be done or to be avoided, &c. who blamed things laudable and good in themselves, or recommended or practised things evil. On this footing the Ethicoproscoptæ, though a numerous body, were no particular sect.

ETHIOPIA, in *Ancient Geography*, was a name given to several countries, both of Asia and Africa, whose inhabitants were either perfectly black or of a swarthy complexion; but Ethiopia, in a more restricted application of the term, or Ethiopia propria, was limited on the north by Egypt, extending to the lesser cataract and the island Elephantina; on the west by Libya interior; on the east by the Red sea; and on the south by a part of Africa unknown to the ancients, but probably comprehending that space which includes the modern kingdoms of Girgiro, Alaba, Machida, and part of Adel or Zeila. Proper Ethiopia, however, seems to have varied in extent at different periods; but for several ages it seems to have been the tract which at this day comprehends the kingdoms of Dongola, Sennaar, and Abassia, with part of Adel or Zeila; and consequently to have taken up 17 degrees of longitude, and to have reached from the tropic of Cancer to within six degrees of the line. Some geographers have restricted it to the tract of country that lies between Egypt and Abyssinia, about 600 miles in length, and 500 in breadth, which was called by the Arabian geographers Nubia.

The proper Ethiopia was anciently distinguished by a variety of appellations. Sometimes it was called India; sometimes Cephenia; and most usually Abasene, in sound and signification approaching very near to the modern Habash, Habesh, or Abassia. We also find Chaldæa, Assyria, and even Persia denominated Ethiopia by some authors of reputation; and it must be allowed, that the ancients called all those countries, extending themselves beyond each side of the Red sea, indiscriminately India or Ethiopia.

According to the Jews, the LXX, the Vulgate, and other versions, Cush, when applied in scripture to a country, is always to be understood of the proper Ethiopia. This opinion is supported by Philo, Josephus, Eupolemus in Eusebius, Eustathius, the author of the Alexandrian Chronicon, and the concurrent testimony of the Greek and Latin fathers. See Cush.

Ethiopia did not abound in cities and towns of any considerable fiderable note. Auxume, Auxumis, or Axome, reckoned the metropolis of Ethiopia, was undoubtedly the fame city as the modern Axuma, or Axum. This country was extremely mountainous, and therefore the climate in different parts of it was very various. (See ABYSSINIA.) The days and nights, as Ethiopia lay betwixt the tropic of Cancer and the line, were for the moft part nearly equal. The winds that blew on the mountains were, generally fpeaking, falubrious and pleafant; but the atmofphere over the plains ftagnated and became unwholefome. The foil in thofe parts that admitted of cultivation was extremely fertile, and produced vaft quantities of grain, pulfe, and fruit. It abounded with metals, particularly gold, minerals, vegetables, and a great variety of animals. (See ABYSSINIA.) The moft famous river that waters this country is the Nile. (See NILE.) The chief ports and emporia of ancient Ethiopia were thofe of Adulis, Mondus, Opore, Mofylon, and the principal city of the Aualitæ, feated upon the Red fea. The Arabs imported from their country into thefe ports fruit, corn, wine, and cloaths; and exported from thence to Ocelis and Mufa, oppofite harbours in Arabia, fpices, caffia, perfumes, ivory, myrrh, and feveral other commodities. The moft noted iflands pertaining to Ethiopia were Meroe, the Sporades of Agathareides, Aftratæ, Ara Palladis, Gythitis, Myronis, Daphnine, Magi, Acanthine, Ifis, Mondus, and Menuthias.

According to Pliny, Ethiopia was anciently divided into 45 kingdoms, of which the moft powerful and flourifhing was Meroe; but he does not inform us, whether they were independent of each other, or under one fupreme head. There is reafon to believe, however, that the kings of Ethiopia always ruled with an uncontroulable fway. If we admit the Ethiopian tradition, that a long fucceffion of princes, defcended from Solomon, reigned in this country, it can fcarcely be denied, that their authority was unlimited, as that of the Hebrew monarch knew no bounds. It appears from Strabo and Pliny, that fome Ethiopic nations were governed always by queens, whofe common name was Candace, as that of the Egyptian kings was Pharaoh, and Ptolemy. From Diodorus Siculus we learn, that a great part of Ethiopia was compofed of feveral elective monarchies, the heads of which were chofen out of their priefts; and that all thefe princes made the laws of their refpective kingdoms the bafis of their government. According to Diodorus Siculus the laws of Ethiopia agreed in fubftance with thofe of Egypt; which the Ethiopians accounted for by the affertion, that Egypt was firft peopled by colonies that migrated out of their country. Herodotus, however, reprefents the Ethiopians as having been civilized by the Egyptians, and as having learned the cuftoms and manners of that people at fo late a period as the reign of Pfammitichus I. Jupiter Ammon, according to the Greek and Latin authors, appears to have been the principal object of religious worfhip in Ethiopia; though the natives paid likewife divine honours to Ifis, Pan, Hercules, Æfculapius, and others, whom they confidered as the greateft benefactors to mankind; and if thefe authors may be credited, their religion differed not much from that of the Egyptians. Diodorus Siculus tells us, that the Ethiopians valued themfelves upon their being the firft nation that had a religious eftablifhment; and for this reafon they believed, that their facrifices were more acceptable to the gods than thofe offered by any other people. He affures us, however, that fome of them were atheifts, who looked upon the fun, on account of his fcorching rays, as their implacable enemy. If a tradition of the modern Abaffines could be relied on, the Ethiopians, or at leaft a confiderable part of them, adhered zealoufly to the law of Mofes from the time of Solomon till their converfion to Chriftianity. According to this tradition, the queen of Sheba, whom our Saviour calls the queen of the fouth, and who ruled over a powerful nation of Ethiopia, had a fon by Solomon named Menileck, who was educated at that prince's court, and inftructed, under the care of his father, in the law of God. Being afterwards anointed king of Ethiopia, and fent home to take poffeffion of his kingdom, at the defire of feveral eminent Ifraelites and doctors of the law that attended him, he introduced his father's religion, which continued among his fubjects and their pofterity till the time of St. Athanafius. See ABYSSINIA.

Ethiopia, in ancient times, was a country of vaft extent, inhabited by different nations; and, therefore, it is natural to fuppofe, that a confiderable variety of languages, or at leaft of dialects, muft have prevailed in it. The moft ancient of thefe was that called the Ethiopic, into which the fcripture was formerly tranflated, and in which all the books of the Abaffines, both facred and profane, are written. According to fome authors, this language nearly refembles the Chaldee; but, according to Ludolfus, who fpent 60 years in the ftudy of it, it bears as great an affinity to the Hebrew and Syriac, and approaches nearer ftill to the Arabic, from which it appears to be immediately derived. Ludolfus afferts, that a competent knowledge of the Hebrew, or any other of the oriental tongues, will enable a ftudent foon to make a very rapid progrefs in the Ethiopic. The pureft dialect of this tongue was that ufed in the kingdom of Tigré, where Axuma and the old Ethiopian kings refided. Upon the failure of the Zagæan line, a Sewan prince afcended the throne, upon which the Amharic dialect was introduced at court, and gradually diffufed over the whole empire. (See ABYSSINIA.) From comparing the ancient Ethiopic alphabet, as given by the learned Job Ludolfus, in his "Hiftory of Ethiopia," with the old oriental alphabets, it feems not improbable, that fome of them were derived from the old Affyrian, Phœnician, Samaritan, and Syriac characters. The number of letters likewife in this alphabet, and the names of feveral of them, tend to eftablifh the fame fuppofition; though Ludolfus believes thefe characters to have been invented by the Axumites or Ethiopians themfelves, and to be much older than even the Cufic character of the Arabs. The Ethiopians both write and read from the left hand to the right, contrary to the cuftom of the orientals: a circumftance which indicates that their alphabet was not entirely of the fame extraction with that of the Arabs.

The Ethiopians agreed in feveral points with the Egyptians, though they had many cuftoms peculiar to themfelves, fome of which were very fingular and uncommon. From this mutual agreement in moft of their laws, their fplendid funerals, the deification of their princes, the feveral colleges of priefts, circumcifion, and moft of their facred and civil inftitutions, it is highly probable that the fame arts, fciences, and learning, as well as religion, prevailed in both nations.

The Ethiopians were naturally bold and intrepid, but violent in their temper. They likewife furpaffed the people of moft other nations in beauty and fize, to which a proportionable degree of ftrength was generally annexed. According to various authors, the proper ancient Ethiopians were, in general, perfectly black, as we find their pofterity at this day, though thofe of fome particular cantons were white, called by Pliny white Ethiopians. Their women were ftrong and lufty, and brought forth their children with little pain. From the teftimony of Herodotus, compared with the relations of fome modern authors, it is not

 unlikely,

unlikely, that they died of old age, a few only excepted, who fell by the fword, or were devoured by wild beafts, as Salluft has obferved of the ancient Africans. Anc. Un. Hift. vol. xvi. See ABYSSINIA and CUSH.

ETHIOPIA, in *Modern Geography*, is a denomination including the countries of Nubia, Abyffinia, Abefh or Abex, and Anian, which are bounded by Egypt and the defart of Barca on the north; by the Red fea and the eaftern ocean on the eaft; by Zanguebar and Caffraria on the fouth; and by Guinea, Nigritia, and Zaara, on the weft. Neverthelefs, all the countries ftill, according to the ancient divifion, that lie almoft in a ftraight line from Egypt to the Cape of Good Hope, may be comprehended under the general name of Ethiopia. Ethiopia is divided into Upper and Lower, the former including Nubia and Abyffinia; and the latter comprehending all the kingdoms fouth of the equinoctial line, as Congo, Lower Guinea, Caffraria, Monomotapa, &c. which fee refpectively.

ETHIOPIC VERSION. See BIBLE, *Ethiopic*.

ETHIOPIC *Year*. See YEAR.

ETHLEC, in *Ancient Geography*, a town of Upper Mœfia, according to Antonine's Itinerary.

ETHMOID, or ETHMOIDAL, in *Anatomy*, a name given to one of the bones of the head. See CRANIUM.

ETHNARCHA, ETHNARCH, formed of ἐθνος, *nation*, and αρχη, *command*, a governor and ruler of a nation.

There are fome medals of Herod I. furnamed the *Great*, on one fide whereof is found Ηρωδου, and on the other Εθναρχου, q. d. *Herod* the *Ethnarch*. After the battle of Philippi, we read that Antony, paffing over into Syria, conftituted Herod and Phafael his brother tetrarchs, and in that quality committed to them the adminiftration of the affairs of Judea. (Jof. Ant. lib. xiv. cap. 23.) Herod therefore had the government of the province before ever the Parthians entered Syria, or before Antigonus's invafion, which did not happen till fix or feven years after Herod was commander in Galilee. (Jof. lib. xiv. cap. 24, 25.) Confequently Herod was then truly ethnarch, for he can be no otherwife denominated; fo that it muft have been in that fpace of time that the medals were ftruck, which only gave him this title: which medals are a confirmation of what we read in hiftory of the government which that prince was intrufted with before he was raifed to the royalty.

Jofephus gives Herod the appellation of tetrarch in lieu of that of ethnarch; but the two terms come fo near to each other, that it is eafy to confound them together.

Though Herod the Great left by will to Archelaus all Judea, Samaria, and Idumea, yet Jofephus tells us he was then only called ethnarch.

ETHNOPHRONES, in *Antiquity*, a fect of heretics in the feventh century, who made a profeffion of Chriftianity, but joined thereto all the ceremonies and follies of paganifm, as judicial aftrology, fortileges, auguries, and other divinations.

They derive their denomination from ἐθνος, *nation*, and φρην, *thought*, *fentiment*. q. d. *paganizers*, or perfons whofe thoughts or fentiments were ftill heathen or gentile.

They practifed all the expiations of the gentiles, celebrated all their feafts, and obferved all their days, months, times, and feafons. See Damafcenus, Hæref. N° 94.

ETHOLOGUS, among the *Ancients*, a mimic, or actor, who could reprefent all the various habits and difpofitions of the mind.

ETHOPŒIA, or ETHOPEA, in *Rhetoric*, called alfo *Ethology*, a draught or defcription, expreffing the manners, paffions, genius, tempers, aims, &c. of another perfon.

The word is of Greek original, being formed of ἠθος, *mos*, *confuetudo*, and ποιεω, *facio*, *fingo*, *defcribo*. Quintilian, lib. ix. cap. 2. calls this figure *imitatio morum alienorum*; and in Greek, μιμησις, *imitation*. In Englifh we denominate it a *picture* or *character*.

Such is that beautiful paffage in Salluft, in his "Bellum Catilinarium," wherein he gives us a picture of Cataline: "He had an uncommon ftrength both of body and mind, but an ill-turned and wicked difpofition. When very young, his great pleafure was in inteftine broils, rapine, flaughter, and civil difcord. His body was formed to undergo fafting, cold, and watching, beyond all belief. His mind was daring, deceitful, and various, and could imitate or accommodate itfelf to every body; he was extremely covetous of other people's goods, and profufe of his own. His lufts and defires were very high; his ftock of eloquence confiderable, but he had little or no difcretion."

The ethopœia is divided into *profopographia* and *ethopœia*, properly fo called; the former of which is a picture of the body, countenance, make, drefs, gait, &c. and the latter of the mind.

ETHULIA, in *Botany*, a name concerning whofe origin or meaning we have met with no conjecture. Linnæus its author rarely explained names of his own contrivance, nor is any thing upon this occafion mentioned in his fon's Decas Prima Plantarum, where *Ethulia* firft appeared. Could he poffibly allude to the remote country whence it came, as *e*, *extra*, (beyond) *Thule*, fuppofed by the ancients the uttermoft part of the earth? If the plant had been of American origin, fuch an appellation would, not inelegantly, have alluded to the famous prophecy in Seneca's Medea, fo expreffive of the difcovery of the weftern world, and ending

—— "nec fit terris
Ultima Thule."——

It was however fuppofed to come from Ceylon, and is actually a native of the banks of the Nile. If the above conjecture be inadmiffible, the name muft depend on its harmony for protection. Linnæus might well be glad to get rid of the harfh *Sparganophorus* of Vaillant, to which he would object as compofed of *Sparganium*, a generic name already eftablifhed. But it is probable he did not at firft obferve that Vaillant's genus was his *Ethulia*, though he foon recognized it. Linn. Gen. 413. Schreb. 545. Willd. Sp. Pl. v. 3. 1740. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 158. Juff. 184. Gærtn. t. 164. (Sparganophorus; Vaill. Act. Paris. Ann. 1719. Gærtn. t. 165.) Clafs and order, *Syngenefia Polygamia-æqualis*. Nat. Ord. *Compofitæ difcoideæ*, Linn. *Corymbiferæ*, Juff.

Gen. Ch. *Common Calyx* rounded, fimple, of many linear, equal, fpreading-pointed fcales. *Cor.* compound, difcoid. Florets all fertile, numerous, uniform, tubular, funnel-fhaped, with fome fpace between them; their limbs five-cleft, erect. *Stam.* Filaments five, very fhort, capillary; anthers united into a cylindrical tube. *Pift.* Germen angular; ftyle thread-fhaped, the length of the ftamens; ftigmas two, recurved. *Peric.* none, except the permanent calyx. *Seeds* folitary, truncated, top-fhaped, five-fided, five-furrowed; crown none, except a prominent margin. *Recept.* naked, convex, dotted with minute excavations.

Eff. Ch. Receptacle naked. Seed-down none. Florets tubular, five-cleft, numerous. Scales of the calyx pointed.

This is but a vague and confufed genus, depending properly on the three following fpecies only.

1. E. *conyzoides*. Linn. Sp. Pl. 1171. L. fil. Dec. Pl. Rar. 1. t. 1. "Flowers panicled."—Seeds of this were fent

fent by Profeffor David Van Royen to Linnæus, who raifed them in his ftove at Upfal, and the plant proving new, was defcribed and figured by his fon, in a work of which only two fafciculi ever appeared. Linnæus fuppofed it a native of Ceylon, which may poffibly be correct. No new information appeared concerning it, till it was mentioned in the Hortus Kewenfis as fent by Thouin, and foon afterwards Vahl difcovered it to be the *Kahiria* of Forfkall, fo that we hence learn it to be certainly a native of the muddy banks of the Nile, where it flowers early in November. The *root* is annual, fibrous. *Stem* four feet high, alternately branched, hollow, downy, leafy. *Leaves* alternate, on fhort ftalks, lanceolate, pointed, equally ferrated, fragrant, downy beneath, three inches long; without ftipulas. *Flowers* pale blue, in compound corymbofe panicles about the tops of the branches, remarkable for the flender and diftant tubes of their florets. The *feeds* form an almoft globofe head; each of them is crowned with a pale undivided angular border.

2. E. *Sparganophora*. Linn. Sp. Pl. 1171. (Sparganophorus Vaillantii; Gærtn. v. 2. 395. t. 165.) "Flowers in feffile axillary clufters. Calyx-fcales recurved."—This we know only from the work of Vaillant, (from whom Linnæus adopted it,) and that of Gærtner; nor is its native country afcertained. The *leaves* are faid to be like thofe of Golden Rod. *Seeds* exactly like the laft in general ftructure, nor does there feem any doubt of their belonging to one and the fame genus.

3. E. *Struchium*. Swartz. Prod. 111. (Struchium; Browne Jam. 312. t. 34. f. 2.) Flowers axillary, feffile, moftly folitary. Calyx with ftraight fpinous points.—Gathered by Browne in Jamaica. *Stem* herbaceous, two or three feet high, leafy, fmoothifh. *Leaves* elliptic-lanceolate, four or five inches long, pointed, ftrongly ferrated, thin, very flightly pubefcent, on ftalks an inch in length. *Flowers* fmall, axillary, feffile, either folitary or in pairs, or if more together, they have fmaller leaves between them. We prefume the ftraight fpinous points of the calyx-fcales will afford a certain fpecific difference between this and the laft, whether their foliage be different or not.

In his firft Mantiffa, p. 110, Linnæus added three fpecies to his genus *Ethulia*. Of thefe *E. tomentofa* muft be entirely ftruck out of the fyftem, being no other than his own *Artemifia chinenfis*, and not having either the habit or characters of an *Ethulia*. The fecond is *E. divaricata*, Burm. Ind. 176. t. 58. f. 1. (Chryfanthemum bengalenfe anguftifolium pufillum, fummo caule ramofum; Pluk. Phyt. t. 21. f. 4.) Leaves linear, toothed, decurrent. Flowers folitary, ftalked, terminal. Stem divaricated.—Native of rice-fields in Malabar. *Koenig*. *Root* annual. *Stem* three or four inches high, erect, much branched in a corymbofe manner; branches leafy, quadrangular, winged, fomewhat cottony. *Leaves* alternate, linear-lanceolate, toothed, running down into the wings of the branches. *Flowers* on fhort, fimple, folitary, terminal ftalks; *Calyx* of numerous, imbricated, fharp and fomewhat fpinous, fpreading, purplifh fcales. *Seeds* without any crown.—We have, as Willdenow has already done, prefumed to correct the defcription of Linnæus, and his quotation of Burmann. Linnæus moreover quotes his own *Artemifia minima*, Sp. Pl. ed. 1. n. 19, with the original fpecimen before him, for this *Ethulia*, but very erroneoufly, and his citation of Burmann is fo placed as to imply that he had committed the fame fault, which is not true. We cannot but obferve here that Burmann in his Flora Indica has copied *E. conyzoides* and *E. Sparganophora* from Linnæus, without any real knowledge of them, fo that his authority is of no avail refpecting thofe fpecies. Gærtner, v. 2. 389. t. 164, retains this *E. divaricata* as the only real *Ethulia*, adding a good fynonym from Plukenet (who figures the plant twice), Chryfanthemum parvum ramofiffimum, membranaceo caule maderafpatenfe; Pluk. Phyt. t. 160. f. 5. Gærtner therefore preferves the name and genus of Vaillant's *Sparganophorus*, which he contends is a very diftinct genus from this plant. In the laft particular he appears to be right, but the above three fpecies unqueftionably conftitute what Linnæus meant by *Ethulia*, and they only agree with his generic defcription, fo that the *divaricata* ought perhaps to be referred, notwithftanding its want of a feed-crown, to the *Grangea* of Adanfon and Juffieu, as the latter fufpects, or rather to make a genus by itfelf. (See GRANGEA.) Juffieu indeed preferves Browne's *Struchium* as a genus, but, as we prefume, improperly.

One more fuppofed *Ethulia* remains to be noticed, named *bidentis*, Mant. 110, from its refemblance to *Bidens tripartita*. This has nothing to do with the genus under confideration, being the very identical *Flaveria capitata* of Juffieu, of which we fhall fpeak under that name hereafter. It is a native of Chili.

With the *Ethulia uniflora* of Walter and Willdenow we are not at all acquainted. S.

ETIENNE, in *Biography*, the name of a family who have been celebrated as learned printers, and are more commonly known by the epithet of Stephanus, or in Englifh by that of the learned Stephens. The founder of the family was Henry, a printer at Paris. He is chiefly diftinguifhed as the editor of a Pfalter, in which the compofitions were divided into verfes, and diftinguifhed by figures, being the firft book of Scripture in which this practice was obferved. He died at Lyons, leaving behind him three fons, all eminent printers, of whom the fecond was,
