drawing. The openings have a wrought iron band around the top anchored into the concrete by four short rods bent downward, and are closed with a malleable iron cover.

Details of the longer span bridge floors are shown in Fig. 3. For the alleys and narrow streets the I-beams run longitudinally and girders are not used. The floors are the same for both kinds. The concrete slabs, which are a 1:2:4 gravel mixture, are reinforced with ½-in. corrugated steel bars. The slabs are waterproofed on the horizontal portion with "Medusa" compound contained in a 1-in. sidewalk finish top coat, overlaid with a ½-in. coat of gum asphalt and above this 1 in. of asphalt mastic. In the inclined side sections, where a trowel finish could not be applied on account of the forms, the "Medusa" compound was put in the body concrete. The small triangular-shaped trough next to the girders is filled with gum asphalt. At the overlap of slab and abutment two thicknesses of tarred felt are placed. Four of the bridges are exception to this form of construction, limited clearance preventing the use of the concrete slabs. In these instances metal plates are laid directly on the I-beams.

The stations for the elevated railroad on the Kenwood extension are a feature of special interest. Details of a typical station are shown in Fig. 1. They are at the street level and are of fireproof construction throughout. Entrance and exits are through the abutment, the face of which is bush-hammered, presenting a good appearance. The station interiors are roomy, well-lighted and well-arranged. The train platforms are concrete and the roofs are the usual umbrella type with steel framework and transite board roof covering. The stations between Lake and Ellis avenues and between Drexel boulevard and Cottage Grove avenue have entrances from both streets. All subways are lighted by the railroad company, the power being furnished by the station at the stock yards. The wall conduit already described is used east of Dearborn street.

The Kenwood line has been in service for about two months. It is expected to have the work west of State street ready by the first of the year or shortly thereafter. All of the concrete work, street paving, sidewalk and sewer work was done by James O. Heyworth, Contractor, Chicago. The steel work for the elevated railroad, including erection, is being done by the American Bridge Company. W. M. Hughes, Consulting Engineer, Chicago, designed all of the steel work, which included the subway bridges and the elevated railroad structure. The filling and tracklaying are being done by company forces. The work was designed and executed under the direction of J. B. Cox, until recently Chief Engineer of the road. O. F. Cole, who as Principal Assistant Engineer was in active charge of the work, succeeded Mr. Cox as Chief Engineer and now has entire supervision of the work.

The Hudson & Manhattan Tunnels.

The first of the Hudson & Manhattan Railroad tunnels under the Hudson river will be opened to the public on February 25. This section consists of a twin tube tunnel from Hoboken, N. J., to Morton street, New York, and thence northeasterly to Sixth avenue and Nineteenth street, nearly three miles in all. The accompanying map shows the entire system, which has direct connection with the principal transportation lines on both sides of the river. The first section comprises the north tunnels, which are about to be opened. The second section, the south tunnels, is to be opened next September. They run from Cortlandt and Fulton streets, New York, to Jersey City, where a large terminal station has been built in solid rock directly beneath the present Pennsylvania Railroad station. The third section is a tunnel, 1¼ miles long, connecting the terminal in Jersey City with that in Hoboken. The principal point on this line is the Erie terminal, where the tunnel station is nearer the train shed than the entrance to the Erie ferry itself is. The fourth section is a branch line running from Jersey City to Newark. This runs underground through Jersey City and then comes to the surface near the Summit avenue station, from which point the trains will run over the Pennsylvania tracks to Newark. Another branch is now being built in Manhattan. It runs from Sixth avenue east under Ninth street and will connect with the Interborough Rapid Transit subway near Astor place.

The project of building a tunnel under the Hudson river for handling local passenger traffic between New Jersey and New York City dates back to 1878, when D. C. Haskins, a civil engineer, planned a brick tunnel from Hoboken to New York. Trains were to be operated by steam and the New York terminal was to be in the vicinity of Washington Square. A company was formed which spent a good deal of money and built about 1,200 ft. of tunnel. This company failed and in 1889 the undertaking was temporarily abandoned. Ten years later another company was organized with English capital, and S. Pearson & Son, the firm which is now building the East river section of the Pennsylvania tunnels, resumed work where the Haskins company had left it. This company added about 1,800 ft. to the part already built and then also failed. These early attempts were marked by several accidents. The tunnel was

Interior of Tube; Hudson & Manhattan.

finally allowed to fill with water. In 1899 the property was sold at a receiver's sale and in 1902 it was taken over by the New York & Jersey, organized by William McAdoo. The Hudson & Manhattan was incorporated the next year to build the south tunnels and the former company and other subsidiaries have since been merged with it. The Hudson Companies is a construction company. The old tunnel was completed as one of the north tubes, of which the westbound tube was driven through in March, 1904, and the eastbound some months later. Work on the south tunnels was begun in the summer of 1905, and both of these tubes have now been driven from the New Jersey side to about the pier-head line at New York. The

Station Platform; Hudson & Manhattan.

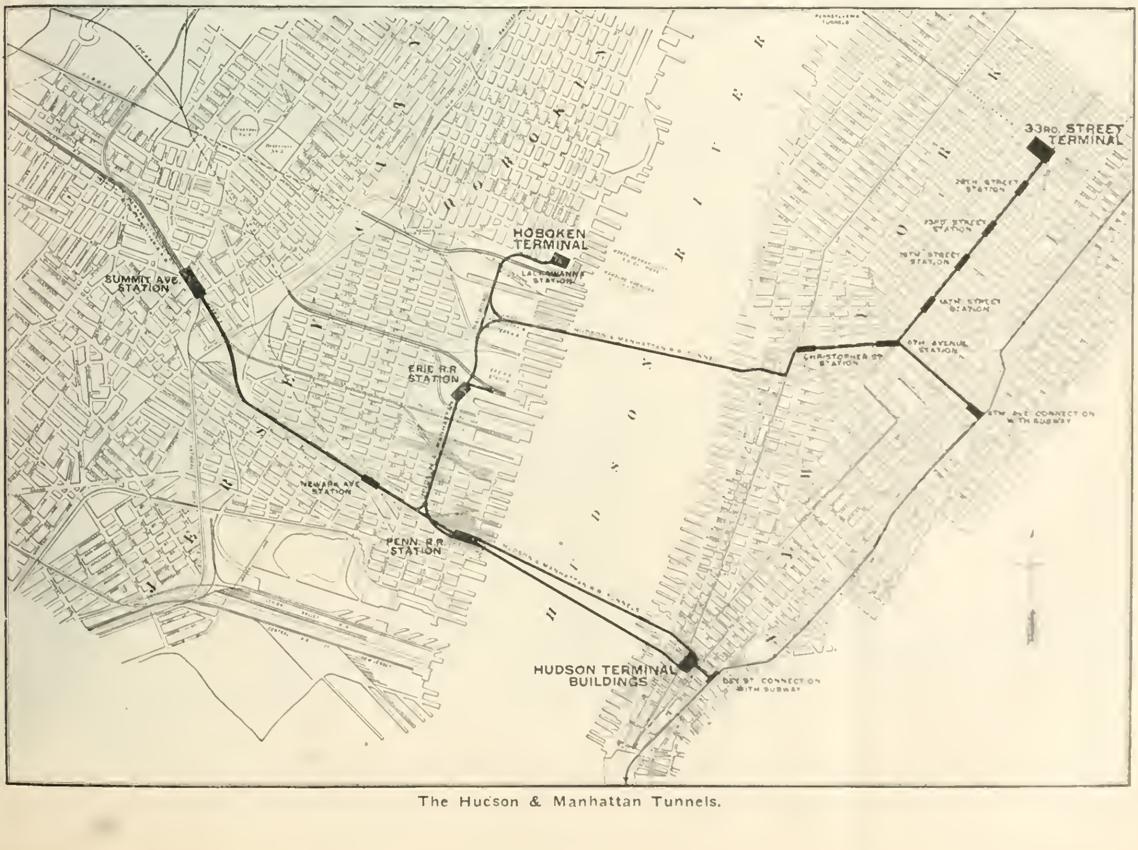
entire system, nearly nine miles, is to be double-track and will be put in operation during the coming summer. The cost is estimated at $70,000,000.

There will be no rail connection with other lines except, as mentioned above, at the Summit avenue station. Passenger stations in Manhattan, on the line about to be opened, will be located as follows: Christopher and Greenwich streets, connecting with the Ninth avenue elevated; Christopher street and Sixth avenue, connecting with the Sixth avenue elevated; and, in Sixth avenue, at Fourteenth, Nineteenth, Twenty-third, Twenty-eighth and Thirty-third streets. For the present, trains will run only to Nineteenth street and Sixth avenue. At the Hoboken terminal, connection is made with the Delaware, Lackawanna & Western, where all through and local passengers coming in from the west may get out of the trains and descend directly to the tunnel cars without leaving the station. The first section is to be operated by eight-car trains, and the time between Hoboken and Nineteenth street, New York, will be about 10 minutes. The cars were described in the *Railroad Gazette* of June 14, 1907.

View Near Hoboken Terminal; Hudson & Manhattan.

The platforms are so arranged at the terminal stations that passengers enter and leave the cars at the same time, those leaving go out on one side and those entering come in on the opposite side. This, it is hoped, will do away with much of the congestion which occurs at terminal stations on other lines. The tracks at all station platforms are on a tangent, so that there is no dangerous space between the cars and the platform, as is the case where stations are built on a curve.

The stations are intended to be large enough to accommodate present traffic and provide room for increased crowds if improved train service later gives the tunnels more carrying capacity. Every part of the stations is of either concrete or metal. One of the accompanying photographs shows the interior of a station. A noticeable difference between the appearance of these stations and those of the Interborough Rapid Transit subway is that in the former there is a curtain wall between the tracks at all points except where there are crossovers as shown in the photograph taken near the Lackawanna terminal. This view shows the form of construction of the tunnels under city streets in part of Hoboken and Jersey City and under Sixth avenue in New York. Most of the line, however, is tube construction. A typical view of this is shown in another photograph. The tubes are entirely lined with concrete except in the under-river sections and on certain curves. In these cases, the concrete is carried only half-way up the walls. The object of separ-



The Hudson & Manhattan Tunnels.

ating the tracks by curtain walls in the sections where they do not run in tubes is to secure natural ventilation due to the movement of trains. A system of power ventilation has also been installed.

The interior diameter of the tubes is 15 ft. 3 in. Under the river the rails are from 60 ft. to 90 ft. below the surface of the water. The depth of earth and rock between the roof of the tunnel and the water ranges from 15 ft. to 40 ft., the deepest part of the river being on the New York side. The two tubes are about 30 ft. apart for the greater part of the distance under the river.

The down town New York terminal is to be under the Hudson Terminal buildings at Church and Cortlandt streets. These structures occupy the larger part of two city blocks and are 22 stories high. They will accommodate 10,000 office tenants and will be opened on May 1. They contain more than 25 acres of floor space. One building is on Cortlandt street and one on Fulton street. They are separated by Dey street and are connected by a bridge at the third story. The tunnels come from under the Hudson river and under the terminal buildings about 30 ft. below the street level, forming a loop. The train platforms are two stories below the street level. A foot passage runs under Dey street to a station on the Interborough subway under Broadway.

It has been estimated that 75 per cent. of the passenger traffic now carried between New York City and the New Jersey side of the river by ferries will be diverted to the tunnels when they are all in operation. The numbers of passengers carried in the last three years by three of the largest ferries are as follows:

	1907.	1906.	1905.
Pennsylvania	43,406,750	37,745,012	32,829,182
Erie	19,718,465	18,796,871	17,321,759
Lackawanna	46,389,825	40,252,022	34,986,798

The officers who have been in charge of the building of the tunnels are: Walter G. Oakman, President of the Hudson Companies; William G. McAdoo, President of the Hudson & Manhattan; Pliny Fisk and William M. Barnum, of the banking firm of Harvey Fisk & Sons; Charles M. Jacobs, Chief Engineer, and J. Vipond Davies, Deputy Chief Engineer.

Increasing the Capacity of Brooklyn Bridge.

Improvements looking to a considerable increase in the traffic capacity of Brooklyn Bridge, with especial relation to the Manhattan terminal, are now underway and an important part of the work covered by the plans in their entirety—the extension of the bridge approach over Park Row—has been completed and is now in operation. The plans for adapting the bridge to its part of the service required as a section of the loop now being built, which is designed to form a close connection between the boroughs of Manhattan and Brooklyn, are now being carried out. This improvement involves principally the widening of the Manhattan approach so as to afford room for team traffic to the outside of the space now utilized for that purpose, which latter will be occupied by tracks connecting with the loop subway near Park Row and Centre street.

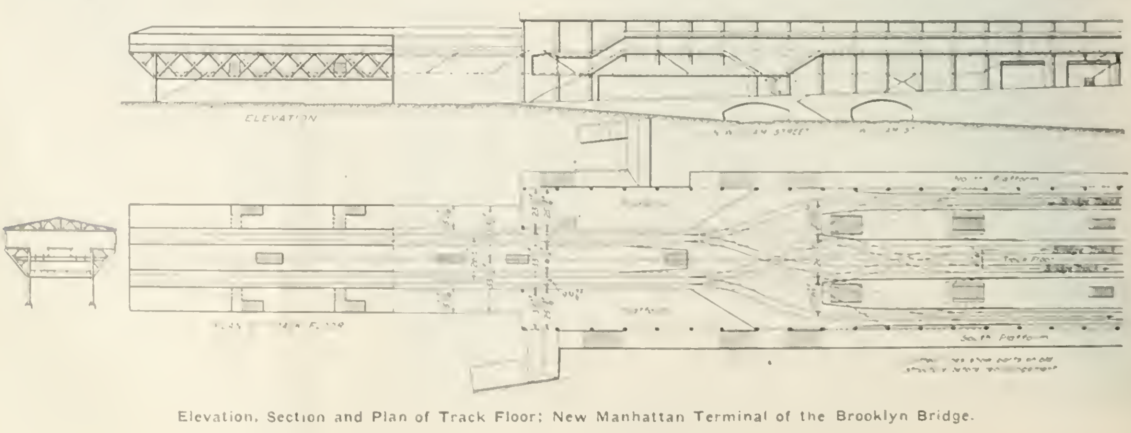
The object of the widening and its general character will appear clearly from an examination of the accompanying engravings. From North William street to Pearl street the bridge approach is being widened to the building line on each side by the erection of steel structures supported from the ground upon columns and attached to the existing stone masonry of the approach. These additions are of a general width of about 20 ft. on each side as far as Cliff street, at which point the widening is tapered off, so that at Pearl street the outer limit of the new structure ends on a line with the present approach.

How the connection will be formed between the subway level and the level of the bridge tracks is shown upon the plan and elevation of the bridge approach. The tracks will be brought up on a gradual incline from Park Row and Centre street so as to reach the present bridge level at or near Cliff street. This will involve cutting through the upper part of the various warehouses now occupying the space underneath the arches of the bridge approach. At the extreme Manhattan end, in order to avoid interference with other bridge traffic the tracks leading from the subway will be carried at the outer edge of the approach structure. Hence the necessity of the widening to afford teaming space. Beyond Cliff street, when the incline has reached the present bridge track level, the tracks will

Widening of Manhattan Approach.

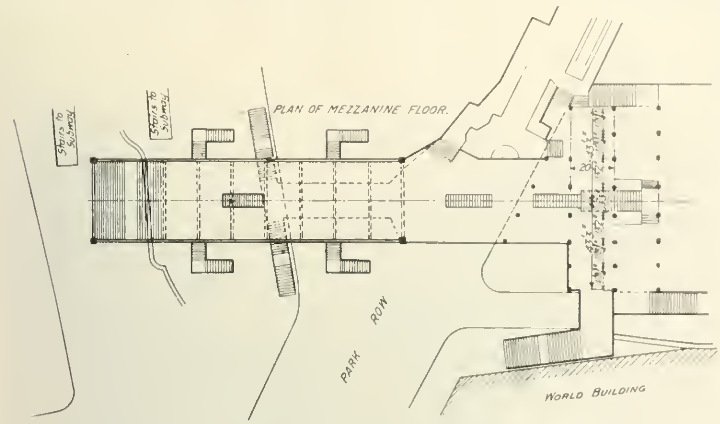
be brought closer together, as shown upon the plan, and occupy the space now used by bridge trains.

On account of the nature of the location and the close quarters within which the work is confined, the character of the structure forming the lateral extensions varies somewhat in detail. Typical bents, however, are composed of girders made up of web plates 38½ in. by ⅜ in., four angles each 5 by 5 by ⅝ in., a top flange 16 in. by ½ in., and a bottom flange 12 in. by ⅝ in. These are supported upon built-up columns. The floor beams are generally 20-in. I-beams of a 65-lb. section, and these are supported by three rows



Elevation, Section and Plan of Track Floor; New Manhattan Terminal of the Brooklyn Bridge.

of tie-rods 1 in. in diameter upset at the ends to 1¼ in. It is required that all outside fascia girders be exactly 40 in. deep from the top of the top cover plate to the bottom of the first cover plate of the bottom flange. The floor beams vary in spacing on different sections in order to equalize spacing between block limits, but it is ordinarily 4 ft. 2 in. or 4 ft. 3 in. The whole length of the steel structure is 612 ft. 6¾ in. on the south side of the approach and approximately the same on the north.



Plan of Mezzanine Floor of New Terminal at Park Row, Manhattan.

Work upon the widening has progressed to the extent that most of the steel work is now in place. A general idea of the nature of the work may be gained from the photograph.

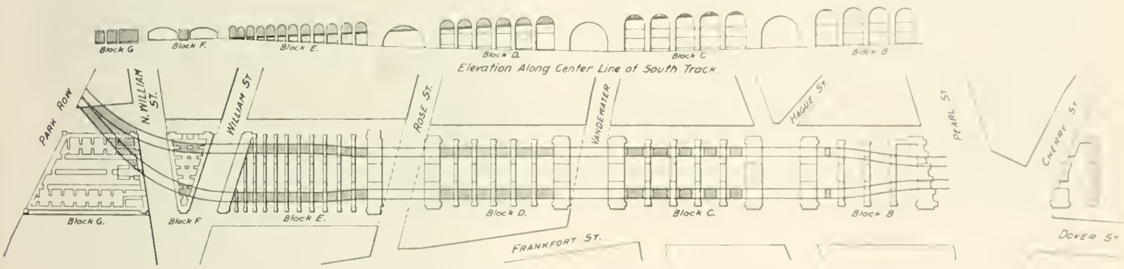
The improvements above described are entirely independent of those now about completed and which are involved in the extension of the elevated track floor of the bridge over Park Row. This was put into service on January 27. The difficulty which this temporary extension was designed to remedy was the lack of room at the Manhattan terminal to handle trains of sufficient length to care for the traffic in rush hours. Previously bridge cable trains of five cars each were run which involved a change at the Brooklyn terminal for all passengers destined for points on the elevated lines of the Brooklyn Rapid Transit—a very large percentage of the entire bridge travel.

On the date above named, six-car trains from the several Brooklyn elevated lines began running through to the Manhattan terminal without change at the Brooklyn end; and during the evening rush hours similar trains now run from the Park Row terminal to the terminals of the several lines in Brooklyn without change.

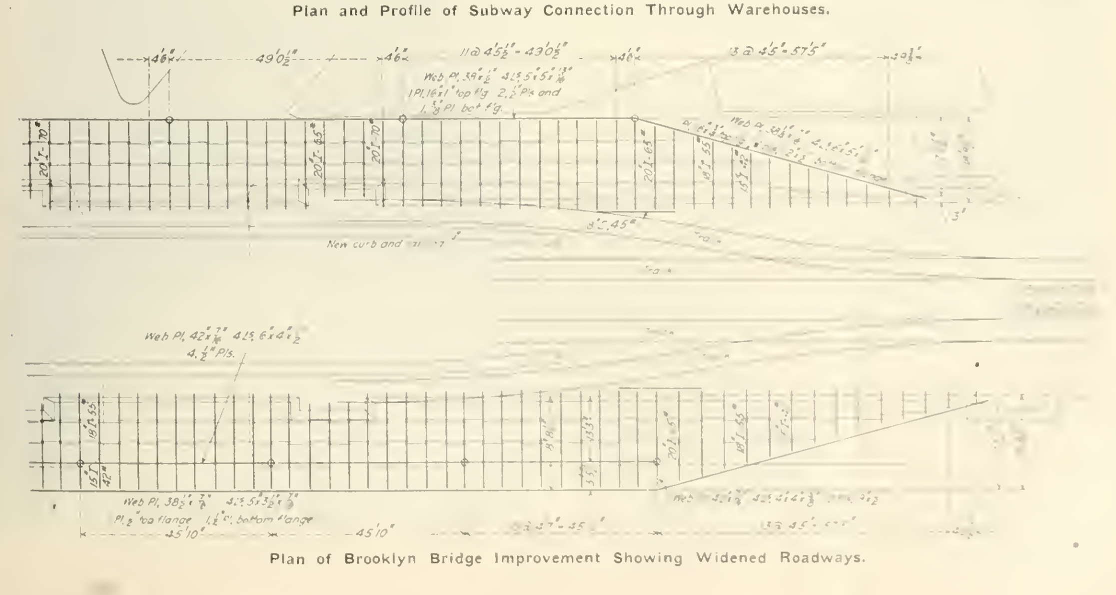
It is also expected to increase the bridge trolley service from 270 to 310 cars in the morning rush hours and from 300 to 320 cars in the evening rush hours.

The extension and the rearrangement of terminal facilities rendered possible by its completion are clearly shown in the engravings and one of the photographs. A steel structure 160 ft. long has been erected over Park Row, having a main floor on a level with the level of the previously existing elevated tracks, and with tracks extending to the end of the addition. The latter reaches almost to the line of fence of City Hall park and is directly opposite the entrances to and exits from the subway. It is architecturally in harmony with the previous structure and has a broad stairway, 40 ft. wide, leading to a mezzanine floor whence the crowd is distributed by five stairways leading to the train floor above and designated according to the destination of trains. Aside from the additional track room afforded, this whole amount of space is a substitute for the two stairways and narrow platform which formerly extended over Park Row. This is shown in dotted lines upon the engraving of the plan of the mezzanine floor.

With sufficient room for the extension of tracks to accommodate



Plan and Profile of Subway Connection Through Warehouses.



Plan of Brooklyn Bridge Improvement Showing Widened Roadways.

six-car trains. It has been possible to rearrange the crossovers between inbound and outbound tracks. These were formerly at the point shown by the dotted lines, but have now been moved toward the end to the location shown in full lines. Under this arrangement about 310 ft. of free space for loading and unloading is afforded between the end of the tracks and the fouling points of the switches, ample room for six-car trains. This change of tracks also made necessary some changes in platforms, lengthening some and shortening others, as indicated in dotted lines upon the track plan, with, however, little change in the amount of available space.

It is estimated that the increase in loading and unloading facilities, the use of six-car trains and the avoidance of change at the Brooklyn end of the bridge, will increase its capacity about 9,000 passengers per hour. The two weeks during which the extension has been in service afford some ground for hope that bridge crushes of unsavory notoriety are things of the past—temporarily, at least. The first few days of service were marked, during the hours most favorable to congestion, by crushes perhaps equal to anything in the previous history of the bridge, but both by the engineers of the city bridge department and the officials of the operating tenant, the Brooklyn Rapid Transit Company, these were attributed to the lack of familiarity with the proper lines of passenger progression on the part of the public and of the company's employees. Since the first week, however, there has been no noticeable difficulty in handling traffic as fast as it presented itself and even during that week 61 trains per hour were despatched from the Manhattan terminal. With the completion of the signal and interlocking arrangements it may be expected that trains will be handled regularly and smoothly under this or even less headway.

New Extension of Manhattan Terminal of Brooklyn Bridge.

It has, however, been suggested that a considerable improvement could be effected by increasing the door and gate space. It is calculated that in the absence of side doors and on account of the narrow gates upon the regular cars of the Brooklyn Rapid Transit Company, the entrance space is some 18 ft. less than upon the cable cars of which they take the place. This would be roughly equivalent to a stream of nine persons abreast. Even with the present equipment it is apparent that a great improvement has been made, though it is possible to attribute some of the decreased congestion upon the bridge to the relief afforded by the East river tunnels from the battery to Borough Hall.

Both of the improvements herein described were planned and executed, or are under execution by the city bridge department, C. M. Ingersoll, Chief Engineer. The extension and rearrangement of tracks was made in accordance with general plans accepted by the Brooklyn Rapid Transit Company. Though the work was accomplished under a daily traffic of 126,000 persons, it has been brought to completion with remarkable rapidity.

Foreign Railroad Notes.

The French Minister of Public Works has submitted to Parliament a bill for pensions to railroad employees, by which all employees who have served as long as two years will be entitled on reaching the age of 55 to a pension at the rate of 17 per cent. of their regular pay, and at the same rate if invalided at an earlier age. In case of the employee's death his widow is to be entitled to one-half of this pension. In case of death before 55, widow and orphans will have the same rights as if he were already enjoying a pension. This is to apply to employees of the railroad companies as well as to those of the small system of State Railroads.

The Prussian State Railroad authorities lay stress on providing trainmen, etc., with facilities for taking something hot to eat or drink when on duty during cold weather. One group of lines offers them powdered sweet chocolate, put up in packages each of which is enough for a large cup, which can be prepared very quickly with boiling water kept ready for the men at a large proportion of all the stations. The prepared chocolate is sold to the men for $1.20 per 100 packages, which may be charged against wages.

To encourage traveling for winter sports, the Swiss railroads will accept those long snow shoes which the Norwegians call "skis" and small toboggans as baggage, but not bob-sleighs (spelled out in just those letters as if the Swiss were Yankees), which are a little clumsy for baggage cars.

To show how much more important to France is the old Mont Cenis Tunnel than the new Simplon the statistics of French traffic passing by the two routes in the first quarter of 1907 are cited, when 93,115 tons of freight went from France to Italy by the Mont Cenis and 3,336 by the Simplon.

Car Surpluses and Shortages, February 5.

The following table is from bulletin No. 17 of the American Railway Association's Committee on Car Efficiency. It summarizes the car surpluses and shortages from October 30, 1907, to February 5, 1908, inclusive, being similar to the table published in the *Railroad Gazette* of February 7, 1908, but carried to a later date, and with the figures for January 8 and January 22, 1908, revised to include reports since received.

While the figures for February 5 represent fewer roads than those for January 22, the omitted roads are small and would make no material change in the totals. The total surplus of all cars on February 5 is larger than on January 22 because of some large increases in coal, gondola and flat cars.

Considering all classes of cars together, the surpluses have decreased slightly in the Eastern, Middle, Central Western and South-western groups. All the other groups show increased surpluses of cars, the highest percentage of increase appearing in the Southern group. The surplus of box cars has considerably decreased, showing an improvement in general business. The surplus of box cars decreased in the New England, Eastern, Middle, North Atlantic, Northwestern, Central Western and Southwestern groups, while the other groups reported slightly increased surpluses of box cars. Surpluses of coal and gondola cars show increases in all groups except the Northwestern, Central Western and Pacific. The heaviest increase was in the Eastern group. The increase in the Middle group, where the surplus of these cars has been heaviest, was slight, while there was a continued decrease in the Northwestern group and a slight indication of improvement in the Pacific group. The total surplus amounts to about 15 per cent. of the country's cars.

Raven's Cab Signal.*

BY J. PIGG.

Actuation of Apparatus. As already stated, this system is electrical, and it is designed to collect indications by the rubbing of metallic brushes (Fig. 4) carried on the engine over metallic bars (Figs. 8 and 10) placed on the line. This method of collection is not essential to the system, since it is capable of being operated equally well without contact, by causing electromagnets on the line to influence magnets on the engine. This method of collection is not now being put forward.

Characters of Indications.—The system is one which uses visual and audible signals. The visual signals are (1) a small semaphore arm by which the "condition of line" signals are given, and (2) two small pointers showing 1—2 and 3—4 respectively, which are the route indicators. The audible signals, which are of the nature of "call attention" signals, are given by a bell.

Fig. 1—Failure Indicator.

Fig. 3—Diverging Route Indicator.

Besides these indicators, the instrument carried on the engine includes a visual failure indicator, by which the conditions of the apparatus can be gaged.

Figs. 1 and 2 show several forms in which the indicator on the engine has been made the circular form being the latest. Fig. 9 shows in diagrammatic form the complete equipment of engine and line circuits, the latter being for a 3-way diverging junction. Fig. 5 is a photograph of the back of the engine indicator with the cover removed to expose the apparatus.

Details of Indicator.—The action of the apparatus is of the simplest possible character, the main principle being the invariable operation of the apparatus at certain points by the natural action of certain parts without the aid of either the signalman or the driver, and the subsequent continuance of the indications resulting from the natural operations until they are stopped or reversed by the action of the signalman.

Considering Fig. 9, and leaving, for the present, consideration of the line of bars out of the center of the space between the running rails, it will be found that the short-circuiting of brushes 1 and 2 on, say, bar A, causes a current to pass through the main magnet, A¹, by which its armature is raised, putting the semaphore arm to danger. At the same time the armature closes the circuit of the springs *c d*, diverting the current direct back to the battery after passing through A¹. Hence the armature of the latter will remain attracted to the poles as long as may be necessary for the purposes of the apparatus.

Besides passing through A¹ and the brushes, the initial current passes through the bell relay C¹ during the continuance of the short-circuiting of the brushes 1 and 2, the armature is attracted and breaks the circuit through the spring contact (*e*). This contact forms part of the bell circuit, which itself is connected in shunt across the electromagnet A¹. Hence when the armature of A¹ is raised, the current from the engine battery tends to divide, part passing by A¹ and part by the bell. The connections, however, are such that current only passes to the bell when C¹ is unenergized, and this condition only obtains when the brushes 1 and 2 are not short-circuited. When the brushes are on a metallic bar, say A, therefore, the bell is silent, but as soon as they pass off the bars it commences to ring.

In addition to passing through the electromagnets A¹ and C¹, as described, the current to the brush 1 passes through the springs c^1 d^1, and c^2 d^2, each pair of which is normally in contact. These springs are opened by the raising of the armatures of D¹ and D² respectively. Opening the circuit at either c^1 d^1 of c^2 d^2 obviously releases the armature of A¹, and, as a consequence, stops the ringing of the bell and lowers the semaphore arm.

Currents passing through D¹ are collected from the line by the brush 2, currents passing through D² are collected from the line by one or the other of the brushes 3 and 4.

Between the poles of D¹ and D² are placed magnetized needles, n, n^1, pivoted to turn under the polarity of the poles when the electromagnets are energized. The spindles carry the pointers shown in Fig. 1. Each spindle also carries a small metal sector, slotted as shown by Figs. 9 and 5, in which rides a small metallic loop, pivoted at the other end. The passage of a current through, say, D¹ deflects the needle to one side, and the loop drops into a recess at the end of the slot and locks the needle and pointer on the front of the instrument in the deflected position. At the same time that this occurs the lifting of the armature of D¹ breaks the contact c^1 d^1, and lowers the semaphore arm and stops the bell as already stated.

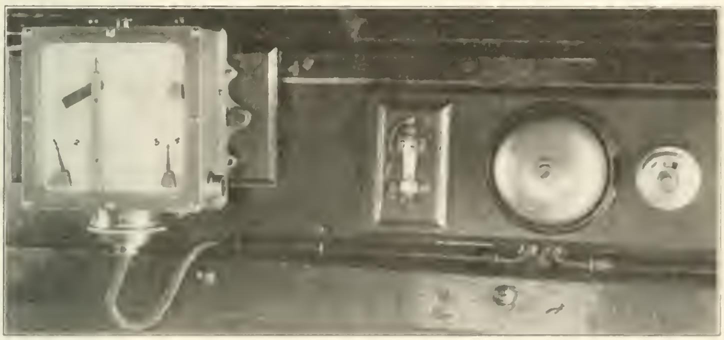

Fig. 2—Apparatus in Cab of Engine.

Auxiliary Apparatus on Engine.—The engine carries, in addition to the apparatus described, two rotary switches, the arrangement of which is shown in Fig. 6. Each switch consists of a cast steel wheel free to rotate, the spindle of which carries a two-part commutator, on which bear two springs. The wheel is weighted so as to take up a normal position. In this position the springs bearing on the commutator are insulated from each other, but when the wheel is rotated they are connected through the commutator. The springs are connected with the brushes 1 and 2 respectively, and each rotary switch, when turned from its normal position, connects the brushes in the same way as the latter are connected when on the bar A, or any subsequent bar of those shown in Fig. 9.

Track Apparatus.—The rotary switches run over fixed bars on the line side of the general form shown on the diagram, and of which more detail is shown by Fig. 7. These bars are fixed in close proximity to the bar A, as shown by Fig. 8. Hence the rotary switches are only actuated at or near the bar A.

Turning now to the line equipment, the point represented as being approached is, as already stated, a three way diverging junction. The six levers shown represent the home and advance signals for each of the diverging lines. Each home lever is fitted with a double-pole, and each advance lever with a single-pole switch, which are operated by the levers in the ordinary movement for operating

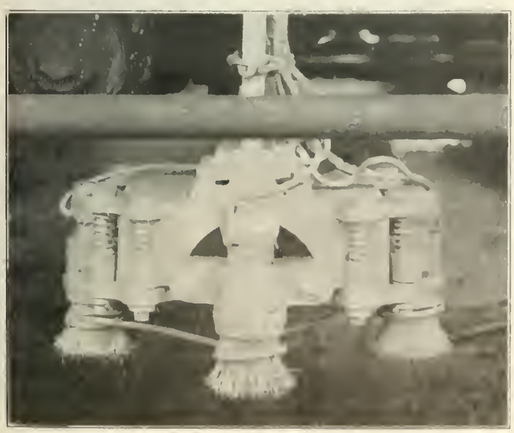

Fig. 4—Brushes.

*From a paper read before the Institution of Electrical Engineers, London, December, 1907. The introductory part was given in the *Railroad Gazette* of Feb. 14.

the signal. The home and advance levers for the lines marked Nos. 1 and 2 connect the battery in the cabin with the bars B, C, D, E, placed in the center of the track, the only difference being that the levers marked 1 apply the positive pole of the battery to these bars, and the levers marked 2 apply the negative pole to the same bars. The two levers, No. 3, connect the battery in the cabin to the supplementary bars, and if the junction was a four-way one, other levers would reverse the polarity precisely as is done by levers No. 2.

As will be seen, the battery is not applied to the bars unless both the home and the advance signal levers are pulled over. The mechanical interlocking prevents the levers for more than one line being pulled over at once, or the home signal for one line and the advance for another, and therefore in the case under consideration there is no need for more than one battery.

A view of the bar A is shown in Fig. 8. It is mounted on wood blocks, which are in turn mounted on stoneware reels. The insulation is not high, as there is no need to aim at a high degree of insulation for this bar. Fig. 10 shows the arrangement for mounting the bars. It is necessary that these bars should be well insulated, and they are therefore mounted upon doubleshed porcelain insulators of the ordinary telegraph pattern.

Fig. 5—Circular Indicator. Rear View. Cover Removed.

A further consideration of Fig. 9 will show that the preparations made for signaling to trains are indicated in the signal cabin. The two indicators required in the case of a three-way or four-way diverging junction are shown in Fig. 9. When the levers are pulled over, the current passes through a high resistance fixed at bar B, which limits the current passing before and after the engine reaches the signaling bars, but which, being in shunt with the engine circuits when signals are being given, does not affect the current to the comparatively low-resistance circuits of the engine. The resistance of the indicator is kept low with the same object. The permanent deflection of the indicator needle is comparatively small. When the signals are being given, the deflection is increased, and it can be used as an indicator to the signalman (1) of the position of the train which is approaching, and (2) whether the signals are being given on the engine.

Consecutive Operations. Consider now in further detail what takes place in a typical instance. Assume that an engine is approaching the junction shown in Fig. 9, and that line No. 1 has been prepared for it to pass forward. The home and advance signal levers No. 1 are both in the off position, and the battery in the cabin is connected positive to line. All the bars, E, D, C and, B, are connected to the battery. Bar A is never connected to the battery, and is in no way under the signalman's control.

When brushes 1 and 2 are on bar A, the current from the engine battery passes through c^2 d^2, c^1 d^1, A', C', brush 1, brush 2, and to the battery. At practically the same instant, the same circuit is separately established by each of the rotary switches 5 and 6. The semaphore arm is put to danger, and as soon as the brushes are clear of the bar, the bell commences to ring. Ordinarily the time occupied in passing over the bar is from ⅛ to 1 second, so that the bell practically begins to ring simultaneously with the raising of the semaphore arm.

The visual and audible indications given at bar A continue until the brushes, or brush 2 comes into contact with the bar B. A current then passes from the bar B to brush 2, thence to the coils of D', and the engine frame, and the rails, etc., to the battery in the cabin. The armature a^1 of D' is raised and breaks the circuit through the springs c^1 d^1, lowering the semaphore arm and causing the bell to stop ringing. At the same time the polarized needle n is deflected so that its pointer indicates 1, and the wire loop drops into the depression and lock, the pointer in the position it has taken up (Fig. 3).

The visual and audible signal given at bar A is a warning signal indicating locality with reference to the signaling point being approached; the reversal of the warning signal is the off signal. If the further passage of the train on its journey to the home signal be followed, it will be found that the bell will ring momentarily at the instant the engine passes over each of the bars C, D, E, but no change is made in the character of the visual indication.

The indicator now shows the off signal by the semaphore arm and route 1 by the pointer. These indications continue until the next signaling point is reached, and are a reminder of the last signal received.

Assume that the engine has reached another bar A. The same actions take place as described for the previous signaling point, but in addition to raising the semaphore arm, the electromagnet A, by the rod R (Fig. 9), raises the wire loop out of its recess and allows the pointer to assume its normal position. We assume again also that the road has been prepared for the train to pass forward, but in this case it is the right hand road of a two-way diverging junction. On reaching the bar B, the same operations are carried out with the exception that No. 2 route is shown. It happens, however, say, that at the time the engine obtains the off signal, and route indication, 1,000 yards away from the cabin, the signalman is being informed of a circumstance which makes it imperative for him to stop the train if possible, and he instantly throws his home signal to danger, and immediately afterward the advance. The engine at the moment is just reaching bar C, say, and on passing on to it, the off signal shown by the semaphore arm is reversed and danger shown, the route indicator is displaced, and the bell commences to ring as soon as the engine is completely over the bar. These indications will continue as long as may be necessary.

These actions constitute the receipt of a warning signal, the off and route indications and an emergency signal, calculated to avert a disaster from circumstances which have suddenly arisen.

Assume now that another bar A, belonging to another signaling point, has been reached. Precisely the same effects are produced there as have been already described. The line, however, has not been prepared for the passage of the train. On arriving at bar B the bell stops ringing momentarily, but the semaphore arm remains

Fig. 5—Fire-Proof Fixtures at Switches.

at danger. Immediately the brushes have left the bar the bell recommences. The same effects are produced at bars C, D and E if no other signal is obtained at either of those points. The last bar is placed close to the home signal and is double the length of the other bars to allow of the train being brought to a stand easily with the brushes on the bar.

Hence the on signal is obtained by the continuance of the warning signal after the engine has passed over bar B, and that indication is continued until a subsequent indication is given by the signalman. The on signal, moreover, is of such a character, considered in view of the momentary stoppages of the bell by the intermediate bars, as to enable the driver to locate his position between the point at which he obtained the warning signal, and the home signal at which he must be prepared to stop.

Assume that as the engine approaches the bar D, the signalman lowers the home and advance signals. When the brushes come upon the bar the off signal and route indication will be received precisely as already explained.

Hence the on signal originally received at B may be reversed, and an off signal may be obtained at points between B and the first stop signal just in the same way as the driver sees the line signal lowered before he reaches it in clear weather by the projection of his vision.

Making another assumption, suppose that the engine has been brought to a stand on bar E close to the home signal, and is waiting for the receipt of an off indication. The semaphore arm is at danger, but the bell is silent. The signalman lowers the home and advance line signals for the train to proceed. Immediately the semaphore arm on the engine is lowered, the route indication appears, and the bell commences to ring and continues to do so until the brushes have left the bar. Hence, the receipt of the off signal when standing at the home line signal is given, and the driver's attention is called to the change by the bell commencing and continuing to ring.

Fig. 7—Spring Bar and Ramp.

Suppose, now, that instead of sending the train straight away after bringing it to a stand at the home signal, the signalman wishes merely to call the train forward to communicate with the driver, or to bring the train forward to the advance signal, the signalman lowers the home signal and works the advance signal lever back and forward. The semaphore arm on the engine will be worked up and down and the bell will ring intermittently and call the driver's attention to the character of the indication given. Hence a cautionary or "calling on" signal can be given to trains standing at the home signal, and the indication is of a different character to other signals obtained in that position.

In the foregoing description the signals have been given for a two-way diverging junction, or for a straight road. Suppose a train traveling to the signaling point in Fig. 9, and that road No. 3 has been prepared for it. The brushes 3 and 4 are connected together so that either is available for the same purpose. As shown by the diagram, brush 4 will engage with the bars parallel to B, C, D and E. The warning signal is given by brushes 1 and 2 on A as before. On the arrival of the engine at B, the brush 4 takes the current from the bar, after which it passes through the coils D^2, deflecting the needle n^1 to 3, and by the raising of the armature breaks the contacts c^2 d^2. The wire loop drops into the recess at the end of the slot in the sector, and locks the route indicator in the position required. The net result is precisely the same as described for the route indications 1 and 2 with the exception that the first of another pair of such indications is given. Had the junction been a four-way one, the action of the levers for the signals for the fourth line would reverse the polarity of the bars, and the indication 4 would be obtained. The next operation of the electromagnet A frees the route indicators, 3—4, precisely as described for 1—2. The double brush, 3—4, is to enable signals to be obtained whether the engine is running engine or tender first, toward a three-way or four-way junction, and it is also used in connection with single line working to be described later.

Failure Indicator on Engine.—The means for testing the condition of the circuits and battery on the engine have not yet been referred to. The actual indicator is a small disc (Fig. 2) or a grid (Fig. 1) appearing at an opening in the front of the instrument, which is white when the engine battery is in operation, and red if the battery fails or is cut off. The failure indicator circuit is independent of the other apparatus. Current is taken to the coils of E^1 from one end of the battery, and thence to the brush 2, which completes the circuit. Interposed in this circuit are two small electromagnets, the poles of which embrace the polarized needles n n^1, and tend to preserve their magnetism. As the failure indicator is always in action when the engine is at work, there is a constant current available for this purpose. In carrying the "failure indicator" to brush 2, the insulated wire is wrapped around all four brushes as shown in Figs. 9 and 4. Hence any obstruction on the line which displaces the brushes will break the failure indicator circuit and bring it into action. The failure indicator magnet E^1 has a back contact, e^1, which is open when E^1 is energized, but is closed if the armature a^3 is released. This contact simply bridges the open springs, c, d, of A^1, and if the armature a^3 is released, through the breaking of the circuit of E^1, the semaphore arm rises to danger, the bell commences to ring, and the disc or grid (Fig. 1) shows red. When the battery fails the disc or grid shows red.

Single Line Working.—Fig. 11 shows the engine equipment available for single or double line working. It only differs from Fig. 9 in the addition of a small three-pole, three-way switch. It is unnecessary to describe this in detail, as the side references afford sufficient information to follow the connections. In the center position of the switch the apparatus is ready for double line working engine or tender first. In the left-hand position it is available for single line working, engine first; and in the right-hand position for single line working, tender first.

The peculiarities of single line working require modifications of the track apparatus to obviate the receiving of signals on an engine proceeding in one direction, from the track apparatus provided for traffic proceeding in the opposite direction on the same pair of rails. A simple form of single line equipment is shown in Fig. 11, an examination of which will show that the bars A are double, but connected together electrically, and that only one spring bar for operating the rotary switches is provided near A, instead of two as in double line working. The additional bar connected to A is always on the left-hand side of the latter looking in the direction in which traffic passes for which the line signals are provided. Similarly the spring bars for the rotary switches are always on the left-hand side.

An examination of the switch circuits will also show that the operation of the switch to right or left always cuts out of use the right-hand rotary switch and the right-hand brush (3 or 4) looking in the direction in which the engine is traveling. It also puts out of action brush 1. Hence only the left-hand rotary switch and the left hand brush (3 or 4, according to whether the engine is running engine first or tender first) are operative, and while the right-hand rotary will be turned by the spring bars for trains going in the other direction, the brush 1 will always bear upon the center bars, and the right-hand brush (3 or 4) will always bear on the right-hand bars, their usual functions are in abeyance in consequence of the position of the switch. The warning signal is given by the short-circuiting of the brushes 2—3 (or 4) and the rotation of the left-hand rotary. The off signals are taken up by the brush 2 for the route indicators 1—2, and by the brush 3 (or 4) from supplementary bars for the route indicators 3—4. All other operations remain as described. Hence a simple movement of the switch to one side or the other, according as the engine is running engine or tender first, is all that is necessary in passing from double to single lines, or *vice versa*.

Fig. 8—Bar A.

Recording Indications Obtained.—The system iends itself readily to the adoption of means by which the "condition of line" signals obtained may be easily recorded for each signaling point. The length of time during which the semaphore arm is maintained at danger differs in accordance with the condition of the line. If an off signal is obtained at B the time is short, if the on signal is received the time will be longer, and will depend upon the point at which the off signal is ultimately received. In any case the difference is appreciable. This difference may be utilized in order to produce marks of corresponding length upon a cylinder which rotates and travels longitudinally at the same time, by adding a marking pen or pencil to the rod b of A, so that a mark is made as long as the armature (a) is raised. The motion of the cylinder causes the marks to form a spiral. For places where the off signal is obtained at the bar B, the mark is a dot only. Where the on signal is obtained at B, the mark is a line of greater or less length according to the time that elapses before the off signal is obtained. The drum carrying the paper cylinder is driven by clockwork, and is under the control of the signaling apparatus, so that it is only running when marks are to be made, and the driving mechanism and the marking cylinder are therefore kept of quite moderate dimensions. Arrangements are made by which the driver can produce a space longer than that provided by the design of the apparatus, and so distinguish between the marks made during one journey and the next.

CONCLUSION.

I. — (a) The natural action of the bar A through the brushes and that of the yielding bars upon the rotary switches upon the engine circuits constitute a signal, warning the driver of his approach to a signaling point, at which further indications must be looked for at once. (b) Neither the engine driver nor the signalman are required to do anything to produce this signal. (c) The indications being given from three independent points for double lines and from two for single lines, provide ample marking for failures of apparatus from any cause outside ordinary maintenance of the battery. (d) The alternative method for producing this indication and the difference in their positions on the engine and track are guarantees that anything likely to affect one means prejudicially is not likely to affect the other.

II. — The continuance of the warning signal constitutes an effective danger "condition of line" signal, relating to the stop signals which are being approached. The bar A is situated at a distance of about 100 yds from B. The warning signal proper is therefore of short continuance only if the stop signals are off. No time is lost in conveying the further indication on when the stop signals are in that position. The subsidiary indications given by the

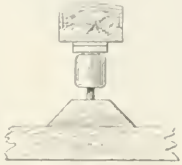

Fig. 10—Support of Insulated Bar.

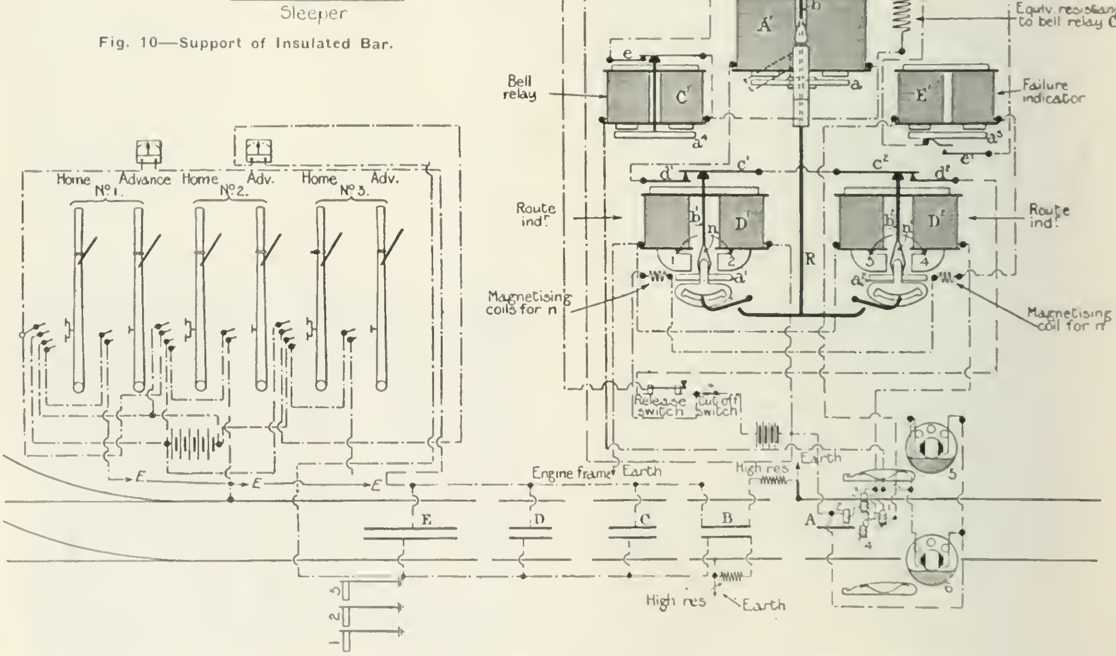

Fig. 9—Electrical Apparatus and Circuits for Raven's Cab Signal; North Eastern Railway.

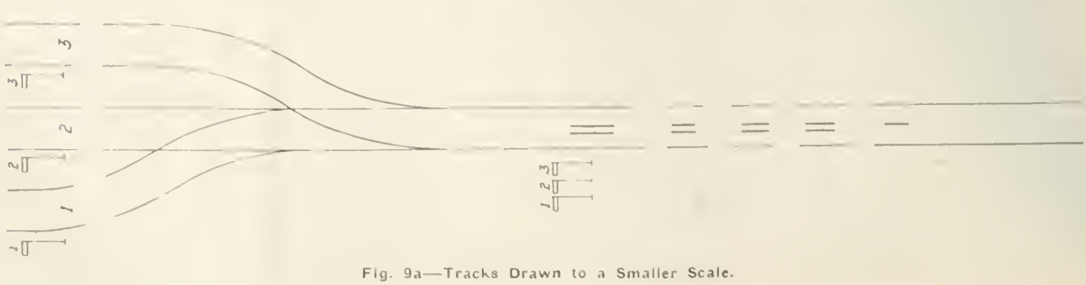

Fig. 9a—Tracks Drawn to a Smaller Scale.

momentary stoppages of the bell, are valuable for indicating the progress of the train toward the stop signal, when conditions of weather prevent the ordinary landmarks from being seen.

III.—The stopping of the warning signal by the return of the semaphore arm to the off position, the stopping of the bell, and the receipt of the route indication constitute a complete off or line clear signal, which, since it cannot be given unless both the stop signals controlling entrance to the next section are off, gives also the exact information now given by the lowering of the line distant signal. The convention under which the route indications are numbered is in strict accordance with the convention under which the line signals are erected. A straight through point is always signaled as 1.

IV.—Either "condition of line" indication received at bar B can be reversed before the engine reaches the stop signal. The number of intermediate points at which these reversals can be obtained is limited only by the number of intermediate bars provided. Additional bars are not costly.

V.—The off signal can be given when the train is standing at the home signal equally as well as when it is traveling, and attention is called to its being given by the audible signal. The signal given when the train is standing at the home signal can be modified by the signalman to indicate a calling on signal, or the equivalent of a flag signal, and this is totally distinct to the off or "line clear" signal.

VI.—Indications are provided in the cabin by which the signalman knows whether his apparatus is in order, and by which he can trace the progress of a train toward the home signal from the bar B, and note whether the signals appear to be given correctly.

VII.—The system, being electrical, admits of the signaling point —the bar B—being put at any distance from the cabin without affecting the efficiency. There is, therefore, no reason why it should be put at the point at which the line distant is now erected. Such signals are usually visible at some distance, and there is no reason why the bar B should not be set at this sighting distance. The increasing speed of trains makes it desirable that the signals given at B should be obtained as early as possible, to admit of easy braking when necessary.

VIII. The line distant signal plays no part in the working of the system, and may be dispensed with if desired.

IX.—A further examination of the system will show that failure of the apparatus on the line will not cause a false off signal to be given. Any failure of the battery in the cabin, or breakage of the line wire puts the bars B, C, D and E into exactly the same condition as A, which can only produce the danger indications. Contact of the line wire with telegraph wires on the same poles is not likely to give a false signal, as the apparatus on the engine requires stronger currents than are to be met with in telegraphy. Failure of the apparatus on the engine provides its own indications.

X. and XI.—* * * The system has been used two winters with no difficulty from ice. The brushes seem to clean the bars at every operation. If films of ice were to make trouble, a daily rubbing with an oiled rag would cure it. The insulation of the energized bars has been found more difficult than the maintenance of the contacts, but the double-shed insulator, now in use more than 18 months, has cured all troubles. * * * It will be seen that the system furnishes the maximum information with a minimum of apparatus. Shocks due to impact have been done away with. * * *

XII.—The system has now been in use experimentally on the North-Eastern Railway for nearly two years, on what is the fastest short-distance train in the world, and on other express passenger trains. No attempt has been made to develop it by trials on slow trains. Under the conditions of use, the apparatus is working perfectly. The directors of the North-Eastern have arranged for the equipment of 20 more of their express engines and of about 14 miles of their main line between Newcastle and Durham.

Dry cells have been found to give the best results on the engine, and have given perfectly good results in connection with the track

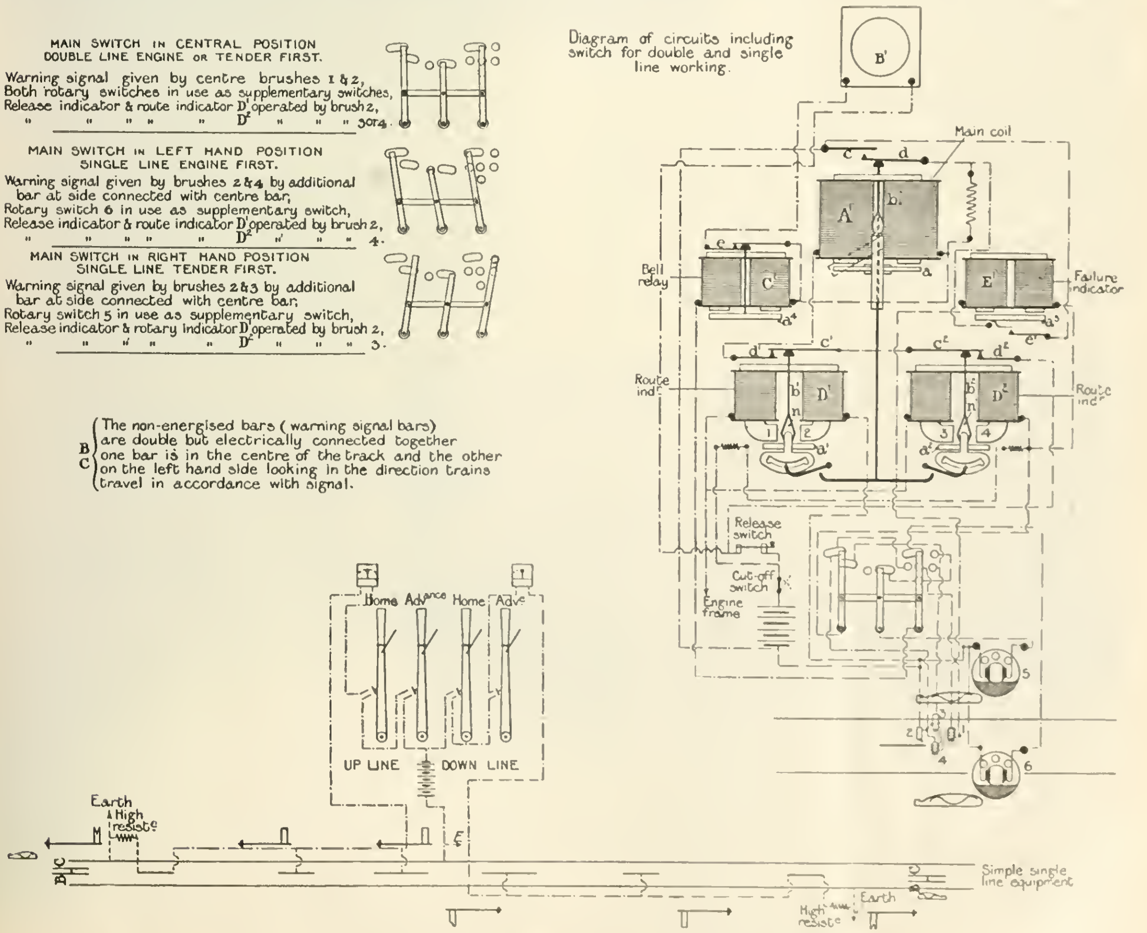

Fig. 11—Raven's Cab Signal Circuits Arranged for Single-Track Operation.

circuits. Six cells are required on the engine, and twelve cells are used in the cabin for the track circuit. The wire for connecting the energized bars with the battery in the cabin is carried on the telegraph poles.

The Ocean Carrier.

BY J. RUSSELL SMITH, PH.D.

VII.

The Railroad Steamship Lines on the Atlantic and Gulf Coasts of the United States.

The previous article has pointed out the tendency of transportation companies to consolidate by both land and sea. There is no reason why the two systems of transportation should stay apart, and it is natural that this process of consolidation should overleap the land and demand the combination of both steamship and rail road lines to complete the requisite unity of service. The railroad line with steamship feeders would be benefited thereby and at the same time steamship lines with railroad alliances would be better served. There is a common want and a mutual advantage—each can help the other in its desired extension of service.

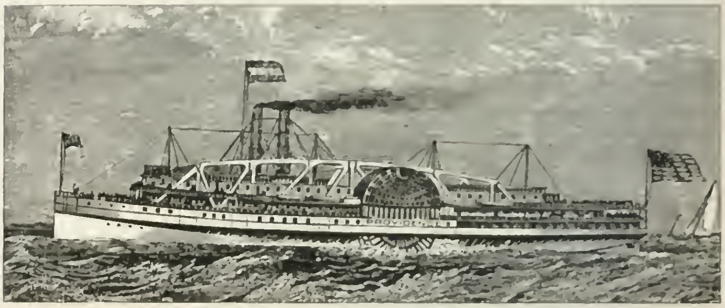
Extension of service does not necessarily mean consolidation of carriers. If it so happens that the desired service can be obtained without consolidation, the consolidation will probably not occur. The railroad that has its terminus in a port with great sea connections finds its wants supplied. Alliances there are unnecessary, and indeed they may be rather more entangling and limiting than beneficial, and are therefore to be avoided. New York, London and Liverpool are not the ports in which we can best study railroad steamship lines. The railroads that reach these ports have practically completed their world connections by reaching a point where these connections have been already established in response to the demands of existing local commerce. The number of ports with such satisfactory connections is small, and in most parts of the world the railroad that reaches the sea finds its wants unsatisfied if it depends upon such sea carriers as may independently seek freight at its terminus. The railroad must extend itself across the seas. It is thus manifest why the railroad steamship line is of a world-wide occurrence. It has its fullest development in America, but it exists also in the Irish, Baltic, Aegean, Yellow and Japan seas.

THE EXPERIENCE OF AMERICAN RAILROADS.

In its larger aspects, the railroad steamship line is coincident with the development of long railroad lines, but it had its American origin on Long Island sound in the early days of railroads in America. This partly enclosed body of water offering a somewhat sheltered route almost directly toward Boston from New York was admirably placed by nature for this combination service, which developed most naturally. The steamboats from New York to Norwich in 1818 connected there with the stage lines to Boston and other eastern points, and from that day to this there has been a varying but generally increased amount of co-operation between the two carriers, which has almost resulted in unanimity of ownership.

The first steamboat line from New York to Providence in 1822 was followed by another in 1827, and connecting stage lines carried the passengers on to Boston. In 1832 there were four of these stage lines, and they competed even more fiercely than the steamboat lines and this competition was keen. This competition between the two groups of carriers promptly worked toward a consolidation of service upon the opening of the railroad from Boston to Providence June 15, 1835. Just at this time Cornelius Vanderbilt put a steamer on this route, and he met the competition of the older line by having a special train take his passengers from Providence to Boston. The boats of the older lines left Providence for New York just after the arrival of the noon train from Boston.

This informal connection between the railroad and the steamboat did not survive, nor was the steamboat's dominance in the relationship to be permanent. Within two years (1837) the Rhode Island Legislature was calling the Boston & Providence Railroad to account for having violated its charter by refusing to some steamboats free access to its wharves for the discharge of through passengers and freight. This fruitless action resulted because the railroad had for some time been interested in some of the steamboats and took this means, though ineffectually, to break the opposition.



Steamer Providence (1866) Fall River Line.

A railroad owned by another company was completed from Providence to Stonington late in the same year, and in the season of 1838 this company made agreements with Vanderbilt and other steamboat owners for a steamboat line connecting at that point for New York. Just at this juncture the Atlantic Steamboat Company, a new corporation, put on a very fast boat to Providence. The Boston & Providence Railroad Company at once put down the fare from Providence to New York to $2 direct and $3 via the quicker Stonington route. The boat of the new Atlantic company was too fast for them and the next step was to offer to purchase Vanderbilt's steamer for $60,000, provided she could beat the boat of the rival Atlantic Company. This she failed regularly to do so the fare by the railroad steamboat line came down to $1. Petty persecutions followed, no special trains would be granted to the passengers of the rival boat when she missed the regular train. But despite these efforts, the rivalry and races were stopped only by the railroad company's purchase of stock in the rival Atlantic Company and consequent strong representation on the board.

Steamer Priscilla (1894) Fall River Line; New York, New Haven & Hartford.

By 1845, upon the completion of the Norwich & Worcester Railroad, the Boston-New York traveler had the option of a third combined water and rail route, that via rail to Norwich, Conn., and thence by boat down the Thames and along the sound, but this did not give any severe competition with the Boston & Providence Company, which was the strong member of the group.

The years 1844-46 were years of active competition with three or four independent steamboat lines running between New York and the Long Island sound terminus of the Boston roads. In 1845 Vanderbilt, Drew and others got possession of the Providence & Stonington Railroad, and Drew took the presidency of the New Jersey Steam Navigation Company, which was the leading boat company of the sound and the successor of the original line. In 1844 there was another combination route opened via the Long Island Railroad from Brooklyn to Greenport, Long Island, whence steamers plied to Stonington & Providence, and also to Norwich to connect with the road via Worcester. This Long Island route, having the longest rail line and the shortest water line, had the advantage over all others in point of time required. In this respect, it had the same advantage over the Stonington route that the Stonington route had over the Providence route. This Long Island line was very popular, was much used for three years and carried the United States mail to Boston, but it was discontinued in 1847 on the completion of the New York, New Haven & Hartford Railroad and the opening of the Fall River Line. The Long Island route was a Vanderbilt interest, and he also had control of the Norwich route. The new steamer "Atlantic," which made its first trip from Norwich to New York, August, 1846, was a vessel 320 ft. long, 1,400 tons, and was described in *Hunt's Merchants Magazine* of that year (v 15:323) as the property of the Norwich & Worcester Railroad & Steamboat Co.

Steamship Colon; Panama Railroad.

It was said to be the acme of perfection, the finest as well as the largest ever built in America.

The Fall River Line (the Bay State Steamboat Co.) commenced business in May, 1847, running in connection with the Old Colony Railroad, which had been opened a few months before giving a through line from Fall River to Boston. The early opening of the steamboat line to complete the service to New York was brought about in the now well known manner of having the steamboat company well represented on the board of the railroad company. At various times during this early period difficulties arose over the division of proceeds between the railroads and the contracting steamship companies. In 1860 the future was foreshadowed and the difficulty settled for the Norwich & Worcester Railroad Company through the company itself taking a large interest in the organization of the Norwich & New York Transportation Company.

In 1860 the Stonington Railroad was extended to Groton, which in that year became the terminus of the steamboat line to New York. The destruction of the terminals at Groton led to the return of the line to Stonington in 1865. In the disturbed period just after the Civil War, there were various rearrangements and reorganizations of lines on the sound, one of which, through the failure of the Merchants Navigation & Transportation Company, left the Stonington road without connections in January, 1867. The company then adopted the thoroughly modern expedient of organizing the Stonington Steamship Company, in which it held 85 per cent. of the stock.

In the same year, 1867, a new route to Boston was opened by a contract arrangement between the steamers and the railroad connecting at Bristol. In 1868 this line and the Stonington line competed until rates went down to a dollar from Boston to New York, but they soon stopped that policy and worked harmoniously until in the hard times of 1877, the Stonington Company opened a new passenger steamship line to connect with Boston via Providence. This precipitated another rate war, during a part of which there were six different combination water and rail routes from New York to Boston, and two of them were operated by the Fall River Line, now in the control of the Old Colony Railroad Company. The rate war lasted until 1881 and was ended by an agreement to divide a part of the traffic among the contestants.

About 1885 the New York, New Haven & Hartford Railroad Company began to strengthen its grip on the steamer lines of the sound and in a decade it had gone a long way toward their absorption. In 1893 the New York, Providence & Boston Railroad was merged and with it went the Providence and Stonington Lines of steamers. Two weeks later a 99-year lease of the Old Colony Railroad followed and with it went the Fall River Line. In 1898 the New York & New England Railroad was absorbed, carrying with it the New York & New London Steamboat Line. In 1899 the New York & Hartford Steamboat Company opened a new line to Providence, calling it the Narragansett Bay Line, but the next year the New York, New Haven & Hartford Railroad got control of the company and withdrew the line.

The monopoly by the railroad steamship lines was, however, hard to maintain. The year after the last purchase just mentioned, the Joy Line, which had before been carrying only freight to Providence, began to carry passengers. The railroad met this by putting on a new steamboat line. The older regular lines were charging $3 to Providence, the Joy Line $1.75 and the new railroad boat line charged $1, and the Joy Line met this with $1.50 round trip.* At this time the rate on the old Fall River Line was still $3 and the traffic was falling. The competition went on until October, 1902, when the railroad with its many steamers and services could protect itself only by making an agreement with the Joy Line. Nor did even this guarantee it in peaceful monopoly, as "every year or so"† new competitors kept springing up. In 1906 this rivalry took the new form of trolley-steamboat competition in an active form at the hands of the Enterprise Navigation Company, which was selling through tickets at low rates in connection with trolley lines from Fall River to Boston.

The checkered experience of the steamboat lines on Long Island sound as they have gradually become more and more nearly railroad appendages is illustrative of the methods that have prevailed the world over, but it is scarcely worthy of the name of ocean transportation.

The Panama Railroad & Steamship Company is probably the first clear example of the oversea line in connection with an American railroad. This railroad, completed in 1855, was almost unique in having no local traffic and in being a connecting link between two sea ports which exist only because of through trade. To improve its traffic this road promptly established a steamship line from New York, and made contract arrangements with the then existing Pacific Steamship Companies plying north to Portland and south to Valparaiso. At times it has operated steamship lines of its own on both oceans, and its traffic contracts have been numerous.

Steamship Momus; Southern Pacific Company.

The year 1870 seems to mark the general beginning of formal

*Railroad Gazette, 1900, p. 499 and 516
†Railroad Gazette, 1906, p. 447.

connections between American railroad lines and transatlantic shipping companies. Before that time coasting lines at various points had come under the control of the railroad companies to benefit the delivery of the railroad freight. This process has gone steadily forward until now many of the lines of coasting vessels in the United States are directly or indirectly controlled by the railroad companies, and most of those which are called independent must apparently have good working arrangements with railroad lines in order to keep out rivals.

About 1870 the eastern trunk line railroads having their termini on the line from Buffalo to Pittsburgh, and down the Ohio to Cincinnati, began to extend their lines to the Mississippi and to Lake Shore points. To secure traffic from across the lakes they put lines of carriers upon the Great Lakes, and on those waters today the independent carriers are in a very small minority. This process began on the Great Lakes shortly after 1850,* when the roads having their termini at Buffalo reached out to the west for traffic by operating or arranging for steamer lines on the lakes. The new western connections won by the expanding eastern railroads gave an increase of through traffic which demanded satisfactory outlet across the Atlantic if the railroads were to prosper. This situation is well described in the words of the Pennsylvania Railroad Report for 1871 (see p. 25): "The main object of the organization of the Pennsylvania Railroad Company was to promote the traffic between this city (Philadelphia) and the west. * * * It was confidently expected on the completion of our railway, that the enterprise and the capital of the citizens of Philadelphia would have been at once enlisted in the marketing of the product brought to their doors, and the means furnished to transport them to the points of consumption. But it soon became evident that this could not be depended upon, and that our cars must pass to New York to meet purchasers of their contents, or the business of the company would be dwarfed to that of a second class railroad, a fact which the interests of the shareholders would not permit."

The situation thus described by the directors of the Pennsylvania was felt keenly by all eastern trunk lines, and they took steps to help themselves out of the predicament. The Pennsylvania organized a steamship company, which operated to Liverpool a line of steamers called the American Line, established in 1871. The majority of the stock of this company was held by the Pennsylvania, which also guaranteed the bonds of the shipping company. The organization of this corporation was similar to that of numerous subsidiary corporations organized by the officials of the Pennsylvania. The venture can scarcely be called a success because of the railroad's needs for more frequent and varied services than the commerce of Philadelphia supported. The reports of the railroad for the next few years very clearly showed this difficulty. As the next step to overcome it, the Pennsylvania secured the United Railroads of New Jersey (leased in May, 1871, for 999 years), giving a direct outlet to New York harbor with its many steamship connections.

In 1884 the railroad company's American Line ceased to run under that name and passed into the hands of the International Navigation Company. Both of these companies were presided over by a director of the Pennsylvania, and this relationship continued until after the formation of the International Mercantile Marine Company in 1902. Intelligent opinion in both England and America held strongly to the opinion that there was friendly and practical relationship between the Pennsylvania Railroad and the shipping company.† It should be remembered that the primary wants of the Pennsylvania Railroad were satisfied by its New York terminal, which accounts for the railroad company's lessened interest in the steamship enterprise.

The Baltimore & Ohio with its terminus at Baltimore, preceded by a year or two the entrance of the Pennsylvania into the shipping business by aiding in the establishment of the Atlantic Transport Line, which grew out of the Baltimore Storage & Lighterage Company, and gave the Baltimore & Ohio a European outlet. As was shown in the case of the Pennsylvania Railroad, ocean service from Philadelphia depended upon the steamship company acting in connection with the railroad itself. This was still more the case at Baltimore, and at such small places as Norfolk or Newport News, a railroad was helpless that did not depend upon some other seaport or furnish its own connections. At first the Norfolk & Western and Chesapeake & Ohio lines were dependent upon New York, through the aid of the Old Dominion and Clyde lines of coasting steamers. Then each of these railroad companies established a line of steamers to Europe. Later the Norfolk & Western gave up its line and lightered its goods across the estuary of the James to the terminals of the Chesapeake & Ohio, to export them by the Chesapeake & Ohio steamers. This steamship company, which is technically a British company with ships under the British flag, was controlled by the Chesapeake & Ohio until June, 1905, at which time the railroad withdrew its interest, but established an arrangement for continuing the service. This steamship line, from the mouth of the James and the Chesapeake, appears, in fact, to have gone through a number of arrangements. In 1900‡ the Southern Railway had been admitted to joint use of it and steamers were despatched to London, Liverpool, Hamburg and Rotterdam. At the same time two of the railroads, the Southern and the Norfolk & Western, had an arrangement with the United States Shipping Co. for the despatch of steamers direct to Dublin, Belfast, Glasgow, Antwerp and Amsterdam.

The ownership of the trans-Atlantic steamship line by the railroad company is not usual on the Atlantic coast, nor has it been from the first, the common method being a freight agreement between a railroad and a steamship owning company. The railroad company builds terminals, which it leases to the steamship company at nominal rates. In the period of the 70s and early 80s it was common for the railroad to guarantee the steamship company a certain amount of freight each month. This practice is not now so common, although the contracts cover periods of from five to ten years, and the railroad guarantees to deliver goods to the steamship line, and the steamship line to take the goods from the railroad and deliver import goods in return. The contracts are not mutually exclusive, but as the railroad controls the terminals, switching charges upon cars from other companies serve as a practical tax upon such shipment. It is easily possible, however, for goods to come by lighters from other railroads and go over the ship's side, although in the city of Boston even this is taxed by a so-called switching charge when the freight comes from the terminal of another railroad company.

This is quite different from the situation in New York, where nearly everything that is shipped is lightered, and each carrier deals with all others on terms of equality. There is also this further difference, that in New York the shipping line being independent of all railroads must provide its own terminal facilities, whereas in other ports they are usually provided by the railroad, which thereby guarantees its outlet. This is plainly evident at present in Philadelphia, where there are several lines operating to European ports in connection with the Reading and Pennsylvania railroads and using their terminals. Boston has such lines, and from Portland, Maine, the Grand Trunk announced in 1903 that there would be four services to British ports, in connection with the Grand Trunk Railway during the ensuing winter, weekly to Liverpool and London; fortnightly to Bristol and Glasgow. These contracts were with three different steamship companies.

The ports upon the Gulf of Mexico usually having small population and little variety of freight are quite as dependent upon formal arrangements between railroads and steamship as are the smaller Atlantic ports. The Atlantic Coast Line, for example, has lines running from Miami to Key West and from Port Tampa to Havana. The vessels, under the flag of the Peninsular & Occidental Steamship Company, are controlled by the railroad company. The small port of Pensacola, served by the Louisville & Nashville, has a line of British steamers in which the railroad company is interested, running to Mexican ports. The company also has a contract with an Austrian steamship company to run a regular line of vessels between Pensacola and southern Europe. This regular service succeeded the occasional despatch of ships which had for eight years past been running between Pensacola, Genoa and Venice. The Louisville & Nashville has also contract arrangements with seven other lines of foreign steamers giving service from Pensacola to Liverpool, Hamburg, Bremen, Antwerp, Havre, Copenhagen, Rotterdam, China and Japan. The railroad took these steps to free itself from the irregular service of tramp vessels.

The Illinois Central Railroad, with its spacious New Orleans terminals, has similar arrangements with lines to some European ports, but in the larger ports of New Orleans and Galveston, the steamers in the foreign trade are more commonly independent than is the case in the smaller ports like Pensacola and Gulfport. The Southern Pacific has long run a line of steamers from New Orleans to New York, and in 1902 a direct line was established between Galveston and New York, thereby shortening the rail haul for western goods, but the New York-New Orleans service was still continued. Since the acquisition of the Cromwell Line passengers as well as freight have been carried between these points by the railroad company's steamers, and three fast passenger steamers have been added to the service, one of which is illustrated herewith.

(To be continued.)

The German Empire more than a year ago imposed what seemed to be a moderate tax on railroad tickets. The result of it has been a diversion of travel from the higher to the lower classes to such an extent that a decrease of about $2,500,000 in the passenger earnings of the Prussian State Railroads alone is attributed to it. Nearly at the same time a new schedule of charges for passengers and baggage was introduced, which on the same railroads reduced earnings about $1,500,000, but this was expected.

GENERAL NEWS SECTION

NOTES.

The Pennsylvania has issued rules forbidding profanity in its shops.

The roads in the Southeastern Passenger Association are to grant no further theatrical rates.

The Southern Pacific is increasing the number of stations which bill through to eastern points.

Railroad employees in Louisiana are preparing a great petition to the legislature not to pass a 2-cent-a-mile law.

The Western Transit Company, the lake line of the New York Central, is to open a traffic office in Spokane, Wash.

The Baltimore & Ohio put the nine-hour telegraphers' law in effect on February 17. The law becomes operative on March 4.

The Jim Crow railroad station built by the Midland Valley, in accordance with the constitution of Oklahoma, at Taft, Okla., was on February 14 burned by negroes.

The Interstate Commerce Commission, through United States attorneys, is to prosecute the Southern Pacific Company for alleged large rebating transactions in California.

The Boston & Maine has cut by 10 per cent. the salaries of all employees receiving more than $100 a month, with the provision that none of these shall be reduced below $100.

The Supreme Court of Kansas has declared the freight demurrage law of 1905 constitutional, imposing a penalty of $1 per car per day for delay in furnishing freight cars ordered.

A general wage conference has been called at St. Paul, March 9, at which contemplated wage reductions west of Chicago will be discussed by railroad officers and union delegates.

The Oklahoma State Corporation Commission has ordered that no passenger on a railroad shall be compelled to give up his ticket or pay his fare until a seat has been furnished him.

The Nebraska State Railroad Commission, on February 11, instructed the Attorney-General to prosecute all pass-holders not included in the list of exceptions to the anti-pass law.

The New York Court of Appeals has awarded damages in a case where "this side up" notice on a number of freight packages were ignored by the railroad, to the damage of the contents of packages.

The differential in favor of Galveston over New Orleans on packing house products carried to Havana has been reduced from 2 cents to 1 cent; in July, 1907, it had been reduced from 4 cents to 2 cents.

President Diaz has ordered that all American railroad employees in Mexico must learn to speak Spanish within six months in compliance with the petition of the Grand Lodge of Mexican Railroad Employees.

Both houses of the Virginia Legislature have passed the bill allowing parallels to the Richmond, Fredericksburg & Potomac to be built. This step was recently favored in a long letter by John Skelton Williams.

The New England Car Service Association has voted to dissolve, effective February 29. The railroads which constituted the association will handle the business and hope to save some $40,000 to $50,000 a year.

Two cylindrical cement kilns, 125 ft. long, each with an outside diameter of 9 ft. 5 in. at the widest point, are being shipped from the Vulcan Iron Works at Wilkesbarre, Pa., to Los Angeles. Each kiln is loaded upon three steel flat cars.

Judge Hanford, of United States District Court, on February 15, at Olympia, Wash., handed down a decision holding that the railroad commission at Washington has no authority to fix rates, this right being vested only in the state legislature.

The Wisconsin Railroad Commission has ruled that the railroads of that state are free to close telegraph stations on account of the nine-hour law. It holds that the stations closed thus far do not interfere with the safe operation of traffic.

On the Cincinnati, New Orleans & Texas Pacific and the Alabama Great Southern, employees whose pay is more than $100 a month are to have it cut 10 per cent.; employees receiving between $50 and $100 a month are to have their pay cut 5 per cent.

A press despatch says that the Georgia Railroad Commission will order the Southern Railway to pay $100 fine for five failures of the station agent of Hiram, Ga., to post late trains. If the railroad does not pay, the Governor will be asked to sue under the law, which places a fine of $200 for such offense.

Colonist rates to the west, to be in effect through March and April, will be $5 higher than formerly from both Chicago and Missouri river gateways. Although stop-overs are not allowed on regular first and second class tickets, they are on these cheap tickets.

The Kansas Railroad Commission ordered the railroads of the state to put a maximum freight tariff which makes a reduction of about 20 per cent. in the freight rates in effect on February 14. The roads have 30 days in which to determine whether they will contest the law.

The railroad commission of Texas on February 18 directed the Attorney-General to bring suit against the Missouri, Kansas & Texas, the Galveston, Harrisburg & San Antonio, and the Texas & New Orleans to recover heavy penalties for failure to run passenger trains on time.

The Railroad Commission of Indiana has given a decision that a railroad may grant lower rates to other railroads than to other shippers. It was shown that to prohibit these lower rates would destroy a market for about 750,000 tons a year of Indiana coal now sold to railroads.

The Union Pacific is to reduce its rates from Missouri river gateways to points in the Northwest to the reduced level in force on the Great Northern and the Northern Pacific as a result of reductions under the 2-cent fare law in Minnesota and 2½-cent fare law in North Dakota.

The Pennsylvania will hereafter use only one engine on passenger trains up the steep westbound grade near Altoona, Pa. The 18 hour Pennsylvania Special Limited will lose six minutes in consequence, but the time will be made up west of the Gallitzin tunnel near the top of the grade.

The Burlington and the Denver & Rio Grande have begun a new joint service for l.c.l. freight from Chicago to Colorado and Utah points. The time over the Burlington from Chicago to Denver is 68 hours, and over the Denver & Rio Grande from Denver to Salt Lake City 48 hours, a total of 116 hours from Chicago to Salt Lake City.

The Central Electric Traffic Association, which has been formed at Dayton, Ohio, is a branch of the Central Electric Railway Association which is made up of electric lines in Ohio, Indiana, Illinois, southern Michigan and northern Kentucky. The new organization is intending to do for electric lines what freight and passenger associations are doing for steam roads.

In spite of the 2-cent clause in the Oklahoma constitution, the Corporation Commission has issued an order exempting the Fort Smith & Western, the Oklahoma Central and the Wichita Falls and Northwestern railroads from the reduced rates. The Fort Smith & Western is to be allowed to charge 2½ cents and the other two roads will be allowed to charge 3 cents.

The Arkansas Supreme Court, on February 10, decided that the state could not compel through trains on the Iron Mountain to stop at Arkadelphia in compliance with a special act passed by the recent legislature. The court held that Arkadelphia was provided with ample facilities, and that to stop through trains there would be an interference with interstate traffic; hence the act was declared void.

The Interstate Commerce Commission, reporting to the Senate in answer to a resolution of Senator Tillman in an inquiry designed to throw light on availability of railroad bonds as securities under the proposed Aldrich currency act, reports that there is a constant tendency toward railroad combination; also that the express companies of the country hold $22,200,000 in railroad stocks and $12,300,000 in railroad bonds.

The Central Passenger Association has resolved not to make summer tourist rates lower than 2 cents a mile, subject to a concurrence of western roads. The Grand Trunk has reserved the right to make a lower rate. Among the difficulties of adhering to this minimum are the competition in certain localities between rail and water lines for summer traffic and the fact that rate fare legislation is threatened unless lower tourist rates are made.

Adversity has its uses. Since the slackening of freight traffic the Pennsylvania Railroad has been extending the use of absolute block signaling in the running of freight trains, and an officer of the road says that he hopes that the facility with which the regulations can be carried out and the satisfaction which the trainmen find in absolute blocking, will be so pronounced that the abandonment of permissive blocking can be made permanent, even after business shall have picked up.

The Ward Line and eastern trunk lines have failed in their effort to make a change in the division of territory for Mexican traffic, and the dividing line remains much as it was; that is, through Buffalo and Pittsburg. The business east of this line to Mexico via New York has been given to the Ward Line, and the business west of this line via New Orleans to the Mexican American Steamship Company. The eastern interests tried to have the line moved west so as to get more of the business.

At hearings held last week before the Public Service Commission of the first district representatives of the Interborough Rapid Transit opposed the proposed order requiring block signals on the local tracks of the subway. They said that the present capacity of the local tracks is from 33 to 36 trains an hour, and improvements were being made which would increase it to 51 trains; the block system and automatic stops would reduce the maximum to 36 trains an hour. Furthermore, that no passenger had ever been killed inside a car on the subway.

Railroad Legislation in Mississippi.

The Governor of Mississippi has sent a special message to the Legislature asking for a 2-cent-a-mile law, with the provision that the railroad commission may increase the rate if it is shown to be unprofitable. He suggests that the law be made effective several months hence. The message also calls for repeal of the fellow-servant law and of the statute relating to contributory negligence, asks the enactment of a law prohibiting railroad blacklists; demands a law prohibiting the drinking of intoxicants on running trains, and asks for new statutes for the regulation of telephone companies.

Representatives of the Southern Railway and the Mobile & Ohio have submitted to the Mississippi House Committee on Railroads a voluntary offer to establish a flat passenger rate of $2\frac{1}{2}$ cents a mile on intrastate business and to issue interchangeable mileage books in 1,000 and 2,000 mile forms at the rate of 2 cents a mile. It is proposed to try the experiment for a year from April 1, with the option of abandonment by the railroad if unprofitable. The representative of the Southern Railway said that these rates embodied the basis of settlement in Georgia, Alabama, Tennessee and North Carolina, and he thought that Mississippi was entitled to obtain by peaceful means what the other states got by fighting. The offer was opposed by the representatives of a number of the other railroads in Mississippi, particularly the Illinois Central.

Appointment at Purdue.

Prof. C. F. Harding has been appointed head of the Electrical Engineering School of Purdue University, Lafayette, Ind.

The East River Tunnels.

The following report regarding the East River tunnels of the Pennsylvania Railroad was made at a recent meeting of the board of directors:

"At the present rate of progress, the four tunnels of the Pennsylvania Railroad Co. now being excavated under the East river from the Long Island and New York City sides will meet within the next three months. This will mean that one of the tunnels will be excavated and iron-lined this month; two additional tunnels will be excavated and iron-lined in March, and the excavation and the iron lining of the fourth tunnel will be completed in April or May. Work will then begin on caulking and lining of the tunnels with concrete 2 ft. thick."

Traveling on a Pass in France.

On the continent of Europe, where the state puts its finger into most pies, railroad traveling is invested with a number of formalities. One of these is in connection with the issue of free passes, on which, like most other things in that country, the French government levies a tax. The said tax is paid by the pass-holder affixing stamps to the value of four cents on the face of each single-journey voucher, and the railroad company does not profit thereby. Other formalities have, however, to be observed by the deadhead. In the first place, only receipt or other commercial stamps must be used. What penalty the unfortunate traveler furnished with a "permit of free circulation" renders himself liable to by the absent-minded employment of an ordinary everyday postage stamp is not definitely stated, but it is evidently a very serious matter. Having pasted the correct adhesives in the spaces provided therefor as the law directs, one must take the pass to the booking office of the station of departure in order that the stamps may be officially canceled. There the voucher must be turned over and signed on the other side. The holder is then free to travel by the train, provided that these operations are completed before its departure.

The Block System in Indiana.

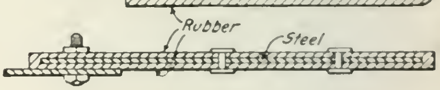
The State Railroad Commission of Indiana which acting under the recent law has ordered the principal railroads of the state to have the block system in use by July 1, 1909, reports that progress is being made already. The number of miles of road now equipped with block signals is 1,891 and the number of miles yet to be equipped, under the order, is 3,423. Lines earning less than $7,500 per mile per year are not subject to the law. The Commission has relieved two roads from complying on account of their light traffic, the Elgin, Joliet & Eastern and the Chicago, Lake Shore & Eastern.

Allowed to Smoke in Shops.

The new General Manager of the International & Great Northern has caused to be posted in the shops and roundhouses at Taylor, Tex., a card giving the employees permission to smoke during working hours and while on duty. Heretofore this was absolutely denied the men. The supposition is that Manager Clarke was of the opinion that smokers would smoke regardless of orders, and that if not allowed to smoke in the shops they would find means to absent themselves.

Flexible Metallic Semaphore Blades.

The Pennsylvania and the Baltimore & Ohio have adopted as standard the flexible metallic semaphore blades for dwarf signals made by Blank & Russell, Wilkinsburg, Pa. The accompanying drawings show the construction of this blade. It consists of a steel rib of clock spring temper, thick enough to be sufficiently strong and

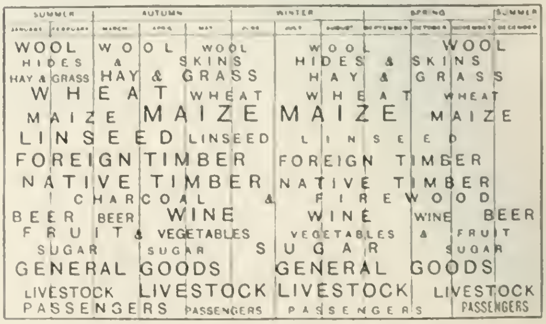


Sections of Flexible Semaphore Blade.

$2\frac{9}{16}$ in. wide x 8 in. long. It is treated in a copper solution to prevent rust and encased in rubber firmly vulcanized to it. It is claimed that this blade will not warp, so its whole face is always presented to the engineman. When struck by projections it bends and afterwards springs back to its original position without damage. Even if the rubber covering should be entirely torn off, the reinforcing rib would be left to give the signal indication. However, they have been tested in exposed places for three years without renewal. It is, of course, impossible for boys or malicious persons to cut or tear the blade from the casting.

Principal Articles of Traffic by Seasons, in Argentina.

The Buenos Ayres & Rosario Railway, which operates 2,361 miles of line in the Argentine Republic, and had gross earnings of $22,822,325 (£4,564,465) for the year shown below, has published the accompanying diagram showing the principal commodities carried, by seasons. The size of the type is intended to indicate the proportion of each class of traffic carried during each period; the most important article is maize (corn).



Traffic Diagram; Buenos Ayres & Rosario.

A Blow to the Tipping System in Business.

A decision has been given by the Appellate Division of New York State, under which it was held that a merchant need not pay for or return goods bought by one of his employees who had accepted a tip from the manufacturer. In discussing the decision, the counsel for many of the largest department stores in New York, including the store which brought the action under which the decision was returned, said:

"The very few convictions obtained under the anti-tipping law proved that law to be impractical as a means of stamping out the nuisance. At the best, it was a small fine for the offender on conviction, and it was found that many were willing to risk this. Therefore, it was determined to refuse to pay for or return $1,555 worth of goods which had been bought by an employee who had received a bribe of $75 from the manufacturer. The grounds for this refusal were that the manufacturer in bribing the buyer was a party to a crime, and that being so, the law says that the parties to a crime cannot get any benefit from it. On appeal to the Appellate Division our view of the matter was held to be correct, and the result, I think, will be to stamp out the practice. It is probable that the value of the goods retained will be given to charity, as, of course, the store does not want to profit by the commission of crime."

Street Railway Fares.

At the same time that a bitter political campaign is raging around the Cleveland and Detroit street railway companies, to bring about universal 3-cent fares, the Lexington & Boston Street Railway Company (Boston Suburban Electric Companies) has demonstrated that it cannot make a living profit out of 5-cent fares, and has raised its rates to the old-fashioned horse-car basis of 6 cents. The Lexington & Boston was built in 1900; it operates 33 miles of track, competing sharply with the Boston & Maine, and has found that its receipts have remained practically stationery, while new financing has been necessary to provide for the upkeep of the property. It has paid no dividends since 1904.

Production of the United States Steel Corporation.

The following table shows the percentage of normal production which the United States Steel Corporation was producing on certain recent dates:

Dec. 31, 1907	28 per cent. of normal.
Jan. 15, 1908	35 " " "
Jan. 31, 1908	40 " " "
Feb. 1, 1908	46 " " "
Feb. 18, 1908	49 " " "

New York City Accidents in January.

The Public Service Commission gives out figures of the January railroad and street railway accidents in New York City, as follows:

Car collisions	170
Persons and vehicles struck by cars	934
Boarding	479
Alighting	416
Contact with electricity	34
Other accidents	1,888
Total	3,921

The following injuries to persons were recorded:

To passengers	1,444
To persons not passengers	570
To employees	486
Total	2,500

Another table gives these statistics:

Killed	44
Fractured skulls	15
Amputated limbs	6
Broken limbs	32
Other serious injuries	91
Total	188

The total number of accidents in December was 3,993 and total killed 51.

Canadian Grain Shipments by Lake.

Fort William and Port Arthur, Ont., during the 1907 season of navigation, shipped by vessel 26,559,685 bushels of wheat in Canadian vessels and 5,838,069 bushels in foreign vessels (all to Port Huron and Buffalo), a total of 32,397,755 bushels, as against 65,172,397 bushels in 1906.

An American Signal Superintendent in England.

Arthur H. Johnson has been appointed Chief Signal Superintendent of the London & South Western, England, succeeding J. R. Annett, retired. Mr. Johnson was born in England, but received his early railroad training in the United States. He was for a time, about 1894, Special Engineer of the Erie, and has been an occasional contributor to the *Railroad Gazette*. From the Erie he went to England, and after two years went to New Zealand, where he was Signal and Telegraph Engineer on the New Zealand Government Railways. For some years past he has been Telegraph Superintendent of the London & South Western. This road has adopted automatic signaling to a greater extent than any other English line. Mr. Johnson is a son of Henry Johnson, the well-known signal engineer, and brother of Sidney G. Johnson, of the Union Switch & Signal Co., Swissvale, Pa.

Atlantic, Pacific and Gulf Ports.

The commerce at the principal customs districts and ports of the United States, calendar years 1897 and 1907 in millions of dollars was as follows:

Ports and customs districts	Imports. 1897	Imports. 1907	Exports. 1897.	Exports. 1907.	Ports and customs districts	Imports 1897	Imports 1907	Exports 1897	Exports 1907
New York	166	820	405	683	All other	71	220	198	428
Boston	86	123	104	105					
New Orleans	14	44	100	165	Total	743	1,423	1,100	1,923

					Interior ports	7	23		..

Organizing a Friendly Union.

At the annual meeting of the Postal Telegraph Co. (Mackay Companies) President Clarence H. Mackay gave the following account of the change in labor organization which the company made last fall. The idea seems capable of extension.

In August, 1907, in several cities part of the employees of the Postal Telegraph Company "struck." They struck without warning, without grievance and without cause. They seem to have struck in sympathy with a strike by the employees of the Western Union Telegraph Company. They did not even formulate their demands until several weeks later. Thereupon the officials of the Postal company, all of whom came from the ranks, became telegraphers again, and with those operators who remained loyal and with clerks from other departments kept the business of the company and of the country going. The trustees do not hesitate to say that a more devoted and expert staff is not to be found anywhere in any line of business.

The strike lasted 12 weeks and then the company took back only the efficient and reliable men. The monetary loss to the company due to the strike only served to demonstrate the soundness of the plan on which the Mackay Companies is formed; namely so wide a distribution of its interests as to minimize the effect of any loss from one particular source.

The Postal Telegraph Company realized, however, that the telegraphers' union was a menace. Telegraphy is a profession, and its messages are so confidential that to divulge them is a criminal offense. Telegraph employees cannot be allowed to give their allegiance to a union in preference to their duty to their business. Accordingly, the company in October, 1907, organized the Postal Telegraph Employees Association, to be open to all its employees who would abjure all unions, to be conducted without dues and without debts and to entitle its members to aid from the company during sickness or disability. This association was enthusiastically received and joined by the employees. It is now thoroughly established, and renders impossible another strike, and further, it strengthens the bond of loyalty and sympathy which always existed between the Postal Telegraph Company and its employees.

INTERSTATE COMMERCE COMMISSION RULINGS.

The Commission, in an opinion by Commissioner Harlan, has announced decision in the case of the Merchants' Traffic Association vs. Pacific Express Company. Complaint was made of a general special rate of $2 per 100 lbs. on milk and cream from St. Paul, Neb., to Denver, Colo., lawfully in force only because of inadvertent omission of defendant to file its mileage scale of milk and cream rates under which the lawful rate between these points would have been 58 cents. After this complaint was brought before the Commission, defendant filed on short notice a mileage tariff making the 58-cent rate. This being satisfactory to the parties, it was stipulated on the hearing that the complaint might be dismissed. The Commission in making the stipulation effective ordered the maintenance of the 58-cent rate for a period of not less than two years, but holds the case under further advisement.

Rulings About Passenger Service.

The Commission on February 15, announced that the railroads in arranging personally conducted tours must keep separate the charges for transportation, meals and hotel accommodations, leaving to the passenger the right to accept the transportation with or without the other accommodations. A railroad is permitted thus to stimulate traffic by providing entertainment to which it may contribute at a point on its lines, but such contributions must be made in a definite sum and be in no way dependent on the number of tickets sold. A passenger traveling on a special limited excursion ticket with stopover privileges who misses connections because of excessive delays of trains, is entitled to have his ticket made good if out of date when he makes the return trip. Passes granted to state railroad commissioners cannot be used in interstate journeys.

Reparation Granted Because of Reduced Rate.

In the case of Minneapolis Threshing Machine Co. vs. Chicago, Rock Island & Pacific (opinion by Chairman Knapp) it appeared that complainant shipped from Dallas, Tex., to Kansas City, Mo., seven carloads of agricultural machinery on which it was compelled to pay a rate of 72 cents per 100 lbs. At the same time the rate from Dallas to Hopkins, Minn., on these articles was 43½ cents. The distance from Dallas to Kansas City is 624 miles, while the distance from Dallas to Hopkins is 1,240 miles, Kansas City being directly intermediate between Dallas and Hopkins. It appears that at the present time the shipments made as above stated would take a rate of 36 cents only.

The Commission decided in this case that the 72-cent rate was excessive and that the 36-cent rate which the defendant now voluntarily affords is reasonable. The defendant was ordered to pay complainant the sum of $641 as reparation.

Powers of the Commission do Not Include Authority Over Rights of Stockholders.

The Commission, in an opinion by Chairman Knapp, has announced decision in the case of John B. Manning vs. Chicago & Alton Railroad and Louisiana & Missouri River Railroad. The complainant alleged that he has for many years been the owner of shares of stock of the Louisiana & Missouri River, which has been merged in the Chicago & Alton Railroad, and that he cannot procure a statement of the earnings and expenses of the Missouri company, and asks the Commission to investigate the matter and require the Alton company to keep a separate set of accounts covering the operation of the Missouri company.

The Commission decided that the powers conferred on it were not intended to be exercised for the purpose of ascertaining whether an individual stockholder has been wronged by such transactions as those in question. The investigation which the complainant desires is not required by considerations of public interest or the proper discharge of official duties. The complaint was dismissed.

Demand for Station Facilities Compromised.

The Commission, in an opinion by Commissioner Clements, has announced decision in the case of John H. Lewis et al. vs. Chicago, Rock Island & Pacific. The complainants prayed for an order requiring the railroad to re-establish its station facilities at Fanshawe, Okla. It seems that defendant had established a station at Fanshawe in 1892, but had discontinued it in 1901. Complainants claim that this resulted in unjust discrimination. At the hearing, defendant agreed to build a spur track at Fanshawe for delivery of freight and to have stopped every day, on signal by flag, one passenger train in each direction. Complainant stated that this arrangement would be satisfactory, and defendant has complied with the understanding in respect to passenger facilities.

The Commission said that since it appears that the public interest, so far as involved, will be subserved by the fulfillment of this understanding, and in the expectation that this will be accomplished by the defendant at an early date, it will not review the fact or express an opinion on the merits of the controversy, but an order will be entered dismissing the case without prejudice.

MANUFACTURING AND BUSINESS.

Robert McF. Doble, Consulting and Supervising Engineer, making a specialty of hydro-electric power development and transmission, formerly of San Francisco, Cal., has moved from Colorado Springs, Colo., to 528 Majestic building, Denver.

At the annual meeting of the directors of the Frost Railway Supply Co., Detroit, Mich., on February 11, the following officers were elected: President, Harry W. Frost; Vice-President, George A. Cooper; Treasurer, Frederick H. Holt; Secretary, James Whittemore; Assistant Secretary, Harry C. Smith.

Among the recent orders taken by the Power Specialty Co., New York, for the Foster steam superheater are the following: Home Electric Light & Steam Heating Co., Tyrone, Pa., 840 h.p. in Heine boilers; Torresdale Filtration Plant, Philadelphia, Pa. (second order), 900 h.p. in Heine boilers; Western Clock Manufacturing Co., LaSalle, Ill. (second order), 300 h.p. in return tubular boilers; Bernheimer & Schwartz Brewing Co., New York, 1,900 h.p. in Heine boilers; Garden City Co., Garden City, L. I., 200 h.p. in return tubular boilers; National Sugar Refining Co., Yonkers, N. Y., 1,134 h.p. in B. & W. boilers. It has also sold independently fired Foster superheaters to the New Jersey Zinc Co., the University of West Virginia; the Abendroth & Root Manufacturing Co., and the Seacoast Canning Co. The latter company has within the past year equipped seven of its plants with Foster superheaters, installing them in return tubular boilers.

Iron and Steel.

The New York, New Haven & Hartford is said to be in the market for 1,000 tons of material for a bridge at Providence, R. I.

The board of supervising engineers in charge of the rehabilitation of the Chicago street railways has, it is said, authorized the purchase of 8,000 tons of rails.

OBITUARY NOTICES.

Asa G. Dailey, formerly Superintendent of Tracks and Bridges of the Michigan Central, died at his home in Detroit February 5.

David P. Barhydt, who died at his home in New York City last week at the age of 92, was for many years President of the Erie & Kalamazoo, one of the first railroads west of Lake Erie; and he was one of the incorporators of the Sixth Avenue Street Railway in New York City, in 1851.

James D. Layng, Vice-President of the Cleveland, Cincinnati, Chicago & St. Louis, died at his home in New York City February 12, at the age of 74 years. Mr. Layng was formerly one of the most active railroad officers in the country and had held important positions for half a century. He had served on a number of different lines but will be most generally remembered as Superintendent and General Manager on the Pennsylvania Lines West of Pittsburgh between 1858 and 1881, and as Vice-President or General Manager of the West Shore Railroad from 1881 to 1899. Mr. Layng was born at Columbus, Pa., August 30, 1833, and was graduated from the Western University of Pennsylvania at the age of 16. He immediately entered railroad service, beginning as a rodman on the Ohio & Pennsylvania. He worked up through different engineering positions on this and other roads until 1856, when he was made Chief Engineer of Maintenance of Way of the Steubenville & Indiana. As the western lines which made up that part of the Pennsylvania system were gradually consolidated, Mr. Layng was promoted to different positions and in 1874 was made General Manager of the Pennsylvania Lines West of Pittsburgh and Erie (?). In 1881 he went to the Chicago & North-Western, but two years later went to the West Shore, then just finished, and he remained with the New York Central lines until his death. When the management of the West Shore was merged with that of the New York Central, Mr. Layng devoted his time chiefly to the "Big Four," of which he had been an officer since 1887, having been President of the Cleveland, Columbus, Cincinnati & Indianapolis before its consolidation with the present "Big Four."

MEETINGS AND ANNOUNCEMENTS.

(For dates of conventions and regular meetings of railroad conventions and engineering societies, etc., see advertising page 24.)

Iron and Steel Institute.

The Secretary announces that the annual general meeting is to be held at the Institution of Civil Engineers, Great George street, London, S. W., May 14 and 15, 1908. The annual dinner will be held under the Presidency of Sir Hugh Bell, Bart., in the Hotel Cecil, on May 14. The autumn meeting is to be held in Middlesbrough on September 29, and following days. The council will soon award Carnegie Research Scholarships, described in the *Railroad Gazette* of January 24, and candidates must apply before February 29. The awards will be announced at the general meeting. Bennett H. Brough, 28 Victoria street, London, S. W., is Secretary.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Canadian Pacific.—Charles Drinkwater, who has resigned as Secretary, will continue in the service of the company as Senior Assistant to the President, with office at Montreal.

Chicago Terminal Transfer.—William T. Nelson and H. H. Hall have been elected Directors, succeeding Fred G. Reighley and Ralph M. Shaw.

Mobile, Jackson & Kansas City.—George R. Sheldon, A. P. Walker and John W. Simpson, of New York; John McLeod, of Philadelphia, and Wallace B. Rogers, of Laurel, Miss., have been elected Directors, succeeding Charles E. Levy, R. W. Jones, Jr., former President of the suspended Oriental Bank of New York City, Edmund K. Stalle, J. W. Whiting and Richard B. Scandrett. Brayton Ives, President of the Metropolitan Trust Company of New York, is Chairman of the Board, and the other Directors are: L. S. Berg, President; W. D. Stratton, Vice-President, and Alexander McDonald.

Southern Pacific.—W. F. Ingram, heretofore in the service of lines controlled by the Southern Pacific in Mexico and Arizona, has been appointed Assistant Auditor, with office at San Francisco, Cal.

Operating Officers.

Erie.—G. W. Kirtley has been appointed Superintendent of Car Service. C. C. Riley, Superintendent of Transportation, has resigned and the office has been abolished.

Fort Smith & Western.—W. M. Bushnell, hitherto Assistant General Freight Agent of the Chicago & Alton, has been appointed General Manager of the Fort Smith & Western and the St. Louis, El Reno & Western, succeeding W. E. Crane, resigned; office at Fort Smith, Ark.

Illinois Central.—J. C. Dailey, Superintendent of the Chicago division, has resigned. See International & Great Northern.

International & Great Northern.—J. C. Dailey has been appointed General Superintendent, office at Palestine, Tex.

Mexican Central.—J. D. Melville has been appointed Superintendent at Cardenas, in place of A. C. Hobart, assigned to other duties.

Missouri Pacific.—E. F. Kearney has been appointed Superintendent of Transportation in place of T. E. Byrnes, resigned, office at St. Louis. John Cannon, who has been succeeded by M. M. Richey at Little Rock, has been appointed Superintendent of the Missouri division; office at De Soto, Mo., in place of J. W. Dean. Mr. Dean will take the place of Mr. Kearney as Terminal Superintendent at St. Louis.

New York Central & Hudson River.—C. I. McCoy, Passenger Trainmaster of the Hudson division, will also assume the duties of Trainmaster of the Putnam division in place of W. W. Currier deceased.

New York, New Haven & Hartford.—J. D. Gallary has been appointed Trainmaster of the Providence division, and J. W. Carr, Trainmaster of the Western division.

St. Joseph Valley.—G. F. Moore, General Manager, with office at La Grange, Ind., has resigned and has been appointed an Inspector of Accounts for the Interstate Commerce Commission, with headquarters at Washington.

Southern.—D. W. Newell, hitherto Superintendent at Rock Hill, S. C., has been appointed Superintendent at Jacksonville, Fla., in place of J. A. Baumgardner, who has been made General Agent at Charleston, S. C. W. R. Hudson has been appointed Superintendent at Birmingham, Ala., in place of E. E. Stoup. W. J. Bell, hitherto Superintendent of the Macon division, has been appointed Trainmaster at Macon, that division having been consolidated with the Atlanta division.

Traffic Officers.

Missouri Pacific.—C. E. Styles, Assistant General Passenger Agent, with office at Kansas City, has resigned. Mr. Styles entered the service of the company 38 years ago at Atchison, Kan., and has served in many different positions in the passenger department.

Benton Quick has been appointed General Baggage Agent, in place of A. G. Brigham, office at St. Louis, Mo.

Engineering and Rolling Stock Officers.

Cincinnati, New Orleans & Texas Pacific.—J. P. McCuen, Superintendent of Motive Power of the lines in the "Queen & Crescent Route," has resigned, the resignation to take effect March 1. Mr. McCuen entered the service of the Queen & Crescent as Road Foreman on March 1, 1882; served as Division Master Mechanic at Chattanooga 1886-1887; was promoted to the position of Division Master Mechanic at Monroe, La., in 1887, and in 1892 was made Division Master Mechanic at Birmingham. On January 1, 1895, he was appointed Superintendent of Motive Power, with headquarters at Ludlow, Ky., which position he has held up to this time.

New York, New Haven & Hartford.—Appointments of Master Mechanics for each of the seven divisions of the company's lines, as reorganized, are announced as follows: New York division, J. M. Collins, office at Harlem river, N. Y.; Shore Line, P. C. Zang, office at New Haven, Conn.; Providence, G. A. Moriarity, Providence; Boston, J. Hocking, South Boston. Old Colony, D. R. Killinger, Taunton, Mass.. Midland, J. B. Gannon, East Hartford, Conn.; Western, H. C. Oviatt, New Haven, Conn. Messrs. Collins, Killinger and Gannon, heretofore at East Hartford, Roxbury and New London, respectively, are the only ones who have to go to new headquarters.

LOCOMOTIVE BUILDING.

The New York Central Lines have asked bids on 200 locomotives.

The Standard Oil Company is said to be in the market for 20 contractors' engines to be used on Staten Island, N. Y. This has not yet been confirmed.

CAR BUILDING.

The New York Central Lines are figuring on passenger coaches.

The New York, Ontario & Western has been figuring on new passenger equipment.

The Keweenaw Central has ordered one smoking car, one baggage car and one express car from the Pullman Company.

The Idaho, Washington & Northern has ordered two passenger cars, one smoking car and one baggage car from the Pullman Company.

The Kiangsu & Chekiang has ordered two first and second class combination passenger cars, two straight second class cars and six third class passenger cars from the Pullman Company.

The Grand Trunk Pacific, as reported in the *Railroad Gazette* of February 7, 1908, has ordered 2,200 Grand Trunk standard box cars and 200 Hart convertible ballast cars from the Canada Car Company, and 500 standard box cars from Rhodes, Curry & Company. These are the cars to be received from these two companies during 1908 under a contract between the Grand Trunk Pacific and these companies covering a period of years.

The Panama Railroad is asking bids, up to February 24, on 300 thirty-ton box cars and 100 forty-ton Hart convertible cars. F. C. Nordsiek, 21 State street, New York, is Assistant Purchasing Agent. The box cars will be 40 ft. long and the Hart convertible cars 35 ft. long. Bodies and underframes will be of wood. The gage of track is 5 ft. The special equipment for all cars includes:

Bolsters	Body (box cars) Simplex; truck Simplex
Brakes	Westinghouse
Brake beams	Simplex
Brake-shoes	Streeter steel back
Couplers	Box cars, Tower; convertible cars, Chicago
Doors (box cars)	Side, Security; Locks Nat. Mall. Castg. Co.
Draft rigging	Miner tandem
Journal boxes	McCord
Roofing (box cars)	Drake & Wiers Co.
Side bearings	Woods' or Miner
Trucks	Arch bar

The Canadian Pacific, as reported in the *Railroad Gazette* of January 17, has ordered 400 steel Roger-Hart convertible ballast cars of 100,000 lbs. capacity from the Dominion Car & Foundry Co., to be built at the Blue Bonnets works. These cars will be 36 ft. 10 in. long between end sills, 8 ft. 7¼ in. high over all, and 10 ft. wide over all; 35 ft. 3 in. long inside as a gondola car, 4 ft. 1¾ in. high from rail to top of floor, and 8 ft. 8 in. wide inside measurements. The tops and underframe will be steel. The special equipment includes:

Bolster, body	Steel, built in the car frame
Bolsters, truck	Simplex
Brake beams	Simplex
Brakes	Westinghouse
Couplers	Tower
Dust guards	Harrison
Journal bearings	Canadian Bronze Co.
Journal boxes	McCord
Paint	Metallic
Side bearings	Susemihl
Springs	Canadian Pacific standard
Trucks	Barber, cored, with channel cross tie and with brake-beams hung to steel columns

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

BURRARD-WESTMINSTER BOUNDARY RAILWAY & NAVIGATION.—Organized to build lines as follows:

Vancouver, B. C., to Fraser river bridge, New Westminster, thence via Port Moody to the proposed Vancouver, Westminster & Yukon Railway bridge at Second Narrows, Burrard Inlet and thence to the place of commencement in Vancouver.

From the proposed Vancouver, Westminster & Yukon bridge to north arm of Burrard Inlet and to Howe Sound.

From Fraser river bridge at New Westminster to the international boundary line between Semiameo Bay and Sumas.

From False Creek, Vancouver, to Point Grey, thence to the Fraser river bridge, New Westminster.

From Port Moody to Stave river and the east boundary of Mission Municipality. Tupper & Griffin, Vancouver, B. C., Solicitors.

CHESTERFIELD & LANCASTER.—This company, which has just finished its road from Ruby, S. C., via Mount Croghan, Gue... and Pageland to Croburk, 21 miles, has projected an extension from that point north to Monroe or Charlotte, N. C., 20 to 40 miles.

FAIRCHILD & NORTHEASTERN.—This company, which last year added five miles of line to its road, expects to finish its extension to Owen by June. It will then have a line from Fairchild, Wis., via Greenwood to Owen, 38 miles. Work is now under way on a change of track near Owen, which is to be finished this summer.

NORTHERN ELECTRIC.—This company has finished work on its extension from Chico, Cal., west to Hamilton, 18 miles, with the exception of the drawbridge over the Sacramento river. The line is now in operation over a temporary bridge. During this year the company will probably build an extension from Marysville, Cal., to Colusa.

NORTHERN DAKOTA.—Grading is to be started in April or May of this year on this proposed line from Edinburg, N. Dak., west to a terminal not yet named, about 21 miles. It is expected to have the line finished by August. Contracts will shortly be let for 60,000 ties. Thomas D. Campbell, President; E. Thorwaldson, Vice-President, and D. F. Bull, Secretary and Treasurer, Edinburg.

OREGON ELECTRIC.—This company has work finished on its line from Portland, Ore., via Tualitin and Wilsonville to Salem, 50 miles, with the exception of some ballasting now under way. An extension is projected from Portland to Forest Grove, 25 miles, for which surveys have been made. Guy W. Talbert, Manager, Portland.

PANHANDLE SHORT LINE.—This company has projected a line from Dalhart, Tex., south via Hereford and Midland to San Antonio, with a branch from Midland to Deepwater at Rockport on the Gulf. Grading contract let to Miller & Jefferson for work from Dimmitt south to Lamb county, 60 miles. Grading finished from Hereford to Dimmitt, 32 miles. There will be a number of bridges. Additional contracts are shortly to be let. W. G. Ross, President, and A. D. Goodenough, General Manager, Hereford, Tex.

PERKIOMEN TRACTION.—Rights of way are being secured by this company for an electric line through Perkiomen Valley, Pa., about 11½ miles. I. H. Bardman, Schwenkville; H. T. Hunsicker, Ironbridge, and J. H. Dager, Norristown, are interested.

PITTSBURGH, CANONSBURG & WASHINGTON (ELECTRIC).—Grading started in November, 1907, from Washington, Pa., via Canonsburg, Thompsonville, Castle Shannon and West Liberty to Pittsburgh, 31 miles. Contract from East Canonsburg to Van Eman, two miles, let to W. H. Murdoch, Pittsburgh; from Thompsonville to Clifton, 1½ miles, to W. J. Payne & Sons Co., Pittsburgh, and from Clifton to Castle Shannon, two miles, to Samuel Gamble, Carnegie, Pa. There are to be bridges at East Canonsburg, Van Eman, Thompsonville and Clifton. F. Uhlenhaut, President, Pittsburgh. The line is being built by the Pittsburgh Railways Company.

PUBLIC BELT RAILROAD.—Contract has been let to the Orleans Engineering Co., of New Orleans, for building part of this double-track line around New Orleans, La. The proposed route is from the upper Parish line along the river front to Kentucky street, around the rear of the city to upper Parish line, thence along the protection levee to the point of commencement, 22 miles. Single-track has been laid from Parish line to Montegut street, 10 miles. W. J. Hardee, City Engineer, is Chief Engineer, and Hampton Reynolds, Assistant Engineer in charge. Work is also under way on storage tracks and bridges at various points.

SACRAMENTO VALLEY & EASTERN.—Grading has been finished on this line from Pitt near Kennett, Cal., via Pitt River and Copper City to Del Mar, 11 miles. It is expected to have the entire line finished by March 1. T. J. Deerborn, Chief Engineer, Kennett.

ST. JOSEPH, SAVANNAH & NORTHERN.—This company has located its line from St. Joseph, Mo., north to Savannah, 15 miles. Construction work is expected to be begun this spring. T. B. Campbell, M. Tootle and F. J. Wheeler, of St. Joseph, are interested.

SAN DIEGO & ARIZONA.—An officer writes that this company has not yet finished its location surveys for its proposed line from San Diego, Cal., east to Yuma, Ariz., 200 miles. A small amount of grading has been done between San Diego and National City; also some in the mountains. Over $1,000,000 has been spent in securing rights-of-way and terminals in San Diego and National City. The company has taken over the franchises and property of the San Diego Eastern, projected over the same route. John D. Spreckels, San Francisco, is the principal promoter, and W. Clayton is Vice-President.

SAN DIEGO EASTERN.—See San Diego & Arizona.

RAILROAD CORPORATION NEWS.

CHICAGO, CINCINNATI & LOUISVILLE.—The United States Circuit Court at Cincinnati, Ohio, on February 14 appointed James P. Goodrich, Chairman of the Republican State Central Committee of Indiana, receiver of this company, on application of George A. Fernald & Co., bankers, of Boston. This action is reported to be a friendly one. The application for a receiver was due both to inability to raise money and to the fact that gross earnings have fallen from $116,000 in October, 1907, to $64,000 in January, 1908. There is said to be a floating debt of $1,750,000. The road was formerly part of the "Great Central Route," but was separated from the Cincinnati, Hamilton & Dayton and the Pere Marquette after their receiverships.

HUDSON & MANHATTAN.—Harvey Fisk & Sons, of New York, have recently offered $5,000,000 of an issue of $15,000,000 two-year 6 per cent. convertible collateral notes of the Hudson Companies at 98½, yielding over 6½ per cent. These notes are secured by first mortgage 4½ per cent. convertible bonds of 1957 of the Hudson & Manhattan Railroad at the rate of $1,500 of these bonds for each $1,000 in notes outstanding. These bonds are convertible after 1912 at par into common stock at $110 a share. The notes are convertible at maturity into these bonds at par. An article describing the present status of the Hudson & Manhattan Railroad, one of whose lines under the Hudson river is to be opened to traffic next Tuesday, will be found in another column. The Hudson Companies is the company formed to build and equip the Hudson & Manhattan Railroad. It has a paid up capital of $21,000,000 and owns over $5,000,000 worth of New York City real estate, largely at Sixth avenue and Thirty-second and Thirty-third streets, where the uptown underground terminal will be built.

HUDSON COMPANIES.—See Hudson & Manhattan.

ILLINOIS CENTRAL.—There is a plan favored by the Harriman party to issue $30,000,000 equipment bonds on $40,000,000 worth of unmortgaged equipment to be used as collateral pending arrangements for permanent financing.

KANSAS CITY, MEXICO & ORIENT.—President Stilwell has sent a letter to stockholders asking that while the officers of the company are again undertaking the sale of bonds and stock in Europe, the stockholders subscribe either to one-year 6½ per cent. joint notes of the two construction companies which are building the railroad, each $1,000 note being secured by $2,000 in first mortgage bonds of the railroad company; or to first mortgage bonds of the railroad company, with a bonus of 40 per cent. in preferred and 40 per cent. in common stock; either of these subscriptions to be made at par. The funds thus obtained are to be used in pushing construction as fast as possible. Mr. Stilwell concludes as follows:

"I cannot urge on you too strongly the necessity of completing the 67 miles of track necessary to connect the road between the Red river and Benjamin. This will give us a line in operation from Wichita, Kan., to Sweetwater, Tex., and will enable us to secure a great deal of through business. We have experienced very trying times and it has been difficult to carry on construction work during the past 90 days, but we have continued to do so, and I hope our stockholders will now come to our assistance and enable us to build this 67 miles so necessary to the success of the enterprise. This will give us 434 miles of continuous track in this one section which ought to show earnings of $20,000,000, or much more than we have invested in the entire line up to the present time."

NATIONAL OF MEXICO.—The directors at a meeting held in the City of Mexico on February 14 decided to postpone action on the dividend on the first preferred stock, although it was announced that it had been fully earned. In 1907, 2 per cent. was paid. The first payment, 1 per cent., was in August, 1906.

NEW ORLEANS, MOBILE & CHICAGO.—President Berg of the Mobile, Jackson & Kansas City, says that his company has obtained about $1,500,000 under the plan of reorganization with which to pay off floating debt, improve the property and provide new equipment. (Jan. 10, p. 71.)

NEW YORK, NEW HAVEN & HARTFORD.—Total operating revenue for the six months ended December 31, 1907, was $29,500,000. Operating income (after taxes) was $7,450,000. There was a deficit after fixed charges and dividend payments of $153,000.

TEXAS & PACIFIC.—The annual interest payment to be made March 1 on the $24,661,770 second consolidated income bonds has been reduced from 5 to 3½ per cent. From 1901 to 1907 inclusive, 5 per cent. was paid. In 1901 4 per cent. was paid, and in 1900 1½ per cent.

TOLEDO & CHICAGO INTERURBAN.—James D. Mortimer has been appointed receiver of the Toledo & Chicago Interurban Railway, which operates about 40 miles of road from Fort Wayne, Ind., to Waterloo.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK
BRANCH OFFICES AT 375 OLD COLONY BUILDING CHICAGO, AND QUEEN ANNE'S CHAMBERS WESTMINSTER, LONDON

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. *We give in our editorial columns* OUR OWN *opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.*

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette:

OFFICERS:

W. H. BOARDMAN, *Prest. and Editor.*
E. A. SIMMONS, *Vice-President.*
RAY MORRIS, *Secretary*
R. S. CHISOLM, *Treas.*
I. B. RINES, *Cashier*
L. B. SHERMAN, *Western Manager*

EDITORS:

RAY MORRIS, *Managing Editor.*
BRAMAN B. ADAMS
CHARLES H. FRY
FRANK W. KRAEGER
GEORGE L. FOWLER
HUGH RANKIN
BRADFORD BOARDMAN

CONTENTS

VOL. XLIV., No. 9. FRIDAY, FEBRUARY 28, 1908.

President Roosevelt is somewhat out of touch with the commercial interests of the country, but we presume he takes cognizance of the fact that earnings of manufacturing industries and railroads alike are lower than they were a year ago at this time, and that urgent need of economy confronts every manager. What was the object, therefore, in including in his recent letter to the Interstate Commerce Commission the following statement?

"If the reduction in wages . . . is caused by misconduct in the past financial or other operations of any railroad, then everybody should know it, especially if the excuse of unfriendly legislation is advanced as a method of covering up past business misconduct by the railroad managers, or as a justification for failure to treat fairly the wage-earning employees of the company."

How long does the President suppose the wage-earning employees of a wicked railroad would stay in its employ if it reduced wages below the figure which these employees could obtain elsewhere? And if economic conditions are such that the supply of labor exceeds the demand, how long does he suppose wages will remain at the plane to which they have been forced in a long series of years when the demand exceeded the supply? Between January 1 and June 30, 1907, the *Railroad Gazette* reported 81 cases of wage increases, involving 67 roads, although no special effort was made to obtain a complete list. Did anybody investigate these increases, on the ground that the vested owners of the properties—the employers of labor—were not treated fairly thereby? We imagine that such investigation would have proved futile; demand was forcing wages up, and the increases had to be paid if men were to be secured and traffic moved. The converse of this (as seen by everybody except Mr. Roosevelt and Mr. Gompers) becomes true when demand ceases, and labor seeks employment. But the President is not opposing natural laws unarmed; he has a pretty formidable club. His letter may be paraphrased as follows: If you reduce wages, you thereby become subject to a governmental inquisition on the assumption that you are unable to continue overpaying your employees because your property is overcapitalized. Choose, therefore, between your present wage scale and an inquisition which will damage your credit!

Low prices in the stock market, idle freight cars and business depression do not delay the maturity of financial obligations which are outstanding against railroads any more than they do those outstanding against individuals. According to a table given in the *Journal of Commerce* there are maturing during the next five months a total of $35,948,000 in bonds and $36,880,460 in notes of steam railroads, the notes including a few of the larger equipment trust instalments. These figures do not include $15,000,000 notes of the Interborough Rapid Transit Company maturing in May, $16,500,000 notes of the Underground Electric Railways of London maturing in June, or $10,818,000 bonds of a subsidiary of the Manhattan Elevated, of New York City, maturing July 1, 1908. The principal railroad note issues maturing are Missouri Pacific, $6,000,000, already refunded; Rock Island, $6,000,000, maturing in April; Erie discount notes, $5,000,000, maturing in April, and Pennsylvania equipment trust instalments estimated at $6,000,000, maturing in June. The largest bond issues are $6,000,000 Delaware & Hudson 6 per cent. bonds maturing this month, $4,700,000 Great Northern 5 per cents maturing in April, and $4,993,000 Oregon Short Line sevens maturing July 1. The Erie has also $2,500,000 in sixes and fives maturing on that same date. The present great difficulty of raising new railroad capital is resulting in the production of some novel forms of corporate securities. The means by which the Missouri Pacific refunded its $6,000,000 two-year 5 per cent. notes which matured February 10 was by an issue of the same amount of two-year 6 per cent. collateral convertible notes. These notes were secured by $12,000,000 Kansas & Colorado Pacific 30-year 6 per cent. mortgage bonds dated February 1, 1908. It is these bonds into which the notes are convertible at par. We are informed by the bankers that these are the first convertible notes ever issued. It is interesting to observe the various ways in which they are made attractive to investors. They are a direct obligation of the Missouri Pacific. They are secured by twice their par value in new mortgage bonds on 1,450 miles of the Missouri Pacific system. They are also convertible into these bonds. Both the notes and the bonds are 6 per cent. issues. The bonds are guaranteed by the Missouri Pacific. This Missouri Pacific issue was soon followed by another convertible note issue. The Hudson Companies, the construction company which is building the Hudson & Manhattan Railroad, the first of whose tunnels under the Hudson river was opened on Tuesday of this week, have recently put out $15,000,000 two-year "secured" 6 per cent. notes with first mortgage bonds of the Hudson & Manhattan Railroad as collateral. The notes are convertible at maturity into these bonds at par. There is a further interesting feature of this collateral convertible note issue secured by bonds. The first mortgage bonds of the Hudson & Manhattan are themselves convertible at par after 1911 into common stock of the Hudson & Manhattan at $110 a share. Thus we here have notes convertible into bonds which are themselves convertible into stock. Other methods which seem to be the favorites at the moment for railroads which are looking for new funds are the issue of mortgage bonds on some part of a big system which either is not bonded at all or has a low bond issue or the issue of equipment notes secured directly on equipment and either sold outright or used as collateral for loans. The Baltimore & Ohio, for instance, last week sold $6,000,000 one-year 5 per cent. notes secured by $8,000,000 Pittsburgh, Lake Erie & West Virginia refunding bonds. The Union Pacific is reported to be planning to issue mortgage bonds on the 1,650 miles of its lines which were on June 30, 1907, free of lien. The sale in January of $30,000,000 New York Central Lines equipment notes is the largest piece of recent railroad financing. The Illinois Central may issue the same amount of equipment notes on some $10,000,000 worth of unmortgaged equipment, but these are likely to be used as collateral for borrowings instead of being sold.

THE COMPLEXITIES OF RAILROAD PENALTY.

In these parlous and somewhat topsy-turvy times, when the big stick of the federal executive and the rods of state legislation are falling upon the backs of the just and the unjust, it is interesting and in the end may be instructive to study the variations of railroad penalty—past, present and proposed—and also its diversity of victims. We are seeing some unprecedented anti-railroad forces in more or less active play. Some primal laws of political economy, recognized alike in the academic classroom and in practical experience, are to be suspended if authority can do it. There is to be one law for the corporation, another for its working units, with the stockholder, whether innocent on the one hand or, in the legal phrase, guilty of "contributory negligence" on the other hand, shouldering the ultimate burden. Under such conditions the incidence and distribution of penalties, their justice or injustice, and the complications that attend them become, as subjects for analysis, something better than a merely intellectual exercise.

Starting with the railroad corporation itself, how vast its variations in history! One corporation projects itself on the screen as speculative from its first inception and speculative in high degree. Or, from the start, it may have been conservative or well-nigh so. Or, again, it may have risen from the low plane of speculation to the upper plane of honesty, or reversed the process and descended. It may have been solidified by a reorganization or it may have been inflated. In the swift progress of railroad consolidation in this country and others many of these changes have been lost sight of. Investors, as well as non-investors, are apt to be forgetful. The great railroad system of to-day is outwardly an entity, but historically made up of units the original status of which has, generally speaking, disappeared in the march of railroad events. Some picturesque features are still held in memory, but only by the older generation. One not far beyond the bounds of middle life may recall the Credit Mobilier in Union Pacific or the Gould "Chapters of Erie" as crystallized in the narrative of Charles Francis Adams, or the 80 per cent. stock dividend of New York Central. But most of the details of railroad history, and nearly all the details of consolidation, have for the ordinary observer and the ordinary investor sunk below the horizon, save as they appear in the form of a long lease of component or subsidiary lines or some special guarantee of bonds or the mortgage quality of bonds as applied to parts of a system. The big railroad of to-day is a composite, broadly speaking.

When one comes then to the application of penalty to past railroad misconduct, whether that penalty is to be exercised under actual law or merely used as a moral force for the regulation of wages, one may well inquire what are the scope and limitations of such a policy. How far does it go back, of what class of offences is it to take moral or statutory jurisdiction, are its methods to be personal or corporative? Will it reach back to the scandals of the Credit Mobilier, or will it stop with Harriman? Will it "go for" the speculative railroad systems alone, or will it include those which have been relatively sane and the investment field of the trustee and the widow? Will it strike at the work of the high financiers who a few years ago, in the case of certain big western lines, financed their stock into bonds, sold out and retained control by a holding company? or will it merely consider present conditions of earning power? Will it, as a test of threatened wage reduction, apply the hydrometer to each railroad corporation and make that the test of equitable earning power?

So much for the corporation considered as the target of penalty. Turning next to the stockholder, we find him in as many diverse situations of responsibility as the railroad system. But excluding him as the mere speculator who takes his risk and is not entitled to much mercy, and treating him as the honest investor he offers us still many investing personalities. He may in a few cases be the now white-haired original investor in a new and successful railroad project, but in that character, as regards steam railroad enterprise, he is not now common. His railroad shares selling in the market at the time of his death on a four or five per cent. basis have passed to others. It may be in fee to direct heirs. It may be to trustees authorized to make up the trust from funds of the estate on a market valuation. It may be that at the same valuation the shares have been sold. But whether held or sold, two points are to be emphasized for the conservative investor in the dividend-paying railroad stock. First, that it has been bought or held on a low interest rate return, and, secondly, that it has been acquired or held under the reasonable assumption that old policies of the government, state or national, would protect it, and that radical policies would not assail it. Such an innocent investor had a right to assume, did assume, and the precedents of federal policy gave him the right to assume, that natural law rather than artificial checks would adjust wages just as it would affect earnings or dividends, that there would not be one rule for earnings and profits and another for wages, and that hard times would distribute its burden on both parties and not load them upon one on the basis of some vague and indeterminate official interpretation of railroad "misconduct." Saying nothing of the federal proposition, as a matter of public policy, does it not invade a basic right of property?

One can push the analysis of the confusing situation still further. It can be asked, for example, how far railroad "misconduct" bears upon the rights of bondholders or holders of leased line stocks, and whether they, too, may not, under certain conditions, come under the federal theory of direct or indirect penalty in the form of fiscal loss? Then there are the street railway corporations, few of them interstate, to be sure, but liable to be the victims of reflex action from the federal capitol playing upon state railroad commissions and legislatures. But this is a look ahead, though not necessarily a far look. For the moment the new executive dicta striking into the vast complexity of corporate relations to wages and into primal rights of property are big enough when limited to steam railroads alone. Time will show whether or not they are more serious and abiding than the political gestures that end with a presidential voting day.

WHAT ARE WE GOING TO DO ABOUT ACCIDENTS?

We print this week three contributions commenting on Mr. Boardman's open letter to newspaper editors, printed in the *Railroad Gazette*, January 31, under the caption "What Are We Going to do About Railroad Accidents?" One of our contributors is Mr. Cease, editor of the *Railroad Trainman*, who says that there has as yet been no evidence submitted to prove that the railroad (labor) organizations have interfered with the enforcement of discipline, that they have advised their employers, or in an arbitrary or unfair manner have intimated to them who should be employed.

Well, let us see. Discipline looks forward as well as backward, and its use in preventing things from happening is a great deal more important than its function of punishing people for things that have happened already. No further instance of this principle is necessary than consideration of what happens to a private in the army who talks back to the sergeant, or of what is done with a sentry who falls asleep at his post, quite regardless of the actual effect which either of these infractions of discipline may have. Now what is the procedure when a railroad officer tries to enforce discipline before trouble comes, instead of after? In building up or in maintaining any organization, the first question is that of the personnel. How is the personnel of appointments in railroad work determined?

The relations between the railroad and its employees are commonly set forth in the form of a contract for which the superintendent, locally, and his employees, locally, have no direct responsibility. This contract makes the superintendent presiding officer of the court of first instance, from which there are unlimited appeals as to fact, interpretation of agreement, etc. This applies to discipline, rates of pay, appointments, or promotions. At such investigation board, the trainman or the employee investigated is represented by a man trained in such work, whose business it is to make as much capital and gain as much as possible for his clients. It is his object to make exceptions, to pick flaws, and otherwise to hinder any prompt and efficient measures to remedy a condition by disciplining the man at fault. When a run becomes vacant the fact is advertised and, other things being equal, seniority determines the right to that position. By "other things being equal" is meant not the judgment of the superintendent as to the qualifications of the man, but tangible facts against his records which can be proved and substantiated. This means that the opinion of the superintendent as to the ability or efficiency of the man in question counts for nothing. He is merely there in a judicial capacity, with power to keep out men who have already made mistakes that prove their lack of qualification for the position. He becomes, therefore, a judge of the past, and his authority to provide against trouble in the future is greatly restricted.

The superintendent has not the authority to enforce discipline which, for instance, is considered absolutely necessary for the commissioner of police in New York. The investigations become wrangles, compromises, deals, in which the employee feels that he is being attacked by the railroad and defended by his organization. Disregarding for the present the question of punishment for infractions of discipline which have made trouble, it is clear enough that this arrangement ties the hands of the superintendent desiring to place his personnel on a basis of efficiency only, and requires him to base his action on an entirely different set of facts, the principal one being that trouble with the unions is costly and has got to be avoided whenever it can be. We have a case in mind where there were thirteen brakemen in line for promotion on the basis of seniority. Numbers 5 and 7 (according to the time of service) were two experienced conductors from other roads who were first-class railroad men and entirely competent to take charge of a train as conductor. On the other hand, numbers 1, 2, 3, 4 and 6 were all young men who had been in the service of the road less than two years and who were unable to pass an examination under which they were required to take a time card and figure themselves over the road with an assumed extra train at a speed of 30 miles an hour; a very simple proposition for an experienced trainman. Numbers 5 and 7, the two experienced men who had come from the outside, were promoted, but the Brotherhood of Railroad Trainmen appealed from the decision of the superintendent, claiming that the rights of its men were being ignored, since the men promoted were members of the Order of Railway Conductors. The case was appealed to the general manager, who felt obliged, in the interests of harmony, although against his own judgment, to reverse the action of the superintendent, sending Numbers 5 and 7 back on the list, and promoting Numbers 1 and 2—an action exactly opposed to the kind of discipline that looks ahead and prevents accidents.

Here is another instance. As is well known, the Order of Railroad Telegraphers does not permit the members of the order to teach students; consequently agents or operators who are members of this organization openly refuse to take orders from superintendents to give any instructions whatever to young men to learn their business. If we revert again to the army for an instance, we find this kind of attitude described by the term "insubordination," and punished promptly and severely. What does the editor of the *Railroad Trainman* suppose would happen to a group of corporals in the army who refused to instruct their squads when ordered to do so by the lieutenant? Yet are we not right in assuming that if a railroad telegrapher should be discharged for a similar refusal, his organization would sustain the insubordination to the last ditch, even to the point of a strike? We have another case in mind, somewhat parallel, occurring where two railroads were consolidated. The employees of one road were dissatisfied with the positions of their names as placed on the seniority list by the superintendent, and they appealed to the general superintendent and then to the general manager. The question was not one which affected the company very directly or tangibly, and so the general manager, fearing a strike, reversed the action of the superintendent. Of course the employees of the other part of the consolidation did not like this decision, and they appealed to the general manager to reverse himself, which he declined to do. The four train service organizations, represented by their grand chief officers, then appealed to the president of the road and obtained a reversal of the decision. At time of writing, we understand that the first set of employees is now working up another appeal, and it is expected that the general manager will again be called upon to reverse himself and come back to his first decision. Whether he does or does not do so, it is very clear that the position of the superintendent, from whom the case was originally taken, is humiliating, and that the situation is certainly not conducive to good discipline. Under such circumstances as these a superintendent naturally hesitates to discharge a man who is a member of a strong organization unless he has a clear, tangible case that he can prove against him. The fact that to the best of his knowledge and belief the man is untrustworthy, is not enough. His position is closely comparable to that in which the chief of a track gang would find himself if he were allowed to remove broken rails but not cracked ones.

On a large railroad, with 10 divisions, for example, there are at least 100 chairmen of division organizations, and some four or five general chairmen. The latter, as a rule, are paid by the year to look after the interests of the members of their organizations and are not engaged in actual railroad work. The 100 division committeemen are engaged in railroad work, but their principal interest lies in looking after their associates. It is the practice for every member of the organization who is disciplined either by dismissal or suspension to take up his case in writing with the committee, and probably 98 per cent. of all the applied cases of discipline are brought to the attention of the division officers by the local committees. If there is any loop hole in the investigation, or if there are any differences in the testimony, a pretext for an excuse is thereby furnished, and if no possible excuse can be found, the plea of sympathy is then set up for the delinquent. The members of the committee are all selected for their special power in pleading, they are what are known as good railroad lawyers. If the division people fail with the local officers, the general chairmen, who have no other occupation, will take the question up with the higher officials.

It must be said in all fairness that there are times when these committees do secure evidence which was not brought out when the discipline was first applied. There have been numerous cases where they have seen justice done to their associates, but it is impossible to confine committees to the pursuit of entire justice. They take up the plaints of the just and the unjust alike, and the superintendent knows well that enforcing discipline means a struggle while the young employee who has recently entered the service is very much impressed with the knowledge that his labor organization has in its membership thousands of men, with a million or three million dollars in the treasury to defend its members when they get into trouble. It would be strange indeed if he did not feel that his union came first and his railroad second. It would be untrue to human nature if he did not possess the conviction that a discipline case was a sort of feud between two strong clans, one composed of the officers of the road and the other of the members of his brotherhood, and that his clan duty was clear—and the worst of it is that the man most affected by this is the superintendent, the officer on the ground, who knows the facts and has more power than anybody else to make travel safe or unsafe. Of course he hesitates to enforce necessary discipline when he has reason to fear that his decision will be overruled, and that continued appeals will lead his superiors to regard him as unfit to handle labor.

The point is, that discipline to prevent accidents should look forward and not backward. While the labor agreements do not prevent a superintendent to dismiss a man for the harm he has done, they make it exceedingly difficult to dismiss him for the harm he is likely to do.

Train Accidents in January.[1]

Our record of train accidents occurring on the railroads of the United States in January includes seven collisions and 10 derailments and one boiler explosion, 18 accidents in all. This record is not published in full except in the cases of the few accidents which are especially prominent—in the present instance three collisions and one derailment. The record of "ordinary" accidents—which term includes, for our present purpose, only those which result in fatal injury to a passenger or an employee or which are of special interest to operating officers—is given at the end in the shape of a one-line item for each accident, showing date, location, class and

[1]Abbreviations and marks used in Accident List:

rc........Rear collision.
bc........Butting collision.
xc........Other collisions; as at crossings or in yards. Where only one train is mentioned, it is usually a case of a train running into a standing car or cars, or a collision due to a train breaking in two on a descending grade.
b.........Broken.
d.........Defective.
dr........Defect of roadway.
eq........Defect in car or engine.
n.........Negligence.
unf.......Unforeseen obstruction.
unx.......Unexplained.
derail.....Open derailing switch (negligence of engineman or signalman).
ms........Misplaced switch.
acc. obst..Accidental obstruction.
malice....Malicious obstruction of track or misplacement of switch.
boiler.....Explosion of boiler of locomotive on road.
fire.......Cars burned while running.
Pass......Passenger train.
Ft........Freight train (includes empty engines, work trains, etc.).
*Wreck wholly or partly destroyed by fire.
†One or more passengers killed.

number of deaths and injuries. The items of which details are given are indicated in the tabular statement by the use of italics. This record is based on accounts published in local daily newspapers, except in the cases of accidents of such magnitude that it seems proper to send a letter of inquiry to the railroad manager.

The collision at Vinegar Bend was reported in the newspapers as having involved a passenger train, but it did not; it was on a logging road, and we are informed that each of the trains consisted of an engine and some empty cars; one was a log train and the other a work train. The log train had been brought to a stop before the collision occurred. Neither was it true that a trestle bridge was demolished. Four employees were killed, nevertheless.

The collision at Crockett, Va., occurred at 2.25 a.m. at a water tank, a westbound freight train, with two engines, which was standing there, being run into by the eastbound Chattanooga-Washington Express. Two engines and the mail and express car were damaged, and two postal clerks and one passenger were slightly injured. The collision was due to the freight train being on the time of the passenger train on the main track without proper protection. The passenger train was running 4 hours and 15 minutes late, exactly as had been stated in the order. Both of the enginemen on the freight were young, and they offer no rational explanation. The telegraph block system which had been in service on this district about three months had just been discontinued by reason of a decrease in business and in order to reduce expenses.

The collision at Cameron, N. C., is reported as having been due to an error made by a telegraph operator in copying a train order. One of the trains was to wait at Southern Pines until 12.15 a.m., but the order was delivered to the other train reading 12.50 a.m.

The cause of the derailment near Hiram, Ga., on the 7th was not discovered. The second section of the southbound Florida Special was derailed at a trestle bridge, the engine being overturned just as it had passed over the bridge. Four of the cars fell 20 ft. to the ravine below. One of the car bodies was broken in two, and in this car most of the serious injuries occurred. The engineman, a travelling engineer, a fireman and one passenger were killed and 62 passengers and 13 employees and five Pullman employees were injured. At the time of derailment the train was running about 40 miles an hour. Close investigation following the accident failed to develop any cause for it. The track and equipment were in good order.

In the reports of the electric car accidents published in the newspapers in January we find no account of any fatality.

Pressed Steel Car Company.

The gross sales of the Pressed Steel Car Company during the year ended December 31, 1907, were $36,400,000, the largest in the company's history, though little larger than in 1906. Operating expenses, including "liberal charges on account of renewals and up-keep of plant and machinery," increased more than gross sales, so that the net profits, not including dividends from subsidiary companies, were $2,900,000, against $3,100,000 in 1906. No dividends were paid by subsidiary companies last year, as all of them needed their surplus earnings to add to working capital. In 1906, on the other hand, the Pressed Steel Car Company received a dividend of $225,000 from the Pennsylvania Car Wheel Company. For depreciation and renewals there was $365,000 set aside in 1907 and $350,000 in 1906. The 7 per cent. dividend on the $12,500,000 preferred stock which has been continuous through the nine years since the organization of the company, was paid, leaving a surplus of $1,668,000, which is equal to 13.3 per cent. on the $12,500,000 common stock. The surplus earned in 1906 was $2,157,000.

The percentage of profit realized last year was lower than in some previous years for two main reasons. During March work at both the Allegheny and McKees Rocks plants was stopped for several days, owing to the greatest flood since 1832 in the Ohio river. Several weeks passed before output was again normal. Most of the machines were badly damaged and some had to be entirely rebuilt, all of which expense was charged to operating cost. The other cause was higher wages and lower efficiency of labor during the first half of the year. As a result of the great demand for labor in the Pittsburgh district the company had to choose new men out of the newer foreign population who represented a lower average standard of efficiency than those who formerly came to the district. This had a distinct effect in lowering profits. In this connection, President Hoffstot remarks that the slowing down of business which came at the end of the year, although it decreases profits, has some redeeming features, for it makes the supply of labor larger than the demand and thus makes it possible both to choose better men and to get better work out of the whole force. During the last six months the company has been able without any lowering of efficiency, substantially to reduce labor costs, so that cars built in the latter part of the year cost less to build than those built previous to the decrease of business, when the demand for labor equaled or exceeded the supply.

Another favorable feature is that when work is being done at low pressure, time and attention can be devoted to economies and development along new lines. The company's policy in regard to prices is not to artificially maintain prices which under existing business conditions would be unsubstantial and unreal, but to reduce prices to a point which will create and restore a normal demand. Mr. Hoffstot believes that the policy of maintaining the same prices during periods of depression as in prosperous times retards rather than helps the speedy return of normal conditions.

Additions and betterments costing $268,000 were made during the year, over two-thirds of which went for a new water purifying system, additions to the planing mill and wooden car shops, and new machinery for the passenger car equipment of the McKees Rocks plant. The rest of the expenditure was used in the Allegheny plant for additional power. Here also a water purifying plant is to be put in if the one at McKees Rocks, which is not yet finished, is successful.

The Pennsylvania Car Wheel Company earned less than in former years; what it did earn was added to working capital. Its smaller earnings were due to an increase in the cost of pig iron and coke greater than in the price received for car wheels. No statement of earnings is given for any of the subsidiary companies, including the Canada Car Company and the Western Steel Car & Foundry Company. In 1905, the last year in which figures for this last company were reported, its gross sales were $7,563,194. In that year a 6 per cent. dividend was paid.

Generally speaking, the report, like that of most industrial companies is inadequate. The only figures shown, except those included in the condensed balance sheet filling one page, are the two of gross sales and net profits. Publicity is one of the most important tendencies of the times and is becoming more and more important. There are, of course, certain facts in regard to the operation of a manufacturing company whose business is sharply competitive which ought in justice to it never to be shown, but there is a golden mean possible between the present meager information given by this and other similar companies, and injurious publicity.

The steel passenger car department is just finishing an order for 85 steel passenger train cars for the Pennsylvania Railroad. Although the all-steel passenger car is as yet a pioneer and cannot be relied on as a fixed source of revenue, the company believes that these cars will before long be standard in this country. Mr. Hoffstot takes occasion at this point to decry the hostile public sentiment toward railroads. A changed attitude toward railroad securities, he believes, would make it possible for all railroads to offer the best equipment and the greatest safety and thus speedily result in replacing wooden passenger cars with fireproof steel cars. This department of the company has been so arranged, however, that semi-fireproof and wooden passenger cars can be turned out when steel passenger cars do not require its full capacity.

The following table gives for each of the nine years of the company's life the gross sales, net profits including dividends from subsidiary companies, dividend payments and surplus for the year.

	Gross sales	Net profits	Dividends	Year's surplus
1907	$36,443,304	$2,907,920	$875,000	$1,667,920
1906	36,158,586	3,881,884	875,000	2,158,884
1905	19,337,826	1,106,901	875,000	56,901
1904	4,198,268	707,111*	1,250,000	2,037,111†
1903	20,601,249	2,768,897	1,500,000	1,008,897
1902	33,883,519	4,578,114	1,375,000	2,903,114
1901	23,032,191	1,927,925	1,375,000	409,290
1900	22,510,115	2,075,181	1,625,000	1,200,181
1899	11,198,212	2,237,000	875,000	612,000

*Loss. †Deficit.

The uptown tunnel of the Hudson & Manhattan Railroad was opened last Tuesday afternoon, when a train carrying officers of the companies concerned, the Governors of New York and New Jersey, and other distinguished men, was run from Nineteenth street and Sixth avenue, New York, to Hoboken, N. J. At midnight of the same day the line was opened to the public. For the present, cars will be operated on three minutes headway during the rush hours, the time for the three miles now in operation being 12 minutes, including five stops. At other times, they will run on five minutes headway. These twin tubes are the first of the several tunnels under the Hudson river to be opened for service. This line also is the oldest of the projects, its history going back 30 years. Its checkered career was summed up in our issue of last week, in the description of the completed tunnel. As mentioned in that article, the southern tubes of the company are nearly finished and will be opened in the summer. Farther north are the four-track Pennsylvania tunnels, which will be ready still later. The line just opened will have no immediate result in relieving existing lines of the burden of taking care of the enormous daily movement of people within New York City, as the great part of this traffic is between the upper part of the city and the southern part of the island. However, when the connecting line is built from Sixth avenue, under Ninth street to a connection with the Interborough Rapid Transit subway near Astor place, it is to be expected that many people living between Fourteenth and Thirty-third streets, west of Fifth avenue, will take this route in going up and down town and so relieve the older subway of some of the traffic originating between Astor place and Forty-second street. The great value of the new tunnel lies, of course, in making the journey from Hoboken and Jersey City to Manhattan quicker and surer. The extent of this traffic was suggested last week in the article mentioned. It is now being taken care of by ferries, which are subject to delays by fog and storm, and, during most of the winter, by floating ice. The completion of the various Hudson river tunnels will therefore result in extending westward the area available for residence of people who come to business daily in New York.

NEW PUBLICATIONS.

Principles of Reinforced Concrete Construction. By F. E. Turneaure and E. R. Maurer. New York: John Wiley & Sons. 317 pages, 6 in. x 9 in.; 130 illustrations. Price, cloth, $3.00.

To quote from the preface, "the authors have endeavored to cover, in a systematic manner, those principles of mechanics underlying the design of reinforced concrete, to present the results of all available tests that may aid in establishing coefficients and working stresses, and to give such illustrative material from actual designs as may be needed to make clear the principles involved." The book opens with a brief historical review of the use of reinforced concrete and then takes up its properties, dealing first with the materials and methods of mixing and the strength of the whole after setting. In dealing with the material the standard assertion is made that "Portland cement only should be used." It is curious that in spite of the unanimity of opinion upon this point among all authorities of the subject, none of them state the reason why, or give any data showing the difference of action between Portland and natural cement when used in reinforced construction.

In discussing the physical properties of concrete, the authors go very elaborately and thoroughly into the elasticity, and show that, contrary to preconceived ideas, there is no change in the characteristics of concrete in this respect when it is reinforced, and that it does really crack when stretched beyond its elastic limit, and that it is the steel reinforcement that holds it together, preventing the cracks from becoming visible and the concrete from failing. Great emphasis is, therefore, placed not only upon the extensibility of the concrete but its adhesiveness to the steel.

In the third chapter there is a full theoretical discussion of the method of resisting the stresses imposed, including the general stress distribution in a homogeneous beam, the common theory of beams, the formulas for working and ultimate loads and the parabolic formulas. This chapter also includes a mathematical discussion of double reinforcing, flexure and the strength of columns.

This is followed by a presentation of the results of many important tests, which are analyzed and correlated, with reference to the theoretical principles that have already been set forth. Then comes a consideration of working stresses and economical proportions, with a collection of such formulas and diagrams as may be needed for general use.

The final chapters deal with building construction, arches, retaining walls, dams and miscellaneous structures, all of which are illustrated by examples taken from practice and then analyzed mathematically in accordance with the principles previously enumerated.

Proceedings of the Traveling Engineers' Association, 1907. 340 pages; 6 in. x 9 in.; 10 illustrations.

The association meeting was held at Chicago, in September, 1907. The subjects presented were all connected with the operation of the locomotive, as follows: The Best Means of Locating the Fault of a Poor Steaming Engine without Removing the Draft Appliances; Advantages of Hot Water Washing and Filling for Boilers; Best Methods of Eliminating the Smoke Nuisance on Soft Coal Burning Engines; Air-Brake Requirements to Effect a Proper Train Control; Superheated Steam and the Best Methods of Getting Good Results; Waste of Energy in Railroad Operation; Lubrication of Cylinders Using Saturated and Superheated Steam; Reduction of Coal Consumption and Increase of Locomotive Efficiency; Relation of the Road Foreman to Indifferent Enginemen; Advantages of the Automatic Stoker and the Performance of the Automatic Stoker on the Iowa Central.

The report on the mechanical stoker is interesting in that it states, in outline, the work that has been done by the Monarch and Hayden stokers. Satisfactory results have apparently been obtained with both, so far as maintenance of steam pressure is concerned. In the matter of economy of coal consumption, some definite information is given, and, in the report of the work done on the Iowa Central a marked saving is shown by the use of the stoker. Taken on the basis of the coal consumed per 1,000 ton-miles, the schedule shows that for runs without the stoker there was a marked increase in the amount of coal consumed. For example, on engines with the same cylinder and firebox dimensions, the coal consumed was 181 lbs. and 206 lbs. per 1,000 ton-miles without the stoker and 143.7 lbs. and 166.6 lbs. with the stoker; an average saving of nearly 20 per cent. The engines used in the two tests had 20-in. by 26-in. and 22-in. by 26-in. cylinders respectively. It was probably on the basis of such a showing as this that the report concluded by expressing the opinion that "the stoker has come to stay, as it can do all that is claimed for it if the care is taken of it that it is entitled to."

Another paper of value, the subject of which has been discussed with all the variations imaginable, is The Waste of Energy in Railroad Operation. This time the discussion is confined to the locomotive, and there is a staggering array of causes of waste, divided under the headings of coal, heat, steam, power, time at roundhouse and time on the road. The paper concludes with the statement that "in view of the many ways in which energy may be wasted it may seem surprising that there is really any left." Then it must be borne in mind that "while one or two of them alone would make a small item, nevertheless a man must be alert and watchful to keep them down to a minimum for waste is a prolific creature and unless watched and controlled increases and multiplies to such proportions as to ruin good men's careers and wreck good roads."

In the other papers listed the subjects were well handled in a practical manner, and were up to the standards of the previous proceedings of the association.

Machine Shop Work. By Frederick W. Turner, Instructor in Machine Shop Work, Mechanic Arts High School, Boston, Mass. Chicago: American School of Correspondence. 190 pages; 6½ x 9½ in.; 248 illustrations. Price, cloth, $1.50.

This book contains part of the series of papers used by the publishers in their correspondence course of machine shop instruction. These papers have already appeared, for the most part, in Vol. III relating to the Foundry, Forge and Machine Shop of the set on Modern Engineering Practice that was issued two or three years ago. This statement holds for the whole book with the exception of the chapter on the Milling Machine, which has been re-written and extended for the present volume. Of course it cannot be expected that the whole science of machine shop practice can be taught or even touched upon extensively within the limits of a book of the size of this one, but it can serve, as indicated in its preface, as a practical working guide for those who are employed in shops. Naturally, where such brevity is demanded, much has to be taken for granted, and the reader is assumed to know many things that can only be learned by actual experience. This appears from time to time by reference to certain things of whose use and construction there is no explanation, and in this it frequently falls just short of giving very specific instructions. It is, however, valuable in its suggestiveness, and for the reasons that are given for the performance of certain operations in a certain way, and the use of certain methods. The book is concise in its language and is made to cover the ordinary ranges of work with hand tools, the lathe, planer, drill, milling and grinding machines; and, while it does not attempt to enter upon a description of the construction of these tools, it does give a very clear idea of the class of work that may be expected to be done on each.

The Slide Rule. By Charles N. Pickworth. London and Manchester: Emmott & Co. New York: D. Van Nostrand Co. 105 pages; 7 in. x 5¾ in.; 24 illustrations. Price, cloth, $1.00. Tenth edition.

It is characteristic of the slide rule that it is used either very persistently and constantly or not at all. The engineer who has once acquired the slide rule habit, uses it for any and all varieties of calculations, fully aware of its inaccuracies but knowing that these inaccuracies lie well within the limits of permissible error. The probability is that many would use the instrument who do not now do so were the principles of its construction and manipulation understood. The book under consideration is intended to furnish just that information and will do so if it is carefully studied. Of course the best way to acquire the needed information and skill would be to read the book with a slide rule in hand.

It starts in with the simplest of propositions, the adding together of two numbers of a single digit each, and then shows how identically the same thing is done when the two logarithms of the same numbers are added, the result being a multiplication of the two original numbers. In the same manner the simple act of a subtraction becomes a division. Nothing is taken for granted and each step in the process is explained with painstaking elaboration, leaving nothing to conjecture, and nothing for even the most stupid to desire. Having explained in the fullest detail this simple principle of construction and operation, the author goes on to show the methods to be followed in solving certain definite problems, such as proportion, multiplication, division, combined multiplication and division, involution and evolution, and the solution of examples in technical computation, such as the weights of metals, falling bodies, centrifugal force, steam engine problems, screw cutting, strength of shafting, moments of inertia and a mass of trigonometrical applications.

The book closes with a description of the log-log slide rule and other special rules that have been designed with a particular object in view. Taken all in all, the book is a complete, and therefore a valuable, guide to the use of the common slide rule, and withal it is so simply written and the explanations are so clear and comprehensive that it cannot fail to be understood by even the most indifferent of students; and, if it can but be placed in the hands of those who do not use the instrument, it cannot fail to lead many of them to adopt it as a time and labor saver for all ordinary and many extraordinary calculations.

Report of the Proceedings of the Fifteenth Annual Convention of the International Railroad Master Blacksmiths' Association, 1907. 244 pages; 6 in. x 9 in.; 11 illustrations.

The convention was held at Montreal in August, 1907, and some of the papers have already been reviewed in the *Railroad Gazette*. The subjects presented and discussed were: Tools and Formers for Bulldozers and Steam Hammers; Forging Machine and Bulldozer Work; Discipline and Classification of Work; Flue Welding; Case Hardening; Best Fuel to Use in Smith Shop; Piece Work; Frame Making and Thermit. In addition to these topics the proceedings contain a number of others reprinted from previous proceedings. These are: The Clean Shop; Relative Importance of the Blacksmith Shop to the Cost of Rolling Stock Maintenance; The Foreman Blacksmith; Case Hardening; Uniform Methods; Treatment of Tool Steel; Heating for Hardening and Annealing; Annealing; Track Tools; Scrap Materials; Iron vs. Steel and Shop Discipline.

Subject Matter Index of Mining, Mechanical and Metallurgical Literature for the Year 1902. Edited by M. Walton Brown, Secretary of the North of England Institute of Mining and Mechanical Engineers. Newcastle-upon-Tyne, England. Published by the Institute. 180 pages; 6 x 9¾ in. Price, paper, 12 shillings.

This is an index, for 1902, of articles which appeared in 993 journals, proceedings of societies, government reports, etc. A large number of separate books are also indexed. The publications selected are from countries all over the world. The index is arranged according to subjects, each being minutely subdivided. They include: Geology, mining technology, metallurgy, machinery, navigation, railroads, legislation, etc. An index of authors is included.

What Are We Going to Do About Railroad Accidents?

Cleveland, Ohio, Feb. 5, 1908.

TO THE EDITOR OF THE RAILROAD GAZETTE:

Your open letter to newspaper editors, under date of Jan. 30, 1908, captioned, "What Are We Going to do About Railroad Accidents?" while interesting and timely, lacks proof to substantiate the statement made by you that holds the railroad employer responsible for railroad accidents, because he does not enforce discipline and holds the employee responsible because he, through his organizations, will not permit of the enforcement of discipline.

In answer to the inquiry propounded by the *Evening Post*, New York, which had the question of railroad accidents under discussion, "What Are You Going to Do About It," you answered for the railroad managers as follows: "We are doing more than ever before; are making progress, but cannot be successful until we are allowed to control our employees." In the employment and discharge of enginemen and train crews, the trade unions have rather more authority than the employers, and except perhaps on the Reading and the Chicago, Burlington & Quincy, which have paid millions for the privilege, dangerous men cannot always be weeded out. Nevertheless, many railroad officers do less than their full duty in organization and vigilance, and are legally and morally guilty of criminal negligence. The force of public opinion, which the newspapers aim to express and often influence, together with the enforcement of the present laws is probably the only hope for a better condition.

The statement made by you is simply a repetition of others that have been made from time to time but, as yet, there has been no evidence submitted to prove that the railroad organizations have interfered with the enforcement of discipline, that they have advised their employers, or in any arbitrary or unfair manner intimated to them who should be employed.

The enforcement of discipline is entirely in the hands of the railroad employer. He makes his rules and he can and does enforce them. The organizations have not by threat, intimation of trouble, or by unfair or arbitrary performance, insisted on the retention of any employee who justly has been disciplined. The railroads employ whom they please. In order to protect themselves against inexperienced employees, the railroad organizations will not accept an employee to membership until he has served an apprenticeship of from six months to one year.

The railroad organizations naturally prefer the employment of members of their organizations, the first reason being that there is assurance that the employee knows something of the duties of the service. The "student" does not and until he does he is a dangerous fellow servant, and consequently not as desirable a fellow employee as one who is experienced.

When you say "In the employment and discharge of enginemen and train crews, the trade unions have rather more authority than the employers," you are in error.

We will welcome a statement from any railroad manager, giving specific instances that will prove the often repeated charges that railroad organizations interfere with discipline, the employment or dismissal for cause of men, or that they have prevented the safe and proper operation of any railroad property.

This statement has been made in *The Railroad Trainman*. Courteous treatment has been assured any operating officer who will come forward with his bill of particulars, and *The Railroad Trainman* will give him, or as many of him as there may be, full opportunity to state his case and show wherein the Railway Associations have hampered him.

There has never been anything offered to back up the statements made, and I request for the Brotherhood of Railroad Trainmen that the *Railroad Gazette* make request that every railroad operating officer come forward with a bill of particulars setting forth in clear, unmistakable language, just when and how he has been prevented from safely operating his property or enforcing proper discipline.

So far as the Brotherhood of Railroad Trainmen is concerned, and I feel that the other railroad organizations will voice the statement, it welcomes anything of the kind and is anxious for the opportunity to meet every question offered, with your permission, in the *Railroad Gazette*, taking it for neutral ground, and let your readers judge the questions for themselves.

Let us get at the bottom of these assertions. Let us have a clearing up of the statements that have been made concerning the interference of the railroad organizations with the right of the railroad managers safely to operate their properties.

It might be just as well to say in this connection that the conductors and trainmen have had a splendid organization on the Burlington for many years, and that the Reading is very well organized. Your comparisons, therefore, are not well selected.

Inasmuch as you have taken up this matter and made answer of your own, for the railroad managers, in all fairness we ask you to kindly continue the discussion and let us get the facts. Let us tell the public the truth not only about the "interference of the railroad organizations," but while we are at it, it might be well to introduce other questions that affect the safety and efficient operation of railroad properties.

I trust that the *Railroad Gazette* will throw open its columns for signed articles, showing just how far this great abuse has been carried.

D. L. CEASE,
Editor *The Railroad Trainman*.

New York, Feb. 15, 1908.

TO THE EDITOR OF THE RAILROAD GAZETTE:

I have read with interest the proof of Mr. Cease's letter, and could give him all the specific instances he wished, if it were not for the effect which this might have on our present friendly relations with our employees. But I can cite the following actual cases, omitting places and dates, which have come under my personal observation:

(1) A locomotive engineer was discharged for running by a disc signal at red at an approach to a drawbridge, running into the open draw, the engine and two or three of the cars going into the river, the engineer and fireman saving themselves by swimming. Investigation disclosed that neither engineer nor fireman could have been looking for signal as brakeman back on box car in middle of freight train saw signal at red, and bystanders also saw signal at red as train was approaching. The B. of L. E. appealed from decision of the Division Superintendent to the General Manager, the Committee of Engineers claiming that both engineer

and fireman saw disc signal at white and claimed statements of their men should be taken against other witnesses. The General Manager confirmed the decision of the Division Superintendent. The case was appealed from one official to another, going up to the highest official of the road, the decision of the Superintendent being sustained up to the last appeal, the engineers meanwhile trying to force their man back at all hazards.

(2) An engineer was discharged for burning a crownsheet of his engine because of low water, the engineer being dismissed after investigation by roundhouse foreman and Master Mechanic. The engineer claimed he would not stand for the decision, appealed to the General Superintendent and then to the General Manager, the decision of the Master Mechanic being sustained. He then took his case up with the Grand Chief Engineer of the B. of L. E., who notified the General Manager that the organization would not stand for the decision, and that it would have a state inspector inspect the boiler of the engine, and it surreptitiously sent an inspector to examine the boiler. This case is still pending, the Grand Chief Engineer claiming that he is going to force it to the end, and that this man shall be reinstated regardless of the facts, which cannot be controverted, as the General Manager of the road in question had the Master Mechanic of another road send its inspector, who made an investigation and a full report confirming the original report of the Master Mechanic who discharged the engineer.

(3) A conductor who refused by telegram to pick up a car when ordered to do so by despatcher, claiming that because he was on through freight he did not have to pick up this car. When the Superintendent wired him to either pick up this car or take his time at the end of the run, he answered that he would take his time. The brotherhood organization struggled for a long time trying to get this man back in the service, claiming that his action was entirely correct, and that the Superintendent had no business to instruct him to do something that was not customary. This case was appealed to the General Manager, by the organization, the action of the Superintendent being sustained.

(4) An engineer on a passenger train collided with another passenger train standing between switches at a station, running clear through the first coach and half way through the second, killing over 40 persons, there being straight track for a distance of over five miles, the marker lights of the standing train burning brightly on a clear night. The engineer being dismissed from the service, the organization appealed from decision of the Superintendent, because it was shown that the flagman was out only about 1,000 ft., the organization of engineers claiming that the collision was the result of the carelessness of the flagman in not being out the full flagging distance, and this case has been appealed from time to time, the organization claiming strongly that the engineer was not to blame.

GENERAL MANAGER.

Feb. 16, 1908.

To the Editor of the Railroad Gazette:

Referring to the article in your issue of January 31, with respect to railroad accidents, which I read with a great deal of interest. Every thinking railroad operating officer to-day is greatly concerned about this question. In addition to the accidents that result in loss of life and property, practical officers know of continual slips that "might have" resulted in serious accidents.

It is unquestionably practicable to at least lessen the number of train accidents. On nearly all large systems, the labor organizations have committees who take up nearly every case of discipline. On many of the roads the organizations pay a traveling chairman, whose time is devoted to investigation grievances real or alleged, appealing the discipline from officer to officer, and endeavoring to strengthen the loyalty of the employees toward the organization rather than toward their employers, the railroads. On many of the roads it is a common practice for committees to appeal cases of discipline right up to the Vice-President and President. I have personal knowledge of two instances where the dismissal of conductors for having over-run meets, resulting in serious loss of life, was appealed from the Superintendent to General Superintendent, to General Manager and finally to the President. In both cases the collision occurred 1,000 to 1,500 ft. beyond the switches, and the evidence showed that the conductor could have stopped the train had he been on the alert. I have no doubt many similar cases can be furnished by operating officers on other roads.

On some lines, I am sorry to say, the decisions of the Superintendent are frequently overruled. It is only human nature for a Superintendent, knowing that his decision is likely to be overruled, and that continual appealing by committees is liable to make those in charge regard him as unfit to handle labor, to forego necessary discipline or make it milder than the case warrants. I have read recently a number of results of alleged surprise tests, showing that almost 100 per cent. of the men obeyed the signals, etc. Every practical man will agree with me that if the tests resulted as stated, the men had been advised in advance where and when the tests would be made.

A strictly divisional organization, with the right of appeal in questions of discipline limited to the General Superintendent, together with a continual and properly conducted system of surprise testing, and greater care in the selection of men, will do more than anything else to minimize the number of train accidents. On the road I am connected with, every officer from the Superintendent down is required to make continual surprise tests, submitting a report of them monthly, and it is the intention to transfer to a less active sphere of usefulness such officers as have not the moral courage or backbone to make these tests.

GENERAL MANAGER.

The Draft Gear Line.

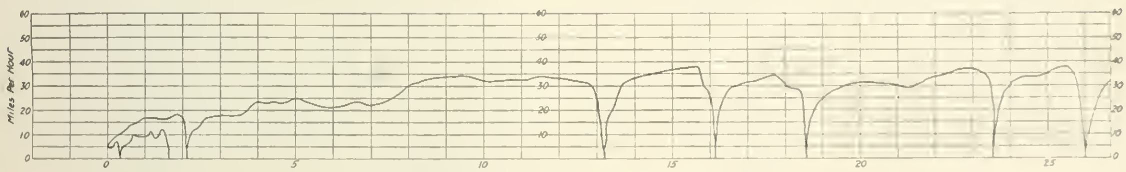
Feb. 15, 1908.

To the Editor of the Railroad Gazette:

One of the points the standing committee of the Master Car Builders' Association is asked to pass upon in connection with its report on friction draft gear is the so-called line of resistance, the committee being asked to "recommend the most desirable resistance during each ¼-in. compression." This opens up a sea of imagination and theory that is possibly going to flood the committee, as it has sent out to motive power and car men a circular asking for opinions and suggestions.

If there is any hard and fast rule to guide in this matter, it has so far escaped the mechanical engineers who have figured on this thing, for out of any hundred of these men you might select there would be almost, if not quite, a hundred different opinions, all backed up by more or less technical argument, and all more or less right.

The writer does not pose as a mechanical engineer, and is not versed in the science of determining the work done and other items that flow so glibly from this school of students, but there is a parallel in railroad mechanics for determining the proper line, and it is submitted as being the only thing so far discovered that sheds any real and practical light upon the subject. Every railroad owns one or more speed recorders, attached most generally to private cars, and from these can be obtained a graphic record of the speed of trains and the line made in starting and stopping. There is a marked similarity between the service of stopping a train and stopping a car; in fact, the relation between the two is so intimate that it is impossible to disassociate them. Why not, therefore, consult these speed recorder tapes for evidence?



Speed Diagram to Illustrate Drawbar Stresses.

The drawing shown here is taken from the catalogue of the Boyer Speed Recorder, and perhaps is as accurate as any that can be made. It shows a run of 26½ miles of a train at varying speeds, and making stops from 20, 30 and 40 miles an hour. The lines are similar in every case, and if they were inverted would give you some idea of a draft gear line based upon actual practice. If anything is to be deducted from this showing it is that a draft gear should offer to the load a low resistance until the actual stopping is to be effected, and then the line should show a sharp and continuous rise to its ultimate capacity.

X. Y. Z.

[If that portion of the record showing a stop near the thirteenth milepost be taken as typical of the resistances required to stop the train it will be found that their total amounted to 1.85 per cent. of the weight of the train. They include the frictional resistance of the brakes, air, journals, etc., provide the stop was made on a level track. If now the stop were to be made from a speed of 30 miles an hour, as indicated on the record, in 1,625 ft., the approximate total resistance against a car weighing 160,000 lbs. would be about

2,960 lbs. But if this were to be uniformly distributed throughout the entire train, then there would be no compression of the drawbars at all, while if the whole resistance were to be set up from the front end there would be an accumulated pressure at that point equal to 2,960 lbs. less journal and air-resistances, for each car, or for a 25-car train of something between 62,500 lbs. and 74,000 lbs., which the draft gear at the front end of the first car would have to withstand. At the same time, this gear must necessarily support the whole tractive effort of the locomotive, so that the lesson to be learned from an inspection of stop records seems to be somewhat more difficult than would appear at first sight.]—EDITOR.

Steel Car Design.

New York, Feb. 25, 1908.

TO THE EDITOR OF THE RAILROAD GAZETTE:

On page 238 of your issue of February 21, I find that a slight omission in the second column makes the formula read incorrectly. About two-thirds from the top of the page, in the right-hand column, the formula for compression is given as $12{,}000 - l \div r$; whereas it should read $12{,}000 - 70\ l \div r$, where l is the length and r the radius of gyration. As it is printed in the paper it is incorrect and would not give satisfactory use in practice.

O. R. HENDERSON.

The Location of Brake-Shoes.

Feb. 20, 1908.

TO THE EDITOR OF THE RAILROAD GAZETTE:

Commenting on the article on brake-gears and slid-flat wheels, in the February 7 issue of the *Railroad Gazette*, I would suggest three objections to the plan of hanging brake-shoes at the height of the centers of the wheels: (1) The brake hangers would be short, resulting in wide variations of their inclinations as the shoes wore. (2) There is greater danger that the brake pressure will force the journal away from the bearing far enough to allow waste or grit to get between them. (2) The pounding between the shoes and heads, the heads and hangers, and the hangers and bearings become severe with a high shoe, while it can be practically avoided with a sufficiently low one.

By inclining the hangers at the proper angle, the shoe pressure can be increased on the forward wheel of the truck and diminished on the rear one. This simple, inexpensive and highly effective method of increasing the efficiency of brakes seems not to be appreciated, though it is perfectly successful when properly designed.

G. E.

The Value of Railroad Records.

New York, Feb. 17, 1908.

TO THE EDITOR OF THE RAILROAD GAZETTE:

I read with extreme interest that the Brotan locomotive, described in your issue of Feb. 14, consumes, per 1,000 ton miles, 563 lbs. of coal, and that the standard Austrian locomotives under the same conditions consume 699 lbs. of coal. On the Atchison, Topeka & Santa Fe the coal charged against all the locomotives in freight service on the Eastern division, in Kansas, averages about 200 lbs. per 1,000 ton miles, but on special test runs where every pound used was carefully measured, the actual consumption from train start to train delivery was about 80 lbs. per 1,000 ton miles. Tabulating these different results, we have:

	Per 1,000 Ton Miles.
Competitive standard Austrian practice	699 lbs.
Brotan locomotive in competitive trial	563 "
Coal charged to Santa Fe freight locomotives	200 "
Actual coal consumed on trial run on Santa Fe	80 "

Question. How much coal ought a locomotive to consume per 1,000 ton miles on a level track in good weather?

What were the conditions that increased the normal consumption from 80 lbs. to 699 lbs.?

HARRINGTON EMERSON.

Commerce Regulation in Theory and in Practice.*

There are fortunately only a few subjects of government that cannot well be left to the municipality or state. Yet there are some that can only be dealt with by the central government. At the head and front of these stands interstate commerce. The manufacturer to-day could not sell his products if he were restricted by as many different laws as there are states in the Union. A man shipping a carload of oranges from California to New York would have to send along with the freight a caboose full of lawyers. Our forefathers recognized the necessity of some central control over interstate shipments when they placed the commerce clause in the constitution. The difficulty to make a uniform law to cover this immense subject is seen by the fact that our present Interstate Commerce law, time and again, when laying down a rule, qualifies it by the phrase, "Under substantially similar circumstances and conditions." We read that in the time of Cicero, there was a law that those who forsook a ship should forfeit all property therein, and that the property should belong to those who stayed with the ship. Once in a dangerous tempest all passengers left the ship but one sick man who was too weak to leave with his mates. By chance the ship came to port. The sick man took possession and claimed benefit of the law. All the learned men of the time agreed that the sick man was not in the reason of the law, which was to encourage sailors to save vessels in distress.

I mention this simply as an example of the universally acknowledged fact that all laws should be construed in the manner which will best carry out their reason and spirit. And if this principle of interpretation is true of any law ever passed by man, it is true of the Act which regulates the commerce of this country. We have a good law. It would perhaps be impossible to obtain a better one. Its avowed object is to effect reasonable rates and stop discrimination. All constructions placed thereon should be to that end. These objects, mark you, are co-ordinate, that is, of equal importance. I sometimes think the Act, in its perfectly laudable desire to prevent discrimination, effects a rate which is not only unreasonable but discriminatory. Let us take, for example, the 30-day clause. The theory of this, of course, was to prevent midnight tariffs in favor of large shippers. But how does it work in practice? A bridge is to be erected across a stream near the little town of "X." Perhaps there never was a pound of steel shipped to this place before in the memory of man, and perhaps there never will be again. There are no rates, save the almost prohibitory class rates. The railroad stands willing to publish immediately a commodity rate to "X," which is reasonable and non-discriminatory. But the law says, No. Wait until that rate has been posted for 30 days before you may profit by its terms. The shipper is compelled to hold forwarding of his goods or else pay an unreasonable rate. I submit that this interpretation of the law effects the very thing it was intended to guard against, namely, unreasonable rates.

So again in the matter of the sum of locals versus through rates, we have an example of an impractical interpretation of the law. Suppose the rate from A to B is 10 cents. From B to C is 10 cents, making a combination of 20 cents. The through published rate from A to C is 25 cents. All these rates are properly published and filed with the Commission. Section 6 of the Act says, "every common carrier subject to this Act shall file with the Commission, agreed by this Act, and print and keep open to public inspection schedules showing all the rates, fares and charges for transportation between points on its own routes, and points on the route of another, carried by railroad, by pipe line or by water, when a through route and joint rate have been established. If no joint rate over the through route has been established, the several carriers in such route shall file, print and keep open to public inspection, as aforesaid, the separately established rates, fares and charges applied to through transportation." You will note the statute tells you how to publish a through rate and how to publish a combination rate, nor is it silent as some claim it is, as to which rate shall take precedent over the other. The text of the Act clearly states that charges made for any service rendered or to be rendered in the transportation of passengers or property as aforesaid, or in connection therewith, shall be just and reasonable, and every unjust and unreasonable charge for such service, or any part thereof, is prohibited and declared unlawful. It seems to me where the published combination of locals is lower than the published through rate, the shipper should have the advantage of the lower rate. This has been the universal and undisputed custom since the early days of railroading. Neither has this custom ever worked an injustice nor do we see how it could. Since such is the case, does it not seem unreasonable to so arbitrarily construe the law that the higher rate shall be charged. This impracticable construction is working an injury to-day to commerce.

So it will be seen that any law dealing with as necessarily a practical thing as commerce must in a sense be elastic. The great advantage of the unwritten constitution and unwritten law of England is its elasticity. Each case is regulated by the surrounding conditions. When a legislature endeavors to include all sorts of conditions, in the confines of the law, it is attempting the impossible. The legislatures of several of our states have lately passed laws and I believe Congress is at present considering a law which would make 50 miles per day a reasonable rate for moving freight. I contend that you cannot arrive at a reasonable time by any arbitrary standard. What would be a reasonable time on a 50-mile shipment would not be proportionately reasonable on a 3,000-mile shipment. Again, what would be reasonable on a carload of coal would not be reasonable on a carload of watermelons. Because it is reasonable that it should take two days to haul a car of iron from Philadelphia to New York, a distance of a hundred miles, it does not follow that it would be reasonable to allow a railroad

*From an address delivered Feb. 25 before the Traffic Club of New York, by Charles S. Belsterling, Traffic Manager of the American Bridge Company.

company 60 days from New York to San Francisco, a distance of 3,000 miles. And looking at the question from the railroad standpoint, what would be a reasonable time under ordinary conditions would be unreasonable under other conditions. It is horn book law that negligence is the "want of cars under the circumstances," and no legislature in the world can measure negligence by a yard stick and a Waterbury watch.

The matter of the equipment that a railroad should furnish its patrons is more capable of being regulated by a general rule than the one just mentioned. If there were always an abundance of cars, the distribution would be comparatively simple, but most of us know that there are times of insufficient car supply.

A railroad in its original conception was simply the highway on which tracks of iron or other materials were laid. The vehicles were the means of transportation and were to be supplied by the shipper, excepting, of course, the engine and its fuel. The impracticability of such a custom was soon apparent, and to-day the law compels the railroad company to not only supply the highway, but also the instrumentalities of transportation. All freight tariffs are figured with this in view. Certain industries grow to enormous proportions. Large numbers of cars are required to carry on the business. The railroad company itself had not sufficient faith in such particular business to spend millions of dollars for the necessary equipment. The industry, in order to live, reverted to the original idea and secured its own cars at enormous outlays of moneys. I do not suppose there is any man, save a demagogue or an anarchist, who would question the right of the owner to provide his own cars, yet I fail to see by what theory of law the fact that a shipper has cars of his own should deprive him of a fair and equitable share of the general equipment of the railroad company in its distribution of cars. You must not overlook the fact that millions of dollars that these concerns have invested in private equipment is to-day totally unproductive. At times of car shortage they certainly should have their proportionate share of the general equipment of the road. That they have cars of their own works no hardship on the other shippers. In point of fact, by depriving him of his proportionate share in the distribution of the general car supply, you are taking away from the private car owner a right that he would have had had he not put a dollar in an investment which inured to the benefit of the general shipping public.

So I have mentioned a few instances of the difficulty of regulating practice by theory. There must be elasticity in all the laws pertaining to commerce. When I advocate an elastic law I do not mean an indefinite one, but a law that will allow an honest shipper to move freely without suffering unwarranted injury. There is no greater fallacy than that rigidity of rules will compel honesty. A law, like anything else, when too rigid is apt to be brittle. Especially is this so when applied to trade. Commerce and liberty can go hand in hand. Give us laws; without law there can be no liberty. But just as truly with too much law there is no freedom. It has been said, "commerce is sometimes destroyed by conquerors, sometimes cramped by monarchs; it traverses the earth, flies from the places where it is oppressed and stays where it has liberty to breathe; it reigns at present where nothing was formerly to be seen but deserts, seas and rocks; and where it once reigned now there are only deserts."

Theory is too straight laced. Practice is often too loose as it is very apt to run along the lines of least resistance. It looks to the ends and cares very little for the methods. What we need is the golden mean: where theory will listen to the lessons that practice can teach and practice be guided by the less impetuous and cooler brain of theory.

The Subway Car.

The following report on the subway car of the Interborough Rapid Transit Company of New York City is part of a report to the Public Service Commission of the First District, State of New York, by Bion J. Arnold, Consulting Engineer. It is a full and careful investigation of the general problem of the best type of car for use in rapid transit subways.

The following is the concluding paragraph of Mr. Arnold's letter of transmittal, dated February 18, 1908, to the Commission:

"After studying the conditions surrounding the operation of cars in the present subway, I have reached the conclusion that the present car, when provided with an additional side door located near each end, thus making four doors in each side of the car, will best meet the conditions of the present subway, and that, when these cars are properly operated through the stations as rapidly as the signal system, when modified as recommended in my report of January 18, 1908, will permit, a marked increase in the capacity and comfort of the subway will be realized."

The report follows:

That part of the subway which is of greatest interest to the traveling public is the design and operation of the car. The passenger is mostly concerned about the convenience with which he can get to and from the car which carries him, the ease with which he can enter or leave this car, and the comfort, speed and safety with which it transports him to his destination.

THE PRESENT CAR.

The car equipment at the present time consists of 500 composite cars in which some wood is used, 300 all metal, strictly fireproof cars, and 50 additional all metal cars which have been ordered and are now being delivered, making a total of 850 cars. All of the cars are practically the same size, with seats and doors similarly arranged. Each car is 51 ft. 2 in. over all in length and 8 ft. 7 in. in width and is provided with 52 seats, 16 of which are cross seats near the center of the car, with the other 36 seats placed longitudinally near the end. The cars are as long as the curvature of the tracks will admit, and as wide at the top as the clearance on critical curves will allow. All the cars have closed vestibuled platforms, with sliding doors, instead of the usual gates. The accompanying drawing indicates the seating plan and general dimensions of the car.

The operation of these cars in actual subway service has disclosed certain fundamental defects in design which should be remedied before the subway can furnish the speed, comfort and capacity which the passenger has a right to expect.

PRESENT SERVICE SUPPLIED.

The distinguishing feature of the subway is the intimate connection between the local and the express tracks. Of the four parallel tracks extending between Brooklyn Bridge and 96th street, the two center tracks are used for express trains running on a time-table which requires a schedule speed of nearly 25 miles per hour. Between Brooklyn Bridge and 96th street these express trains stop only at 14th street, Grand Central Station and 72d street, and they are scheduled to make this run of nearly 6½ miles, including the three intermediate stops, in 16 minutes. During rush hours, however, on account of excessive station waits and the resulting caution signals, which require reduction in speed, this run usually takes 18 to 20 minutes, and often much longer.

The local trains are scheduled to make this same distance between Brooklyn Bridge and 96th street in 26 minutes, the additional 10 minutes being due to the four extra intermediate stops made by the local trains between express stations. In actual service during rush hours the local trains usually require from 28 to 30 minutes, and sometimes more, the delay being caused by the long station waits at the express stations.

At each express station the passenger has the privilege of transferring from the local trains to the express trains, and vice versa, and, to facilitate this transfer, the five express stations are arranged with island platforms between the tracks, so that the passengers can leave the trains of one service, cross the platform and directly enter the cars of the other service, and this privilege is much used and even, to a great extent, abused.

Owing to the excessive use of this transfer privilege, many passengers, in traveling from their starting points to their destinations, are loaded and unloaded twice, and a large number of them three times, so that many of the passengers use the car doors four times, and some six times, while in an ordinary railroad without the transfer privilege the car doors are used but twice by each passenger. On account of the excessive use of the doors, the present type of car, which ordinarily gives satisfactory service, has proved to be extremely inadequate for the subway.

Some of the express stations have been built with separate local platforms, but, on account of the confusion resulting from the use of two platforms serving one train, these local platforms have been abandoned and closed up, except at the 96th street station.

The express station platforms are nearly all 350 ft. long, and at present serve 14 of the 16 doors on one side of an 8-car express train, thus leaving the first and the last doors without platform service. Most of the local platforms are 200 ft. long, and are arranged to serve 8 of the 10 doors on one side of a 5-car local train, the first door and the last door of these trains being out of service at all times.

At the time my study of the subway began (October, 1907), the schedule or time-table on which the cars were run called for 30 trains per hour during the rush-hour periods upon both the local and the express tracks south of 96th street. Owing to the excessive delays of the trains at the station platforms, the schedule was not maintained, invariably falling to less than 27 trains per hour at Grand Central Station, during the morning and evening rush. Recent improvements, however, have made it possible, except on very busy days, to get 30 trains an hour through the limiting stations on both the local and the express tracks.

Each express train consists of 8 cars, and each local train of 5 cars, and each car contains 52 seats. Under these conditions, the number of seats per hour which pass a given station are (30 x 8 x 52) or 12,480 seats on the express tracks, and (30 x 5 x 52) or 7,800 seats on the local tracks. Actual records show that during the rush hours the cars often carry twice as many passengers as there are seats, and that during the height of the rush period there are times when three times as many passengers are carried on some express cars as there are seats, although the latter condition exists only for short periods of time on very busy days.

Since the opening of the tunnels to Borough Hall, Brooklyn, on January 10, 1908, a schedule has been prepared calling for 40 express trains per hour between 96th street and Brooklyn Bridge during the rush periods, this schedule having been adopted in order to provide the Brooklyn extension with 20 trains an hour, corresponding to a 3 minute headway. The delays of the trains at the station platforms, however, have seriously interfered with the carrying out of the improved schedule, and, although there are parts of the system where 40 trains per hour are supplied during certain periods of the day, this rate is not maintained at the critical part of the rush hour period, the time when it is most needed. In other words, as soon as the demand for seats increases beyond a certain limit, the supply of seats begins to decrease.

ANALYSIS OF DELAYS AT STATION PLATFORMS.

The present arrangement of loading and unloading passengers through the same end doors of the cars is the chief cause for the inefficient operation during the rush hour period. The crowded condition of the car entrances and station platforms under the present arrangement results in passengers leaving the cars in single file and with considerable difficulty and discomfort. The unloading under such conditions usually requires from 15 to 30 seconds, and in extreme cases 50 seconds during the most congested period at the principal points of transfer.

Passengers desiring to board the cars must wait until the unloading has been practically completed, unless they wish to force themselves against the outcoming passengers, and this loading must be effected quite frequently through an entrance obstructed by passengers waiting to get off at nearby stations who prefer to hold their positions and thus obtain an earlier and easier exit. It will be seen, therefore, that the streams of outgoing and incoming passengers not only meet, but do so under peculiar and trying conditions, as the same doorway is used for both entrance and exit.

An analysis of the average time required by an express train at a station platform during the height of the rush hours shows the following figures:

		Average
1.	To open doors of cars after train has stopped.............	2 secs.
2.	To unload an average of 163 passengers through 11 doors (15 to 50 seconds)............	20 "
3.	To load an average of 206 passengers through 11 doors (15 to 30 seconds)............	20 "
4.	To close the car doors and give the signal by means of bell rope to motorman............	13 "
5.	Total average time of express trains at station platforms between stopping and starting during the height of rush hours	55 secs.

DEFECTS IN PRESENT ARRANGEMENTS.

Two of the defects which stand out prominently in the operation of the subway are, first, the excessive use of the transfer privilege, and second, the use of the same end doors in the cars for both the entering and the leaving passengers.

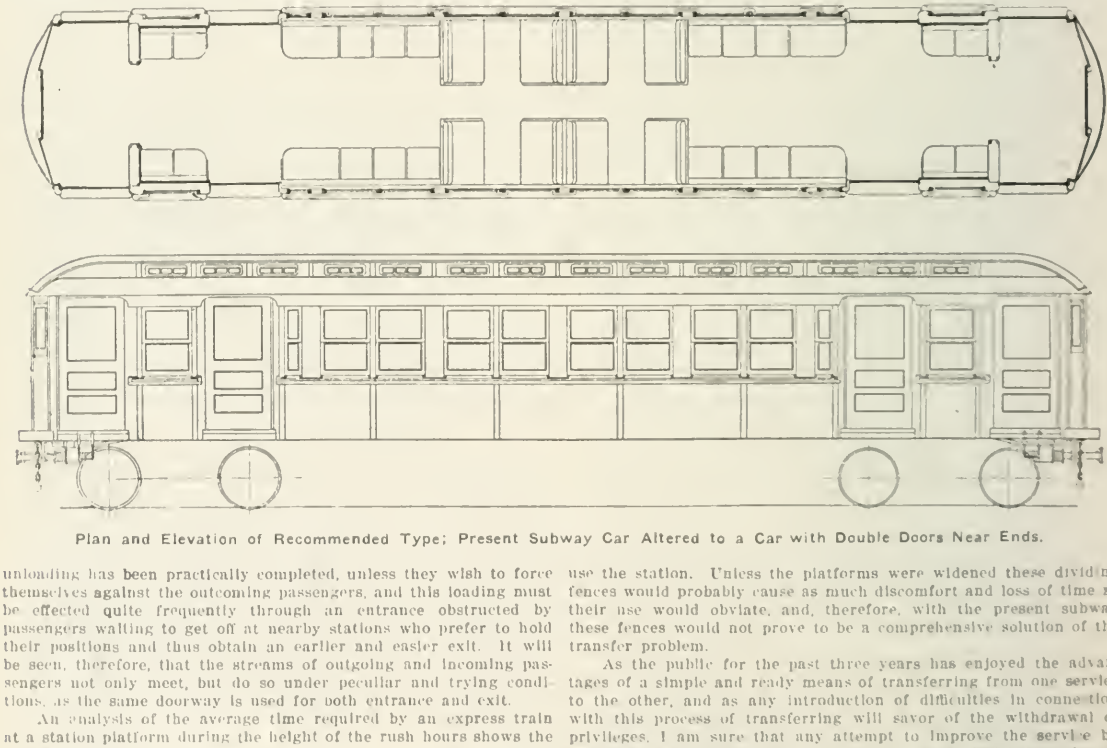
Apparently the only permanent way to improve these conditions is either to reduce or abandon the transfer privilege, or to change the car.

There are several ways in which the transfer privilege could have been reduced or curtailed. For instance, at Grand Central Station and at 14th street, where the greatest amount of transferring is done, separate platforms might have been arranged to serve the local and the express trains, but this would have made it necessary for all passengers wishing to transfer from one service to the other to climb the stairs from one platform to the mezzanine walkway which connects all platforms, and go down again to the level of the platform serving the other train. As the maximum time that can now be saved by transferring from a local train to a northbound express train at Grand Central Station is 4 minutes, and the average time saved by transferring at 14th street is about 6 minutes, and, as it would require on an average 2 minutes of this time to make the transfer on account of the necessity of climbing up and down the stairways, it will be seen that much of the present unnecessary transferring at these two points might have been discouraged by the use of separate platforms.

It is also possible to divide the island platforms longitudinally at certain express stations by means of a central iron fence, which could be provided with gates, to be closed at such times as it would be absolutely necessary to discourage the present practice of excessive transferring. These gates could be closed, for instance, at the times during rush hours when a local train and an express train both occupy the station platform, so as to make it possible to rush from one train to another, but they could be open at all other times. With the present narrow platforms, this dividing fence would add considerably to the platform congestion, and thus would interfere with the prompt handling of the passengers, who must necessarily use the station. Unless the platforms were widened these dividing fences would probably cause as much discomfort and loss of time as their use would obviate, and, therefore, with the present subway these fences would not prove to be a comprehensive solution of the transfer problem.

As the public for the past three years has enjoyed the advantages of a simple and ready means of transferring from one service to the other, and as any introduction of difficulties in connection with this process of transferring will savor of the withdrawal of privileges, I am sure that any attempt to improve the service by rearranging the station platforms so that those desiring to change from local express service, or vice versa, would be delayed, would meet with strenuous objection, and, with the present subway, would not be justified. While it may be contended that such convenient means of transferring at so many points should not have been provided, it is my opinion that this principle, having been established, cannot now be withdrawn, and that the only remedy, therefore, is to change the cars.

It has been suggested that even with the present car the passengers could be made to enter at one end door and leave at the other end door, but when it is considered that passengers leaving the train at the express stations under this regulation would be forced to push their way past every standing passenger throughout the entire length of the car, and that this discomfort to all would be constantly recurring during the rush hours, it can be understood that this solution of the difficulty would be neither popular nor efficient. Furthermore, if the entering passengers were to be confined to the use of one door in each car, and the leaving passengers

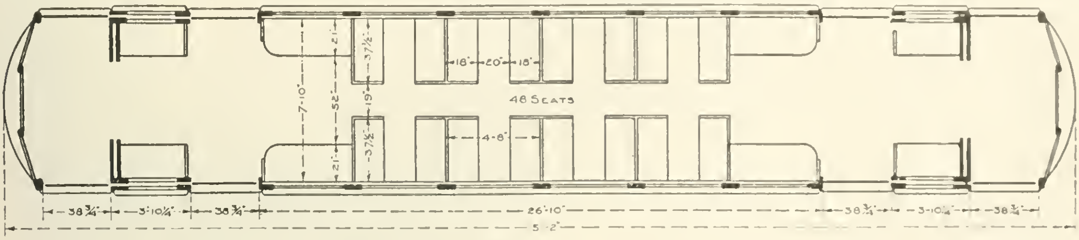


Plan and Elevation of Recommended Type; Present Subway Car Altered to a Car with Double Doors Near Ends.

to the other, the number of entrances to the train would be cut from the present number of 14 to a maximum of 8 doors, and the exits likewise reduced. This would be a disadvantage, particularly at 14th street, where the great majority of passengers using the car doors of the local trains are leaving passengers, and those using the express trains are entering passengers. Moreover, since the present station platforms are not long enough to serve the doors at the extreme ends of an 8-car train, it would be impracticable to establish a circulation in the end cars.

The present car works very well during periods of light and fairly heavy travel, but as soon as it is called upon to carry upwards of 100 passengers, the single-end doors become a decided disadvantage, and their inefficiency in handling large crowds seriously interferes with the prompt movement of the trains. It might be subway officials are of the opinion that it is impossible to confine the waits to the 45-second limit suggested in that report. Their efforts, however, in improving the service have resulted in cutting these station waits down from an average of 65 seconds to an average of 55 seconds.

In the preliminary report referred to, I pointed out the fact that if the wait at the station platform could not be limited to 45 seconds by efficient methods of handling the passenger traffic, it would be necessary to consider an improved type of car which would accomplish this result. As the station waits have not been thus limited by the subway officials, and, further, as it is their opinion, as expressed in their reply to my preliminary report, that it will be impossible to always limit these waits with the present type of car to the 45 seconds, it is necessary to consider a car de-

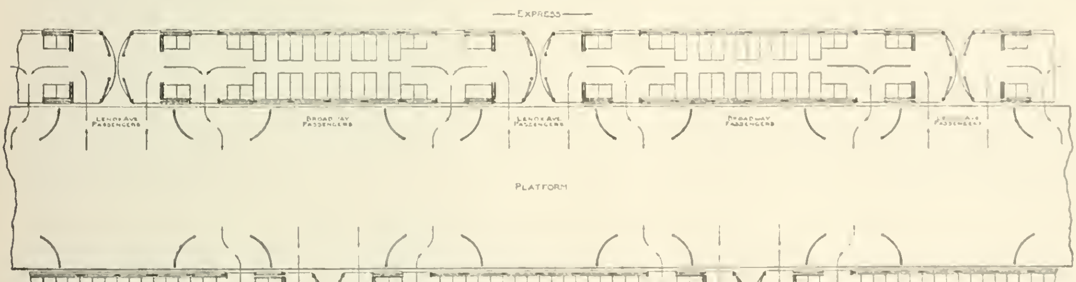


Recommeded Future Car for Present Subway; Car with Double Doors near Ends, Combining Cross and Longitudinal Seats, Seating Capacity 48; More Compact Seats Than in Present Car.

maintained that all of the passengers who *should* be carried in the cars can enter and leave the present end-door cars within the time to which the station waits should be limited, and that any further loading of the cars should be prohibited and prevented. If there were other ample and equally as good means of transportation paralleling the subway, this regulation of the amount of loading would be a practical solution of the difficulty, but until other subways are built, the people will demand transportation in the present subway even at the sacrifice of comfort, and, therefore, every effort should be made to give transportation to as many as possible. As the limit of capacity under present circumstances will be the maximum carrying capacity of the car, it is essential that a type of car be used in which this limit can be easily and quickly reached.

In order to accomplish this purpose it is clear that the ease of loading will be greatly increased when the entrance is cleared to a great extent of passengers waiting to leave the car. Passengers signed so that it will considerably reduce the present platform delays.

In my study of the signal system I found that the trains can be run *between* stations on a headway of 90 seconds, or at the rate of 40 trains per hour. However, on account of the delays at the station platforms and also on account of the arrangement of the signals on the tracks approaching the stations, it is just possible under present conditions to pass 30 trains an hour *through* the busiest stations during rush hours. Changes in the signal system were pointed out which would make possible a headway of 105 seconds (34.3 trains per hour), even with the present car, and still allow a station wait of 50 seconds. If the platform delay can be reduced to 35 seconds and the signal system improved as suggested, then it will be possible to get the trains through the limiting stations in 90 seconds, thus maintaining a headway of 1½ minutes, corresponding to the capacity of 40 trains per hour, which is the



Arrangement of Guiding Rails on Subway Station Platforms, to be Used in Connection with Recommended Type of Altered Car.

could be handled with greater ease and comfort by having separate doorways for exit and entrance and the process of unloading and loading should take place simultaneously, thus reducing the station wait now required by nearly or quite one-half. To state the case briefly, the principal defect in the present car is due to the fact that a definite and ready circulation of traffic is not provided for and that owing to the lack of sufficient doors properly located, the maximum carrying capacity of the car cannot be easily and quickly reached.

POSSIBLE IMPROVEMENTS.

In my preliminary report reference was made to the excessive time required by the express trains at the station platforms during rush hours, which the record showed to be 65 seconds at that time (November, 1907). Suggestions were therein made with the idea of limiting these station waits, if possible, to 45 seconds. Many of these suggested improvements have been put in operation, but the maximum rate at which the signal system between stations will allow trains to pass.

To secure the desired capacity of 40 trains per hour without making any changes in the signal system, will require that the station wait be limited to 20 seconds. To thus limit the time required for unloading and loading the passengers and for opening and closing the car doors and transmitting the starting signal to the motorman to 20 seconds, means an entirely different type of car than that used at present and a rearrangement of the stations, as this result could not be accomplished without the use of a large number of doors along the entire length of the car and suitable gates for preventing an excessive number of passengers reaching the car at any one time. In other words, if the present arrangement of signals is retained, the only possible way to secure an increase in the capacity of the subway from 30 trains per hour to 40 trains per hour is to scrap or use elsewhere the entire subway car-body equipment and build new cars at an expense of at least $35,000,000, and to rearrange the present platforms which is practically prohibitive.

If on the other hand, the signal system can be improved in such a way that even the present trains can be passed through the stations on a headway of 105 seconds (1¾ minutes) it will require only a comparatively simple alteration in the car to reduce the allowed stop of 50 seconds to 35 seconds and thus secure the 15 seconds' saving which will make the desired 90-second headway possible. The most economical and efficient as well as the quickest way, therefore, to secure a capacity of 40 trains per hour in the subway is to improve the signal system (as recommended in my report of January 18, 1908) and at the same time alter the present cars sufficiently to limit the platform waits to a maximum of 35 seconds. It should be understood that this 35 seconds is a limit which, if exceeded, would at once affect the headway, and that the average platform delay should be somewhat less than this limit in order to provide a leeway for operating exigencies.

To secure this result it is evident that the loading and the unloading must be carried on at the same time. Some improvement should also be expected from the use of pneumatic door-handling equipment and an electric door signal. These changes should easily bring the actual wait at the station platform down to the following figures:

1.	To open doors after train is stopped	2 secs.
2.	To unload 163 passengers through 14 doors, and to load 206 passengers through separate doors, both processes being carried on at the same time	20 "
3.	To close doors and give signal to motorman	8 "
4.	Total average time of trains at express stations during rush hours should not exceed	30 secs.

ARRANGEMENT OF SEATS.

From the foregoing discussion it is plain that in order to run 40 trains per hour through the subway, it is essential that more door openings be provided than are found in the present cars.

There are a number of different types of cars which will provide extra doors, thus reducing the station waits and increasing the present number of cars which can be run through a station during rush hours. Each type, however, will allow for a number of different arrangements of the seats, and therefore before taking up the most desirable location of these extra doors, it will be well to discuss the arrangement of seats in order to determine how best to utilize the additional carrying capacity provided by the increased number of trains.

Before determining upon the proper arrangement of the seats, the question of policy submitted to your Honorable Commission in my preliminary report of November 26, 1907, must be decided. In that report I requested a decision as to whether the capacity of the subway should be limited to the number of passengers who could be carried if the cars contained the maximum number of seats, or whether it would be preferable to sacrifice somewhat the possible number of seats, thus providing a relatively larger amount of standing room and correspondingly increasing the total carrying capacity.

Not having been instructed by you on this subject, in order to complete my report upon the subway car I take the liberty of suggesting the following policy for your consideration:

It seems to me that it should be the aim to eventually provide a seat for every long-haul passenger, but until this can be at least approximated by the construction of additional subways or other transportation lines, it will be necessary to furnish transportation for all, even though existing conditions compel many passengers to stand during rush hours. While it seems at present impracticable to provide seats for all except during non-rush hours, every possible improvement that tends in this direction consistent with justice to the subway company should be made, in order to gradually reduce the proportion of standing passengers to those seated, and no change should be allowed which will reduce the total number of seats per hour now provided by the subway cars.

It has just been pointed out that the maximum number of cars per hour can be secured only by the introduction of additional side doors in the cars. Although these extra doors may slightly reduce the seating capacity per car, their use should so limit the station waits that the total seating capacity carried by a station within a given time is not reduced from the present number of seats. In other words, the rule should be that the increased number of seats made available by the extra cars must be at least equal to the total number eliminated on account of the space occupied by the extra doors.

Owing to the overcrowded condition of the subway it will be necessary for the present to utilize the extra carrying capacity made available by the additional cars for standing passengers, until such a time as additional subways can be built. If these subways are built sufficiently in advance of the demand for subsurface transportation, a part of this extra space can eventually be fitted with seats and thus approach nearer to the condition of a seat for every passenger.

If 40 trains of eight cars each are passed through a station each rush hour, each car having additional doors to provide for the more comfortable and rapid handling of the passengers, it will require but 40 seats per car to provide the same number of seats that are at present supplied by 30 eight-car trains per hour. The new cars, therefore, should not have less than 40 seats. Any greater number of seats than 40 per car will indicate a corresponding increase in the total number of seats available.

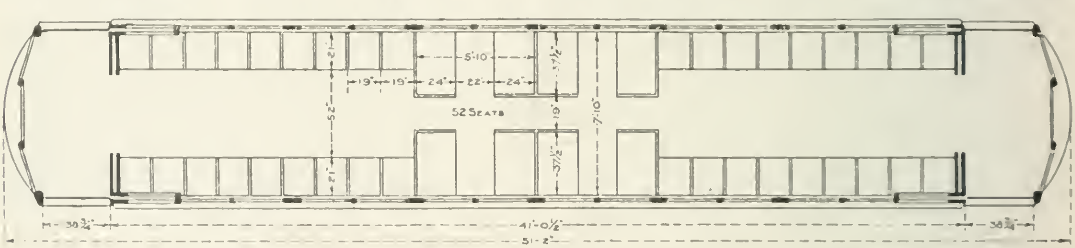
The number of seats which can be placed in a car depends upon the type of seat, and there are three kinds of seats which by common use have become standard practice in cars of the subway type.

The longitudinal seat usually occupies a space 19 in. in length along the side of the car. This type of seat has long been in use in surface cars, in many elevated cars, and the ends of the present subway cars.

The cross-seat of the "back-to-back" type has been adopted for use in the center of the cars on a number of elevated urban roads and for the present subway car. As the elbow of the passenger occupying the seat next to the aisle can encroach upon the aisle space, only 18 in. in width is required for each passenger. The space between the seat cushions varies from 14 in. to 30 in., a fair average being from 18 to 20 in.

The cross-seat of the "walk-over" type is being quite generally adopted by the interurban electric roads and by a number of city lines. A width of 17 in. per passenger makes the seats 34 in. wide, although in some instances, such as the new cars now in use in Chicago, the seat is 36 in. wide. The distance from the center to center of back varies from 27 in. to 36 in., a fair average for a properly designed seat being about 30 in.

The advantages and disadvantages of the various kinds of seats are pointed out in discussing the possibilities of seating arrangements in the different types of cars which are most suitable for subway conditions.



Plan of Present Subway Car, Showing Arrangement of Seats and Single Doors at Ends.

TYPES OF SUBWAY CARS.

A successful car for the present subway should possess as many as possible of the following requirements:

1. Separate entrances and exits.
2. A space which can be cleared so as to be ready to quickly receive the passengers boarding a car.
3. Convenient means of circulation inside a car.
4. Standing room space contiguous to the exits.
5. As many cross seats as practicable.
6. Exit and entrance doors sufficiently removed from each other to allow for the car's stopping convenient to guiding rails on the platforms.
7. Doors located so as to minimize the danger from open spaces at curve platforms.

The various cars may be classified in accordance with the number of doors in the sides of the cars as follows:

Cars with center side doors and end doors.
Cars with two quarter side doors.
Cars with three doors near center.
Cars with multiple side doors.
Cars with double doors near ends.

Each one of these types may have seats of either the longitudinal, the cross "back-to-back," or of the "walk-over" style, or a combination of two or more styles, as will be shown more in detail as the cars are described.

CARS WITH DOUBLE DOORS NEAR ENDS.

Without weakening the present car, or adding materially to its weight, it is possible to introduce additional side doors, one near each end of each side of the car and as near as practicable to the present end doors, the distance between the doors being at least sufficient to furnish a pocket for the sliding doors.

It will be seen by referring to the accompanying drawing that these additional doors can be added without disturbing the present seating arrangement of the car to any great extent. It is true that the introduction of these doors will make it necessary to remove eight seats from each car, but the operation of the cars in actual service will make it possible to pass so many more cars through the subway that the loss of eight seats in each car will be more than offset by the additional seats in the added cars, and the extra standing room, so convenient to the separate exit, is a feature which will decrease the station waits, and thereby increase the schedule speed.

This proposed change in the present car has many advantages, which even a casual study will reveal. The new doors can be used for exits, and the present end doors for entrances, thus providing at once the means of carrying on the process of unloading and loading simultaneously and without the present conflict which during rush hours has become so objectionable.

This car provides a separate space for leaving passengers to collect around the exit doors without blocking the space which should be provided for the passengers entering the car. The result will be that passengers will move in and out much more quickly than at present, and the movement of passengers into the car will facilitate the movement of passengers out of the car.

With this car it would be possible to keep the platforms clear of standing passengers, particularly at the time of approaching a station where considerable additional load is to be expected. With the present cars it is impossible to keep the platform clear, as the passengers readily make the excuse that they are getting ready to leave the train at the next station. With a clear platform there should be none of the discomfort now experienced in boarding a crowded car; the passengers will pass rapidly into the empty car vestibule, and can move at once into the space which has been vacated by the leaving passengers.

There should be no hesitation on the part of a passenger in the selection of an entrance with this type of car, as is so often the case with the multi side-door car. Under these circumstances there is no reason why a rate of flow of passengers in and out of the car amounting to at least five passengers per car per second should not be expected with this car with double doors near the end, and this rate is fully as good as the experience in Chicago would lead us to expect from the multi side-door cars, even with eight doors distributed the entire length of the car.

While this type of car provides for setting up and maintaining a circulation, this circulation is not obtained at the expense of comfort to the through passengers, as the circulation is confined to the two ends of the car, and it is therefore not necessary for a passenger boarding a train at one station and getting off at another to pass through half the length of the car, with the attendant discomfort to both himself and to all of the other passengers in the car.

Both the exit and the entrance doors are directly under the eye of the guard, who is thus in a position to accentuate the circulation, and, therefore, the rapidity of handling the passengers, by opening the exit door slightly in advance of the entrance door, which can easily be done by either mechanical or pneumatic means.

This car lends itself readily to the introduction of platform railing at all of the more important station platforms. These railings can be arranged as shown in the accompanying diagram, which will indicate at once the advantages of collecting the passengers who are waiting for a train at definite loading points, thus leaving the remaining parts of the platform free and ready to receive the unloading passengers. This particular double-end-door car fortunately allows for an arrangement of platform railings in such a way that loading points can be provided for the Broadway passengers separate from those set apart for the Lenox passengers. Should the distance between the doors as shown be considered too close for ease in stopping at the proper points, the distance could be increased by moving the supplemental doors one seat nearer the center of the car.

The standing room in this car can be increased during rush hours by folding up the two seats between the doors, and, while this practice is not to be commended, there will be times, and particularly on heavy days, such as Mondays, when this feature could be utilized.

The present cars can be changed to conform to this arrangement for an expense of about $2,000 for each steel car, and about $1,500 for each composite car.

For the present subway this car seems to me to possess more advantages and fewer disadvantages, both from the standpoint of the public and the operating company, than any other type, and its use will increase the capacity of the subway sufficiently to fully justify the expense of altering the present cars into cars of this type.

RECOMMENDATIONS.

My recommendations, summarized, are as follows:

First.—That every car used in regular passenger service in the present subway be provided with two additional side doors located near the ends, approximately, as shown in the drawing already mentioned. I recommend this car for the following reasons:

A. The double door space at each end of the car will greatly reduce the present station waits.

B. The separate exits and entrances will remove the present uncomfortable conflict at the car doors.

C. The present cars can be altered to this type of car without detracting from their structural strength, or materially altering the present seating arrangement.

D. The result in increased carrying capacity due to changes will abundantly justify the investment.

E. This is the only type of car with additional doors that will not necessarily increase the present trouble due to curved platforms.

Second.—That all cars be provided with pneumatic or other means for quickly opening and closing the doors, and with signals, which will automatically indicate to the motorman when the last door is closed.

Third.—That all new cars bought in future be of metal and provided with seats more economically arranged, as shown in the accompanying plan.

Fourth.—That when the cars of the double end-door type are put in service, a system of platform railings, similar to that shown in the accompanying plan, be provided to direct the passengers.

Fifth.—That for future subways a wider car should be considered. This car may be a multi side-door car, if separate platforms can be arranged for each class of trains, and if the stations can be designed to control the flow of passengers at the entrance to the platform, instead of directly at the car doors. If, however, it is found that it is impracticable to design stations with sufficient room for waiting passengers independent of the station platforms, it will probably be found that the best car for future subways is a wide car of the type with double doors near ends.

Sixth.—That if it is found that future subways cannot be built without the occasional use of curved platforms, the cars for these future subways should be designed so as to allow the station platforms to extend under the car in such a way that the necessity for sliding platforms will be obviated.

[The part of the report given above covers the general discussion of the problem, a description of the recommended type to which the present subway cars should be converted and Mr. Arnold's general recommendations. The report also includes an extended discussion of the various types of subway cars and the various kinds and arrangements of seats in them. This will be published in a later issue of the *Railroad Gazette*.—Editor.]

Perkins of the Burlington.*

Charles Elliott Perkins, who was for some 20 years president of the Chicago, Burlington & Quincy Railroad, was a strong personality with a marked and effective individuality. He was honored, respected and beloved, and his character, which was typical of the age which produced him, is for all time inseparably connected with the history and the development of the Middle West during the past 50 years.

As a railroad builder he was perhaps as great a strategist as any man this country has produced; and yet his name will never be connected with those who, in undertaking daring things, have brought ruin to themselves and their associates. With all of his personal courage and his unwavering faith in the future of the West, he was a man who recognized his position of trusteeship for others. There was a very strong line of division, as he viewed things, between his rights as an individual and his duties as a trustee and guardian for others' interests. This very quality made him a careful and safe guide, and made the railroad, the development of which he presided over, a wonderful example of careful and sound financing, and well able in times of stress and money panics to weather the fiercest storms.

In 1901, when the sale of the Burlington was made to interests representing the Great Northern and Northern Pacific roads, he showed not only his business sagacity, but his determination to protect to the fullest extent the interests of all the stockholders. Before negotiations had been opened for the purchase of the road he had learned that a considerable portion of the stock had been bought in the open market. In fact, to his surprise, as well as that of other directors of the company, many of the so-called "widows and orphans" and little stockholders of the company in Massachusetts who had held the stock for years, had parted with their holdings to the syndicate which was making the purchase. As soon as Mr. Perkins

*From an article by Frederic A. Delano, President of the Wabash Railroad, and formerly General Manager of the Chicago, Burlington & Quincy, in *Appleton's Magazine* for March.

saw what was going on, he at once entered into negotiations with the syndicate, taking the position with his own directors that it would not do to let this syndicate acquire a majority of the stock and leave the minority stockholders to take what they could get. The result, as is well known, and now a matter of railroad history, was that a proposition was made by the purchasing syndicate and submitted to all stockholders alike, and finally accepted and ratified by upward of 97 per cent. In other words, regardless of his own personal ambitions, for it must have been a keen disappointment to him to part with the control of a property with which he had grown up, he concluded an arrangement for the sale of it which was as fair and as liberal to the interests which he felt it his duty to protect as it was possible for such an instrument to be.

Mr. Perkins saw the state of Iowa grow from a population of some 675,000 in 1860 to a population of 2,232,000 in 1900; he saw the Burlington road develop, and actually and personally superintended the construction of much of its mileage, from a railroad of a few hundred miles to one of more than 8,000, opening for development 14 states, and yet, such was his modesty and such his insistence on remaining in the background that he was far less in the public eye than many men who have achieved only a fraction of what he did. He belonged to the class of men which, in the nature of things, must grow fewer as time goes on—men who have great constructive gifts and who have had the opportunity to develop and work in a new country, free and untrammeled by precedent or conventionality.

Starting out from a small position in the railroad he became paymaster and assistant treasurer, and soon the general superintendent. But the road of which he had charge extended only from Burlington to Ottumwa, 76 miles, and as it grew and developed he grew and developed with it. When it was merged with the Chicago, Burlington & Quincy, then wholly an Illinois corporation, with a mileage of some 210 miles, he was for a time put in charge, as vice-president, of the Burlington & Missouri River Railroad, in Nebraska, which extended then from Plattsmouth, Neb., to Kearney and was being developed in a wholly new country. This was only a temporary assignment and he retained his headquarters at Burlington. In 1881 he was made the president of the united company—the Chicago, Burlington & Quincy.

With the increased importance and responsibility of this position, he was one of the most influential and best-known railroad men in the western country. During the prosperous years which followed, the road was extended to ramify through a very large area of Nebraska and beyond it into the states of Colorado, South Dakota and Wyoming.

The Burlington became the leader of the granger roads and its stock a favorite investment for trustees and others. The management of the road was successful and efficient, and the property well maintained. It was naturally so under such a leadership. Indeed, to have grown up and to have done creditable service in the "Burlington school" was as good a diploma as a railroad man could ask for. The graduates of this school have carried its influence far and wide throughout the country. Included among them are four railroad presidents, Edward P. Ripley, of the Santa Fe; Howard Elliott, of the Northern Pacific, and George B. Harris, now President of the Burlington. [The fourth is Mr. Delano himself.—Editor *Railroad Gazette*.] Paul Morton, of the Equitable Life, is a Burlington graduate, so is W. C. Brown, the Senior Vice-President of the New York Central lines. Out of many men of prominence may be mentioned a few such as C. M. Levey, Third Vice-President, and H. C. Nutt, General Manager of the western end of the Northern Pacific; George W. Holdrege, General Manager of the Burlington lines west of the Missouri, T. E. Calvert, now Chief Engineer of the Burlington system. Among those who have passed on may be mentioned T. J. Potter, once the Vice-President of the Union Pacific, and Henry B. Stone, who left the Burlington to become the President of the Central Union and the Chicago Telephone companies.

All through American railroad service are to be found men trained by Mr. Perkins to be "thorough" railroad men. Thoroughness was something that he insisted upon. Mr. Perkins never liked to hear a man spoken of as "a good operating man," "a track man," "a motive power man." He wanted "railroad men", that is to say, all around and efficient "business" men. He believed that fundamentally a railroad was a commercial enterprise and should be governed accordingly both in its management and its relations with the public. He dealt with the fundamentals, with the underlying principles of railroading, and to serve under and in close contact with him was an inspiration. He was quick to form his judgment of men, and when he decided that he could place his faith in one, his method of developing him was to give him large responsibilities. To those who knew him not he was at times brusque, for he could assume an almost fierce manner. He was a big man physically, and untiringly active. Both his father, the Rev. James Handasyde Perkins, and his mother, Sarah H. Elliott, were of Puritan stock, and he had many of the Puritan qualities, mellowed perhaps by the western environment in which he grew up, for in 1840 Cincinnati, where he was born, was pretty close to the frontier.

He received a common school education, and being the oldest son in a minister's family, it was necessary for him to go west at the age of nineteen, not only to become self-supporting, but, in the then familiar language of Horace Greeley, to grow up with the country. He went to Burlington, Iowa, in 1859. Leading business men in our larger cities often wondered that Mr. Perkins was content to remain in a small town, for he retained his residence in Burlington until the end of his life. They marveled that he did not come to live in some great city where he might be in closer contact with men of equal prominence and ability, but, in this particular, Mr. Perkins showed his character as clearly as in any other. It was his thought that a man could do his work better if freed from the diversions and distractions of the city life. He preferred to keep a little apart from these conditions and exactions of the city, and remained in his country home—a home where he was surrounded by every possible comfort, yet where he avoided every evidence of display and magnificence.

He was a profound student of the problems of every-day life, and, while not a university man, he was a man who, by close reading, had trained his mental qualities to an exceptional degree. There was scarcely a single broad question of policy concerning the duties of an officer of the railroad, the functions of the railroad or its relations to the public, upon which he had not prepared "memoranda"—papers which were comprehensive and thorough in the fullest degree. Then, again, he liked to associate with men who were thorough, painstaking and forceful. He loved to have young men about him and to discuss and argue with them on every conceivable topic. He liked opposition if it was intelligent and backed up by sound reasoning. Needless to say, he hated hypocrisy and demagoguery in any form.

A contemporary of Mr. Perkins in railroad administration, himself a man of notable ability, said of him recently, that he knew of no man in the profession of better intellectual capacity and training, no man so well equipped to understand all the problems, technical, economical and commercial. High praise this, for a man who had acquired this equipment wholly by his own labor.

People who knew him best in the community where he lived and along the line of the railroad which he managed for so many years, knew that he appreciated in a way that few railroad executives have appreciated, the true importance of the good will of the community with which he did business. He laid the greatest possible stress, in the organization which he developed, on the importance of local self-government. While he appreciated fully the advantage of supervision by centralization of authority, he recognized and always preached the importance of letting the man on the ground have the authority, the tools and the men to do with.

The railroad over which he presided was not only recognized as a model of honest management and careful capitalization, but it also enjoyed an almost unexampled popularity and even affection in the communities along its line. His idea of keeping a community satisfied was to give all the service which it could reasonably demand, and yet he did not tamely submit to harsh treatment or exactions. Indeed, few men ever fought more stubbornly for the rights of their stockholders against some of the senseless legislation resulting from the wave of popular hostility in the Granger movement and afterward. He should have the credit, more than any other one man, of supplying the initiative and the arguments which finally secured a decision from the United States Supreme Court in favor of the railroads in the "Nebraska Rate Case." His logical mind, his capacity for reasoning closely and clearly, and for analyzing complex questions made him alike a strong advocate and a powerful combatant.

It is not to be supposed that this man's career was one unbroken procession of triumphs. He had his trials and his sore disappointments, as many another, bearing them so manfully withal that few ever knew of them; but in his railroad career, perhaps, his hardest experiences were the repeated disappointments in carrying out his ambitious plans for the development and extension of the Burlington road. Without criticising his associates and directors, who took what they thought to be a safer and more conservative course, he was keenly disappointed that he could not make them appreciate the grand opportunities which lay before them; first, in the purchase of the then bankrupt Northern Pacific, and later in the purchase of the Oregon Short Line. Finally, of course, the loss of control of the property by his friends was a severe disappointment, but, after all, to his reasoning mind, only a natural sequence of the failure to grasp opportunities which had been offered and had been allowed to slip.

With all of his great qualities as an administrative and executive officer, so successful in his achievements, Mr. Perkins was even more. He was a great, large-hearted, generous man, doing in a quiet way many things for his friends and neighbors. He was capable of inspiring in his associates loyalty and devotion to a remarkable degree, and yet he was exacting in his demands for thoroughness and accuracy, while generous in his approval of work well done. His life-work is a sufficient monument to him, but the business ideals and the inspiration which he gave to many a man who came under his influence will perhaps mean even more in the long run.

After all, the most encouraging thing that can be said is that Mr. Perkins' methods and his success were not absolutely unique, for he was a product of American civilization, a thoroughly typical American. In these days when sensationalism runs riot and public attention is constantly directed to everything unfavorable, it is worth while to remember that there are such men, and to realize that business methods are fundamentally sound, for the reason that men in business believe, and fortunately so, that corporations must be fairly conducted in order to survive.

Picked Up on the Road.

BY GULF.

Every one ought to have read the discussions on track stresses on curves that have been published during the past year, if only from curiosity to see how men are seeking the solution, though it must be admitted that the mathematics of the case has many will-o'-the-wisp features. Mathematics is an exact science, but its usefulness depends on correct premises. When we have an equation of two unknown quantities that are treated as variables, the construction of the line by the assignment of a known value to one of them is an easy matter, but when it comes to solving an equation involving a score or more of unknown quantities, the case assumes different proportions. If we could know the value of all of the variables that enter into and affect the pressures of the wheel on the rail, then there is no doubt that a mathematical solution of the result could be obtained. But who knows the values of these elements? For example, who really knows the simplest one of the lot—the height of the center of gravity? Then, who knows just what position a four-wheel truck will assume on a curve, and what effect gage widening has on that position? If you don't even know that, how can you make even a wild guess at the position that will be taken by a consolidation locomotive; and how dare you assume that that position will be the same at all speeds? Will the centrifugal action that shifts the center of gravity affect the position? I don't know. Do you?

Now, everybody knows that in rounding a curve one wheel must slip to make up the difference in the length of the rails. Which wheel slips? Is the slip all on one wheel, or is it distributed between the two? Is there any difference in the slip of the front and rear wheels of the same truck? I don't know. Do you?

What is the coefficient of friction between the wheel and the rail when both are worn? Rather, how much will it take to slip a worn wheel laterally? Doesn't it jump up in the air to a point that rather tends to take your breath away? I have been told confidentially that an attempt to measure the matter on a consolidation locomotive running at 10 miles an hour resulted in putting the measuring apparatus out of commission, with a good big margin to spare, and that this didn't happen until a load of 30,000 lbs. had been exceeded. Won't it take more to slip a wheel toward the outside of the rail than in? Anyhow, can you guess what the coefficient of that resistance—whether frictional or something else—may be on a worn wheel? I can't.

How much of this thrust is due to side bearings sticking; how much to engine stiffness, and how much to speed?

Now, with such an array of ignorance before us, what possible basis does a mathematical calculation have to stand upon? It looks like attempting to solve a problem in calculus before the value of the common numerals had been learned. It reminds one of the answer given by a certain superintendent of motive power to a question as to the method he used in calculating the strength of his main rods. He said: "I calculate a little and guess a good deal." From the lessons of past experiments, it looks as if an engine or car rarely behaved twice alike in going around the same curve at the same speed, so that the only thing to do is to take a cut across lots, drop the calculations and measure up the results. We ought to do this often enough to be sure that we have the most destructive effects, and then we ought to act accordingly.

History occasionally repeats itself, and the old invention has a habit of bobbing up serenely as a novelty. I suppose that ever since the first mail bag was dropped from a passing express some one has been scheming to do the same thing with passengers, and inventing ways for picking them up is just as attractive. Cars have sometimes been cut loose from a moving train and allowed to come to a standstill, as in England, and it is not so many years ago that one genius proposed a sort of window-shade affair, in which a coil of rope was to be wound on a drum on a standing car and was to have a projecting loop caught by a hook at the rear of a passing train. The aforesaid drum was to be fitted with a spring, which should be gradually wound up as the rope was paid out, and the resistance to this winding was to start the car and bring it up to train speed. Then the rope was to be wound in, the car coupled to the rear, the passengers transferred to the "car ahead," others for the next stop were to be put in and the car cut off again. This was to be repeated all along the line. Could anything be simpler? But somehow or other the scheme never became popular, probably because of the rope. So now we have another rapid transit car—a "wonderfully simple and very practical invention"—which is, in effect, a car with a number of side doors, attached to the through train. Then there is to be another just like it on a side track. As the express approaches, the side track car starts and runs alongside, and when the doors are exactly opposite, "the cars are to be coupled, the platforms lowered, vestibules fixed and the transfer quickly made," the car cut off, and there you are. We are not informed of the length of side track needed for the transfer at 60 miles an hour, or how the various little details of the arrangement have or have not been worked out. But we are all anxious to put money in it, for we have seen it stated in a reputable paper that "when it becomes generally known that this great improvement in railroading is possible, there will be a universal demand made by the public for its introduction!" The principle is old enough. Away back, fifteen years ago, a newsboy made a practice of transferring from an express to a local on a four-track line, so the paper said, and kept it up until he was stopped. But that boy was a gymnast and had nerve. And now we await the trial trip of the gymnast car.

Colonel Yorke on the Great Western Audible Distant Signal.

The cab signal in use on a section of the Great Western Railway of England, in place of visual distant signals (which have been abandoned) and which was described in the *Railroad Gazette* of November 15, 1907, was the subject recently of a paper by Mr. W. Dawson, read before the Institution of Civil Engineers, and of a discussion following the reading. From this discussion we reprint the remarks of Lieutenant-Colonel H. A. Yorke, Chief Inspector of the British Board of Trade, as reported in the Bulletin of the International Railway Congress:

I think you will all agree with me that this is the most important development of signaling that has been attempted in this country for some years past; and I venture to suggest that the thanks of the community and of the railroad world at large are due to the Great Western Railway, for their enterprise in inaugurating and continuing experiments in this direction. The device under discussion represents the most serious, or at any rate the most continuous, attempt that has been made, as far as I know, to solve the problem of audible signaling on railroads in this country. It has been watched with the greatest interest by the officers of the Board of Trade, and I may say that, through the courtesy of the Great Western Railway, I have been personally kept informed of all the details of apparatus from its inception. I have seen it when it was tried merely in a siding outside the signaling works of the company. I have seen it tried tentatively on the main lines. I have seen it on the Henley branch, and finally on the Fairford branch, where it is now more or less permanently installed. So far as their experience of it goes, the Board of Trade officers have been able to express satisfaction with the results obtained up to the present time. The innovation may seem perhaps somewhat startling to some railroad engineers, the innovation being the substitution of an audible signal for a visible signal, but audible signals are already in existence on railroads in the shape of the detonator, which was introduced in the year 1840, and has done good service since that date. The difference between the appliance now under discussion and the ordinary detonator, seems chiefly to lie in the fact that the audible signal in this case is carried on the engine instead of being placed on the ground, and the driver therefore has the advantage of carrying the signal with him instead of having to hear a momentary explosion. As I understand it, this appliance has resulted from the efforts of railroad companies, and the Great Western Railway Company in particular, to discover some apparatus for fog signaling on railroads as a substitute for the fogmen. The Board of Trade have for many years past been pressing railroad companies to endeavor to seek for some apparatus of this nature. Not that we have any reason to doubt the reliability of our fogmen. I believe our fogmen do their duty in the most devoted manner, and when present on the ground, are quite reliable. I cannot at present call to mind any accident which has been due to the neglect of a fogman when on duty, to his absenting himself from his post; or to his failing to put the detonators on the line when necessary. On the contrary, I believe they constantly expose themselves to danger in carrying out the responsible duty which is put upon them. But the danger of fog arises from its coming on suddenly. At such a time fogmen are not always immediately available to take their posts at the signals to which they are allotted, and then follows a dangerous period. It is to meet that danger that the Board of Trade have always pressed railroad companies to endeavor to find some reliable fogging apparatus. The requirements of a fog-signal are of course well known. It should be absolutely reliable, or at least as reliable as the fogmen are at the present time; it should be always available. It should give a positive as well as a negative indication, it should be easily understood by a driver and it should be placed at such a distance from the stop signal, that the train can be brought to rest before it reaches that signal after the driver has received the communication from the fogging apparatus. It seems to me that the only way in which to ensure compliance with these requirements, is to keep the apparatus in constant use. Unless it is in constant use, it is liable to be neglected, and the maintenance of it might not be sufficiently attended to. Supposing that it were put out of use in the summer months in the anticipation that it was not required, and that fog came on unexpectedly in the autumn, the apparatus would not be available and difficulty and danger would arise. I have always regarded it as essential that any fogging apparatus, to be reliable, should be in constant and daily use. It is then under the observation of the drivers and the signalmen and all the officers of the company, and then it is known to be at all times available. But if it is always in use, and if it is placed alongside the distant signal (which is the most suitable place for it) it seems that the introduction of such an apparatus means the duplication of the signal, that is to say, there would be an audible signal as well as a visual signal, and such a duplication might be disconcerting to a driver. He would get in the habit of regarding one signal and ignoring the other; he might prefer to observe the audible in preference to the visible, or the visible in preference to the audible; but he would get in the habit of attending only to one. In that case, the second signal becomes superfluous, and might as well be taken away, and it would seem that the one to remove would be, not that which is distinguishable at all times, whether the atmosphere be clear or foggy, but that which is only of service under favorable atmospheric conditions. A signal which is sufficiently reliable for the conducting of traffic during time of fog must, it seems to me, be equally serviceable for use when the atmosphere is clear. If, therefore, we are going to pin our faith to an audible signal in time of fog, why should we hesitate to pin our faith to the same apparatus when the atmosphere is clear? The present apparatus, as I say, arose from the desire of the company to find a suitable fog-signal, but if placed alongside or in substitution of the distant signal, it has a further advantage, inasmuch as it enables a distinction to be made between a distant signal and a stop signal. There has always existed in England an anomaly in signaling, inasmuch as at night-time, the red light is used on distant signals as well as on stop signals. That has never seemed to me to be entirely satisfactory. If such an apparatus as this should be found to be reliable and be introduced into this country, it will enable that difficulty to be overcome, and the distant signal would at all times be easily distinguishable from the stop signal. Mr. Jacomb-Hood suggested that the time is approaching when possibly we might dispense with semaphore or visible signals altogether. I think that is looking rather far ahead. At present I should prefer to see this apparatus tried only in substitution of distant signals. It is doubtful whether it would ever be suitable for stop signals, as these must indicate the exact spot where the driver has to bring his train to rest, and an audible signal on an engine does not meet that requirement. But when all is said and done, the opinion of the drivers is one of the most important factors in all signaling questions, and I suggest that the company should endeavor to arrive at the feeling of the drivers in regard to an audible signal such as this carried on the engine, and to ascertain whether in the driver's opinion it is a better signal, than a fixed signal alongside of the line. There are debating societies among railroad men, and institutes where men can meet, and I think it would be a good thing if the drivers were encouraged to discuss the utility of this apparatus among themselves.

Express Locomotives—State Railroads of Sweden.

The standard express locomotive that has formerly been used on the State Railroads of Sweden has been known as the Class Cc and has rendered very satisfactory service until recently, when the weight of trains has been so increased that it has been very difficult to maintain the schedule without either double heading or using the company's 4-6-0 two-cylinder compounds. The objection to this substitution lay in the fact that these engines had a rated speed limit somewhat below that called for by tho express train schedules. Consequently an Atlantic locomotive was designed by the Bureau of Motive Power Design for the State Railroads at Stockholm in order to meet the increased requirements of the service, which sometimes called for the hauling of 12 sleepers. After considering the relative merits of the four-cylinder balanced compound and the simple engine, the latter was chosen and an order placed with the works of Nydquist & Holm, of Trollhattän, Sweden, for an engine of which the following aro some of the principal dimensions:

Cylinder diameter	19¾ in.
Piston stroke	24 "
Driving wheels, diameter	75 "
Steam pressure	170 lbs.
Tubes, ordinary diameter	2 in.
" superheater, diameter	5¼ "
" ordinary number	111
" superheater number	18
Tubes, length	23 ft. 8 in.
Heating surface, firebox	126.[illegible] sq. ft.
" tubes, superheater	341.04 "
" tubes	962.88 "
total	1,430.87 sq. ft.
Superheater surface	352.88 "
Grate area	27.97 "
Weight on driving wheels	67,980 lbs.
" front truck	40,920 "
" rear truck	23,540 "
total	132,440 lbs.
Tractive power on basis of 65% of steam pressure	1[illegible],650 "
Tractive power on basis of 85% of steam pressure	17,[illegible] "

$$\frac{\text{Weight on drivers}}{\text{Tractive power}} = [illegible]$$

$$\frac{\text{Total weight}}{\text{Tractive power}} = 7.42$$

$$\frac{\text{Tractive power x diameter drivers}}{\text{Heating surface}} = 934.[illegible]$$

$$\frac{\text{Heating surface}}{\text{Grate area}} = 51.16$$

$$\frac{\text{Firebox heating surface}}{\text{Total heating surface}} = 8.87^{*}$$

$$\frac{\text{Weight on drivers}}{\text{Total heating surface}} = 47.59$$

$$\frac{\text{Total weight}}{\text{Total heating surface}} = 92.56$$

Volume of two cylinders = 8.51 cu. ft.

$$\frac{\text{Total heating surface}}{\text{Volume of 2 cylinders}} = 168.13$$

$$\frac{\text{Grate area}}{\text{Volume of 2 cylinders}} = 3.29$$

Tube heating surface equated to firebox heating surface (Vaughan formula), sq. ft. 248.54

Total equated firebox heating surface, sq. ft. 375.49

$$\frac{\text{Total heating surface}}{\text{Equated heating surface}} = 3.81$$

*Per cent.

The two tractive powers are given because, according to the Swedish formula only 65 per cent of the boiler pressure is used in estimating it. In all the comparisons, however, that calculated on the 85 per cent. basis is used so as to make it comparable with American practice.

The boiler has an internal diameter of 59½ in. and the rather remarkable length between tubesheets of 23 ft. 8 in., an increase beyond even the most advanced practice of the United States. The foundation ring is of cast steel and rests upon the frame by four lugs. These lugs are of a peculiar shape and are grooved on the sides to take pads having corresponding projections. They are bolted to the frames so that a rigid attachment is secured for the boiler both laterally and vertically and yet it is free to move fore and aft under the influence of its expansion and contraction due to changes of temperature. The only notable feature about the boiler itself is to be found in the fact that the first course is welded instead of being riveted for the longitudinal seam, which was done in order to simplify the connection with the front tubesheet and thus make it easier to secure a tight joint.

The superheater is arranged in accordance with Schmidt's latest design, with its pipes placed in enlarged fire tubes in the upper part of the shell. The steam leaves the boiler in the ordinary manner by way of an enlarged T head which is divided into two chambers in such a way that one of them is in direct communication with the dry pipe and the other with the steam chest of the cylinders. Steam reaches the second chamber from the first by way of eighteen 1¼ superheater pipes placed in the enlarged firetubes. The course is the usual one back toward the firebox, through a return bend and thence to the smokebox, making two round trips through the four pipes, finally reaching the second chamber of the T head and the cylinders in a highly superheated condition. A damper is placed in the smokebox by which the firebox gases may be prevented from passing through the large tubes and coming in contact with the superheater tubes when there is no steam in them, thus avoiding possible overheating. This damper is also so connected with the blower that it is always shut when the latter is in use.

The smokebox is very large, being about 80 in. long, and the old spark extinguisher at the base of the stack is replaced by a mantle of perforated plate set between the exhaust pipe and the base of the smokestack, by which less resistance is offered to the passage of the gases than in the old method.

The grate has a slight slope down to the front, but otherwise is of the standard pattern.

The cab appliances are the same as in the later types of State Railroad locomotives, with a few additions that are only used in the United States for experimental purposes. These include a pyrometer, made by Steinle & Hartung, that is placed in the steam chest and shows, by means of a dial in the cab, the temperature of the superheated steam. There is also a steam gage to indicate the steam chest pressures; an apparatus for cleaning the tubes by steam and a mercury controlling gage.

The steam turret is of comparatively new design and is made in one piece with the throttle stem stuffing box on the back head of the boiler, and will be seen to have a dry pipe connection to the dome. The advantage of this arrangement lies in the small space occupied and the accessibility of the whole to the engineman.

The design of the engine differs in many respects from that of the ordinary European locomotive, and, with the exception of the cylinder location and the crank axle, shows a decided leaning towards American practice. The frames are of the bar type, flattened at the front to a thin slab to give more room for the cylinders and simplify their fastenings.

The cylinders are between the frames and are cast with half saddles and valve chests, are made reversible and interchangeable and are bolted together and to the boiler in the American manner.

The main rods connect to the front driving axle, which, being cranked, is of nickel steel, while the others are of open hearth steel. All the rotating weights are fully balanced in each wheel, and, in addition, 30 per cent. of the reciprocating forces are equally distributed over the driving wheels. The crank pins for the side rods are set diametrically opposite the inside cranks for the main wheels in accordance with the usual practice.

The driving boxes are of a novel design in that they are provided with adjustable side bearings for taking up the side wear, and thus maintain a smooth working engine for a longer time than is possible with the ordinary boxes. The adjustment is effected by means of two vertical bolts with countersunk heads on the top of the box and double nutted beneath the oil cellar, which, in turn, supports the side brass that abuts solidly against the upper brass through an intermediate liner. The truck journal boxes are of the ordinary form but are placed outside the wheels in order to secure better accessibility to springs and bearings, and at the same time give more room between the frames for the cylinders. All boxes, wheel centers and engine and truck frames are of cast-steel.

The pistons are of cast-steel and are supported by an extended piston rod with bearings and stuffing boxes in the front cylinder head. This is in accordance with current practice in Europe, where it has been found that large pistons with three rings, working under highly superheated steam, wear the cylinder unduly unless they are given this support.

The piston valves were designed by Mr. Carlquista, the designing engineer of the State Railroads, and are operated by the Heusinger von Waldegg, or Walschaerts gear, the usual screw working on the reach rod by means of a hand wheel of European practice being used.

The springs and spring suspension closely resembles that in use on American Atlantic locomotives, though, at the rear driver, the springs are underhung by means of an extension of the jaws of the boxes. This effects the three-point suspension system, where the truck carries the front end on a swiveling or swinging center bearing and the driving and trailing wheels are equalized together on each side of the engine. Further than this; especial attention was paid to so proportioning the springs that a soft and easy motion will be secured.

Single bar guides are used because of the lack of room for a lower one.

The cab is of wood, instead of plate for the purpose of avoiding the slamming noise that is apt to occur at high speeds with a metal construction. It is provided with a wind-splitting front so as to reduce the atmospheric resistances.

As the machine is built for high speeds, equalized brakes are applied to all the wheels, including those of the truck. Those on the drivers and trailers are worked by a vacuum cylinder at the rear of the engine while those on the truck are operated by a separate cylinder connected to the same suction pipe and vacuum receiver but capable of being cut in or out at will. The brake valve is so arranged that only the train brake is applied by a partial movement of the handle, as a normal condition of operation. But, for the requirements of a quick stop, a further movement of the handle brings the locomotive brakes into action also. The brakeshoes are attached to the head by a key which facilitates replacements when they are required. The vacuum ejectors discharge the steam to the atmosphere through a muffler on top of the cab so as to avoid the usual long discharge pipe leading to the stack.

The engine is provided with a speed recorder of Haussbalter's latest design, indicating the speed at three-second intervals. Lubrication of the valves and pistons is obtained by means of a Michalk's oil compressor, driven by an eccentric pin on one of the trailing wheels, thus forcing the oil to place, a provision that has been found to be necessary when using superheated steam.

At present the tender is of the standard type used on the old passenger locomotives, because the existing turntables are not large enough to accommodate a longer wheel base than these call for; but, as soon as the contemplated changes in turntables have been made, a larger tender will be used. Several runs were made with the new engine in order to obtain a comparison of its performance with the old Class Cc, or eight wheelers. Two weights of trains were taken, one having a weight equal to the maximum load of the smaller Class Cc engines, and the other one suited to the new locomotive. These heavier trains were hauled with the Cc engines double heading and the fuel consumption compared with that of the single superheater engine doing the same work.

The tests were run between Malmo and Nassjo, a distance of 167

New Express Locomotive for the Swedish State Railroads.

miles, giving the following results for three trips with the light trains:

Engine.	Train weight, net tons, Excluding engine & tender	Train weight, net tons, Including engine & tender.	Consumption Coal, lbs.	Consumption Water, gals.	Saving effected by superheater Coal, lbs.	Saving effected by superheater Water, gals.
Superheater	231.0	334.3	7,590	5,839	5,390	2,110
Cc	225.5	310.8	12,980	7,949		
Superheater	258.5	360.8	5,610	4,165	3,300	978
Cc	253.0	353.3	8,910	5,143		
Superheater	242.0	344.6	6,930	5,522	5,940	2,325
Cc	242.0	322.3	12,870	7,847		

According to this comparison based on ton-miles, the new engine consumed 46.5 per cent. less fuel and 21.5 per cent. less water than the Class Cc.

In a trial with the heavier trains weighing 400 net tons without engines and tenders, which were run as specials, over the same track, making one round trip with the superheater engine and one with the Class Cc double-headed, the schedule was laid out for an average speed of 34 miles an hour, but, owing to delays, considerable lost time was made up by both trains so that the actual average speed with the superheater engine was 42 miles an hour, and that with the Class Cc, 39 miles an hour. The maximum observed speed with the former was 65 miles and with the latter 62 miles an hour.

The coal consumption per 1,000 ton-miles, weight of engine and tender included, was 113.29 lbs. for the locomotive with the superheater, and 211.78 lbs. for the smaller engines, showing a saving of 46.6 per cent. in coal and 49.5 per cent. in water.

It will be noticed, of course, that the light engines were at a disadvantage with their comparatively small boilers, short tubes and restricted grate area, so that they had to be forced to maintain speed and burned 116.5 lbs. per sq. ft. of grate per hour as compared with 84.7 lbs. in the superheater engine. Further than this, it should be borne in mind that only about 80 per cent. of the tractive power of each engine is utilized at the drawbar of the second engine. So that comparisons from an engineering point of view are weak, though when considered from that of the traffic department it can readily be shown that a considerable saving can be effected with the new type of engine.

The highest power developed by the superheater engine was 1,095 h.p., and was done at 48 miles an hour with a 40 per cent. cut-off.

The temperature of the superheated steam averaged about 454 deg. Fahr., though on two occasions it rose to 490 deg. Fahr., or a maximum superheat of about 180 deg. Fahr.

The illustration shows the curves of the drawbar pull of the two classes of engines at various speeds and also the train resistances, exclusive of engine and tender, for three trains consisting of 12, 10 and seven bogie sleeping cars respectively. They show that the locomotive with superheater can haul a train of 333 net tons, that is to say, locomotive, tender and seven cars, at a speed of 31 miles per hour on a continuous 1 per cent. grade or 64 miles per hour on a level, while the speed of the lighter engine will be limited to 17 and 56 miles an hour respectively.

In the case of a 10-car train the superheater engine can haul it up the 1 per cent. grade at 22 miles an hour and over a level at 58 miles an hour, while the light engine cannot take it up the grade at all. Finally the superheater locomotive can haul a 12-car train up a 1 per cent. grade at 17 miles an hour and over a level at 52 miles per hour.

These curves are based upon the assumption that the superheater engine can evaporate 9.5 lbs. of water per sq. ft. of heating surface per hour and that the Class Cc engines will evaporate 10.8 lbs., although it has been found that this latter figure can be exceeded by forcing the fire.

An endurance test was run with the superheater engine from Malmö to Katrineholm and return, a distance of 300 miles in each direction, changing crews midway on each trip, when it was found that the engine could make the run in ordinary express service with no appreciable loss of steaming qualities at the end. This is naturally regarded as of great importance from an economic standpoint as it will make it possible to greatly reduce the number of engines required for the service. The results of these tests were so satisfactory in every respect, including ease of motion, accessibility of working parts and as well as economy of operation that 10 more were ordered of the same design.

Consumption of Pulpwood in 1906.*

The chief features of the year 1906 in connection with the manufacture of wood pulp were

(1) A consumption of wood greater by 469,053 cords than that of any previous year.

(2) The highest average value per cord for all kinds of wood.

(3) An increase of 93,000 cords in the imports of pulpwood. Of the two woods imported—spruce and poplar—spruce alone showed an increase—poplar decreased by over 5,000 cords.

(4) Since 1899 the amount of wood consumed each year for pulp has increased, in round numbers, from two million cords to $3\frac{1}{2}$ million cords.

In 1906 the consumption of wood for pulp exceeded the high-water mark of 3,192,123 cords reached in 1905 by nearly one-half million cords, making the total consumption by 250 mills, 3,661,176 cords. The year showed a heavy increase in the consumption of hemlock wood. Except balsam, the consumption of which fell off by nearly 23,000 cords, or 40 per cent., all other kinds of timber show a normal increase in quantities consumed. The increase for poplar was less than for any of the others, and its consumption remained nearly stationary.

The following table shows the quantity of wood of different kinds used for the manufacture of pulp in 1899, 1905 and 1906

Kinds and Amounts of Wood Manufactured into Pulp.

Kind.	Quantity, cords. 1899.	1905.	1906.	Per cent. of inc. (+), or dec. (—) 1899 to 1905.	1905 to 1906.
Spruce	1,509,202	2,273,254	2,507,002	+ 50.6	+ 10.3
Poplar	256,953	322,058	328,470	+ 25.3	+ 2.0
Hemlock	*	375,422	528,381	......	+ 40.7
Pine	*	57,399	69,277	......	+ 20.7
Balsam	*	56,741	33,886	......	— 40.3
Cottonwood	*	10,507	......	......	
All other	220,155	96,739	194,160	—56.1	+ 100.7
Total	1,986,310	3,192,123	3,661,176	+ 60.7	+ 14.7

*Included in "All other."

In both the consumption of wood and manufacture of pulp New York has ranked first from the earliest time of which there is record. In 1906 New York alone consumed 1,295,904 cords, or more than twice as much as Maine, which ranks next, with 617,743 cords. Wisconsin ranks third, with 512,354 cords. New Hampshire follows, with 319,729, Pennsylvania with 282,973, and Michigan with 115,272 cords. No other state consumed as much as 100,000 cords. It is interesting that the consumption of New York shows a small decrease from the 1905 figures, while Maine, Wisconsin, Pennsylvania and New Hampshire have all increased their consumption. It should be borne in mind in connection with these figures that in practically no case is all the wood produced in the same state in which it is consumed. In New York, for example, the report of the state forest, fish and game commission shows a cut of 516,778 cords of pulpwood in 1906, or approximately 40 per cent. of the amount of wood used by the pulp mills of the state.

The following table summarizes by states the quantity and value of wood used for pulp and the amount of pulp produced during the years 1905 and 1906.

Wood Used for Pulp in 1905 and 1906.

State	1906 Amount cords.	1906 Value	Average price per cord at mill.	Estimated quantity pulp produced, tons	1905 Amount, cords.	1905 Value	Average price per cord (at shipping point.)	Estimated quantity pulp produced tons.
Maine	617,743	$4,575,100	$7.41	383,535	501,807	$2,950,625	$5.88	323,012
Massachusetts	33,302	262,030	7.87	18,086	34,362	171,810	5.00	16,095

Vermont	34,968	290,384	8.30	38,403	22,271	122,490	5.50	20,207
Virginia	81,761	621,002	7.60	43,902	89,540	492,470	5.50	44,649
West Virginia	61,736	383,687	6.21	33,577	96,357	497,202	5.16	40,857
Wisconsin	512,354	3,708,540	6.84	338,997	382,471	1,686,697	4.41	240,657
Others	136,686	855,020	6.26	75,289	87,337	389,438	4.87	42,455
Total	3,661,176	$26,411,887	$7.21	2,327,841	3,192,223	$17,735,665	$5.56	2,084,482

New York led in both 1905 and 1906. In 1906 Maine ranked second, Wisconsin third, New Hampshire fourth and Pennsylvania fifth. In 1905, however, Pennsylvania ranked fourth and New Hampshire fifth, a reverse of the order of 1906. All of the wood imported into the United States for the manufacture of pulp comes from Canada and is free from duty. The amount has increased from 369,217 cords in 1899 and 622,515 cords in 1905 to 738,872 cords in 1906.

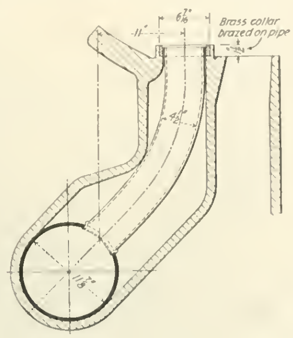
*Abstract of a report of the Forest Service, issued Nov. 26, 1907.

A Method of Repairing Cracked Piston Valve Cylinders.

BY B. P. FLORY,
Mechanical Engineer, Central of New Jersey.

Most roads that use locomotives with piston valves built several years ago have been troubled more or less with cracked cylinder castings. These cracks usually form in the walls of the piston valve chamber and it is very hard to patch them so that they do not leak.

The Central of New Jersey has a large number of piston valve engines and quite a few of these have cracked cylinders. On some classes of engines these cracks run vertically around the valve chamber, and on others they extend longitudinally. Just what causes these cracks has not been determined. One explanation is that the relief valve let cold air into the valve chamber while the engine was drifting. Another reason that may be advanced is that the cylinders may not have their metal distributed properly to take care of shrinkage strains.

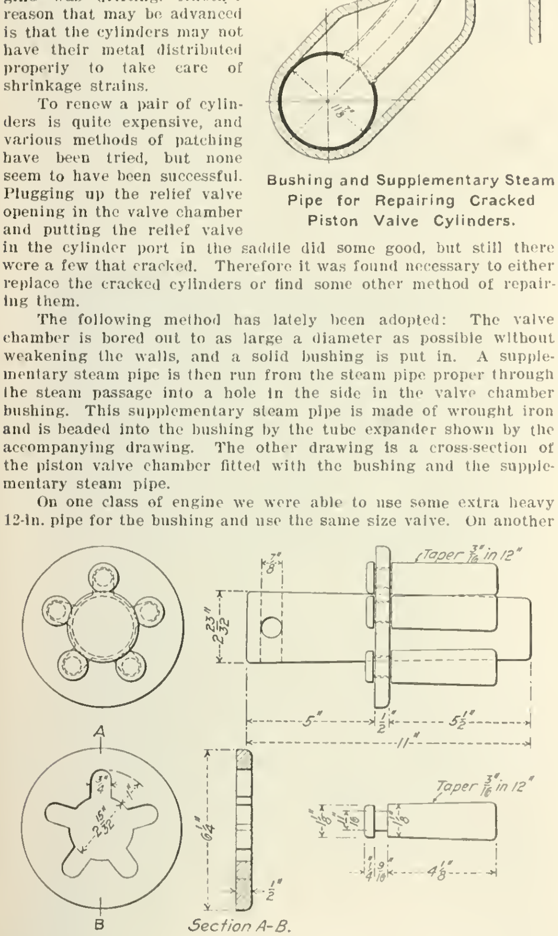


Bushing and Supplementary Steam Pipe for Repairing Cracked Piston Valve Cylinders.

To renew a pair of cylinders is quite expensive, and various methods of patching have been tried, but none seem to have been successful. Plugging up the relief valve opening in the valve chamber and putting the relief valve in the cylinder port in the saddle did some good, but still there were a few that cracked. Therefore it was found necessary to either replace the cracked cylinders or find some other method of repairing them.

The following method has lately been adopted: The valve chamber is bored out to as large a diameter as possible without weakening the walls, and a solid bushing is put in. A supplementary steam pipe is then run from the steam pipe proper through the steam passage into a hole in the side in the valve chamber bushing. This supplementary steam pipe is made of wrought iron and is beaded into the bushing by the tube expander shown by the accompanying drawing. The other drawing is a cross-section of the piston valve chamber fitted with the bushing and the supplementary steam pipe.

On one class of engine we were able to use some extra heavy 12-in. pipe for the bushing and use the same size valve. On another



Tube Expander for Beading Supplementary Steam Pipe Into Bushing.

type, however, a heavy freight engine, it was necessary to put in a new valve 10¼ in. in diameter, while the original valve was 12 in. diameter. It was also necessary to provide another place for the relief valve, so a pipe was tapped into the T head and the relief valve attached to the pipe outside of the smoke box. Because of the reduction of the area in the steam port, due to the use of the pipe, it was thought that, perhaps, the amount of steam passing through would not be sufficient, and so an indicator test was made to determine this.

The test was made on the engine that had the valve reduced to 10¼ in., in comparison with another engine of the same class fitted with the original valve and cylinders without the supplementary steam pipe. The train was made up of all-steel coal cars to insure uniformity of loading. No difference could be noticed in boiler pressure and admission pressure on the two engines with the throttle open. The cards showed that the engine with the smaller valve had a slightly higher back pressure and a slightly more rapid drop along the steam admission line. The coal and water tests showed that with the same weight of train there was almost no difference in their consumption. The heavy freight trains on the Central of New Jersey are not loaded to the maximum hauling capacity of the engine. The train load is that which experience has proven best for getting the greatest tonnage over a division in a given time. On a road where the train load is based on the maximum hauling capacity of the engine, the reduction in area of the steam pipe may necessitate a slight reduction in this train load.

The cost for fitting up a pair of cylinders as above described is about $90; the cost of a new pair of cylinders and the labor of installing them is $700. This method was devised by William McIntosh, Superintendent of Motive Power, assisted by G. L. Van Doren, Superintendent of Shops, and the writer.

Signaling of the East River Tunnels, New York.

Though the signaling arrangements for the recently completed tunnel under the East river between Bowling Green, Manhattan, and Borough Hall, Brooklyn, are on the same general principles as those followed in the New York subway, there are a number of interesting variations from the previous practice. In this as in the previous installation, the distinguishing feature is the use of an alternating track circuit for the operation of the relays by means of which the electro-pneumatic apparatus is controlled, while the rails act as returns for the current. It was shown by experiment before the installation in the New York subway was made that an alternating track circuit could be successfully used with a high-voltage direct-current return-power circuit provided that the return-power circuit was carried through only one rail and that the other rail was insulated at the ends of blocks. This principle controlled on the previous and on the present installation.

This extension of the subway system of Greater New York consists of a double tube under the East river connecting with the Manhattan lines at Bowling Green, beyond which the Manhattan lines terminate in a loop. It runs to Borough Hall in Brooklyn at the present time, though construction work has already been completed as far as Hoyt street, Brooklyn, and the continuance of the line to Atlantic avenue is in progress. The present account, however, deals only with the line between Bowling Green and Borough Hall, a distance of about 8,000 ft. This section is of especial interest, since for the greater part of the distance the tunnel lies under the waters of the East river and has grades much heavier than found in ordinary subways.

The new tunnel line, like the Manhattan subways, is operated by the Interborough Rapid Transit Company, though it is owned by the city.

Eighteen signals are included in this section, of which 14 are in the "tubes"—by which is meant the under-river portion in distinction from that part which is under land only on either side. The tubes are wholly separate and the signaling of each is to a great extent a separate proposition, except so far as current supply is concerned. Alternating current at 550 volts is carried in mains each consisting of two No. 2 wires in each tube, from the sub-station in Brooklyn. These are carried overhead in the tunnels in iron pipe to avoid disturbance by dampness. This voltage is transformed twice, reducing the voltage to 10 or 12 volts, the transformers being fixed on columns in the subway outside of the tubes and on the outer walls in the tubes. At Borough Hall station the cables are carried across overhead to avoid dampness and deterioration from oil. An extra set of alternating current mains is carried through the tubes for use in emergency. Air for the operation of switches and the automatic stops is taken from compressors situated at City Hall, New York, and in the Brooklyn sub-station. It is conveyed from the sub-station to the pipes by two 3-in. mains. These have expansion joints about 1,000 ft. apart. The compressors are of Ingersoll-Rand manufacture. There is also a small compressor under the Borough Hall station for use in case of emergency.

The principal compressors maintain a pressure in the pipes of 75 lbs. to 80 lbs. They are driven by Westinghouse type S-10 direct-connected motors. The compressors are of the straight tandem-compound single-acting type, having a capacity for compressing 240 ft. of atmospheric air at 120 r.p.m. Between the high-pressure and low-pressure cylinders is an intercooler. The cylinders have diameters of 12¼ and 19¼ in. respectively and a stroke of 12 in. Each is provided with an automatic starting and stopping device governed by the pressure, which operates to start at 80 lbs. and to stop at 90 lbs.

From the nature of the location lights only are used for signal indications. The signals differ from those in the New York subway. They are similar in respect to color indications, green being used for clear, yellow for caution and red for stop. In the New York subway the bull's-eye lenses are of clear glass, and in the front of them are placed two four candle-power incandescent lamps so connected that light is maintained in one if the other is out of order. The color indication is given by means of colored glasses mounted in slides which are raised by rods working in air cylinders in the base of the signal box, and lowered by counterweights. In the tunnel installation this arrangement is done away with. No movement takes place within the signal box. There are separate lenses and a separate set of lamps for each color. As the relay is picked up the lights behind the green lens are turned on, and when it is dropped the red or the yellow is displayed according to whether the signal is home or distant.

In the tubes (where there are no columns) the various parts of the signal apparatus are arranged along the right-hand wall in separate boxes, as shown in one of the accompanying illustrations. They are conveniently reached by maintainers from the shelf forming the top of the enclosure containing the conduits and a hand rail is provided at each signal as a measure of safety. The apparatus consists, in addition to the signal box, of a transformer to which current is brought from the alternating current main overhead, a resistance box for preventing the short-circuiting of the alternating current relay, a relay box with impedance coil and a box containing the valves for the operation of the automatic stop. Current for the operation of these is furnished from storage batteries, situated at Bowling Green and Borough Hall stations, which are charged by direct current motor generators furnishing current at 16 volts and taking power from the third rail.

An interesting detail in connection with the signal boxes fixed on the columns outside the tubes is the provision of a solid block of concrete in the form of a step, in place of the usual ladder. This affords an easy foothold and is free from any possible objection in the way of short-circuiting. Along similar lines and as indicating the care which has been taken in working out the details of the installation may be mentioned the use of asbestos wood guards along the third rail opposite the signal apparatus and the enclosing of all track instruments with a covering of the same material. (See Fig. 5.) The utmost care has everywhere been taken to guard against the possibility of fire. At Borough Hall station most of the switches now in use are temporary, being required for terminal purposes for which there will be no occasion when the line is extended further, but on all permanent switches the valves are insulated from pipes and from the third rail.

The automatic stop apparatus is the same as that in use on the Manhattan section of the subway. It consists of a rod extending across under the rails opposite each signal and having an arm or trip on the end next to the third rail. In a cast-iron box between the rails are contained an air cylinder, an electro-pneumatic controlling valve and a counterweight on the end of an arm attached to the rod. When the signal stands to indicate stop the air in the cylinder is cut off by a circuit-breaker connected with the signal.

Fig. 1—Signals and Overlaps, Eastbound Track.

Fig. 2—Signals and Overlaps, Westbound Track.

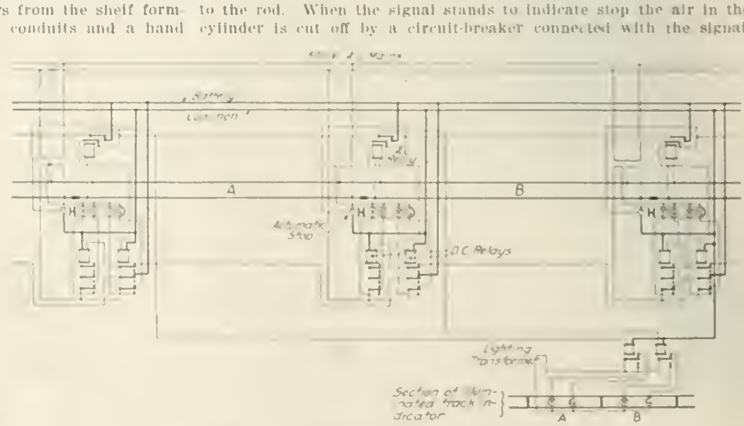


Fig. 3—Typical Block Signal Circuits.

The counter-weight drops and throws the trip arm to an upright position projecting it above the level of the rail. The trucks of all cars are provided with an arm which is connected with a valve in the air-brake train-pipe, and this arm, in case of a train running past a signal set at stop, engages with the trip. The valve in the train-pipe is opened and the brakes are set so as to stop the train before it enters the second block ahead. In order to provide against unnecessary delays to traffic, trainmen are furnished with a socket key by which the air valve may be turned in case of any derangement of the stop.

The location of the signals has been determined by a careful consideration of grades, time-interval and speed of trains. The

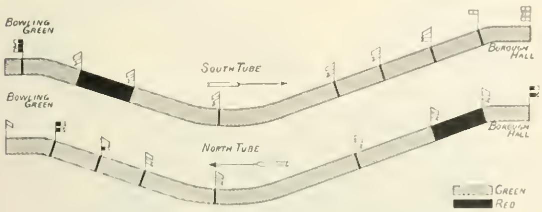

Fig. 4—Sketch of Illuminated Track Indicator.

grade each side from the lowest point is 3.1 per cent., the length of the incline on the Brooklyn side being nearly 50 per cent. greater than on the New York side. Full-block overlaps are provided giving two clear blocks in advance of each train, and they vary in length from 800 ft. to 2,400 ft., as shown upon the accompanying engravings. Circuits are so arranged as to make it possible to run trains in either direction on either track, thus providing for single-track operation in case of emergency or when track work is going on. They are so arranged as to make it impossible to admit trains from opposite directions at the same time. Assuming that the south tube is to be used alone, the operator at Borough Hall, having assured himself of a clear track, gives a signal to the operator at Bowling Green and one train may be admitted to the south tube from the Brooklyn end—a reversal of the traffic; and after it is once admitted the signals admitting to the tube are locked beyond control of the operator at Bowling Green. In case of an accident to the train from Borough Hall, and the fact is communicated to Bowling Green by telephone, the operator at the latter point can tie up the line at Borough Hall so that no other train can be admitted to the tube from the Brooklyn end.

Fig. 5—Fire-Proof Fixtures at Switches.

In the signal cabin at Bowling Green there is an illuminated track indicator, illustrated in the accompanying engravings. Primarily, the indicator consists of a case with a glass front on which are shown representations of the two tubes divided into blocks corresponding in proportionate length to the actual blocks. All of the glass except the representations of the longitudinal sections of the tubes is painted and made opaque. The tube sections normally appear green (clear of trains) and are illuminated by incandescent lamps within the case. A relay at each signal is connected up with the lamps in the indicator circuits in such a manner as to change the color of the space on the indicator representing a block from

Fig. 6—Track Indicator.

Fig. 7—Signal No. 312 and Accessories.

green to red upon the entrance of a train to that block. The position of every train in either or both tubes is thus clearly shown at all times to the operator at Bowling Green. As a further measure of safety a telephone connection is provided at every manhole in each tube by means of which trainmen may communicate with the operating tower. These connections are available about every 100 ft. throughout the length of the tubes.

The lower story of the Bowling Green cabin contains the junction boxes and the relays for operating the illuminated indicator, and in the maintainer's quarters nearby are kept the storage batteries and the motor generator set for operating electro-pneumatic valves, etc. The maintainer's quarters are fitted up with lockers, etc., in the neatest possible manner. The primary motor generators have compound wound motors and shunt wound generators, and are designed for a range of from 400 to 700 volts. The generator at the Borough Hall station is somewhat larger on account of the larger storage batteries. The latter are larger than required but were on hand and therefore were utilized.

The equipment of the sub-station at Brooklyn includes two oil-cooled transformers designed to operate either at 25 cycles for the third rail rotary transformers or at 60 cycles for the light circuit.

Electric detection is used on switches in place of detector bars.

All cables are of Okonite or of Standard make. As in the case of the Manhattan subway, the apparatus throughout was furnished by the Union Switch & Signal Company and is largely from designs of its engineers. The installation was in charge of J. M. Waldron, Signal Engineer of the Interborough Rapid Transit Company.

Boring Multiple Cylinders.

BY E. J. M'KERNAN,

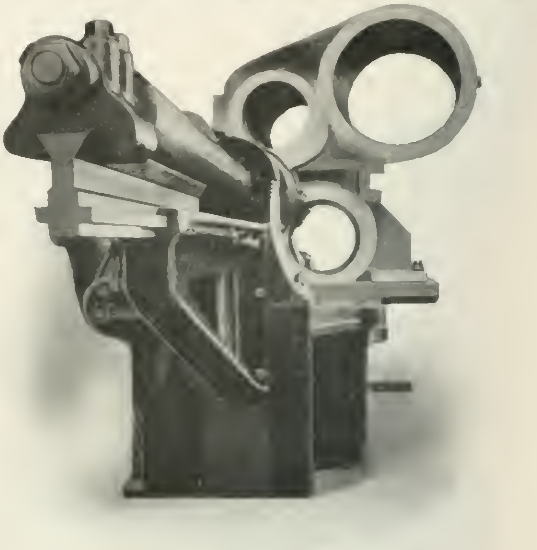
Tool Expert; Atchison, Topeka & Santa Fe.

The usual locomotive cylinder boring machine consists of a horizontal spindle and table permitting of no adjustment at all or of only lateral adjustment. With these machines of the old design much time is consumed in properly setting the cylinder so that the boring bar will strike the true center; and high speeds and rapid cutting are not obtained. These disadvantages are, of course, magnified when cylinder castings having two or more cylindrical chambers are to be bored and faced, because the work has to be set twice, and the cylinders and valve chambers (where piston valves are used) must be truly parallel with each other. If the cylinders should be out of parallel the working of the engine will throw great strain upon the guides, with consequent detrimental effect on the locomotive machinery, causing undue wear, strain and trouble.

The machine of the old single bar type, designed when simple slide valve cylinders of not more than 18 in. or 20 in. diameter were the prevailing type on locomotives, were adapted for use with the slow speed carbon steel which was the most efficient material for making cutting tools at that time. The mechanism of these old machines was simple, but the driving and feed gears were weak cast-iron affairs which drove the tool along at an unprofitably slow speed. Later as the art of cutting materials was on a more scientific basis, and tool steels of greater cutting capacity and speed were introduced in shop practice, attempts to work these new cutting tools to their proper limits in boring machines of this class would result in stripping the gears or other injury to the machine.

With the latter developments in high-speed cutting tools of great capacity, and in locomotive construction, with engines having piston valves and often compound cylinders on the Vauclain principle or on the four cylinder balanced compound principle, a machine capable of the most effective service under the latter conditions becomes a shop necessity. In order to meet this demand, one manufacturer produced a three-spindle machine which would require but one setting of the work and which would insure the parallel boring of all cylinders and chambers. While this type of machine possesses a number of advantages for certain classes of work, the single bar machine has been found superior for general railroad practice. A comparison of the two types of machines shows that the single bar has less gearing and is the simpler machine of the two and is consequently much easier maintained. On account of the lesser number of parts, the single bar machine is the more economical to drive, hence the power required can be obtained from a small motor. Where there are some advantages in boring three chambers at once it has been found in practice that chatter in one tool is transmitted to the other tools, causing a rough finish in all bores. It is apparent that this is entirely obviated in the single bar machine. From experience in the ordinary railroad shop it has been found that the single bar machine is best suited to locomotive work. It is economical in operation, in power consumed and in adjustments and owing to the fact that less machinery is involved the single bar machine is the most economical to buy.

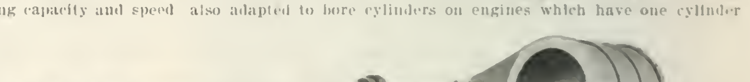
There have recently been built several heavy and solid single bar machines, with the boring bars capable of the heaviest strains, and of such a design as to insure working the cutting tools to the very highest capacity. The accurate setting of the work, especially in connection with multiple cylinders, is brought about by the application of a table having both lateral and vertical motion, and these



Boring Non-Parallel Cylinder Chambers.

machines produce very excellent work. But the examples thus far constructed are heavy, ponderous affairs, costing a great deal for the weight of metal in them alone, and they do not have the universally wide range for accommodating all classes of locomotive cylinder boring that should be a requisite in modern machines for this purpose. Their first cost is high, and the best results are not always obtained from them, not to speak of the relative large amount of shop room required.

At the Topeka shops of the Santa Fe there has been built a cylinder boring mill which will answer all requirements in boring cylinders for all classes of compound engines. This machine is also adapted to bore cylinders on engines which have one cylinder or chamber at an angle to the others. All cylinders or chambers may be bored at one clamping of the cylinder, by merely raising or lowering the table. This table has an elevating movement of 37 in. and a cross travel of 35 in. The table, which has the cross travel movement, has also a swiveling motion by which a range of 15 deg. incline may be had. (Fig. 1.)



Single Bar Cylinder Boring Machine.

This new boring mill is direct motor driven. The table is raised or lowered by power connection with the main motor through beveled gears and clutches, handled from the operator's side of the machine. All the mechanism is of the latest design and is strong and durable, all gears being made from good gray iron, all bushings of phosphor bronze; the boring bar is 7 in. in diameter and is made from open hearth steel, and is fed through the cylinder by means of a spur gear and rack which makes it very rigid in operation and gives a very smooth bore.

One of the facing heads on the machine is made so that it will move along on the bar and is driven by means of a 1-in. key and set screw, and will pull any kind of a cut that is put on the machine.

The facing heads are fed by means of a star feed attachment. The screws that elevate the table are made from soft steel and are 5½ in. in diameter and are three-quarters pitch, the screws set at right angles to the boring bar, making everything rigid. The total weight is about 15 tons, and the machine takes up floor space of 223 sq. ft., having an extreme length of 21 ft. and an overall range in width of 14 ft.

This machine is capable of boring a three chamber compound cylinder in 15 hours, or in a year of 3,000 working hours it can bore 200 three chamber compound cylinders. It can also bore a simple cylinder in three hours, or 1,000 in a year of 3,000 working hours.

On the old style boring mill it has taken from 26 to 28 hours to bore a three chamber compound cylinder. It will be noted that by the use of a modern boring mill of this kind 11 hours can be saved on each three chamber compound cylinder, where it used to take from eight to ten hours to bore a simple cylinder. One of these cylinders can now be bored in three hours on this machine, thus making a saving of five hours on each simple cylinder bored, or over $1,500 per year in operator's wages alone, in addition to increasing the machine capacity from only 375 cylinders per year to 1,000 simple cylinders, giving an output of 625 more cylinders per year. Where only 115 three chamber compound cylinders could be handled with the old style boring mill the new machine will bore 200 cylinders, thus increasing the output of compound cylinders about 77 per cent.

If a machine which bores only one chamber of a locomotive cylinder casting at one time is to compete successfully with one which can bore three chambers simultaneously it must not only bore rapidly, but it must be so made that only one setting will be required to bring the chambers into position to bore. This arrangement has been attained in the machine described, and after a cylinder has been lined up and clamped on the table any of the chambers may be brought exactly into position for boring, making it impossible to bore two chambers out of parallel unless desired.

A machine of this design has been in operation for some time at the Topeka shops, and is giving first class satisfaction, both in its convenience in handling, and in the lower production cost. It is understood that arrangements have been made for the Tool & Railway Specialty Manufacturing Company of Atchison, Kansas, to handle machines of this type on the market.

Eight Years of Development of the Illinois Central and the Chicago & Alton, as Compared by Stuyvesant Fish.

Stuyvesant Fish, ex-President of the Illinois Central, has given out a statistical comparison between the eight years' development ended June 30, 1906, of the Illinois Central under his management and the development during the same period of the Chicago & Alton under the more or less direct management of E. H. Harriman. Comparisons between different railroads, especially between two railroads so different as the Illinois Central and the Chicago & Alton, can seldom be made with exact accuracy. Without attempting to examine into the qualifying circumstances of each case, we present below some of the most striking comparisons, showing in percentages alone the increase or decrease of the figures for the year ended June 30, 1906, over those for the year ended June 30, 1898:

Increases in Per Cent. 1906 *over* 1898.

	Illinois Central.		Chic. & Alton.	
Gross earnings	89.03	per cent.	84.30	per cent.
Net earnings, taxes deducted	75.46	"	41.22	"
Fixed charges	16.64	"	154.02	"
Available for dividends	147.51	"	*37.08	"
Disbursed for permanent improvements, etc.	141.23	"	*96.83	"

The Ocean Carrier.

BY J. RUSSELL SMITH, PH.D.

VIII.

THE RAILROAD STEAMSHIP LINE.

On the Pacific Coast of the United States and in Europe.

The Pacific coast of the United States and Canada is the terminus of great transcontinental railroads, and also of long trans-Pacific ocean lines. Furthermore, the population of Pacific sea ports is comparatively small, the local traffic is light, and the consequent mutual dependence between the railroads and the steamships is strong. There results here a more complete and extensive alliance between railroads and steamship lines than in any other section of the globe. Every transcontinental line has its secure arrangements, and several of them own steamship lines plying to all important countries of East Asia.

The alliance began soon after the first transcontinental road reached San Francisco in 1869. At that time the Pacific Mail Steamship Company had a line to China and Japan, to Australia, to Vancouver, local lines on the United States Pacific coast, and reached New York via Panama, where it connected through its contract arrangements with the Panama Railroad & Steamship Company. This was a well organized and strong system. The company had long exercised the independence that arises from monopoly, and the Pacific Railroad Company soon became dissatisfied with the freight supply in which the steamship company did entirely as best suited its own arrangements and its eastern service. In 1874 the railroad objections took the form of a California Company formed by the Union & Central Pacific Railroad Companies. This company, called the Occidental & Oriental Steamship Company, chartered four White Star steamers, and established an Oriental service. In the rate war that followed, rates went down to almost nothing, but the railroad made the quicker connections with New York. This competition, making loss to both parties, resulted in a working agreement between the rivals, which came near to being a real consolidation of shipping interests. The ships of the two companies alternated in dates of sailing, they had the same rates, rules and conditions of service; they had joint agents to solicit freight, and the agents were not permitted to make any discrimination whatever between the two companies on pain of discharge. There were two companies to watch the workings of this plan and protect their own interests.

This friendly competition went on for nearly 20 years, when the Southern Pacific bought a controlling interest in the Pacific Mail Steamship Company, but it did not in any way alter its service or apparent relations to the partner steamship company. In 1897 a group of Japanese capitalists backed by $6,000,000 and government influence and subsidy concluded to go into the shipping business. They formed the company known as the Toyo Kisen Kaisha and toured the Pacific coast of the United States for a suitable terminus. The Southern Pacific interests, foreseeing a destructive rate war, admitted them to a place at once in the San Francisco service, and this third company joined the others on the terms identical with those established at the close of the rate war in the '70s, when the two companies first agreed on the conduct of this service.

Encouraged by this result, some Chinese merchants in Hong Kong formed the China Commercial Company shortly after this, chartered four steamers and started to carry passengers to Manzanillo, Mexico, and to compete at San Francisco with the combined lines. These new comers were not received on terms of equality, but were beaten off the Pacific after six months of furious rate cutting.

The Atchison, Topeka & Santa Fe Railroad for several years after 1898 maintained a line to the Orient from San Diego, but the local trade was not satisfactory, and the relations of this railroad company with the Southern Pacific were so intimate that the San Diego service was discontinued in 1901, and in its place the company used the San Francisco lines maintained by the Southern Pacific interests. Portland, Ore., has the Portland & Asiatic Steamship Company rendering a service, almost exclusively freight, in connection with the Oregon Short Line and the Harriman roads. The steamers are chartered from the Hamburg-American Company.

Puget Sound and the Hill roads are served by a variety of Pacific carriers. The Great Northern has the Great Northern Steamship Company, which ran the splendid new steamers, the "Minnesota" and "Dakota" until the "Dakota" was wrecked in 1907. They operated alternately after the San Francisco manner with the vessels of the Japanese Nippon Yusen Kaisha and extended their services to Manila. The Northern Pacific once had a Northern Pacific Steamship Company operating with chartered steamers, but it now has a traffic agreement with the Boston Steamship Company, which operates a line of steamers to the Orient. The Boston Company seems to have a preferred claim. Such resione of traffic as it cannot handle is provided for by outside contract.

The Hill interests are also engaged in the coasting trade of the Pacific. In 1901 the Pacific Coast Steamship Company, a company subsidiary to the Great Northern, took over the ships and good will of the Alaska Steamship Company, and it also operates a line from Seattle, Tacoma and Victoria to San Francisco, and to Guaymas and Mazatlan in Mexico, also minor lines on the California coast. The wide reach north, south and west of these distributaries and feeders gives the Hill roads a strong hold on Pacific commerce.

The population of regions adjacent to the Pacific is scanty and the new railroads at present under construction towards that coast will find the local traffic of ports aside from that produced by themselves to be so small that it has now apparently become the custom to prepare for the steamship line at the same time the railroad is decided upon. Some years hence the Grand Trunk Pacific Railway will reach the Pacific coast. Its first plan was to go to the now unused harbor of Port Simpson near the south point of Alaska. In 1904 the company announced that a contract had been made with the Allan Line (Steamship Company) for a trans-Pacific service from this port similar to their trans-Atlantic service now in operation in connection with that railroad. This will require a new fleet of steamers. New railroads to the Pacific ports of Mexico are also making contracts for steamer service for lines yet unbuilt.

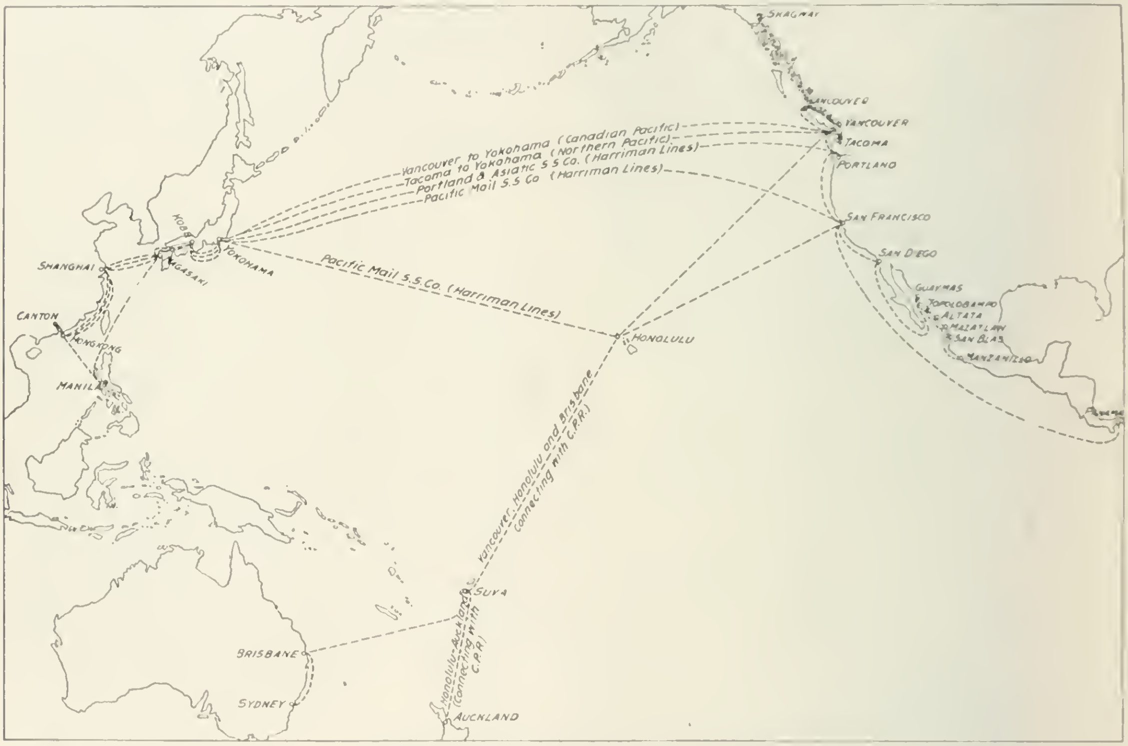
The Hamburg-American Steamship Company has entered into a contract with the Kansas City, Mexico & Orient road to run a line of steamers from Topolobampo across the Pacific as soon as the Orient road is completed. In 1906 the Orient Company already had a steamer in service from Topolobampo running north to Guaymas and south to San Blas. It has also a sailing vessel service from Topolobampo, which was being extended to San Diego in southern California.

The Canadian Pacific may be presented as the railroad with the most widely organized water transportation auxiliaries to be found upon the surface of the globe. In 1891 the establishment of its Hong Kong line set a new mark in transportation annals for then one company had a road clear across the American continent and steamers extending it to the limits of the China coast. In 1898 two steamers were also operated to Vladivostok.* In the company's report for the year ending June 30, 1907, the following fleet is reported:

Canadian Pacific Steamships.

Atlantic service	16
Pacific Coast service	11
British Columbia Lake and River service	17
Pacific service	6
Upper Lake service (Great Lakes)	3
Ferry service	2
Total all classes	55

That is to say, a transcontinental railroad operated two transoceanic services, connecting East Canada with Europe, and West Canada with Japan, China and Hong Kong. Lakes and rivers are used as feeders, and there were at one time rumors of proposed connections with the Trans-Siberian Railroad, and with the Yukon river through purchase of the White Pass & Yukon Railroad and a line of Alaska steamers. The steamship lines of this railroad company are not operated on working agreements, but are run by companies frankly owned by the railroad company. It also charters steamers which it operates on a line to New Zealand on alternate sailings with the Union Steamship Company of New Zealand.



Principal Railroad Steamship Lines on the Pacific.

THE THEORY OF THE RAILROAD STEAMSHIP LINE.

In this widespread combination of the railroad and the steamship line, the railroad is the dominant factor, the steamship is but a railroad attachment. When one stops to consider the capital involved, it appears natural that it should be so. Great Britain is properly hailed as the mistress of the seas, the world's great ocean carrier, and yet her merchant marine has a value not exceeding one-seventh part of the capital value of the British railroads* and a much smaller part of the value of the American railroads. The amount of money involved affects the order of development of transportation more than it reflects the value of the commerce. This is because the railroad is primarily a costly road, the ship but a vehicle using the highways of Providence.

That sea investments of railroad companies are but props to the railroads is clearly brought out in the annual report of the Canadian Pacific Railway for 1904. After giving a list of shipping amounting to nearly 150,000 tons,† the report states

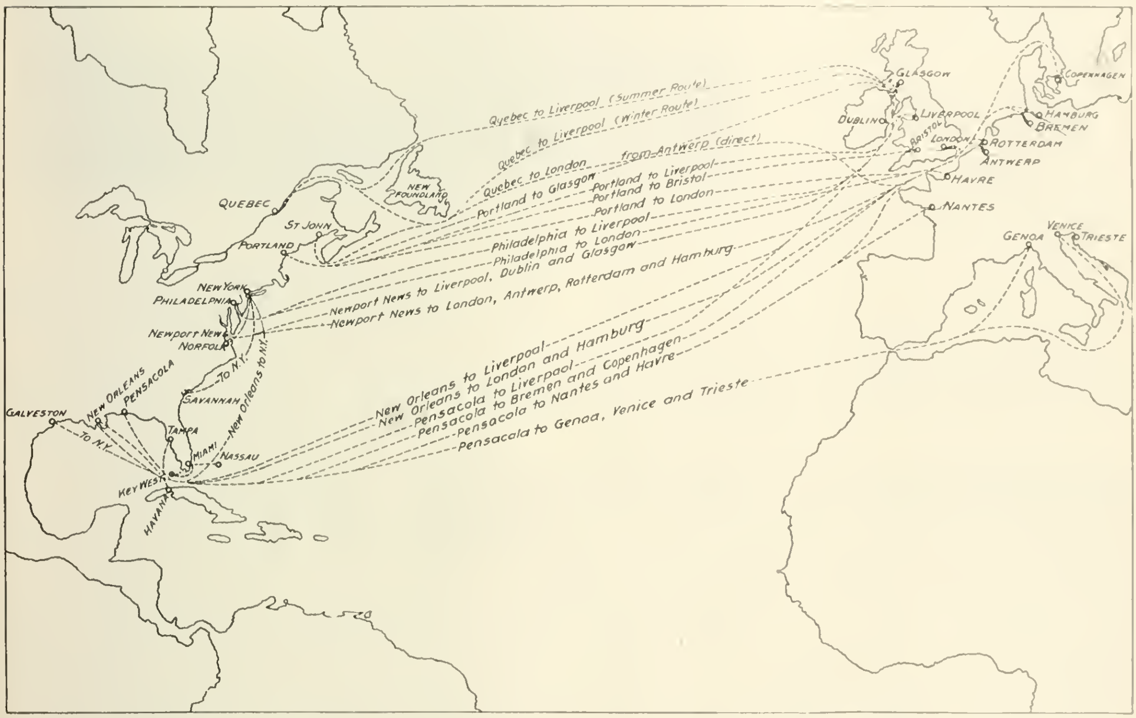
*Social Economist, 6: 283; Scribner's 10: 280; *Railroad Gazette*, Aug. 15, 1898, p. 615.

*The paid-up capital of British railroads at the end of 1906, was £1,283 million. The total British tonnage was 17,611,096. New freighters can be launched at from £10 per ton. Granting this rate of valuation (and it is too high) the value of the fleet is less than £180,000,000.

†An amount several times as great as that employed in the European commerce of the British Colonies two centuries ago, and it is also about six times as efficient per ton.

that the Atlantic steamer service shows no net revenue, due to demoralizing conditions, "nevertheless the steamship line has, as anticipated, proved a valuable auxiliary of the railroad." The report to the stockholders then proposed more new ships. The inevitable conclusion from the above seems to be that the railroad company can sometimes afford to lose money on a steamship line which serves as a freight collector or distributor for the railroad line.

British opinion also bears out this conclusion. The privilege for a railroad company to run steamers must be secured by special grant from Parliament, and such grants are bitterly opposed by shipping interests, because of the fear that the private vessel owner might be driven from the business, through the railroad steamers making rates that would be ruinous to a competing company that was an ocean carrier only. In the words of an editorial in *Fairplay*:* "It is well known that these steamers (belonging to the railroad companies) generally run at a loss, but the accounts of the steamers are merged in the general accounts of the companies and the steamers are supposed to make up as feeders for the lines what money is lost on their own making." Three years later an editorial in *Lloyd's Gazette*† stated that there seemed to be an attempt to make them more profitable. But this can scarcely be general.



Routes of Principal Steamship Lines Run Primarily in Railroad Service on the Atlantic.

A recent British government report (Dept. Paper 210 Foreign Merchant Shipping, London, 1905), discussing the fact that the Great Central Railway Co. runs steamers from Grimsby to Hamburg and carries emigrants pursuant to all the expensive regulations of the German law, says that this practice "is rendered profitable solely owing to the fact that this company is able to carry the emigrants through England on its own railroad lines to the port of embarkation for their trans-Atlantic destinations."

The building of terminal facilities is a necessary part of the connection between railroads and ships. It might apparently be undertaken by either of these carriers, it being the essential to one as to the other, but as a matter of fact the dock is usually built by the railroad because of the fixed location of the land carrier. The freedom of the seas gives the ship the opportunity to go to the best port that is already prepared, so it devolves upon the land end of the investment to provide the port and the harbor. Hence we find the state, the municipality and the railroad furnishing the necessary funds to provide the unloading facilities for the carriers by sea. The shipping company sticks to its element.

British harbors are usually enclosed stone docks—yet with so costly a type of construction several British railroad companies have built docks, thereby practically making harbors to which ships are glad to come. The railroads in question have in effect done for themselves the same thing that American roads have done when they contracted with foreign lines.

BRITISH RAILROAD STEAMSHIP LINES.

The distribution of British railroad steamship lines responds to the same laws as prevail in America. They are more common in the small ports than in the great ports. Harwich, Dover, Brighton, Southampton, Hull, Goole, etc., lack the traffic temptations to induce the establishment by ship owners of the complete and varied connections desired by railroads. They needed them and made them themselves. It was a very easy step for the British roads to operate steamers because the short sea journey to the continent bore about the same relation to railroad activity that our lake carriage does to our railroads. It has a local rather than an oceanic quality. The lively trade with the continent continues with a small type of vessel because of the frequent voyages required by the perishable nature of the traffic, and the large number of passengers carried. These continental connections almost resemble ferries in the frequency of the service. From Hull on the east coast to Southampton on the south coast and at many intervening ports steamers pass each day to and from the continent. This daily service includes Hamburg on the east and Havre on the west and where the sea is narrowest there are at times several railroad steamer connections daily, as at Dover and Brighton.

The small type of vessels required combines with British thoroughness to make ownership the prevailing practice rather than the traffic agreement, which is common in the trans-Atlantic steamship services of American railroads. The sea connection of British railroads with termini on the Humber estuary affords an interesting example of the British methods. The North Eastern Railway Company with a port at Hull, and the Lancashire & Yorkshire, having its port at Goole, have duplicate privileges from Parliament to own and run steamers to the following 17 ports: Copenhagen, Antwerp Ghent, Dunkirk, Hamburg, Rotterdam, Bruges, Amsterdam, Delfzyl, Flushing, Hulst, Harlingen, Stettin, Lubeck, Danzig, Stockholm and Warhus. This grant guarantees the railroads in such connections as they may care to establish, it is not necessarily for immediate use.

The North Eastern Railway actually runs no steamers in its own name. It controls majority stock in a company running a line to Amsterdam, Rotterdam and Harlingen, and has an agree-

*See September, 1901, p. 482.
†Weekly, Sept. 16, 1904.

ment with Thos. Wilson Sons & Company, Ltd., ship owners of Hull, to work in unison with them to the remaining ports.

The Lancashire & Yorkshire Railway runs steamers to the first nine of the 17 ports named in the Parliamentary grant.

The Great Central Railway, having terminus at Grimsby, also on the Humber, has a Parliamentary grant to own and run steamers to eight ports as follows: Antwerp, Hamburg, Rotterdam, Gothenburg, Malmo, Landscrona, Ellsingberg and Halmstadt. The company runs steamers to the first three and had an understanding with Thos. Wilson & Company not to run lines to the other five ports so long as Wilsons kept a regular service.

The traffic with Ireland partakes of all the economic characteristics of that with the continent, and is chiefly carried on by the railroad steamship lines. There were announced for 1906 twelve of these lines connecting Great Britain with Ireland. Nearly all of them (two only are for Liverpool) run from small and often unnoticed ports where the five railroads have been able to reach the sea. From Liverpool and Glasgow there are lines of independent steamers.

The maturity of British industries gives less prospect than in America for probable extension of this form of organization in transportation.

Thus far the British railroads have not ventured on trans-oceanic steamship connections, nor is it likely that they will find it necessary to do so. If it should be the case it will occur through the growth of some of the small ports, which are now lacking in connections, and probably in harbor facilities, but the large British ports are so well supplied with steamer connections, and cover the needs of a small country so adequately, that we may not expect much change in the near future.

Steamer Scotia, 21½ Knots; Holyhead-Dublin Service, London & North-Western.

EXPERIENCE IN OTHER FOREIGN COUNTRIES.

The managers of the newer railroads of Europe and Asia seem to be as generally convinced of the necessity of developing steamer connections as do those in America. The Anatolian Railroad Company loaned $600,000 to a steamship company to enable it to give better service in the Aegean sea. In 1901 the Chinese Eastern Railroad (Trans-Siberian) had 11 steamers at its disposal and was increasing them; in 1902 the railroad had six separate steamer lines running from Vladivostok, some of them running as far as the sea of Okhotsk, but Japanese competition made this service rather unsatisfactory—and it has since done worse things.

The Empress of Ireland; Atlantic Service, Canadian Pacific Railway.

The Roumanian State Railroads have been operating steamers from the Danube for a decade, and for a part of the time the line reached points as remote as Egypt and Antwerp.

The railroads of an undeveloped country like Russia are in a position akin to those of the United States. Gulf ports and steamship contracts are the rule. Since 1873 there has been a traffic association attending to this matter in the Baltic and usually making new arrangements each season upon the opening of navigation. This association ("Northern Oversea International Traffic") regulates arrangements and even goes so far as to deny to some lines permission to run steamers where they wish. In 1901 the contracts thus arranged by the Moscow Windau Rybinsky Railroad Company provided for service by four steamship companies from Windau to 10 ports distributed between Dundee, Dunkirk and Copenhagen. Arrangement was also made for service to the Rhine and for French and Spanish trans-shipments at Dunkirk.

In the management of state railroads in monarchial Europe we see the bureaucracy doing by rate control exactly the reverse of the common practice of American and English companies. The Anglo-Saxon Company runs a steamship line for the benefit of the railroad. The governments of Germany and Hungary, dominated by different and national motives and endowed with strong control arising from national power, use the railroads to favor and make profits for the pet national steamship line or lines, to which the railroad is made subservient. It is a part of the German export subsidy policy to give in some cases much lower railroad rates for export goods than for domestic traffic. This is a policy, however, which must be supported by taxation rather than industry. It is political rather than economic. In Hungary, the state has a railroad line to Fiume, and a subsidized line of steamers in the Adriatic. The Austrian government, using the port of Trieste, has the same. Four years ago competition arose and the Austrian steamers were cutting in on the trade of the Hungarian steamers at Fiume. The Hungarian government stopped this by arranging its railroad tariff, giving preferential rates on goods going out by the Hungarian steamers.

(To be continued.)

Foreign Railroad Notes.

A Berlin association of merchants which we may, perhaps, compare with the New York Chamber of Commerce, takes three standards for estimating the economic situation in Germany: Railroad earnings, number of workmen employed, and reports of the Imperial Bank. Now in 1907 (11 months) passenger earnings were 3 per cent. and freight earnings 6.4 per cent. larger than in 1906; against increases of 8 per cent. and 11.8 per cent. from 1905 to 1906. In the last half of 1907 fewer men were employed than one year before; and the average rate of discount of the Imperial Bank, which had been 4.99 per cent. in 1906, was 6.03 per cent. in 1907.

The Prussian State Railroad estimates for the fiscal year beginning with April next ask for 240,200 kilometric tons of rails, 105,800 of joint fastenings, spikes, etc., and 141,600 of ties and switches, the whole to cost about $18,000,000. The fuel requirements will be 8,815,900 tons of coal, 1,294,900 of coke, and 111,600 of lignite, to cost $31,700,000.

GENERAL NEWS SECTION

NOTES.

Figures have just been compiled by the Long Island Railroad showing that the company carried 23,950,547 passengers during 1907 on its trains. No passenger has been killed on the company's trains in 15 years.

The railroads of Mexico, particularly those connected with the government system, report heavy passenger and freight traffic. There is a considerable blockade at Vera Cruz of freight awaiting shipment to interior points.

The Iowa Railroad Commission has informed the express companies that they must comply with the long-and-short-haul provision of the Iowa railroad laws which have hitherto been applied only to freight and passenger rates.

An officer of the Erie is quoted as saying that the company will stand firm on its determination not to do away with piece work. The machinists of the road have bitterly opposed the piece work plan ever since its inception in the company's shops.

It is understood that the state of Sinaloa has voted a subsidy of $1,000 for every kilometer of road which the Kansas City, Mexico & Orient builds through that state on its way to Topolobampo. The company also has large bonuses from the state of Chihuahua.

Employees of railroads in the state of Mississippi are said to be preparing a large and impressive petition to the legislature opposing the proposal that a 2-cent law should be enacted. The employees see a connection between reduced fares and reduced wages.

The Ohio legislature has before it a bill to prevent the inspection of railroad men's watches by private individuals and to place the inspectors under the supervision and direction of the state. The bill requires watches to conform to certain standards but avoids reference to any specific makes.

The Midland Valley has this week been authorized by the State Corporation Commission of Oklahoma to charge 3 cents a mile for passengers. The state constitution makes a general rate throughout the state of 2 cents a mile, but allows the Corporation Commission some latitude. Other exceptions to the 2-cent rate were noted last week.

The County Attorney of Platte county, Neb., is about to bring criminal action against the Union Pacific under the new Nebraska anti-pass law. The company, through its attorney, has sent a letter to the railroad commission stating that it has given transportation to surgeons in accordance with continuing contracts made before the anti-pass law was enacted.

The Pennsylvania has collected data showing that 43 of its 85 principal officers are graduates of American colleges. The average age of these officers is 51 years and the average length of service with the Pennsylvania is 26 years. Sixty-seven of the 85 started their work for the company as beginners and, with a few exceptions, have been with the company ever since.

The Railroad Commission of Ohio decided on Feb. 17 that Ohio railroads are permitted, but not compelled, to issue excursion, commutation, mileage, and party-rate tickets; therefore, it is not in itself unreasonable and unjust discrimination for a railroad voluntarily to establish commutation rates between certain stations and to fail and refuse to establish like rates between all other stations on its lines.

Conferences have been held in New York during the past week on the proposal of the trunk lines to increase materially the terminal charge for split delivery of carload goods. A statement of the matter has been forwarded to the Interstate Commerce Commission by a special committee of the New York Produce Exchange, although it is not generally considered that the commission has jurisdiction in this case.

W. W. Finley, President of the Southern Railway, has openly challenged an examination of the circumstances which have led his company to contemplate a reduction of wages in the operating departments of his system. Mr. Finley, in effect, asks the Commissioner of Labor and the Chairman of the Interstate Commerce Commission to bring out all the facts, as a demonstration that his road is entitled to practise economy.

The Southern Pacific, through its counsel and special engineer, appeared before the United States Committee on Claims at Washington, February 24, advocating a favorable report upon the bill appropriating $1,600,000 to reimburse the company for its expenditures in reclaiming territory in southern California from the Colorado river floods of 1906. The committee has referred the bill to the Secretary of the Interior for a report from the government reclamation service.

The New York, New Haven & Hartford has given notice to the Interstate Commerce Commission that it will continue until May 1 the traffic arrangements with the Central Railroad of New Jersey, the Philadelphia & Reading, and the Baltimore & Ohio, for interchanging traffic via New York harbor. In December the New Haven gave notice that the arrangements with these roads would be canceled, but after a hearing by the Commission extended them to March 31. They are now to be extended further.

Governor Haskell, of Oklahoma, has ordered the Attorney-General of the state to institute proceedings to dissolve an alleged merger between the Chicago, Rock Island & Pacific and the St. Louis & San Francisco in Oklahoma. The Governor's order says that the interests of the two roads are pooled and are under the same management and that they are (meaning perhaps that they should be) in every sense competitive lines. The order demands a complete dissolution of the alleged combination and the perpetual maintenance of the two systems as distinct and separate roads.

In the controversy between the New York Central and John H. O'Brien, Commissioner of Water Supply, Gas and Electricity, with regard to the requests by the commissioner that the Public Service Commission require the railroad company to remove its overhead high tension transmission pole line and conductors along its right of way from a point north of Macomb's Dam bridge along the Harlem river, Harlem ship canal and the Hudson river to the city line, the railroad has filed a denial of the jurisdiction of Commissioner O'Brien and the Public Service Commission in the case at issue.

The Supreme Court, on February 24, gave the first decision in a series of cases attacking the validity of the Elkins anti-rebate law on the ground that this law was repealed by the Hepburn law. The case at issue was concerned with the appeal of the Great Northern from a $15,000 fine for granting a concession of 20 cents per 100 lbs. on 15 different shipments of oats from Minneapolis to Seattle in 1905, prior to the passage of the Hepburn law, so that the indictments, although returned after the passage of the law, were under the Elkins law. The court held that the anti-rebate provisions of the Elkins law were not repealed.

The annual report of the Insurance Department of the Pennsylvania Railroad shows that the company's employees extinguished 195 fires in 1907. These occurred in property valued at $7,500,000, yet the loss from them amounted to only $16,000. Fifty-one of the fires in Pennsylvania Railroad property during last year were caused by adjacent burning property. A loss of about $3,000 followed explosions of benzine, naphtha and lamps. Lighted cigars and cigarettes and matches cost the Pennsylvania over $49,000 in fires. Fires following wrecks caused a loss of about $43,000. Spontaneous combustion was responsible for a loss of $6,498.

The Rights of Capital.

The Canadian Board of Investigation, a body created to assist in adjusting difficulties between labor and capital, has given an opinion on the occasion of a demand by Grand Trunk telegraph operators for increased pay based on the increase which has been granted operators on the Canadian Pacific. The board held as follows:

"There are many considerations entering into this question. In our view there is the right of the man to receive a living wage and that right is paramount. The workman is entitled to get a fair day's wage for a fair day's work. What, however, often seems to be ignored is that capital and labor are both necessary in order to produce a profit.

"The object of the laborer should be to secure a fair share of this profit. But there is also to be considered the position of the man who advances the money to enable the undertaking to be carried on which gives employment. He, too, is required to receive a return for his money and his risk. A hundred millions of the capital stock of the Grand Trunk Road receives no dividends whatever. If such dividends on the preferred stock as are now being paid are still further reduced by the wage bill being increased, what must necessarily follow? The company cannot obtain further money for expansion, for it can be more remuneratively employed in other undertakings.

"This certainly would be a disadvantage to the vast number who find employment on the railroads. Then there are the constant demands of the public for the betterment of the service and equipment, for the increase of facilities and the bettering of the roadbed and general improvement in the accommodations. These can only be obtained where the parties asked to advance the money can see some possibility of return for the advance.

"Our experience has led us to the conclusion that there seems to be an oversight on the part of the public of two things. First, that there is a continual demand for an increase of expenditure on the part of the company for facilities, and second, a continual demand for the reduction of the tariffs which furnish the moneys necessary to provide these facilities and accommodations.

"The growth of earnings is not keeping pace proportionately with the growth of expenses. If operating expenses and wages must be increased from time to time and the public so demands, very serious consideration must be given to the proposals for the reductions of freight and passenger rates, inasmuch as every reduction directly affects the ability of the railroads to pay the wages asked by their employees.

"There is no doubt that the cost of living has greatly increased, and that the employees of a railroad company are entitled to be better compensated to meet such increased cost, but surely they are not entitled to be compensated at the sole expense of people who have invested their money and who would in return be deprived of their means of livelihood. The public should bear their share. The railroad employee spends his money for the benefit of every other member of the community, from farmer to manufacturer, and if the employee has to obtain more money to meet his increased cost of living, other classes of the community who receive the benefit of the money he spends should contribute their share toward enabling him to get the money he has to spend."

More Investigations.

"I see by Bradstreet's and Dun's reports that buyers in the dry goods trade are placing very small orders. You will look into this, and ascertain whether it is due to the state of trade or to past financial transactions of theirs.

"I am informed that large wholesale houses in Chicago and New York have cut prices on certain classes of goods as much as 20 per cent. You will inquire about this, and discover whether it is alleged that legislation, state or national, has been the cause. Of course lower prices would lead to great disorder at the bargain counters, which it would be my first duty to put down.

"I learn that the quotations of stocks have been low and business on the Exchange dull. You will investigate and report to me whether it is true that the sales of stocks have been so small that the revenues from stamp taxes have fallen off in a way to embarrass the treasury of New York, and that many worthy brokers have been brought to the verge of want. I desire that stocks be at once advanced in price."—*New York Evening Post.*

The World's Iron Production.

It is estimated that the production of pig iron in the world in 1907 was about 61,000,000 tons, as compared with 59,000,000 tons in the preceding year. Had it not been for the depression in the last quarter the increase would have been much greater. Of the total, the United States contributed about 42.3 per cent., Great Britain 17 per cent., and Germany 21.4 per cent.

The following table shows the world's production for a series of years.

Year	Tons	Year	Tons	Year	Tons	Year	Tons
1907	*61,000,000	1904	45,000,000	1902	43,400,000	1900	40,200,000
1906	59,000,000	1903	45,700,000	1901	40,200,000	1890	27,000,000
1905	53,700,000						

*Estimated.

The production of the three leading producing countries, the United States, Germany and Great Britain, in past years was as follows.

Year	United States, gross tons	Great Britain, metric tons	Germany, metric tons
1907	25,781,361	10,500,000*	13,045,760
1906	25,307,191	10,100,000	12,473,760
1905	22,992,380	9,592,737	10,987,623
1904	16,497,033	8,562,658	10,103,941
1903	18,009,252	8,811,204	10,085,634
1902	17,821,307	8,679,535	8,529,810
1901	15,878,354	7,928,647	7,860,893
1900	13,789,242	8,959,691	8,520,541
1890	9,202,703	7,904,214	4,658,450
1885	4,044,526	7,415,469	3,687,434

*Estimated.

In 1810 the United States produced less than 54,000 tons, and the 1,000,000 ton mark was not reached until 1864. In 1876 the country produced only 1,867,000 tons.—*Wall Street Journal.*

New Sound Steamboat Line.

A concern known as the New York & Providence Steamship Company has been incorporated in New York and proposes to compete with the Sound lines of the New York, New Haven & Hartford. Captain W. F. Bowman, who was master of the Enterprise Line steamship "St. Croix" when this company suspended business, is said to be the leader in the enterprise.

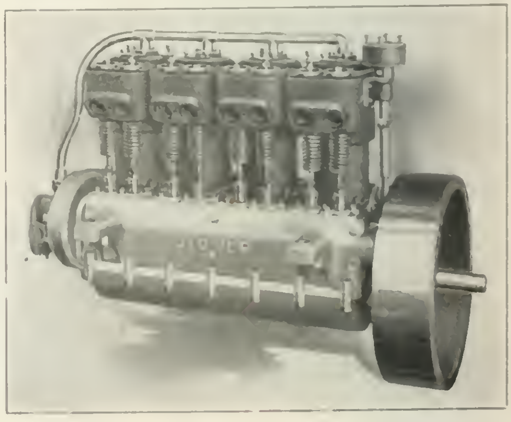
Stover Twelve-Passenger Motor Car.

The 12-passenger motor car illustrated herewith is the larger type of car made by the Stover Motor Car Co., Freeport, Ill. The company has been making six-passenger cars and is now making also this new type because of demand for cars of greater seating capacity. The six-passenger car answers the ordinary requirements of the division officer and a large number of them are in service on various roads. The three seats of the larger car flare beyond the body enough to give room on each for four good-sized men.

The car is driven by a vertical four-cylinder [illegible] h.p. gasolene engine. The accompanying photograph shows the engine with

Stover Twelve-Passenger Motor Car.

wiring and intake and exhaust pipes removed. The cylinders are 4½ in. x 5 in., water cooled. The crank case is of aluminum alloy and is in two castings, the upper half containing all of the bearings. The engine is attached to the frame by supporting arms cast on the upper half of the crank case, so that the lower half can be taken off in order to get at the bearings without disconnecting any other parts. The crankshaft is drop forged. Each cylinder is cast separately. The pistons have oil recesses and are fitted with four rings with square-cut joints. The piston rods are of large diameter and hardened. The connecting rods are drop forged, the bearings are phosphor-bronze and babbitt bronze, and the valves are drop forged in one piece and are interchangeable. The valve lifters are hardened steel and bronze. The timing gears are drop forged steel; they



Engine of Stover Gasolene Motor Car.

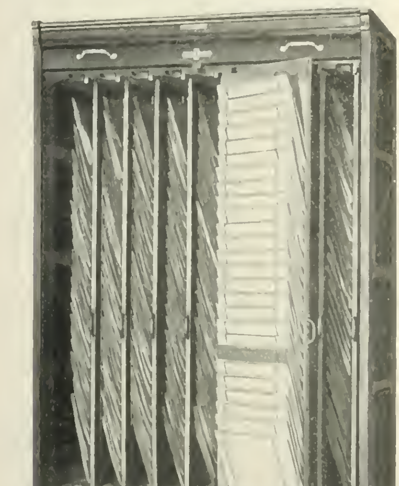
are completely enclosed in the crank case and run in oil. The cam shafts and cams are in one piece made of steel, case hardened, and also run in oil. The intake and exhaust pipes can be quickly removed by loosening four nuts. There are no gaskets in the joints between pipes and cylinders. The water pipes are brass, and the pump is the gear type, made of bronze except the bearing shaft, which is steel. The commutator has hardened steel contacts and the terminals are all protected by a glass cover. The cylinders and bearings are lubricated with a Hill Precision oiler. The ignition is jump spark, operated ordinarily on a storage battery circuit, but the makers will also wire the engine for a dry battery to be used in emergencies.

The transmission is through friction cones, instead of the usual trains of gears. This mechanism is under the front seat. Two small cones, mounted on the transmission shaft, bear against the face of a large wheel on the transverse jack shaft. By shifting the cones toward the center or towards the circumference of this wheel, the transmission ratio may be lowered or raised. As one cone bears on the wheel, the car is driven forward; when the other bears, the motion is reversed, so that the car can move at maximum speed in either direction. All these changes are governed by the vertical lever at the right of the driver. The power is transmitted from the jack shaft to the rear axle by a chain on cast steel sprockets. The spark and gas levers are on a vertical column in front of the driver. The car is designed for 30 m.p.h. with full load on level track. There are brakes on all four wheels, applied through a hand wheel mounted on the same column as the gas and spark levers.

The frame is of heavy pressed steel channels and the body is suspended on long semi-elliptic springs with cast steel hangers, making an easy-riding car. The axles are $2\frac{1}{2}$ in. in diameter and run in Hyatt roller bearings. The wheels are cast steel, 22 in. in diameter. The seats are upholstered in leather, and the floor and running board are covered with rubber matting. The standard body color is Brewster green. A chime whistle, operated by the exhaust, and a 9 in. acetylene headlight, generator and an oil tail light, are included in the equipment. The fuel consumption of the car is given as one gallon of gasolene for 12 to 15 car miles.

The Cook System of Filing Tariffs.

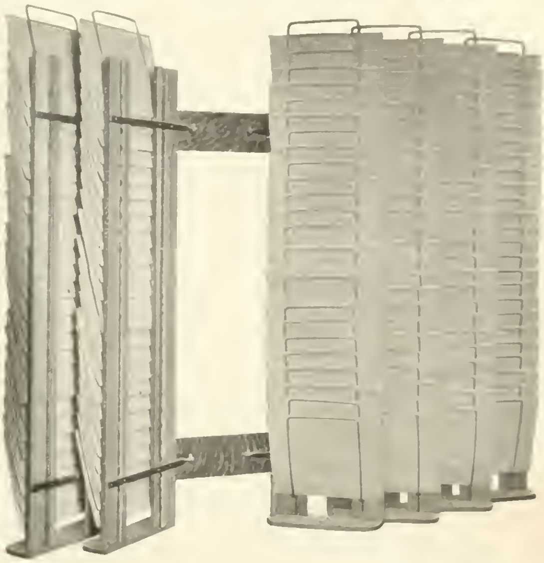
The file for railroad tariffs illustrated herewith is in use in the general offices and stations of a number of railroads by some of the largest commercial concerns in the country and by the War



Tariff Cabinet for General Freight Office.

Department. It was invented by C. W. Cook, Assistant General Freight Agent of the Atchison, Topeka & Santa Fe, and has been improved to its present form through several years of experience. It is convenient, simple and flexible as compared with the usual methods of filing tariffs, both in the general office and by station agents.

The basic feature of this file is a narrow rack or frame about 13 in. wide and 10 in. high, carrying wire holders rectangular in form, as shown in the illustrations. These holders are fastened to the rack with nuts and washers, and are adjustable vertically for pamphlets of any thickness. A rack has 26 wire holders. For general office use the racks or frames are mounted in a cabinet, usually holding eight racks. One of the illustrations shows this form and how a rack is drawn out and swung into position for use. Each tariff is separately filed so that it may be taken out and put back without disturbing any others. The tariffs are put in special folders to protect them. These folders carry the number and description of the tariff and the numerical filing order. Since



Station Frames for Filing Tariffs by the Cook System.

they are thus in place, much time is saved in consulting or filing them. It is said that tariffs seldom get disarranged.

A satisfactory system for a large number of tariffs in a general office is as follows: (1) Distance tables; (2) distance tariffs; (3) class tariffs, own issue first, followed by class tariffs joint with foreign road alphabetically arranged according to roads; (4) association tariffs; (5) special commodity tariffs alphabetically arranged according to commodity, local tariffs coming first and then joint tariffs alphabetically arranged according to roads.

For stations the plan is much simpler. The racks can be hung on the station wall, or any suitable support. One or more frames, as needed, can be put in, and others added as required. The agent thus has his tariffs conveniently and systematically arranged and instantly accessible. They also are convenient for public inspection and thus enable easy and satisfactory compliance with the law.

The use of this system of filing at local stations tends to do away with having agents wire the general freight office for rates and copies of tariffs which they may already have in the station, thus saving work at the general office, as well as use of the wires. The arrangement for quick and easy reference enables agents to quote rates promptly, and they quickly become trained to a better understanding of the tariffs. With a uniform plan for all stations, an agent changing from one station to another only needs to be instructed in the few details peculiar to that station. All details of the system are worked out in the general office and all an agent needs to do in familiarizing himself with the system is to follow the printed instructions furnished him.

The frames and cases used in the Cook filing system are made by the Rockwell-Wabash Co., Chicago.

Warren S. Stone on Wage Reduction.

Warren S. Stone, Grand Chief of the Brotherhood of Locomotive Engineers, is quoted as follows on the question of proposed wage reductions by the railroads:

"The threatened reduction of the wages of employees in train service is absolutely unjustified from any point of view. Their pay is based on a mileage basis, practically piece work, and they are only paid when there are services to be performed. Wages of employees in train service fall parallel with the shrinkage in business plus the increased living expenses away from home. When their earnings are \$150 per month their expense of living away from home is about 15 per cent, while at the present reduced rate of \$70, which has to be met by hundreds—under present conditions, that expense will increase to at least 20 per cent. of earnings because they are held away from the home terminal until there is a full ton nage train to be handled, making a total automatic reduction already in wages from 60 to 70 per cent.

"The roads are getting the same return in freight receipts for the service rendered as they did when the business was good, and there is no consistency in asking men to accept further reduction than result from the present business shrinkage, and the full power of the Brotherhood of Locomotive Engineers will be used, if necessary, in an effort to prevent any further reduction, because it would be absolutely unjust."

Lower Per Diem Adopted.

The resolution adopted by the American Railway Association at Chicago, February 7, in favor of reducing the per diem rate on interchanged freight cars from 50 cents a day to 25 cents, has been confirmed by the letter ballot which was ordered, and the new rate goes into effect March 1. The vote represented almost the entire number of cars in the association, being as follows:

Yes—243 memberships, representing 1,601,355 cars owned or controlled.

No—75 memberships, representing 589,635 cars owned or controlled.

Not voting—17 memberships, representing 30,142 cars owned or controlled.

The total membership of the Association is 335, and the cars owned or controlled by the members, 2,221,132.

The majority requisite for approval is 168 memberships and 1,480,755 cars.

The Traffic Club of Philadelphia.

A meeting has been called for March 3, 1908, to adopt a constitution and by-laws, elect officers and formally organize The Traffic Club of Philadelphia. The proposed constitution and by-laws are similar to those of the New York Traffic Club. The first steps toward organization were taken at a meeting on December 17, 1907, called by a circular letter signed by 75 industrial firms in Philadelphia. A nominating committee has made a ticket with Robert S. Perry, President of Harrison Brothers & Company, President, and Henry C. Trumbower, Treasurer of John Wyeth & Brother, Secretary. Apparently industrial concerns are to be more largely represented than in the New York Traffic Club, for out of the 18 proposed officers and directors only three (and these directors, not officers) are railroad men. Of the 19 officers and governors of the New York Traffic Club, 12 are officers of railroads, steamship lines or traffic associations.

Effects of Texas Legislation and Taxation.

The following remarks are taken from an address by B. F. Yoakum at Fort Worth, Tex., Feb. 15:

It is for the people of Texas to consider whether or not it is to their interest to treat the existing railroads fairly, and fix laws on a fair and equitable basis as will invite capital to make further railroad investments in the state. I am not going into details in this connection further than to illustrate one point which should appeal to every man as being unjust and prejudicial to existing railroads and a hindrance to further construction. The railroads of Texas are capitalized at about $100,000,000, or $33,000 a mile. The Railroad Commission of Texas in its last annual report valued the properties at $16,500 a mile, or one-half of the capitalization. The tax assessors of Texas have assessed the railroad properties on the 1907 tax rolls at $23,000 a mile. One of these valuations must be wrong—either that fixed by the Railroad Commission for rate-making purposes or that assessed by the tax assessors for taxable purposes. If, however, the tax assessors use the same percentage of true value of property in preparing their assessment roll for railroads as they do for other property—which is about 38 per cent.—then they have placed the true value of the railroads at more than they are capitalized, and the owners are entitled to consideration.

Now let us see for a moment what restrictive legislation has accomplished for the state. During the last sixteen years there have been only 3,900 miles of railroad built in Texas, and more than one-third of this entire mileage has been constructed in the last few years by interests with whom I have been associated and largely under my influence. Texas needs and should have as rapidly as money can be found for such investments 10,000 miles of new railroad, and if the 10,000 miles cannot be financed and constructed more rapidly than railroad construction has taken place in Texas during the last sixteen years, which has been on an average of 245 miles a year, it will require forty years to furnish the 10,000 new miles necessary for the best interest of our state—too long for most of us to hope to see its accomplishment.

Let us see what our new sister state, Oklahoma, has accomplished within the last sixteen years, where they have until recently had liberal laws. There have been constructed in Oklahoma 4,100 miles of railroad within the same period—sixteen years—with only 25 per cent. of the area of Texas. To put it in another way, within this period capital has come forward for over four times as much railroad in Oklahoma, considering the area, as in Texas. In Louisiana, to the east of you, during the last sixteen years the railroad mileage has increased 150 per cent., and now has twice as many miles of railroad as that of Texas to the square mile. The liberal laws of Louisiana were the inducement.

Economy in Train Crews.

In connection with the Pennsylvania Railroad's present plan of retrenchment, about 75 brakemen have been taken off through line passenger trains between Jersey City and Washington, Harrisburg, Altoona and Pittsburgh. The purpose is to reduce each crew to a conductor, a baggageman and one brakeman. The front brakeman is the one dispensed with. The new plan will make all inter-division trains comply with the standard in operation which has been in vogue for a long time on the New York division between Jersey City and Philadelphia. The new rule affects the Philadelphia, Baltimore and Washington and the Philadelphia Middle and Pittsburgh divisions, of the Pennsylvania, which with the New York division, make up the lines east of Pittsburgh. Eighteen men have been taken off trains running out of Jersey City on the inter-division schedules, and the others come off trains having their headquarters on the other three divisions. The taking off of these men from the head end compels the younger men to fall back into the freight train service.

A Committee on Automatic Stops and Cab Signals.

The Railway Signal Association in assigning work for 1908 has appointed the following committee on the above subject: W. H. Elliott, New York Central, Chairman, New York City; A. R. Raymer, Pittsburgh & L. E., Vice-Chairman; E. M. Weaver, Long Island; G. D. Fowle, Penna.; J. V. Young, Boston & Maine, G. N. MacDougald, Virginian, W. E. Bullard, New York, New Haven & Hartford; W. McC. Grafton, Penna. Lines West; H. J. Foale, Wabash; D. M. Case, Cincinnati, N. O. & T. P.; E. E. Mack, Chicago & E. Ill.; Wm. Hiles, C., C., C. & St. L.; A. C. Holden, Great Northern; J. R. Decker, Michigan Central, G. W. Hulsizer, Southern; G. H. Dryden, Balt. & Ohio; E. G. Graham, Boston & Albany; J. A. Beoddy, Norfolk & Western.

The committee has been instructed to report on:

1. Cab Signals and Automatic Stops which are worthy of recommendation.

2. On proper location of Automatic Stop Trips for varied conditions of traffic.

3. The advisability of the use of Cab Signals as a substitute for fixed signals or adjuncts thereto.

The committee invites inventors, manufacturers and others interested to communicate with the chairman giving full descriptions, patent specifications and drawings.

Fellowships at the University of California.

In July, 1906, Clarence W. Mackay and Mrs. John W. Mackay jointly, gave the University of California $100,000 to endow a professorship of electrical engineering. Part of the income was to be used for the salary of the incumbent of the chair, and the rest devoted to the furtherance of research work in electrical engineering in the university. Accordingly, two John W. Mackay Junior Fellowships in Electrical Engineering, of $600 a year each, have been established; they are open to all properly qualified university graduates.

The object of the fellowships is to enable students who have completed a college course to do research work with a view to aiding the advance of the application of electricity to scientific and industrial purposes. The holders of the fellowships are to live at the University of California. Experimental or other work, however, may be carried on outside the laboratories of the university. The appointment to each fellowship shall be for one year, which appointment may, however, be renewed, at the discretion of the Graduate Council of the university. Applications should be filed, as early as March 15, if possible, with the Recorder of the Faculties, Berkeley, Cal., to whom application should be made for announcement of courses and details of the work in electrical engineering and related subjects, and for application blanks, etc.

Eight Thousand Miles from Stump to Mill.

An Australian corporation has received a concession from the Russian Government to take out 30,000,000 ft. of timber a year from a forest in Siberia, which is 900 miles from Vladivostok. This is to be delivered in Melbourne, Australia, approximately 8,000 miles away, and nearly three times the distance from New York to San Francisco. In taking out the Siberian timber the Melbourne lumbermen will have to ship the entire year's cut in July, August, September and October, for during the rest of the year there is no open water at Vladivostok. Unmanufactured logs are admitted free in Australia, while there is a heavy duty on all manufactured wood, the duty on lumber, for instance, being nearly $5 a thousand board feet. At Melbourne a new mill is being built to manufacture these logs into dressed stock and lumber. These Siberian lumber operations illustrate the pinch in the timber supply in all parts of the world.

Trolley Route from Boston to Chicago.

A traveler who has covered the trolley route between Boston and Chicago reports that out of 1,497 miles he had to travel but 230 by steam train. two by stage and two on foot. He changed cars 68 times.

Surprise Tests on the Lehigh Valley.

The superintendents of the Lehigh Valley have just had made 197 surprise tests of enginemen, and report perfect records in all cases; no engineman was caught napping. It is a rule on the Lehigh Valley that at least three officials shall take part in every test, and they sign a report giving full details.

TRADE CATALOGUES.

San Pedro, Los Angeles & Salt Lake.—The passenger department has prepared a unique booklet entitled "A Souvenir of Delightful Journeys." It is made to resemble an orange both in size and cover color, and the inside has suggestions, in the form of halftone views, of what may be seen on short journeys out of Los Angeles. Another book is entitled "The A B C of the Salt Lake Route," having a page for each letter of the alphabet, with a suitable sentiment thereon.

Hammer Drills for Mining.—Bulletin 60-A of the Sullivan Machinery Co., Chicago, is a 12-page pamphlet on Sullivan hammer drills for mining work. This is a comparatively new type of rock drill, similar, in a general way, to the large pneumatic hammer. The bulletin gives full information about their construction and operation.

Lightning Arrester.—Bulletin S. 118 of the Railway Specialty & Supply Co., Chicago, consists of six pages describing lightning arresters for either a.c. or d.c. circuits. It is called the Arc Damp Arrester, and the circular describes its application to block signal layouts and interlocking plants.

Rubber Belt Conveyors.—The Jeffrey Manufacturing Co., Columbus, Ohio, has published a 48-page booklet of illustrations to show the application of rubber belt conveyors for handling material of various kinds. Price lists and details of parts of the machinery are also given.

Roofing.—The current issue of *The Exchange*, published by the Standard Paint Co., New York, has among other examples of the use of Ruberoid roofing, photographs of a large freight shed of the Northern Pacific, and of a large hotel at Monte Carlo.

Water Proofing.—The Hydrex Felt & Engineering Co., New York, is distributing a reprint of the paper on "Water Proofing Engineering" read before the Boston Society of Civil Engineers in October, 1907.

Lighting Current Transformers.—Bulletin 1,061 of the Allis-Chalmers Co., Milwaukee, Wis., is about lighting current transformers. It also gives information on insulating oil and insulation tests.

MANUFACTURING AND BUSINESS.

The office of the Vulcan Iron Works, Chicago, has been moved to the new plant at 28 N. Irving avenue, near Fulton street.

C. E. Walker has gone to the Locomotive Appliance Co., Chicago, in charge of sales of locomotive cylinders and valves, effective March 1.

The Conley Frog & Switch Co., New South Memphis, Tenn., has decided to double its capacity by erecting another building and buying additional machinery.

Philip J. Nash has taken charge of the sales department at 863 Monadnock building, Chicago, of the Ernst Wiener Co., New York. Mr. Nash has had long technical and practical experience in the industrial railroad business.

Kopp signal glass is used for most of the signal glass, lenses and roundels in the installation in the yards of the new Washington terminal. The Railway Specialty & Supply Co., Chicago, are agents of the Pittsburgh Lamp, Brass & Glass Co., makers of this glass.

F. T. Hyndman, until recently Mechanical Superintendent of the New York, New Haven & Hartford, is now representing the Eldo Co., 100 William street, New York City. "Eldo" is a protective coating for metal. The claims for this product are that it is made from a mineral gum and is perfectly elastic, is applied easily, dries rapidly, will resist high temperature, is a non-conductor of electricity and will not deteriorate. In color it is a glossy black.

The Federal Railway Signal Co., a New Jersey corporation, with office and works at Albany, N. Y., has been reorganized. A new company, the Federal Signal Co., formed with a New York charter, assumes all the assets and liabilities of the old company, and new capital has been provided for carrying on the business. The officers of the new company are: President, A. H. Renshaw, Vice-Presidents, Eugene Seitz and John T. Cade; Secretary, Frederic Pruyn, and Treasurer, Eugene Seitz.

Richard S. Mercer, who has for several years been representative at New York of the American Brake-Shoe & Foundry Co., Mahwah, N. J., died on February 23. Mr. Mercer was 16 years old. He was born at West River, Md., and, after being educated at Charlotte Hall Academy, began work in 1882 on the Pennsylvania. He was in the construction department for a number of years and then went to the maintenance of way department, serving for some years as supervisor of the Middle division until he resigned to go to New York.

The Robins New Conveyor Co., New York, which was recently incorporated, will be operated under the management of Thomas Robins, who founded the Robins Conveying Belt Co. in 1896 and was President of that concern until March, 1907, when its management passed into other hands. C. Kemble Baldwin is Chief Engineer of the new company. He has served in the older company in the same capacity for the last seven years. The offices of the company are at 38 Wall street, New York, and 1240 Old Colony building, Chicago.

The Allis-Chalmers Co., Milwaukee, Wis., will furnish the equipment for the central station in the electrification of the plant of the Clark Thread Co., Newark, N. J., plans for which have been completed. The plans call for a generating plant of 10,000 k.w. supplied by five steam turbine units. Only one unit will be installed at the outset; this will drive a three-phase, 60-cycle, 600-volt generator, rated at 2,500 k.w. on normal load. The turbine will run condensing. About 2,500 h.p. in induction motors will be installed at the start. The complete electrification of the plant will be carried out gradually.

H. U. Wallace, President of the Wallace-Coates Engineering Co., Chicago, has resigned to become General Manager of the Chicago, Lake Shore & South Bend, an electric line nearing completion between South Bend, Ind., and Kensington, Ill., where it connects with the Illinois Central. Mr. Wallace is a graduate of Purdue University, and was with the Illinois Central for a number of years, being Division Superintendent for three years and Chief Engineer for three years. He then became Third Vice-President of J. G. White & Co., New York, and for the past two years has been at the head of the Wallace-Coates company.

Robert F. Carr and several associates in the Dearborn Drug & Chemical Works, Chicago, makers of boiler compounds, have bought the holdings of the estate of the late William H. Edgar, who died two years ago. At a meeting of the stockholders, followed by a meeting of the Directors, the following officers have been elected: President and General Manager, Robert F. Carr; Vice-President, George R. Carr; Vice-President, Grant W. Spear, Vice-President and Eastern Manager, William B. McVicker, Assistant General Manager, J. D. Purcell; Assistant Secretary and Chemical Director, W. A. Converse; Assistant Treasurer, R. R. Browning; Superintendent, A. E. Carpenter. C. M. Eddy's holdings were also taken over; he desired to devote all his time to personal business interests.

Wynn Meredith, Member of the American Institute of Electrical Engineers, has become a partner in the firm of Sanderson & Porter, New York, engineers and contractors, and will have charge of the western office which they have opened in the Union Trust building, San Francisco, Cal. After technical training at the University of Illinois, Mr. Meredith, in 1888, worked on construction and operation of lighting and electric railway properties. He was connected with the electrical plant of the World's Fair at Chicago in 1893 and the California Fair in 1894. He was later associated with Hasson & Hunt, and then became a member of the firm of Hunt, Dillman, Meredith & Allen, San Francisco, Cal. During 15 years' residence in California Mr. Meredith has been engaged in general engineering work, and including much of the hydro-electric and power transmission work on the Pacific coast, in the United States and Canada.

Iron and Steel.

The New York, Ontario & Western is reported to have ordered 1,100 tons of rails from the Lackawanna Steel Co.

The Chicago & North Western has given the McClintock-Marshall Construction Co. a bridge contract requiring 1,400 tons of fabricated steel.

The Delaware, Lackawanna & Western has ordered 8,500 tons of open hearth 90-lb. rails from the Bethlehem Steel Co. The price will be somewhat higher than the standard figure for Bessemer steel.

The Great Northern has ordered 20,000 tons of rails from the Carnegie Steel Co. and 15,000 tons from the Lackawanna Steel Co. The Pennsylvania Steel Co. has orders from the Great Northern for 5,000 tons of open hearth and 5,000 tons of Bessemer rails, from the Atlantic Coast Line for 8,000 tons, and from other roads for 12,000 tons. The latter amount is in addition to the company's share in the recent Pennsylvania Railroad order.

OBITUARY NOTICES.

William F. Hallstead, formerly General Manager of the Delaware, Lackawanna & Western, died last week at his home in Scranton, Pa., at the age of 82. Mr. Hallstead was born at Benton, Pa. He entered the service of the Lackawanna as brakeman in 1852, and continued in the service of the company 47 years. He was promoted through the different grades of the operating department until in 1872 he was made Superintendent of the main line. In 1886 he was appointed General Manager, which office he held for 13 years.

James Dun, Consulting Engineer of the Atchison, Topeka & Santa Fe, died at St. Augustine, Fla., of heart trouble, on February 23. Mr. Dun had been on the Santa Fe for the past 17 years. He was born on September 8, 1844, at Chillicothe, Ohio. He began railroad work when he was 22 years old as a chainman in an engineer corps on the Indianapolis & Cincinnati, which is now part of the Cleveland, Cincinnati, Chicago & St. Louis. Next year he was appointed Assistant Engineer of the Atlantic & Pacific, now part of the Atchison, Topeka & Santa Fe. Four years later he went to the Missouri Pacific as Assistant Engineer, and in 1874 was made Engineer of Union Depot Co., at St. Louis, Mo. In 1877 he was appointed Superintendent of Bridges and Buildings of the St. Louis & San Francisco, and, after serving in this position for a year, went to the Atchison, Topeka & Santa Fe as Chief Engineer. In 1900 he was made Chief Engineer of the whole Santa Fe system, including the Coast Lines. He was appointed Consulting Engineer of the system in the fall of 1906.

James Dun.

MEETINGS AND ANNOUNCEMENTS.

(For dates of conventions and regular meetings of railroad conventions and engineering societies, see advertising page 24.)

American Society of Mechanical Engineers.

The March meeting of this society is to be held on Tuesday evening, March 10, in the Engineering Societies building, West Thirty-ninth street, New York. An address will be made by Dr. Charles P. Steinmetz, Professor of Electrical Engineering at Union University, on "The Steam Path of the Steam Turbine."

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Canadian Pacific.—F. W. Peters, Assistant Freight Traffic Manager of lines west, has been appointed Assistant to the Second Vice-President, with office at Winnipeg.

Philadelphia & Reading.—Harry E. Paisley has been appointed Treasurer of the railroad company and also of the Reading Company and the P. & R. Coal & Iron Co., in place of Richard Tull, deceased. John S. Sneyd has been appointed Assistant Treasurer in place of Mr. Paisley.

Seaboard Air Line.—L. G. Haas, heretofore Assistant General Manager of the Baltimore & Ohio, has been appointed Agent for the Receivers of the S. A. L. He will have charge of certain engineering features of extensions and of the industrial department, his duties not conflicting with those of Mr. Garrett, chief executive officer for the Receivers. George Hodges, heretofore Assistant to the General Manager of the Baltimore & Ohio, has been appointed Assistant Receivers' Agent of the S. A. L.

Operating Officers.

Baltimore & Ohio.—L. G. Haas, Assistant General Manager, has resigned. See Seaboard Air Line under Executive, Financial and Legal Officers.

Fourche River Valley & Indian Territory.—William Collins has been appointed General Manager in place of F. C. Fauth, resigned, office at Fourche, Ark.

Kansas City Southern.—Charles C. Riley has been appointed General Manager and Superintendent of Transportation, effective February 15. Mr. Riley was born in Indiana and was educated at Butler University. He prepared himself for the medical profession, but in 1888 entered the railroad service on the Cleveland, Cincinnati, Chicago & St. Louis. He held various positions in the transportation department until April 10, 1897, when he went to the Baltimore & Ohio Southwestern as Superintendent of Car Service and Superintendent of Transportation, which place he held until December 1, 1900. In 1901 he was instructor at the College of Physicians and Surgeons at Indianapolis. From October, 1901, to July, 1903, he was Car Service Agent of the Chicago Great Western, and then for a year was Superintendent of Car Service of the Erie. From that place he was promoted to be Superintendent of Transportation, resigning from this position this month.

National of Mexico.—J. C. Sielski has been appointed Superintendent at San Luis Potosi, in place of A. Larkin, deceased.

New York, New Haven & Hartford.—E. T. Horn has been appointed Assistant Superintendent and D. F. Stevens Trainmaster of the Shore Line division. P. W. J. Smith has been appointed Passenger Trainmaster of the New York division, with office at the Grand Central Station, New York City. C. H. Motzett has been appointed Freight Trainmaster of the New York division, with office at Harlem River, N. Y. E. H. Morse has been appointed Passenger Trainmaster of the Boston division, with office at Boston, F. S. Hobbs Freight Trainmaster of the Boston division, with office at South Boston.

New York, Chicago & St. Louis.—The lines of this company have been divided into three operating divisions, as follows: Buffalo division, Buffalo to Conneaut; Cleveland division, Conneaut to Bellevue; Fort Wayne division, Bellevue to Chicago.

The Superintendent of the Buffalo division is W. F. Watterson, office at Buffalo, N. Y.; Trainmaster, G. C. Todd, office at Conneaut, Ohio.

The Superintendent of the Cleveland division is R. W. Mitchener, office at Cleveland, Ohio; Trainmaster, C. E. Maxfield, office at Cleveland.

The Superintendent of the Fort Wayne division is S. K. Blair, office at Fort Wayne, Ind.; Trainmaster, E. S. Kirby, office at Fort Wayne.

W. I. Bliss has been appointed Superintendent of Telegraph, in place of R. W. Mitchener, promoted.

Traffic Officers.

Canadian Pacific.—W. B. Lanigan has been appointed Assistant Freight Traffic Manager, at Winnipeg, Man., in place of F. W. Peters, promoted.

Chicago, Milwaukee & St. Paul.—R. M. Calkins, hitherto Assistant General Freight Agent at Chicago, has been appointed General Freight and Passenger Agent of the lines west of the Missouri River, with office at Butte, Mont. E. C. Nettels, also Assistant General Freight Agent at Chicago, will succeed to the place vacated by Mr. Calkins.

Mobile & Ohio.—E. A. Bynum, appointed Assistant General Freight Agent, with office at New Orleans, in place of N. M. Leach, has taken up the duties of his office.

Pennsylvania Lines West of Pittsburgh.—W. M. Wallace has been appointed Division Freight Agent of the Erie & Ashtabula division, in place of H. M. Bradley, office at Erie, Pa.; effective April 1.

Engineering and Rolling Stock Officers.

Chicago, Rock Island & Pacific.—E. E. Chrysler, Master Mechanic at Chickasha, Okla., has resigned.

International & Great Northern.—F. S. Anthony has been appointed Master Mechanic of the Gulf division at Palestine, Tex. J. B. Dolsen, Foreman of the Car Department at Palestine, has resigned.

Mexican Central.—F. L. Carson has been appointed Master Mechanic of the Torreon division in place of O. R. Hale, transferred.

CAR BUILDING.

The Atlanta, Birmingham & Atlantic has ordered 112 coal cars of 80,000 lbs. capacity and 30 cabooses from the South Atlantic Car & Manufacturing Co.

The Mexico, Santa Fe & Perry Traction Co., under construction in Missouri, intends to ask bids on rolling stock soon. S. L. Robson, Mexico, Mo., is President and General Manager.

The J. D. MacArthur Co., Ltd., Winnipeg, Man., as reported in the *Railroad Gazette* of February 14, has ordered from the Hicks Locomotive & Car Works, for delivery on April 1, 50 flat cars of 60,000 lbs. capacity and one caboose. Bodies and underframes will be of wood.

RAILROAD STRUCTURES.

ALEXANDRIA, LA.—A contract has been given to Edward Crebo, of Kansas City, to build the union passenger station to be used by the Texas & Pacific and the St. Louis, Iron Mountain & Southern.

CAINSVILLE, ONT.—The Toronto, Hamilton & Buffalo is planning to put up a new steel bridge on heavy concrete abutments here.

GRAND FORKS, B. C.—It is said that the Canadian Pacific will make improvements here, including roundhouses, at a cost of $150,000.

MINNEAPOLIS, MINN.—The Chicago, Milwaukee & St. Paul, it is said, has bought 40 acres of land adjoining the city limits as a site for shops and terminals. This is preparatory to changes which will follow the extension of the company's lines to the Pacific coast.

MONTREAL, QUE.—Bids are being asked for by the Canadian Pacific for the construction of the new stock yards in this city.

OTTAWA, ONT.—The Canadian Railway Commissioners have authorized the Canadian Pacific to build bridges as follows: Over Belly river at Lethbridge, Alta.; at mile 35.2 over Carpenter creek, B. C.; at mile 0.72 over Fraser river, Mission branch, B. C.; at highway crossing at Bala, Ont.; at mile 7.32, Mud Branch, Thames river, Ont.; at mile 8.2 over Thames river, Ont.; at mile 9.44, Huron street crossing, Embro, Ont.; at mile 18.9, Brockville branch, Ont.; at mile 34.6 over Badger creek, Man.; at William street subway, also approved plan of abutment and piers of proposed bridge over Pine street, at Woodbridge, Ont.

QUEBEC, QUE.—The Quebec Bridge Co. has decided to rebuild the steel cantilever bridge over the St. Lawrence which collapsed last spring.

ST. STEPHEN, N. B.—The New Brunswick Southern is asking Parliament for authority to build a bridge over the St. Croix river.

TRINITY, TEX.—The Beaumont & Great Northern is planning to make improvements here, to include shops and a roundhouse.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

AMERICAN RAILROAD OF PORTO RICO.—This company expects soon to finish the cut-off from Hormigueros south to Lajas, 12 miles. (April 12, p. 531.)

A branch line is to be built this year from San German, east to Sabana Grande, nine miles. This work includes one large bridge and several smaller structures. All the work is being done by the company's forces.

ATLANTIC, QUEBEC & WESTERN.—The Canadian Railway Commissioners have approved the location of this company's line in the townships of Perce, Mal Baie and Douglas, county of Gaspe, Quebec, mile 60 to 90; also in section 3, mile 20 to 30.8, and section 10, mile 90 to 102.4 through the townships of Douglas and York, county of Gaspe.

BATON ROUGE, HAMMOND & EASTERN.—See Illinois Central.

CANADIAN NORTHERN.—This company, it is said, has had a large force working all winter on the Hudson Bay line from Etoimami, Sask., north. The line is finished to Pass Mission, at the junction of the Saskatchewan and Carrot rivers, about 100 miles. The surveys to Ft. Churchill call for a line 125 miles long.

Several improvements, it is said, are to be made this year on the line between Port Arthur and Winnipeg. The company intends to replace 30 miles of the present rails between Atikokan, Ont., and Rainy River with 80-lb. rails, and make extensive improvements on this division, mainly at Fort Frances.

CHERRYVALE, OKLAHOMA & TEXAS.—Surveys reported made by this company for its proposed line from Cherryvale, Kan., via Pawhuska, Okla., and Guthrie, to Geary. General Manager J. H. Brewster is quoted as saying that capital has been secured to complete this section of the line. S. M. Porter, President, Caney, Kan. (July 19, p. 83.)

DENVER, LARAMIE & NORTH WESTERN.—This company, which has projected a line from Denver, Colo., to the northern boundary of Wyoming, about 500 miles, is said to have bought recently 160 acres of land in Denver as a site for terminals. Rights of way are reported secured for the line. S. Johnson, President; J. O. Curry, Treasurer; J. T. West, Secretary, and former Senator Harris and Judge J. T. Millkan, of Kansas, are said to be interested. (Sept. 27, p. 370.)

EVANSVILLE, MT. CARMEL & OLNEY INTERURBAN.—Incorporated in Indiana, with a capital of $10,000, to build an electric line from Evansville, Ind., northwest to Olney, Ill., about 60 miles. A. Knoop, President, Olney; G. W. Couerter, Secretary, Mt. Carmel. The directors include G. J. Siebert, J. Laubscher, E. O. Lockyear, of Evansville; T. Newall, E. B. Bixby, of Cynthiana; J. F. Siebert, J. O. Smith, of Lancaster; A. Knoop, F. W. Boyer, J. F. Hyatt, of Olney.

FORT WAYNE & SPRINGFIELD TRACTION.—Plans under way to build a line from Decatur, Ind., south to Richmond, Ind., 70 miles. Officials of this company are reported to be interested.

GRAND TRUNK PACIFIC.—Foley, Stewart & Welch, contractors for 120 miles of the line from Edmonton, Alb., west, have sublet 30 mile sections to J. McAllister, M. McKenzie and B. Baker. The remaining 30 miles is to be sublet in one and two-mile sections.

ILLINOIS CENTRAL.—Construction work on the connecting links on the Birmingham extension to a connection with the Central of Georgia have been finished, and the line is to be ready for operation April 1. The line from Jackson, Tenn., to Birmingham, Ala., 219 miles, is over the Illinois Central tracks to Perry, 5.80 miles, thence over the Mobile & Ohio to Ruslor, Miss., 51.48 miles. The Mississippi & Alabama in Mississippi and the Alabama Western in Alabama extend from Ruslor to Haleyville, Ala., 80.07 miles. From Haleyville the company has trackage rights over the Northern Alabama to Jasper, 40.69 miles, and from Jasper over the Kansas City, Memphis & Birmingham to Birmingham, 40.96 miles. This will give the Illinois Central a through line to Birmingham. The line from Corinth, Miss., to Haleyville, Ala., 80.1 miles, was opened for traffic Feb. 10. The company has finished terminals in Birmingham at a cost of $2,000,000. It is announced that through trains from Chicago to Birmingham, Ala., will probably be established about April 1.

Work on the Memphis & State, which is to be a double-track line from Anlon, Tenn., to the Nonconnah yard, about seven miles, has grading finished and about one-half the track laid. It is expected to have the line open for traffic about March 15.

The work under way on the Yazoo & Mississippi Valley relaying the present track from Natchez, Miss., northeast to Harrison, 27.8 miles, with 75-lb. rails, will probably be finished about March 15th.

The new double-track belt line being built around Memphis, Tenn., is expected to be put in operation March 15th.

Train service was begun on the Baton Rouge, Hammond & Eastern on February 27. This line joins the Illinois Central at Hammond, La., and connects at Baton Rouge with an extension of the Southern Pacific, which is being built from Lafayette, La., to Baton Rouge. A saving of about 50 miles is accomplished by this short route between the Illinois Central and the Southern Pacific, which also saves going through the congested terminals at New Orleans.

MATAMOROS & SANTA CRUZ STREET RAILWAY.—A St. Louis syndicate organized by W. H. Bixby, T. West, S. Fordyce, H. Harstick, E. Scott and R. Brookings, has recently bought this Mexican line. It is the purpose of the new owners to rebuild and electrify the line, also to extend it to a connection with the National Railroad. The proposed improvements include a line to Brownsville and the absorption of the Rio Grande Railroad, operating 22 miles from Brownsville, Tex., north to Point Isabelle. This is a steam road, which it is proposed to convert into an electric line. The work will include a bridge over the Rio Grande at Brownsville, for which permission to build will have to be obtained from both the United States government and the Mexican government.

MEMPHIS & STATE.—See Illinois Central.

MEMPHIS, PARIS & GULF.—This company is now in operation from Nashville, Ark., southwest to Ashdown, 26.9 miles. The company proposes to extend the road this summer. The projected route is from Memphis, Tenn., via Little Rock, Ark., to Paris, Texas, 400 miles.

MEXICAN CENTRAL.—This company is improving its track between Chihuahua and El Paso and adding heavier rails. Five thousand tons of 75-lb. rails are being distributed to replace the 56-lb. rails now in use.

MONTANA RAILROAD.—This company has finished grading work on a revision of line from Lombard, Mont., to mile 36.2, near Minden. Ditmer, Bradbury & Wheelbrew, contractors. Tracklaying is expected to be finished in March. The work included eight tunnels and one viaduct.

PITTSBURGH, BINGHAMTON & EASTERN.—The New York Public Service Commission (Second district) has granted permission to this company to change that portion of its proposed route within the state of New York. The line is projected from Binghamton, N. Y., to Clearfield, Pa., 225 miles. Twenty-one miles built in 1907. The Holbrook, Cabot & Rollins Corporation, contractor. (Jan. 17, p. 105.)

RIO GRANDE RAILROAD.—See Matamoros & Santa Cruz.

TEXAS ROADS.—A company is being organized by Dr. C. F. Simmons, of St. Louis, and associates to build a line from San Antonio, Texas, south to Rio Grande, on the Mexican border, about 200 miles, with a branch east to Corpus Christi, 50 miles. Rails are said to have been bought to be laid on the first 40 miles.

UNION TRACTION COMPANY.—Incorporated in Texas, with office at Clarksville, in Red River county. The company proposes to build an electric line from Texarkana via Sherman and Ft. Worth to Mineral Wells. C. P. Moore, President, and J. T. Upchurch, Secretary and Treasurer.

WEST TEXAS & NORTHERN.—The West Texas Construction Company has been organized to build this proposed line from Stanton on the Texas & Pacific to Lubbock, the county seat of Lubbock county, 110 miles. Fourteen miles graded north from Stanton. (Nov. 15, p. 666.)

YAZOO & MISSISSIPPI VALLEY.—See Illinois Valley.

RAILROAD CORPORATION NEWS.

ATLANTIC COAST LINE.—The Atlantic Coast Line Company of Connecticut, which is the holding company for the Atlantic Coast Line Railroad, has declared a quarterly dividend of 2 per cent., reducing the annual rate from 10 to 8 per cent.

BALTIMORE & OHIO.—This company has sold $6,000,000 one-year 5 per cent. collateral notes dated March 2, 1908, to Speyer & Co. and Kuhn, Loeb & Co., of New York. These notes are in denominations of $10,000 and $25,000 and are secured by $8,000,000 refunding 4 per cent. bonds of the Pittsburgh, Lake Erie & West Virginia "System," which includes 1,687 miles of Baltimore & Ohio lines, including the Pittsburgh & Western and the Cleveland, Lorain & Wheeling.

Gross earnings for January decreased $1,188,000, or 19 per cent. Expenses were $201,000 less, leaving net earnings of $1,013,000 against $2,000,000 in 1907, a decrease of $1,988,000, or 17 per cent. For the seven months ending January 31, 1908, the net earnings were $14,000,000 against $16,009,000 in 1907, a decrease of 17 per cent.

CAMDEN & TRENTON (ELECTRIC).—Wilbur F. Sadler, Jr., of Trenton, was, on February 18, appointed receiver of this company by Vice-Chancellor Walker, of New Jersey, on a bill of complaint by former President Henry V. Massey, alleging insolvency and mismanagement. The road is controlled by the New York-Philadelphia Company.

CANADIAN NORTHERN.—The Canadian Northern is applying to the Parliament of Canada for permission to issue $19,250,000 new stock, increasing its authorized stock to $50,000,000.

CANADIAN PACIFIC.—This company has sold $10,000,000 4 per cent. debenture stock in London at a price slightly above par. There was previously $106,045,111 of this stock outstanding.

DELAWARE & HUDSON.—A temporary injunction restraining the company from paying the four quarterly dividends of 2¼ per cent. each (9 per cent. for the year) payable at four different dates during 1908, was given by Judge Platzek in the Court of General Sessions of New York City this week to ex-Judge Rufus B. Cowan, who, at the annual meeting in May, 1907, made an attack on the present management criticising especially the purchases of coal lands, of traction properties about Albany and of railroad properties in Canada.

ERIE.—No action was taken on February 19 or on February 26 by the directors on the first preferred dividend. The former is the date on which the semi-annual dividend is usually declared. The question as to whether the company had the right to issue dividends in scrip without the approval of the New York Public Service Commission is still pending.

ILLINOIS CENTRAL.—Judge Ball, of the Superior Court of Illinois, on February 20 dissolved the injunction granted on October 11 to Stuyvesant Fish restraining the Railroad Securities Company and the Union Pacific Railroad from voting $28,123,100 Illinois Central stock (29.56 per cent. of the total) held by them at the adjourned annual meeting on March 2. Stuyvesant Fish has sent a letter to the stockholders saying that any stockholders who wish to withdraw proxies given to him may do so on request.

INTERNATIONAL & GREAT NORTHERN.—T. J. Freeman, Solicitor of the Texas & Pacific, was on February 26 appointed receiver of this company by Judge McCormick in the United States Circuit Court at Fort Worth, Tex. President George J. Gould issued a statement that the receivership came as a result of orders of the Texas Railroad Commission for extensive improvements at a time when earnings were rapidly decreasing. The International & Great Northern operates 1,160 miles of line, all in Texas.

INTERBOROUGH-METROPOLITAN.—President Shonts, of this company which controls the surface, elevated and subway lines of the borough of Manhattan, New York City, has sent a circular to stockholders summarizing the financial condition of the company for the year ended December 31, 1907. The general balance sheet on that date was as follows:

Assets.		
Interboro R. T. stock, at cost in securities of this company		$104,763,012.00
Metropolitan St. Ry. stock at cost in securities of this company		68,684,155.00
Metropolitan Securities Co. stock at cost in securities of this company		28,720,695.00
Metropolitan Securities Co. loans secured by notes and stocks and bonds of subsidiary companies as collateral		8,844,700.48
Real estate, at cost		594,464.89
Office furniture and fixtures		5,461.06
Engineering in suspense (additional subways)		50,114.78
Metropolitan Securities stock full paid		30,773.16
Cash and accounts receivable		1,835,802.84
Total		$212,944,509.51
Liabilities.		
Capital stock, common	$100,000,000.00	
Reserved against outstanding stocks not acquired	6,737,808.00	
		$93,262,192.00
Capital stock, preferred	$55,000,000.00	
Reserved against outstanding stocks not acquired	9,260,000.00	
		45,740,000.00
Collateral trust 4½ per cent. bonds	$70,000,000.00	
Reserved against outstanding stocks not acquired	2,175,000.00	
		67,825,000.00
Notes payable		1,545,000.00
Accounts payable		42,309.76
Accrued interest 3 mos. to Jan. 1, 1908, on Inter-Met. 4½ per cent. bonds (covered by dividend of Interborough R. T. Co., paid Dec. 31, 1907)		763,091.25
Profit and loss surplus		766,916.50
Total		$212,944,509.51

The income of the year, largely made up of dividends on Interborough Rapid Transit and Metropolitan Street Railway stock, was $4,753,561, and the expenses, largely made up of interest on its own bonds and dividends on its preferred stock, were $4,511,569. The surplus for the year therefore was $241,992. This, added to the profit and loss credit balance on December 31, 1906, of $524,924, makes up the profit and loss surplus of $766,916, shown on the balance sheet.

KANSAS CITY SOUTHERN.—Gross earnings for January, 1908, were $646,000 against $773,000 in 1907, a decrease of $127,000, or 16 per cent. Net earnings were $203,000 against $320,000 in 1907, a decrease of $117,000, or 37 per cent. For the seven months ended January 31, the net earnings were $1,929,000 against $2,028,000 in 1907, a decrease of $99,000.

LONG ISLAND.—In the year ended December 31, 1907, gross earnings increased $535,000 and operating expenses $1,045,000. Net earnings decreased $510,000. In the month of December, 1907, the excess of expenses over gross earnings was $53,000 larger than in the corresponding month of 1906.

NEW YORK, CHICAGO & ST. LOUIS.—Gross earnings for the year ended December 31, 1907, were $10,385,288 against $9,901,947 in 1906. Net earnings were $3,151,549 in 1907 and $2,322,511 in 1906. These are high record figures.

PERE MARQUETTE.—Arrangements have been made for refunding the $2,600,000 5 per cent. equipment bonds maturing March 2 with the same amount of 6 per cent. equipment notes, which are to be redeemed in four annual instalments of $650,000 each, due March 1, 1909-1912 inclusive. These $2,600,000 bonds are the outstanding balance of $3,500,000 five-year equipment bonds issued in 1903 to pay for $5,503,000 worth of equipment, for which $2,103,000 was paid in cash.

PITTSBURGH, CINCINNATI, CHICAGO & ST. LOUIS.—Gross earnings for January decreased $506,000, operating expenses and taxes, $375,000, and net earnings, $132,000.

TEXAS & PACIFIC.—Estimated gross earnings for the week ended February 21, 1908, were 16 per cent. less than in the corresponding week of 1907.

UNION PACIFIC.—See Illinois Central.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK
BRANCH OFFICES AT 375 OLD COLONY BUILDING CHICAGO, AND QUEEN ANNE'S CHAMBERS WESTMINSTER, LONDON

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. *We give in our editorial columns* OUR OWN *opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.*

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette:

OFFICERS:

W. H. BOARDMAN, *Prest. and Editor.*
E. A. SIMMONS, *Vice-President.*
RAY MORRIS, *Secretary*
R. S. CHISOLM, *Treas.*
I. B. RINES, *Cashier*
L. B. SHERMAN, *Western Manager*

EDITORS:

RAY MORRIS, *Managing Editor.*
BRAMAN B. ADAMS
CHARLES H. FRY
FRANK W. KRAEGER
GEORGE L. FOWLER
HUGH RANKIN
BRADFORD BOARDMAN

CONTENTS

VOL. XLIV., No. 10. FRIDAY, MARCH 6, 1908.

The directors of the Erie Railroad on August 28, 1907, declared the regular semi-annual dividend on the first preferred stock and the regular annual dividend on the second preferred stock, in 4 per cent. interest-bearing scrip, payable in cash in 1917. Under the Public Service Commissions law of the state of New York, the company applied for authority to issue these interest-bearing dividend warrants. Decision of this application was delayed until March 1, 1908, when the Albany Public Service Commission, in an opinion written by Chairman Stevens, denied the application. The Commission holds that in order to authorize, under the Public Service Commissions law, the issue of stocks, bonds or other evidence of indebtedness (1) capital must be secured by the issue, (2) the use of such capital must be necessary for acquisition of property, construction or extension of facilities, improvement or maintenance of service, or for refunding, and (3) that the amount authorized be reasonably required for such purpose or purposes. Furthermore, that dividends can be declared only from surplus profits, which belong to the corporation and not to the stockholders until a dividend is declared. The Commission then points out that by the declaration of a dividend payable in the future no capital is secured, and that the issue of warrants evidencing such dividends is not necessary for any of the four specified purposes to which new capital may, under the law, be applied. By the declaration of a scrip dividend a company secures nothing which it did not possess before, and therefore under the law the issue of dividend warrants cannot be approved. In other words, the Commission will not authorize a company to put itself in debt for the purpose of paying dividends. As was remarked in the *Railroad Gazette* shortly after the declaration of these dividends, they represented what was really an enforced loan from the stockholders at 4 per cent., while the Erie was able to get money in the open market only at rates more than twice as costly as this. The decision of the Commission is in the direction of straightforward methods of railroad finance. It means that in New York state a railroad company will either decide to pay dividends or not to pay them, and that there will be no attempt to compromise by issuing obligations on the future. One of the interesting sidelights of this case is the fact that there is small reason to doubt that with the industrial depression which has come about since last August, the directors of the Erie are likely to be the people most pleased by this decision.

The extent to which it is possible to control locomotive fuel expense by careful and systematic purchase and distribution of the coal, based on exact knowledge of its quality and other conditions affecting its economic use, was described in the paper presented at the November meeting of the Western Railway Club (*Railroad Gazette*, January 10, 1908). The scheme outlined is more or less theoretical, although it is backed up by about a year of experience on the Burlington, where the ideas and methods described are being gradually introduced. Naturally, it requires a long time—years—to get such a scheme fully in operation. While the plan has been worked out primarily on the basis of the conditions peculiar to the Burlington, the purpose of the paper is to present it in such form as to be generally adaptable. There is so much to commend in the plan that it is well worth the careful study of every manager interested in lowering the cost of this, the largest single item in his operating expense. The competitive points for the different kinds of coal determined by the equation used in the paper will, in nearly all cases, fall between division termini. While it is not so stated in the paper, it is not the intention that there actually should be a change of coals at such a point. The best results are got, of course, when the quality of coal is uniform over a division, since a change of adjustment in the locomotive is necessary to burn each different grade of coal with the best economy. A locomotive drafted for poor coal, if given a good coal would burn it wastefully, throwing an unnecessary quantity out of the stack. Practically the change of coal would doubtless be made at the division point nearest the competitive point. Other factors of primary practical importance are grade conditions and the volume and direction of traffic. The former, the author points out, can be taken care of by the cost of haulage, which it is important to determine accurately. Concerning the latter, the plan would, of course, be subordinate to traffic requirements at all times. Traffic fluctuations and the exi gencies of operation incident thereto might disarrange the plan seriously at times, but the general good effect would not be lost. The chief advantages of the scheme as outlined have been summed up as follows: (1) Material reduction in the cost of fuel is shown to be possible. (2) Improved locomotive service, due to the use of uniform grades of coal. (3) Increased mileage and consequent increased earning capacity of coal cars.

A VAGARY OF THE RAILROAD SITUATION.

If one looks back on the panic periods of this country in their bearing on railroad affairs he finds that the period of 1837 had no such bearing at all simply because at that early date our railroads were practically non-existent. Coming down twenty years to the panic of 1857 conditions were essentially the same because the railroads had not risen to be a great fiscal interest. The two sharp panics of those periods were at bottom financial, with, of course, their shadows on general industry. Very different, as related to the railroads, were the panic of 1873 and the long drag of five years that followed it. By that time the railroads had grown to be a vast interest, and the panic of 1873 was, in fact, rooted in undue railroad expansion which in the two or three years preceding had become a kind of craze. Similarly in the later panic periods, including the present one, the impact on the railroads has been quick and severe. Having grown to a larger size and become closely identified with the industrial energy of the nation, railroads have also been the first to receive the shock. And this is also true probably of any panics to come in future years. We refer, of course, to the steam roads regarded as a great and pretty homogeneous transportation system and as distinguished from the street railways which, in the main, are still localized institutions and outworking their destiny, whatever it may be, under different and more limited conditions as contrasted with the steam lines.

Looking more closely into the panic periods in which our railroads have figured actively one notes, however, between those of the past and the present a sharp distinction. In the earlier panics of 1873 and later down to the present period the railroads, like other great vested interests, have been allowed to recuperate under natural law. It was a hard and inexorable law, but its workings were simple and logical. Credit was contracted, business receded, earnings fell off and the weaker roads went to the wall. There were receiverships, reorganizations and heavy individual loss, sometimes inflicted even upon the conservative investor, though, in his case, apt to be temporary. Combinations of capital and transitory devices like the clearing house certificates, modified and assuaged panic, but they did not affect much the railroad situation which had to work itself out through adversity and pain. But painful as was the ordeal of the railroads it was not intensified by artificial and extraneous agencies, and prosperity re-established itself under a law just as natural as was that which had brought adversity. The railroad corporations had one load, and a heavy load, to carry, but they did not have two loads, and, in a general way, and under the teachings of experience, they could foresee results, brace themselves to bear the burden and adopt the means to alleviate it.

For the first time in our national history one finds now those normal conditions shifted and the railroads in effect singled out from other great vested interests to be the victims not only of economic, but of artificial and man-made law. The man-made law even goes further and repeals or arrests the recuperative statute of political economy. There is no foe of the railroad, however demagogical he may be, who questions the place of the railroad not only as an industrial asset, but also as an element in public convenience and necessity. He would not have to be hard pushed to admit that the railroad is a more important ingredient of prosperity than the great factory. Yet not only does public policy not single out the great factory for attack, but even protects it under the tariff. Here and there in the form of conspicuous combination it becomes a target, but in the main public policy is protective. Not so with the railroad. It must be picked out from the mass of vested interests for assault from every quarter. Legislatures must raid it. State commissions must hamper it. Federal authority, with its far-reaching influence on public policy and temper, must menace it. It may raise wages liberally in good times, but it must be denied the right to lower them in hard times. Fundamental rights of property conceded to the meanest citizens—and to private corporations—must be refused the railroad carrier. The dollar placed in private enterprise is guarded by law, the dollar placed in the public serving railroad must be penalized. Recession of pay and prices is the normal process by which hard times emerge into better times. Yet authority is doing its best to suspend, in the case of the railroads, that remedial process and, unless all precedent misleads us, is thus postponing the recovery.

The times indeed are extraordinary and unprecedented. For the first time in American history, and it may even be said, in the history of nations, great forces are seeking to check or, at least retard the normal remedies of panic and after-panic and administer to the patient medicines not only novel but in their character directly opposed to normal therapeutics. Big trade combinations are declaring that prices must be maintained however low the volume of business falls. The unions, in a somewhat similar combination and mood, are declaring that wages must be sustained even though men be discharged and the profits of the employer still fall; and a great branch of the nation's industry, the railroads, is not merely marked for continuous attack, but refused the primary right of the employer and property owner to help himself. These may be policies that will cure hard times and be panaceas for industrial ailment, but they are of a nature to amaze Adam Smith or John Stuart Mill.

PENALTY LAWS IN THE SOUTH.

We print this week, on another page, an abstract of the principal railroad penalty laws in a group of southern states. The list is very instructive. Most of the penalty laws were enacted during the extraordinary pursuit of state legislation which followed the activity of the national government in 1906, and the schedule perhaps illustrates as well as any other single document the effect which the federal government's methods of invective has had on the minds of state politicians who have seen and remembered the success which has attended this sort of thing in the highest quarters. The plain assumption that the railroads are acting unfairly and that their occasional failures of service are wilful, runs through all this mass of penalty legislation. The tone and moderation of these laws suggests the tone and moderation of the popular tribunal which meets Saturday evenings in the village store. There is no thought of fair play or of giving the railroads a chance to explain or justify their own position. Thus, in Alabama the free time under the car service rules is 72 hours on a large range of commodities, and carriers are not permitted to release cars by unloading carload freight for storage into their own warehouses or into public or private warehouses until $5 demurrage charges have accrued; that is to say, until the carrier has suffered about ten days' delay. If a company enters suit through the federal court, its license to do business in the state is canceled, and the carrier must, to all intents and purposes, insure freight more broadly than any chartered insurance company in the world, since it is illegal for it to enter into any contract limiting its liability for loss or damage to property in transportation, whether or not this loss or damage is caused by act of God or the public enemy. In Georgia, there is a penalty of a dollar per car per day for failure to furnish cars for loading within four days, Sundays and legal holidays excepted; there is a penalty of full damage to be paid by the initial line, regardless of place of damage, for failure to trace freight and advise applicant within 30 days of the cause and place of delay or damage; and there is a penalty of $50 for failure to pay loss or damage claims on intrastate business within 60 days. In North Carolina, the penalty for not furnishing cars within four days of application is $5 per car per day, entirely regardless of the car supply situation, although the North Carolina legislature doubtless knew or was in position to find out that there have been times within the last two years when the Angel Gabriel could not have gotten freight cars for $10 a day.

The discouraging thing about an exhibit of enactments like this is that the state legislatures do not care in the least whether they are unjust to the railroads or not. It is a comparatively simple matter to right law-made wrongs which have been occasioned by ignorance and misapprehension, but it is not so easy to remedy grievances that are the result of direct intention. We feel sure, however, that it will not be long before the most harmful and injurious of these laws are repealed. Wisconsin gave an example of this in the seventies, as everybody knows, and it must always be remembered that lawmakers, however dim their economic vision, may be counted upon to have a perfectly clear sense of the things that make for popularity. Railroad development in some of the states that have been hardest hit by this legislation has received a setback the extent of which cannot yet be realized, but will be seen plainly when capital is again actively seeking investment and turns away from the states where it is treated with conspicuous injustice.

We have already expressed the opinion in these columns that repeal of the most iniquitous statutes will occur before they have time to get to the Supreme Court, and we should be very much surprised if the pendulum of legislative enactment did not swing a long way back from its present position, which is certainly high above the point of equilibrium, on the radical side. Meantime, there is one feature of the situation which must not be overlooked. If the existing lines in some of the most troubled states can contrive to live under the state laws at all, they ought to be able to live without competition, and it may well be that there are areas where the 1907 crop of legislation is preferable to the competition which would surely have come within a year or so if the attitude of the state had been friendly to corporations. This principle has for some time found an example in New Jersey, where the tax requirements are so onerous that new capital keeps away from steam and electric enterprises alike. Thus, after all, it may turn out that the existing lines in some of these southern states will not eventually be hurt as much as they anticipate.

THE LAW OF LATENT DEFECTS.

A recent decision in the courts of the state of New York in which an interpretation is given of the law governing responsibility for mechanical defects of such a nature or so located as to make their discovery an impossibility under any ordinary system of inspection is of peculiar interest to those who have to deal with such matters in railroad rolling stock equipment. An investigation covering the whole range of decisions discloses the somewhat remarkable fact that reliance is placed in nearly every case subsequently decided upon a decision rendered in 1852 in Hegeman vs. Western Railroad Corporation, 16 Barbour, 353, and affirmed on appeal, 13 N. Y. 9, two justices, however, dissenting. The facts may be stated as briefly as possible: Plaintiff on September 9, 1850, was on his way from Greenbush to Boston. Near Hinsdale, Mass., the car in which he was seated was derailed and broken up by the breakage of an axle. Examination subsequently disclosed a firecrack 11 in. inside the wheel and about 16 in. from the middle of the axle, where the breakage occurred. The accident resulted in the death of three passengers and the plaintiff was permanently crippled.

An interesting side issue brought out during the trial was the existence of something known as a safety beam, which it appeared had been in use upon New York and New Jersey roads for some 10 or 12 years. The use of this beam it was said would prevent a broken axle from falling on the track or thrusting up against the car and a car could run a long time with a broken axle. Among the witnesses upon this point were Mr. Bradley, of the Bradley Car Works, and Mr. Bouton, master mechanic of the Watervliet arsenal.

In his charge the judge stated to the jury that defendant was responsible for all defects in the axle whether the car had been built by the railroad company or by an outside manufacturer, and it was for the jury to say whether the defect could have been discovered by investigation and remedied; that if the safety beam were capable of preventing serious results from such an accident it did not necessarily follow that defendant was liable because the device had not been adopted. It was for the jury to say whether defendant had been negligent in this regard. The jury gave a verdict for plaintiff for $9,900.

On appeal, the prevailing opinion held that defendant was responsible for damages if the defect could have been discovered in the process of manufacture by the application of any test known to men skilled in the business. The significant feature, however, of this decision was in sustaining this position in the charge of the trial judge: That although the defect was latent and could not have been discovered by vigilant external examination, yet if it could be discovered by a known test applied either by the manufacturer or by the defendant, the latter was responsible. The dissenting opinions were offered on the ground that the position of making a railroad company responsible for all defects whether discoverable or not was not tenable and it would be dangerous to establish such a rule. Another point of dissent was to the position that defendant was as responsible as if the car had been built in the company's shops. The manufacture of cars is a distinct business and the workmen employed are in no sense servants of the railroad company.

It is of interest to note in passing a citation from an earlier case that "a coach proprietor is liable for all defects in his vehicle which can be seen at time of construction as well as for such as may exist afterwards and be discovered on investigation; if not, he might buy ill-constructed vehicles and his passengers be without remedy." It was affirmed also that the degree of caution required in stage-coaching was not as great as in steam railroading where trains run at a high rate of speed, which, in this case, was shown to have been 25 to 30 miles per hour, or "the ordinary speed of passenger trains." The car was a new one and had been laid up during the two winters of its life because the company "did not want to deface it by putting stoves into it."

In the appellant's brief it was contended that carriers are not insurers and to hold them responsible for latent defects was tantamount to making them insurers. It is an impossibility for a railroad to do all its own work; it must depend upon others and the law will protect it against things which elude human sagacity. If greater care is required than in the case of the stage-coach, the passenger takes the risk for the benefit of the higher speed. The whole charge was characterized as "singularly inaccurate" and as requiring defendant to possess greater knowledge that was available at the time. Nevertheless, the judgment of the Supreme Court was affirmed.

In several other cases, notably in Palmer vs. D. & H. C. Co., 46 Hun, the rule laid down in the Hegeman case was sustained in every particular. In the case cited, the court said: "These cases sufficiently indicate and illustrate the views of the Court of Appeals of this state and of the Supreme Court of the United States with reference to the duty of railroad companies towards the passengers they carry on their trains."

But far more stringent is the doctrine laid down in Alden vs. New York Central, 26 N. Y. 102. In this case the accident was caused by breakage of an axle from a crack so concealed by the hub of the wheel as to be undiscoverable without removing the wheel. The Court of Appeals affirmed the judgment sustaining a verdict for the plaintiff. It adopted the rule of vigilance and care laid down in the Hegeman case, but suggested that the ground of that rule lay not in the negligence of the carrier but rather in that the carrier seems to be an absolute insurer of the passenger's safety.

The Alden case was, however, disapproved in McPadden vs. N. Y. Central, 44 N. Y., and the rule in the Hegeman case reasserted and followed with the limitation that the rule did not apply so as to render a railroad company liable for injury caused by the breaking of a sound rail by reason of extreme cold which could not have been anticipated or avoided by any human foresight.

In Brignoli vs. Chicago Great Western, 4 Daly 182, the defendant was held liable for a broken rail owing to a defective cross-tie. The car in which the plaintiff was a passenger overturned and his shoulder blade was broken without negligence on his part.

While none of these cases is especially remarkable of itself, a mention of them appears to be of value as indicating the closeness with which subsequent decisions have followed the Hegeman case. Notwithstanding the development in all lines of railroading since 1852 when there were less than 10,000 miles of railroad in the country, and when the precedent established by that case was itself supported upon precedents of stage-coaching days, the law so far as it relates to hidden defects in mechanical appliances in railroad equipment appears to have then been established beyond probability of disapproval.

Pennsylvania Railroad.

The Pennsylvania system now includes 11,176 miles of line, of which 6,078 are East and 5,097 West of Pittsburgh and Erie. The gross earnings of all lines East in the year ended December 31, 1907 were $216,000,000, and of all lines West for the same period, $110,000,000. Thus the total earnings of "all transportation companies owned, operated or controlled by or affiliated in interest with" the Pennsylvania were just under $327,000,000, an increase of $31,000,000, or 10 per cent., over the year 1906. Net earnings of all companies were $83,600,000, against $84,400,000 in 1906, a decrease of $700,000, or less than 1 per cent. During the year these lines carried 3,800,000,000 passengers one mile and 37,700,000,000 tons of freight one mile.

The Pennsylvania Railroad proper includes the cream of this immense system. The operations covered by the sixty-first annual report, just issued, are those of the 3,903 miles including trackage rights, directly operated by the Pennsylvania Railroad, of the total 6,078 miles of line east of Pittsburgh and Erie. These returns do not include the Philadelphia, Baltimore & Washington; the Northern Central; the West Jersey & Seashore; the Cumberland Valley; the New York, Philadelphia & Norfolk; the Baltimore, Chesapeake

& Atlantic, the Maryland, Delaware & Virginia, or the Long Island Railroad, all of which are east of Pittsburgh.

The lines directly operated are in five grand divisions. The Eastern Pennsylvania division includes 1,248 miles of line, made up of the main line and branches between Philadelphia and Altoona. The Western Pennsylvania division has 632 miles of line and includes the main line and branches between Altoona and Pittsburgh. The New Jersey division includes 475 miles of railroads, the ferries from Jersey City to Manhattan and to Brooklyn, two miles, and the Delaware & Raritan canal, 66 miles. The Erie division, the old Philadelphia & Erie, has 695 miles and runs from Wilkesbarre and Sunbury to Erie, on Lake Erie. The Buffalo & Allegheny Valley division has 830 miles and reaches Buffalo and Rochester on the north and Pittsburgh on the south. The lines directly operated, and these only, except for the New York & Long Branch Railroad, which is operated under special contract jointly with the Central Railroad of New Jersey and is included, are shown on the accompanying map.

The gross earnings of these 3,903 miles directly operated were $164,800,000 last year, against $148,200,000 in 1906, an increase of 11 per cent. But the Pennsylvania had the same experience as other railroads and operating expenses rose from $101,800,000 in 1906 to $119,600,000 last year, an increase of 17 per cent., which was larger in amount than the gain in gross earnings. Net earnings, in consequence, were $1,200,000 smaller than in 1906. To the 1907 net earnings was added the "other income," mostly income from investments and interest, amounting to $13,800,000, making a total fund of $59,000,000 available. After deducting from this, rentals paid to roads operated on the basis of net earnings, $4,900,000; taxes, $4,000,000, and other fixed charges, $16,600,000, there was a net income of $33,600,000, against $35,700,000 in 1906, a decrease of $2,100,000.

Dividends paid amounted to $21,900,000, against $19,900,000 in 1906. Payments of principal of car trusts amounting to $3,200,000 were made, as against $4,200,000 in 1906. There was a sharp reduction in the extraordinary expenditures, from $8,700,000 in 1906 to $3,300,000 last year, but in addition $2,500,000 was transferred to the extraordinary expenditure fund in each year. The year's surplus was $2,400,000, which was transferred to profit and loss, while in 1906 no part of net income was so applied.

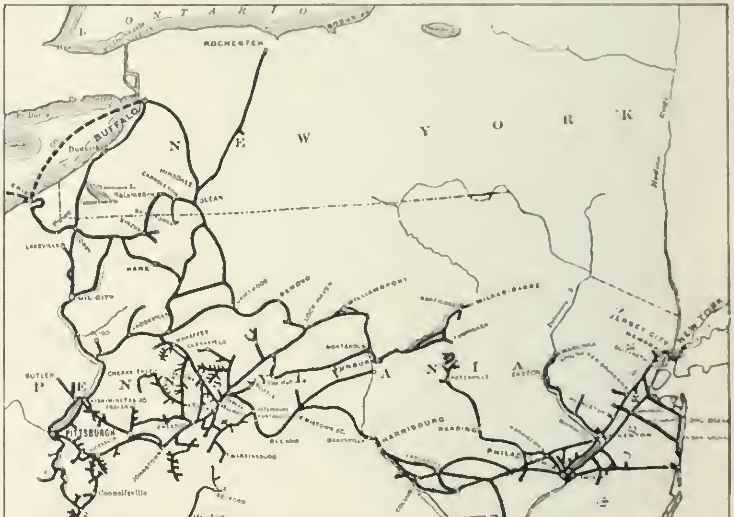
Profit and loss account was also credited with $1,600,000 received as profit from the stock dividend of the Northern Central, adjustment of value of securities owned in roads absorbed, and settlements of sundry accounts. In 1906 profit and loss was increased $15,200,000 mainly through the sale of Baltimore & Ohio and Chesapeake & Ohio stock. It is through this account that the New York tunnel line is being financed. There was $7,000,000 taken from this credit balance for this purpose in 1907 and $13,000,000 in 1906. In 1906 there was also $2,200,000 transferred from profit and loss to the extraordinary expenditure fund. As a result of these various adjustments, the profit and loss credit balance on December 31, 1906, and December 31, 1907, was the same—$24,700,000.

The cost of the New York tunnel extension to December 31, 1907, appears to have been $69,500,000, of which $39,500,000 is capitalized on the balance sheet and $30,000,000 has been charged against income and profit and loss. The present status of the work, as shown more in detail in our Railroad Construction column, is that the tunnels under the Hudson river are finished, the foundations for the station between Seventh and Ninth avenues at Thirty-second street are finished and work on the steel structure of the building has begun, the tunnel under Manhattan Island is nearly finished and two of the four tunnels under the East river have been joined, with every prospect that the other two headings will meet by the end of next month. There have been and will be substantial credits to the cost of the work from the sale of real estate not permanently required. From this source $1,600,000 was received last year, the main item in this amount being the payment by the United States Government for the post office site on Eighth avenue between Thirty-first and Thirty-second streets.

President McCrea sums up the operating results of the year as follows:

"There was a heavy increase in the volume of freight traffic until December, the tonnage and ton mileage for the year showing a large gain and the revenue, an increase of more than 12½ per cent. over the previous year; but there was a material reduction in the gross and net earnings per ton mile. While the increase in the passenger traffic was much below the percentage shown in 1906 over 1905, being but 9.13 per cent. as against 14.41 per cent., the gross revenue therefrom increased barely 4½ per cent., as compared with a gain in 1906 of 14 per cent. over 1905. The expenses, also, were largely increased, the cost per passenger mile showing an increased percentage of nearly 13 per cent. and the cost per train mile an increase of nearly 17 per cent. As a result there was a reduction of nearly one-third in the net earnings per passenger train mile; and while this was due in part to a more accurate distribution of expenses as between freight and passenger traffic, it was clearly shown that the lower fares which prevailed during part of the year had not stimulated traffic to the extent necessary to offset the loss of revenue and the higher cost of operation due to the increase in wages and cost of supplies. It may be noted that the average rate received on the entire system during the year was less than two cents per mile."

The detailed operating expense accounts are made up in a peculiar way, as a result of the changes in classification made by the Interstate Commerce Commission on July 1, 1907. Each sub-heading which is the same under the old and the new classification, is shown for the full year. On the other hand, sub-accounts which were changed by the new classification are shown under the old heading for the first half of the year and under the new heading for the second half. For instance, under maintenance of way, engineering and superintendence covers one-half of the year and superintendence the other half. Under maintenance of equipment, depreciation accounts are shown for the second half of the year. Depreciation on steam locomotives amounted to $275,000, on passenger train cars $267,000 and on freight train cars $2,000,000. Conducting transportation has disappeared, and in its place are the two accounts, traffic expenses and transportation expenses abbreviated in the general summary to "traffic" and "transportation."



Pennsylvania Railroad.

Lines East of Pittsburgh and Erie directly operated.

Maintenance of way per mile operated cost $5,192 per mile, against $4,378 in 1906; repairs, renewals and depreciation of equipment (no renewals of steam locomotives) cost $3,315 per locomotive, against $2,652 in 1906; $1,381 per passenger car, against $1,144 in 1906, and $118 per freight car, against $103 in 1906. There were 7,728 cars bought during the year, which with 2,540 other cars bought for the Lines West were provided for by $11,900,000 of new car trust securities. At the close of the year the Pennsylvania Railroad owned 3,210 locomotives, 2,070 passenger train cars and 128,024 freight cars. No new locomotives or passenger cars were acquired during the year, but the number of freight cars available for service rose from 119,036 on December 31, 1906.

One of the most remarkable results shown is an increase of over 40 per cent. in the tonnage of the combined Eastern and Western Pennsylvania divisions, which carried 142,000,000 tons, against 101,000,000 tons in 1906. The increase in tonnage carried by the five grand divisions was 12 per cent., and the increase in ton mileage 16 per cent., which was handled with an increase of only 7 per cent. in freight train mileage.

Mr. McCrea sums up the company's policy for the immediate future and the present business situation as follows:

"In pursuance of the policy announced in the last report, the expenditures for the year were confined almost exclusively to completion of work actually under way; and it is gratifying to note that with the exception of a part of the relief freight lines for which no present necessity exists, substantially all the improvements outlined in the report for 1902 as essential to put the road in condition to meet the legitimate demands of its traffic have been completed. As a result, the average daily mileage of freight cars moved over its lines increased about 20 per cent. between 1903 and 1907. The expenditures for the present year will be practically confined to finishing the work now in progress on the main line and to the tunnel extension to and through New York and the terminal station in that city.

"The prosperity which had existed for a number of years in all branches of industry and which had so exceptionally increased the traffic on the railroads met with a severe check in November last, which is now largely affecting the revenues of the system. While a number of causes seriously disturbed public confidence and thus brought on the financial panic which has so sharply affected the business interests of the country, an important one undoubtedly was the fear that, as the result of recent federal and state legislation, the regulation of the railroads had approached so nearly to an effort to control their management and revenues, that the investments therein were not assured of that protection to which they are justly entitled. Eventually, it may be assumed, the questions that arise will be fairly adjusted, but in the meantime the railroads have to face the loss of revenue consequent upon the enforced idleness of a large portion of their equipment, while to a proportionate number of their employees this has necessarily brought about either an entire loss of employment or a material reduction in the hours of labor."

A summary of Mr. McCrea's remarks about the various construction projects of the company and its affiliated lines will be found in the Railroad Construction column.

The following table shows the operating and income results of the Pennsylvania Railroad, including only the lines directly operated:

	1907	1906.
Mileage worked	3,903	3,897
Freight earnings	$123,826,165	$109,960,888
Passenger earnings	32,623,889	31,231,338
Gross earnings	164,812,826	148,239,882
Maint. way and structures	20,265,845	17,060,498
Maint. of equipment	31,721,614	26,201,245
Traffic expenses	2,034,705	1,772,012
Transportation expenses	61,835,024	53,504,168
Operating expenses	119,607,348	101,805,641
Net earnings	45,205,477	46,434,238
Other income	13,794,106	12,784,262
Net earnings and other income	58,999,583	59,218,500
Net income	33,575,056	35,674,301
Dividends	21,908,436	19,869,661
Principal of car trusts	3,150,694	4,246,039
Extraordinary expenditures	3,260,651	8,701,475
Transferred to extraordinary expenditure fund	2,500,000	2,500,000
Year's surplus	2,351,424	....
Applied from profit and loss to New York tunnel line	7,000,000	13,000,000
Applied from profit and loss to extra. expenditure fund.	....	2,200,849

NEW PUBLICATIONS.

Air-Brake Catechism. Twenty-first edition; revised and enlarged. By Robt. H. Blackall. New York: Norman W. Henley Publishing Co. 375 pages; 5 x 7 in.; 131 illustrations. Cloth. Price, $2.00.

Perhaps the most salient feature of this book is the fact that the text and illustrations are confined exclusively to apparatus made by the Westinghouse Air-Brake Company. The discussion is confined to practice on this side of the Atlantic, where the author has gained his experience. As its name indicates, the work is in the form of a catechism, and the questions and answers are couched in simple language, readily understood even by those who are not in the habit of acquiring information from books. In its arrangement the catechism follows the chronological order of the development of the brake itself, starting in with the very simple construction of the straight-air design, as first introduced, and proceeding through the plain automatic, the quick-action, the high speed and the new "K" triple valve that is now superseding the earlier form of quick action triple valve. In this way the reader is led on from the simple to the complex, in construction and action, just as the railroads have been led on in the use of the air-brake itself. Thus the book represents the evolution of the brake, and it would be exceedingly difficult for a novice in any other way to grasp the complexities of the operation of the latest developments, though it becomes comparatively easy to do so when led up to it, step by step, provided, of course, that close attention is given.

The book deals not only with the air-brake mechanism and operation in themselves, but takes up the auxiliary apparatus, such as the brake slack adjusters, the hanging of brake-shoes, the water brake, the Sweeney compressor, the air signal and the calculation of leverages.

The general description of the apparatus is either followed or accompanied by instructions regarding the operation and maintenance, including inspecting and testing, together with an outline and indication of the principal causes of trouble with the system. Here much detail must necessarily be omitted, otherwise the one volume would be expanded to a dozen or more, as would be indicated by a reference to the reports of the Air-Brake Association. Still there is enough to serve as a reliable guide for practical, everyday work, whether on the engine, in the cars or on the track as inspector. As a whole, the book serves as a striking object lesson of the magnitude and importance of this branch of the railroad service; a branch which, in the eyes of the general public, is only seen in a vague and indefinite way and then usually in connection with a disaster.

The weak point in the book is one common to many of its class, and it lies in the index. This is incomplete, in that some things in the book are not mentioned at all, while others would be made much more available by a better cross-indexing. If a book is to be used for quick and ready reference the short-comings of the index will quickly make themselves known. With this exception, however, the design and arrangement of the book is to be heartily commended.

Table of Quantities for Preliminary Estimates. By E. F. Hauch and P. D. Rice. New York: John Wiley & Sons. 92 pages; 4 in. by 6½ in.; cloth. Price, $1.25.

This book contains a series of tables of quantities contained in 100-ft. sections with roadbed widths of from 12 ft. to 32 ft. varying by 2 ft. and for a width of 35 ft. These are worked out for side slopes of ¼ to 1; ½ to 1; ¾ to 1; 1 to 1; 1¼ to 1, and 1½ to 1. These are followed by tables of toe slopes for the same widths of roadbeds and for slopes of 1¼ and 1½ to 1. In all cases the quantities are estimated for heights running from 0 to 50 ft. at 1 ft. intervals and for transverse slopes ranging from level to 35 deg. on 5 deg. differences. At the back of the book there is a table of cubic yards based on calculations made from the sum of end areas for lengths of 100 ft.; a table of decimals of a mile expressed in feet; one of acreage for a right-of-way 100 ft. wide; one of chains reduced to feet; another of feet reduced to decimals of a chain, and a table of fractions of an inch in equivalent decimals.

The tables have been prepared to meet the requirements of the locating engineer, and the calculations were made for each successive value of the height by means of differences that checked with the calculation of the final height, so as to avoid all possibility of mistakes. In making these calculations, five (and in some cases seven) place logarithms have been used, and it is believed that the tables are correct to the nearest cubic yard.

Statistical Tables. Information Relative to American Railroad and Industrial Companies, and Details of Securities Dealt in on the New York Stock Exchange. 84 pages; 3¼ x 5¼ in. Published by Spencer Trask & Co., Bankers, New York. 1908 edition.

The bankers who prepare this handbook for distribution, free of charge, to their customers and prospective customers, have done a thorough job in small space. The tables show at a glance the principal points on which an investor wants information, and cover a wide range of investments.

The Men Who Sell Things. By Walter D. Moody. Chicago: A. J. McClurg & Co., 1907. 295 pages; 5 x 7 in.

This breezy little book is described as containing the observations and experiences accumulated by the author in over 20 years as traveling salesman, European buyer, sales manager and employer. It is exceedingly easy to read, and in a rather slangy, narrative style, brings out a good many ideas which ought to be helpful to young salesmen.

Late Trains.

New York, March 2, 1908.

To the Editor of the Railroad Gazette:

There is an unconfirmed rumor that the New York Public Service Commission of the Second district is going to try to cure that crying evil, the late train. Whether with this end in view or not, the railroads have recently been ordered to make an itemized report each month of the number of delayed trains, the length of the delay and the causes. Primarily this is a report of engine failures, and there is a list of 53 items classified under the general headings of heating or hot bearings, steam failures, leakages, breakages and miscellaneous causes. The inference to be drawn from the arrangement of the report is that engine failures in one form or another, are responsible for the majority of train delays. But in order that the showing may be complete, there are three causes of delay that, under a rigid interpretation, may be made to cover all others outside of the engine failures. These are heavy trains, terminal, and other causes. These reports will necessarily throw light on train delays and the reasons for them and certainly there is need for some such independent gathering of the facts. This evil is surely capable of being remedied. The rolling stock in use is as a whole not in such a dilapidated condition that it cannot be run over a division without a breakdown. If, then, it can do this, the trouble must be looked for in a schedule faster than the engine can make, in such defective terminal facilities that trains cannot be run through the yards, or in inadequate train and station crews for expeditiously handling passengers, baggage and express. The natural remedy would be either to cut the schedule speed down till it comes within the limits of the facilities or to increase the facilities. As matters stand, except on a few roads, notable exceptions, it is the general expectation of the public that trains will be late. People merely wonder how late. If the Public Service Commission can reform this state of affairs it will have done a very great thing toward establishing itself in public favor. It will have brought about a lasting and substantial service to the railroads as well, by removing one great cause of irritation that has contributed much toward the unpopularity of railroad corporations.

TRAVELER.

The Subway Car.

[There was published in the *Railroad Gazette* of February 28, 1908, part of a report to the Public Service Commission for New York City by Bion J. Arnold, Consulting Engineer, on subway cars. This part of the report covered the general discussion of the problem of handling the traffic in the present subway operated by the Interborough Rapid Transit Company, a description of the recommended type to which the present subway cars should be converted to get maximum efficiency, and Mr. Arnold's general recommendations. The rest of the report, which follows, is a discussion of the various types of cars which can be used in rapid transit work and the various kinds and arrangements of seats in them. In order to start the argument intelligently, the brief summary of the desired requirements for a successful car and of the classification of the various cars is repeated.—EDITOR.]

TYPES OF SUBWAY CARS.

A successful car for the present subway should possess as many as possible of the following requirements:

1. Separate entrances and exits.
2. A space which can be cleared so as to be ready to quickly receive the passengers boarding a car.
3. Convenient means of circulation inside a car.
4. Standing-room space contiguous to the exits.
5. As many cross-seats as practicable.
6. Exit and entrance doors sufficiently removed from each other to allow for the car's stopping convenient to guiding rails on the platforms.
7. Doors located so as to minimize the danger from open spaces at curve platforms.

The various cars may be classified in accordance with the number of doors in the sides of the cars as follows:

Cars with central side doors and end doors.
Cars with two quarter side doors.
Cars with three doors near center.
Cars with multi side doors.
Cars with double doors near ends.

Each one of these types may have seats of either the longitudinal, the cross "back-to-back," or of the "walk-over" style, or a combination of two or more styles, as will be shown more in detail as the cars are described.

CARS WITH CENTRAL SIDE DOOR AND END DOORS.

It has often been suggested that cars provided with an additional door in the center of each side would at once do away with the conflict of passengers which now takes place at the present end doors of the cars, and at the same time, by providing additional door space, materially reduce the station waits.

The present cars could be altered to provide central side doors. I have made a number of studies of details of construction and general arrangement of seats applicable to a car of this type. I find that at present the all-metal cars can be rebuilt at an expense of $2,000 per car, and the composite cars altered at a cost of $1,500 per car. A drawing of the present car before and after being altered to a car with central side doors is shown in Fig. 1. These figures contemplate the reinforcing of the sides of the car and the trussing of the under frames in such a way as to leave the changed cars practically as strong as the present car. The weight in both cases will be slightly increased by the introduction of the central side doors in the present car.

Cars of this type have been in use on the Brooklyn Bridge shuttle trains for many years. They have recently been introduced for subway and elevated service in Boston and Philadelphia, and have been adopted by the Hudson & Manhattan Railroad for use in the new tunnels between Manhattan and Hoboken. The Hudson & Manhattan cars are fireproof cars with central side doors and at the same time weigh less than the present subway end-door cars, demonstrating that, if desired, future cars can be built with central side doors without excessive weight and at the same time possess the fireproof qualities desirable for subway cars.

In the Brooklyn Bridge shuttle-train service, the cars were unloaded to one platform and then loaded from a separate platform, thus avoiding the conflict of passengers, which is such a noticeable feature of the subway. The advantage of the center door in this case was simply that of additional door space, and for the Brooklyn Bridge conditions the location of this extra door space in the center of the car side was most advantageous. At the time the shuttle trains were abandoned on account of running the Brooklyn Elevated trains directly into the Manhattan terminal, the lack of this extra door space in the present elevated cars was decidedly noticeable, emphasizing the fact that the cars of the single-end door type are not adapted for handling the New York City rush-hour crowds. No difficulty in connection with maintaining a circulation of passengers was experienced with the central door cars because of the separate loading and unloading platforms,

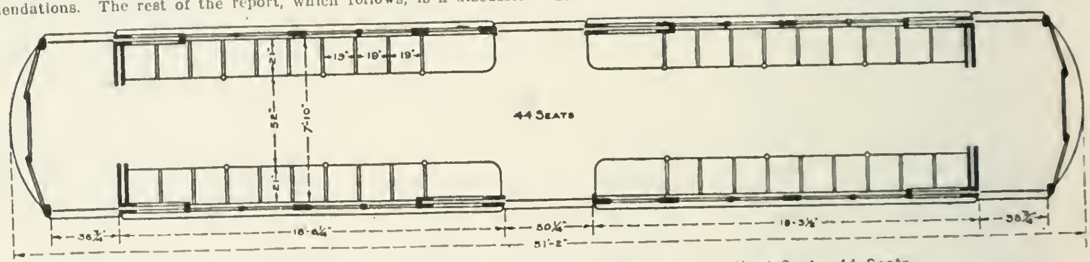

Fig. 2—Car With Central Side Door and End Doors. Longitudinal Seats, 44 Seats.

so that little can be learned from the operation of these cars on the Bridge that can be applied to the study of the car problem of the present subway.

In Boston conditions are more nearly similar to the subway service, although the excessive transfer of passengers at the stations is lacking. In many stations, however, passengers now enter and leave the cars, using the same station platform, and, in order to avoid the conflict between these two streams of passengers, an effort was made, when the central-door cars were first put in commission in Boston, to set up a circulation by making it the rule for passengers to enter this car at the end doors and leave by the center door. Signs were posted in the cars, and at the same time the car guards and station attendants were instructed to carry out this regulation, but the effort has proved futile. It has been found that the Boston passengers could not be controlled sufficiently to maintain this much-desired circulation. Some passengers would persist in getting off through the end doors, while others would insist on getting on the cars through the central doors, thus causing considerable annoyance to passengers who were endeavoring to obey the rule, and ending generally in confusion. The operation of the cars in actual practice, therefore, has finally resulted in partially reverting to the old plan of allowing passengers to leave and enter the same door. Under these circumstances the extra door in the side of the car has reduced the conflict of passengers by providing additional door area, resulting in somewhat decreasing the station waits, although the time of these station waits has not been reduced much below that found in the present New York subway.

With the Boston experience in mind, it is hard to see how the car of the central side-door type would greatly relieve the New York subway conditions, on account of the usual excessively congested condition in the cars during rush hours. When a passenger boards one of these crowded cars with the intention of getting off at the next station, he should not be compelled to push himself through the standing passengers in the car in the short time which it takes to run between stations, and even if this circulation in the car could be maintained, the movement of the passengers from the end door to the central door would become an objectionable feature, causing nearly as much discomfort to the passengers and delay to the trains as the present method of operation with the single end doors. It would, therefore, seem that to attempt to compel all passengers to maintain circulation by entering the end doors and leaving by the central door would not be effective under the congested condition of the present subway.

The Hudson & Manhattan cars will operate under conditions very similar to the Brooklyn Bridge terminal service; that is, a large majority of the passengers will get on the cars at the stations at one end of the line and get off at the stations at the other end. In such service it is not essential to maintain a circulation of passengers in the car, as the transfer privilege is not a factor to be contended with. Under these circumstances, the central side door, cutting down as it does the average length of time required by a passenger to reach a seat, and at the same time furnishing a wider door space, will add materially to the comfort and speed with which the passengers can be handled. The successful use of the central side-door car in terminal work, however, does not furnish a precedent which demonstrates that this type of car

ever, are not available for use with the present subway car, and the introduction of an additional door in the center of the present car would therefore mean the use of a sliding platform at a number of the stations where the cars stop at curved platforms of which the edges next to the car are concave.

The present platforms have been built of sufficient length to serve only one door of each end car of each train, and the end cars therefore lap over the end of each platform. To get the full benefit of the introduction of central doors in the sides of the cars, it would be necessary to extend each platform at least 50 ft. There are no difficulties, however, in accomplishing this extension, except the matter of expense, which would be considerable, on account of the inconvenience of carrying on the work and at the same time keeping the subway trains in operation, but this expense and inconvenience could not, in my judgment, be justified by the advantages gained.

With the central side-door car it would be expected that the train guard, who now opens and closes the doors from his position between two cars, would experience difficulty in operating the addi-

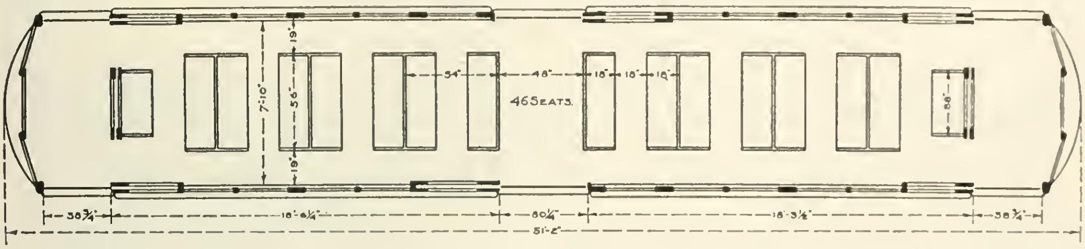

Fig. 3—Car With Central Side Door and End Doors, Using Present Subway Car Body. Cross Seats Back to Back With Two Aisles, 46 Seats.

would be satisfactory under subway conditions, whereas the failure of the center-door car on the Boston subway to reduce the length of stop to much less than the time required in the New York subway even with the present end-door cars, does not furnish any encouragement toward rebuilding the present subway cars so as to provide them with central doors.

The difficulty of operating the central side-door car in the present subway with curved platforms at many stations has been often pointed out by the subway officials. There is no doubt that the use of these curved platforms, even with the present type of car, is a source of danger and the cause of considerable delay, both of which could have been avoided if the platforms had been built with straight edges.

The stations at which the curved platforms would give trouble with a central door in the side of the car are shown by the follow-

tional center doors, particularly during rush hours, but as station attendants are now provided at express stations for handling passengers at times of heavy traffic, this difficulty should not be serious.

Several possible arrangements of seats with a central side-door car are shown in the accompanying drawings. The number of seats above the established minimum of 40 indicates at once the increase over the present seating capacity secured by each car.

CAR WITH CENTRAL SIDE DOOR AND END DOORS.
Figure 2.
Longitudinal Seats.
(44 Seats.)

The seating arrangement in this car is similar to that used in the Hudson tunnels, the Boston and the Philadelphia subways, and the Brooklyn Bridge cars. Side doors can be introduced in the

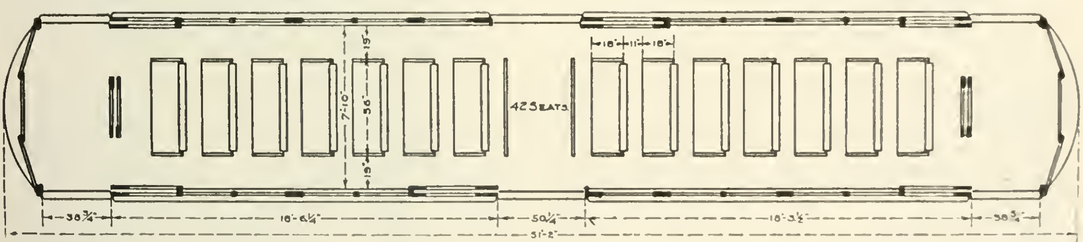

Fig. 4—Car With Central Side Door and End Doors, Using Present Subway Car Body. Cross Seats of "Walk-Over" Type With Two Aisles, 42 Seats.

ing table, which also gives the minimum radius of the platform curves and the width of the open spaces at the center of the car between the platform and side of the car:

Station.	Minimum radius of platform curvature.	Width of spaces bet. car and platform at center of car.
City Hall	147 ft.	26 in.
South Ferry	191 "	24 "
Fulton St.	250 "	16 "
Brooklyn Bridge	410 "	12 "
Worth St.	480 "	10 "
14th St.	485 "	10 "
Times Square	452 "	11 "
177th St.	470 "	10¼"

At many of these stations, if a central door car were used, it would be necessary to provide a sliding platform similar in operation to the ones used in the Boston subway, and also at the South Ferry station of the Manhattan Elevated. In future subways it is possible to obviate the necessity for these sliding platforms either by avoiding the use of a curved platform or by designing the under framing of the car in such a way that the station platforms could project under the car body. These solutions, how-

present subway cars, as indicated by Fig. 1, which shows the plan of the present car altered to a car with a central side door.

This design contemplates the removal of all cross seats in the present car. A number of partitions can be placed between the seats, as is done in the Hudson tunnel cars, which will compensate in a degree for the removal of the cross seats. The vertical hand rods can be introduced, which will be more convenient for the support of standing passengers than the usual straps. With the circulation idea maintained, the distance which each passenger must move in getting to and from a seat is the same in every case, so that with this car all passengers are treated exactly the same, and there is no advantage of position or comfort to be secured by crowding.

This car allows the most effective arrangement of seats and standing room that can be devised. All seats are equally good, thus removing the objection of having three kinds of seats, as found in the present subway car. The rates of acceleration and retardation in the subway, although rapid, are accomplished smoothly, and very little fault can be found with longitudinal seats, although it must be admitted that seats of this kind are not as popular as cro[illegible] seats.

CAR WITH CENTRAL SIDE DOOR AND END DOORS
Figure 3.
(Using Present Subway Car Body.)
Cross Seats Back to Back with Two Aisles
(16 Seats.)

This car combines a car of the central side door type with the style of seating used in the Illinois Central suburban car Two seats more per car than is provided by the longitudinal seat plan are secured by this arrangement, but at a considerable sacrifice in the efficiency of the standing room. The location of the standing room in the center of the car next to the exit will have a tendency to make passengers "move up in the car." The backs of the seats at this point will give something solid to lean against, thus making this standing space somewhat more comfortable than in the longitudinal seat car.

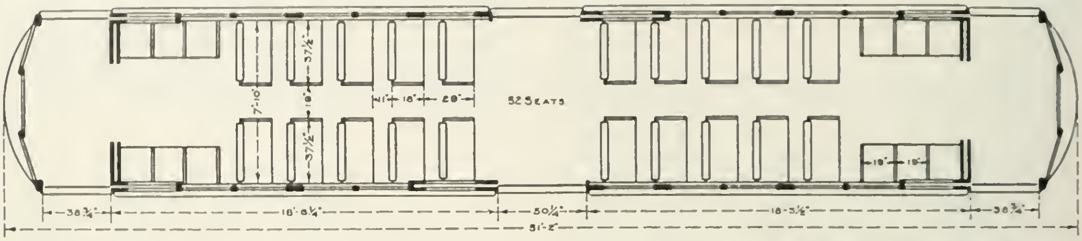

Fig. 5—Car With Central Side Door and End Doors, Using Present Subway Car Body. Cross Seats of "Walk-Over" Type With One Aisle, 52 Seats.

Half of the seats in this car "ride backward," and this may be considered objectionable by some passengers. In the subway, however, riding backward is not as uncomfortable as in a car running in the open. In the subway the eyes are occupied with objects inside the car, while in a surface or an elevated car a disagreeable sensation may be caused to a passenger riding backward by looking at objects which are receding from him. Owing to the use of seats of the "back-to-back type" on the present subway cars, on many of the elevated cars, and on Pullman coaches, the public is becoming educated to ride backward, and the fact that seats of this type do not involve turning over at stub-end terminals gives this arrangement quite an advantage from an operating standpoint.

Owing to the narrowness of the aisles this car is not well adapted for the easy circulation of passengers during rush hours.

CAR WITH CENTRAL SIDE DOOR AND END DOORS.
Figure 4.
(Using Present Subway Car Body.)
Cross Seats of "Walk-Over" Type with Two Aisles.
(42 Seats.)

In this car all seats are arranged so that passengers can "ride forward," which will make it necessary for the train guards to turn the backs of the seats at all stub-end terminals. It will be necessary to limit the space between seats to 29 in in order to provide a central standing room space as well as a cross-over aisle at each end of the car If a greater space between seats is allowed, either this standing room must be reduced and the aisle removed, or some of the seats sacrificed. In any event the car cannot be made to compare favorably with the "back to back" cross seat type.

To make the center seat of a bank of three seats acceptable, it must be made easy of access and egress, as the passengers naturally take the outside seats first, which makes it inconvenient to get in and out of the center seat To use the "walk-over" type of seats therefore, with two aisles, would practically mean a reduction of seating capacity of this type of car to 36 seats, instead of the 42 seats, shown in Fig. 3. The inefficient use of room, therefore, with the "walk-over" cross seats and the extra care required for the operation of seats of this type are objections which would prevent the adoption of such a car.

CAR WITH CENTRAL SIDE DOOR AND END DOORS.
Figure 5.
(Using Present Subway Car Body.)
Cross Seats of "Walk-Over" Type with One Aisle.
(52 Seats.)

If a single aisle is used a very satisfactory seating capacity with the present subway car fitted with central side doors can be obtained by using cross seats of the "walk-over" type, spaced in the car without reference to the present windows. The seat spacing can be rearranged much better with the seat of the "walk-over" type than with a seat of the "back-to-back" type, as the former is not required to fit the framing of the car

The average passenger appears to prefer a "front-facing" seat, and this car provides the maximum number of seats of this kind If a sufficient number of cars could be passed through the subway to keep the standing passengers down to 50 passengers per car, there is no doubt that a car of this type would give excellent satisfaction, but as soon as this car is called upon to carry 100 passengers standing in addition to 52 seated passengers, the congestion in the long, narrow aisle will slow down the movement of passen-

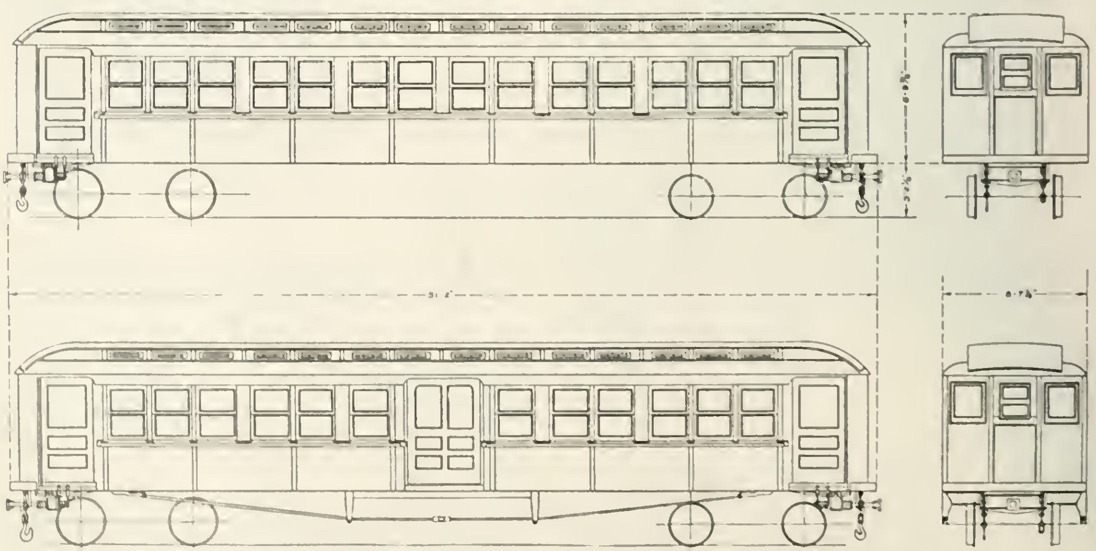

Fig. 1—Present Car Before and After Being Altered to a Car With Central Side Doors.

gers inside the car, and the car would then unload slowly and neutralize the advantages gained by the introduction of the central door.

CAR WITH TWO QUARTER SIDE DOORS.

On roads where the traffic is not as heavy as in the subway, a type of car with two doors, each located about one-fourth the length of the car from the end, is sometimes advocated. This type of car would have as many doors as the present end-door car, but the doors dividing the car into quarters would give the quarter-door car the advantage of providing the shortest average distance from the door to the seat. This car would therefore cause the passengers to occupy the center of the car and thus use the entire length of the car more effectively than it is now used in the present end-door type.

With cars of this type, each door should be of double width, if it is to accommodate subway traffic, so that two streams of passengers could pass through the doors at the same time; that is, at each quarter of the car there would be practically two doors. The circulation may be provided for by using one set of doors as entrances and the other set as exits. There would be no objection to a division post in the center of the double door with this type of car, as the door openings are large enough to require two separate doors, each of which could close toward the dividing post, and thus do away with the danger of a sliding door opening past the middle post. Owing to the distance of the doors from the end of the car the same difficulties at curved platforms would be met that are encountered with the center door car.

The location of the train guards would be a problem with this type of car, as these guards could not work to advantage from between the cars as at present. If the guards are moved into the car their most effective location would be at the center of the side of the car, from which position they could not only control the movement of the doors but also encourage the circulation of the passengers from the rear toward the front exit door.

CAR WITH TWO QUARTER SIDE DOORS.
Figure 6.
Longitudinal Seats.
(44 Seats.)

It would be difficult to alter the present car frame so as to introduce the wide doors shown in Fig. 6 without making the car considerably heavier than at present or sacrificing its structural strength, and this latter expedient would not be advisable.

Except for the fact that all the passengers entering one car must gather at one place on the platform, and that, therefore, the inevitable crush would take place in loading, this type of car has many advantages. This car, however, would work much better during non-rush hours than during rush hours. It would be difficult to maintain a circulation of passengers in one door and out the other as soon as the space in the car between the doors became filled with standing passengers. As soon as passenger on the platforms desiring to enter the car became blocked at a time when the exit doors were empty and open, there would be a rush to board the car through the exit doors, as has been proven by the experience with the Boston public. The only way to control the circulation with this car would be by means of platform railings. At stations where it is desirable to divide the Broadway passengers from the West Farms passengers, as is now done at Grand Central, this type of car would not lend itself to a satisfactory division of the platform space, as the doors would bring the passengers leaving one train in conflict with passengers on the platform waiting for the next one.

CAR WITH QUARTER SIDE DOORS.
Figure 7.
Cross and Longitudinal Seats.
(48 Seats.)

A certain number of cross seats could be introduced in the quarter-door car, and these cross seats could be placed to advantage in the ends of the car. Such an arrangement would leave the central part of the car free, so as to provide the two open standing spaces contiguous to the entrance and to the exit doors. The location of the cross seats with the one central isle at both ends of the car leaving the two standing spaces near the doors connected by a broad aisle between the longitudinal seats in the center of the car, is an arrangement which should materially assist the circulation in the car from entrance to exit. Passengers who are slow in leaving the cross seats in the rear of the car would no doubt have some trouble in reaching an exit, as they would encounter the stream of entering passengers.

Either type of cross seat could be used with this car, though there is some preference for the "back-to-back type," as the back of such seats would present a substantial support convenient to the door openings. The vertical post idea could be advantageously used to make the standing room in this car comfortable.

If future subways could be built sufficiently in advance of the demand for them, this type of car could be used to good advantage, and cross seats could be substituted for longitudinal seats. Under present conditions, however, there would be a temptation to move in the other direction and fold up the longitudinal seats during rush hours, thus providing increased standing capacity.

CARS WITH THREE DOORS NEAR CENTER.

The objections to a car with a central side door, on account of the difficulty which might be experienced by the train guard in controlling the center door from his position between the cars, could be removed by locating the end doors nearer a central door, thus providing practically a large door in the center of the car with two smaller doors, one between the center and each end of the car. This arrangement would also be an improvement over the quarter-door car, as with three doors the moving passengers would be divided into three groups instead of two.

This car should be provided with a separate guard for each car, and this guard should be located so that he could see along the side of the car in one direction, and thus be in a position to quickly close all doors at once.

A circulation with this car can be set up in either direction. In maintaining a circulation, however, this car would not have the advantage of a space such as a platform which could be cleared of passengers while moving between stations, so as to provide an

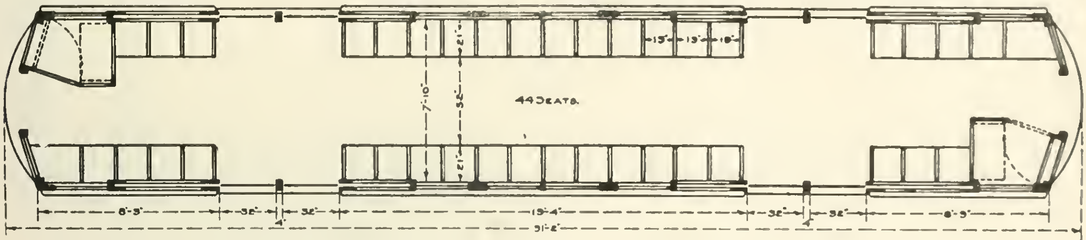

Fig. 6—Car With Two Quarter Side Doors. Longitudinal Seats, 44 Seats.

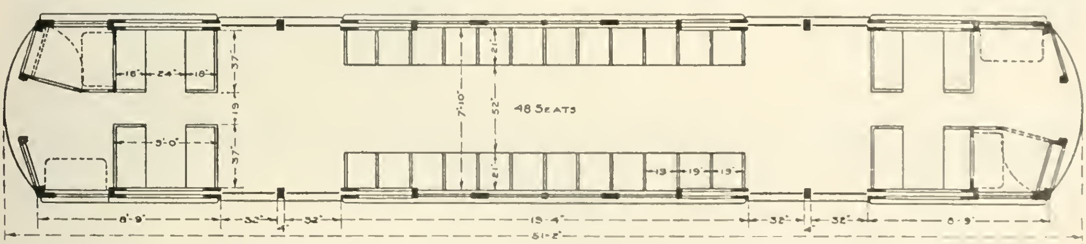

Fig. 7—Car With Quarter Side Doors. Cross and Longitudinal Seats, 48 Seats.

opening space for the entering passengers, as with cars of the end-door type.

The door openings being on the center and near the quarter lines of the car, would lend themselves conveniently to an effective system of platform guard rails, but the center door would be a disadvantage at curved platforms.

CAR WITH THREE DOORS NEAR CENTER
Figure 8.
Longitudinal Seats.
(44 Seats.)

This car is similar to the present end-door car fitted with an additional center side door, with the exception that the end doors are located much nearer the central door. The nearer these end entrance doors are brought to the central exit door, the easier will it be to maintain a circulation in and out of the car through the separate doors.

The location of the end doors at the quarter division points of the car, or even nearer to the central door, is practically the only way that the central door can be used with success in the subway, as a comparatively easy means of reaching the exit must be provided. Otherwise a passenger boarding a car when it is crowded will either find it impossible or will refuse to crowd his way through the standing passengers in the car in order to reach the regular exit, and will insist on leaving the car by the door he entered. As soon as one exemption is allowed to the rule of "in one door and out the other," confusion will at once take place, and the advantage of having the passengers move together in a predetermined way without hesitation will be lost.

This car lends itself to the longitudinal seat plan throughout its length, as there is not enough space in the ends of the car for cross seats, and it would be a mistake to limit the connecting space between the doors by the introduction of an aisle or aisles serving cross seats.

CAR WITH THREE DOORS NEAR CENTER.
Figure 9.
Combination of Cross and Longitudinal Seats.
(44 Seats.)

In order to make room for cross seats in the ends of a car of this type, and at the same time provide the shortest distance possible between the entrance and the exit doors, a large double door may be placed in the center of the car, to be used for an entrance, and two smaller doors at each side to be used for exits.

The circulation in this car would be in the opposite direction to that shown with any of the other cars. The passengers would gather at one place on the station platform ready to enter this car, and would quickly pass through the large double doors. The passengers leaving the cars from the cross seats would not encounter a stream of entering passengers.

The seating capacity of this car is liberal, and the location of the standing room is convenient and efficient. All the doors can be controlled by a guard centrally located where he can see the moving passengers, and to a large extent control their movements.

The troubles with the curved platforms, and the structural difficulties of adapting the present car frame to this design, are serious disadvantages to the use of a car of this type with the present subway.

CARS WITH MULTI SIDE DOORS.

Cars of this type are in successful use in the suburban service of the Illinois Central in Chicago. These cars are 72 ft. long over all, and 10 ft. 6 in. wide over the sheathing. There are 12 sliding doors on each side, opening on a level with the platform, and two doors on each side, opening to steps which are used at stations where there are no high platforms. There are end doors, so that passengers may pass from car to car in the train, and the cars are not provided with extension platforms.

The doors are operated by the train guard from the inside of the car, the operating mechanism being designed so that when the car stops at the station platform the train guard on each car unlocks the doors by means of a single wheel, leaving the doors to be opened by the passengers. Before starting from the station the movement of the operating wheel by the guard in the reverse direction closes the doors which have been opened, and at the same time locks all the doors. When the edge of the door is within 3 or 4 in. of the jamb it stops, and then moves slowly forward to the closed position, the purpose of this being to allow any passenger who may be caught in the door to move aside. An electric signal apparatus is connected with the doors so that a signal is automatically transmitted to the engineer when the last door in the train is closed.

Seats are provided for 100 passengers, 50 facing in each direction, and there is an aisle on each side of the car between the seats and the doors so that passengers entering any door may pass down the aisle to any seat. The seats were originally all of wood, but were found to be uncomfortable, and were changed to rattan. In general, this car has given satisfaction, the principal objections apparently being in regard to the size and the shape of the seats and their arrangement in the car. Some objection is also made to the lack of ventilation in the summer. The problem of heating the cars in winter has not proven to be a serious one, as ample steam coils taking steam from the locomotive are provided under each seat. Under subway conditions it would be better to have the door mechanism designed so as to open all the doors simultaneously, as some delay is now occasioned by passengers hesitating to open the doors.

THE MULTI SIDE-DOOR CAR AND THE PRESENT SUBWAY.

The present length of the subway cars would allow for a maximum of 8 side doors, or for four times as many doors as at present. The present end doors, each about 38 in. wide, or a total door area of 76 in. for each side. With 8 side doors, each 25 in wide, there would be a door opening of 200 in. per car, or nearly three times the door space provided in the present car. The best that could be expected of the multi side-door car, as far as reducing the time required at present for unloading and loading the passengers is concerned, would be to have this time cut down to one-third the present amount.

In order to determine the efficiency of this type of car I have had a large number of observations made of the Illinois Central car in actual operation. The density of traffic on the Illinois

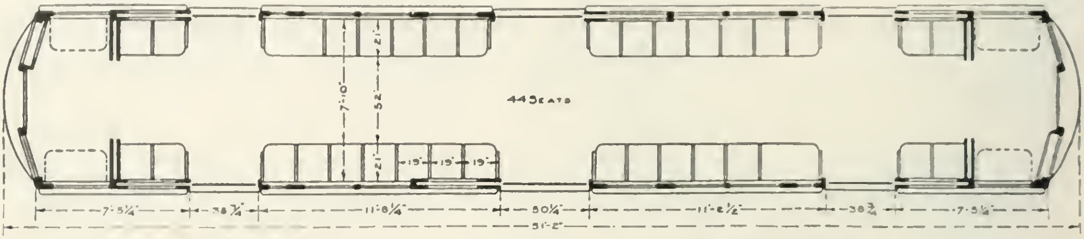

Fig. 8—Car With Three Doors near Center. Longitudinal Seats, 44 Seats.

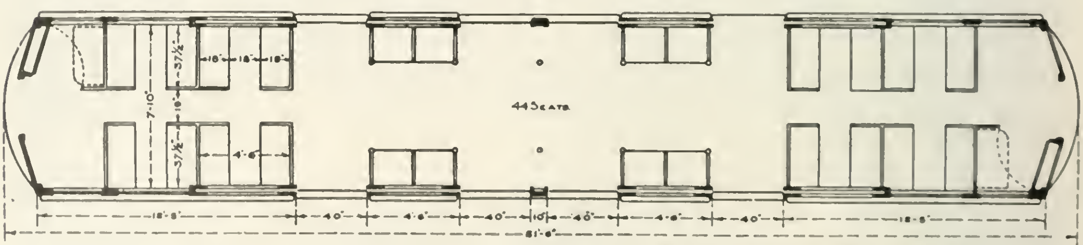

Fig. 9—Car With Three Doors near Center, Combination of Cross and Longitudinal Seats, 44 Seats.

Central suburban line at Chicago does not compare with the density of traffic in the subway, and therefore a conclusion from a comparison of the movement of passengers must be drawn with caution. During rush hours in Chicago the maximum number of passengers passing through the 12 doors of the car was found to be 4.8 per second, and, in making this observation, care was taken to include only the time between the opening and the closing of the doors, so as to eliminate the variable time required for giving the starting signal and in starting the train. It should be borne in mind that the Illinois Central cars are over 72 ft. long, and this result was obtained with 12 doors, and not with 8 doors, which is the greatest number possible for the 50-ft. subway car.

It is fair to assume, therefore, that with the 8-door car in the subway, passengers would be unloaded and loaded at the rate of not more than 4 persons per second per car. As a result of a great many observations of the present rate of passenger movement in and out of the present cars during rush hours in the subway, I find that this rate does not vary far from 1 person per second per door, or at the rate of 2 passengers per second per car, except under extremely congested conditions, when the rate becomes slightly less. During slack periods passengers readily pass in and out of the car doors at this rate, while during rush hours the station platform attendants facilitate the movement, which would ordinarily be considerably reduced by the congestion, and the prompt closing of the doors by the uniformed attendants at the busy stations goes far toward making it possible to load the cars at the rate of 2 persons per car per second, except during the very busiest periods.

At the Borough Hall station of the Brooklyn extension, recently opened, this rate is often increased to an average of 2½ passengers per car per second for the first 30 seconds of loading, but at this station at the present time there exists only terminal conditions without the conflict of transferring traffic.

It would be impracticable to provide a platform attendant for each door of the multi side-door car. It is therefore necessary, in considering the effect of a car of this type on the length of station waits during rush hours, to compare the operation of the multi side-door car without the advantage of a station platform attendant at each door to assist in the loading of the passengers, to the operation of an end-door car with a platform guard to not only expedite the movement of passengers, but also to assist in closing the doors. With this comparison in mind it is difficult to see how the use of the multi side-door car in the subway would reduce the present time of loading and unloading by more than one-half; that is, the present rate of passenger movement of 2 persons per car per second maintained with the present end-door car might possibly be increased to 4 passengers per car per second with the multi side-door car.

This result could only be obtained upon the assumption that all of the multi side doors could be promptly closed by the train guards. In Chicago there is apparently no difficulty in doing this, but it should be remembered that during rush hours the subway traffic is fully 10 times as large as the Illinois Central traffic during the corresponding period, and experience in the subway has demonstrated that in order to close the car doors during the rush period a corps of uniformed, trained platform guards, in addition to the train guard, is absolutely necessary.

It has further been learned that the only way to move trains through the subway on schedule time is to close the car doors promptly, and thus limit the platform delays. It is difficult to see how this could be accomplished with the multi side-door car unless the stream of passengers was stopped before it reached the loading platform. This would transfer the "crush" from the platform in the vicinity of the car doors, as at present, to a platform entrance or a number of entrances, which could be made sufficiently large to considerably reduce the crowding, but the inevitable cutting off of the stream of passengers must be quickly accomplished in some manner, in order to allow the prompt movement of the trains. If the multi side-door cars were to be adopted for the subway, the stations should be arranged so as to control the passenger flow before it reaches the train, as it would be found exceedingly difficult to cut off the passengers at 64 separate places, which would result from the use of 8 doors in each car of an 8-car train.

The introduction of the transfer system, which furnishes a possible saving of a minute or two as a reward for considerable pushing and crowding, has driven a number of the regular subway passengers "minute mad." To deprive these patrons of an opportunity to catch a train by closing a station gate in their faces at the time the train pulls into the station would meet with considerable objection if attempted in the present subway, where the stations are not built to provide for the comfortable carrying out of this arrangement, but the suggestion should be borne in mind in connection with the design of future subways. The only logical place to cut off the flow of passengers is at the entrance to the station platforms, and not at the doors of the cars, a fact which is demonstrated by the design of steam railroad passenger stations and ferry-boat waiting rooms.

To allow the successful use of the multi side-door car would make other changes necessary, particularly with the station platforms. The present platforms serve only one of the end doors of each of the end cars of the train. To get the full advantage of all of the doors along the entire length of the train it would be necessary to extend both the express platforms, which are 350 ft. long, and the local platforms, which are 200 ft. long. This requirement would mean a 50-ft. extension on 38 separate platforms south of 96th street, as well as the extension of a number of platforms north of 96th street, and in some cases this alteration under running conditions would be an expensive and exceedingly difficult piece of work.

The final serious objection to the multi side-door car in the present subway is the fact that practically the entire car bodies now in use would necessarily either be scrapped or used elsewhere, as it would be practically impossible to rebuild them so as to provide 8 side doors on each side of each car. Under these circumstances, the cost of the change would mean an expense of at least $5,000,000 for multi side-door cars, and of about $2,000,000 for plat-

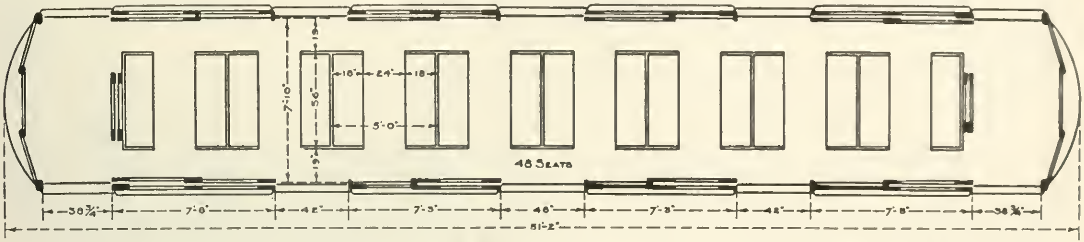

Fig. 10—Car With Multi Side Doors. Cross Seats Back to Back With Two Aisles, 48 Seats.

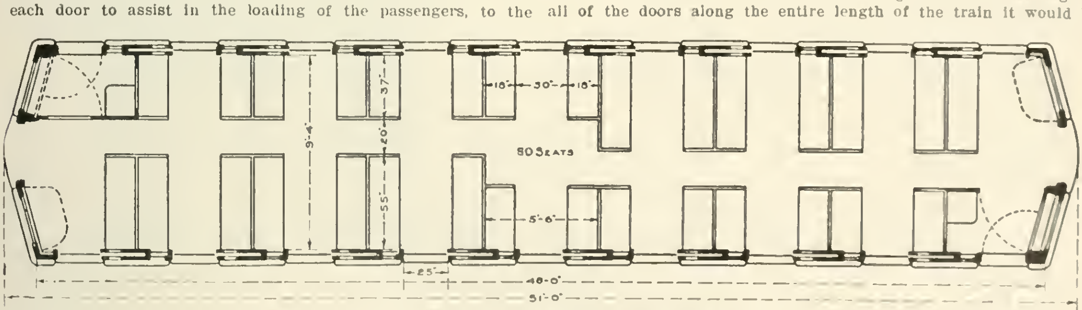

Fig. 11—Car for Future Subways With Multi Side Doors and Cross Seats Back to Back With One Aisle, 80 Seats.

forms, and, in my opinion, the improvement to be expected from these changes with the present subway would not justify the investment.

MULTI SIDE-DOOR CARS AND FUTURE SUBWAYS.

If the multi side-door car is to be considered for future subways, the station platforms should be arranged so that the unloading can be done on one station platform and the loading can be accomplished from another and separate platform. Such an arrangement would necessarily contemplate some inconvenience to the passengers transferring from one service to the other, and the adoption of the separate platform idea would make impossible the use of the island platforms which, under present arrangements, often serve both the express and the local trains, an arrangement which contributes greatly to the convenience of those using the transfer privilege. To make the changes necessary to provide separate platforms for the present subway and at the same time keep the trains in operation on a schedule which calls at frequent intervals for a train on each of the four tracks every two minutes, would be so difficult as to make its cost unjustifiable, and the suggestion, therefore, can only be used in considering an entirely new subway. These remarks apply as well to the straightening of the platforms. The curves of the present platforms would seriously interfere with the operation of the multi side-door car. Sliding platforms, or extension platforms on the cars, to correct this defect are at best complicated and unsatisfactory expedients, and as long as with future subways a different station arrangement and separate platforms would be necessary to make a success of the multi side-door car, it would add little to the station requirements to specify that if multi side-door cars are to be used, the station platforms should be free from curves.

CAR WITH MULTI SIDE DOORS.

Figure 10.

Cross Seats Back to Back, with Two Aisles.

(48 Seats.)

This plan indicates the introduction of three wide doors in the sides of the present subway cars and the rearrangement of the seats in accordance with Illinois Central plan. With this car no attempt would be made to set up and maintain a circulation, and every door would be used as a combined exit and entrance. While this car would lessen the conflict of passengers at the car doors it would not provide a means of entirely removing this cause for discomfort.

At least two platform attendants for each car would be necessary during the busy hours, to assist the train guard in cutting off the stream of passengers entering the car and to aid in closing the car doors. The car platform space would be available for passengers preferring to ride on the platform, as with this car it would not be necessary to enforce the rule that passengers must not ride on the car platforms.

CAR WITH MULTI SIDE DOORS (FOR FUTURE SUBWAYS).

Figure 11.

Cross Seats Back to Back, with One Aisle.

(80 Seats.)

This design has the advantage of one aisle instead of two, and is 18 in. wider than the present car, thus at once increasing the possible seating capacity, and this general arrangement of seats will, therefore, be found the most efficient way to carry out the policy of attempting to provide a seat for every long-haul passenger. The free space between the seats has been increased to 30 in. in an attempt to provide room for the passengers entering and leaving the car to pass by the seated passengers with the minimum amount of annoyance.

This car ought to work well with a load not exceeding 100 passengers, 80 of whom would be seated, but would prove exceedingly uncomfortable if the standing passengers began to encroach upon the space between seats. As the space between seats is sufficient to allow passengers to pass between the knees of those seated, and is the only avenue of entrance and exit, this space would naturally be occupied by standing passengers, particularly during rush hours, much to the inconvenience of the seated passengers, and this is the penalty that must be paid for maximum seating capacity.

There are 8 doors in each side of this car, but the absence of free space near each exit and entrance will cause this car to be loaded and unloaded slowly, and the advantage of the extra number of doors will disappear just at the time that this feature would be of the greatest use.

CAR WITH MULTI SIDE DOORS (FOR FUTURE SUBWAYS).

Figure 12.

The Illinois Central Type of Seat.

(68 Seats.)

This design shows a car 18 in. wider than, and of the same length as present car, with seats in banks of four on 5-ft. centers, which spacing will allow the same number of passengers per foot length of car as is found with the Illinois Central cars. There is a door opening between each set of seats, making eight doors along the side of the car. The two aisles are made a little wider than in the Illinois Central car, and the seats are more comfortable, although the free space between opposite seats has been reduced from 27 in. to 21 in., in order to make each seat deeper.

The car is contemplated only for future and larger subways, as it would be impracticable to rebuild the present cars to allow for the extra width necessary for the four cross seats shown and operate them in the present subway.

The advantages of this type of multi side-door car, although many, are not as great as would at first appear, owing to the delay which would be caused by passengers searching for seats before they selected an entrance and entered, and the conflict of entering passengers with those who would have already entered the car and

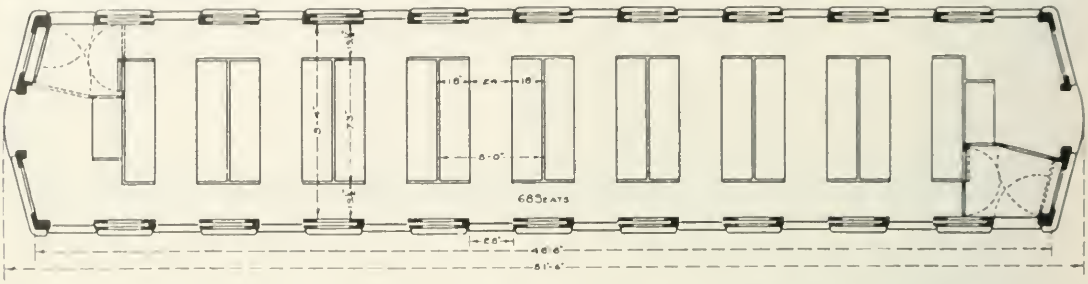

Fig. 12—Car for Future Subways With Multi Side Doors and the Illinois Central Type of Seat, 68 Seats.

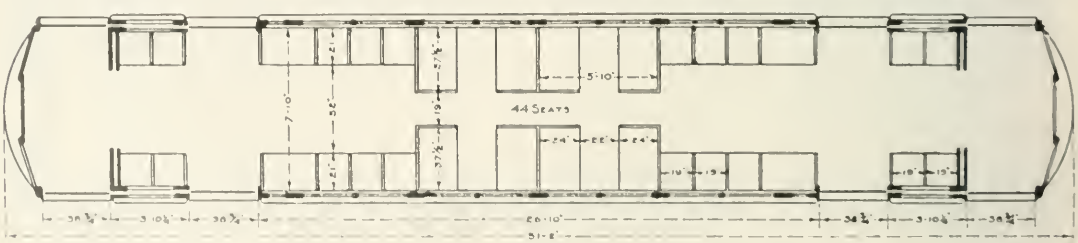

Fig. 13—Car With Double Doors near Ends, Combining Cross and Longitudinal Seats, Using Present Car Body and Seat Spacing, 44 Seats.

would be using the aisles for the purpose of finding seats. For subway use all doors should be operated at once by the car guard, in order to reduce the delay which is sometimes experienced in Chicago, due to the hesitation of inexperienced passengers in opening the doors.

CARS WITH DOUBLE DOORS NEAR ENDS.

Several different seating arrangements possible with cars having double doors near the ends are shown and discussed below:

CAR WITH DOUBLE DOORS NEAR ENDS.
Figure 13.
Combining Cross and Longitudinal Seats.
(44 Seats.)
Using Present Car Body and Seat Spacing.

This design contemplates taking out eight of the longitudinal seats in the present car and introducing four extra exit doors. The design, which is the same as shown in the drawing previously published of the recommended type of the present subway car altered to a car with double doors near ends, shows the most effective change that, in my judgment, can be made with the present subway car, as it introduces the extra doors at places where the framing of the present car and the arrangement of the present seats will be the least disturbed.

When the first consignment of subway cars was built the end doors were only 29 in. wide, but the operation of the cars soon proved this narrow door width to be a mistake, and the doors were widened to 38 in. While this width is not sufficient to allow passengers to pass through the doors two abreast, it is found that they naturally stagger themselves and pass through the door much faster than if they were forced to move in single file. As soon as the doors are made much wider, as in the Brooklyn Bridge shuttle cars, the crowding passengers make an effort to pass through the door three abreast, much to the discomfort of the middle passenger. To avoid this difficulty a dividing post in the center of a wider door might be introduced, but with a sliding door for cutting off the flow of passengers this center post would serve to multiply the danger and increase the accidents. The new doors have, therefore, been shown of the same width as the redesigned doors of the present car.

CAR WITH DOUBLE DOORS NEAR ENDS.
Shown last week.
Combination Cross and Longitudinal Seats.
(48 Seats.)
More Compact Seats for Future Cars in Present Subway.

This is the recommended future car for the present subway, a drawing of which was shown in the previous article. In the present subway cars the space devoted to the cross seats is used in an uneconomical manner. There are 70 in. between the center of the backs of these seats, which is taken up by two 6-in. back cushions, two 18-in. seats and a clear space between seats of 22 in. Where space is as much at a premium as it is in the subway cars, the arrangement of these seats should be made more compact, and this can be done without sacrificing the comfort now secured with the more liberal spacing. For double side seats, served from a center aisle, a clear distance of 20 in. between seats is sufficient, and the allowance of 18 in. for each seat, together with its back, has been found satisfactory, thus making a total over-all distance of 56 in. for one bank of seats. The width of 18 in. for each passenger for the cross seats and of 19 in. for the longitudinal seats in the present car is good practice. With the more economical arrangement of cross seats, more space can be devoted to such seats and at the same time the seating capacity of the car can be increased. This improvement should be kept in mind in ordering future cars for the present subway.

CAR WITH DOUBLE END DOORS (FOR FUTURE SUBWAYS).
Figure 14.
Back-to-Back Seats on 60-in. Spacing.
(62 Seats.)

As it is probable that future subways will be larger than the present one, the cars can be made wider, and thus increase the carrying capacity per lineal foot of car, an increase not practically obtainable in any other way.

The widening of the car could be carried to any reasonable degree, but in Fig. 14 it is designed to allow for five seats abreast. The 60-in. spacing of the seats will provide convenient access to the inside seats. There is but one aisle, the width of which is ample and the standing room is convenient to the exit. During rush hours this standing space can be increased by folding up the longitudinal seats, each of which can have a ledge arranged to provide a comfortable support for part of the standing passengers. Vertical posts can be conveniently located so as to guide and support the passengers standing in the open spaces at the end of the car.

SUMMARY OF TYPES OF CARS.

The various types of cars which approximate fulfilling the requirements for present and future subway service are as follows:

1. Car with central side door and end doors (Fig. 5).
   (a) Longitudinal seats (Fig. 1).
   (b) "Back-to-back" cross-seats, with two aisles (Fig. 2).
   (c) "Walk-over" seats, with two aisles (Fig. 3).
   (d) "Walk-over" cross-seats, with one aisle (Fig. 4).
2. Car with two quarter side doors.
   (a) Longitudinal seats (Fig. 6).
   (b) Cross-seats (Fig. 7).
3. Car with three doors near center.
   (a) Longitudinal seats (Fig. 8).
   (b) Cross-seats (Fig. 9).
4. Car with multi side doors.
   (a) "Back-to-back" cross-seats, with two aisles (Fig. 10). Using present car frame.
   (b) "Back-to-back" cross-seats, with one aisle (Fig. 11). For future subways.
   (c) Illinois Central type of seat (Fig. 12). For future subways.
5. Car with double doors near end.
   (a) Combination of cross and longitudinal seats (Fig. 13). Using present car frame and body.
   (b) Combination of cross and longitudinal seats (drawing shown in previous article). Using more compact spacing of seats; for future cars for present subway.
   (c) Combination of cross and longitudinal seats (Fig. 14). Wide car for future subways.

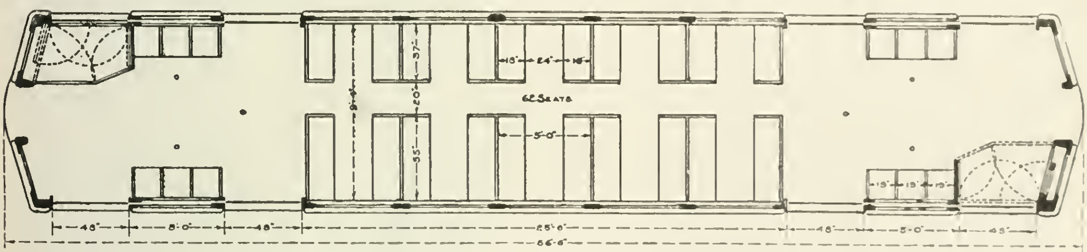

Fig. 14—Car for Future Subways With Double End Doors. Back to Back Seats on 60-in. Spacing, 62 Seats.

Wider cars containing 60 seats and run in 10-car trains at the rate of 40 trains per hour will provide 24,000 seats per hour on one track. The capacity of the express tracks in the present subway is 52 seats per hour in 8-car trains which pass limiting stations at the rate of 30 trains per hour, or 12,480 seats upon one track. In other words, future subways may have twice the seating capacity of the present subway, as now operated.

Depths of the Principal Harbors of the World.

New York.—The approach to the harbor when completed will have a depth at low water of 40 ft.

Boston.—The depths of the approaches are being increased from 36 ft. to 44 ft. at high water. The variation of the tide is 10 to 11 ft.

Baltimore.—Present depth 29 ft. 6 in. at h. w., to be increased to 36 ft.

Newport News.—To have a depth of 36 ft.

New Orleans.—The channel is to be dredged to a depth of 36 ft. h. w.

San Francisco.—Thirty-one ft. l. w., 36 ft. 6 in. h. w.

London. The Thames has a depth of scant 28 ft. l. w. The docks are separated from the river by locks. The dock entrance at Gravesend have a depth of 25 ft. 8 in. l. w. and 44 ft. h. w. It is intended to increase the depths to 29 ft. 6 in. l. w. and 48 ft. h. w.

Southampton.—Twenty-nine ft. to 31 ft. l. w. spring tide, with 14 ft. 9 in. rise of tide.

Liverpool.—The channel in the Mersey has a width of 1,475 ft. with 27 ft. depth at l. w. Rise of tide 19 ft. 6 in. to 26 ft.

Plymouth.—Has a natural depth of 30 ft. l. w., 42 ft. h. w.

Havre.—Depth of dredged channel to deep water 35 ft. 6 in. The lock to the principal basin, Basin Bellot, is 99 ft. wide, with 35 ft. over the sill at h. w.

Antwerp.—The depth of the Scheldt and of the harbors is planned for 24 ft. 6 in. l. w. and 38 ft. h. w.

Rotterdam.—The minimum depth of the channel to the sea, when completed, 24 ft. 6 in. l. w., 29 ft. 6 in. h. w.

Amsterdam.—After completion of the improvements to the North Sea canal, its minimum depth will be 32 ft., which can be increased to 33 ft. 6 in.; the minimum width of bottom 164 ft., with a lock 738 ft. x 82 ft. x 32 ft. 5 in. The depth of the outer harbor, Ymuiden, is 37 ft. h. w.

Bremen and Bremerhaven.—Bremerhaven is the port of Bremen, and extensive dredging operations have secured a channel in the Weser to the sea 26 ft. 3 in. deep at l. w. and 37 ft. at h. w. The principal harbor basin, the Kaiserhafen, has an entrance lock 732 ft. long, 92 ft. wide, with 34 ft. 8 in. depth at the sill at h. w. Since 1888 the fairway of the Weser to Bremen has been deepened to 14 ft. l. w. and 18 ft. h. w.

Hamburg.—Previous to 1902 the fairway in the Elbe was 27 ft. at h. w., compelling the largest vessels to lighter at Cuxhaven or at Brunshausen. Dredging has increased the depth to 32 ft. 9 in. at h. w. As this is barely sufficient for present requirements, extensive improvements on the lower Elbe are contemplated.

Genoa.—Depth in the harbor 52 ft.; alongside quays 29 ft. 6 in.

Naples.—Depth in the harbor 111 ft.; alongside quays 32 ft. 6 in.

Calcutta.—Twenty-seven ft. at h. w.

Bombay.—Twenty-nine ft. 6 in. at h. w. Rise of tide 8 ft. 6 in.

Colombo.—Thirty-six ft. at h. w. Rise of tide 2 ft.

Hong Kong.—Thirty-nine ft. at h. w.

Yokohama.—Thirty ft. 6 in. at l. w., 35 ft. at h. w.

Nagasaki.—Twenty-one ft. to 121 ft. l. w.

Sydney.—Thirty-four ft. h. w. Rise of tide 5 ft.

Melbourne.—Thirty ft. h. w. Rise of tide 3 ft.

Rio Janeiro.—Fifty ft.

Capetown (Table bay).—Thirty-four ft l. w., 39 ft. h. w.

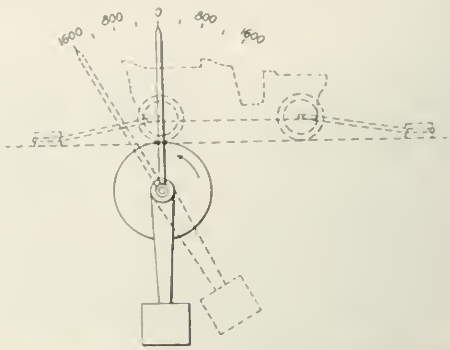
In this connection the following is also of interest:

Suez Canal.—On completion of the work in progress, depth will be 33 ft. 9 in. width at bottom 1,083 ft., so that in this year vessels with a draft of 27 ft. 9 in. can be admitted.

Panama Canal.—The projected depth is 40 ft.; minimum width of bottom 150 ft.

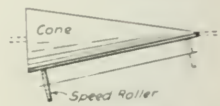
An Automobile Dynamometer.

The Automobile Club of America has learned a lesson from the locomotive testing plants and has had a dynamometer designed for testing automobiles in the same manner that similar work has been done with locomotives at Purdue and by the Pennsylvania Railroad Owing to the fact that but one pair of wheels has to be provided for, the mechanism is, of course, much simpler than that of the locomotive machine. It is the first and only one of its kind, and is arranged to show at once the speed in miles per hour and feet per

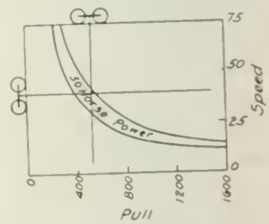


Pendulum Dynamometer; Automobile Testing Plant.

Automobile in Position for Records.



Speed Roller and Cone.



Speed and Power Diagram.

second, the tractive effort, horse-power of motors, grade climbing ability and braking power.

It is also provided with an electric fan for catching the exhaust from the automobile in order that the air in the room may be kept clear of smoke and other products of combustion.

It was designed for the club by Dr. S. S. Wheeler, and is an assemblage of power absorbing and measuring instruments and a large power chart with automatically operated pointers.

The car is held in place by cables, and the driving wheels are carried by drums as in the case of the locomotive testing plant. Instead of the hydraulic brakes the motion of the drums is resisted by a pendulum hanging below the floor and attached to the drum shaft, not rigidly but by means of a frictional resistance that can be varied. This pendulum then swings out from its vertical position according to the pull exerted by the car upon the drums. This is indicated by a pointer attached to the pendulum and reaching above the floor. The indications thus obtained are transferred to a ruler traveling across the face of a large chart.

The speed of the car is obtained by moving another ruler vertically across the chart by means of a special piece of apparatus.

A cone is revolved by an electric motor at constant speed. To verify this speed, a bell, attached to the cone, shaft, rings at each 100 revolutions, or at intervals of 30 seconds. A wheel or roller, driven by the automobile and therefore revolving slowly or fast to correspond, rolls upon the surface of the cone and is pulled, by an independent motor, back and forth between the small and large ends of the cone until it finds the point where it does not slip because that portion of the cone presents the same speed as the roller. This longitudinal adjustment of the roller is transmitted by a wire cable to the speed ruler on the chart, and the power required for moving the ruler is thus made independent of the automobile. The roller, driven by the car if running at 60 miles per hour, must be drawn to a position near the large end of the cone in order to run with the cone. Whereas, if the car drives the roller at only five miles per hour, it must be drawn to a position near the small end of the cone. A system of electric contacts is arranged with a motor to shift the roller automatically until it finds the point where it will roll on the cone without slipping.

The speed and power rulers are thus moved across the chart automatically to correspond with the speed and the tractive effort or pull that the dynamometer shows the car is making.

On the board are painted the horse-power corresponding to each different speed and pull so that the result at each moment can be read at a glance and without calculations.

The chart is on a heroic scale and can be read easily by the driver of the car. The speed of the car may be read from the chart in either of the popular ways of stating it: Miles per hour; minutes per mile, kilometers, etc., by means of the several different scales provided.

All of the measuring apparatus is made reversible so that when running backward the performance of the car may be measured.

As a secondary apparatus, a grade meter is provided, operated by the pendulum indicator of the dynamometer. To use the grade meter the clamp is set upon the sliding scale at the point representing the weight of the car. The moving lever then assumes at each moment the angle of inclination of the grade the car would climb (if there were no wind resistance, slipping, etc.) with the effort that the car is then making.

To observe an automobile coasting down hill, either forward or backward, it is necessary merely to start the electric motor on the shaft carrying the two large drums upon which the driving wheels of the automobile rest. The brakes may then be tested and the wheels or gears or engine may be run free (not run by the power of the automobile) and the relative friction loss in the principle of the automobile may be ascertained.

The consumption of petroleum for fuel in Russia has been suddenly checked, due largely, and perhaps chiefly, to higher prices. During the first nine months of 1907 the six railroads which have been the chief users of petroleum consumed but 142,500,000 gallons in 1907, against 261,500,000 in the corresponding nine months of 1906, a decrease of no less than 45 per cent. Meanwhile the production of the Donez coal mines increased 2,115,000 tons, which is more than 20 per cent. In fuel value this increase in coal is about equivalent to four times the decrease in petroleum consumption on these six railroads.

Penalty Laws in the South.

The following abstracts cover the principal penalty laws in a group of southern states:

ALABAMA.

Free time under car service rules, 72 hours on fertilizers, hay, coal, coke, brick, lumber in box cars, bulk meat, potatoes, grain and grain products, cotton seed, cotton seed meal and cotton seed hulls, and 48 hours on other freight, Sundays, holidays and bad weather days not counted.

The 1907 Legislature passed 52 bills inflicting severe penalties, the effect of which was to decrease earnings, to increase expenses by inflicting penalties, forfeits, increased taxes, etc.

The demurrage laws of Alabama as enacted by the 1907 Legislature differ from the requirements of any other state, in that the maximum charge for car service is fixed at $10 per car. No other state imposes a maximum charge for car service, and under the state laws, when a receiver of freight has detained a car long enough to accumulate a demurrage charge of $10 he is at no expense for any additional detention of the car.

Among the penalties fixed by the 1907 Legislature are the following:

Penalty of $500 for each failure to give receipt for application for cars to be loaded.

Penalty of $1 per car per day, maximum $10 per car for failure to furnish cars for loading within the specified periods.

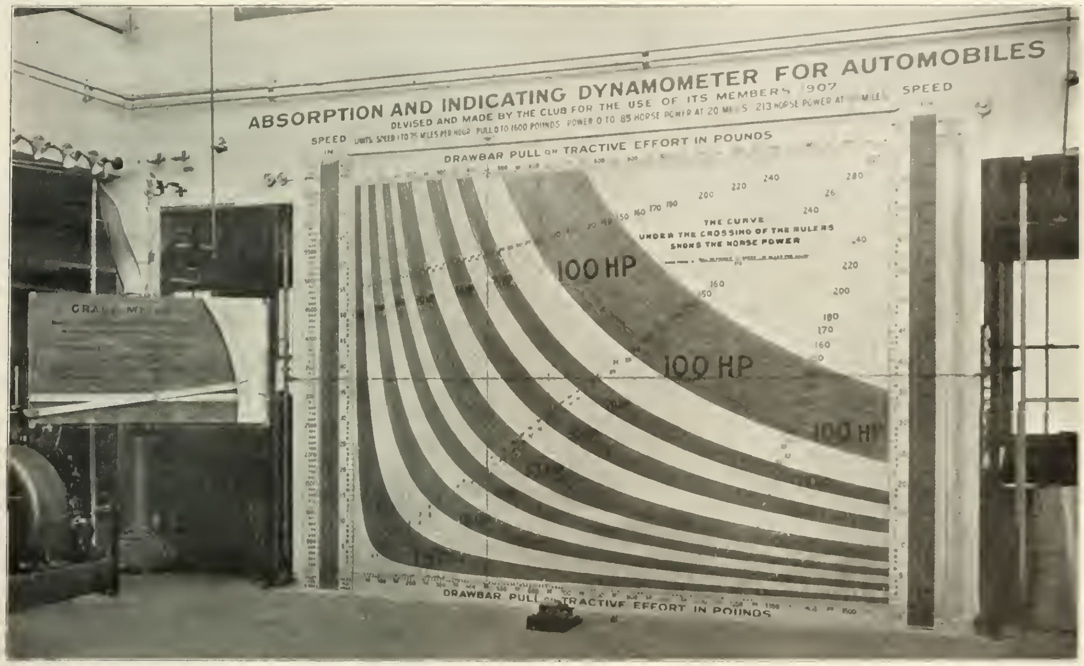
Penalty, carloads $1 per car per day, less than carloads 1 cent per 100 lbs. per day, for failure to receive freight and issue bills of lading therefor.

Penalty on carloads $1 per car per day, and on less than carloads 1 cent per 100 lbs. per day, maximum penalty $10, for failure to transport shipments at the rate of 50 miles per day of 24 hours, computing from 7 a.m. of the day following receipt of shipment.

Penalty on carloads $1 per car per day, less than carloads 1 cent per 100 lbs. per day, maximum penalty $10, for failure to give consignees notice of arrival within 24 hours after arrival of the shipment.

Penalty of $1 per car per day for failure to deliver freight or to place cars for unloading within 24 hours after arrival, computing from 7 a.m. of the day following arrival.

Carriers are not permitted to release cars by unloading carload freight for storage into their own warehouses or into public or



Wall Chart; Automobile Dynamometer.

private warehouses until $5 demurrage charges have accumulated. This practically means, until the carrier has suffered 10 days delay.

Penalty of 115 per cent. to 100 per cent. of the amount of the claim for failure to pay loss and damage claims within 60 days, the penalties varying with the amount of the claim.

Penalty of $1 per day maximum penalty $100, for failure to pay overcharge claims within 60 days.

Penalty for entering suit through federal court, cancelation of license to do business through the state of Alabama

Penalty for reissuance of license, one-tenth of 1 per cent. of corporation's capital stock

Franchise tax, foreign corporations with actual capital of over $1,000 employed within the state of Alabama to pay annual franchise tax of 25 per cent. of the first $100, 5 per cent. on the amount in excess of $100 up to and including $1,000, and one-tenth of 1 per cent. on the amount over $1,000, this applying only to that part of the capital employed in the state of Alabama.

Penalty of $100 per day for each day's failure to make annual reports of State Railroad Commission within specified time.

Penalty of $100 for each day's failure to file with the State Railroad Commission abstracts or lists of vouchers or receipts within specified time.

An act prohibiting carriers from entering into any bill of lading contract, stipulation, receipt, rule or regulation in any way limiting their liability for loss of or damage to property received for transportation, thereby requiring carriers to become responsible for acts of God and the public enemy.

FLORIDA.

The free time under car service rules is from 72 to 96 hours, according to the commodity. The Florida commission indulges in a system of fines when the railroads fail to move freight promptly; for diversion of business, and for other irregularities which might occur in the operation of the line through fault of agent, trainmen or workmen.

Penalty of $1 per car per day for failure to deliver freight or to place car for unloading within 72 hours, computing from 10 a.m. of the date following arrival.

Penalty of $2 per car per day for failure to furnish cars for loading within two days on perishables and four days on other freight.

Penalty on carloads $2 per car per day, and on less than carloads 1 cent per 100 lbs. per day for failure to transport freight 50 miles within two days, and each additional 50 miles within one day 24 hours additional time allowed for transfer to connecting line.

Penalty of 25 per cent. of the amount of claim for failure to settle claims within reasonable time.

GEORGIA.

Under car service rules the free time in Georgia is generally 48 hours. The penalty rules of Georgia were largely imposed by the State Railroad Commission in the year 1906, and they stand to-day as follows:

Penalty of $1 per car per day on carloads and 1 cent per 100 lbs. per day for less than carloads for failure to give notice of arrival within 24 hours.

Penalty of $1 per car per day for failure to furnish cars for loading within four days, Sundays and legal holidays excepted.

Penalty of $1 per car per day on carloads and 1 cent per 100 lbs. per day on less than carloads for failure to forward freight at the rate of 50 miles per day, computing from 7 a.m. of the day following receipt of shipment.

Penalty on carloads $1 per car per day, less than carloads 1 cent per 100 lbs. per day, for failure to deliver freight or to place cars for unloading within 48 hours from 7 a.m. following day of arrival.

Penalty of $1 per car per day for failure to deliver cars to switch connection within 24 hours after notice from consignee.

Penalty of $1 per car per day for failure to receive and place switch cars within 24 hours.

Forfeit of value of goods with interest at 10 per cent., penalty not to exceed actual damage plus 25 per cent. for failure to observe shipper's routing.

Penalty of double the amount of overcharge for failure to pay overcharge claim within 30 days.

Penalty of full damage to be paid by initial line regardless of place of damage for failure to trace freight and advise applicant within 30 days of the cause and place of delay or damage.

Penalty of $50 for failure to pay loss or damage claim intrastate within 60 days and interstate within 90 days.

NORTH CAROLINA.

The car service rules of the North Carolina commission allow 72 hours free time on fertilizers in sacks or in bulk, and on brick, cotton seed, cotton seed hulls, coal, coke, fertilizer materials, grain and lime and tanbark in bulk, and dressed lumber in box cars, and 48 hours free time on other freight, Sundays, holidays and bad weather days not included.

The following forfeit and penalty requirements are a result of legislative enactment

Penalty of $50 for failure to forward freight by route designated by shipper.

Penalty on carloads $15 first day and $20 each succeeding day and on less than carloads $10 first day and $1 each succeeding day for failure to transport and deliver freight within the time specified within the statute, this penalty being in addition to actual damages, if any, sustained by the claimant

Penalty of $50 for failure to deliver freight upon tender of legal freight charges.

Penalty of $50 for failure to pay loss and damage claims intrastate within 60 days and interstate within 90 days

Penalty of $5 per car per day for failure to furnish cars for loading within four days from 7 a.m. of the day following such application.

The 1907 Legislature of North Carolina passed a bill limiting hours of trainmen, enginemen and telegraphers to conform with the Federal law which becomes effective March 4, 1908

SOUTH CAROLINA.

Demurrage rules of the South Carolina Commission allow 48 hours free time in the case of personal notice, and 72 hours free time in the case of mail notice, except that 24 hours additional free times allowed on grain and grain products cotton seed, coal, lumber in box cars, brick, etc The various penalty laws and rules are as follows:

Penalty of $50 for failure to deliver freight upon tender of lawful freight charges.

Penalty of $500 for failure to pay loss and damage claims intrastate within 40 days, interstate within 90 days.

Penalty of $1 per car per day for failure to furnish cars for loading of dead freight within four days, and of perishable freight within three days.

Penalty of $1 per car for failure to deliver freight or to place cars for unloading within 48 hours from noon of the day following

Penalty of $1 per car for failure to issue bill of lading and forward dead freight within 48 hours, and perishable freight within 24 hours.

Penalty of $5 for each and every failure to bulletin passenger trains in accordance with the legislature's requirements.

Forfeit of five times the value of property so confiscated for confiscation by carrier of fuel or other property for its own use

Penalty of $25 for failure to advise consignee of live stock delayed more than three hours of the cause and extent of the delay and expected time of delivery.

Fine of $5,000 for each and every failure to provide union and other depots as required by State Railroad Commission.

Penalty of $5 per shipment per day (maximum value of goods and transportation charges) for failure to transport freight within the time specified within the state statute.

Penalty of $1 per day for failure to furnish consignee within 10 days information as to the cause of delay to delayed freight.

VIRGINIA.

Storage, demurrage and car service rules, including penalties, are made by the State Corporation Commission, and the current rules have been in effect since Aug. 15, 1903. The Commission has now under consideration changes that will not in any way lessen the burdens imposed upon the carriers by the existing rules. The existing rules provide, among other things, as follows:

Forfeit of $1 per car for failure to furnish car for loading within four days.

Forfeit of $1 per car per day on carloads, and 1 cent per 100 lbs. per day on less than carloads for failure to transport freight at rate of not less than 50 miles per day of 24 hours, computing from 7 a.m. of the day following receipt of a shipment.

Forfeit of $1 per car per day on carloads and 1 cent per 100 lbs per day on less than carloads for failure to give consignee notice of arrival of freight within 24 hours.

Forfeit of $1 per car per day for failure to place cars for unloading within 24 hours, computing from 7 a.m. of the day following arrival.

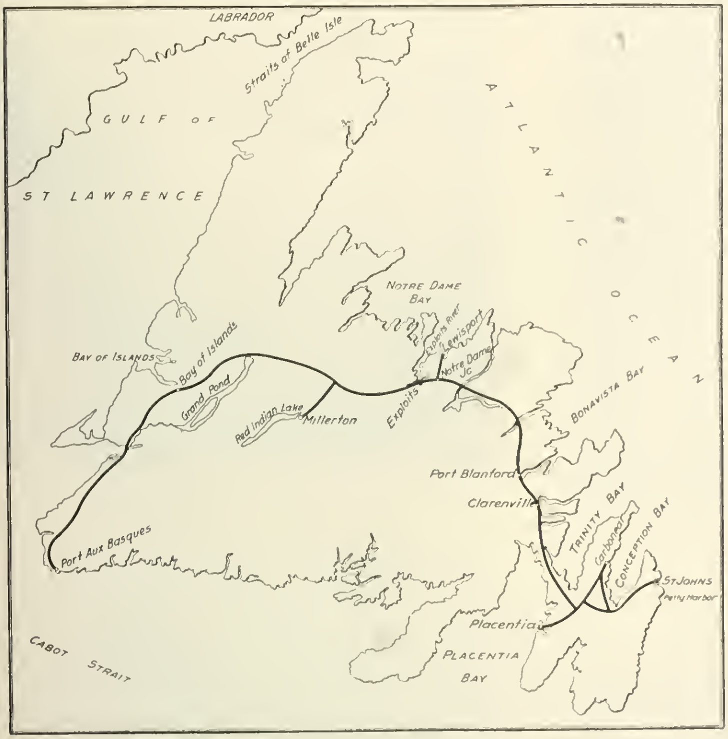
Free time on freight to be trans-shipped by water: 10 days on fertilizers, hay, coal, coke, brick and lumber in box cars, meat, potatoes, grain and grain products, cotton seed and cotton seed hulls in bulk 72 hours, and on other freight 48 hours, Sundays, holidays or bad weather days not included, and free time allowed

---

The estimates of the Prussian State Railroads for additions to rolling stock to be delivered before Oct. 1 next amount to the tidy sum of $31,423,140, to be expended for 710 locomotives at an average cost of $16,425 each, 2,105 passenger and baggage cars at $4,390 each, and 14,160 freight cars at $757 each—the latter nearly all four-wheeled cars of less than half the average capacity of our cars. It is expected that about 16,000 more cars will be needed between October and April.

The Railroad System of Newfoundland.

Newfoundland has a unique position in the railroad world. It has a narrow gage railroad system 635 miles long, with steamer connections to different parts of the island and to the peninsula of Labrador, making a total mileage of steamer lines of 3,364 miles. The railroad lines and the steamship lines are all under the same management. They are the property of the Reid Newfoundland Company, whose President, Sir Robert Reid, was recently knighted for his conspicuous services in the development of Newfoundland. The same company owns at St. Johns, the capital of the island and the eastern terminus of the railroad, a large dry dock, an electric light plant and the local street railway.



Newfoundland and Its Railroad System.

The railroad runs from St. Johns on the east coast of Newfoundland westward across the island to Port aux Basques, connecting either directly or by branches with most of the large bays with which Newfoundland is surrounded, which are served by special steamer services. Express trains which are scheduled to cross the island in 28 hours are run three times a week. The Reid Newfoundland Company's steamship "Bruce," a 17-knot flyer, plies nightly across the 90 miles of Cabot strait, which lies between Cape Breton island and the southwestern extremity of Newfoundland. This steamship connects with the Newfoundland system at Port aux Basques and with the Intercolonial Railway at North Sydney. On the other days of the week local railroad service is operated across the island. Other trains twice a day serve the more populous centers within 100 miles of St. Johns.

The railroad is equipped with 25 locomotives, 38 passenger cars and 364 freight cars. It has two rotary snow plows and other snow fighting equipment. A large granite station at St. Johns built at a cost of $100,000, holds the general offices of the company. The rolling stock is of modern construction and of good design. The locomotives were especially designed and built by the Baldwin Locomotive Works; the passenger cars were built by the Dayton Manufacturing Company, of Dayton, Ohio; Rhodes, Curry & Company, of Amherst, N. S., and by the company's own shops, which turn out cars equal to the best bought abroad. The best class of cars are mahogany finished inside and out. Through trains have sleeping, dining, colonist, day and baggage coaches. The roadbed is well built and has been considerably improved during the last ten years. The bridges are built on masonry abutments with steel girders.

The passenger traffic of the system is large and steadily growing. The colony of Newfoundland has 250,000 people and the movement of local passengers is one of the main sources of traffic. At certain seasons of the year a large number of the people of Newfoundland find employment in the steel works and coal mines on Cape Breton island, and this makes a considerable passenger movement. There is also a steadily growing tourist travel from Great Britain, Europe and the American continent.

The freight traffic is made up of lumber and the commodities required by a community scattered over 6,000 miles of coast line and of itself producing nothing except its catches of cod, seal, herring, lobster and whale. All other necessities of existence, such as food and clothing, come from St. Johns. A large increase of the freight business is assured through the recent establishment by two large corporations financed in London, the Harmsworth and the Albert Read companies, each capitalized at $5,000,000, of pulp mills on the Exploits river, inland from the coast. These two enterprises promise to become important factors in the industrial development of the colony. Near St. Johns are iron mines and in the northern part of the island copper mines which furnish traffic. Agricultural settlements also are springing up at various points along

Bay of Islands, Newfoundland.

the railroad and large additions of traffic are expected from this source.

From Port aux Basques the steamer "Glencoe" plies eastwardly along the south coast to Placentia bay, 371 miles, where connection is made with a branch of the railroad connecting directly with St. Johns. From the railroad at Bay of Islands station, on the west coast, the steamer "Home" plies north to Battle Harbor, Labrador, on the straits of Belle Isle, 379 miles. The railroad connects with Notre Dame bay on the north coast by a branch from Notre Dame Junction to Lewisport, from which the steamer "Clyde" furnishes a weekly service around the bay. This trip is 362 miles long. From Port Blandford the steamer "Dundee" performs a similar service for Bonavista bay; a 148-mile trip. Trinity bay and the west side of Conception bay as far south as Carbonear, are served by the steamer "Ethie," which connects with the railroad at Clarenville and Carbonear. This is 152 miles. A branch of the railroad touches every important place on the rest of Conception bay. These last three bays are on the east coast. Placentia bay, on the southwest, is served by the steamer "Argyle." This route is 294 miles long. During the summer there is fortnightly service from St. Johns by the steamer "Virginia Lake" to Labrador, which is 1,021 miles away.

The operations of the Reid Newfoundland Company are large and varied. The steamship "Bruce," the connecting link for through traffic between Newfoundland and Cape Breton Island, was built on the Clyde for this particular service at a cost of $250,000. A photograph of this steamer is shown. The seven other steamers of the company's fleet represent an outlay of $1,000,000 more. The company is adding new railroad equipment at the rate of $250,000 a year. Owing to the increasing demands of traffic it is probable that

Reid Newfoundland Company's Steamship Bruce.

a daily train and steamship express service will be begun in the near future. Passenger and freight tariffs are made on a mileage basis, the distance by rail or by boat being counted as part of the one journey. Through tickets are on sale between all important points in Canada and the United States to Newfoundland points and baggage can be checked through on these tickets. Joint traffic arrangements for freight have been made with Canadian and American railroads and there is a steadily growing interchange business. The company has a monopoly of the public service facilities of the city of St. Johns, including the electric light system and the street railway, whose earnings in the calendar year 1907 were $31,948, an average of about $87 a day. During the year it carried 638,967 passengers, An electric power house has been built at Petty harbor, nine miles from the city, which furnishes power for both these operations and for various other industrial enterprises. The Colonial dry dock owned by the company is situated at the western end of the harbor and is capable of taking up the largest ocean going steamships. Here steamers can be found under repair the year round, for St. Johns is a noted haven for shipping in distress on the western ocean. The machine shops are near the dry dock and are used for both car and ship repairs. As an adjunct to the dry dock the company owns a powerful wrecking tug equipped for marine salvage work.

A large part of the company's expectations for future increases in traffic are based on the wonderful natural resources of the island as a tourist and sporting resort. It has beautiful scenery, bracing climate and a wide range of hunting and fishing opportunities. There is sport at Newfoundland at all seasons of the year. Of large game there are bears, wolves, caribou, otter, marten and beaver. Other game, migratory and indigenous, includes the hare, rabbit, ptarmigan, spruce partridge, Canada goose, ducks of many varieties, snipe and plover. There is fine trout and salmon fishing. Most of the interior of the island is untraveled. Only a few sportsmen have crossed its broad barrens and climbed its rugged mountains.

J. C. Millais, the English naturalist, son of the famous painter, has recently published an elaborate volume describing his journey in the untrodden interior of Newfoundland in which the joys of caribou hunting are enthusiastically described. This sport can be obtained more cheaply and with less discomfort than deer hunting can in other parts of the world. From New York and New England it is only a three days' journey to the best hunting grounds in the interior of Newfoundland. Guides and helpers can be obtained at rates much below those charged elsewhere, the only fee imposed by the colonial government on sport of any kind is one of $50 on visiting caribou hunters. Payment of this fee entitles one to shoot three stags. Every other form of sport with rod and gun is free. One of the photographs shows caribou near the railroad line. Moose have recently been introduced and are thriving well, but are still protected. The number and variety of wild fowl is very great.

For the summer tourist the air is bracing, the climate salubrious and the surroundings stimulating. A variety may be given to a visit to Newfoundland by cruising on the different steamers, visiting the various bays about the island and observing the fisher folk engaged in the operations which yield them subsistence. The cod and other fishing has many picturesque incidents, though tragedy often accompanies it, for the wind and sea are at their strongest in this region. One of the most remarkable attractions is the daily procession of majestic icebergs drifting south along the Newfoundland coast from the arctic region. These present the most striking pictures. The Labrador trip is also a remarkable one. The region compares with Norway, and besides the wonderful beauty of its scenery, offers fine sport for rod or rifle.

Signals and Automatic Train Stops in the Hudson & Manhattan Tunnel.

The signaling of the recently opened up-town tunnel of the Hudson & Manhattan Railroad under the Hudson river consists of automatic block signals and automatic train stops, covering the double-track line between Nineteenth street, New York, and Hoboken, N. J. Between Hoboken and Greenwich avenue, New York, the river section of the tunnels, signals are placed, on the average, 367 ft. apart, making 14 blocks to the mile. The minimum distance where speed is low is 115 ft., and the maximum is 1,620 ft. On steam railroads, block signal sections average 2,640 ft., or two to the mile; on the express tracks of the Interborough Rapid Transit Subway the distance is 800 ft., or nearly seven to the mile.

The signals give three indications: Proceed, indicated by a green light; proceed with caution, yellow light; stop, red light. There is an automatic stop at each stop signal. This device has two movable short arms or trips, one placed alongside each rail. When the signal is in the stop position, these arms are raised to engage with the trigger of a valve in the air-brake pipe of the train, releasing the air and setting the brakes. Each car is equipped with two of these valves, one at each end and on opposite sides of the car. When the signal moves again to the proceed position, the electric motor lowers the stop arms, permitting the train to pass without setting the brakes; the arms return to stop position by gravity after the train has entered the block. This device is used on the Boston Elevated and on the Interborough Rapid Transit subway express tracks, but on these lines only one arm is used.

The arrangement of the block sections is unusual and so designed to provide more train capacity without loss in safety. In steam railroad signaling, with few exceptions, the block sections end at the home signals, no clear space being provided at each signal in case a train should overrun it. In the Interborough Rapid Transit subway the block sections overlap each other for half their length. In the Hudson & Manhattan tunnel, one block section is the length of three overlaps. Thus each train is protected by three stop signals, four caution signals and two automatic train stops. The length of overlap is equal to the distance in which a train moving at maximum speed can be stopped, plus a 33⅓ per cent. safety margin.

Both rails of each track are used for the train propulsion current and also for the signal current. This constitutes broken rail protection.

There are seven interlocking plants: One, the largest, at the Hoboken terminal; two at caisson No. 1; two at caisson No. 2; one at Greenwich avenue, and one at Nineteenth street. The Taylor all-electric system is used. The signals are the same type as used in the block system. Illuminated track indicators are placed in front of each interlocking machine for the information of the operator.

In all, 90 home signals, 82 distant signals, 10 dwarf signals, 13 switches and 85 automatic train stops are used.

The signal system was furnished by the General Railway Signal Co., Rochester, N. Y., and the automatic stops by the Kinsman Block System Co., New York.

The Ocean Carrier.

BY J. RUSSELL SMITH, PH.D.

IX.

The Organization of Ocean Carrying

We naturally think of the traffic of the land as being carried on by this or that railroad, and we think of the railroad as a carrying unit. Further than this the wide prevalence of the steamer lines tends to produce in the minds of those not directly interested, the idea that upon the ocean also the world's traffic is moved by the steamship line—as it is upon the land by the railroad line. Such an idea of marine uniformity is far from the facts, for the ocean traffic differs profoundly from that upon the land in that it has three distinct types of service. These are the common carriers, the merchant or private carriers and the charter carriers, the host of single independent ships that are for hire to any bidder.

The sea has a freedom and a cheapness unknown to the large scale land carriers and it profoundly affects the organization of the ocean carrying. The most pronounced and far-reaching difference between ocean transportation and land transportation arises from the fact that the ocean is a highway without the efforts of man, and the navigator has but to provide his vehicle. By land roads must be made even for a pack train. For carrying upon the ocean the completion of the ship is all that is necessary, and if she be a sailer the winds of Providence will drive her into all seas and around the world. This fundamental difference in the ocean trade produces many peculiarities unknown upon the land. Because of the smaller capital that is required upon the ocean, we find relatively more individuals and groups of individuals acting independently than we do in the railroad traffic of the land. The single vessel operated as a unit has as much independence as the great line of steamers, and in some respects more independence. Both are alike free to pass over the high seas, to take advantage of the government surveys thereupon, and to enter the harmors that connect with the land, for every port welcomes the greatest possible multitude of ships.

In closer examination of this traffic the first to be considered is the single vessel that is managed as an independent unit. Such vessels do not attract much attention. They come and go unnoticed in news columns of the public press unless perchance they meet with accident, and the reading and traveling layman does not often have his attention called to them. They do not carry his mail, his baggage or his person. These choice and exacting services are rendered by the aristocrats of the deep, the great lines, whose names and performances and owning companies are known by tens of thousands of people scattered over all parts of the reading world. The advertisements of these ships, photographs included, reach the inland hamlets of the five continents, and their movements are heralded as news by numerous journals. They are very important. They carry passengers, mail and much freight with speed, regularity and high cost, and for that reason they do not and cannot do all the ocean's work. The single ship gives a cheaper service and there is therefore a large part of the world's ocean carrying left for it to do, and it is done with little comment or public notice.

If every port in the world had a large trade, made up of a wide variety of articles shipped in fairly even quantities throughout the year, there would probably be no vessels operated singly. With such an even and dependable commerce ships could be organized into lines which would handle the traffic in regularly recurring shiploads. But those conditions of evenness and variety and dependableness do not exist. The nearest approach is in the great commercial ports such as New York, Liverpool, London, Hamburg. In these ports the per cent. of traffic in the line vessels is increasing and that in independent vessels is decreasing. One cannot generalize on world commerce from the world's great ports, for they are few in number and the small ones are very numerous.

During the decades that have made up the railroad era many new lands have been opened to commerce, new products introduced, new parts established. In the vast majority of the many hundred of ports upon the world ocean, the bulk of the commerce is limited to a very small variety of articles, often a single article, and that again is often shipped during only part of the year. It is most likely to be a raw product, cheap, and heavy, which must be carried at as low a rate as possible. This then is not work that can be done by the carefully organized line of vessels. This simpler, unorganized and cheaper service falls to the independent vessel that is for hire and works as a unit wherever there is work to be done. These vessels are built and owned for just this work. The contract that the lessor and lessee sign when the vessel is hired is called a charter, and the ship is spoken of as being chartered, but if regularly for hire she is commonly called a "tramp." Such vessels carry a large share of the world's trade and are utilized for any freight that may go in shipload lots. For the carrying of raw materials, and cheap, heavy or bulky goods the regularity and promptness of the line vessel are not often required. Cheapness is the prime factor. This is true of a long list of commodities lying at the very foundation of modern industry.

As the prime requisite of the charter traffic is cheapness with safety, the combined efforts of the marine architect and the shipowner have been toward economy in cost of operation, while the managers of lines are often striving for regularity and speed regardless of cost. The economics of the tramp steamer fall under three classes:

1. Construction.
2. Navigation.
3. Management.

1. The tramp steamer is built upon a sort of general average model to fit her for as many kinds of service as possible and to go into all oceans and ports. The first object of the designer is to fit her for holding much cargo rather than making high speed. These two diverse objects in design give a great difference in the resulting shape of the ship. The sharp bow and curved ribs of the fast line steamer are replaced in the tramp by a blunt bow, a flat bottom and straight sides, producing in her model a strong resemblance to the cubical form of a section of a squared log. The ship builders' term, "block coefficient of fineness," shows the per cent. that the ship's displacement is of the content of a circumscribing parallelopipedon of the following dimensions: length of ship on the load line, draft and breadth. This coefficient for an ocean greyhound is about sixty-two per cent.; for a nine-knot tramp steamer about eighty per cent. The keel of romance is replaced by a steel bottom as flat as the floor of a warehouse. The keel, as a center of construction, is inside rather than outside the line of the hull, enabling the ship to store freight in every foot of her depth. To prevent the rolling of the vessel, this freighter has bilge keels—fin-like strips of metal riveted to her hull near the blunt angles between the bottom and the sides. With her flat bottom she can cross bars to enter the shallow harbors of any ocean and engage in almost any trade.

Satsuma; Barber & Co., Typical of the Charter Fleet.

2. The economics of navigation group themselves around the central question of speed. It is a fact in mechanical engineering that high speed is attained at much greater expenditure of power per unit than that required to traverse the same distance at low speed. In automobile tests a four horse-power car has made fifteen miles per hour, but seventy horse-power was required for sixty miles per hour. The increase in fuel required is in a similarly high ratio, sometimes approaching in steamships the square of increase in knots per hour. The fast steamer, in addition to form that does not make resistance in passing through the water, must have enormous engines and heavy coal consumption, and larger crew to handle it. These factors mean more expensive construction, less space for freight because of engine room, coal storage and crew quarters; more expensive operation because of greater wear of machinery, and cost of coal and crew. The advantage side of the account arises from the fact that there are more voyages in a year and consequent greater carrying power and because of the speed higher freight rates may be charged. But at twenty, twenty-two or twenty-four knots per hour the cost of this service is more than traffic in raw materials can stand.

At the other extreme of the mechanical question is the fact that low speeds cost a surprisingly small sum. A steamer could make four knots per hour with modern engines at a very small percentage of the cost required for twenty knots, but she would make such a small number of voyages per year and command such low freights that it, like the high speeds, would not be profitable for freight carrying. For freight carrying there is a point of equilibrium in speed above which additional speed costs more in outlay than it adds in income, and below which a lessened speed costs more in loss of earning power than it saves in operating expenses. This point of equilibrium rises with every improvement in engine construction. At present the usual speed for tramp steamers is about nine to ten knots per hour, and it may be confidently expected to increase, some of the newest steamers being already somewhat above it.

These comparisons between the chartered vessels and the liner may be brought out more clearly by the examination of the actual facts of operation of typical vessels of each class.

The "Baron Eldon" is a British tramp steamer, built at Sunderland (1899) for general work. The gross tonnage is 3,705 net tonnage, 2,385 and the crew, 29 men, all told. Her dead weight capacity is 6,100 tons and she has actually carried as cargo 5,360 tons of coal on one voyage and on another 5,550 tons of rice. Her coal consumption at nine knots per hour is 22 tons per day. The "Kaiser Wilhelm II" and the "Cedric" are two modern ocean giants, and built for the North Atlantic line traffic. The "Cedric" is not a racer, however, and has a displacement of 37,870 tons, will carry 18,400 tons of freight, 3,000 passengers, a crew of 350 and has a coal consumption of 260 tons per day at 17 knots per hour. The "Kaiser Wilhelm II" built to break all records, has a displacement of 26,000 tons, will carry less than 1,000 tons of freight, 1,888 passengers, and has a crew of 600, with a coal consumption of 750 tons per day at 24 knots per hour. She could beat the "Cedric" by about two days in a voyage from New York to Liverpool, but to make this gain her crew is nearly doubled and the daily coal consumption nearly trebled. The coal consumed by the "Kaiser Wilhelm II" in one day would run the "Baron Eldon," with her large amount of freight for thirty days, and carry her from New York to Liverpool and back to New Orleans. In this comparison the fact should not be overlooked that the "Kaiser Wilhelm II" carries 1,888 passengers. The "Baron Eldon" carries none, but her gross tonnage of 3,705 tons is a disproportionately large fraction of the Kaiser's 19,500.

Baltic; White Star Line, 23,876 Tons. Best Type of Liner, Less Than Express Speed.

3. The economies of management are possible because of the lack of dependence upon other ships and because the work is always of a temporary nature. The tramp has no schedule, and is free from the exactions of any particular round of engagements or the disadvantages of any particular route. She undergoes no unnecessary dallying at ports waiting for sailing day. The coming of passengers, the arrival of mails, long time contracts to carry certain freight, none of these handicaps of the liner affect her movements. As soon as her special cargo is loaded she is dispatched without loss of time. No further time is lost in making unprofitable calls at intermediate ports, and as soon as her destination is reached she is free to unload and seek further employment. No announced schedule requires her to be run, half empty, over a certain route or to lie in port awaiting freight as advertised. She has the freedom of the seas to seek freight in any port in any continent, to take advantage of any local conditions, any single shipment, that may appear to her advantage. If a bad harvest in America cuts off the grain export, the tramp that has been working in the north Atlantic may seek freights at the mouth of the Danube or South Russia or in the Indian Ocean or in the East Indies; wherever freight is offering, there may she go.

As there is no effort to hold patrons and develop a clientele, there is little expensive advertising done, and the simplicity of the cargoes requires a minimum of office force.

The business of managing this charter traffic is one of the most characteristic developments of the world's commerce of the present era, the epoch of the ocean cable. Several thousands of ships are scattered over the ocean of the commercial world, engaged in the traffic that is supplied by hundreds of ports in all climes and all continents, from Greenland to New Zealand. Every day scores or even hundreds of these independent vessels are seeking freight to carry. It is a complicated world puzzle to bring together the ships and the freight so that the one may be most profitably employed, and the other most economically carried. The work is done by the ship brokers and steamship agents who receive their pay in the form of a commission or brokerage, a percentage on the transaction. In all shipowning countries these firms have their headquarters, and each one has agents and "correspondents" in many other countries, so that among them all they make a complicated web that reaches to all cities of commercial importance. The whole is so bound together by telegraph and cable, that, like a spider's web, if touched by anything of importance at any point, the whole structure vibrates with the news. The departure of a steamer loaded with sugar from a small port in Jave or ore from Chile, is reported by telegraph in Europe and America. There is practically a complete record of all vessel movements published daily by Lloyds, the great British Association of Underwriters. The men engaged in world commerce have, through their world telegraph, a world community of information.

The method of securing cargoes for ships, and ships for cargoes, is best described by the relation of some common incidents of every day occurrence. A Liverpool shipowner had a steamer in the Mediterranean loaded with jute, which she was carrying from Calcutta to Dundee. The owner desired another cargo for the steamer at the end of the voyage. Knowing there was nothing in Dundee he wrote to his agent in Newcastle, and himself made inquiries among the shippers of Liverpool. The Newcastle man suggested a cargo of coal to Hamburg, but this the owner declined, and sought the aid of his correspondents in Dumbarton, but the iron trade of Dumbarton was not promising. Meanwhile the days were passing, the vessel had reached Dundee and there was nothing provided for her. The Liverpool man was himself the correspondent of a London firm of ship brokers, who telegraphed him at this juncture that they had offers of a shipment of German coke to go from Rotterdam to Santa Rosalie, lower California, and of another of Cardiff coal for Buenos Ayres. The first the shipowner declined, as being only suitable for a sailing vessel, and because of news from across the Atlantic he allowed the second to go to a steamer then lying at Antwerp. Three days before this he had cabled to his New York correspondent a description of the steamer, and offering her services to carry grain to the United Kingdom at a certain rate and saying that she could load after a certain date or between certain dates. As New York freight was dull, the firm in that city telegraphed their Boston and Philadelphia agencies. At the same time a Chicago grain exporter decided to export 150,000 bushels of corn, and telegraphed to his agents in New York and Philadelphia to secure offers of transportation. In the shipping exchanges of those cities the representatives of the Chicago exporter and the Liverpool shipowner bargained face to face. Offers were, however, made at the same rate by the New York representative of the owner of a ship then off Rio Janeiro with a cargo of Chilean nitrate bound for New York, and also by a Philadelphia broker who sought future employment for a vessel then in the Red Sea with a cargo of Java sugar for Philadelphia. The Liverpool owner was informed of this competition, and still having nothing for his steamer he cabled that he would charter his ship for three pence (6 cents) less per ton than he had offered, or for the same rate he would take freight to continental ports as far as Copenhagen. He added to his cablegram the word "range" which means in cable code that he would send the ship to the Delaware Bay with the understanding that she might be ordered to New York, Philadelphia, Baltimore or Norfolk to load. This offer secured the freight for the representatives of the sugar ship and the nitrate ship having more time at their disposal preferred to take chances rather than cut rates. The steamer, which, pending negotiations, was still lying at Dundee, proceeded to Newcastle to coal, and departed thence in ballast for the Delaware. Meanwhile the Chicago exporter found that railroad conditions made Norfolk the most convenient port to deliver his corn at the appointed time. When the steamer reached the Delaware Breakwater (just inside Cape Henlopen) the captain received telegraphic instructions to go to Norfolk. There he loaded a full cargo of corn and, as the final destination of the corn was still undecided, he sailed to the Channel port of Falmouth for orders. There he was instructed by signal to proceed to Copenhagen, where the corn was discharged and the vessel was ready for another contract which the agents had been trying to arrange since the day they learned of the final destination of the corn cargo.

That operation is typical of scores that are enacted daily. In almost every exchange of ideas connected therewith, the ocean cable or land telegraph plays an important part. The manager of a merchant fleet may control his ships almost as perfectly from his office in London, Liverpool, Hamburg or New York as does a chess player the men on a board before him. There are signal stations over the greater part of the world where the captain of a ship can receive cabled instructions from the central office. It is common to send vessels to sea with the final destination unknown, the captain reporting at some prearranged signal station where he receives further instructions. This is also true with vessels without cargo and seeking it. Nearly all of the grain ships going from the Pacific Coast of the United States to the United Kingdom sail to Cork, southwest Ireland, "for orders" announcing the final destination. Whether the cargo is to be finally consigned to a port in Britain or any one of four or five continental countries is decided by the grain shipper according to the latest market conditions. Vessels bound for northwest Europe, via Suez, often receive final orders at Gibraltar or Falmouth or Lizard's Point. If coming up the South Atlantic, orders are received at Cape Verde or Madeira Islands. A typical case is that of a vessel, which, lying idle at Singapore, was ordered to proceed for orders to a signal station in Lower Burmah. While en route her owner in London sought cargo. By having the vessel go to Lower Burmah he had the possibility of getting a cargo of rice from Rangoon, or proceeding to Calcutta if cargo were offered there. By ordering his ships from station to station the owner or manager on the shores of the North Atlantic keeps in touch with his scattered fleet in the Indian Ocean, Eastern Asia, Australia or the East Indies almost as easily as if they were a mile or two away in the harbor of his own city. The recent equipment of oil barges with wireless telegraph suggests the arrival of the day when the ship owner may under normal conditions be in constant communication with his ship in all places.

The tramp vessel has earned the name by her absolute freedom of restraint to particular localities, routes or trades. In the constant search for freight she may traverse every sea, and in the course of years, often circumnavigates the globe many times. This roving tendency is increased by the fact that so much of the work done by these vessels is of a seasonable nature, a certain region shipping its product at a certain time only. California wheat is ready to ship at a different season from that of Argentine Republic or India. The corn of the Mississippi Valley is ready to ship later than the wheat from the same region. There is a different sugar season from Hawaii, Peru, Java and Germany. There is a cotton season and a nitrate season, the latter being decided by the greater demand for nitrate fertilizers in the spring planting of the northern hemisphere.

The seasonal nature of the traffic adds to the complexity of the business of ship management. The shipowner has to keep in mind not only the conditions of the contract he is making, but also the prospects ahead of the ship when she must again seek cargo. It is like a game of chess, in that each move must be made with regard to succeeding moves. The shipowner is glad to arrange a voyage that will release the ship in a good location to secure freight, and loath to send her to regions that are devoid of freight, and rates are made accordingly. A cargo of lumber would be taken at a lower rate to New Caledonia, with its export of ores, than to some coral isle in the Mid-Pacific with no export but a few cocoanuts. Thus the possibilities of two or even three voyages enter into the decision of the rates for one. The manager of vessels that happened to be in India or Java or South America would give, under usual conditions, a relatively more favorable rate for a full cargo to New York than to London because he is reasonably sure of getting a profitable freight cargo away from an American port, and an unprofitable coal or ballast cargo away from Great Britain. As a result of judgments of this character steamers are sometimes started upon a chain of voyages requiring months to complete. For example, a man in London, may have an opportunity to secure a cargo of goods from Liverpool to China, and he takes it because he thinks that by the time his ship has reached China he can arrange for a cargo of Java sugar to New York or Philadelphia, and from that point he can get grain back to Liverpool or London; or the same man might send out his ship from London with a cargo to Australia, because she could there get a cargo of coal and take it over to Chile in season to secure a cargo of nitrate for a European or American port.

The tendency of the tramp steamer to rove is intensified by the fact that none of the world's greatest trade routes has equal amounts of freight moving along in both directions. North America sends across the North Atlantic more than twice as many tons of freight as Europe sends back. China and Japan import twice or more than twice as much (in bulk) as they export and the Dutch East Indies, the west coast of South America and the Pacific Coast of the United States all export more than they import. As a consequence the tramp vessel cannot expect to secure cargo both ways and regularly run back and forth on the same route. Ordinarily the tramp must expect, if carrying a profitable cargo, to pass over a certain route in a certain direction, the direction of heaviest freight movement. The ideal of the manager is, therefore to have his ship always discharge one cargo at the profitable or freight surplus end of another trade route. This is clearly impossible. The world's freight can not be carried without sending vessels to places where there is no return cargo. The fewer the voyages of this character, the greater is the profit and skill of the manager. But voyages without cargo must be taken even under the most careful management.

Lacking cargo the vessel must take ballast to steady her, and for this cause thousands of tons of useless sand, earth, stone and water are carried from country to country. But rather than take ballast for nothing the tramp vessel can afford to carry bulky cargo very cheaply, so it happens that coal and sometimes ores are carried practically as ballast substitutes, and at or even less than, the actual cost of running the ship. The voyage must be made to secure profitable cargo at the other end, and the cheap coal freight is that much clear gain. Shipowners are sometimes compelled to send vessels from England to the Pacific Coast of the United States, with no choice but to carry sand or coal, and with plenty of competition for the coal. Under these conditions the product of the Welsh mines has been carried from Cardiff to San Francisco for eight shillings a ton, while the return cargo of wheat paid thirty-five or forty, or fifty or more shillings a ton, and gave the shipowner his profit.

Idaho; Wilson Line. Type of Freighter in Line Service.

The distribution of coal by ocean carriage may, in most cases, be considered a by-product of the charter traffic. There are some cases where coal is carried short distances in lines of vessels especially built for the purpose, but this represents but a small proportion of the total coal carriage. The consideration of the by-product phase of the carrying trade shows that nations are in the best position to export their products cheaply when they import a greater quantity of merchandise than they export, for there is then competition among the shipowners to get the outgoing freight. For this reason the greatest coal exporter is Great Britain, the greatest importer of bulky freight. Next, in respect of the wide distribution of this product, come Australia and Japan, both fourth-rate coal producers, but countries whose imports are more bulky though less valuable than their exports. These countries are able to export coal, widely, yet in none of them is coal so abundant or cheap as in the United States. The United States has not become an important coal exporter, except to adjacent countries, because the heavy exports of raw materials have employed more shipping than our imports required, so vessels come to us in ballast, and a ship that carries coal from an American port must usually return in ballast, making it necessary for the coal freight to pay for both voyages. This cannot be done, because the somewhat more expensive British coal is carried at very low rates as ballast cargo and undersells the American in most foreign ports. The American export of coal is limited almost entirely to Canada and Mexico and to the West Indies, whence we are importing iron ore, sugar and woods, all of them bulky articles, and the outgoing vessels carry the coal. In contrast to this British coal goes more than half way around the world. The tramp is cheap but slow and uncertain, she suffices for raw materials, but for a large share of the ocean work she cannot compete. The exchanges of articles of high value per ton, require, because of that value, the more dependable and expensive service of the line vessel.

The regular service in its turn stimulates trade by its regularity, and is a necessary part of the commerce of highly civilized states. Passengers cannot make their arrangements to sail on vessels whose time of departure is uncertain. Like the mails, the passenger traffic requires a definite schedule of sailings, which must be made out months in advance, and announcement made of the day and hour of sailing. Certain classes of valuable freight are scarcely less exacting and there are many lines of vessels carrying freight only that are made to follow an advertised schedule almost as punctually as do the passenger lines.

The distinction between line traffic and charter traffic is in some cases hard to point out. The difference between the work of the best Trans-Atlantic liners and that of a typical tramp steamer or sailing vessel is unmistakable, but there is a point where the two kinds of traffic approach each other closely and, from the standpoint of the vessel, there are many cases in which the distinction cannot be drawn at all, because many vessels pass repeatedly from one service to the other. This transition service is best explained by describing the methods of operating some of the cheaper all-freight lines.

With these, as all other lines, the amount of freight to be carried fluctuates, and the company will often do it all with chartered vessels or own only enough vessels to attend to a sure minimum of business, and when temporary increase of traffic comes the managers turn to the ship market for additional vessels to be taken on time charter, and operated in the line service so long as it seems expedient to do so. When trade decreases the charters of these vessels are allowed to lapse and the fleet is reduced. In this work steamers are often chartered for a year or even two years if rates promise, in the opinion of the charterer, to be steadily rising. Vessels are also taken into the line service for only a single voyage, particularly where there is much more traffic one way than the other. It is common for some of the lines regularly carrying freight from New York to Australia and the Orient to charter vessels for the out voyage only. On these routes returning freight is so scarce that even the vessels owned by the companies may become tramps or are "put upon the berth" at the end of the voyage, and work their way back to New York by whatever indirect route offers the best chance of earning freights. It is a common, almost a regular occurrence for some of the companies operating steamship lines in these trades to announce the date of a steamer's sailing when they cannot give her name, because the yhave not yet chartered her. Any good tramp steamer may be secured for the assignment at the latest available date.

New York; American Line, 10,798 Tons. Largest and Fastest Type Until 1893.

This elasticity of service is not possible with the lines having passenger service, specialized freight traffic and vessels especially adapted to the trade and built for it. A fleet of such vessels cannot be enlarged by chartering at will.

Despite the traffic of uncertain qualities there is a vast line traffic having pronounced differences from the charter traffic. From the standpoint of traffic these differences may be summarized in the two words, regularity and speed, or in two others, increased efficiency.

The efficiency of the line of steamers is only obtained by incurring certain expenses that are not necessary if the vessel is working independently and carrying special cargoes. These expenses may be classed under the heads: 1. Maintenance. 2. Management and advertising. 3. Costly construction. 4. Speed.

1. The most important single factor about line service, the schedule and its maintenance, is one of the great cares and costs of the managers. When a vessel is scheduled to sail on a certain date, her time may be up before she is fully loaded, or she may be loaded or ready to load and have to wait till the appointed time. Both are expensive to the owner. The making of a schedule must provide for the worst conditions of weather, and then in good weather, the vessels may lie idle in their expensive docks. In keeping up a regular schedule it may be necessary to enter ports when the freights do not warrant the delay and the cost.

In contrast to this is the freedom of the chartered vessel. She takes things as they come, she has made no promises, she sails as soon as she is ready, can be delayed without any further inconvenience than the loss of time, and proceeds only to such ports as best suit the particular conditions of a particular voyage.

Accidents fall with cumulative force upon a steamship line because of the effect upon the schedule. In addition to the direct loss due to the accident, the future sailings and service are often demoralized, and the fulfillment of outstanding contracts becomes a matter of great difficulty and financial loss rather than profit. If a ship is disabled a few days before time for putting to sea, her place must be filled, and it is difficult and often costly to secure a good steamer in an emergency or even to secure accommodation elsewhere for the passengers and freight that have been engaged. Such necessary shiftings may make a month or more of losses where high profits were expected.

2. Line traffic, particularly when an object is made of carrying passengers, requires a large amount of advertising to catch and keep the attention of the would-be traveler and to create the desire for travel. Allied to the advertising is the elaborate arrangement of offices and agencies in many cities for the selling of tickets and securing of freight. At the port of sailing, the office of the steamship agents managing a high grade steamship line requires an efficient force of clerks. The staff must be organized on the basis of its ability to manage the work at the times of greatest rush—sailing day—although it may be partly idle in the intervals.

To handle the line traffic in freight requires more clerical work and more warehouse room than the same amount of charter traffic, because of the greater number of shipments to be received, invoiced, cared for till loading time, placed safely in the hold of the ship and finally assembled at the point of discharging cargo. Such cargo is often spread out in separate lots over a large area of quay or warehouse space. The bulk equipment of grain or other uniform charter cargo can be discharged more easily into coasting or river craft alongside or it may be thrown in great heaps, so that it occupies less warehouse space than any other kind of cargo.

3. Many kinds of line traffic require special types of ship construction. First among these is the passenger service, which is provided for wherever the travel is sufficient to give passengers for a part of each year. Human freight is more exacting than inanimate cargo and while the business is very profitable, it adds greatly to the cost of construction of the steamer, increases the crew and decreases the freight space.

Many kinds of freight require nearly as much special construction as do passengers. This statement applies especially to perishable goods requiring refrigeration. There is a large traffic in frozen meat between Great Britain and the southern hemisphere. The frozen carcasses are taken from a cold-storage warehouse in Argentina or Australasia and carried to Europe in the ship's freezing chambers. Another division of the refrigerator traffic is the larger and rapidly growing use of chambers where the freight is chilled, but not frozen. In this manner is carried the American fresh meat en route to Europe, and the most of the ocean trade in fruits and dairy produce. Some other forms of special construction are found in ships prepared for carrying live cattle, and in tank steamers for the carriage of oil in bulk, and the fruit steamers that carry oranges and bananas from Caribbean and other tropical countries.

4. High speed is not a necessary part of all line traffic, but it is an essential factor and a large element of the cost in those lines carrying passengers and mail, and in some freight lines. The

increased consumption of coal has been referred to in the discussion of charter traffic. High speed requires, along with greater coal cost, greater crew to handle the coal, larger bunkers and machinery space, and consequent lessened freight space. Machinery running at high speed wears out sooner and requires more repairing per mile than when operated at lower speed. The fast vessel is also more liable than a slow one to accidents at sea, especially collisions.

As a compensation for the various costs the line steamer has several strong advantages over the chartered vessel. 1. It can charge higher rates of freight on some goods. 2. It can secure more advantageous loads through mixing cargo. 3. It wins patrons and develops trade through acquaintance.

1. The liner monopolizes the passenger traffic, the carriage of mails, and because of its speed or regularity, or both, it can charge a higher freight rate for much valuable express cargo in the transportation of which time is an important factor.

2. In the carriage of ordinary freight the liner has an advantage in its ability to secure mixed cargo, and stow into a given space more tons of freight than can usually be secured by the special cargo vessel, which ordinarily carries a cargo of one article only.

The question of the relation of the bulk of cargo to its weight is a very important one for the ocean carrier. The ship has a certain capacity in dead weight tons, and an absolutely inelastic amount of cubic space into which those tons must be stowed. It is important that both space capacity and weight capacity be utilized, and to do this there should be some heavy cargo to give the weight and some light to fill the space. A full cargo of either is unsatisfactory.

The ocean carrier solves the problem by basing his freight rate on two different units, one of weight and one of cubic contents. Both are called tons, the weight ton and the measurement ton, the latter consisting of 40 cubic feet. The shipowner exercises his discretion as to whether he receives freight on the weight or measurement basis, and, of course, uses the one most favorable to himself. The measurement ton happens to have its particular size because a weight ton of wheat occupies about 40 cubic feet, and as wheat has long been a staple, and often the greatest staple of ocean commerce, shipowners came to think of their vessels in terms of their wheat-carrying capacity, and this grain became the norm for measuring other commodities. Freight goes by weight or measure, at the discretion of the carrier. Hence a shipping company's report of the number of tons of freight carried, gives neither an accurate measure of weight nor cubic content of the traffic, because it is usually composed of unknown quantities of both kinds.

A mixed cargo will give a greater cargo tonnage than a full cargo of either kind, because all vessels will contain more heavy cargo than they can float, and they will float more light cargo than their space can contain. A vessel that can carry 1,000 tons dead weight would have four-fifths of her space empty when carrying a full cargo of iron. On the other extreme a full cargo of wagons or wooden manufactures would not weigh more than 300 or 400 tons. In one case the ship is wasting space, in the other carrying power; but with 700 tons of iron or steel in the bottom of the hold there is still space for possibly 700 tons of light measured cargo, say, wagons and furniture—1,400 freight tons in all. The possibility of making such combinations is constantly before the managers of line vessels, and freight is sought and rates are made with such arrangements in view. If 1,400 freight tons of wagons and steel rails can be put into the vessel that can only carry 1,000 tons of rails alone, the agents can well afford to take both articles at a rate somewhat lower than could have been offered for a full cargo of either, and yet have greater returns than would have come from a full cargo of a single commodity at the full rate—1,000 tons at \$5 per ton equals \$5,000 and 1,400 tons at \$4 per ton equals \$5,600.

The steamer is also much safer to navigate with a full dead weight rather than a light measurement load.

3. The line has also the advantage of getting regular patrons, of making contracts for long periods and of reaping the advantage of the increased trade that its regularity fosters, but it must also maintain its reputation and preserve that regularity of performance during periods of depression and loss.

(To be continued.)

Electrification of the Suburban Lines of the Western Railway of France.

As a result of the campaign which it has been conducting against delays to trains in the suburban work of the Western Railway of France, the Paris *Matin* has received a letter from the managing director, a portion of which might well have been written by any one of a dozen managers of American railroads who is dealing with congested terminal facilities. The writer states that inasmuch as *le Matin* has opened its columns to complaints of passengers that are made because of trains that are late in reaching the Saint Lazare station, he confides in the spirit of justice with which the paper is endowed to publish the reply of the railroad company.

In a station like that of Saint Lazare, where the engine and train movements are more than 1,200 a day, it is quite inevitable that there should be some incidents to delay operation. The complaint is that these delays are excessive, and the suburban patrons very properly insist that even the most insignificant of these delays interfere with the satisfactory performance of their daily work. What the public wants to know is whether the company has done all in its power to remedy the situation.

Negotiations were opened with the city of Paris in 1902 for the purpose of running the Auteuil line beneath the Rue de Rome, but the construction of the second Metropolitan line killed all hope of doing away with the Batignolles tunnel. From that time on every effort has been bent towards the suppression of the throat through which all traffic to the Saint Lazare station must pass. And as soon as it was understood that prompt action on the plans could be counted upon, a definite project was presented. This was done in July, 1906, but it was not until May, 1907, that the plans were approved whereupon work was undertaken at once. But while the execution of these works of improvement are being pushed as rapidly as possible, the suburban traffic is constantly increasing. It was 20,000,000 passengers in 1884; 40,000,000 in 1904, and 42,000,000 in 1906.

This expansion of the traffic has not been evenly distributed, as, for example, the line to Versailles and its branches have fallen far behind other portions of the system because of the competition of the tramway lines, whereas that of St. Germain d'Argenteuil has advanced by leaps and bounds. It was 11,100,000 in 1884; 26,000,000 in 1904, and 29,300,000 in 1906. The consequence of this has been an enlargement of the original program and an announcement that the road is prepared to electrify this line.

It is the expectation that the completion of these works will make an entire transformation of the service, not only in the case of the short distance runs, but also of the long ones, and that great elasticity will be given to the Saint Lazare station and its approaches.

The electric lines, starting from a subterranean station below the level of the Cour de Rome, will make it possible to run electric trains between the Saint Lazare station and Germain and Argenteuil without any grade crossings.

The rolling stock will be like that of the Metropolitan, but enlarged. It is estimated that the schedule time will be cut down one-half and that it will be possible to run 20 trains an hour.

The letter concludes with the statement that the Western Railway Company, against whom these constant recriminations have been hurled, has not ceased for an instant in spite of the difficult situation in which it has been placed to struggle for an improvement of its service, and this is manifested by the magnitude of the work which it has undertaken.

Coal Production in 1906.

According to the *Moniteur Industriel* the total coal production of the world for 1906 was about 905,000,000 tons. In this there has been a decided increase in some countries over the preceding year, Great Britain, for example, showed an increase of 15,000,000 tons, Germany of about 15,500,000 tons, and the United States nearly 19,000,000 tons. The production of the principal countries is given as follows:

	Tons
United States	370,000,000
Great Britain	251,000,000
Germany	135,000,000
France	33,500,000
Belgium	23,250,000
Russia	20,000,000
Other countries	72,250,000
Total	905,000,000

France produced about 1,000,000 tons less than in 1905, probably because of the trouble in the north at the beginning of the year, for, though the output was but 15,000,000 tons during the first six months, it rose to 18,500,000 tons in the last. The United States furnished 50 per cent. more than England; Germany about half as much, and France and Belgium scarcely more than a quarter. If, on the other hand, these figures are compared on the basis of the population of the interested countries, we find that the production in England amounts to 4.75 tons per capita, while that of the United States yields but 4.50 tons; Belgium, 3.25 tons; Germany, 2.25 tons, and France less than a ton. England, which holds the first place in this proportional production, exported, during the first nine months of last year, 46,884,000 tons of fuel, a figure that indicates a considerable advance over the same period for the two preceding years. This was

	Tons
For 1905	35,309,000
For 1906	41,230,000
For 1907	46,884,000

The increase of 1906 over 1905 was due to large orders from France, Italy, Belgium, Russia and Argentina; while that of 1907 over 1906 came from exportations into Germany, Holland, Belgium, France and Italy; orders from Argentina having been comparatively insignificant.

GENERAL NEWS SECTION

NOTES.

The Chicago & North-Western has issued an executive order prohibiting throwing rice and other missiles at or around any bridal party entering or leaving trains.

The Pittsburgh Car Service Association reports that 122,130 cars were handled in its territory during January, 1908, as against 220,654 cars in January, 1907, a reduction of about 44 per cent.

The Supreme Court of Montana, on February 25, declared valid the state law providing that employees must not be worked for more than 16 hours without eight consecutive hours for rest.

The Rock Island has reopened its traffic office at the city of Mexico, indicating apparently another change of policy by the road, which had temporarily withdrawn from the Mexican field.

Announcement is made that the Seaboard Air Line, beginning April 1, will act independently in the matter of party rates and will give a flat rate of 2 cents a mile for parties of 10 or more persons.

It is understood that 85 per cent. of the telegraph operators on the Northern Pacific voted against the proposition made by the road in regard to the new schedule of hours and wages, to become effective this week.

It is understood that the Per Diem Commission to be named by the executive committee of the American Railway Association will consist of Lucius Tuttle, Marvin Hughitt, James McCrea, W. W. Finley and Howard Elliott.

The Nebraska Railroad Commission has ordered the railroads of that state to show cause by March 10 why certain radical reductions should not be made in freight rates and why a maximum distance tariff should not be established.

Announcement is made that there will be a rail connection between the Hudson & Manhattan tunnel at Jersey City and the Erie station, with the ultimate intention of running Erie suburban electric trains of special type into New York City.

The Union Pacific is now charging passengers not holding tickets, 3 cents a mile for 10 miles or less in Kansas and 25 cents excess fare where the regular rate is between 50 cents and $1.50. If the rate is more than $1.50, 50 cents excess fare is charged.

The Louisville & Nashville and the Atlantic Coast Line have instigated a friendly suit in Alabama to test the new franchise tax of the state. The Louisville & Nashville paid approximately $23,659 on account of this tax on February 2 and at once brought suit to recover it.

The Inland Empire System, operating approximately 150 miles of road by steam and electricity in the state of Washington, has adopted a compact rate schedule card for class rates out of Spokane, which is designed to be simple enough so that the shipper can use it himself without difficulty.

Effective March 1, it is understood that a 10 per cent. reduction will be made in the salaries of officers and subordinates on the New York, New Haven & Hartford receiving $2,000 and upward per year, and that a 5 per cent. reduction will be made in salaries between $1,200 and $2,000 a year.

Attorney-General Bonaparte, on March 2, directed United States attorneys to institute suits against 27 railroad companies to recover penalties incurred by them for alleged violations of the safety appliance law, as reported to the Interstate Commerce Commission by its inspectors of safety appliances.

On February 25 the House committee on interstate and foreign commerce authorized a favorable report on the Esch bill, requiring railroads to make reports monthly of all accidents on their lines to the Interstate Commerce Commission, and authorizing the publication of those reports by the commission.

The Erie allows members of the faculty of the Cornell College of Agriculture, who are traveling through the state in the interests of good farming, to travel free on its trains, and also carries seed samples and agricultural matter free when sent to the college for examination, or when sent from the college to the farmer.

The Central Freight Association has agreed to reduce the rate on grain and wheat originating west of St. Louis $1\frac{1}{2}$ cents, and on oats, flour and other grain products, destined to the Atlantic seaboard, half a cent, effective April 15, to protect the St. Louis market, since St. Louis has no direct lake route for eastbound traffic.

A local surgeon of the Union Pacific in Nebraska, and the editor of the Gothenberg (Neb.) *Independent*, have been bound over for trial for accepting free transportation from the Union Pacific. These are regarded as test cases, in which the company will make a strong fight against the validity of the state anti-pass law.

Announcement is made that the Burlington has abolished its industrial department, effective March 1. The department was created by W. H. Manss, now with the Chicago Association of Commerce, and for several years the company made large expenditures in educating farmers in various branches of farming along the route.

The Texas Railroad Commission has given the Texas & Pacific until March 15 to make answer whether or not it will comply with the commission's order to make improvements to its physical property in Texas, costing about $2,000,000. If the railroad refuses to obey the order, the state will seek to have a receiver appointed for it.

The Western Union Telegraph Company has instituted suit against the state of Wisconsin to recover $12,886, which it alleged was paid as excessive taxes in October, 1907. The complaint says that under the ad valorem law the company's property within the state was assessed at $1,800,000, whereas the true value was but $653,544.

Circulars have been sent to shippers in New York providing for a reduction on the charge for all split deliveries from $9.00 to $3.00, this action having been made possible by the Interstate Commerce Commission in authorizing the trunk lines terminating at New York to make changes in rates under certain conditions on one and three days' notice.

The Long Island Railroad announces that a year's experience has proved that the refunding of fares because of the failure of commuters to have their commutation tickets with them causes a greater loss of revenue than anticipated or warranted by the legitimate accommodation thus afforded. Therefore these refunds have been discontinued since March 1.

On February 29 the Louisville & Nashville rescinded its recent order reducing the pay of engineers and conductors 10 per cent. on all its lines. The engineers had declined to accept the cut, but the conductors had agreed to a compromise at a reduction from the former scale. Both classes will continue for the present to receive pay on the former basis.

A series of joint rate meetings is to be held, beginning with one in Chicago, March 9, at which the revision of the Chicago joint passenger rate sheet will be undertaken. As soon as this is completed the revision of the St. Louis sheet will begin and others will follow, in accordance with an agreement reached by the Central, Western and Southwestern passenger association lines.

It is not true, as currently reported, that the Erie has abolished piece work in its shops. After a year's trial it has made certain modifications to meet service conditions, but retains the principle as strongly as before. General laborers working in and about the shops have had a reduction of 10 per cent. in their pay but no reduction has been made on the piece work scale.

The Union Pacific is standing firm in its refusal to make any changes in its system of elevating charges on grain, as opposed to the efforts of certain grain-carrying roads south of the Ohio river to reduce the elevation charge to the shipper. The Union Pacific believes that the assumption of the maximum part of this charge by the railroad has its principal effect in furthering speculation.

Five bishops of the African Methodist Episcopal Church have complained to the Interstate Commerce Commission about the accommodations furnished negro passengers on trains in the South, alleging that the cars are dirty and have inadequate accommodations, and that negroes are not allowed to buy sleeping car tickets or to eat in dining cars, although they pay the full first class fare.

As a result of the reduction in per diem from 50 cents to 25 cents a day, the New York, New Haven & Hartford has re-entered the American Railway Association, but with the proviso that in any future change of rate it shall receive notice a sufficient time ahead to give it opportunity to withdraw from the association if it should desire to do so. The New Haven has stood aloof since October 1, but has charged to itself over $600,000 per diem at the 50-cent rate.

The Texas Railroad Commission is in a state of mind at the criticism it has received because of its extreme requirements of the railroads at a time when they are unable to raise funds, contributing to the causes of the International & Great Northern receivership. The commission declares that it will put every railroad in Texas in receivers' hands rather than permit operation under hazardous conditions, forgetting, perhaps, that from time immemorial operation on bankrupt roads has been more hazardous than on roads able to provide for the upkeep of the property.

The Chicago, Milwaukee & St. Paul has asked authority to cancel through passenger tariffs from eastern points to Seattle, via Portland, owing to the recent opinion of Commissioner Clark that through tariffs, involving travel over more than one line, must have the sanction of all the roads involved. The commission has had the question of the establishment of a through rate and joint rate via Portland before it since last summer.

At a labor mass meeting of 1,500 men at Atlanta, Ga., February 21, President Roosevelt's action in ordering an investigation of reductions in railroad wages was endorsed. On the following day the Georgia Railroad Commission ordered all carriers contemplating reductions to furnish the commission with a statement of the proposed reductions and the reasons for them in full. The order is issued under the state law which requires carriers to maintain reasonable service, the commission holding that the reduction of wages without sufficient reason would tend to produce discord and prevent carriers from maintaining a satisfactory service.

At the same time that Georgia was strenuously opposing wage reductions, last week, a delegation of railroad men had an audience with the House committee in Mississippi, protesting against any legislation that would interfere with the management of Mississippi railroads and give the corporation an excuse to reduce wages. When the Mississippi legislature, now in session, first assembled, the Governor sent a message strongly urging a 2-cent law, but the Senate committee, to which this part of the message was referred, has recommended that no action be taken, expressing the opinion that no rate lower than 3 cents is advisable under present conditions in the state, and this report has been adopted by the Senate, to the great encouragement of the railroads.

At a hearing on the nine-hour law before the Interstate Commerce Commission, February 27, the representative of the St. Louis & San Francisco testified that the company would have to increase its rates to offset the charge. The representative of the Southern Railway testified that it would be necessary under the law to employ 220 additional operators, and that the company was unable to do this and meet its other obligations. Similar arguments were presented by a large number of other roads, but the commission showed no desire to help, and on March 2 definitely denied all petitions. It is understood that the Pennsylvania will require 700 additional operators to meet the requirements of the law. The immediate results of this legislation, effective March 4, have been the closing of an exceedingly large number of small telegraph stations all over the country.

The chairman of the Public Service Commission for New York City called attention in a recent address to the very urgent need for new subways in New York and to the fact that under present conditions nobody is interested in building these lines. He felt it was necessary that the state constitution should be so amended as to enable the city to build the subways directly, or else that laws should be passed that would allow private capital to build and operate new lines under conditions which would tempt capital instead of frightening it away. The commission in its recent report to the legislature said that it was necessary to start with the idea that the city's rights were to be protected, and then to make a reasonable and safe contract with the man who is willing to risk his money. If a capitalist is shown that his principal is safe, and that he is reasonably sure of a fair profit on his investment, he will take hold; otherwise he will not.

Reducing Liquor Sale on Pullman Cars.

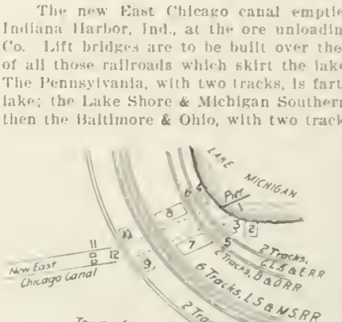
There are now only about eight states where the Pullman Company is selling liquor on its cars. Partly because of state prohibition laws and partly on account of changing public sentiment, the company has for ten years been reducing gradually its liquor business, and has recently added Pennsylvania to the non-liquor list.

Acetylene Insurance Rules.

The rules formulated by the National Board of Fire Underwriters for the use of acetylene have hitherto required outside installation of acetylene generators. Although in most sections throughout the United States this rule has not been insisted on, in certain limited sections it has been rigidly enforced. At a meeting on January 30 the board, after considering reports submitted to it by its various committees, amended these rules by striking out such words as prohibited inside installation and substituting the following: "Generators, especially in closely built up districts, should preferably be placed outside of insured buildings in generator houses constructed and located in compliance with Rule 9." Where outside installation is preferred, as above, the rule regarding construction of generator houses has been modified. Such houses formerly had to be fireproof, built of brick and located as far as practicable from other buildings; they may now be located adjoining an insured building, and fireproof construction is not required.

Lift Bridge Foundation Work at Indiana Harbor.

The new East Chicago canal empties into Lake Michigan at Indiana Harbor, Ind., at the ore unloading slip of the Inland Steel Co. Lift bridges are to be built over the canal to carry the tracks of all those railroads which skirt the lake shore on their way east. The Pennsylvania, with two tracks, is farthest from the shore of the lake; the Lake Shore & Michigan Southern, with six tracks, is next; then the Baltimore & Ohio, with two tracks; and nearest the lake is the Chicago, Lake Shore & Eastern, with two tracks. The accompanying plan shows the tracks and the foundations for the bridges.

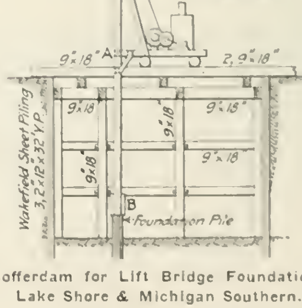


Location of Foundations for Lift Bridges Over New East Chicago Canal.

The average amount of excavation for the piers of these lift bridges is about 5,000 cu. yds. for each two-track lift bridge. On the Lake Shore three double-track bridges are to be built side by side, so the excavation work is obviously less for each bridge than in the case of the other three roads, which have only one double-track bridge each.

At the beginning of the work on the Lake Shore, Wakefield sheet piling, consisting of 2 x 12 yellow pine timbers, 32 ft. long, was driven and jetted. As shown in the accompanying section of the cofferdam, which is 42 ft. x 105 ft., the piling is 6 in. thick, the joints between the planks being staggered. One 2,000-lb. drop hammer, with a gang of 12 men, at an average of $2.45 per day, drove 15 ft. of the sheet piling each day. The piling generally sank under the weight of the hammer because of the jetting, and little driving was needed. Excavation began about the middle of September; by the first week in November the work had been carried down 26 ft. and foundation pile-driving started. Ten men at $1.60 per day, one hoisting engineer at $3 per day and two men at the gondola car, dumping the 1-yd. cylindrical buckets, constituted the gang for this work. The first 8 ft. was dry sand. Six feet below the top of the sheet piling, 9 x 18 in. walling pieces, with the wider sides against the sheet piles, were placed all the way round the cofferdam. As cross bracing, 9 x 18 timbers, with the greater dimension vertical, were then strung across at intervals of every 15 ft., along the longer dimension of the excavation, and every 14 ft. along its shorter dimension. Vertical posts were set at the junctions of the longitudinal and transverse bracing; these posts were secured to the bracing timbers with ½ in. x 4 in. forged angles, each leg 5 in. long, with two holes for 8-in. lag screws. The 9 x 18 in. timbers used in the cofferdam were taken from old bridges and trestles.

As the excavation was carried down, new walling pieces were added at intervals of about 5 ft. until the full depth of 28 ft. was reached. These lower walling pieces, however, were composed of two 9 x 18 in. timbers lagged together and placed on edge against the sheet piling to gain additional strength. Beneath the points of intersection of the walling pieces and the cross bracing vertical 8 x 16 in. timbers were lagged on with the wider side against the sheet piling.



Cofferdam for Lift Bridge Foundation; Lake Shore & Michigan Southern.

About 8 ft. below the surface, water was found, and two type B Emerson Junior pumps, 180 gals. per minute capacity, each with 4-in. suction and 3-in. discharge pipes, were hung from the upper timbers. These kept the excavation dry down to its lowest level, 25 ft. below the water line, during the time the foundation piles were being driven. Two other Emerson pumps were used also in the cofferdam for the smaller pier. These weighed 250 lbs. each.

A total of 1,200 piles were driven in the main and minor excavations and 24 men, averaging $2.45 per day, with one 2,800-lb. and one 2,000-lb. drop hammer in 65-ft. guides, drove an average of 30 piles a day, each pile about 45 ft. long. The method of mounting the pile-drivers is shown in one of the drawings. Two chords, 9 x 18 in. each, were lagged together, with joints staggered, and in about 30-ft. lengths, so as to make an 18 x 18 in. beam 60 ft. long. Two of these, spaced about 10 ft. apart, rested on the transverse and vertical cross bracing of the upper tier. Across these two were laid two extra heavy 10-in. wrought-iron pipes which served as rollers for the hoisting engine which operated the drop. Since the piles were not driven until the excavation had reached its lowest level, there were four different tiers of cross bracing which interfered with the lateral movement of the pile-driver guides; instead, therefore, of lifting the entire 65-ft. length out of the excavation whenever the progress of the pile-driving made it necessary to cross a longitudinal or transverse bracing timber, the lower 30-ft. section of the pile-driver guides was made detachable. By taking out eight bolts the hoisting engine could lift this lower section above the upper tier of cross bracing and the engine was pushed over into the next shaftway, where the lower section was again dropped into place, attached, and the pile-driving resumed. The change required a little over five minutes.

A 1-yd. Hayward orange peel bucket was used in the excavation for the Pennsylvania bridge. One No. 3 Emerson standard pump, with 725 gals. capacity, 5-in. suction, 4-in. discharge and 1¼-in. steam pipe was used. A similar size was used in the B. & O. excavation and another of the same size in the C., L. S. & E. excavation.

Southern Pacific Service Accelerated.

The Southern Pacific rail and water lines have put into effect the following revised service:

Freight leaving Boston Tuesday by New England Steamship Co. or Metropolitan line will go forward from New York on Morgan line steamer, sailing the following Thursday.

Freight leaving Boston Thursday by New England Steamship Co. or Metropolitan line will go forward from New York on Morgan line steamer, sailing the following Saturday.

Freight leaving Boston Saturday by New England Steamship Co. or Metropolitan line will go forward from New York on Morgan line steamer, sailing the following Tuesday.

Freight leaving Philadelphia Monday and Tuesday by Clyde line will go forward from New York on Morgan line steamer, sailing Thursday.

Freight leaving Philadelphia Wednesday or Thursday by Clyde line will go forward from New York on Morgan line steamer, sailing Saturday.

Freight leaving Philadelphia Friday and Saturday by Clyde line will go forward from New York on Morgan line steamer, sailing the following Tuesday.

Freight leaving Baltimore Monday by New York and Baltimore Transportation line will go forward from New York on Morgan line steamer, sailing the following Thursday.

Freight leaving Baltimore Wednesday by New York and Baltimore Transportation line will go forward from New York on Morgan line steamer, sailing the following Saturday.

Freight leaving Baltimore Saturday by New York and Baltimore Transportation line will go forward from New York on Morgan line steamer, sailing the following Tuesday.

Freight leaving Richmond Monday by Old Dominion line will go forward from New York on Morgan line steamer, sailing the following Thursday.

Freight leaving Richmond Wednesday by Old Dominion line will go forward from New York on Morgan line steamer, sailing the following Saturday.

Freight leaving Richmond Friday by Old Dominion line will go forward from New York on Morgan line steamer, sailing the following Tuesday.

President Urges Improvement of Inland Waterways.

President Roosevelt has transmitted to Congress the preliminary report of the Inland Waterways Commission and accompanies the report with a message of considerable length in which he reviews the whole subject. He says, in part:

"Our river systems are better adapted to the needs of the people than those of any other country. In extent, distribution, navigability and ease of use, they stand first. Yet the rivers of no other civilized country are so poorly developed, so little used, or play so small a part in the industrial life of the nation as those of the United States. In view of the use made of rivers elsewhere, the failure to use our own is astonishing, and no thoughtful man can believe that it will last.

"The Commission finds that it was unregulated railroad competition which prevented or destroyed the development of commerce on our inland waterways. The Mississippi, our greatest natural highway, is a case in point. At one time the traffic upon it was without a rival in any country. The report shows that commerce was driven from the Mississippi by the railroads. While production was limited, the railroads, with their convenient terminals, gave quicker and more satisfactory service than the waterways. Later they prevented the restoration of river traffic by keeping down their rates along the rivers, recouping themselves by higher charges elsewhere. They also acquired water fronts and terminals to an extent which made water competition impossible. Throughout the country the railroads have secured such control of canal and steamboat lines that to-day inland waterway transportation is largely in their hands. This was natural and doubtless inevitable under the circumstances, but it should not be allowed to continue unless under careful Government regulation.

"Comparatively little inland freight is carried by boat which is not carried a part of its journey by rail also. As the report shows, the successful development and use of our interstate waterways will require intelligent regulation of the relations between rail and water traffic. When this is done the railroads and waterways will assist instead of injuring each other. Both will benefit, but the chief benefit will accrue to the people in general through quicker and cheaper transportation."

Mr. Truesdale on the Railroad Situation.

The following comments are taken from the current annual report of the Delaware, Lackawanna & Western:

The two great political parties of the country, in planning their forthcoming presidential campaigns, make the sins of the railroads and their management, and drastic correction of the same, their leading issues, and herein may be found the real underlying cause of the general, indiscriminate abuse of the railroads and of their management, and of the paralytic stroke which they and all interests connected with them have suffered. With great foresight and shrewdness those who have planned and are responsible for this political program have alienated from the railroads the chief political influence that they might and should have every reason to expect would use their influence to protect them against a campaign of this kind, their own employees. This has been accomplished by the passage of certain laws governing the hours of service, wages, conditions of employment generally, and others more far-reaching have been promised and are now pending.

After declaring that the sweeping denunciation of the managing authorities has weakened their authority over their employees, Mr. Truesdale added:

"No greater blow has been dealt the railroad interests of the country, none that will react more quickly or with greater permanency on the public at large, than the legislation that has been enacted and that is proposed and pending, the effect of which is to take from those in charge of the management of railroads the reasonable and proper control of these properties, including especially the army of employees engaged in their service in various capacities. The tendency, furthermore, to place the control of the railroads and their operations, down to the minutest detail, in the hands of public officers, boards or commissions, all of which are subject to political influences to a greater or less degree, is by no means hopeful or reassuring as respects the future value or efficiency of the transportation facilities of the country."

TRADE CATALOGUES.

Spiral Riveted Pipe.—The American Spiral Pipe Works, Chicago, has issued circular No. 21, showing some of the many uses, as well as the advantages and economies, of Taylor's spiral riveted pipe with forged steel flanges. It is claimed to be the strongest riveted pipe made, by 30 to 50 per cent. A half-tone from a photograph shows a section of 12-in. pipe, 16-gage steel, which is stated to have withstood a hydraulic pressure of 650 lbs. per sq. in. The parts between seams bulged ¾ in., but the seams were practically unaffected. Strength to resist collapse under vacuum or heavy fills, and strength and rigidity against bending are other good qualities claimed. Many photographic views of the pipe in use in various applications are shown, and details of the different joints, and other details, are illustrated and described. The circular is 8 in. x 10 in. and has 20 pages.

Shoulder Flange Tie Plates.—The Railroad Supply Co., Chicago, has issued an attractive 16-page pamphlet on Wolhaupter shoulder flange tie plates. This is a new form of tie plate, being the standard Wolhaupter plate with a shoulder rolled on it. The results of some interesting tests made by R. W. Hunt & Co., Chicago, are recorded. A compression test to determine the comparative loads required to imbed the Wolhaupter and a flat-bottom plate in a tie showed a difference in favor of the former of 9,100 lbs. Other tests were for track spreading and for transverse bending strength.

Missouri Pacific.—The passenger department has issued a pamphlet describing the attractions of Hot Springs, Ark. It treats the resort from different points of view as it appeals to different classes of travelers—those who go to get the benefit of the springs, those who are looking for open air combined with rest and comfort, or those who want to play golf. The pamphlet gives estimates of living expenses, and a list of hotels and their characteristics and rates. The passenger department is to be complimented on the taste shown in the photographs selected for illustrating the pamphlet and for such a high grade of press work that the views lose nothing in reproduction.

Santa Fe Employees' Magazine. The February number has 60 pages and is full of interesting matter. The run of the "Scott Special," made in July, 1905, which holds the world's long-distance speed record, is re-described. Other articles are "Teamwork—Avoiding Claims"; "Investing Money," reprinted from the *Outlook;* "Locating Piston Valve Defects"; "The Past, Present and Future"; "Brave Work in the Rockies," the first prize winner in the short-story contest, and a number of shorter articles, with the usual items and notes of interest.

Switchboards.—Bulletin No. 4,558 of the General Electric Co., Schenectady, N. Y., describes and illustrates isolated switchboard panels with circuit breakers. These panels are for controlling 125-volt generators of from 5 to 120 k.w. capacity, and 250-volt generators of from 10 to 240 k.w. capacity. Bulletin No. 4,544 is devoted to direct-current switchboards for railroad use, which include generator panels, rotary converters, panel circuit breakers, etc.

Journal Boxes.—The T. H. Symington Co., Baltimore, Md., has issued a pamphlet describing and illustrating, with half-tones, different types of journal boxes, including the torsion spring lid box for freight service, and the pivot lid box for locomotives, tenders, steam passenger cars and electric cars. The company is also prepared to furnish boxes with M. C. B. pressed steel or malleable lids, Fletcher lids and lids of special design.

Air Compressors.—Bulletin No. 4,564 of the General Electric Co., Schenectady, N. Y., is devoted to centrifugal air compressors for industrial air blast and exhauster service. These compressors are made to deliver air at pressures from 0.88 to 4 lbs. per sq. in., and in capacities of from 750 to 10,000 cu. ft. of free air per minute. The compressors are driven by Curtis steam turbines or electric motors.

Steel Rail Specifications.—The American Bureau of Inspection and Tests, Monadnock block, Chicago, has prepared a booklet containing the specifications for standard Bessemer steel rails recently adopted by the manufacturers of the United States and Canada. The booklet also contains useful tables for figuring quantities of track material. Copies may be had on request.

Electrical Switch Indicators.—Bulletin No. 4,563 of the General Electric Co., Schenectady, N. Y., illustrates and describes S. I. 104 switch indicators.

MANUFACTURING AND BUSINESS.

The main office and works of the Pennsylvania Brake-Beam Co. have been moved from Easton, Pa., to Danville, Pa.

The offices of the American Car & Foundry Co., New York, will, about May 1, be moved from 25 Broad street to the new City Investing building.

The Wisconsin Engine Co., Corliss, Wis., has established a branch office in the Candler building, Atlanta, Ga. Julius M. Dashiell has been appointed Sales Manager.

The American Water Softener Co., Philadelphia, Pa., has opened a filtration department under the management of George F. Hodkinson. The company is prepared to install filtration plants of any capacity.

L. R. Pomeroy, who has been for a number of years special representative of the railroad department of the General Electric Co., Schenectady, N. Y., has gone to the Safety Car Heating & Lighting Co., New York, as Assistant to the President.

Frank Engelhardt, in charge of the Chicago sales office of the Wisconsin Engine Co., Corliss, Wis., has resigned. The company has closed the office and, for the time being, the business from that district will be under the direct charge of C. T. Myers, General Sales Manager, at Corliss.

The Southern Railway Supply Co. has bought the business and good will of the H. F. Vogel Contracting & Railway Supply Co., St. Louis, Mo. The new company will do a general railroad supply business. The management is in the hands of J. F. Hartman, Secretary, and the offices and storerooms are at 117 Walnut street, St. Louis.

E. H. Symington, Manager of Western Sales of The T. H. Symington Co., Baltimore, Md., who suffered a fractured skull by being thrown from his horse in Chicago nearly a year ago, has returned from a trip around the world which he took to regain his health. Under the advice of doctors, however, he is about to make another tour of the world, expecting to be at work again in his office in Chicago by next fall.

The Ward-Packer Supply Co., recently organized, with office at 1107 Fisher building, Chicago, has elected the following officers: President, A. D. Ward, St. Paul, Minn.; Vice-President, A. A. Packer, Chicago. J. E. Chisholm, formerly with the motive power department of the Chicago Great Western, is mechanical engineer. The company was organized to deal in railroad, factory, mill and general supplies, and has secured exclusive control of a number of articles of merit, including boiler compounds, bell ringers, metallic piston rod packing, boiler feed pump and vacuum car cleaner.

An Ohio paper mill which had ordered several engine type generators of the Northern Electrical Manufacturing Co., Madison, Wis., did not specify who should mount the armature on the engine shaft. When the generator was being erected it was found that no jobbing shop was in a position to make the force fit of about 150 tons required for mounting the armature. Accordingly, the manufacturer sent a motor-driven hydraulic press, with necessary rigging, for pressing the armature on the shaft. A small generator was rigged up to furnish current, and the work was quickly done, thus saving the time and expense of shipping parts back to the factory for mounting.

The United States Circuit Court of Appeals for the Third circuit in a decision just handed down has reversed the federal Circuit Court for the District of New Jersey in the suit of the Ajax Metal Co., Philadelphia, Pa., vs. the Brady Brass Co., Jersey City, N. J. The Appellate Circuit finds that the Ajax patent on which infringement was claimed is invalid. The case has been in the courts since 1903. The Ajax Metal Co. claimed that it had invented and patented an alloy capable of holding up within itself more lead than had been previously possible without the use of nickel and had thus produced a bearing consisting of less than 7 per cent. of tin, more than 20 per cent. of lead, and the balance of copper. The validity of the patent had been sustained by the trial court. The recent decision says, in passing on the claims of the plaintiff, that "the patent is for a product and not for a process. There is no claim for any particular method of combining the constituents of this alloy, and the specification only states the ordinary foundry practice well-known and recognized by those skilled in the art." The written opinions and evidence of experts are quoted to confirm the main point, that the alloy in question was not patentable as it "differed in degree and not in kind" from that which had been on the market for a long time. Testimony is quoted to show that the so-called "critical point" in copper-tin alloys was known at least three years prior to the application for the patent. The opinion also says: "A mere difference in the proportions of the constituents of an alloy, however useful the result may be, does not entitle the originator to the monopoly of a patent, in the absence of other circumstances than those here disclosed. Being of the opinion that the patent in suit is invalid, it is unnecessary to consider other grounds of defense, though we may be permitted to say that the prior public use, set up in the answer of the defendant, seems to us to have been sustained by the testimony."

Iron and Steel.

The Great Northern has ordered 10,000 tons of rails from the Cambria Steel Co. and 5,000 tons from the Bethlehem Steel Co., these orders being in addition to those for 45,000 tons placed with other companies recently.

OBITUARY NOTICES.

Russell Harding, formerly Vice-President and General Manager of the Missouri Pacific system, and later President of the Pere Marquette and Vice-President of the Cincinnati, Hamilton & Dayton, died on March 3 in New York City. A fuller record of his railroad career will be published later.

William A. Washburne, New York rail sales agent of the Cambria Steel Company, died at his country home in Salisbury, Conn., on February 26. Mr. Washburne had been ill for nearly two months, but continued to come to his office in New York until a week before his death. He had represented the Cambria Steel Company and its predecessor, the Cambria Iron Company, for 14 years. Before this he was in the rail department of the New York sales office of the Pennsylvania Steel Company.

Charles T. Hempstead, formerly General Passenger Agent of the New York, New Haven & Hartford, died at his home in Glenbrook, near Stamford, Conn., on March 4, from Bright's disease. He was 61 years old. When Mr. Hempstead retired in 1905 on account of ill health, he had completed a service of 43 years, his first position being ticket agent at Hartford. He became Paymaster of the old Hartford & New Haven Railroad, Paymaster of the New Haven system, and, finally, General Passenger Agent.

MEETINGS AND ANNOUNCEMENTS.

(For dates of conventions and regular meetings of railroad conventions and engineering societies, see advertising page 24.)

Railway Club of Pittsburgh.

At the meeting of this club, Feb. 28, a paper on Steel Car Construction and Maintenance, by G. E. Carson (P. & L. E.) was read.

Canadian Society of Civil Engineers.

At the meeting of this society, Feb. 27, a paper on the Mechanical Equipment of the Ottawa Mint, illustrated by lantern slides, was read by the author, A. H. W. Cleave.

Railway Signal Association.

The March meeting of this association will be held at the Great Northern Hotel, Chicago, on Monday, the 16th, beginning at 10 a.m. The subjects to be discussed are the report on specifications for electric interlocking, beginning at No. 60; the report on specifications for automatic block signals; also the paper on storage batteries which was presented at New York in January. All these reports have been discussed in part at previous meetings. In this announcement the Executive Committee gives the names of representative members of the association who have been appointed by 25 railroads. The committee also gives the result of the letter ballot, ordered at the Milwaukee meeting, last October, the result of which is the adoption of the report of the special committee on interlocking and block signals, which was presented at Milwaukee, and which was given in the *Railroad Gazette* of October 18. This report, it will be remembered, presented a comprehensive scheme of uniform signal indications. The letter ballot was as follows:

Active members		394
Representative votes cast	225	
Individual votes cast	119	
		344
Affirmative		257
Negative		87

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Canadian Pacific.—F. W. Peters, Assistant Freight Traffic Manager of the western lines, has been appointed Assistant to the Second Vice-President, with office at Winnipeg, Man.

Chicago Great Western.—See Minneapolis, St. Paul & Sault Ste. Marie.

Delaware, Lackawanna & Western.—W. S. Jenny, General Attorney, has been elected also a Vice-President. The other two Vice-Presidents are in charge, respectively, of the coal department and of the traffic department.

Illinois Central.—Joseph F. Titus, Assistant to the President, was elected a Director at the adjourned annual meeting held March 3, succeeding Stuyvesant Fish. Mr. Titus is to resign shortly and be succeeded by J. Ogden Armour, who is not yet a stockholder of record.

Minneapolis, St. Paul & Sault Ste. Marie.—J. L. Erdall, Assistant General Solicitor of the Chicago Great Western, has been appointed Assistant General Solicitor of the Minneapolis, St. Paul & Sault Ste. Marie.

Philadelphia & Reading.—Llewellyn Snowden, Assistant Auditor of Passenger Traffic, has been appointed Auditor of Passenger Traffic, succeeding Charles H. Quarles, retired.

Operating Officers.

Boston & Maine.—Fred A. Hortter has been appointed Superintendent of Car Service, succeeding H. E. Howard, relieved from service at his own request. Mr. Hortter will report to the Second Vice-President and General Traffic Manager on matters relating to car distribution, and to the Fourth Vice-President and General Auditor on matters relating to car accounting.

Canadian Pacific.—J. W. Leonard, Assistant General Manager of Eastern Lines, has been appointed to the new office of General Manager of the eastern lines in charge of maintenance of way and operation, with office at Montreal, Que. G. J. Bury, Assistant General Manager of Western Lines, has been appointed to the new office of General Manager of Western lines, in charge of maintenance of way and operation, with office at Winnipeg, Man.

J. G. Taylor, Superintendent of Terminals at Ft. William, Ont., has been appointed Superintendent of the Moose Jaw division, succeeding J. Brownlee, transferred.

C. S. Maharg, Superintendent at Souris, Man., has been appointed Superintendent of Operation and Construction on the new Saskatchewan division.

See this company under Special Officers.

Chicago, Burlington & Quincy.—F. L. Johnson, General Inspector of Stations, has been appointed Superintendent at St. Louis, Mo., succeeding J. A. Somerville, resigned to go to another company. See Missouri Pacific.

Cleveland, Cincinnati, Chicago & St. Louis.—See Lake Erie & Western.

Lake Erie & Western.—C. S. Rhoads, Superintendent of Telegraph, of the Cleveland, Cincinnati, Chicago & St. Louis, with office at Indianapolis, Ind., has had his authority extended over the Lake Erie & Western.

Mexican Central.—Ralph Nelson Elliott, who was recently appointed Superintendent of the Torreon division of the Mexican Central, was born on July 28, 1871, at Marysville, Kan. In his early boyhood he lived at San Antonio, Tex., where he had a common school education, and, at the age of 15, entered railroad service on the Texas-Mexican Railroad, part of the National Railroad of Mexico. Two years later he went from Texas to the Northwest, where he was employed on the Columbia & Puget Sound Railroad, a small line belonging to the Oregon Improvement Company. He then served on the Northern Pacific and the Great Northern and was employed by the Puget Sound Reduction Company. In 1894 he went to the National of Mexico, but soon left railroad service again to go to the Waters-Pierce Oil Company. He returned to railroad work in 1902 on the Interoceanic of Mexico, from which he went to the Tehuantepec National. In 1903 he was on the Durango Central and since 1904 has been on the Mexican Central.

Missouri Pacific.—J. A. Somerville, Superintendent of Terminals of the Chicago, Burlington & Quincy at St. Louis, Mo., has been appointed Superintendent of Terminals of the Missouri Pacific at Kansas City, Mo., succeeding C. E. Carson, resigned.

Traffic Officers.

Chicago, Indianapolis & Louisville.—A. C. Tumy has been appointed Assistant General Freight Agent, with office at Chicago, a position which has been vacant since the death of N. Staat last November.

Norfolk & Western.—DeLos Thomas, Division Freight Agent at Winston-Salem, N. C., has been appointed Assistant General Freight Agent, with office at Roanoke, Va., succeeding O. H. Rogers, deceased.

Engineering and Rolling Stock Officers.

Chicago & Alton.—See Toledo, St. Louis & Western.

Grand Trunk.—See Grand Trunk Pacific.

Grand Trunk Pacific.—Wm. Gell, Master Mechanic of the Grand Trunk at Ottawa, Ont., has been appointed Master Mechanic of the Grand Trunk Pacific, in charge of motive power, cars and shops, with temporary office at Winnipeg, Man.

Mexican Central.—O. R. Hale, Master Mechanic of the Torreon division, has been appointed Master Mechanic of the San Luis division, with office at Cardenas, San Luis Potosi, succeeding C. F. Roberts.

Missouri Pacific.—F. T. Carberry, Master Mechanic at St. Louis, Mo., has been appointed Master Mechanic at Fort Scott, Kan., succeeding J. J. Reid, transferred.

New York, New Haven & Hartford.—On the reorganized divisions named in this column on February 14, maintenance of way officers have been appointed as follows: New York division, H. A. Weaver, Division Engineer, office at Harlem River, N. Y.; Shore Line division, F. H. Ellsworth, Division Engineer, New Haven, Conn.; Providence division, J. S. Browne, Division Engineer, Providence, R. I.; Boston-Midland division, G. T. Sampson, Division Engineer, Boston, Mass.; C. J. Bennett, Assistant Engineer, Hartford, Conn.; Old Colony division, J. W. Pearson, Division Engineer, Taunton, Mass., Western division, W. T. Spencer, Division Engineer, New Haven, Conn.

E. W. Wiggin has been appointed Superintendent of Bridges and Buildings, with office at New Haven, Conn., vice E. E. Pratt, Jr., resigned.

Toledo, St. Louis & Western.—H. H. Eggleston, Supervisor of Bridges and Buildings of the Eastern division of the Chicago & Alton, has been appointed Acting Superintendent of Bridges and Buildings, being also in charge of water station service and interlocking plants, with office at Frankfort, Ind., succeeding C. H. Kinney, temporarily relieved on account of ill health.

Special Officers.

Canadian Pacific.—G. Erickson, Superintendent at Cranbrook, B. C., has been transferred to the forestry department.

LOCOMOTIVE BUILDING.

Dr. Barrioslde Lacarda, Pernambuco, Brazil, has ordered from the American Locomotive Co., through Ellerton D. Hitch & Co., New York, two 2-4-0 type locomotives, with cylinders 9 in. x 16 in.

The South Manchurian has ordered five locomotives from the American Locomotive Co. The motive power ordered by this road last spring was built and shipped some time ago, but five locomotives were lost in a shipwreck and the above order is to replace them.

CAR BUILDING.

The Northern Pacific is figuring on 200 refrigerator cars.

The Great Northern is asking prices on from 40 to 45 passenger cars.

The Chicago, Milwaukee & St. Paul is asking prices on 15 passenger cars.

The Cold Blast Transportation Co., Chicago, is in the market for 200 stock cars.

The Atlantic Coast Line is understood to be figuring on 100 ventilated box cars.

The Cadiz Company, Cadiz, Ky., has ordered one passenger car from the Hicks Locomotive & Car Works.

The Toledo & Indiana has ordered five flat cars of 60,000 lbs. capacity from the Hicks Locomotive & Car Works.

A Japanese railroad has ordered through Frazar & Sale, New York, 168 coal cars from the American Car & Foundry Co.

The Chilian State Railroads have ordered, through W. R. Grace & Co., New York, 20 passenger cars from the American Car & Foundry Co.

The Independent Packing Co., St. Louis, Mo., is in the market for 75 second-hand refrigerator cars, but will buy new cars if it cannot secure good second-hand cars.

New York City Railway.—Frederick W. Whitridge, Receiver of two subsidiary street railways of this company, has ordered 75 cars for these roads from the J. G. Brill Co.

The Canadian Pacific is building, at its own shops, one sleeping car, 72 ft. 2 in. long and 9 ft. $10\frac{1}{2}$ in. wide over frame; two first class cars, with smoking room, 72 ft. long and 9 ft. $10\frac{1}{2}$ in. wide over frame; two tourist cars, 72 ft. long and 9 ft. $10\frac{1}{2}$ in. wide over frame; one colonist car, 67 ft. long and 9 ft. $10\frac{1}{2}$ in. wide over frame; one baggage car, 60 ft. long and 9 ft. $10\frac{1}{2}$ in. wide over frame; five mail and express cars, 60 ft. long and 9 ft. $10\frac{1}{2}$ in. wide over frame; six mail cars, 60 ft. long and 9 ft. $10\frac{1}{2}$ in. wide over frame; 84 thirty-ton box cars, 36 ft. 8 in. long and 9 ft. $\frac{5}{8}$ in. wide over frame; four refrigerator cars, 41 ft. long and 9 ft. $1\frac{5}{8}$ in. wide over frame; 22 stock cars, 36 ft. 8 in. long and 9 ft. 5 in. wide over frame; 162 thirty-ton flat cars, 36 ft. 8 in. long and 8 ft. 10 in. wide over frame; two Hart convertible cars, 36 ft. 8 in. long and 8 ft. 10 in. wide over frame; 12 baggage cars 29 ft. long and 9 ft. wide over frame; three baggage and smoking cars, 65 ft. long and 9 ft. $10\frac{1}{2}$ in. wide over frame; one pile driver, 45 ft. long and 8 ft. 9 in. wide over frame. Bodies and underframes will be of wood. The special equipment includes:

Bolsters (for freight equipment)	Simplex
Brake-beams	Simplex
Brake shoes (for passenger cars)	Flanged steel back diamond S
Brake shoes (for freight equipment and baggage cars)	Steel back, diamond S
Brakes	Westinghouse
Center bearings (for box and Hart convertible cars)	One malleable and one steel
Couplers	Tower
Curtain fixtures	Forsyth
Curtain material	Pantasote
Door fasteners (for box cars)	Positive
Doors (for box cars)	Security
Doors (for refrigerator cars)	Refrigerator standard, with La Flare insulation
Draft rigging	Miner tandem
Dust guards (for freight cars)	Harrison
Journal boxes	McCord
Lighting	Pintsch
Platforms	Standard Coupler Co.
Roofs	Canvas, Canadian Pacific standard
Seats (for sleeping cars)	Pullman standard
Seats (for tourist and colonist cars)	Slatted wood
Side bearings (for freight cars)	Susemihl
Roofs (for box cars)	Chicago
Trucks (for freight cars)	Barber roller Simplex
Trucks (for baggage cars)	Goff
Vestibules	Pullman wide
Wheels (for passenger equipment)	Steel tired

The New York, Ontario & Western has ordered nine passenger coaches and one chair car from the Pullman Company. The specifications for this equipment were published in the *Railroad Gazette* of October 18, when bids were first asked, the purchase having been, at that time, postponed.

RAILROAD STRUCTURES.

ALTOONA, PA.—Plans are made and now under consideration for putting up a combined highway and street car bridge at Seventh street, to be 160 ft. long and 50 ft. wide, to cost about $[illegible],000.

BEACON PARK, MASS.—Work is under way by the Boston & Albany putting up a new engine house here, to cost about $250,000. Similar work has been authorized at Worcester, to cost $200,000.

ELLWOOD, PA.—The town council has passed an ordinance requiring the Pittsburgh, Harmony, Butler & New Castle railroad to pay for the construction of a subway on Fifth street.

SCRANTON, PA.—The Scranton Railway Company will provide a temporary bridge during the construction of the new bridge over the Lackawanna river.

WINNIPEG, MAN.—The Grand Trunk Pacific, it is said, is making soundings for a proposed bridge over the Red river.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

BOW RIVER COLLIERIES.—Application is being made to incorporate this company to build a line from the Bow River collieries to a point on the main line of the Canadian Pacific near Cassils, Alb., about 47 miles. The incorporators include: R. F. Reeve, W. C. Simmons, W. L. Hamilton, C. V. Bennet, B. C. Moore, of Lethbridge, Alb., and Harry P. Cherry, Winnipeg, Man.

CAPE BRETON.—Surveys are under way for an extension to be made early this spring from St. Peter's, N. S., to Louisburg, 31 miles. G. E. Johnson, St. Peter's, General Manager.

CHICAGO, MILWAUKEE & ST. PAUL.—This company, it is said, is operating its Pacific coast line from Mobridge, S. Dak., west to Terry, Mont., about 250 miles.

CHICAGO, SOUTH BEND & NORTHERN INDIANA (ELECTRIC).—This company has decided to let contracts and push work on the extension from South Bend, Ind., west to Laporte, 28 miles, at which point connection will be made with its line in operation from Laporte northwest to Michigan City.

CHICAGO RAILWAYS COMPANY.—This company, it is said, will reconstruct many subways beneath the rivers on the North and West sides, to permit the use of larger cars.

CLEAR LAKE & SOUTHERN (ELECTRIC).—Surveys are under way and rights of way are being secured for this proposed electric line from San Francisco, Cal., north via Napa, to Lake Port, 135 miles. Grading is expected to be started this summer. LeGrand Brown, Chief Engineer, 31 Ellis street, San Francisco, Cal.

CROWS' NEST & NORTHERN.—Incorporated to build from a point on the Crows' Nest line to Michel, B. C., about 27 miles. E. V. Bodwell, the attorney representing the company, says that construction will be started at once. R. G. Belden, J. A. Hemphill, C. L. Butterfield, E. A. Wayland, all of Spokane, Wash., are incorporators.

EASTON & SOUTH BETHLEHEM TRANSIT CO.—This company has given a mortgage, the proceeds of which are to be used for finishing the line from Easton, Pa., through Freemansburgh to South Bethlehem.

INDIANAPOLIS, LOGANSPORT & OHIO.—This company, which has been projected from Indianapolis, Ind., north via Sheridan, Russiaville and Kemptin, to Logansport, 68 miles, has been granted franchises by the city of Indianapolis, and expects to let grading contracts in June. W. A. Osmer, C. E., Logansport.

KANSAS CITY TERMINAL CO.—This company, which was incorporated to build a new passenger station for the railroads entering Kansas City, Mo., is now negotiating with the city authorities for the necessary franchises. The work will include a number of yards and retaining walls, highway viaducts and railroad viaducts. Detail plans are not yet made. John V. Hanna, Chief Engineer, Kansas City, Mo.

LONG ISLAND.—See Pennsylvania.

MEXICO MILLING & TRANSPORTATION COMPANY.—This company has been authorized to build railroads in the municipalities of Guanajuato, La Paz and Santa Rosa, with branches, a total of about 50 miles. Six miles must be built this year, and a similar amount each year until the line is finished. The Department of Communication and Public Works and Geo. W. Bryant will build the line.

PENNSYLVANIA.—The report of this company for the year ended December 31, 1907, shows that the four track system on the main line between Pittsburgh, Pa., and Jersey City was extended, and also the revision of the low grade freight line, formerly the Western Pennsylvania, along the Conemaugh river. There were also improvements to yards and terminal facilities at various points. Rights of way for additional relief lines were bought. On the Middle division, between Van Dyke, Pa., and Port Royal, the four-track system was put in operation early in 1907. Similar work has been continued during the year between Ryde and Mt. Union. This includes building a new 10-mile line, also two stone arches over the Juniata river, the elimination of grade crossings in the borough of Mt. Union, and a reduction in grade and curvature. The section from Ryde to Vineyard was put in service in October, and from Newton Hamilton to a point west of Mt. Union, at the end of 1907. It is expected to have the section between Vineyard and Newton Hamilton finished in May. This will give a continuous four-track system on the Middle division, from Harrisburg to Petersburg, where connection is made with the double-track relief freight line over the Allegheny mountain, also from Petersburg to Altoona, except on about 6½ miles between Spruce Creek tunnel and Tyrone Forge, where there are only three tracks.

On the Pittsburgh division the four-tracking was finished in October from Sang Hollow to Bolivar, including a revision of grade and alinement on about 14 miles. The revision work on the Sang Hollow extension, and laying second track from Dornock Point to Bolivar Junction was finished. Grade reduction work and double-tracking on the Conemaugh division, from Bolivar Junction, west six miles, including a new single-track bridge over the Conemaugh river, was finished. Similar work is under way on this line between Blairsville and Tunnelton, eight miles. On this section, five double-track stone arches have been built over the Conemaugh, and double-track laid on the steel bridge at Social Hall. A new double-track tunnel 760 ft. long has been built west of Bow Station, and grade crossings on this section in the town of Blairsville are to be eliminated. This work is to be finished this summer.

Four tracks between Beatty and Southwest Junction were put in service during the year. A new line was built from Beatty to George, four miles, and an additional track from that point to Southwest Junction. As a result, passenger and through freight service no longer pass through the double-track tunnel at Donohoe. The westbound classification yard at Hollidaysburg was finished, and considerable progress made on the eastbound gravity yard at Pitcairn, part of which is now in use.

On the New Jersey division, track elevation was continued through Camden to eliminate grade crossings between the Delaware river and Cooper's Creek. Similar work was started on the Kensington branch in the northeast part of Philadelphia. The storage and classification yards at Greenville, N. J., were finished and work is being continued on the Pacific street terminal yard in Brooklyn, N. Y.

Improvements finished on the Western New York & Pennsylvania included building the Ebenezer branch in South Buffalo to connect the main line with the ore docks on the lake front so as not to carry freight through the city of Buffalo. Improvements to yards and shops at Olean, N. Y., and at Buffalo were also made.

The Brownsville extension, of the Monongahela division, was built for 4½ miles up the river to a connection with the Pennsylvania, Monongahela & Southern, which is finished to Rice's Landing, Pa., 7½ miles. The Ten-Mile Run branch, which is ultimately to extend from Ellsworth, on the Monongahela division, to Millsboro, on the Pennsylvania, Monongahela & Southern, 15½ miles, has been finished from Ellsworth south for eight miles, and from Millsboro north for 1.6 miles. From the old Redstone extension, the Grindestone branch has also been built. Both these branches were built to supply facilities for extensive coal and coke operations.

Work is now under way on a connecting line at Newberry, along Lycoming creek, between the main line of the Erie division and the Elmira division of the Northern Central; and the line between Jersey Shore and McElhattan is being improved in grade and curvature.

On the tunnel extensions to the new terminal in New York satisfactory progress has been made, and it is expected to finish the work in 1910. From the New Jersey division at Harrison, east of Newark, to the west portal of the Bergen Hill tunnels considerable progress was made on the masonry, superstructure and embankment necessary to carry the line over the railroad tracks on the meadows and the streets. The two tunnels through Bergen Hill, except for about 700 ft., have been excavated, and concrete lining is being put in. The two tubes under the Hudson river are also being lined. Excavation work is finished from the river to the tunnel station approach at Tenth avenue in New York City. Between Tenth avenue and Ninth avenue over half the work has been finished, and on the terminal station site between Seventh and Ninth avenues all the retaining walls and foundations are in place. Steel viaducts are also nearing completion to support adjoining streets and avenues crossing the station site, and work on the steel structure of the station itself is under way. From the terminal site east, tunnel excavation work is finished to the First avenue shafts on the west side of the East river, with the exception of the section between Fifth and Sixth avenues, and about one-half the concrete lining, and other work is finished. On the four tunnels under the East river two of the iron tubes have now (March 4) been finished, and it is expected to connect the remaining tubes within two months or less. The tunnels under Long Island City from the East river to the East avenue shaft in the borough of Queens have been excavated and iron lined, and two-thirds of the concrete lining is in place. Work is under way between the East avenue shaft and the western end of the Sunnyside yard, near Thompson avenue, where the tunnels reach the surface. This work is being done by the Pennsylvania Tunnel & Terminal Railroad. Work on the Sunnyside yard has been delayed by the necessary relocation of city streets and the construction of highways across the yards to eliminate grade crossings. Work on the viaduct and embankments and bridge masonry is under way. Near the Sunnyside yard, which will be 5,500 ft. long and 1,550 ft. wide, there will be a connection with the Long Island Railroad and the New York Connecting Railroad.

During the year the elevation of the Philadelphia, Baltimore & Washington road through Wilmington, Del., and the new passenger station at that place was finished; also the joint coach yard and north approach to the new union station at Washington, D. C., and revision of the line through Washington.

On the West Jersey & Seashore, grade elevation work and revision of the line was carried out and a freight connection built between Haddonfield, N. J., and Westville.

On the Long Island Railroad additional tracks were put in at various points and yard improvements made. The Bay Ridge line was also improved and the Atlantic avenue improvement was finished.

Pennsylvania Lines West.—The most important work carried out by this company, as shown in its annual report, for the year ended December 31, 1907, was track revision work in Chicago and in Allegheny City; revision of line and construction of second and third tracks on the Pittsburgh, Cincinnati, Chicago & St. Louis; improvements of yards, docks and other terminal facilities, increased sidings and securing new rights of way.

Pennsylvania Tunnel & Terminal.—See Pennsylvania.

Philadelphia, Baltimore & Washington.—See Pennsylvania.

Quebec Eastern.—Right of way secured and surveys made by this company for a line from Lyster, Que., on the Grand Trunk, to Lime Ridge, and thence to Sherbrooke, 110 miles. Address W. H. Lamby, Secretary, Inverness, Que.

Southern Pacific.—It is said that this company has authorized the relaying of about 50 miles of track with 75-lb. rails on the West Side division from Beaverton, Ore., south to McCoy.

West Jersey & Seashore.—See Pennsylvania.

RAILROAD CORPORATION NEWS.

Atchison, Topeka & Santa Fe.—Gross earnings for January decreased 6 per cent.; operating expenses increased 3 per cent., leaving a decrease in net earnings of 25 per cent.

Baltimore & Ohio.—The Baltimore & Ohio, which since 1901 has owned about 75 per cent. of the stock of the Cleveland, Lorain & Wheeling, has bought the minority stock. The Chicago, Lorain & Wheeling has 192 miles of line. Its gross earnings in the year ended June 30, 1907, averaged $24,000 a mile. In January, 1908, a semi-annual dividend of 2½ per cent. was declared on its common stock, which was the first dividend on this stock. The Baltimore & Ohio has sold $1,000,000 one-year notes, $1,000,000 two-year notes and $1,000,000 three-year notes, secured by the newly purchased Cleveland, Lorain & Wheeling stock.

Canadian Pacific.—According to report from Spokane, Wash., the Canadian Pacific is planning a line from Spokane to Pacific tidewater, through purchase of the right of way of the projected North Coast Railway.

Chicago Railways Company.—The National City Bank and N. W. Harris & Company, of New York, recently offered at a price to yield about 5½ per cent., $2,500,000 first mortgage 5 per cent. bonds of this company, which recently took over the West Chicago and the North Chicago street railway companies. This offering was six times oversubscribed.

Chicago, Rock Island & Pacific.—A quarterly dividend of 1½ per cent. has been declared on the stock of the Chicago, Rock Island & Pacific Railway. In January, quarterly dividend of 1 per cent. was paid. In 1907, 1 per cent. was paid in January, 1½ per cent. in April, 1 per cent. in July, 1¾ per cent. in October. This year's record, thus far, is, therefore, the same as that of 1907.

Gross earnings for January were $16,000,000, against $18,000,000 in 1907. Net earnings, after taxes, were $1,100,000, against $1,300,000 in 1907.

Delaware & Hudson.—Gross railroad earnings for January were $1,500,000 against $1,400,000 in 1907 Net railroad earnings after taxes were $481,000 against $459,000 in 1907 There was a falling off in net earnings of the coal department from $129,000 in 1907 to $69,000, so that the total net earnings from all departments were $551,000 against $587,000 in 1907.

Detroit, Toledo & Ironton.—The issue of $300,000 receivers' certificates was, on February 25, authorized by the United States Circuit Court at Detroit, Mich. Of these, $100,000 are to be issued at once. There has been a falling off of 50 per cent. in gross earnings, but owing to economies the loss in net income has been only 15 per cent.

Erie.—Gross earnings of the lines in New York State for the three months ended December 31, 1907, were $11,800,000 against $12,500,000 in 1906. Net earnings were $1,700,000 against $4,100,000 in 1906.

The Erie's cash on hand on December 31, 1907, was $4,000,000 against $6,300,000 on June 30, 1907. Bills payable were $5,575,000 against $6,500,000 in June.

The New York Public Service Commission of the Second district has denied the application of the Erie Railroad for permission to issue 4 per cent. interest-bearing dividend warrants, payable in 1917, covering the semi-annual dividend of 2 per cent. on the first preferred stock and the annual dividend of 4 per cent. on the second preferred, declared August 28, 1907. See editorial columns.

Grand Trunk.—A new issue of $5,000,000 4 per cent. guaranteed stock has been sold at 92½, a yield of about 4½ per cent., in London. There was already $8,392,200 of this stock outstanding out of an authorized issue of $50,000,000 (£10,000,000). The new issue, whose proceeds are to be used for double-tracking and other improvements of the line and for new rolling stock, was oversubscribed by about 50 per cent. Its success indicates the advantage which the Canadian roads have at this time over roads in the United States, both in having a market for their securities in London and in being freer from legislation, actual and threatened.

Gulf & Ship Island.—Fisk & Robinson, of New York, have offered, at a price to yield 6¾ per cent., $750,000 of the $1,000,000 authorized 6 per cent. mortgage bonds of 1909-1911.

Gross earnings for January were $161,000 against $225,000 in 1907. Net earnings were $28,000 against $68,000 in the earlier year.

Hocking Valley.—William Salomon & Co., of New York, have offered at a price to yield 6 per cent., $500,000 4 per cent. equipment notes due semi-annually from August 15, 1908, to February 15, 1918. These notes are secured by 500 new steel underframe drop bottom gondola cars, whose cost exceeds by 23.5 per cent. the total par value of the notes.

Gross earnings for January were $329,000 against $522,000 in 1907, a decrease of 37 per cent. Net earnings were $42,000 against $123,000, a decrease of 66 per cent.

Interborough Rapid Transit.—The stockholders of this company at a special meeting to be held March 17, will vote on making a new mortgage, securing $50,000,000 5 per cent. bonds, covering the power houses and rolling stock, the Steinway tunnel from Manhattan to Long Island City and the Long Island traction properties owned by the company, and that $20,000,000 of these bonds will at once be issued. Of these, $15,000,000 will be used to meet the $15,000,000 notes maturing on May 1 and the rest to pay off the floating debt, which now stands about $5,000,000.

Louisiana & Arkansas.—Gross earnings for January were $79,000 against $88,000 in 1907. Net earnings were $21,800 against $21,500 in 1907

Louisville & Nashville.—Gross earnings for January were $3,300,000 against $4,100,000 in 1907, a decrease of $800,000. Operating expenses decreased $73,000. Net earnings were $621,000 against $1,326,000 in 1907, a loss of $705,000, or 47 per cent.

Mexican International.—Gross earnings for January were $716,000 against $711,000 in 1907. Operating expenses decreased $60,000, leaving net earnings of $263,000 against $199,000 in 1907

National Railways of Mexico.—The merger plan for the consolidation of the Mexican Central, the National of Mexico, the Mexican International, the Interoceanic of Mexico and the Hidalgo & North Eastern was ratified on February 28 at the city of Mexico. It is reported that the terms of the agreement are little changed from those previously announced (July 12, 1907, page 54).

New York Central Lines.—Gross earnings for the month of December, 1907, and for the year ended December 31, 1907, were as follows:

Month of December 1907

	1907	—— Change ——	
New York Central & Hudson River	$7,432,066	Dec	$520,711
Lake Shore & Michigan Southern	3,308,011	"	254,369
Lake Erie & Western	344,424	"	68,630
Chicago, Indiana & Southern	259,508	Inc	25,390
New York, Chicago & St Louis	868,248	Inc	62,493
Michigan Central	2,108,729	"	202,503
Cleveland, Cincinnati, Chicago & St Louis	1,967,658	"	292,081
Peoria & Eastern	230,450	"	38,568
Cincinnati Northern	97,395	"	15,230
Pittsburgh & Lake Erie	716,047	"	413,118
Rutland	200,939	"	10,129

Year Ended December 31 1907

	1907	—— Change ——	
New York Central & Hudson River	$98,369,090	Inc	$6,279,291
Lake Shore & Michigan Southern	41,953,475		2,406,087
Lake Erie & Western	5,066,940	Dec	145,872
Chicago, Indiana & Southern	3,004,483	Inc	671,751
New York, Chicago & St Louis	10,465,671	"	563,462
Michigan Central	28,547,110	"	2,271,522
Cleveland, Cincinnati, Chicago & St Louis	26,447,804	"	1,852,888
Peoria & Eastern	3,010,347	Dec	48,934
Cincinnati Northern	1,005,158	"	22,530
Pittsburgh & Lake Erie	14,804,401	Inc	422,905
Rutland	3,058,087	"	258,878

New York, New Haven & Hartford.—The Hartford & New York Transportation Co., which owns the line of steamers running between Hartford and New York and is owned by the New Haven, is to take over the United States Transportation Co., which controls several steamship lines affiliated with the New York, New Haven & Hartford. These are the Joy line, between New York and Providence; the Neptune Line, between New York and Fall River, and the Maine Steamship Co., between New York and Portland, Me.

New York, Ontario & Western.—The operating ratio (taxes included in operating expenses) was 80 per cent in January, 1908, as compared with 72.6 per cent. in January, 1907. Net earnings for January decreased 30 per cent., and net income after charges, 50 per cent.

New York-Philadelphia Company (Electric).—J. Kearney Rice, of New Brunswick, N. J., was on February 21 appointed by Judge Lanning, in the United States Circuit Court, Receiver of the New York-Philadelphia Company, and David F. Carver, of Newark, was appointed Receiver of the Trenton & New Brunswick and the New Jersey Short Line. Wilbur F. Sadler, Jr., of Trenton, was, on February 18, appointed Receiver of the Camden & Trenton, another subsidiary of the New York-Philadelphia Company. (*Railroad Gazette*, Feb. 28, p. 298.) The various companies have 63 miles of road in operation and 20 under construction out of Trenton south toward Camden and north toward New York. The parent company has contracts with the Public Service Corporation by which it operates cars between New York and Philadelphia.

Pennsylvania.—The annual dividend rate on the $9,641,600 common stock of the West Jersey & Seashore has been reduced by the declaration of a semi-annual dividend of 2 per cent. In 1906 and 1907 6 per cent. a year was paid; in 1905, 5½ per cent.; from 1897 to 1904, inclusive, 5 per cent., and in September, 1896, 2½ per cent.

Pere Marquette.—This company is now reorganized and has arranged to exchange its 6 per cent. equipment notes, secured also by $500,000 refunding mortgage 4 per cent. bonds, for the $2,600,000 5 per cent. equipment bonds of the Eastern Equipment Company which fell due March 1, 1908. These notes cover equipment bought in 1903 and 1904 and now insured for $2,745,000.

Philadelphia & Reading.—Gross earnings of the Philadelphia & Reading Railway for January decreased 17 per cent., operating expenses decreased 17 per cent., and net earnings decreased 16 per cent., as compared with the corresponding month of 1907.

Seaboard Air Line.—The coupons which fell due on March 1 on the three-year 5 per cent. collateral trust bonds of 1911 and the series H car trust certificates, as well as the interest due January 1, 1908 on the first mortgage Seaboard & Roanoke 5 per cent. bonds, have been paid by the Receivers.

Southern.—Gross earnings for January decreased 14 per cent., operating expenses, 11 per cent.; and net earnings, 28 per cent. Net earnings after taxes decreased 37 per cent. The operating ratio was 89 per cent., against 85 per cent. in the corresponding month of 1907

Union Pacific.—The Oregon Railroad & Navigation Company has declared an extra dividend of 75 per cent. on its $11,000,000 4 per cent. non-cumulative preferred stock, almost all of which, as well as the common, is owned by the Union Pacific. This appears to be similar to the 50 per cent. dividend declared in 1906 by the Oregon Short Line.

West Jersey & Seashore.—See Pennsylvania.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK
BRANCH OFFICES AT 375 OLD COLONY BUILDING CHICAGO, AND QUEEN ANNE'S CHAMBERS WESTMINSTER, LONDON

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. *We give in our editorial columns* OUR OWN *opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.*

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette:

OFFICERS:

W. H. BOARDMAN, *Prest. and Editor.*
E. A SIMMONS, *Vice-President.*
RAY MORRIS, *Secretary*
R. S. CHISOLM, *Treas.*
I. B. RINES, *Cashier*
L. B. SHERMAN, *Western Manager*

EDITORS:

RAY MORRIS, *Managing Editor*
BRAMAN B. ADAMS
CHARLES H. FRY
FRANK W. KRAEGER
GEORGE L. FOWLER
HUGH RANKIN
BRADFORD BOARDMAN

CONTENTS

VOL. XLIV., No. 11. FRIDAY, MARCH 13, 1908

RAIL CIRCUITS AND TREATED TIES.

The report that a well-known road which is planning to build a timber preserving plant is hesitating about adopting a zinc-chloride process through fear of trouble to the track circuits of automatic signals, is drawing attention anew to a phenomenon first observed several years ago, and noted in these columns at the time. In view of the present interest in the matter and of the fact that most people have forgotten the investigation referred to, it seems worth while to give again the essential points reported at that time.

The investigation was made by V. I. Smart, then signal inspector of the Illinois Central. The trouble is, of course, caused by the greatly increased conductivity of a zinc-treated tie. By introducing enough of these ties, the leakage between rails becomes so great that there is not enough current to hold the relay. As this leakage is directly proportional to the number of ties in track, a temporary reduction in the length of the section relieves the trouble by increasing the resistance between rails. The trouble disappears after a time, when the section may again be extended to its original length. The reason for the disappearance of the trouble after the track circuits have been working for a while was explained in the report. The ties lose in conductivity, because the electric current causes electrolysis of the zinc solution (ZnCl, HO). "The Cl is freed at the positive pole, which in this case is one of the iron spikes holding the rail to the tie. Zn is deposited at the other spike, the negative pole. The Cl enters into combination with the H in HO, forming HCl, or hydrochloric acid. This attacks the iron of the spike, producing FeCl, or chloride of iron, which is deposited on the spike, or rather between the spike and the wood of the tie, in greenish-blue, hydrated crystals. This deposit of chloride of iron offers sufficient resistance to the weak track circuit to reduce the conductivity of the tie to such an extent that the track section may be lenghened considerably without trouble to the relay reappearing." It is therefore suggested that where track circuits are to be installed in conjunction with a large number of such ties, trouble to the signal circuit may be obviated by putting several cells of the battery in series on the track for some time before the signals are put in service in order to insulate the spike in the manner described; but care must be taken not to change the polarity of the rails afterward. It must be remembered, also, that the trouble will return if the spikes on the positive rail are renewed, since the presence of the FeCl crystals is essential to successful working.

The foregoing, as it specifically states, applies only to the use of a large number of these ties. For ordinary renewals—12 to 15 per cent. a year, and even up to 25 per cent.—there seems to be no trouble. In addition to the effect already described, signal engineers claim recently to have established the fact that there is a storage battery effect from these ties, but that it does not interfere with the working of the circuits under the renewal conditions mentioned. It is reported that on long circuits—4,000 ft. or over, say—where there are a good many of these ties in track, there is considerable leakage. But track circuits of this length are uncertain in their operation under any circumstances and need to be shortened where possible. We understand that on the Santa Fe, which was perhaps the largest user of zinc-treated ties in the country until its recent change to the creosote process, the track circuits were reduced to a maximum of half a mile.

There seems to be apprehension in some quarters that creosoted ties, as well as zinc-treated ties, will have a bad effect on the track circuits; in fact, some signal men claim to have had experience proving that creosoted ties act as partial conductors, and they say that a sufficient number will cause a short circuit. There seems to be no reliable data on the subject, however. On one of the Southern Pacific lines a few tests were made of untreated ties, of zinc chloride and of creosote-treated ties, to determine their relative resistances. There was such a wide variation in results, however, under apparently like conditions, that it was not considered safe to draw any conclusion but the very general one that the resistance of the zinc-treated tie is considerably less than that of the creosoted or of the untreated tie. At the 1907 convention of the Southwestern Electric and Gas Association, its president vouched for the fact that creosoted poles are good conductors. He stated that in Galveston, Tex., where they are compelled to use creosoted poles because of the soil conditions, the linemen have a practice of mounting and dismounting from the poles with a jump so as not to have a spur in the pole and a foot on the ground at the same time.

One signal engineer who was asked about his experience with treated ties responded that he was having far more trouble from the brine from refrigerator cars. This long-standing trouble the signal men share with the bridge men. The only effective remedy is one such as a committee of the Superintendents of Bridges and Buildings recommended at the last convention, namely that instead of allowing the brine to drip on the track it should be caught in a receptacle to be emptied at intervals by the trainmen. We understand that a committee of the Signal Association now has the subject in hand for the collection of data and report. It is interesting to note, in this connection, that trouble was experienced with the track circuits on the trestles on the Ogden-Lucin cut-off across Great Salt Lake from salt water dashing over the track and wetting the tops of the ties. During a quiet period, when the ties were dry, they were given a coating of crude oil on top, which ended the difficulty.

NEW RAILROAD BUILDING

The fourteenth regular Construction Record of the *Railroad Gazette* is published in this issue. This comprehensive list of railroad construction work was compiled semi-annually from the spring of 1898 until March, 1902, when it was made an annual record.

A change of policy in its compilation has this year been carried out. In earlier years the list included, besides lines on which work was actually under way, projects not yet undertaken and new companies incorporated since the previous Construction Record was issued; it was, in short, a complete summary in condensed form of all the information printed during the year in our railroad construction columns. This sort of a record, though complete, contained many companies which never had built, and, as experience proved to us, never would, build a mile of railroad. This year the aim has been to list only such work as is actually being carried out or which there is strong likelihood will soon be undertaken. A very large majority of the items in this year's Construction Record—probably as large a proportion as 95 per cent.—are made up of official information sent us. The small proportion remaining is made up of projects on which we know work is under way, projected lines of companies which built railroad last year and seem likely to carry on construction, and a very few projects of large railroads which, although they are not likely soon to be undertaken, are so important in showing the direction of their future expansion, that they should be included in the record. By following out this policy the length of the Construction Record has been reduced but its convenience and value greatly increased. The list has been prepared with great care, by experienced men, under an improved system for securing official information. It is, we believe, the best summary in existence of actual railroad construction in America.

This record of new railroad construction accurately reflects the present financial and industrial conditions. Not a single new project of large importance has recently been undertaken. Certain important companies operating thousands of miles of line do not appear in the record at all. Many of the larger railroads which are included in the list are simply finishing small improvements or extensions which were begun a year or more ago. The big undertakings in the United States, the extension of the Chicago, Milwaukee & St. Paul to the Pacific coast, the Western Pacific, the Denver, North-Western & Pacific and the Spokane, Portland & Seattle, which is the new name of the Hill low grade line down the north bank of the Columbia river to Portland, were already begun back as far as 1905 or earlier, and have to be carried on to completion in order to make the already large investments profitable.

The hard times have, however, brought one important advantage to those companies which have funds on hand for carrying on extensions and improvements. During 1906 and the first half of 1907 construction work was carried on at the largest expense both for labor and materials ever known. Now prices have gone down and large savings accrue as compared with the cost of construction a year ago. President Earling, of the St. Paul, estimates that present costs of labor and materials are fully 30 per cent. less than those which prevailed when work was begun on the extension in 1905 and 1906.

But this is small comfort to the average railroad. For lack of credit almost all of even the strongest railroads have reduced construction expenditures to the lowest possible minimum. The present situation of a road like the Southern Railway is particularly unfortunate. A little more than a year ago its tracks and yards were literally swamped with traffic. One yard at the junction of a through main line and a branch line was so full that for days more than 100 cars were stored on the main line of the branch and had to be shifted on to the through main line and back for every branch line train. Per diem and penalties on many cars more than ate up the freight charges. To-day, when all is changed and there is little traffic, is the time that a large campaign of double tracking and yard enlargement should be undertaken and pushed to completion with all possible speed. But the Southern neither has any funds nor can secure them for such work.

North of the Canadian boundary line the outlook is different. Although even there construction plans have been modified by the present financial situation, the large undertaking of the Grand Trunk Pacific, backed by the Dominion government, for a new line from ocean to ocean, is being fast advanced, and important extensions and improvements are being continued on the Canadian Pacific. A great deal of progress has been made by the Grand Trunk Pacific during the year 1907 not only in the complete location of the 3,5?? miles of line, but in laying more than 500 miles of track, 100 miles on the Lake Superior branch from Winnipeg, Man., to Fort William, Ont., and 415 miles from Portage La Prairie, Man., to Saskatoon, Sask. The Canadian Northern was not so active during 1907, and is going more slowly than in recent years in its plans for extensions.

In Mexico also there is extensive work under way. The Southern Pacific forces are pushing construction of a line south along the west coast of the Republic which, when completed, will connect the United States boundary over the Sonora Railway with Guadalajara, state of Jalisco, Mex., nearly 1,000 miles south. Now that the merger of the principal Mexican roads has been formally carried out, it is probable that certain important pieces of new construction which have been postponed while the merger negotiations were pending, will shortly be undertaken and carried through, the most important of these being the construction of a cut-off which will furnish a direct line between the city of Mexico and the very important port of Tampico and be less than one-third as long as the Mexican Central's present route.

RAILROAD TRACK TANKS

Although track tanks have been a feature of railroad operation for 50 years, and have been used in America for nearly 40 years, there is little published information on the subject, at least in this country. This is doubtless due principally to their limited use, since at present there are only seven or eight roads, all eastern lines, which have them. But although comparatively few in number they have been developed and improved wonderfully, so that the track tank installation of to-day is an elaborate and expensive plant as compared with its prototype of a generation ago. Hence the article on another page, which describes present practice, especially as found on the Lake Shore, presents much that is new and brings the record up to date.

A feature of special interest in that article is the record of scooping tests, graphically shown. Data thus obtained gives information on three essential points. The efficiency of the design of the scoop, its correct adjustment, and the most effective scooping speeds. The importance from the money standpoint of having these right is referred to in the article. An interesting point is suggested by these records: Each road has its own design of scoop and it is fair to assume that they are not all equally efficient. Tests of this character for all designs would enable their relative efficiencies to be determined and would suggest improvements in the less efficient designs that might mean a material saving in operating costs.

Another interesting point is the evolution in trough dimensions and the reasons the Lake Shore has for preferring a trough 28 in. wide, 7½ in. deep and 2,000 ft. long. The Pennsylvania once experimented on its Philadelphia division with a trough 29 in. wide, but the results were unsatisfactory and no change was made from the standard of 19 in. Trains running at ordinary speeds wasted more water and received less than with the standard trough. To correct this, flanges were put along the top of the trough extending inwardly so that the opening provided for the scoop was about the same as with the standard trough. This put more water into the locomotive tank than the standard trough but also wasted more. It was decided from these results that any saving in water would have to be made by a modification of the scoop, rather than of the trough. The experiments included the placing of deflectors on each side of the scoop, but they did not reduce the waste appreciably and were objectionable because they impeded inspection and repairs to the scoop details.

While track tanks are installed primarily for passenger service some of the lines having them consider it almost as essential to water freight trains from them as well, since this expedites all train movement, particularly on congested sections. It also lessens the number of stops of long, heavy freight trains, and the roads which have tried it believe that the saving from the use of track tanks is greater in freight traffic than it is in passenger traffic. With the improvement in design, equipment and size of track tanks the cost has, of course, increased considerably. A double track installation on the Baltimore & Ohio 16 or 17 years ago cost around $10,000. Now a modern plant will cost $15,000 to $30,000, exclusive of grading and track work, depending on the width and length of troughs and the methods used for filling and for heating. The total cost is greater than this by the amount spent on grading, drainage, ballasting and track work, which is different for each job. The maintenance, we understand, will probably average about 8 per cent. of the cost. Track at troughs costs about twice as much for maintenance as elsewhere. The cost of operation varies considerably. The labor cost is about double that at a station of equal importance without track tanks; the fuel for pumping will probably be at least double because of the waste of water, and of the heating. The heating cost is a great variable, not only as between stations, depending on local conditions, but for the same station for different years. As regards local conditions, a station supplied from a river will need more heat than where the water comes from a well; the regularity of train movements also has considerable effect, frequent scooping being a great help in cold weather.

The Lake Shore at present has nine track tank stations between Chicago and Buffalo. There are some pretty long stretches between some stations, and we understand these will be broken up, the ultimate plan being to have track tanks or regular stops at intervals of about 20 miles. This is to meet the requirements of freight service, passenger trains not needing intervals shorter than 10 miles.

KEEPING PERMANENT WAY MAINTENANCE DOWN.

It was in 1900 that the quantity of traffic carried by our great transportation systems began to advance in ever increasing strides, so that in the years 1901, 1902 and 1903, the amount was so great as to well nigh swamp even the best managed and best equipped railroads, and cause those years to be ever after remembered as strenuous ones. This increase was slightly checked in the latter part of 1903, but the struggle to make the improvements and additions surpass or "get ahead of" the business had already begun in 1900, and the work was advancing with ever increasing vigor. Money was literally poured in for additional facilities, and the increasing tonnage together with the increasing rapidity of the service, the units which hammer down the permanent way, caused the expenditure of heavy sums for the maintenance and improvement of the roadbeds and tracks, which were the foundations for this mighty business. These heavy expenditures were kept up with scarcely a halt to the very threshold of the panic of 1907, when they were brought to an end more suddenly than has been known before in the memory of the present railroad officers, although the signs were apparent for some time in advance.

We have been examining into the record of maintenance of way and structures expenses given in the annual reports of some roads, and have reduced those of one of them for several years back to the cost per mile of all tracks, and the cost per train mile, both passenger and freight, in order to facilitate comparison, and present the results in the accompanying tables:

TABLE 1.—*Maintenance of Way and Structures Expenses.*

Year.	Per mile, all tracks included.	Per train mile, pass. & frt., cts.
1895	$946	....
1896	875	....
1897	933	....
1898	1,165	....
1899	1,220	19.451
1900	1,298	21.571
1901	1,247	20.616
1902	1,363	21.906
1903	1,363	21.343
1904	1,218	19.730
1905	1,421	23.164
1906	1,610	25.506

By examining Table I, it will be seen that the expenditures from 1895 to 1897 were moderate, at $875 to $946 per mile, but that with 1898 they began to increase, and in 1906 reached the large expenditure of $1,610 per mile of all tracks, including sidings and yard tracks. There is evidence of a slight check in 1904 but it is well known that some companies did not even check their new construction work in that year. It is to be noted that the expenditure per train mile unit increased as well, indicating that for every train run over the road more money was being spent for an improved roadbed and track. It reached 25½ cents per train mile in 1906.

In Table II, the maintenance expenditures have been separated into their component parts, and in addition to the expenditure per unit of track and of traffic, the percentage which each account bears to the total M. of W. & S. expenses is shown. The main object of the statement is to show how large a proportion of the expenses is on account of labor directly employed by the railroad company. Of course, labor enters into the manufacture of articles which are regarded strictly as materials, but in such a case it is not directly employed by the railroad company. Accounts Nos 3 and 4, amounting to from 25 to 30 per cent. of the total, are, therefore, to be regarded as strictly material accounts, and are for rails, track appliances and cross ties; the labor for applying them is not charged to the material.

Accounts Nos. 2, 5, 6 and 7 are partly material and partly labor, while No. 1, amounting to from 30 to 40 per cent., is wholly for labor. It is thus probable that from fully 50 to 65 per cent. of the entire M. of W. & S. expenses are on account of labor actually employed by the railroad company. In times of depression, it is quite possible and entirely safe to cut the rail and track appliance allotment, because a large percentage of rail is removed from the tracks, not because it is worn out, but because its surface has become impaired, and trains do not ride quite as smoothly as the administration desires. By referring to the table, it will be observed that from 1896 to 1899 the expenditures to this account varied within narrow limits, $139 to $170 per mile of track, while from 1900 to 1906, both inclusive, with the exception of two years, the expenditures were much larger, $216 to $268 per mile of track.

In the case of ties, it is necessary to carry on the renewals with more regularity, as will be observed, because their replacement is governed by the law of decay, not of traffic units, but even in the case of ties, it is possible to reduce the requirements somewhat by the exercise of close scrutiny. There will also be irregularities in the tabular record due to the necessity from time to time for beginning the renewal of a large number of the ties in tracks which were built a few years before, and are now ready for the first replacements. An interesting feature of the table is the increase in expenditures per mile for account No. 2, bridges, and all kinds of buildings and structures, for the past ten years, due largely to the increase in the size and weight of rolling stock. It has been necessary to replace bridges which were only from ten to twenty years old, to enlarge round houses, turntables and shop buildings, and to improve the coaling stations and freight houses. It has been a transition stage with which the transportation lines have had to contend during the period of greatest expansion of traffic in a short time in their history.

Item No. 1, Section Labor, is noteworthy. Since 1896, or in ten years, the expenditure for keeping the roadbed and tracks in good condition has doubled. From expenses of $300 to $396 per mile of track between 1895 and 1901, the amount jumped to $485 in 1902, $498 in 1903, dropped back to $442 during the slight depression in 1904, rose higher than ever to $573 in 1905, and reached a maximum

TABLE II.—*Maintenance of Way and Structures Expenditures Separated into Their Component Parts.*

1906	39.2	632	9.98	16.1	259	1.09	14.8	236	3.77	11.6	187	2.95	9.0	156	2.30	5.2	83	1.32	4.1	67	1.01

of $632 in 1906. This certainly indicates an excellent condition of permanent way. The cost per train mile points out, too, a steadily increasing quality of roadbed and track. Whereas about six cents were spent for labor in 1899 for each train run one mile, in 1906 almost ten cents were spent on the roadbed and track for each train run one mile.

There is no task so pleasant to the operating officer as that of employing a large number of men to keep his property in line condition at all times. This has been the characteristic task of the past seven or eight years, but now storm clouds have arisen and it has become necessary to close-reef and sail under almost bare poles on account of a reduction in earnings which has amounted to 20 per cent. and more. No such drop in earnings has taken place since the depression of 1893 and the railroad manager has before him the plain duty of reducing his expenses to an extent that will enable him, so far as possible, to show a profit from operating under the changed conditions. The disbursement during the last decade has been so generous and open handed that railroad companies in making these reductions have to go back ten years to establish a comparison. The tables we have quoted prove amply that liberal reductions can be made without impairing the efficiency of the property. They show also that the very high cost which has been paid for labor, both by unit of time and by unit of performance, must certainly bear its share of the reduction—were any other evidence needed to prove this than that of the many workmen now without employment.

A DECADE OF BRIDGE DESIGN AND CONSTRUCTION.

The introduction, about a dozen years ago, of modern freight cars of large capacity, and the practice of hauling heavy train loads to reduce the most of operation, led to a rapid increase in the weight of locomotives, which in turn required extensive rebuilding of bridges on the principal railroads of the country. Whenever it was possible to reduce the span by the addition of extra piers, plate girders replaced old pin trusses as well as plate girders designed for light loading. In building new railroads, the plate girder has likewise been favored, so that during the past decade the construction of bridges of this class has been unprecedented. As the span and loading have been increased, new forms of flange sections as well as more effective web splices were designed. The most decided change relates to the extensive adoption of pin bearings and segmental expansion rollers. In several important particulars, theoretic considerations are given more consideration than formerly.

In order to secure greater stiffness as well as strength, riveted truss bridges have been substituted for pin bridges and gradually their span has been increased to about 160 ft. and occasionally to nearly 200 ft. Increasing attention has been paid to the design of details calculated to develop the full strength of the main sections of members. In pin-connected trusses, the widths of eye bars for short spans are now equal to those formerly used for spans two or three times as long. The sizes of pins have been similarly increased, while the reinforcing pin plates are more scientifically designed, not merely to furnish adequate bearing, but to distribute the stresses properly among the shapes composing the members. Secondary stresses are reduced as far as practicable by making the axes of connecting members intersect in a point. Not only are adjustable members in short pin spans more generally avoided in the main trusses, but the lateral systems as well as the portal and sway bracing are built of shapes designed to resist both tension and compression.

There has been a tendency to increase the depth of the floor system and to lengthen the panels, the maximum length for simple trusses now being 37 ft. for a span of 407 ft. The use of end floor beams for short spans is coming into more extensive use, although originally designed for only long span truss bridges. A reaction has set in against the extreme curvature of the upper chord of long span trusses that was in vogue for some years. The relative reduction in depth adds some metal to the chords but secures posts of greater stiffness. At the same time the general appearance of such trusses is improved. A good illustration of this may be seen in the bridges at Port Perry and at Brilliant, Pa., on the Pennsylvania Railroad.

Several railroads are now designing all their bridges for Cooper's E 60 loading. Class E 50 was the highest loading tabulated in the 1906 revised edition of Cooper's Specifications; E 40 in the edition of 1896. The latest specifications designate E 40 as the minimum loading for railroad bridges.

An important step in the progress of bridge design was the adoption in 1906 of general specifications for steel railroad bridges by the American Railway Engineering and Maintenance of Way Association. The details of design were under discussion by the committee and before the Association for several years, while the specifications on materials and workmanship were under consideration for six years. Special studies of the literature and the latest practice regarding some topics were made before the adoption of the corresponding paragraphs of the specifications. The adoption of these recommended standard specifications by the railroads will help to secure still further improvement in details and in the general character of bridge structures.

Last summer the Association, through its Committee on Iron and Steel Structures, began to determine experimentally the actual stresses in bridge members when trains cross the structures at different speeds, in order to find the effect of impact or the dynamic increment to be added to the computed live load stresses. During the previous year the Association secured the co-operation of many railroad companies in defraying the necessary expenses, and it is expected that these tests will be continued during the coming summer. The allowances made for impact in specifications prepared by various prominent engineers differ widely from each other and it is gratifying to look forward to the early elimination of this element of uncertainty from the design of railroad bridges. The need for such tests has been advocated for a long time by competent critics. A beginning was made in a small way a number of years ago, and more recently over two thousand records were obtained on the Baltimore & Ohio Railroad, but, unfortunately, they were destroyed in the Baltimore fire before they could be thoroughly studied.

During the decade, 1888-1898, a large amount of solid floor construction of various designs was introduced in connection with the abolition of grade crossings in several large cities, notably in Chicago, while a few railroads adopted it as the standard for other bridges also. Observation of these structures has shown that in most cases the solid floors as designed were too shallow either for stiffness or for durability, so that the more recent designs employ greater depths and simpler details, affording more convenient inspection of the steel work. The substitution of creosoted timber and water-proofing in place of steel plates has been made to reduce to a minimum the metal subject to corrosion and thereby to diminish the cost of maintenance.

A more radical change in the design of solid floors consists in placing reinforced concrete slabs on the metal floor system in order to support the ordinary railroad track with ballast. This construction has been adopted experimentally with a view to more extensive use if experience proves it to be satisfactory. Some bridge engineers are of the opinion that ballasted floors should finally replace all open floors in railroad bridges. There is an impression that the use of ballasted floors will materially reduce the effect of impact for live loads and the results of experiments on this subject will be awaited with keen interest.

One of the most characteristic features in bridge development during the past decade is the extensive adoption of the lift bridge both for railroad and for highway traffic. Only three bridges of the type known as the Scherzer rolling lift bridge were in use before 1898, all of these being located in Chicago, while since that time more than thirty of the same type have been built in various parts of the country, nearly half of them carrying railroad traffic. During this period the greatest span has been increased from 127 to 275 ft. A modification of this type known as the Cowing lift bridge was introduced a few years ago, the first one being built at Cleveland.

Since 1901, more than a score of trunnion bascule bridges have been built, including some of the Page and of the Strauss forms, but most of them were designed by the bridge departments of municipalities, especially Milwaukee and Chicago. The spans range from about 33 ft. to 205 ft. 7 in.

The hinged lift bridge has been revived to some extent with different counterweight arrangements than those used in ancient times. Some improvements have likewise been made to the direct lift bridges, a type which, with one exception, is used only for very short spans crossing canals. In these modern forms both the trusses and floor are lifted vertically, air-tight pontoons replacing the counterweights in some cases. The most novel form of movable bridge is the aerial ferry bridge crossing the ship canal at Duluth, completed in 1905. The movable car is supported by a track on the lower chord of a truss having a clearance of 135 ft. above the ordinary stage of the water.

The advances made in the design of swing bridges have been mainly those required to keep pace with the increase in live loads and in improving the mechanical details so as to reduce the cost of operation and maintenance. Only nine swing spans over 400 ft. long were built in the last decade, the maximum span being raised exactly one foot over that reached before. More cantilever bridges with spans exceeding 400 ft. were erected than in the decade immediately preceding—in fact, almost as many as were built in the two previous decades, a period extending back to the introduction of the cantilever in this country, in 1877. Counting short as well as long spans, ten cantilever bridges were erected between 1877 and 1897, 25 between 1888 and 1897, and 19 between 1898 and 1907, exclusive of the Blackwell's Island bridge, not yet completed.

The Blackwell's Island bridge has a span of 1,182 ft., which is 370 ft. longer than the next in order, the Monongahela river bridge at Pittsburgh. This 182-ft. span was in turn to be exceeded 618 ft. by that of the Quebec bridge, nearly one-half of which had been erected when it collapsed August 29, 1907. The design of the Quebec bridge has covered nearly the entire decade just closed. Its collapse has been properly characterized as the greatest engineering disaster of the period.

The engineering profession awaited anxiously the publication of the complete report of the Investigating Commission of the Canadian government, the findings of which are printed this week in another column. That the profession will take the lessons of this disaster to heart is indicated in many ways. Hardly a week has passed without the publication of articles in the technical periodicals on the design of compression members, including that of lacing, and on full-size tests, some of which were made many years ago and ought to have been published then for the benefit of bridge design. Prominent engineers representing the interests involved in both the design and manufacture of bridges, are trying to induce the government to build a testing machine of far greater capacity than any now in use, in order to extend materially the investigation of full-sized compression members. It may not be amiss in this connection to call attention to the tendency to cut down the weights of details of other than great cantilever bridges which, like lacing, have not been subjected heretofore to a satisfactory theoretic treatment. The careful analysis of the weights of details of bridges of all classes would do much to correct mistaken ideas of economy where they exist.

Only three suspension bridges with spans over 600 ft. long have been erected in this country in the last ten years. The Williamsburg bridge belongs to this decade. While its span is only seven inches longer than that of the Brooklyn bridge, completed 21 years before, it was designed for a much greater traffic.

Although the Chestnut street cast iron bridge in Philadelphia was completed 42 years ago, and the famous Eads bridge at St. Louis was begun a year later, one-half of all the metallic arch bridges without hinges have been built within the last decade. The number of such structures is comparatively small, American engineers preferring the use of two or three hinges. The first bridge with two-hinged arches in this country is only about 20 years old; hence it is not surprising that at least one-half of the bridges of this type were built during the past 10 years, the span being increased 290 ft. over that reached in 1897. The progress in the design of this class of structures is indicated by the projected four-track bridge for the New York Connecting Railroad over the East river at Hell Gate and Wards' Island, the span being 977½ ft. between centers of end pins.

About one-third of the existing three-hinged arch bridges were built during the last decade, while 75 per cent. of the balance belong to the previous one. Only one bridge of this type has been built with a larger span than that reached as early as 1889, the difference being 84 ft. Undoubtedly the number of metallic arch bridges is smaller than it would have been if concrete construction had not assumed such large proportions. Nearly 30 per cent. of those with three hinges are used for railroad service.

The most characteristic feature of bridge construction in the period under consideration is the enormous development in the use of both plain and reinforced concrete for arches with spans ranging from those of small culverts to 233 ft. This length is the clear span of the main arch of the Walnut Lane bridge in Fairmount Park, Philadelphia, which is approaching completion, and is the largest concrete arch in the world. The problem of the erection of an arch of such magnitude required as careful study by the designing engineer as the proportioning of the structure itself. The method of erection was made the subject of definite specifications, as no contractor had sufficient experience to enable him to build the structure without the advice and direction of a competent engineer. In this case two narrow arches are built near together and the intervening space is bridged over by the floor system.

Another example worthy of especial mention is the Connecticut avenue bridge in Washington, D. C. The outside blocks were cast separately and hoisted into position, while the remaining concrete was deposited in place in the usual way. By using yellow sand in some parts of the exposed surface and bluish crushed stone in place of sand in other parts, two tints are shown according to a definite color scheme instead of the ordinary single color of concrete.

A view of a train crossing a concrete arch viaduct which carries it out of sight of land, has recently been published in the *Railroad Gazette*. This novel structure is two miles long and consists of a series of reinforced concrete arches of 50-ft. in span. It is known as the Long Key viaduct on the Key West extension of the Florida East Coast. As several other viaducts more than a mile long, besides numerous shorter ones on this railroad, are to be built, some idea may be gained of the part which concrete, either with or without reinforcement, plays at present in the development of bridge construction. When the number of concrete bridges now in use is considered, it seems surprising that the first one in this country was designed as recently as 1895 and built in 1896. Study of this problem by a large group of engineers has produced many changes in form and arrangement, effecting the arch ring, spandrel walls, spandrel arches, columns, floor beams and slabs, and reinforcement and the surface treatment of the concrete. In first-class practice the elastic theory is applied in the design of the arches.

While the extensive development of concrete bridges has been in progress, a considerable number of stone arch bridges and viaducts have been built, notably in rebuilding the Pennsylvania Railroad, in replacing many short metal structures, and in eliminating grade crossings. Some of these bridges are of unusual magnitude, like those crossing the Susquehanna river at Rockville and Shock's Mills. The bridge at Hartford, Conn., is a corresponding example of a large highway structure. In the design of statically indeterminate structures, it is now recognized that special means should be used to complete the erection in such a manner as to make the actual conditions agree closely with those assumed in making the design. Excellent examples of this are given by the means adopted to close the great arches of the Niagara and Clifton bridge; by the erection of the floor system and stiffening trusses of the Williamsburg suspension bridge, and by the manner in which the arch rings of the Walnut Lane bridge were completed by filling in the narrow keys between the segments of the concrete ring previously placed.

In reply to charges made by Social-Democratic members of the Diet of the German Empire that accidents are caused by too long hours of service, Dr. Schulz, President of the Railroad Bureau, said that the accident statistics showed that much the larger number of accidents occurred, not in the later hours of the employees' days' service, as would be the case if due to over-fatigue, but in the earlier hours, when the men are fresh.

The American Railway Engineering and Maintenance of Way Association differs from kindred railroad associations in one important respect, in that its active membership includes a good many men who are not, and never have been, connected with railroads. These men form some of the most valued members of the committees. To get the best results from committee work there must be full meetings and all the members must work. But every committee meeting means a railroad trip, and some incidental expense, at least, to the members attending. The railroad men having passes are, ordinarily, at only a nominal expense for such a meeting unless the session is prolonged. But for the member who cannot have a pass the railroad fare may be a considerable item of expense, which he probably must pay himself. In most instances such members will feel that they cannot afford to attend many committee meetings, perhaps not any, if they intend going to the convention. Committee work naturally suffers under these circumstances. Just how the situation can best be helped is a matter for some thought, and it needs to be thought about, for the valuable work this association is doing for the railroads should be freed from such hindrances as much as possible. As a matter of fact, a good many of the railroad men who do committee work cannot afford the expense incident to this work. It is enough if they give of their time and energy. Some means should be provided for reimbursing members of committees for any personal outlay incident to their work. The association cannot do this; it hasn't the means. As the chief beneficiaries of this work the railroads might well feel that they can afford to subscribe to a special fund to be used by the association for this purpose. In thus aiding the activities of this organization they are materially furthering their own interests.

NEW PUBLICATIONS.

Electric Railways. Vol. II. By Sidney W. Ashe, B.S., E.E. New York: D. Van Nostrand Co. 282 pp.; 5¼ x 7½ in.; 115 illustrations. Cloth. Price, $2.00.

This volume, while forming the second of a series that the author has in preparation, is complete in itself and deals, in the early chapters, with the engineering preliminaries that must be taken into consideration in locating and building electric railways, closing with a discussion of direct-current sub-station work. The first volume of the series, which was issued some time ago, dealt with the subject of rolling stock.

The first consideration in the location of an electric railway should be, will it pay? And in the discussion of the preliminary investigations that should be made, the author outlines the methods to be pursued. These include a study of the character and amount of population, the probable number of passengers the territory will contribute, the type of cars and motors, the speed and load diagrams, and many other items of first cost and operation that will have an influence in the solution of the problem. The empirical basis for the work is given in a long list of electric railways, located all over the United States from Maine to California and from the Lakes to the Gulf. There are 46 centers of propulsion thus selected, and from the summary prepared, it appears that the railways carry, annually, about 68 passengers per inhabitant. Having determined the present population, the next step is to consider future growth, and instances are cited to show the method of plotting the curves.

When the probable traffic has been estimated, the next step is to determine the electrical features and the type of rolling stock to be used, and various methods for accomplishing this are explained and discussed, including the speed, acceleration and power curves of various cars and motors, followed by the methods of arranging for schedules and the load diagrams of the power plant.

This part of the work occupies the first four chapters. In the fifth, the power house location takes first place, and in this is included that of the sub-stations. In this the capacity is taken up, as well as the cost. Examples are given of the range of these costs per kilowatt, which shows such great variance that it is evident that no calculations for a specific case can be made on general principles or from average data, but each one must be worked out from its own local conditions.

In this treatment of the subject no attempt is made to discuss the electrical features or the details of the apparatus used. The work is confined to the arrangement of the buildings, the purposes to be served by the station, and the only reference to the construction of the apparatus occurs in connection with this arrangement. For example, in considering the local storage battery, the voltage and amperage that are giving good results, the author states the methods of charging, the usual arrangement and the switch connections. In chapters VII. and VIII. the rotary converter and transformer and their methods of operation are described, but this is in connection with their functions rather than in the details of their construction.

In chapter IX. specifications are given for insulating oils, in which greater emphasis is put upon purity than on any other quality. In fact, they are based upon the proposition that, "all oils whether mineral, vegetable or animal, when pure, are good insulators," and the wide range found in the insulating qualities "seems to be due, not to the chemical composition of the oil but to its purity." The book closes with a brief description of the auxiliary sub-station apparatus and the methods of its operation.

Cram's Standard American Railway System Atlas, 1908. World edition, with detailed Maps of Foreign Countries. 612 pp., 14 x 18½ in. Cloth, $12.50. George F. Cram, 130 Fulton St., New York, and 55 Market St., Chicago.

Cram's atlas has several excellent features; it shows interurban trolley lines, indicates important towns with a red circle, prints its railroad lines in colors, so that they may be more readily distinguished, and uses type that is easy to read. We have always found it serviceable and accurate.

CONTRIBUTIONS

Car Wheels.

Philadelphia, March 10, 1908.

TO THE EDITOR OF THE RAILROAD GAZETTE:

The work done in the last five years by the Master Car Builders' Association's standing committee on car wheels has resulted in efforts by the makers of cast iron wheels to improve their product so as to make them serviceable under cars of 100,000 lbs. capacity. There has been, however, so little improvement that it is now time to admit that the passing of the use of cast iron wheels under high capacity cars is as sure as is the passing of the wooden car affirmed by A. M. Waitt in his recent paper on steel cars.

It has been said that 72 per cent. of the cars built last year were of either steel or steel underframe construction. Probably 50 per cent. of these were of 100,000 lbs. capacity. Investigations have proved that steel wheels under these cars are safe and because of longer life cheaper per car mile than cast iron wheels. If it is felt necessary or advisable to try something still better than the steel wheel, or as good and cheaper, then let all efforts be bent to this end. But someone must take the lead. A number of years ago a standing committee of the Master Car Builders' Association was appointed to design steel underframes and steel cars. This committee went on from year to year making progress reports but no definite progress. The problem was finally taken up by a manufacturer, who put into it all the energy and enthusiasm he had. What he did not know he hired. As a result there are to-day, probably $500,000,000 worth of these cars in use in this country. On many roads they mean the difference between a deficit and a dividend; and in all cases, increased profits. The car wheel will be developed in the same way. In the meantime let us all put our energy into going ahead on the lines already proved best, instead of criticising and wondering if this or that thing could not be better done in some other way. If we put off doing anything at all as long as any one has a theory that other ways may be better, we shall never get anywhere. CHAS. T. SCHOEN.

What Are We Going to Do About Accidents?

TO THE EDITOR OF THE RAILROAD GAZETTE:

The correspondence on "What are we going to do about accidents" in your issue of February 28, does not, I think, fix any large measure of responsibility for accidents on railroad labor organizations. The inference to be drawn from "General Manager's" letter dated Feb. 15th, is that on the road with which he is connected discipline is maintained and that just decisions made by Superintendents are not reversed at the behest of the "Brotherhoods."

The other "General Manager" who writes under date of Feb. 16th seems to me to place most of the responsibility on those officials who either kept incapable Superintendents in place or failed to support capable officers in the proper disciplining of their subordinates. In the final paragraph of this letter, "General Manager" sets forth plainly how good discipline may be obtained and maintained.

My knowledge of military affairs is superficial and I may be mistaken in thinking the likeness between an army and a railroad equally so, but even in the army is there no method of appealing from disciplinary decisions? If the sentry accused of falling asleep at post protests his innocence, can the sergeant forthwith put him in clink for 30 days? And if the group of corporals believed their lieutenant had set them tasks not provided for in the articles of war, or whatever the form of their contract with the state may be named, have they no appeal? And if they have and use it, does the discipline of the army suffer thereby? Do you think the grant of arbitrary power to the Superintendent will bring about order and good service from subordinates?

On one of the best managed roads in this section, the right of appeal was recognized. In minor cases the appeal from the Superintendent's decision was to the General Superintendent only, but should the employee's position be in jeopardy he might have his case reviewed by the General Manager. This rule involved no humiliation to the Superintendent, its operation occasioned no retaliation by him on the subordinate. Appeals were frequent, reversals rare and discipline well maintained. The possibility of appeal from a Superintendent's decision and practical certainty that, if well founded, it will be enforced should and will serve to make that official more careful in his investigations and more secure in his authority.

It is not unusual for railroad officials to disregard the violation of rules when there is apparently no danger to result therefrom and when some immediate advantage is to be gained. A train on which I was traveling recently was stopped between stations by the bursting of an air hose. One of the principal operating officers of the road who was in his car at the end of the train came out and looked on while conductor and brakemen replaced the hose. He apparently did not note the failure of the flagman to comply with the rule.

Do you not think the laxity of discipline, and consequent accidents, may arise from an indisposition on the part of officials always and indiscriminately to enforce train and other rules, and enforce them whether the offender be a Brotherhood man or not? Appeals, even though backed by "Brotherhoods," don't mean reversals; one "General Manager" gives testimony to that, and the other "General Manager" shows us how to build up discipline, enforce rules and minimize accidents. To his general recommendations, I would add one more: appoint one or more experienced railroad men as inspectors (not detectives) reporting to the chief executive officer of the road direct. Require the Inspector to note not only how the men obey, or disobey, the rules, but how officials enforce the rules.

VICE-PRESIDENT.

Railroad Track Tanks.

BY H. H. ROSS,
Assistant Engineer, Lake Shore & Michigan Southern.

Track tanks have been used since 1857, when they were installed on the London & North Western Railway of England. In the United States, the New York Central used track tanks in 1870. The practice in England is to use troughs of sheet steel, or iron; in a few cases cast iron is used, and one road—the Great Northern of England—uses troughs of creosoted wood fastened by cast iron brackets to the ties. The English trough is usually supported upon wooden stringers fastened to the ties, the top edge of the trough being bent over and bolted to the top of these stringers. In the United States, troughs are of sheet steel and are supported directly upon the ties, although at one time the Chicago, Milwaukee & St. Paul had a track tank between Chicago and Milwaukee made up of cast iron sections, each section being 6 ft. long.

The relative elevation of the top of rail and top of trough is governed by circumstances. In England the trough is about 3 in. higher than the rail and at the ends the rail is raised 6 in., this change in grade being made very rapidly, usually in 180 ft. In the United States the top of rail and top of trough are about the same height. The main advantage of English practice is that the scoop does not have to work through such extreme limits, and there is no necessity for inclines at the ends of the trough, but this would not be practicable on our railroads, as the bottoms of hopper cars, the brake rigging and other apparatus do not have as great clearance as in England and the troughs would be injured. American practice is to allow nothing between the rails which projects above the rails. It is entirely possible to maintain track tanks on curves—English roads not hesitating to place them thus, and there are several in this country—but it is not advisable to do this unless absolutely necessary, as much better results are secured on tangents.

Fig. 1—Passenger Train on the Lake Shore & Michigan Southern Taking Water.

Track tanks must be located where the supply of water is abundant as well as of good quality, as, under the best conditions we can hope to obtain, at least 15 or 20 per cent. of the water put into them is wasted by being forced out over the sides and ends by the engine scoops; and if engines scoop at too slow or too great speed, or if the scoops are not kept adjusted, but are allowed to drag on the bottom of the trough, a greater percentage is wasted, probably averaging 50 per cent. for all engines scooping. This difference in adjustment makes more difference in scooping than one would imagine. An engine with scoop properly adjusted will not throw the water badly even at high speed, whereas one too low will throw water all over the right-of-way. Another curious feature is that an engine seems to scoop as much when the water in the trough is an inch or so low as when the trough is full, the reason probably being that the scoop piles up the water ahead of it or else the force of the water pulls the scoop down deeper. The photograph, Fig. 1, shows about the average amount of water thrown out by the scoop of a passenger engine running 40 or 50 m.p.h.; this amounts to 15 or 20 per cent. of the total taken out of the trough.

Prof. I. P. Church, of Cornell University, made a mathematical investigation of water scoops, and later our road made some practical tests which checked up almost exactly with Prof. Church's formula, viz., that 22 m.p.h. is the minimum speed for taking water and at 25 m.p.h. water is scooped satisfactorily, although more water is forced into the tender at higher speeds, 40 to 50 m.p.h. working about the best, speeds exceeding this are apt to spill the water badly unless the scoop is very carefully adjusted. The grades approaching track tanks must therefore be such that all trains which are to take water can easily attain a speed of 25 m.p.h., and for this reason track tanks should be away from stations, yards, railroad crossings, drawbridges, etc.

The results of the latest Lake Shore tests are shown graphically in Fig. 2. Curve 1 of this figure shows the amount of water theoretically possible to take; that is, the depth of water above the scoop, multiplied by the width of the scoop, multiplied by the distance the scoop is in the water. Curve 2 shows the actual amount of water taken out of the trough by measurement before and after scooping. No. 3 shows the amount actually put into the engine tank. No. 4 shows the depth of water above the tip of the scoop for each of the tests, which explains the irregularities of the curves. No. 5 shows the amount of water taken up by the scoop in percentage of the theoretical amount. No. 6 shows the amount of water taken up by the scoop in percentage of the amount actually taken out of the trough. No. 7 shows the gallons of water delivered per inch of dip of scoop.

Of the above diagrams, No. 6 is the most interesting as it shows that the amount of water actually wasted is about 15 per cent. for a scoop in adjustment and running at a speed of 40 to 45 m.p.h. It is evident from this diagram that speeds below 25 and above 60 m.p.h. waste a good deal of water. This is more important to the maintenance of way department than to the motive power depart-

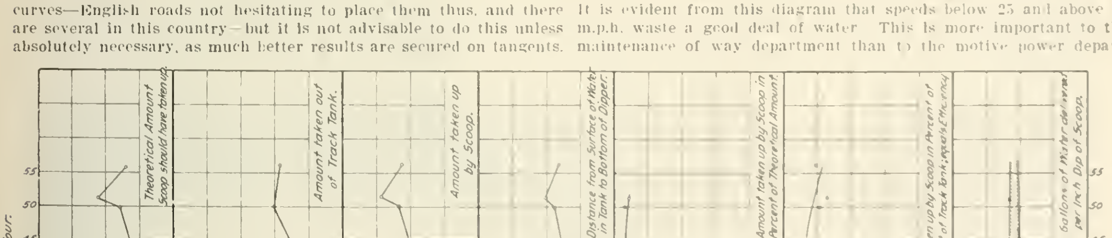

Fig. 2—Graphic Results of Water Scoop Tests on the Lake Shore & Michigan Southern.

ment, as is shown by curve No. 7, from which it is evident that an engine will get nearly as much water at 25 m.p.h. as it will at 50 m.p.h. All of this reduced to dollars and cents means that if trains are run at proper speeds for scooping, the bills for water will be 10 to 20 per cent. less than if they try to scoop at speeds below 25 or above 60 m.p.h. Fig. 3 shows the outlines of the scoops used in these tests.

Next to the problem of water supply, that of drainage is most important. The large amount of water wasted keeps the ground under the troughs continually soaked. Therefore unless the sub-grade for a considerable depth is composed of material that will drain itself quickly and thoroughly, artificial means to this end must be provided. This has always been one of the hardest obstacles to overcome. The track would ride badly even if it were being continually worked over. At the present time the construction used on the Lake Shore, which is shown in Fig. 4, seems to meet all requirements. The essential points are to carry away quickly, by means of tile laid between tracks, such water as gets into the bank, and to minimize this amount of water by covering the ballast with large flat stones, so placed that the water will run off rapidly. These flat stones answer another purpose also, as, being very heavy, the force of the water cannot dislodge them and they hold the ballast from being washed out from between and under the ties. Since the Lake Shore track tanks have been paved in this way the track over the troughs rides as well as elsewhere.

Ties for track tanks should be heavier than those on ordinary track to allow for the recess in which the trough rests, and should be sawed so that there will be a minimum amount of work to get everything lined up. These ties should be of white oak or some other hard wood, and all ties should be tie plated. The practice on the Lake Shore is to use ties 8 in. x 10 in. by 8½ ft. long. It is very essential to do this part of the work well, as the expense of renewing ties in such a place is very great; therefore any reasonable increase in first cost will soon be offset by the saving on maintenance charges. The track should be thoroughly surfaced and filled in with stone ballast and the same quality of ballast should be continued for at least a 1,000 ft. beyond the troughs on the trailing end on account of the large amount of water that will be spilled from the engine tanks for that distance. The photograph of one of the older steam heated troughs (Fig. 5) shows the above features of paving and type of ties, all of these ties being tie plated.

Water for track tanks is usually supplied from elevated tanks,

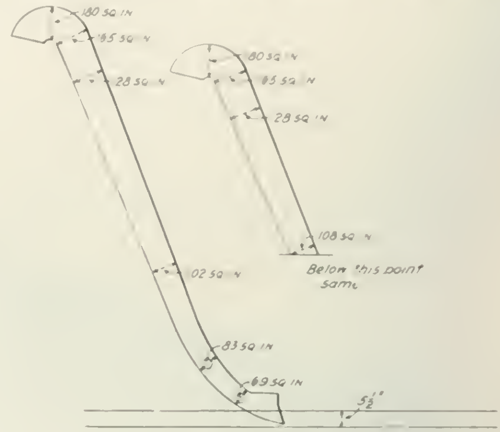

Fig. 3—Outlines of Scoops Used in Tests.

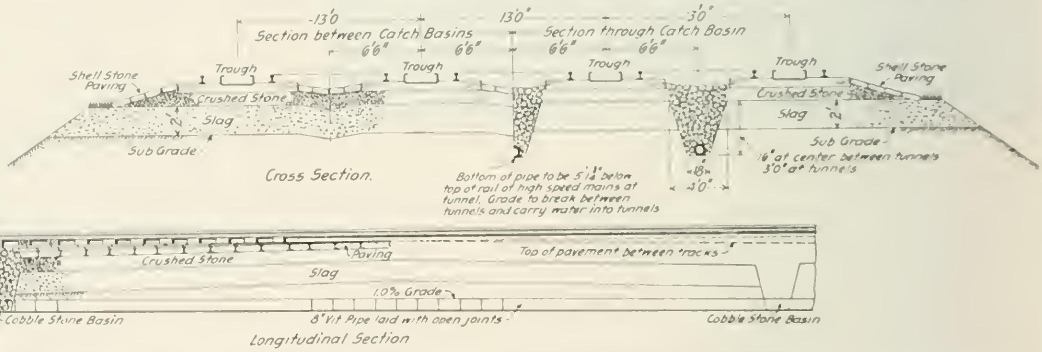

Fig. 4—Details of Track at Troughs; Lake Shore & Michigan Southern.

Fig. 5—Track Tanks at Springfield, Pa.; Lake Shore & Michigan Southern.

the size of the pipe supplying the troughs being determined by the minimum time in which it is desired to fill them. On the Lake Shore a 12 in. main is used, reducing this for the different inlets, and it takes 1½ to 2 minutes to refill the newer troughs after a locomotive has scooped. This filling is done automatically, the valves opening as soon as the water in the trough falls below a fixed level. On the older troughs the water is controlled by a man at the pump house, but on account of the personal equation of pump operators it is found much more satisfactory to make this filling automatic. In England a float system is used for keeping the troughs full and the same object is attained as with our automatic valves.

The number of automatic valves per trough varies according to local conditions and class of traffic. The practice on the Lake Shore is to put in three or four valves per trough—three where the inlets are a part of the heating system, and four where a separate heating system is provided. These valves are placed in small pits at the side of the track and are controlled by an equalizing pipe from the trough, connected to a small tank over each valve. In this small tank a float operates a pilot valve that in turn controls the main valve. From the main valve a pipe is run to each trough, being connected to the latter by a short piece of corrugated rubber hose. All of these pipes are run in small cross tunnels under the tracks. By the use of these tunnels and flexible connections all piping is easily got at, and changes due to expansion and contraction, as well as changes in the level of the track, do not cause leaks or broken connections. Another advantage of these cross tunnels is that all the drains between tracks are connected to them and are thus much more easily maintained. The tunnels will also take care of the water in case of broken pipes and prevent the track from being washed out.

Troughs vary in width from 18 in. to 28 in. and in depth from 6 in. to 7½ in. The majority of troughs at the present time average 19 in. wide, 7 in. deep and 1,400 ft. long. The New York Central and the Lake Shore are using troughs 28 in. wide and 7 in. to 7½ in. deep, the length varying according to conditions. The experience on the Lake Shore favors a trough 28 in. wide, 7½ in. deep and 2,000 ft. long. The old style trough was 19 in. wide, 7½ in. deep and 1,400 ft. long. This was all right for passenger trains, but freight trains running 25 or 30 m.p.h and needing 5,000 to 6,000 gals. of water in the tender required a greater length. The length was then increased to 2,500 ft. and was satisfactory from a freight train standpoint, but the difficulty of keeping the troughs level for this distance was great and it was finally thought best to reduce the length to 2,000 ft. and make the section wider. The main advantage of this wider section is in the greater quantity of water it holds. If a train takes water and for any reason the trough is not immediately refilled, a following train can still get water; furthermore, it is possible to scoop with a double header, the rear engine getting all of the water needed. Other advantages are the possibility of using a wider scoop as larger engines are put in service, and making a stiffer and more rigid construction in the trough itself. The main disadvantages of the wide section are, that with a badly adjusted scoop the waste is greater, and the cost of heating the water in winter is greater on account of the larger surface exposed. This increase in cost of heating is greater than the difference in exposed surfaces would lead one to believe, probably due to the action of the wind.

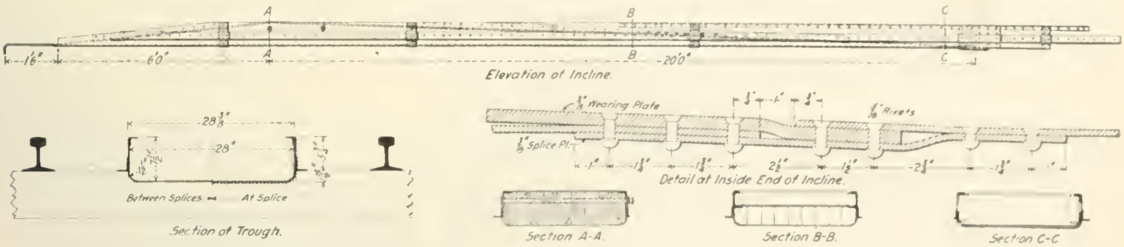

Fig. 6—Details of Incline for Track Troughs; Lake Shore & Michigan Southern.

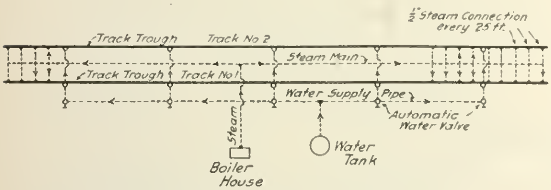
The question of a satisfactory incline at the ends of the trough to raise the scoop, if for any reason it is not raised before the end is reached, has always been one that has caused the maintenance departments a good deal of trouble and annoyance from the loss of ends and breaking of scoops, and other incidental damage. In England, where the practice of lowering the rails at track tanks is in vogue, there is very little possibility of this part of the trough causing trouble. On the Lake Shore the earliest inclines were quite short, consisting of a steel plate running over the end of the trough and spiked to the ties. These were replaced with an incline 12 ft. long, made of cast-iron and riveted to the bottom of the trough, with a steel plate beyond the end, spiked to the ties. Then for a while no incline at all was used; instead simply a board fastened to the end of the trough, and an auxiliary gate so arranged that if the board end was taken out this gate would swing around and stop the flow of water until the end could be replaced. Beyond the end of the trough a piece of sheet steel was fastened to the ties, and two short pieces of rail in line with the edges of the trough to guard against dragging brake rigging. These board ends have been quite satisfactory, but require a good deal of watching. At the present time the incline shown in Fig. 6 is being used. This incline is built in a very substantial manner, has been deliberately and severely tested, and has withstood all attempts to plow it out; also, on account of the length—20 ft.—it is found that at reasonable speeds scoops are not injured. The construction of this incline is virtually carrying the bottom of the trough up and over the end. A sheet of ⅜-in. steel plate is used and this plate is riveted to the sides of a standard trough section, the space between the plate and bottom being packed with oak fillers. The length of the incline is 20 ft. in the direction of traffic and 6 ft. on the outside to guard against dragging brake-beams, etc., on trains running against the current of traffic. This incline is used at both ends of the trough.

When track tanks are used in cold climates it is, of course, necessary to heat the water in some way to prevent freezing. The practice in England is to station men along the track and keep the troughs open by shoveling out the ice. Also, as their trains run at shorter intervals than ours, their troughs are being filled with warmer water more frequently. If the weather becomes too severe the track tanks are kept out of service. On one English road the



Steam Heating Method.

Fig. 7—Diagrams of Heating Systems.

Lancashire & Yorkshire) steam pipes are carried underneath the trough midway between the stringers on which the trough rests, and the water is kept from freezing by indirect radiation. This is possible with the English troughs, as they are higher than the rail, but it would not be practicable with the construction used in America. In this country there are two methods of keeping the water from freezing: (1) By blowing steam into the water at short intervals, and (2) by circulating the water in the trough by means of a pump and heater, or an ejector. Fig. 7 shows diagrammatically the different methods at present employed, and also a proposed method of circulating. Diagram 1 of this figure shows the usual method of blowing steam into the trough. A steam main is run from the boiler house to a box between tracks. In this box a covered steam pipe runs the full length of the trough and at intervals of 25 or 30 ft. a small pipe runs to the trough. The diagram also shows the automatic valves and water lines.

Figs. 8 and 9 show the details of a four-track steam-heated installation on the Lake Shore at Springfield, Pa., Fig. 5 being a photograph of the same. In a general way this covers all track tanks heated directly by steam. The difference between this and earlier installations is that here the steam pipe is carried above the level of trough and does not become filled with water, whereas the old method was to carry the steam main below the surface, and occasionally it would be split from end to end by freezing. The water connections are controlled by automatic valves and all piping under tracks is placed in concrete tunnels and joined to the trough

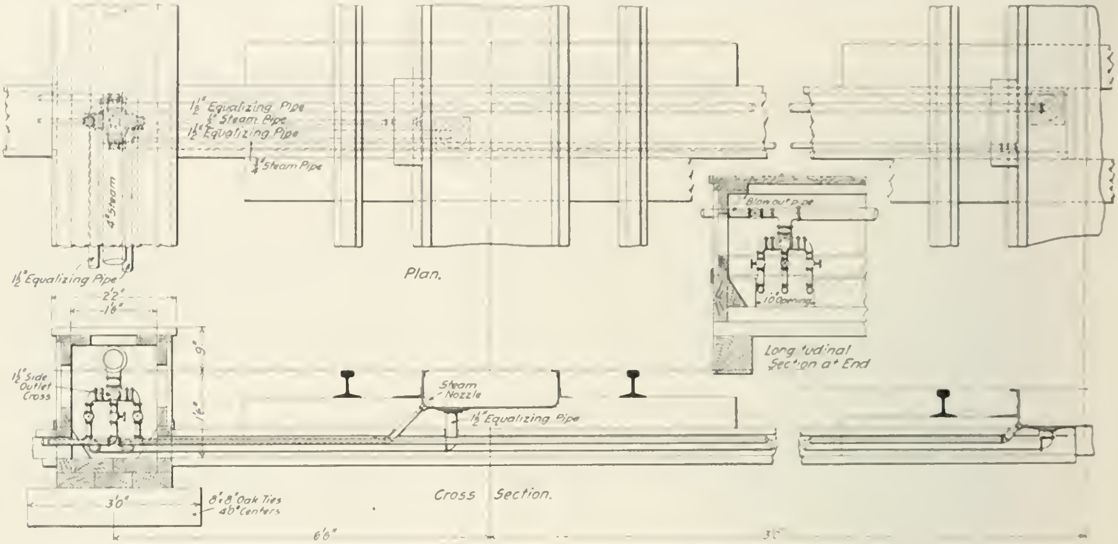

Fig. 8—Details of Typical Direct Steam Heated Installation; Lake Shore & Michigan Southern Track Tanks.

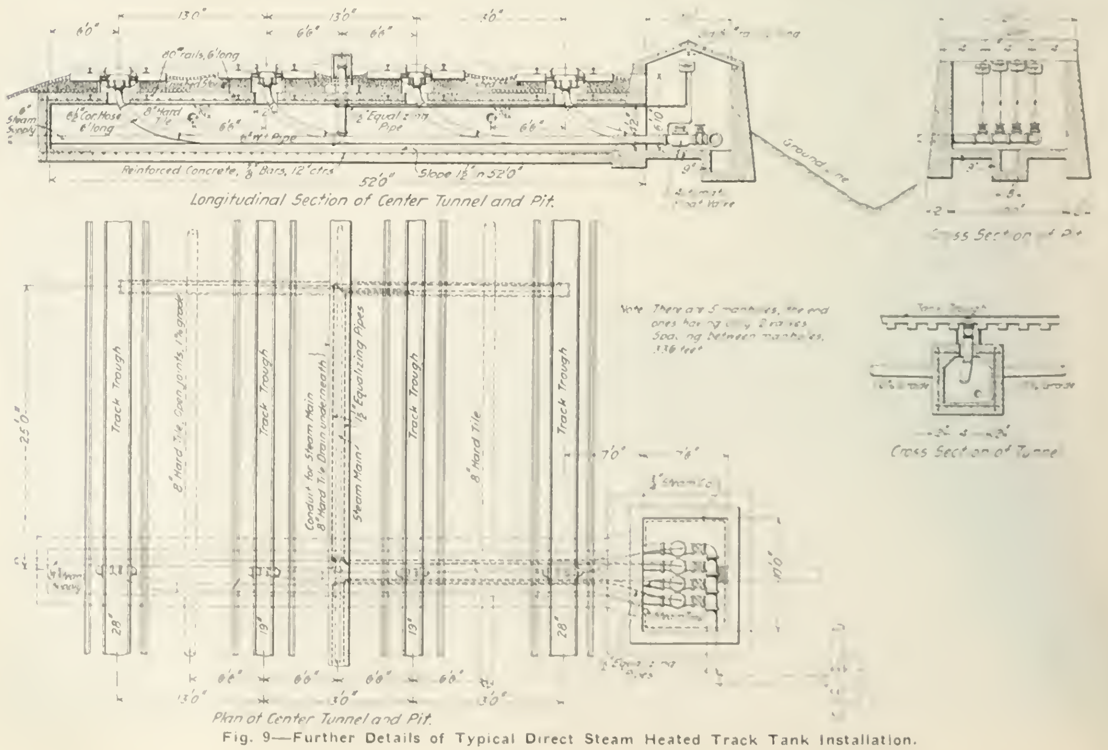

Fig. 9—Further Details of Typical Direct Steam Heated Track Tank Installation.

by flexible connections. The drawings show these features distinctly. In Fig. 5 the valve pits can be seen at the side of the track; also the inclines show plainly in the foreground. It should be explained that the troughs of the two inner tracks in this view are the old, or 19-in., width, and, as may be seen, have been shortened to the present standard length. The outer troughs are the 28-in. width. Markers for night time are placed 150 ft. inside the ends of the troughs. They are switch lights, mounted on a short length of wrought iron pipe having its lower end embedded in concrete, as shown in Fig. 10.

Diagram 2, Fig. 7, shows diagrammatically the double-pipe circulating system used on the Pennsylvania and the Lake Shore.

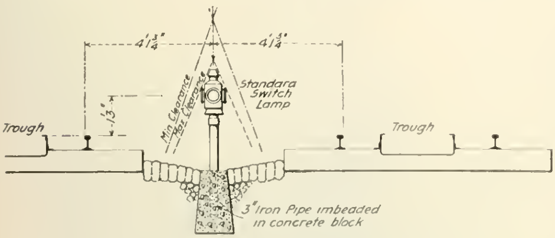

Fig. 10—Standard Marker for Track Troughs.

The water is circulated by an ejector and is heated by the steam while passing through the ejector. The arrows show the direction of flow of water. The water pipes and automatic valves are shown also.

Fig. 11 shows the principal details of this double-pipe system. The top system of piping carries the hot water, and the bottom one brings back the cold water. The advantage of this system over the direct steam is that the track, as far as the maintenance work is concerned, can be handled in the same way as at other points, as there are no steam pipe connections in the way to be easily broken, and there is nothing between the tracks. The piping is all below the surface of the ground and wherever it is connected to the trough a flexible connection is used, so that neither expansion and contraction of trough or piping, nor section men working on the track, interfere with its functions. Trains passing over the direct-steam troughs occasionally have a loose brake rod and this may catch in the steam piping and pull loose all the connections to the trough.

In diagram 3, Fig. 7, is shown a proposed improvement on the double-pipe system. It is proposed to use a single pipe the entire length of the trough for each trough. A steam main will be carried to the next-to-last manhole and ejectors installed as indicated. This will cause a local circulation as shown by the arrows, and if one end of the trough requires more heat it can be easily furnished. The idea is to install all water pipes and the steam pipe in a common conduit underground so that whatever heat is lost by radiation from the steam pipe will be absorbed by

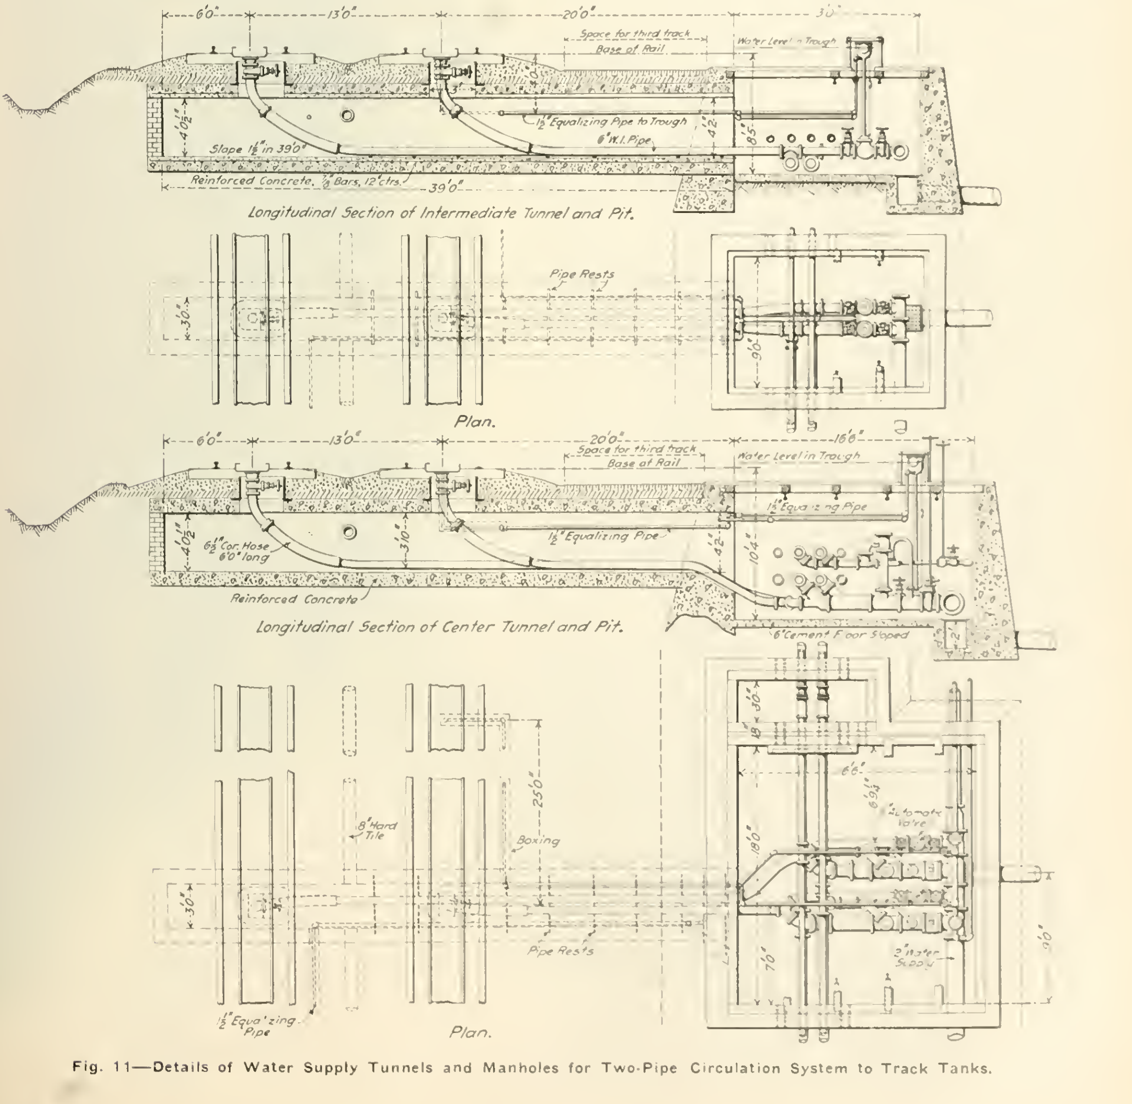

Fig. 11—Details of Water Supply Tunnels and Manholes for Two-Pipe Circulation System to Track Tanks.

the water pipes. The water supply and automatic valves are the same as on the two pipe system. The advantages of the proposed system over the double pipe system are: Less first cost and greater flexibility, as the circulation can be localized, heat radiated by the steam pipes is absorbed by water pipes, all pipes insulated and the heat loss minimized.

The Sunnyside Yard of the Pennsylvania.

BY F. H. SHAKESPEARE.

The management of the Pennsylvania Railroad, having decided on building the New York extension with its two Hudson river tubes, four East river tubes, underground station at Thirty-third street and Seventh avenue, Manhattan, and the cross-town tunnels under Thirty-second and Thirty-third streets to the river tubes, was confronted with the question of how to provide suitable yard facilities for operating this terminal. The location of a large terminal yard in Manhattan was obviously out of the question, owing to the prohibitive cost of real estate, to say nothing of the improbability of getting a franchise permitting its construction in the heart of the city. Having provided for a yard of very limited capacity in connection with the track facilities at the Manhattan station, the choice of sites for the main yards lay between Long Island and New Jersey, inasmuch as the Manhattan station was to be about midway between the ends of the tunnel. After considering the proposed New York Connecting Railroad in conjunction with the Long Island Railroad (controlled by the Pennsylvania) and the probable first cost of yard construction, the location of the site was decided on in favor of Long Island.

Near the eastern end of the tunnel extension is the Long Island Railroad's passenger terminal station in Long Island City. Near it are the much congested North Shore freight yard and float bridges of the same company. From these terminals the Montauk and Main Line divisions of the Long Island run eastwardly on diverging lines which join again at Jamaica, some 10 miles away. About three miles out on the Main Line division is a junction point where a short line called the North Side division diverges to the northward; close to it is the line of the proposed New York Connecting Railroad which is to make an all-rail connection to the New England states. All three of the above mentioned divisions are at present operated by steam locomotives, but in a few years electrification is to be extended so as to include nearly all the lines within the limits of Greater New York.

The Atlantic avenue, Brooklyn, division of the Long Island is now operated with multiple unit electric trains, and it is intended to use this class of equipment for all suburban traffic both on Long Island and in New Jersey. At Harrison, N. J., and Jamaica, L. I., there are to be interchange yards, where the steam locomotives of through trains are replaced by electric locomotives for the run through the tunnel section. The Manhattan station will therefore handle trains of two classes, namely: Multiple unit suburban trains, and ordinary coach and Pullman trains drawn by electric locomotives. The Thirty-third street side of the station and the Thirty-third street tunnels have been designed for use principally by multiple unit trains.

Following its usual custom, the Pennsylvania management appointed a committee to take up this question of terminal yard facilities, decide on a definite location, and formulate a track plan from which detailed drawings could be made and preparations got under way for the work of construction. After various surveys and other investigations, this committee decided on a location in the "Sunnyside" district in Long Island City. The purchase of a strip of land was begun along the Main Line division, commencing about one mile from the East river, and extending eastwardly for two miles, the average width is about 1,500 ft. The plan (Fig. 1) prepared by this committee contained many interesting features. It included an interchange yard with space for motor storage, engine storage, coaling facilities, etc., it being the intention at that time to change the motive power at Sunnyside yard rather than at Jamaica. The yard proper was divided into six sections, and from

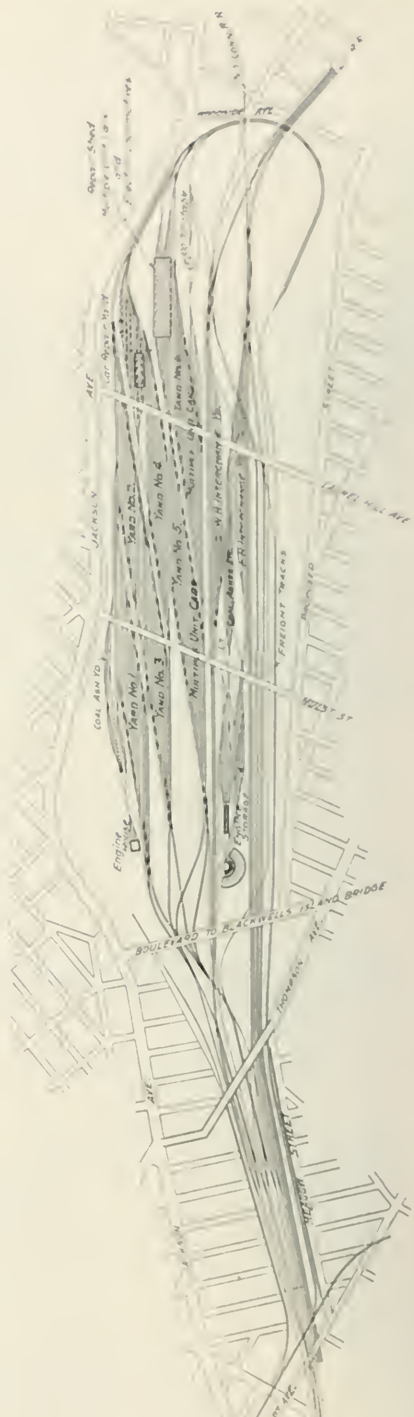

Fig. 1—Sunnyside Yard at Long Island City, As Originally Planned; Pennsylvania Railroad.

Fig. 2—Present Plan for Passenger Terminal Yard at Long Island City.

the head or westerly end of each a double-track line leads to the eastbound and westbound main tracks respectively, grade crossings being avoided by the use of track bridges. These sections were as follows: Two for Pullman cars, having a total capacity of 340 cars with an average of 17 to a track, two for coaches, having a capacity of 375 cars with 20 to a track and two for multiple unit cars having a capacity of 700 cars with 24 to a track. In the multiple unit sections all tracks and ladders were to be electrified, in each of the Pullman and coach sections, all running tracks and ladders, and two yard tracks were to be electrified, it being intended to use these two yard tracks for receiving drafts from the Manhattan station the cars to be thence shifted and distributed by steam switch engines. This plan provided also a single-track connection leading around a three-track loop to the easterly end of the yards, so as to turn complete trains around. The work included among other things 14 distinct track bridges and about a mile of waterproofed subways as approaches to the tunnels. The total first cost was estimated at about $10,000,000.

Negotiations with the city authorities were under way when the idea presented itself that the number of track bridges and the length of subways were rather excessive, also that the ground occupied (some 280 acres) was somewhat large for the storage of only 1,400 cars. After a decision by the late President Cassatt, a new plan was adopted, providing for a yard about 5,500 ft. long and 1,550 ft. wide at its widest point. This has been developed as shown in Fig. 2.

This new plan was made up in accordance with a basic change in the method of operation. The yard tracks were, so far as possible, made continuous, rather than stub end, that is, nearly all drafts will be taken around the loop, entering at the easterly end of the yards and leaving at the westerly end. This will keep all yard traffic moving in the same general direction, avoiding many conflicting movements and lessening the danger of collision. The interchange yard was eliminated, satisfactory evidence having been produced to show that a saving in time of operation could be made by locating it at Jamaica. The idea of using steam switch engines was abandoned and it was decided to operate the whole yard electrically. All crossings of tracks at grade were avoided by the use of track bridges. A freight classification yard, having a capacity of 400 cars, was provided for and has been located just north of and adjacent to the tunnel portals about half a mile from the East river. From here nearly all freight will be carried by means of a Y or switchback along the north side of the passenger yards to an elevated line crossing the passenger tracks and running southward for about half a mile to a junction with the Montauk division. The passage of freight through the Sunnyside yard is thus avoided.

An investigation of the present passenger yard facilities at both Jersey City and Long Island City produced the following working information: At Jersey City there are two yards: the Waldo avenue, which is situated about $1\frac{1}{2}$ miles from the station, and the Jersey City, which is adjacent to the station.

Waldo Avenue Yard.

No. of tracks		27
Capacity of yard		320 cars.
No. of cars per track, varies from	2 to	20 "
Max. No. of cars in yard at one time		250 "
" " Pullman cars in yard at one time		110 "
" " Penn. R. R. cars in yard at one time		140 "
Average No. Pullman cars per 24 hrs.		160 "
" " Penn. R. R. cars per 24 hrs.		160 "
Maximum No. Pullman cars per 24 hrs.		210 "
" " Penn. R.R. cars per 24 hrs.		175 "
No. of wheel tracks		2
Time at which maximum number of cars are in yard, 9 to 10 a m.		

This yard is used exclusively for through line and Pullman business, no attempt being made to separate the Pullman or dining cars from the coaches. The yard people think this is as it should be and also consider that a track holding 12 cars and one engine, or about 900 ft. long, is the most suitable length, even though the make-up sheet shows that few trains carry more than eight cars.

Jersey City Yard.

No. of tracks		13
Capacity of yard		158 cars.
No. cars per track, varies from	1 to	17
Maximum No. of cars in yard at one time		175 "
" " coaches in yard at one time		115 "
" " express cars in yard at one time		31
" " mail cars in yard at one time		30
Average No. of express cars per 24 hrs.		40
Average No. of mail cars per 24 hrs.		37 "
Time at which maximum number of cars are in yard		3 p. m.

This yard is used for local, mail and express service. It is very much congested and to properly handle the present business should have a capacity of 275 cars. The yardmaster recommends tracks having a capacity of 15 cars and a locomotive, or about 1,050 ft. long, his idea being to handle two trains on one track. It is probable that 65 per cent. of the suburban service to Jersey City will continue to be handled at that point either by the present ferry or by the Hudson & Manhattan tunnels.

At Long Island City there are three yards.

Yard No. 1.

No. of tracks	20
Total capacity of yard	285 cars.
Capacity of longest track	15 "
Capacity of shortest track	8 "
Maximum No. of cars in yard at one time	285 "
Time at which maximum No. of cars are in yard	11 a. m.

This yard handles the North Side division and through business.

Yard No. 2.

No. of tracks	[illegible]
Total capacity of yard	[illegible] cars.
Capacity of longest track	15 "
Capacity of shortest track	[illegible]
Maximum No. of cars in yard at one time	[illegible]
Time at which maximum No. of cars are in yard	11 a. m.

This yard handles all the local business excepting the North Side division.

Yard No. 3.

Total capacity of yard	[illegible] cars.

This yard is used to store race trains and is always filled except during racing hours.

During the maximum 24 hours, 576 cars run out of Long Island City. At 11 a. m. there are 450 cars in the yards, 45 of which must necessarily stand on the station tracks. The yard people here recommended tracks having a capacity of 12 cars each.

TRACK SPACING.

Both the Pullman and Pennsylvania yard people agreed that tracks in the through coach yard should be spaced with alternately wide and narrow platforms planking to extend to the rail and level with it, the narrow spacing leaving 6 ft. between cars and the wide spacing 15 ft. The wide platforms are covered by a shed with roof extending over the lower decks of the cars. These spacings mean that tracks are 16 ft. and 25 ft. apart, center to center respectively. In the local yard a space of 4 ft. between cars, i.e., 14 ft. center to center of track is considered ample.

WHEELING FACILITIES.

In the opinion of the yard men, each wheeling track should be long enough to let five cars be worked at once, tracks to be spaced 25 ft., center to center, and each track to have a pit under it. An overhead traveling crane should be provided, together with space for storing wheels and facilities for turning wheels and axles.

PIPING IN YARDS.

The coach and Pullman yards should be piped with separate lines for steam, gas and water, and also air for cleaning and for

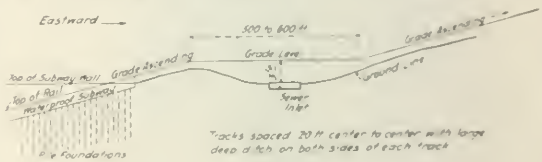

Fig. 3.

brake testing; there should be, also, outlets for charging electric storage batteries. Details are as follows:

Steam: Locate outlets at both ends and middle of all tracks.
Water: Pipe all tracks with 100 ft. between plugs.
Gas: Pipe all tracks with 100 ft. between plugs.
Air for cleaning: Pipe all tracks with 100 ft. between plugs.
Air for testing: Locate outlets at both ends and middle of all tracks.
Battery charging: Wire all tracks with 65 ft. between plugs.

BUILDINGS.

The carpet cleaning shed should have platforms 15 ft. by 75 ft., and about 4 ft. above the ground, the vacuum cleaning system is considered preferable to the blower system. The following table shows the present floor space at the Waldo avenue yard, where 700 men and 30 women are employed; also the floor space required to properly perform the work.

Pullman Store Room Space and Requirements.

	Present	Required
Heavy material storeroom	800 sq. ft.	1,100 sq. ft.
Miscellaneous storeroom	2,500 "	3,800 "
Clean linen storeroom	1,500 "	2,600 "
Soiled linen storeroom	2,000 "	4,000 "
Cleaners' equipment storeroom	360 "	900 "
Plumbers' storeroom	360 "	900 "
Carpenters' storeroom	600 "	1,200 "
Carpet storeroom	700 "	1,100 "
Record storeroom	600 "	1,200 "
Porters' storeroom	750 "	1,200 "
Commissary storeroom	3,600 "	7,200 "
Supt. and foreman's office	360 "	900 "

If the soiled linen is placed on the second floor, an elevator for raising and a chute for lowering the linen should be provided. Ample toilet facilities should be provided throughout the building, the porter's room having separate toilet and bath facilities. The refrigerating boxes in the commissary should be cooled by refrigerator plant rather than by icing.

Pennsylvania Railroad Buildings.

	At present	Required
Battery house	1,850 sq. ft.	5,500 sq. ft.
Maintenance-of-way storeroom	8,500 "	14,400 "
Carpenter shop	1,000 "	1,400 "
Carpet room	720 "	720 "
Steamfitters' room	750 "	1,500 "
Air brake room	240 "	240 "
Tinsmiths' room	375 "	500 "
Officers	600 "	1,200 "
Yardmasters' office	450 "	900 "

The following amounts of waste, cleaning and lubricating oils are used per month, and a suitable building should be provided for the storage of the same together with about 300 sq. ft. each for Pennsylvania Railroad and Pullman paints:

	Used.	Storage-room required for:
Pullman cleanzine	40 bbls.	80 bbls.
" kerosene	30 "	60 "
" cotton waste	16 bales.	30 bales.
Penn. R.R., cotton waste	5 "	10 "
" " woolen waste	1¼"	3 "
" " Galena winter oil	40 bbls.	60 bbls.
" " Galena summer oil	40 bbls.	60 bbls.

The general sentiment of all the yard people is opposed to narrow gage tracks for trucking purposes between the standard gage tracks. It is also agreed that a single post inverted umbrella shed is preferable to any other type.

ELECTRIFIED SERVICE.

There are at present about 150 motor cars and trailers in the Long Island Railroad electric service. The officials in charge of this equipment recommend a spacing of 11 ft., center to center, of track for the multiple unit storage yard, thus giving $5\frac{1}{2}$ ft. between cars.

INSPECTION PITS.

The motor cars are inspected on a mileage basis, cars going over the pits after having run 750 to 800 miles on the road. With the present service, this averages once in four days. The pits now in use have a capacity of four cars each, all light repairs being made while the cars are over the pits. Owing to the excessive weight of the motor cars and trucks, heavy work, such as wheeling, or repairing motors, is done at the repair shops. Pits having standing room for seven cars are recommended so that an entire train can be inspected over one pit. The pits now used are of concrete, $42\frac{1}{2}$ in. deep from top of rail to bottom of pit, bottom being slightly

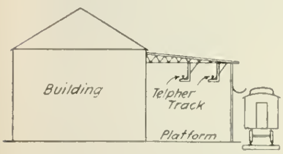

Fig. 4.

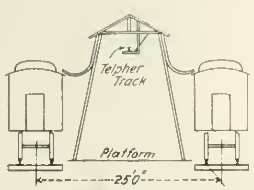

Fig. 5.

concaved. The pits are lighted, piped with air which is used for blowing motors, and are steam heated. There is no third rail along the pits, current being delivered through an overhead trolley. Tracks on the inspection pits are spaced 14 ft., center to center.

From the above mentioned investigation, it will be seen that, in order to handle business of an amount equal to that carried at present, yards must be provided having a capacity of at least 840 cars, about 500 of which are used on through service. In the course of a very few years, all the local or suburban trains will be made up of multiple unit equipment and consequently have been considered as such in the design.

In developing the plans for the Sunnyside yard and contemporary improvements, the following general ideas were kept in mind and the design made to conform thereto: Separation of multiple unit equipment from ordinary coach and Pullman equipment, main tracks separated from the yard proper and the running tracks leading thereto, by being placed on a different level; no crossing of running tracks at grade; all switches to be designed so as to allow as many parallel movements as possible without unduly complicating the track situation or greatly increasing the cost; running tracks and connections between the main tracks and yards arranged so as to allow an alternative route for each movement, these alternative routes being widely separated so as to prevent the yards being tied up and blocked by a serious derailment or wreck occurring at any particular point. In the design of the Sunnyside yard and the Manhattan station provision has been made for two additional tunnels under the East river, which, when built, are to run under Thirty-first street, Manhattan. The city of New York has required the construction of two viaducts carrying streets over the yard approaches, one over the freight yard, and three over the Sunnyside yards proper; also three bridges carrying the main tracks over streets east of the yards, as well as the elimination of several grade crossings on the Long Island City passenger line.

Approaching the Sunnyside yards from the west there will be 10 main tracks, four from the Long Island City station and six from Manhattan by way of the river tunnels. At the easterly end of the yards there will be eight tracks, four leading to the Main Line division, two to the North Side division, and two to the New York Connecting Railroad. These main tracks meet and are joined by a system of interlocked switches, so arranged as to allow three trains to pass in each direction at the same time. In connection with these switches, connections will be provided whereby an occasional interchange of steam and electric locomotives may be effected. Throughout the limits of the Sunnyside yard, all westbound main tracks lie together and all eastbound tracks together. This track arrangement was made possible by a crossing of the tunnels between the portals and the river on the west, and an arrangement of two-track bridges on the east. From the portals eastward all tunnel tracks are in waterproofed subways to a point where the top of rail is 8 ft. above the mean high tide level. Just beyond the ends of these subways the tracks have been so graded as to prevent surface water from draining towards the subways and tunnels. This was accomplished as shown in Fig. 3. Beyond these points, which are in the vicinity of the Thomson avenue viaduct, all main tracks are carried eastward on a rising grade, thus passing through the yards on a level some 20 ft. higher than the yard tracks. A station is contemplated just east of Thomson avenue, whereby passengers may transfer to the trolley cars or other transit facilities which will be in operation over the Blackwell's Island bridge. The general principles followed in making plans for main tracks are as follows: Standard spacing of 13 ft., center to center wherever possible; no masonry walls or abutments placed closer than 8 ft. from center of track to face of masonry; all grade tangents connected by vertical curves having a radius of 30,000 ft. or more, horizontal curves kept as low in degree as possible and easements provided in case of a curve sharper than 2 deg. 30 min.; No. 15 frogs used for all connections in the main tracks.

Near the subway-ends are connections from the main tracks to running tracks which lead to and from the yards. The eastbound running tracks pass along the southerly side of, and on a lower level than the main tracks, leading thence around the loop to the easterly end of the yards. Provision has been made for the ultimate construction of four loop tracks, one from each of the New York lines and one from Long Island City. In addition to the loop tracks there will be, ultimately, a double-track connection to the yards passing under track bridge No. 6 as shown in Fig. 2. Previous to the construction of No. 6 bridge, a single-track emergency connection will lead from the westbound main tracks at the interlocking plant down along the embankment so as to connect with the yard tracks adjacent to the motor storage space. On the plan in Fig. 2 the following points of interest should be noted. Running track heading to loop from line B (Thirty-third street, eastbound) is crossed over other loop tracks, thus affording a route for multiple unit traffic to the yard, independent from the routes used by coach and Pullman or combination traffic; an emergency connection from main eastbound tracks to this multiple unit running track near bridge No. 3; an emergency connection located west of Line A portal between Line C (Thirty-second street, westbound) and running track to Long Island City. On the loop is a system of switch work whereby drafts may be passed to either the multiple unit section or the coach and Pullman section of the yards.

From the loop switching plant, multiple unit equipment may be sent direct to the storage yards or may be diverted to the inspection pits, whence it may pass on to the storage yards or, again, be diverted to the repair shops. The multiple unit storage yard will, ultimately, have 42 tracks, each with 800 to 900 ft. of clear standing room, thus giving a total capacity of 550 cars. These tracks are divided into seven groups of six tracks each, the tracks in each group being spaced 15 ft., center to center, with spaces 25 ft. wide between groups. The westerly or leaving ends of these tracks are connected to a double-track ladder, and the easterly or entering ends to a three-track ladder. The reason for three tracks on the easterly end is to provide for some switching movements and also to allow drafts to leave the yard by these easterly ladder connections, as would be necessary in case of a movement to line E (Thirty-first street, westbound). The spacing of 25 ft. between groups of tracks was necessary to allow the introduction of slip crossings in the near ladder without fouling the adjacent track in the next group.

The coach and Pullman storage yard consists of 11 tracks, spaced alternately 25 ft. and 16 ft., center to center, and 35 tracks divided into groups of six tracks each with a spacing of 14 ft., center to center, between the tracks of each group and 19 ft. between groups; these tracks vary in length from 950 to 1,100 ft. of clear standing room and have a total capacity of 600 cars. The southerly or leaving ends of these tracks are connected to a three-track ladder, the far track of which serves to connect with a small storage space for electric locomotives or motors. The northerly or entering ends of these tracks are connected with a ladder increasing from one to five tracks as the number of storage tracks connected thereto increases. While the general design of the Sunnyside yards is such that much switching of cars will be avoided, yet it has been thought best to provide the above-mentioned five ladder tracks with connections which will let a considerable number of switching movements be made without interfering with the movement of drafts entering the yard. It is the intention to equip at least one track in each group with inspection pits. With a track spacing of 14 ft., center to center (1.5 ft. where column foundations for viaducts are introduced) it will be noted that by removing each third track and lining over each second one of the remaining two, a spacing of 26 ft. and 16 ft. may be obtained, thus affording a ready means of increasing the number of wide spaced tracks should traffic conditions require it. A yard for private cars, with a time-table, has been provided as shown on the plan.

A portion of the space within the loop has been utilized in the design for an additional storage yard, having stub end tracks with a total capacity of 350 cars. The construction of this yard is not contemplated for some years as yet. Throughout the yards, all ladders and running tracks have been spaced 13 ft., center to center, and all connections have been designed for No. 8 frogs except at the loop switching plant, where a few No. 10's and No. 12's were found necessary.

The various yard buildings will be in the space lying between the multiple unit section and coach and Pullman section of the yards. There will be stairways for the use of yard employees leading from these spaces to two of the street viaducts crossing the yard; also an incline driveway leading to the Honeywell street viaduct. Among the various buildings contemplated are the following: Pullman store building, motive power store building, Pennsylvania Railroad service building, storage battery house, bunk house for yard men, carpet cleaning sheds, wheel crane shed and crane, multiple unit inspection sheds, multiple unit repair shops, car inspector's building, oil house, air compressor plant, heating plant, pump house, yardmaster's office.

In excavating near the space set apart for multiple unit repair shop, a very good supply of water has been found. It has been decided, therefore, to build a reservoir located south of the main tracks and within the loop, thus placing it high enough to supply by gravity flow the whole yard and also the Long Island City power house. A pump house and wells are to be located near the Honeywell street viaduct and within the space for buildings.

In a yard so large as that to be built at Sunnyside, the problem of handling supplies, etc., is quite serious. In this case, a system of telpher tracks has been designed whereby the overhead single rail trolley, or telpher can be used to meet this need without in any way interfering with the train movements or other operations of the yards. These telpher cars are to carry linen, storage batteries, commissary and other supplies, and even employees, back and forth between the yard buildings and the various tracks. The layout of telpher tracks is shown in Fig. 2, and the methods of supporting them are as in Figs. 4 and 5.

Construction of the Sunnyside yards and approaches was commenced about January 1, 1907, and the yards will probably be put in operation some time during the year 1910. The construction requires the moving of 1,000,000 cu. yds. of earth, the driving of 300,000 lineal feet of piling, the erection of 200,000 cu. yds. of concrete masonry and the laying of some 75 miles of track. The estimated cost is about $7,000,000.

Coaling Stations on the Belen Cut-off.

Illustrations are shown herewith of the locomotive coaling stations on the Eastern Railway of New Mexico, better known as the Belen cut-off of the Atchison, Topeka & Santa Fe, which was recently completed between Belen, N. Mex., and Texico, on the Texas-New Mexico boundary.

The terminals for the eastern end are located at Clovis, N. Mex., 10 miles west of Texico, where the conditions were particularly favorable for a model arrangement. The coaling plant, which is shown on page 347, is built of reinforced concrete and steel. The bin has a storage capacity of 750 tons and four tracks are served, two outside and two underneath. The bin is filled by a belt conveyor. The receiving track is 250 ft. away, has room for 10 cars and is sloped 1 per cent. for ease in moving the cars across the hopper. The elevating capacity of the belt is 120 tons an hour. The incline for the belt conveyor is of steel frame construction and the roof trusses over the bin are steel. All siding and roofing on the plant is "asbestos protected metal."

Coal is weighed in steel hoppers suspended on a special "Buffalo" pipe-level scales, having plus and minus beams and a type registering device to record on the coal ticket the exact weight of coal taken on a locomotive.

Coaling and Cinder Plant at Belen, N. Mex., Under Construction; Atchison, Topeka & Santa Fe.

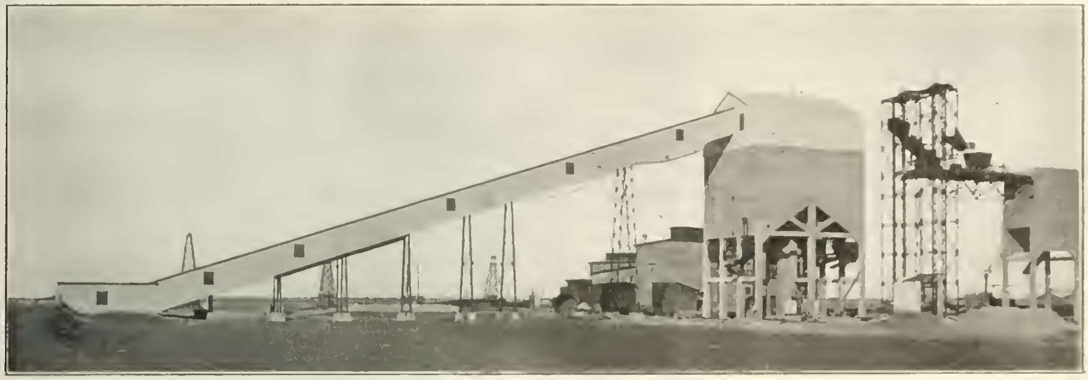
In addition to the coaling plant is a novel cinder handling plant, seen at the right in the photograph. Underneath the two tracks passing under the coal pocket are cinder pits lined with fire brick. Between these two pits is a hoisting tower of steel construction in which travels a pair of large Holmen buckets. These buckets automatically operate gates which deliver the cinders to the buckets. At the top of the tower the buckets automatically deliver their load to steel-lined cars working in time with the elevator and operated by it, a system recently patented. These cars, which dump and close automatically, deliver the cinders to a concrete storage bin a short distance from the elevator, arranged to deliver to railroad cars underneath. Both the cinder plant and coaling plant are worked by electric motors.

In connection with the coaling plant is a reinforced concrete sand storage bin. The sand is elevated by the belt conveyor and discharged into a bin under the coal pocket. A stove dryer and screens are so arranged that the sand is dried and screened without hand labor. The dry sand is raised by compressed air.

At Taiban, 45 miles west of Clovis, is the coaling plant shown herewith. This is a wooden frame plant of 250 tons storage capacity. The coal is elevated by means of large Holmen buckets in the usual manner. Another plant is located at Yesso, 42 miles west of Taiban, and is a duplicate of the Taiban plant in all respects.

The next plant is at Vaughn, 13 miles west of Yesso. There is a novel feature connected with this plant, which is also shown. The coal is received on a track about 48 ft. from the storage pocket. A Holmen elevator and Barrett automatic tram car system is used to convey the coal to the storage pocket as described for the cinder plant at Clovis.

A sand plant is also a part of the equipment at this place. The sand is elevated in the Holmen buckets and discharged into a reinforced concrete bin between the elevator tower and the coal bin. The sand gravitates through a stove dryer, over screens and into a steel drum from which it is blown to the dry sand bin by compressed air.



Coaling and Cinder Plant at Clovis, N. Mex., on Belen Cut-Off of the Atchison, Topeka & Santa Fe.

A coaling plant at Willard, 55 miles west of Vaughn, is a duplicate of the ones at Taiban and Yesso. Another at Becker, 39 miles west of Willard, is also a duplicate of these in general design, but of 350 tons capacity.

The plant at Belen, the western terminus (page 346) is like the one at Clovis, except in the method of elevating coal. This is done in Holmen buckets, and by means of the Barrett automatic tram car system it is delivered to the coal bin, 135 ft. from the receiving track. Two kinds of coal are handled here and to prevent their getting mixed, the receiving hopper is divided into two parts. One Holmen bucket handles the coal from each hopper and the tram cars deliver the coal independently to their respective bins. A Holmen-Barrett cinder plant here is a duplicate of the Clovis plant.

With the exception of the Clovis plant all the plants are equipped with the weighing hoppers mentioned with the Clovis plant, and all but this plant are driven by "Ohio" gasolene engines.

The plants were all designed and built by Roberts & Schaefer Co., Chicago.

A molder employed in the Baden State Railroad shops at Karlsruhe was elected on the Social Democratic ticket a member of the city common council. The railroad authorities informed him that if he accepted this office he would be discharged from the State Railroad service. In the Baden Parliament Social Democratic members declared this notice to be in contravention of a citizen's rights. The Prime Minister answered that the action of the government was due to the fact that the Social Democratic party regards as one of the most important means of obtaining its ends strikes by workmen, and especially by railroad men. The State Railroad management is responsible for the regular and uninterrupted operation of the railroads in the interest of the public at large, and cannot keep in its service any man who openly declares that it may become his purpose to prevent such regular and uninterrupted operation.

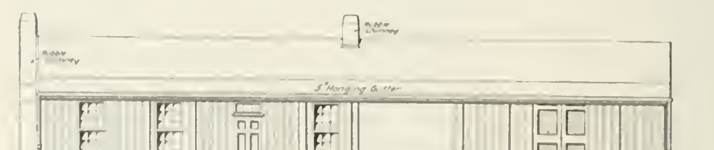
Station Standards; Virginian Railway.

In the previous articles (see *Railroad Gazette* of March 15 and August 23, 1907, under caption "The Tidewater and the Deepwater Railways") the general features of the road and the methods of track and bridge construction were considered. The same system of standardization that has already been outlined has been carried on to other departments of the work.

It is not often, however, that railroad standardization is carried to such an extent as to include the station buildings and section men's houses, so that they can be built and located where desired, without further attention from the engineering department. This has been done in this instance, and is working successfully. The plans, as prepared, could only be made applicable to places where the conditions to be met are practically uniform; but as there are no large towns along this line, the plans are applicable to nearly every place upon it. The original plans were of three main types; one for towns of considerable size; one for small places in Virginia, and one for small places in West Virginia. Later it was found that a modification of these would be required in certain localities. For example, new stations were designed for use in the tobacco section of Virginia for both large and small towns; and, in West Virginia there has been a revision of the plans for small towns. The reason for the distinction made between the two states is that the laws of Virginia require separate waiting room accommodations for white and colored people, while those of West Virginia do not. The first design of station for large towns is 80 ft. long by 22 ft. wide. The second is 70 ft. long by 26 ft. wide, and both are combination freight and passenger stations. The original station for small Virginian towns contains waiting rooms for white and colored passengers and a ticket office and a freight house and measures 60 ft. by 22 ft. That for West Virginia has but one waiting room, the ticket office and freight house, and measures 40 ft. by 16 ft.

Of the smaller sized stations of the original design that at Mullens, W. Va., is typical. It is a frame building and the specifications permit that the rough framing shall be of either white, Norway or southern pine, spruce, Pennsylvania white hemlock or fir, provided only that it is sound and free from defects. The interior finish is in natural wood, kiln dried and varnished on the exposed surfaces. The flooring of the offices and waiting rooms is of quarter sawn Carolina pine or maple of 2½ in. face and ⅞ in. thick and matched for the whole length. The baggage and freight house flooring of all stations is of 2-in. southern pine 6 in. wide, quarter sawn and smooth. The exterior is given three coats of standard paint, one priming coat and two finishing coats, the body color to be a standard light yellow with white trim. Six settees are provided along the walls of the waiting rooms, and these are made of ⅞-in. oak or ash slats with V joints screwed to cast iron brackets or supports of the form shown. These specifications as to finish also apply to the larger sized stations.

Station at Mullens, W. Va.; Virginian Railway.



Side Elevation of Rustic Combination Station.

In the Mullens and similar stations the waiting room has an inside measurement of 10 ft. by 14 ft. 10 in., or the full inside width of the building; the ticket office has a width of 6 ft. 6 in. and the freight house 21 ft. 4 in. The latter has sliding doors at the front and back and, on the track side, has a gangway of 4-in. planks for an approach. In the second design of "rustic stations," as they are called, the total plan of the building covers an area of 62 ft. by 16 ft. with an operator's window at the ticket office end projecting 5 ft. 6 in. on the track side. This projection is merely the extension of the ticket office out to the edge of the overhang roof of the platform. This roof is carried at its outer edge by eight round wooden columns. The ticket office at one end has a width over the partition walls of 11 ft. and extends the whole width of the building. The total length of the ticket office and waiting room section of the building is 34 ft., of which the waiting room occupies 23 ft. Beyond this is an open driveway 11 ft. wide and then a freight room occupies the remaining 23 ft. of the plan. The floors of these freight rooms are either on the ground or raised 2 ft. 11 in. above the level of the waiting room floor. The intention is to use the rustic station with an elevated freight floor in the tobacco country of Virginia, while that with a low floor will be used in West Virginia. The interior finish of these stations is essentially the same as that of the design already described. Externally they have a rubble chimney for both the ticket office and waiting room, which gives them the characteristic feature of the other buildings of the country, and it is the intention to plant climbing vines about the one at the end of the building. This will be an innovation and add to the attractiveness of the structure.

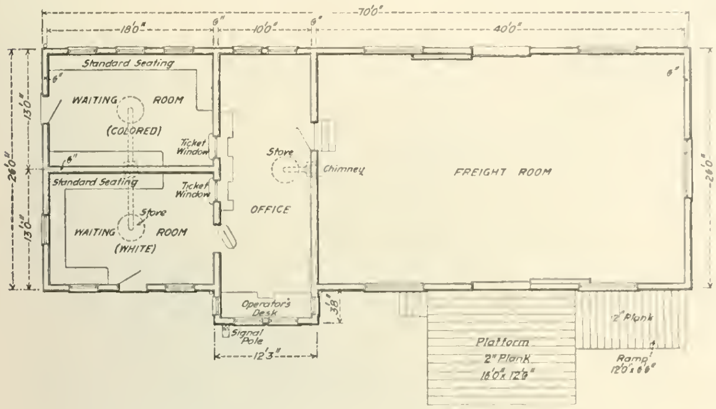
The floor plan of the 60-ft. by 22-ft. station for small towns in Virginia is the same as that of the larger 80-ft. by 22-ft. station, except in dimensions, and the inside and outside finish is like that of the smaller West Virginia stations.

The 80-ft. by 22-ft. station, of which that at Brokneal, Va., is a sample, has a freight room at one end 34 ft. 6 in. long and two waiting rooms for white and colored people respectively, each with a width of 21 ft. 9 in. at the back and 16 ft. at the front, where the ticket office is located. In modifying this design, the building has been widened to 25 ft. and the waiting rooms placed one back of the other at one end of the building with the ticket office between them and the freight room. These stations are also frame buildings erected to the same general specifications as the smaller stations and with the same interior and exterior finish.

In addition to these regular stations that are to be built in towns and villages, a smaller building known as an operator's house has been designed for use at points where it will be necessary to make station or water stops and where no freight will be received. Such a place, for example, as Elmore on the Deepwater section, where there will be an assembling yard and water tank. Here it will be necessary to have an operator and accommodations have accordingly been provided for such passenger traffic as may offer. The outside dimensions of the building are 12 ft. by 30 ft., and it is divided in the plan into two rooms; one a waiting room and one for the operator. The interior and exterior finish is the same as that of the standard stations, and it has the same large opening between the two rooms filled with a wire mesh that obtains in the case of the other buildings.

This standardization of station buildings is possible, of course, only for small towns. For large places special designs would have to be prepared, and this has been done in the case of the road's large places, Norfolk and Roanoke. Here there will be a yard and a freight house of dimensions suited to the requirements of the cities. The passenger stations have not yet been designed.

The layout of the tracks and building is given on the plan. These are located at the south side of the city at the crossing of the Roanoke & Southern or the Winston-Salem division of the Norfolk & Western. The passenger station will be 40 ft. wide by 150 ft. long and will be approached by a screening driveway from Jefferson avenue along which there is a line of street cars. This street will be raised about 5 ft. to meet the grade of the road. The road is single track and will have a connection with the Norfolk & Western over a 13-deg. curve, and there will be a long passing siding in front of the depot, with a track leading off to a double-track siding in front of the freight depot with space left for additional tracks when the traffic offered may require it. Beyond the freight house there will be a number of team tracks as shown. In all of this layout the plans have been prepared for present construction and future extension.



Plan of Standard Combination Passenger and Freight Station.

The freight depot, as designed, will have a width of 40 ft. and a length of 231 ft., of which but 134 ft. 11 in. will be built at present, and the remainder added when the requirements of the traffic shall demand it. The part to be built first will be the east end and will include the offices. The building is to be of brick set on concrete foundations of 1-4-7½ mixture except around the basement beneath the offices, where a 1-3-6 mixture is to be used. Provision is made in these foundations for expansion and contraction due to variations of temperature by the use of vertical tarred paper joints. The piers for the posts supporting the freight house floor are also of concrete of the 1-4-7½ mixture, and these are spaced on 9 ft. 6 in. centers longitudinally and 9 ft. 5 in. centers transversely. Everything is carried down to at least a foot below the natural surface of the ground, or as much lower as may be required in order to get a good footing. The floor of the freight house is carried on 12 in. x 12 in. posts capped by 12 in. by 14 in. girders, upon which 2 in. by 12 in. joists are laid on 12-in. centers, over which the 2-in. flooring is laid. The top of this floor will be 4 ft. 6 in. above the base of the rail and will have a drop of 2 in. in the slope of the outside platform, so that the latter will be 4 ft. 4 in. above the base of the rail. This platform, which will be on the track side only, will have a width of 8 ft. 2 in. The sliding doors opening upon the platform will be spaced on 38-ft. centers so that a string of five cars can be spotted in front of the house, each with its door opposite one in the house. Scales will be placed near the center of the floor of the first section to be built, and this will be completed with a brick end wall, which will afterwards form a brick firewall extending up through the roof.

A basement with a headroom of 8 ft. will be located beneath the offices and will be used as a heater room. The floor of this space will be of waterproofed, reinforced concrete on a screening foundation, the whole having a thickness of 21 in.

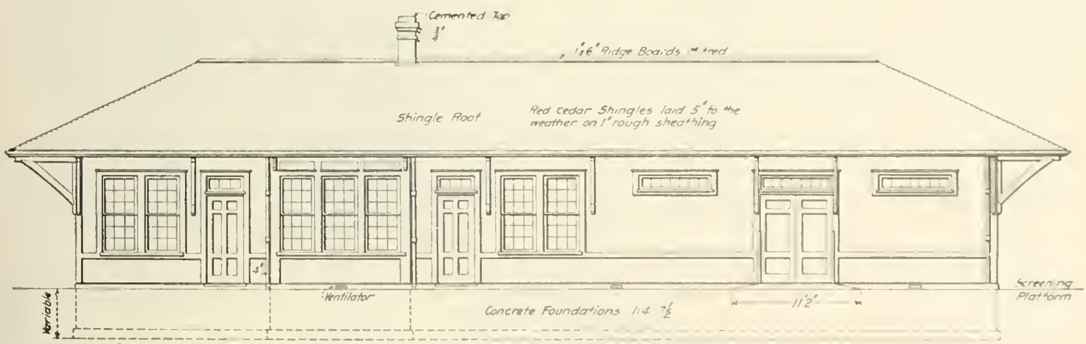
The roof is carried by a simple wooden truss and the whole floor space will be clear and unimpeded by columns. These trusses are spaced on 19-ft. centers. Skylights are put in each slope on 38-ft. centers so that there is ample light admitted from above. The curbing around these skylights is to be of white pine with wooden bars glazed with ⅜-in. ribbed plate, shingled and set in putty with clips. The roof covering will be of No. 1 American Bangor slate laid with a 3-in. lap.

The drainage of the roof water is provided for by five down-spouts on each side. Those on the track side deliver into a 6-in. vitrified sewer pipe that leads down the side of the building to the ends where it empties into 8-in. pipes that run across the ends of the building into a sewer opposite the center of the building and set some distance out from it. At the back corners where the 8-in. pipes turn from the ends, lamp or cleaning holes will be placed, and at the sewer opening there will be the usual manhole and cover. In this way the water from the roof is led away from the foundations at once and the seepage of dampness beneath the building will be avoided, as the pipes are run at a minimum distance of 4 ft. from the walls.

The offices are to be finished in natural wood, with rubbed down shellac, followed by two coats of hard oil rubbed down to an egg-shell gloss.

This is the only large freight house that has, thus far, been designed, as there is no need of so extensive a provision at other points along the line. Work is also in progress on the yard that will be located at Roanoke.

Roanoke Yard.—This yard is the only one of any magnitude that has, thus far, been designed, and even this is small in comparison with other distributing and classification yards that have been built in recent years. The reason for this, at so important a point as Roanoke, is that the traffic that is expected will consist almost exclusively of coal bound for tidewater and originating on the Deepwater section. This traffic will be made up and classified in the Princeton yard, which will be the main point of assembly for the road as well as that from which the empties will be distributed among the mines. Hence both east and westbound trains will for the most part pass through Roanoke without breaking bulk.



Combination Passenger and Freight Station at Brookneal, Va.

The total length of the Roanoke yard is about 7,800 ft. and it is located almost entirely west of the passenger station at Jefferson avenue. The layout is somewhat peculiar and is based upon the exigencies of the case and the topographical limitations imposed. In general the yard follows the bend of the Roanoke river, whose banks it reaches a short distance west of the roundhouse. On entering from the east there is a lead from the main line to the left which runs parallel to the same for the whole length of the yard and forms a passing track. Before reaching the passenger station there is another lead to the left which branches into the double track in front of the freight house already referred to with two extra tracks that may be used for storage. The total capacity of these four tracks from a point east of the freight house to the switches giving access to the team tracks is 111 cars. This team track yard is placed between the freight house and the storage yard and is arranged with double blind-end tracks with a screening driveway approach to one side of each track. These have a total capacity of 126 cars, and beyond, between the team tracks and the

Plan of Freight Yard and Station at Roanoke, Va.; Virginian Railway.

roundhouse, is a storage yard composed of 18 blind tracks served by a single ladder track and having a capacity of 300 cars. As will be seen from the engraving, the switching lead for all of these tracks is one running parallel to the main line and extending down into the eastbound yard, where it is to be used as far as the necessities of the string of cars being handled will require.

The roundhouse is to be in the angle formed by the line of Jefferson street and Prospect avenue. At present a house of 10 stalls will be erected but provision will be made for extending it by 20 stalls, making it 30 in all, as soon as it may be needed. The coal trestle, water column and sand pockets are placed between the incoming and outgoing tracks, with ash pits set in the incoming tracks, and these are doubled at that point. The coal pockets have a length of 200 ft. and stand 30 ft. above the tracks, being reached over a trestle on a 5 per cent. grade.

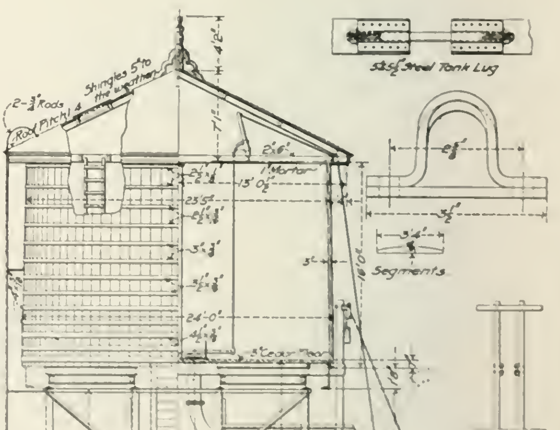
The repair tracks are south of the approach tracks to the roundhouse and are served by a single ladder track that is extended by a switching lead running along the southern side of the main yard and connected with it in such a way that cripples can be taken to the yard and the repaired cars removed and placed in either the east or westbound yards without interfering in any way with the engine movements to or from the roundhouse.

Next to the repair tracks come those for cabooses and the wrecking train. This arrangement of caboose tracks necessitates special switching for the caboose both on incoming and outgoing trains in each direction.

The neck of the yard is formed below the Franklin Road bridge, which is about 3,000 ft. west of the eastern end of the yard or near the middle of the same when it is considered as a whole. At this point there are five tracks, that on the north is the main line, then comes the passing track, then two cross-overs and engine tracks, and last the switching lead for the repair tracks.

The east and westbound yards lie side by side and, except for the arbitrary assignment of tracks to the two, are essentially a single yard consisting of 14 tracks exclusive of the running track at the south side and the passing track at the north, and having a common ladder at each end, that at the west end being run into the passing track and then used as a switching lead. The total capacity of the yard is 1,128 cars, of which 1,385 are assigned to eastbound and 743 to westbound traffic.

The movement of the cars through the yard will be very simple in that, as already explained, there will be very little breaking up of the trains. On entering from the west the trains come in over the passing track and switching lead and in upon the eastbound tracks. The engine is cut off from the train and passes on directly to the roundhouse. The caboose is cut off and hauled back and thence around the running track to the south to the caboose tracks, and whatever classification may be needed will be done over the latter at the east and the running track extending down past the freight station, the cripples being taken out and dropped in on the

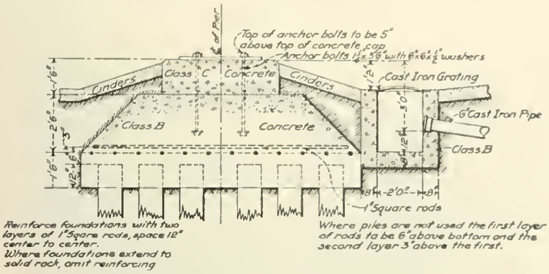


Standard Water Tank; Virginian Railway.

repair tracks to which a direct lead is provided by way of the ladder from every track in the yard.

Entrance to the westbound yard is effected in a similar manner. The train leaves the main line at the first switch and runs over the passing or running track by way of the cross-overs beneath the Franklin road bridge to the yard ladder and thence in upon the westbound tracks. The engine returns to the roundhouse over the running track to the south of the yard and the caboose is cut off and hauled directly back upon the waiting tracks. Classification and the cutting out of cripples is accomplished in the same manner as in the case of the eastbound traffic.

From east to west the yard grade is level as far as the station



Standard Masonry for 80-ft. Turntable.

when it begins to rise and continues to do so to the western extremity at a rate varying from 0.20 to 0.358 per cent.

The yard is in no sense a classification yard although some work of that character will necessarily be done there, but it is more of a halting place where engines can be changed and cars inspected and repaired prior to their onward movement to tidewater or the mines. For this reason a complication of operation is not provided for as it will be in the case of the great assembling yard at Princeton, which will be dealt with at length in a future issue.

Miscellaneous Standards.—In connection with the station and yard work certain other standards have been adopted that are based upon good American practice and which will serve to simplify the work of the engineering department as already intimated. Among these are standards for water tanks, signals, turntable foundations, crossing signs, methods of running wires, fencing, towers, etc.

One example of these standards is given in the 16-ft. by 24-ft. water tank having a capacity of a little less than 52,000 gallons. As in all other foundation work concrete is used for these tanks, in this case the proportions being 1-3-6. Ordinarily the footings are 4½ ft. sq. but these are increased where the soil is soft. All of these columns are formed of 6 in. by 6 in. by ½ in. angles rising to a height of 17 ft. 9 in. above the rail and there carrying the floor beams, which are made up of 12 in. I's with 8 in. I beam braces. The floor of the tank is made of 3-in. cedar plank, and its upper surface is 7 in. above the tops of the columns, so that it is 20 ft. above the top of the rail. In the general features of the construction the tank does not differ essentially from others of a similar character and is illustrated as an example of good current practice.

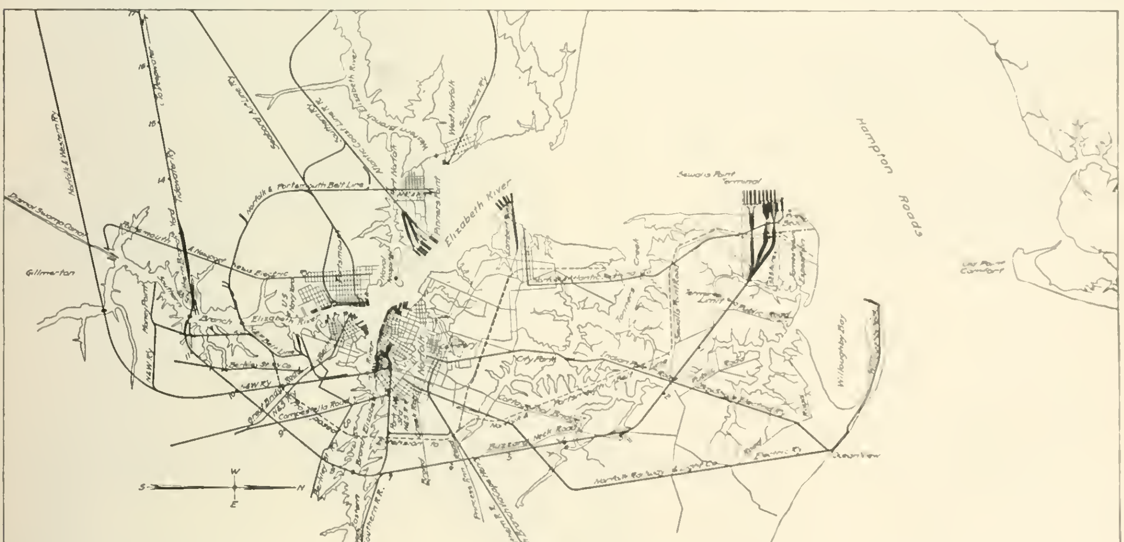
With the design adopted the only flexibility required is in the adjustment of the foundations to the soil upon which they stand, and the same holds true of those for turntables. In that for the 80-ft. table, which is the size adopted, the engraving shows the center arranged to be carried on piles, and these are ordinarily calculated to carry 15 tons. The concrete is of the 1-3-6 proportion as in the case of the water tank piers, and is reinforced with 1-in. square rods spaced on 12-in. centers and in two rows which are 3 in. apart horizontally; the lower rows being 6 in. above the tops of the piles when these are used and projected 12 in. into the concrete.

When piles are not used the lower row of reinforcing is placed 6 in. above the bottom of the concrete, and when the concrete is carried down to a rock foundation the reinforcement is omitted. The foundation is finished with a cap of richer concrete of the C class or 1-2-2 mixture 18 in. thick, upon which the base of the center is to rest.

In the matter of signals the final decision has not yet been reached as to what will be done all along the line, except that it is probable that some system will be adopted whereby a space interval can be maintained between trains. Meantime the details of the signal posts and semaphores have been worked out in accordance with standard practice, being identical with that adopted on the New York Central lines.

In working out these standards allowance had to be made in some cases for the variations in the laws of the two states through which the road runs. These usually make themselves felt in minor details but are of sufficient importance from a legal standpoint to make themselves felt. For example in the case of crossing signs. In Virginia the simple wording "Railroad Crossing" suffices, but in West Virginia there must be added to this the words "Look Out for the Locomotive."

From what has been said in this and previous articles it will be seen that thoroughness in all of the details that go to make up the sum of the construction of the road from the preliminary surveys to the construction of the buildings and tracks has been the watchword of the management throughout.



Map of Norfolk, Va., Showing Railroad Connections and Terminals.

It now remains to say a few words regarding the terminal facilities at the coast. It will be remembered that this road is built with the intention of building up a traffic that does not yet exist and of developing coal properties that have not yet been fully opened.

Further, as there is no market for this coal along the line of the road and the outlet to the west is restricted, it is evident that the seaboard must be the destination of practically all of the traffic that will originate along the line, and that provision must be made to handle it in a coastwise traffic. For this reason no attempt has been made to enter Norfolk over its own lines, but on the other hand, a wide detour carries the line well beyond the limits of the city and around to the north of the same to the terminal at Sewall's Point. Before reaching the Elizabeth river it runs parallel to the Norfolk & Western, but about two miles to the north, thus skirting the Dismal swamp. A yard will be located on the west bank of this southern branch of the Elizabeth river at the point of crossing of the Portsmouth & Newport News Electric Railway, beyond which it crosses all of the roads centering in Norfolk and then runs down on the sand spit that forms Cape Henry and so reaches Sewall's Point. This point is opposite Old Point Comfort and borders the deepwater of Hampton Roads, but is still sufficiently sheltered to make it possible for vessels to lie securely at the wharves that will be built, without experiencing any inconvenience from the seas that may roll in from the capes outside.

The terminal property as acquired by the railroad was a barren stretch of sand, and on this the heavy wharves and coal handling apparatus will be built. Soundings have been made to determine the qualities of the underlying ground and it is probable that the methods of transferring the lading from the cars to the steamships will be similar to that used upon the lakes, where the cars are lifted and dumped into the hold or weighing hoppers direct without the use of the conveyors or hoists that usually accompany coal-handling plants. It is thought that these car dumps can be made of greater capacity and can handle a large tonnage more expeditiously and economically than a trestle and incline, and for that reason it is probable that they will be adopted. The road will thus be a further exemplification of the predominance of the progressive ideas which it has been shown have controlled every step in its construction from its first inception to the completion of those facilities that will play so important a part in the delivery of its traffic to the markets of the country.

Symmetrical Masonry Arches.

UNIT LOADS AND COEFFICIENTS.

BY MALVERD A. HOWE.

The application of formulas based upon the elastic theory leads, necessarily, to approximate results unless the moments of inertia at all sections of the ring and the curve of the axis are such that the expressions for the horizontal thrust, bending moments at the supports, etc., can be integrated.

In the case of masonry arches it is seldom that the integration can be performed. Summation formulas, however, can be used. These simply mean that the moment of inertia is assumed constant for a finite length of the arch axis and that for this length the axis is a straight line. It is evident then that the shorter the length assumed as straight the more nearly will the results approach the true values.

In applying the summation formulas the method of procedure is as follows. (See Fig. 1.) The span is divided into equal parts ($n = 20$ will be sufficiently close for most cases) and each part is bisected. At these points the values of the co-ordinates x and y of the arch axis are either computed or scaled from a carefully made drawing. The moments of inertia I of the sections of the arch ring at the points for which x and y have been determined, are next computed, and then the lengths δs of the arch axis for each equal division of the span determined.

Let $\Delta = \delta s \div I$, then if H_1 represents the horizontal thrust at the supports, for vertical loads

$$2 H_1 = \frac{\Sigma m_x \Delta \left(y - \frac{\Sigma y \Delta}{\Sigma \Delta}\right)}{\Sigma y \Delta \left(y - \frac{\Sigma y \Delta}{\Sigma \Delta}\right)} = \frac{\Sigma m_x B}{D} \quad \ldots\ldots\ldots (A)$$

in which m_x is the common moment for the given loading plus an equal and symmetrically placed load on a beam supported at the ends.

In a previous* article it was shown for two arch rings having spans of L and 40 and rises of f and 1 respectively, that when the ordinates $y_1 : y_1' = y_2 : y_2' = y_n : y_n' = f$ (f' = unity) and $\Delta_1 : \Delta_1' = \Delta_2 : \Delta_2' = \Delta_0 : \Delta_0'$ (Δ_0' = unity)

$$H_1 : H_1' = \frac{L}{40 f} : 1 \text{ or } H_1 = \frac{L}{40 f} H_1'$$

Now if $n = 20$ and $\delta x = L \div 20$, then $\frac{L}{40} = \frac{\delta x}{2}$ and $H_1 = \frac{\delta x}{2 f} H_1'$ also $H_1' = \frac{2 f}{\delta x} H_1$.

Supposing that formula (A) has been solved for a unit load at each point of division respectively, then the values of H' for each load are readily found by simple multiplication. In a like manner the expressions for the moments at the supports become $M_1 = \frac{\delta x}{2} M_1'$ and $M_2' = \frac{\delta x}{2} M_2$. The vertical reactions remain the same regardless of changes in L and f.

Table A contains a complete set of coefficients which were based upon an arch having a span of 100 ft. and a rise of 16.67 ft. The depth of the ring at the crown and the springing being in the ratio of about 1 to 2.

Columns 1 and 2 of Table A contain the coefficients which must be satisfied by each arch ring to which the coefficients in the remaining columns apply. That is, each y for the axis must bear the ratio to the rise f of the axis as the coefficient in column 1 bears to unity, and each value of $\Delta = \delta s \div I$ must bear the relation to Δ_{10} that the coefficient in column 2 bears to unity. The use of the coefficients in Table A will become evident in the solution of a problem.

Assume that for some reason that the rise must be changed from 16.67 ft. to 12.5 ft. while the span remains unchanged or 100 ft.

In Table B, column 1 gives the new values of $y = 12.5\ y'$. In Fig. 1 divide the span into 20 equal parts and, at the centers of these divisions, lay off the ordinates y and draw a curve through

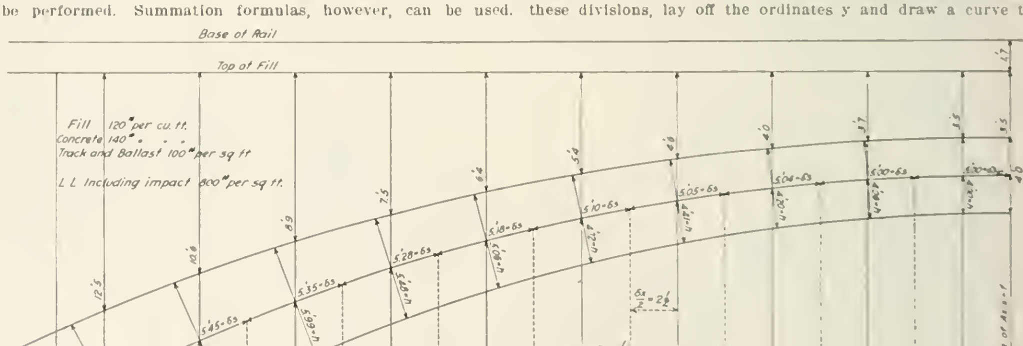


Fig 1.

the extremities. This will be the new arch axis. Then scale the values of δs and place the results in column 2 of Table B.

The next step will be the assumption of the depth of the arch ring at the crown, or for all practical purposes at the section numbered 10. This depth will depend upon the loading and the material composing the ring as well as the radius of curvature at the crown. Let it be assumed that the ring is to be composed of concrete and that the fill will be composed of gravel and about 3 ft. deep over the crown. The moving load will be assumed at 5,000 lbs. per foot of span with 100 per cent. impact. In other words, a single-track railroad bridge is the structure to be designed. The depth at the crown by various empirical formulas will be somewhere in the vicinity of 4 ft., and, as a little error now can be easily corrected later, the depth will be assumed as 4 ft. at the section numbered 10. A longitudinal slice of the bridge 1 ft. thick is assumed. Then $I_{10} =$

*Railroad Gazette, Aug. 20, 1907.

5.333 and $\Delta_{10} = \delta s_{10} \div I_{10} = 5.00 \div 5.33 = 0.938$, and hence $\Delta_n = 0.938\,\Delta_n'$. These values are given in column 3 of Table B.

Since $\Delta = \frac{\delta s}{I}$, $I = \frac{\delta s}{\Delta} = \frac{h^3}{12}$ $\therefore$ $h = \sqrt[3]{\frac{12\delta s}{\Delta}}$ for each point.

The values of h are given in column 4 of Table B.

Assuming that the fill weighs 120 lbs. per cubic foot, the rails, ties and ballast to be equivalent to 100 lbs. per square foot, and that the concrete in the ring weighs 140 lbs. per cubic foot, the dead load concentrated at each point becomes as shown in column 5 of Table B. The dimensions employed are shown in Fig. 1. In column 6 of Table B are given the values of H_1 for unit loads at points 1, 2, 3, etc., respectively. These coefficients multiplied by the actual loads at these points will give the values of H_1 as shown in column 7

The equilibrium polygon is now located since $\frac{M_1}{H_1} = y_1 = -0.55$ ft., or the polygon starts 0.55 ft. below the axis at the support. For convenience in drawing the equilibrium polygon, the moment at crown should be computed by the formula,

$$M_x = M_1 + V_1x - H_1y - \Sigma^x P(x - a)$$
$$\text{or } M_c = M_1 + \tfrac{1}{2}LV_1 - H_1f - \Sigma^{\frac{1}{2}L}P(\tfrac{1}{2}L - a)$$

In this case $M_c = -13{,}900$ and $y_c = \frac{-13{,}900}{124{,}500} = -0.11$ ft., or the polygon passes the crown 0.11 ft. below the axis. This polygon is shown on Fig. 2, one-half only being drawn as it is symmetrical. For convenience and accuracy in drawing the polygon, start at the support and at the crown and close at the quarter point.

Inspection shows that this polygon lies well within the middle

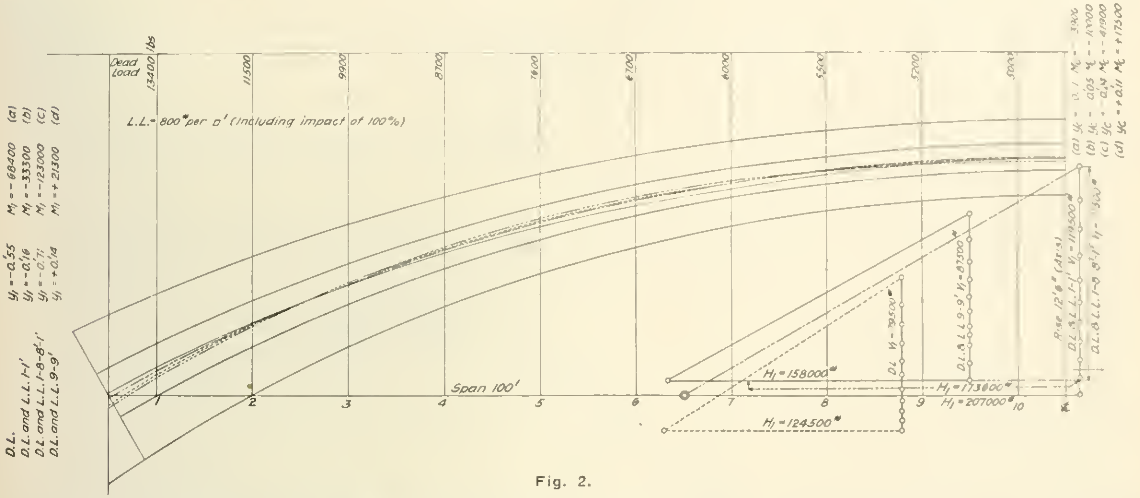

Fig. 2.

of Table B. The values of H_1 for the loads 1 to 10 is 62,230 lbs. and for the entire dead load this becomes $2 \times 62{,}230 = 124{,}500$ lbs. The vertical reactions V_1 and V_2 each equal one-half the entire dead load, or 79,500 lbs.

The computation of M_1 now follows: Since the coefficients M_1' are each multiplied by $\frac{\delta x}{2} = 2.5$ to obtain the values of M_1 for unit loads, this may be considered as a constant factor and introduced at the end of the calculation. In column 8 of Table B are given the sums of each pair of symmetrical values of H_1' as given in columns 5 and 6 of Table A. These multiplied by the dead load (column 9, Table B), and the sum multiplied by $\frac{\delta x}{2} = 2.5$ gives the value of M_1 and M_2 for the total dead load, or $M_1 = M_2 = -27{,}359 \times 2.5 = -68{,}400$ lbs. feet.

third of the ring and that the maximum compression is very much below the safe strength of the concrete.

The live load will now be considered. Let this be 800 lbs. per square foot or $5 \times 800 = 4{,}000$ lbs. per division.

Table A, column 11, shows the fields of loading which produce maximum moments. (Approx.)

Live Load 1 to 8.

$H_1 = \frac{L}{40f}H_1' = 0.2\ H_1'$ or $H_1 = 0.2 \times 30.668 \times 4{,}000 = 24{,}500$ lbs.

$M_1 = \frac{\delta x}{2}\ M_1' = 2.5\ M_1'$ or $M_1 = -18.819 \times 2.5 \times 4{,}000 = -188{,}200$ lbs.-ft.

$V_1 = 7.203 \times 4{,}000 = 28{,}800$ lbs.

$V_2 = 32{,}000 - 28{,}800 = 3{,}200$ lbs.

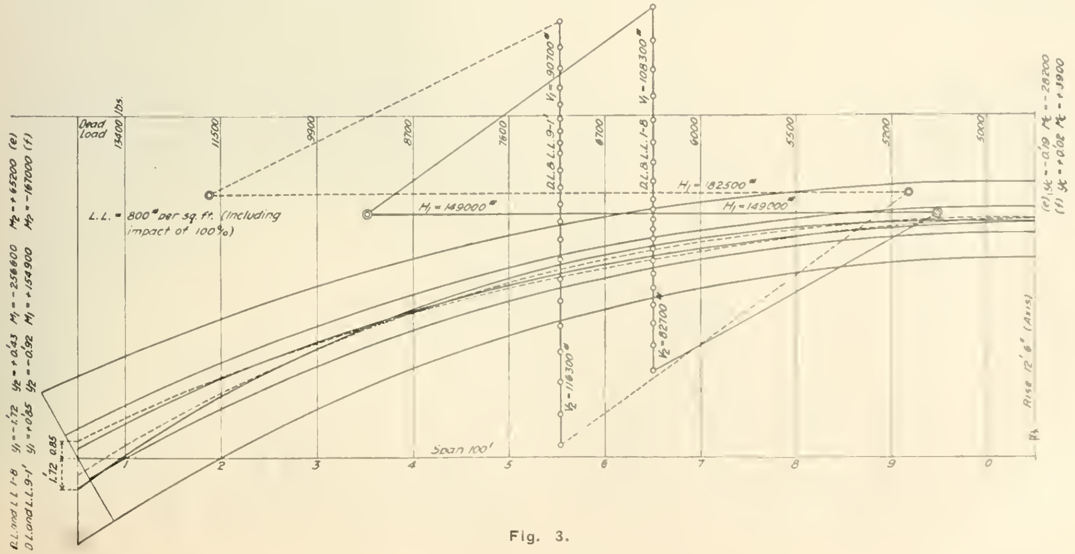

Fig. 3.

$M_c = +13.360 \times 2.5 \times 1{,}000 = +133{,}600$ lbs.-ft.
$M_2 = -14{,}200$ lbs.-ft.

Combining these values with those obtained for the dead load the following results obtain

Dead Load and Live Load 1 to 8.

M_1	D. L.	= 68,100 lbs.-ft.	M_c	D. L.	= −68,100 lbs.-ft.
	L. L.	= 188,200 "		L. L.	= +133,600 "
	D. L. + L. L.	= 256,600 lbs.-ft.		D. L. + L. L.	= +65,200 lbs.-ft.
H_1	D. L.	= 124,500 lbs.-ft.	M_2	D. L.	= −13,900 lbs.-ft.
	L. L.	= 24,500 "		L. L.	= −14,200 "
	D. L. + L. L.	= 149,000 lbs.-ft.		D. L. + L. L.	= −28,200 lbs.-ft.
V_1	D. L.	= 79,500 lbs.-ft.	V_2	D. L.	= 79,500 lbs.-ft.
	L. L.	= 28,800 "		L. L.	= 3,200 "
	D. L. + L. L.	= 108,300 lbs.-ft.		D. L. + L. L.	= 82,700 lbs.-ft.

$$y_1 = \frac{256{,}600}{149{,}000} = 1.72 \text{ ft.} \qquad y_c = \frac{-28{,}200}{149{,}000} = -0.19 \text{ ft.}$$

$$y_2 = \frac{+65{,}000}{149{,}000} = 0.43 \text{ ft.}$$

In like manner each set of loadings is considered. Any other field can be taken by simply adding the values of H_1, M_1', V_1, etc., in Table A corresponding to the loading used.

The moment at the support is

$$M_1 = H_a \frac{\Sigma y \Delta}{\Sigma \Delta} = H_a Y' f = 0.817 (12.5) H_a = (10.21) H_a \text{ (see Table A).}$$

By a brief calculation it becomes evident that the concrete will be subjected to tensile stresses greater than its safe strength when the axial thrust is considered without taking into account the effect of a drop in temperature, hence it becomes necessary to either reinforce the rib with steel or increase its depth. Assuming that the latter is not feasible the rib will be reinforced with steel.

Let $E_c = 1{,}500{,}000$ lbs. per square inch and $E_s = 30{,}000{,}000$ lbs. per square inch, then $\frac{E_s}{E_c} = 20$ and each square inch of steel is equivalent to 20 square inches of concrete.

Let 1 per cent. of the area at the crown be assumed as steel, or 0.8 of a square foot of equivalent concrete, and place the center of the steel 0.25 ft. from the outside of the concrete. The effective area is now $4.0 + 0.8 = 4.8$ sq. ft. $= F$ at the crown, and practically at section number 10.

I = the moment of inertia = 7.78 and the section modulus $S = 3.89$.

Since the values of Δ must always remain in the relative magnitudes shown in column 2 of Table A, if the moment of inertia is

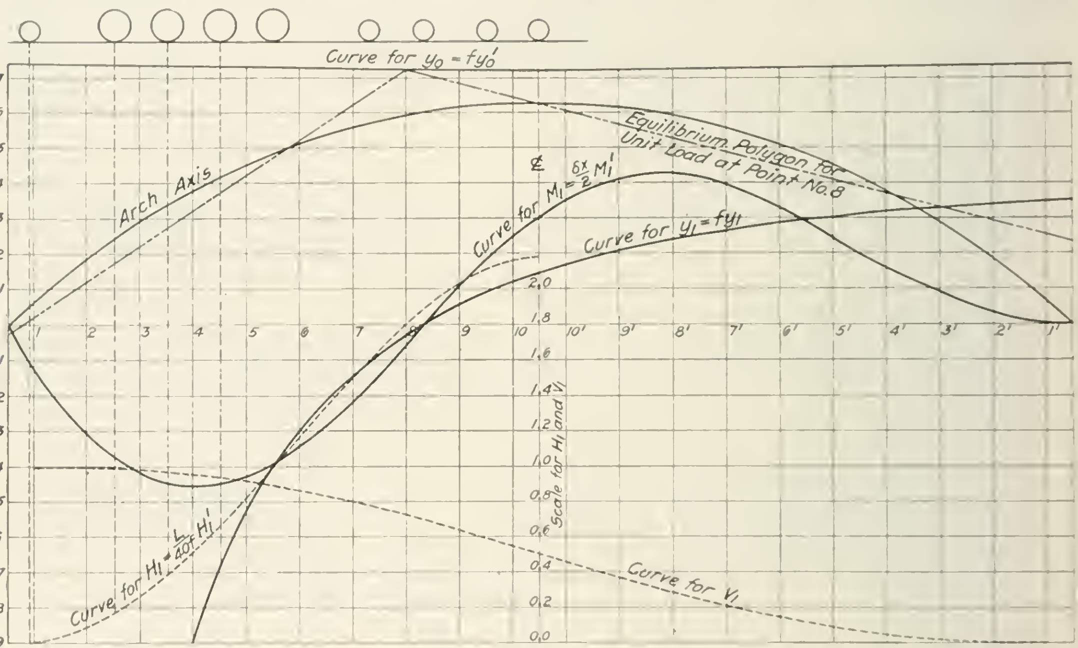

Fig. 4.

increased at any section, the moment of inertia at each other section must be increased in like proportion.

At the crown the original I was 5.33 and $7.78 \div 5.33 = 1.46$, or each section must have its I increased 46 per cent.

For example take section number 1. The original I was 32.68, and adding 46 per cent. to this I becomes 47.72, then

$$\frac{h^3}{12} + 0.8\left(\frac{h}{2} - 0.5\right)^2 = 47.72 \text{ or } h = 7.65 \text{ ft. (nearly).}$$

The effective area is $7.65 + 0.80 = 8.45$ and the section modulus is 12.42.

In like manner the proper depths of the arch ring at other sections can be determined.

It is not feasible or necessary in this article to compute the fiber stresses for all loads at all points. The method is identical in each case so one example only will be given. Point number 1 will be selected and the fiber stress for the dead load, dead load axial thrust and a change of temperature of − 20 deg. be determined.

In Table C are given the values of H_1, M_1, etc., for the various loadings considered. Since the first four sets are symmetrical, only one-half of each equilibrium polygon is drawn, as shown in Fig. 1. In the last two sets the loading is not symmetrical and hence the polygons must be constructed for the entire span. Proceed as follows: Lay off y_1 and y_2 at the left support and y_c at the crown and construct both halves of the polygon on the left of the crown as shown in Fig. 3.

All of the above results are obtained with comparatively little labor and in a short time. As usually considered the arch rib, as shown in Fig. 1, would be passed as quite safe for the given loadings. But the effect of the axial thrust and temperature changes remain to be considered.

The effect of the axial thrust will be first taken up. The horizontal thrust is

$$H_a = H_1 \left\{ 1 - \frac{D}{D + \Sigma \frac{(\delta x)^2}{\delta s F}} \right\}$$

where

$D = D' f^2 \Delta_{10} = 0.589 f^2 \Delta_{10}$ or $D = 86.32$ (see Table A)

$\delta x = 5.0$ ft.

F = area of rib at section considered.

$\Sigma \frac{(\delta x)^2}{F \delta s} = 19.43$ ∴ $H_a = .18 H_1$ (nearly)

Point Number 1.

$F = 8.45$ sq. ft.	$S = 12.42$.	$\sin \Phi = 0.454$.
$\cos \Phi = 0.885$.	$y = 1.36$ ft.	$x = 2.5$ ft.

Dead Load.

The axial thrust $= N_x = H_1 \cos \Phi + V_1 \sin \Phi = 146{,}300$ lbs.
The moment $M_x = M_1 + V_1 x - H_1 y = -39{,}200$ lbs.-ft.

The fiber stress $p = \frac{N_x}{F} \pm \frac{M_x}{S} = \frac{146,300}{8.45} \pm \frac{-39,200}{12.42}$

Or the stress in the upper fiber = + 14,100 lbs., and the stress in the lower fiber = + 20,500 lbs.

Dead Load Axial Thrust.

Assume H_a = 1,000 lbs. and determine the fiber stresses. N_x = 1,000 (0.885) = 885 lbs. M_x = 1,000 (10.21 — 1.36) = 8,860 lbs.-ft.

$$p = \frac{-885}{8.45} \mp \frac{8860}{12.42}$$

Or, the stress in the upper fiber = — 818 lbs., and the stress in the lower fiber = + 609 lbs.

Then for H_a = 1 lb., these quantities become — 0.818 lbs. and + 0.609 lbs. respectively.

For the dead load H_a = 18 per cent. H_1 = 18 per cent. 124,500 = 22,400 lbs.

Therefore, the stress in the upper fiber = 22,400 × 0.818 = — 18,300 lbs., and the stress in the lower fiber = 22,400 × 0.609 = + 13,600 lbs.

Temperature change of ± 20°:

$$H_t = \frac{e\,t^\circ E\,L}{0.589\,f^2\,\Delta_{10}} = \frac{e\,t^\circ E\,L}{86.32} \qquad \begin{array}{l} e = 0.000006. \\ E = 1,500,000 \times 144 \text{ per sq. ft.} \\ L = 100 \text{ ft.} \\ t^\circ = 20^\circ. \end{array}$$

and H_t = 30,000 lbs.

Reducing this for the effect of the axial thrust
H = 82 per cent. 30,000 = 24,600 lbs.

The stress in the upper fiber = 24,600 × 0.818 = ± 20,100 lbs., and in the lower fiber 24,600 × 0.609 = ∓ 15,000 lbs.

In precisely the same manner any other loading can be considered or any other section of the arch ring examined.

Table D contains the fiber stresses for section number 1 and at the crown for various loadings. Exclusive of the temperature effect the maximum tension in the concrete is 12,700 lbs. per square foot, or a little less than 100 lbs. per square inch. The maximum compression is at point 1 and equals 52,800 lbs. per square foot, or about 370 lbs. per square inch. The stress in the steel is less than 20 × 370 = 7,400 lbs. per square inch.

If the temperature effect is considered, the maximum tension in the concrete is 38,500 lbs. per square foot, or about 270 lbs. per square inch, and in the steel less than 20 × 270 = 5,400 lbs. per square inch. The maximum compression, including the effect of temperature, is 67,800 lbs. per square foot, or about 470 lbs. per square inch, and in the steel, less than 20 × 470 = 9,400 lbs. per square inch.

In case the tension values are considered too large the arch ring can be made a little deeper.

The dead load was based upon a plain concrete ring which now has been increased in depth a maximum amount at the supports and not at all at the crown. At section number 1 the additional concrete increases the dead load about 150 lbs., which is of no practical importance when it is considered that the dead load assumed for this section was 13,400 lbs. Increasing the depth of the ring actually decreases the effect of the axial thrust and hence the values given in Table D are a little large. Since the stresses due to temperature changes include the axial thrust effect, the values given in Table D are a little small.

The above solution shows that the use of unit loads in determining the values of H_1, M_1, V_1, etc., for an arch ring, enables the designer to change at will the loads, the span and the rise of the arch as well as the depth of the ring with very little labor.

Although the loads have been assumed as concentrated at the points of division as being most convenient for determining H_1, M_1, V_1, etc., for unit loads, it is not at all necessary that the actual loading should be so arranged. The actual loading may be placed anywhere and the unit values of H_1, M_1, V_1, etc., are determined from a curve drawn with the computed values of these quantities based on unit loads placed at the points of division. (See Fig. 4.)

That the summation method is approximate must be conceded by all, but it can be made a very close approximation. The largest errors in the values of H_1 lie near the supports where the actual values are small. For a parabolic arch computed by the integration method and the summation method the difference in the values of H_1 was 0.16 per cent. By the integration method the values of M_1 were — 63.004 and + 62.936, and by the summation method — 62.510 and 61.940.

Rebuilding the Northern Pacific in Minnesota.

BY H. COLE ESTEP.

From Staples, Minn., to Fargo, N. Dak., a distance of 109 miles, the Northern Pacific is now engaged in one of the most important and interesting pieces of reconstruction work on the entire main line between St Paul and Portland This Minnesota work is distinguished both for its quantity and quality. It is the largest single continuous betterment now under way on the Northern Pacific system, and is at the same time the most thorough and complete. While the engineering problems encountered lack some of the spectacular features of mountain work, they are much more difficult and interesting by virtue of their very subtlety.

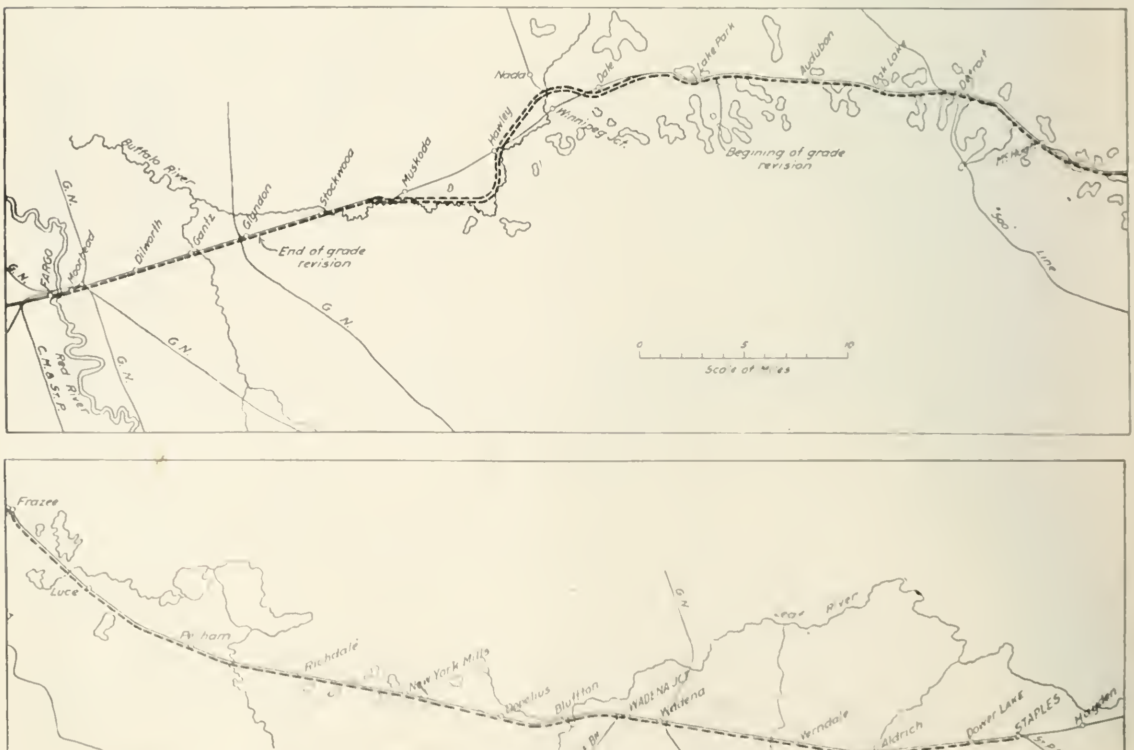
The improvements include double tracking, reballasting, reduction of grades and modifications of alinement throughout the whole of the 109 miles from Staples to Fargo. Some of the simple double-tracking and reballasting was done in 1903 and 1904. The heavier reconstruction work between Wadena and Glyndon was commenced during the spring of 1906. All of that between Wadena and Lake Park, 54.1 miles, is now practically completed; about one-fifth of the work on the 25 miles from Lake Park, Minn., west to Glyndon, remains to be finished this spring.

At Staples the main line from Duluth joins the line from St. Paul and Minneapolis. As a result this division between Staples and Fargo bears the densest traffic of any similar stretch on the Northern Pacific system. It not only carries the normally heavy main line freight and passenger travel, but in addition, every autumn must take care of all the eastbound grain and live stock coming from Montana and North Dakota, as well as the westbound coal and supplies going into the same district. Between Lake Park and Hawley on the old line there was a heavy pusher grade against both east and westbound traffic. It was to relieve the pressure on the single track due to the unusually dense traffic over this division and to eliminate the expensive, time-wasting pusher service between Lake Park and Hawley that the present improvements were undertaken.

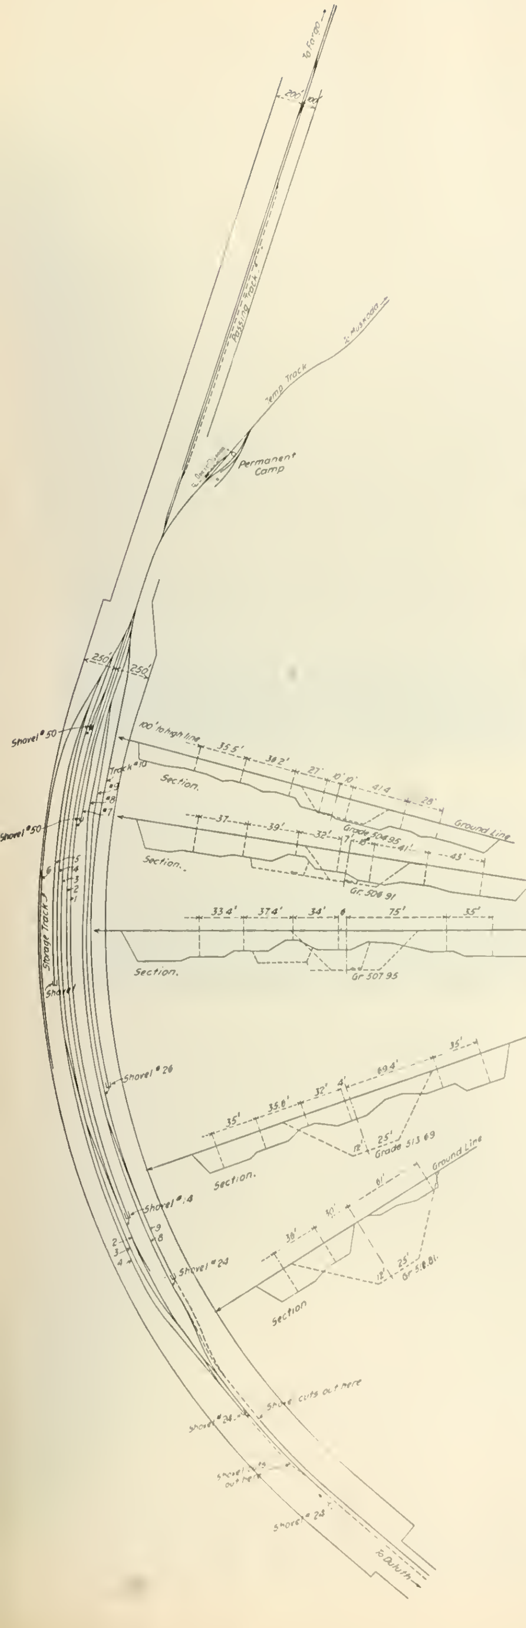
The work falls naturally into five sections, as follows: From Staples west to Dower Lake 2.8 miles, from Dower Lake to Wadena, 14.5 miles, from Wadena to Lake Park, 54.1 miles, from Lake Park to Glyndon, 27.6 miles, and from Glyndon to Fargo, 9.9 miles.

View Showing Fill, Temporary Trestle, and Old Main Line.

In 1903 the first section, 2.8 miles between Staples and Dower Lake, was double-tracked and reballasted without change of grade or alinement. Similar improvements were made on the second section, 14.5 miles between Dower Lake and Wadena, in 1904.



General Location; Northern Pacific Grade Revision and Second Track Work.



Steam Shovel Operations in Big Cut; Northern Pacific.

The third section, 54.1 miles between Wadena and Lake Park, contains aside from the usual double-tracking and reballasting, grade revisions of importance and one notable line change. Before the improvements on this section were made there was a 0.4 per cent. virtual grade east and westbound. This has been lowered to 0.3 per cent. actual east and westbound; the total rise and fall has been reduced 176 ft., while the total curvature has been cut down 130 deg.; 1,800,000 cu. yds. of material were required for the improvements. The work was commenced in April, 1906, was suspended during the winter of 1906-07, resumed in the spring of 1907, and is now practically finished.

The one line change occurs near McHugh, Minn. 40 miles west of Wadena. It is one mile in length. As is seen from the accompanying map, the old line was carried northward following the arc of a circle around the contour of the hills, and thus avoiding the heavy cut and fill necessary on the new location, which goes directly across the hills. The new line contains a 2,000-ft. fill averaging 50 ft. in height, and a cut 2,500 ft. long, approximately 30 ft. deep. By virtue of this line change a heavy grade is reduced, the main line is shortened and the soft, uncertain foundation upon which the old grade was built is replaced by firm, unyielding construction.

The fact that in a thorough revision of the 54.1 miles comprising this section of the work only one line change was required to bring the new double-track road fully up to the requirements of today is highly complimentary to the ability and foresight of the engineers who originally located this division. It is not often that we find an old road so located as to combine the low first cost which was necessary in the first instance, with the possibility of economical revision to meet the requirements of later and more prosperous days. The task confronting the original locating engineers can be better appreciated when we consider the topography of the region through which the road is built. This territory—known as the lake park region of Minnesota—is strewn with innumerable sheets of water varying in size from mere ponds to lakes 15 or 20 miles in length. Separating these bodies of water are rolling hills from 20 to 100 ft. in height, while various chains of ponds and lakes are connected by creeks and small rivers.

We have here the old problem of choosing the best of the several possible routes which lie in a lightly rolling country, complicated by the presence of the lakes. The large ones must be skirted, while the small ponds are often too soft to fill economically. This results in a strong tendency to locate a very crooked line in order to avoid heavy and expensive cuts and fills. The original engineers, however, seeing into the future, located a comparatively straight line in spite of the lakes, and attained the requisite economy of construction by introducing rather heavy grades.

The problem of revising and modernizing this line was comparatively simple. All that was necessary was to cut down the humps and with the material so obtained fill in the sags. The economy of this is patent. Where a radical revision is necessary, interest must be paid on the cost of an entirely new road, including new right-of-way, and also on the cost of the old road and right-of-way which is abandoned. In this case the company had only to finance the cost of the second main track and of the work required to bring the old construction into line with present day requirements.

The fourth section of the work comprises 27.6 miles between Lake Park and Glyndon, Minn. Here we find the heaviest construction and most daring engineering of any piece of railroad in the state of Minnesota. For a prairie country, the new work on this 27.6 miles is in every sense spectacular.

At Winnipeg Junction, seven miles west of Lake Park, is the Buffalo river, which is the controlling feature of the situation. The old line, in order to cross this valley, contained grades of 0.9 per cent. against eastbound, and 0.75 per cent. against westbound traffic. Expensive pusher service had to be maintained between Stockwood and Hawley, 11 miles, in order to assist heavy freight trains over these hills. The exigencies of the situation demanded a complete relocation of this section, which resulted briefly as follows: Increase in distance, 2.3 miles; increase in total curvature, 120 degs.; reduction of east and westbound grades respectively to 0.3 and 0.01 per cent. The resultant reduction in operating expenses will fully justify the heavy expense incurred by this relocation.

To complete the improvement 5,850,000 cu. yds. of material, mostly earth, must be removed. Of this total, 4,750,000 yds. have been moved to date, leaving 1,100,000 yds. to future operations. The work was commenced in May, 1906, was suspended during the winter of 1906-07, resumed in March, 1907, and is again suspended on account of winter weather. West of Hawley, both the engineering and the construction work is being done by the railroad company.

The new line is a succession of heavy cuts and fills. Cuts from 1,800 to 2,500 ft. long, 35 to 40 ft. deep, and containing 150,000 to 280,000 cu. yds. alternate with fills of equal length, height and bulk. The channel of the Buffalo river has been changed and the river is now crossed on a pile trestle 45 ft. high. At several points the new line crosses over the old, which was kept open by timber bulkheads, a temporary pile bridge spanning the gap in the new embankment.

The largest cut on the work is located near mile post 238, between Muskoda and Hawley. It is 7,000 ft. long with an average depth of 45 ft. This cut is followed by a stupendous fill 50 ft. high at its maximum and 31,000 ft. long. The cut, which also served as a borrow pit, was excavated by steam shovels in standard American fashion. The accompanying plan and sections of this cut show the general scheme employed in operating the shovels. The extra wide section to which the cut was excavated was adopted so that there would be no snow blockades at this point, even in the worst Minnesota blizzards.

In making the big fill a pile trestle 25,000 ft. long, consisting of four pile bents spaced 15 ft. apart, was built. The material from the steam shovels in the cut was loaded on trains of flat cars, which were pushed out on the trestle and unloaded with a ballast plow. In this way very low unit costs were obtained. The culverts under the big fill are all of permanent construction, the larger ones being monolithic reinforced concrete arches.

From Glyndon to Fargo, the last section of the work under consideration, the improvements consisted simply in reballasting and laying the second track without change of grade or alinement. The work between Glyndon and Moorhead was finished in 1906, that between Moorhead and Fargo the year previous. The bridge across the Red river at this point is a single-track structure protected by automatic block signals.

It will not be amiss to emphasize again that the chief reason why this work has been carried out with economic success is that the division, taken as a whole, was so located originally that permanent and effective betterments could be made at a minimum of expense. To get a clear understanding of the matter the previous betterment work that has been done on this district should be known.

Temporary Trestle Nearly Five Miles Long; Northern Pacific Grade Revision.

Originally the road was built from Staples to Fargo with 1 per cent. ruling grades. In 1897, by an expenditure of $217,000, the district was so revised that the grades were reduced to 0.4 per cent. virtual, leaving, however, 20 miles of eastbound pusher grade near Hawley. At that time more expensive improvements were not economically advisable, but all of the work was done with a view to future permanent revision.

In 1906 traffic had grown to such large proportions that the construction of a second main track became an absolute necessity. This track could not be laid alongside the old one, but had to be properly and permanently located, fulfilling the demands of the present and anticipating those of the future. Ultimate economy was the aim.

The Northern Pacific is not only stronger financially by reason of this betterment, but is also owner of what is undoubtedly the finest stretch of railroad in the state of Minnesota. The new line, indeed, compares equally with the best modern construction on the trunk line systems of the east; a fact which is pregnantly suggestive of the true status of western ideals in railroad construction and of the firm, solid character of the prosperity of the great empire lying west and north of the Mississippi and Missouri valleys.

The construction work which was done directly by the company was carried out under the supervision of S. A. McCoy, Assistant Engineer. W. L. Darling, Chief Engineer, is responsible for the general design and execution of the entire project.

The writer wishes to acknowledge his indebtedness to the Northern Pacific Railway Company for the data, maps, etc., which accompany the article, and also to acknowledge the personal courtesy and assistance of Howard Elliott, President of the Northern Pacific, W. L. Darling, Chief Engineer, and S. A. Bratager, Principal Assistant Engineer.

The Proposed Elimination of Grade Crossings at Worcester, Mass.

BY CHARLES B. BREED,
Associate Mem. Am. Soc. C. E.

Although the state of Massachusetts was the first to undertake, in a systematic manner, the abolition of grade crossings, this has sometimes been accomplished with such deliberation that the progress of the work has not been as rapid in Massachusetts as in some other states. There has been more than one reason for delay in the advancement of this work in Massachusetts. In the first place, the grade crossing statute of 1890, together with its subsequent amendments, provides that the apportionment of cost shall be divided as follows: The steam railroad shall pay 65 per cent., the municipality not over 10 per cent., and the remainder shall be apportioned between the state and the street railway companies which may be operating in the streets where grade crossings occur, and which are benefited by their elimination. With this fixed apportionment of costs, it is evident that the interested parties, in their overzealousness for certain advantageous features of design or construction may delay the settlement of the whole matter for an unreasonable length of time. Furthermore, it always takes considerable time to awaken public interest in these important matters, so that it frequently happens that the municipality does not realize what its needs and desires are until the hearings relative to the grade crossings have been well under way. The whole proceeding is one of education for the municipal authorities, who, as a rule, are dealing with this important problem for the first time. The railroads, on the other hand, are thoroughly familiar with such matters and frequently their preliminary studies of any particular situation have been made several years in advance of the city's designs.

The city of Worcester, in the early stages of the grade crossing discussions, furnished a good example of lack of preparation and familiarity with the problem. The earliest commission to consider the grade crossing problem in Worcester, appointed by the Superior Court in 1890, reported on the elimination of the crossing at Grafton street only, and recommended that the railroad should be elevated 2 ft. and the street depressed 13 ft. The city then appointed a commission of three civil engineers, including the city engineer, who, after making an exhaustive study of the problem, reported on five different methods of abolishing the crossings and recommended the adoption of a plan for elevating the railroad and depressing the streets a small amount. Later, a commission, composed of 12 citizens, considered the whole subject and reported favorably on track elevation. Several Acts, presented by the city of Worcester, passed the state legislature and delayed the settlement of these questions until finally, in 1900, another special grade crossing commission was appointed by the Superior Court under the statute of 1890. The report of this commission has recently been made a decree by the court. After nearly 17 years of study and discussion the matter has finally been decided and the work, which will be briefly described hereafter, will probably be started next spring.

The city of Worcester is located about in the middle of the state, where the topography is somewhat rolling. The northerly portion of the city is quite hilly, that district being given up almost entirely to residences. In the southerly and easterly portions are the railroads, located through rolling country, and adjacent to them are the manufacturing industries for which the city is noted.

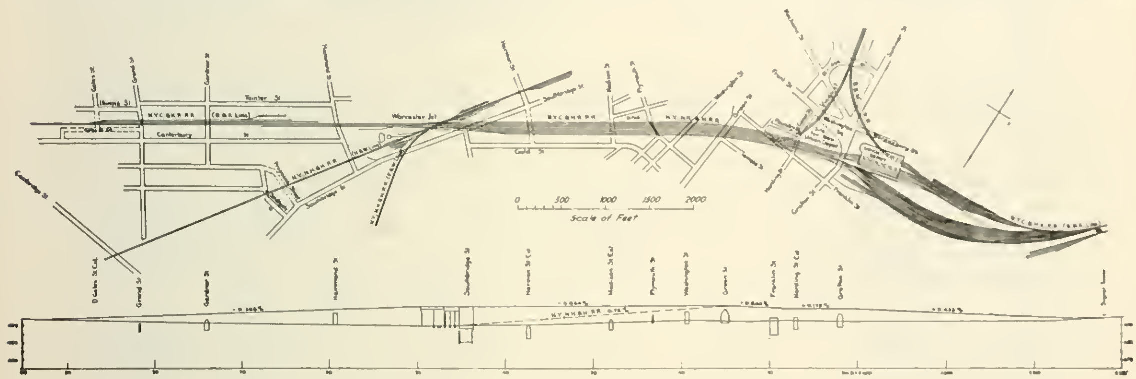
Referring to Fig. 1, it will be seen that the Boston & Albany division of the New York Central runs in a general east and west direction. At the present time the Norwich & Worcester and the Providence & Worcester divisions of the New York, New Haven & Hartford run along parallel to and on the south side of the Boston & Albany from Worcester Junction to the Union Depot, the passenger traffic running into the station on the south side of the Boston & Albany tracks. The freight traffic of the New Haven, however, crosses the Boston & Albany at grade at Worcester Junction to reach the New Haven freight house, which is located on the north side of the Boston & Albany. Furthermore, all interchange of freight between the New Haven and the Boston & Maine is made by crossing the Boston & Albany at grade near Franklin street and by passing over the short location, called the "Viaduct," which is used at the present time for freight traffic only. The Boston & Maine joins the Boston & Albany at the Union Passenger Station. Its passenger trains run into the Union Station, crossing Summer street and Shrewsbury street at grade, and its freight traffic goes over the Viaduct and connects with the Boston & Albany or crosses it at grade to reach the New Haven road. The work which is to be undertaken is the elimination of these two railroad grade crossings at Worcester Junction and at the connection with the Viaduct, and it is proposed to abolish all the highway grade crossings on the Boston & Albany and two on the Norwich & Worcester, but those on the Boston & Maine have been left for future independent consideration. The remaining street crossings on the New York, New Haven & Hartford within the city limits already pass either over or under the railroad. There are also no grade crossings on the Viaduct, this connection having been originally so built as to pass above the streets. The proposed work also involves building a new union passenger station and the necessary connections with the New Haven tracks from the south side to the north side of the Boston & Albany road, the railroad grade crossing at the junction with the Viaduct is eliminated. On account of this feature it will be seen from the profile that it has been necessary to depress the Hermon street extension and Madison street extension considerably, so as to pass under the New Haven tracks.

From the Union Depot to Worcester Junction, two streets, Franklin and Southbridge, already pass under the railroad and the elevation of the tracks will evidently require no change in the grade of these streets. Grafton street will be depressed about 7 ft. and pass under the tracks, the railroad being supported on a masonry arch, the clear headroom above the street to be 16 ft.; this will be cut down slightly by trolley wire connections for electric car lines which occupy this thoroughfare. This arch is illustrated in Fig. 2.

To eliminate the grade crossings at Summer street and at Shrewsbury street, it was at first suggested that the passenger traffic of the Boston & Maine could be carried over the Viaduct and then switched back into the Union Depot. This objectionable feature of switching led to the suggestion that the new passenger station should be located between the Viaduct and Green street, but it was finally decided that the location, shown on Fig. 1, in the angle between the Viaduct and the Boston & Albany tracks would be serviceable for all three railroads.

The site for the new union passenger depot having been decided upon, it seemed advisable to continue Harding street, carrying it under the railroad so as to connect with Canal street, on the other side of the tracks. The railroad above this street is to be supported on a steel bridge with watertight floor and with provision for deadening the sound of passing trains.

Green street, a street of very heavy traffic, including two electric car tracks, is to be depressed only about 3 ft. The railroad, as at Grafton street, is to be supported on a masonry arch with a headroom of 16 ft., this clearance being measured from the crown of the street to the soffit of the arch.



General Layout of Worcester Grade Revision, and Profile of Boston & Albany Entrance.

Boston & Albany freight yard, which is to remain undisturbed in grade.

On the Boston & Albany this work will involve the elevation of two and a half miles of the two-track main line, a mile and a half of which will be raised to an average height of about 17 ft. above the present grade, while the "run-offs" at each end of the track elevation will require the remaining mile. Fig. 1 shows the plan and profile of this location. It will be seen that the maximum grade on this elevated portion of the road will be 0.540 per cent. for westbound traffic, and 0.398 per cent. for eastbound. Worcester is a division point. The ruling grades on the division from Boston to Worcester are, both westbound and eastbound, 0.57 per cent. For the division from Worcester to Springfield they are for westbound 0.97 per cent., and for eastbound 0.99 per cent. It is obvious, then, that the proposed railroad grades are well within the required limits. Throughout this entire elevation the railroad is to be on an earth embankment with side slopes, except for occasional side retaining walls, where the location is too narrow to admit of side slopes and where the adjacent property is too valuable to be purchased for slopes.

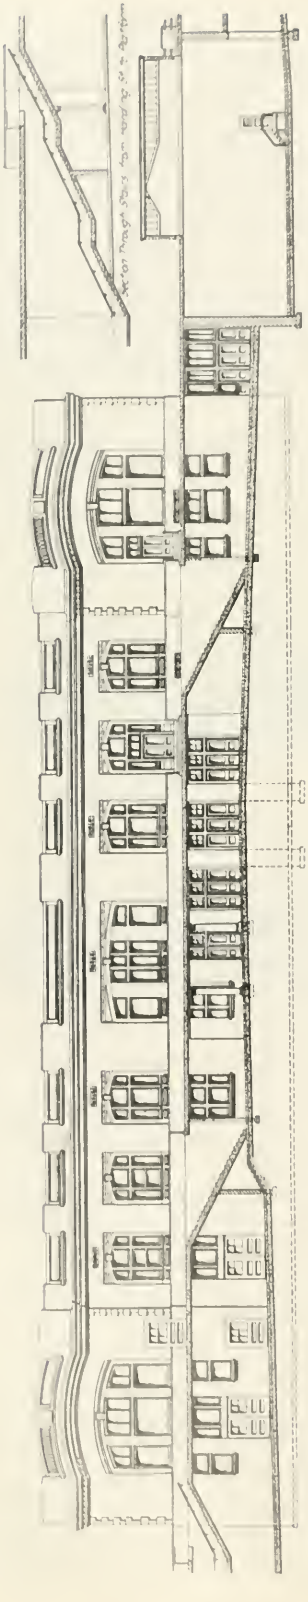
Beginning with Grafton street, which is located just west of the present Union Depot, the work is to be carried on jointly by the Boston & Albany and the New Haven to Worcester Junction, where the New Haven branches off toward the south. At this junction point the New Haven at the present time crosses the Boston & Albany at grade and it has been decided to eliminate this railroad grade crossing at the same time that the highway grade crossings are abolished. Beginning at this junction point, the New Haven tracks will pass under the Boston & Albany tracks with a clear headroom of 18 ft. and will ascend on an 0.72 per cent. grade toward the east on the north side of the Boston & Albany tracks (as shown in Fig. 1) until they meet the grade of the Boston & Albany tracks, about at the junction with the Viaduct. By relocating the New

Washington street will be depressed about 5 ft. and the railroad will be carried over the street by a solid floor steel bridge, the clear headroom to be 14 ft. At Plymouth street, where the present grades on the street are already steep, it has been deemed advisable to close the street to team travel, providing only a subway for pedestrians to pass under the railroad. This subway is to be 12 ft. wide and 10 ft. high, the outer walls to be of quarry-faced ashlar granite and the abutment walls to be of concrete, faced on the interior of the subway with white enamel bricks. The subway will be approached by stairs at either end, these stairs and the floor to be granolithic.

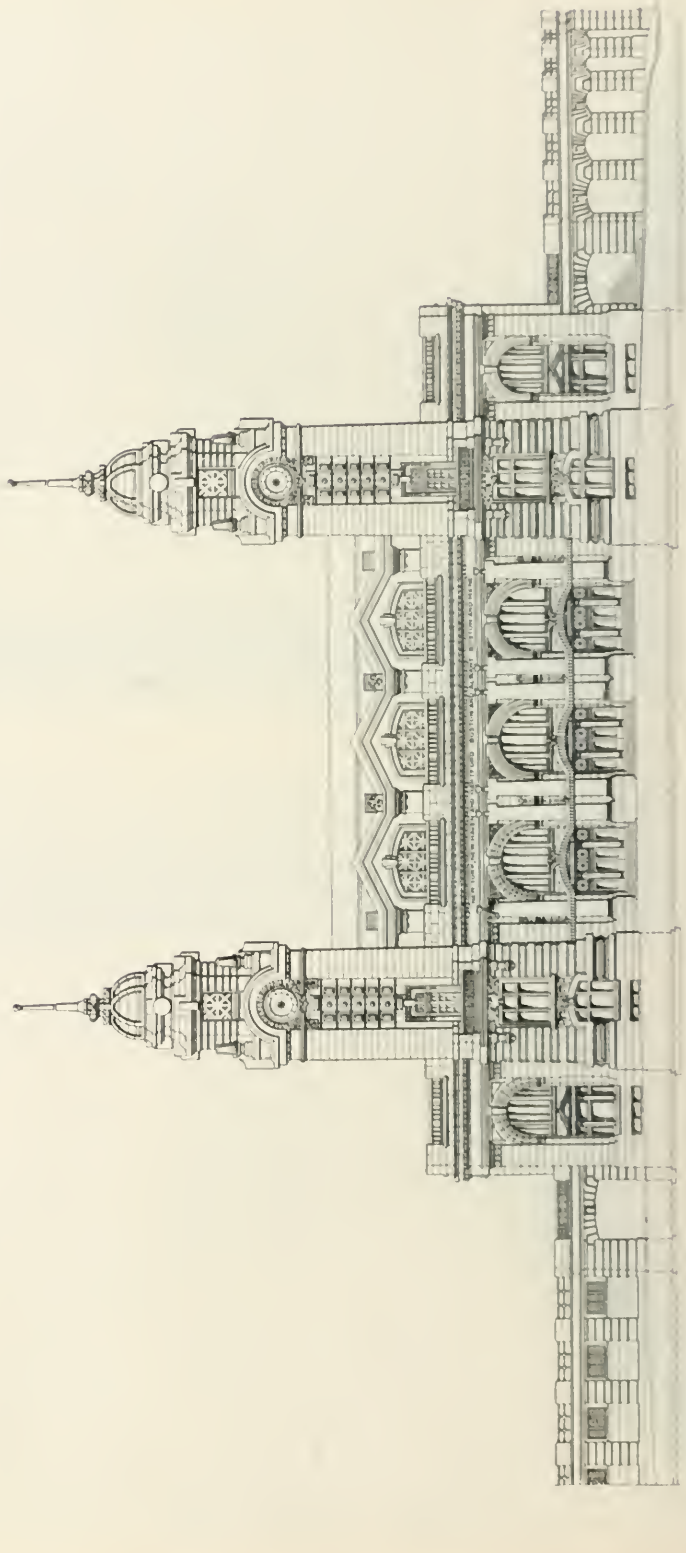
On account of the necessity of closing Plymouth street to carriage travel, Madison street, which does not now cross the railroad location, is to be extended and carried under the railroad by means of masonry arches whose headroom will be 14 ft. In a similar manner Hermon street is carried under the railroad with a headroom of 16 ft.

West of Worcester Junction there are but three grade crossings on the Boston & Albany, Hammond street, Gardner street and Grant street. At Hammond street it is proposed to leave the street at its present grade, and to carry the railroad above it by means of a solid floor steel bridge with a headroom of 13 ft. Gardner street is to be depressed about 11 ft., this heavy depression being necessary because the railroad grade has begun to fall rapidly so as to allow Gates street to be extended and to be carried above the tracks. At Gardner street a masonry arch with a clear headroom of 15 ft. will be constructed.

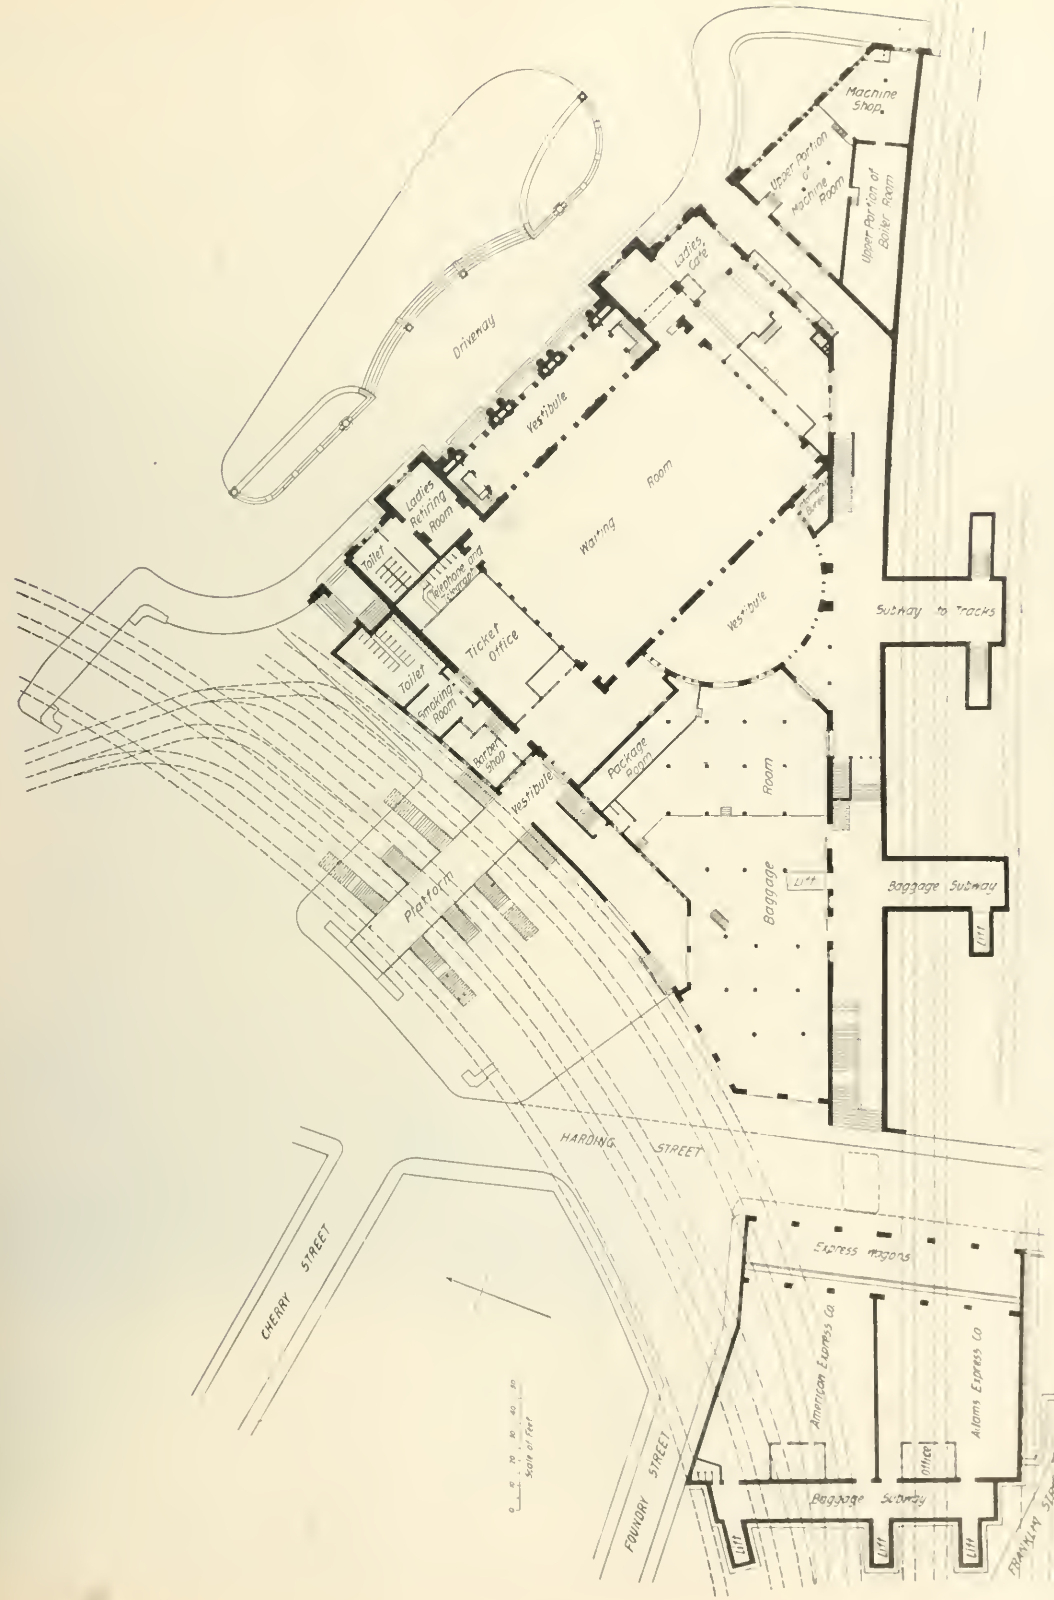
Grand street, which now crosses the railroad, will be closed to team travel; but a foot subway, slightly smaller but similar



Side Elevation and Section Through Subway; Proposed Worcester Station.



Front Elevation of Proposed Worcester Station.



Ground Plan of Proposed New Station at Worcester, Mass.

to that proposed for Plymouth street will be provided. In partial substitution for Grand street, an additional street, Gates street, which does not now cross the railroad, will be extended and carried above the railroad crossing of the Boston & Albany by means of a steel highway bridge having a clear headroom of 18 ft. above the rail. On the southerly side of the railroad location this new street will branch and run in both an easterly and westerly direction connecting with Grand street and Canterbury street, as shown in the plan of Fig. 1.

These changes in street grades will in several instances affect the grades of adjoining streets, the most extensive changes being on Illinois street, where it is made to conform to Gates street. The proposed street grades are in some instances large. On Washington street, for example, the grade will be 5.75 per cent.; on Madison, 5.50 per cent.; on Hammond, 7.86 per cent., and on Gates, 5.60 per cent. These somewhat steep grades on Washington and Hammond streets are practically no steeper than exist on these streets to-day and neither of them is occupied by street car tracks. The steepest grade to be introduced on thoroughfares where street cars are operated is on Green street, where there will be a short 2 per cent. grade.

In all cases where the streets are to be depressed or extended, the roadways are to be paved to conform to the rest of the street, sewers are to be relaid and strengthened, and gas and water pipes are to be lowered where necessary, the latter to have a cover of at least 5 ft. of earth. The sidewalks are to be at the same grade as the roadway in all instances and to be paved in most cases with granolithic.

On the Norwich & Worcester line, the grade crossings at two streets, Southgate and Cambridge street, are to be eliminated as a part of the entire project. The grade of the New Haven tracks from Worcester Junction to Southgate street will remain practically unchanged, the railroad passing over Hammond street as at the present time, and as the grade of the Providence & Worcester line is not to be changed, Southbridge street, which now passes under the railroad, will be unaffected.

Southgate street, in its present location, will be abandoned except that a footway will be carried under the tracks. A new street, however, is to be constructed just north of Southgate street so as to pass under the tracks by means of a masonry arch which will have a clear headroom of 14½ ft., the grades of approach being 6.25 per cent. on the west side and quite flat on the east side where it runs to a junction with Southbridge street.

In a southerly direction from Southgate street, the grade of the railroad is to be depressed by a 0.20 per cent. grade until Cambridge street is reached, where the tracks will then be about 11 ft. lower than at present. Cambridge street is to be raised about 10 ft. so as to pass over these tracks with a clear headroom of 18 ft. The street will be carried over the tracks by a steel highway bridge with wooden plank floor, the grades of approach on both sides being 5 per cent.

On account of the elevation of the Boston & Albany tracks at their junction with the Viaduct it will be necessary to raise the entire Viaduct, beginning at the point where it joins the Boston & Maine and ending with a raise of about 15 ft. where it joins the Boston & Albany tracks. This will impose an up-grade of 0.55 per cent. in the place of a down-grade of about 1.3 per cent. on the portion of the Viaduct south of Front street. The grade proposed for the Viaduct between Front street and the Boston & Maine Railroad will be 1.42 per cent., which is a little steeper than the present grade. The Viaduct will be on an earth fill for the most of its length except the portion between Front street and Foundry street which will be built on a steel viaduct. Since these tracks already pass above the streets this extra elevation of this railroad will evidently require no change in the streets in that vicinity.

The tracks of the Boston & Maine from the junction of the Viaduct to the present union station will be discontinued and removed, and in the future all the trains both freight and passenger of the Boston & Maine will approach the new union passenger station over the Viaduct.

The new union passenger station (Fig. 3) is intended to be one of the handsomest and best planned stations in Massachusetts. Its proposed site will be nearer the business center of Worcester than the present station and its approach much more convenient. The foundations of the building are to be of reinforced concrete. On the granite base, which is to show about 7 ft. above the first floor level, will rest the exterior walls of light cream colored brick, the same brick is to be used for inside walls in the baggage rooms and toilets. The ornamentation for the exterior walls will be of dull finished cream-colored terra cotta. The building is to be fireproof throughout.

The floors of the main waiting room and of the vestibules, restaurant and siderooms will be of cement. The waiting-room will be finished with a wainscoting of marble and with marble door and window finish to match, and the plastering is to be finished in imitation of Caen stone. All interior wood finish will be of red birch.

The staircases will be either cement or iron, the plumbing and lighting thoroughly modern. Subways and elevators are provided where necessary and there will be installed in the building the Kenney Vacuum System for cleaning as well as the necessary heating and hot water facilities for the restaurant. The architects are Watson & Huckel, of Philadelphia. It is estimated that this station will cost about $500,000.

In apportioning the cost of this entire work the grade crossing commission has decided that the Boston & Albany shall pay the entire cost of the site for the new union passenger station and also 65 per cent. of the total cost, including land damages, of all work west of Worcester Junction, and 32.5 per cent. of the alterations between Worcester Junction and Harding street, and also 65 per cent. of the cost of alterations east of Harding street.

The New York, New Haven & Hartford Railroad will pay 65 per cent. of the total cost of alterations, including land damages, on its railroad south of Worcester Junction, 32.5 per cent. of all work between the junction and Harding street, and 32.5 per cent. of the total cost of raising the Viaduct.

The Boston & Maine is to pay 32.5 per cent. of the cost of alterations on the Viaduct and 65 per cent. of the cost of removing their tracks from the junction with the Viaduct to the present union depot. The commonwealth of Massachusetts is to pay 25 per cent. of the total cost of all alterations ordered except the cost of the site for the new station and for constructing Harding street extension. The city of Worcester is to pay the entire cost of extending and building Harding street and also 10 per cent. of the total cost of all other alterations ordered by the decree.

In apportioning the cost that shall be borne by the street railways, the commission has decided that all public service corporations having rights in the streets within the limits of the alterations prescribed are to care for the several structures owned by them at their own expense.

The grade crossing commission which has finally brought this difficult problem to a solution is made up of the Hon. James R. Dunbar, Professor George F. Swain and Judge James H. Flint, the latter succeeding Henry P. Moulton, deceased. The cost of the entire project will be in the neighborhood of $3,000,000.

New Bridge Derrick Cars; Chicago, Milwaukee & St. Paul.

The bridge and buildings department of the Chicago, Milwaukee & St. Paul has recently built a heavy steel derrick car and some wooden derrick cars of unusual design and capacity. An illustration of each kind is shown herewith.

The steel derrick car is of 50 tons rated capacity, and is designed to allow construction of steel trestle work 80 ft. ahead of the trucks, or place a 95-ft. steel girder in position without the use of falsework. The car frame is structural steel. It is 51 ft. long over end sills and 9 ft. 10 in. wide over side sills. The frame overhangs the trucks 5 ft. on the boom end and 6 ft. on the cab end. The trucks are 30 ft. center to center. The boom is adjustable, its smallest length being made up of two 21-ft. sections. By the use of various combinations of 15 and 21 ft. intermediate sections this length can be increased successively from 42 ft. to 57, 65 and 80 ft.

30-Ton Wooden Underframe Derrick Car; Chicago, Milwaukee & St. Paul.

In the subjoined table the figures in the second column show the capacity of the boom for the corresponding length in the first column. The third column gives the distance the boom can swing from the track center line when carrying the respective loads shown in the second column and using the outrigger. The fourth column gives these distances when not using the outrigger. The lower end of the boom swivels in a self-lubricating ball-and-socket joint bushed with phosphor bronze.

Length of boom.	Capacity of boom for this length.	Swing of boom — Using outrigger	Swing of boom — Without outrigger.
80 ft.	10 tons.	26 ft. 9 in.	12 ft. 0 in.
65 "	20 "	19 " 6 "	8 " 6 "
57 "	35 "	19 " 0 "	8 " 3 "
42 "	50 "	15 " 6 "	6 " 9 "

The boom tackle is composed of two seven-sheave blocks with $\frac{1}{2}$-in. side plates, reeved with 15 parts of $\frac{7}{8}$-in. steel wire rope. The sheaves, which are self-lubricating, are 24 in. in diameter and have phosphor bronze bushings. The tackle supporting the 50-ton hook is composed of a five-sheave and a four-sheave block, with $\frac{3}{16}$ in. side plates reeved with 10 parts of $\frac{3}{4}$-in. wire rope. The sheaves are 21 in. in diameter, and, like the boom sheaves, are phosphor bronze bushed and self-lubricating. These blocks were designed and made by the railroad company. The A frame, when erected for operation, stands 21 ft. above the top of the rail. It folds back by revolving on a casting at its base, so as to reduce for shipment the height from top of rail to top of frame to 16 ft. 8 in.

The outrigger for increasing the capacity of the car for side lifts is an I-beam almost as long as the car is wide. It slides in and out of the casting at the foot of the A frame, and when extended affords a point of support 5 ft. 9 in. from the center of the track.

The cab frame, which is steel, is sheathed with common box car siding, and has a sliding front and folding side doors which afford ample view for the engineman and wide openings for exit. The cab contains a 50-h.p. hoisting engine, with two drums and four spools. Besides the air-brakes, the air-pump supplies four riveting hammers, at 100 lbs. pressure, from two storage tanks under the car floor. A propelling device and enough excess counterweight are provided to move the car with an 80-ft. girder at the end of a 57-ft. boom.

The 30-ton derrick cars are similar to some others recently built by the St. Paul, except the A frame, which has been added to the top of the tower to increase the effective height of the mast and thus diminish the stresses on the top tackle and boom. This A frame can be removed when the car is to be shipped, reducing the height of the tower to 15 ft. The car is of extra heavy construction, with center and side sills reinforced by 15-in. channels. In the attachment of the steel tower to the car there is provision for resisting any twisting due to side lifts by the derrick. The trucks also are extra heavy.

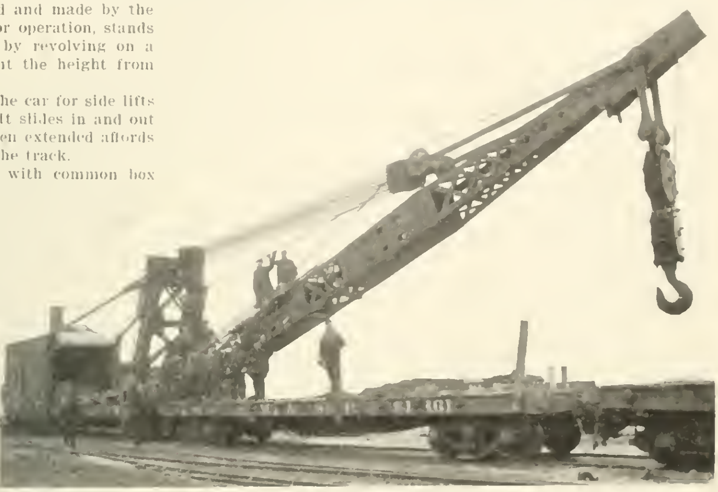
The tower has a foot-step for the boom at the base and a revolving connection at the top for the top tackle. These connections are in a vertical line, making the mast the greatest effective height which the height over all will allow. This latter dimension is limited by through truss bridge clearances. It is important that it should not exceed this height to enable the car to work in and around such trusses.

The top tackle consists of a four-sheave block fastened by eye-bars to a forging. This forging revolves horizontally about a vertical axis, while the block itself revolves vertically on a horizontal pin. The other end of this tackle has a similar block turning on a pin which passes through plates on the boom. These connections allow movement in any direction without introducing eccentric stresses. A $\frac{3}{4}$-in. wire rope is used. The load tackle consists of three-sheave blocks and $\frac{5}{8}$-in. wire rope, the rope passing over the end of the boom and back to the engine. The hoisting engines, water tanks, coal bins, etc., are so placed in the cab as to have the greatest effect as counterweights, and yet give enough working space for the engineman and winchman.

Equipped for work these cars will weigh 132,000 lbs., of which 74,000 lbs. is on the front truck and 58,000 lbs. on the rear truck. They are equipped with a self-propelling device attached to one of the rear axles. The weight on the rear truck exceeds the counterweight requirements by an amount sufficient to enable the car to propel itself while carrying a 70-ft. girder at the end of a 50-ft. boom. The rated capacity of the car is 30 tons at the end of a 30-ft. boom and 20 tons at the end of a 50-ft. boom.

These cars are fitted for any class of bridge work. One car can put a 70-ft. girder in place without falsework, and an 80-ft. girder in place using falsework. Two cars working together are needed for anything longer or heavier than this. One car has the capacity and boom reach to erect, without traveler, all single track through or deck truss spans of 200 ft., C., M. & St. P. specifications. The cars are part of the bridge and building department's erecting organization, which erects all of the company's bridges.

We are indebted to C. F. Loweth, Engineer and Superintendent of Bridges and Buildings, for this description.



50-Ton Steel Derrick Car; Chicago, Milwaukee & St. Paul.

Track and Ballast.

At a recent meeting of the Iowa Railway Club two papers on "Track and Ballast" were read, the first written by H. Rettinghouse, Division Engineer of the Chicago & North-Western at Boone, Iowa; the second by R. R. Auerbach, Roadmaster of the Chicago Great Western at Marshalltown, Iowa. These papers were followed by a discussion. An abstract of the papers and the discussion is given below.

Mr. Rettinghouse. Good track means first, good roadbed and drainage. Often I have seen carload after carload of gravel, cinders or other dry material put under track in some particularly soft cuts, only to churn up in a short time with the underlying soft mud. In such a case good judgment would dictate a little work on drainage ditches and tiling, with better results certain. Good drainage should be had in mind during construction of the roadbed, which should be built with extreme care. Ditches in cuts and along low embankments should wherever possible be made continuous and leading to the nearest outlets. Adequate waterways under tracks should be built. The question of drainage should be paramount. Modern engineering methods of determining drainage areas and the consequent volumes of drainage to be disposed of, are doing much toward perfecting drainage conditions and thereby helping to make good track. In the colder climates, especially where track maintenance is a difficult problem because of the heaving of track, there should be more attention paid to perfect drainage of roadbed, than at a location where frost does not penetrate deep enough to cause heaving of track. The roadbed should not only be perfectly drained, but should be of proper consistency to receive ballast and track, so that the material from it will have no tendency to churn up with the ballast after it is placed. If the material forming the roadbed is of such nature that it will not fulfil these conditions, it is often necessary to place a layer of cinders or coarse rock on top of it so as to leave the ballast unimpaired.

Second, comes good ballast. The proper preparation of the roadbed and sub-grade is most important. The roadbed should be slightly sloped from the center line of track each way so as to permit quick drainage of such moisture as will penetrate through ballast. It is easy to do this with new beds previous to the track laying. When there is old track to be reballasted it is essential that the old ballast be removed from between the ties to the bottom of ties at the ends, and the excavated material leveled off to the shoulder of the roadbed so as to leave no ridges and leave no obstruction to the flow of sub-drainage.

Of the different kinds of ballast that have come under my personal charge and observation I will name the following:

(a) Broken stone or slag. (b) Gravel or sand. (c) Cinders. (d) Earth.

(a) Broken stone or slag.—From all points of view there is nothing better than stone ballasted track. Opinions differ, however, as to the size of crushed stone or slag. Some favor crushed stone averaging 2-in. cubes, washed so as to be absolutely clean and free from stone dust. Others advocate a size as small as $\frac{3}{4}$ in.; a mixture of all sizes between and including these two extremes, a crusher run article with a limit to 2-in. stones and a certain proportion of dust in the mixture. I advocate the last of these classes. I find that with broken stone or slag there is a tendency for the sharp edges of the fragments of stone to bury themselves in the bottom of the ties through the impact of trains. It is difficult to keep track in good line through the further tendency of broken stone fragments to roll one way or the other. On lining track they tend to again crowd back and throw track out of line. With the mixed material this objection is reduced to a minimum and the smaller particles will fill out the voids. As to the small amount of dust, it will with a few rains wash down to sub-grade and by forming a coating over the subgrade be helpful to drainage.

It is often held that broken stone or slag is too expensive as compared with gravel. I cannot agree with such an opinion as the one item of life of ties is an important factor in the cost of maintenance. The porous nature of stone ballast prevents its speedy rotting and thereby proves a long time investment. The thickness of stone or slag ballast and for that matter all other ballast should be no less than 12 in. from sub-grade to bottom of ties, while 18 in. is much better. The material should be hard and not subject to crushing. Limestones and granites, trap and flint rocks are most commonly in use. Only the hardest sand stones are admissible.

(b) Gravel and sand. Good gravel which must be composed of stony parts that will not rapidly decay, and run in sizes from coarse sand to pebbles 2 in. in diameter, is extremely scarce. There must be no clay or earthy substance in it in order that it may drain freely and not churn when soaked by rain. The proportion of sand must not be too large nor must there be an excess of pebbles. The proportion should be about three parts sand and five parts coarse pebbles. These specifications are hard to fill. Utter and nearly ruinous disappointment has followed the opening of certain gravel pits, which were said to have been thoroughly tested, and on the strength of such tests bought at fancy prices, only to be found composed of three-quarters fine sand and one-quarter fair and usable gravel.

Good track can be made with gravel ballast. The ballast can be maintained somewhat more cheaply than stone ballast, but as it is less porous it will foul more speedily and will hasten decay of ties. Sand ballast is used only when other material is unavailable or on unimportant track. It is objectionable on account of the large amount of dust raised from it by passing trains, although excellent track can be made with it. The coarser the sand the better. The greatest objection to sand ballast is that it is less porous than other ballast and therefore greatly hastens decay of ties and fouls quickly.

(c) Cinders. I know a railroad manager who will not allow the use of cinder ballast on either main or branch lines. He does not even favor it on passing or side tracks immediately adjoining main track. He objects to the so-called "sink holes," but his opinion is rather radical. I know of one important western railroad which has cinder ballast on several hundred miles on one of its most important main lines. Cinder ballast has been advocated as giving less resistance than any other and appears springy and therefore would make a good riding track. Because it is springy it requires frequent "picking up" and consequent renewal. It never gives the appearance of first class track and is for that reason tabooed on most of first class lines, though it is used a great deal on side tracks and industrial spurs.

(d) Earth. Track ballasted with earth is in trackman's language called "mud track." It is well named. There is yet a good deal of earth ballasted track in this and other western states. I know of many miles of such track, which is really good as long as it does not rain, but when the rain comes down it is very poor track indeed. Maintenance of earth ballasted track is quite expensive and ties are eaten up rapidly. One big item of expense during the summer months is the removal of weeds.

Ties.—Good ties are essential to good track. All ties of soft as well as hard wood have doubled and trebled in price in a very few years. Economy in their use is therefore imperative. It requires good judgment on the part of section foremen and road masters not to jeopardize the safety of track for the sake of false economy. The percentage of oak ties used to-day is far larger than the soft wood ties such as cedar, hemlock and tamarack, and is greater than it was some years ago, notwithstanding the fact that many more miles of railroad have been added since that time and the total number of ties used enormously increased. Experiments are being made to find a substitute for wooden ties in steel or concrete, but as yet no satisfactory substitute has been found. The only salvation for the railroads seems to lie in planting trees and it is gratifying to see that many railroads are starting to do that.

Rails and Fastenings.—There is a great variety in fastenings. The old style fish plates have seen their day and the cast chair is a curiosity. The effort is to get a rigid joint. There is a little danger of overdoing this by creating such rigidity of joints as to overshadow the rail proper.

Good Men.—When the young Edwin Booth set out in his dramatic career, he went to an old actor with this question: "What must I do to play Hamlet? I wish to play Hamlet, I must play Hamlet, and I will play Hamlet." The old man, with the fire of enthusiasm in his eye, said: "Well, if you put it that way, if you want to play Hamlet you must read Hamlet, you must eat Hamlet, you must drink Hamlet, and by the Gods you must *be* Hamlet." I have often said to a young man fresh from college who wishes to be a trackman and roadmaster: "If you want to be a trackman you must read track, eat track, drink track and live track."

The American roadmaster or supervisor of track, as he is sometimes called, is a type distinctly of his own. Whether he has a college training or has risen from the ranks, in all cases he must be a good general, and above all a good trackman. Unlike his brother on the European continent, he has a comparatively large district under his charge and is always a busy man. Every wreck, every washout and every mishap demands his personal attention. It has become a serious problem of late to find section foremen, and this is at present one of the greatest difficulties with which the roadmaster has to deal. Most track laborers to-day are foreigners who offer no suitable timber for promotion, and it takes considerable discretion and ability of the foreman in dealing with that class of labor to accomplish what he is expected to do and keep his track in good condition. Railroads have seen fit to pay track laborers less than other laborers and as a result the intelligent and promising men in this department tend to go into other fields.

Mr. Auerbach: Cinders for ballast cannot seriously be considered by a road doing anything but a small business, although they are undoubtedly cheapest in the first place. When traffic is not heavy they do very well to widen narrow fills to put in wet cuts and other weak places. These places can usually be repaired with the cinders that are made by the company using them. On a road using heavy power and running a good many trains a day, cinders are not a satisfactory ballast. They are altogether too light to stand much heavy pressure from above, and they are not heavy or compact enough to keep track in line unless an unusually broad shoulder is used. Consider the substance of cinders, the non-compact clinkers, the brittle and uneven stone-like pieces, and the almost powdered ash. Per cubic foot cinders weigh about one-fourth as much as gravel and one-sixth as much as rock. When cinders are used as ballast, the clinkers are not broken by the bar or shovel when tamped, but soon become crushed by the heavy weight of the rolling stock. You can dig down under ties where cinder ballast has been in for a year or more and you will not find one clinker. They become crushed by the traffic over them. This crushing puts the track out of line and subsequently out of surface. The track goes out of line because the weight of the cinder shoulder is not sufficient to hold it. To be sure track will always go out of line if allowed to get out of surface, or vice versa, but it will not get as much out of line or surface, or as easily so, with a stiff and substantial shoulder and a firm bed as it will with a light and loose one such as cinders give.

Cinders are best in wet places where there is a broad, flat subsoil such as yards. But on new dumps they are decidedly bad. The water easily drains through them, but does so mostly in certain places, forming pockets and cutting away parts of the dump. This year on my territory we filled some 20 bridges. Where cinders were unloaded on these filled bridges and rained on heavily, we had parts of the new dump cut away by an unequal amount of water going through the less compact part of the cinders. I unloaded 200 cars of cinders on one section this summer. The cinders were put under as fast as received. Two months after they were put in, leaving a good top and line on track, it was necessary to re-raise this track. This was done about September 1, and track is in such condition now that it will have to be gone over again in the spring. The ground formation under these cinders is of the best. Cinders in yards are excellent. They drain well, are hard and present a good appearance if kept clean.

Ballast cannot be entirely taken away from a track. Roads that are dissatisfied with their cinder track and want to improve it should put gravel on and reballast it. I have seen gravel put on over cinders with excellent results. The coarser gravel very soon forms a cushion with the cinders.

Gravel or rock? This is the vexing question.

Gravel.—The reasons for having coarse gravel for ballast are obvious. With fine gravel there is too much sand. The sand washes, is dusty and while the fine gravel is almost as heavy as the coarse, it is not nearly as substantial or enduring. It cannot be tamped to give as firm or lasting a bed as gravel made up mostly of stones about the size of the end of your finger, because the large amount of sand found in the finer gravel will work out when dry and when wet will churn.

Coarse, pure gravel is considered by many to be the ideal ballast, but let me surprise some by saying that if a small amount of clay is added to this gravel we have more nearly a perfect ballast. The need of this clay is not so apparent in newly ballasted track, but as the track gets older and parts of the gravel wash away and rain begins to form small ditches in the shoulder of it, then it becomes noticeable that the gravel has not packed hard enough to turn water or to leave it as originally dressed. But if mixed with this gravel is about 10 per cent. of clay, just enough to cement it, rains will not affect it, and the older it becomes the harder it gets, forming a strong, cement-like shoulder and bed. It can be maintained with less work and expense than any other ballast. I can show you four miles of such ballast on a trunk line in this vicinity that has not been touched for three years, and is at present in as good line and surface as any track in this part of the country. I can also tell you of a large road in this state that has coarse gravel for ballast, which has issued instructions to its section men that they should, whenever possible, mix with the gravel a small amount of clay. However, great care must be taken that there is not too much clay in the gravel, as too much would be worse than none at all, for in wet weather the track would churn and work.

The cost of maintenance of gravel ballast is approximately the same as for cinders and the finer grade of gravel, except that it does not have to be gone over so often. What I mean to get at in comparison to rock is that a light raise of joints or centers can be made. I might add here that, except rock, track should be lifted as little as possible, and should never, if it can be avoided, be raised out of face. The old tie bed made by years of service is always preferable to a newly made one.

Rock.—It is true that from section men to roadmasters comparatively few handle crushed stone intelligently. The reason is, rock ballast is comparatively new to us. There is a vast difference between rock and the nearest thing to it, coarse gravel. Rock track cannot be kept up with less than from 10 to 15 per cent. more force than is necessary to maintain gravel or any other ballast the year round. You cannot lift a joint here or a center there in rock. It must all be taken out of face. That is, you cannot make a light raise of a joint or center, such as a half inch, because the dimensions of crushed stone generally used cannot be got under such a light raise, and in order to get up the low place of a half inch you must raise it higher than necessary to make it level with the rail on each side of it; consequently, in order to get a true surface you will have to raise the rails adjacent to this joint, and so on, and in doing so you are lifting the track out of face, or making a new cushion for it. It is impossible to make light raises and keep them up. You cannot get under enough ballast to hold them. You lift a joint only. The quarters on each side will come up somewhat, too, and there is no crushed rock small enough to put under these quarters where the joint is raised a little. But still you will find foreman after foreman trying to do this kind of patchwork on rock track. It is simply time wasted.

In rock track you practically have no choice of the quality of ties. Nothing but oak or ties of equally hard wood should be used. Rock on a solid formation will penetrate softer ties, shorten their life, and ultimately affect the surface of the track. In the maintenance of rock track too much attention cannot be paid to the way in which the ties are tamped. No track becomes so easily center-bound and swinging as rock. Ties in rock should only be tamped at the ends and under the rail, never in the centers. Don't try to do this tamping with anything but tamping picks. Bars are not properly shaped and shovels are out of the question. Rock track should always be lined before being raised. Raising track before lining it will invariably disturb its surface. Compared with other ballast the care of rock track is very slow. But when once laid it will remain that way for some time, and the force caring for it can be reduced half until such time as it requires attention again. Perhaps this possible reduction of half the force when rock is in good shape would seem to lessen the cost of maintenance of rock to equal that of other ballast. But on the other hand the additional force required to put rock in good order when it is partly run down more than offsets by from 10 to 15 per cent.

The best feature of rock ballast is its drainage. Nothing short of a cloud-burst will affect it, and churning and working track is unknown. I have in my territory about two miles of track on a hill that washed out every time there was an unusually hard rain. It was so situated that the water poured on it from the adjacent hills. We had both gravel and cinders on this piece of track. That is, we had them from one washout to another. We finally put rock ballast in, and since then have never been troubled with washouts. I might mention here that this piece of rock track, two miles long, has not been raised or lined for two years, and is in good shape now.

Mr. Rettinghouse: There is one point in the last paper that I cannot entirely agree with. The claim was made that the best track men would not disturb track after it has been once settled. I have found in my experience that the raising of the joints was always considered as an expedient. We go over a piece of track every year, and if the material is there we always have found it better to raise the track two or three inches and it would keep the track in better shape.

Mr. Farquharson (Roadmaster, Chicago, Rock Island & Pacific): It is all right to raise track if you don't raise it too high, but enough so you can bar tamp it. But when you raise it so you can't bar tamp it, the places where it is settled away will have to be bar tamped to make good track. Two or three inches would make good track with bar tamping.

Mr. Hayes (Roadmaster, Chicago, Rock Island & Pacific): In 1905 I made some tests for gravel ballast. It was almost entirely under water on the Coon river, what would be called a practical well-washed gravel. We put a large amount of this in track in 1905 but found that the gravel did not hold as well as it should because there was not enough clay in it to bond. Therefore it has not given good satisfaction. We have been using a large amount of gravel the last year or so which gives good satisfaction and which has a certain amount of clay which causes it to bond. I think gravel ballast is a great deal cheaper than rock and gives just as good satisfaction.

Burnt gumbo has not been mentioned. I think from experience that it gives about as good track as you can want with as small an amount of attention as any other and less attention than gravel requires. It costs a little more in the beginning.

Mr. Jones (Superintendent, Chicago, Rock Island & Pacific): A good track man has the same opinion of water that the devil has of holy water. He wants to get rid of it as quickly as possible. Some experience we have had in the last two years on our road may be of value. Our dumps were pretty narrow and also the cuts, so that all the water that fell near the track ran down on it. It was impossible to secure money necessary to widen our cuts with steam shovels and use the material taken therefrom to widen our banks, so we were forced to take care of it with tile. On our division we have put in the last two years something like 27 lineal miles of tiling, using sizes from 4 and 6 to 8 in. In placing the tiling we put it as nearly as possible in the bottom of the cut, which, as the cuts were narrow, was from 3 to 4 ft. from the end of the ties. We put the tiling from 3 to 4 ft below the bottom of the tie and gave it a good drainage from the center of the cut to each end, making the ditch we dug to place the tile as narrow and as straight as possible. Then we filled our ditches with cinders from the top of the tile to the bottom of the ditch. The result has been that with the heavy downpours of rain or cloudbursts which we have occasionally in Iowa, there is little if any water that runs on the surface of these ditches out of the cuts. The water goes down through our cinder bed and into the tile and runs out through the tile instead of over the surface, the result being the water does not get much opportunity to get into the track or dump through the cuts and we have secured with a small outlay what we consider the best possible results from this method.

Burnt gumbo is too expensive in this part of the country because of the price of coal and high comparative cost of slack. There was a time 20 years ago when coal mines were glad to give the railroads the slack for hauling it out and some coal mines paid the railroads something for hauling it away. At that time the burnt gumbo could be made at a very reasonable price, as the principal cost is the burning of it for ballast. A couple of years ago some burnt clay we burned because we had to carry coal so far and paid so much for it, if I recollect it correctly it cost close to $1.50 per yard deposited on the roadbed for placing under the ties, making an almost or quite prohibitive figure for that class of ballast.

The ballast Mr. Hayes speaks of that we got from the Coon river, river washed gravel near Commerce, I think we placed under the ties for approximately 43 cents a yard. I think it was figured 43 or 43½, and that included the cost of loading the ballast which we were able to load at about 6 cents per yard and we hauled that 70 or 75 miles. During the summer of 1906 we put in nearly 60 miles of Grettinger ballast which we hauled I think 250 miles, paid a foreign railroad company a pretty heavy mileage, and my recollection is that it cost, loaded by steam shovel, 3 cents a yard and cost us 72 cents a yard placed under the ties at that distance. Stone ballast ordinarily costs considerably more than that, at least 50 to 75 per cent. more. In this country I believe it is extremely difficult to get a first class quality of solid rock, and unless you do, it is very expensive and makes mighty bad track in a short time. The softer particles disintegrate very fast from the moisture and the frost. Then they break and pump under the joints in a short time. I know of stone ballast put in within two or three years in an adjoining state which at the time was considered very good ballast, but within the last six or eight months they have been compelled to ditch at almost every tie and joint allowing the water to get away from the track on account of disintegration. Yet it was considered fairly good rock at that time.

These papers have stated the differences between maintenance of gravel ballast and rock ballast too closely. I believe it must cost us at least 25 per cent. more to maintain rock ballast than gravel and from 75 to 100 per cent more to change out ties in rock than it does in gravel ballast. The ballast we secured that Mr Hayes spoke of being river washed has proven rather unsatisfactory ballast. As mentioned in one of the papers it is "alive." we can't tamp it with a bar because if we do we drive it out from the other side of the tie and we can only shovel tamp it. I am satisfied, however, that this ballast is getting better. It has been in now over two years and it is getting better because the dirt and clay blown or carried in is becoming mixed with it and holds it in bond. The Graettinger gravel has a fair quantity, perhaps from 5 to 10 per cent. of foreign matter in it, that is, a sort of a clay, more like a disintegrated iron ore, and that gravel in a very few weeks or months at least after put on a track will become perfectly solid almost as much so as disintegrated granite, which without question is the best ballast that is in use to my knowledge.

I think the gentlemen in their papers where they have spoken so harshly against cinders have gone a little too far. Cinders without any question are "the poor man's friend," and we have cinder ballast on our railroad under heavy traffic, under heavy engines; one stretch I recall of some three miles put in two years ago last spring about 12 in. under the ties still remains good track and the section on which this three miles of cinder ballast is located, averages one man, besides the foreman, during the past season because we could not get men in that vicinity because the other railroads were paying higher wages than we were permitted. They may have lost sight of the fact that there is a great difference in cinders, perhaps greater difference in cinders than in gravel. Some coal makes ashes almost entirely, with some clinkers mixed in. Other coal makes hard sharp cinders and the hard sharp cinders in our experience do not disintegrate and bed down as explained in the papers, and while cinders are not so good as rock nor as good as gravel, they are better than poor gravel and they are much better than no ballast at all.

Mr. Bettinghouse: I believe I said in the paper that my experience was limited to that one instance and also that the suggestion had been made to wash all gravel. I got this information from the proceedings of the American Railway Engineering and Maintenance of Way Association of a few years since, but there was nothing said about the outcome of that experiment. It reminded me of that one instance where we used naturally washed gravel. The statement has been made by Mr. Jones that he found track that was ballasted with such washed gravel improving through the addition of clay. It is evident that you are not much bothered with heaving track in this vicinity. My experience has been in a very cold climate and heaving track was one of the greatest troubles we had. The minute we put any particle of clay in our ballast we would have a great time. I have seen track heaving so much that it required a full sized tie each side of the heave. Consequently it heaved over 6 in. This was all due to poor gravel or clay sub-soil. If there is no trouble with heaving, perhaps clay would be best.

The exchange of ties or renewing of ties in stone ballast will cost a great deal more than in gravel ballast. The cost of gravel ballast depends on the equipment at your disposal. That is to say the kind of steam shovels and ballast cars and the methods of unloading, etc. It is a most important item, as every practical man will know, to have the equipment as perfect as possible. In the years 1905 and 1906 I was in charge of track in Wisconsin and no expense was spared. We had some very large steam shovels with 5-yd. dippers; we had ballast cars, side dump cars; Lidgerwood unloaders, any quantity of them—no scarcity of equipment whatever. We had spreaders that were operated with air, and as a consequence I think that we handled our gravel about as cheaply as it could be handled, and I think it came very near to the figures mentioned by Mr. Jones, so I presume he had the same kind of equipment. We ballasted about 60 miles of single track with a yardage of 4,500 to the mile, which is very heavy ballast indeed, amounting to practically 18 in. under the ties. That ballast cost us from 23 to 33 cents a yard for different sections and depending on the haul. I had in the same year another stretch of 10 miles with a different kind of a ballast where the cost ran up to something like 50 cents a yard. It was because we had to haul over another road, and our calculation as to the number of trains we could haul each day was knocked in the head. Instead of hauling four trains I could only get three through, and of course that means a whole lot of difference. The cost of broken rock ballast is I think safe to assume a dollar a yard as an average cost, meaning the entire cost of the production of rock, hauling and putting under the track. We have on the North-Western now a crusher near Cedar Rapids which has been put in operation in the early spring, and we have not produced this year the rock as cheaply as we should. A great deal of that is due to the fact that much more stripping was necessary than we first anticipated. We will undoubtedly get the cost down during the coming year to about 40 cents a yard and perhaps less. It should be gotten out for 35 cents a yard. In that case the rock ballast track should not cost more than 75 cents a yard complete figuring on a 10-cent basis. It should be put in for 25 cents a yard and we figured 10 cents for hauling.

I mentioned in my paper broken stone and slag as you notice but I had particular reference to the Chicago & North-Western track between Chicago and Milwaukee. I don't know whether any of you gentlemen have traveled over that line, but it is said to be one of the best tracks in the country. The trains are very fast and very numerous. I believe that most of that distance, some 83 miles, is ballasted with broken slag, obtained from the rolling mills in that vicinity.

Mr. Breheny: Drainage I consider primarily essential. From my observation of the results from placing tile in some of the wet cuts recently, I am about ready to believe that considering the expense to which the managements feel able to go, that it is a very good alternative and very satisfactory. As to the cinder ballast, I must take exception to what the papers infer or intimate, for I believe that the cinders from the Iowa coal when a sufficient amount of it is put under the ties with a good sub-grade and provision made for good drainage and track properly put up, that it does make a comparatively good riding track and the maintenance expense is nominal, about equal to gravel. The quality of the cinder is no doubt to be considered in this respect. I did have a little experience this summer with cinders made from Colorado coal which approaches very nearly a lignite in lightness. The cinder is so light as to be almost entirely unsuitable as ballast. In the second paper on ballast I notice at the outset the use of cinders in wet holes is suggested, but later condemned in arguing against placing cinders where they will produce a pocket. I believe if you put cinders in a wet hole in an embankment and the track continually settles it will produce what is called a sore spot.

With the rock I believe that the class of soil making the subgrade should be considered. There are localities in Colorado where the sub-grade is a gumbo or material known as "doby," and the slag or rock is shown by experience to be too heavy in that it settles very readily into the "doby" and the "doby" works up around the end of the tie and you have got to be continually digging it out and refilling. We found by experiment that it was impracticable to place anything heavier in the way of ballast than cinders or disintegrated granite.

Disintegrated granite is the best ballast I have seen. Rock ballast is no doubt first class, but I do believe it has a rigidity that is not experienced in the riding of gravel or cinder ballast. It has an effect very close to that produced by slag. The slag in the vicinity of Denver or Pueblo is not used as much for ballast as might be expected considering the quantity in which it is furnished, and when asking as to why this is so the majority of the answers were that it was too heavy for the sand or "doby" sub-grade and they did not consider it provided as good a ballast for the locality in which it was burned as did the disintegrated granite. The expense of the disintegrated granite, both in its original cost and considering its ultimate cost in the maintenance, compares favorably with that of our gravel, and while it is in itself a material that drains well, yet I believe that in a proper cross section there can be exceptionally good drainage. In the locality to which I refer the slag was used for the most part in rip-rapping, protecting embankments, covering trestle bridges as a protection against fire hazard and comparatively little of it under track as a ballast. The disintegrated granite is readily obtainable, works nicely, and we found by experience that it was a little more easy to secure labor to work in the disintegrated granite than it was where stone or slag was used as a ballast. This is possibly a feeling that existed in that locality only. We got the disintegrated granite from the Colorado Springs & Cripple Creek District Railway in the North Cheyenne canyon, beginning at mile post 5, about five miles up in the hills from Colorado Springs. The available granite pits have been worked out from that to mile post 8, three miles.

The Illinois Central's Birmingham Line.

The Illinois Central began active investigation for a line to Birmingham, Ala., early in 1901. The topography of the region presents many difficulties to railroad construction, and to determine the feasibility of a line from some point on the present line required careful investigation. Surveying parties were put in the field in 1902, and a number of routes projected from points all the way from Jackson, Miss., to Jackson, Tenn., on the existing line. As a result of these surveys, the most feasible location appeared to be between Jackson, Tenn., and Jasper, Ala., 176 miles, by way of Tuscumbia and Sheffield, passing through Chester, McNary and Hardin counties in Tennessee, Tishomingo county in Mississippi, and Colbert, Franklin, Winston and Walker counties in Alabama. It was decided to make traffic arrangements with the Frisco System between Jasper and Birmingham, 41 miles. The line, as located, followed the general direction of the headwaters of Deer river out of Jackson, through Madison and Chester counties, ascended to the summit of the divide between the valleys of the Mississippi and Tennessee rivers in Hardin county, and thence descended to the valley of the Tennessee river and followed it to Tuscumbia, 104 miles. At Tuscumbia, the line broke sharply from the Tennessee valley and ascended to the top of Sand mountain, the watershed between the Tennessee and Black Warrior rivers, near Double Springs. From Double Springs south, a tortuous descent was made into Jasper by way of the valleys of Sipsey and Clear creeks, both tributaries of the Black Warrior. The maximum grade on this section was 1 per cent., and the maximum curvature 4 degs.; but from Jackson to a point 17 miles south of Tuscumbia the maximum grade was only 0.5 per cent. and the maximum curvature 3 degs. The air line distance from Jackson to Birmingham is 184 miles and the distance by the location described is 215 miles. The 176 miles of this to have been built would have cost about $10,000,000, or $50,000 a mile.

The financial depression of 1904 deferred further action in the matter until the spring of 1905, when arrangements were made for the following trackage rights:

Mobile & Ohio from Perry, Tenn. (near Jackson), to Corinth, Miss., 51 miles.

Northern Alabama from Haleyville, Ala., to Jasper, 41 miles.

Kansas City, Memphis & Birmingham from Jasper into Birmingham, 41 miles.

This lessened considerably the mileage to be built. It was necessary only to build a connection 3.06 miles long with the Mobile & Ohio at Jackson; a line 80.1 miles long, leaving the Mobile & Ohio at Corinth and connecting with the Northern Alabama at Haleyville; and freight terminals in Birmingham. The connection at .01 per cent. for half a mile each way from passing siding stations. The maximum curvature for the line is 3 degs., except for one curve of 4 degs., 2,085 ft. long, near the Haleyville end, which was necessary to secure the most economical location for crossing Brush creek. All curves of 2 degs. and over have spiral easement approach curves. The profile, parts of which are shown herewith, gives a clear idea of the work encountered, and the accompanying photographs show the nature of the cuts which were made. The geology of northern Alabama according to the authorities shows sub-carboniferous rock masses and coal measures. As a matter of fact, however, very little rock was encountered in large masses, but many of the cuts contained disintegrated rock, cemented gravel and rock seams separated by clay and sand. In certain cuts this clay was indurated and very difficult to remove.

Stephenson Hill cut, stations 3,991 to 4,022, near Corinth and

Birmingham Line of the Illinois Central.

Jackson presented no particular problems in railroad construction, being a standard single-track line laid with 85-lb. rails on gravel ballast. The corporate name of the line is the Jackson & Southeastern Railroad.

The line from Corinth ascends directly to the top of the ridge dividing the watersheds of the Tombigbee and Tennessee rivers, known locally as the "dividing ridge." This ridge is cut up by cross ranges of hills of moderate elevation, which are well wooded but without undergrowth. They are made of clay, with an occasional seam of sandstone. The location continues on the top of this ridge into northern Alabama, striking the Northern Alabama at Haleyville. The section traversed in Alabama is a portion of what is known as "Apalachian America," and the foot-hills of the Blue Ridge

Railroad Terminals in Birmingham.

mountains. This district has been referred to as the "land of saddles and bad roads," where a great variety of climates prevail, and where there is a survival of pioneer conditions, woodcraft and the open fire-place with the "stick and mud" chimney—in every way an unpromising land for railroad building. The line runs through Alcorn, Tishomingo and Itawamba counties in Mississippi, and Franklin, Marion and Winston counties in Alabama. The part in Mississippi, 42.28 miles, was built under the corporate name Mississippi & Alabama Railroad, and the portion in Alabama, 37.82 miles, under the name Alabama Western Railroad.

While the line is laid on the dividing ridge, it, nevertheless, involved very heavy grading to get the kind of line desired, that is, a maximum grade of 26.4 ft. to the mile, compensated .04 per cent. per degree of curvature, with an additional compensation of

Chub Hill cut, stations 1,781 to 1,798, shown in the illustrations, are two of the largest cuts on the line. The former contained 196,000 cu. yds. and the latter 106,000 cu. yds. Besides these, there were numerous cuts of over 100,000 cu. yds.; the fills were correspondingly large, as the line was built on a balanced grade line. The total material moved on the entire line from Corinth to Haleyville was 5,500,000 cu. yds., or about 70,000 cu. yds. to the mile.

Near the Haleyville end of the line, Brush creek, a small tributary to the Tennessee river, cuts a wide, deep gap in the dividing ridge, and it is here that, after thorough study and careful investigation requiring numerous preliminaries, it was decided to cross the gap by a steel viaduct, in preference to increasing the length of the line by staying on the top of the ridge and building around the gorge into Haleyville. The general dimensions and weights of this viaduct are:

Total length, face to face of parapets . . .	1,230 ft. 7¼ in.
Maximum height, base of rail to masonry	171 " 2 "
Total weight of structure . .	1,943 tons
Total amount of masonry . . .	1,550 yds.

It consists of ten 75-ft. deck plate girder spans, nine towers with 40-ft. deck plate girders, and two 60-ft. deck plate girder approaches. The 60-ft. approach spans rest on concrete abutments and rocker bents. The towers and rocker bents rest on masonry piers on solid rock foundations. The tops of the piers are all 5 ft. 6 in. square, varying from 6 ft. to 24 ft. in depth, according to conditions. The masonry piers are all stepped on the outside to permit future extensions to the masonry for a second track.

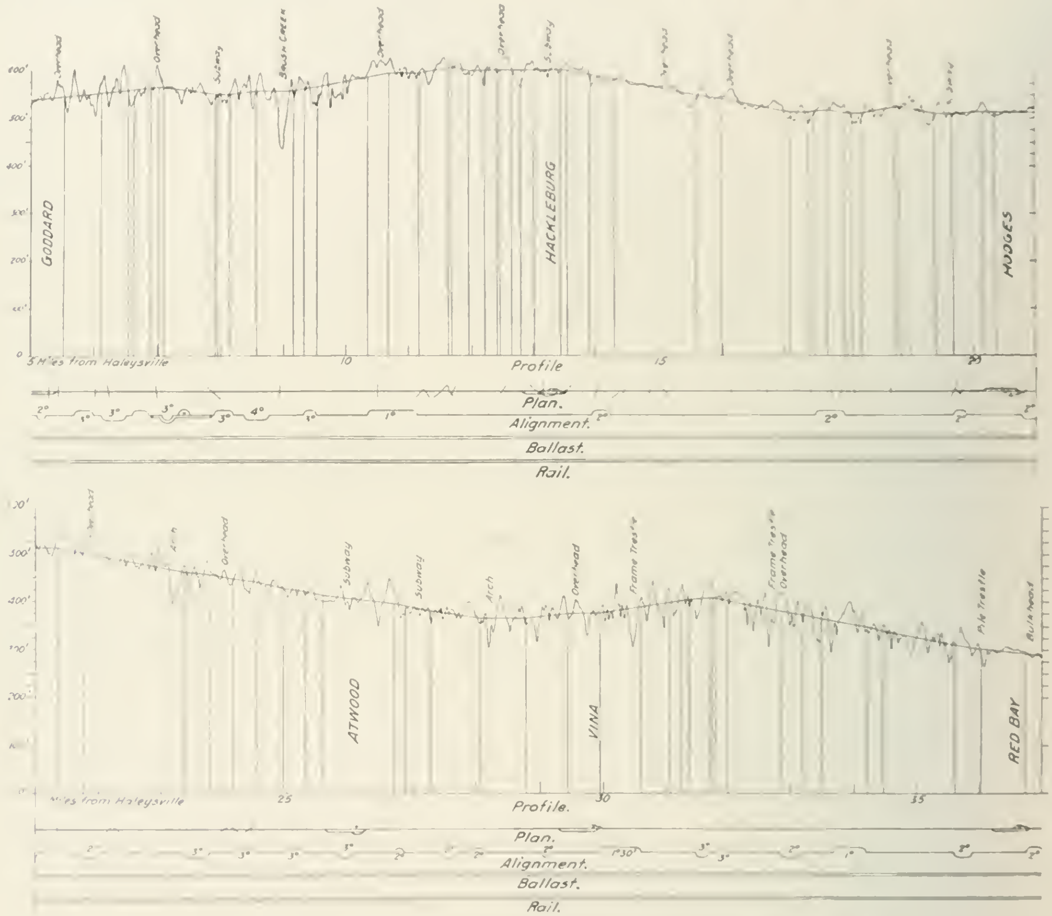
The tower spans are fixed at both ends on the columns and the 75-ft. spans on each side are alternately loose and fixed at the ends. The towers themselves are fixed at diagonally opposite corners of the bases, expansion being provided for at the other corners. Each of the towers consists of four columns joined by diagonal braces of channels. Each column is made up of two plates and four angles. Two angles are riveted to each plate, the two plates being spaced 21¼ in. and laced with 3-in. x 2-in. x ⅜-in. angles. The towers are built in one, two or three sections, according to the height. The top sections, the middle sections, and the base sections, respectively, for all towers, are built of similar elements. The steel for the viaduct was furnished by the McClintic-Marshall Construction Co., Pittsburgh, Pa. It was erected by the Strobel Steel Construction Co., Chicago, with a double trolley traveler as shown in one of the photographs herewith. The total time from beginning the work of erection until trains were allowed to cross the viaduct was 40 days.

The design of the columns in the present towers allows for future double-tracking of the viaduct by erecting additional columns on each side. To install this second track, the masonry will be extended and additional columns placed and connected to the present columns by struts and diagonal braces, and one additional deck plate girder span will be added to each side of the viaduct 8 ft. from the center line between the present girders, the present track being moved to one side so as to rest on one of the present girders and one of the new girder. The new track will rest on the other two girders, one new and one old.

The Brush Creek viaduct and the overhead crossing of the Southern Railway are the only noteworthy bridge structures on the line. The Southern Railway crossing, which is the only railroad crossing on the line, is a through girder bridge, 71 ft. long on concrete abutments. All other bridging is Illinois Central standard six pile, open deck, single-track trestle. The smaller openings have cast iron pipe.

The buildings for the line are in keeping with the kind of country in which they are located. The depot and office building at Corinth, shown in the illustration, is a combination freight and passenger station, with operating officers' headquarters on the second floor. The local stations have combination freight and passenger depots of a size suitable to the needs of the community. A cotton platform and a stock pen are provided at each station.

The section foremen's and agents' houses, which are alike, are story-and-a-half frame structures, designed to afford comfortable living quarters in a warm climate. They have two large living rooms, 16 ft. x 16 ft., separated by a wide hall leading to a porch



Condensed Profile from Goddard to Red Bay; Birmingham Line of the Illinois Central.

Overhead Crossing of Southern Railway near Corinth, Miss.; Mississippi & Alabama Railroad.

in front, 8 ft. wide, and a rear porch 6 ft. wide. Back of the dining room, and connected with the main portion of the house by a latticed porch, is a large kitchen. The second floor, or attic, is fitted up for sleeping rooms and is reached by a stairway from the hall. The interior furnishings are plain. The two living rooms each have an open fire-place finished in common ashlar and red sandstone.

Houses are also provided for section laborers, near the section foremen's houses. These laborers' houses are also story-and-a-half, with a front and back covered porch, each 6 ft. wide, extending the full length of the house. The two rooms are 16 ft. x 16 ft., but are not separated by a hall as in the section foremen's dwellings. The attic is reached by a stairway from the kitchen and is fitted up for sleeping rooms.

The type of water station used is shown in a photograph; it is a 100,000-gal. tank with steel underframe on concrete footings. Those water stations located at points where there is a passing track have a penstock between the tracks.

Brush Creek Viaduct, Showing Traveler.

Stephenson Hill Cut; Mississippi & Alabama Railroad.

Type of Water Station.

Chub Hill Cut; Alabama Western Railroad.

The finished grade is 24 ft. wide in cuts and 18 ft. wide on fills. The theoretical side slope in cuts is 1 to 1, and on fills 1½ to 1. In the cuts are side ditches 4 ft. wide and 1 ft. deep. The track is laid with A. S. C. E. section, 85-lb. rail, and is ballasted with gravel, the ballast being obtained from pits located on the line. Passing tracks 3,200 ft. long are placed at intervals of about six miles.

Wherever possible, public highways are carried either over or under the tracks. In many instances it was necessary to buy extra property on which to divert a highway, in order to eliminate a grade crossing.

To operate the line at the outset to the best advantage, terminal facilities have been provided at Corinth and Haleyville. These comprise a coaling station, water station, turntable and the necessary tracks.

Traffic arrangements with other companies provide that improvements be made on their respective lines which will enable the Illinois Central to operate from Jackson, Tenn., into Birmingham, 220 miles, by providing only a few additional facilities at Jackson, where it now has freight terminals, and by building complete freight terminals in Birmingham. The passenger trains will use the new union station along with all other roads now entering Birmingham. The freight terminals in Birmingham consist of a city yard, a freight house and a three-story storage warehouse equipped with electric freight elevators, on the property bounded by First and Second avenues, and Thirteenth and Sixteenth streets; also an outer yard at East Thomas. The city yard is convenient to the wholesale district, as well as being centrally located for the entire city business.

The storage warehouse at the corner of Sixteenth street and First avenue was formerly the Brewer building. It is 196 ft. 6 in. x 111 ft. and has been entirely remodeled. It is three stories high and equipped with electric freight elevators. In remodeling, it was divided into three sections, separated by fire walls. The entire top floors and two-thirds of the second floor are used for the storage of freight. One-third of the second floor is used for offices. Two of the yard tracks extend into the building on the ground floor. The ground floor space fronting on the alley between First and Second avenues is for inbound freight. A one-story addition, 342 ft. long and 30 ft. wide, has been built along First avenue. This addition, with the portion of the first floor of the original building facing First avenue, constitutes the outbound freight house.

The city yard connection is made with the 'Frisco System at Ninth avenue and Twelfth street, and required the construction of 2,800 ft. of double main track in Twelfth street from Ninth to Second avenues laid with 85-lb. rails. The yard contains 7,000 ft. of track. At First avenue and Twelfth street a single-track connection, 700 ft. long, is made with the Birmingham Southern. The outer yard, containing 47,000 ft. of track, connects with the Frisco at East Thomas, through which suburb a single track 1.95 miles long has been built.

Other terminal facilities are located adjacent to the outer yard; they comprise a 20-stall engine house, a machine and repair shop, a store-room and a joint office building for the operating and mechanical departments. These buildings are all of brick. There are also a 75-ft. turntable, two Illinois Central standard 125-ton coal pockets, two standard concrete cinder pits, a 100,000-gal. water tank with steel underframe on concrete foundations, a 10-in. penstock, a pumphouse and at [illegible], and the necessary piping and fire protection.

The construction of the line was begun in February, 1906. The grading and track laying of the section in Mississippi was completed during October, 1907, and the Mississippi & Alabama Railroad was put in operation during December, 1907. The part in Alabama was put in operation February 1 of this year.

The line should have good traffic from the start. Birmingham is an important manufacturing center, the iron trade being its leading industry. The Alabama ores, because of the phosphorus and silicon they contain, are especially suited to the open-hearth process. The steel industry in Birmingham has grown to large proportions in the last 12 years. In the same period the manufacture of cotton goods has quadrupled. The resources of the country traversed by the new line include coal, timber and agricultural products, of which cotton is the most important.

Brush Creek Viaduct; View of Structure.

Among Austrian railroads, briquettes are used only by the State Railroads. They used, last year, 33,000 tons made at Pilsen, Bohemia, and 11,000 tons of English briquettes. The coal used during the same period amounted to 1,400,000 tons. The briquettes were of two sizes, one weighing 2.2 lbs. and the other 4.4 lbs., both kinds being oval. The price for the Bohemian briquettes was about $3.60 a ton and for the English briquettes, about $5.80.—*Consular Report.*

Combination Freight and Passenger Station and Division Offices; Corinth, Miss.

Russell Harding.

Russell Harding died in New York City on March 3, 1908, from complications following a surgical operation. He was an exceedingly able railroad man. His early railroad experience was largely on the Gould lines, to which he later returned as an executive, but his first great reputation was made under James J. Hill on the Great Northern, of which entire system he was made general superintendent two years and a half after going to the road as superintendent of the Dakota division. His rapid advancement on the Great Northern resulted in his return to the Gould lines, which he had left as Superintendent and Division Engineer, as Vice-President and General Manager of the St. Louis Southwestern, an office which carries with it the presidency of the St. Louis Southwestern of Texas. In this capacity he proved himself a bright and capable executive officer and after about two years was called to be executive head of the Missouri Pacific system as Vice-President and General Manager, his authority later including the Denver & Rio Grande and the Rio Grande Western. It was on the Missouri Pacific that Mr. Harding made his most notable record. The road during the four years in which it was in his charge made great advances both in prosperity and in physical condition.

Mr. Harding was born on July 24, 1856, at Springfield, Mass. At the age of 14 he entered railroad construction service; three years later he was office boy and paymaster for his father, who was then a contractor on the Portland & Ogdensburg, a road part of which now belongs to the Maine Central, and the Vermont division of which belongs to the St. Johnsbury & Lake Champlain. In 1873, when he was 17, he went to Texas and worked for three years in the engineering department of the International & Great Northern. During the three years from 1877 to 1880 he was station agent, operator and ticket seller on the same road. In 1880 he was appointed Assistant Engineer of Construction of the International & Great Northern, and during the next six years was Engineer of Construction, Superintendent of Construction, and Resident Engineer in charge of tracks, bridges and buildings. In 1886 he was transferred to the Missouri Pacific as Superintendent and Division Engineer of the lines in southern Kansas, with headquarters at Wichita Falls, a post which he held for eight years.

Russell Harding.

Then he went to the Great Northern as Superintendent of the Dakota division, with headquarters at Grand Forks, N. Dak. Eighteen months later he was appointed General Superintendent of the Western district, with headquarters at Spokane, Wash., and 11 months after that General Superintendent of the entire Great Northern system. This position he held for a year and nine months. In the fall of 1898 he became the operating head of the St. Louis Southwestern, and on March 12, 1900, of the Missouri Pacific. In August, 1904, he left the Gould lines to take active charge of the "Great Central Route," made up of the Pere Marquette, the Cincinnati, Hamilton & Dayton, and the Chicago, Cincinnati & Louisville, being elected President of the first and Vice-President of the other two. When this system was bought by J. P. Morgan & Company for the benefit of the Erie Railroad, Mr. Harding was elected Vice-President of the Erie also, a position which he held for only a month, when the Erie retired from its purchase of these roads. In November, 1905, he left active railroad service to act as an adviser of H. B. Hollins & Company, bankers, of New York, to whom his extensive and successful experience proved to be of great value. He was associated with this firm up to the time of his death.

Mr. Harding had both ability and an attractive personality. In his business life he was courteous and kind; by his employees he was beloved, and to the lowest of them he was accessible. The men on the Missouri Pacific, with whom and over whom he worked, he regarded almost as his children. One of his strong points as a railroad officer was the fact that during his whole career there was harmony between him and his employees. His gracious manner and courtly dignity were bound up with a kind heart.

His genial character was shown to best advantage in his home life. He and his wife, who survives him, were an unusually congenial and loving couple. He was also a devoted son. His loyalty and affection to his mother were outwardly evidenced during her lifetime by the fact that a week never passed without his writing to her.

His remains were taken to Portland, Me., and laid beside those of his father and mother at a point chosen by himself on the slope of a hill overlooking the railroad.

Corporate Management Versus Government Control.*

My experience in the conduct of independent and impartial examinations of books of account and affairs has covered many years and has been concerned with the federal government, state governments and city governments. It has covered the field also of railroad, street railway, light, power and other public service corporations. It has dealt with industrial corporations, the so-called "trusts." It has taken me into banks, trust companies and insurance companies; into educational and charitable institutions. I think I may say it has taken me pretty generally over the whole field of public and private busi- my eyes have seen, it is the unas- ness, and if I am to judge by what sailable truth that almost any one of the men who stand at the head of our great business institutions is far more competent to run the government, and would run it more economically, more wisely and more honestly than any of those who are in the business of running governments.

I know as a matter of fact that the management of our great properties is generally intelligent and economical, and that the management of our government bureaus is generally loose, irregular and frequently dishonest; and when I read the articles with which so many of our newspapers and magazines are filled nowadays, reflecting on the men whose genius is developing the country's resources, and when I hear the proposals of politicians, from the most eminent to the least, for the passage of laws to hamper and restrict the energies of these men on the theory that their integrity is open to suspicion, my mind inevitably brings up the contrast that I always observe between a corporation's way of doing things and a government's, as disclosed by their respective records and books of account.

For the purpose of this comparison, incompetency and dishonesty need not be separated. Putting them together it is my deliberate estimate, that, judged by the highest standards prevailing in the best conducted corporations, there is less than 10 per cent. of both among men in the management of corporations generally, and at least 90 per cent. of both among public office holders, and I base this estimate upon my experience as a public accountant.

The men entrusted with the management of the corporations are better fitted to administer the affairs of such corporations and to exercise judgment in matters concerning both the investor and the public which takes their product or utilizes their franchises, than are those men who hold public office qualified to fill even their own positions, much less to undertake administrative control over corporations. The facts that prove this do not deal with the mere matter of honesty and efficiency. The organization of a public bureau is much less compact, much less harmonious in its operation than the organization of a great railroad or a great industrial corporation. The men at the head of such business organizations, in practically every case are experts, working diligently, in harmony, and ready to work to the limit of their endurance, with full and direct control of their subordinates. On the other hand, nothing can be more notorious (the results are obvious to every public accountant who investigates) than the fact that in nine cases out of 10 the

*From an address by Elijah W. Sells, C. P. A., before the Certified Public Accountants of New Jersey.

head of a public department spends most of his time promoting his political interests, and the employees generally, protected by the civil service regulations, are looking to see how little rather than how much work they can get into their appointed short hours.

Curve Superelevation.

BY M. L. BYERS,
Chief Engineer, Maintenance of Way, Missouri Pacific Railway.

The constantly increasing speed of trains, together with the radical change in the height of the center of gravity of the locomotive, due principally to the introduction of the wide firebox, has caused the subject of superelevation of curves to assume greater importance than was formerly the case.

The usual basis for determining the amount of superelevation is a formula in which the factors are the radius of the curve and the speed of the train. If it were possible to regulate the speed of trains so that all passed around the curve at the same speed, this formula might be practically satisfactory; on the contrary, however, it is always necessary to make the superelevation a compromise between the speed requirements of various trains. If the curve is prepared to exactly suit the speed of the fastest train, such as the limited mail train when it is several hours late, then difficulty is experienced in connection with the operation of the slow freight trains. If, on the contrary, the curve is elevated to suit the speed of the slow freight trains, then the track may be absolutely dangerous for unrestricted high-speed traffic and it may be necessary to place restrictions on the speed at which the curve can be used. It becomes important, therefore, to determine the limitations of safe operation and also to understand the practical effects on curved track of the various forces encountered in connection with train operation thereon.

Some years ago Mr. J. C. Bland, Engineer of Bridges, of the Pennsylvania Lines West of Pittsburgh, proposed to apply to the solution of the problem of superelevation of curves the fundamental principle employed in the design of masonry structures, namely, that the resultant of all of the forces must, for safety, lie within the middle third of the structure. Translating this into terms of track conditions, it means that the resultant of the centrifugal force and the weight of the locomotive (or car) must fall within the middle third of the space between the two rails of the track, the proper speed for a given elevation, or the proper elevation for a given speed being that which will cause the resultant to fall in the center of the track. From these assumptions we may derive formulae as follows:

Let G = Gage of track in feet (assumed in tables as = 4 ft. 9 in.)
- E = Superelevation of outer rail in feet.
- E_1 = Superelevation of outer rail in inches.
- V = Velocity of train in feet per second.
- V_1 = Velocity of train in miles per hour.
- F = Centrifugal force in pounds.
- W = Weight of locomotive in pounds.
- R = Radius of curve in feet.
- H = Height of center of gravity of locomotive in feet.

Proper Speeds and Elevations.

Construct Fig. 1 so that *df* shall represent the gage of the track G, *fe* the superelevation E; *bc* the horizontal line from the middle point *c* of the line *df* will represent the centrifugal force F, and the perpendicular *ab* the weight W of the locomotive, such that the resultant shall be perpendicular to the track and shall pass through the center point *c*.

In the similar right triangles *abc* and *def*, we have

$$ab : bc :: dc\ (= df, \text{ approx.}) : ef,$$

or W : F :: G : E

$$\text{or } E = F\frac{G}{W}$$

$$\text{but } F = \frac{W}{32.2} \times \frac{V^2}{R} \text{ (= Centrifugal force)}$$

Substituting we have

$$E = \frac{W}{32.2} \times \frac{V^2}{R} \times \frac{G}{W} = V^2\frac{G}{32.2\,R}$$

$$\text{or } V^2 = 32.2\,R\frac{E}{G}$$

$$\text{or } V_1^2 = 1.2\,R\frac{E_1}{G} = R\frac{E_1}{4} \text{ when } G = 4.75$$

$$V_1 = \sqrt{R\frac{E_1}{4}} = \text{Proper speed for a given elevation and curvature} \quad \text{(A)}$$

$$E_1 = \frac{4V_1^2}{R} = \text{Proper elevation for a given speed and curvature} \quad \text{(B)}$$

Maximum Safe Speed.

In Fig. 2, lay off the horizontal line *al*, and from any point *b* lay off *be* so that *be* shall represent the gage of the track and the perpendicular *em* to the line *al* shall represent the superelevation of the outer rail. From *c*, the center line of the track, erect a perpendicular to *be* such that *cd* shall represent the distance from the top of rail to the center of gravity of the locomotive, the point *d* representing such center of gravity.

Lay off on *be* the point *f* such that it shall lie on the middle third of the track and, consequently, that $cf = \frac{1}{6}$ gage of track $= \frac{G}{6}$.

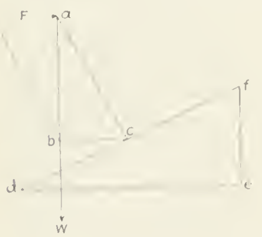


Fig. 1.

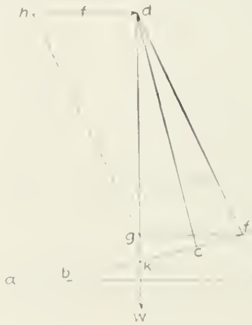

Fig. 2.

Fig. 3.

Draw *df*, and draw *fg*, a horizontal line intersecting at *g* the vertical line *dg* let fall from *d*.

Draw *gh* parallel to *df*.

If *dg* represents the force of gravity W, equal to the weight of the locomotive, acting through its center of gravity *d*, then will *dh* represent the centrifugal force F, acting also through the center of gravity *d*, of the locomotive, such that the resultant of these two forces shall pass through the point *f* on the edge of the middle third of the track, and being the maximum safe centrifugal force under the conditions.

As it does not involve a material error we will assume that

$$be = bm\ (= G)$$
$$cd = kd\ (= H)$$
$$fg = fk.$$

In the similar right triangles *bme* and *dck*

$$bm : em :: cd : ck$$

$$G : E :: H : ck, \text{ or } ck = H\frac{E}{G}$$

As $cf = \frac{G}{6}$, we have

$$kf\ (= fg) = ck + cf = H\frac{E}{G} + \frac{G}{6} \quad (1)$$

In the similar triangles *bme* and *fgk*,

$$bc : cm :: fk : kg$$

$$G : E :: \left(H\frac{E}{G} + \frac{G}{6}\right) : kg$$

$$\text{or } kg = E\,\frac{\left(H\frac{E}{G} + \frac{G}{6}\right)}{G}$$

$$dg = dk - kg.$$

Substituting for *dk* its value H and for *kg* its value in (1)

$$\text{we have } dg = H - E\,\frac{\left(H\frac{E}{G} + \frac{G}{6}\right)}{G} = H - \frac{E}{G}\left(H\frac{E}{G} + \frac{G}{6}\right). \quad (2)$$

If, in the right triangle *dgf*, we represent *dg* as equal to W, the weight of the locomotive, and fg as F, the maximum allowable centrifugal force, we have

$$dg : gf :: W : F$$

$$\text{or, } F = W\frac{gf}{dg} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (3)$$

Substituting in (3) the values of dg and gf in (2) and (1) respectively, we have

$$F = W\frac{gf}{dg} = W\frac{\left(H\frac{E}{G} + \frac{G}{6}\right)}{H - \frac{E}{G}\left(H\frac{E}{G} + \frac{G}{6}\right)}$$

But $F = W\frac{V^2}{32\frac{1}{6}R}$ ($32\frac{1}{6}$ representing g, the force of gravity).

Eliminating F, and dividing through by W, we have

$$\frac{V^2}{32\frac{1}{6}R} = \frac{\left(H\frac{E}{G} + \frac{G}{6}\right)}{H - \frac{E}{G}\left(H\frac{E}{G} + \frac{G}{6}\right)} \text{ or, } V^2 = \frac{32\frac{1}{6}R\left(H\frac{E}{G} + \frac{G}{6}\right)}{H - \frac{E}{G}\left(H\frac{E}{G} + \frac{G}{6}\right)}$$

$$\text{or, } V_1^2 = 14.95\,R\frac{\left(H\frac{E_1}{57} + 0.8\right)}{H - \frac{E_1}{57}\left(H\frac{E_1}{57} + 0.8\right)}$$

But, as E_1 will seldom or never be greater than 12 in., and as H will seldom or never be greater than 10 ft., the expression $\frac{E_1}{57}\left(H\frac{E_1}{57} + 0.8\right)$ will never exceed 0.61, or say, 6 per cent. of H, and so may be neglected, causing the formula to become, for practical use

$$V_1 = \sqrt{R\left(\frac{E_1}{4} + \frac{12.0}{H}\right)} = \text{Maximum safe speed in miles per hour} \ldots\ldots\ldots\ldots (C)$$

If we assume that the locomotive may stop on the curve, we have for that condition $V_1 = 0$, whence $\frac{E_1}{4} = -\frac{12.0}{H}$, or, $E_1 = -\frac{48.0}{H}$ = maximum safe depression of low rail. ....(D)

Determination of Height of Center of Gravity of Locomotive.

The height of the center of gravity of a locomotive can be determined experimentally as follows:

1. Weigh the locomotive, which should, for the purpose, contain the maximum amount of water in the boiler.

2. Place the locomotive so that the wheels on one side are on the track scale in such position that they are some 6 in. higher or lower than the opposite wheels; measure carefully the exact difference in elevation of the two sets of wheels and obtain the weight S, carried by the wheels on the scale. The forces acting are as shown in Fig. 3, where a represents the center of gravity of the locomotive, ac the line of action of the weight of the locomotive through its center of gravity, and S and S' the reactions of the supports of the two sets of wheels.

In the similar right triangles abc and dfe we have $ab : bc :: dc : fe$ (1)

in which $de = G = df$ (approximately, since ef is small)
$ab = ac$ (approximately, since bc is small)
$cf = E$ = superelevation,
and $ab = H$ = height of center of gravity of locomotive.

Substituting in (1), we have

$$H : bc :: G : E$$

$$\text{or } H = bc\frac{G}{E}.$$

If we let W = weight of locomotive, acting along the line ac, and S and S_1 the portions of the loads carried by the two rails c and d respectively, then, taking the origin of moments at d, we have

$$S_1 \times de = W \times dc, \text{ or } dc = S_1\frac{G}{W}.$$

Since $de = G$

$$dc = bd - bc = \frac{G}{2} - bc$$

Substituting, we have

$$S_1 \times G = W\left(\frac{G}{2} - bc\right)$$

$$bc = bd - dc = \frac{G}{2} - S_1\frac{G}{W}$$

$$H = \left(\frac{G}{2} - S_1\frac{G}{W}\right)\frac{G}{E} = \frac{G^2}{E}\left(\frac{1}{2} - \frac{S_1}{W}\right) =$$

Height of center of gravity of locomotive. (E)

Lateral Movement of Track Due to Centrifugal Force Exceeding Frictional Resistances Between Tie, Ballast and Subgrade.

Superelevating the outer rail of a curve does not destroy the centrifugal force; it merely transfers its effect to the track, and, in order to prevent motion resulting from the action of this force, the frictional resistance between the different layers of the ballast or subgrade, must be equal to, or greater than, the centrifugal force. When the speed is greater or less than that given by formula A, there is also a tendency for the tie to slide on its bed of ballast.

Let F = Centrifugal force = $\frac{W}{32\frac{1}{6}} \times \frac{V^2}{R}$

F_1 = Frictional resistance = cW, where
c = Coefficient of friction between tie and ballast, etc.

For safety, F should probably not exceed $\frac{c}{2}W$

$$\text{Then } \frac{c}{2}W = \frac{W}{32\frac{1}{6}} \times \frac{V^2}{R}$$

$$\text{or } V = \sqrt{16\,Rc}$$

Velocity which will cause sliding of track, ballast or subgrade. (F)

Let us investigate the case of R = 640' (a 9 deg. curve, about).

Then $V = \sqrt{10{,}240\,c}$.

For $c = 1$, V = 100 ft. per second = 70 mi. per hour = safe speed.

$= \frac{1}{2}$ = 71 ft. per second = 47 mi. per hour = safe speed.

$= \frac{1}{4}$ = 50 ft. per second = 33 mi. per hour = safe speed.

So the danger is not one to be entirely neglected; it is practically evidenced by the difficulty experienced in maintaining, in good line and surface, curves used at widely varying rates of speed.

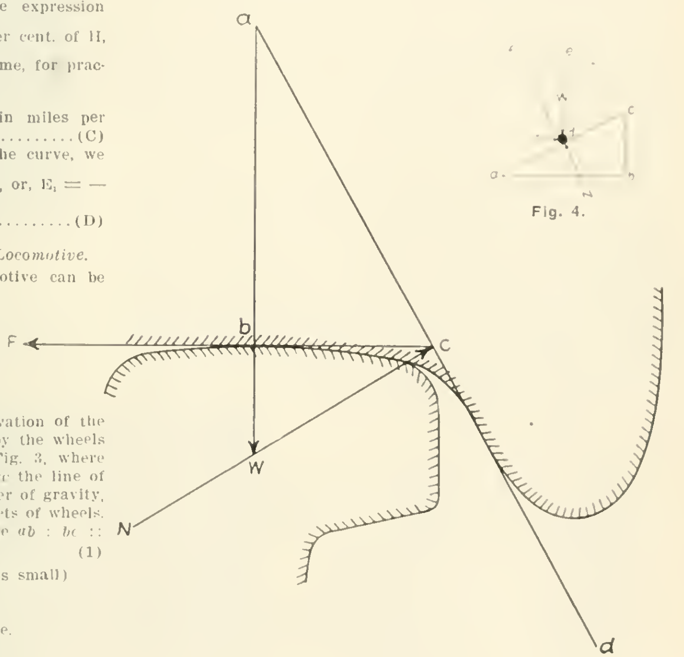

Fig. 4.

Fig. 5.

Lateral Movement of Track Due to Excessive Superelevation.

The slowly moving train is in the position of a weight on an inclined plane, where the three forces, W, N and T produce equilibrium (see Fig. 4).

From which we obtain $ab : bc :: de : ef$
or, $G : E :: W : T$

$$T = W\frac{E}{G}$$

Figure 4.

But the horizontal component T should not, for safety, exceed $\frac{c}{2}W$, so that $W\frac{E}{G} = \frac{c}{2}W$

$$\text{or } E = G\frac{c}{2} = 2.37\,c = \ldots\ldots\ldots\ldots (G)$$

For $c = 1$ E = 2.37 ft.

$= \frac{1}{2}$ = 1.18 ft.

$= \frac{1}{4}$ = 0.59 ft. = 7 in., which is a lower limit than that usually required to keep inside the middle third the resultant of all the forces for the fast moving train.

Wheel Flange Mounting Rail.

Fig. 5 shows the relative position of the wheel and rail when the flange is crowding the side of the rail. It is evident that one effect of centrifugal force exerted on the wheel will be to cause it to rise and that sufficient pressure would enable the wheel to mount the rail.

As the force F is resisted by the normal to the line *ad*, the vertical component resulting must equal W, the weight of the wheel before the wheel can rise, this condition will result under the following relation:

$$F : W :: ab : bc$$

$$F = W \frac{ab}{bc}$$

but, in practice, $ab = 2bc$,

which gives $F = 2W$.

But, $F = W \frac{V^2}{32^1/_6 R}$

Substituting, $2W = W \frac{V^2}{32^1/_6 R}$

or $V^2 = 64^1/_3 R$

$V = 8 \sqrt{R}$ approx. or $V_m = 12 \sqrt{R}$

For a 6° curve, $V = 12 \sqrt{955} = 360$ miles per hour approximately.

Evidently under ordinary conditions there is no danger of accident on this score; however, where an engine is improperly counterbalanced and running at high speed it is known that at times there is almost no pressure exerted by the wheel on the rail and it would seem possible that, under these conditions, a case might arise where the wheel will be lifted up and forced over the rail by the centrifugal force.

General Remarks.

All formulas in regard to the proper superelevation and safe speed for curved track are more or less open to the criticism that they are far more accurate theoretically than the data upon which their practical use is based.

All track, and especially curved track, requires more or less constant attention in order to preserve a reasonable degree of accuracy of line and surface. Inasmuch as any deviation from the true circular curve means a sharper resultant curve, errors in alinement produce the same effect as the uneven superelevation of a circular curve, and conversely, errors in uniform superelevation of a circular curve produce the effect of the curve being out of line.

When curves are not spiraled it is necessary to commence the encountered and the tendency of course is toward overturning the locomotive in the direction of the high rail. Naturally perfect results cannot be obtained under this condition and it has become the general practice to spiral all sharp curves.

It is known from shop tests of locomotives that with some engines at high speeds, due to imperfect counterbalancing, there are times in the revolution of the driving wheel where there is absolutely no pressure on the rail from that wheel, the pressure having been transferred to the opposite driver which carries an abnormal load for the instant. This, of course, introduces a new factor in determining the resultant of the various forces at work on curved track and with a locomotive running at a speed higher than that corresponding to the elevation of the curve serious results might in some case be produced.

The long rigid wheel base of some locomotives has, of course, the effect of considerably increasing the pressure of the flange against the head of the rail.

General Conclusions.

1. It is undesirable to use a greater superelevation than that which will permit any locomotive to stop with safety on the curve.

2. Curve tables which state not only the proper elevation for a given speed, but also the safe maximum speed for a given elevation for the locomotive with the highest center of gravity in use on the railroad, should be used.

3. All curves should be given such superelevation as will make them safe for the maximum speed at which a fast train will be apt to use them, or special instructions restricting the speed should be placed on the time cards.

4. All curves of 1 deg. or over and used by trains at high speed should be spiraled and the change from zero to maximum superelevation should occupy the limits of the spiral.

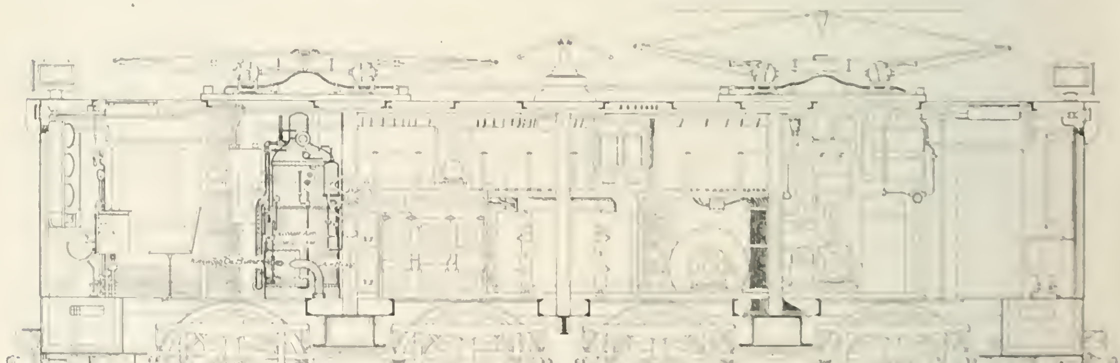
5. The ill effect of high center of gravity, long wheel base, and inadequate counterbalancing of locomotives, should be kept in mind with a view to minimizing their undesirable results on the track.

6. As the superelevation selected is usually a compromise between opposing speed conditions, the extent of the variation of the extreme conditions from the compromise should be kept in mind and the character of the track regulated accordingly.

Train Heating on Electric Divisions of Steam Railroads.

BY CHARLES M. RIPLEY.

The establishment of great passenger terminals in New York City, involving extensive tunnel systems and other improvements looking not alone to the more economical and expeditious handling of traffic, but also (and in a measure primarily) to the minimizing



Locating of Heating Apparatus in New Haven Electric Locomotive.

superelevation on the straight line some distance in advance of the point of the curve, a very general practice being to place one-half of the run-off on the straight line and one-half on the curve. The result of this practice may be illustrated as follows:

Assume a curve with 6 in. of elevation, then the elevation at the point of curve will be 3 in.; just before reaching the point of curve the effect produced is that of encountering on a straight line a spot where one rail has become 3 in. out of surface, this would be regarded as a dangerous condition inasmuch as it tends to overturn the locomotive in the direction of the low rail; immediately upon passing beyond the point of curve on to the curve, the condition of a curve with but one-half of the proper superelevation is

of accidents due to the obscuration of signals by reason of smoke in the tunnels, has led to the employment of electric traction within the terminal stations and for a distance of several miles along the right of way. The adoption of electric traction at once gave rise to the problem: How shall the passenger coaches be heated after the steam locomotive is supplanted by the electric locomotive which is to haul the incoming train a distance of several miles, and, conversely, must haul the outgoing train an equal distance before it can depend upon steam from the steam locomotive to heat its coaches?

In the solution of this problem economy as well as efficiency must be studied. To install obsolete stoves for temporary use in the individual coaches, a method of heating as ineffective as it is fraught

End View of Heating Apparatus.

with danger, was not to be thought of. To heat the cars by electricity, while perfectly feasible, involves not only the expense of equipping every coach with electric heating apparatus, in addition to the steam pipes which would be in use during the major portion of the run, but also involves the considerable loss of efficiency always accompanying heating by electricity.

Side View of Heating Apparatus.

The mechanical engineer has been called in to give assistance to the electrical engineer in this heating problem, and there have been devised two methods now in successful operation; one adapted to the rolling stock of the New York Central and the other to that of the New Haven.

So far as these methods are identical, they may be briefly described as follows:

In the electric locomotive is installed a vertical boiler, which, as soon as the steam locomotive is unhooked and replaced by the electric motor, is connected to the regular piping system of the train. Thus, with virtually no interruption steam heat is supplied to the coaches, regardless of the change in the mode of traction, without necessitating any addition to the regular heating apparatus of the coaches. The fuel for this boiler is ordinary commercial fuel oil.

The photograph shown herewith was taken in the inside of one of the New York Central electric locomotives, and shows the oil-fired auxiliary steam boiler now used in heating trains on the electric division. The apparatus consists of a multi-tubular boiler mounted on a cast iron firebox lined with brick. The boiler has 800 copper tubes ½ in. in diameter and fitted with steam and water gages, try cocks, safety valve set to 80 lbs., blow-off connection and automatic feed-water regulator.

Water and oil are carried in two steel tanks under pressure. The pressure of the water is 135 lbs. per square inch, which is sufficient to supply the boiler without employing a feed pump. The oil is stored at a pressure of 25 lbs. per square inch. The air for supplying this pressure is taken from the main reservoir in the locomotive air-brake apparatus and is reduced to feed the oil tank by means of a regulating valve.

The water tank is of 200 gal. capacity and is filled by attaching a hose on either side of the locomotive and opening the vent valve on the top of the tank. The water is then forced up into the tank by the pressure on the mains. Try cocks are fitted to test the height of the water in the tank. The oil tank, which is 40 gals. capacity, is fitted with two glass gages to enable the operator to ascertain the amount of oil contained.

Water is led to the boiler through an air trap. In the photograph the screen is shown thrown back to better show the apparatus under the boiler. The Kirkwood oil-burning system manufactured by Tate, Jones & Co., Inc., of Pittsburgh, Pa., which supplies the fuel for the boiler, is arranged to use either air or steam to atomize the oil. The change is made from one to the other by means of a three-way cock. Air is used to start the fire and steam when boiler pressure is reached.

The main difficulty in connection with oil as a fuel is to obtain complete combustion of the ordinary commercial fuel oil. In order to obtain this complete combustion of such oil it must first be completely atomized. To atomize each gallon of oil there is required approximately 60 cu. ft. of free air at a pressure of 15 to 25 lbs. per square inch. There must then be supplied by one or the other of two means, approximately, 1,440 cu. ft. more to give sufficient oxygen to the flame.

The New York Central apparatus is arranged to allow considerable space around the nozzle of the Kirkwood burner, through which air from the surrounding atmosphere is drawn into the combustion chamber by the force of the injected atomized oil. This method of drawing in the 1,440 cu. ft. of air has been known to result in a noisy burner at times, and it has been open to the objection that it is difficult to control the amount of air drawn in. It is also obvious that the use of a greater amount of compressed air than is necessary for atomizing is required in order to draw in a sufficient amount of the surrounding air. This method makes out with compressed air any deficiency in the quantity of surrounding air drawn in. A decided advantage, however, in this method is that it makes unnecessary the expense of installing any extra blowing apparatus and drive for same, both of which take up considerable room in the rather confined space of the electric locomotive.

The electric system of the New Haven road is rather unique in the field of American electric traction, inasmuch as transformers are used in the locomotive to reduce the voltage of the alternating current supplied. The advisability of cooling these transformers by air needs no comment; an air-blast apparatus has been used both to cool the transformers and to assist in burning the oil. The accompanying drawing illustrates a New Haven electric locomotive, in which a Kirkwood oil burner is installed. A low-pressure fan blast at from 3 to 4 oz. pressure is used for blowing into the combustion chamber the necessary air for combustion. Thus compressed air is needed only for atomizing the oil.

This scheme cuts down the amount of compressed air used and increases the efficiency of the fire. It enables the operator or fireman to completely control the nature of the fire by varying the quantity and pressure of the air pressure blast for combustion. The oil and compressed air for atomizing is regulated by one lever, and the ratio between the oil and the compressed air for atomizing always remains at a constant point, which has been found to be the best for complete atomization. The fireman or operator cannot make an inefficient or smoky fire, the regulation of the air blast varying only the nature of the fire from a soft and non-oxydizing flame to a hot concentrating fire.

Both the New York Central and the New York, New Haven & Hartford railroad heating systems are simple to operate, and no extra men are required in the cab to operate them, this work being part of the duty of the fireman.

The Ocean Carrier.

BY J. RUSSELL SMITH, PH.D.

X.

LINE TRAFFIC IN THE UNITED STATES COASTING TRADE.

The United States coasting trade has always been composed of two elements and the line traffic in its service has been the sport of at least two circumstances.

The two elements of the coasting trade are, first, the local exchanges between the various parts of the United States, which are ever growing; and second, the collection of produce at convenient places for export, and the distribution of imports from greater to lesser ports. This foreign trade factor is an uncertain one, having fluctuated greatly from time to time in our history. This fluctuation arises, and with it the changes in line traffic, from the differing degree of development of our line traffic from the various American ports to foreign ports. If there are many ports on an equality of foreign connection there is little need for collection and distribution among them in connection with the foreign trade. If some ports have a great predominance in foreign line connections the coasting trade will center at such ports and develop largely.

The second factor that has influenced the line traffic, has been the growth of the American railroad system. At one time the coasting vessel was almost the only means of getting from port to port. Then came the railroad which took away from the coasting vessel all possible claim to being a fast line connecting the various parts of the United States. This left the coasting lines only such traffic as they could snatch from the competition of the speedy railroads above and from the slower and cheaper schooner and latterly the yet cheaper barge below.

In its origin, coasting line traffic is closely akin to the ocean line traffic as was pointed out in the article on the "Origin of Line Traffic." In the Colonial time the coasting trade was light and with the small vessels of that day each colony traded direct with the mother country, more directly, indeed, than do many of the American commonwealths at present. In the era between the Revolution and the War of 1812, the same conditions prevailed and one port was almost as good as another. This was the period of greatest democracy among American seaports. New Orleans, Charleston, Savannah, Baltimore, Philadelphia, New York, Boston and Salem were more nearly on an equality than they ever have been since. The difference in their population was surprisingly small. Each had that breadth of sea connection which the enterprise of her merchants brought; and it was a wide range, as these cities, with the exception of Salem, were the metropoli of states which in the days of the confederation were not only politically independent, but also commercially independent and isolate except for the merchant ship that roved alike to foreign and to coasting ports.

The close of the war of 1812 changed all this. New York straightway, upon the declaration of peace in December, 1815, became the center of packet lines to Europe, especially Liverpool the great market for cotton and other American produce. By 1820, these lines had multiplied until there was a weekly sailing on regular schedule and the ships were the fastest on any sea. These New York packets carrying mail, passengers and fast freight straightway put into our coasting trade the stimulus for regularity that ripens into line traffic. If the New York packet left regularly it was an advantage to reach New York just before she started, and it was desirable to get the European mail and passengers and goods started down the coast at regular intervals so the New York lines were really the mother of the coasting line services that sprung up promptly upon its inception.

The New York foreign connections had an influence not measured solely by the founding of coasting lines, for they served also as a magnet to draw to New York the chartered vessels from the South Atlantic ports. This influence was not alone in producing this result, for the claim was also advanced that the New York merchant gave better credits and other inducements than were to be obtained further south. Transportation, however, was no weak force in this drawing influence, and the decade 1821-31, the ten years following the establishment of New York's weekly service to Liverpool, saw a marked shifting of foreign trade. The country at large and particularly the south was prosperous. The foreign trade of the port of New York increased 100 per cent. in eleven years following 1821, and that of Virginia with its tidal estuaries declined two-thirds, and so did that of South Carolina. This, however, did not mean a declining commerce, despite the alarm and the investigations by commission and convention. It was merely a growth in the coasting trade by which New York absorbed the foreign trade of smaller ports that had dealt directly with Europe in the epoch of the merchant carrier 20 years before.

New Orleans was far enough away not to be so greatly influenced by New York's maelstrom and retained her commercial independence all through the packet ship epoch and practically down to the Civil War. The gulf packet lines went to New Orleans as did those of the Atlantic to New York and to a lesser degree to Boston. Until 1860 Galveston traded entirely through New Orleans, and the connection of New York and New Orleans was rather slow in founding. The reasons of this were that New Orleans was rather independent of New York in the foreign trade, and New York was rather independent of New Orleans in the coasting trade through her ability to secure cotton, lumber, meat and grain and naval stores at nearer ports.

From 1820 to 1840 there was a large development of coasting packet lines along the American coast from Portland, Maine, to New Orleans. The earliest of these lines appears to have been in 1820 from New York to the southern ports. Baltimore had had a line to Norfolk as early as 1785, but this can scarcely be called a coasting line because it was entirely on inland waters. In 1826 Baltimore had its first regular service by sea, a line to Savannah and New Orleans.*

Upon the founding of steam connection between New York and Savannah in 1848 there were six packet lines connecting these two ports.†

The difficulties of sail navigation on such a windy, stormy and dangerous coast as that of the American Atlantic made the line service of packets, at best, but irregular and undependable. Efforts were early made to put steamers in the coasting service, but the steamer in its origin was a river craft and its first successes in giving that line traffic with a schedule having an arriving as well as a departing end, was in that part of our shore waters which partly resembles a river and which is also adjacent to the Hudson the original home of the steamboat.

Long Island sound, being a kind of compromise, half sea, half bay, was a good place for the steamer to experiment with line traffic on salt water. In its traffic development, Long Island sound was a sort of offshoot from the Hudson river, the first home of the steamer. For at least 40 years the same boats were used interchangeably on the two bodies of water. During the war of 1812, boats built for the Long Island route to New Haven were unable for fear of the enemy to run on the sound and were put on the Hudson in 1811. In March, 1818, the two steamers built for the sound began a service from New York to Norwich, the steamers connecting with each other at New Haven, one attending to each end of the route. In 1822 they were withdrawn from the New York, New Haven and New London route, because of the retaliatory law of Connecticut against the New York steamboat monopoly of Fulton, and sent instead to Providence and Newport. This action of the New York and Rhode Island Steamboat Co. was regarded as hazardous in the extreme, because of the dangers of going into the open sea to round Point Judith. The venture was a success, and the forbidden Connecticut traffic was picked up at Long Island points whither it was taken in connecting sailing packets. The Providence line kept on and the two trips each way per week in 1822 were changed to four trips per week in 1825. In November, 1821, the New Haven Steamboat Company was organized by the shareholders of the packet company running between New York and New Haven and steamers were put on the route.

The efforts of sailing vessel owners to get a tax laid upon steamboat passengers failed in the sound states, but a new line to Providence in 1827 was a more serious blow to the finances of the pioneer company, because it cut the fare down from $10 to $6. In 1831 it was cut to $1, then to $3, but the next year it was $7 by each line.

By this time, line traffic by steamers was well established on the sound, and it has continued from that day to this. In 1835, when the railroad connecting Providence and Boston was completed, the sound steamers established schedule connections which were as good as those of the trains with which they connected, and such connection by high-class steamers has been continuous, although there are freight lines having no such scrupulous schedule connection with the railroads.

The thorough and efficient line organization of the steamers on Long Island sound in 1830 was far different from the situation on those routes that had to stand the full fury of the Atlantic

*"Chronicles of Baltimore," J. T. Scharff, p. 420.

†Morrison's history "American Steam Navigation," p. 448.

The 20 years 1818-1838 were a time during which the steamer was evolving from a river craft to a sea craft and the short journeys along the Atlantic coast tempted men to try the coasting trade before the ship was ripe for it. For five years beginning in 1820 the steamer "Robert Fulton" plied unprofitably on the route from New York to New Orleans via Charleston and Havana. At the end of this time she was converted into a sailer. Between 1836 and 1839 steamers were run from New York to Charleston and from Baltimore to Savannah, and another attempt was made on the route to New Orleans. Two terrible disasters, coming in the midst of the great financial depression, caused all these attempts to be given up by 1839; and just at the time the Cunard and other companies were succeeding with their steamer lines on the Atlantic, the coasting lines in the open sea came again to consist entirely of sailing packets. In 1842, there was no steam coasting line outside of protected shore waters, but the North Atlantic steam lines with their previously unknown precision made louder the demand for relief from the uncertainties of packet, and 1846 was the real beginning of steam service and therefore of regular line service between New York and Charleston. Spofford & Tiletson, shipping merchants of New York, contracted to carry the United States mail, and despatched the first steamer in September. In 1848 there were similar steam mail contracts to Savannah and New Orleans. The service to Norfolk, which had been tried and given up in 1835, was permanently established in 1844 by the founding of the Clyde Line to Baltimore. Richmond was connected with New York in 1835 and Boston with Philadelphia in 1852. For ten years, beginning 1850, Philadelphia was actively connected with New York by the outside route.

The Quaker City, 1854; 1,143 Tons. Regular Line to Charleston.

The route affording the most excitement during this period was that to the Isthmus of Panama. The gold rush of 1849 made plenty of travel in that direction and put a high price upon transportation in that direction. Lively competition ensued for the prize, sometimes the vessels stopped at Charleston or Havana or New Orleans, or all three, or none of them. Sometimes there was one line, sometimes there were several. The keenest competition was that between the Pacific Mail and the United States Mail Company, whose rivalry wound up in a consolidation in 1850 of the service to Chagres in the hands of the United States Mail Company.

In March, 1852,† there plied from New York seven lines of coasting steamers, one to Philadelphia, two to Norfolk, two to Charleston, one to Savannah and one to New Orleans via Havana. There were no less than ten diligent advertisers of lines to the Isthmus of Panama making connection for the Pacific at Chagres or San Juan de Nicaragua. Some of these lines had only one steamer, and during this month of March, 1852, a total of 20 steamers left New York in the San Francisco trade, while 30 departed on the seven lines of the coasting trade, Charleston being the destination of nearly one-third of the 30,000 gross tons involved. The height of the San Francisco rush was probably in February, 1849, before the isthmian routes were in full operation; during that month 22 sailing vessels left New York for California with 2,000 passengers. There were ten from Boston and other ports in proportion.

†*Railroad Gazette*, Aug. 15, 1902, p. 638. An excellent and thorough article by Ray Morris, to which the author is much indebted.

The date 1850 may be taken as marking the firm establishment of steamer lines on the transatlantic service, and it also marks their thorough establishment and extension in the coasting trade. In this work perfection followed quick upon the heels of installation, for the fifties mark the period of highest relative development of the coasting trade. The Collins and Cunard liners raced across the Atlantic to and from New York, and the wealthy, luxurious southerners had no such service from their own ports to Europe. They must connect with New York, but the railroads were in that day a poor dependence for they were new, rough and bad, breakdowns were common, changes were frequent, sleeping cars were practically unknown. What roads there were in the south commonly connected the interior with the nearest port rather than with the North. Hence the traveler who could sought the coasting steamer to New York whether he were bound to Europe or only to the northern states. The coasting steamers that went to Charleston and Savannah were next only to the Collins line in comfort and luxury, and they were as fast as the coasting lines have ever been until very recently. Their passenger traffic was extensive.

The Civil War, of course, entirely demoralized the trade and transportation with the south for a time. During a few years succeeding the war, however, the lines resumed their antebellum importance. The railroads were still inadequate and the passengers still sought the steamer. At the same time there was general prosperity and a great traffic movement that brought shipping profits and led to the creation of many lines. There were in March, 1872, 23 deep water lines in the place of the seven lines in 1852 at New York, besides smaller lines and sound and river boats. During this month these lines despatched 117 steamers with about four times the tonnage total of 1852. The average tonnage was almost exactly 1,000 tons per vessel.

The predominance of New York in the transatlantic line traffic and consequently in the coasting lines caused it to become quite largely the clearing house for the coasting trade. Go to New York and transfer was the easiest way. From the Civil War onward that city had steam connection with the coast of Maine at Portland, with the leading gulf ports, and with the chief ports between. In 1859, the Boston Chamber of Commerce tried to improve the connections of its port, because the only way from Boston to points below Baltimore was by sailing vessel direct or by transshipment at New York. In 1854 the Merchants & Miners' Transportation Company, a combination of Maryland and Massachusetts capital, had started service which connected Baltimore with Boston without making a New York stop, and the agitation of commercial interests in Boston in 1859 had the service which also included Providence extended to Savannah in addition to the two Chesapeake ports of Baltimore and Norfolk. Excepting the interruptions due to the war, this service has been steadily maintained, and is one of the few important services that does not touch New York, and the only one that steams regardlessly past that port. The other services on a par with this have been the Boston services to Maine and the Canadian Maritime Provinces and the Philadelphia lines to Savannah and Florida points, but these Philadelphia lines have not been steadily maintained.

Steamer Texan. The American-Hawaiian Line Connects New York and San Francisco via the Tehuantepec National Railway.

The decade following 1873 marks an epoch in the coasting line traffic. The country then suffered from general hard times with the accompaniment of reduced traffic, loss of dividends, failures, reorganizations, consolidation and forced economies. For the coasting lines, this was accentuated by the development of the railroads into effective competition for through passengers, mail and fast freight. This loss threw the coasters into a distinctly secondary position. They could not compete with the railroad in these respects, and it was recognized as being of no use to try, so the speed did not increase. Greater efficiency was sought in a larger and more economical vessel. The passenger traffic had changed from the general body of travelers to those persons who, for special reasons, wanted a slow sea journey. This brought about a considerable summer traffic and a negligible winter traffic.

These changes in condition recorded themselves in the statistics of the traffic. In March, 1882, the 23 New York lines of 1872 had become 11, the 117 clearances had become 109, but the average size of steamer had increased about 50 per cent. During this period, also, the railroads which had dealt such competition, also began to annex the steamer lines, the best examples of this being the Morgan Line to New Orleans and the Savannah Line. Ten years later, these were the most efficient lines on the coast.

From 1880 to the present there have been surprisingly few changes in the coasting line traffic, other than in its increase in quantity. The departures from New York in the month of March have been approximately as follows: 1872, 120,000 tons gross, 1882, 160,000, 1892, 280,000, 1902, 410,000. In 1872 Boston led by being the destination for over a sixth, with Norfolk and Charleston closely following. In 1882 Norfolk had a fourth with Boston and Charleston considerably in the rear. Ten years later Norfolk was still first with more than a fifth, and Savannah and New Orleans following. In 1902, Norfolk led with a fifth of the whole, with New Orleans and Boston pushing it for first, and crowding each other for second place.

This growth of tonnage is essentially for the freight service, as passengers and speed have been steadily declining in the manager's mind, since the loss to the railroads of the mail service that occurred 30 years ago. Exceptions to this should be made for the Morgan Line (Southern Pacific), which connects New Orleans with New York in five days, and is a link in a transcontinental route, and also of the passenger service of the Old Dominion Line to Norfolk and the much advertised passenger line to Maine through Long Island sound. The extensively patronized passenger boats of the Long Island sound routes are not included in the above cited figures of New York traffic which are for deep sea vessels only.

Mention should also be made of the regular services that have been maintained throughout nearly the whole of the last hundred years between New York and Philadelphia by sea, and between Philadelphia and Baltimore via the canals during the season of open navigation. The Chesapeake bay with lines connecting Norfolk with Baltimore and Washington is in the class with the Hudson river in respect to earliness of the development of lines, the frequency of service and the type of steamer used.

The years 1906 and 1907,* following a long period of quiescence, were a time of interest and excitement in coasting trade circles. At the beginning of 1907 Boston had seven coastwise companies with lines to ten American ports between Eastport and Jacksonville. New York had 12 companies with lines to 19 ports between Portland and Galveston. Philadelphia had five companies with lines to eight ports from Boston to Savannah. Baltimore had three companies reaching six ports, including Boston and Savannah. The interest of the year centered in the rapid and mysterious consolidation of at least nine companies in the hands of Chas. W. Morse. His plans were uncertain, but he was in a position to go far towards controlling rates where he had no competition, or to make lively war with the two great railroad coasting line owners, the New York, New Haven & Hartford and the Southern Pacific. These companies made some defensive moves. The latter company announced† its intention of ordering very large new ships and of improving the service and extending it to give Galveston and New Orleans connections for New York, Philadelphia and Baltimore with stops also at Havana. The New Haven road purchased the Boston and Philadelphia steamship line and the fleet of the Merchants & Miners' Transportation Co.

The ten companies controlled by Mr. Morse in 1907 were, first, the Kennebec, Boston & Bangor Steamship Company with services from Boston to Maine points; second, the Eastern Steamship Company with lines from Boston to Portland, Eastport and New Brunswick ports; third, the Clyde Line with 21 steamers running from Boston to Charleston, Brunswick (Georgia) and Jacksonville; from New York to Philadelphia, Charleston, Jacksonville, Wilmington, N. C., Georgetown, S. C. and lastly to ports in San Domingo; fourth, the Maine Steamship Company, which with the Eastern Steamship Company has 22 ships, New York to Portland; fifth, the Metropolitan Line, four ships, New York to Boston; sixth, the Mallory Line, 11 ships from New York to Mobile, Brunswick, Ga., and Galveston; seventh and eighth, two lines on the Hudson river; ninth, the New York and Porto Rico Steamship Company with nine ships, and tenth, the Ward Line to Cuba with 20 ships.‡

From the examination of such an array as this it becomes plain why the newspapers referred to Mr. Morse's almost complete control of the Atlantic and Gulf shipping. He had more than half of the companies, much more than half of the ships and a complete equipment of services to the whole coast and all of the Greater Antilles except Jamaica. The lines that remained without the grip of Mr. Morse or a strong railroad company were few and comparatively insignificant. The developments of the enterprise were watched with great interest by persons taking cognizance of the coastwise situation. Despite the many theories few anticipated the sudden and spectacular toppling of the whole structure.

The structure itself was impressive but showed its weakness from afar. Physically its anatomy was good. With one focus at Boston many lines radiated to the eastern ports. New York, the greater of the two service foci, had a fine array of lines to the southward, including as extreme ports San Juan, Porto Rico and Vera Cruz. With these southern lands there is great and growing trade. The service groups were finally articulated by lines connecting New York and Boston.

The elements of weakness were financial. Some of the purchased companies were secured at a high figure. The whole was held by a holding company, "The Consolidated Steamship Lines Company," which had an ambitious scheme of capitalization for replacing $86,757,000 of securities with $118,757,000. Watering stock on land is one thing, but watering it on the water is another. It seems to be a case where like cures like. The real property value of the 97 steamships, 65 lighters, seven tugs and the wharves, piers, etc., was put at $45,000,000 by the bankers who tried to justify it on the basis of prospective profits because "The fundamental idea of this consolidation was the benefits to be derived from concentration of control which would result in the working of all lines under one management, the securing of the lowest possible cost of operation, the elimination of idle tonnage, the curtailment of pier room, harmonious working arrangements between the various lines, the most favorable price for the purchase of supplies and fuel, the lowest cost of insurance, repairs, legal expenses, etc."

High purchase prices, watered stock, over-building of new ships and strong competition with strong rivals were bad, but despite these drawbacks, some well-informed steamship managers think that he might have succeeded had he stuck to the shipping business. But this was not to be. Mr. Morse busied himself in Wall street where high finance, trust companies, pyramid banking, corners in copper and alliances with Mr. Heinze caused his financial downfall to be one of the first symptoms of the 1907 panic. The steamship pyramid fell with the banking pyramid and by the end of October 1907, the great holding company of the year before had become an empty shell. Its 120 millions of securities were worth six millions, its New York offices even were closed up and its headquarters removed to Boston. Within a week the underlying companies were transferred to their old managements. In explanation of this move H. P. Booth, President of the Cuba Mail Steamship Company said: "The different lines forming the Consolidated Steamship Co. will in future be run independently, just as they were before the consolidation. We shall attend to our business just as if there had never been a consolidation and the other companies will do the same as we do." Any earnings after paying interest on the underlying bonds were to go to the Consolidated Company.

But this reorganization was insufficient and by February 1908 the clamor of the holders of unpaid coal and other bills was so great that receivers were appointed in three states and the final dissolution of this greatest of coastwise combinations into its original elements was assured. For a time it was questionable even if its promoter would be able to maintain his personal liberty while attempting to extricate himself from his wonderful financial tangle.

New Railroad in Africa.

The Benguella Railroad is now being built between Lobito and Katanga, Africa. The principal object of the new road is to tap the rich mineral field of Katanga, in the southern part of the Congo Free State. It will traverse the entire province of Angola and open vast areas to commerce. It may eventually be extended to connect with the Cape to Cairo and Rhodesian systems. This would shorten the journey to Pretoria or Johannesburg by 3,000 miles, and reduce the time occupied in transit by four or five days. It is expected that the line will reach Katanga in about four years. It will open up a copper industry which, it is believed, will become one of the greatest industries in Africa. Besides copper, the minerals of Katanga are tin and gold.

*Marine Review, Mar. 14, 1907.

GENERAL NEWS SECTION

NOTES.

The pay of freight handlers on certain districts of the Erie has been reduced from $1.50 to $1.35 a day.

It is estimated that 20 per cent. more people went to the New Orleans Mardi Gras festivals this year than last.

It is understood that over 200 short-line railroads have joined in a petition to Congress for a readjustment of the pay for carrying mails.

The Pennsylvaania Railroad has opened a new headquarters at Trenton, N. J., for the instruction of motive power men of the New York division in the operation of air brakes.

The third of the Pennsylvania's four tunnels under the East river, connecting New York and Long Island City, joined its headings on March 5. The fourth may be through by the end of this week.

The Erie is said to have annulled the movement of all freight trains on Sunday, except those carrying live stock and perishable merchandise. The order will remain effective until business conditions improve.

The Baltimore & Ohio has announced that it will restore, on April 1, the old rate of $1.15 per ton on bituminous coal from the Fairmont district to Cleveland and Lorain. The rate has been $1.05 for some little time.

The Burlington announces for the coming summer excursions to Colorado common points between June and October, on the same basis as last year without regard to the efforts to maintain passenger business on a uniform 2-cent basis.

The Boston & Maine has sent a circular to its conductors, trainmen and firemen asking them to accept a 5 per cent. wage reduction to continue only until July 1, it being agreed that upon the first day of July this reduction shall be discontinued. This arrangement has been accepted by the employees of the road.

Announcement is made that the United States Steel Corporation has 95,000 stockholders on its books, a number considerably larger than any before recorded in the history of the company. The Steel Corporation believes that the entire number of shareholders probably approximates 125,000, owing to the fact that many bankers and brokers carry blocks of Steel securities under one name for a large number of holders.

The Wisconsin Railroad Commission has dismissed a complaint against the use of gasolene motor cars between Madison and Freeport, Ill., on the Illinois Central Railroad. The complaint was made on the ground that the motor was "dangerous and inadequate as a means of locomotion." The commission, in dismissing the complaint, held that the use of the motor cars marks an advance in railroading and will result in great benefit to the public.

The Interstate Commerce Commission is opposed to the Fulton bill prohibiting railroads from advancing rates in the face of a protest made by a single shipper until the commission shall have passed upon the reasonableness of the increase. The commission says that to give to the protest of a single shipper the effect of preventing the advance of any rate until the reasonableness of that advance can be affirmatively determined by the commission, would establish a hard-and-fast rule of doubtful fairness to the railroads and of questionable advantage to the public. Until conditions become more stable, the commission believes that wider latitude of discretion on the part of carriers than this measure allows, should be permitted.

The Sargent Re-Railer.

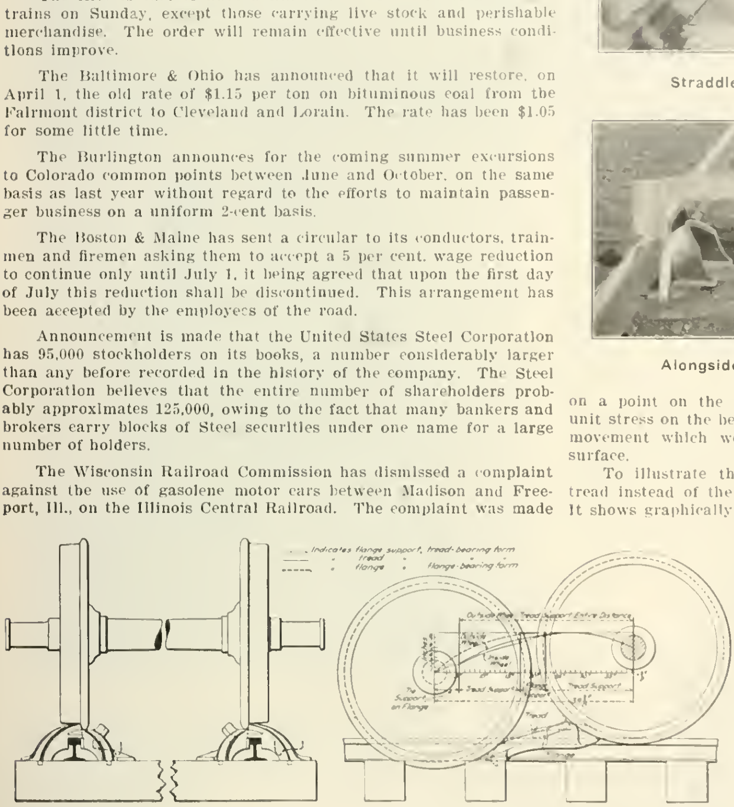
Two improved forms of car replacers, on which the treads of the wheels, instead of their flanges, bear, are illustrated herewith. The principle on which all car replacers work is to raise the wheels by inclines and guide them laterally to the rails by ridges or grooves engaging on the flanges, or by sloped surfaces down which the wheels slide to the rails. By using the tread-bearing principle in the replacer here shown, the concentration of weight

Straddle-Rail Type of Sargent Re-Railer.

Alongside-Rail Type of Sargent Re-Railer.

on a point on the wheel flange is avoided, thereby reducing the unit stress on the bearing surface, and also the resistance to lateral movement which would result from the flange cutting into this surface.

To illustrate the advantage of picking up the wheel on its tread instead of the flange, the accompanying chart was prepared. It shows graphically the travel of a 36-in. wheel from a position off of the rail, between two ties, to complete rerailment, and shows the proportionate rate of elevation for both the tread-bearing and flange-bearing forms. It will be observed that the former affords tread support for the outside wheel for the entire distance, and for the inside wheel for all but 15 per cent. of the distance. The initial lift for this form as compared with the other is lessened by an amount equal to the height of the flange, or $1\frac{1}{8}$ in. Also, the use of wooden wedges to start the wheel on the replacer is unnecessary; the derailed wheel rests on the ties on its flange, so that the tread runs directly on the replacer.



Comparative Wheel Travel on Tread-Bearing and Flange-Bearing Re-Railers.

Another advantage claimed for this form of replacer is that because of the tread-bearing construction the metal may be so disposed as to produce a lighter section than commonly used, without sacrificing strength. The weight of a pair of either of the two types—straddle-the-rail and alongside-the-rail—is from 160 to 180 lbs., as compared with some other replacers weighing 220 to 270 lbs. George H. Sargent, Chicago, is the designer.

Waterproofing a Track Elevation Bridge on the Lake Shore.

The track elevation bridge on the Lake Shore & Michigan Southern at Sixteenth street and Park Manor, Chicago, was waterproofed with "Sarco" waterproofing. As on most track elevation bridges, the space below ties was small and it was essential to have a hard-surfaced, elastic waterproofing which would withstand the effect of vibration from moving loads and the cutting of the rock ballast. A first coat of "Sarco" primer No. F. was thoroughly brushed over the surface of the concrete to form an anchorage for the heavier following coats. Next a coat of "Sarco" No. 6 waterproofing was mopped on while hot. Above this were laid two coats of "Sarco" mastic with joints broken, about a 6 in. lap being allowed. These coats of mastic were made from "Sarco" mastic and flux, and grit about the size of torpedo gravel No. 2, in such proportion as to form a hard surface and yet be elastic enough to take care of contraction and expansion and vibration without checking.

The mastic was taken from the mixing kettle and poured on the concrete, being floated fairly smooth with a wooden spatula. The joints were made by using a strip of wood ⅝ in. thick against which to work the mastic waterproofing. After the mastic was applied, a coat of the No. 6 waterproofing was mopped on the surface while hot. The ends of the bridge were waterproofed by carrying a burlap curtain over the drain. This curtain was made by applying a coating of "Sarco" primer to the surface of the concrete followed by a coat of No. 6, a layer of burlap, another coat of No. 6, a second layer of burlap and a final coat of waterproofing forming an impervious curtain to carry the water from the bridge floor to the drain. This method, it is claimed, makes a satisfactory, durable and efficient waterproofing for the special needs of track elevation work. The work was done by the Standard Asphalt & Rubber Co., Chicago.

Climax Track Drill with Forged Steel Hooks.

An improvement in the "Climax" track drill is shown in the accompanying illustration. The new feature is a forged steel hook. The regular hooks, which answer well the requirements of ordinary work, are made of malleable iron and therefore will break, and when broken they must be replaced with new ones. To do away with this trouble the forged steel hook was designed. It is made amply strong, the material being $^9/_{16}$ in. x $1\frac{1}{2}$ in., and it is fastened to the body by ⅝ in. bolts, which are ⅛ in. larger than used with the malleable iron hooks, to obviate shearing them off.

The form of the hook makes it possible to drill a hole within

Improved Climax Track Drill.

½ in. of the end of the rail. The set screw at the top saves making adjustments at every hole, one setting only being necessary. The handle is a convenience in moving, and also in collapsing the drill for the passage of trains. Another device, quickly adjusted, enables the hook to be extended over a guard rail or a patent rail joint, which is a great convenience and a time-saver. This hook permits the use of a special combination chuck for either flat or twist drill bits; this chuck is too long for the ordinary hooks. "Climax" track drills are made by Cook's Standard Tool Co., Kalamazoo, Mich.

If the State Mined the Coal.

The retail price of coal in Philadelphia is always an important theme in that city of small salaries and keen economists. State ownership finds favor with many. What a fine thing that would be! Quay is dead, but his spirit still lives. Think of the rake-off on the \$50,000,000 of necessary purchases each year for the hard coal mines! Mules at 25 cents per pound, pipe at 10 cents per cu. in., rope 3 cents an ounce and other mystifying bills as for furnishing the Harrisburg capitol! Under state control coal would cost the people of Philadelphia \$20 per ton.—*Coal Trade Journal.*

Scherzer Rolling Lift Bridge at Cleveland, Ohio.

The Cuyahoga river winds for several miles through the city of Cleveland. It was originally narrow, shallow and crooked, but many improvements have been made, and it is now navigable for large vessels. The river is spanned by more than 20 bridges, both highway and railroad. Nearly all of these structures were originally

End View, 230-ft. Scherzer Bridge, Showing Method of Construction Without Interference with Traffic.

of the center pier swing type, a number of them have been removed and replaced by rolling lift bridges.

The Baltimore & Ohio crossed the old river bed (a short branch of the Cuyahoga) on the line of West River street to reach the ore docks on the north side of the river. A long span single leaf Scherzer rolling lift bridge was placed in service at this point a few months ago, replacing a swing bridge used by the railroad company for many years. The accompanying plan contrasts the channels of the old and new bridges. The old bridge had its center pier on the westerly side of the river, with an approach extending well out into the channel on the opposite side. In the new structure the main supporting piers on which the bridge rolls are on the easterly side of the river with the front or rest pier on the edge of the far side of the channel, making the entire width of the river available for navigation. The plan illustrates, too, the particular advantage of the rolling lift bridge in making available all dock space adjacent to the bridge, the disadvantage of a swing bridge in this respect being particularly apparent when the main pier is at one side of the channel, as was the case in this instance.

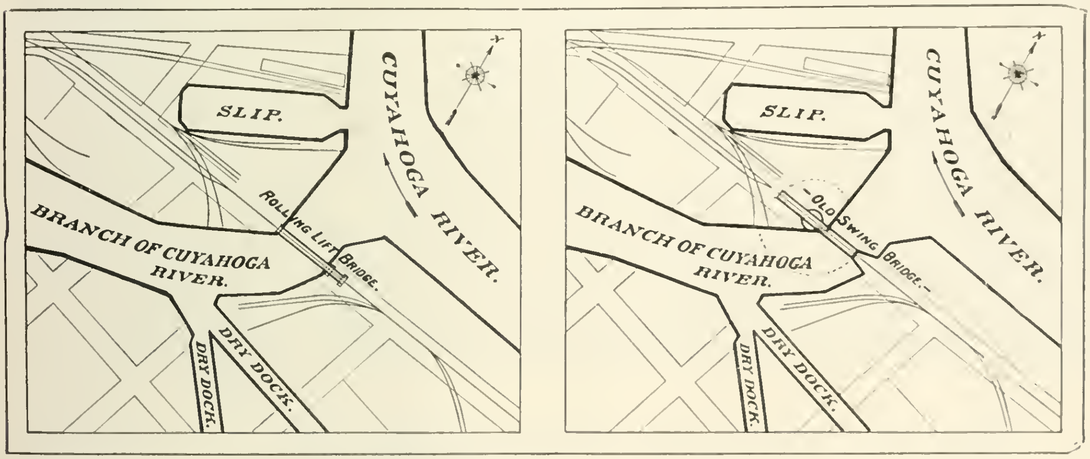
Drawings of this bridge were shown in the *Railroad Gazette* of March 15, 1907. The movable span is 230 ft. long, center to center of bearings. It is the longest span single leaf bascule bridge in the world, the clear channel for navigation, measured between faces of piers, being 210 ft. The total length of steel work, including the short plate girder fixed approach span at the rear end of the bridge, is 334 ft. The bridge is 20 ft. wide, center to center of trusses, and the minimum clearance above the ties is 22 ft. The counterweight is of concrete carried in steel boxes in the plane of each truss, the bridge being counterweighted so as to be at rest in all positions.

It is operated by two a.c. electric motors of 75 h.p. each, the controller governing the motors being in the operator's house. The motors are equipped with solenoid brakes operated by an independent switch on the switchboard in the operator's house. Power is applied in the operation of the bridge by pinions on the main operating shaft engaging with fixed racks placed on independent supports outside of each truss. The operator's house also contains indicators which show to the operator, both day and night, all positions of the bridge during operation. Indicators are also provided showing the positions of the end latch. Signals are placed at each end of the bridge interlocked with derailing switches and with the end latch and main operating controller.

The substructure consists of one front pier, three main piers, carrying the track girders on which the bridge rolls, and an abutment supporting the rear end of the plate girder approach span. These piers are of concrete carried on piles.

The bridge was erected without interfering with traffic over the old swing bridge or with the operation of the old bridge for the passage of vessels. Two of the photographs show the method of erection, the front pier of the new bridge being built under the old swing span on the channel side of the center pier. The main piers of the new bridge were built under the approach to the swing bridge, the superstructure being erected on these piers

Side View of 230-ft. Scherzer Bridge in Cleveland, Under Construction.



Location of New Lift Bridge and Old Swing Bridge Over Cuyahoga River.

Scherzer Bridge in Closed Position.

so as to provide ample clearance for the operation of trains over the old bridge at all times. The building of the bridge was in charge of J. E. Greiner, Assistant Chief Engineer of the Baltimore & Ohio. The superstructure, operating machinery and electrical equipment was designed by the Scherzer Rolling Lift Bridge Co., Chicago, which also supervised the construction and erection. The substructure was designed and built by the railroad. The superstructure was built by the King Bridge Co., Cleveland, Ohio, and the steel work erected by the Pittsburgh Construction Co.

The Hurley Track-Laying Machine.

The Hurley track-laying machine, illustrated herewith, does its work automatically. A pair of reversible, stationary engines supply power for operating the machine and for propelling the construction train of some 30 cars. The supply car following the disconnected from those in the rear by taking out one bolt and slackening the other, leaving the angle-bars on the rear end of each rail. After the rail is disconnected it is brought forward by means of power rollers located on the lower chords of the truss to a point about 20 ft. in advance of the machine car wheels. Here the rail is grasped by specially constructed tongs and lowered until it drags on the previously laid rail. When within about a foot of the end of the latter it is swung forward by one man until the angle bars drop over the ball of the first rail, when it gravitates to place. The clamp over the angle-bars then is applied and the tongs released. The joints are completed while the train is moving the 20 ft., and the quarter spiking is continuous.

The gearing is so arranged that as the train moves forward it supplies the required amount of material at the front. The front end of the truss is made to admit of swinging to curvature and depositing the ties to the center line. It is immaterial whether

Hurley Track-Laying Machine on the Chicago, Cincinnati & Louisville.

machine has an elevated platform for coal and water, and the rails and ties pass under this platform to the machine. The cars nearest the machine carry the ties and the rail cars are back of these.

The rails and ties are moved forward to the machine car as follows: The construction train consists of ordinary flat cars, each equipped with two flanged rollers, one on each side, 7 ft. center to center, equidistant from each end of the car. The rails are fed to these rollers from the rear cars by a hoist, and are connected together by inserting one bolt in each end of their angle bars. The continuous line of rails thus formed on either side, from the rail cars over the tie cars and to the machine, are utilized as tie conveyors. The tie cars are provided with a crossing plank on which the ties are loaded so as to permit the rails to pass over the rollers and freely under the ties.

On each side of the machine car, 7 ft. center to center, is a cluster of upper and lower power rollers which grasp the rails between them and pull the entire line of connected rails forward. the rails are laid with square or broken joints, as each side is worked independent of the other.

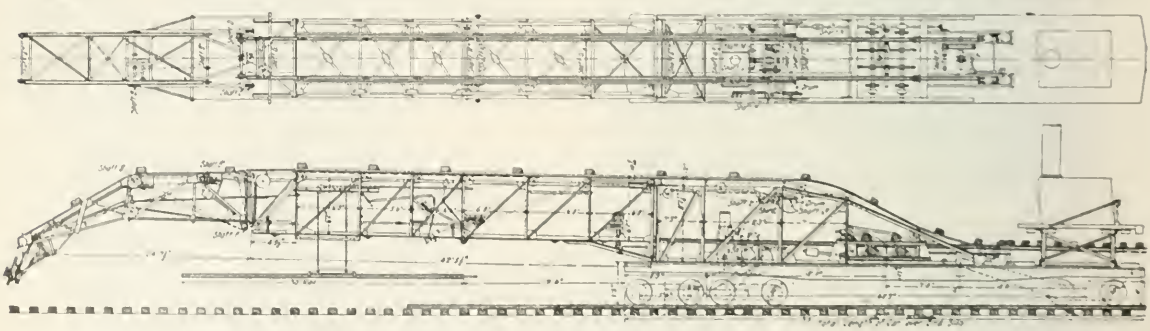
Among the claims made for it are: The machine car has high tractive power while the actual power consumed is small.

The machine is moving constantly though slowly in order to economize the power and time usually lost by stops and delays. It requires no locomotive, and therefore saves this cost.

It begins laying track in 15 to 20 minutes after starting to connect up; it can be stopped and disconnected by simply uncoupling cars from machine.

It lays track to line, to any curvature, on any grade, on trestles, or in tunnels. Has been successfully operated in long tunnels by artificial light. Lays track equally well night or day, in winter or summer, and in any kind of weather.

It lays track at the rate of 2 to 4 miles a day. The capacity of the machine is determined by the number of rails that can be laid and connected in front. On one occasion 84 rails per hour



Plan and Elevation of the Hurley Track-Laying Machine.

Work is begun on the tie car nearest the machine. As the rails pass beneath the ties, men roll the latter down on to the moving rails, as many ties being placed on each rail length as are needed in track. The ties are carried to the machine in this way, the tie men working backward from car to car.

From the front end of the machine car, extending over the roadbed and about 8 ft. above it, is a 68-ft. steel truss. When the rails with the ties arrive at the machine they separate. The required number of ties per rail are delivered, one at a time, by a trip, to an endless chain tie conveyor (with attachments) and are carried over the top chords of the truss to its extreme end, where they are deposited on the roadbed, one at a time, as the machine moves forward, thus spacing them so that they are easily straightened by two men.

The rails move along the lower chords of the truss, and, after passing through the friction rolls previously mentioned, they are were laid on each side. Forty good men will lay and quarter-spike 3 to 4 miles per day.

The office of the Hurley Track-Laying Machine Co. is at 1740 Railway Exchange building, Chicago.

For Railroad Library at Wisconsin University.

James J. Hill has given the University of Wisconsin, Madison, Wis., an additional $2,000 for the development of the "James J. Hill Railway Library," which was established by him with an endowment of $5,000 in 1905. Nearly 9,000 books, pamphlets, periodicals and papers have been secured for the library. The material relates to the history and development of railroad systems of England, Germany, France, Belgium and Holland, besides those of the United States. Mr. Hill's gift was the result of his interest in the work of Prof. Balthazar H. Meyer, of the department of political economy in the University of Wisconsin, and chairman of the Railway Commission of Wisconsin, while Prof. Meyer was securing material for his monograph dealing with the Northern Securities case, published some time ago.

Report on Quebec Bridge Failure.

The three commissioners appointed by the Canadian government to investigate the cause of the collapse of the Quebec bridge, August 29, 1907; Henry Holgate, C.E., John G. C. Kerry, C.E., and John Galbraith, Dean of the Faculty of Applied Science and Engineering in the University of Toronto, have presented their report to the Canadian Parliament. The commissioners do not think that either the general design of the Quebec bridge, the methods of financing the enterprise, the payments of money that have been made to or by the company, or in its interest, or the obligations that the company has undertaken under various contracts and agreements have direct connection with the fall of the bridge. Their positive findings are as follows:

(a) The collapse of the Quebec bridge resulted from the failure of the lower chords in the anchor arm near the main pier. The failure of these chords was due to their defective design.

(b) The stresses that caused the failure were not due to abnormal weather conditions or accident, but were such as might be expected in the regular course of erection.

(c) The design of the chords that failed was made by P. L. Szlapka, the Designing Engineer of the Phoenix Bridge Company.

(d) This design was examined and officially approved by Theodore Cooper, Consulting Engineer of the Quebec Bridge & Railway Company.

(e) The failure cannot be attributed directly to any cause other than errors in judgment on the part of these two engineers.

(f) These errors of judgment cannot be attributed either to lack of common professional knowledge, to neglect of duty, or to a desire to economize. The ability of the two engineers was tried in one of the most difficult professional problems of the day and proved to be insufficient for the task.

(g) We do not consider that the specifications for the work were satisfactory or sufficient, the unit stresses in particular being higher than any established by past practice. The specifications were accepted without protest by all interested.

(h) A grave error was made in assuming the dead load for the calculations at too low a value and not afterward revising this assumption. This error was of sufficient magnitude to have required the condemnation of the bridge even if the details of the lower chords had been of sufficient strength, because, if the bridge had been completed as designed, the actual stresses would have been considerably greater than those permitted by the specifications. This erroneous assumption was made by Mr. Szlapka and accepted by Mr. Cooper and tended to hasten the disaster.

(i) We do not believe that the fall of the bridge could have been prevented by any action that might have been taken after August 27, 1907. Any effort to brace or take down the structure would have been impracticable, owing to the manifest risk of human life involved.

(j) The loss of life on August 29, 1907, might have been prevented by the exercise of better judgment on the part of those in responsible charge of the work for the Quebec Bridge & Railway Company and for the Phoenix Bridge Company.

(k) The failure on the part of the Quebec Bridge & Railway Company to appoint an experienced bridge engineer to the position of Chief Engineer was a mistake. This resulted in a loose and inefficient supervision of all parts of the work on the part of the Quebec Bridge & Railway Company.

(l) The work done by the Phoenix Bridge Company in making the detail drawings and in planning and carrying out the erection and by the Phoenix Iron Company in fabricating the material was good, and the steel used was of good quality. The serious defects were fundamental errors in design.

(m) No one connected with the general designing fully appreciated the magnitude of the work nor the insufficiency of the data upon which they were depending. The special experimental studies and investigations that were required to confirm the judgment of the designers were not made.

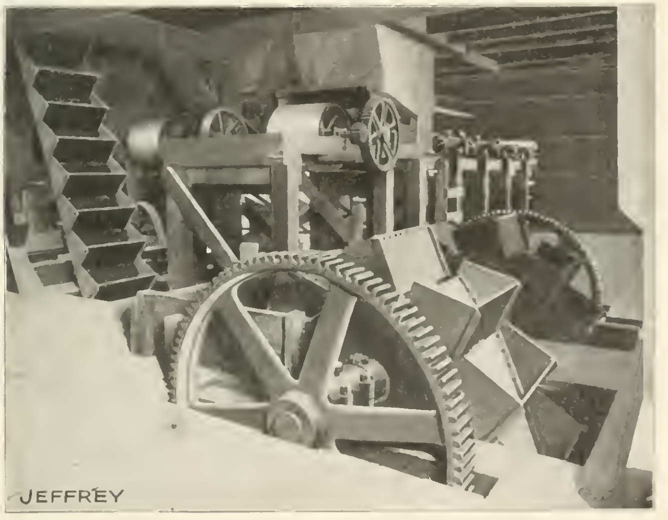
(n) The professional knowledge of the present day concerning the action of steel columns under load is not sufficient to enable engineers to economically design such structures as the Quebec bridge. A bridge of the adopted span that will unquestionably be safe can be built, but in the present state of professional knowledge a considerably larger amount of metal would have to be used than might be required if our knowledge were more exact.

(o) The professional record of Mr. Cooper was such that his selection for the authoritative position that he occupied was warranted, and the complete confidence that was placed in his judgment by the officials of the Dominion Government, the Quebec Bridge & Railway Company, and the Phoenix Bridge Company was deserved.

The report contains appendixes describing the history of the proposal to bridge the St. Lawrence river at or near the city of Quebec; the history of the Phoenix Bridge Company; the effect of financial limitations upon the design of the bridge; the history of the development of the specifications; a description of the organization of the development of plans and of the method followed in the design; a statement of material, shop work and inspection; a statement discussing transportation and erection, and a discussion of the difficulties that arose during erection, and of the events at the time of the collapse of the structure. Some of the parts of especial interest will be treated more fully in a subsequent issue of the *Railroad Gazette*.

Elevating and Conveying System of the Cedarcliff Stone Co.

An unusually large stone crushing and shipping plant was recently completed by the Cedarcliff Stone Co. at its works near Cedarcliff, N. Y. An important feature of the plant is the complete system of elevators and conveyors for handling stone through the various processes of preparation and shipment. A series of elevators and conveyors takes the stone from the crushers to the revolving screens and thence to the storage grounds. Another series delivers the sized product from the storage grounds to cars, or to vessels on



Elevators to Crushers and Screens, and Belt Conveyors to Storage Bins.

a nearby river, as the case may be. The first system, illustrated herewith, consists of three elevators and two belt conveyors. Each of the elevators is 65 ft. high from center to center of wheels. Two of these elevators, standing side by side, handle the product of one No. 9 and four No. 6 Gates crushers. The stone from each elevator is delivered to a revolving screen, from which the tailings go back to two No. 6 crushers on each side and are recrushed. Everything which passes through the screens is received by the third elevator, which stands directly behind the other two, and which delivers it to the finishing screen in the top of the building.

The finishing screen separates the stone into 2 in. and $\frac{3}{4}$ in. sizes and screenings, which pass through a $\frac{3}{4}$-in. hole. The screenings are carried away about 100 ft. by a 14-in. "Century" belt conveyor. The 2-in. and $\frac{3}{4}$-in. products are carried to the storage grounds by separate belt conveyors 24 in. and 18 in. wide, respectively. They are shown in one of the accompanying illustrations. They discharge into the proper compartments by automatic trippers.

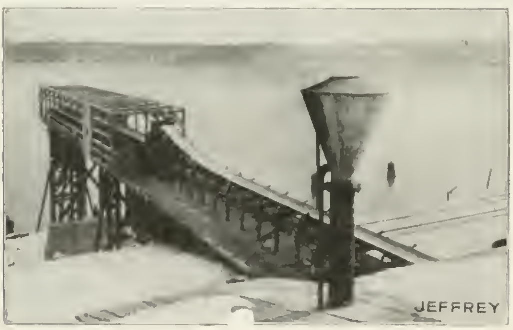
The plan of ground storage is, so far as we know, unique in stone-crushing plants. It is said to be much cheaper in first cost and maintenance than bins. The plan is the same as is used for coal, the storage space being 160 ft. x 100 ft. The distributing conveyors are 35 ft. above the ground, giving a storage capacity of about 8,000 cu. yds.

The distributing conveyors rest on concrete columns 35 ft. apart, center to center, each column being 12 ft. x 7 ft. in plan, and having a ventilating shaft 8 ft. x 3 ft. in its center from top to bottom. Underneath the column, in the center and running the length of the storage ground, is a conduit cut out of solid rock, 8 ft. x 8 ft.

inside and 160 ft. long. The walls and floors are concrete and the roof is of 12-in. I-beams, 2 ft. apart, filled in with concrete. In this roof bin-gates are placed every 6 or 8 ft. Over the tunnel stone will be piled to a height of 35 ft.

To convey the crushed stone to railroad cars or to barges a 36-in. belt conveyor travels the length of the tunnel. It receives the stone through the roof gates and delivers it to an elevator 45 ft. high, center to center of wheels. This discharges to another belt conveyor, 36 in wide by 200 ft. long, which goes over the railroad tracks and to the wharf, as illustrated herewith. The stone is discharged by a tripper either at the wharf or into a small pocket over the railroad tracks, from which it is loaded into cars. The loading conveyors have a capacity of about 400 tons an hour. They are driven independently, so that the barges or cars can be loaded without reference to the main plant.

Conveyors over Storage Bins.



Conveyor from Bins to Cars and Vessels.

The elevator buckets, which are 30 in. long, are carried by two parallel chains of special design, made for the heaviest work. They are the "Michigan" type of Jeffrey "Climax" steel chain, made double width to give greater bearing surface on the head and foot wheels. They are designed to carry a steady load of 6 to 7 tons, and have a factor of safety of 15.

This elevating and conveying system was installed by the Jeffrey Manufacturing Co., Columbus, Ohio.

Bitumen-Emulsion Waterproofing Compound.

Wunner's "Bitumen-Emulsion" waterproofing is a German preparation for use on masonry or concrete. Among the properties claimed for it, verified by tests and in service, are: It is non-porous and impermeable to water under all pressures; makes an absolute bond with the protected material, and if this is metal expands and contracts with it without injury to the bond; is unaffected by heat, cold or sudden temperature changes, does not separate from masonry under settlement, jars or vibration, and does not break unless the foundation breaks first, is not abraded by wind or weather, will not decompose or disintegrate, and is insoluble; does not interfere with the setting of cement mortar, and is easily applied.

This waterproofing compound is a thick black fluid which mixes readily with cement mortar. It is applied by mixing a small quantity in ready made cement mortar or in concrete. A report of a test made in Germany by the Royal Building Inspection Department at Saarburg at the request of the Imperial authorities shows excellent results for this compound. The test was in competition with seven other highly recommended waterproofing materials. As a result of the tests the German Empire became the largest consumer of the Bitumen-Emulsion, using it in fortifications, harbors, railroads, bridges, canals, canal locks, etc.

This material has been in use in this country for about a year. A photograph is shown herewith of the Junction Avenue bridge of the Wabash in Detroit, Mich., which is waterproofed with this material. This bridge is of I-beam and concrete construction. It is claimed that the bond between the metal and the waterproofing coat is absolute, and is unaffected by the vibration, which is considerable. The Wabash bridge, at Forest Park, St. Louis, which is of ornamental design (*Railroad Gazette*, Oct. 28, 1904), was waterproofed with the Bitumen-Emulsion last May, after other materials had failed. In the basement of the West Street building, New York City, leakage was completely stopped by this compound after various other methods had been tried without success.

Junction Avenue Bridge of the Wabash, Detroit, Mich.

Theodore F. Koch & Co., Chicago, are sole agents for the United States.

A New Wooden Smoke-Jack.

The smoke-jack here illustrated represents several years of experiment and effort to produce a light, durable, fireproof jack that will stand the test of acid, smoke fumes, steam, etc., without decay or corrosion. It is made of the best quality of dressed and matched lumber. The inside surface is smooth and offers no projections or cracks in which sparks can lodge. The wood is noncombustible. It is said that tests extending over three years have proved this, and that the fireproofing compound is hermetically sealed within the cells of the wood so that its effectiveness is permanent. Cast iron bands, which are specially treated to resist the effect of smoke and acids, are placed outside and inside the jack to give it the necessary strength and rigidity.

The Dickinson Smoke-Jack.

The part of the jack above the roof is octagonal in section so as to better resist wind pressures. The short inside diameter is 36 in.; below the roof the jack is 24 in. square. This allows ample ventilating space for removal of the steam, smoke and gases from the upper part of the roundhouse. The ends of the hood are given a steep pitch to prevent smoke from rebounding into the house. The hood is 8 ft. long, 6 ft. high and 40 in. wide at the bottom, with 12 in. hanging sides to enclose the locomotive stack. These dimensions, however, can be made to suit any requirements.

These jacks are made by Paul Dickinson, Inc., Chicago.

Strauss Trunnion Bascule Bridges.

The trunnion bascule type of drawbridge is almost as old as the swing bridge, there being many early examples of it in Europe. In 1839 the North Eastern of England built a double-leaf trunnion bascule, which remained in service until recently. In 1867 the city of Copenhagen, Denmark, built a double-leaf highway bridge, 56 ft. 8 in. clear span, which is also still in service. In 1892 the city of London built the famous Tower bascule, which is 226 ft. 6 in. span, c. to c. of trunnions. This is the largest and heaviest bascule in the world.

In 1902 the city of Chicago began building a series of trunnion bascules over branches of the Chicago river; it has built seven to date, some of them being unusually large and heavy structures. The city of Milwaukee has five trunnion bascule bridges in successful operation.

The Strauss designs of bascule bridge are claimed to represent the complete development of the trunnion type. The first one was built at Cleveland, Ohio, for the Wheeling & Lake Erie in the fall of 1905. Since then 11 additional bridges of this type have been built, are under construction, or are ordered. These include the monumental Knippels bridge at Copenhagen, Denmark, and the 170-ft., single leaf, double-track bascule bridge for the Chicago & North-Western at Kinzie street, Chicago.

The Strauss designs embrace a number of modified forms of trunnion bridge, all intended to increase economy and effectiveness. The principal features are the pivoted counterweight and the parallel link mechanism, which apply to both the overhead and underneath counterweight types illustrated herewith. The following are some of the claims made: It was the first bascule bridge in which a concrete counterweight was substituted for cast iron. It is the only bascule which is exactly balanced, and, being at the same time positively connected to the foundations, it is free from any danger otherwise attendant on the erection and service operation of such a structure, especially in case of accident. The truss members all center in the trunnions, and all the loads are transmitted directly to the foundations at the same point, in all positions of the span. The trunnions give a surface bearing, thus avoiding any injurious effects of line bearing. The absence of tail locks and other adjusting devices lessens maintenance cost and danger. The ease with which the number of tracks can be increased, the lessened delay to traffic because of the single channel and the greater speed of operation, and finally, its moderate cost, make it a desirable bridge for railroads.

The Strauss Bascule & Concrete Bridge Co., Chicago, is the designer and builder.

Strauss Bascule Bridge, Overhead Counterweight Type; Staten Island Rapid Transit.

Strauss Bascule Bridge, Underneath Counterweight Type; St. Louis, Iron Mountain & Southern.

A Cast Steel Tie.

The accompanying illustrations show designs for the use of cast steel for a tie body, both in ballasted roadbed and in special structures, such as tunnels. The steel is placed in the ballast or embedded in concrete as part of the permanent structure, and it need not be disturbed in ordinary track work, except as the ballast itself is raised or moved. The metal is so distributed as to give the greatest strength where it is needed and to give a large area of bearing surface underneath the rails. The ribs, flanges, projections and openings are so placed as to provide a firm hold. In the design, three stresses have been considered: the downward pressure under load, the lateral thrust and the tendency of the rail wave under moving trains to lift the tie. The necessary resiliency of the rail support is provided by the wooden block to which the rail may be fastened in any of the usual ways. This block is carried in a pocket formed near the end of the tie, for such maintenance work as ordinary alinement it is evident that the steel portion need not be disturbed.

In designing the cast steel tie it was held that the following requirements should be fulfilled: (1) The tie should be such as could easily be substituted for an ordinary wooden tie in existing track. (2) There should be a certain amount of elasticity in the rail support. (3) After the tie is imbedded in the ballast it should be possible to make the ordinary adjustments necessary to maintenance without disturbing the tie or the ballast. (4) The design should be such that the bearing surface could be varied to suit different kinds of traffic, roadbed and ballast. (5) The tie should resist downward, lateral and lifting forces. (6) The bearing surface should be greater under the rails than under the middle of the tie, to tend to prevent center binding. (7) The tie should not interfere with ordinary provisions for drainage. (8) It should have a definite scrap value if removed within the period of its assumed life. (9) It should be heavy enough, aside from its grip on the ballast, to partially counteract the lifting force of the rail wave.

These ties were originally designed for use in tubular tunnels where the bearing surface of the tie outside of the rail is restricted. One of the designs illustrated is for use in concrete roadbed, as in tunnels, paved streets, terminals, etc. The tie designed for ordinary use may be extended to hold a third-rail bracket. It is claimed that fewer of these need be used to a rail length, and that lighter rails can also be used without lessening the stability of the track.

A modification of this tie has been considered. It involves substitution of longitudinal stringers on the permanent steel cross ties instead of the wooden blocks. Paul D. Ford, who was a member of the committee on the form of track construction for the Interborough Rapid Transit subway in New York City, recently calculated that the pressure on the stringers under Cooper's E 50 specification, or 50,000 lbs. axle load, with axles spaced 60 in. apart and with 100 per cent. allowance for impact, would be 833 lbs. to the lineal inch and 152 lbs. to the square inch under a rail 5½ in. wide. The calculations of the U. S. Forestry Bureau indicate that 215 lbs. to the square inch is a safe working stress for yellow pine. As a basis for Mr. Ford's calculations, he took creosoted yellow pine timbers 7½ in. wide, 11¾ in. deep and 33 ft. long, the joints between stringers and between rails being alternate. In this design it is proposed to space the ties 55 in. apart, except when laid in concrete or in track not in service during construction, and 33 in. apart at rail joints.

Combination Cast Steel and Wood Tie for Ordinary Track.

In one design illustrated herewith, the inverted T form of the tie body as shown is reduced in height from 6 in. to 3¾ in., and in width from 7¾ in. to 5½ in., including both flanges. These dimensions are tentative and may be varied to any extent. The pockets for the wooden blocks are closed at each end and on one side, and the end walls incline inward at the top so that the block dovetails into them and is held from lifting. The rails can be fastened to the block or the block replaced without disturbing the ballast or the metal part of the tie. It is believed that the tie should have a long life because of the enduring qualities of cast steel.

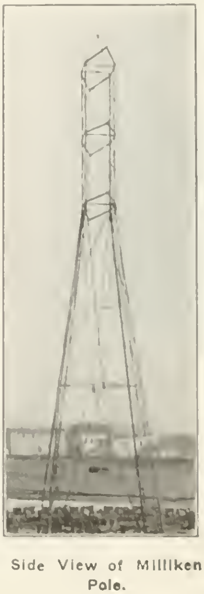
Combination Cast Steel and Wood Tie for Special Track Construction.

The Metal Ties Company, with office at 21 Park Row, New York City, has been formed to handle this tie. J. Stewart Andrews is President, and associated with him are Edgar M. Smith, Charles F. Quincy and James W. Leahy, the inventor of the tie.

Galvanized Steel Poles for Transmission Lines.

The Great Western Power Company, of California, has adopted the Milliken pole, shown herewith, for use in carrying its high voltage power transmission line. It is intended eventually to carry these lines a distance of about 1,000 miles. The power is transmitted on two circuits of three wires each, carrying a current of 100,000 volts. In view of this high voltage and the consequent danger to life and risk from fire involved, great care was exercised in selecting the particular class of poles to be adopted. The pole is designed with three crossarms, the intention being to carry a feed wire on the outer end of each crossarm by suspended insulation. The top of the pole is arranged to take a guard wire. The poles are intended to be used about 750 ft. apart. The bottom of the pole at the ground level occupies a base 17 ft. square. The stub ends of the pole are separate pieces of steel and are of such length as to allow 6 ft. for bedding in the ground. These poles are made entirely of structural steel shapes and are designed to follow the theoretical stresses and produce a pole of given strength and stiffness with a minimum amount of material. There are a great many duplicate pieces, thus making it a simple matter for the purchaser to put the same together in the field.

The poles are designed to stand the following tests: When tested in a vertical position, on an immovable foundation, and with a proper margin of safety a simultaneous horizontal side pull of 1,000 lbs. at the top and 2,500 lbs. at each of the three crossarms, or in other words, a total strain of 8,500 lbs. The crossarms were to support a suspended weight of 1,000 lbs. at their extreme end, and any one of the crossarms to carry at one of these ends a horizontal pull along the line of 3,000 lbs.



Side View of Milliken Pole.

The receivers of Milliken Bros. (Inc.), 11 Broadway, New York City, are manufacturing these poles at Milliken, Staten Island, N. Y., where complete arrangements have been made in the bridge and structural shops for getting out this particular class of structural work.

MANUFACTURING AND BUSINESS.

The Sandusky, Ohio, plant of the Sandusky Portland Cement Co., which was closed down early in December, has resumed work with a full force. The plants at Syracuse, Ind., and Dixon, Ill., are to be started up at once, it is said.

The Lock Joint Pipe Co., 316 Broadway, New York, has secured contracts from the United States Quarantine Department for protecting from marine wood borers, with lock joint pipe, the Department's docks at Charleston, S. C., and Boca Grande, Fla.

The sales of railroad and structural iron paints made by The Alcatraz Company, Richmond, Va., were twice as large during January and February, 1908, as during the corresponding months of 1907. Trade increased particularly in the Middle West and the West.

G. Fred Collins, who has for many years been identified with the railroad supply business as representative of Valentine & Co. and others, and recently as manufacturers' agent in Mexico, has returned to this country to take a position with the Gold Car Heating & Lighting Co., New York.

The Continental Fibre Co., Newark, Del., which started in business in November, 1906, has recently completed an addition to its plant that will enable it to double its output. This company is now one of the largest manufacturers of vulcanized fiber for track insulation. J. P. Wright is General Manager, with headquarters at Newark, and the Wallace Supply Co., Chicago, is western representative.

W. C. Lawson and J. E. Simons have formed a partnership under the name of Lawson & Simons, 505 Fisher building, Chicago, to act as selling agents for various companies. At present they are prepared to quote prices on long leaf yellow pine, oak, fir, creosoted lumber, ties, piling and telegraph poles, tool steel, bolts and nuts, and bar iron and steel. Mr. Lawson has had experience with the American Car & Foundry Co., New York, and has been salesman for the Pressed Steel Car Co., Pittsburgh, Pa., and the Scullin-Gallagher Iron & Steel Co., St. Louis, Mo. Mr. Simons was recently with the Fitz-Hugh Luther Co., Chicago.

To avoid possible confusion through similarity with the name of another corporation, the title Maryland Railway & Electric Supply Co. has been substituted for Maryland Railway Supply Co. of Baltimore city, of which the organization was recently noted in these columns. Changes in the officers of the company have also been made. Charles Elliott is now President and General Manager, Nelson Perin, Vice-President, and Thomas D. Claiborne, Secretary and Treasurer. Mr. Elliott is the son of W. G. Elliott, who was President of the Atlantic Coast Line up to the time of his death. Mr. Elliott served for a number of years in the engineering corps of that road, later going into the railroad supply business, in which he has had considerable experience. Mr. Perin is the son of the late President of the United Railways of Baltimore, and has for some time been engaged in the contracting business, being also Treasurer of the Johnston-Perin Contracting Co. Mr. Claiborne is an engineer and also President of the Johnston-Perin Contracting Co. The headquarters of the Maryland Railway & Electric Supply Co. will be continued at 510 Continental building, Baltimore, Md.

The Fibrous Paint Co., Real Estate Trust building, Philadelphia, Pa., having succeeded to the business of the Pennsylvania Standard Rubber Paint Co., is now the sole maker of "Standard Fibrous" paint. This is a preservative coating for protecting iron and steel structures. It has for the past ten years been used successfully for the preservation of metal structures under conditions where paint mixed with a linseed oil binder is rapidly disintegrated. By adhering closely to iron and steel, its design is to prevent oxidation by forming an elastic waterproof coating impervious to rust-producing agencies, acid fumes and the mechanical abrading action of exhaust blasts; these properties are especially desirable in the coating of bridges, train sheds, car roofs and other metal surfaces exposed to similar conditions. The Standard Fibrous paint is put up in a variety of colors in one, five and ten-gallon packages ready for use. Sales through agencies have been discontinued and the manufacturers now deal direct with the consumer through their own salesmen.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Augusta Southern.—J. M. Featherston has been appointed Assistant Auditor, with office at Augusta, Ga., succeeding B. Anderson.

Birmingham Southern.—Geo. G. Crawford has been elected President, succeeding J. A. Topping; L. T. Beecher, Treasurer, succeeding W. A. Green; F. B. Winslow, Auditor, succeeding S. A. Cameron, who has been appointed Car Accountant. All have headquarters at Birmingham, Ala.

Brookhaven & Pearl River.—M. E. Olmsted, Secretary, has been appointed General Counsel, with office at Harrisburg, Pa., and his duties as Secretary have been transferred to H. C. Homeyer, General Freight and Passenger Agent, who also becomes Treasurer, succeeding G. C. Lignon. Mr. Lignon continues his duties as Auditor. W. H. Baumes is Comptroller, with office at Buffalo, N. Y.

Canadian Pacific.—W. T. Payne, Superintendent at Vancouver, B. C., has been appointed to the new office of Manager of the Pacific steamship service, having charge of company's interests in China, Japan and Hong Kong, with office at Yokohama, Japan.

Cincinnati, Hamilton & Dayton.—F. M. Carter has been appointed Treasurer, with office at Cincinnati, Ohio, succeeding J. E. Howard, resigned. The office of Assistant Treasurer for the Receiver, previously held by Mr. Carter, has been abolished.

De Queen & Eastern.—C. C. Ray has been appointed Assistant Treasurer and General Freight and Passenger Agent, with office at De Queen, Ark., succeeding T. E. Brown, resigned.

Gulf Line Railway.—J. H. Hillhouse, Traffic Manager at Sylvester, Ga., has been elected also Vice-President. C. H. Reynolds, Treasurer at Sylvester, Ga., is now Secretary and Treasurer.

Idaho & Washington Northern.—J. T. McDevitt, Secretary, has been appointed also Auditor, succeeding W. T. Hireen.

Licking River.—A. Siegworth has been appointed Auditor, with office at Chicago, Ill., succeeding C. M. Mohr, who continues his duties as Treasurer.

McCloud River.—D. M. Swobe has been elected Vice-President and Traffic Manager, with office at San Francisco, Cal., succeeding H. O. Johnson, resigned.

Mexican Central.—W. G. Lerch has been appointed Assistant to the President, with headquarters in the city of Mexico.

Peoria & Pekin Union.—H. K. Pinkney, Secretary, has been elected President, with office at Peoria, Ill., succeeding Curtiss Millard, resigned. The duties of Auditor and all matters pertaining to the traffic department have been assumed for the present by the President. J. F. Kiefer succeeds Mr. Pinkney.

Sandy River & Rangeley Lakes.—The officers of this new company, a consolidation of three narrow (2-ft.) gage railroads in Maine, are: Weston Lewis, President; Josiah S. Maxcy, Vice-President and General Manager; Geo. A. Farrington, Secretary and Treasurer; F. N. Beal, Freight and General Passenger Agent, and F. A. Lawton, Superintendent.

Santa Fe Central.—E. R. Paul has been elected Assistant Treasurer, with office at Santa Fe, N. Mex., succeeding Frank Dibert.

Southern Railway & Navigation.—The officers of this company, which operates a terminal line at Chicago, Ill., also steamers and barges on the Ohio and Tennessee rivers, are: D. K. Jeffris, President; Marvin Hugitt, Jr., Vice-President; A. B. Donaldson, Secretary and General Manager; J. T. Jeffris, Treasurer, and W. T. Beckman, General Superintendent; all with office at Chicago, Ill.

Tionesta Valley.—P. M. Newman, General Manager of this company and President and General Manager of the Susquehanna & New York, has been also elected President of the Tionesta Valley, with office at Williamsport, Pa. W. R. Campbell is Assistant to the President, with office at New York.

Operating Officers.

Arkansas & Louisiana.—M. M. Richey has been appointed Superintendent, with office at Little Rock, Ark., succeeding J. Cannon.

Astoria & Columbia River.—E. E. Lillie has been appointed Superintendent of Car Service, with office at Portland, Ore.

Atlanta, Birmingham & Atlantic.—Alexander Bonnyman, Chief Engineer, has been appointed General Manager, with office at Atlanta, Ga.

Buffalo & Susquehanna.—This road for purposes of economy is now operated in one division instead of in two, as formerly. F. W. Allen, heretofore Superintendent of the Northern division, is now in charge of the whole road, with office at Galeton, Pa. The business heretofore handled by the maintenance of way department is now in direct charge of the Superintendent, who will appoint the necessary subordinates.

Boston & Maine.—Fred A. Hortter, who was recently appointed Superintendent of Car Service of the Boston & Maine, was born on May 8, 1870, at New Brighton, Pa. He was educated in the public schools at Boston, Mass., and in 1889 entered railroad service with the Railway Clearing House Association. The next year he went to the Boston & Maine as a tracing clerk in the car service department, being made chief clerk of the car service department three months later. From 1890 to 1908 he served in this position, and on March 2, 1908, was appointed Superintendent of Car Service, succeeding Hoyt E. Howard, who retired at the age of 70 years after 49½ years of continuous service with the Boston & Maine.

Central of New Jersey.—The office of H. G. Sherman, Superintendent of Telegraph, has been moved from Jersey City, N. J., to New York.

Chicago, Burlington & Quincy.—Robert Rice, Superintendent at Hannibal, Mo., has been transferred to the St. Joseph division, with office at St. Joseph, Mo., succeeding A. N. Willsie, who takes Mr. Rice's place at Hannibal.

Coal & Coke.—Edwin Bower, Assistant General Manager, at Gassaway, W. Va., has been appointed Acting General Manager, with office at Elkins, W. Va., succeeding General Manager W. H. Bower, resigned. J. A. Emmart, Purchasing Agent at Elkins, W. Va., has been appointed Assistant Acting General Manager, with office at Gassaway, W. Va., succeeding Mr. Bower. Mr. Emmart also continues his duties as Purchasing Agent.

Delaware & Eastern.—O. F. Wagenhorst, Chief Engineer, has been appointed Superintendent, with office at Margaretville, N. Y., in charge of the transportation and motive power departments.

Delaware, Lackawanna & Western.—E. M. Rine, Superintendent of the Scranton division, has been appointed Superintendent of the Morris and Essex division, with office at Hoboken, N. J., succeeding C. H. Ketcham, resigned; H. H. Shepard, Superintendent of the Syracuse and Utica division, succeeds Mr. Rine, with office at Scranton, Pa. G. A. Poore, Superintendent of the Bangor & Portland Railway division, succeeds Mr. Shepard, with office at Syracuse, N. Y. William Fletcher, Trainmaster of the Bangor & Portland Railway division, will perform the duties of Superintendent of that division until further notice.

Mexican Central.—G. W. Vanderslice has been appointed Superintendent of Terminals at Ciudad Juarez, Chihuahua, Mexico.

Mississippi River, Hamburg & Western.—A. J. Abell has been appointed Superintendent, with office at Monroe, La., succeeding C. H. Bevington.

Missouri Pacific.—The Central district has been abolished. The superintendents of the Central division and the White River division will hereafter report to the General Superintendent at Little Rock, Ark. The Superintendents of the Joplin, the Wichita and the Southern Kansas divisions will report to the General Superintendent at Kansas City. W. J. McKee, General Superintendent of the Central district, has been appointed General Superintendent, with headquarters at Little Rock, Ark. A. De Bernardi, General Superintendent at Little Rock, has been appointed Superintendent of the Omaha division, with headquarters at Atchison, Kan., succeeding W. E. Brooks, transferred, and of the Northern Kansas division, succeeding W. E. Merrifield, assigned to other duties. Mr. Brooks has been appointed Superintendent of the Joplin division, with headquarters at Nevada, Mo., succeeding G. H. Stapp, resigned. J. F. Murphy, Superintendent of the Memphis division, has been appointed Superintendent of the Central division, with headquarters at Van Buren, Ark., succeeding J. M. Walsh, assigned to other duties. H. J. Scheuing, Trainmaster at De Soto, Mo., has been appointed Superintendent of the Memphis division, with headquarters at Wynne, Ark., succeeding J. F. Murphy, transferred.

Morgantown & Kingwood.—C. R. Metzler has been appointed Trainmaster, with office at Morgantown, W. Va., succeeding G. W. Glenn.

Portland & Seattle.—See Spokane, Portland & Seattle.

St. Louis, El Reno & Western.—W. M. Bushnell has been appointed General Manager, with office at Fort Smith, Ark.

Southern.—The office of A. H. Westfall, Superintendent of the Northern division, is now at Greensboro, N. C., instead of at Danville, Va. G. P. Walton has been appointed Superintendent of the Danville division, with office at Greensboro, N. C., succeeding W. R. Hudson, transferred.

Spokane, Portland & Seattle.—E. E. Lillie has been appointed Superintendent of Car Service of this road, formerly the Portland & Seattle, with office at Portland, Ore.

Tonopah & Tidewater.—John Ryan, General Superintendent, has been appointed General Manager, with office at Ludlow (Stagg post office), Cal. The position of General Superintendent has been abolished.

Traffic Officers.

Chicago Great Western.—W. H. Burke, New England agent at Boston, Mass., has been appointed General Eastern Agent at New York, succeeding B. G. Saunders. W. A. Dolan succeeds Mr. Burke.

Licking River.—Malcolm Stone has been appointed General Freight and Passenger Agent, with office at Chicago, Ill.

Missouri Pacific.—R. T. G. Matthews, General Agent of the passenger department at Cincinnati, Ohio, has been appointed Assistant General Passenger Agent at Kansas City, Mo., succeeding C. E. Styles, resigned.

Raleigh & Charleston.—A. T. Vannerson has been appointed to the new office of General Freight and Passenger Agent, with office at Marion, S. C.

Raleigh & Southport.—J. O. Hendley has been appointed to the new office of General Freight Agent, with office at Raleigh, N. C.

St. Joseph & Grand Island.—W. H. Bryning, Assistant General Freight Agent at St. Joseph, Mo., has been appointed Assistant General Freight Agent at Kansas City, Mo., succeeding H. V. Clark.

Engineering and Rolling Stock Officers.

Chicago, Rock Island & Pacific.—W. A. Nettleton, General Superintendent of Motive Power of the St. Louis & San Francisco, has been appointed General Superintendent of Motive Power of the C., R. I. & P. See Delaware, Lackawanna & Western.

Delaware, Lackawanna & Western.—T. S. Lloyd, General Superintendent of Motive Power of the Chicago, Rock Island & Pacific, has been appointed Superintendent of Motive Power of the Delaware, Lackawanna & Western, succeeding R. F. Kilpatrick, resigned.

Mississippi Central.—T. S. Myers, Division Engineer at Brookhaven, Miss., has been appointed Chief Engineer, with office at Roxie, Miss.

St. Louis & San Francisco.—George A. Hancock, Superintendent of Motive Power, has been appointed General Superintendent of Motive Power, succeeding W. A. Nettleton, resigned to go to the Chicago, Rock Island & Pacific. The office of Superintendent of Motive Power has been abolished.

CAR BUILDING.

The Colorado & Southern is asking prices on 200 steel underframe gondolas.

The Calumet Electric is said to be in the market for 15 cars. This is not yet confirmed.

The Illinois Traction Co. is said to be in the market for 60 cars. This is not yet confirmed.

The Chicago, Milwaukee & St. Paul will build 2,500 freight cars of miscellaneous types at its own shops.

The Northern Pacific, as reported in the *Railroad Gazette* of January 31, is asking prices on 80 passenger cars.

The Duluth, Missabe & Northern is again said to be asking prices on 20 passenger cars. This report is not yet confirmed.

The Canadian Pacific passenger equipment referred to in the *Railroad Gazette* of March 6 is to be equipped with the Gold heating system, with Frumveller heater.

RAILROAD CORPORATION NEWS.

BOSTON & MAINE.—A special meeting of the stockholders of the Fitchburg will be held March 18 to authorize $2,400,000 in bonds to refund $2,000,000 bonds maturing on May 1 and to provide part of the funds for improving the line from Johnsonville, N. Y., to Troy. At the last annual meeting an issue of $2,900,000 bonds was authorized for these same purposes. This is to be rescinded. The amount desired has been reduced by $500,000, as some of the purposes of the larger issue have been provided for by the issue of $500,000 one-year notes.

CENTRAL OF GEORGIA.—The Georgia Railroad Commission announces that the Central of Georgia is now the property of E. H. Harriman and that it will be turned over to the Illinois Central whose Birmingham extension, described in another column, is nearly finished. In June, 1907, all the $5,000,000 stock of the Central of Georgia was sold by the Richmond Terminal reorganization committee to Oakleigh Thorne and Marsden J. Perry. It now appears that they were acting as agents for Mr. Harriman, for which service they received 5 per cent. on $3,000,000, the purchase price. The announcement of Mr. Harriman's ownership of the Central of Georgia was postponed until the Illinois Central contest was settled by the election at the recent postponed annual meeting of four directors favorable to Mr. Harriman.

CHICAGO & MILWAUKEE ELECTRIC.—Receivers' certificates up to $1,000,000 are to be issued. The present receivers were appointed on January 28, 1908.

CHICAGO, MILWAUKEE & GARY.—This is the new name of the Illinois, Iowa & Minnesota, which runs from Rockford, Ill., to Momence, 125 miles, and with which has been consolidated the Rockford Belt Railway, a small subsidiary. It is planned to extend the line north to Milwaukee and south to Gary, Ind.

CHICAGO RAILWAYS COMPANY.—The National City Bank and N. W. Harris & Co., of New York, who recently offered $2,500,000 first mortgage 5 per cent. bonds of this company at a price to yield 5½ per cent., have offered another $2,500,000 of these bonds, to yield 5⅜ per cent. The first offering was six times oversubscribed. (March 6, 1908, p. 329.)

CHICAGO, ROCK ISLAND & PACIFIC.—The Chicago, Rock Island & Pacific Railway has arranged with Speyer & Co. for extension of its $6,000,000 two-year 4½ per cent. collateral trust notes which mature April 1, 1908. The extension is for one year with interest at 6 per cent. The extended notes will be secured by $9,000,000 Rock Island, Arkansas & Louisiana first mortgage 4 per cent. bonds, a first lien on 308 miles of road and equipment and the entire amount outstanding. A cash payment of $5 is to be made on each $1,000 note extended, so that there will be a yield of 6¼ per cent. on the extended notes. Holders of the old notes who desire cash will receive it in exchange for their notes. Speyer & Co. are offering the extended notes at 99½ and interest, yielding 6½ per cent.

DETROIT, TOLEDO & IRONTON.—The lien of the receiver's certificates is junior to that of the Detroit Southern, Ohio Southern division, 4 per cent. bonds of 1941, which cover the middle part of the line and the Detroit, Toledo & Ironton general lien and divisional first mortgage 4 per cent. bonds of 1955, which cover the two ends of the line, from Detroit, Mich., south to Lima, Ohio, 125 miles, and from Ironton, Ohio, north 30 miles.

ERIE.—This company is reported to have sold about two weeks ago $1,000,000 Lehigh Valley stock, which it acquired in 1901. Some of its other Lehigh Valley holdings are also reported to have been sold several months ago. Lehigh Valley stock has recently been selling slightly above par.

Gross earnings for January decreased 11 per cent. and net earnings after taxes, decreased 77 per cent. Net earnings after taxes, were $210,000, against $922,000 in 1907.

GREAT NORTHERN.—Gross earnings for February were $2,841,000, an increase of $184,000, and for the eight months ended February 29, 1908, were $40,800,000, an increase of $5,100,000.

ILLINOIS CENTRAL.—There is to be a special stockholders' meeting on May 18 at which the directors will submit a plan for raising between $30,000,000 and $50,000,000; probably by a combined stock and mortgage bond issue.

See Central of Georgia.

ILLINOIS, IOWA & MINNESOTA.—See Chicago, Milwaukee & Gary.

INTERBOROUGH RAPID TRANSIT.—Plans for the proposed bond issue (*Railroad Gazette*, March 6, 1908, p. 330) have been changed. The special meeting of the stockholders will be held on March

28, and the new mortgage will secure $55,000,000 of 45-year bonds. The company has applied to the New York City Public Service Commission for authority to make this issue, also to issue $25,000,000 notes dated May 1, 1908, payable within three years with interest at not more than 6 per cent., these notes to be secured by not more than $30,000,000 of the new mortgage bonds.

INTERNATIONAL & GREAT NORTHERN.—Gross earnings for the week ended February 29, 1908, were $152,000, against $216,000 in 1907, a decrease of $64,000, or 30 per cent.

MOBILE & OHIO.—This company has issued $600,000 first mortgage three-year 5 per cent. notes dated February 15, 1908, secured by $603,000 first mortgage bonds of the Warrior Southern guaranteed by the Mobile & Ohio, and $145,000 equipment trust notes of the Warrior Southern, as well as real estate.

NEW YORK, NEW HAVEN & HARTFORD.—President Mellen, answering an inquiry of the New York City Public Service Commission, says that work is not being carried out on the New York, Westchester & Boston because of a cloud on the validity of this franchise, and is not being carried out on the New York & Port Chester because consent of the Board of Estimate and Apportionment to cross certain streets is lacking. The two companies together have all the necessary authority for building the line, but neither has complete authority separately. Mr. Mellen says that the New Haven will proceed without delay to finish the line as soon as the legal difficulties are settled.

NORFOLK & WESTERN.—Gross earnings for January decreased 25 per cent.; operating expenses decreased 20 per cent., and net earnings decreased 34 per cent. The operating ratio was 67 per cent., against 63 per cent. in 1907.

PORTLAND & SEATTLE.—See Spokane, Portland & Seattle.

SANDY RIVER & RANGELEY LAKES.—This company is a consolidation of the Sandy River Railroad, the Franklin & Megantic, and the Kingfield & Dead River, which together operate about 54 miles of narrow (2 ft.) gage line. The Phillips & Rangeley may also be taken over later. (February 14, 1908, p. 234.)

SOUTHERN PACIFIC.—Gross earnings for January were $9,300,000, against $10,800,000 in 1907, a decrease of $1,500,000, or 14 per cent. Net earnings after taxes were $2,000,000, against $3,500,000, a decrease of $1,500,000, or 43 per cent. The higher price of coal and fuel oil was responsible for $128,000 of the increase; taxes increased $108,000, and renewals of ties $197,000.

SPOKANE, PORTLAND & SEATTLE.—This is the new name of the Portland & Seattle, which is building a low grade cut-off from Spokane, Wash., via Pasco, to Portland, Ore., for the Great Northern and Northern Pacific. This new line is to be finished from Spokane to Portland this year.

TEXAS & PACIFIC.—Gross earnings for the two months of January and February were $2,500,000, against $3,100,000 in 1907, a decrease of $571,000, or 19 per cent.

UNION PACIFIC.—With 200 more miles operated than in the previous year, gross earnings for January, 1908, were $5,200,000, against $6,000,000 in 1907, a decrease of 13 per cent. Net earnings after taxes were $1,800,000, against $2,800,000 in the earlier year, a decrease of 35 per cent. There was an increase in expenditures for renewal of rails and of ties of $195,000; taxes increased $62,000.

WABASH-PITTSBURGH TERMINAL.—The following is the statement of earnings filed with the Interstate Commerce Commission for the month of January and for the seven months from July 1, 1907, to January 31, 1908, inclusive:

	January.	Seven months
Freight revenue	$49,369	$797,971
Passenger revenue	7,472	80,523
All other revenue from transportation	2,284	15,805
Revenue from operations other than transp.	201	3,396
Total operating revenues	$59,327	$897,700
Maintenance of way and structures	7,679	67,188
Maintenance of equipment	7,679	90,960
Traffic expenses	1,618	11,751
Transportation expenses	19,027	200,343
General expenses	3,554	22,114
Total operating expenses	$38,915	$392,969
Net operating revenues	20,411	506,738
Taxes	5,976	45,716
Operating income	$14,135	$461,021

WESTERN MARYLAND.—Judge Morris in the United States Circuit Court at Baltimore on March 5 appointed President B. F. Bush of this company its receiver. The company was embarrassed by lack of working capital. Its earnings were increasing, gross earnings for the week ended February 29, 1908, being $120,000, against $108,000 in the corresponding week of 1907, and from July 1, 1907, to February 29, 1908, having increased over $500,000, or 15 per cent. The management was also embarrassed by the uncertainty as to the proper procedure under the commodity clause of the Rate Law. The Western Maryland owns large bituminous coal workings.

ANNUAL CONSTRUCTION RECORD.

A

ABERDEEN & TOMBIGBEE.—Building from Okolona, Miss., southeast to Pickenville, Ala., 65 miles; surveyed. Grading finished between Okolona and Aberdeen 17.5 miles, also Columbus to Pickensville, 11.5 miles. W. T. McKee, Chief Engineer, Aberdeen, Miss.

ALASKA CENTRAL.—Building from Seward, north to Tanara river, 450 miles. Contract to Snow & Watson, for 23 miles. Surveyed to mile 183; also for branch from Kulk, mile 150, east to Matanuska, 40 miles.

ALASKA PACIFIC.—Building from Martin Island, near Katalla, Alaska, to Bering river coal fields. Surveyed to Copper river valley

AMERICAN RAILROAD OF PORTO RICO.—Cut-off from Hormigueros south to Lajas, 12 miles, to be finished this month.
——Branch to be built this year from San German, east to Sabana Grande, 9 miles. Includes one large bridge and several smaller structures.

ARIZONA & CALIFORNIA.—See Atchison, Topeka & Santa Fe.

ARKANSAS, LOUISIANA & GULF.—Building from Monroe, La., north to Pine Bluff, Ark., with a 7-mile branch to Crossett, Ark. in all 143 miles. Built from Monroe, La., north to Bastrop, 24 miles, and graded 38 miles further to Hamburg, Ark.; also on the branch to Crossett. Track-laying in progress. The 80-mile further extension from Hamburg to Pine Bluff has been surveyed, and grading is to be begun soon as line is finished to Hamburg. E. T. Bond, Chief Engineer, Bastrop, La.

ARKANSAS, OKLAHOMA & WESTERN.—Surveys being made for extensions from Rogers, Ark., northeast to Eureka Springs, 30 miles, and from Siloam Springs, Ark., west to Pryor Creek, Okla., 65 miles. Contract let for some of the work to the W. R. Felker Construction Co., of Rogers, Ark. Bonds offered in January, 1908, at par by Merriam Smith & Co., of New York.

ASHEVILLE & HENDERSON (Electric).—Surveys being made from Asheville to a point in Henderson county, about 20 miles. C. E. Van Bibber, 60 Wall street, New York, Chief Engineer.

ATCHISON, TOPEKA & SANTA FE.—Building new double-track tunnel through Raton Mountain, near Raton, N. Mex. To be 5,000 ft. long, through solid rock, 144 ft. below the existing tunnel. Work 70 per cent. finished. The Lantry Construction Co., Kansas City, Mo., contractors.
——Contracts let to A. Moore, of Newton, Kan., for reconstructing 14 miles of road from Shattuck, Okla., west towards Higgins, Tex.
——Contracts let for change of line and grades, Belle Plaine, Kan., southwest to Cimarron river, near Waynoka, Okla., to the C. H. Sharp Con. Co. and L. J. Smith, of Kansas City, Mo., S. Dolman & Son, Topeka, Kan., and Wood, Bancroft & Doty, Omaha, Neb.
——Contracts let to Wood, Bancroft & Doty, Omaha, Neb., and Dolman & Son, Topeka, Kan., for rebuilding the line from Cicero, Kan., to Mayfield, and for enlarging the yards at Wellington.
——The Southern Kansas of Texas, permitted to take up the track on the Panhandle Railway from a point 1.25 miles west of Panhandle, Tex., to Washburn, 14.3 miles, and to build a new line from the point 1.25 miles west of Panhandle to Amarillo, 25 miles. Work finished on 75 per cent. Wood, Bancroft & Doty, Omaha, Neb., contractors.
——Contract let to Ransom & Cook for grading new yards at Chanute, Kan.
——The Arizona & California projected from Wickenburg, Ariz., on Santa Fe, Prescott & Phoenix, west to Bengal, Cal., on main line, 205 miles. In operation from Wickenburg west 113 miles to the Colorado river. Work under way on bridge over Colorado river and northwest across the Mohave desert to Bengal.
Projected connecting line shown on map in 1907 annual report from Texico, N. Mex., the eastern end of the Belen cut off, southeast via Plainview, Tex., Floydada, Dickens, Aspermont, Hamlin, Anson and Abilene, to Brownwood, Tex., on San Angelo branch of Gulf, Colorado & Santa Fe, about 300 miles. This would give the Santa Fe a short through line from San Francisco to Galveston. Not likely to be built for some time.
See Gulf, Colorado & Santa Fe.

ATLANTA & ST. ANDREWS BAY.—Building an extension from Youngstown, Fla., south to Panama City, 25 miles.

ATLANTA, BIRMINGHAM & ATLANTIC.—Work under way on extension of main line from Talladega, Ala., west to Birmingham, 75 miles. Graded for about 65 miles, and on branch from Bessemer, Ala., to Mulgay, 14.5 miles. Lane Bros. Co., Atlanta, Ga., and C. D. Smith & Co., Birmingham, Ala., contractors.
——Surveys are being made from Atlanta, Ga., southwest to New Orleans, 500 miles.

ATLANTIC COAST LINE.—Contracts let to Wade & Bell, Trinity, Fla., Wade & Morrison, Washington, N. C., and Phillips & Allport, Richmond, Va., for building extension from Wilcox, Fla., northwest to Perry, 55 miles, for a change of line at Goldsboro, N. C., 4 miles, and a change of line at St. Mary's river, Fla., 1.5 miles. Surveys being made for a change of line 4 miles long at Inverness, Fla.

ATLANTIC, NORTHERN & SOUTHERN.—Built last year between Atlantic, Iowa, and Kimballton, 17 miles. Extensions to be built this year north from Kimballton to Manning, 20 miles, and south from Atlantic to V[illegible], 40 miles. C. B. Judd, Chief Engineer, Atlantic.

B

BAKERSFIELD & VENTURA (Electric).—Building from San Francisco, Cal., southeast via Santa Paula, thence southwest to Ventura, on the Pacific coast, with franchises from Sunset northeast to Bakersfield, and from Saticoy south to Hueneme, on the Pacific coast, a total of 270 miles. Branch also projected from Santa Paula southeast to Santa Monica, thence east to Los Angeles, 50 miles. The work will include several tunnels and eight or ten bridges; 20 miles finished. T. B. Blackburn, Ch. Engr., Los Angeles, Cal.

BALTIMORE & OHIO.—Plans for a freight line to be built under charter of the Patapsco & Susquehanna, around Baltimore, Md., 40 miles. The Maryland Court of Appeals has decided that the legislation enacted in 1906 to prohibit building this line is ineffective.

BANGOR & AROOSTOOK.—The annual report for year ended June 30, 1907, includes a map showing a line projected north from the main line at Sebools, Me., along the east bank of the Allagash river to St. Francis, 140 miles. Surveys made over the most difficult parts

BAY POINT & CLAYTON.—Building from Bay Point, Cal., southeast to Clayton. Finished to Cowell, 10 miles. W. H. George, Secretary and General Manager, San Francisco.

BEAUMONT & SARATOGA TRANSPORTATION.—Building extension from Sour Lake Junction, Tex., to Saratoga, 13 miles. Projected 15 miles further to Batson.

BESSEMER & LAKE ERIE.—Extension of the Western Allegheny located from Kaylor, Pa., northeast to Reidsburg, on the projected Franklin & Clearfield line of the Lake Shore & Michigan Southern.

About 12 miles of track to be laid, to finish double-tracking between Conneaut Harbor, Ohio, and North Bessemer, Pa.

BIG STONY.—See Norfolk & Western.

BILLINGS & NORTHERN.—See Great Northern.

BIRMINGHAM, COLUMBUS & ST. ANDREWS BAY.—Contract let to Lemuel E. Miller, Philadelphia, for building from Green Head, Fla., to St. Andrews Bay, 38 miles. Grading under way by J. M. Willis, from Sodom to Taylers, 10 miles.

Surveys for an extension from northern terminus at Chipley, Fla., to Enterprise, Ala., 100 miles. W. M. Gordon, Pres., Columbus, Ga.

BOSTON & ALBANY.—See New York Central & Hudson River.

BOSTON & MAINE.—Plans being made to abolish 19 grade crossings between Johnsonville, N. Y., and Troy.

BOSTON ELEVATED.—Work on the Cambridge subway postponed, awaiting a court decision on question raised by the Mayor of Cambridge. Plans approved and land bought on the East Cambridge elevated extension, including the section in Boston, the viaduct over Charles river and the connections with surface tracks in Cambridge.

Surveys under way for a subway from Sullivan square, Charleston, to Malden, about 3 miles.

——Permission granted by city and by property owners for subway from point near Park street station of present subway, west under Boston Common to south bank of Charles river, and under Charlesbank to beyond Harvard bridge. To be used by trolley cars for Newton, Brighton, Allston and other outlying points. Work not to be begun for some months yet.

BRINSON RAILWAY.—To build in 1908 from Springfield, Ga., northwest to Sylvania, 32 miles. Last year built 25 miles from Savannah, Ga., north to Springfield.

BROOKLYN RAPID TRANSIT.—Plans made for Flatbush avenue extension to the Manhattan bridge. This work, including third and fourth tracking of other lines, to cost $8,600,000.

BROOKVILLE & MAHONING.—See Pittsburgh, Shawmut & Northern.

BUFFALO & DEPEW (Electric).—See Buffalo, Genesee & Rochester.

BUFFALO & SUSQUEHANNA.—Plans made to rebuild parts of this road south from Juneau Junction southwest to Sagamore, 23 miles. Proposed extension from Sagamore southwest toward Pittsburgh. Surveyed to Southbend.

BUFFALO CREEK & GAULEY.—Extension surveyed from Cresmont, W. Va., to Camden-on-Gauley, 40 miles. Wm. D. Janney, Ch. Engr., Clay, W. Va.

BUFFALO, GENESEE & ROCHESTER (Electric).—Certificate of necessity granted for double track line from Depew, N. Y., to Rochester, 60 miles. Will also take over the Buffalo & Depew, now in operation. The road will run through the towns and villages of Lancaster, Crittenden, Corfu, Batavia, LeRoy and Chili. Henry H. Kingston, J. J. Collier, J. A. Harris, Jr., S. Welch and T. H. Dixon, of Philadelphia; W. B. Cutler, J. H. Baker and H. P. Bissell, of Buffalo, are interested.

BUFFALO, LOCKPORT & ROCHESTER (Electric).—Work under way from Rochester west to Lockport, 54 miles. Contract let to J. G. White & Co., New York. From Lockport the company expects to use the tracks of the International Traction Co. into Buffalo. Chas. B. Hill, President, Ellicott square, Buffalo, N. Y.

BUFFALO, ROCHESTER & PITTSBURGH.—Ten-mile section from Carman, Pa., south to Brockwayville, to be revised and a double-track tunnel about 1,000 ft. long, built. Contracts for grading let to Eyre-Shoemaker & Co., of Philadelphia.

BURRS FERRY, BROWNDEL & CHESTER.—Projected from Chester, Tex., east to Louisiana State line at Burr's Ferry, on Sabine river, 85 miles. Surveyed from Rockland to Burkville, 56 miles, graded for 29 miles, track laid on 11 miles. There will be a 200-ft. steel bridge over the Angelina river. Grading finished last year on 21 miles by the Wormack Construction Co., of Browndel. Work suspended. S. C. Omohundro, Ch. Engr., Beaumont.

C

CAIRO & KANAWHA VALLEY.—Proposed extension from Macfarlan, W. Va., to Smithville, 8 miles. Work to begin as soon as bonds can be sold.

CAIRO & THEBES.—Building from Cairo, Ill., northwest to Thebes, 25 miles. J. B. Magee, President. J. L. Armstrong, Ch. Engr., Cairo.

CAROLINA & TENNESSEE SOUTHERN.—See Southern.

CAROLINA VALLEY.—Building extension from Thomasville, N. C., to High Point, 6 miles, and from High Point to Greensboro, 16 miles; two miles built last year also from High Point to Winston-Salem, 21 miles.

CENTRAL CALIFORNIA.—See Southern Pacific.

CENTRALIA EASTERN.—Contract let to W. F. Nelson, of Seattle, Wash., to build from Centralia, Wash., northeast 9 miles. Grading to be begun at once. Contracts for 5 miles additional may soon be let. B. A. Johnson, Ch. Engr., Centralia.

CHARLESTON & SUMMERVILLE (Electric).—Contract let to the General Contracting & Engineering Co., New York, to build from Charleston, S. C., northwest to Summerville, 27 miles. Grading finished on 23 miles. Julius G. Hocke, President, New York. George Topper, Secretary-Treasurer, Summerville, S. C. W. O. Spriggs, Ch. Engr., 15 Whitehall street, New York.

CHARLESTON, PARKERSBURG & WESTERN.—Track laid for 30 miles on the line building from Charleston, W. Va., north to Parkersburg, 60 miles. Engineering work under way on the rest of the line, but undecided when grading will be begun. C. P. Peyton, Ch. Engr., Charleston.

CHARLOTTE HARBOR & NORTHERN.—Last year built 37 miles in Florida. Building with its own men a 3-mile line known as the Hull cut-off to Holst No. 7. Extension from Arcadia to Plant City, 60 miles, surveyed.

CHATTAHOOCHEE VALLEY.—Plans filed for extension from West Point, Ga., north through Troup county, Ga., to Standing Rock, in Chambers county, Ala., thence to a point near Texas in Heard county, Ga.

CHESAPEAKE & OHIO.—The Raleigh & Southwestern, building from the Piney branch at Raleigh, W. Va., up the Piney river and over the divide, thence down the tributaries of the Guyandotte river in Raleigh or Wyoming counties, also extension from Raleigh up Beaver creek into the Glade creek valley. Johnson & Briggs, Richmond, Va., contractors. Work suspended July 1, 1907, on all but 2 miles, which is now under construction on Piney creek above the mouth of Soak creek, Raleigh county.

—Contracts for extending the Coal River Railway let to Carpenter, Haley & Co., of Clifton Forge, Va., for work on Little Coal branch from Rock creek, W. Va., to mouth of Laurel Fork, 17 miles; Laurel to Seng Camp, 5 miles; Laurel to point 5 miles up Laurel Fork. On Big Coal branch to J. C. Carpenter & Co., Dartmouth, to Racine, 8.5 miles.

Double-tracking work on 67.8 miles at various points, and a change of line on 6.4 miles between Norge, Va., and Diascund, which had been temporarily abandoned, was resumed last fall on certain sections that were nearly finished.

—Extension of the Potts Creek branch, 25 miles; work stopped July 1, 1907.

CHESTERFIELD & LANCASTER.—Recently finished line from Ruby, S. C., to Croburk. Extension projected from Croburk north to Monroe or Charlotte, N. C., 20 to 40 miles.

CHICAGO & MILWAUKEE (Electric).—Grading under way by the MacArthur Bros. Co. on last 8 miles north to Milwaukee, Wis. The company is in the hands of receivers, but hopes to have 23.5 miles double track line from Chicago to Milwaukee finished by May. Republic Construction Co., contractors. F. J. Geraghty, Ch. Engr., Highwood, Ill.

CHICAGO & NORTH WESTERN.—Work under way on track elevation and a new passenger station in Chicago.

CHICAGO & WABASH VALLEY.—Building an extension from Dinwiddie, Ind., north to Gary, 20 miles.

CHICAGO, BURLINGTON & QUINCY.—Contracts let last year to the Kilpatrick Bros. & Collins Construction Co., of Beatrice, Neb., for new line to reduce grades from Lincoln, Neb., including new yard at that place west to Milford, 20 miles. Work suspended.

CHICAGO, INDIANAPOLIS & EVANSVILLE.—Contract let to the Carter Construction Co. to build from Indiana Harbor, Ind., south through Indianapolis to Evansville, 346 miles. Branch from Logansport, Ind., north to South Bend, 70 miles, projected. W. M. Kenefick & Co., of Kansas City, are the financial backers. William Kenefick, President; J. B. Carter, Vice-President; C. A. Dunnem, Secretary, and R. Zenkere, Treasurer, Indianapolis, Ind.

CHICAGO, LAKE SHORE & SOUTH BEND (Electric).—Building from South Bend, Ind., west to Chicago, Ill., 71 miles; track laid on 48 miles. Grading finished on 13 miles additional. Seven bridges finished and two being built. It is expected to have the entire line in operation by July. J. B. Hanna, President, South Bend.

CHICAGO, MILWAUKEE & ST. PAUL.—Extension from Glenham, S. Dak., west via Butte, Mont., to Seattle, Wash., 1,372 miles, with a branch from the main line at Black River Junction south to Tacoma, 20 miles. There will be 7 steel bridges aggregating 5,725 ft., with steel approaches 3,425 ft. long, 1,500 ft. of steel trestles, 4 tunnels with a total length of 15,630 ft., and later at Snoqualmie Pass a tunnel about 2 miles long. The line from Glenham to Butte is under contract to McIntosh Bros., of Milwaukee. The Bitter Root tunnel in Montana, and approaches for 2½ miles on each side, are being built by Nelson Bennett, of Tacoma, Wash. The line between the Bitter Root mountains and the coast is under contract to H. C. Henry, of Seattle. All steel bridges and trestles will be erected by the company's men. Track laid on Jan. 1 from Glenham west to Ives, N. Dak., 183 miles, and on 144 miles in Montana, out of 731 to finish the line to Butte. Much grading has been done in the Yellowstone and Musselshell valleys and all contracts have been let. It is expected that construction will be completed to Butte by May of this year, and to the coast by the end of 1909, except for the Bitter Root tunnel.

Work reported under way elevating tracks on the south side of Milwaukee at a cost of between $500,000 and $700,000.

CHICAGO, ROCK ISLAND & PACIFIC.—Work nearing completion on 33 miles of new yard tracks in the Kansas City terminals.

Projected line from Amarillo, Tex., west to Tucumcari, N. Mex., 110 miles. Grading under way from Amarillo west 20 miles, and track laying on this section is expected to be finished in May. Nothing to be done at present on the remaining 90 miles.

CHICAGO, SOUTH BEND & NORTHERN INDIANA (Electric).—Contracts to be let soon for extension from South Bend, Ind., west to Laporte, 25 miles.

CIMARRON & NORTHWESTERN.—See St. Louis, Rocky Mountain & Pacific.

CINCINNATI BELT LINE.—Surveys made and right of way being secured for a double-track belt line around Cincinnati, Ohio. J. F. Williamson, Union Trust building, Cincinnati, is interested.

CINCINNATI, BLUFFTON & CHICAGO.—Contracts for work on the southern extension from Portland, Ind., southeast to Versailles, Ohio, 35 miles, expected to be let early this year.

CLARK & ROCHEPORT COAL RAILWAY.—Right of way secured from Clark, Mo., south to Rocheport, 28 miles. Grading to be resumed in May, 15 miles graded last year. James D. Wade, Ch. Engr., St. Louis, Mo.

CLEAR LAKE & SOUTHERN (Electric).—Surveys under way and rights of way being secured for this proposed line from San Pablo bay, Cal., north via Napa, to Lakeport on Clear lake, 135 miles. Grading to be started this summer. LeGrand Brown, Chief Engineer, 34 Ellis street, San Francisco, Cal.

CLEVELAND, CINCINNATI, CHICAGO & ST. LOUIS.—Surveys being made under charter of the Evansville, Mt. Carmel & Northern from Mt. Carmel, Ill., south to Evansville, Ind., 43 miles.

CLEVELAND SHORT LINE.—Building an 18-mile belt line around Cleveland, Ohio. Located from West Park, 7 miles west of Cleveland southeast to near the Cleveland city limits, thence east and northeast toward Collinwood. In southeast Cleveland the line passes under the main streets, also under the tracks of the Pennsylvania Lines, the Erie and the Wheeling & Lake Erie, through double-track tunnels 40 ft. below the surface. A viaduct 1,980 ft. long will carry it over the Cuyahoga river. There are no grade crossings. The line will furnish interchange facilities between 8 railroads. Work started in May, 1906. Contracts all let, to John Marsch, Cleveland, for grading and masonry, and the King Bridge Co. and the American Bridge Co. for bridges on the section from Rockport to the Cuyahoga river south of Cleveland. Graded for 5 miles and considerable work done on balance. Track laid for 4 miles. H. M. North, Engr. of Con., Cleveland.

COAL RIVER.—See Chesapeake & Ohio.

COAST LINE.—See Southern Pacific.

COLORADO & SOUTHERN.—Terminals being built by the Galveston Terminal Co. at Galveston, Tex., at a cost of $5,000,000; $850,000 has already been spent filling in and putting up a freight house. Over 40 miles of track have been laid.

COLORADO SOUTHERN, NEW ORLEANS & PACIFIC.—See St. Louis & San Francisco.

COLUMBUS, MAGNETIC SPRINGS & NORTHERN.—Consolidation of the Delaware & Magnetic Springs and the Richwood & Magnetic Springs, operating 18 miles from Delaware, Ohio, via Magnetic Springs to Richwood, of which 5 miles built last year. Extension to be built from Richwood north to La Rue, 12 miles. W. M. Galbraith, President; C. Magee, Vice-President and Treasurer, Pittsburgh, Pa.; H. E. Buck, Secretary, Delaware, Ohio.

COPPER RIVER & NORTHWESTERN.—Building from tidewater at Katalla, Alaska, through Copper river valley to the interior of Alaska, about 500 miles. A breakwater about 1 mile long will be built at Katalla. Contract let to M. J. Henry for some of the work. This road is one of the J. P. Morgan and Guggenheim projects in Alaska, and will be built by the Katalla Co. M. K. Rogers, President and General Manager, Seattle, Wash. John Krey, Ch. Engr., Katalla, Alaska.

CORVALLIS & ALSEA RIVER.—Building logging road from Corvallis, Ore., southwest to Alsea river, 25 miles; 13 miles graded, track being laid. Stephen Carver, President, Corvallis.

CUMBERLAND RAILROAD.—Contracts let to S. P. Condon, of Knoxville, Tenn., for extension from Artemus, Knox county, Ky., south to Jellico, Tenn., 32½ miles. Track laid from Artemus to Cumberland, 8.2 miles. B. C. Milner, Ch. Engr., Warren, Ky.

CUMBERLAND RIVER & NASHVILLE.—Contracts let to the Monticello Construction Co., of Monticello, Ky., to build from Burnside, Ky., southwest to Monticello, 20 miles; graded for 12 miles, and foundations being built for South Fork bridge. Projected from Corbin, Ky., west to Burnside, and thence southwest to the Tennessee State line, 100 miles, and from this point under the name of the Nashville & Northeastern to Clarksville, Tenn., 60 miles. S. Woodward, President, Carlisle building, Cincinnati, Ohio.

D

DANBURY & PORTCHESTER.—See New York, New Haven & Hartford.

DAYTON, LEBANON & CINCINNATI RAILROAD & TERMINAL CO. Work to be begun this year on an extension of the Dayton branch from Lambeth, Ohio, west to the union station in Dayton, 1.9 miles.

DEEPWATER.—See Virginian Railway.

DELAWARE & EASTERN.—Proposed northern extension to be built by the Schenectady & Margaretsville from Arkville, N. Y., to Schenectady, 70 miles.

——Proposed southern extension to be built by the Hancock & East Branch from East Branch, N. Y., southwest to Wilkesbarre, Pa., 160 miles.

DELAWARE & HUDSON.—Contract let to O'Brien & Mularkey, of Montreal, for extending the Quebec, Montreal & Southern from Pierreville, Que., to St. Jean des Chaillons, 48½ miles, toward Quebec. About three-fourths of the rails are on the ground and sub-structures of the bridges at Nicolet, Becancourt and East Gentilly and for several smaller structures are about finished. Contracts for 41 miles more soon to be let.

DELAWARE, LACKAWANNA & WESTERN.—Work under way on double track tunnel through Bergen Hill, N. J., to parallel the present tunnel at 51½ ft. between centers.

——Surveys made for a main line cut off from Port Morris, Morris county, N. J., west through Warren county to Slateford, Pa., on the Delaware river, 28.7 miles. Will save 11½ miles of distance, and have lighter grades and curves and no tunnels of which there are two on the present line. Will take three years to build. Contracts to be let in the near future.

DENVER & RIO GRANDE.—Double-tracking from Florence, Colo., west to Canyon City, 8 miles.

DENVER NORTH-WESTERN & PACIFIC.—Contract let to the Denver-Steamboat Springs Construction Co., recently incorporated in Colorado with capital of $1,500,000, to extend this line from Yarmony, Colo., west to Steamboat Springs, 68 miles. Col. D. C. Dodge is president of the construction company. The line is being built from Denver, Colo., west to Salt Lake City, Utah, 490 miles. In operation from Denver to Yarmony, 147 miles, leaving 343 miles to finish the line to Salt Lake City.

DETROIT RIVER TUNNEL.—See Michigan Central.

DULUTH & NORTHERN MINNESOTA.—Surveys being made in Minnesota for an extension from mile 50 north to mile 170.

E

EAST SIDE VIADUCT.—Incorporated to build an elevated railroad from the terminus of the Harlem river branch of the New York, New Haven & Hartford at Willis avenue in the borough of the Bronx, New York City, southward across the Harlem river and thence between First avenue and Avenue A to East 34th street, Manhattan. Proposed to build a six-track steel and concrete viaduct between Avenue A and First avenue and across Jefferson Park. "The only work has been topographical examinations, plans, profiles, maps, estimates of cost of lines of location and comparison of their totals." O. W. Barnes, Fishkill, N. Y.; C. H. Cooke, O. B. Mairs and William B. Dinsmore, Jr., of New York, and Thomas H. Loomis, of Steubenville, Ohio, directors.

ERIE.—Improvement work under way on Jersey City terminal. The plans provide for a four-track open cut 70 ft. deep and 4,500 ft. long through Bergen Hill for passenger trains. The tracks will run on an elevation in the city east of the tunnel to a new station. The present tunnel will be used for freight trains. The company has bought a large tract of land at the western end of the tunnel, and the city has vacated five blocks on the meadows. The work includes excavating about 120,000 cu. yds. of earth and 480,000 cu. yds. of rock, and building 15,000 cu. yds. of concrete masonry. The Penhorn Creek Railroad incorporated to build this line, 4.74 miles. Contract let to the Millard Construction Co., Philadelphia, Pa.

——Work under way on extension of Penhorn Creek Railroad to New York & Greenwood Lake Railway, 1.16 miles; also under the name of the Newark & Hudson Railroad, a connecting line from this extension to the Newark branch, 1.95 miles.

——Work under way on 34 miles of the Guymard cut-off (Erie & Jersey) building from Howells, N. Y., to Guymard, 42 miles. Contract let to Bennett & Talbot, of Greensburg, Pa., for building the first section of 12 miles, including a 5,300-ft. double-track tunnel through the Shawangunk mountains. Additional contracts let between Highland Mills and Guymard as follows: Newburg Junction to Woodbury, Sund strum & Stratton, New York. Woodbury to Moodna Creek, John F. Shields, Richmond Hill, Long Island; Moodna Creek viaduct, steel work is being done by the company's forces, masonry work by Smith McCormick Co., Belfast, N. Y.; Moodna Creek to Otterkill, Ferguson Contracting Co., New York City; Otterkill to Stony Ford, Lathrop, Shea & Henwood Co., Scranton, Pa.; Stony Ford to Howells, F. M. Clement & Co., Philadelphia, Pa. Four miles built last year.

——Contracts let and work under way on the Genesee River Railroad from Hunts, N. Y., south to Cuba, 33 miles, as follows: Hunts to Rossburg, Millard Construction Co., Philadelphia, Pa.; Rossburg to Black Creek, W. H. Coverdale & Co., New York; Black Creek to Cuba, Bennett & Smith, Wilkinsburg, Pa.

——Double-tracking from Carrollton, N. Y., to Cuba, 25 miles. Five miles finished; work suspended.

ERIE & JERSEY.—See Erie.

EVANSVILLE, MT. CARMEL & NORTHERN.—See Cleveland, Cincinnati, Chicago & St. Louis.

F

FAIRCHILD & NORTHEASTERN. Last year built 5 miles. Expects to finish extension to Owen by June, to complete line from Fairchild, Wis., via Greenwood to Owen, 38 miles.

——Building with its own men a yard about 1 mile long at Owen, Wis.

FLORIDA CENTRAL.—In operation from Thomasville, Ga., south to Roddenbery, 13 miles, and from Fanlew, Fla., south to Veren, 12 miles. Work under way from Roddenbery, Ga., south to Fanlew, 34 miles.

FLORIDA EAST COAST.—Building extension from Homestead, Fla., southwest along Florida keys to Key West, 156 miles. Opened for traffic to Knight's Key, 109 miles. From Key West north, track laid on about 15 miles.

FORT WAYNE & SPRINGFIELD (Electric).—Grading to begin in April on an extension from Decatur, Ind., south to Berne, 12 miles.

FRANKLIN & CLEARFIELD.—See Lake Shore & Michigan Southern.

FREEO VALLEY.—Contracts let last year to S. R. Neu, of Princeton, Ark., for extension in Arkansas from mile 22 to mile 26. E. Bower, Gen. Mgr., Eagle Mills, Ark.

G

GALVESTON TERMINAL.—See Colorado & Southern.

GENESEE RIVER.—See Erie.

GEORGIA & FLORIDA.—Projected connecting links aggregating 150 miles between existing lines to complete a through line from Augusta, Ga., to Madison, Fla. Contract let to Schofield & Sons, Philadelphia, for part of the work.

GREAT NORTHERN. The Billings & Northern building a connecting line between the Great Northern and Montana Central on the north and the Northern Pacific and Burlington on the south. Grading about two-thirds finished from Armington, Mont., to Laurel, 199 miles. Track laid last year on 32 miles.

——Contracts let to extend the Vancouver, Victoria & Eastern from Keremeos, B. C., west to Princeton, 45 miles. J. H. Stewart, of Grand Forks, B. C., reported to have grading contract for 40 miles, and F. P. Howard, of Maroon Valley, B. C., for work near Hedley. Work also under way from the Pacific coast east to meet the line building west from Keremeos and from Cloverdale, B. C., east to Abbotsford, 26.25 miles. The V., V. & E. and the Victoria Ferry & Railway Co. are building a low-grade line from New Westminster, B. C., south to Blaine, Wash. The part of the line from New Westminster to Olivers, 9.80 miles, is being built by the V., V. & E., and from that place to the international boundary north of Blaine, 11.32 miles, is being built by the V., F. & R.

——Work under way on the Crow's Nest Southern, building a 24-mile extension from Fernie, B. C., north to the mines of the Crow's Nest Pass Coal Co. at Michel, B. C.

——Proposed double-tracking of the mountain district to be begun as soon as surveys are made on the west slope of the Rockies from Summit, Mont., northwest to Whitefish, 68 miles. Much of the line will be rebuilt.

——See Spokane, Portland & Seattle, formerly Portland & Seattle.

GREENVILLE & KNOXVILLE.—Last year built 15 miles north to Marietta, S. C. Building extension from Marietta north to River Falls, 11 miles. Projected from River Falls to the North Carolina state line, 22 miles.

GULF, COLORADO & SANTA FE.—The Texas & Gulf is building from Center, Tex., via Tenaha to Zuber, 21.3 miles. John Scott & Sons, St. Louis, Mo., contractors. Work suspended Feb. 18, 1908.

GUYANDOTTE & TUG RIVER.—See Norfolk & Western.

H

HANCOCK & EAST BRANCH.—See Delaware & Eastern.

HOLSTON RIVER.—See Virginia & Southwestern.

HUDSON & MANHATTAN RAILROAD.—The two tubes of the south tunnel from Jersey City under Hudson river terminating between Cortland and Fulton streets in Manhattan have been driven from the New Jersey side to about the pier head line in New York. The terminal station at Cortland, Fulton and Church streets, New York, under which is the loop terminal of the south tunnel, is nearing completion and the building is to be opened May 1. The station is to be opened by the time the south tunnel is ready for operation. The station at the western terminus of the south tunnel at the Pennsylvania Railroad terminal in Jersey City is about finished. Work under way on the approach to the river tunnel on Railroad avenue and the connecting tunnel under Washington street in Jersey City. The north tunnel from the D., L. & W. station in Hoboken to Morton street, New York, thence northeast to Nineteenth street and Sixth avenue was opened to the public Feb. 25. Extension north to Twenty-third street to be opened shortly, and to the Thirty-third street terminal, later. Work under way in Manhattan on branch from Sixth avenue east under Ninth street to the subway at Astor place.

HUNTINGTON RAILROAD (Electric).—See Long Island.

I

IDAHO & WYOMING.—See Oregon Short Line.

ILLINOIS, IOWA & MINNESOTA.—Final surveys made for extension from Momence, Ill., northeast to Gary, Ind., 42 miles. Work to be begun this year.

ILLINOIS TRACTION SYSTEM.—This system comprises various lines from Danville, Ill., southwest to St. Louis, Mo., having a total of about 530 miles. The projected entrance to St. Louis includes an independent terminal in Venice, also a new bridge over the Mississippi river from Venice to the foot of Salisbury street, St. Louis. Ground secured for yards, terminals and stations at Salisbury street in St. Louis and adjacent to the stock yards at Venice. Work on the bridge piers soon to be begun.

ILWACO RAILWAY & NAVIGATION COMPANY.—See Oregon Railroad & Navigation Company.

INDIANAPOLIS, LOGANSPORT & CHICAGO.—Projected from Logansport, Ind., south to Indianapolis, 66 miles. Surveys made and rights of way for 25 miles and franchises for entering Indianapolis secured. Graded for 2½ miles at Indianapolis. Walter Osmer, Ch. Engr., Logansport, Ind.

INDIAN CREEK VALLEY.—Location surveys made for 10-mile extension from Jones Mills, Pa. C. F. Hood, President, Normalville, Pa.

INTERBOROUGH RAPID TRANSIT (New York City).—Building an elevated line from 230th street on the Broadway division of the subway (on this section an elevated line) to Van Cortland Park, 1 mile; and a subway from Borough Hall, Brooklyn, to Atlantic avenue, .89 mile. The work is being done by the Rapid Transit Subway Construction Co.

——Plans for additional subway tracks north from 96th street and Broadway to 102d street. Work to be begun soon.

INTER CALIFORNIA.—See Southern Pacific.

INTERIOR & WEST VIRGINIA.—See Norfolk & Western.

INTERSTATE RAILWAY (Electric).—Grading to be begun this spring from St. Joseph, Mo., to Kansas City, 47 miles. Right of way secured. Address Smith H. Braney, 1606 Tribune building, Chicago.

J

JOPLIN & PITTSBURG (Electric).—General contract let to A. L. Register & Co., of Philadelphia, Pa., to build extension from Pittsburg, Kan., southeast to Joplin, Mo., 25 miles. Track being laid. Another extension building from Scammon west to Mineral, 5½ miles, also one from Joplin for 12 miles. H. F. Coleman, Ch. Engr., Joplin.

JOLIET & SOUTHERN TRACTION.—Built last year 3 miles in Joliet, Ill., and 7 miles from Joliet to New Lenox. Expects to finish work on the Blue Island division this year; also south from Joliet through Elwood to Wilmington, 16 miles.

K

KANSAS CITY, MEXICO & ORIENT.—Building from Kansas City, Mo., via Wichita, Kan.; Fairview, Okla. T.; Sweetwater and Presidio, Tex., and Chihuahua, Minaca and El Fuerte, Mex., to Topolobampo, on the Pacific coast, in the state of Sinaloa, 1,661 miles. In operation for 714 miles. Track laid in Kansas, 91.45 miles; Oklahoma, 173.86 miles; Texas, 101.87 miles, and Mexico, 357.49 miles, a total of 724.67, leaving 940 miles still to be built. Track is being laid in the United States northeast from Eldorado, Kan., northeast from Benjamin, Tex., southwest from Sweetwater, Tex.; in Mexico west of Falonier on the Chihuahua division, west of Sanchez in the Sierra Madre mountains and east of Hornillos on the Pacific coast division. Contract let to the International Construction Co., of Kansas City, for building 152 miles.

——Rights of way being secured for a branch from Sentinel, Washita county, Okla., southeast to Lawton, 70 miles. Extension from Lawton east to Sulphur, about 100 miles, also projected. Some grading done at Lawton.

——Surveys made to Kerrville for a branch from San Angelo, Tex., southeast to San Antonio.

——Branch projected from San Antonio, Tex., south to Del Rio, 180 miles.

——The Kansas City Outer Belt & Electric, which is to be the Kansas City (Mo.) terminal of the K. C. M. & O., building double-track line. Grading, masonry and bridge work finished, except bridge over Missouri river. L. J. Smith, contractor.

KANSAS CITY OUTER BELT & ELECTRIC.—See Kansas City, Mexico & Orient.

KANSAS CITY SOUTHERN.—Building 3-mile cut-off south of Howe, Okla., to reduce grades. Some bridge work. Extensive surveys made last year for other similar work.

KANSAS SOUTHERN & GULF.—Expects to build extension this year from Westmoreland, Kan., to Manhattan, 22 miles, including a 300 ft. bridge over the Blue river. Surveys made for extension from Blaine, Kan., to Falls City, Neb., 65 miles. Grading to be begun about May 1. O. J. Collman, Gen. Mgr., Lincoln, Neb., and J. E. Williams, Ch. Engr., Westmoreland, Kan.

KENTUCKY MIDLAND.—Last year built 8 miles in Kentucky. Contract let to A. B. Wood, of Cottage Grove, Ore., for an extension from Cypress Creek, Ky., to Midland, 5 miles, including 800 ft. tunnel near Midland. Surveys under way from Midland to Madisonville, 13 miles. M. M. Wheeler, Ch. Engr., Central City.

KEWEENAW CENTRAL.—Building branch from Phoenix, Mich., to Eagle River, 2 miles.

L

LAKE ERIE & PITTSBURG.—See Lake Shore & Michigan Southern.

LAKE SHORE & MICHIGAN SOUTHERN.—Projected extension of the Pittsburg & Lake Erie from Youngstown, Ohio, to Lake Erie. Contract let last year by the Lake Erie & Pitts-ing to Carter Construction Co. from Mill Creek Junction, near Cleveland, southeast to Kent, 26 miles.

The Franklin & Clearfield projected from Franklin, Penn., southeast to Brookville, 56 miles. Contracts let last year to the Crary Construction Co., McNally Co., Ferguson Contracting Co., Mills Construction Co., King Bridge Co., and American Bridge Co.

LAKE SUPERIOR & ISHPEMING.—Surveys being made for change of main line through Negaunee, Mich., about 3 miles, also for reducing the grade on a 5-mile branch and to extend this branch 3 miles. The work will be heavy and includes several steel bridges.

LARAMIE, HAHN'S PEAK & PACIFIC.—Contracts about to be let for work on extension from Centennial, Wyo., south to Hebron, Colo., 77 miles. Part of the work is being done by J. F. White and part by the company's men.

LAS VEGAS & TONOPAH.—Preliminary surveys made from Goldfield, Nev., to Tonopah, 16 miles. Last year 74 miles built on extension from Rhyolite to Goldfield.

LIMA & TOLEDO TRACTION.—See Ohio Electric Railway.

LINCOLN NORTHERN.—See Southern Pacific.

LITTLE RIVER.—Contract let to J. W. Anderson & Co., of Townsend, Tenn., for extension from Forks, Tenn., to Trenthams, 15 miles. Six miles finished and 4 miles in operation.

LITTLE ROCK, MAUMELLE & WESTERN.—Surveys being made for 12-mile extension from Douglas, Ark. Last year built 16 miles in Arkansas.

LONG ISLAND.—Final details not yet settled with the city officials about change of line of the Manhattan Beach line, which is part of the Bay Ridge improvement. It will remove, altogether, about 80 grade crossings between Bay Ridge and East New York and between Manhattan Beach Junction and Manhattan Beach. Contract let to Walter H. Gahagan. Work suspended.

Plans made to eliminate grade crossings at Old West road, Westbury, and New York avenue, Huntington.

—Work started last year on following: Huntington Railroad (electric) from Huntington, N. Y., south to Amityville, 15.75 miles. Includes 3 bridges. Track laid on 7 miles. Surveys on the Babylon extension (electric) from Babylon west to Amityville, 5.82 miles. Jamaica & South Shore branch from Springfield Junction south to Cedarhurst, 3½ miles. All of this work suspended.

—For other work in connection with the Pennsylvania's tunnel extension to Long Island City and the New York Connecting Railroad, see Pennsylvania.

LOUISIANA & PINE BLUFF.—Contracts let to S. R. Neel, of Huttig, Ark., for extension from Dollar Junction, Ark., to New London, 15 miles. Further extension projected from New London to Wilmington, 15 miles.

LOUISVILLE & ATLANTIC.—Contracts let to Mason, Hanger & Coleman, of Richmond, Ky., and to the Canton Bridge Co., of Canton, Ohio, for building 3 miles from Heidelberg, Ky., to Elk City. C. W. Moorman, Engineer Maintenance of Way, Richmond, Ky.

LOUISVILLE & NASHVILLE.—During 1908 second track to be laid from Perth, Ky., to East Bernstadt, 9 miles, and a new double-track line to be built between Pittsburgh and Little Laurel river, 6.80 miles. Also between Frantz and Lynn Camp Creek, 6.50 miles.

Work under way on the South & North Alabama between Graces, Ala., and Hardy, 17 miles, reducing grades and revising the line. Second track to be added.

Work under way extending the Pine Mountain Railroad between Clear Fork river, Ky., and Catliff coal mines, 17 miles; also branch diverging from Yost to Mahan, 2.30 miles.

The Swan Creek Railway is to be finished to Flanigan, Tenn., this year. Track laid from Mount Pleasant, Tenn., 4 miles, leaving 13½ miles yet to be built.

LOUISIANA WESTERN.—See Southern Pacific.

M

MANILA RAILROAD.—Grading started about a year ago on lines on the Island of Luzon, P. I., aggregating 428 miles, to be built by a syndicate formed by Speyer & Co., New York. No contracts to be let for any of the work.

MASSILLON, WOOSTER & MANSFIELD TRACTION.—Contracts let to the Northern Engineering & Construction Co., Cleveland, Ohio, to build from Massillon, Ohio, west to Mansfield, 50 miles. Graded for 4 miles between Smithville and Madisonburg. G. A. Bartholomew, Ch. Engr., 1123 Williamson building, Cleveland.

MEMPHIS & CHATTANOOGA.—See Southern.

MEMPHIS, PARIS & GULF.—Projected from Memphis, Tenn., via Little Rock, Ark., to Paris, Texas, 400 miles. In operation from Nashville, Ark., southwest to Ashdown, 26.9 miles. Extension to be built this summer.

MEXICO, SANTA FE & PERRY TRACTION.—Grading under way from Mexico, Mo., northeast to Perry, 27 miles. J. M. Wolfe, Collinsville, Ill., contractor. About 3 miles graded. Expected that whole line will be in operation about September. Contracts soon to be let for bridges. Extension from Mexico southwest to Columbia projected. S. L. Robison, President and General Manager, Mexico, and C. O. Thon, Ch. Engr.

MICHIGAN CENTRAL.—Detroit River Tunnel Co., building the Michigan Central's new railroad tunnel under the Detroit river between Windsor, Ont., and Detroit, Mich. The length of the underground part of the tunnel will be 1.5 miles, and the distance from surface to surface about 2½ miles. Contract let to the Butler Brothers, Hoff Co., of New York. Contract calls for the completion of the work by June 1, 1909.

MINNEAPOLIS & RAINY RIVER.—Building with its own forces extension from Big Fork, Minn., north to Second Crossing, 11½ miles. Graded for 10 miles.

MINNEAPOLIS, ST. PAUL & SAULT STE. MARIE.—Work under way by Foley, Welch & Stewart, St. Paul, on extension from Brooten, Minn., northeast to Duluth, 189 miles. 49.6 miles built last year.

MISSISSIPPI CENTRAL.—Contract reported let to O. A. Gibson to build 14 miles from Roxie, Miss., east toward Brookhaven.

MISSISSIPPI VALLEY INTERURBAN.—Organized to build from Springfield, Ill., south to Hillsboro, 53 miles, absorbing as part of the line the Springfield Clear Lake & Rochester, building from Springfield to Rochester, 10 miles; also the Sangamon Valley, building from Hillsboro, north 8 miles. J. E. Melick, President, Springfield.

MISSOURI & NORTH ARKANSAS.—Operates 130 miles from Seligman, Mo., southeast to Leslie, Ark. Track laying just finished on 31½ miles from Woodruff, 9 miles north of Seligman, northwest to Neosho, on the Kansas City Southern, over which the Missouri & North Arkansas has trackage rights to Joplin. The roadbed for 100 miles south of Leslie is being graded by M. C. Burke and L. S. Joseph. 26 miles of track laid and grade ready for 20 miles more. It is expected to finish tracklaying on this section by July. From Kensett, Ark., for 30 miles southeast toward Helena grading contracts let for 11 miles to the Dalhoff Construction Co., of Little Rock, Ark., and the next 15 miles, one-half to the Alabama Construction Co. and one-half to James Dishman. These firms are putting up the embankment across the White and Cache river bottoms. From Cotton Plant to Helena, 55 miles, grading is 80 per cent. done and track material being received. It is the intention to finish the through line from Joplin, Mo., to Helena, Ark., 361 miles, about Oct. 1, 1908.

MISSOURI, OKLAHOMA & GULF.—Building extension from Wagoner, Okla., north to Joplin, Mo., 120 miles, and another from Rose, Okla., south to Denison, Tex., 102 miles.

MISSOURI PACIFIC.—Work under way extending the Springfield Southwestern, from Gulf street through Springfield, Mo., 1.33 miles.

—Track-laying and ballasting under way on 11 miles of yard tracks at Dupo, Ill.; 27 miles finished last year.

—Grading under way for passenger yard west of the new Union station at Little Rock, Ark., which is nearly finished.

MISSOURI SOUTHERN.—Built 4 miles in 1907. Contracts let to the S. H. R. Robinson & Son Contracting Co., of St. Louis, Mo., for extension from Ohlman, Mo., to Bunker, 8 miles. A further extension projected from Bunker to Salem, 20 miles.

MONTANA RAILROAD.—Contract let to Dittner, Bradbury & Co., of Lombard, Mont., for rebuilding from Lombard, Mont., east to Minden, 36 miles. Surveys made from Minden north to Summit, 14 miles.

MOREHEAD & NORTH FORK.—Building with its own men extension from Paragon, Ky., southeast to Redwine, 10 miles.

MORGAN'S LOUISIANA & TEXAS.—See Southern Pacific.

MORGANTOWN & DUNKARD VALLEY (Electric).—The Morgantown Interstate is grading from Morgantown, W. Va., to Star City, 4 miles. The work includes a 600-ft. bridge. W. W. Smith, Secretary and Treasurer, Morgantown.

MORGANTOWN INTERSTATE.—See Morgantown & Dunkard Valley.

MOUNT VERNON & EASTERN.—See New York, New Haven & Hartford.

N

NASHVILLE & NORTHEASTERN.—See Cumberland River and Nashville.

NEBRASKA, KANSAS & SOUTHERN.—Bids are to be asked about May 1 for building this proposed line from Stockton, Kan., southwest to Garden City, 167 miles. Rights of way partly secured. J. C. Hopper, President, Ness City, Kan. Baxter L. Brown, Ch. Engr., St. Louis, Mo.

NEVADA-CALIFORNIA-OREGON.—Building with its own men extension from Likely, Cal., to Alturas, 20 miles. Projected extension from Alturas north to Lakeview, Ore., 60 miles.

NEVADA COUNTY NARROW GAGE.—Work begun last year on cut-off between Colman Station, Cal., and Long Ravine, 3½ miles. Work is being done by the company's men, and includes a steel bridge 190 ft. high and about 800 ft. long, which is to be begun April 1. Graded for 1½ miles and track laid for about three-quarters of a mile.

NEVADA NORTHERN.—Reported plans for extension from Ely, Nev., southwest to Goldfield, about 170 miles.

NEWARK & HUDSON.—See Erie.

NEW ORLEANS GREAT NORTHERN.—Contracts let last year to W. J. Oliver, of Knoxville, Tenn.; Smith & Scott, Memphis, Tenn.; the Worthington Construction Co., of Alabama; E. W. Hanson, of New Orleans, La., and Shea & Ford, Buffalo, N. Y., for building various sections of this line as follows: May's Creek, Miss., to Jackson, 84 miles; Lawrence Creek, La., to Tylertown, Miss., 23 miles, and Slidell, La., via Mandeville to Abita Springs, 26 miles. Last year 53 miles built in Mississippi and 42 miles in Louisiana.

NEW YORK & PORTCHESTER.—See New York, New Haven & Hartford.

NEW YORK, AUBURN & LANSING (Electric).—Building from Auburn, N. Y., to Ithaca, 37 miles. All graded and track laid on 30 miles, and on branches 2 miles. Work under way by the Auburn Construction Co. from South Lansing to McKinneys, 4.1 miles. Projected as steam road, but changed to third-rail. H. A. Clarke, Ch. Engr., Auburn, N. Y.

NEW YORK CENTRAL & HUDSON RIVER.—Excavation and masonry work under way by company's men on second section of reconstructed Grand Central terminal in New York. Steel work being erected by Terry & Trench.

—Buffalo grade crossing elimination work; contract let to the Eyre-Shoemaker Co., Inc., of Philadelphia, for grading the middle section, about one-third of the whole. The city of Buffalo has given contract to John Johnson for changes in streets and street construction.

—Large new yard at Gardenville, near Buffalo, N. Y. Work under way. 10 miles of track laid in 1907.

—Tracks in Tenth and Eleventh avenues, New York, to be removed from the surface of the streets. Not yet determined whether they will be elevated or depressed in a subway.

—Elimination of grade crossings on Harlem division in Mount Vernon, N. Y. Grading for new line in progress.

—Proposed elimination of grade crossings on Harlem division at Tuckahoe, N. Y. Plans being considered by village authorities.

—Proposed elimination of grade crossings on Hudson division through Yonkers, Tarrytown and Ossining, N. Y. Necessary before electrification can be extended to South Croton. Some work done, but now suspended.

—Work under way on the Boston & Albany on 14½ miles of third track between Pittsfield, Mass., and Albany, N. Y.

NEW YORK, NEW HAVEN & HARTFORD.—Harlem river branch from Harlem river to New Rochelle, N. Y., now double track, is being six tracked. Daly & Holbrook, contractors. Four tracks will be equipped electrically with the third-rail system. Estimated cost of entire work, $7,101,891; $4,825,891 for roadway and stations, and $2,286,000 for electrical equipment and apparatus.

—The Providence Terminal Co. building a double track connecting line from the main line station at Providence, R. I., under the river to East Providence, 2.70 miles, including a tunnel under the city. The tunnel is being driven from both ends; about 2,100 ft. have been driven, leaving 2,900 ft. yet to be bored.

—Double-tracking on the Highland division between Waterbury, Conn., and Bristol. Work under way from Waterbury to Terryville Summit, 9 miles, which is expected to be finished early this year, and the rest at the close of the year. This work involves the re-location of much of the line and a 3,500-ft. tunnel at Pequabuck, Litchfield county.

—Widening cut through the city of New Haven for 4 tracks, 1.65 miles. C. R. Blakeslee & Sons, of New Haven, have the contract. Nearly finished.

—Building electric roads from Waterbury, Conn., to Woodbury, 13 miles, and from Waterbury to Thomaston, 6 miles. Work under way.

—Elimination of nine highway crossings at New Bedford, Mass., under way and to be finished in about a year. New engine house and freight yard also to be built.

—Building an extension of the Springfield & Eastern (electric) from Monson, Mass., to Fiskdale, 12 miles; and to South Monson, one-half mile. Palmer to Fiskdale, 11 miles, finished.

—The Danbury & Port Chester is to build a new double track cut-off from the New York division near Greenwich, Conn., via Ridgefield, to Highland division west of Danbury, 30 miles; will shorten distance between New York and Danbury 15 miles. Postponed.

—Negotiations with city of Springfield, Mass., whereby the lands on which the railroad enters Springfield on the east side of the Connecticut river will be sold to the city of Springfield, the tracks transferred to the west side of the river and a new line built from Warehouse Point northward to Springfield, 12 miles. When the change is made trains will run all the way from Hartford to Springfield on the west side of the river. The railroad will build a new bridge over the Connecticut river at Springfield. Under investigation.

—Proposed line from present southern terminus of main line at Woodlawn, 12 miles north of New York, south along the east bank of the Bronx river, 4 miles, to connection with Harlem River & Portchester branch near West Farms, 4 miles north of Harlem river terminus. Investigated only.

—Proposed cut-off from Plantsville, on the Northampton division, southeast to Yalesville on the Hartford division, 8 miles. Investigated only.

—Some work done over a year ago by the New York, Westchester & Boston (electric) from 177th street, New York, north to the city boundary, 4¼ miles. The proposed line is from Harlem river at 129th street, north through West Farms, Westchester, Bay Chester, Pelham Manor, Pelham, New Rochelle, Larchmont, Mamaroneck, Harrison and Rye to Port Chester to the Connecticut line, with branch from Pelham through Mount Vernon, Alameda Park, Fairview Park, Tuckahoe, Arthur Manor and Scarsdale to White Plains, N. Y., in all 38 miles. The New York & Port Chester, which has franchises over nearly same route, is also controlled by the New Haven. No new construction in last year. Mace Moulton, Ch. Engr., 37 Wall street, New York.

——The Mount Vernon & Eastern (Electric) has been incorporated in the interest of the New Haven through the New York, Westchester & Boston, to build from Mount Vernon, N. Y., northeast to Lewisboro, near the Connecticut State line, 35 miles. Preliminary surveys in progress.

——See East Side Viaduct.

NEW YORK CONNECTING.—See Pennsylvania.

NEW YORK, PITTSBURG & CHICAGO AIR LINE.—Surveys being revised for this line. Projected from Pittsburg, Pa., east via Indiana, Cherry Tree, Irvona, Sandy Ridge, Loveville, Tusseyville, New Berlin, Sunbury, Mahanoy City and Tamaqua to Allentown, 298 miles. Joseph Ramsey, Jr., Orange, N. J., is interested. No connection with electric line projected under similar name.

NEW YORK SUBWAYS.—Work under way on a four-track subway loop to connect the Brooklyn and Williamsburg bridges in the Borough of Manhattan. Contracts let on five sections, aggregating $9,094,606 as follows: Bradley Contracting Co., in Centre street between Pearl street and Park Row; Degnon Contracting Co., in Centre street between Pearl and Canal streets, including a spur from Centre street to the Manhattan bridge approach; Cranford Co., in Centre street between Canal and Broome streets; Bradley Contracting Co., in the new extension of Delancey street between Centre street and the Bowery; same company in Centre street between Bowery and Norfolk street. No work has been done on the Brooklyn side.

——The New York State Public Service Commission, First district, has approved the route for the Fourth avenue subway in Brooklyn. It is to be a four-track subway through Flatbush avenue to Fourth avenue, from where a two-track subway will run to Coney Island; also one to Fort Hamilton. Bids will soon be asked for. The estimated cost is $20,000,000.

——The Public Service Commission, First district, has approved plans for the Broadway-Lexington avenue subway from the Battery at the south end of Manhattan Island, north under Church and Vesey streets to Broadway, thence under Broadway and Lexington avenue to the Bronx side of the Harlem river, where it will branch into two spurs, one to Woodlawn Cemetery and the other to Pelham Bay Park. The estimated cost of the work with a line across the island at Canal street, is $67,000,000. The Commission passed a resolution asking the Board of Estimate to assent to the scheme. It is expected that bids will be asked shortly after contracts are let for the Fourth avenue subway.

NEW YORK, WESTCHESTER & BOSTON.—See New York, New Haven & Hartford.

NORFOLK & SOUTHERN.—Contracts let and work under way in North Carolina as follows: Between Farmville and Snow Hill, 10.10 miles; Bayboro and Oriental, 9.80 miles; Mackay's Ferry and Edenton, 9.37 miles; Mackay's Ferry and Columbia, 22.40 miles, and Bishop Cross and Pine Town, 10.95 miles.

NORFOLK & WESTERN.—Work is to be carried out by this company as follows: Extension of the Tug Fork branch, 2.13 miles up the right fork of Sand Lick, in West Virginia; also an extension above Pageton, 4.03 miles. Work under way.

——The Pocahontas & Western to be extended 4 miles in Virginia to the Pocahontas Consolidated collieries.

——The Interior & West Virginia, building from the terminus of extension of Big Stony through Monroe county, W. Va., to Virginia State line, 17½ miles.

——The Virginia & Potts Creek, to be built from the terminus of the Interior & West Virginia to Potts Creek, Va., 11 miles. Work under way to Paint Bank, 4.2 miles.

——The Big Stony started work last year on extension from Interior, Va., to West Virginia State line, 6 miles.

——The Guyandotte & Tug River has secured nearly all the right of way for main line between Clarks Gap, W. Va., and Wharncliffe, 62.27 miles; also located the Barker Creek branch, 10.7 miles, from the mouth of Pinnacle Creek up Guyandotte river, and secured most of the right of way. Extension located to a point on Guyandotte river above the mouth of Slab Fork, 3.03 miles. Branches also located as follows: Pinnacle Creek branch, 7.35 miles, and Still Run branch, 3.56 miles.

NORTHERN DAKOTA.—Grading to be begun in April or May on line from Edinburg, N. Dak., west to a terminal not yet named, about 21 miles. Work expected to be finished by August. Contracts shortly to be let for 60,000 ties. Thomas D. Campbell, President; E. Thorwaldson, Vice-President, and D. F. Bull, Secretary and Treasurer, Edinburg.

NORTHERN OF MAINE.—Grading to be begun about May 1 from Van Buren, Me., west along the northern boundary of Maine via Grand Isle, Madawaska, Frenchville, Fort Kent and St. John to St. Francis, 62 miles. Contracts soon to be let. One bridge. Edson E. Goodrich, President, Waterville, and Henry F. Hill, Ch. Engr.

NORTHERN PACIFIC.—Rebuilding and double-tracking main line from Lake Park, Minn., west to Glyndon, 25 miles. Work 80 per cent. completed and to be finished this spring.

——New alternative line being built from Alta, N. Dak., to Berea, 9.4 miles north of Valley City

——New track on revised grade being built for westbound trains from Wheatland, N. Dak., to Buffalo, 11.2 miles; the present line will be used for eastbound trains.

——Double track work between Casselton, N. D., and Wheatland, to be finished this year.

——Second track under construction from west end of Bozeman tunnel to Bozeman, Mont., 11.8 miles. This is expected to be put in operation in 1908.

——Work under way changing the line and grades in connection with new second track between Garrison, Mont., and Missoula, 69.1 miles.

——Alternate line to eliminate mountain grades from St. Regis, Mont., to Paradise, 21.8 miles; this in connection with the proposed line and grade revision between De Smeth and St. Regis, now operated as a branch line, will reduce the eastbound grade to 0.3 per cent. and westbound grade to level between Tunah and Paradise. It is expected to have this finished in 1908.

——On the White Pine Hill line, 28.4 miles, in Montana, work is under way on a change of line to reduce grades.

——In Washington between Kalama and Vancouver second main track work and improving line and grades on 29.9 miles is under way, and is expected to be finished in the fall of 1908.

——See Oregon, Washington & Idaho under Oregon Railroad & Navigation.

——See Spokane, Portland & Seattle, formerly the Portland & Seattle.

NORTHWESTERN.—See Oregon Short Line.

NORTHWESTERN PACIFIC.—Contracts let to Warren Improvement Co., of San Francisco, for surveys made from Willits, Cal., north 3 miles. Surveys made from Willits north to Shively, 108 miles, on the main line, and from Eledgate south 63 miles, on the branch from Albion to a junction with the main line at Healdsburg.

O

OCEAN SHORE (Electric).—Building double-track line from San Francisco, Cal., south to Santa Cruz, 79.5 miles. Grading 85 per cent. finished. Track laid for 36 miles. J. Downey Harvey, President; Burke Corbet, Secretary; J. B. Rogers, Ch. Engr., San Francisco. In operation from San Francisco to Pedro Valley, 17 miles.

——The Ocean Shore & Eastern to build a branch from Santa Cruz, Cal., southeast to Watsonville, 19 miles. Surveyed.

——The San Joaquin Valley Western to build from Hollister, Cal., to Coalinga, 200 miles. Surveyed.

——The San Juan Pacific to build from Watsonville, Cal., to Hollister, 25 miles. Surveyed. In operation for one-third of the distance.

OCEAN SHORE & EASTERN.—See Ocean Shore.

OHIO ELECTRIC RAILWAY.—The Lima & Toledo Traction, building extension from Deshler, Ohio, northeast to Toledo, 30 miles. Reinforced concrete bridge 1,220 ft. long over the Maumee river near Waterville finished. Graded to Toledo city line. Work suspended, to be resumed this spring and finished this summer.

OPELOUSAS, GULF & NORTHEASTERN.—See Texas & Pacific.

OREGON & WASHINGTON.—See Oregon Railroad & Navigation.

OREGON EASTERN.—See Southern Pacific.

OREGON ELECTRIC.—Work finished from Portland, Ore., via Tualitin and Wilsonville to Salem, 50 miles, except ballasting, which is under way. Extension projected from Portland to Forest Grove, 25 miles. Surveyed. Guy W. Talbert, Manager, Portland.

OREGON RAILROAD & NAVIGATION.—Work under way finishing extensions as follows:

——Between Elgin, Ore., and Joseph, on remaining 56½ miles. Contract for 47 miles let to Erickson & Peterson, of Portland.

——Between St. John and Woodlawn, 1.80 miles.

——On the Oregon, Washington & Idaho, between Riparia, Wash., and Lewiston, Idaho, 37 miles.

——On the Ilwaco Railway & Navigation, between Ilwaco, Wash., and Knappton, 9.40 miles. Erickson & Peterson, Portland, Ore., contractors.

——The Oregon & Washington, projected from Portland, Ore., north to Tacoma and Seattle, 230 miles. At Tacoma there is to be a 8,700-ft. tunnel. Surveyed to Tacoma.

OREGON SHORT LINE.—The Northwestern Railroad projected from Huntington, Ore., north along the Oregon-Idaho State line following the Snake river to Lewiston, Idaho. Contracts let last year to Utah Construction Co., Ogden, Utah, from Blakes Spur north to Homestead, 58 miles; includes 2,200-ft. tunnel east of Huntington. Graded for 25 miles. Work suspended.

——Location surveys made for the Idaho & Wyoming from Elva, Idaho, east to Jackson, Wyo., 105½ miles. Work not yet started.

OREGON WESTERN.—See Southern Pacific.

OWENSBORO & ROCKPORT BRIDGE & TERMINAL CO.—Work expected to be started this year from Owensboro, Ky., north to Rockport, Ind., 12 miles, including a bridge over the Ohio river. A. H. Kennedy, President; G. H. Cox, Secretary, Owensboro.

P

PACIFIC & EASTERN.—Surveys being made for extension from Eagle Point, Ore., to Butte Falls, 21 miles.

PACIFIC & IDAHO NORTHERN.—Surveys being made for extensions from Evergreen, Idaho, east to Roseberry, 35 miles.

PANHANDLE SHORT LINE.—Projected from Dalhart, Tex., south via Hereford and Midland to San Antonio, with a branch from Midland to Rockport on the Gulf. Grading contract let to Miller & Jefferson from Dimmitt south to Lamb county, 60 miles. Grading finished from Hereford to Dimmitt, 32 miles. There will be a number of bridges. Other contracts soon to be let. W. G. Ross, President, and A. D. Goodenough, General Manager, Hereford, Tex.

PATAPSCO & SUSQUEHANNA.—See Baltimore & Ohio.

PAYETTE VALLEY.—Surveys being made for extension from New Plymouth, Idaho, southeast to Falk's Store, 7 miles.

PENHORN CREEK.—See Erie.

PENINSULA RAILWAY (Electric).—Built 8 miles from Bartow, Fla., west to Mulberry, last year. Rights of way secured and 1,000 tons of rails on hand. Expects to begin work soon on remaining 37 miles to Tampa. The Florida Engineering Co. in charge, and W. H. Evers, Bartow, is Ch. Engr.

PENINSULAR RAILROAD.—See Southern Pacific.

PENNSYLVANIA.—Terminal improvements at New York being carried out by the Pennsylvania Tunnel & Terminal Railroad as follows:

——New line from Harrison, N. J., the point east of Newark where the tunnel line leaves the present main line, to the Weehawken shaft of the Hudson river tunnel. Much of the masonry, superstructure and embankment work finished.

——Work being carried on from both ends and from a shaft in the center on two single-track tunnels under Bergen Hill. William Bradley & Sons, contractors. Excavation on tunnels finished, except on 700 ft., and concrete lining being put in.

——Two single-track tube tunnels from Weehawken under Hudson river to 11th avenue shafts; tubes completed and concrete lining being put in. O'Rourke Engineering Construction Co., contractors.

——Western approach to passenger station between 11th avenue and Ninth avenue. New York Contracting Co., contractors. All excavated and work from Ninth and Tenth avenues half finished.

——Contract for construction of the station building and all electrical equipment for the entire terminal and approaches let to Westinghouse, Church, Kerr & Co. Steel work under way on station building.

——Tunnels under 32d and 33d streets, Manhattan, from terminal station at Seventh avenue to East river. United Engineering & Contracting Co., contractors. All excavated except between Fifth and Sixth avenues, and about one-half lining and other work finished.

——Four single-track tubes under the East river, from Manhattan shaft to Long Island. Three of the iron tubes have been joined, and it is expected to connect the fourth by March 20, or earlier. S. Pearson & Son, Ltd., contractors.

——Tube tunnels from river shaft east under Long Island City to East avenue shaft. Excavated, iron lined and two-thirds of concrete lining in place. S. Pearson & Son, Ltd., contractors.

——Tunneling under streets in Long Island City from East avenue shaft to western end of Sunnyside yard, near Thompson avenue; about two thirds finished.

——Large terminal to be known as the Sunnyside yard, between Jackson and Thompson avenues, Long Island City. To be 5,500 ft. long, 1,550 ft. wide at widest point and include about 400 acres. Work on viaducts, embankments, and bridge masonry under way.

——Franchise granted to the Long Island Railroad for Glendale cut-off between Glendale Junction and Woodside, at the entrance to Sunnyside yard. The cut-off is to be a four-track line. All grade crossings between Jamaica and Woodside will be eliminated.

——Franchise granted the New York Connecting Railroad for line through Brooklyn and Queens boroughs, New York City, and over the East river on a bridge to connection with the New York, New Haven & Hartford at Port Morris on the Harlem river. New line to be built from Manhattan Junction, on Long Island Railroad, to the East river and bridge over the East river and Ward's and Randall's islands, with a connection at Long Island City to the Sunnyside yard. The line is to include on its south end through Brooklyn the Bay Ridge line of the Long Island Railroad from East New York to Bay Ridge, on which improvements are under way to eliminate 115 grade crossings, at a cost of about $7,000,000.

——Work to be started soon on large freight terminal at the Bay Ridge waterfront, Brooklyn. This is to be the western terminus of the New York Connecting Railroad, where cars will be put on boats to be sent to the Pennsylvania yard at Greenville, N. J. Contracts for piers and float bridges let. There is to be a pier 600 ft. long with four tracks. The yard will have a frontage on the upper bay of 565 ft., extending to Fifth avenue between 64th and 65th streets. About 40 tracks, with a capacity of 1,800 cars, are to be laid west of First avenue.

——Terminal yard at Pacific street, Brooklyn, N. Y. Work under way.

——Work under way by the Pennsylvania Railroad on the four-track system on the Middle division, between Vineyard, Pa., and Newton Hamilton. To be finished in May. Revision of line on the Conemaugh division, between Blairsville and Tunnelton, 8 miles, and elimination of grade crossings in Blairsville. Under way and to be finished this summer.

——Eastbound classification yard, at Pitcairn, Pa. Work under way.

——Track elevation on the New Jersey division through Camden, N. J., to eliminate grade crossings between the Delaware river and Cooper's creek. Work under way.

——Track elevation begun on the Kensington branch in the northeastern part of Philadelphia. Contract let to the James McGraw Co.

——On the Monongahela division the Ten Mile Run branch, from Ellsworth, Pa., to Millsboro, 15.5 miles, has been finished from Ellsworth south 8 miles, and from Millsboro north 1.6 miles.

——Connecting line from Newberry, Pa., along Lycoming creek, from the Erie division to the Elmira division of the Northern Central. Under construction.

——Improvement of grades and curvature between Jersey Shore, Pa., and McElhattan. Under way.

——Proposed relief freight line, to be built under the name of the Pennsylvania & Newark, from West Morrisville, Pa., to Newark, N. J., 50 miles. With its completion, the six track system will extend from Trenton to Jersey City. Includes new bridge across the Delaware river from Trenton, N. J., to Morrisville.

PENNSYLVANIA ROADS.—The Blair Lumber Co. has given a contract to Vito Greco, of Ligonier, Pa., to build from Laurel Summit, Pa., to Indian Creek, 4 miles. Address J. W. Baker, Ligonier.

PENNSYLVANIA TUNNEL & TERMINAL RAILROAD.—See Pennsylvania.

PHILADELPHIA & READING.—Agreement made with the city of Philadelphia to elevate tracks. Some of the grade elimination work on the Philadelphia, Germantown & Norristown recently let.

PHILADELPHIA RAPID TRANSIT.—Work under way on extension of Market street subway. Contract let to E. E. Smith Contracting Co. from Fifteenth street around the City Hall and east to Juniper street, and to the Millard Construction Co. for eastern section from City Hall loop to Front street. Work from the Delaware river west to City Hall may be finished by July.

PHILIPPINE RAILWAY.—Work under way by the Philippine Railway Construction Co., which has let contract to J. G. White & Co., New York, to build 300 miles of road on the islands of Negros, Panay and Cebu, P. I. William Salomon, Chairman, and Charles M. Swift, President, New York.

PINE MOUNTAIN.—See Louisville & Nashville.

PITTSBURGH & LAKE ERIE.—See Lake Shore & Michigan Southern.

PITTSBURGH, BINGHAMTON & EASTERN.—Building from Binghamton, N. Y., southwest to Clearfield, Pa., 232.5 miles. Grading under way from Renova, Pa., to beyond Westport. Contract let to the Holbrook, Cabot & Rollins Corporation, Boston, Mass. About 21 miles built from Cedar Ledge, Pa., to Powell last year. Other contracts will probably soon be let.

——Branch located and most of the rights of way secured from Cedar Ledge, Pa., to Oregon Hill, 32 miles.

PITTSBURGH, SHAWMUT & NORTHERN.—Work is to be begun in April on extension of the Brookville & Mahoning from Freeport, Pa., to Mahoning, 20 miles.

PITTSBURGH, SUMMERVILLE & CLARION.—Millcreek branch being extended from Millcreek, Pa., 10 miles, by A. Cook's Sons Co., to connect with lumber properties. Four miles built.

POCAHONTAS & WESTERN.—See Norfolk & Western.

PORTLAND & SEATTLE.—The name of this company has been changed to Spokane, Portland & Seattle, which see.

PORT O'CONNOR, RIO GRANDE & NORTHERN.—Projected from Port O'Connor, Tex., north to San Antonio, 190 miles, with branches from Gonzales north to Smithville, 50 miles; Yoakum north to La Grange, 61 miles, and Seguin northwest to New Braunfels, 15 miles. At Port O'Connor, the Gulf terminus, it is planned to develop a deepwater port. Graded for 100 miles and track laying soon to be begun. W. S. Hipps & Co., Houston, contractors. L. A. Gueringer, Ch. Engr., Victoria, Tex.

PORTLAND, EUGENE & EASTERN (Electric).—Projected from Portland, Ore., via Eugene to a point in eastern Oregon, about 182 miles. Grading under way from Eugene to Springfield, 6 miles, and track laid in Eugene for 3 miles. The project is financed by A. Welch, of Portland.

——The Salem-Mehama Railway projected from Salem, Ore., southeast to Mehama, 24 miles. Surveys and rights of way secured by Walters Bros., of Salem.

PUBLIC BELT RAILROAD.—Contract let to the Orleans Engineering Co., of New Orleans, for building part of this double-track line around New Orleans, La. Proposed route is from the upper Parish line along the river front to Kentucky street, around the city to upper Parish line, thence along the protection levee to starting point, 22 miles. One track laid from Parish line to Montegut street, 10 miles. W. J. Hardee, City Engineer, is Ch. Engr.; Hampton Reynolds is Assistant Engineer in charge. Work under way on storage tracks and bridges at various points.

Q

QUEBEC, MONTREAL & SOUTHERN.—See Delaware & Hudson.

R

RANDOLPH & CUMBERLAND.—Work temporarily stopped on extension from Hallison, N. C., northeast to Tillman, $3\frac{1}{2}$ miles. Grading finished.

RALEIGH & SOUTHWESTERN.—See Chesapeake & Ohio.

ROBERT LEE, FORT CHADBOURNE & EASTERN.—Building from Robert Lee, Tex., north east to Winters, 35 miles. Work under way from Robert Lee to Rawlings, $13\frac{1}{2}$ miles. Graded for $2\frac{1}{2}$ miles. J. L. Hoover, Robert Lee, contractor. Additional contracts to be let during first half of 1908. J. Austin Spencer, President, and S. J. Bross, Ch. Engr., Robert Lee.

ROGERS SOUTHWESTERN (Electric).—Building from Siloam Springs, Ark., northeast via Rogers to Eureka Springs, 50 miles. First 27 miles from Siloam Springs finished. Surveys being made on the northern end. Later a line is to be built from a point 7 miles southwest of Eureka Springs south to Huntsville, 22 miles. W. R. Felker, President, Rogers, Ark.

S

ST. JOSEPH, SAVANNAH & NORTHERN.—Located from St. Joseph, Mo., north to Savannah, 15 miles. Work to be begun this spring. T. B. Campbell, M. Tootle and E. J. Wheeler, of St. Joseph, interested.

ST. JOSEPH VALLEY TRACTION.—Building from Middlebury, Ind., east via Shipshewana to La Grange, and, under the name of the St. Joseph Valley Railway, from that point to Angola, 43.7 miles. About finished except some grading, on which work will be resumed this spring. Preliminary surveys made from Middlebury west to South Bend; also from Angola east to Pioneer, Ohio, and Montpelier. G. T. Moore, General Manager.

ST. LOUIS & SAN FRANCISCO.—The Colorado Southern, New Orleans & Pacific, which last year built 121 miles in Louisiana, is putting up a bridge over the Atchafalaya river. This will complete this new line from the Mississippi river to Houston, Tex.

ST. LOUIS, ROCKY MOUNTAIN & PACIFIC.—Surveys reported made for the Cimarron & Northwestern from Cimarron, N. Mex., northwest up the Ponil river to Ponil Park, 22 miles. Grading finished on 15 miles, and 3 miles of track laid. General contract to the Whitescarver Construction Co., Trinidad, Colo., and sub-contracts to Maney Bros., of Oklahoma City, Okla.

ST. LOUIS SOUTHWESTERN.—Three-mile extension under construction at Argenta, Ark.

——Similar terminal extension about 2.75 miles long projected to Fort Worth, Texas.

SACRAMENTO VALLEY & EASTERN.—Building with its own men from Pitt, Cal., to Delamar, 16 miles. Contract for bridge work let to the Globe Construction Co., of San Francisco. Address T. J. Dearborn, Winthrop, Cal.

SALEM-MEHAMA.—See Portland, Eugene & Eastern.

SALT LAKE & OGDEN.—Building extension from Ogden, Utah, city limits to Canyon, 5.60 miles.

SAN ANTONIO & ARANSAS PASS.—Heavier rails being laid from San Antonio, Tex., east to Yoakum, 120 miles; also from Houston west, where 9 miles laid.

SAN DIEGO & ARIZONA.—Location surveys partly made from San Diego, Cal., east to Yuma, Ariz., 200 miles. Small amount of grading done between San Diego and National City; also in the mountains. Over $1,000,000 spent in securing rights of way and terminals in San Diego and National City. The company has taken over the franchises and property of the San Diego Eastern, projected over the same route. John D. Spreckels, San Francisco, is the principal promoter; W. Clayton is Vice-President.

SAN DIEGO EASTERN.—See San Diego & Arizona.

SAN FRANCISCO, IDAHO & MONTANA.—Building, from Caldwell, Idaho, to Homedale, 16.2 miles. Contract let to the Canyon Construction Co., of Caldwell. Graded for 12 miles, track-laying to be begun in April. Surveys from Homedale, Idaho, to Winnemucca, Nev., 275 miles. F. H. Richardson, Ch. Engr., Caldwell.

SANGAMON VALLEY.—See Mississippi Valley Interurban.

SAN JOAQUIN VALLEY WESTERN.—See Ocean Shore (Electric).

SAN JUAN PACIFIC.—See Ocean Shore (Electric).

SANTA FE, LIBERAL & ENGLEWOOD.—See Santa Fe, Raton & Eastern.

SANTA FE, RATON & EASTERN.—Work resumed in Oklahoma on the Santa Fe, Liberal & Englewood, projected from Des Moines, N. Mex., east via Hooker, Okla., to Woodward, Okla.

SARATOGA & ENCAMPMENT.—Building from Walcott, Wyo., south to Encampment, 45 miles. All graded except yards. Track laid from Walcott to Cow Creek, 34 miles. In operation from Walcott to Saratoga, 21 miles.

SAVANNAH, AUGUSTA & NORTHERN.—Surveys being made from Savannah, Ga., northwest to Chattanooga, Tenn., and east to Augusta, Ga., in all 425 miles. Graded for 58 miles and track laid on 30 miles between Statesboro, Ga., and Garfield. Contracts let to W. J. Oliver, of Knoxville, Tenn. W. H. Lynn, 111 Broadway, New York, interested.

SCHENECTADY & MARGARETSVILLE.—See Delaware & Eastern.

SOUTH & NORTH ALABAMA.—See Louisville & Nashville.

SOUTH & WESTERN.—Building from Elkhorn, Ky., south via St. Paul and Clinchport, Va., Kingsport and Johnson City, Tenn., Spruce Pine, Marion and Bostic, N. C., to Spartanburg, S. C. Work under way from Dante, Va., to Bostic, 211 miles. The Meadows Co., of Johnson City, Tenn., general contractors. Work at various points is being done by Walton, Witten & Graham, of Graham, Va.; Carpenter & Boxley Bros., Clinchport, Va., and Jonesboro, Tenn.; Rinehart & Dennis Co., Washington, D. C.; A. H. Jaudy Co., [illegible]; Walton Contracting Co., Falls Mills, Va.; Walton, Wilson, Rodes & Co., Knoxville; Kreis & French Construction Co., Knoxville; J. C. Carpenter & Co., Falls Branch, Tenn.; Carpenter & Boxley, Johnson City; MacArthur Bros. Co., Altapass, N. C.; Patton, [illegible]hardson & Co., Marion, N. C.; Parsons, Aiken, Sheehan & Co., Thermal City, N. C., and Millard-Quigg Construction Co., Marion. Graded and track laid from Dante, Va., to Boltown, 16 miles; Johnson City, Tenn., to Blue Ridge Summit, 69 miles; North Cove, N. C., to Marion, 14 miles, and grading 75 per cent. finished on 67 miles more; 75 miles in operation. Heavy work being done to secure a grade of 1.2 per cent. [illegible] the east slope of Blue Ridge mountains. There are to be 54 bridges and 33 tunnels. Contracts will probably be let this year from Elkhorn to Dante, [illegible] miles, and from Bostic to Spartanburg, 53 miles.

SOUTH OMAHA & WESTERN.—See Union Pacific.

SOUTHERN.—Second-track work under way on 33 miles between Monroe, Va., and Greystone, expected to be finished by June. About 25 miles in operation between Knoxville, Tenn., and Morristown, and 15 more will be finished by April.

——Similar work between Whitethorn and Durmid, including a line through the city of Lynchburg, 6.9 miles, is heavy and includes a tunnel 1,300 ft. long. Now suspended.

——Second-track work between Flowery Branch, Ga., and Austell, 11.56 miles, finished with the exception of bridge over Chattahoochee river.

——On the Knoxville division double-track work is nearing completion between Mascot, Tenn., and Jefferson City, 14.3 miles, including a new double-track bridge over the Holston river, and it is expected to have the entire line between Knoxville and New Line ready for operation in May.

——About half the double-track work between Ooltewah Junction, Tenn., and Citico, 13.75 miles, was finished last year; work suspended.

——The Carolina & Tennessee Southern, projected from Bushnell, N. C., west along the northern bank of the Little Tennessee river to the North Carolina-Tennessee State line, 26 miles, is finished from Bushnell for 14.5 miles; work suspended. From the State line further extension under the name of the Tennessee & Carolina Southern to Maryville, Tenn., 38.8 miles; on the latter grading has been finished for 37.4 miles. Track laid on 4.5 miles. About 25 miles will be ready for operation by July.

——About 150 miles of second track has been finished between Washington and Atlanta, 650 miles; 32 miles more will be put in operation by June.

——The Memphis & Chattanooga projected from Chattanooga, Tenn., to Stevenson, Ala., 42 miles, on which grading and masonry from point near Chattanooga to east portal of Lookout mountain tunnel, about 90 per cent. finished. Work suspended. Work under way lining the double-track tunnel through Lookout mountain, 3,500 ft. long. This is to be finished by July.

——The Louisiana Western building extension from Eunice, La., to Mamou. Graded for 10 miles and work under way on remaining 7 miles.

SOUTHERN KANSAS OF TEXAS.—See Atchison, Topeka & Santa Fe.

SOUTHERN PACIFIC.—Morgan's Louisiana & Texas building extension from Lafayette, La., to Port Allen (opposite Baton Rouge), 21 miles finished, and work on the remaining 32 miles in progress. Extension graded from Bayou Sale to South Bend, 11 miles.

——The Coast Line Railway building north from Santa Cruz, Cal., 12 miles; 9 miles finished and work under way on the remaining 3 miles.

——The Central California, building from Niles, Cal., to Redwood City, 16 miles. Graded for 3 miles and work in progress on rest.

——The Peninsular Railroad building from Mayfield, Cal., to Vasona, 16 miles; 9 miles graded and grading work under way on rest.

——The Inter-California building an extension east from Calexico, Cal., through the northern part of Mexico to Yuma, Ariz., 55 miles. Track laid on 19 miles and 3 miles more graded. Work under way on remaining 33 miles.

——On the 152 miles projected by the Oregon Eastern, surveys between Natron, Ore., and Klamath Falls, and between the eastern side of the Cascade mountains and Ontario have been finished and considerable right of way secured.

——Oregon Western projected, 82 miles. Surveys made from Drain, Ore., via Marshfield to Ward and considerable right of way secured. Grading and tunneling under way and a large part of steel bridges, rails, ties and other track material bought.

——The Lincoln Northern organized to build from Lincoln, Cal., to Dairy Farm Mine, 11 miles.

——For Mexican Pacific Coast and Cananea, Yaqui River & Pacific see Southern Pacific under Mexico.

SPOKANE, PORTLAND & SEATTLE.—This road, formerly the Portland & Seattle, is a joint project of the Northern Pacific and Great Northern, to give them a direct low grade line to Portland, Ore. Building from Portland up the north bank of Columbia river and to Spokane, Wash., with branch east along the Snake river to Texas Ferry, Wash., a total of 415 miles. From Vancouver, Wash., to Kennewick, opposite Pasco, 220 miles, finished in 1907. Work under way on double-track steel bridges over the Columbia and Willamette rivers. The line between Pasco and Spokane, 145 miles, and the branch to Texas Ferry, 41 miles, also the 10 miles from Vancouver south to Portland is expected to be finished by August. Contract let to Siems & Shields, St. Paul, Minn., from Portland east to Kennewick, 230 miles. N. D. Miller, Ch. Engr., Vancouver, Wash.

SPOKANE & INLAND EMPIRE (Electric).—Last year built 50.5 miles in Washington. Contract let to Grant Smith & Co., of St. Paul, Minn., for extension on the eastern division from Palouse, Wash., south to Moscow, Idaho, 15.5 miles; graded for 14 miles and track laid on one-half mile.

SPRINGFIELD, CLEAR LAKE & ROCHESTER (Electric).—See Mississippi Valley Interurban.

STEPHENVILLE NORTH & SOUTH TEXAS.—Last year built 43 miles from Stephenville, Tex., south to Hamilton. Projected extension from Hamilton, south 60 miles, and from Stephenville, north 38 miles.

SUGAR CREEK & NORTHERN.—See Wheeling & Lake Erie.

SWAN CREEK.—See Louisville & Nashville.

T

TAMPA NORTHERN.—Built 39 miles in Florida last year. Contract let to B. H. Hardaway, of Columbus, Ga., for 9 miles from Envill Junction, Fla., to Brooksville. Surveying from Brooksville north to Thomasville, Ga.

TENNESSEE & CAROLINA SOUTHERN.—See Southern.

TENNESSEE RAILWAY.—Grading recently finished by Walton, Wilson, Rodes & Co. on 17 miles, from a point 2 miles below Smokey creek, Tenn., to Beech fork, on New river, 8½ miles; also on spur along Smokey creek to Asher fork, 8½ miles. Track laid for 7 miles and in progress on remaining 10 miles. A 3-mile spur to be built at once up Straight fork of Smokey creek. The line is being built to develop the coal and timber lands along New river and is eventually to be 75 or 80 miles long. W. O. Dyer, Ch. Engr., Oneida, Tenn.

TEXAS & GULF.—See Gulf, Colorado & Santa Fe.

TEXAS & NEW MEXICO.—Projected from McKinney, Tex., west via Denton, Krum, Bridgeport and Jacksboro, 175 miles. Surveyed for 80 miles, and grading finished on 4 miles. W. J. Healy, Vice-President, McKinney.

TEXAS & PACIFIC.—The Opelousas, Gulf & Northeastern, building from Opelousas, La., northeast to point on the Mississippi and southwest to Gulf. Finished from Melville, La., to Crowley, 58 miles. Myrick & Andrews, Opelousas, contractors.

TEXAS STATE.—In operation from Rusk, Tex. west 10 miles. Building extension west 18 miles to Palestine; extension also projected from Rusk east 6 miles. Plans reported to extend from Palestine northwest to Dallas, Tex., 100 miles, and on the southern end southeast to Sabine Pass, about 160 miles from Rusk.

TOPEKA & NORTHWESTERN.—See Union Pacific.

TOPEKA-SOUTHWESTERN.—Contracts let last year to the Southwestern Construction Co., of Topeka, Kan., from Topeka, Kan., southwest to Council Grove, with a branch west of Topeka north to the Kansas river, 60 miles. Steel bridge at Dover. W. L. Taylor, President; V. R. Parkhurst, Ch. Engr., Topeka.

TREMONT & GULF.—Building branch from Menefee, La., southeast to Rochelle, 18 miles.

TUSCALOOSA BELT.—Contract let to the Birmingham & Gulf Construction Co., Birmingham, Ala., from Tuscaloosa, Ala., northeast to Gadsden, 120 miles. Eleven miles in operation. Geo. H. Ross, Superintendent, Tuscaloosa.

TWIN CITY & LAKE SUPERIOR (Electric).—Building double track third rail line from Minneapolis and St. Paul, Minn., via Superior, Wis., to Duluth, Minn., 130 miles. Grading contract let from Belt Line, Minneapolis, to St. Croix river, 38.5 miles; graded for 30 miles. Additional contracts for 60 miles to be let April 1. Number of bridges. E. W. Farnham, President; W. H. Crossland, Vice-President. J. H. Thomas, Ch. Engr., Minneapolis.

U

UNION PACIFIC.—The South Omaha & Western is now building a double-track line from South Omaha, Neb., to Lane, 11.60 miles. Four miles finished last year. The Kilpatrick Bros. & Collins Contracting Co., Beatrice, Neb., contractors.

Contract let to Kilpatrick Bros. & Collins Contracting Co., Beatrice, Neb., to build branch from Rock Springs, Wyo., north to coal fields, 8 miles.

——Contract let to the Kilpatrick Bros. & Collins Contracting Co., Beatrice, Neb., from Luther, Neb., northwest to Northport, 51 miles, on the line from Hershey, Neb., to Northport, 115 miles.

——Extension of the Topeka & Northwestern from Onaga, Kan., to Marysville, 32.44 miles. Kilpatrick Bros. & Collins Contracting Co., contractors. Expected to finish the line by May 1, 1908. To be used in connection with part of the St. Joseph & Grand Island as a through line from Kansas City to main line in Nebraska.

Contract let to the Kilpatrick Bros. & Collins Contracting Co., Beatrice, Neb., for the Athol Hill cut-off south of Cheyenne, Wyo., from Carr, Colo., northeast to Borie, Wyo., on the main line; also on branch on the main line between Carr and Borie 3 miles south of Corlett, connecting with the Wyoming division 4½ miles west of Cheyenne. Total length of the new lines 17 miles.

UNITED TRACTION CO.—Contract let to A. W. Sykes, of Sykesville, Pa., to build from Sykesville, Pa., to Big Run, 7.5 miles. Grading finished and track laid on 6.5 miles. E. W. Hess, Ch. Engr., Du Bois, Pa.

V

VALLEY RIVER.—Projected from Mill Creek, W. Va., south to Clover Lick, 43 miles, surveys. Work under way from Mill Creek south to Valleyhead. John Alden, Ch. Engr., Elkins, W. Va.

VANDALIA.—Second track and grade reduction work under way from Harmony, Ind., west to East Yard at Terre Haute, 15 miles, including a better line between Seelyville and Brazil, 8 miles. Will be 9 reinforced concrete subways and 2 reinforced concrete bridges for highway traffic, eliminating 11 grade crossings; also 8 reinforced concrete culverts. Contracts let last year to Jones Bros., of Columbus, Ohio. To be finished in April.

About one mile of second-track being laid between the west end of the Wabash river bridge at Terre Haute and Macksville. To be finished by April.

VIRGINIA & POTTS CREEK.—See Norfolk & Western.

VIRGINIA & SOUTHWESTERN.—Contract let to Callahan Construction Co., of Knoxville, Tenn., for extension from Moccasin Gap, Va., south to the Tennessee State line, 6 miles, thence under the name of the Holston River Railway, southwest to Persia, Tenn., 38 miles. Work started in 1906, partly suspended in October, 1907, and now under way by small forces "at ruling points." All grading and structures 80 per cent. finished.

VIRGINIA AIR LINE.—Building from Lindsay, Va., south to Upper Bremo, 30 miles. Graded for 27 miles, and track laid on 8 miles. Expects to begin operation in July. J. N. H. Cornell & Co., contractors. W. Washabaugh, Ch. Engr., Charlottesville, Va.

VIRGINIAN RAILWAY.—Consolidation of the Tidewater and the Deepwater roads. Building from Norfolk, Va., west through Virginia, 332 miles, and north through West Virginia to Deepwater, 118 miles. Grading finished, except on few cuts between mile 215 near Leesville, Va., and mile 235, east of Roanoke. Track laid on 306 miles. Work under way on large viaducts prevents finishing track-laying. In operation from Norfolk west to Victoria, 125 miles, and from Deepwater south to Matoaka, 80 miles.

W

WALCOTTVILLE & COLDWATER.—Is to build from Walcottville, Mo., to Coldwater, 30 miles, during 1908. O. G. Wales, Kansas City, Mo., interested.

WARREN, JOHNSVILLE & SALINE.—Projected from Warren, Ark., southeast to Longview, 25 miles, with branch southwest to Hermitage. Built from Warren to Fullerton 6 miles, also from Fullerton on the branch 7 miles. Grading under way on 1 mile. Grading to be begun in May on 5 miles from Fullerton south. J. F. Forsyth, General Manager; C. W. Holderbaum, Ch. Engr., Warren.

WASHINGTON, WESTMINSTER & GETTYSBURG.—Projected from Washington, D. C., northeast to Gettysburg, Pa., 90 miles. Built 25 miles last year. Surveys under way on 3 miles in District of Columbia. Grading soon to be resumed. Ira Taylor, New York, contractor.

——Branch projected west to Frederick, Md. Contract for grading and materials agreed upon. Will probably be operated by gasolene motor cars. J. B. Colegrove, President, Washington, D. C. Walter Atlee, Ch. Engr., Baltimore, Md.

WATERLOO, PELLA & SOUTHWESTERN.—Projected from Waterloo, Iowa, southwest to Chariton, 120 miles. Contracts will probably be let this spring. E. A. Harris, Vice-President and General Manager, Pella, Iowa.

WEST CHESTER & WILMINGTON (Electric).—Projected from West Chester, Pa., south to Wilmington, Del., 17 miles. Work to be begun in March. Two bridges. Thomas E. O'Connell, President; C. P. Faucett, Secretary and Treasurer, Delaware Trust building, Wilmington.

WESTERN ALLEGHENY.—See Bessemer & Lake Erie.

WESTERN PACIFIC.—Building from Salt Lake City, Utah, west to Oakland, Cal., 929 miles, of which 122 miles are in Utah, 427 in Nevada and 380 in California. Contracts let to the Utah Construction Co., of Ogden; E. B. & A. L. Stone, of Oakland, Cal., and Maney Bros. & Co., of Winnemucca, Nev. Up to Feb. 20, 1908, grading finished on 620 miles and track laid on 275 miles, including the section from Salt Lake City west to the crossing of the Nevada Northern at Shafter, Nev., and in California from Stockton east 35 miles, and from Marysville east 34 miles. There will be 43 tunnels aggregating 15,342 lineal ft., three of which are to be over a mile long and a fourth over 4,287 ft. Tunnel work about 55 per cent. finished. There are to be 75 steel bridges, a total of 15,535 ft. long; 7 of these have been finished.

WEST TEXAS & NORTHERN.—The West Texas Construction Co. organized to build this line from Stanton on the Texas & Pacific to Lubbock, 110 miles. Fourteen miles graded north from Stanton.

WHEELING & LAKE ERIE.—Considerable amount of double tracking and minor grade and curvature reduction work contemplated, also the completion of the Sugar Creek & Northern, a new cut off from Bolivar, Ohio, northwest to Orrville, 22 miles, now three-fourths finished. All work suspended.

WICHITA FALLS & NORTHWESTERN SYSTEM.—Building with its own men extension from Olney, Tex., south to Belknap, 14 miles.

WISCONSIN & NORTHERN.—Projected from Menasha, Wis., north 153 miles. In operation for 43 miles. Projected extensions from Menasha to Shawano, 45 miles; Van Ostrand to Crandon, 32 miles, and from junction with the Minneapolis, St. Paul & Sault Ste. Marie, to the northern boundary of Wisconsin, 33 miles. All but 12 miles surveyed. Three miles partly graded from Crandon south.

WISCONSIN CENTRAL.—About 28 miles to be built to finish the line from Ladysmith, Wis., north to Superior. In Duluth, Minn., building about 4½ miles. Contracts let to H. P. Basch, of Rice Lake, Wis., and to Lantry Construction Co., of Duluth.

WOLCOTTVILLE & COLDWATER.—Projected from Wolcottville, Ind., northeast to Coldwater, Mich., 30 miles. Contract let to Panama Construction Co. Grading to be begun in June. O. G. Wales, President, 541 Frisco building, St. Louis, Mo.

Y

YELLOWSTONE PARK.—To build from Bridger, Mont., southwest to Cook, 125 miles, including branches. Thirty miles in operation. Contracts let last year to Western Development Co., of Belfry, Mont. "Arrangements pending to continue construction." No connection with recently built Oregon Short Line road of same name.

CANADA.

ATLANTIC, QUEBEC & WESTERN.—Built last year from New Carlisle, Que., north to Port Daniel, 20 miles. Contract let to the New Canadian Co., Ltd., of Paspebiac, and work under way from mile 20 to mile 102.

CANADIAN NORTHERN.—Grading finished by Cowan Construction Co. and track laid from Etoimami, Sask., northeast to Pas Mission, Keewatin, 100 miles. The first section of projected line to Fort Churchill on Hudson bay, 425 miles.

Branch from Dalmeny, Sask., to Coulter, Man., 45 miles, graded from Dalmeny north 21 miles.

—Extension of Rossburn Junction Rossburn branch, from Rossburn, Man., northwest to western boundary of Manitoba. Track laid from Rossburn to Russell, 25 miles. Further extensions projected, one northwest to Buchanan, Sask., on main line, the other west via Dundurn, on the Q., L. L. & S. to point near western boundary of Saskatchewan.

——Branch projected from Edmonton, Alb., north to Athabasca Landing, 100 miles. In operation to Morinville, 23 miles. Only surveys beyond that point.

Proposed extension of Thunder Hill branch from Benito, near western boundary of Manitoba, west to proposed Aberdeen-Fenton connecting line. Nothing done in 1907.

Proposed connecting line from Prince Albert, Sask., southwest to main line at North Battleford. Bridge being built over North Saskatchewan river.

Projected line from Saskatoon, Sask., southwest to Calgary, 300 miles. Graded for 30 miles. This is to form part of through line between Calgary and Fort Churchill on Hudson bay by connection with the line north from Etiomami, Sask.

——Contract let for rebuilding 8.4 miles of the Qu'Appelle, Long Lake & Saskatchewan, between Lumsden, Sask., and Disley.

Plans approved for the joint terminals to be built at Main street and Broadway, Winnipeg, by the Canadian Northern and the Grand Trunk Pacific at estimated cost of $3,000,000.

Improvements reported will be made this year on line between Port Arthur and Winnipeg. About 30 miles of present rails between Atikokan, Ont., and Rainy river to be replaced with 80-lb. rails, and extensive improvements at Fort Frances.

CANADIAN NORTHERN ONTARIO.—Building a 6-mile line to Key Harbor on Georgian Bay to carry iron ore from the Moose mountain deposits.

Extension from Parry Sound, Ont., northwest to Sudbury and beyond; 111 miles built in 1907 and in operation for freight service to Sudbury. Projected west to the Canadian Northern at Port Arthur, 600 miles from Sudbury.

Projected line from Key Inlet, near Sudbury, Ont., east to Ottawa, 350 miles.

Grading nearly finished last year from Ottawa east to junction with Canadian Northern Quebec at Hawkesbury, 50 miles.

—Contract let last year to Central Contracting Co., Toronto, to build from Nepigon, Ont., north to Lake Nepigon.

CANADIAN NORTHERN QUEBEC.—About 65 miles graded and track laid for 20 miles on extension from Gatineau Junction, Que., to Quebec, 84 miles. Work is being pushed to completion. O'Brien & Mullarkey of Montreal, contractors.

Charter granted last year for proposed line from Quebec bridge east to Moncton, N. B.

Proposed line from Moncton, N. B., to Pugwash, N. S., with branch in New Brunswick south to St. John.

CANADIAN PACIFIC.—Work under way on 196 miles to complete the double-tracking from Winnipeg, Man., east to Fort William, 426 miles. Foley, Welch & Stewart, Winnipeg, general contractors. A 100-ft. tunnel at Kilmar.

——Work started last year on the St. Mary's & Western Ontario from Woodstock, Ont., west to Sarnia, 95 miles. Contract let to John F. Webb, of Toronto, from St. Mary's to Embro, 15 miles, including a reinforced concrete subway under the Grand Trunk at St. Mary's; grading finished and track laid on 3 miles. Surveys being made on 71 miles toward Sarnia. J. G. Macklin, Ch. Engr., St. Mary's.

——Second track laid on about 50 miles between Ste. Annes, Que., and Smiths Falls, Ont.; the remaining 58 miles to be finished this year.

——Line from Saskatoon, Sask., west to Wetaskiwin, Alb., 325 miles. Contract let last year to Foley, Welch & Stewart, from Wataskiwin, Alb., east to Battleford, 250 miles. Grading 95 per cent. finished and 97 miles built from Wetaskiwin east and 26 miles west from Saskatoon. Sub-contract reported let to J. D. MacArthur, of Winnipeg.

——Work under way on 37-mile extension of the Yorkton branch from Sheho, Sask., northwest. Projected to Lanigan, 82 miles. Grading 50 per cent. finished.

——Contract let last year to J. T. Hargrave, of Winnipeg, for grading 30 miles on branch from Stoughton, Sask., west to Weyburn, 37 miles. All graded and 12 miles built last year. Projected from Weyburn, Sask., west 100 miles to Range 30, west of the second meridian.

——Building branch from Reston, Man., northwest to Wolseley, Sask., 122 miles, 98 miles built to Kaiser in 1907.

——Reconnoissance for proposed line from Killam, Alb., northwest to Strathcona, 80 miles.

——Extension of Kootenay Central from Golden, B. C., southeast to Fort Steel or Jaffray, about 180 miles. Contract for grading 10 miles from Golden south let last year to the British Columbia General Contract Co., of Vancouver. Track to be laid by the railroad.

——Projected branch from Moose Jaw, Sask., northwest to Lacombe, Alb., 375 miles. Grading contract from mile 50 to mile 123 let to J. D. MacArthur, Winnipeg, for work from Moose Jaw north via Tuxford to point 30 miles beyond Rutland, 50 miles. Track being laid by the railroad on first 50 miles; finished to Tuxford, 15 miles. Work also under way from Lacombe east 100 miles toward Moose Jaw. Surveyed, and 51 miles in operation to east Stettler, Alb. Foley, Welch & Stewart, contractors.

——Contract let last year to Foley, Welch & Stewart for work on Toronto-Sudbury line from Bolton, Ont., north to Romford, 226 miles; 160 miles built; whole to be finished in June. Ross & Harris, contractors for 40 miles.

——Agreement made with the Northern Colonization Railway to build extension from Nominingue, Que., west to Rapide de L'Original, in Wright district, 34 miles.

——The Walkerton & Lucknow building from Walkerton, Ont., to Proton, 37.5 miles. About 25 miles built.

——On the branch of the Guelph & Goderich from Linwood, Ont., to Listowel, 16 miles, there are 3 miles still to be built. B. Gibson, Toronto, contractor, and P. A. Peterson, Goderich, Ch. Engr.

——Contract reported let to McDonnell & Gzowski, of Vancouver, B. C., for improving the main line grades near Field, B. C. The work includes two new tunnels aggregating about a mile and a half, one on each side of the Kicking Horse river, and two bridges. To cost about $1,500,000. Preliminary work begun.

——Additional work to be carried out this year as follows: Line to Hardisty, Alb., and extension of the Winnipeg Beach line north to Icelandic river. A large amount of bridge work is also to be done in British Columbia; many wooden bridges will be replaced by permanent structures.

——Extension of 4 years granted to complete the Esquimalt & Nanaimo branch from Nanaimo, B. C., west to Alberni, 50 miles. Location work finished. Contract let to John Bright, of Nanaimo, for grading from Wellington to Nanoose bay, 12 miles, and to A. Carmichael for clearing right of way from Nanoose bay to Alberni, 46 miles.

CAPE BRETON.—Surveys under way for extension to be built this spring from St. Peters, N. S., northeast to Louisburg, 31 miles.

CENTRAL ONTARIO.—Contracts let to build extension from Maynooth, Ont., to Lake St. Peter, 8 miles; also from Lake St. Peter to Whitney, 19½ miles.

CROW'S NEST SOUTHERN.—See Great Northern under United States.

ESQUIMAULT & NANAIMO.—See Canadian Pacific.

GRAND TRUNK PACIFIC.—To extend from Moncton, N. B., 3,550 miles across Canada to Prince Rupert, B. C., a new port on Kai En Island, about 25 miles south of Port Simpson. The total length of all the projected lines is 7,000 miles.

——Moncton to Winnipeg, Man., 1,807 miles, called the National Transcontinental, to be built by the Canadian government. Contracts let for 859 miles and bids asked for 365 miles more. Total expenditure to Jan. 28, 1908, $21,364,364. Contracts let last year as follows:

——To Grand Trunk Pacific Construction Co., from Moncton, N. B., west to point near Chipman, N. B., 50 miles.

——To Lyons & White, of Ottawa, from Grand Falls, N. B., west to New Brunswick-Quebec boundary line, 62 miles.

——To M. P. & J. T. Davis, of Ottawa, from point 52.4 miles west of the New Brunswick-Quebec boundary west to southern end of the Quebec bridge, 150 miles.

——To Hogan & McDonald, Montreal, for 150 miles from north end of Quebec bridge west to La Tuque. Thirty-four miles of track laid in short sections. Over 6,000,000 yds. of earth and 1,000,000 yds. of rock excavation on this stretch, of which part is finished. Sub-contract for 50 miles from Quebec bridge west let to M. T. Davis, Ottawa. Work under way on Cape Rouge viaduct, 3,000 ft. long.

——To Grand Trunk Pacific Construction Co., from La Tuque, Que., west to Weymontachene, 45 miles.

——To Grand Trunk Pacific Construction Co., from point 8 miles west of Abitibi river, east 150 miles. Some of this sublet to J. H. Reynolds Construction Co. Work to be started on this section this spring.

——To J. D. MacArthur, Winnipeg, from junction to Lake Superior branch with main line, west to point a few miles east of Winnipeg, 244 miles. Sub-contracts let to A. Herbert, 20 miles; W. Wardrup, 15 miles; F. W. Smith, 2 miles of rock work; Guy Campbell, Ottawa, rock work, and W. T. Parsons, of Kenora, Ont., 15 miles, including about 1,000,000 yds. of rock excavation. Excavation on this section amounts to over 11,000,000 yds. of earth and 3,500,000 yds. of rock.

——Bids asked up to March 11 for the following sections: District A.—From about 58 miles west of Moncton, N. B., to the crossing of the Intercolonial, at mileage 97.7, a distance of 39.7 miles. From the latter point to the Tobique river, at mileage 165.7, less one mile, 67 miles. From the Tobique river to about 2½ miles west of Grand Falls, N. B., 31.5 miles. District B.—From the Quebec-New Brunswick boundary westerly for 52.4 miles. District D.—From a point about 8 miles west of the Abitibi river crossing in Ontario, west about 100 miles. District E.—From a point 19½ miles west of the crossing of Mud river, near Lake Nepigon, easterly 75 miles.

——The western line, Winnipeg, Man., via Saskatoon, Sask., Edmonton, Alb., and Yellow Head pass to Prince Rupert, 1,750 miles, and the Lake Superior branch east of Winnipeg to Fort William, to be built by Grand Trunk Pacific. All located. Contracts let for 1,108 miles from Winnipeg, Man., west to 120 miles west of Edmonton. Track laid from Portage la Prairie, Man., via Brandon and Touchwood Hills to Saskatoon, 415 miles. Grading finished from Winnipeg to Portage La Prairie. Contracts let last year as follows:

Lake Superior branch, from Lake Superior Junction southeast to Fort William, 210 miles, to Foley Bros., Larsen & Co. (now Foley, Welch & Stewart), Winnipeg, Man.; 100 miles of track laid.

——To MacDonald-McMillan Construction Co., Winnipeg, from Winnipeg west to Portage la Prairie, 56 miles. Work under way.

——To MacDonald-McMillan Construction Co., Winnipeg, for grading from Portage la Prairie, Man., west to Touchwood Hills, Sask., 275 miles. Finished.

——To Canadian White Co. (J. G. White & Co.), Montreal, from Touchwood Hills to Saskatoon, Sask., 140 miles. Sub-contracts let to M. C. Cance, Rainy River, Ont., J. H. Armstrong, and S. D. Lake. Finished.

——To Foley Bros., Larsen & Co., Winnipeg, Man., from Saskatoon to Edmonton, Alb., 328 miles. Sub-contracts let to Cash Bros. for work in Alberta near Battle river. Work under way and to be finished this year.

——To Foley Bros., Larsen & Co., Winnipeg, from a point 6 miles east of Edmonton, Alb., to Wolf Creek, 120 miles west. The section will be the most expensive of any of the western lines yet under contract. Work under way. Contracts let for ties to H. A. Calder, $200,000; Carruthers, Round & Co., and McPhee Bros. & Hislop, each $100,000.

——Work under way on 100 miles of main line east from Prince Rupert, B. C., to Kitselas canyon, which is the junction point between located direct line eastward and located loop line which is to run north along the Skeena river to Hazelton, then southeast to junction with main line again at point 350 miles east of Prince Rupert. The 100-mile section directly east of Prince Rupert includes much rock work, and it is expected will take two years to build, and cost $7,000,000.

——The Grand Trunk Pacific Branch Lines Co., authorized to build branches from the main line as follows:

——From Moncton, N. B., south to St. John; New Brunswick-Quebec boundary west to the St. Lawrence river, near Riviere du Loup, Que., south to Montreal; from a point further west southeast to Montreal; to Ottawa; to North Bay; from point northeast of Fort William, Ont., southeast to Orilli, Ont.; Winnipeg south to international boundary; Brandon south to international boundary with a west line from Brandon to Regina, and from point on the international boundary in southeastern corner of Saskatchewan northwest to Regina, thence northeast across main line south of Springside, Sask., to Fort Churchill, on Hudson bay; point east of Saskatoon, north to Prince Albert; point near western boundary of Saskatchewan, north to North Battleford; point near eastern boundary of Alberta, southwest to Calgary, thence southeast to international boundary; Fort George, B. C., south to Vancouver; point near Hazelton, B. C., northwest to Dawson, Yukon. Also line from the southeast end to the northwest end of Vancouver Island.

GREAT NORTHERN.—See Great Northern under United States.

GUELPH & GODERICH.—See Canadian Pacific.

INTERCOLONIAL.—Double-tracking under way between Moncton and Halifax. Contract from Moncton to Painsec Junction, 7 miles, let to J. B. McManus Co., Ltd., of Memramcook, N. B.

——Contract let to Willard Kitchen Co., of Fredericton, N. B., for Cotton Factory branch from Richmond, N. S., to Kempt Road, Halifax, 1.69 miles. Work under way.

NORTHERN COLONIZATION.—See Canadian Pacific.

ORFORD MOUNTAIN.—Building extension from Mansonville, Que., to North Troy, Vt., 4.5 miles, and from Windsor Mills, Que., to Brompton-ville, 9 miles. Both to be finished early this year.

QUEBEC, MONTREAL & SOUTHERN.—See Delaware & Hudson under United States.

ST. MARY'S & WESTERN ONTARIO.—See Canadian Pacific.

TEMISKAMING & NORTHERN ONTARIO.—Extension of main line from mile post 2[illegible] at the Watabeag river to mile post 2[illegible]1 near Transcontinental Junction, 4[illegible] miles. A. R. McDonald, New Liskeard, Ont., and McRae, Chandler & McNeil, Driftwood City, Ont., contractors.

——Branch from Englehart to Charlton, 8 miles. Canadian Construction Co., Montreal, contractors.

——Branch from Cobalt to Kerr Lake, 4 miles. McQuigge & Hunt, Cobalt, Ont., contractors.

——Surveys for branch from Cobalt to Sudbury, 110 miles.

VANCOUVER, VICTORIA & EASTERN.—See Great Northern, under United States.

VICTORIA FERRY & RAILWAY.—See Great Northern, under United States.

WALKERTON & LUCKNOW.—See Canadian Pacific.

MEXICO.

CANANEA, YAQUI RIVER & PACIFIC.—See Southern Pacific, under Mexico.

KANSAS CITY, MEXICO & ORIENT.—See this company under United States.

MEXICAN CENTRAL.—On the Tampico cut-off about 101 miles remain to be built, 54 miles of which (from the Panuco river south) is under contract. The line as located from the city of Mexico to Tampico will be 364 miles long, as against 1,000 miles by the present route. The 142 miles from Tampico to the foot of the plateau, will have a .5 per cent. grade, and on 54 miles the maximum will be 2.5 per cent. with 8 deg. curves.

——Building Manzanillo extension from Tuxpan, Jalisco, to Colima, capital of Colima, 45 miles. Hampson & Smith, Mexico City, contractors. Number of important bridges and 12 tunnels. Much heavy work to be done between Colima and the port of Manzanillo. Connection at Colima with reconstructed line of Mexican National Construction Co. to Manzanillo. Whole extension to be finished this summer.

——Large terminal to be built at Manzanillo. About 1,000 acres of land bought.

MEXICAN PACIFIC COAST.—See Southern Pacific, under Mexico.

MEXICAN WESTERN.—Grading soon to be begun from Gutierrez, Zacatecas, west to Sombrerete, 100 miles. Final surveys made. R. S. Towne, President of the Mexican Western Construction Co., interested. Vinton P. Safford, Gutierrez, Ch. Engr.

MINERAL BELT OF GUANAJUATO.—Contract let to E. J. White, of Guanajuato, to build 40 miles to mines in state of Guanajuato. Heavy work. Graded from Tepetapa, 2 miles. The Guanajuato Development Co., is building the line.

PAN AMERICAN.—Contract let to H. L. Heintz of San Geronimo, Oaxaca, to build from Huixtla, Chiapas, to the Guatamala line, 30 miles, including 3 large bridges. Track laid from Tapachula, Chiapas, to San Bineto, 20 miles.

——This company has concessions for main line to Panama through San Salvador and Nicaragua.

——The Pacific, Gulf & Yucatan is a projected branch from Jallaco, Chiapas, to point in state of Yucatan, 660 miles.

PACIFIC GULF & YUCATAN.—See Pan American.

PARRAL & DURANGO.—Last year built 3 miles south of Mesa de Sandia, Durango. Work under way on 12 miles from kilometer 75 to Paraje Seco. Contract let to R. M. Dudley, of Mesa de Sandia.

SOUTHERN PACIFIC.—The Cananea, Yaqui River & Pacific is building a branch from Corral, Sonora, north along the Yaqui river. Projected to international boundary, 388 miles. Built to Cumuripa, 41 miles. Grant Bros. Construction Co., Los Angeles, Cal., has contract to Tonichi, 63 miles.

——Work under way on branch from Rio Yaqui, Sonora, north to Nacozari, 108 miles.

——Work under way from Del Rio Sonora, on the Naco-Cananea line, northwest to Nogales, 75 miles.

——The Mexican Pacific Coast building from Navojoa, Sonora, south of Corral on the Cananea, Yaqui River & Pacific, southeast to Guadalajara, Jalisco, 780 miles. About 84 miles finished last year from Navojoa south, and work progressing. The Grant Bros. Construction Co., Los Angeles, Cal., has contracts for some of the work.

ZACATECAS & EASTERN.—Projected from Camacho, Zacatecas, via Tesolate and Cedros to Bonanza, Coahuila, with a branch from Cedros to Salverna, a total of 80 miles. Concessions granted to John Cooper through J. P. Taylor, of Mexico City. Contracts soon to be let and grading started within 6 months.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK

BRANCH OFFICES AT 375 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. *We give in our editorial columns* OUR OWN *opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.*

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette:

OFFICERS:

W. H. BOARDMAN, *Prest. and Editor*
E. A. SIMMONS, *Vice-President*
RAY MORRIS, *Secretary*
R. S. CHISOLM, *Treas.*
I. B. RINES, *Cashier*
L. B. SHERMAN, *Western Manager*

EDITORS:

RAY MORRIS, *Managing Editor*
BRAMAN B. ADAMS
CHARLES H. FRY
FRANK W. KRAEGER
GEORGE L. FOWLER
HUGH RANKIN
BRADFORD BOARDMAN

CONTENTS

VOL. XLIV., No. 12. FRIDAY, MARCH 20, 1908

Bion J. Arnold, who was some time ago engaged by the Public Service Commission for New York City to report improvements which might be made to the present Interborough Rapid Transit subway, has made a further report to the Commission dealing with improvements which can be made to the express stations and to the signal system of the subway. Mr. Arnold's report on the Subway Car was published in the *Railroad Gazette* of February 28 and March 6, 1908. Mr. Arnold declares that the existing signal system, when it was put in in 1904, was as complete as it was possible to make it, but that the art of signaling has made rapid strides since that time. Besides advocating a change in the signal system on the express tracks, which will provide an automatic stop for trains entering stations and the extension of the signal system used on the express tracks to the local tracks, Mr. Arnold's most novel recommendation is that the express stations should be double decked, so as to make it possible for two express trains to lie in a station at the same time, alternating on one and the other side of the express platform, the local trains running underneath the express level. This he believes would increase the capacity of the subway by fully 50 per cent., because the great delays in the subway come in unloading and loading passengers. There is said to be room for double decking the express stations without additional excavation, with a possible exception at Ninety-sixth street. At present during the rush hours each express train usually has to wait just short of each express station while the train in advance is discharging and taking passengers at that station platform. With capacity for receiving two express trains at the same time at each platform, a second train could pull into the platform and begin unloading while the first train was finishing its loading and about to pull out. Mr. Arnold's recommendations in regard to the signal system are summed up in another column.

We print this week in pretty full detail a very noteworthy document: the report of the commissioners appointed to investigate the Quebec bridge failure. The finding that the professional knowledge of the present day concerning the action of steel columns under load is not sufficient to enable engineers to design economically such structures as the Quebec bridge is immensely important, but it tells only part of the story, for the commissioners specifically deny that there was any improper desire of economy or any neglect of duty. The bridge fell because its design was fundamentally wrong, insufficient provision having been made for unit stresses higher than any established by past practice. The dead load upon which the calculations were based was assumed at too low a value and the error got past all the engineers who should have detected it. But this error, great as it was, might have been detected early or might at least have been prevented from working terrible harm had it not been for the fact that "the greatest bridge in the world was being built without there being a single man within reach who by experience, knowledge and ability was competent to deal with the crisis." The bridge company had the services of an excellent consulting bridge engineer, but, owing to Mr. Cooper's advancing years and ill health, they were absentee services. The correspondence quoted from the report shows perfectly clearly the instant apprehension of the consulting engineer at the first sign of danger; but he was ill, he was a long distance from the work, and there was nobody on the ground possessing either the experience to grasp the full meaning of the desperate situation which had arisen or the combined experience and authority needed to deal with it. The commissioners say, "the impression left with us is that throughout the work Mr. Cooper was in a position of a man forced in the interests of the work to take responsibility which did not fully belong to his position and which he was not authorized to take, and that he avoided the assumption of authority whenever possible." So here we have the two great causes of the disaster, defective design, and a defective organization for doing the work. No further comment need be made. The rewards which compensate the engineer who has succeeded are not great, apart from the joy and pride of conquering quietly and progressively all the difficulties, old and new, which nature provides with such abundance and of realizing that there are a few who know and appreciate: the penalties and the sorrow of failure are perhaps greater than in any other profession.

The announcement by the Georgia Railway Commission that Mr. Harriman and his associates bought the Central Railroad of Georgia last summer through their agents, Oakleigh Thorne and Marsden J. Perry, is of unusual interest, for several reasons. First of all because a transcontinental system has been created within the boundaries of the United States under common control. Details of Mr. Harriman's exact holdings in the Georgia Central are lacking, just as they are in the case of the Illinois Central, but it is clear that the Harriman party commands the policy and resources of both these roads, which together afford a through route from Omaha, Neb., to

Savannah, Ga., by way of the new Illinois Central extension to Birmingham, Ala., described on another page last week. The Gould interests have been measurably close to a transcontinental line for some years, and when the Western Pacific is completed the only gap between Oakland and the terminus of the Western Maryland at Baltimore will be a stretch of 100 miles or so (of exceedingly difficult country) in the West Virginia mountains between the West Virginia Central & Pittsburgh and the Wheeling & Lake Erie. But Mr. Harriman has a good deal better through route than this could have been. The grades on the Denver & Rio Grande and on the West Virginia Central & Pittsburgh are not adapted to a heavy through haul, and the difficulties in connection with the West Virginia mountain strip of intervening territory are so great that no active attempt to close the gap is being made. On the other hand, the Harriman route from the Pacific coast right through to Birmingham, Ala., is thoroughly well adapted for heavy traffic, and the Georgia mileage, although not yet developed for that purpose, ought to be capable of development at comparatively small expense. To what actual use this combination of roads will be put in its capacity as a transcontinental line, is another question. The Illinois Central has a most excellent, substantial, capacious line from Chicago to New Orleans, with easy grades favoring southbound traffic. The Southern Pacific has a line of freight and passenger steamers from Galveston and New Orleans to New York which can handle through business with the greatest advantage and economy, and it is not clear that it would benefit the system to haul transcontinental traffic over the Central of Georgia to Savannah, thereby competing with the Illinois Central gulf lines and with the great fleet of Southern Pacific coastwise steamers. The Central of Georgia also has an excellent fleet running between Savannah and New York. This steamship property has been carried upon the Georgia Central balance sheet at an absurdly small figure, in view of the fact that all the steamers now in commission are large, new boats, none of them except the "Kansas City" being more than six years old and all being excellently adapted to the traffic, and the inference is a fair one that this service has been so profitable that much of the actual cost of this fleet has been met out of surplus earnings. It is not clear how the Harriman system will derive any advantage from using this Savannah fleet to compete with the New Orleans fleet for through traffic. It seems more likely that the best use of the Georgia Central will be as a large and very important local railroad, fully able to take care of itself, with its sphere of usefulness extended by the additional traffic which the western connections will be able to give it. But, after all, the greatest value of this property to the Harriman system probably lies in the fact that it is thereby kept out of the hands of the Rock Island.

RIFTS IN THE RAILROAD CLOUDLAND.

The president of a great railroad system, itself not so severely visited by adverse legislation as some other systems, recently in a semi-private talk expressed his fears that the present general onset upon the railroads presaged ultimately one of two things—compulsory and arbitrary scaling down of their values by state action or a smaller scaling down under federal ownership. Such words were the language of pessimism albeit they represent in these strange times what too many people who are always looking toward the sunset rather than to the dawn, are saying or thinking. It is one of the evils of hard times that their ills are not merely concrete. They also tend to create a kind of atmosphere which, breathed in, infects overmuch the vision and distorts the perspective. In such atmospheric conditions it is well now and then to take a draught of ozone and readjust vision to its true focus. Nor, somber as the general outlook may be, is such a search for rifts in the railroad cloudland in vain, nor like an attempt to draw rays from the cucumber, nor to demonstrate the much-disputed canals of Mars. The bright rifts in the railroad situation are really there and likely to widen rather than narrow—especially after election.

Let us take, for one example, that valuation idea which rises every few days like an uneasy ghost and has but lately assumed somewhat clearer apparent outlines, while not more tangible really, in the Nebraska platform which is known to be Mr. Bryan's own, and which may be rebuilt at Denver along the same lines. It scares somewhat conservative railroad investors already made nervous by previous events. But how many of them remember in that connection the "due process" clause of the federal constitution relating to property and how it stands right athwart anything that savors of confiscation? "Valuation" of railroad properties means a process of such intricacy, such an excursion into an infinity of varying values, such an unraveling of tangled and snarled skeins of interests complicated by time and change as would defy the labors of the economic gods. But even were it practical, how much have the railroads actually to fear? Not a few of them if extinction of old investment by reorganization is reckoned in, are under-capitalized rather than over-capitalized by a fair valuation test. Others have been solidified by the immense increase of their realty values, especially when they include terminals in great cities. Under constitutional limitations and checks the very worst that valuation could do in the case of the steam roads, would be the clipping of the edges of speculative securities. Even in the case of speculative issues, which morally deserve small pity, most of them are protected behind state law though that does not prevent them, perhaps, from being reached by legislative reduction of rates. This would apply, however, to street railways rather than to the steam roads, honest investors in which can afford to treat valuation as a bogy and rely pretty confidentially on the courts to resist confiscation by statutory rate-making.

Another rift in the clouds is descried when one studies the present phase of railroad contraction. We have now begun to reach the after-panic period when the procession of receiverships has started. But no great railroad system has yet joined it. What is of more importance, unlike the after-panic periods of the seventies and early nineties, the recent receiverships have come, usually not as the sequel of basic railroad weakness but of credit contraction. There has, of course, been contraction of earnings, but this has been a minor factor; there has been a malign influence reaching somewhat further in the form of state and federal action, but the main cause has been stagnated credit at a time when only the highest security commands funds. Though the distinction may seem a fine one, the recent receiverships in railroads have been fiscal rather than physical, as they were after 1873 and 1893. Then they were the result of an undue mass of debt in ratio to physical capacity and earning power; now they come when physical capacity is good and indeed so good that it has been seeking extension, but has been met by sudden and unlooked for collapse of borrowing power. The distinction seems obvious, as also its corollary that the railroad receiverships of 1908, unless hard times greatly deepen and lengthen, will perhaps not involve any great railroad system, and will many of them be transitory without root and branch reorganizations—in this respect not unlike the suspension of certain New York banking institutions.

In this connection another rift to be watched for hopefully is the market for railroad bonds, the real financial criterion of railroad credit. Through that fissure in the gloom there gleamed a cheering light in January. The normal reaction from panic conditions seemed then to have set in. Capital, made timid by panic, had begun to seek actively senior classes of good railroad bonds for investment, and the demand had even begun to reach the junior bonds of the stronger roads, and promised to extend downward still further and alleviate the strain on railroad credit. Why the upward movement of railroad credit ceased within three weeks is partly conjectural. Those who attribute it to the exhaustion of dividend investments may possibly be as near to the truth as those who charge it to the untimely utterances of the President. But whatever the cause, the normal drift of capital into railroad bonds has probably suffered a pause, not a check. That the free capital exists to renew it is at least suggested by the great over-subscription to the New York City loan and the success and high premium of the new $39,000,000 loan of the New York, New Haven & Hartford. Upon the future of railroad bonds during 1908 the solution of the railroad situation very largely depends and, on the whole, the outlook is not unpromising save for "politics" and unnatural interference by high officialdom with the national law of post-panic recovery.

We have referred to certain breaks in the railroad obscurity which are secondary in character and remote from others which are primary and more visible, such as the underlying strength of the nation's industries, the powers of common law as a check on demagogism, the final triumph of common sense and of the axioms of political economy and the bracing fact that a presidential campaign cannot last forever. But while optimism still has the vantage of pessimism the deeper must be the regret that the rifts in the railroad cloudland are not broader, that they do not open faster and that in the commercial quarter the horizon still remains so thick. The curt phrase, "net earnings" of the railroads are the final test words, and those in time rest on general trade conditions. How far and how long they, in their turn, are to be distempered by policies external, hasty and rash, only time will inform us. If they could only be let alone prophecy would be both more definite and more reassuring.

THE ENGINEERING DIFFICULTIES OF THE HUDSON & MANHATTAN TUNNEL.

The shield method has now been used so often for subaqueous tunneling that from the engineering standpoint there is nothing new or particularly interesting about its general principles. The striking features of such work are the means devised to meet unique difficulties. It is here that the duties of the engineer in overcoming natural forces branch out into the romance of achievement. The twin Hudson & Manhattan tunnels recently opened for traffic under the Hudson river between New York and Hoboken, had their full share of such critical situations, which were successfully handled by new methods. In an address before the Yale Club in New York City recently, Charles M. Jacobs, chief engineer of the Hudson & Manhattan, spoke of a few of the most striking of these problems. They are worth special mention as illustrating the highest type of engineering achievement.

At the beginning of the work on the south tube of the uptown tunnel, the shield from the Hoboken side through the silt was being advanced with the shield doors closed so as to save the cost of excavation. While the heading was still under the Lackawanna coal dock the night superintendent, thinking that the shield was moving very slowly, determined, contrary to orders, to open one of the center doors so as to let the mud come in and so let the shield go ahead faster. The silt shot in under such pressure that it buried some of the men before they could escape; the rest of the shift got away through the upper emergency lock which was then 115 ft. from the shield face. The heading was lost and, the tunnel between the shield and the lock being filled solid with mud, there was no space for air pressure in which men could be put to work digging out the mud. The coal dock was crowded with shipping and, furthermore, the Lackawanna at that time was not particularly favorable to the tunnel enterprise, so it would have been almost impossible to get permission to dredge out the bed of the river in front of the shield so that a diver could go down and timber up the exterior opening to the doorway. The problem was solved as follows: Two heavy mainsails (one being an old one of the cup defender Reliance) were procured and a double canvas cover, about 60 ft. by 40 ft., made of them. Around the edges were secured small weights of pig iron. The canvas was spread on a flat barge and lines carried to fixed points to hold the mainsail in the position; the barge was withdrawn and the mainsail allowed to drop to the bed of the river, 30 ft. of it covering the shield and the remaining 30 ft. extending out beyond the face toward the middle of the river. One of the pipe valves in the lock was then opened and the mud, under the direct pressure of the river, shot into the tunnel westward of the lock for 40 ft. It came in a solid stream for eight days and nights. Finally it let up for a few minutes, began again and then stopped. A cavity had formed in the bed of the river outside the cutting edge of the shield until the canvas dropped with the cavity and was eventually drawn into the opening of the doorway through which the mud was pouring. A small cavity was excavated in the mud-filled tube ahead of the lock and air pressure being put on, it immediately relieved much of the strain on the temporary canvas cover. Miners were then able to get into the tunnel and dig out the mud. In about nine days the heading was recovered and the door on the inside closed.

The north tube is an extension of an old tunnel abandoned some years ago. Within 100 ft. from the point where the shield stopped in the previous attempt, was a reef of rock, standing from 1 to 16 ft. above the intended grade of the tunnel. Before the shield arrived at this point, it was necessary to build a temporary workshop in the river ahead of the shield, so as to build on the front of it a steel apron under which men could work in drilling the rock and blasting it out of the path of the shield. Above the rock was soft silt and, above that, from 60 to 65 ft. of water. It was expected that, in blasting the rock with so slight a cover and with such heavy water pressure, the heading would probably be blown out. Clay loaded on barges was, therefore, always held in readiness to be dumped into any such blowout. After a few weeks the expected blowout occurred and the 900-ft. of tunnel from lock to heading was flooded. The men at work escaped. The clay scows were immediately brought over the blowout and dumped, thus blocking the hole. The water was pumped out into the western workings, and within 11 hours men were able to reach the heading on a small raft. No damage was found and work was soon under way again. In all, only 21 hours time were lost. There were two more blowouts while the tunnel was being built across the 700 ft. of reef, and in each case they were similarly dealt with. Finally, however, there arose a problem which could not be dealt with by dropping these clay blankets. At the extreme eastern end of the reef the rock rises about 16 ft. above the bottom of the cutting edge of the shield. The tunnel at this point is so near the bottom of the river that the clay was almost fluid and continually slipped into the pockets of the shield, so that the men could not get out underneath the apron to drill the rock. Scow after scow was dumped, but the clay would not hold. Finally blow pipe flames, fed from two tanks of kerosene, were directed against the exposed clay until it was indurated, so as to hold its position while the men drilled the rock. The blow pipe process took eight hours, during which time streams of water were continually played on the shield structure to prevent its being damaged by the high temperature. This is probably the first time that man has made brick in the bed of a river.

There was a serious problem on the New Jersey side in regard to the transverse tunnel running from the river tubes north to the Lackawanna terminal and south to the Erie and Pennsylvania terminals, and thence to the downtown tunnel of the Hudson & Manhattan. The problem was to eliminate, as far as practicable, all crossings of the tubes at grade and still give each track a connection with all the terminals mentioned. The south tube of the uptown tunnel was, accordingly, carried under the north tube at the Fifteenth street shaft, Jersey City. About 200 ft. west of this shaft a reinforced concrete caisson (known as caisson No. 1) was sunk from the surface; the caisson is a two-story structure, carrying two tracks on each level. The south tube enters on the lower level, and trains are switched in the caisson to the north or to the south. The north tube comes on the upper level, and branches similarly north and south. The caisson is 105 ft. long, 23 ft. wide at the easterly end, and 46 ft. wide at the westerly end; it is 51 ft. high, is sunk 85 ft. below tide level, and the total weight is about 10,000 tons. There is a similar caisson (No. 2) about 700 ft. west of the first one. In caisson No. 2 trains from Hoboken may be switched over to New York or to the Erie and Pennsylvania stations in Jersey City. Caisson No. 3 is south of caisson No. 2, the three caissons making a triangle. In caisson No. 3 trains from the Erie and Pennsylvania stations are switched either to Hoboken or to New York. It was originally intended to use steel caissons, but the high cost of steel and uncertainty as to the delivery of material resulted in the decision to make them of reinforced concrete with steel cutting edges, being the first of their kind. They were sunk to position and the shields then run into them, making in a unique way underground switch yards, and saving a large amount in cost and in time, the latter being of the utmost importance. It would probably have taken about nine months and cost $75,000 to make one steel caisson. All the caissons were sunk under air pressure.

Perhaps the greatest, though not the most spectacular, feat in all the construction thus far completed was the building of the tunnels at the intersection of Christopher street, Ninth street and Sixth avenue, in Manhattan. From this point two tunnels go east under Ninth street and two north up Sixth avenue. Here there was the elevated railroad overhead, the Metropolitan Street Railway lines on the street surface, and buildings on each side of the street. It was a problem similar to the intersections in Hoboken, just described, but in this case, of course, sinking a caisson was out of the question. To accommodate the two tubes coming up from the south and the four diverging to the east and north it was necessary to build an arch whose maximum width was 68 ft. The work was all in running sand and was done under air pressure. Two iron-lined tunnels were run through this intersection first, and the side-walls then built in. Openings were then made at the tops of the tunnels and timbering for strutting was carried up so that sufficiently heavy false work could be put in for springing the arch. After the arch was completed the two temporary tunnels were taken out. This work required the greatest ingenuity and care for at least eight weeks. Any accident to the timbering, any loss of the necessary air pressure, or any carelessness of the men, would have undoubtedly caused a cave-in, and the elevated structure and the surface lines, together with the streets and the buildings on each side, would have fallen into the excavation. Every square inch of the treacherous ground had to be protected by wooden sheathing the moment it was exposed, otherwise the vibration of the passing trains above would start the sand running. This part of the work was the last of the excavation necessary for opening the railroad to traffic, and although it was early in last December when the spring of this large arch was under way, it was finished so that trains could be operated on February 10, 1908.

Committee Reports at the Maintenance of Way Convention.

Following are brief synopses of the committee reports presented at the convention of the American Railway Engineering and Maintenance of Way Association, held in Chicago this week. An abstract of the discussion of these reports will be given next week.

ROADWAY

The report on Roadway deals with the subjects of "Track Elevation and Depression in Cities," and "The General Practical Work of Grade and Curve Improvement Work Outside Cities."

Under the first heading, the committee presents, in tabular form a summary of replies received in answer to a circular of inquiry. The roads reporting are the Chicago & Western Indiana; the Burlington; the Rock Island; the Chicago Terminal Transfer; the Delaware, Lackawanna & Western; the Illinois Central; the Long Island; the Michigan Central; the New York, Chicago & St. Louis, and the Pennsylvania. The information included the extent of the work; how it was handled; how it was organized; where the material for filling was obtained; how unloaded; number of cubic yards a day, and the equipment for unloading; method of handling the bridge work, and the methods of handling water, sewer and gas pipes, electric conduits and wires, street cars and general traffic.

The second subject has been confined to the practical work of grade and curve improvement, with particular reference to the consideration of practical methods and organization.

The committee reports progress on the "Determination of Waterway for Culverts," and presents a list of references to articles published on this subject.

The committee recommends the adoption of the following conclusions:

GRADE AND CURVE IMPROVEMENT WORK INSIDE OF CITIES, SUCH AS TRACK ELEVATION AND DEPRESSION.

(1) Organization.—There should be a superintendent of construction in complete charge of the work. To him should report the following officers in charge of the various branches of the work: The engineers having charge of the contract work and giving lines and grades; the roadmaster in charge of earthwork and track work; the engineer in charge of masonry and bridges; the yardmaster in charge of engines and switching; the trainmaster, with a despatcher in charge of the operation of traffic over the territory covered by the work in hand. If the proportions of the work allow, every person connected with this organization should be relieved from all other duties relating to the operation of the road.

(2) The railroad company should handle with its own force all work which may interfere with the operation of the road, such as track raising or lowering, filling and excavating, handling and laying tracks, moving switches and putting in bridges under traffic. All other work which can be done without any interference with the operation of the railroad should be let by contract, both for economical and political reasons; this consisting of street work and concrete work where practicable.

(3) As far as practicable, all earthwork should be handled by machinery; that is, loaded by steam shovels and unloaded by plows, handled by cable unloaders and moved by spreaders.

(4) The best material to use for filling is sand.

(5) Bridge work, both railroad and highway, must ordinarily consist of temporary bridges, to be replaced by permanent bridges after tracks are elevated or depressed.

(6) Water, sewer and gas pipes, electrical conduits and wires should be taken care of and the work of moving them should be done by the companies owning them, whether or not the work is paid for by the railroad company.

GRADE AND CURVE IMPROVEMENT WORK OUTSIDE OF CITIES.

The following rules of practice are recommended:

(1) Establish the lowest gradient and lightest curvature which physical conditions and the present and prospective business of the road will admit.

(2) Complete the location entirely before entering on work of construction.

(3) Attend, first of all, to surface and waterway drainage, and last to the roadway drainage in excavations.

(4) Separate grades of railroads and highways, wherever practicable.

(5) Eliminate temporary bridges, etc., by the substitution of permanent structures in concrete and steel, wherever it can be done, having in view the formation of a continuous roadway on ballast.

(6) Do all light, short haul and preparatory work with teams or other light working plant.

(7) Provide separate tracks for work and traffic, wherever it can be done.

(8) Have a well defined plan for conducting heavy excavation before starting work.

(9) The simplest organization is the best. Some one man should be in responsible charge of the work, with a staff of engineers under him, and enough supervisors to cover the work, who have full control of men, material and means for each section, with foremen and gangs everywhere needed.

The report is signed by H. J. Slifer, Chairman, G. H. Bremner, Vice-Chairman, John C. Beye, D. J. Brumley, F. R. Coates, W. M. Dawley, Paul Didier, C. Dougherty, S. B. Fisher, D. MacPherson, W. D. Pence, J. G. Sullivan, J. E. Willoughby and R. C. Young.

BALLASTING.

The committee presents a revision of the ballast sections for crushed rock and slag, Classes A and B, with a slope of 2 to 1. The 1907 convention adopted a rock slope of $1\frac{1}{2}$ to 1, but the committee believed that this was passed under a misapprehension and therefore submitted the question to letter-ballot. The result of the letter-ballot showed 79 votes in favor of the slope recommended by the committee, and 21 votes against.

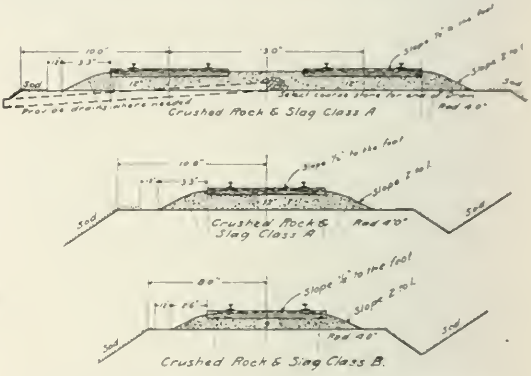
CONCLUSION.

The committee recommends the adoption of the ballast sections for crushed rock and slag, shown herewith, as being good practice.

The report is signed by John V. Hanna, Chairman; C. A. Paquette, Vice-Chairman; Willard Beahan, W. B. Causey, G. D. Hicks, B. C. Milner, F. J. Stimson, G. M. Walker, Jr., W. J. Bergen, J. B. Dickson, Alfred Jackson and A. F. Rust.

TIES.

The report on ties contains a compilation of answers received in reply to a circular of inquiry as to causes of crosstie failure



NOTE: The Slag which should be dressed to section shown for Crushed Rock and Slag is broken slag, similar in its character to Crushed Rock. Granulated Slag should be dressed to section shown for Gravel, Cinders, Chats, etc.

Crushed Rock and Slag Ballast; Recommended Practice.

whether due to decay, rail cutting or spike cutting, a suggested method for analyzing coal-tar creosote, and determining the amount of zinc in wood treated with that material; a discussion of the future policy of railroads with reference to tie supply, and a list of wood preserving plants in the United States and Mexico.

Conclusions.

The committee recommends the adoption of the following conclusions:

(1) That the method for analysis of coal-tar creosote shown on pp. 98-101 of Bulletin 96 be approved as good practice.

(2) That the method for determination of zinc in treated timbers shown on pp. 102-105 of Bulletin 96 be approved as good practice.

The report is signed by E. B. Cushing, Chairman; W. W. Curtis, Vice-Chairman; E. G. Erickson, W. F. H. Finke, E. O. Faulkner, E. E. Hart, H. C. Landon, J. D. Isaacs, A. S. More, Dr. H. Von Schrenk, J. C. Nelson and H. J. Simmons.

RAIL.

The committee reviews the report of the American Railway Association committee on Standard Rail and Wheel Sections, and points out the desirability of all railroad companies uniting on a single rail section. The American Railway Association committee submitted two series of proposed rail sections, which are shown in the body of the report. (*Railroad Gazette*, Nov. 22, 1907.)

A form for reporting rail failures is submitted for adoption by the railroads represented in the association. The arguments advanced for the approval of the proposed blank are the following:

(1) The desirability of keeping the size of the form to that of a letter-size sheet.

(2) The majority of the railroads of the country require reports of rail failures to be made out by a track foreman, as he is generally the first on the ground after a rail failure, and they will have to depend very largely on him for the information; therefore it seems desirable to put the questions in such a way that men of ordinary intelligence can answer them.

(3) Certain questions were asked by the blank submitted by the American Railway Association committee which were to be answered by reference to diagrams. We believe it better to have

written replies as far as possible to all questions. We have, however, made use of the diagrams showing rail failures suggested by the American Railway Association committee in connection with the instructions on the back of the blank recommended.

Conclusion.

The committee recommends the adoption of form M. W. 1200 for reporting rail failures by the railroads represented in the association.

The report is signed by Wm. R. Webster, Chairman; R. Montfort, Vice-Chairman; F. E. Abbott, J. W. Kendrick, E. F. Kenney, J. Kruttschnit, E. B. Ashby, A. S. Baldwin, D. D. Carothers, J. A. Colby, C. H. Ewing, S. M. Felton, J. F. Hinckley, Robert W. Hunt, D. W. Lum, F. H. McGuigan, H. T. Porter, J. T. Richards, R. Trimble, G. W. Vaughan, H. U. Wallace and G. B. Woodworth.

TRACK.

The report on Track embodies formulas and tables for computing the elements of the split switch (straight points) from a tangent. A diagram showing a 15-ft. reinforced split switch was presented. For main track, the committee recommends split switches in accordance with the diagram, with distant switch signal interlocked with switch-stand and pipe-connected derail. The bolted type of frog is recommended, the length to be such that the standard angle bars can bo applied; flangeway to be 1⅞ in.; rails to be of open-hearth steel, fillers to be made of rolled steel and to fit snug; bolts of fine B. B. iron, round and true to size, with U. S. standard ends and threads; bolt holes to be accurately drilled, holes to be made 1/16 in. less in diameter than bolts to be used; parts of frogs to be then assembled and holes reamed in order to be straight and of such size as to give the bolts a driving fit. Bottom plates to be made of rolled steel. A plan of the proposed frog was shown on the diagram.

The guard rail recommended is 15 ft. long, with flangeway 1⅞ in. where track is maintained to standard gage. If turnouts are located on curve, it is recommended that flangeway be widened to maintain a distance of 4 ft. 6⅝ in. from the gage of frog to the gage of the guard rail.

The diagrams and formulas for the widening of gage were prepared for the standard spacing of wheels of consolidation engines. The tables given are for consolidation engines having 18 ft. wheel base, consolidation engines having 19 ft. wheel base, and decapod engines having wheel base of 19½ ft. In making the calculations, the distance from back to back of tires for forward and rear drivers is assumed to be 53½ in., and for middle drivers 54¼ in. The clearance between the hubs of the wheels and the driving boxes is taken as 1¼ in. The committee recommends to the American Railway Master Mechanics' Association that the present clearance between wheels and driving boxes for new and repair work be increased from ⅛ to ¼ in.

Conclusions.

The committee recommends the adoption of the following conclusions as representing good practice:

(1) That the elements of the split switch turnout from a tangent be computed according to the formulas given and as indicated by Table No. 1.

(2) The adoption of the reinforced split switch shown.

(3) The adoption of the frog and specifications for same, outlined in the body of the report.

(4) The adoption of the guard rail and throat clearance, shown with the 15 ft. reinforced split switch.

(5) That tie-plates be used on all ties throughout the leads.

(6) That glazed sewer pipe with bell ends be used for the drainage of wet cuts, pipe to be laid without cemented joints, and to be covered with hay or straw and cinders, and laid below frost line where possible. French or pillar drains to be used for the curing of slides.

(7) That the widening of gage on curves be calculated according to formula on diagram A in the report, like tables B, C and D.

The report is signed by L. S. Rose, Chairman; T. H. Hickey, Vice-Chairman; Wm. Ashton, R. K. Brown, G. C. Cleveland, A. L. Davis, Garrett Davis, R. L. Huntley, W. S. Kinnear, C. E. Kinkerbocker, R. K. Rochester, F. A. Smith, Earl Stimson, R. A. Van Houten and A. A. Wirth.

..................DIVISION

Report of RAIL FAILURES in Main Tracks

Section No........ Date of Report.......19..

1	Weight per yard, New lbs Rerolled lbs	16	By whom discovered?
2	Rail Section	17	Date and Time found
3	Brand on Rail	18	Was Rail removed?
4	Heat No. on Rail	19	If removed, give date
5	Rail No or Letter (See Note D on back)	20	Exact gauge of Track at break
6	Original length of Rail	21	Was break over or between ties?
7	Month & Year rail was laid	22	Was break square or angular?
8	Location ft of Mile Post	23	Distance between Edges of Ties at break
9	Which track? Which rail?	24	Condition of Ties each side of break
10	On curve or straight line?	25	Kind of Ties?
10½	No of curve	26	Were Tie Plates used? Kind?
11	Degree of curve	27	Condition of Line and Surface
12	High or Low rail, if on curve?	28	Kind of Ballast?
13	Superelevation of curve at break	29	Was track properly ballasted?
14a	Was Rail Broken?	30	Kind of material in roadbed under ballast
14b	Was Rail Damaged?	31	Was track well drained?
14c	Was Rail Defective?	32	Was roadbed frozen?
15	Was Rail much or little worn?		

33 Condition of Weather (wet, dry, warm or cold freezing or thawing)

34a If Break was at Joint, state kind, number of holes, and whether it was full bolted or insulated..........

34b Were any Bolts at Joint loose? If so, how many?

35 If broken, state cause of break and describe any flaws found at point of break..........

36 If damaged, describe nature and cause, if known. (See instructions on back)..........

37 If defective, describe location of flaws or defects and if possible, what caused them (See back of report for description of failures)..........

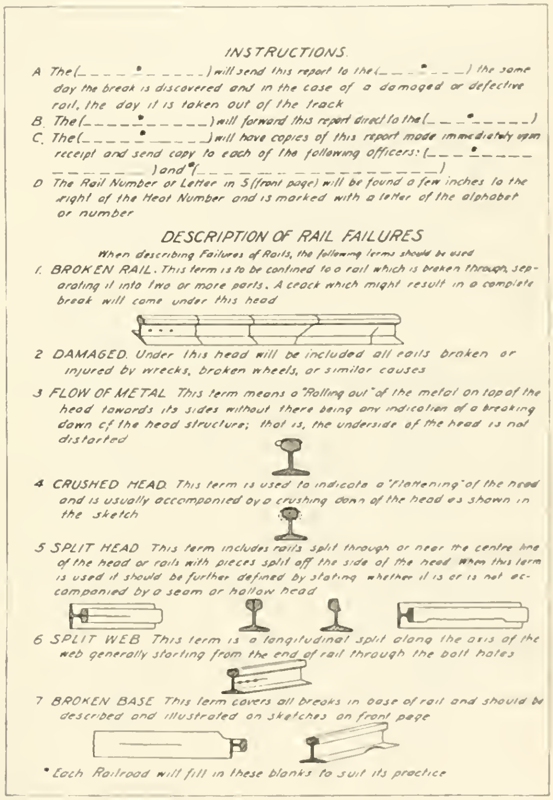
38 Draw on Diagram lines of break or partial fracture, such as long pieces from side of head and half moon pieces from base, showing dimensions. Hollows in head should be shown on end section. Defects may also be indicated on diagram. Mark distance from end to break. *If break is nearest Receiving End, draw pen through words "Leaving End." If nearest Leaving End draw pen through words "Receiving End" (* Refers to track upon which the current is in one direction)

39 If accident or detention to trains was caused by break, state circumstances..........

Approved Correct

..........(....*....)..........(....*....)

*Each Railroad will fill in these blanks to suit its practice.



INSTRUCTIONS.

A The (....*....) will send this report to the (....*....) the same day the break is discovered and in the case of a damaged or defective rail, the day it is taken out of the track

B. The (....*....) will forward this report direct to the (....*....)

C. The (....*....) will have copies of this report made immediately upon receipt and send copy to each of the following officers: (....*....) and *(..........)

D The Rail Number or Letter in 5 (front page) will be found a few inches to the right of the Heat Number and is marked with a letter of the alphabet or number

DESCRIPTION OF RAIL FAILURES

When describing Failures of Rails, the following terms should be used

1. BROKEN RAIL. This term is to be confined to a rail which is broken through, separating it into two or more parts. A crack which might result in a complete break will come under this head

2 DAMAGED. Under this head will be included all rails broken or injured by wrecks, broken wheels, or similar causes

3 FLOW OF METAL This term means a "Rolling out" of the metal on top of the head towards its sides without there being any indication of a breaking down of the head structure; that is, the underside of the head is not distorted

4 CRUSHED HEAD. This term is used to indicate a "Flattening" of the head and is usually accompanied by a crushing down of the head as shown in the sketch

5 SPLIT HEAD This term includes rails split through or near the centre line of the head or rails with pieces split off the side of the head. When this term is used it should be further defined by stating whether it is or is not accompanied by a seam or hollow head

6 SPLIT WEB This term is a longitudinal split along the axis of the web generally starting from the end of rail through the bolt holes

7 BROKEN BASE This term covers all breaks in base of rail and should be described and illustrated on sketches on front page

* Each Railroad will fill in these blanks to suit its practice

Recommended Form for Reports of Rail Failures.

BUILDINGS.

The subjects assigned the committee were as follows:

(1) Report and present recommendations relative to best type of locomotive coaling station to adopt for various conditions.

(2) Report on use of reinforced concrete for roundhouses.

(3) Report on best method for smoke removal, ventilation and heating of roundhouses.

(4) Report on use of movable or fixed cranes for facilitating locomotive repairs in roundhouses.

(5) Report on best arrangements of windows and roof lights and proper ratio of light area to floor surface in roundhouses.

Under the first heading, the committee submits its conclusions.

as follows (conclusions 1 to 4 were adopted in 1907, but are reproduced for convenience in discussion)

(1) The cost items should include charges for interest and depreciation, charges for maintenance and operation (the cost of switching cars onto trestles should be included), and a charge for the use of cars for storage purposes.

(2) Provision should be made for fire protection, the avoidance of damage to the coal, and its delivery in the best possible condition.

(3) The use of self-clearing cars should be made possible, and ordinarily it should also be possible to shovel from flat-bottomed cars.

(4) Storage for emergency purposes and fireproof construction are, in general, to be recommended, and in some cases duplicate machinery is desirable.

(5) It is not possible to give absolute limits between which different types of coaling arrangements are to be used. Each installation must be considered as an individual problem. Prices of materials, cost and character of labor, the possible track arrangements, the amount of storage desired, the power and attendance, and shifting service available, all are to be considered.

(6) Where the quantity of coal handled is small, particularly at terminal points where locomotives lie over night, it is recommended that the locomotives be coaled, either directly from cars by the hostler, or by handling from cars to an elevated platform provided with a jib crane and one-ton buckets, and from these buckets to the locomotive.

(7) At terminals where the daily consumption of coal does not exceed 75 tons, a locomotive crane with clam-shell bucket is desirable, provided that there is at such terminal other work that can be economically performed by the locomotive crane.

(8) At terminals where the requirements are from 75 to 200 tons per day and a deep foundation is practicable, a "balanced two-bucket hoist type" of coaling station is recommended.

(9) For terminals larger than those previously considered, the type of coaling station which should be selected as most desirable is dependent entirely upon local conditions. Where it is required that coal be delivered to not more than two tracks, and where the necessary ground space is available, a coaling station of the "trestle type," with incline approach, is recommended. In yards where delivering locomotives are constantly in attendance a plant with a 5 per cent. incline is preferable to one with a 20 per cent. grade operated by a hoisting engine. Where it is required to deliver coal to more than two tracks, or where the ground space for a "trestle type" is not available, a "mechanical conveyor type" is recommended.

(The following substitute for conclusions 8 and 9 is submitted by a member of the committee as a minority report.)

(8) At terminals where the requirements do not exceed 200 tons a day, when the desired storage is not so great that auxiliary buckets are necessary, and where a deep foundation is practicable, a two-bucket hoist is recommended.

(9) At points where the requirements are greater than this a mechanical conveyor plant is recommended, except that when the track arrangement and the ground space available permit, especially where it is difficult to obtain proper care of a mechanical plant, the use of a trestle should also be considered.

Under the second heading, "Use of Reinforced Concrete for Roundhouses," the following conclusions are submitted:

(1) Reinforced concrete should be used below the floor when it is cheaper than plain concrete.

(2) The additional security against interruption to traffic warrants the construction of a roundhouse with a reinforced concrete roof.

(3) When the roof is of reinforced concrete the columns should be of the same material.

(4) Reinforced concrete should be used for the walls only where special conditions reduce its cost below that of brick or plain concrete and where plaster is not considered satisfactory.

Subject No. 3 "Best method for smoke removal, ventilation and heating of roundhouses" no definite recommendation is made

Subject No. 4 "The use of movable or fixed cranes for facilitating locomotive repairs in roundhouses" the conclusion of the committee is that:

Jib cranes attached to the posts alongside of a number of pits in roundhouses, or, in the case of large roundhouses, a small traveler working around the outer circle, capable of handling two tons should be installed, in such roundhouses as may be designated by the motive power department as requiring such appliances for light locomotive repairs.

Subject No. 5—"Best arrangement of windows and roof lights, and proper ratio of light area to floor space" the committee concludes that:

(1) The disadvantages of roof or skylights in roundhouses are so much greater than their advantages as to make them undesirable.

(2) Windows in the outer walls of roundhouses should be made as large as practicable and contain the largest glass or light area consistent with the requisite strength. In general, the lower sill should be not more than 4 ft. from the floor and only sufficient space left between pilasters and sides of window frames, and girders and window heads to properly secure the window frames. Windows or transoms as large as practicable should be provided over all doors where locomotives enter.

The report is signed by O. P. Chamberlain, Chairman, Maurice Coburn, Vice-Chairman, J. W. Cowper, H. M. Cryder, C. H. Fake, J. S. Metcalf, A. G. Norton, L. D. Smith, Wm. Graham, E. W. Wiggin, C. H. Stengel, S. D. Brady, M. J. Caples and W. H. Sellew.

WOODEN BRIDGES AND TRESTLES.

The report on Wooden Bridges and Trestles contains standard specifications for bridge and trestle timber, revised specification for piling; a discussion of wooden trestle bridges with ballast floors, including plans typical of the two general designs for ballast floor trestles in use on the Santa Fe, Illinois Central, Mobile & Ohio, and Union Pacific railroads; safe unit stresses for timbers used in wooden bridges and trestles, with a graphical comparison and tables of unit stresses; a discussion of preservation of structural timber, its effect on the strength of timber, cost of treatment, method of treatment, etc.; specifications of the Santa Fe for creosoting Pacific coast piling and timber; standard names for structural timbers and classification of southern yellow pine.

Conclusions.

The adoption of the following conclusions is recommended:

(1) That the standard specifications for bridge and trestle timbers be approved as good practice.

(2) That the revised specifications for piling be approved.

(3) That there be added to the definitions of standard defects of structural timber the following:

16. *Ring Shake.*—An opening between annual rings.

17. *Through Shake.*—A shake which extends between two faces of a timber.

The report is signed by Henry S. Jacoby, Chairman; James Keys, Vice-Chairman; F. H. Bainbridge, A. L. Bowman, R. D. Coombs, R. T. Darrow, H. G. Fleming, Hans Ibsen, S. S. Roberts, W. F. Steffens, I. O. Walker, C. C. Wentworth and B. A. Wood.

MASONRY.

The specifications for stone masonry, presented in 1907, have been revised and are submitted for final approval.

The committee was instructed to report on the most economical size or combination of sizes of stone to be used in stone concrete, as applied to the different classes of work. A circular of inquiry was issued, requesting an expression from the members of the association as to their preferences, and a summary of the replies is given in the report. From the answers received the committee draws the following conclusions:

"Considering plain concrete only, and assuming that the aggregate will range in size from ¼ in. to the maximum named, a preference is shown for the following maximum sizes:

"For foundations, 2½ in.; for abutments, 2 in., for arch rings, 1½ in.; for coping, bridge seats and thin walls, 1 in."

The committee reports progress on the subject of waterproofing masonry, and on the subject of failures of concrete structures.

A comparison of standard plans in use on a number of railroads for masonry culverts is in preparation, and will appear in a bulletin after the convention.

The report is signed by A. O. Cunningham, Chairman; C. W. Boynton, Vice-Chairman, W. B. Hanlon, W. K. Hatt, H. H. Knowlton, C. H. Moore, W. H. Petersen, Job Tuthill, J. W. Schaub, Richard L. Humphrey, F. B. Scheetz, G. F. Swain and G. H. Tinker.

SIGNS, FENCES AND CATTLE GUARDS.

The committee reports progress on the subject of "snow fences, snow sheds and other means of preventing snow accumulating and the best methods of clearing tracks and snow removal." A large amount of valuable information has been obtained in response to a circular of inquiry, and a report will be made on the subject during the coming year.

The report is signed by W. D. Williams, Chairman; F. P. Gutelius, Vice-Chairman; L. G. Curtis, Ole Davidson, A. E. Doucet, Paul Hamilton, C. W. Pifer, W. A. Wallace and H. F. White.

SIGNALING AND INTERLOCKING.

The report contains an historical review of the efforts made by various railroad companies towards formulating an ideal system of signaling, and the committee briefly summarizes the requirements thus far adopted by the association and published in the Manual of Recommended Practice.

The committee has developed and presents the indications deemed requisite, with their application, shown by means of a diagram, and from which it has deduced the necessary requisites of installation and adjuncts.

Requisites of installation for telegraph block, controlled manual, automatic block and other systems are given. The requisites of installation recommended depart from the Standard Code of the American Railway Association in six important features:

(1) A distinctive position is recommended for the caution indication of the distant signal, in lieu of a special form of arm displayed in stop position of other signals.

(2) Two lights are recommended on every signal in lieu of one, two, three, four or even five lights under present practice.

(3) The requisite use of two lights is taken advantage of in distinguishing between the different types of signals.

(4) A differentiation is made between signals requiring stop until authorized to proceed, stop and proceed, and stop and investigate, because the first two have been provided properly and necessarily by the standard code, and the third one is recognized in universal practice and should be embodied in the rules laid down for the proper conduct of transportation.

(5) A differentiation is made between the indication regulating the approach to another signal and the indication permitting a train to enter a manual block that is not clear.

(6) Adequate approach indications are provided for all high-speed signals.

The following arguments are advanced for the adoption of the committee's plan:

(1) The advantages resulting from uniformity of signaling on the different systems of the country are:

(a) A considerable mileage of track in the country is operated jointly by two or more roads, and at present if the signal practices of the parties to the joint use of tracks are at variance, as frequently occurs, the same crews may have to run under different systems of signaling on a single run. Under a uniform system these crews would have but one system of indications to learn.

(b) Men leaving the employment of one road will not have to unlearn one system of signaling and learn another in order to qualify to work upon another road.

(c) Uniformity of indications will tend to uniformity in a considerable portion of the apparatus used, resulting in a decrease in various manufacturing expenses, and amount of stock to be carried by manufacturers and railroads, especially at jointly operated plants, and will result in quicker delivery of material.

(d) The expense for damage claims should be reduced and a better legal status secured to the railroad companies on account of less liability to confusion of indications, and on account of the system of signaling proposed having the endorsement of general adoption.

(2) Quicker and more accurate interpretation of signals by enginemen.

(3) Indication of diverse functions by the signals themselves, instead of by general orders, special orders, etc., thus relieving the enginemen's minds of a burden of detail.

(4) Classification of indications of the same general meaning, thus avoiding misunderstanding.

(5) Information by the aspect of the signal of the improper display of an indication.

The report also contains three papers by members of the committee, on "Signal Indications and Aspects," and "Suggestions as to the Selection or Development of a Basis for a Correct System of Signaling."

Conclusions.

(1) The committee recommends that the "requisite indications," as shown on page 12 of Bulletin 94, are adequate and embody all essential and proper indications and that they be recommended to the American Railway Association for adoption.

(2) That the "requisites of installation" set forth on pages 11-17 of Bulletin 94 are practicable and form an adequate and proper basis for the design of a system of aspects required for the display of the requisite indications and are essential for a uniform, universal system of signaling, and that they be referred to the American Railway Association for adoption as proper for new work and renewals.

The report is signed by A. H. Rudd, Chairman; L. R. Clausen, Vice-Chairman; Azel Ames, Jr., C. C. Anthony, H. S. Balliet, Chas. A. Dunham, G. E. Ellis, M. H. Hovey, J. C. Mock, F. P. Patenall, J. A. Peabody, Frank Rhea, W. B. Scott, Thos. S. Stevens, J. E. Taussig, H. H. Temple, H. M. Waite and Edwin F. Wendt.

RECORDS, REPORTS AND ACCOUNTS.

The report on Records, Reports and Accounts contains a review of the subjects of Right-of-Way and Track Maps and Individual Ledger Accounts. Three blank forms are submitted—Form M. W. 1,020, Monthly Progress Statement of Expenditures; Form M. W. 1,014, Standard Method for Recording the Cost of Individual Pieces of Work; and Form M. W. 1,017, a suggested substitute for the Estimate Form shown in the Manual of 1907.

The following conclusions are submitted for adoption:

RIGHT-OF-WAY MAPS.

Definition: "Right-of-Way Map.—A plat representing the actual location and dimensions of all property, rights or franchises that are owned or controlled by a railroad company."

(1) Right-of-way maps should show the state, county, township, town or city; the right-of-way alinement complete; the station plusses of the crossing of all important land or property lines and streets, with the distance to all permanent land or street corners. The angle which the center line of the road makes with property lines; the number of the right-of-way sheet; the points of the compass; the scale and date of the map; the boundaries of the several parts of the land owned by the company, and the width of the right-of-way, particularly at those points where the widths change; any additions, or subdivisions of towns or cities, with numbers and sizes of lots and blocks, and names of streets. It should also show all main tracks, sidetracks and structures that were built in connection with the original construction of the road; the exact location of all crossings of steam, electric or other roads.

(2) On or near each part of the land on the right-hand side of each map should be shown the deed custodian's number; the date of grantor and grantee, mileposts, kind of instrument, date and book and page where recorded. This also includes reference to leases, franchises, ordinances and grants concerning the use of land.

(3) The original right-of-way map should be traced, and the tracing filed away for a permanent record of the conditions existing at the time the railroad was completed. The map from which this tracing is made should be corrected from time to time as changes are made in important tracks and structures, which are of value as reference to the right-of-way boundaries, as well as any transfers of property made to and from the railroad company, and any important tracks or structures.

(4) The property of adjacent railroads or of subsidiary and associated companies should be shown in different colors for the purpose of ready distinction.

(5) It is important to show on the original right-of-way map a profile of the same horizontal scale and of the same station numbers as the map and of suitable vertical scale, which profile should show the original subgrade, the location, character and size of opening of each bridge, waterway or under-crossings, and the original surface of the ground, the necessity for this being the knowledge of physical conditions at the time the road was built, often needed in defending litigation and settling questions arising from time to time.

(6) In regard to the scale, size and methods of filing maps, it is not considered advisable to make a definite recommendation as to the scale of such maps, because of the different conditions that require greater or less detail. It is suggested, however, that a range of from 50 ft. to the inch to 400 ft. to the inch should cover all possible conditions, except, possibly, in undeveloped portions of the country, where a smaller scale could be used.

TRACK MAPS.

Definition: "Track Map.—A map used primarily for showing physical conditions, including tracks, bridges, buildings, water service and mains, leases, station facilities and all of the physical and operating features."

(1) Track maps should show all physical conditions pertaining to the construction and operation of the railroad and the limits of the right of way without reference to title or ownership. They should show all main and sidetracks and their alinement, distance between them, capacity and car lengths; all buildings upon the right of way and adjacent thereto, dimensions and character thereof and location with reference to main or sidetracks, bridges, culverts, water stations, coaling plants, turntables, shop buildings, water mains, electric light wires, fences, street car and other railroad crossings, and the angle they make with the railroad track, sewers, signals of all kinds and all physical conditions on the property. All structures on such maps should be located by chainage numbers and plusses.

(2) They should be corrected whenever any changes are made in any of the features shown thereon and a corrected copy sent to the general office for record.

(3) It is recommended that a scale of 100 ft. to the inch be used for such maps except in territories and cities of large industrial development, where varying scales may be used to suit the local conditions.

(4) The map should show very plainly the north point, scale, original date and date corrected.

(5) The conventional signs adopted by the association should always be used where it is possible and convenient to do so.

INDIVIDUAL LEDGER ACCOUNTS.

(1) The adoption of form M. W. 1020, to be used for a monthly progress statement of expenditures (p. 55, Bulletin 97).

(2) The adoption of form M. W. 1014 as a standard method for recording the cost of individual pieces of work, such form to be used in making a report to the officer in charge of the department doing the work (p. 54, Bulletin 97).

(3) Your committee recommends for consideration and, if possible, approval, a suggested change for form M. W. 1017 (pp. 56, 57, Bulletin 97).

The report is signed by H. R. Safford, Chairman; J. B. Austin, Jr., Vice-Chairman; W. Archer, Edward Gray, Henry Lehn, A. W. Newton, J. E. Schwitzer, V. D. Simar, R. C. St. John, J. E. Turk and E. K. Woodward.

UNIFORM RULES.

The committee submits for adoption the following rules pertaining to supervisors of signals:

(1) They shall report to and receive instructions from the (To be filled in by each road).

(2) They shall be responsible for the safe condition and proper maintenance of all signals and interlocking plants in their districts. They must inform themselves of the condition of signals and interlocking plants, make necessary repairs of such defects as

may endanger or delay the movement of trains and promptly report defective condition to (Title).

(3) They shall employ in the discharge of their work, such men as are necessary for carrying out the duties for which they are responsible.

(4) They must know that all foremen are provided with all rules, circulars, forms and special instructions pertaining to their duties, and that they fully understand and comply with the same.

(5) They must see that all foremen are familiar with the rules in regard to train signals and flagging, and that they fully understand and comply with the same.

(6) They must know that all foremen are supplied with tools and material necessary for the efficient performance of their duties and must see that they are properly cared for and used.

(7) They shall conform to the prescribed standards and plans in the execution of the work under their charge.

(8) They shall not permit experimental trials of appliances or devices not standard with the company, nor give out information of the results of any trial, except by proper authority.

(9) They shall keep general oversight of all work performed in their districts by contractors or others who do not come under their direct charge, and see that nothing is done by them that will interfere with the safety of track or movement of trains.

(10) They must make frequent inspections of all signals and interlocking plants in their districts and have necessary repairs made as promptly as conditions require.

The report is signed by R. C. Barnard, Chairman; J. H. Abbott, Vice-Chairman; C. C. Anthony, Robert Bell, C. N. Kalk, F. L. Nicholson, J. O. Osgood, J. C. Mock, J. A. Peabody, G. H. Webb, and C. A. Wilson.

WATER SERVICE.

This committee took for the subject of its report a revision of the conclusions previously adopted by the association on the "Quality of Water, with Methods of Treatment and Results Obtained Therefrom." The matter appearing in the Manual of 1907 under the above heading has been rearranged, condensed and a portion eliminated.

Conclusions.

The committee recommends that the material in the "Manual of Recommended Practice," edition of 1907, be revised to read as follows:

QUALITY OF WATER, WITH METHODS OF TREATMENT AND RESULTS OBTAINED THEREFROM—CONCLUSIONS AND RECOMMENDED PRINCIPLES OF PRACTICE.

(1) In locating water stations along a railroad, an investigation should be made of all the available water supplies, and care should be taken to avoid the use of poor water, or to curtail its use as much as possible.

(2) Most water used in locomotive boilers contains scale-forming matter in solution or suspension, causing much trouble and expense in operating and maintaining locomotives.

(3) Hard water can be softened before it is put into locomotive boilers by treating it with chemicals.

(4) Water whose hardness is due to carbonates of lime and magnesia can be softened at a moderate expense for chemicals by the use of lime alone, without adding any soluble salts to the softened water.

(5) Water whose hardness is due to sulphates of lime and magnesia can be softened, but at a greater expense, by the use of soda ash, a more expensive chemical. In this case soluble sulphate of soda will be added to the softened water, increasing the tendency to foam.

(6) The mechanical methods of modern water-softeners are new and differ widely, but consist of two general types, the continuous and the intermittent.

(7) At stations where hard water is used, special study should be made relative to the economical value of treating the water, and the method best adapted to meet the conditions.

(8) The cost of installing a water-softening plant varies according to the capacity of the plant, its type, cost of material and labor in its locality, and other local conditions.

(9) The cost of operating a water-softening plant varies according to the efficiency of the water-softening apparatus and the cost of lime and soda ash or other chemicals available for softening water in its locality.

(10) The cost of chemicals required to soften water varies according to the quantity of hardening matter in the water, and also its composition.

(11) The benefits derived from water-softening plants are: Fewer boiler failures due to leaking; longer life of flues and firebox sheets; reduced cost of labor for repairing and washing boilers; increased locomotive mileage between shoppings; decreased number of locomotives required to perform the same service; less expense in cost of overtime and delayed time.

(12) The removal of the sulphates of lime and magnesia is of greater value than the removal of the carbonates alone, as the carbonates of magnesia, without the presence of the sulphates of lime or magnesia, do not form hard scale but are precipitated in the boiler as soft scale and mud.

(13) The greatest disadvantage in treating water is the increased tendency to foam, due to the reaction of soda ash on the sulphates of lime and magnesia.

The report is signed by A. K. Shurtleff, Chairman; W. P. Bonright, J. L. Campbell, John P. Congdon, J. P. Hanahan, E. N. Layfield, C. A. Morse, John P. Ramsey, C. L. Ransom, G. J. Ray, O. E. Selby and M. H. Wickhorst.

YARDS AND TERMINALS.

The report on Yards and Terminals deals with the subjects of Freight Yards for Hump Switching; Track Scales; Conveying Car Riders in Hump Yards; Yard Lighting; Freight Transfer Station, Railway Freight Houses and Warehouses and Freight Handling Machinery.

Plans and profiles of a number of gravity switching yards are shown, also plan of entrance to classification yard with double ladders, plans of freight transfer stations, illustrations of freight conveying machinery in use at ocean terminals, tables giving car capacities of freight yards on the Pennsylvania Lines, track scales in freight yards on various railroads, methods adopted for weighing cars, and descriptions of railroad freight houses and warehouses at Newark, N. J., and Pittsburgh, Pa.

Conclusions.

The committee recommends the following changes in conclusions, and the recommended principles of practice:

HUMP YARDS.

(1) Hump yards should consist of receiving, classification and departure tracks, in consecutive order.

(2) A hump yard is a desirable form of yard for receiving, classifying, and making up trains, because cars can be handled through it faster and at less cost than through any other form of yard.

(3) Receiving tracks should be of sufficient length to hold maximum trains of the various classes handled.

(4) Receiving tracks should be sufficient in number to hold a number of trains arriving in quick succession. The number will depend on the amount and character of traffic handled, and upon the relative location of the yard with respect to the other yards and connections.

(5) If it is possible, the grades of the receiving tracks should be such that one engine can push the maximum train over the hump.

(6) No definite recommendation can be made as to length or number of classification tracks, except that when they are to be used as departure tracks they should be long enough to hold full trains, and that when conditions permit, there should be as many of them as can be used to advantage to avoid subsequent classification and consequent delay.

(7) Departure tracks should be full train length and of sufficient number to provide ample standing room for trains while being tested for air, and while waiting for engines.

(8) An air brake testing plant should be provided in the departure yard; the tracks should be piped, and sufficient outlets furnished with hose to test air brakes on all outgoing trains.

(9) To secure the greatest possible efficiency or to so construct a hump that the greatest number of cuts of cars may be classified over it, the steepest part of the grade should be reached in the least available distance after passing the summit, and the grade or fall should provide sufficient momentum to carry all cars to lower ends of classification tracks.

(10) Where cars to be classified are largely empty or light, and the scale is on the hump, grades are recommended for average conditions as follows:

The summit of the hump should be reached by vertical curves with radius of about 1,500 ft. that raise the grade about one foot in a distance of 60 ft.; the curve over the summit to be continued on the descending grade a distance of about 30 ft. to join a grade not exceeding 2 per cent. for a distance not exceeding 60 ft. Thence descending by a vertical curve with radius of about 2,000 ft. a distance of 10 ft.; thence descending on a grade of 4 per cent. a distance of 50 ft.; thence descending by a vertical curve with radius of about 5,000 ft. a distance of about 155 ft. to join a grade of 1 per cent. at the heads of the ladder tracks. Thence down through ladder tracks and turnouts, 1 per cent.; thence down through classification tracks, 0.5 per cent.

(11) Where cars to be classified are largely heavy or loaded, and the scale is on the hump, the same grades are recommended for use over the hump as for light cars, but as the proportion of light cars diminishes the length of the grade of 4 per cent. may be reduced.

It is recommended, however, that the length of the 4 per cent. grade be at least 25 ft.; that the grade of ladder tracks be at least 0.8 per cent., and that the grade of classification tracks be at least 0.4 per cent., where conditions permit.

(12) Where traffic or climatic conditions require, the summit of a hump may be made higher in the winter and restored when the increased height is not needed.

(13) When required by traffic conditions, a track scale not exceeding 60 ft. in length should be located at such a distance from the summit of the hump (30 to 40 ft. is recommended) that when cars to be weighed reach the scale they will be properly spaced from following cars and will be running slowly enough to easily secure correct weights. The grade over the scale should not exceed 2 per cent.

(14) For average conditions it is recommended that No. 8 frog be the sharpest used in classification yards.

YARD LIGHTING.

(1) For yard lighting the use of arc lamps of 2,000 candle-power is recommended.

(2) For lighting hump and ladder tracks, the lamps should be spaced 140 to 150 ft. apart and hung 28 ft. (or more) above the tracks.

(3) For lighting body tracks, the spacing should be such that cars will be clearly visible.

FREIGHT TRANSFER STATIONS.

(1) Freight transfer stations should be located at points where traffic converges or diverges, or both, and where necessity exists for its consolidation of separation.

(2) The installation should provide for the greatest possible economy of operation, both as to time and cost of handling.

(3) Where fixed platforms are used, they should be covered, and it is recommended that the width under ordinary conditions be not more than 24 ft., and that the tracks on either side be built in pairs. If greater facilities are required, additional platforms 8 ft. in width may be provided outside of the first two tracks and additional tracks placed outside of them. The width of these additional platforms may be 8 ft. if without roofs, or 12 if covered by roofs supported by a line of posts in the middle.

(4) Where large amounts of freight are to be transferred, the use of power-driven covered traveling platforms, instead of fixed platforms, is suggested.

FREIGHT HANDLING MACHINERY.

(1) The use of freight handling machinery at railway freight houses, warehouses and shipping piers is worthy of consideration.

The report is signed by F. S. Stevens, Chairman; E. E. R. Tratman, Vice-Chairman; E. P. Dawley, A. C. Everham, A. P. Greensfelder, F. G. Jonah, Paul Jones, B. H. Mann, J. D. Mason, A. Montzheimer, G. F. Morse, H. J. Pfeifer and M. E. Shire.

IRON AND STEEL STRUCTURES.

The report on Iron and Steel Structures embodies a discussion of Inspection, Reports and Records of Bridges, and Classification of Bridges as to Safe Carrying Capacity.

Under the heading of Inspection, the committee recommends the following plan:

INSPECTION.

(1) *Daily*, by trackmen, who, in connection with the inspection of track, shall examine every bridge, with the object of discovering any change in condition or movement of super- or substructure, damage from drift, high water, falling objects, broken or loosely hanging bars or members, broken or badly damaged ties, missing bolts or nuts.

(2) *Monthly*, by competent bridgemen, who shall examine every member and every part of the super- and substructure of every bridge whose inspection is not governed by Article 3, with the object of detecting cracks, wear of parts, loose bars or members, loose rivets, excessive deterioration, crushing or breaking of the masonry, scouring or undermining of foundations and any defects whatsoever. They shall carefully observe the action of the structure under traffic, with the object of directing any new, unusual or excessive motion.

(3) *Quarterly*, by competent bridgemen, who shall inspect, in the manner and with the object as defined in Article 2, those good and substantial bridges which shall be particularly designated by the proper officer.

(4) *Annually*, by an experienced bridge inspector, who shall with thoroughness examine in detail the condition of every part of the super- and substructures. The object of this inspection is to obtain a check on the monthly and quarterly inspections, a report on the *extent* of defects, deterioration, motion, etc., from which may be determined the degree of safety of the structures, the necessity for repairs and extent of strengthening and renewals required.

(5) *Annually*, by the authorities in charge of bridges for the purpose of officially deciding the *extent* of reinforcing, renewals or traffic restrictions which must be made during the following year.

(6) In addition to the foregoing, the following special inspections should be made, as occasion may require:

(a) Of all structures which are severely strained or show signs of distress under traffic.

(b) Of all substructures which show signs of movement, until the movement ceases, or the conditions causing it have been remedied.

(c) After heavy freshets for evidence of damage to superstructures by drift and to substructures by scour.

(d) By the engineering department whenever a structure is reported as requiring "extensive" repairs or renewal.

Reports.

The following reports are considered necessary by the committee:

(1) It is not necessary for trackmen to make reports unless something wrong is discovered, in which case the proper authorities should be immediately notified, in order that necessary measures may be taken to insure the safety of the bridge.

(2) Bridgemen making monthly and quarterly inspections should report on each structure each time examined. These reports should cover briefly all the items outlined in Article 2, under the heading of Inspection, as well as any other items shown on the printed forms.

(3) The annual report, by experienced bridge inspectors, should be complete in detail, as it will form the basis from which will be determined the degree of safety of the structures, the necessity for repairs and the extent of strengthening and renewals required.

(4) In addition to the foregoing, reports should be made of all special inspections.

Records.

The following records are deemed essential to show a complete history of structures:

(1) General drawings of bridge sites, showing alinement of tracks, span lengths, skews, etc., with all necessary profiles. When the structure is over a stream, the profile of the river bottom should be revised from time to time, to show the rate of scour and condition of foundations.

(2) Set of strain sheets and detail drawings of the superstructures, preferably on tracing cloth.

(3) Detail drawings of the substructures as actually built, showing all information relating to the foundations.

(4) Copies of all specifications, contracts, tests of material and inspector's shop and mill reports.

(5) Records of all repairs, repainting, renewal of ties, etc.

(6) Copies of the annual inspection reports, kept up to date by frequent revisions.

(7) Tabulated statement of all clearances, covering the traffic through, under or over the structure.

(8) Copies of all documents relating to the work, such as special legislative acts, licenses, findings and awards of commissions, agreements relating to the sharing of cost of construction, maintenance, etc.

(9) Complete calculations and schedules, showing classification of the bridges as to their safe carrying capacity.

(10) For convenience of reference in the office, it is advisable to make a synopsis of the above information on cards or loose sheets. This should include:

(a) Name and location of the structure.
(b) Character of crossing.
(c) Spans, skew, height above rail, clearances, high-water mark, number and alinement of tracks.
(d) Brief description of the super- and substructure.
(e) Specifications under which structure was built.
(f) Quality of materials.
(g) Date of building and name of builder.
(h) Details of timbering.
(i) Abstracts of inspection reports.
(j) Records of painting and repairs.

(11) In addition to the above, each division officer and inspector should have a list containing every bridge coming under his supervision, and copies of all inspection reports pertaining thereto.

Classification of Bridges.

The subject of Classification of Bridges has been subdivided into (1) carrying capacity, and (2) classification for operating purposes.

Under the first subdivision, the committee offers the following conclusion:

(1) The *carrying capacity* of a bridge is here understood to mean the heaviest moving loads which may be operated over it in regular service for a limited time without subjecting it to such severe strains, motion or wear of parts as to seriously impair its safety and serviceability.

(2) The carrying capacity of any bridge will depend upon a large number of controlling factors, all of which must be taken into consideration. Some of these factors are design, material, workmanship, speed, strains, behavior, physical condition and the possibility of maintaining falsework for a considerable time should the bridge show distress under increased loading.

(3) A railroad bridge which has been constructed in accordance with a specification which provides for strength, design, material and workmanship at least equal to the standard of the American Railway Engineering and Maintenance of Way Association specifications will, when in good condition, carry for a limited period a loading in excess of that for which it was originally designed. The bridge, however, will be subjected to a greater amount of motion and wear of parts, have a lower margin of safety, less efficiency and a shorter life.

(4) When the span is less than 200 ft., all controlling factors

given in Article 2 good, the mathematical analysis made in accordance with the American Railway Engineering and Maintenance of Way Association specifications of 1906, using full specification allowances for impacts for regular service fast speed and one-half of these impact allowances for slow speed, then, so long as the controlling factors remains good, unit strains in tension to the extent of 26,000 lbs. in structural open-hearth steel and 22,000 lbs. in wrought iron, will not in themselves, be sufficient justification for suspending traffic or condemning the structure.

(5) When the controlling factors as outlined in Article 2 are not good the limiting strains or capacities cannot be determined by any general rule, as they are questions of actual conditions, judgment and experience, supplemented by a close watch on the structure in service.

Under the second heading classification for operating purposes, the committee advances the opinion that bridges should be classified according to their efficiencies under a loading of the type outlined in the association's specifications, that the efficiencies should be indicated by figures representing either the total weight or driving axle weight of the heaviest permissible engine of the specification type, and that these figures should be placed on the map of the railroad in such a manner as to show at a glance the capacity of the weakest structure on the main line, branches and engine districts. A schedule on the map giving the service classes of engines and cars whose operation is permitted by the stated efficiencies is recommended. Notes on the map would indicate restrictions as to speed and double-headers. The scheme outlined is illustrated by a map and schedule.

IMPACT TESTS.

The convention of 1907 by vote authorized the inauguration of a series of experiments to determine the effect of moving loads on railroad bridges, and the committee on Iron and Steel Structures was entrusted with the work of conducting the tests. A fund was provided to defray the expenses of making the experiments, and the work commenced during the summer of 1907.

A sub-committee, composed of Prof. F. E. Turneaure, University of Wisconsin; C. H. Cartlidge, Bridge Engineer, Burlington Railway System, and Prof. C. L. Crandall, of Cornell University, were appointed to take charge of the work.

Twelve instruments were constructed at the shops of the University of Wisconsin, with which the experiments were made. The first bridges tested were on the Illinois Central Railroad; subsequent tests were made on the Chicago, Burlington & Quincy; Chicago, Milwaukee & St. Paul; Chicago, Rock Island & Pacific, and New York, Chicago & St. Louis railroads. The results of these tests are embodied in a preliminary report, published in Bulletin 97, pp. 13-25. The experiments will be resumed next summer.

The report is signed by J. E. Greiner, Chairman; C. F. Loweth, Vice-Chairman; M. F. Brown, C. H. Cartlidge, C. L. Crandall, B. W. Guppy, A. J. Himes, Charles M. Mills, A. D. Page, C. D. Purdon, A. F. Robinson, C. C. Schneider, J. P. Snow, F. E. Turneaure and J. R. Worcester.

OPEN VERSUS BALLAST DECK STRUCTURES.

By A. F. Robinson, Bridge Engineer, A., T. & S. F. System.

The object of the author is to demonstrate that it is more economical to use ballast deck structures than open decks, and presents comparisons as to cost of the two types.

Formulas giving the distribution of the wheel loadings of the various kinds of decks are embodied in the paper.

The author assumes a life of 28 years for creosoted ballast decks on metal bridges and seven for the untreated pine used in open decks on metal bridges. He also assumes 24 years as the average life of creosoted ballast deck pile bridges and eight years as the average life of ordinary open deck pile bridges with soft wood timber and piles untreated.

The author has given in the paper in itemized form the total cost and the average annual cost per lineal foot of track for various kinds of decks, which he has designated by numbers. Following is a summary:

	Per lin. ft. of track — Total cost.	Avg. an'l cost
Open deck No. 1	$23.40	$0.86
" " " 2	27.46	95
" " " 3	30.62	1.03
" " " 4	34.12	1.10
" " " 5	41.70	1.32
Ballast deck No. 6	18.19	66
" " " 7	21.18	74
" " " 8		76
Open deck pile bridge No. 9	46.13	1.79
" " " " " 10	58.03	2.12
" " " " " 11	53.13	1.99
Ballast deck pile bdge. No. 12 ($19)	50.62	1.82
Ballast deck pile bdge. No. 12 ($20)	53.18	1.90
Reinforced concrete plan No. 13		1.67
Plan No. 13, average $30 per ft.	...	1.83
Ballast deck No. 6 A	21.93	76
" " " 7 A	26.68	85
" " pile bdge. plan No. 14	63.13	2.23

In presenting the foregoing comparisons for various structures, the author recognizes the fact that any great variation in market prices for material or labor may show decidedly different results.

Conclusions.

The advantages of the use of ballast deck structures, in the opinion of the author, are given in the following conclusions:

(1) Ballast to a large extent absorbs or dissipates and distributes the effect of impact in such a manner as to materially increase the life of structures.

(2) Ties will not "bunch" in good stone or gravel ballast and this kind of floor gives increased safety in case of derailment.

(3) It almost entirely prevents accidental fires that can catch from falling coals, thereby rendering insurance unnecessary.

(4) It gives a more nearly perfect riding track, there being no breaks in ballast from beginning to end of division.

(5) It gives an increased feeling of safety to the traveling public, to the trainmen and operating officials.

(6) It gives a more stable structure in time of high flood.

(7) By the use of ballast floor structures we are enabled to use the poorer or second grades of timber, thereby tending to reduce the great and dangerous drain on our visible supply of first grade material.

In final conclusion, the writer believes ballast deck structures are advisable from all points of view, that they should be used on bridges of all kinds, both on main and branch lines, and believes the time not far distant when open deck structures will be ancient history.

The Signal System of the Interborough Subway

In a report on the signal and interlocking system in use in the New York subway, Bion J. Arnold, Consulting Engineer, has recommended to the Public Service Commission that improvements be made in the signal apparatus by which less headway for express trains may be obtained without sacrificing the safety of passengers, and that after these improvements are perfected the local tracks be equipped with the same block signal system as is now used on the express tracks. The signal changes he recommends would make possible a headway of 90 seconds, or 40 trains an hour, on both express and local tracks. At present the rate is about 30 trains an hour.

Mr. Arnold declares the existing signal system as complete as it was possible to make it at the time it was put in (1904) but says that the art of signaling has made rapid strides since that time. According to the records furnished him by the Interborough company for the two years from October 1, 1905, there were 155,064,891 signal and stop operations with 497 failures, or one failure to 312,001 of block and interlocking signal and automatic stop movements. This he considers a satisfactory test of the signal system in use, but he believes that with new methods and appliances perfected since the installation of the system, it can be greatly improved.

"Although the original installation of the signal system," says Mr. Arnold, "was such that safety was obtained at all points, the congestion due to the long delays at the station platforms caused changes to be made in the station blocks on the express tracks. These changes were based upon the assumption that a reduction in speed would be made when trains approached stations, and it therefore follows that safe automatic control of trains is not now always obtained. In other words, the motorman's intelligence and judgment, as well as his physical condition now entered as a factor in the safety of train movements, particularly when approaching stopping stations. To maintain a uniform standard of safety over the entire system, it is necessary to introduce some device that will insure this reduction in speed when approaching the stopping point."

Several observations were made of the movement of trains in the subway. The highest observed speed was 40 miles an hour. The usual speed of express trains at places favorable for fast running was 35 miles an hour. Heavily loaded northbound express trains leaving the Brooklyn Bridge made 32 miles an hour. At the Grand Central Station, where observations were confined to the movement of trains at express platforms, the number of trains moved an hour was 27 northbound and 29 southbound, and the average time interval between the arrivals of trains was 2 minutes and 12 seconds northbound and 2 minutes and 1 second southbound. The average length of stop was 58 seconds northbound and 35 seconds southbound. The shortest stop was 25 seconds on both tracks and the longest stop was 82 seconds on the northbound and 62 seconds on the southbound track.

Summing up these observations, Mr. Arnold concludes:

"These figures show the average length of time required for the trains to pass from Grand Central Station block and indicate that under present conditions it is hardly possible to maintain a two-minute headway upon the express tracks during rush hours. A two-minute headway corresponds to the rate of 30 trains an hour whereas trains were passed through this station at the rate of only 27 trains an hour northbound at night, and at the rate of 29 trains an hour southbound in the morning rush hours."

There is a special signal placed just outside of each express station which operates to prevent approaching trains from running into a train standing at the station. Since the system was installed this stop signal has been brought nearer the station platforms for the purpose of reducing the delay in trains stopped by it, and thereby increasing the capacity of the express tracks. Inasmuch as the alertness and attention of the motorman are relied upon to prevent collisions, Mr. Arnold thinks that some automatic device should be added so as to make the safety absolute in the case of signals at express stations. Final changes in the present system should move the automatic stop further away from the platform rather than closer to it. The existing system with its automatic safety trip insures absolute safety on the express tracks between stations, and it should be important to provide the same degree of safety in the station blocks by means of automatic stops.

Speaking of the design of the express stations, Mr. Arnold says: "The subject of the proper design of express stations will be discussed in another report, but it is proper to state here that, had the express stations been constructed from the beginning, by being double decked or otherwise, so that trains could have been alternated first on one side of the platforms and then on the other, the capacity of the subway could have been increased at least 50 per cent. with the signal system as originally installed, but as this was not done it seems necessary under present conditions to revise the present signal system to the greatest extent practicable consistent with safety in order to secure capacity.

As a temporary means of increasing the efficiency of the existing signal system, Mr. Arnold suggests a visual and audible signal to be given by a stopped entering train to a subway platform station attendant that it has been delayed to the extent of a full stop. He also suggests a manually operated switch whereby an attendant can release the emergency stop holding the entering train and give it the signal to proceed after the leaving train has begun to move. Much time is now lost, he says, because the proceed signal is not given to the motorman of the entering train until the last car of the leaving train has left the platform.

In regard to the signal system for the local tracks, Mr. Arnold says that the only difference between train movements on the different tracks is that more frequent stops are made by local trains. As the introduction of more frequent stops between the terminals introduces a risk, the need for safety signals on the local tracks is really greater than it is on the express tracks. It would therefore appear that if the practical degree of safety decided upon for subway operation demands the installation of the signal system and automatic stopping devices on the express tracks, the same or similar equipment is necessary on the local tracks.

As the local and express trains alternate on the same tracks north of 96th street, it is desirable that the same headway should be maintained on both systems south of 96th street. As far as the signal system is concerned, there is nothing to interfere with such an arrangement up to the capacity of the express tracks which can eventually be operated with a headway of 90 seconds, corresponding to 40 trains an hour, although it cannot be denied that the introduction of the block signal system on the local tracks will thus reduce their present possible capacity from 50 trains an hour to 40 trains an hour. Inasmuch as there are now being operated on the local tracks during rush hours only about 30 trains an hour, it will be seen that the block signal system can be installed upon these tracks and at the same time allow an increase in the number of trains of $33^1/_3$ per cent. over the present number."

Mr. Arnold's conclusions are:

(1) The subway signal system is in the main, modern, effective and well maintained.

(2) There is no reason so far as the signal system is concerned why a 90-second headway cannot be maintained.

(3) This 90-second headway will eventually be desirable upon both local and express tracks.

(4) The signal system at the present time does not afford positive safety at the approach to stations, as the motormen are relied upon to reduce the speed of the trains.

(5) In addition to the excessive platform waits additional time is lost at each station stop by holding the following train a considerable distance out of the station until the leaving train has entirely cleared the platform.

(6) As at present operated delays at the station platform have a cumulative effect upon the following trains, so that even one prolonged stop may disarrange the schedule for the entire hour.

The report recommends the following changes:

1. That the necessary steps be taken to develop and install an automatic speed control signal system to be used as an auxiliary at station blocks, which will allow the incoming train to safely approach the rear of the train at the platform and to enter the platform promptly upon the leaving of the outgoing train without sacrificing any of the standard of safety which is now maintained between stations.

2. That during the development of the system there be installed at every express station the changes in the block signal system proposed by the Interborough company for Grand Central Station. The equipment required for these changes will reduce the present possible headway by 7 seconds, and could ultimately become a part of the permanent recommended arrangement.

3. That the subway officials consider for the purpose of effecting temporary relief the installation of a manually operated permissive signal at every express station to be used to expedite a delayed incoming train and thus overcome the cumulative effects on the schedule of a prolonged station wait.

4. That the local tracks be protected by a complete block signal system when the automatic speed control system herein suggested has been perfected.

5. That, when the load on the subway increases to such an extent as to require additional conductors for carrying the electrical energy to and from the trains, the present signal system be altered so as to use both rails for carrying the return current, and at the same time make the system conform to the latest accepted practice whereby the signal system detects and indicates a broken or removed rail, provided the system shall at that time have proven superior to the single-rail system.

The Failure of the Quebec Bridge.

The Royal Commission appointed by the Canadian government to inquire into the cause of the collapse, on August 29, 1907, of the Quebec bridge, has recently published its report which is dated February 20, 1908. The scope of the inquiry was described and the summarized findings of the Commission published in the *Railroad Gazette* of March 13, 1908, page 383. The Commissioners were Henry Holgate, C.E., of Montreal; John G. G. Kerry, C.E., of Campbellford, Ont., and John Galbraith, Dean of the Faculty of Applied Science and Engineering and Professor of Engineering in the University of Toronto.

The Commission acknowledges its great indebtedness to the following gentlemen: Charles Macdonald, formerly Chief Engineer of the Union Bridge Company, contractor for the superstructure of the Memphis cantilever bridge; H. W. Hodge, of Messrs. Boller & Hodge, engineers of the Monongahela cantilever bridge; Ralph Modjeski, of Messrs. Noble & Modjeski, engineers of the Thebes cantilever bridge; Colin M. Ingersoll and Henry B. Seaman* of the Department of Bridges of the city of New York, and Messrs. Reynders and Kunz, of the Pennsylvania Steel Company, respectively the engineers and the contractors for the superstructure of the Blackwell's Island cantilever bridge; Prof. Mansfield Merriman, Prof. W. C. Kernot, Prof. W. H. Burr, Prof. Edgar Marburg, Prof. H. M. MacKay, Prof. G. F. Swain, and Messrs. W. R. Webster, T. K. Thomson and W. W. Stern, Consulting Engineers; also "the hearty co-operation of all officials of the companies directly concerned. Messrs. Cooper, Szlapka, Deans and Hoare especially have made every effort in their power to assist us to establish the facts and have not attempted to spare themselves."

Most of the Commission's discussion of the difficulties that arose during erection of the bridge and of events at the time of its collapse, including the correspondence between the interested persons immediately preceding the catastrophe, follows:

The contract for the construction of the main spans was made conditionally on June 19, 1903, and finally accepted by the Phoenix Bridge Company on March 15, 1904. By the 1st of August 1904 the assembling of materials for the falseworks on the south shore had commenced, and by the beginning of September 1904 the erection of the falsework was well under way. The wooden falsework for the supply tracks, and the steel falsework for the traveler and bridge trusses were erected simultaneously, not quite one half of the falsework being put up before December 1, 1904. The erection of the big traveler was commenced, and the storage yard at Chaudiere was in working order before the end of the season of 1904.

A considerable amount of material was delivered at the Chaudiere yard during the succeeding winter, but the work was not pushed in the spring of 1905, because there was no rail connection between the bridge site and the Chaudiere yard. This connection was completed on July 9, 1905, at which time the framework of the big traveler was being completed, and the falsework had been erected to the main pier but was not finished.

The equipment of the traveler was installed and the erection of the steelwork was begun at the anchor pier on July 22, 1905. By the middle of September the lower chords of the anchor arm had been erected, the pedestals and feet of the center posts were being placed and the erection of the web members and upper chords had commenced. By the end of the season six panels of the anchor arm, out of a total of 10, were in place. The total amount of metal erected during 1905 was about 10,500,000 lbs.

In 1906, erection commenced on April 16 and the south anchor arm was all in place, except for some decorative details by June 27. Erection continued on the south cantilever arm and this was completed with the exception of some connecting pieces between it and the suspended span, before work closed down for the year on No-

*Mr. Seaman is now Chief Engineer of the New York Public Service Commissioner, First District.—Editor.

vember 26. The total weight of metal erected during this season was about 21,000,000 lbs. Work on the north shore commenced about the middle of July and a small portion of the falsework was in position by the end of the season.

During this season few difficulties occurred, and these were of a kind usually met with on all large work. The following quotation from Mr. McLure's report to Mr. Cooper, under date of July 21, 1906, gives a fair idea of the conditions existing on the work: "The whole policy of the Phoenix erection department seems to be to make things safe and take no chances, which is a very satisfactory one to us, and in pursuance of this everything is being bolted up full in cantilever arm, with the largest size bolts the holes will take, post and chord splices, main and sub-diagonal splices as well as all lateral and transverse bracing connections."

The Commission has been unable to satisfactorily determine the respective duties of Mr. Hoare and Mr. Cooper. According to Mr. Deans, Mr. Cooper had to approve all plans, but all other authority was vested in Mr. Hoare, and this opinion Mr. Deans continued to hold throughout the work. According to Mr. Parent, Mr. Hoare was practically an executive officer acting in all technical matters on the direction of Mr. Cooper, who was, *de facto*, Chief Engineer. Mr. Cooper himself has stated that the erection plans were not subject to his authority and has disclaimed any responsible connection with the inspection either in the shop or in the field. With few exceptions, all his directions are advisory and not imperative, and he seems to have endeavored throughout to avoid encroaching on the privileges and rights properly pertaining to Mr. Hoare's position. He gave frequent directions to both Mr. McLure and Mr. Edwards on technical matters, but throughout the construction period (August, 1905 to August, 1907) he had practically no correspondence with Mr. Hoare. Mr. Cooper's opinions, when given, were accepted by the Inspectors as instructions. The impression left with us is that throughout the work Mr. Cooper was in a position of a man forced in the interests of the work to take responsibility which did not fully belong to his position, and which he was not authorized to take, and that he avoided the assumption of authority whenever possible. Such an organization cannot from an executive standpoint be considered entirely satisfactory.

Work for the season of 1907 began in March, it being necessary to have a yard prepared to receive material on the north shore by early spring. The yard was located at Belair, close to the junction of the Canadian Pacific and the [projected] National Transcontinental Railway. Work on the trusses began on May 1, but until May 31 was confined mainly to riveting. Using the big traveler, the connecting links between the cantilever arm and the suspended arm were put in, and the small traveler was built. On July 13 the erection of the suspended span was commenced, the small traveler being used and the dismantling and removal of the big traveler was begun. Both of these operations were in progress when the bridge fell, on Thursday, August 29. On the north shore, work continued at a leisurely rate from about May 15 until the day of the accident. The north shore falsework was not fully erected by that date, there being no reason to hurry, because rail connection could not be obtained. During this season less than 3,000,000 lbs. of metal were erected. The last progress estimated (August, 1907) showed that about 34,400,000 lbs. in all had been erected.

The difficulties with the lower chords that finally resulted in the collapse of the bridge were noted early in the season, but those first observed were considered to be of minor importance.

On June 15 Mr. McLure reported to Mr. Cooper as follows:

In riveting the bottom chord splices of south anchor arm, we have had some trouble on account of the faced ends of the two middle ribs not matching as per following sketch. (The sketch shows that at the lower sides the middle ribs of the abutting chords were out of line by 1/8 in. to 1/4 in., this offset decreasing to nothing near the mid depth of the ribs.) This has occurred in four instances so far and by using two 75-ton jacks we have been able to partly straighten out these splices, but not altogether. These were probably in this condition when erected, but owing to the presence of the bottom cover plate it was then impossible to detect them, and it was only when this plate was removed for riveting that the inequality was noticed. The chords found in this shape were between 3 and 4, 7 and 8, and 8 and 9 in east truss, and 8 and 9 in west truss. You will note that this occurs only on inside ribs, which are provided with but a single thin splice plate each. I think that a heavy plate on each side of these ribs, bolted up tight when chords were erected, would have remedied this, *i. e.*, drawn the ribs together till the "faced ends matched."

Mr. Cooper replied on June 17 saying:

Make as good work of it as you can. It is not serious. It would be well to draw attention to using as much care as possible in future work to get the best results in matching all the members before the full strains are brought upon them.

It should be noted that of the four joints mentioned, those between chords 3 and 4 and 7 and 8 had originally been opened at the lower side and had come together by "camber" movement; but the 8 and 9 joints had been set with the lower edges abutting. During the first stages of erection, the upper edges of all the ribs at a joint were exposed to view, as the upper cover plate was not in place. Mr. Kinloch states in his evidence that he observed gaps between abutting ribs as great as [illegible] in. due to irregular finish of the planed ends of the chords. In the examination of the material in Belair yard the Commissioners found irregularities of workmanship which would account for the conditions described above, and in our judgment these could have been avoided only by matching the chords together in the shop previous to shipment. The small gaps between abutting ends of chords closed as the pressure on the chords increased, with no result other than producing irregularity of stress, but the lateral deviations had to be corrected by the use of jacks.

As Mr. Cooper, in his evidence, has expressed the opinion that these lower chord joints were, during erection, the weakest and most hazardous part of the structure, and that they suffered from lack of appreciation of the necessary care to be given them, it is advisable to closely review all evidence concerning them.

The chords consisted of four deep and narrow ribs latticed together and finished with square ends so that the pressure might be transmitted from one chord to the next by contact of the abutting ends. Under the system of erection adopted it was possible to place the adjoining chord ends in contact only at either the upper or lower edges, and it was expected that the chords would gradually turn during the settlement of the bridge until the end surfaces came fully in contact. This expectation was realized. The adjoining chords were held together by eight splice plates; an upper and a lower horizontal plate, two vertical plates on each outside rib and one vertical plate on each inner rib. The order of erection required that the lower plate should be put in position before the next chord was set; the vertical plates were next placed and the erection of the joint was finished by bolting on the upper plate. Owing to erection angle at the joint it was possible to use full size bolts on only one horizontal plate and one edge, either upper or lower, of each vertical plate.

The instructions with regard to the bolts were very definite and read as follows: "All bottom chords to have two-thirds of all holes of web splices filled with 1-in. bolting on the outer ribs, and 7/8-in. bolts on the inner ribs, or their equivalent in smaller bolts or drifts. For top splice plate apply rule (1), (this requires that every hole shall be filled with a bolt) and never take off splice plate again, not even while driving rivets in web splices. Bottom splice plate to be bolted with bolts two-thirds value. While driving rivets in web splices of chords, remove bottom splice plate and bolt across flanges temporary angles to keep flanges in place." Owing to the camber openings at the joints it was found necessary in some cases to use 5/8 in. bolts, as no larger bolts could enter the holes in their erection condition.

The evidence shows that these instructions were carried out but not with a full appreciation of their importance. Mr. Birks, who was admitted by all witnesses to have been an exceptionally accurate and painstaking Inspector, examined all the bolting towards the end of the season of 1906 this examination being made on direction of Mr. Deans, and at the express request of Mr. Reeves, the President of the Phoenix Bridge Company. He reported as follows:

"All bottom chord splices in anchor arm—top plate full—bottom plate and webs 67 per cent.—all joints bolted as per instructions" and also "all chords in the first five panels of the cantilever arm top plate full—rest 67 per cent."

Mr. McLure's report about bolting has already been quoted and Mr. Kinloch, in his evidence, states that the Phoenix Bridge Company's instructions about bolting were fully obeyed but that he personally did not pay much attention to the bolting of the bottom cover plate as he knew that it had to come off during riveting. We are of the opinion that the top and bottom cover plates and the splice plates for the outside ribs, all of which could be readily seen by the Inspectors, were correctly bolted, but there may have been some cases of insufficient bolting on the inside ribs. Such cases were, we think, rare.

It was intended that, as the camber openings closed, the smaller bolts should be taken out and replaced by larger bolts on all outside plates, the inner plates being difficult of access until the bottom chord plate was removed. This idea does not seem to have been followed in practice to any extent nor is there any evidence to show that the bolting was systematically tightened up as it worked loose with the adjustment of the structure. The evidence also shows that the bottom cover plates were left off during the whole period of riveting a joint (usually from ten days to two weeks), and that in the case of 7-8 L cantilever arm this plate was off for nearly the whole month of August, 1907. We must therefore conclude that the splice plates at the joints were rather loosely attached and that the importance of rigidity at these points were strangely overlooked.

It should be noted that this system of bolted splices was a necessity due to the method of erection adopted, but that there was no reason why the end details of the chords and the splice plates themselves should not have been much more strongly and rigidly designed. The erection problem was unique in magnitude, particularly in the camber requirements, and the method followed by the Phoenix Bridge Company closely corresponds to that in general and successful use on smaller structures. It is open to criticism on theoretical grounds and it is possible that other engineers might.

by other design serve the same ends; the problem in its dimensions is so entirely new, that there is room for much study and invention in erection methods for great structures.

We know of no reason why the method adopted cannot be successfully used, but the evidence shows that the Phoenix Bridge Company failed to appreciate the important influence that end details and splices had on the strength of the chords. Steps were not taken to insure that the work was so handled that the maximum rigidity consistent with design was secured at these joints. Considering the circumstances, we know of no good reason why the riveting should not have been much further advanced before the great stresses created by the erection of the suspended span were thrown upon the joints. The report of Mr. McLure on November 10, 1906, shows that all but eight of the 40 lower chord joints were then closed and ready for riveting. Mr. Cooper has clearly stated that he did not consider that the erection methods were subject to his control, although the evidence shows that he was frequently consulted about them, both by Mr. Szlapka and by Mr. McLure. The erection problem in this case was of great importance, and the Quebec Bridge Company did not place their interests under the direct and responsible control of an experienced engineer acting solely on its behalf.

Difficulties developed almost as soon as the erection of the suspended span got well underway. On August 6 Mr. McLure reports as follows:

New Liverpool, P. Q., Aug. 6, 1907.

Mr. Theodore Cooper, Consulting Engineer, 45 Broadway, New York.

Dear Sir:—In riveting up the splice between chords 8 and 7 in the west truss of south cantilever arm we found the condition of the inside ribs at splices as indicated in following sketch. Owing to the limited space between the two inside ribs, it would be impossible to jack this splice back, and as the condition is not nearly as bad at the top of the splice, we have proposed putting a diaphragm between the two inside ribs to cover the first five rivets up from the bottom on each side of the splice, as indicated in red in the sketch above. The splice plates being riveted on the two inside ribs, it will be necessary to cut out and re-drive twenty rivets to do this. This provision, together with the top and bottom cover plates, should be sufficient to hold this splice against the thrust due to its being out of line, which thrust when under its maximum compressive stress I estimate at not over 60,000 lbs.

The Phoenixville office is being notified of this plan, and if they will approve will wire us. If this also meets with your approval or if you wish to suggest another way to remedy the difficulty, will you please wire me at St. Romuald, P. Q., care Phoenix Bridge Company, as the riveting gangs are ready to finish riveting this splice. Very truly yours,

N. R. M'LURE.

On receipt of this letter, Mr. Cooper wired the Phoenix Company as follows, August 8:

New York, Aug. 8, 1907.

Phoenix Bridge Co., Phoenixville, Pa.:

Method proposed by Quebec for splicing joints of lower 7 and 8 chords is not satisfactory. How did bend occur in both chords?

THEODORE COOPER.

and wrote Mr. McLure on August 9 as follows:

New York, Aug. 9, 1907.

N. R. McLure, Esq., Inspector for erecting Quebec Bridge, Liverpool, P. Q.

Dear Sir:—Yours of the 6th, regarding bent condition of lower 7 and 8 chord joints, came yesterday. I wired Phoenix that the proposed method as sketched by you for repairing was not satisfactory. Also asked, what you should have reported, how did both these chords get bent?

In my opinion these webs can be brought back to proper line by use of 15 to 20 1-in. bolts, threaded at both ends for nuts, passing through the two webs of that half of chord. Of course, means must be taken to stiffen the straight web against its bending when the bolts are tightened.

If necessary, after getting the bent web in line, to hold them, spacers and possibly some through bolts may be used.

Some more satisfactory method than the one shown in your sketch must be devised.

Mr. Deans telegraphs that upon Mr. Szlapka's return he will give me fuller facts. Yours truly,

THEODORE COOPER.

Then the following telegram was received from Mr. Deans:

Phoenixville, Pa., Aug. 9th, 1907

Theodore Cooper, Consulting Engineer, 45 Broadway New York:

Mr. Szlapka happened to be at bridge site yesterday—expect him home tomorrow, with full information concerning chord joint, will then write you fully.

JNO. STERLING DEANS.

To which Mr. Cooper replied as follows:

New York, Aug 9, 1907

John Sterling Deans, Chief Engineer, Phoenix Bridge Co., Phoenixville, Pa.

Dear Sir: Your telegram regarding chord joint at hand. The method proposed as sketched by Mr. McLure is not satisfactory, as I telegraphed yesterday.

These bent webs can be pulled back by use of about 15 to 20 1-in. bolts (in 1 1/16-in. holes) threaded at both ends for nuts, passing from the outer to the inner bent web, the outer straight web being stayed in some manner against its bending.

If the bent webs after being pulled into line, tend to go back when released from the bolts, stays must be introduced to hold them in position. Possibly it may be necessary to permanently rivet in some of these 1 in. bolts.

Please let me know what method you propose to use.

It is a mystery to me how both these webs happened to be bent at one point, and why it was not discovered sooner. Yours very truly,

THEODORE COOPER.

On August 10th, Mr. Deans wrote to Mr. Cooper as follows:

Dear Sir:—"Splice cantilever chords 7 and 8." Mr. Szlapka did not return to-day as expected, but will no doubt be here on Monday, when we will write you at once. Yours truly,

JNO. STERLING DEANS.

And on the 12th Mr. Deans again wrote to Mr. Cooper as follows:

Dear Sir: Chord splice south cantilever arm, 7-L and 8-L.

Mr. Szlapka reached the office this morning and I am able to give you information in connection with this one joint.

All ribs of the chord 7-L have a complete and full bearing on ribs of 8-L. The bend was no doubt put in the rib in the shop, before facing and was probably done when pulling the ribs in line to make them agree with spacing of these ribs and the clearance between ribs, called for on the drawing. The bend being on only one rib of one chord, there being a full bearing over the entire rib, all splice plates being readily put in position, we do not think it necessary to put in the diaphragm, suggested by the erection department.

Please let us hear from you on this subject promptly and oblige.

Yours truly,

JOHN STERLING DEANS,

Chief Engineer.

On August 13, in reply to Mr. Deans, Mr. Cooper wrote as follows:

Dear Sir.—The information regarding chord splice 7 and 8-L, is so different from the dimension sketch sent by Mr. McLure, I can take no action on this matter till the exact facts are presented. Please have your resident engineer and Mr. McLure re-examine this joint and send the exact condition of this rib, as to the amount of the bends and relation of the bearing services to each other.

I don't see how one rib being bent only, as stated in your letter, there can be a complete and full bearing of these ribs. Neither can I understand how pulling the rib into line at the shop could bend it out of line.

I will write Mr. McLure to-day to have a further investigation of this joint and to report as promptly as possible. Yours very truly,

THEODORE COOPER.

And on the same day Mr. Cooper wrote to Mr. McLure:

New York, Aug. 13, 1907

N. R. McLure, Esq., Inspector for erection, Quebec Bridge, New Liverpool, P. Q., Canada.

Dear Sir:—Mr. Deans writes me that only one rib at joint 7 and 8 L is bent and still that there is a full and complete bearing; that the bend was no doubt put in the chord in the shop before facing.

I have asked him to instruct his resident engineer to join with you in making an exact report, with dimensions of the conditions of this joint, with amount of bearing, and if it is a square bearing or askew.

In reference to the splicing of T 5 and T 50, mentioned in your letter of 10th, I do not care to interfere with the regular programme, as I have not followed the various actions of the loadings at different stages, without going into it carefully. I think there will be more compression at these points with more of the suspended span in place.

Please report promptly regarding joint 7 and 8 L with all the facts.

Yours truly,

THEODORE COOPER.

Mr. Deans wrote Mr. Cooper on August 14 as follows:

Dear Sir.—Chord splice 7 and 8 L. Your letter Aug 13.

I will have a full and complete report made of this joint by Mr. McLure and Mr. Birks, and submit it to you earliest possible moment.

Yours truly,

JOHN STERLING DEANS,

Chief Engineer.

On August 14, Mr. Cooper received the following letter of the 12th from Mr. McLure:

Dear Sir: I beg to acknowledge the receipt of your letter of Aug 9 and have noted what you say regarding the method of repairing splice between chord 7 and 8 cantilever arm west truss. We will not do anything with this then until the matter has been arranged between yourself and Mr Szlapka

The reason I did not report at first as to how these chords got bent was because there were many different theories here as to the cause, no one of which I was at that time ready to accept. One thing I am reasonably sure of, and that is, that the bend has occurred since the chord has been under stress and was not present when the chords were placed. This being the case, the cause of the bend would seem to be the slight overrunning in length of the bent rib in either chord 7 or 8. Owing to the fact that these chords are faced on the rotary machine the four ribs at once this would at first seem to be out of the question, but it seems to me that after the first end of a chord has been faced in turning it with the crane, to bring the other end into position for facing, it might be possible for one rib to work slightly by the others longitudinally, without being noticed, and in spite of the latticing and thus cause a slight difference in length. In fact, in taking the opening in the chord splices on the south anchor arm, it has often been noticed that a considerable variation existed between the openings of the different ribs at the same splice, which difference I was not able to account for except by the above theory that during transportation, and in the handling before erection, some of the ribs have worked slightly in a longitudinal direction by each other In the case in question, of course, this must have happened between the time of facing one end and the other If this is correct, then it will be a pretty hard matter to draw this splice back into line with bolts, and our idea in suggesting that a diaphragm was to prevent this eccentricity from increasing, rather than to correct that already there

As I had supposed, the strike in force for the last three days of last week has been settled, and work has again resumed this morning. A meeting of the union was held Saturday night and enough of the discontented element had been lost so that when the matter was brought to a vote the majority were found to be in favor of returning to work under the original agreement. Those who were not in favor of returning to work, however, are now leaving so that our force is reduced greatly on both sides of the river.

Since writing the above I have discovered that splice between the chords

8 and 9 on west truss of south cantilever arm is in the same condition exactly as that between 7 and 8, except that the bend is only $^5/_{16}$ in., instead of $^3/_4$ in., at the bottom, and runs out so that on top this rib is in line as are the other three.

This is the same rib and the bend is in the same direction as that reported for the other splice. When it is decided in what way to treat the splice between chords 7 and 8 we will repair that between chords 8 and 9 in a similar manner. Yours very truly,

N. R. M'CLURE.

To this Mr. Cooper replied to Mr. McLure on August 15 as follows:

Dear Sir: None of the explanations for the bent chord stand the test of logic.

I have evolved another theory which is a possible, if not the probable one. These chords have been hit by those suspended beams used during the erection, while they were being put in place or taken down. Examine if you cannot find evidence of the blow and also make inquiries of the man in charge. Yours very truly,

THEODORE COOPER.

A further report was made by Mr. McLure to Mr. Cooper on August 16th:

Dear Sir: Referring to your letter of 15th, regarding splice between 8 L and 7 L on south cantilever arm, you have not doubt by this time received my letter of the 12th inst., giving my theory of the cause of this bend. These conditions are as indicated in my report of Aug. 6. Mr. Birks, the resident engineer for the Phoenix Bridge Company, reported exactly the same thing, in somewhat different language to Phoenixville, but Mr. Deans had evidently taken a different meaning from his report than was intended. He evidently thinks that only one rib of one chord is bent, whereas it is the same rib at each chord, as indicated in the sketch I sent you. There is really nothing to add to the two letters I have already written regarding this bend, except to say that all the four ribs have full bearing on each other, as indicated also in the sketch of Aug. 6. In order to verify our first reports, Mr. Birks and I made a careful and more thorough measurement of this splice to-day, both top and bottom, and I am enclosing a blueprint of a sketch made as a result of these measurements. It indicates practically the same condition as described in my first letter, except that it is given more in detail.

As to the cause of this bend, regarding which I wrote you on Aug. 12, Mr. Deans seems to think that it was put in in the shops; but that is because he did not understand the condition existing. Aside from the fact that it would be hardly probable that these two ribs of different chord sections should be bent the same way exactly the same amount in the shops—to dimensions $^1/_2$ in. to $^3/_4$ in. less than called for, I am reasonably sure, as I said before, that this condition did not exist before the erection of these chords, as I have personally inspected every member yet erected in this bridge thus far, except the bottom chords of another arm, on the cars just before the erection, looking particularly for bends in ribs of compression members, and whenever discovered have taken measurements of the amounts and recorded them. If these ribs then had been this much out of line before erecting, it would be well nigh impossible to miss seeing them. Consequently, the only way the bend could have occurred, it seems to me, is that reported in my letter of Aug. 12.

I trust that these explanations, with the enclosed sketch, will make the matter entirely clear. Mr. Birks is sending same sketch to Phoenixville to-day. Very truly yours,

N. R. M'LURE.

Mr. Deans also received a copy of this sketch and wrote Mr. Cooper on August 20 as follows:

Dear Sir: We have advice from your field that you received copy of sketch No. 28, giving further details in connection with cantilever chord splice 7 L and 8 L. You will notice that the two chords have a perfect bearing with each other at all ribs. Both chords having one bent rib and not one chord only as we first understood. Yours truly,

JOHN STERLING DEANS,
Chief Engineer.

To which Mr. Cooper replied on August 21 as follows to Mr. Deans:

Dear Sir: I received copy of sketch of joint 7 and 8 L two days ago.

I wrote Mr. McLure last week telling him none of the theories as to how this bending occurred was logical. That my theory was a blow on this rib after the two sections were in contact, and that it probably was done in moving those suspended beams used in erecting. To examine carefully to see if he could find any evidence of this. He has not yet reported. He did report a similar bend in L 8 and 9 west truss in same rib, but of less amount.

I still believe this bend can be partly removed by use of long bolts with threads at each end: outer rib being stiffened to prevent its bending. If it can be pulled nearer straight, stays or bolts must be provided to hold it against future movement.

I cannot consent to let it go without further action as the rivets in the cover splices would not satisfy the requirements to my mind.

Yours very truly,

THEODORE COOPER.

This letter was acknowledged by Mr. Deans on August 23 in the following letter to Mr. Cooper:

Dear Sir: "Joint 7 L and 8 L south cantilever arm."

Referring to your letter of Aug. 21, I notice you expect to hear again from Mr. McLure. As soon as you have this report kindly let us hear from you again, and oblige. Yours truly,

JOHN STERLING DEANS,
Chief Engineer.

On August 26 Mr. Cooper wrote the following letter to Mr. Deans:

Dear Sir: Mr. McLure reports that he can find no evidence of the bent ribs having been hit and does not think they could have been struck. This only makes the mystery the deeper, for I do not see how otherwise the ribs could have been bent.

When convenient I would like to discuss with Mr. Szlapka the best means of getting these ribs into safe condition to do their proper work.

Yours very truly,

THEODORE COOPER.

This was acknowledged August 27 by Mr. Deans to Mr. Cooper.

Dear Sir: Chord splice 7 and 8 cantilever arm south side.

Replying to your letter of Aug. 26, I will have Mr. Szlapka call to see you first opportunity to discuss this question. He will write you later the day he will be in New York. Yours truly,

JOHN STERLING DEANS,
Chief Engineer.

This was the last that transpired with regard to the bent ribs at joint 7 L and 8 L cantilever arm, and it is plainly indicated that no one except Mr. Cooper looked on this matter as serious or as indicating any constitutional weakness. It will be noted that the bends at 7 and 8 were reported on August 6, the bends at 8 and 9 discovered on August 12, and that both bends were in the west truss, that previously from time to time chords with ribs more or less wavy had been reported, and Mr. McLure gave it as his opinion that these bends were caused by stress since erection because he was sure they were straight when erected, while Mr. Deans thought the bends were made in the shop.

While Mr. Deans after Mr. Szlapka's return gives certain information as to the bend in the 7 and 8 splices, Mr. Szlapka states that on his visit to the bridge he did not examine this splice, and further says that during none of his three visits to the bridge did he examine any chords. Mr. Kinloch states in his evidence that he did not notice the bends at the 7-L and 8-L joints when the bottom cover plate was first removed, and that he felt confident that these distortions took place after the removal of the cover plate.

It seems clear from the above that Mr. Cooper's statement that the delicacy of the joints was not sufficiently appreciated by the Phoenix Bridge Company is substantiated. Mr. Szlapka was on the ground and made no special examination in the matter, and Mr. Deans endeavored to throw the blame for the distortions entirely on the shop work. No evidence has been shown to us to prove that Mr. Deans had any grounds for this assertion, and his inspector, Mr. Morris, was in possession of information that indicated that there was no great probability that such an error could have escaped detection. On August 20, Mr. Kinloch discovered that chord 8-R of cantilever arm was bent, and afterwards found that 9-R and 10-R also showed distortion, he called Mr. Birks' attention to this condition, but neither of them considered it of importance. Mr. McLure was ill and did not see these bends until several days after they were found (August 23), but Mr. Yenser was made aware of them. On August 23 the joint at chords 5 and 6-R of cantilever arm was found to be off on one center rib $^1/_2$ in. at bottom, the offset running to nothing at top. Mr. Kinloch visited chord 8-R daily for several days and imagined that the bend was becoming greater, all four ribs being bent, but not alike.

The bend in chord 9-L anchor arm was discovered about 9.30 a.m. August 27 to have greatly increased, it having been previously noted and being under observation. Owing to the fact that the 25th was a Sunday and that there was practically no work done on the 26th, it is doubtful whether this chord was examined between the 24th and the 27th. Mr. Kinloch, who made the discovery, in his evidence says:

Q. Please relate the occurrences following your discovery of the bent chord on Aug. 27.

A.—Immediately after discovering the bend I brought the matter to the attention of Mr. Yenser and Mr. Birks, and with them re-examined both chord A 9 L and several other lower chord members. We did not know what to make of the matter and then went up to our office and arranged with Mr. McLure to have the deflections of the suspicious chords measured—this measurement, which was made by Birks, McLure and myself, showed the extent of the deflections, and their cause and their ultimate result immediately became a matter of very active discussion. Mr. Birks expressed himself definitely as being of opinion that there was no danger and endeavored to persuade me that the bend had always been in the chord. Mr. Yenser and I were uneasy and considered the matter serious, and finally suggested that Mr. McLure and Birks should go to New York and Phoenixville for advice. It was considered that the matter could not be satisfactorily explained by telegraph or telephone, and none of us expected immediate disaster. Mr. Birks and Mr. McLure did not welcome our suggestion, saying that they would only be laughed at on arrival, and it was finally agreed to refer the matter of sending to headquarters to Mr. Hoare, who decided in favor of our suggestion. Mr. Hoare visited the bridge on the Wednesday and spent most of the day there. He appeared very anxious that I should abandon my position of being positively convinced that the bend had occurred since the erection of the cantilever arm was completed, and argued both this and some possible method of strengthening the chord by bracing, several times with me. I was somewhat excited and much annoyed at the unwillingness of all the engineers to accept my statement of facts, and on both Wednesday and Thursday avoided further discussion of the matter as much as possible. It was understood that Mr. McLure would immediately wire me if Mr. Cooper took a serious view of the situation, but this he failed to do. Mr. Birks, however, told me on the morning of the 29th that he had been advised by 'phone from Phoenixville that they had a record which showed that the bends had been in the chord before it was shipped from Phoenixville, and that he had just advised Mr. Hoare by telephone at the request of Mr. Deans to that effect.

As soon as the measurements above referred to were made, it was recognized by Mr. Yenser and the inspectors that they were face to face with a crisis. Mr. Yenser announced his intention of stopping erection until he had referred the matter to Phoenixville. The measurements were plotted and were reported by mail to Mr. Cooper and to Phoenixville, these reports being delivered on the morning of the 29th. Owing apparently to anxiety already existing among the workmen it was not considered wise to use either telegraph or telephone. As suggested by Mr. Kinloch, Mr. McLure reported the matter fully to Mr. Hoare on the evening of the 27th, the delay of about 12 hours being accounted for by the making and plotting of the measurements and the necessity of using a personal messenger as it was not wished to report particulars over the telephone. It is clear that Mr. Yenser, Mr. Kinloch and Mr. McLure were very much alarmed, but Mr. Birks could not be convinced that the bends had recently taken place. He knew better than anyone else on the work the care with which the calculations and designs had been made; he was familiar with the experience and abilities of the designers, and could calculate that the stresses were then far below the expected maximum.

To engineers the force of such reasoning is very great and we do not consider that the confidence Mr. Birks placed in his superiors was in any way unusual or unreasonable. There was no misunderstanding, however, on his part; he realized that if the bends had not been in the chord before it was erected, the bridge was doomed, and although Mr. McLure had evidence that the bends had increased more than 1 in. in the course of a week, although Mr. Kinloch was positive that the bends had very recently greatly increased, and although Mr. Clark stubbornly maintained that the chord was absolutely straight when it left Chaudiere yard, Mr. Birks still strove to convince himself that they must have been mistaken. Mr. Hoare evidently concluded that the matter was too serious for him to settle by any offhand decision, and approved Mr. McLure's mission to New York, wisely requiring that he should get all possible facts before leaving, so that Mr. Cooper need not wait for further information on which to base a decision.

The text of Mr. McLure's report of August 27 is as follows:

New Liverpool, P. Q., Aug. 27, 1907.

Mr. Theodore Cooper, Consulting Engineer, 45 Broadway, New York.

Dear Sir: I enclose sketches showing condition of bottom chord sections "606—9 L" of south anchor arm and "621—9 R and 8 R" of south cantilever arm, as found from measurements made to-day by the Phoenix Bridge Company's Assistant Engineer and myself, by stretching a line from batten plate to batten plate as indicated on the sketches and measuring from this line held taut, to each rib, top and bottom. It was noticed this morning that these chords were bent in this manner, as it is very evident to one walking over them, and as it looked like a serious matter, we measured them.

Although a number of the chords originally had ribs more or less wavy, as I have reported to you from time to time, it is only very recently that these have been in this condition, and their present shape is undoubtedly due to the stress they are now receiving. Only a little over a week ago, I measured one rib of the 9—L chord of anchor arm here shown, and it was only ¾ in. out of line. Now it is 2¼ in.

In the sketches the red indicates straight lines and black ones the ribs of chords. A top and bottom view is shown in each case. You will note that chords 606—9 L and 621—9 R have all ribs bent in same direction, while 621—8 R has its ribs bent in reverse curves. These bends had become so apparent by to-day that the gangs riveting at these points noticed them, and called Mr. Kinloch's attention to them.

This matter is being reported in this mail, with sketches from the same measurements, to the Phoenixville office, and the erection will not proceed until we hear from you and from Phoenixville. Yours very truly,

N. R. M'LURE.

Wednesday, August 28, was a day of waiting and uncertainty. Mr. Yenser had changed his mind during the night and in the morning continued erection. The men were uneasy and alarmed and the officials were anxiously awaiting instructions from Phoenixville or New York. Mr. Yenser's decision to continue work was laid before Mr. Hoare, upon whom, as Chief Engineer, the final responsibility for every step taken rested, who decided that Mr. Yenser had acted wisely. Mr. Hoare makes this clear in the following letters to Mr. Cooper:

Letterhead (The Quebec Bridge & Railway Co.).

Quebec, Aug. 28, 1907.

Theodore Cooper, Esq., 45 Broadway, New York City.

Dear Sir:—I wired you to-day as under:

"Have sent Mr. McLure to see you early to-morrow to explain letter mailed yesterday about anchor arm chords."

Also the following message to the Phoenix Bridge Co.: "Mr. McLure will call to-morrow to explain Birks' letter *re* anchor arm chords. Will see Mr. Cooper first."

Regarding this matter I thought it best for McLure to go at once to be able to explain matters and answer questions. He did not have much time for extended investigation before leaving.

I have been at the bridge all day trying to get some evidence in connection with the bending of the ribs in this chord. Mr. Kinloch noticed it for the first time yesterday and all inspectors declare that no such pronounced distortion existed a few weeks ago. Mr. McLure made measurements yesterday afternoon and brought them to my house late last night, and stated that the erection foreman hastily concluded that he would not continue erecting to-day, which alarmed me at the time. Upon arriving at the work this morning he thought better of it and decided to go ahead, at the same time asking me if it would be all right. After ascertaining that the effects from moving the traveler ahead and proceeding with the next panel would be so insignificant I requested him to continue, as the moral effect of holding up the work would be very bad on all concerned and might also stop the work for this season on account of losing the men. From further investigation during the day I cannot help concluding that the metal received some injury before it was erected, as the corresponding chord in the same panel and stressed the same is in good condition. These panels are being stressed to-day, approximately, about 7/10 of their maximum, and it is difficult to believe that this is the entire cause of the distortion. Now and again a rib in certain members is found to be a trifle longer than another, which, when compressed, might cause a trifling kink in it. There are a few examples of this. The chord in question, when being lifted to the cars in the storage yard broke loose from the grips, one end of which fell a distance of 6 ft. on to timber sills; the other end fell a distance of 2 ft. on to a block of eyebars. In falling it fell over on its side, breaking one of its angles on the north end splice and twisting some of the lacing bars, all of which were renewed. After this the inspectors reported the ribs perfectly straight. On account of this chord falling on to two rigid higher points at ends, with no support in the middle but soft material, the conclusion would be that the deflection would be downward, as a matter of fact the evidence shows that it was in the opposite direction. Since Mr. McLure left, Mr Birks has made careful examination of the chord and states that the actual bending commences at the south splices and was not confined entirely to the length between the bottom plates, where the lacing angles are used. As the foreman and inspectors declare that these defects were not noticeable until recently, perhaps the stress in this chord has made previous defects more pronounced. I thought I would give you the above story from further investigation by to-night's mail to help you to come to some conclusion

Yours truly,

E. A. HOARE.

Letterhead (The Quebec Bridge & Railway Co.).

Quebec, Aug. 22, 1907

Theodore Cooper, Esq.

Dear Sir:—Mr. Birks has just called me up on the telephone from the bridge and states that he has received a message from Phoenixville stating that they have positive evidence that the chord was not straight before it left the shops. This possibly clears up the mystery why the deflection was in the opposite direction to what it should have been, due to its fall in the storage yard. Mr. Birks has wired that information to Mr. McLure at your office. Mr. Birks further stated that he is positive that the chord ribs were more or less out of line when the splices at the south end was riveted up in the bridge. Yours truly,

E. A. HOARE.

Letterhead (The Quebec Bridge & Railway Co.).

Quebec, Sept. 2, 1907

Theodore Cooper, Esq.

Dear Sir:—I thank you for replies to all our messages. I am sorry that you are not well and of course, this appalling disaster has made you feel a thousand times worse.

Mr. Berger will answer our purpose very well for the present. The investigating commission may find it necessary later to interview you in New York, due notice of which will be given you.

I wish to correct a misstatement in my letter to you of the 28th of August, which was written late and very hastily to confirm telegram and conversation with Mr. Birks about the chord under discussion. The statement in my letter as follows

"Mr. McLure made measurements yesterday afternoon and brought them to my house late last night and stated that the erection foreman hastily concluded that he would not continue erecting to-day, which alarmed me at the time. Upon arriving at the work this morning he thought better of it and decided to go ahead, at the same time asking me if it would be all right. After ascertaining that the effects from moving the traveler ahead and proceeding with the next panel would be so insignificant I requested him to continue, as the moral effects of holding up the work would be very bad on all concerned and might stop the work for this season on account of losing the men."

is to some extent a misstatement of facts and not clearly stated, due to too much haste, and which I wish now to correct as under

"Upon arriving at the work that morning the foreman told me that he had considered it during the night and had already removed the traveler forward, asking myself, Mr. McLure and Mr Birks if we thought that what he had done would do any harm. We all thought that it would not as they stated it would only add 50 lbs. to the square inch to the chord in question We all thought at the time that to discontinue the work would entirely stop the work for this season as the men would not wait and would go elsewhere to prepare for the winter."

As stated in my last letter, strictly speaking, I did not request the foreman to continue the work, as he had already done so; at the same time we thought there was no immediate danger in adding so small a load. This letter more clearly states the conversation between us, and I am sorry that I have misstated in my hurry one or two points which would be more or less confusing. Yours truly,

E. A. HOARE.

It was clear that on that day the greatest bridge in the world was being built without there being a single man within reach who, by experience, knowledge and ability was competent to deal with the crisis. Mr. Yenser was an able superintendent, but he was in no way qualified to deal with the question that had arisen. Mr. Birks, well trained and clear headed, lacked the experience that teaches a man to properly value facts and conditions, and Mr. Hoare, conscious that he was not qualified to give judgment, simply assented to the courses of actions that had been determined on by Messrs. Yenser and Kinloch and made no endeavor to make a personal examination of the suspected chords.

Some measurements were made to test the stability of the main pier, but no one seems to have thought of testing the span for alinement or levels, and, above all, to measure the chords again to see if they showed any increase of deflection. Mr. Moore discussed some means of bracing the chords, but decided to postpone action until Mr. Cooper was heard from. At Mr. Hoare's request Mr. Birks inspected the chord A 9 L and the A-L 8 9 joint carefully, and his observations tended to reassure both Mr. Hoare and himself, as he thought that he found evidence of original crookedness in the chord.

His report to Phoenixville, which was received on August 30, reads as follows:

New Liverpool, P. Q., Aug. 28, 1907.

The Phoenix Bridge Company, Phoenixville, Pa.

Dear Sirs: I have made a further investigation of chord 9 A, and beg to report following additional data: The bend in the chord starts at the faced splice at the shore end and not at the edge of the splice batten. It appears from this that at least a large portion of the bend was in the chord when the top and bottom splice battens were riveted early in June. This and the fact that the lacing angles are not disturbed leads me to believe that the ribs were bent before erection, in spite of the fact that Mr. Clark and Mr. Kinloch think all ribs were straight when the chord was repaired. From the evidence, so far, I do not think we are justified in assuming it to be a fact that the ribs of any of the chords have buckled since erection, and Mr. Yender has come to the same conclusion. Yours truly,

A. H. BIRKS.

After he had made his examination, Mr. Birks called Mr. Kinloch and waited at track level, while Mr. Kinloch went down to the chord and checked Mr. Birks' observations. After careful discussion with Mr. Kinloch of what was then done we are forced to conclude that the sketch in Mr. Birks' letter shows only his personal idea of the shape and extent of the existing distortion and cannot be considered as furnishing data on which to base engineering conclusions, as no actual measurements were taken.

On August 29 Mr. Birks' report of the 27th was received at Phoenixville and was immediately discussed by Messrs. Deans and Szlapka and Milliken. It was finally decided that it was safe for the work to proceed and a telephone conversation took place between Messrs. Milliken and Yenser and another between Messrs. Deans and Birks. Mr. Szlapka had made some calculations and Mr. Birks reported his observations of August 28. Messrs. Yenser and Birks were assured that the office approved their action in continuing work of erection and Mr. Birks was told to tell Mr. Hoare that the bends had been in the chords before they left Phoenixville. This Mr. Birks did.

Mr. Deans also telegraphed Mr. Hoare as follows:

Phoenixville, Pa., Aug. 29, 1907.

E. A. Hoare, Esq., Chief Engineer, Quebec Bridge Co., Quebec, Canada:

McLure has not reported here; the chords are in exact condition they left Phoenixville in and now have much less than maximum load.

Mr. Hoare had telegraphed to both Mr. Cooper and Deans on August 28 advising them of Mr. McLure's mission. Mr. Deans has since explained that his telegram did not refer to the chords measured on the 27th, but after considering the circumstances, we are entirely satisfied that Mr. Hoare was justified in thinking that it did, and in so doing he was confirmed by Mr. Birks' telephone message previously received.

From the time these assurances were received, anxiety at the bridge practically ceased, and there is no evidence that any further measurements were made to determine the movements of the suspected chords. As Mr. Hoare expressed it: "I felt quite comfortable that day about it. I knew it could not be long before the matter would be taken up."

Shortly after 11 a.m. on August 29, Mr. Cooper reached his office and found Mr. McLure there. After a brief discussion, Mr. Cooper wired to Phoenixville as follows:

New York, Aug. 27, 1907, 12:16 p. m.

Phoenix Bridge Co., Phoenixville, Pa.:

Add no more load to bridge till after due consideration of facts. McLure will be over at five o'clock.

This message was received at Phoenixville at 1:15 p.m. Mr. Cooper has explained in his evidence that he was not aware at the time that erection was proceeding. Mr. McLure having advised him to the contrary, and that he telegraphed to Phoenixville instead of to Quebec because he thought action would be more promptly secured by so doing.

Mr. McLure had promised to wire Mr. Cooper's decision to Mr. Kinloch immediately, but he did not do so.

Mr. Deans reached his office about 3 p.m. and found Mr. Cooper's telegram there. He arranged for Mr. Szlapka and Mr. Milliken to be on hand to meet Mr. McLure, but otherwise took no action. After Mr. McLure arrived there was a brief discussion during which Mr. McLure mentioned that he had received a wire from Mr. Birks giving him the result of that gentleman's observations on August 28. It was decided to postpone action until the morning and to await the arrival of Mr. Birks' letter of August 28. This decision was made almost at the minute that the bridge fell.

As a conclusion reached from the evidence and from our own studies and tests, we are satisfied that the bridge fell because the latticing of the lower chords near the main pier was too weak to carry the stresses to which it was subjected, but we also believe that the amount of those lattice stresses is determined by the deviation of the lines of center pressure, from the axes of the chords, and this deviation is largely affected by the conditions at the ends of the chords. We must, therefore, conclude that although the lower chords 9 L and 9 R anchor arm which, in our judgment were the first to fail, failed from weakness of latticing, the stresses that caused the failure were to some extent due to the weak end details of the chords, and to the looseness, or absence of the splice plates, arising partly from the necessities of the method of erection adopted and partly from a failure to appreciate the delicacy of the joints, and the care with which they should be handled and watched during erection. We conclude from our tests that owing to the weakness of the latticing, the chords were dangerously weak in the body for the duty they would be called upon to do. We have no evidence to show that they would have actually failed under working conditions had they been axially loaded and not subject to transverse stresses arising from weak end details and loose connections. We recognize that axial loading is an ideal condition that cannot be practically attained, but we do not consider that sufficient effort was in this case made to secure a reasonable approach to this condition. The Phoenix Bridge Company showed indifferent engineering ability in the design of the joints and did not recognize the great care with which these should be treated in the field.

We consider that Mr. Deans was lacking in judgment and sense of responsibility when he approved of the action of Mr. Yenser in continuing erection, and when he told Mr. Birks and Mr. Hoare that the condition of the chords had not changed since they left Phoenixville.

No evidence has been produced before the Commission in proof of the correctness of this statement about the chords, and Mr. Szlapka's calculations, as stated in the following letter, showed that the rivets were even then loaded to their maximum specified stress of 18,000 lbs. per sq. in.

Montreal, Jan. 24, 1908.

Phoenix Bridge Company, Phoenixville, Pa.

Gentlemen.—Will you please file with the commission a copy of the calculations made by Mr. Szlapka on Aug. 29, 1907, and which are referred to on pages 967 and 968 of the evidence.

As we are nearing the completion of our report, we would esteem it a favor if you would have this information sent to us immediately.

It is possible that you may not have an exact copy of these calculations, but no doubt they can be duplicated, and Mr. Szlapka's certificate to this effect will be sufficient. Truly yours,

HENRY HOLGATE.

Phoenixville, Pa., Jan. 31, 1908.

Henry Holgate, Esq., Chairman Royal Commission, Montreal, Canada.

Dear Sir:—Replying to your letter of Jan. 24, I enclose herewith letter from Mr. Szlapka of this date giving calculations similar to that made on Aug. 29, regarding chord 9 L south cantilever arm. Yours truly,

JNO. STERLING DEANS,
Chief Engineer.

Phoenixville, Pa., Jan. 31, 1908.

John Sterling Deans, Esq., Chief Engineer the Phoenix Bridge Co., Phoenixville, Pa.

Dear Sir:—Referring to Mr. Holgate's letter of Jan. 24, addressed to the Phoenix Bridge Company, I beg to give you below the calculations similar to the one made on Aug. 29, 1907, referring to chord 9 L south anchor arm.

Taking $1\frac{1}{2}$ in. as the average reported curvature of chord 9 L, we have

$$\frac{W\ L}{1} \times 12 = 780 \times 18{,}000 \times 21{,}060{,}000 \text{ in. lbs.} \qquad W = 61{,}000 \text{ lbs.}$$

$$\text{Stress in each lattice, } S = \frac{61{,}000 \times 1}{\ } = 21{,}600 \text{ lbs.}$$

Yours truly,

THE PHOENIX BRIDGE COMPANY,
PER P. L. SZLAPKA.

The theory underlying these calculations is very questionable, but it was adopted in the design of the bridge, and we cannot understand why its warning was so entirely disregarded in the face of the consequences that might result.

With reference to Mr. Cooper's telegram, Mr. Deans knew that he was in possession of later information from the bridge than had reached Mr. Cooper and therefore decided to wait for Mr. McLure and afterwards for the arrival of Mr. Birks' letter of August 28 before taking action. The whole incident points out the need of a competent engineer in responsible charge at the site.

Mr. Hoare was the only senior engineer who was able to reach the structure between August 27 and August 29. He was fully advised of the facts, yet did not order Mr. Yenser to discontinue erection which he had power to do. We consider that he was in a much better position than any other responsible officer to fully realize events that had occurred, and his failure to take action must be attributed to indecision and to a habit of relying on Mr. Cooper for instructions.

We are satisfied that no one connected with the work was expecting immediate disaster, and we believe that in the case of Mr. Cooper his opinion was justified. He understood that erection was not proceeding, and without additional load the bridge might have held out for days. Our tests have satisfied us that no temporary bracing such as that proposed by Mr. Cooper could have long arrested the disaster, struts might have kept the chords from bending, but failure from buckling and rivet shear would soon have occurred.

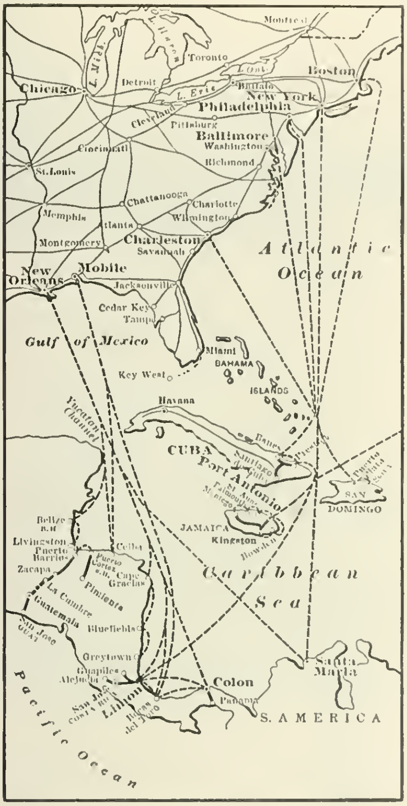
The Ocean Carrier.

BY J. RUSSELL SMITH, PH.D.

XI.

The Renaissance of the Merchant Carrier: The Private Steamship Line.

The nineteenth century has witnessed the evolution of the common carrier by sea. At the beginning of the period the merchant carrying his own goods was the conspicuous figure. But, by one of the strange repetitions of history, his disappearance was quickly followed by reappearance. The twentieth century opens with private carriers, operating on such a scale that they are able to run lines of steamships as links in huge productive and mercantile enterprises. This change is due to the magnitude of the modern corporations, which outrank the individual as a regiment outranks a policeman.



Map of United Fruit Lines.

Present operations in coal, iron, petroleum, asphalt, fruit and other industries are prosecuted on a scale unprecedented in size and made possible only by the modern corporation, in which property and resources sufficient for a medieval kingdom are bound together by telegraph and telephone by which a more than military organization can control an army of men laboring towards a common result. Like a state or a regiment, the corporation has an organization and a continuous existence that depends upon no man's life, and it can, by this scope and continuity of action, attain a scale enabling it to incorporate and use a steamship line as a part of a single business. This has occurred in both agriculture and manufacture, in the marketing of products, and the assembling of raw materials.

There are several reasons for this development of the line as an adjunct to an industry:

First.—The freight for shipment from the ports of a certain region may be only of the coarse and bulky character that goes in full cargoes. There is then small demand for the services of a common carrier to furnish line service. It is chiefly in such regions that the industrial steamship line has arisen.

Second.—With private-carrier traffic of the character just referred to, it is natural for the large operations of modern business to demand regularity of movement. Hence a line arises within the service that naturally belongs to tramps.

Third.—Special service may be required with specially designed vessels to supply it.

Fourth.—The ordinary arguments in favor of consolidated enterprises—elimination of intermediate profits and reduced cost of supervision per unit of output incident to the enlargement of the business are potent in water transportation.

Probably the best examples of the industrial steamship lines are to be found in the oil industry and in the American banana industry. Well over 100 steamers are engaged in carrying bananas from the West Indian and Caribbean region to the United States and Europe. Over nine-tenths of these vessels are operated or controlled by a single company. The evolution of the business and its transportation organizations have been rapid. In the beginning bananas were occasionally sent to this country on consignment, a group of growers sometimes combining to send a small schooner, leaving the sale to some American commission merchant. This method is the one followed by the distant farmer who sends his produce to a large city market, but in the banana trade the practice did not survive. The usual method, even in the early days of the trade, was for the importer to send or take his ship to purchase the fruit at export points and bring it to our ports for sale on his own account. This has led to rapid changes in the business because of its especial need for organization and because the banana trade, owing to the perishable nature of the fruit, requires a faster ship than can commonly be found for hire. Ship owners will gladly build such boats if the banana merchant will promise to hire them all the time or for long periods; otherwise the ship might be compelled to take employment for which she was not well suited. The result is that the banana merchant must hire his ship for a long period, if at all.

The banana importer enters the business with heavy stakes and it is a business in which competition is particularly destructive. There is no middle ground upon which competition can exist. A steamer holds a great many bananas, and as they are a perishable commodity sometimes sold at auction in the process of dis-

Steamship Ellis; United Fruit Co.—Designed Especially for the Banana Trade.

tribution, two steamers arriving at one port at about the same time may easily so overstock the market that there would be low prices and loss for both parties. It is therefore necessary for each company to know what the others are doing and keep out of the others' way or make conditions of mutual loss. Agreement is hard to maintain for some firm must exercise the whip hand, a position usually not to be accorded without competitions and wars. In the tropical fruit business these fights have come often and have usually been fights to a finish or to consolidation, so that by 1899 the chief survivor, the United Fruit Co., handled 98 per cent. of the American banana traffic, and with its hundred steamers it now scours the West Indian and Caribbean coasts, runs lines to Boston, New York, Philadelphia, Baltimore, New Orleans, Mobile and Bristol, England, and occasionally sends steamers to other ports in both England and America. At the present time this company's monopoly is not so complete as in 1899, but the independent companies do so small a business that they are not worth the cost of the general price reduction that would result from attempts to drive them out. A small company running one steamer to Philadelphia, for example, could not be forced out by competition unless the large company reduced the price on eight cargoes in that and other ports easily reached by rail. The independent knows that he dare not grow, or he would be big enough to be dealt with and put out of business. He has seen others die the death through prosperity in just that manner.

Captain A. F. Lucas; Standard Oil Coastwise Towing Service.

These vessels of the banana fleet do not usually belong to the fruit company. There is a drawback to the full working out of the process of consolidation at this point. Why does it not pay the fruit companies to stop paying profits to ship owners? Some of the earlier companies tried it, but it is being given up. The fruit is marketed in the United States and the companies are American companies, but owing to the cost of building and operating American ships they cannot afford to use American ships, and they must be operated under foreign flags and through foreign companies. This, combined with the large capital involved, has served to limit the fruit companies to carrying on most of their traffic in foreign steamers. It is, however, currently reported that there is some American money in these steamers. They are built on the specifications of the user, who often charters them for four-year terms before they are built, and some vessels have been taken for ten-year periods. These long charters show the real solidarity of the enterprise.

This process of consolidation is complete so far as water transportation is concerned, but it is only the beginning of the fruit company's enterprise. When a fruit company owns or is financially responsible for a steamer, that steamer must be kept employed as constantly as the banana seasons will permit. If she goes for bananas and cannot get them, there is loss on the steamer and loss of profits on the bananas that are not secured. As a consequence, the fruit business, which began as a mercantile operation and was compelled to include a carrier to have something to sell, has been compelled to become a producer to have something for the steamers to carry. Private producers on the hot, turbulent and sparsely peopled shores of the Caribbean could not be induced to produce a regular and sufficient supply of bananas and other fruits, and in self defense the underlying companies of the United Fruit Company long ago started plantations and orchards. The present company produces a large part of the fruit that it carries and sells. It is stated by their representatives that the cost to them of producing their own fruits is as great as that of the purchased fruit, but the quality is better and the supply more regular. The process has even gone farther* for the fruit company has organized subsidiary companies that build and lease railroads to carry the fruit from the plantations to the port of original shipment.†

Narragansett; Anglo-American Oil Company.

Once the steamer service of the United Fruit Company was organized, it was inevitable that this regular service should devote some room to other freight and to passengers, particularly as the other freight is almost exclusively return freight which can be put into an otherwise empty ship as she goes out for another cargo. The managers of the fruit company are also cognizant of the fact that the passenger traffic is profitable and that the fruit steamer is speedy and well suited for it. The addition of a limited number of state rooms does not seriously interfere with the fruit carrying capacity, so the fruit steamer has become a common carrier to a limited extent, for both freight and passenger, but this, like the company's ownership of Jamaica hotels for the entertaining of the tourists, is purely incidental to the main business which is the marketing of its own fruit. When the passenger business sprung up, the fruit company merely completed this circle also by providing hotels of the elegance and comfort necessary to satisfy the tourists attracted by their ships.

The formation of the United Fruit Company has in nearly all its steps been the result of economic causes and has resulted in the great enlargement of the industry. If some Czar should sell separately at public auction every single piece of property owned by the United Fruit Company and common carriers should attempt to carry the fruit, it would not be three years until some central power guided its distribution. It is but a step to the guidance of the ships themselves. If conditions demand the sending of one cargo to a port not regularly served, the ship, under central control, can be sent. If this business depended upon a line or lines of common carriers such a shifting would be impossible.

The even supply of bananas is in strong contrast to the spasmodic supply of strawberries, peaches and other perishable, seasonable produce shipped by rail to the same markets. The lack of common carriers has compelled the banana shippers to become their own carriers and then distribute their product by central control. The peach and strawberry business is larger when it comes, but it is not organically advanced beyond the stage of the banana business in its first beginnings. Each shipper sends, as suits his fancy, to commission men here and there. Markets are alternately glutted and starved, the demand is half met. The California orange growers have, by voluntary association, learned to control the distribution of their product, and in a few years probably other important industries will similarly organize and distribute their prod-

*President's address, 1905, meeting Royal Mail Steam Packet Co.

†It is easy to see here the possible basis for the bitter complaints that arise from the independent banana planters who declare that they have been forced out of the business. A returning traveler tersely puts it "The United Fruit Company owns Costa Rica." In this country the fruit company has some of its most extensive land operations.

uct as the exigencies of ocean transportation have compelled the banana shippers to do.

The marketing of asphalt, lumber, coal and petroleum is less exacting than fruit, in that these commodities are not perishable or easy of injury. There is consequently no imperative need of prompt despatch and the commodities may be carried in ships not especially constructed for one commodity. In the case of oil, however, tank steamers specially designed to carry kerosene or naphtha or crude petroleum in bulk show very great economies over other methods of shipment. The table appended indicates that the Standard Oil Company owns or controls nearly a third of the total tank steamer tonnage.

The first carrying of oil in bulk seems to have been in the Caspian sea in 1873. In the same year two vessels were built for the Philadelphia-Antwerp service and equipped for carrying bulk oil as a part of their cargo.* Oil and passengers, however, will not mix, owing to the regulations for the protection of the passengers, and as these steamers of the Red Star Line were in a very profitable place for passenger traffic, their oil tanks were unused. The use of tank steamers requires a corresponding large scale shore equipment of pipes and pumps and tanks that can only be provided by distributors on the largest scale. The carriage of bulk oil, therefore, is not a simple question of ships, shipping and ship management. In many parts of the world where there is large oil traffic there is no equipment for the accommodation of tank vessel cargoes. Consequently it was not until 1888 that vessels of this character were used on the Atlantic. Since that date, the extension of their use has been rapid. The larger ports of the great consuming countries of western Europe have the necessary receiving equipment and the pipe lines from the Ohio valley to the Atlantic coast ports, from the Caspian field to the Black Sea ports, and latterly from Texas and adjacent fields to the Gulf of Mexico, give wide sources for the supply of the cargo. The same method of distribution prevails east of Suez, where the chief supplies are in Burma, the Dutch East Indies, and to a lesser extent in Japan. Some firms† of tank carriers make a practice of supplying large users throughout the world and avoid paying Suez tolls by using Texas oil for points west of Suez and East Indian oil for stations to the east of the high tolled canal.

Tank steamers are used also in the American coasting trade, Texas crude oil being carried to the refineries on the Atlantic coast and the refined oil thence to Europe.

Recently the economy of this specialized transportation has gone one step farther than the tank steamer. It is the tank barge which the tank steamer tows. For several years prior to 1905 the Texas product had gone to Atlantic refineries in Standard Oil Company's steel barges. In that year the barges were first sent to Europe. This, however, was not the oceanic barge record, as a year before a barge had been towed by a tanker from New York to San Francisco, 13,090 miles, in 72 days.‡

Of late years these tank steamers have almost superseded the older form of oil traffic by which barrels were carried in any available vessel of ordinary type. Some of the tankers are owned and operated by European refining companies. In the old-fashioned way, 12,000 barrels were considered an enormous cargo, but the efficiency of special construction and the private industrial line is demonstrated by the 30,000-barrel cargoes of the new tank steamers.

The growth of the bulk oil traffic is indicated by the tonnage of the fleets engaged in that traffic. According to the Bureau of Corporations, this tonnage is as follows:

Companies.	Vessels.	Gross tons.
Standard Oil Co.	61	204,506
Standard Oil Co.	18*	11,367
Independent American	21	58,847
Independent American	8*	11,367
Russian companies	30	96,559
Dutch East Indian traders	41	125,161
Burmese and Japanese traders	6	12,810
English tramp steamships	18	55,831
English tramp sailing vessels	1*	8,209
French companies	2	2,525
Unclassified	9	12,707
Unclassified	4*	4,224
Total steam	188	568,946
Total sailing vessels(*)	34	51,866
Grand total	222	620,812

*Sailing vessels

The enormous tonnage of this fleet of specialized vessels of peculiar type, for carrying one commodity only and belonging to a few owners, and nearly all of them merchant carriers, shows how in this age of common carriers the present merchant carrier, inconspicuous in his ocean work, nevertheless outranks by far his conspicuous prototype of a century ago in the actual amount of transporting that he does.

Nor does the above list of bulk vessels tell the whole story for petroleum. Many ordinary vessels are also used by the oil companies. The Oriental countries are heavy importers of American refined oil, and their markets, devoid of tank equipment, require it in small tin cans called cases. The transportation of this refined case oil has long employed a large amount of shipping, and the greater part of it has gone in full cargoes in sailing vessels. Oil alone comprises a high percentage of the value of American exports to China and much more than one-half of the total tonnage of the traffic. The Standard Oil Company for many years chartered other people's ships for this work, but some years ago it changed this policy and became sailing vessel owners for the better marketing of their own case oil product. The oil company does not own enough vessels to do all the ocean work, and some are still chartered, but all are operated under one management, so that the oil company's vessels now sail from Philadelphia and New York for the ports of East Asia, and one ownership carries the oil from the well in the Ohio valley to the Mongolian merchant in Shanghai or Yokohama. Inasmuch as the oil company had nothing for these sailing vessels to bring back, they have frequently aided the exchequer of the company by bringing back, from Calcutta, Manila and other ports, any available cargo that might be obtained.

The asphalt industry in America is one with a multitude of companies, but beneath them is a simplicity of interests that sifts down to two rival concerns. The raw asphalt comes almost exclusively from the island of Trinidad and the northern shore of Venezuela. It is consumed in all of the larger American cities and many of the smaller ones, and also in Europe, South America and elsewhere. The companies are international in their field of opera

Coal Barge; Philadelphia & Reading.

*Fry, "The History of North Atlantic Steam Navigation."
†*Fairplay*, London, June 20, 1901, p. 1005.
‡*Railroad Gazette*, 1905.

tion. New York, being a city with much paving, with a good harbor, and near many other cities requiring asphalt, is a convenient base for the operation of an asphalt company. This large traffic is much like that in oil. A line of steamers has succeeded irregular vessel movements and now regularly carries asphalt from Trinidad to Perth Amboy on New York bay. There is even some effort made to have the ships get return freight and thus develop, as a strictly side issue, the services of a common carrier for the out voyage. The same company that operates the asphalt steamship line is constantly in the ship market to charter steamers on the single trip basis, to handle any sudden increase of traffic for New York or to send a special shipment to other ports in the United States or foreign countries. The amount of this irregular shipment is very great, because of the fact that the paving contracts are constantly being let and executed in scores of cities, necessitating a very wide and constantly shifting field of operation for the paving companies and their steamship traffic, which is all managed from a common center.

The production of anthracite coal in Pennsylvania has led to operations on a large scale. It is well known that the larger share of the coal is owned and mined by railroad companies, which get most of their income from coal freights. Much of the coal sent to New England goes thither in the company's coal fleet, which is regularly employed in plying between Philadelphia, Boston and other New England points. This fleet consists of powerful tugs and barges or sea lighters that transport several million tons a year. The enormous extent and the divided ownership of the soft coal lands of the United States have not yet resulted in any such organization of the soft coal traffic, but it is within the bounds of probability that steel barges will carry coal down the Ohio and Mississippi rivers, and across the Gulf and the Caribbean to soft coal markets along those shores in a manner analogous to the shipping of anthracite to New England. The present aggressive action of railroads in taking possession of bituminous coal lands in the Ohio valley indicates that they will be in a position to take up this barge traffic if they so desire.

The traffic on the American Great Lakes is not classed as maritime, but the only difference is a matter of 3 per cent. of salt in the water and a barrier that keeps the lake ships from extending their voyages to sea. In its economic essentials it is sea traffic, and in the magnitude of the commerce, the size of the ships, and the waters traversed, it ranks with, and in some respects outranks the commerce between England and the nearby Continent. This lake commerce should be discussed here because it possesses the world's most thoroughly organized and largest example of an industrial steamship line.

The United States Steel Corporation manufactures iron and steel in Pittsburgh from ore brought a thousand miles from mines beyond the western end of Lake Superior. This company owns the ore mines, the coal mines, coke ovens and lime stone quarries necessary to produce all of the raw material used. It also owns and operates the necessary railroads and steamship lines to carry all of these materials to the points of manufacture. The lake ore fleet must carry many million tons per year, and, owing to the ice of the winter, it has only about seven months in which to do the year's work. The largest of these ore vessels carry about 12,000 tons of cargo, while 8,000 and 10,000 tons are very common sizes, and the new vessels are usually of largest type. This one company owns and employs in its own business over 200 vessels with an aggregate tonnage that puts it in the class with the second rate maritime powers. No ocean fleet in the world except the oil fleet equals this in the speed with which its vessels are loaded and unloaded. The work is practically all done by gravity and machinery, and the ratio of the time the steamers are actually under way doing the work of going from port to port to the time they are at the docks has no equal in the general commerce of the salt seas. At the end of each lake and at other places there are opportunities for the giving of telegraphic orders to the captains of the vessels. The ease of communication, combined with the great number of the steamers, and the fact that they connect with the company's railroads at each end of their route, enables one man in his Pittsburgh office to manage this whole fleet and order the vessels from place to place and dock to dock as a train despatcher manages the trains on the tracks under his control. These lake ore steamers, sometimes carrying coal on the return voyages, are as absolutely a part of the steel company's industrial organization as is a blast furnace or an overhead crane in a mill.

What is to be the future of the industrial or merchant steamship line? Is it to be eliminated again as was the merchant carrier of the eighteenth century? Probably not. The present private operator seems to be large enough in his operations to hold his own and grow and keep up with the growth of the ocean steamer.

The operating unit in each of the industries mentioned in this chapter seems to be enlarging and, therefore, becoming more able to maintain among its activities a private transportation system. The trade in tropical fruits especially is one showing rapid increase. It was stated on the best authority in 1901 that the imports of bananas had doubled every five years for 30 years.

Many forms of tropic agriculture adapt themselves to the type of large scale production above described. Sugar plantations on the coast of Peru are owned by firms having steamship lines to New York, where the sugar is marketed. The sugar plantation is a late addition to the list of activities of the firm. It began as an exporting house, but the late addition of productive industries is a suggestive move. In Chile the nitrate for export is sometimes carried in lines of vessels belonging to the firms manufacturing the nitrate.

These examples of incidental combination of ocean transportation and production, taken in connection with the more formally organized services mentioned above, are suggestive of the continued growth of this form of organization in ocean transportation.

(To be continued.)

J. Pierpont Morgan; United States Steel Corporation Fleet on the Great Lakes.

Before the Telegraph Was Invented.

To compare the present with the ancient means of communication is to appreciate that you are living in the commercial twentieth century.

One of the first systems of aerial telegraphy was attempted in the fifteenth century. The originator was Amontons, at that time considered one of the cleverest scientists of the world. He developed a system of signal telegraphy so that a message could be sent from Paris to Rome in three hours. Those who assisted in the transmission of the message along the line were unable to tell the nature of the message.

Posts were placed from Paris across the Alps at consecutive points, where men were stationed with telescopes. Different signals, representing combinations of letters, were run up at each post. The man at the other end, seeing the signal, placed a similar one before his post, and so the message was carried to its destination. The key to the signal was known only to those who sent the message in Paris and the recipients a thousand miles away. Amontons was not encouraged in his work by the puffy, gouty functionaries of the time and discontinued his efforts.

Perhaps the real inaugurators of the system of long-distance transmission of messages were the Gauls. If you leave your office some afternoon and see a friend across the street and cry, "Oh there!" you are using a system of telegraphy in vogue in Europe until 1792. The cry of "huppa," from which the English "Oh, there!" was derived, was the mouth telegraphy of the ancient Franks, by which they sent a message at the rate of 150 miles a day.

A number of men, stationed at certain intervals over a long stretch of country, sent messages, one to the other, so quickly that Caesar, in his Commentaries, said the natives forwarded warnings of his approach at the rate of 50 leagues from sunrise to sunset.

At night they used signal fires or "bauchees." While tympans were beaten, fires were lighted from mountain top to mountain top.

To the tourist wandering through France and over the Pyrenees into Spain the old towers which appear from time to time across the mountain may seem purposeless and strange. Yet they are vestiges of the greatest system of old time aerial telegraphy in existence. These towers—both square and round—are situated on the most prominent hillocks. Up to 1844—when experiments assured the success of the electric telegraph—these towers were the means of communication in France. In that year there were 535 stations. The towers were two stories high, with index signals of light wood or iron mounted at the top of a pole on the roof.

This system was originated by Claude Chappe, and was presented to the National Assembly of France on March 22, 1792. Chappe had prepared a secret vocabulary composed of 9,999 words, represented by characters. The convention conducted a series of trials, and, elated by what its members called the simplicity of the scheme, adopted it.

At that time France was at war with nearly the whole of Europe. The first telegraphic national message was received by Carnot, grandfather of a recent French president, telling of the restoration of Conde to the Republic.

The news of the taking of Brussels by the French was transmitted from that city to Paris in 25 minutes. Messages were sent by placing signals at the top of the poles on the towers. The telegrapher at the one end mounted a ladder and changed them by hand. There was always someone on watch on the towers to note the signals from the others. The line of stations was extended by the first Bonaparte to Milan, Italy, and thence to Mayence, Germany. As the French army retreated the telegraph posts were destroyed.

During the Crimean war (1854) a system of sending messages by the use of semaphores was adopted, by which messages were conveyed from one camp of the allied armies to another. Arms extended from a framework of wood, which could be operated by wires by a man below in a tent. By lifting or lowering the arms messages were sent from one division to another.

While the efficiency and success of the electric telegraph was assured by 1850, and wires were strung up all over Northern France, it was not until the end of that year that they were opened for public use. Even when private individuals were allowed to send messages, they were required to give proof of their identity, but the secrecy of the despatches was considered inviolable. A few months after the wires were given for public use the first submarine cable was laid.—*Express Gazette.*

Foreign Railroad Notes.

The latest development in Russian passenger traffic is the use of counterfeit tickets. These, it is said, neither the gatemen nor the train ticket collectors are usually able to distinguish from genuine tickets. A train ticket collector who had that ability recently found 140 counterfeit tickets on one train! The holder of one of them protested by shooting the collector, who, however, escaped with his life and the 140 counterfeit tickets.

That traffic may grow even in the "effete European despotisms" is shown by a statement of the number of cars and locomotives on the railroads of Prussia and Hesse (which are worked as one system, under one management) since 1893. We give below the numbers at five-year intervals:

	1894.	1899.	1904.	1908.
Locomotives	10,715	12,460	14,837	18,306
Passenger cars	17,871	22,674	27,393	34,910
Baggage cars	1,648	5,861	7,222	10,327
Freight cars	218,033	276,933	310,653	393,998

From 1894 to 1908 there has been an increase of 70 per cent in locomotives, 95 per cent. in passenger cars, 123 per cent. in baggage cars, and 87 per cent. in freight cars. There has doubtless been a large increase in the tractive capacity of locomotives since 1894, and some increase in freight car capacity.

In the United States, with a much more rapid increase in population and railroad mileage, the rolling stock has increased as follows:

	1895.	1899.	1902.	1906.
Locomotives	35,699	36,703	41,225	51,672
Passenger train cars.	33,112	33,850	36,987	42,262
Freight cars	1,196,119	1,295,510	1,546,101	1,837,914

The "year" here ends with June. The figures thus begin six months later and end 18 months earlier than those for the Prussian railroads. The increase in locomotives for the 11 years here was 44 per cent., against 70 per cent. for the 14 years in Prussia; the increase in passenger cars 28 per cent. here and 31 per cent. there; the increase in freight cars 54 per cent. here and 87 per cent. there. The increase in engine and freight car capacity has doubtless been much greater here than there since 1894; though it began here much earlier than that year.

The Metal Tie.*

BY DR. ING. A. HAARMANN.
Geheimer Kommerzienrath.

In January, 1892, 16 years ago, I discussed in this place, "The Use of Metal and Wood in Permanent Way." To-day, permanent way, as such, is not my theme. I shall confine myself to the examination of only one of its parts, the tie, for it seems to me that the time has come that metal should get its due recognition as a material for supporting rails.

Our society has, for a long time, been deeply interested in clearing up the points connected with this subject. I need only refer to the illuminating work of Bueck, of Brauns and of Beukenberg. In the same way the various German railroad managements and the "Verein für Eisenbahnkunde" and the "Stahlwerks-Verband" have labored for a more general use of the metal tie. The paths followed may not always have been the best. Even in our own ranks many occupied the untenable position that the field of activity of the manufacturer of iron and steel was limited to the production of good rails or ties following the specifications furnished by railroad managements, while their design was solely the concern of the railroad engineer. I am the last to deny or to minimize the propriety of collaboration on the part of the railroad officer in so important a matter; on the contrary, I have often pointed out, in this society and elsewhere, that hearty working together of both is necessary. Indeed, I am convinced that the prominence which metal permanent way has attained in Germany, and especially in Prussia, is due to this very collaboration.

For the information of those who think it premature to speak of the existence of a recognition of the capabilities of the metal tie, I will preface my remarks with some statistics. I will not go back further than 1898, as the figures prior to that date are arranged on a different basis.

TABLE 1. *Comparisons of the Mileage and the Number of Wooden and Metal Ties in the Standard Gage Tracks of Germany.*

Fiscal year	Standard gage track: Wooden ties, miles.	Standard gage track: Metal ties, miles.	Percentage of metal tie track to: Total track.	Percentage of metal tie track to: Wooden tie track.	Number of: Wooden ties.	Number of: Metal ties.	Percentage of metal ties to: Total.	Percentage of metal ties to: Woodn ties
1898.	28,479	10,005	25.9	35.0	56,250,330	19,904,493	26.1	35.4
1899.	29,213	10,314	26.0	35.4	57,748,211	20,616,468	26.3	35.7
1900.	29,914	10,687	26.3	35.7	59,326,504	21,190,912	26.6	36 2
1901.	30,680	10,948	26.3	35.6	61,459,928	22,272,430	26.6	36.2
1902.	31,484	11,247	26.3	35.6	63,434,161	23,066,490	26.7	36 4
1903.	32,166	11,515	26.4	35.8	65,224,411	23,908,406	26.8	37 7
1904.	32,526	12,057	27.0	37.7	66,351,513	25,226,882	27.5	38 0
1905.	32,932	12,491	27.7	38.0	67,885,129	26,575,507	28.1	39 1

TABLE 2. *Number of Ties Used for Reconstruction and Renewals on the Standard Gage Tracks of Germany.*

Fiscal year of	Number of: Wooden ties.	Number of: Metal ties.	Cost of ties: Wooden, per 100.	Cost of ties: Metal, per ton
1898.	4,218,007	1,413,230	$99.84	$22.18
1899.	4,199,690	1,498,707	107.52	23.31
1900.	4,355,415	1,743,298	108.00	24 41
1901.	4,305,011	1,654,241	110.64	24 88
1902.	4,342,440	1,929,561	104 61	23.81
1903.	4,280,468	1,727,890	105.60	23.81
1904.	4,013,003	1,954,447	106.56	23.56
1905.	4,126,828	2,098,611	106.04	24 44

TABLE 3.—*Wooden and Metal Ties in Service in the Tracks of the Prussian and the Prussian Hessian State Railroads*

Fiscal year of	Wooden ties: Total No.	Wooden ties: Per mile.	Metal ties: Total No.	Metal ties: Per mile
1898.	35,991,584	1,926	11,992,182	1,920
1899.	36,829,657	1,950	12,576,920	1,936
1900.	37,799,131	1,959	13,201,525	1,955
1901.	38,880,771	1,966	13,689,567	1,982
1902.	40,099,309	1,985	14,552,280	2,005
1903.	41,856,235	1,995	15,499,252	2,032
1904.	42,321,031	2,005	16,551,418	2,055
1905.	43,338,050	2,032	17,730,362	2,100

In 1892 the ratio of length of track laid with metal ties to track with wooden ties was 30.2 per cent.; in 1898 the ratio had increased to 35 per cent., and in 1905 to 38 per cent.

Table 3, giving the total number of ties in the tracks of the Prussian State Railroads, is of particular interest. By referring to columns 3 and 5, it will be noted that the number of ties per mile has steadily increased to keep up with the greater demand of traffic, but that the rate of increase has been more marked in the case of the metal tie. This is due to the more rapid increase of these latter in recent years. The result is that there are relatively more metal ties in the newer sections of track over which fast trains requiring closer tie spacing pass, while in the older sections, on which traffic is not so heavy, there are more wooden ties. Thus the specifications of the Prussian State Railroads for 1905 required 2,467 ties for tangents and 2,576 for curves per mile of track. This proved increase in the use of metal ties is in no way the result of arbitrary preference. Had not the metal tie been markedly improved from the structural point of view, no amount of unmerited preference could have enabled it to compete successfully with the wooden tie.

Judging from a recent address by the secretary of the asso-

*Address delivered at the meeting of the "Verein der deutschen Eisenhüttenleute," Dec 8, 1907 at Dusseldorf Reprinted from *Stahl und Eisen*, by permission.

ciation for furthering the use of wooden ties, there is a tendency among its advocates to champion its cause in a narrow, partizan spirit. The railroads have, in a sense, become public property, and the public is vitally interested in their development. It demands that their operation be in accord with the laws of economics, that the maximum of safety attainable be secured, and that a track be provided over which trains may pass smoothly and with the least possible jar. As the public, so the railroad management is interested in these matters, and as the constituted guardian of safe and economic operation it must satisfy these demands. Only after they have been satisfied is it reasonable to consider particular interests such as forestry, the wood industry or the iron and steel industry.

To get a clear conception of the development of the tie, it will be profitable to present illustrations of some of the most character-

Fig. 1—Cast Iron Rails on Stone Blocks at Merthyr Tydfil, Wales, 1804.

istic exhibits in the Track Museum at Osnaburg, taken from my work on railroad track.

The beginning was stone. The first metal railroad track was built of cast-iron angles fastened to blocks of stone. Fig. 1 shows a section of the track used by Trevethik at Merthyr Tydfil, in southern Wales, more than 100 years ago, for the notable trials of his primitive locomotive with flangeless wheels. The stone blocks, while of various shapes and sizes, still furnished fixed points for the support of the yard long angles of cast iron. In spite of the small strains to which they were subjected, they were not able in practice to remain long in service. The line of rails was only a chain made up of short links on which the primitive "iron horse" pounded along. There was no thought given to joint connections, or stiffness or distribution of pressure, etc.; every stone support in carrying the load had to be sufficient unto itself.

Twenty five years later George Stevenson, whom we rightly call the father of railroads, and who with his "Rocket" opened a new

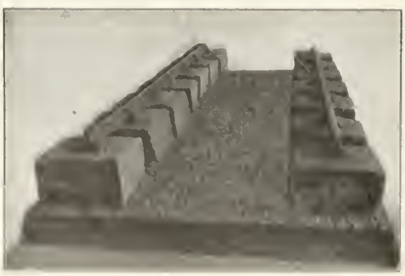


Fig. 3—Mushroom Rails on Stone Ties; Nuremberg-Fürth Line, 1835.

era in railroading, improved on this method. He introduced regular shaped stone for the rail supports, and used a rail (designed by Birkenshaw and originally rolled with fish bellies) that reached over five stone blocks (Fig. 2). In spite of firm tamping these blocks gradually settled and the difficulty of tamping them condemned them as not fit for the work. But they were not abandoned at once, their inherent qualities of resistance to atmospheric influences and to compression securing them adherents for a few years longer. Our first public steam railroad, the line from Nuremburg to Fürth, opened in 1835, was provided with stone blocks (Fig. 3). Following this, a number of small lines in Bavaria were built with them, some retaining them up to a comparatively recent time, they were provided, however, with wooden ties at the joints (Fig. 4). Wooden

Fig. 2—Fishbelly Rails on Stone Ties; Stockton-Darlington Line, 1825.

ties, binding together the two strings of rails and furnishing a larger bearing surface, were evidently so superior to stone blocks that they soon reigned supreme in railroad construction.

Thus stone gave way to wood. In the early decades of modern railroading, the shape and dimensions of the wooden tie varied considerably. At that time there was ample room for choice of wood both as to kind and age, and the price was comparatively low. It was not uncommon to cut six ties out of one section of a tree while to-day a single tie is the rule. Unfortunately, no ties of this early period have come down to us, and we are unable to determine by personal inspection their weaknesses and defects. For the purpose of studying the changes due to weathering and to mechanical wear, we must content ourselves with specimens that have been taken out of the track in recent years, after having seen service. For a long time it has been one of the important problems of the railroad engineer to minimize the effects of weather and wear. The illustrations show clearly the depression and wearing away of the tie at the places where the rail was in contact with it.

Fig. 4—Chair Rails on Stone Ties; Bavarian Railroads, about 1850.

In addition, we have the splintering and crushing caused by spikes and screws, effects that are more evident in the original specimens in the Track Museum at Osnaburg.

The rapid introduction of wooden ties in Germany dates from the building of the railroad from Dresden to Leipsig in 1838 (Fig. 5). The broad-flanged rails were laid directly on the wooden ties, being the first use of this enticingly simple method of construction which has remained the model for Germany and for many other countries. In the same year, in the construction of the London-Birmingham Railway, Robert Stevenson used a track consisting of double-headed rails supported on cast-iron chairs resting on wooden ties. The English have held fast to this chair-rail system and it is in use at the present day.

A few samples will illustrate the development of the wooden tie permanent way. First, I will call attention to a section of track with broad-flanged rails that was in service between Copenhagen

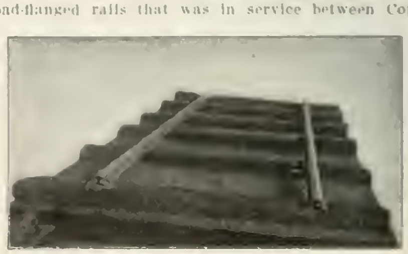

Fig. 5—Broad-Flange Rails on Wooden Ties; Leipsic-Dresden Line, 1838.

and Roskilde for 11 years, 1847 to 1858 (Fig. 6). The cross ties are fir and the rails are fastened to them by spikes; they have butt joints and one of the oldest styles of splicing, only one splice bar, and that on the outside. For 15 years, 1870-1885, track such as shown in Figs. 7 and 8 was in use. The considerable wear on the impregnated fir tie, especially where no tie plates were used, is apparent, and, indeed, small plates placed under the joints did not afford much protection (Fig. 8).

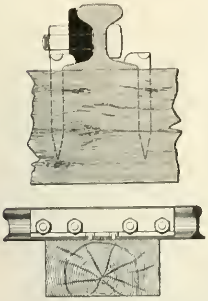

Fig. 6—Rail Joint with Single Splice Bar; Copenhagen-Roskilde Line, 1847.

The reason for the rapid introduction of tie plates is evident on examining Figs. 9 and 10. Fig. 9 shows an impregnated fir tie that had been in service from 1875 to 1885, and on which the rail had rested directly. The great diminution of cross section at the points of contact due to the repeated resurfacing or spotting of the tie is very noticeable; its neighbor (Fig. 10) of the same wood suffered less, on account of the plate with which it had been provided. Worthy of note are the attempts made to counteract the splitting of the ends of ties, especially beech ties, by means of wooden dowels or metal screws and clamps (Figs. 11 and 12).

Wooden ties, rather irregular in shape and size but closely spaced, are found on American roads (Fig. 13). The rails are spiked to the ties and, of late, tie plates are being used more liberally. A sample of the Pennsylvania Railroad's track is of interest as showing the staggered joint system of laying track in vogue on many American roads. This track arrangement, with 14 white oak ties of tolerably uniform dimensions under rails 30 ft. long and weighing 100 lbs. to the yard, is probably the heaviest in America and has been in use for 12 years on lines with very heavy traffic. Undoubtedly when the track is in perfect condition the staggered joint system furnishes a better bond and diminishes somewhat the jar. As an offset, the number of jars is doubled and, after a while, with fast running trains lateral as well as vertical oscillations of the cars are produced. The advantage of this system is rather doubtful, and this would especially be the case in comparison with a track laid with opposite joints, in which, with the joints supported by appropriate ties, the jar would be very slight, if noticeable at all.

The Pennsylvania is undoubtedly one of the best built, most carefully maintained and best operated roads in North America. The life of its ties, as I was informed, is seven years, and replacements are made almost constantly. The ties taken out of the track, in spite of the comparatively short time of service, are in such condition that their use for other purposes, especially if they have to be transported any considerable distance, would not be profitable. On this, as on other American roads, the ties are either simply dumped over an embankment and allowed to rot, or they are burned. Some important divisions of the Pennsylvania, e.g., that between Philadelphia and Altoona, have four tracks, the two inner serving for freight, the two outer for passenger traffic. Standing on the rear platform of the train it is an impressive sight to watch the mighty freight trains, with their 50-ton cars, following each other in rapid succession.

Fig. 14 illustrates the combination of Goliath rails and impregnated oak ties introduced on the Belgian State Railroad in 1893. At the joints, the horizontal flanges of the angle splice bars take the place of tie plates. We have no permanent way with wooden ties that equals the American and Belgian construction in weight

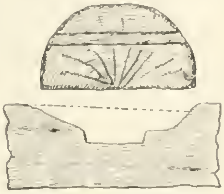

Fig. 9. Fir Tie without Tie Plate, 1875-1885.

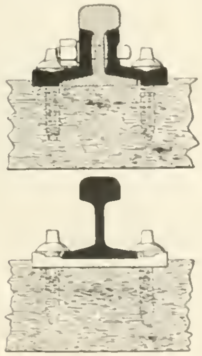

Fig. 14—Heavy Rails and Large Tie Plates; Belgian State Railroads, 1889.

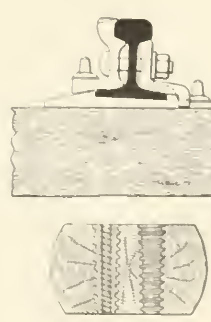

Fig. 15—Hardwood Dowels in Fir Tie; Bavarian State Railroads, 1900.

of metal, although the Bavarian track of 1900 (Fig. 15) makes a very respectable showing. The comparatively heavy rails and the tie plates of this permanent way certainly afford a better protection to the ties than do the hardwood dowels. These last, on account of the large holes required, weaken the tie, and the repeated tightening of the screw spikes ultimately strips the wooden thread.

The Prussian permanent way of 1892 has large plates at the joints and smaller ones on the intermediate ties (Fig. 16). At present the latter are only used in connection with oak ties. It is well known that more recently the Prussian State Railroads,

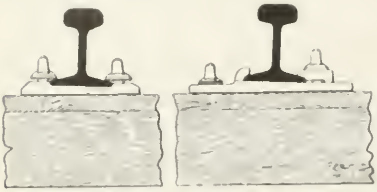

Fig. 16—Intermediate and Joint Ties; Prussian State Railroads, 1892.

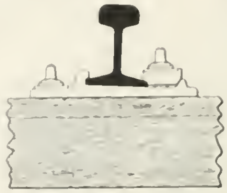

Fig. 17—Heavier Rails, 1905, and Hook Plates with Long Ribs, 1907, on Fir Ties; Prussian State Railroads.

on the lines serving for express trains, employ a rail with a larger profile, No. 15, weighing $90\frac{1}{2}$ lbs. per yard and supported throughout on large plates resting on ties spaced $21\frac{3}{4}$ in. between centers. The weight of metal per lineal yard of completed track is $257\frac{1}{2}$ lbs. (Fig. 17).

Since 1893 the Prussian government has made comparative tests with the materially heavier chair-rail system of the English roads, following the construction of the Midland Railway. The ties are not so thick as those customary in Germany, but are wider. The illustration (Fig. 18) shows the line between Minden and Bückeberg, which, ballasted with river gravel, was operated for $9\frac{3}{4}$ years. This gravel is not the best kind of ballast and is probably responsible for the very marked wear of the ties by the chairs (Fig. 19), greater than is usually the case in England. There, as now with us, crushed stone predominates on express tracks, no matter what kind of ties are used. So far, the trial has not demonstrated the economic advantage of the English permanent way with chair rails. The newer English constructions are still more massive. In 1896, the Midland Railway introduced a permanent way having 98-lb. rails, 55-lb. chairs and a total of 340 lbs. of metal per lineal yard of track (Fig. 20). The line between Derby and London, serving for very fast and heavy trains, is of this construction. From recent personal experience, I know that the track rides smoothly and is quite free from jars, a condition due in a great measure to the considerable weight of metal and to the good distribution of pressure. Still, as the joints are distinctly noticeable even when riding in the large corridor cars of the fast trains, I am convinced that securing the butt joints with flat splice bars would not suffice were it not for the heavy chairs. If these chairs, in spite of their great weight and large bearing surface (108 sq. in.), do not protect the wooden ties, it is not surprising that plates, the largest and heaviest of which have not half the bearing surface and one-quarter the weight of the chairs, should prove inadequate when used on wooden ties in conjunction with flange rails. In time they invariably grind into the tie, and the spikes or screws become loose; tightening these, adzing the tie and renewing the fastenings become necessary from time to time, until finally the ties are no longer fit for service. With the greater demands made on the permanent way, this goes on at a steadily increasing rate in spite of all the protective measures that have been employed. The average life of wooden ties does not increase; it decreases, while its cost fluctuates but does not become cheaper, the offerings of the better grades of ties lessen, but the demand, naturally, is steadily becoming greater. Repeated trials with beech ties have not given encouraging results. The untreated, or, following older methods, the insufficiently treated, beech tie, while presenting an apparently sound exterior, decays in the interior, so that in the course of a few years the inside is utterly rotten. It is hoped that this serious defect will be remedied by better methods of treatment, but while satisfactory results are uncertain, increase in cost is sure. We in Germany are not alone in being affected by an increase in the cost of ties. From my notes of a recent trip to the United States, I find that ties which in 1893 cost 45 to 50 cents apiece are now (1907) selling for 95 cents, an increase of 100 per cent., and with the steady diminution of the forests, a further increase is to be expected. English roads, I am informed, obtaining their supply from Norway and Sweden, are paying \$1.10 to \$1.22 per tie.

Fig. 18—Heavy Cast Iron Chairs on Fir Ties; Minden-Bückeburg Line, 1893-1903.

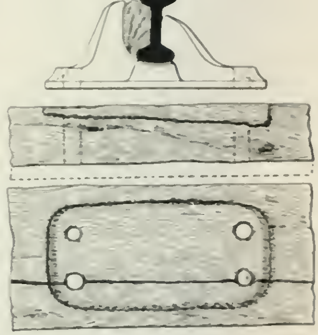

Fig. 19—Wear of Tie Under Chair; Minden-Bückeburg Line, 1893-1903.

The increasing difficulty of supplying our requirements, together with the problems connected with properly fastening the rails so as to meet the greater strains to which a steady increase of load subjected the permanent way made it imperative to consider the availability of a substitute for the wooden tie, one that would better meet all requirements. Thoughtful economists early recognized this and pointed out that to neglect the protection of the forests was markedly unthrifty, as far as the interests of agriculture were concerned. In this connection, the query naturally arises whether, in view of the progress in the iron and steel industry, the importation of large quantities of ties from foreign countries could be justified? The reply that the iron and steel industry, just as the wood industry, does not confine itself to utilizing the natural resources of our country but also works up large quantities of foreign ores, is not convincing to the earnest investigator. In the case of iron ore, we have to do with a raw material that is made to furnish an increase to our national wealth by German intelligence, by German work and by German capital. Then against that importation of iron ore is the offset of the export of iron. The excess of imports during the last five years has averaged 10 per cent. of the total quantity smelted in Germany. Moreover, this foreign material not only does not compete with the product of domestic mines, but is of advantage to it since the rich Spanish and Swedish ores mixed with the lower grade German ores enable larger quantities of the latter to be smelted. Finally, that answer does not apply because our country is deficient in ore supplies, both in quantity and quality, and because we lack a substitute of domestic origin to take the place of the ore. It must also not be forgotten that foreign wood is steadily deteriorating owing to the disappearance of the old trees,

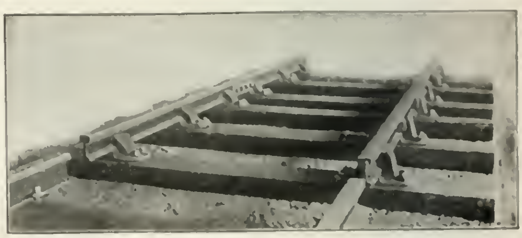

Fig. 20—Heavy Rails and Heavy Chairs on Oak Ties; Midland Railway, 1896.

the quality of whose heart wood is not being attained by that of the younger growth. Moreover, the more complete utilization of the wood of the forests for a great variety of purposes is increasing the difficulty of obtaining good ties. Although the decrease in the resisting power of the wood is being remedied, more or less successfully, by the use of larger and heavier tie plates and by screwing in hardwood plugs, yet this increases the cost to such an extent that only the superiority of this system can justify its adoption.

(To be continued.)

GENERAL NEWS SECTION

NOTES.

The Louisiana Railroad Commission in its annual report, March 11, asked the state legislature for a large increase of power.

The mail car on the Oriental Limited was robbed on March 15 near Bonners Ferry, Idaho, by a lone robber dressed as a post office inspector.

Announcement is made that the Baltimore & Ohio resumed all construction work on improvements in the Pittsburgh district, March 16.

The General Manager of the San Pedro, Los Angeles & Salt Lake is quoted as saying that 30,000 carloads of oranges will be shipped east this spring.

Roads in the Western Passenger Association have lowered their excess baggage rate from 18 per cent. to 16⅔ per cent. of the regular single-trip passenger rate.

The Cincinnati, New Orleans & Texas Pacific has laid off a large number of shopmen, following the refusal of the men to accept a 10 per cent. reduction in wages.

The Pennsylvania will run over the Buffalo & Allegheny Valley division a train with special apparatus to instruct farmers in the scientific growing of corn and alfalfa.

The Western Passenger Association has authorized a stopover of thirty days in Chicago on all tickets sold to summer tourists to all parts of the West, North and South.

The Brooklyn Rapid Transit Co. announces that on March 11, between 5 and 6 o'clock in the afternoon, 340 trolley cars made the round trip over the Brooklyn bridge and back.

It is announced that the Chicago & Alton has not renewed its contract with the United States Express Co., but has made a new long-time contract with the American Express Co.

The Texas Railroad Commission believes that the railroads are dismissing more employees than is necessary and proposes to take action if further reductions are made in working forces.

Five chiefs of national organizations of railroad employees are now in Washington trying to prevent the enactment of any legislation which will reduce further the earnings of the railroads.

Mississippi railroads have been ordered by the state commission to require their passenger conductors to reserve an extra seat for women passengers accompanied by an infant or young child.

The up-state New York Public Service Commission has appointed a public hearing on April 13 to consider complaints about commutation rates for service within the suburban zone of the New York Central.

The St. Louis & San Francisco pleaded guilty to 13 indictments charging the road with granting rebates to a Kansas City lumber company, and on March 11 was fined $1,000 on each count, the minimum penalty.

On March 16 the state of Oklahoma withdrew from the suit to dissolve the alleged merger between the St. Louis & San Francisco and the Rock Island, that part which asks that a receiver be appointed for the Frisco.

The lower house of the Mississippi legislature has passed a 2½-cent railroad rate bill applicable to all railroads except those that can prove that this rate is not just compensation, but it is not believed that it will become a law.

On March 12 representatives of the American Traveling Men's League argued in Washington that interchangeable thousand-mile mileage books good on any road in the country be required by law to be sold on a 2-cents-a-mile basis.

Employees of the Big Four have been advised by circular letter that wage pay checks must not be cashed in saloons, but that the money must be collected upon them at one of the banks designated in the letter. The order has stirred up a good deal of protest.

E. H. Harriman and O. H. Kahn have appealed to the Supreme Court of the United States, the decision of the Circuit Court requiring them to answer certain questions regarding the ownerships of stocks in the Chicago & Alton, Illinois Central and other railroads.

Arthur Hale appeared before the railroad committee of the Massachusetts legislature, March 11, and argued against the reciprocal demurrage bill, which provides for the payment of a dollar per car per day for failure to deliver cars within four days of the time ordered, and for a demurrage charge of the same amount to be paid by the shipper in case the car is not unloaded within 96 hours.

On March 10 the railroads of Kansas appealed to the United States Circuit Court for a restraining order enjoining the Kansas Board of Railroad Commissioners and the state attorney from putting into effect on April 1 the schedule of maximum freight rates ordered by the board of February 14.

The Central Vermont has been fined $1,000 by Judge Holt of the United States Circuit Court of the New York district for granting a rebate on a shipment of coffee from Boston to Western points. There were seven counts in the indictment and the road pleaded guilty to one of them on which this fine was based.

The Receiver of the New York City Railway Co. announces that 155 pay-as-you-enter cars will be installed on the Fourth and Madison avenue line before April 1. The cars accommodate 75 persons comfortably and it is not proposed to allow any more on board, though how this theory is to be carried out in rush hours is not stated.

On March 16 1,500 machinists, boiler makers and other shop employees of the Denver & Rio Grande went on strike. The new shop rules, which were rejected by the men, provided for the payment of all employees according to individual merit, regardless of maximum or minimum scales, the right to change shop rules without consultation with employees, a graduated scale of wages, refusal to give specific recognition to union men and other open shop features.

On March 16, Justice Davis, of the New York Supreme Court, awarded damages to a property holder claiming trespass against the Manhattan Elevated Company in building and operating a third track on Ninth avenue, on the ground that the legislative authority granted the railroad to build and operate a double-track elevated railroad in front of the plaintiff's premises made no provision for a third track, and that the building of this third track interfered with the plaintiff's easement.

The Attorney-General has prepared a report alleging that the Oregon & California Railroad has violated the terms of the grant under which it secured large holdings of land from the government. The report says that the railroad secured about 3,800,000 acres of government land under condition that the land so granted should be sold to actual settlers only, in quantities not greater than one-quarter section to one purchaser and for a price not exceeding $2.50 an acre. The Attorney-General alleges that in making sales the railroad company has always observed the law of supply and demand and has never obeyed the law of Congress.

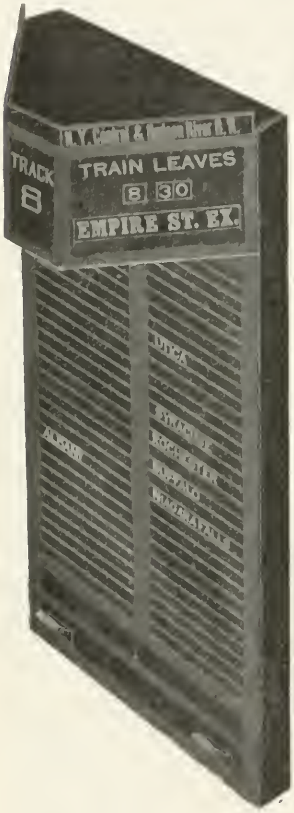
On March 16 the Supreme Court of the United States again upheld the validity of the Elkins anti-rebate law in a decision sustaining the conviction of the Armour, Swift, Morris and Cudahy packing companies for accepting rebates on packing house products, and of the Chicago, Burlington & Quincy for granting them. Each of the five defendants were fined $15,000. The court was divided five to three. Justice Moody took no part, while Justice Brewer delivered a dissenting opinion for himself, Chief Justice Fuller and Justice Peckham. Justice Brewer's dissent was based largely on the question of contract right. He asked who would engage in any new enterprise or invest money in a manufacturing industry if he knew that he could not make a definite contract for rates of transportation to and from his factory, but was advised that whatever contract he might make was liable, at the whim of the carrier, to be set aside and a higher rate imposed.

Editorial Manager for American Society of Mechanical Engineers.

Lester G. French has been put in charge of the editorial department of the American Society of Mechanical Engineers. Immediate improvements are to be begun; one of them is the establishing of departments in the monthly proceedings, thus providing a greater variety of technical articles of interest. Other features are planned and it is hoped that the value of the Proceedings will be much increased. All such papers, however, will, as formerly, first be presented and discussed before the society. Mr. French was born in Keene, N. H., in 1869. At an early age he worked under his father, who was the publisher of "The Vermont Phoenix," at Brattleboro, Vt., and a partner in a large printing establishment in that place. In 1891 Mr. French took his degree in mechanical engineering at the Massachusetts Institute of Technology. After four years' apprenticeship, drafting room and shop experience, principally at iron foundry shops in Providence, he wrote several text books. He then became one of the editors of *Machinery*, and for nine years was editor-in-chief. Mr. French has recently published text books on Algebra and Applied Mechanics and a treatise on Steam Turbines.

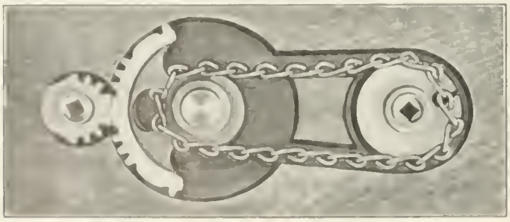
The Boynton Station Indicator.

The first Boynton indicator was put on the market in 1883. During the last few years it has been modified to provide for a larger number of station and train names. The indicators recently put up at the Grand Central Station in New York were an improved type, and a still later design is to be used in the new Hoboken terminal of the Lackawanna. One of the accompanying photographs shows the indicator used in the Grand Central Station. It differs from the first type installed in this terminal in that the upper part, which shows the name of the road, the leaving time and the train name, projects so that it can be read from any part of the concourse; in the older type, this portion was flat and could be read from in front only.



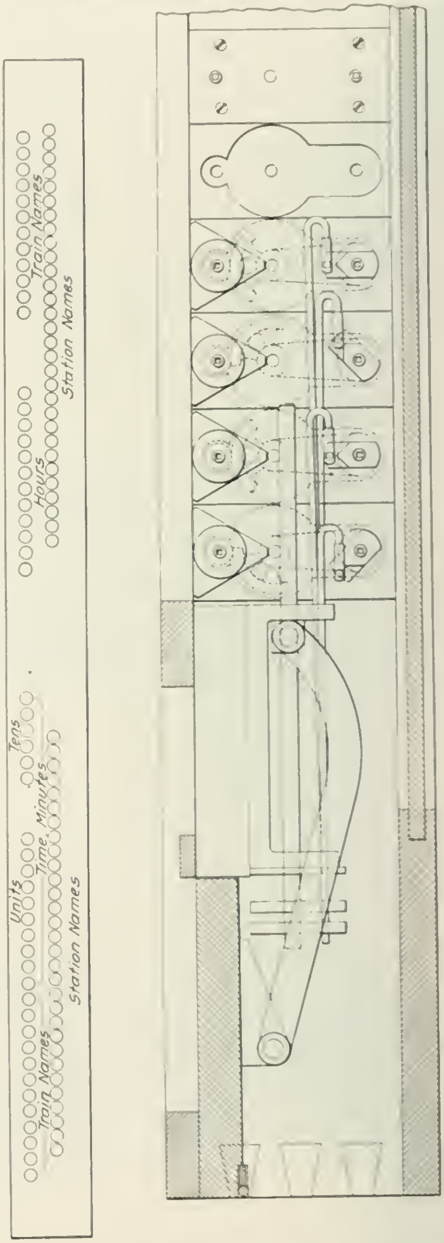
Boynton Train Indicator.

The accompanying drawing shows a vertical section of the newest design of indicator. The three-sided slats are blank on one side and bear station names on the other two sides. Each is revolved by a quadrant and pinion gear, driven by a chain from a rocker shaft to which a vertical wire is connected by a bell crank. The lower ends of the wires are centered over holes in bed plates extending the width of the machine. The bed plates are raised by closing the door at the bottom of the indicator. A perforated card of stiff pasteboard is laid on one of the bed plates. Where there is a hole in the card, the wire passes through the bed plate as the latter is raised and the slat is not revolved. Therefore it still shows blank. Where no hole is punched, the card lifts the wire and moves the slat. When the card is laid on the upper bed plate, the slat is turned through 240 deg.; when on the lower, the movement is only 120 deg. This drawing shows slats in all three positions; this does not occur in practice, as only one card is used at a time, making possible but two positions. The slats could take the three positions shown only if cards were laid on both bed plates at once. There is a separate card for each train, and one can be used until the time-table is changed. The makers furnish a matrix from which blank cards can be printed and the holes then punched out. The drawing shows a card for an indicator in which there are two columns of station names. The card has 60 station name spaces, so that with three-sided slats 120 stations can be shown (by putting the card on the upper or lower bed plate) or 180 stations if four-sided slats, with three bed plates are used. The latter is the type at the Grand Central Station. The card shown herewith has also spaces for train names, which are on revolving slats, and for time; the hours and minutes are on slides and the time is shown by lifting the proper slides according to the combination punched out on the card. The names of the railroads using the terminal are on revolving cloth curtains, which are not operated automatically.



Pinion and Quadrant Mechanism; Boynton Indicator.

Each quadrant and pinion is enclosed in a separate wooden box. As shown in the accompanying photograph of a model of one of these units, the cogs at three points on the quadrant and the pinion are replaced by smooth surfaces, convex and concave, respectively. These lock the slat in position, and also allow enough play at these points to compensate for errors in adjustment of the operating wires, which, if ordinary gearing were used, would leave the visible side of the slat out of parallel with the front of the indicator. Each slat may be removed for relettering without disturbing the rest of the mechanism.



Card and Vertical Section of Boynton Indicator.

These indicators are made by the Boynton Indicator Co., 1307 Pembroke street, Bridgeport, Conn.

Blackwell's Island Bridge.

The Blackwell's Island bridge, from East Fifty-ninth street, Manhattan, to Long Island City, was on March 18 connected from end to end by placing a steel girder in the bottom chord of the span over the east channel of the East river. The bridge was begun in 1901. The contract for the steel superstructure was awarded to the Pennsylvania Steel Co. in 1903 and the masonry piers and anchorages were completed in 1904.

The total length of the bridge is 8,231 ft. The roadway of the river span is 143 ft. 3 in. above mean high water. On the lower floor of the bridge is to be a roadway 53 ft. wide between curbs and four trolley tracks. On an upper floor will be two elevated train tracks and two footpaths, each 13 ft. wide. The width of the bridge is 88 ft. The weight of steel in the superstructure is 52,000 tons, and the cost, including land and approaches, will be about $20,000,000.

Transcontinental Traffic via Tehuantepec.

The agents of the American-Hawaiian Line of steamers claim that freight now moves from New York to San Francisco *via* the Isthmus of Tehuantepec as fast as it moves all-rail. According to the *Journal of Commerce*, the company's schedule of weekly sailings from New York shows delivery of freight in California in 26 days. Cargo is transshipped at Puerto Mexico (Coatzacoalcos), Mex., over the Tehuantepec National Railway, a distance of 180 miles, to Salina Cruz. The freight is handled at the Isthmus rapidly and carefully and delivery at destination shows that transshipment of cargo can be made without damage. From Salina Cruz freight is forwarded by connecting steamer to San Diego, San Francisco, Seattle and Tacoma.

The steamship company operates three services:

1. New York, Puerto Mexico.
2. Salina Cruz, Puget Sound, Hawaiian Islands, returning to Salina Cruz.
3. Local service between San Francisco, Puget Sound and the Hawaiian Islands.

The line carries practically all the sugar shipped from the Hawaiian Islands to Philadelphia and New York, and will shortly operate a regular eastbound service from Pacific coast ports to New York. It has modern piers at Tehuantepec and modern appliances for handling cargo.

The steamers of the Pacific service burn oil, thus demonstrating its success as fuel.

Following is the company's fleet:

Steamers—	Tons.
Atlantic Service.	
American	8,000
Californian	8,000
Hawaiian	8,000
Oregonian	8,000
Isthmian	6,000
Pacific Service.	
Alaskan	12,000
Arizonan	12,000
Columbian	12,000
Missourian	12,000
Mexican	12,000
Texan	12,000
Virginian	12,000
Nebraskan	5,000
Nevadan	5,000

The new westbound schedule follows:

Sailings from New York:	Due to arrive— San Diego or Los Angeles.	San Francisco.	Portland.	Seattle or Tacoma.	Hawaiian Islands.
March 7 and 14	Apr. 9.	Apr. 13.	Apr. 20.	Apr. 22.	May 9.
March 21 and 28	Apr. 23.	Apr. 27.	May 4.	May 6.	May 23.
April 4 and 11	May 7.	May 11.	May 18.	May 20.	June 6.
April 18 and 25	May 21.	May 25.	June 1.	June 3.	June 20.
May 2 and 9	June 4.	June 8.	June 15.	June 17.	July 4.
May 16 and 23	June 18.	June 22.	June 29.	July 1.	July 18.
May 30 and June 6	July 2.	July 6.	July 13.	July 15.	Aug. 1.
June 13 and 20	July 16.	July 20.	July 27.	July 29.	Aug. 15.
June 27 and July 4	July 30.	Aug. 3.	Aug. 10.	Aug. 12.	Aug. 29.

The rolling stock of the Tehuantepec National, both passenger and freight, is in good condition. Some of the latest passenger coaches are included, and Pullman cars are provided for service between Santa Lucretia and Salina Cruz. In view of the growth of the traffic, actual and prospective, the number of freight cars is being rapidly increased. Recently there were 929 box cars, 120 gondolas (each of 30 tons capacity), 60 stock cars and 50 locomotives. The Tehuantepac National was the first railroad in the Republic of Mexico to burn oil for fuel on its locomotives. It now has 14 oil-burning locomotives, and 23 others are being adapted to burn oil as rapidly as the shops can change them. Oil is found to be about 30 per cent. cheaper than coal or wood. The company at present obtains its oil from Beaumont, Texas. It is loaded on to tank steamers at Port Arthur, Texas, and is delivered at Coatzacoalcos, where the company has a 1,500,000-gal. steel storage tank, from which it is distributed to smaller supply tanks along the line, each having a capacity of 6,500 gallons. Before long it is expected that the locomotives will be burning oil obtained from local oil wells. Already the stationary boilers in the company's shops at Rincon Antonio are burning oil from the Isthmus.

When Pearson & Son took up the contract, Salina Cruz had merely an open roadstead. Now the Pacific port of the Tehuantepec National has a sheltered outer harbor of about 20 acres, and an inner dock basin capable of taking the largest vessels.

The saving in distance of the Tehuantepec route over Panama is shown by the following table in nautical miles:

	Via Tehuantepec.	Via Panama.
New York to—		
San Francisco	4,226	5,495
Acapulco	2,363	3,613
Mazatlan	3,017	4,055
Yokohama	8,666	9,825
Honolulu	5,639	6,688
New Orleans to—		
San Francisco	3,091	4,700
Acapulco	1,262	2,861
Mazatlan	1,759	3,458
Liverpool to—		
San Francisco	7,182	8,038
Acapulco	5,274	6,035
Honolulu	8,511	9,263
Yokohama	11,478	12,500

Anthracite Coal Production.

As in previous years of depression following panic the anthracite coal demand has stood up extremely well. The following comparative figures are shown of anthracite output per month:

Month.	1907-08.	1906-07.	1905-06.
November	5,666,205	5,182,153	5,421,584
December	5,343,477	4,836,028	5,395,113
January	5,618,339	5,249,916	5,458,084
February	4,503,756	4,563,720	4,712,099
Total	21,131,777	19,831,817	20,986,880

The stock of coal at tidewater on October 31, 1907, was 819,757 tons, and on February 29, 1908, it was 700,404 tons, so that as far as these figures indicate, the consumption of coal was greater than the supply. To arrive at an accurate result as to consumption, it would be necessary to have the state of stocks at interior points, but these are not available.—*Wall Street Journal.*

The Short Line Railroad Association.

The Short Line Railroad Association, which is endeavoring to increase the mail compensation of short line roads, was incorporated last October under the membership corporation law of New York state. The purpose of its organization is to protect and promote the business interests of short line railroads engaged in the transportation of mail, passengers and freight, doing business in this and other states; to advocate and use its influence in the enactment of just and equitable federal and state laws to govern these railroads; to establish social and commercial relations between short line railroads for the betterment of the same and for the economies which can be practised.

In December last the association appointed a legislative committee for the purpose of taking action in regard to increasing the pay for railroad mail transportation and also for the purpose of doing away with the mail deliveries beyond railroad terminals, also to look after and oppose all legislation inimical to the railroads, particularly the independent short line roads represented by the association.

For the accommodation of the committee and to promote the work of the association, headquarters were opened in Washington and an active campaign has been carried on there in favor of the passage of a bill which was prepared by the association and introduced in Congress. This bill does not interfere in any way with compensation paid the longer or trunk lines; it simply covers the minimum rates.

Previous to 1876, all roads carrying the minimum quantity of mail received $50 per mile per year for carrying 200 lbs. of mail per day, while roads carrying 500 lbs. received $75 per mile per year. In 1876 Congress made a reduction of 10 per cent from the rate then allowed, and this was followed two years later by a further reduction of 5 per cent. The result is that short lines, or roads carrying 200 lbs. of mail per day, are now receiving $42.75 per mile per year, while those carrying 500 lbs. receive $64.13 per mile per year.

Many of these short line roads carrying from 500 to 1,000 lbs. of mail per day supply apartment space from 10 to 25 ft., equipped with post office accommodations, also carrying a messenger to distribute the mail and receive no compensation whatever for the use of their car space nor anything for heating or lighting the car. They are also compelled to deliver their mail from the terminal of the railroad to the post office or postal station, no matter what the distance may be. It is claimed that there are roads in the organization receiving from $100 to $500 a year that disburse more than two-thirds of that amount to cover the messenger service.

The three principal changes suggested in the bill are as follows: That the roads carrying not more than 500 lbs. of mail per day over the entire route shall be paid $75 per mile per year; that they shall not be required to deliver the mails at a post office or a postal station unless it be located in the railroad depot or station of the carrier; that the Postmaster-General shall be authorized to allow for space used for post office purposes in compartment cars on roads where the daily average weight of mail carried does not exceed 500 lbs. a proportion of the rate of compensation allowed for postal cars forty (40) feet in length. For the use of these cars the longer or trunk lines are allowed 5½ cents per mile.

Report on Boston & Maine Merger.

The Commission on Commerce and Industry, authorized by the state of Massachusetts to report on the proposed merger of the Boston & Maine with the New York, New Haven & Hartford, finds that the New Haven holds 109,948 of the 302,928 Boston & Maine shares, which it is now by law disqualified from voting, and makes the following recommendations:

1. The New York, New Haven & Hartford Railroad Company to be permitted to hold and acquire stock of the Boston & Maine Railroad and vote thereon, and to be required to exchange its own stock, share for share, for all stock of the Boston & Maine Railroad that may be offered for exchange prior to July 1, 1909.

2. The Boston & Maine Railroad and the New York, New Haven & Hartford Railroad Company to be and remain subject to all the provisions of the laws of this Commonwealth which are now applicable to them respectively and not inconsistent with the act now to be passed.

3. The rates for the transportation of freight or passengers within, across, into or from this Commonwealth by any steam railroad or street railway or steamship line controlled by either of said companies not to be increased or the facilities therefor diminished without the approval of the Board of Railroad Commissioners, so far as it is within the power of this Commonwealth to regulate such transportation.

4. The principal office of the Boston & Maine Railroad and the control of its operation in this Commonwealth to be in Boston, its principal managing officers to be residents of this Commonwealth, and every director to be a resident of some state in which the company is incorporated.

5. All stock of the Boston & Maine Railroad at any time owned by the New York, New Haven & Hartford Railroad Company, or in which it has any interest, to stand of record in the name of the latter company; and, unless with the permission of the Railroad Commissioners, given after a public hearing, not to be disposed of or encumbered, or affected by any contract, arrangement or understanding in respect to its ownership, use or control, and not to be voted on, except for the choice of directors, unless in pursuance of a vote of the directors of the New Haven Company communicated to and approved by the Board of Railroad Commissioners prior to the meeting at which the stock is to be voted.

6. No conveyance, contract, agreement, arrangement or understanding to be made by the Boston & Maine Railroad or by the New York, New Haven & Hartford Railroad Company for the acquisition or use by any third company of any of the road, tracks, terminals or equipment of either of the said two companies, or of any of those of a third company by either of said two companies, or for the exchange of business, unless with the approval of the Board of Railroad Commissioners.

7. If at any time subsequent to December 31, 1913, the growth, development, maintenance or management of any of the railroads now operated by the Boston & Maine Railroad shall not be satisfactory, or shall not adequately meet the requirements of the public and the interests of the Commonwealth, and if the Board of Railroad Commissioners shall so certify to the Governor and Council either of its own motion or in response to an inquiry from the Governor or the Legislature, then the Commonwealth shall be entitled to buy all the stock of the Boston & Maine Railroad owned or controlled by the New York, New Haven & Hartford Railroad Company at a price to be determined as prescribed in the act now to be passed.

8. If at any time the substantial control of the New York, New Haven & Hartford Railroad Company shall pass to any other corporation, by lease, consolidation, change in the ownership of stock, contract, understanding or arrangement, and if the Board of Railroad Commissioners shall so certify, then the Governor may notify the New Haven Company that the stock of the Boston & Maine Railroad acquired by it shall not be voted on, and such prohibition shall continue until removed by the Board of Railroad Commissioners, with the approval of the Governor or the Legislature.

9. There shall be permitted a reciprocal use by the New York, New Haven & Hartford Railroad Company, the Boston & Maine Railroad and the Boston & Albany Railroad Company, of their respective terminal facilities in and near the city of Boston including tracks, docks, vacant land and water front and also of the Commonwealth property at South Boston to such extent and manner, upon such terms and for such compensation as may be for the public advantage; the matter to be determined in the manner provided in the act now to be passed.

Proposal to Sell Steinway Tunnel to New York City.

The New York City Public Service Commission announces receipt of a letter from the Interborough Rapid Transit Company offering to sell all the tunnel railroad and rights, excluding certain real estate of the New York & Long Island Railroad Company known as the Steinway tunnel, at its actual cost to the Interborough company for construction, etc; a cost estimated at about $7,000,000 to be paid in city bonds, and proposing that the city enter into an operating contract with the New York & Queens County Railway Company to operate the tunnel in connection with its surface railroad in Queens county for a term of 25 years at a 5-cent fare, the city to pay half of a certain sum agreed upon to represent operating expenses, and the balance to be met by the company; the city to take the local fares until reimbursed for its advances for operating expenses and interest on bonds issued to pay for the tunnel and 1 per cent. for a sinking fund; the company to take the through fares and, when the city has been reimbursed, the local fares to be divided equally between the city and the company. The counsel to the commission is of the opinion that this proposal is one for the decision of the city authorities concerned with the expenditure of public money. If the city authorities look upon it with favor, the matter may later come before the commission for its approval under the provisions of the law. But the present form of the Rapid Transit act gives to the commission no power which would allow the purchase of an existing railroad or tunnel with public money, and the Rapid Transit act would have to be amended to grant any such authority for the purchase of a railroad or tunnel instead of building it at public expense, and to provide for any such co-operative arrangement for operating and taking of fares in lieu of a guaranteed rental as now provided to cover interest and sinking fund for bonds issued to pay for the public improvement.

Better Feeling in Maryland.

State Senator Gorman, of Maryland, leader of the Democratic majority, has strongly advised against any adverse railroad legislation. Governor Crothers, in commenting on the Western Maryland receivership, finds a warning to Congress and to the legislatures of the states that the railroads are in no condition to withstand the assaults of adverse legislation or to endure increased burdens and decreased revenues. The Governor is quoted as saying that it is a bad time for 2-cent rate bills. Attorney-General Straus believes that legislatures and other government agents should realize the grave peril of legislation adverse to the railroads and the danger of indiscriminate attacks upon financial and public service institutions. President Seth, of the state senate, believes that it is time that legislatures try to assist the railroads through their troubles, and that they should refrain from oppressive and injurious action.

INTERSTATE COMMERCE COMMISSION RULINGS.

Shippers Held to Their Agreement.

The Commission has announced decision (opinion by Commissioner Cockrell) in the case of Laning-Harris Coal & Grain Co. and Kansas City Hay Co. vs. St. Louis & San Francisco. It appeared that certain shippers applied for cars in which to ship hay, which the carrier, because of car shortage, could not furnish at the time and place desired. The carrier informed the shippers that it had certain cattle cars which it could furnish if the shippers would clean and suitably prepare them for their shipments of hay at their own cost and expense. The shippers accepted these cars on these terms, cleaned and prepared them, and shipped their hay therein, and then claimed reparation for the cost and expense incurred by them. Upon the foregoing statement of facts the Commission held that the shippers' claim for reparation be denied and their complaint dismissed.

Through Route and Joint Rate Established.

The Commission, opinion by Commissioner Prouty, has announced decision in the case of F. J. Gentry vs. Atchison, Topeka & Santa Fe et al. The complaint alleged that defendants failed to establish a through route and joint rate on lumber, lath and shingles from Ashland, Tex., to Nash, Okla. It appeared that there formerly existed joint rates over two established routes between these points, but that they have been recently canceled. The Commission decided that there is no satisfactory through route or joint rate for the shipment of such commodities between said points, and that a joint through rate of 28½ cents per 100 lbs. should be established over a through route specified in the decision.

Class Rates to Pecos, Tex., Upheld.

The Commission, opinion by Commissioner Clements, has announced decision in the case of Pecos Mercantile Co. vs. Atchison, Topeka & Santa Fe et al. The complaint alleged that the class rates of defendants for transportation of commodities from Chicago, St. Louis, Omaha and Denver to Pecos, Tex., are unreasonable as compared with rates from said points of origin to El Paso, Tex. The Commission declared that it is unable to find that the class rates now in effect from said points of origin to El Paso, Tex., unduly prejudice Pecos, or that the lower rates from such points of origin to El Paso constitute a violation of the fourth section of the Rate Law as that section is construed by the courts. Complaint dismissed.

Reparation Because Low Rate Temporarily Suspended.

In the case of North Bros. vs. St. Louis & San Francisco (opinion by Commissioner Cockrell) it appeared that the defendant carrier for some years had a proportional rate of 15 cents per 100 lbs. on hay when carried from Kansas City, Mo., through a part of the state of Kansas, to Cape Girardeau, Mo. This rate was canceled and a higher rate went in effect for a short time. Thereafter the 15-cent rate was restored. During the time the higher rate was in effect complainant shipped two carloads of hay over the route named. The Commission decided that the rate in excess of 15 cents per 100 lbs. on hay in carloads shipped under the circumstances named is unjust and unreasonable, and that North Bros. are entitled to an order for reparation.

Roads Built for Special Purpose May Charge Higher Rates.

The Commission, opinion by Commissioner Prouty, has announced decision in the case of the American Asphalt Assoc. vs. Uintah Railway. The Commission decided that under the peculiar circumstances of this case a rate of $8 per ton is a reasonable charge to be imposed by the Uintah Railway for transportation of gilsonite, a low-grade commodity, for a distance of 54 miles. The former rate of $10 per ton was declared unreasonable. The Commission further held that where a railroad has been built for a special purpose, and does not form part of any general industrial development, it does not stand in the same relation to the public as a railroad chartered and built for general purposes, and the reasonableness of its rates must be determined by the financial returns which they produce rather than by comparison with rates in effect elsewhere.

No Reparation for Misrouting by Shipper.

The Commission, opinion by Commissioner Prouty, has announced decision in the case of Hollis Stedman & Sons vs. Chicago & North-Western et al. In February, 1904, complainant shipped three carloads of potatoes from Wautoma, Wis., to Springfield, Mo., via the Chicago & North-Western, the Illinois Central and the St. Louis & San Francisco, and paid the combination of locals rate of 38½ cents per 100 lbs. The complainants insisted that this rate was unreasonable, because the shipments might have been made from Wautoma to Springfield over other lines for 25 cents per 100 lbs. The Commission held that the higher charge was due solely to complainants' error and that the Commission has no jurisdiction to establish a joint through rate, since a satisfactory one already exists, and that the rate charged is not found to be unreasonable in itself. If these shipments had been routed via St. Louis instead of via East St. Louis, the rate would have been 1½ cents less per 100 lbs. The Commission said that the Illinois Central was at fault in billing the shipments to East St. Louis instead of to St. Louis, and should make good this overcharge.

Car Shortage Answers Complaint of Discrimination in Car Supply.

In the case of Wagner, Zagelmeyer & Co. vs. Detroit & Mackinac and Michigan Central (opinion by Chairman Knapp), the complaint alleged that since July 13, 1906, the Detroit & Mackinac has discriminated against complainant in furnishing cars for interstate shipments of ice from Tobico, Mich., and the rates charged by defendant on ice from Tobico to points in Ohio are unreasonable. It appeared that the evidence clearly establishes and complainants submit that prior to September 15, 1906, the service was satisfactory, and since that time and continuing until after January 1, 1907, a car shortage, amounting to famine of freight transportation facilities throughout the country after October 1, 1906, existed. This car shortage, which prevailed on the Detroit & Mackinac in common with all other railroads, was brought about by circumstances over which that company had no control and for which it was not responsible. There was no evidence that the joint rates on ice from Tobico to Toledo and Cleveland are unreasonable. Under these circumstances the Commission held that complainants were not unduly prejudiced in their car supply, and that the joint rates on ice from Tobico to points in Ohio are not shown to be unreasonable *per se* or relatively. Complaint dismissed.

Joint Rates and Combination Rates.

In the case of the Laning-Harris Coal & Grain Co. vs. Missouri Pacific and Wabash (opinion by Commissioner Lane) it appeared that two cars of coal were shipped by complainant from Springfield, Ill., to Kansas City, Mo., via the Wabash, and after arrival at Kansas City one car was forwarded by complainant to Salina, Kan., and one to Kipp, Kan., both via the Missouri Pacific. The joint rate on coal from Springfield to Salina or Kipp via Kansas City is $3.73 per ton, whereas the combination rate is $3.50. On the foregoing shipments defendants charged and collected the higher joint rate. On complaint that this charge is unreasonable, the Commission held that these shipments consisted of strictly local shipments into and out of Kansas City, and that the application of the joint through rate was not in accordance with the published tariffs, but that the lawful rate applicable on such shipments was the combination of locals. Reparation was awarded.

The Commission further declared that there can be but one legal rate between two points. This rate must be either the local rate if over one road, or the joint rate if over a through route composed of two or more roads which have agreed to a joint rate, or a combination of separately established rates applicable on through business over a through route which does not enjoy a joint rate. In general, said the Commission, joint through rates are lower than the sum of the locals between two points, and obviously there can seldom be any transportation reason why this should not be the case.

Intra-State Private Cars as Affecting Interstate Car Supply.

The Commission, opinion by Commissioner Harlan, has announced decision in the case of Henry Ruttle et al. vs. Pere Marquette. The rulings of the Commission in this case are as follows:

While the right to use private cars may doubtless be denied to shippers by appropriate legislation, in the absence of a specific enactment to that effect the Commission is not prepared to say that their use in itself is unlawful; but if their use results under a given set of circumstances in an unlawful advantage to their owners and an unlawful disadvantage to other shippers, a question is presented which under existing legislation is within the control of the Commission and may be made the basis of such relief as the facts may justify. Because of defendant's insufficient equipment, a number of worn-out cars no longer serviceable for interstate movements were acquired and fitted up by certain shippers for the transportation of their hay from local points on the Port Austin division of the Pere Marquette to junction points with other lines, where the hay was transferred to empty system cars and moved forward to eastern markets. The Commission held, on the foregoing state of facts, that defendant's course in stopping its own cars as well as the cars of connecting carriers in its control at such junction points there to be loaded with hay from the "private" cars, instead of sending them up the line to the loading points where all shippers might share in their distribution, was to the detriment and at the expense of complainants and other independent dealers, and amounted to a denial to the complainants of the equal enjoyment of the facilities of defendant and was therefore an unlawful discrimination.

Unreasonable Rates Should be Paid and Reparation Sought.

The Commission, opinion by Commissioner Clements, has announced decision in the case of Coomes & McGraw vs. Chicago, Milwaukee & St. Paul and Chicago, Rock Island & Pacific. Complainant shipped over defendants lines from Elk City, Okla., seven carloads of broom corn to Sioux City, Iowa, via Omaha, paying 60.85 cents per 100 lbs. on one car, 80.5 cents per 100 lbs. on another car, and on the remaining five cars $1.14 per 100 lbs. The combination of locals on this commodity from Elk City to Sioux City, based on Omaha, is 60.85 cents per 100 lbs., whereas the joint through rate was at the time of the shipments $1.14; but subsequently defendants voluntarily established a joint through rate of 60.85 cents. Pending protest against paying the $1.14 rate on two of these cars unloading was delayed, causing demurrage charge, which was paid by complainant.

The Commission held that the joint through rates of 80.5 cents and $1.14 were unjust and unreasonable, in so far as the same exceeded the sum of the locals, and awarded reparation on that basis; but reparation on account of demurrage charges was denied. The Commission declared that rates duly established are binding on carriers and shippers alike so long as they remain in effect. The law requires that such rates shall be reasonable and just and authorizes the Commission to award reparation on account of the exaction of unreasonable transportation charges. It follows that although a rate is by the terms of the law binding on all so long as it remains in effect, such rate may be found and declared to be unlawful and reparation awarded on account of its exaction. To hold otherwise would be to make the mere establishment of rates by a carrier conclusive of their reasonableness and justness and leave shippers without recourse for recovery of excessive charges. It is the duty of carriers and shippers to observe the established rates, and there can be no waiver of demurrage charges which accrue by reason of the refusal of consignees to accept shipments and unload cars pending a contest or dispute as to the reasonableness of the established rates.

Present System of Compression Points for Cotton Upheld.

The Commission, opinion by Commissioner Clements, has announced decision in the case of the Chickasaw Compress Co. vs. Gulf, Colorado & Santa Fe et al. and of the Pauls Valley Compress & Storage Co. vs. the same defendants. The complainants in these cases, owning cotton compresses at Ardmore and Pauls Valley, Okla., respectively, alleged that the practice of defendants whereby cotton originating at points north of Ardmore and Pauls Valley is carried by those points to Gainesville, Tex., for compression, while cotton originating south of Gainesville is not permitted to be carried north through Gainesville to Ardmore and Pauls Valley for compression, results in unjust discrimination against them; and asked that the Commission establish a rule requiring defendants to have all cotton compressed by the compress nearest the point of origin. The Commission declared that carriers are permitted to adjust their rates, regulations and practices with due regard to the circumstances and conditions confronting them and the natural currents and laws of trade and commerce.

It appeared that cotton would not move from points in Texas south of Gainesville northwardly into Oklahoma for compression at Ardmore and Pauls Valley unless the rate to Ardmore and Pauls Valley should be as low as the rates to Gainesville. This would be true whether or not a higher rate were in effect from the compression point. It would also be true of all points as far south of Gainesville as the distance that cotton may be moved to Gainesville from points north of Ardmore and Pauls Valley, Okla. To require the rates from these points of origin in Texas south of Gainesville to be the same to Ardmore and Pauls Valley, Okla., as to Gainesville, Tex., would be to entirely disregard the added expense of the back haul. The movement of cotton is almost entirely southward from all points on defendants' lines, and cotton originating at points north of Ardmore and Pauls Valley naturally moves through Gainesville. To require the defendants to haul cotton northwardly through Gainesville for compression at Ardmore and Pauls Valley, and to protect on such shipments rates not higher than those in effect from points of origin to ultimate destinations, where such cotton must be ultimately hauled back through Gainesville to southern ports would not be justified. The Commission decided that the discrimination complained of is not undue. Complaints dismissed.

Prosecution to be Begun for Alleged Rebating and Destruction of Records.

The Commission, through Commissioner Lane, makes the following report in regard to a hearing in Richmond, Va., on February 19, 20 and 21, 1908, from which the following facts appear:

1. For some years a fraudulent practice, participated in by certain dealers in grain and also by certain dealers in packing house products and also by the Chesapeake & Ohio, has obtained at Richmond by means of which this railroad company has favored such shippers at the expense of the Seaboard Air Line and Atlantic Coast Line, its southern connections. This practice has resulted in obtaining for such shippers rates less than local rates over the Seaboard Air Line and Atlantic Coast Line for shipments of grain and also for shipments of packing house products, which local rates such shippers were legally bound to pay. This result has been accomplished by means of transfer slips issued by the station agent of the Chesapeake & Ohio on the written instruction of the Assistant General Freight Agent, said transfer slips falsely conveying to the southern lines the statement that such shipments had originated at points beyond Richmond and were entitled to move from Richmond to destination in the Carolinas at a division of a through rate, such division being less in amount than the local rates to which these shipments were legally subject.

2. The benefits of this arrangement have been reaped by the shippers enjoying it and also by the Chesapeake & Ohio, which, whether by express agreement or not, has received all of the inbound business of the shippers so favored by it.

3. It also further appears that the Assistant General Freight Agent of the Chesapeake & Ohio responsible for the above described abuse on discovering that the same was under investigation by special agents of this commission undertook to make amends for the same to the Seaboard Air Line and the Atlantic Coast Line. To this end he ordered that a list be prepared of all cars which had by his orders been moved at a division of the joint through rate less in amount than the local rates to which they were legally subject. Being informed by one of his subordinates that this list would be a very long one, he then gave orders that the list should show only the cars moving during the months of August, September and October, 1907. Having been furnished with a list covering these three months he forwarded it to the southern lines with a statement that it showed "all" cars so misbilled which he had been able to discover.

4. It also appears that certain records of the Chesapeake & Ohio have been destroyed, contrary to the provisions of the Rate Law. The testimony showed that the freight claim department of this road is under the charge of the Assistant General Freight Agent, he being the officer responsible for the false transfer slips. The testimony further shows that the auditor of disbursements on receiving from the freight claim office claims from shippers with direction that they be paid inquires no further into the merits or legality of such claims than to ascertain from the auditor of freight receipts that the shipments to which the claims relate have moved and that the charges have been collected. All claims so passing through the freight claim office and paid on the order of the Assistant Freight Agent prior to January 1, 1907, were destroyed during the latter part of the year 1907. This destruction appears to have been made by the auditor of disbursements under authorization of the comptroller of the Chesapeake & Ohio.

So far as the matters disclosed are criminal in their nature they are to be referred to the United States District Attorney at Richmond with the request that prosecution be instituted against all parties therein involved.

TRADE CATALOGUES.

Mine and Quarry.—The current number of this quarterly bulletin of the Sullivan Machinery Co., Chicago, has 30 pages of interesting articles, including the following: "Mining with Hammer Drills"; "Carthage Limestone"; "Adaptability of Hammer Drills"; "Diamond Drilling at Mapimi"; "New York, New Haven & Hartford Railroad Tunnels," and "Mechanical Conveyors as Applied to Long-Wall Mining." They are all written especially for this magazine by men having technical knowledge of the subjects, and are illustrated with interesting half-tone engravings.

Union Pacific.—A pamphlet just issued by the passenger department, entitled "Colorado—A Winter Resort" presents by half-tone engravings from photographs and by interesting text the attractions of Colorado as an all-the-year-round health resort and as a delightful place of residence.

MANUFACTURING AND BUSINESS.

The 2,500 steel underframe stock cars of 60,000 lbs. capacity to be built by the Chicago, Milwaukee & St. Paul will have Bettendorf cast steel trucks and swing-motion bolsters made by the Bettendorf Axle Co., Davenport, Iowa.

The Nathan Manufacturing Co., New York, has appointed Clifford Nathan General Western Manager. Mr. Nathan will make his headquarters at the Chicago office in the Old Colony building and will have charge of the Nathan Manufacturing Co.'s business in the West.

J. W. Scull has resigned as Purchasing Agent of the Pressed Steel Car Co., Pittsburgh, Pa., to become Manager of the Pittsburgh office of the Summit Lumber Co., St. Louis, Mo., makers of yellow pine lumber. Mr. Scull had been with the Pressed Steel Car Co. for the past ten years.

Frank F. Fowle has opened an office as consulting electrical and telephone engineer at 201 Dearborn street, Chicago, giving particular attention to railroad telephone systems, including simultaneous and multiplex telephony and telegraphy, and power transmission and distribution.

R. S. Stangland has been placed in charge of the construction office at New Fort Lyon, Colo., of Muralt & Co., New York, and will superintend the erection of the complete lighting, heating and power plant which this firm is building for the United States Government at the New Fort Lyon naval hospital.

The offices of A. P. Witteman & Co., makers of high-speed and special steels, have been moved to 112-116 North Broad street, Philadelphia, Pa. These will also be the Philadelphia sales offices of the

Chester Forging & Engineering Co., Chester, Pa. A feature of the offices will be desk, stationery, stenographer and telephone facilities for the exclusive use of customers.

George R. Carr, Vice-President of the Dearborn Drug & Chemical Works, Chicago, is on a combination business and pleasure trip to Mexico City. John W. Brashears, who for many years has been first assistant to W. A. Converse, Chemical Director of the Dearborn company, in charge of the analytical laboratories, has been appointed Assistant Superintendent of the manufacturing department.

During January the Duquesne Steel Foundry, which operates a large plant in the Pittsburg district, decided to adopt gas power to operate the works formerly driven by steam. The initial equipment will consist of a 400-h.p. (max.) Westinghouse gas engine of the three-cylinder vertical enclosed type, direct connected to a 240-k.w. generator, supplying current for motor drive. The engine will operate on natural gas.

At the annual meeting of the Union Switch & Signal Co., Swissvale, Pa., the following officers were elected President, George Westinghouse; Directors, George Westinghouse, Robert Pitcairn, William McConway, George C. Smith, Thos. Rodd, H. G. Prout, and John B. Jackson. After the stockholders' meeting, the directors met and reappointed the same executive officers as had served during the preceding year. The regular quarterly dividend of 3 per cent. was declared.

Harold A. Clark, President of the Central Inspection Bureau, New York, Auditor of the Middletown Car Works, Middletown, Pa., and President of the H. A. Clark Company, New York, domestic sales agents for the Middletown Car Works, died last week at Phoenix, Ariz., where he had recently gone for his health. Previous to Mr. Clark's removal to Middletown, Pa., and his connection with these three companies, he was Assistant Auditor of the American Car & Foundry Company, New York.

The United States Circuit Court of Appeals for the Third Circuit has decided that the Nolan patent, owned by the Westinghouse Electric & Manufacturing Co., Pittsburgh, Pa., is valid and that the Prudential Insurance Co. has infringed on it. This decision upholds the lower court, from whose decree the insurance company appealed. The Nolan patent is a device for fastening together, and to the supporting castings, the laminae of the cores of electric machines by using a spring split-ring.

The Athens Electric Railway, Athens, Ga., originally generated power at two hydro-electric plants, one about 6½ miles and the other 2½ miles from the city. Extension of the street railway lines and the rapidly increasing power and lighting load made it necessary to build a new power house in the town itself, where for some time past a horizontal steam turbine has been in operation. The requirements have now increased so much that a second steam turbine, of 1,000 k.w. capacity, is to be installed. This, with the generator designed for direct connection to it, is now being built by the Allis-Chalmers Co., Milwaukee, Wis. The unit will deliver three-phase, 60-cycle current at a terminal pressure of 2,300 volts, and is to be excited by a 40 k.w. induction motor generator set, also of Allis-Chalmers manufacture.

OBITUARY NOTICES.

William Horace Holcomb, President of the Holcomb & Hayes Company, died recently at Hinsdale, Ill. He was for two years soon after the war General Manager of the Union Pacific lines and was active in the early establishment of the Railroad Y. M. C. A.

MEETINGS AND ANNOUNCEMENTS.

(For dates of conventions and regular meetings of railroad conventions and engineering societies, see advertising page 24.)

Canadian Society of Civil Engineers.

At a meeting of the Mechanical Section of this society March 19 a paper on "The Handling of Locomotive Coal and Ashes," by C. F. Whitton, was read by the author.

American Society of Civil Engineers.

At the meeting of this society, March 18, a paper on "The Electrification of the Suburban Zone of the New York Central & Hudson River Railroad in the vicinity of New York City," by William J. Wilgus, was presented for discussion, illustrated with lantern slides. This paper was printed in the "Proceedings" for February.

New York Railroad Club.

At the next meeting of this club, March 20, in place of a technical paper and its discussion, short talks by recognized authorities are to be made on the application of electricity for the operation of trains or important signal systems. Among those who have accepted invitations to speak are: W. J. Wilgus, George Gibbs, Hugh Hazleton, B. G. Lamme and Walter C. Kerr.

Franklin Institute.

At the annual meeting of the institute, March 18, the programme included an address on the Engineering Practice as Applied to the Fueling Equipment of Power-houses, by Harry P. Cochrane. A series of slides of the collapsed Quebec bridge were also shown by Norman R. McLure, who was an inspector during the erection of the bridge. See article on the Quebec Bridge Failure in another column.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Canadian Pacific.—Francis White Peters, who was recently appointed Assistant to the Second Vice-President, who is in charge of the western lines, was born March 25, 1860, at St. John, N. B. After three years education in the schools of that place, he entered railroad service when 13 years old as an operator working with the engineers who were building the Intercolonial. Also in his thirteenth year he was made agent of the road at Jacquet River, N. B. For the next three years he was agent at other points, and in 1876 assistant agent at Newcastle, N. B. In 1878, at the age of 17, he was agent at Chatham Junction, N. B. In 1880 he went to the Chicago & Grand Trunk, now the Grand Trunk Western, as agent, and a year later to the Canadian Pacific as a bill clerk in the local freight office at Winnipeg. Within seven months he was appointed agent at Brandon, Man., where he served for seven years, being then appointed agent at Fort William, Ont. For the next seven years he was local freight agent at Winnipeg, Man. From 1896 to 1899 he was freight agent of the West Kootenay district, with headquarters at Nelson, B. C., and in 1899 was appointed Assistant General Freight Agent with authority over the same territory. In 1900 he was appointed Assistant General Freight Agent of the Pacific division, with headquarters at Vancouver, B. C., and in July, 1901 General Freight Agent of the same division. On January 1, 1903, he became Assistant Freight Traffic Manager of the western lines of the Canadian Pacific, and on March 1 of this year was appointed Assistant to the Second Vice-President, with headquarters at Winnipeg.

Chicago Great Western.—W. J. Ainsworth has been appointed Assistant General Attorney, succeeding John L. Erdall, resigned.

Cincinnati, New Orleans & Texas Pacific.—W. J. Murphy, Vice-President, with headquarters at Cincinnati, Ohio, will take over the duties of T. C. Powell, Vice-President, who has been transferred to St. Louis in charge of the St. Louis-Louisville lines of the Southern Railway. On August 1, 1907, Mr. Powell was elected Vice-President of the Queen & Crescent lines in charge of the operating, traffic and purchasing departments, with Mr. Murphy as the chief executive officer at Cincinnati.

Illinois Central.—J. Ogden Armour has been elected a Director, succeeding Joseph F. Titus, who succeeded Stuyvesant Fish.

Mexican Central.—J. A. Naugle, Assistant to Vice-President C. R. Hudson, has resigned.

Mobile, Jackson & Kansas City.—H. M. Hood, who has been local auditor at Beaumont, Tex., of the St. Louis & San Francisco, has been appointed Auditor of the Mobile, Jackson & Kansas City, with headquarters at Mobile, Ala.

Southern.—The headquarters of T. C. Powell, Vice-President, have been changed from Cincinnati to St. Louis. See Cincinnati, New Orleans & Texas Pacific.

Operating Officers.

Buffalo & Susquehanna.—G. D. Reynard, who has been Trainmaster of the Northern division, has been appointed Assistant Superintendent at Galeton, Pa. His former office has been abolished.

Canadian Northern.—J. R. Cameron, now General Superintendent of the Canadian Northern, entered railroad service in 1882 on the Canadian Pacific at Winnipeg as brakeman. In the next year he was made conductor. In 1887 he went to the Northern Pacific in Montana as conductor, and in 1898 was appointed Trainmaster at Grand Forks, N. Dak., with jurisdiction over the Northern Pacific lines in Manitoba, then known as the Northern Pacific & Manitoba Railway. When in 1901 the Canadian Northern took over these Manitoba lines, Mr. Cameron went with them as a passenger conductor. Three years later, in August, 1904, he was appointed Superintendent of the Canadian Northern at Kamsack, Sask. In December, 1905, he was appointed Superintendent of the First district of the Canadian Northern, with headquarters at Port Arthur, Ont., and on January 20, 1908, General Superintendent, with headquarters at Winnipeg.

Canadian Pacific.—George J. Bury, who was recently appointed General Manager of western lines, was born March 6, 1866, at Montreal, and was educated at the Montreal College. At the age of 17 he entered railroad service as a clerk in the purchasing department of the Canadian Pacific. He has been with this company ever since. After four years in the purchasing department, he was in 1887 transferred to the General Manager's office. In 1889 he became secretary to T. G. Shaughnessy, then Assistant to the President, now President of the Canadian Pacific. In 1889 he was made Acting Superintendent of the dining, sleeping and parlor car services which, on the Canadian Pacific, are directly controlled by the railroad company. In March, 1890, he was appointed Superintendent of the Western Ontario division. In 1899 he was appointed Superintendent at Fort William, Ont. In 1901 he was transferred as Superintendent to Cranbrook, B. C. For three months in 1902 he was Assistant General Superintendent of the Lake Superior division and then was appointed General Superintendent of the same division. In February, 1904, he was made General Superintendent of the Central division, with headquarters at Winnipeg, and on March 1, 1907, Assistant General Manager of western lines. One year later, on March 1, 1908, he was appointed General Manager of the western lines in charge of maintenance of way and operation.

G. J. Bury.

Delaware, Lackawanna & Western.—George Arthur Poore, the new Superintendent of the Syracuse and Utica division, was born August 21, 1867, at Liverpool, England. He was educated at private schools in England. After having come to America he began railroad work in 1889 on the Illinois Central in the office of a Superintendent, and later was in the offices of the Superintendent of Transportation, the Assistant General Superintendent and the General Superintendent, becoming assistant chief clerk to the General Superintendent. In July, 1900, he left the Illinois Central to become chief clerk to the General Superintendent of the Lackawanna. After four years in this position he was made Superintendent of the Bangor & Portland division from which he was, on March 15, promoted to be Superintendent of the Syracuse and Utica division.

Denver & Rio Grande.—A. F. Brewer, Superintendent of Transportation at Denver, Colo., has resigned to go to another company, and the office has been abolished, the duties being assumed by the Assistant General Manager.

Great Northern.—F. S. Elliott, Assistant Division Superintendent at Willmar, Minn., has been appointed Superintendent at Crookston, Minn., succeeding T. F. Lowry, transferred to the Montana division.

Illinois Central.—The authority of P. Laden, Superintendent of the Peoria division, has been extended over the Indianapolis Southern Railroad division. The authority of A. H. Egan, Superintendent of the Louisville division, has been extended over the Nashville division, and L. E. McCabe, heretofore Superintendent of the Nashville division, has been appointed Assistant Superintendent of both divisions. The office of Trainmaster of the Nashville division has been abolished. B. F. Galvani, Trainmaster at McComb, Miss., has been appointed Superintendent of the New Orleans division of the Yazoo & Mississippi Valley, with office at Vicksburg, Miss., succeeding F. A. C. Ferguson, resigned.

Missouri Pacific.—W. E. Merrifield, Superintendent of the Northern Kansas division, has been appointed Trainmaster of the Atchison, the Omaha and the Northern Kansas divisions, with office at Atchison, Kan., succeeding J. J. Skinner, now chief despatcher. E. C. Wills, Trainmaster in charge of the line from Coffeyville, Kan., to Osawatomie, has been appointed Trainmaster of the entire Southern Kansas division, with office at Coffeyville, succeeding C. S. Welsh, in charge of the Chatopa-Larned division, transferred.

Southern Pacific.—T. F. Rowlands, Assistant Superintendent at Sparks, Nev., has resigned.

Yazoo & Mississippi Valley.—See Illinois Central.

Traffic Officers.

Canadian Pacific.—W. C. Bowles, General Freight Agent of the Kootenay district, with office at Nelson, B. C., has been appointed General Freight Agent at Winnipeg of the Central and the Western divisions, succeeding W. B. Lanigan, now Assistant Freight Traffic Manager at Winnipeg.

Chester, Perryville & Ste. Genevieve.—Ralph H. Schultz, Auditor and Assistant General Freight and Passenger Agent at Cape Girardeau, Mo., has been appointed General Freight and Passenger Agent.

Chicago & Alton.—G. W. Quackenbush, Assistant General Freight Agent at Peoria, Ill., will in future have charge of local territory in Illinois and Missouri, with headquarters at Springfield, Ill. E. C. Coffey has been appointed Assistant General Freight Agent, with headquarters at Peoria, in charge of Peoria and Pekin, Ill., and traffic through these places.

Chicago, Rock Island & Pacific.—DeWitt Hammond has been appointed General Agent of the Freight and Passenger departments, with office at the city of Mexico, succeeding C. B. Cleveland, resigned.

Illinois Central.—Thomas James Hudson, General Traffic Manager, has resigned, and the office of General Traffic Manager has been abolished.

Missouri Pacific.—L. D. Knowles, General Agent at Milwaukee, Wis., has resigned.

Northern Central.—Gamble Latrobe, Assistant Engineer of the Baltimore division, has been appointed Acting General Agent at Baltimore, Md., in place of H. W. Kapp, Superintendent and General Agent, who is on leave of absence.

Engineering and Rolling Stock Officers.

Chicago, Rock Island & Pacific.—J. W. Monroe, Shop Foreman at Cedar Rapids, Iowa, has been appointed Master Mechanic at Chickasha, Okla.

Delaware & Eastern.—Otto Franklin Wagenhorst, Chief Engineer, has recently had his authority extended over the operating department with title of Superintendent. Mr. Wagenhorst was born April 25, 1871, at Gouldsboro, Pa. In 1896 he graduated from the University of Pennsylvania. His first railroad service was in 1898, as engineer locating a line for the proposed New York, Wyoming & Western Railroad, which was to have been built by the (then) independent anthracite coal operators from the western anthracite fields to New York City. After this project was given up because of the purchase of the independent anthracite holdings, he worked as transitman in the coal mining department of the New York, Ontario & Western. In 1901 he was appointed Resident Engineer of the Ellenville & Kingston division of this road, where he served for two years; in 1903 going to the Delaware & Hudson as Resident Engineer of the Chateaugay division. On April 10, 1905, he was made Chief Engineer of the Delaware & Eastern, which is now in operation from East Branch, N. Y., northeast to Arkville, 37.5 miles, with an eight-mile branch from Uniongrove north to Andes, and is projected north to Schenectady, and south to the anthracite coal fields.

Kansas City Southern.—George S. Hunter has been appointed Master Mechanic at Pittsburgh, Kan.

LOCOMOTIVE BUILDING.

The Keweenaw Central has ordered one 65-ton mogul locomotive from Ralston & LeBaron.

CAR BUILDING.

The Keweenaw Central has ordered 30 ore cars of 60,000 lbs. capacity from Ralston & LeBaron.

The Maine Central has ordered fifty 50-ton steel side dump gondola cars from the Pressed Steel Car Co.

The Western Glucose Co. has ordered ten tank cars of 100,000 lbs. capacity from the McGuire-Cummings Manufacturing Co.

The Sandoval Zinc Co., Chicago, has ordered four tank cars of 100,000 lbs. capacity from the McGuire-Cummings Manufacturing Co.

The Mt. Hood Ry. & Power Co., Los Angeles, Cal., has ordered 40 flat cars of 60,000 lbs. capacity from the Hicks Locomotive & Car Works.

The New Orleans Railway Light & Power Co. has ordered 35 closed, single-truck electric cars from the McGuire-Cummings Manufacturing Co.

The Cold Blast Transportation Co., Chicago, as reported in the *Railroad Gazette* of March 6, has ordered 200 refrigerator cars from Haskell & Barker.

The Ardmore Traction Co., Ardmore, Okla., has ordered four double truck electric cars and two 30-ft. 10-bench open cars from the McGuire-Cummings Manufacturing Co.

The Chicago, Milwaukee & St. Paul, as reported in the *Railroad Gazette* of March 6, has ordered 12 passenger cars from Barney & Smith and three passenger cars from the Pullman Co.

The Atlantic Coast Line, as reported in the *Railroad Gazette* of March 6, has ordered for the Washington & Vandemere 100 ventilated box cars of 60,000 lbs. capacity from the South Baltimore Steel Car & Foundry Co.

RAILROAD STRUCTURES.

NEW CARLISLE, QUE.—Plans are reported made by the Atlantic, Quebec & Western to replace about 26 of its present bridges with concrete and steel structures, at a cost of about $1,000,000.

NEW CASTLE, PA.—Plans, it is said, are being made for building a bridge over the tracks of the Pennsylvania at the foot of Croton avenue.

PHOENIXVILLE, PA.—The Phoenix Iron Company is putting up a steel bridge 578 ft. long, with approaches at each end of about 100 ft., over the tracks here. It is expected that the work will be finished about May 1st.

PROVIDENCE, R. I.—Plans for improving the dock facilities of the New York, New Haven & Hartford at Providence, it is said, have been completed. From Fox Point to India Point and 700 ft. out from the present wharf line a retaining wall with cuts for three slips, each wide enough for two of the big boats of the Consolidated's fleet, is to be constructed. The space at the rear of the retaining wall is to be filled in, and this will give 30 acres of wharf property over which tracks will be built to connect with the new route to Boston, via East Providence and East Junction. These improvements will cost about $2,000,000.

VERA CRUZ.—The Mexican government is understood to have approved plans for improvements here to cost about $8,000,000. The proposed union passenger station and office building is to cost about $1,000,000, and the rest will be spent for wharfs and warehouses, enlarging track facilities and putting in modern loading and unloading devices. The work is to be carried out by the Vera Cruz Terminal Company, composed of representatives of the various railroads entering Vera Cruz. Local directors of the company were recently elected as follows: J. D. Casasms, to represent the Mexican government; M. G. Ribon, the Interoceanic; Col. Palbo de Escandon and W. Moreon, the Mexican (Vera Cruz) Railway; J. B. Body, the Vera Cruz & Pacific and the Alvarado Railroads; M. Moreon, General Manager of the Mexican (Vera Cruz) was elected Director of the Board, and L. O. Brown, Secretary. The improvements are to be finished in about two years.

YORK, PA.—The Northern Central and Western Maryland Railroads, it is said, have agreed to pay $35,000, and the York Street Railway $25,000 toward building subways at West Market street. The total cost of the improvements will be $75,000.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

BALTIMORE & OHIO.—Work is now under way for this company as follows:

New yard, engine terminal, etc., at East Side, Philadelphia, nearing completion.

Double-track bridge over the Susquehanna river at Havre-de-Grace.

New freight pier at Locust Point, Baltimore (about 400 ft. of the water end of this pier collapsed when its construction was nearly completed); about 85 per cent. of the wrecking of this part of the pier has been finished. It will be rebuilt. Very little damage was done to the land part of the pier.

Building a 500,000-bushels capacity grain elevator at Mount Clare, Baltimore; work in progress on one-half; provision being made for adding the other half when desired to replace the one destroyed by fire last August.

New engine terminal and enlargement of yard at Parkersburg, W. Va., nearly finished.

Passenger station jointly with the Western Maryland and Coal & Coke at Belington, W. Va.; passenger station and office building at Wheeling, W. Va., to be finished in several months; Medical Examiner's office and Hospital at Holloway, Ohio.

Laying second track between East End, Connellsville, Pa., and Mount Braddock; third and fourth tracks between McKeesport and Glenwood.

Extension of the Gardner Avenue yard, New Castle, Pa.

Construction of freight yard; also in and outbound freight house and office building at Columbus, Ohio, nearly finished.

CANANEA, YAQUI RIVER & PACIFIC.—See Southern Pacific.

CHICAGO, MILWAUKEE & GARY.—This company, organized at Springfield, Ill., with a capital of $10,000,000, is a consolidation of the Illinois, Iowa & Minnesota and subsidiary companies. Plans made for an extension from Rockford, Ill., north via Beloit, Wis., and Janesville to Milwaukee, and on the southern end from Momence, Ill., northeast to Gary, Ind. The Board of Directors include H. W. Seaman, B. H. Harris, Frank M. Clark, William F. McSwiney and Jonas Wafflie, all of Chicago, Ill.

COLORADO, OKLAHOMA & SOUTHEASTERN.—This company, which has projected a line from Weatherfield, Okla., northwest via Independence, Taloga Cestos and Mutual to Woodward, 90 miles, including a bridge over the Canadian river, has negotiations under way to finance the project. P. A. McCarthy, Chief Engineer, Lufkin, Tex.

DULUTH, RAINY LAKE & WINNIPEG.—This company, which last year finished the extension of the Duluth, Virginia & Rainy Lake to the Canadian boundary, at Ranier, Minn., expects to have the bridge over Rainy lake finished about May 1st, thus completing a connection with the Canadian Northern.

GRAND TRUNK PACIFIC.—The National Transcontinental Railway Commission recently received 19 bids for building 365 miles of line, 138 miles in New Brunswick, 52 miles in Quebec, and 175 miles in Ontario. When these contracts are let, 1,224 miles of the total of 1,807 of the government section of the Grand Trunk Pacific will be under contract, leaving 583 miles yet to be let. The bids submitted were as follows:

Section 1.—From a point 58 miles west of Moncton, N. B., 40 miles; Grand Trunk Pacific Construction Co.

Section 2.—For 67 miles to the Tobique river; MacDonald & O'Brien and Grand Trunk Pacific Construction Co.

Section 3.—From the Tobique river to a point 2½ miles west of Grand Falls, N. B., 31 miles; Craig & Thompson; MacDonald & O'Brien; J. T. Davis; Kennedy & MacDonald; the Willard Kitchen Co.; Trites, McPhail, Moore & Miller, and the Grand Trunk Pacific Construction Co.

Section 4.—From New Brunswick-Quebec boundary, west 52 miles; O'Brien & Fowler, J. T. Davis and the Grand Trunk Pacific Construction Co.

Section 5.—From Abitibi, west 100 miles; E. F. & G. F. Farquier and the Grand Trunk Pacific Construction Co.

Section 6.—For 75 miles west of Lake Nepigon; J. D. MacArthur, E. F. & G. F. Farquier, Chambers Bros., McQuigge & McCaffery and the Grand Trunk Pacific Construction Co.

It is estimated that during the summer about 30,000 men will be at work on the whole line from Moncton, N. B., west to Prince Rupert on the Pacific coast.

GREAT NORTHERN.—According to reports this company proposes to resume improvement work this sprong, including the reconstruction of the Kalispell, Mont., division, where the old ties and rails are to be replaced with new ties and 90-lb. rails.

ILLINOIS, IOWA & MINNESOTA.—See Chicago, Milwaukee & Gary.

INDIAN CREEK VALLEY.—Plans reported made to extend this line immediately from Rogers Mills, Pa., northeast to Ligonier, 30 miles. Surveys made for 10 miles. C. F. Hood, President, and S. M. Faust, Chief Engineer, Connellsville, Pa. (March 13, p. 391.)

KANSAS CITY & KANSAS SOUTHWESTERN (ELECTRIC).—Incorporated in Missouri to build an electric line to connect Kansas City with Topeka and Independence, Kan. The company proposes to take over the rights, surveys and other property of a number of projected lines between these places. It is expected to begin work this summer. The directors include J. E. Martin, Minneapolis, Minn.; W. L. Moyer, New York; N. L. Laming, Tonganoxie, Kan.; E. M. Lamken, Kansas City, Mo.; S. M. Brewster, Chanute, Kan.; H. E. Hopper, Indianola, Kan., and C. L. Dudley, Minneapolis, Minn.

LAKE SHORE & MICHIGAN SOUTHERN.—Plans for the elimination of grade crossings on this road have been submitted to the Erie, Pa., City Council for approval. The improvements are to cost $1,500,000.

MEXICAN ROADS.—Surveys are being made by the Creston de Cobre Company for a line from Cerro de Cobre, Sonora, to Port Libertad on the gulf of California, about 40 miles. It is stated that contracts will soon be let.

Compania Industrial del Oro, it is said, will soon begin work on a line from La Huerta, Michoacan, to Tlalpujahua.

The federal government recently amended the concession previously granted to John Henderson to build a line from the port of Lobos, on the Pacific coast, to Sasme, Sonora. The new agreements require that 15 miles shall be finished by April 1, 1909, and that the entire line shall be finished by December, 1917.

The Gigante Tunnel Railway Company is arranging to begin the construction of a railroad from LaLuz, Guanajuato to Leon and Guadalajara.

A British syndicate is said to have recently bought extensive coal fields in Mier Tamaulipas from the Compania Carbonifera y Irrigadora of Nuevo Laredo, and right of way has been secured over the old grade, originally intended for an extension of the International & Great Northern down the valley of the Rio Grande from Laredo, along the Mexican side of the river to Mier, about 100 miles. Plans have been made by the new owners to build a line to connect its coal fields with the National of Mexico at Nuevo Laredo.

MEXICAN (VERA CRUZ) RAILWAY.—This company, according to reports from Mexico City, has started betterment work on its line between Mexico City and Vera Cruz. About 3,000 tons of rails are being distributed along the line, and new steel ties will be laid where new tracks are put down. A large amount of bridge work is also to be carried out on the line.

MOLINE, ROCK ISLAND & EASTERN TRACTION.—This company, incorporated to build an electric line from Rock Island, Ill., to Carbon Cliff, also from Rock Island south to Galesburg, last year laid 1.55 miles of track from East Moline, Ill., to Silvis. J. T. Porter, of Rock Island, is interested.

SOUTHERN PACIFIC.—The Cananea, Yaqui River & Pacific has concessions from the Mexican government for two branch lines, one from Naco, Sonora, on the Arizona boundry, west along the international boundary to Nogales, Ariz., on the Sonora Railway just north of the boundary, 100 miles. According to the terms of the concession this must be built within 14 months. The other concession is far a branch from Naco, east to Juarez, Sonora, 150 miles.

TACOMA EASTERN.—An officer writes that this company has finished a new branch from Anderson, Wash., to McKenna, 16 miles.

RAILROAD CORPORATION NEWS.

ALBANY & HUDSON (ELECTRIC).—The holders of the $1,750,000 first mortgage 5 per cent. bonds of this company have been asked to surrender their coupons for 1908 and 1909 and receive in return negotiable certificates which shall be convertible into first mortgage on the basis of $1,000 in bonds for $875 in coupons.

ATLANTIC COAST LINE.—The Attorney General of the state of Connecticut has given an opinion that bonds of the Atlantic Coast Line Railroad no longer fulfill the requirements of the savings bank laws in that state, because the last dividend on the common stock of the company was paid, not in cash, but in certificates of indebtedness. A similar decision was given some time ago in New York state in regard to the Missouri Pacific.

BALTIMORE & OHIO.—Gross earnings for February decreased 21 per cent., operating expenses 8 per cent., and net earnings 61 per cent.

CAROLINA, CLINCHFIELD & OHIO.—This is the new name of the South & Western. The new company has authority to increase its capital stock from $7,000,000 to $27,000,000, of which $15,000,000 is to be 6 per cent. preferred stock and $12,000,000 common stock. The road is owned by the Cumberland Corporation and is being built through the coal fields owned by the Clinchfield Coal Corporation, which also is owned by the Cumberland Corporation. It is projected to run from Elkhorn, Ky., on the Chesapeake & Ohio, south via Hostic, N. C., to Spartanburg, S. C., 285 miles. Of this, 101 miles is now built from Johnson City, Tenn., south beyond Altapass, N. C. Work is under way on about 100 miles more. A mortgage is to be made on the railroad, securing $15,000,000 bonds, part of which will be reserved for refunding bonds of constituent companies. The Cumberland Corporation has recently issued $3,000,000 one-year 6 per cent. notes due in February, 1909, by bonds of three of these constituent companies, and also has $15,000,000 six-year 5 per cent. collateral notes of 1912 outstanding. The cost of the road to date is said to be $18,000,000.

CHICAGO, ST. PAUL, MINNEAPOLIS & OMAHA.—Moffat & White, of New York, have offered at 127, yielding about 4.15 per cent., $1,000,000 consolidated mortgage 6 per cent bonds of 1930. The consolidated mortgage covers the entire railroad of this company and all other property, and is a first mortgage on 627 miles of line. These bonds are outstanding at the rate of $11,871 per mile. Junior to them is $11,300,000 preferred and $18,607,000 Common stock, each paying 7 per cent.

CINCINNATI, BLUFFTON & CHICAGO.—John C. Curtis, General Manager, was on March 14 appointed receiver of this company, which operates 52 miles of line from Huntington, Ind., via Bluffton to Portland.

DAYTON & XENIA.—C. N. Ferneding, of Dayton, Ohio, was on March 13, appointed receiver of the Dayton & Xenia Transit Co., which operates 51 miles of trolley road from Dayton, Ohio, to Xenia and to Spring Valley. Twenty miles of the line is on private right of way.

GREAT NORTHERN.—The trustees of the Great Northern Ore Properties have made a report for the first fiscal year of the trust, ended December 7, 1907. The total receipts during the year were $1,650,000, administration expenses were $67,750, and the dividend paid September 7, 1907, to holders of certificates of the trust amounted to $1,500,000, leaving a profit and loss credit balance of $82,250. In addition to the 39,296 acres of ore lands leased to the Great Western Mining Co., a subsidiary of the United States Steel Corporation, there are owned and leased 31,238 acres more of ore lands.

Holders of the $4,700,000 first mortgage 5 per cent. bonds, of the Eastern Railway of Minnesota, maturing April 1, 1908, may receive cash for their bonds or may exchange them for Northern division 4 per cent. bonds of the Eastern of Minnesota, due 1948, in which case a payment of $20 per $1,000 bonds will be made.

ILLINOIS CENTRAL.—The special stockholders' meeting which has been called for May 18 is to vote on authorizing $28,600,000 new stock, half of which is to be offered to stockholders at par (to the extent of 15 per cent. of their holdings) and the other $14,300,000 reserved against an issue of convertible bonds which may be made.

INTERNATIONAL & GREAT NORTHERN.—Gross earnings for the week ended March 14, 1908, decreased 21 per cent., as compared with the corresponding week in 1907.

LAKE SHORE ELECTRIC.—Charles D. Barney & Co. and the Guaranty Trust Co., of New York, have offered at 87, yielding slightly over 6 per cent., a block of the general mortgage 5 per cent. bonds of 1933 of this company, of which $2,160,000 are outstanding.

LEHIGH & HUDSON RIVER.—See Lehigh Coal & Navigation Co.

LEHIGH COAL & NAVIGATION.—It is probable that this company will offer $1,737,850 new stock at par to its stockholders which will be to the extent of 10 per cent. of their holdings. The proceeds are to be used for improvements on the Lehigh & Hudson River and for other purposes.

MINNEAPOLIS, ST. PAUL & SAULT STE. MARIE.—A semi-annual dividend of 3 per cent. has been declared on the common stock, raising the annual rate from 4 to 6 per cent.

NATIONAL LINES OF MEXICO.—See St. Louis, Brownsville & Mexico.

NEW YORK CENTRAL & HUDSON RIVER.—A quarterly dividend of 1¼ per cent. was on March 18 declared. This is a reduction in the annual rate from 6 per cent. which it has been since the last quarter of 1906 to 5 per cent., which it had previously been since 1899.

NEW YORK CITY RAILWAY.—Messrs. Joline & Robinson, as receivers of the Metropolitan Street Railway, have applied to the United States Circuit Court for permission to issue $3,500,000 receivers' certificates for improvements. They have also filed a complaint against the Metropolitan Securities Co. to recover $4,964,000 claimed to be still due the Metropolitan Street Railway from that company.

NORTHERN PACIFIC.—Freight earnings for February increased 18 per cent. and passenger earnings 5 per cent. Mail and express earnings decreased 25 per cent. Gross earnings increased 12 per cent. Comparison is with a month of terribly severe winter weather in 1907.

ST. LOUIS, BROWNSVILLE & MEXICO.—This company is reported to have bought from the National of Mexico, the Texas Mexican Railway, which runs from the international boundary at Laredo, Tex., east to Corpus Christi, 162 miles.

SEABOARD AIR LINE.—The voting trust formed in 1903 to last until 1910 is to be dissolved, on request of the receivers, on March 25.

SOUTH & WESTERN.—See Carolina, Clinchfield & Ohio.

SOUTHERN RAILWAY.—Directors of the Southern Railway have taken no action in regard to declaring a dividend on the preferred stock.

TEXAS & PACIFIC.—Gross earnings for the week ended March 14, 1908, were 23 per cent. less than in the same week of 1907.

WESTCHESTER TRACTION.—Edward G. Benedict was on March 14, by Judge Ward of the United States Circuit Court, appointed receiver of the Westchester Traction Company, which operates three miles of trolley line in Ossining, N. Y.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK
BRANCH OFFICES AT 375 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS WESTMINSTER, LONDON

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. *We give in our editorial columns* OUR OWN *opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.*

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette:

OFFICERS:

W. H. BOARDMAN, *Prest. and Editor*
E. A. SIMMONS, *Vice-President*
RAY MORRIS, *Secretary*
R. S. CHISOLM, *Treas*
I. B. RINES, *Cashier*
L. B. SHERMAN, *Western Manager*

EDITORS:

RAY MORRIS, *Managing Editor*
BRAMAN B. ADAMS
CHARLES H. FRY
FRANK W. KRAEGER
GEORGE L. FOWLER
HUGH RANKIN
BRADFORD BOARDMAN

CONTENTS

VOL. XLIV., No. 13. FRIDAY, MARCH 27, 1908.

We print this week in another column a paper on the strength and endurance of steel rails, by James E. Howard, Inspecting Engineer of the Watertown Arsenal, which is one of the most valuable contributions on rails that has been brought out in recent years. This is the first report of results obtained at the Watertown Arsenal under the increased appropriation. The bulletins which it is proposed to issue from time to time should perform important service in a branch of metallurgy which has been greatly in need of this kind of work.

The Pennsylvania Railroad, with that foresight and intelligent enterprise which characterize its management, has arranged to have freight claims paid more promptly. Not only has the force employed in the claim department been increased, but division freight agents have been empowered to settle small claims which are obviously valid, in cash, instead of waiting to have them audited and paid through the general offices. An attempt has also been made to hasten the settlement of claims in which other carriers are involved by addressing such correspondence more directly to the officers of such companies. This example of the Pennsylvania should be very generally followed. One great cause of dissatisfaction against the railroads has been the result of the methods too often adopted in handling claims. There have been vexatious delays in settlement. Oftentimes, whether because of inefficiency or shorthandedness of the claim department, lack of co-operation between different companies, or although we believe this to have been rare—actual intent to delay payment, it has seemed as though the railroad company was trying to avoid payment of the claim by discouraging the claimant. Not infrequently the vexation of a small shipper with a delayed claim has been increased and turned into bitterness by knowledge that his large competitor or his competitor with friends among the officers of the road has received prompt payment. It is easy enough to see the disadvantages which have come to railroads as a result of the legislation and agitation of the past two years. The advantages also should be recognized. One exceedingly important advantage, which is typified by this changing attitude of the railroads toward freight claims, is the fact that railroad managers now pretty generally recognize what many of them have in practice long denied—that railroading is a commercial business and that to succeed in it they must have satisfied customers.

The Interstate Commerce Commission in two cases just decided has established a through route and a joint rate between points which formerly lacked such opportunities for through shipment. A summary of these cases will be found in our "Interstate Commerce Commission Rulings" column. The more important of these is the case of the Cedar Falls & Iowa City (Electric) Railway against the Chicago & North-Western. Shippers at points on the electric line had no satisfactory through route from and to Chicago. It appeared that these points were not mere loading points serving one or two shippers, such as those involved in a similar complaint brought earlier by the Chicago & Milwaukee Electric Railway whose contention was denied by the Commission, but small local centers where general merchandising is done and the products of the countryside are concentrated for shipment and, on the other hand, coal, lumber and other commodities are brought in to supply the local needs of the immediately surrounding country. Under these circumstances the Commission ordered through routes and joint rates to be established by the electric line and the steam railroad between interstate points on their respective roads. This decision is likely to have far reaching effect in broadening the usefulness and increasing the importance of interurban electric railways, for it establishes the general principle that for interstate traffic any small community served only by an electric road which carries freight can have the benefit of reasonable joint rates over the electric line and its connecting carriers for through service. If past experience is a criterion, an ultimate result of this decision will be that electric lines will more and more be taken over by their steam railroad connections on exactly the same principle that branch lines of steam railroad have in the past been so extensively acquired.

One of the fundamental questions between employer and employed seems to be coming slowly but steadily to a focus in the case of the New Haven and its shopmen, to the number of some thousands. Forced, like other companies, to sharp economies, that corporation gave notice some weeks ago of a general scheme of piece work in its shops to go into effect March 10. The object was to secure the greatest efficiency in shop labor, to adjust wages to that efficiency and, probably, also to get rid, sooner or later of a class of shop workers described in the vulgate of shop toil as those who "lie down on their jobs." Representatives of the shopmen's unions met the general manager recently and are understood to have stated curtly and unqualifiedly that they would resist the new order; and, although the order has been suspended until March 28 the company is reported to be equally firm in enforcing it then. The policy of the unions of equalizing wages in the same classes of workmen and sinking the individual in the wage scale seems to be the only ground upon which the New Haven shop unions stand

and no question of breach of contract is raised. It looks therefore now like a head-on collision between the right of the New Haven company as employer to fix the *form* of its labor and the union policy—as the union sees it—of resisting the form. Legally, of course, the union has a right to reject such a form which, in fact, determines the nature of the job. But in that larger domain of bed-rock equities in which both employer and employed must appeal to public sentiment it will be interesting, should both sides remain firm, to see where a mere policy aimed at securing "dead level" wages comes out as against the basic right of the employer to an efficiency scale. But we must not forget that there is an Olympian judgment seat at the federal capital where such a conflict of fundamentals can be assuaged by official search warrant into corporative "misconduct." President Mellen may yet be informed by the voice of authority that he mustn't order piecework so long as the New Haven system includes watered trolleys or holds stock in the Boston & Maine.

BALLAST AND TRACK SURFACE.

In considering the papers on track and ballast, published in the *Railroad Gazette* March 13, it must be kept in mind that it is not possible to make general statements as to the value of particular kinds of ballast, or particular methods of track work, which will be true for all roads, or even for all roads in the same territory. Track that will stand up for two years without resurfacing under slow traffic will not last six months under high speed traffic. The divisions of which Mr. Rettinghouse and Mr. Auerbach are in charge are main line, but the density of traffic is, for example, not comparable with that on road beds within the limits of New York City. At one point on one of these lines, the substructure consists of stone blocks on which is a layer of broken stone, while the ballast proper is large sized, silicious limestone from Clinton Point. The rails are 100-lb. section and shoulder tie plates ⅝ in. and ½ in. thick are used. Yet this track will not maintain line and surface a year. Mr. Rettinghouse recommends stone ballast in sizes from 2 in. down, including a certain proportion of dust. The value of such a mixture depends on the quality of the stone. The dust of certain rocks forms too thick a mud to wash down to subgrade and the result will be a churning track. The depth of ballast to use also depends on local drainage conditions and overhead clearances. He recommends a mixture of three parts sand and five parts coarse pebbles in gravel ballast. Sand washes out easily unless water be prevented from flowing through it. It certainly has a tendency to squeeze out under heavy and fast traffic. The statement that gravel ballast can be maintained more cheaply than stone ballast is generally true. Yet the standard of track to be maintained, the kind of traffic, and the cost of each sort of ballast, must determine this for each place. There are divisions where the use of stone ballast would be as absurd as the use of gravel would be on others. More delicate surface can be obtained on gravel ballast, but it is more difficult to hold it.

Cinder ballast makes excellent track for light traffic until its structure is too far broken down. It has the proper resiliency to make an easy riding track, and it drains freely. It lasts about three years, but then begins to churn. As Mr. Auerbach says, it makes a good basis for gravel ballast; the layer should be about 6 in. thick. It has the advantage of mixing well with other forms of ballast. All ballast will let water through unevenly, which is Mr. Auerbach's criticism of cinder ballast on a new fill. New fills will settle somewhat, but the fill itself and not the ballast is at fault if rain falling on the area of the track alone will cut it away. Ballast is not intended to shed water; its function is to hold up the track and give the water every opportunity of soaking through and getting away somehow and anyhow, so long as it gets away quickly. His suggestion that 10 per cent. of clay be mixed with gravel is hard to understand, except under very light traffic. To be sure, if the surface of such ballast were so water tight as not to let in any water and so keep the bottom of the ties dry, it would be most desirable from the point of view of tie maintenance, but under heavy traffic such ballast would not hold its shape, and the idea is exactly opposed to the required porousness just mentioned.

Mr. Auerbach says that, except on rock ballast, track should never be raised out of face. Although in gravel and sand ballast track can be well surfaced by lifting only at centers and joints, a smoother riding track can be obtained in some ballast by lifting the whole track several inches, and this makes it easier to renew ties. On some divisions, the amount of a section which the gang could raise in a year has been taken as a rough measure of the efficiency of the gang. Part of the section would be raised out of face when repaired, and the rest would be surfaced and lined and tie renewals made not so freely. He says also, that no track becomes so easily center bound as rock. This is a matter of opinion. The statement has been made by one officer that he never had a case of center binding in rock ballast, and only a few in gravel or cinder. His practice is to tamp hard under the rail and for 16 in. each side, and to fill in snugly in the centers of the track, driving stone under at that point with a tamp pick to make sure the ballast is up against the bottom of the tie. As to lining track before raising, this depends on how much lining is necessary. Of course if the track is a foot out of line, it is a waste of time to raise it first. The lining and surfacing should be carried on as nearly as possible at the same time. Mr. Rettinghouse speaks of the difficulty in getting good section foremen because wages are too low to tempt good men. The remedy is to hunt up promising material and give bonuses, which need not be large enough to make any material difference in maintenance cost. Much can be done for a division by paying 10 or 12 section men $5.00 more a month.

THE MASSACHUSETTS MERGER REPORT

In these times when the axioms of political economy seem to have turned turtle, and radical speech as well as radical law is turned loose against railroad corporations, it is pleasant to hear one clear call to conservatism and common sense emanating from an official state body. The majority report of the Massachusetts Commission on Commerce and Industry is one of these comforting exceptions to the rule. It is to be sure but a special commission with a single year of legal life which has already expired by statutory limitation. But it has lived long enough to inject a clarifying stream into the turbid whirl of a railroad situation in Massachusetts where politics tipped with demagogism have been confusing alike policies and principles. From a commission that included in its membership such a name as that of Charles Francis Adams was to be expected not only an analysis of the local problem, but an exposition of certain broader principles as applicable to other states as to Massachusetts. The report has, in fact, this double character.

Taking up first certain general principles of the report it is important to notice that it places in the foreground not the penalizing of the New York, New Haven & Hartford Railroad, nor, on the other hand, the promises of that company to make certain specific improvements should the merger with the Boston & Maine be conceded. In place of such penalties and promises the report substitutes the broader and deeper question of the larger public policy for the state, of the merger as an ultimate fact. It is the long look ahead as contrasted with the near and superficial vision filled with the doubts, the passions and the prejudices of the short-sighted onlooker. This calm, dispassionate long distance reasoning is just the sort that our fevered times need. Everywhere, even in mentally well-endowed Massachusetts, is heard the "anti-monopoly" and not much less often the "anti-railroad" cry. A good many of the western and southern railroad commissions, even under the chastening experience of hard times, doubtless charge them up still to the railroads and look on the roads only as objects of punishment. It were well could such bodies, and higher authorities as well, catch the spirit of the Massachusetts commission report.

The commission so far recognizes the existence rather than the value of the anti-monopoly cry in Massachusetts as to combat it by the geographical facts. It shows what the briefest study of the railroad map of New England will show, that the New Haven and the Boston & Maine are connected and not competing systems. Perhaps, in the existing temper of public sentiment in Massachusetts it was not prudent, but the commission might have gone much further and shown certain absolute benefits of monopoly as represented by New England experience. In an editorial article (July 20, 1906, "The Outworkings of Railroad Monopoly") we set forth the facts. In brief, southern New England has had in the New Haven system a complete railroad monopoly made up largely of competing lines consolidated. Northern New England has had in the Boston & Maine a qualified monopoly due also to consolidation of competing lines. And between, has been the Boston & Albany, not a monopoly. In these three systems the variations downward in freight and passenger rates during the 10 years, 1896-1905 inclusive, were essentially in inverse ratio to the monopoly feature. Allowing for change of rates due to absorption of the New England by the New Haven and of the Fitchburg by the Boston & Maine, the New Haven's average freight rate fell during the ten years a little more than 3.8 per cent.; on the Boston & Maine a little less than 4.6 per cent.; on the Boston & Albany a little more than 1 per cent. But had the comparison been made for 11 years the New Haven's reduction would have been more than 9 per cent. Or, taking the Fitchburg merger (1900) as the date point, the New Haven freight rate fell during the five years .07 cents, while the Boston & Maine's rose .02 cents and the Boston & Albany's rose .10 cents. In passenger rates during the 10 years the New Haven showed a decrease per passenger mile of a little more than 7.3 per cent.; the Boston & Albany a little less than 6.3 per cent., and the Boston & Maine about 1.7 per cent. But public feeling in Massachusetts is probably more responsive to the "connecting systems" argument than to any returns based on monopoly outworkings in New England. It is to be noted, however, that elsewhere in the report the commission declares that "a monopoly in the case of a public service corporation has no necessary tendency to injure the public. On the contrary it may benefit it and the question in every case is purely one of expediency to be examined on its own merits."

Another point of wide and national interest is the finding of the commission on the question of allowing prosperous public service corporations to issue new stock at par. In Massachusetts prior to 1871 railroad stock could be offered stockholders at par; from 1871 to 1878 it was to be sold at auction; from 1878 to 1893 it could again be offered at par, and since 1893 it and new street railway stock have had to be issued at or above par, but at market price as fixed by the state railroad commission. The fifteen years' test of the law convinces the special commission that the old "par" plan is sane and expedient. The commission's main argument rests upon the theorem that the compulsory market price establishes a new par which the state must adhere to as a basis of regulation. Probably it would be fairer to say that it establishes really two "pars" with very confusing results to the relative rights of old and new stockholders when it comes to a matter of state regulation, especially if based on dividends. The commission also asserts that the "market price" law has deprived the state of the new capital needed for the development of her transportation systems. The subject has been and will always be a complex one with arguments on both sides, and it becomes especially perplexing in a period of rapidly fluctuating and falling values—perplexing not only to the state, but to the corporations. For example, the New Haven company in its last annual report practically announced a new issue of stock at $125 a share, and rights to the stock "to be delivered when as and if issued" were freely sold in the market. A rapidly falling market compelled the company to drop the plan and an issue of 6 per cent. debentures was substituted. From both the public and corporative viewpoint evidently an element of opportunism thus enters the question, resting on stable or fluctuating values. But what cannot be gainsaid as a piece of objective and telling evidence is the unqualified approval of the "par" plan of issue by an intelligent commission in a state whose policy for fifteen years has been in favor of the market value rule.

Turning from the broader meanings of the report to those features which bear specifically upon the merger a long and affirmative argument can be condensed into a few points. The New Haven is a New England corporation in organization, operation and interests. Solidarity with the Boston & Maine spells not only better control of traffic as against outside interests, but better service to the New England public, directly in operation, more remotely in improvements, especially on the Boston & Maine. The actual ownership already by the New Haven of what amounts to a controlling interest in Boston & Maine shares raises obstacles almost or quite insuperable to any plan for diverting such ownership, no matter what the courts decide—and the commission might have added that a final decision of the courts on the serious constitutional questions involved would probably be a matter of years. Almost the same line of reasoning holds good in the matter of the New Haven control of its Massachusetts trolleys. Finally, the financial ability of the New Haven to "handle" the Boston & Maine is certified by the commission's own experts. Their report is based upon the returns for the last fiscal year ended June 30. It might have been better if they had referred to certain changed fiscal conditions since. But if the New Haven has dropped in earning power so has the Boston & Maine, and what may be called the financial ratios of the two companies have remained substantially constant, or, if changed, the variation has been in favor of the New Haven. Incidentally may be noted in the report the first official statement showing the size of the New Haven's trolley system in Massachusetts with its sixteen lines, 565 miles of track, $11,626,200 of capital stock, $6,360,000 of funded debt and $3,234,924 of loans and notes payable. These street railways represent a fifth of the total mileage and about a sixth of the capitalization of the Massachusetts street lines, showing the magnitude of the problem of the proposed severing of the connecting link.

The proposals for safeguarding the merger of the two large railroad systems, which combined, create a unique and firm railroad monopoly in the six New England states, are naturally the real nucleus of this important report. They can be summarized almost in a single sentence. They allow well nigh free control and operation by the New Haven of the Boston & Maine—the localization features not being important—but subject to some pretty radical restrictions based on new and contingent conditions. Those restrictions are twofold: (1) The right of the state, if the merger in a public sense after five years is unsatisfactory, to buy in the New Haven's Boston & Maine shares, and (2) suspensive repeal of the voting power on Boston & Maine shares if control of the New Haven itself passes to an outside interest. On their face these provisions look severe; striking at a principle of ownership and opening a vista of future legislative interference. But five years, barring a "long drag" of hard times, seems long enough for the swift policy of President Mellen to try out the merger, and, under the prospective as well as existing state of public feeling in New England any transfer of the great property seems extremely remote. President Mellen, in his later letter to Governor Guild seems, in fact, to have practically accepted the commission's plan. To the twofold conditions named of Boston & Maine control, should be added a third one suggested by the commission for control by the New Haven of its Massachusetts trolley system by a Massachusetts corporation in which the state shall be represented on the board of directors with provision for sale of control if the plan after ten years works out badly for the public. This applies to the trolleys substantially the same policy as that outlined for the steam railroad merger and with the same arguments in its favor.

The brief report of the minority of two in the commission, one of them a "labor" representative and neither of them entering fully into its deliberations, may be dismissed with short shrift. It is hardly more than a variation of the familiar "anti-monopoly" and "special privilege" pleas coupled with charges against the methods of the commission the high character of whose majority furnishes alone prompt vindication. It is too early to forecast what effect the report will have on the Massachusetts legislature. But at least that body has now before it a working hypothesis for a solution of the merger question and a defined plan supported by constructive criticism where before have been crude utterance and frothy conflict.

The Belgian State Railroads have suffered the common railroad fate in the last year of an increase of expenses out of all proportion to the increase in gross earnings. For the last four years earnings have increased steadily: 7 per cent from 1904 to 1905; 4½ per cent. from 1905 to 1906, and 2.7 per cent. from 1906 to 1907. But the net earnings remained nearly uniform in the first three years, and last year fell 11 per cent. below those of 1906, in spite of an acquisition of a private railroad which added 3 per cent. to the fixed charges. The surplus over charges has fallen from $2,372,000 in 1904 to $1,856,000 in 1905, and $1,378,000 in 1906; while there is a deficit of $914,500 in 1907. In a country like Belgium, a large part of the production of which competes with other countries for a foreign market, it may be policy for a state railroad system to keep its rates close to cost, to support industry; but a loss which must be made good by taxation can only be regarded as a calamity. The proportion of expenses to gross earnings has grown from 60.03 per cent. in 1904 to 62.60 in 1905, 64.07 in 1906, and 68.61 in 1907. The Parliamentary Committee considering the matter estimates an increase for 1908 of 16 million francs in gross earnings and a further increase of 23 millions in expenses, which would bring up the percentage of expenses to 72.87 per cent.

Train Accidents in February.

Our record of train accidents occurring on the railroads of the United States in February, 1908, includes seven collisions and six derailments. The month of February has broken a long record in that it has furnished no especially prominent accident, using the term "prominent" in the sense with which readers of this column are familiar. It will be recalled, of course, that under the method now used in preparation of this record, accidents which two years ago would have been included in the list are now left out; but even on this basis there have been until now very few if any months in the past ten years in which the most serious accident did not result in five or more fatalities. The causes of this shrinkage are, in a sense, negative, and may be briefly comprised under two heads;

a month in which there was little severe winter weather and that in a restricted territory, and a falling off in traffic. The diminution of traffic means not only fewer trains, but a better average quality of men managing those trains; and the men, whether experienced or inexperienced, working under less severe conditions. The two most serious accidents of the month were each caused by a broken rail. The derailment by this cause of the three rear coaches of Southern Pacific passenger train No. 3 near Forest Grove, Ore., resulted in the death of three passengers and injury to 23 other passengers. As usual, our record is based mainly on accounts published in local daily newspapers.

Of the nine serious electric railway accidents reported in the newspapers as happening in the month of February, four resulted in fatal injury to one or more persons; namely, Chicago, Ill.; Hackensack, N. J.; Cambridge, Ohio, and Toledo, Ohio. The Toledo accident caused eight deaths and injury to ten other persons. It was a collision between a passenger train on the Cleveland, Cincinnati, Chicago & St. Louis and an electric car on the Toledo & Western.

NEW PUBLICATIONS.

The Elements of Railroad Engineering. By William G. Raymond, C.E., LL.D., Member American Society of Civil Engineers, Professor of Civil Engineering, and Dean of the College of Applied Science, State University of Iowa. 405 pages; 5½ x 9 in.; 107 figures, 18 plates. Cloth. Price, $3.50. John Wiley & Sons, New York; Chapman & Hall, Ltd., London. 1908.

The book at hand is Volume 2 in a series of three works on railroad engineering in preparation by Dean Raymond. Volume 1, which is to deal with railroad field geometry, and Volume 3, a railroad engineer's field book, have not yet made their appearance, but it should be observed that the three are intended to go together and supplement each other. This fact is important, for it answers what might possibly otherwise be a criticism—that the book on "Elements of Railroad Engineering" covers a tremendous amount of ground and that it is, therefore, impossible for it to handle quite enough of any one topic to entirely complete that topic and put it in shape for use by a practical man. Viewed as one of a series of books, however, and presuming that the other two volumes will complete the stock of detail working knowledge required by the field engineer the work at hand is admirable.

Perhaps A. M. Wellington did more than any other one man to impress upon the minds of railroad engineers that their work was a means and not an end, and that the successful engineer must keep always in mind the cardinal principle that he was building a railroad to haul freight and passengers and to pay interest on its charges and make some profit for its owners. Dean Raymond does not discuss the economics of railroad location with anything like the detail of Wellington, but he keeps the fundamentals perfectly clear in the mind of his reader. So far as the main scope of the work is concerned, it may be said that the author has brought Wellington up to date better than anybody else has done He was probably wise in not attempting, himself, to handle, in one volume, all the detail necessary for practical working. A volume big enough to hold this is too big to carry around, and the information contained in it is likewise too big to carry around. The author therefore adopts the expedient of giving principles with quite remarkable clearness, and then of supplying references (not too many of them, either,) to the books that the engineer in the field really ought to read to complete his researches.

The author says in his preface that a railroad with its rolling stock and buildings constitutes a manufacturing plant which its owners operate in the manufacture and sale of transportation. The layout or arrangement of a modern manufacturing plant is as much an item of design as is each individual machine or process, hence the book attempts to describe the fixed portion of a railroad plant and to give the underlying principles of the design of its layout.

After treating of the inception of a railroad enterprise, of the formation of companies, of stocks, bonds (in which the minor error is made of saying that the promises to pay are generally in units of $100 instead of $1,000), of engineers' estimates, construction, failures, overcapitalization, stock watering, valuation, the relation of the railroad to the public and the duty of the engineer, the author proceeds to the more technical parts of the work. There is a chapter on alinement, entirely descriptive and mathematical, a chapter on rails, in which manufacture, chemical composition, form, life of rail and specifications and inspections are touched upon; a chapter on rail fastenings and joints, on ties, ballast and roadbed, on culverts and bridges, turnouts, side tracks and yards, elevation of the outer rail, signaling, the locomotive and its work, locomotive and grade problems, railroad expenditures, effect on operating expenses of changes in the number of trains when tonnage remains constant, etc. Thus it will be seen that the book is really a mixture of descriptive engineering and of operating and engineering economics.

It is very clear that the author's aim throughout has been to give only salient points, and so to express them as to clear up absolutely the real and vital theory of each topic in the engineer's mind. In this he has succeeded extremely well, and we regard the work as being useful and important.

Bond Offerings Indexed, a Directory of Miscellaneous Bonds, showing where they possibly may be bought or sold. By Roger W. Babson, by whom the book is also published, at Wellesley Hills, Mass. 1908 Edition 284 pages; 4 x 6½ in.; leather. Price, $5.00, with reductions for large orders.

This pocket book in a highly specialized field is of very great utility. It purports to give a complete list of all bonds, except municipal bonds, offered during 1907 in this country, together with the names of the bankers offering them and the high and low prices at which the bonds sold during the year. We know of no other way in which bond offerings can so readily be ascertained and checked as by the use of this book. Mr. Babson is well known for his statistical work in preparing card catalogue descriptions of bonds and in issuing many other records and aids to the bond business, and we have considerable confidence in the accuracy of his results. Entirely apart from the purposes for which the book is issued, it throws an interesting light on the bond issues which are placed before the American investor each year and upon the necessity of dealing with careful and trustworthy banking houses. Without attempting to count the offerings, but estimating the whole by a count of a few pages, it is apparent that there must be over 4,000 offerings listed in this book, which, as stated, excludes municipals.

Rail Circuits and Treated Ties.

Jamaica, N. Y., March 15, 1908.

TO THE EDITOR OF THE RAILROAD GAZETTE:

I have read with much interest your editorial on the above subject in your issue of March 13, 1908. I note that you say that "Signal engineers claim recently to have established the fact that there is a storage battery effect from these ties, but it does not interfere with the working of the circuits under the renewal conditions mentioned." I wish to take exception to this statement. At one time I had charge of a track-circuited section about 3,500 ft. long in which there was a cut section. All the ties were creosoted. The cut section merely broke the circuit for the track in its rear but did not shunt it. During the summer the signal governing the section stood clear after a train passed the cut section. Investigation disclosed the fact that the ties were acting as storage cells. Between trains the tie storage battery was charged by the track battery. When the battery circuit was opened by the cut section relay the ties discharged into the rails and picked up the main track relay clearing the signal. The trouble was remedied by adding a shunt to the cut section. This happened several years ago.

W. H. ARKENBURGH.

[1] Abbreviations and marks used in Accident List

re........Rear collision.
bc.......Butting collision.
xc.........Other collisions: as at crossings or in yards. Where only one train is mentioned, it is usually a case of a train running into a standing car or cars, or a collision due to a train breaking in two on a descending grade.
b.........Broken.
d.........Defective.
dr.........Defect of roadway.
eq.........Defect in car or engine.
n.........Negligence.
unf.......Unforeseen obstruction.
unx.......Unexplained.
derail.....Open derailing switch (negligence of engineman or signalman)
ms.........Misplaced switch.
acc. obst. Accidental obstruction.
malice....Malicious obstruction of track or misplacement of switch.
boiler.....Explosion of boiler of locomotive on road.
fire.......Cars burned while running.
Pass......Passenger train.
Ft.......Freight train (includes empty engines, work trains, etc.).
*Wreck wholly or partly destroyed by fire.
†One or more passengers killed.

The Engineering and Maintenance of Way Association Convention.

The ninth annual convention of the American Railway Engineering and Maintenance of Way Association was held in the Auditorium Hotel, Chicago, March 17, 18 and 19. The meeting was the largest the association has had, 266 members being in attendance. The total membership is now 650; there were 106 new members added during the year, the net gain being 78. The officers for the ensuing year are: President, Walter G. Berg (Lehigh Valley, First Vice-President; W. McNab (Grand Trunk), Second Vice-President; L. C. Fritch (Ill. Cent.); Secretary, E. H. Fritch, re-elected; Treasurer, W. S. Dawley (Mo. & N. Ark.) re-elected. Directors for three years, C. S. Churchill (N. & W.) and E. F. Wendt (P. & L. E.).

President A. W. Johnston (N. Y. C. & St. L.) called the meeting to order at 10.20 a.m., March 17. His address congratulated the association on the record of progress made during the nine years of its existence and the influential position it occupies in the railroad and engineering world. Reference in detail to the work of various committees was prefaced by comment on the condition of public mind which has been created by official reports of railroad accidents. "The make-up of such reports does not enable the ordinary reader to differentiate between those accidents arising from defects in railroad structures or equipment and those occurring from neglect or disobedience of employees, nor is the public rightfully informed as to the casualties to persons not employed in train service, so that the impression has gone forth, in spite of the increasing efforts of the railroads to promote the safety of travel, that the companies are indifferent and indisposed to heed suggestions or commands from authoritative sources. The answer to this may be found in the reports of committees of this association and of allied associations dealing with railroad problems. Among the questions particularly affecting public travel, more prominently discussed in legislative and other official bodies and by the public press and made the subject of serious inquiry, are those dealing with secure permanent way and efficient train protection." The work of the committees on Rail and on Signaling and Interlocking were particularly referred to in this connection, and also because these topics have been the subject of special consideration by the American Railway Association.

Other special topics for association work which were discussed in the address were the impact tests to determine the effects of moving loads on bridges—investigation of the question of flat spots on wheels in co-operation with the Master Car Builders' Association—a special committee having been appointed for this purpose, and the troubles from brine drippings from refrigerator cars, with the resultant bad effect on bridges, rails and particularly on signal circuits. This last evil, caused by brine, has only recently been brought to the attention of the association. Since it may have a serious bearing on the question of safe train operation it is worthy of careful inquiry by a committee.

DISCUSSION OF REPORTS.

Uniform Rules.—The committee submitted as its report a set of rules governing supervisors of signals. These were printed in the *Railroad Gazette* last week in the synopses of reports. The ten rules were adopted without change except a slight modification of wording in No. 9. Some objection was raised to the use of the word "foreman" in Nos. 5 and 6, because men maintaining signals are not always in charge of a gang foreman and may report direct to the supervisor. It was pointed out by the chairman of the committee, however, that these rules followed the form of others already adopted and printed in the Manual of Recommended Practice, and a change of the character desired would have to be made there also. A motion to change the wording was lost.

Two suggestions were made for points to be considered by the committee during the coming year: (1) Regarding the responsibility of the supervisor of signals in connection with the proper maintenance of switch points as affected by the working of signals, and (2) the responsibility of the supervisor with reference to the maintenance of insulated rail joints.

Signaling and Interlocking.—The committee changed the wording of the two conclusions printed in Bulletin 94 to read as follows:

(1) That the Requisite Indications, Exhibit No. 1, are adequate, permit a uniform system of signaling, are not in conflict with existing systems, and are recommended to the American Railway Association for approval.

(2) That the Requisites of Installation as set forth are practicable, form an adequate and proper basis for the design of a system of aspects by which the requisite indications may be displayed, provide an excellent means for attaining a uniform, universal system of signaling, and are, therefore, indorsed by this association and submitted to the American Railway Association for such action as may be necessary to enable roads desiring to use them to do so with the approval of that association.

The chairman also stated that this report was submitted by letter ballot to the Railway Signal Association, and was adopted, and that the requisites of installation were those of the Standard Code, with such changes and additions as the committee deemed essential.

Under the requisites of installation for the telegraph block system, light was asked on the paragraph reading: "A distinctive position of the arm for the caution approach indication."

The chairman explained that it was simply the use of a signal in the 45 deg. position for the distant signal, instead of a fish-tail arm standing at horizontal for caution—the same position of the arm as the stop indication for the home signal. The idea is to make the arm distinctive by position instead of by form.

Information was asked as to why no mention was made of disc signals in the requisites of installation for the automatic block system. It was thought by some that this omission might appear to discredit disc signals as good practice. In explanation it was stated that in order to get a uniform system of signals one form only could be used, and the semaphore, as the form generally used, was the one taken. All of the indications can be given with disc signals. It was pointed out that the Standard Code mentions only semaphores directly in its requisites of installation, discs being mentioned in a foot note and in the rules.

The requisites, "Adequate approach indications for all high-speed signals," which was one of the additions by the committee, occasioned considerable discussion.

Mr. Ewing (P. & R.).—Take a junction on a four-track railroad, where there are several routes, some high speed and one or more low speed, what does the "adequate approach indication for all high-speed signals" mean in a case of that kind?

Mr. Rudd (chairman of committee).—It would mean the distant signal for high-speed signals. Under these requisites of installation the interlocking signal would have a high, a medium and a low speed arm. There would be two "distant" arms for the high and the medium speeds.

Mr. Ewing.—As I understand it this method contemplates one blade for all high speeds. The one distant signal would give one distant indication for that high-speed route. There is no indication to the engineman as to what route he is going to take.

Mr. Rudd.—If there are two diverging routes of equal speed the second arm will govern both. He would get no indication in that case any more than when he comes to a terminal with a number of different ways of going from one signal to another. He gets an indication that he can proceed at a certain rate of speed. That is all he needs.

Following this there was considerable questioning and explanation concerning speed and route signaling, although attention was called to the fact that the 1907 Manual has signal arrangements and indications covering speed signaling, and the subject therefore is not a new one to the association.

W. C. Cushing (Pennsylvania Lines West) moved that in the requisite under interlocking signals reading "short arms and short range lights for all low-speed indications and dwarf signals" the words "short range lights" be stricken out.

Mr. Rudd explained the two-light system for speed signaling and the confusion that might result from having a long-range low-speed light. After some further explanation of the advantages of the short range light by other members the motion was put to a vote and lost.

Exhibit No. 1 referred to in the first conclusion was an outline of indications for a method of uniform signaling. Four indications were given under "stop," the fourth one being "stop within certain limits." This indication has been eliminated by the Railway Signal Association. It was included in this report by a vote of six to five of the committee because it conforms to present practice on a great many roads in respect to train order signals, although it is not sanctioned by the Standard Code. The reason for the practice is that the signal being placed in front of the telegraph office a passenger train, for instance, is allowed to pull by the signal far enough to do its station work conveniently. Discarding this indication necessitates providing a substitute. After considerable discussion it was voted to strike out this indication from the table.

The two conclusions proposed by the committee were then adopted.

Water Service.—The report of this committee consisted merely of a revision of the material in the Manual of Recommended Practice on the subject of quality of water, with methods of treatment and results obtained therefrom. These were adopted by the convention as printed, except for one slight change in wording in paragraph 11.

Buildings.—The conclusions on locomotive coaling stations were considered first. The first four having been adopted last year and reproduced in this report for convenience of discussion No. 5 was taken up first. This was adopted without discussion.

No. 6 covered points where the quantity of coal handled is small, it being recommended that the coaling be done directly from cars, or from cars to an elevated platform provided with a jib crane. Objection was made to specifying an elevated platform, the idea being that this would cost more than one not raised. The chairman pointed out that it saved in lifting the coal by the crane and saved time. However, by striking out this word it allowed any kind of platform to be used, and the conclusion was finally adopted in that form.

No. 7 read "At terminals where the daily consumption of coal does not exceed 75 tons, a locomotive crane with clam-shell bucket is desirable, provided that there is at such terminal other work that can be economically performed by the locomotive crane."

The question was asked why a limit of 75 tons was established for the locomotive crane, and considerable discussion followed regarding the advisability of setting capacity limitations for different devices and methods. Mr. Coburn, of the committee, said: "We feel that the association has given us a very difficult task. The coaling plant question is something which has not been thoroughly developed. There are a great many different kinds, and very few of the members have had a broad experience. We feel that it is going to be impossible for this association to agree on any satisfactory conclusions in regard to coaling plants. But we endeavored to meet the wishes of the association and prepared recommendations, and, as the minority report shows, we could not agree among ourselves. Referring to this particular point, it seemed to us that the locomotive crane was not a successful appliance where a large number of engines were handled or where they were liable to come in bunched. The experience at terminals has not been satisfactory. Another thing about the locomotive crane is that it provides no storage. If storage be provided, the cost of the plant is so heavy that its total cost, including interest and depreciation, and the cost of storage in cars, makes the cost of a locomotive crane excessive."

The first result of the discussion of this conclusion was to refer it back to the committee for further consideration, but this action was later reconsidered and a substitute conclusion adopted instead. This substitute, offered by Mr. Ewing, was: "At terminals, under certain conditions, a locomotive crane, with suitable bucket, is desirable, particularly where other work can be economically performed by the crane."

No. 8 read: "At terminals where the requirements are from 75 to 200 tons per day and a deep foundation is practicable, a 'balanced two-bucket hoist type' of coaling station is recommended." Mr. Coburn submitted a minority conclusion reading, "At terminals where the requirements do not exceed 200 tons a day, when the desired storage is not so great that auxiliary buckets are necessary and where a deep foundation is practicable, a two-bucket hoist is recommended." His reason was that he did not consider the two-bucket hoist suitable for large storage. It was moved to adopt the minority recommendation, changing "200" to "300," however; in this form the conclusion was adopted.

The last conclusion recommended, for plants larger than previously provided for, the trestle type where conditions permit, and where not permissible, a mechanical conveyor type. The minority recommendation was primarily for the mechanical conveyor plant. Some discussion of the relative economy of the two types ensued and the majority recommendation was adopted.

It was then decided to consolidate conclusions 6, 7, 8 and 9 with No. 5, making them sub-paragraphs marked a, b, c and d.

On the subject of Reinforced Concrete for Roundhouses, four conclusions were submitted. The first, providing that reinforced concrete should be used below the floor where it is cheaper than plain concrete, was adopted without much discussion.

The second, reading "The additional security against interruption to traffic warrants the construction of a roundhouse with a reinforced concrete roof," occasioned considerable discussion. Asked in what way the roof of the roundhouse might insure additional security against interruption to traffic, Mr. Coburn explained that the committee had in mind the question of fire. "Our idea was that the difference between the cost of the two types of houses shown was so slight that the matter should depend entirely upon the results to be gained from the use of each of the types; that while the figures showed that the reinforced concrete house was cheaper, still the advantages was so slight that there must be some other advantage to warrant the additional first cost, and we thought the saving from danger from fire was well worthy of that cost." It was then suggested that the words "from fire" be inserted after "traffic," which was done.

Mr. Schwitzer, of the Canadian Pacific, told of the troubles they had had with the reinforced concrete roofs on the roundhouses of this material on their line. "We put up several of these houses and came to the conclusion that they are a failure for the reason that steam makes such heavy condensation inside. We had to put slabs under the roof to prevent the bad effect of the moisture in extremely cold weather. Because of this, we have practically given up altogether the idea of concrete. We have had six or eight houses with the protecting slabs made of expanded metal and cement plaster. The fumes seemed to get through to the expanded metal and eat it out, and I expect it will be only a short time before the main roof itself is acted on in the same way. We also find it extremely difficult to make the roof water-tight."

It was suggested to omit the conclusion, but after some further discussion it was changed to read, "The additional security against interruption to traffic from fire warrants the serious consideration of the construction of a roundhouse with a reinforced concrete roof," and in this form it was adopted.

No. 3 read, "When the roof is concrete, the columns, except those supporting doors, should be of the same material." This was amended by striking out "except those supporting doors."

No. 4 was adopted as printed.

The committee asked that the topic of "best method for smoke removal, ventilation and heating of a roundhouse" be referred back for further investigation and report.

On the use of movable or fixed cranes the conclusion offered by the committee was: "Jib cranes attached to outer posts alongside of a number of pits in roundhouses, or, in the case of large roundhouses, a trolley hoist working around the outer circle, capable of handling two tons, should be installed in such roundhouses as may be designated by the motive power department as requiring such appliances for light locomotive repairs." The committee asked that this be substituted for the present paragraph in the Manual on the subject of air hoists and portable goose-neck cranes. The conclusion was adopted and the matter of the substitution referred to the committee.

On the last topic—best arrangement of windows and roof lights, and proper ratio of light area to floor surface—two conclusions were offered, as follows:

(1) The disadvantages of roof lights in roundhouses are so much greater than their advantages as to make them undesirable.

(2) Windows in the outer walls of roundhouses should be made as large as practicable and contain the largest glass or light area consistent with the requisite strength. In general, the lower sill should be not more than 4 ft. from the floor, and only sufficient space left between pilasters and sides of window frames, and girders and window heads, to properly secure the window frames. Windows or transoms as large as practicable should be provided over all doors where locomotives enter.

Both were adopted without change.

Iron and Steel Structures.—The report of the sub-committee on Impact Tests was presented first. There was no discussion

The first subject considered in the regular report was Classification of Bridges as to Safe Carrying Capacity. The five conclusions of the committee were included in the synopses of reports printed last week. Mr. Greiner (B. & O.), Chairman of the committee, in presenting the report said: "The committee considers this question of safe carrying capacity of bridges one of the most serious problems which have been placed before it. The determination of what is the maximum load which can be operated over an old bridge is a question of serious moment. We have had some difficulty in coming to any positive conclusions, that is, conclusions which can be shaped in such manner as to be worthy of presentation to the association. One difficulty is the manner in which different engineers are accustomed to analyze a structure. Some will take impacts in considering the unit strains, others will not; and when one engineer says that he will allow a strain of 15,000 lbs. per sq. in. and another one says 26,000 lbs., there is ambiguity and it needs explanation. In our report we have followed the analysis that is outlined in our bridge specifications, wherein unit stresses are based upon the assumption that impacts are being taken care of in the enlarged stresses. That will account for the apparently high unit stresses mentioned in our conclusions. In presenting these conclusions we do so with considerable hesitation. There is a fear that they may be misinterpreted or misquoted or misused. We have therefore prepared an additional conclusion, No. 6.

"(6) It is of the utmost importance that the carrying capacity of a bridge be determined only by a bridge engineer of sound judgment and experience in similar questions, and the foregoing conclusions are based upon this assumption."

The first three conclusions were adopted without much discussion. No. 4 read, "When the span is less than 200 ft., all controlling factors given in Article 2 good, the mathematical analysis made in accordance with the American Railway Engineering and Maintenance of Way Association specifications of 1906, using full specification allowances for impacts for regular service fast speed, and one-half of these impact allowances for slow speed, then, so long as the controlling factors remain good, unit strains in tension to the extent of 26,000 lbs. in structural open-hearth steel and 22,000 lbs. in wrought iron, will not, in themselves, be sufficient justification for suspending traffic or condemning the structure." The question was asked, what was meant by "slow speed," and this brought on a long discussion on the advisability of stating at what speed the reduction in impact allowances should occur. The committee thought it should be left to the judgment of the bridge engineer, this being one of their reasons for proposing conclusion No. 6. Some members thought the clause might be changed to make the reduction in impact allowance proportional to the reduction in speed. The paragraph was finally amended by striking out "slow" and making the clause read "for speeds not exceeding 15 m.p.h."

Conclusion 5 was adopted without discussion, and the new conclusion, No. 6, likewise.

The next topic was Classification for Operating Purposes, and the conclusion, recommending the acceptance of the plan outlined, was adopted.

The portion of the report on Inspection, Reports and Records was referred back to the committee for further consideration, at its request.

A topic considered by the committee, not mentioned in the report, was the length of flat spots on wheels. Chairman Greiner explained that the length of flat spots causing the rejection of a wheel by the rules of the M. C. B. Association is 2½ in. The effect of such a spot on a wheel under a 100,000-lbs. capacity car, moving at high speed, is very bad, and it has been recommended that the M. C. B. rule be changed to 1¾ in. The question has been considered by the Executive Committee of the M. C. B. Association and the subject referred to the Arbitration Committee of that association, with instructions to confer with a committee from the American Railway Engineering and Maintenance of Way Association. President Johnston designated the committee on Iron and Steel Structures to act in the matter.

A sub-committee was appointed, A. J. Himes (N. Y. C. & St. L.) being chairman, and he presented a progress report. At its conclusion he spoke of a design prepared by Prof. Benjamin, of Purdue University, for apparatus to determine the effect of flat spots. As the latter was present in the convention when the report was presented, the courtesy of the floor was extended to him for the purpose of describing the proposed method of test.

Ballasting.—The conclusion to this report, asking the adoption of the ballast sections for crushed rock, was accepted, after explanation by the chairman of the committee regarding the recommended change of slope from 1½ to 1, adopted last year to, 2 to 1

Wooden Bridges and Trestles.—This committee had framed a conclusion asking the approval of the Standard Specifications for Bridges and Trestle Timbers as good practice. But since its report was put in type, the announcement was received that on January 22 the Yellow Pine Manufacturers' Association adopted, with but slight modification, the Specifications for Structural Timber adopted September 1 by the American Society for Testing Materials. A committee was also appointed to confer with committees of the American Institute of Architects, the American Society for Testing Materials and of the Maintenance of Way Association for the purpose of reviewing the specifications and adjusting differences. This action indicates a desire to co-operate definitely in the effort to secure uniform specifications. Therefore the committee desired to withdraw its conclusion and asked that the work be allowed to go over for another year. The committee gave in the report the differences between its specifications and those reported by Committee Q of the American Society for Testing Materials. The list was as follows:

General Requirements Applying to Both Grades.

Committee Q allow dead timber to be used.

Committee Q have no specification regarding wind.

Committee Q allow sawing ¼ in. scant from given size, with loss in area of from 4½ to 10½ per cent.

Committee Q permit loose knots, except within 4 in. of the edge of stringers.

Committee Q permit knots in the corners of posts.

Grade No. 1.

Committee Q permit 5 per cent. less heart in stringers.

Committee Q permit knots over 2½ in. in stringers, if not within 4 in. of the edge.

Grade No. 2.

Committee Q require no limit to sap.

Committee Q do not give an alternative wane on two corners of stringers.

Committee Q allow knots up to 4 in. in 16-in. sides, and 3 in. in 12-in. sides, for stringers, caps and posts.

The convention was asked to discuss these differences in order that the committee might know its attitude relative to the various points of difference. The points were therefore taken up one at a time. Much time was occupied by this discussion. Dr. Herman von Schrenk, who is a member of the American Society for Testing Materials, as well as of the Maintenance of Way Association, was present, as was also Prof. Hatt, of Purdue University, and both gave full and valuable information on the points discussed. The net result of the discussion was that the convention expressed agreement with Committee Q on three of the five points under the first heading—General Requirements Applying to Both Grades—disagreeing on the first and fourth. It approved both points under the second heading, and disapproved the second and third points under the last heading.

The committee asked that the Revised Specifications for Piling be referred back for further consideration.

The matter in the report on Ballasted Floor Bridges was offered as information. The portion on Safe Unit Stresses was offered as a progress report, as was also the portion on the Preservation of Structural Timber.

A list of standard names for structural timbers was submitted, being the same as submitted last year. No change was made from the previous year, it having been decided from the year's investigations that no change was justified. In discussing the difficulty of distinguishing long-leaf, short-leaf and loblolly pine, Dr. Van Schrenk exhibited a number of samples of the last named, which, while true loblolly, in some cases were impossible to distinguish from other kinds of pines.

Two definitions were adopted, as follows:

(16) Ring Shake.—An opening between annual rings.

(17) Through Shake.—A shake which extends between two faces of a timber.

Track.—The first conclusion recommended that the elements of the split switch turnout from a tangent be computed according to the formulæ given in the report and as indicated by the table which had been worked out for various kinds of frogs. Objection was made that the formulæ contained errors; it was also suggested that the frog angle should be deduced from the sine rather than the tangent. A motion was therefore made that the frog angle be determined by twice the sine of half the angle divided into the radius; but after some discussion it was put to a vote and lost.

Mr. Cushing objected to the table containing such a large number of switch rails, there being seven. He therefore moved that the conclusion be referred back to the committee.

Mr. Stevens (P. & R.) thought the committee's method of getting the switch angle would introduce an appreciable error, as it assumed the switch rail to come to a point. There were other objections to certain features of the table, and after considerable discussion of these points Mr. Cushing's motion to refer back was adopted.

Conclusion 2 asked the adoption of the design of reinforced split switch shown in the report. Mr. Cushing thought it would be better if the committee prepared a specification rather than individual designs, and other members supported this view. The discussion was extended, and ended in referring the conclusion back to the committee.

Conclusion 3, asking the adoption of the frog design, was likewise referred back. The chairman of the committee called attention to the fact that the design showed a bolt at the end of the rigid wing rail, and he expressed the hope that members would incorporate this in their frog practice, as it would save money and much tightening of bolts. Some slight criticism of the design was offered before it was referred back.

Conclusion 4 was on the guard rail. The principal point of discussion was the clearance, which was put at 1⅞ in. The American Railway Association standard is 1¾ in., although many roads use 1⅞ in. Some members were in favor of making 1⅞ in. the standard of this association. It was pointed out, however, that this should not be done without conferring with the M. C. B. Association, as the latter's standard gage-points are made for a 1¾-in. clearance, and this, of course, is supported by the American Railway Association. A motion in favor of the 1⅞-in. distance was lost and the conclusion was referred back to the committee.

Nos. 5 and 6 were passed and No. 7 taken up. This had reference to the widening of gage on curves. The chairman explained that there was an error in the table calculations. The tables were therefore received as information. Mr. Ewing asked the committee what was the maximum excess gage it would be safe to have. The committee was unable to say, stating that it would be necessary to make some experiments on the effects of four-wheel trucks on widened gage before they would know.

Rail.—The committee asked the adoption of the conclusion to the report, which recommended the adoption of the form M. W. 1200 for reporting rail failures.

Mr. Cushing had made to the committee some suggestions for rearrangement of the form, and while these were not presented to the convention, he requested that they go into the Proceedings as a part of the discussion The conclusion offered by the committee was adopted.

Yards and Terminals.—The Recommended Principles of Practice for hump yards were taken up first. As the first ten of these were practically the same as already indorsed and published in the Manual, they were passed without discussion, except No 8, which provided for an air-brake testing plant in the departure yard Mr. Rhea (Penna. Lines West) told of a plant being put in the receiving yard of the P., C., C. & St L. at Logansport, Ind., at the request of the master mechanic, and they are well satisfied with it. After some explanation of the advantages derived, he made a motion that the conclusion be amended to include the receiving yard as well as the departure yard. The motion was adopted.

Conclusion 10, specifying the grades for the hump, was adopted, as were Nos. 11 and 12 Some members asked if the latter conclusion meant raising and lowering the track for winter and summer conditions. The chairman explained that it merely recognized that a higher hump is needed in winter, and where a hump is built for summer conditions it is necessary to raise it for winter conditions.

In No. 13, providing for a track scale, a space of 30 to 40 ft. was recommended as the distance it should be put from the summit. Objection was raised to this distance, some members thinking 90 ft. was better. A motion to strike out the reference to distance was carried, the conclusion then being adopted without other change.

No. 11, recommending that a No. 8 frog be the sharpest used in classification yards, was adopted.

The report stated that it had been suggested to the committee that 1,200 cars to be classified in 24 hours should be the minimum limit in a hump yard. Mr. Pfeifer (T. R. R. of St. L.), of the committee, who had made the suggestion, explained that hump yards require large switching crews on account of the great number of riders. A crew sometimes contains 18 or more men. Such a crew, to be economical, must be employed constantly. If there are fewer cars than that to be switched, the rate of switching will leave a large amount of idle time on their hands. His company has on its lines an ordinary gravity yard in which from 60 to 70 cars can be switched with a crew of three switchmen and an engineer and fireman. They have switched as many as 1,100 cars in one day, and the car breakage is not excessive. Having switched the cars that ought to be switched, a small crew can do some other yard work in addition to classifying, but there is no other kind of yard work which would require such a large crew. It was, therefore, as a measure of operating economy that the suggestion was made.

The conclusions on Yard Lighting were adopted without discussion, and also those on Freight Transfer Stations. However, questions were asked about the last one of the latter, reading, "where large amounts of freight are to be transferred, the use of power-driven covered traveling platforms, instead of fixed platforms, is suggested." The committee stated that, so far as they knew, no such installation had ever been made, except that something of the sort had been used as an emergency measure and worked well. It was therefore thought well to submit the idea to the association.

It was decided that this conclusion, and the one following it recommending freight handling machinery as being worthy of consideration, should be omitted from the Manual of Recommended Practice.

Roadway.—The conclusions on grade and curve improvement work inside cities, such as track elevation and depression, were considered first.

The first was on Organization. Objection was made to the provision of a special trainmaster and despatcher, as it was thought such matters could be handled better by the regular officers. The committee explained that it was the intention that the work should be handled entirely separately from the regular operation, assuming, of course, that it was large enough to justify such an organization; this had reference only to the territory covered by the work, as stated in the conclusion. The conclusion was therefore amended to have this part read: "A trainmaster, with a despatcher, in charge of the operation of traffic over the territory covered by the work in hand, may sometimes be required." With this change the conclusion was adopted.

No. 2 related to the handling of the work. J. A. Atwood (P. & L. E.) suggested that the paragraph should only distinguish between the work to be done by the company and that to be done by contract, omitting any reference in detail to the kind of work. He therefore moved to amend the conclusion by striking out such references, making it read:

"(2) The railroad company should handle with its own force all work which may interfere with the operation of the road. All other work which can be done without material interference with the operation of the railroad may be let by contract."

No. 3, reading "As far as practicable, all earthwork should be handled by machinery; that is, loaded by steam shovels and unloaded by plows, handled by cable unloaders and moved by spreaders," was amended by striking out everything after "machinery."

Objection was made to No. 4—"The best material to use for filling is sand"—on the ground that it was too sweeping to go into the Manual, which goes to all countries. And while it was admitted that sand unquestionably is the best material, it would be better to name the qualities which the best material should possess. Mr. Byers (Mo. P.) therefore moved to substitute for No. 4 the following: "The best material to use for filling is that which combines low first cost, ease of handling and stability."

This was adopted.

The last two were adopted without discussion.

Grade and Curve Improvement Work Outside Cities was next considered, there being nine conclusions. No. 1, reading "Establish the lowest gradient and lightest curvature which physical conditions and the present and prospective business of the road will admit," was adopted after changing "admit" to "warrant."

Nos. 2, 3 and 4 were adopted without change. No. 5, reading "Eliminate temporary bridges, etc., by the substitution of permanent structures in concrete and steel, wherever it can be done, having in view the formation of a continuous roadway on ballast," was amended by striking out everything after "structures."

No. 6 was accepted without change, and No. 7, which read "Provide separate tracks for work and traffic, wherever it can be done," was changed to read "Provide separate tracks for work and traffic where conditions warrant."

No. 8 was not changed. No. 9 was on organization: "The simplest organization is the best. Some one man should be in responsible charge of the work, with a staff of engineers under him, and enough supervisors to cover the work, who have full control of men, material and means for each section, with foreman and gangs wherever needed." The last nine words after "means" were changed to "necessary for the sections respectively under their charge," and the conclusion adopted.

Some criticism of the form of the conclusions was offered during the discussion. After their adoption by the convention the following resolution, offered by Mr. McDonald (N. C. & St. L.), was adopted: "Resolved that the committee be requested to recast the language of the conclusions so as to make them suggestive instead of mandatory, before publication in the Manual."

Masonry.—The committee had been instructed to revise the specifications for stone masonry and present them for final approval. As the changes made were slight, the specifications were indorsed by the convention without reading. No other matters in the report were considered.

Records, Reports and Accounts.—The conclusions on right-of-way maps were considered first.

The definition was adopted with one slight change in wording.

Conclusion No. 1 was adopted after adding the portion printed below in italics, and omitting the word "all" before "permanent."

(1) Right-of-way maps should show the state, county, township, town or city; the right-of-way alinement complete, *with particular reference to, and with suitable notation of, short and long stations;* the station plusses of the crossing of all important land or property lines and streets, with the distance to all permanent land or street corners; the angle which the center line of the road makes with property lines; the number of the right-of-way sheet; the points of the compass; the scale and date of the map; the boundaries of the several parts of the land owned by the company, and the width of the right of way, particularly at those points where the widths change; any additions of subdivisions of towns or cities, with numbers and sizes of lots and blocks and names of streets. It should also show all main tracks, side tracks and structures that were built in connection with the original construction of the road; the exact location of all crossings of steam, electric or other roads.

Conclusion No. 2 read: "On or near each part of the land on the right-hand side of each map should be shown the deed custodian's number; the name of grantor and grantee; mile posts, kind of instrument, date and book and page where recorded. This also includes reference to leases, franchises, ordinances and grants concerning the use of land." The words "references to" were inserted before mile posts.

No. 3 was amended by striking out the last six words of the following, as indicated by brackets:

(3) The original right-of-way map should be traced, and the tracing filed away for a permanent record of the conditions existing at the time the railroad was completed. The map from which this tracing is made should be corrected from time to time as changes are made in important tracks and structures which are of value as reference to the right-of-way boundaries, as well as any transfers of property made to and from the railroad company [and any important tracks or structures].

No. 4 was likewise amended by striking out the final six words:

(4) The property of adjacent railroads or of subsidiary and associated companies should be shown in different colors [for the purpose of ready distinction].

No. 5 was amended by striking out the portion shown in brackets:

(5) It is important to show on the original right-of-way map a profile of the same horizontal scale and of the same station numbers as the map, and of suitable vertical scale, which profile should show the original sub-grade, the location, character and size of opening of each bridge, waterway or under crossing and the original surface of the ground [the necessity for this being the knowledge of physical conditions at the time the road was built, often needed in defending litigation and settling questions arising from time to time].

No. 6 was adopted without change. An effort was made to have definite scales stated in this conclusion. The chairman of the committee explained, however, that, after a thorough consideration of the matter in the light of information concerning what scales it was practicable and impracticable to use in different parts of the country, it would be impossible to recommend a scale that would meet the views of a majority of the members.

The conclusions on track maps were amended as follows:

Definition: "Track Map.—A map used primarily for showing physical conditions, including tracks, bridges, buildings, water service and mains, leases, station facilities and all of the physical and operating features."

The word "existing" was inserted ahead of "physical conditions" and "other" substituted for "all of the" in the latter part.

Several changes were made in the first conclusion.

(1) Track maps should show all physical conditions pertaining to the construction and operation of the railroad and the limits of the right of way without reference to title or ownership. They should show all main and side tracks and their alinement, distance between them, capacity in car lengths; all buildings upon the right of way and adjacent to main or side tracks; bridges, culverts, water stations, coaling plants, turntables, shop buildings, water mains, electric light wires, fences, street car and other railroad crossings, and the angle they made with the railroad track; sewers, signals of all kinds and all physical conditions on the property. All structures on such maps should be located by chainage numbers and plusses.

"Physical" was struck out in the first line; "cars" was substituted for "car lengths"; for "electric light wires" the words "conduits, wire lines of all kinds and their supports" were substituted; in the last sentence "all" was changed to "important."

No. 2 was amended by striking out the portion shown in brackets:

(2) They should be corrected whenever any changes are made in any of the features shown thereon [and a corrected copy sent to the general office for record].

No. 3 was amended by striking out the words "and cities."

(3) It is recommended that a scale of 100 ft. to the inch be used for such maps except in territories and cities of large industrial development, where varying scales may be used to suit the local conditions.

No. 4 was amended by striking out "very" and substituting "meridian" for "north point."

(4) The map should show very plainly the north point, scale, original date and date corrected.

No. 5 was amended by striking out "always," "it is" and "to do so":

(5) The conventional signs adopted by the association should always be used where it is possible and convenient to do so.

Mr. McDonald (N. C. & St. L.) asked if on maps of 100 ft. to the inch the tracks should be shown in double or single lines. The committee had not considered this and were instructed to make a suggestion concerning it in their next report.

Under Individual Ledger Accounts there were two conclusions asking the adoption of the forms recommended. These conclusions were adopted, following suitable explanation by the chairman of the committee concerning the forms.

Ties.—There were two conclusions to this report which were adopted without discussion. They were:

(1) That the method for analysis of coal-tar creosote shown on pages 98-101 of Bulletin 96 be approved as good practice.

(2) That the method of determination of zinc in treated timbers shown on pages 102-105 of Bulletin 96 be approved as good practice.

The committee on Signs, Fences, Crossings and Cattle Guards and Economics of Railway Location made progress reports.

Car Surpluses and Shortages, March 4.

The following table is from bulletin No. 19 of the American Railway Association's Committee on Car Efficiency. It summarizes the car surpluses and shortages from October 30, 1907, every two weeks to March 4, 1908, inclusive, being similar to the table published in the *Railroad Gazette* of February 21, 1908, with the figures for February 5 revised to include reports later received.

The improvement in the general situation first noted on February 19, 1908, is continued. On March 4 there was a further reduction of 7,521 cars in the idle equipment, making a total decrease in the idle cars since February 5 of 28,936 cars, or 8.4 per cent. On February 19 there was a marked improvement in the demand for coal cars, but this appears to have been checked, and on March 4 there was a slight increase in the surpluses of this class of equipment. On the other hand, there is an encouraging reduction in the number of surplus box cars. There is a fair decrease in the surplus flat cars, while the surplus of miscellaneous cars remains little changed. It is worthy of note that every marked change in the situation since the maximum shortage of October 30, 1907, has first shown itself in the figures for box cars.

The greatest percentage of decrease of surplus equipment was in the Canadian group, although the largest numerical reduction was in the Northwestern group. Both of these groups report smaller surpluses of all classes of cars. On the other hand, there was a continued increase in the surpluses in the Southern, Central, Western and Southwestern groups. The Middle group, although showing less surplus box and flat cars, reports an increase of idle coal and gondola cars which more than offsets the decreases, making a net increase in the total surplus of all classes of cars for that section.

Surpluses and Shortages Bi-Weekly from Oct. 30, 1907.

	Number of roads.	Surpluses. Box.	Flat.	Coal, gondola and hopper.	Other kinds.	Total.	Shortages. Box.	Flat.	Coal, gondola and hopper.	Other kinds.	Total.

The Strength and Endurance of Steel Rails.*

BY JAMES E. HOWARD,
Engineer of Tests, Watertown Arsenal.

In the use of steel rails, as with other materials of construction, interest is directed to the limiting values of applied stresses, their accurate definition, and how closely they may be approached with safety under those conditions of service to which the materials in question are to be subjected. In the constructive arts are found examples of steel exposed to stresses of different kinds and in varying degrees of intensity, but it is not recalled where there is greater diversity of action than is found in the case of steel rails. The whole gamut of conditions are here present in the same piece of metal; and an unusual feature is the fact that the stresses are received on so limited an area of contact on the rail head. The feature of intense local pressure between the wheels and the rail is an important one, and one which does not allow the adoption of those corrective measures which can be applied to other features of the rail question.

Tests have been made on rails at the Watertown Arsenal Laboratory in earlier years. At present a series is in progress which was begun in connection with the current study of ingots and derivative shapes. The laboratory is co-operating with, and is being aided by, members of this association and others.

In the earlier work of the laboratory, the tests comprised rails of domestic manufacture, some of the early English rails, and one or two examples of French and German make. Many of these had been in service. The tests showed that rails from the track were generally less tough when loaded so that the head was in tension; in fact, they were quite brittle, and fractured after comparatively little permanent deflection. By planing off metal from the running surface of the head, the rail was restored to a tough condition, and then bent well with either the head or the base on the tension side. Planing off one-eighth inch of metal was sufficient, but it was necessary to remove all of the affected metal, which included some from the sides as well as that from the top of the head. Restoration of toughness was also accomplished by annealing the rail, without planing off any of the metal.

This loss in toughness is due to the flow of metal under wheel pressures. It will, of course, take place promptly and quite easily in the softer grades of steel. From this point of view, a soft steel has the disadvantage of low strength and is not free from brittleness, in spite of the inherent toughness of the metal. The original properties of such steel are apt to be misleading and encourage greater confidence in its ductility than is warranted by its subsequent behavior. It does not follow, however, that the initially harder steels will not also become more brittle at the running surface of the head of the rail, since all grades of steel are probably affected in this manner by wheel pressures under present practice. It is not known whether present service conditions are such as to allow the metal at the surface of the head of the rail to retain its original tensile properties unimpaired until lost by abrasion and wear. In the harder rails, the depth of the affected metal is thought to be less than in the softer rails; still, the depth is appreciable and has an influence on the toughness of the steel.

Loss of ductility is due to the flow of the metal of the surface of the head and not directly to the high compressive stress between the wheel and the rail. Other tests have shown that high compressive stresses unaccompanied by relative displacement of the metal do not change the physical properties as evidenced by subsequent ten-

*A paper presented at the ninth annual meeting of the Am[illegible] R[illegible] Engineering and Maintenance of Way Association. Read [illegible] Bridge Engineer, Boston & Maine sion tests. High compressive stresses of this kind may be applied in tests by cubic compression, specimens being immersed and subjected to hydrostatic pressure up to 100,000 lbs. per square inch.

Alternate tension and compression tests have shown that overstraining in either direction lowers the opposite elastic limit, that is, a tension load applied in excess of the elastic limit has a detrimental effect on the compressive elastic limit, materially lowering the latter value. On making similar tests with rails, but loading them transversely instead of by direct tension and compression, it was found that the application of a high load—one causing decided permanent sets—resulted in lowering the elastic limit of the rail when it was reversed in position and loaded in the opposite direction. Examination of a rail 11 months later did not show a restoration from this disturbed state during the interval of rest. Repeated reversals resulted in lessening the magnitude of the deflection sets, over the first sets, an effect which would pass as a stiffening of the rail, in common parlance, although the modulus of elasticity of the steel is lowered by over-straining of the metal. Bringing the metal to a red heat brought about a partial restoration, but did not fully return the rail to its original condition as regards the development of sets. The effect on the surfacing of the track from overloading a rail is apparent from these results.

Since the cold straightening of a rail at the time of manufacture is another illustration of loading beyond its elastic limit, similar results to the above are certain to follow. A rail thus straightened is left with initial strains in equilibrium when the rail is without a load, but such as to develop sets in the track upon the application of very moderate loads. The opposing internal strains augment the effects of the wheel loads and facilitate early sets. Surfaces of metal first to cool from higher temperatures are left under initial compression, and this tends to further complicate the condition of the rail.

The lines of magnetic scale which leave the rail in the vicinity of the gagged parts show where the steel has been overstrained locally. Unless the metal is structurally unsound in the paths of such lines, no unfavorable results of the gagging would be immediately expected. The number and magnitude of repeated stresses necessary to cause rupture of the steel would be such as to relieve anxiety as to early failure of the rail from this cause, although this action, such as it is, is detrimental. While a given effect is more easily produced in a soft steel rail than in a hard one, on account of the difference in strength, yet a slight defect existing in the hard metal is of greater consequence than in the softer metal.

Seemingly minor and accidental causes may lead to early rupture. Some are so slight as the abrasion of the base by a spike or an indentation of the flange by a chance hammer blow.

In deciding on the cause of rupture, the line of fracture should be traced back to its beginning. Fortunately in steel fractures this may generally be done. A well defined nucleus marks the origin of a granular fracture, from which a fan-like or radiating pattern diverges. It is usually possible also to tell the order in which the fractures occurred, when more than one surface is presented, by inspecting the fractures and noting their appearances as above indicated. In this way rail fractures might be exhibited in which the first break detached a moon-shaped fragment from one flange, having its origin near the middle of the base, followed by a secondary fracture separating the other flange and extending up through the web and then through the head, fractures beginning at one edge of the flange, extending across the base and thence through the rest of the rail; fractures beginning at a bolt hole and extending each way until the fracture is complete, or fractures having their origin at the running surface of the head and extending downward through the rail.

The flow of the metal under wheel pressures is one of the most important of the causes of fractures. Whatever may be done to strengthen the rail in other respects, the fact still remains that the load is applied on a very limited surface of contact. This obstacle is insuperable and imposes a limit on the size of concentrated wheel loads.

The influences enumerated tend to develop fractures in rails structurally sound and with good physical properties, but it is recognized that rails are not always free from structural defects, although they may have satisfactory tensile properties. Some of these defects are serious and apparently have led to a considerable number of fractures in recent years. It has been found in a number of rails examined that longitudinal streaks are present in both the head and in the base, streaks of a different color from the adjacent metal as they appear when etched with tincture of iodine. Some of

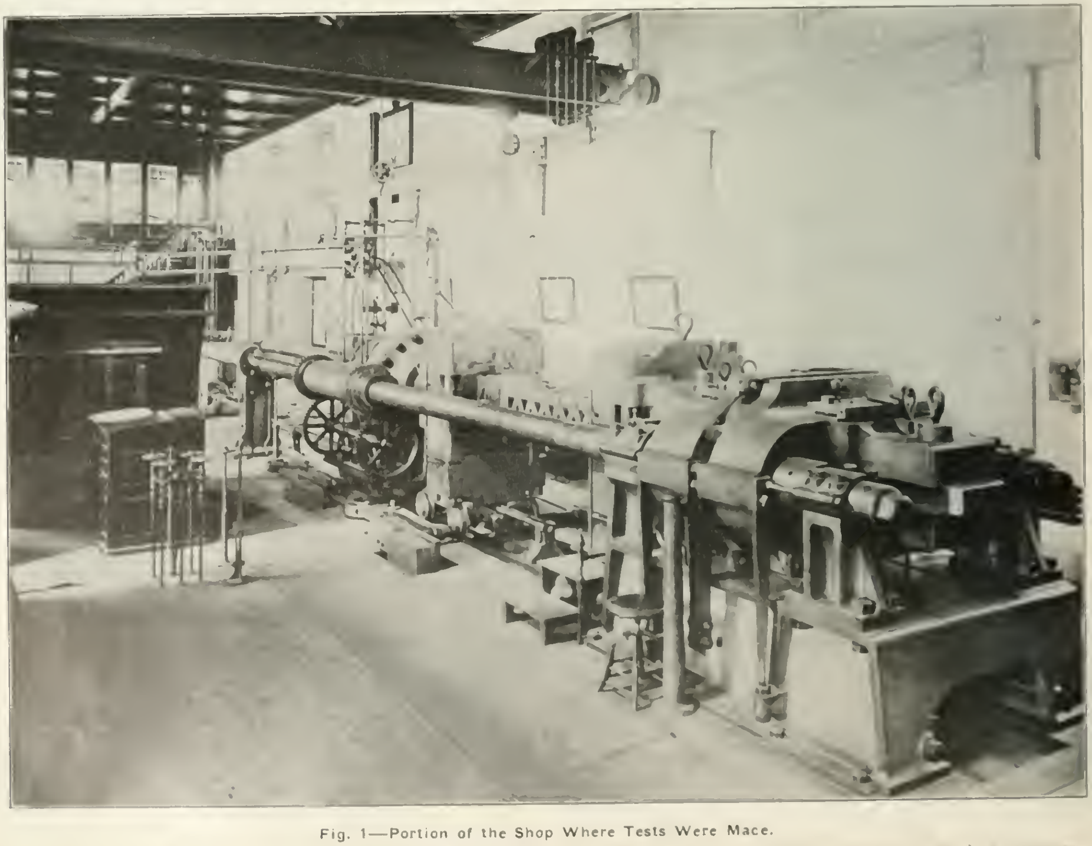

Fig. 1—Portion of the Shop Where Tests Were Mace.

In front is the old Emery testing machine of 800,000 lbs. capacity. There is a latticed column in the machine arranged for a test by compression.

the streaks are several feet long, others a few inches or only a fraction of an inch in length. They are of different widths, from a few hundredths of an inch to upwards of an eighth of an inch, and not infrequently have a fine hair line or crack along the middle. The cracks are commonly short, less than an inch, and in depth penetrating the metal but a few hundredths of an inch. They are, in some rails, quite numerous, and in planing the metal away for examination new hair lines appear in succession as those first in view are planed away. The steel fractures without elongation when ruptured by stresses applied at right angles to the direction of the cracks. That the streaks represent lines of weakness there is hardly a doubt, and their elimination, if practicable, is desirable and would be of advantage to the rails. The development of moon-shaped fractures may be traced to streaks or hair cracks in the rail at or near the surface of the base. It is of deep interest to discover the causes of these lines of structural unsoundness or lack of continuity and the means by which they may be avoided, if such is possible.

These streaks and fissures are not a recent development. They are found in rails of early manufacture, and even more pronounced than is general in rails of current make. Examination of a number of early English rails shows streaks and fine cracks. They have been found in rails of domestic make from different mills, and in a sufficient number to show that their presence is not restricted to any particular make. It does not seem, however, that all rails from the same mill are equally affected. There are wide differences among them, although it may be difficult to find those which are strictly sound throughout.

There is urgent need of information as to the state of the metal in the ingot and through each successive stage to the finished rail. In this inquiry, all the metal from the several ingots comprised in the series of tests should be available for examination. This has reference to the metal usually discarded from the ingot, and to crop ends of the rails, which should be comprised in the tests as well as the portions of the ingots made use of in the rails.

These rail tests are included in the general series of ingots and derivative shapes, previously mentioned, in which the laboratory is aided by the following committee: Major C. B. Wheeler, Commanding Officer, Watertown Arsenal (ex-officio); J. E. Howard, Engineer of Tests, Watertown Arsenal (ex-officio); William R. Webster, Consulting Engineer; Edgar Marburg, Professor of Civil Engineering, University of Pennsylvania; James Christie, Consulting Engineer; Charles B. Dudley, Chemist, Pennsylvania Railroad; E. P. Kenney, Metallurgical Engineer, Cambria Steel Co.; J. P. Snow, Bridge Engineer, Boston & Maine; A. A. Stevenson, Superintendent, Stan-

Fig. 12.

Fig. 13.

Fig. 6. Cross section of 100-lb. rail. Familiar markings brought out by etching are here shown as in the earlier slide. To find out how bending qualities of the metal at these dark streaks and patches compared with the lighter portions of the metal, a thin section of the rail, taken in cross section was slotted off and bent along the lines of the dark streaks and over the patches. Fig. 7. Results of bending the thin section are here shown, but imperfectly because of the deflection of light. On bending these thin strips, fractures occurred more easily over the dark streaks and patches than over the white portions. The section of the web was bent about a vertical axis and rupture occurred along one of the dark streaks. The edges of the top side of the base were bent over where dark blotches occurred and fracture occurred in these blotches. The head was also bent about a vertical axis and it ruptured in the dark lines.

Fig. 8. Web of a rail in horizontal section, looking down on the central streak. The streak of dark metal extended through the depth of a piece of web which was cut off. Structural weakness along this dark streak was not enough, however, to allow the section to be split along the streak. The specimen was sawed into and on wedging the prongs of the forked-shaped end apart, the metal fractured transversely instead of splitting along the streak. Fig. 9. Shows some streaks and hair lines on the head of the 100-lb rail. Lines run longitudinally. Rail was prepared by planing off about 1/16 in. from running surface of head, smoothing the metal with file and emery cloth, and then etching with tincture of iodine. Fig. 10. Short section of base of same rail. Dark lines run longitudinally, as, in fact, all such lines run. Finer lines running crosswise are those left by the machine tool or the file. Fig. 11. Photograph of a part of the head of the rail shown in Fig. 21. Streaks here shown are typical white streaks. Along the middle of some of these streaks, hair lines or cracks are evident, in which there is plainly a separation of the metal. In all white streaks examined with a high-power microscope, cracks at some points are found. A well-defined crack will usually pinch out to a series of very short cracks, exactly in line, but perhaps only a few hundredths of an inch long. After these there may occur clusters of minute holes, four or five together, hardly discernible under 200 diameters. Following this, the white streak will show, looking like a pathway irregularly strewn with light-colored gravel. The white specks are not rounded, but seem to be little chips, which might be cut by the polishing grit and caught on the fibers of the adjacent steel. The white metal looks softer than the ordinary metal surrounding it. This, however, may be only an appearance. Fig. 12. Streaks in head of early rail made by the Landore Siemens Co. They appear to be of the dark variety. Fig. 13. Base of same Landore Siemens rail.

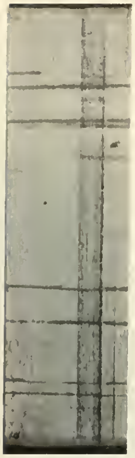

Fig. 14.

Fig. 15.

Fig. 16.

Fig. 17.

Fig. 18.

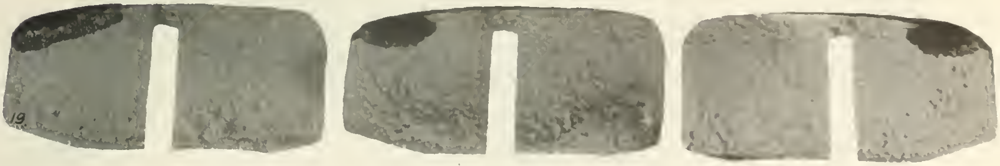

Fig. 19.

Fig. 14. Streaks in base of a John Brown rail (early English). This and preceding illustrations may be taken as typical of common longitudinal streaks. Though those selected show more streaks than others, streaks are certainly very common, and no rails have yet been found entirely free from them. Some rails which had given good service and had a good track record had fewer streaks than those which had failed in service. Moon shaped fractures appear to originate in streaks like those just shown in the bases of rails. Fig. 15. Fractured rail, 5 in. 75 lb., which failed in track after nine years of service. Evidently a moon-shaped fracture. A piece was first detached from the flange, followed by a second fracture through the other flange and the rest of the rail. A radiating structure will be noticed in the fracture. The center of radiation marks the origin of the fracture. The primary fracture was clearly the one extending not quite half the width of the base. Fig. 16. Rail fractured in testing machine. Shows how slight indentation of the metal may locate fracture when tested to destruction. A chance hammer blow had slightly indented the upper right hand edge of the flange. From this the fracture began. The radiating structure could be traced on the rail itself, but this is more obscure on the photograph. Fig. 17. Two pieces of rails, after testing. Both tests made from same rail, which had been some time in service. Effects of wheel pressures shown by flow of metal on the sides of the head. Tests show difference in strength which may be expected when a worn rail is loaded with the base in tension or the head in tension. The upper piece, loaded with the base in tension, sustained a maximum fiber stress of 146,700 lbs. per sq. in.; the lower piece, with the head in tension, ruptured with fiber stress of 110,900 lbs. per sq. in. Lower piece deflected only 4½ deg. and ruptured; other bent 21 deg., the test being discontinued without rupture. Illustrates serious damage to the rail from flow of metal under wheel pressures. Fig. 18. Rail in which the running surface of the head has been seriously affected by the skidding of engine wheels. Effect of the drivers is to cause flow of the metal of the head, and also cause the development of transverse fractures at the corners of the head. Fig. 19. Fractures of the head of [illegible] rails (Fig. 18); incipient cracks, due to effect of wheels, shown by dark spots at the corners of the running surface. These cracks appear to indicate the limit of heavy loads for rails made of carbon steel.

dard Steel Works, S. M. Vauclain, Baldwin Locomotive Works, F. W. Wood, President Maryland Steel Works.

A number of lantern slides, prepared to illustrate some of the current work of the Watertown laboratory were presented and are reproduced herewith.

After exhibiting the slides, Mr. Snow discussed the probable cause of rail breakages, saying: The specimen which I now show you is the one shown by the last slide exhibited (Fig. 21). It has been planed, as you see, to different depths in the head and in the base. The surface where the planing is shallow shows prominent white streaks; one portion of the head being that shown on slide No. 11. White streaks appear in the deeper cuts, but they are generally not in line with those above, showing that they are diffused throughout the metal. As we get deeper into the metal, however, white streaks become scarce and finally disappear, but in this particular specimen the deeper cuts show dark streaks. These are not so definite in their widths as the white streaks, but they penetrate the metal somewhat more deeply, and show in the end section of the rail, whereas the white streaks do not show in this location. White streaks with their accompanying cracks lead to flange breaks and, perhaps, to split heads. Dark streaks appear to be the results of segregation and lead to crushing of the head. In addition to these two kinds of streaks, there is another defect which is not in evidence on this specimen, but which is very common in the rails rolled during recent years. I have previously called the cracks found in white streaks "gas seams." I called the defects which I am now describing "rolling flaws." The cracks of the gas seams are strictly parallel to the line of rolling and are straight. The plane of the cracks is, also, at right angles to the surface of the metal. The seams called rolling flaws are parallel to the rolling in a general way, but are usually somewhat crooked. They are similar to the flaws called snakes in plates, but in the case of rails, they are practically straight. The planes of these seams are generally inclined to the surface of the metal and their sides are fluted and usually of a bluish color, similar to mill scale, indicating that they were oxidized while the metal was hot.

The crescent fractures that I have examined have almost all shown their origin to be one of these rolling flaws, although occasionally the origin seems to be a gas seam, but my observation leads me to think that by far the largest number of recent breaks are due to seams of the rolling flaw type. The older rails examined, while they show plenty of white and dark streaks, do not exhibit the defects which I call rolling flaws; this, undoubtedly, accounting for the greater prevalence of flange breaks and split heads in rails of recent make.

In view of the fact that in all of the crescent breaks which I have examined—and that is a good many—it has always been possible to discover a manifest flaw from which the break started, and from the fact that Mr. Howard in his paper claims that this class of breaks are due to seams which are in the rails when they leave the mill, I claim that the case is fully proved that flange breaks, and perhaps split heads, are due to incipient flaws existing in the rails when purchased. It is a remarkable fact that the rail tests prescribed in our specifications do not in any way tend to develop these defects. I wish to recommend that tests be prescribed which will show whether or not these flaws exist.

Perhaps I ought to rest my case here, as it is all that has been fully proved. The temptation is strong, however, to make guesses as to what causes these defects. I stated, in a paper printed in Bulletin No. 93, that in my opinion the flaws here called gas seams were due to gas bubbles in the ingot. I still think so, but the flaws which I call rolling flaws appear to me to be due to shrinkage cracks, or checks in the ingots, or tears in the bloom, or perhaps the gas holes which are so near the surface of the ingot as to burst out in the soaking pit, due to softening the metal, or afterwards under the pressure of the blooming rolls.

If we go a little farther and try to investigate the cause of gas bubbles in the ingot, we get on more uncertain ground. Professor Howe, of Columbia University, claims they are largely due to mechanical action, the shrinking of the interior of the ingot tending to cause tension in the plastic metal, thereby relieving the pressure and allowing the formation of gas bubbles. The metallurgist of the Chicago Steel Co., Mr. Von Maltitz, in a paper read before the London meeting of the American Institute of Mining Engineers,

Fig. 20.

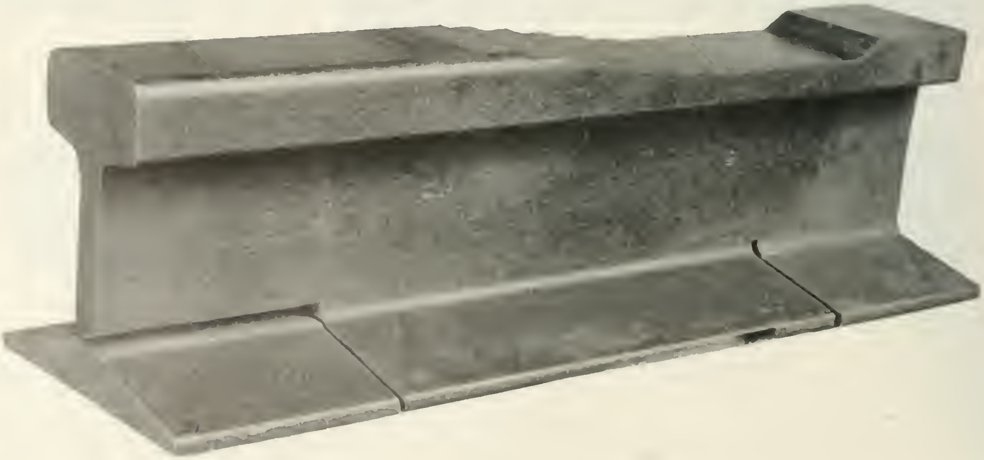

Fig. 21.

Fig. 20. View of crude side of a rail, showing moon shaped fracture made in testing machine. It was just beyond one which had been caused while rail was in track. The base of this rail showed characteristic streaks, such as were previously illustrated. Fig. 21. Piece of rail which has been planed down in successive steps, to show the presence of streaks at different depths in the head. The base of this rail was also examined and a section of the flange subjected to cross bending, the cross bending resulting in a brittle fracture along the line of a streak.

claims that they are wholly due to chemical and thermic action. Both of these investigators prescribe means of lessening the difficulty.

As to the cause of the cracks, etc., which lead to rolling flaws, the remedy is self-evident. Chipping ingots and blooms, as was formerly done, will remedy the shrinkage cracks, checks and gas holes. Less severe reduction in the blooming and roughing rolls will obviate tears, provided the metal is not unduly hot—short from excess of oxygen or sulphur.

Mr. Howard is on the trail of these defects. We ought to encourage him all we can to trace them to their origin, whether it be in the rolling, the ingot, the ladle or the bath.

William R. Webster spoke as follows on the work of the committee:

"Professor Marburg and I were called in to assist in this work by the ordnance bureau, and in order to make it representative work we had a meeting last October in New York, to which we invited about 40 engineers and manufacturers to meet Major Ruggles and Mr. Howard, of the Watertown Arsenal. Dr. Dudley, of the Pennsylvania Railroad, presided. Dr. Dudley was given authority by the meeting to appoint two committees, one committee on the compression tests and the other on the investigation of ingots, blooms, billets and slabs. The whole matter was brought up originally by a report of Mr. Howard to the ordnance bureau, suggesting an investigation of this kind and asking for a larger appropriation. The appropriation for this year's work is about $35,000, or about twice the amount received before. I am glad to say that both of the committees have fairly started on their work, and that there has been no red tape or anything of that kind to hinder us in the work. Some of the members of this association and some of the steel manufacturers are co-operating with us and furnishing freely samples of their material, including ingots and different finished products, and I have no doubt that other members and other manufacturers will call on them when they understand more clearly what they are doing at Watertown."

Mr. Howard sent me samples and wrote as follows:

"Mr. Snow will hand you a piece of the base of a rail which was fractured transversely and which shows a laminated streak of several hundredths of an inch in depth, and which occasioned a very short and brittle fracture. This piece was annealed before testing, for the purpose of seeing whether any reduction in brittleness could be effected by annealing the metal, but none resulted; that is, these streaks are a detriment, in spite of anything we can do toward softening the metal in which they exist.

"Another piece which Mr. Snow is kindly bringing out to you is a thin slice from the base of a 100-lb. rail. There were a number of streaks in one end of this sample. Bending transversely opened one of these seams you will see; the other end was also bent transversely and opened up some short cracks. When bent in the other direction, across the middle of the length of this piece, the bending qualities were much better and no fractures were caused. These two samples are the best I can do; they are not precisely what you may have preferred, but I did not have time to get out other pieces similar to those which we exhibited at the New York meeting."

A. A. Stevenson in discussing a paper by Mr. Howard before the American Institute of Mining Engineers at the February meeting, 1908, said:

"There is one very important point that I have not heard mentioned by Mr. Howard, and that is the question of the minimum amount of work. In the opinion of some of us there is too much work put upon steel at the present time and just as good results can be obtained by a lesser amount of work; in fact, maximum results may be obtained by a minimum amount of work on the material."

Planes of cleavage may be also developed by pressure in a material having no gas bubbles or other internal defects. The best illustration of this was given years ago by Professor Tindale in an article on the cleavage of roofing slates. He claimed that the planes of the cleavage in the slates were at right angles to the bedding and were caused by lateral pressure of the earth. To illustrate this he cast a cylinder of wax about 3 in. long and 3 in. in diameter and at the normal temperature compressed this cylinder to a cake about ⅜ in. thick. This was then cooled in a mixture of salt and ice and could be split like a piece of mica. In 1874 I repeated this experiment with similar results.

Many of us have known for years that there was a decided difference in the tensile strength and bending properties in transverse tests and longitudinal tests on pieces from universal steel plates; also that there was a much greater difference in similar test pieces cut from universal iron plates, but we did not appreciate the great difference in the strength and bending properties of the higher carbon rail steel as has been shown by Mr. Howard's paper to-night.

With this information before us it is not hard to account for rails with a shallow head failing by the side of the head breaking off in service in the plane of web, but it is the strongest plea for making a rail with a deep head and a good large fillet connecting the head to the web.

We are always going to have transverse weakness perceptible in steel rails and we should appreciate this in designing our rails and do the best we can with what we have to work with.

Preliminary Report of the Interstate Commerce Commission on Railroad Earnings.

"The preliminary report on the income and expenditures of operating railroads in the United States" for the year ended June 30, 1907, has been issued. It includes the results of operation of 894 operating companies, representing 225,584 miles, or approximately 99 per cent. of the mileage to be covered by the complete report.

There is given below the general summary of the earnings from operation and operating expenses of these companies for the year ended June 30, 1907, with comparisons for the eight preceding years:

Item.	Amount.	Proportion to total earnings.*	Per mile of line.									Increase, 1907 over 1906.
			1907.[1]	1906.[2]	1905.[3]	1904.[4]	1903.[5]	1902.[6]	1901.[7]	1900.[8]	1899.[9]	
Passenger service	$683,980,921	26.45	$3,032	$2,787	$2,647	$2,552	$2,492	$2,378	$2,194	$2,067	$1,928	$245

Exhibits at the Maintenance of Way Convention.

Each year for the past three or four years it has seemed that any further addition to the number of exhibitors at the Maintenance of Way convention would compel some change which would involve seeking new quarters. And still the number continues to grow and in some way they are crowded into the parlor floor and adjacent hallways and rooms of the Auditorium Hotel.

The Road and Track Supply Association held its annual meeting on Wednesday, March 18, and elected the following officers: President, George Stanton, Sales Manager, Cleveland Frog & Crossing Co., Cleveland, Ohio; Vice-President, W. F. Schleiter, Secretary, Dilworth, Porter & Co., Pittsburgh, Pa.; Secretary and Treasurer, J. N. Reynolds, Vice-President, The Wilson Co., Chicago; Executive Committee, John C. McKinnon, Secretary and General Manager, Kalamazoo Railway Supply Co., Kalamazoo, Mich.; J. H. Martin, Hussey-Binns Shovel Co., Pittsburgh, Pa.; William Goldie, Sr., William Goldie, Jr., & Co., West Bay City, Mich.; T. W. Snow, President, Otto Gas Engine Works, Chicago; Robert E. Belknap, Chicago Agent Pennsylvania Steel Co. and Maryland Steel Co., Chicago; Theodore Huss, Secretary and Treasurer, Lufkin Rule Co., Saginaw, Mich.

Following is a list of the exhibits:

Adams & Westlake Co., Chicago.—Samples of "Adlake" signal lamps and long-time burners.

Adreon & Co., St. Louis, Mo.—Model of "Security" combination rail brace and tie plate, main rail brace and switch-point slide plate. "Security" guard rail brace.

Allith Manufacturing Co., Chicago.—Full-sized door, showing application and operation of Allith adjustable door hanger.

American Casting Co., Birmingham, Ala.—Samples of "National" short length, light weight, cast iron culvert pipe.

American Flange Frog & Railway Improvement Co., Roanoke, Va.—Model of Graham flange frog.

American Guard Rail Fastener Co., Philadelphia.—The "Anchor" guard rail clamp; tie-plate guard rail fastener; pressed steel rail braces.

American Hoist & Derrick Co., St. Paul.—Photographs of "American" railroad ditchers.

American Nut & Bolt Fastener Co., Pittsburgh.—Samples of Bartley nut and bolt fasteners.

American Railway Tie & Girder Co., Pittsburgh.—Model of Duff continuous longitudinal steel track structure.

American Steel & Wire Co., Chicago.—Samples of steel wire fence; concrete reinforcement; rail bonds.

American Valve & Meter Co., Cincinnati, Ohio.—"Economy" switch stands, and model of track and switch showing operation of Anderson interlocking switchstand; Poage water columns and tank fixtures.

Asbestos Protected Metal Co., Canton, Mass.—Samples of asbestos protected metal for roofing and siding, and model of Robertson standard car roof.

Atlantic Equipment Co., New York.—Photographs of "Atlantic" st[illegible] shovels and [illegible] locomotive [illegible] steam and electric locomotives.

Atlas Railway Supply Co., Chicago.—Atlas rail [illegible] braces and tie plates, including the Atlas insulated and compromise joint; Atlas switchstand.

Automatic Nut Lock Co., Rockford, Ill.—Samples of nut locks.

Barker Mail Crane Co., Clinton, Iowa.—Full sized Barker mail crane.

Barrett Manufacturing Co., New York.—Roofing and waterproofing materials.

Battery Supplies Co., Newark, N. J.—Samples of primary batteries.

Beaver Dam Malleable Iron Co., Beaver Dam, Wis.—Samples of malleable iron tie-plates and rail braces, also F. & N. anti-spreader and anti-creeper.

F. W. Bird & Son, East Walpole, Mass.—"Parold" roofing, "Hydrex" waterproofing and "Neponset" insulating paper.

Louis Blessing and Alfred Johns, Jackson, Mich.—Model of concrete tie, also adjustable nut locks.

S. F. Bowser & Co., Ft. Wayne, Ind.—Models of Bowser self-measuring oil storage tanks and pumps.

Jos. M. Brown, Chicago.—Samples of Stone lanterns, also photographs of Buckeye light.

Browning Engineering Co., Cleveland, Ohio.—Photographs of Browning locomotive cranes, railroad ditchers and revolving steam shovels.

Bryant Zinc Co., Chicago.—Samples of crossing bells, batteries, relays, etc.

Buda Foundry & Manufacturing Co., Chicago.—Paulus, Buda and Wilson track drills, switchstands, rail benders, car replacers, ratchet and friction jacks, hand cars, velocipedes and gasolene cars.

Cambria Steel Co., Johnstown, Pa.—Sample "100 per cent." rail joint and "100 per cent." insulated rail joint.

Philip Carey Manufacturing Co., Cincinnati, Ohio.—Samples of Carey cement roofing and magnesia pipe coverings.

Carnegie Steel Co., Pittsburgh, Pa.—Duquesne splice bar; steel cross tie; also samples of built-up steel tie after six years and ten months' service in main track of Lake Shore & Michigan Southern Railway; U. S. steel sheet piling; Friestedt steel piling; steel mine timbers and screw spikes.

Central Iron & Steel Co., Harrisburg, Pa.—Samples of "American" steel cross tie.

Chicago Portland Cement Co., Chicago.—Literature describing Chicago Portland cement.

Chicago Steel Tape Co., Chicago.—Measuring tapes and jointed leveling rods; "Eureka" tape splice.

Cook's Standard Tool Co., Kalamazoo, Mich.—Cook's collapsible rail drill and drill grinders; standard track jacks and Cook's combination steel and wood cattle guard.

Cortright Metal Roofing Co., Philadelphia.—Samples of metal roofing and model showing application.

Credelbaugh & Carter, Radnor, Ohio.—Concrete fence posts and molds.

Detroit Graphite Co., Detroit, Mich.—Samples of graphite paints.

Paul Dickinson, Inc., Chicago.—Dickinson smoke-jacks; models of Dickinson cast-iron chimneys and ventilators; composite wood and cast-iron fireproof smoke jacks.

Dilworth, Porter & Co., Pittsburg, Pa.—Goldie claw tieplates, Glendon flange tieplates and railroad spikes.

H. B. Dodge & Co., Chicago, representing Jas. G. Wilson Manufacturing Co., New York.—Models of swing and rolling doors.

G. Drouvé Co., Bridgeport, Conn.—Sample of "Anti-Pluvious" skylights; photographs of "Anti-Pluvious" skylights installed on Lackawanna station, Hoboken, N. J.

Duplex Metals Co., New York.—Sample showing "Monnot" process of welding steel and copper.

Eastern Granite Roofing Co., New York.—Samples of perfected granite roofing and sand surfaced roofing.

Economy Separable Switch Point Co., Louisville, Ky.—Model of "Economy" separable switch points and "Odenkirk" switch stands; "Clary" tie plate.

Electric Storage Battery Co., Philadelphia, Pa.—Samples of "Chloride" accumulations and "Exide" batteries for car lighting and signals.

Expanded Metal & Corrugated Bar Co., St. Louis, Mo.—Transparencies showing examples of concrete reinforcement with Johnson corrugated steel bars in bridge abutments, culverts, elevators, storage tanks, retaining walls; also model of reinforced concrete trestle having both deck and piles made of concrete.

Eyeglass Tool Co., Newark, N. J.—Eyeless picks and track tools.

Fairbanks, Morse & Co., Chicago.—Full sized No. 2 J inspection car; Barrett track jacks, rail drills, standpipes, wheels, etc.

Federal Cement Tile Co., Chicago.—Samples of "Indestructible" roofing.

Flexible Compound Co., Philadelphia, Pa.—Samples showing the application of "Flexible" waterproof compound.

Franklin Manufacturing Co., Franklin, Pa.—Samples of asbestos shingles, lumber and smoke-jack materials; model of "Century" asbestos smoke-jack for roundhouses (Gutellus patent).

Gartland Manufacturing Co., Marion, Ind.—Samples of picks.

General Fireproofing Co., Youngstown, Ohio.—Samples of cold-twisted lug bars for concrete reinforcing, expanded metal lath and diamond mesh fabrics and pin-connected frames for concrete girders and beam reinforcement; also "Trussit" metal for reinforcing light concrete roofs.

Gibraltar Manufacturing Co., Chicago.—Model of new structural steel "Gibraltar" bumping post, and "Gibraltar" mail crane.

Glazier Nozzle & Manufacturing Co., Indianapolis, Ind.—Model of "Glazier" universal nozzle.

William Goldie, Jr., Co., West Bay City, Mich.—Tie plugs.

Gordon Battery Co., New York.—Samples of Gordon primary cells.

Grip Nut Co., Chicago.—"Grip" nuts in various sizes.

Harrington Railway Safety Switch Device Co., Colorado Springs, Colo.—Working model of "Harrington" safety switch.

Hart Steel Co., Elyria, Ohio.—Samples of McKee flange and shoulder plates; also pressed point spikes.

Hayes Track Appliance Co., Geneva, N. Y.—Samples of "Hayes" lifting and pivot derails.

Hurley Track Laying Machine Co., Chicago.—Photographs, drawings and literature of the "Hurley" track laying machine.

Hurst Automatic Switch & Signal Co., Rawlins, Wyo.—Working model of "Hurst" automatic switch.

Hussey Binns Shovel Co., Pittsburgh.—Samples of shovels, spades and scoops.

Ideal Concrete Machinery Co., South Bend, Ind.—Model of concrete building block machine.

Illinois Malleable Iron Co., Chicago.—Small model of the "Bruyn" automatic swinging smoke jack.

Kalamazoo Railway Supply Co., Kalamazoo, Mich.—Hand cars, velocipedes, track drills, track jacks, gages and levels; wheel with reinforced tread; Root scraper and flanger; Moore chuck; pressed steel wheels.

Kennicott Water Softener Co., Chicago.—Photographs of water softening plants, [illegible] storage tanks and towers.

Edwin R. Kent & Co., Chicago.—Photographs and models of [illegible] manganese steel frogs and crossings.

Keuffel & Esser Co., New York.—Samples of steel tapes, transits, surveying and drafting instruments, [illegible] and [illegible] transit.

Kinnear Manufacturing Co., Columbus, Ohio.—Model of Kinnear rolling door, roundhouse type.

Lackawanna Steel Co., New York.—Abbott track gage plate, Abbott track gage and tie plate, Abbott rail joint plate, Abbott reinforced rail and Abbott composite rail tie.

Lehon Co., Chicago.—Samples of [illegible] roofing.

Locomotive Appliance Co., Chicago.—"Smyth" cast steel and "[illegible]" clamp derailer for main line and side track; "Newton" wrecking frogs.

Lufkin Rule Co., Saginaw, Mich.—Metallic and linen tapes, steel rules, etc.

Mann-McCann Co., Chicago.—Model of railway spreader and grader; Mann smoke-jacks; Ravelin system of electric wiring for roundhouses; Chicago ventilator.

McClintock Manufacturing Co., St. Paul, Minn.—Samples in operation of McClintock mercury contact relay, full-sized electric automatic signal, switch indicators, circuit breakers; testing sets for relays.

Metal Ties Co., New York.—Full sized cast steel tie with wood block for rail support.

Mississippi Wire Glass Co., New York and Chicago.—Samples of ribbed, mazed and plain wire glass.

Morden Frog & Crossing Co., Chicago.—Model of track and switch showing "Unity" switchstand.

National Lock Washer Co., Newark, N. J.—Samples of "National" lock washers.

National Railway Materials Co., New York.—Samples of Murray anti-rail creepers, guard-rail braces and clamps, rail braces, etc.

National Roofing Co., Tonawanda, N. Y.—Samples of "Security" mineral asphalt roofing.

Newman Clock Co., Chicago.—Samples of Newman watchman's clocks, also railroad special clock for yards, depots, docks, etc.

Robert Ogle, Pueblo, Col.—Model of Ogle turntable derailer.

Otto Gas Engine Co., Philadelphia and Chicago.—Photographs of coaling stations, water tanks and cranes, sand blast and pneumatic tool car.

The Pennsylvania Steel Co., Philadelphia, Pa.—Models of "New Century" adjustable switchstand with double crank; Manard anvil-faced frog; photographs of steel bridges.

Pepple Metallic Railway Tie Co., Hillsboro, Tex.—Metal tie and safety mail catcher.

Percival Wood Preserving Co., Houston, Tex.—Samples of timber treated with "Diamond" preservative by the open-vat method.

Phillips Signal & Electric Co., Owensboro, Ky.—Blueprints, printed matter, etc., regarding Phillips automatic crossing, block and bridge signals.

The Frederick Post Co., Chicago and New York.—Samples of surveying instruments, drawing materials, etc.

D. & A. Post Mold Co., Three Rivers, Mich.—Full sized machines for making concrete fence posts (shaking device method).

Quincy, Manchester, Sargent Co., Chicago and New York.—Bonzano rail joint; Q & C insulated joint and compromise joint; Q & C Sampson rail bender; anti-rail creepers.

The Rail Joint Co., New York.—"Continuous" insulated rail joint, standard "Continuous," Wolhaupter and Weber joints, insulated rail joints and step joints.

Railroad Supply Co., Chicago.—Samples of Wolhaupter, Q & W and Servis tie plates; B. R. S. derailer; Wolhaupter shoulder flange tie plate; signal materials.

Railway Chemical Sprayer Co., Owensboro, Ky.—Photographs of chemical weed killing car.

Railway Specialty & Supply Co., Chicago.—Smith improved lock nut; P. & M. rail anchor; "Kopp" signal glass, bond wire protectors, arc damp lightning arrester; "Paine's" vise-grip rail anchor.

Raymond Concrete Pile Co., Chicago.—Small model illustrating Raymond method of placing concrete piles.

Railway Equipment & Contractors' Supply Co., Chicago.—Literature describing the "Giant" rail bender.

Arthur E. Rendle, New York.—"Paradigm" fireproof windows and skylights.

Ritter Folding Door Co., Cincinnati, Ohio.—The Ritter horizontal folding door for roundhouses, freight houses and warehouses.

Roberts & Schaefer Co., Chicago.—Photographs of railroad coaling stations, coal washeries and tipples.

Safety Switch & Semaphore Co., Battle Creek, Mich.—Switchstand operated by a semaphore for single-track use on main line for facing point switch.

Sandusky Portland Cement Co., Sandusky, Ohio.—Samples of Medusa waterproof compound, and snow white Portland cement.

Scherzer Rolling Lift Bridge Co., Chicago.—Album and miscellaneous photographs of Scherzer rolling lift bridges.

Scott Manufacturing Co., Racine, Wis.—Model of "Hercules" bumping post.

Sellers Manufacturing Co., Chicago.—Samples of Sellers anchor-bottom tie plates and splice bars.

Spencer Otis Co., Chicago.—Samples of "Economy" tie plates.

Standard Asphalt & Rubber Co., Chicago.—Samples of waterproof bridge coatings and mastic floors; also pipe dips and insulating materials; "Sarco" asphalt filler for brick paving; concrete and brick reservoir lining; new moisture and damp proofing for buildings.

Arthur L. Stanford, Chicago.—Model of Stanford rail joint; sample "American" track jack.

Strauss Bascule & Concrete Bridge Co., Chicago.—Working model of the Strauss trunnion bascule bridge; model of ribbed reinforced concrete bridge.

L. S. Thomas, Fairfield, Iowa.—Sample of the "Endless" rail, a new form of rail joint.

Tool and Railway Specialty Manufacturing Co., Atchison, Kans.—Leaflets illustrating the "Au-tra-kar" spike screwing machine.

U. S. Metal & Manufacturing Co., Chicago and New York.—Samples of "Columbia" lock nuts; full sized "Hillman" whistling post.

U. S. Wind Engine & Pump Co., Batavia, Ill.—Switchstands and semaphores; literature describing the new U. S. adjustable water columns, water tanks; model of "Mansfield" water column.

Universal Portland Cement Co., Chicago.—Samples of raw materials in various stages of manufacture.

Variety Manufacturing Co., Chicago.—The Cross horizontal folding door, and "Variety" steel rolling door; Cross compound lift up door.

Verona Tool Works, Pittsburg, Pa.—Track tools.

Vulcan Iron Works Co., Toledo, Ohio.—Photographs of Vulcan steam shovels.

C. H. Whall & Co., Boston, Mass.—Samples of Whall special railroad insulating fibre.

Wm. Wharton, Jr., & Co., Inc., Philadelphia, Pa.—Photographs and models of Wharton manganese steel frogs, crossings, switches, etc.; Wharton guard rail clamp.

Whiting Foundry & Equipment Co., Harvey, Ill.—Photographs of electric travelling cranes, transfer tables, turntables, roundhouse cranes and equipment.

Williams White & Co., Moline, Ill.—Blueprints of new automatic bucket hoist coaling station.

Jas. G. Wilson Manufacturing Co., New York.—Full sized sample of sliding swing door; also samples of rolling doors.

M. F. Wood, New York.—Harrington safety switch device.

Julian L. Yale & Co., Chicago.—Samples of "Universal" cast iron pipe.

The Metal Tie.*

BY DR. ING. A. HAARMANN.
Geheimer Kommerzienrath.

II.

Permanent way with metal ties is no longer a novelty. In the last 40 years it has had a checkered career. The first attempts at using metal for supporting the rails date back still further. We will only refer to them here for the sake of completeness.

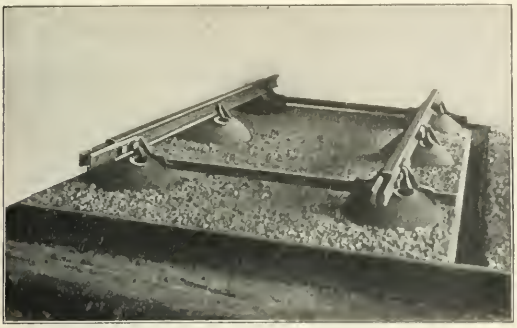

Fig. 21—Greaves Cast Iron Pot Ties; Alexandria-Cairo Line. 1854-1887.

During the period in which skill in rolling metal had not advanced to the point that enabled the rolling mill to put into proper shapes the tougher puddle iron, the Bessemer and open hearth steels, cast-iron attained some prominence as a tie material for railroads, especially in tropical countries where wood does not resist the climate and is attacked by white ants. Cast-iron pots (Fig. 21) were in use on the railroad between Alexandria and Cairo in 1854, and it was many years before they were replaced by creosoted wooden ties and by metal ties. The piece of track pictured was in service 20 years, using double-headed chair rails. The life of the tie is, however, greater than this. This system was abandoned, not because iron was used, but because of the difficulties of maintenance due to its construction. Flat cast-iron ties with a rectangular base were extensively introduced in East India in connection with flange rails fastened to jaws on the ties by means of wedges (Fig. 22).

For us, in Central Europe, the cross tie is the only one that is of moment in connection with a metal permanent way. It is interesting to note that the first trials, made over 40 years ago, scored a remarkably long life for the metal tie (Fig. 23). They were the "Cosyns" ties made of I-beams laid on their sides in the main track between Deventer and Zwolle in 1865, and, in part, are still in the track, having outlasted the rails several times over. Originally they were provided with wooden saddles (Fig. 24), which were later replaced by metal saddles. The small dimensions of these last furnished insufficient bearing surface, which was bad for the ties and caused distortions and fractures. Those of the ties which are still serviceable have been equipped anew with wooden saddles but of much larger dimensions. The deep bedding in the ballast, the firm position of the saddles between the flanges and the good bracing are acknowledged advantages of these ties, but they are lacking in stiffness and are too narrow, being only 8 in. wide. Each tie is 8 ft. 3 in. long, giving it 792 sq. in. bearing on the ballast.

*Address delivered at the meeting of the "Verein der deutschen Eisenhüttenleute," Dec. 8, 1907, at Düsseldorf. Reprinted from *Stahl und Eisen*, by permission.

After such a beginning, the introduction of the metal tie might have progressed more rapidly than was the case had not erroneous conceptions delayed its development. Metal permanent way was to cost no more than that with wooden ties. Low in cost, indeed, but much too weak, too light and therefore really too dear were the characteristics of the metal ties prominent at the end of the sixties in Germany. To this class belongs the Vautherin tie, laid in the line between Wittenberg and Leipsic, at first with rails resting directly on the ties, but afterwards, when wear had begun, supported on plates riveted to the ties (Fig. 25). Still, these small ties with their little clips stood the service for 17 years, from 1870 to 1887, of course not without suffering severely from wear, distortion, breaks and splitting (Fig. 26). I do not intend to pass in review the large number of different ties and methods of attachment that were tried more or less extensively or that were proposed as improvements. I will only bring forward the most important of these various designs (Figs. 27 and 28). Merely glancing at this selection of widely used ties, it is evident that railroad men and rolling mill men were too long under the impression that they could get along with a minimum quantity of metal, a mistaken notion not entirely overcome at the present time. The shape, indeed, was extensively varied, the lower edges were made thicker or thinner or were given a vertical or again a horizontal direction, but the original weight of about 65 lbs. was only slowly increased until a weight of 165 lbs. was reached, accompanied by a lengthening of the tie from 7 ft. 3 in. to 8 ft. 10 in.

The metal cross-ties developed from Hilf's longitudinal tie and from its variants were in part equipped with wedge fastenings, in part with clips and screws. A permanent way of this kind was in operation from 1889 to 1892 between Hagen and Haspe, on the old Bergisch-Mäkische

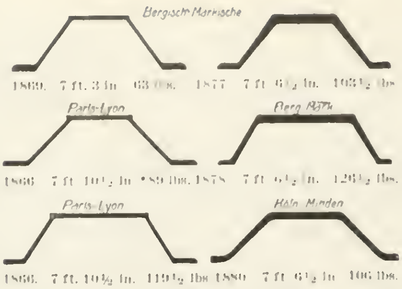

Fig. 27—Older Tie Sections.

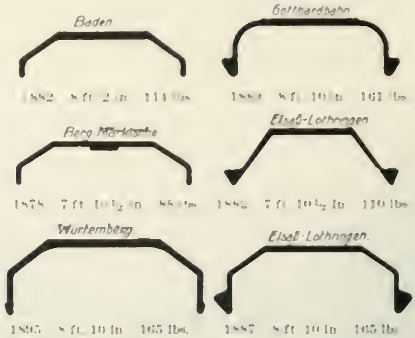

Fig. 28—Newer Tie Sections.

Railroad (Fig. 29). The small bearing surfaces occasioned excessive wear. As wedge fastenings did not get a firm hold, those by means of clips were developed and have come into general use.

The permanent way of 1896 of the St. Gotthard Railroad will serve as an example of the newest construction, in which the inclination of the rail is still obtained by bending the tie, while the gage is regulated by the use of different sizes of clips (Fig. 30). Inspection shows plainly that the rails and clips in the course of five years' service have begun to wear into the ½-in. upper surface of the ties.

In the Carnegie tie, used experimentally in the United States during the last few years, clip fastenings have also been employed, the rails resting directly on the ties (Fig. 31). But the clips are not utilized to relieve the side pressure on the bolts by dropping them into slots (Fig. 32). As the American rails are not inclined, but are placed vertically, bending the ties was not necessary. I have examined several stretches of track equipped with Carnegie ties, and am confirmed in my opinion, expressed in the *Railroad Gazette*,* that the derailment of February, 1907, at Mineral Point, which was accompanied by a shearing of the outer bolts, was not to be ascribed to the use of metal, as such, but to the defects indicated. Moreover, it seemed to me that the track with Carnegie ties rode smoothly but somewhat hard. This may be due to the narrow supporting surface, 8 in., and to the too great stiffness of the tie. To be sure, the stiffness is of advantage for static reasons, as it results in a well distributed, but in this case unnecessarily high, pressure on the ballast. The Carnegie tie (several samples taken from track have been kindly furnished me by the Carnegie Steel Co.) weighs 167 lbs., with a supporting area of only 705 sq. in. Structural improvements are under way, but it seems to me a mistake that, in introducing the steel tie in the United States so little use should have been made of the experience that has been gathered in Germany during the last 35 years.

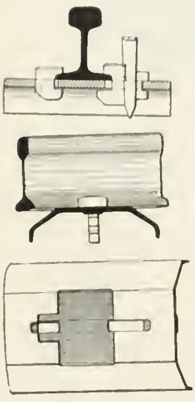

Fig. 29—Wedge Fastening, and Wear of Tie; Hagen-Haspe Line, 1889-1892.

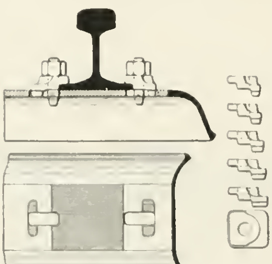

Fig. 30—Clips Recessed in Tie; Gotthard Railroad, 1896.

The Prussian railroads have, at different times, recognized as standard four different tie sections (Fig. 33). The first, introduced in 1881, was the box cross tie modeled after my abandoned longitudinal tie. Its form, however, proved ill adapted for the distribution of pressure, the horizontal flanges tending to curve upward, while the central space could not be solidly tamped. The next two sections, forms 51 and 52, appeared at about the same time, in the middle of the eighties. Form 51, 8 ft. 10 in. long and weighing 128 lbs., with 970 sq. in. bearing area, has enjoyed a preference up to the present day as a standard shape for main line. The fourth and wider section, form 50, originally designed for switches, weighs 167 lbs. and has a bearing area of 1,172 sq. in. In recent years it is coming into use for joint ties and in some cases for intermediate ties.

(To be continued.)

The Ocean Carrier.

BY J. RUSSELL SMITH, PH.D.

XII.

The Leading Routes of Ocean Commerce.

Of vessel tracks upon the world ocean there is an innumerable and increasing multitude. Any one of several hundred ports may from time to time be visited by a vessel from any other of these ports. This movement over a certain track may be isolate, occasional or regular. Even the regular trade routes amount to hundreds, passing in all directions across all oceans between the frigid zones, and some routes invade even a portion of the Arctic ocean.

The routes of the ocean, like those of the land, consist of trunk lines and branches or feeders, which, leaving the main ocean thoroughfares, reach out to the islands or to the ports of the more isolated arms, gulfs and bays that indent the continents. These trunk routes comprise the real circulatory system through which passes the greater part of the commerce of all nations. The advantage of location possessed by the trunk routes causes them to draw to themselves through their feeders the great majority of vessels traversing the ocean.

The number of ocean routes has been more than doubled during the latter half of the nineteenth century by the use of the steamer. This newer type of vessel rarely followed the older route that had sufficed when wind and sail were the sole dependence of the navigator. The sailing vessel must depend upon winds, weather, currents and tides, and in order to take advantage of these factors it is often necessary to make detours to catch favorable conditions or to avoid the danger of being blown upon the shore. The steamer, with greater power of guidance and always desiring to save time and fuel, goes as nearly as possible in straight lines. Hence the two types of vessels rarely follow the same track, and there are, for a large part of the world's oceans, two distinct sets of routes: those followed by steamers and those followed by sailers.

The location of sailing routes differs from that of steamer routes because of the different methods of navigation. With the steamer every mile covered costs a certain coal consumption, so that the steamer routes, reckoned in miles, are almost always the most direct routes possible, deviations only being made to avoid rocks, ice, thick fog or very stormy locations. The steam navigator thinks of his voyage in miles because distance is the chief factor, but the sailing captain reckons his voyage by days because the varying winds may take his ship one mile or 200 miles in a day; or again, headwinds may make it necessary to "tack," or sail from side to side, so that 200 miles of sailing means but 100 miles of progress. Thus it comes about that sailing routes are decided not by the shortest lines, but by wind and other conditions over the seas traversed.

The force and regularity of the wind differ greatly in different parts of the ocean, and to avoid regions of calm or low winds or head winds, the sailing routes often make wide detours in mid-ocean, and owing to the peculiarities of a sailing ship these vessels rarely go to and fro between two given points by the same route, because the wind that speeds the departing retards the returning vessel. Further than this, the winds in many parts of the world change with the seasons, and the sailing routes of winter are different from those of summer. Owing to the lessened certainty of location and lack of freedom along coasts, sailing routes do not lend themselves so easily as steamer routes to the development in trunk routes and branches. Where such classification is possible it is decided more by wind influence than by common destination.

In this article there will be no attempt to describe or enumerate all the routes. For an economic discussion many routes which, from the standpoint of the navigator, are separate, may be grouped under one heading and treated as a unit, as in commercial service they really are.

Western Europe and eastern North America are the greatest manufacturing centers for the rest of the world, and are consequently the starting point or the ending point for the leading ocean routes because the great basis of international trade is the exchange between the regions producing manufactures and those producing raw materials and food. Since the leading commercial countries of Europe are on, or adjacent to, the English channel, that body of water may, in a partly figurative but almost literal sense, be considered as the origin of European routes and similarly New York bay of the American routes.

As North America is also the greatest exporter of food and of raw materials to Europe, the most important of the ocean trunk routes connects eastern North America with northwestern Europe. On this great thoroughfare is regularly employed more than a sixth of the world's ocean shipping, including the largest and fastest ships afloat.

For convenience we will call this the North Atlantic trunk route. It is not strictly accurate to call this a route, for it is a complex group of routes crossing and paralleling each other and converging to several foci, but they are surprisingly close together in mid-ocean. The Liverpool Steamship Owners' Association declared in an address to the British Board of Trade "that all vessels crossing the Atlantic to this country (Great Britain) from ports in North America take practically the same route from 60 W. longitude." This comes about because of the advantage of following the great circle route, which, curving to the northward, makes all vessels, whether from Halifax, New Orleans or Vera Cruz, follow close to the northeastward-trending coast of North America to the Grand Banks off Newfoundland before starting to cross the ocean. During the spring and summer months a somewhat more southerly track is followed, owing to the floating ice, and for this reason the St. Lawrence steamers are compelled to pass to the south of Newfoundland. During the ice-free part of the year, from September to April, the compact sheaf of routes is somewhat scattered, and for a short time St. Lawrence steamers pass to the north of Newfoundland with a considerable saving in distance.

These northern or great circle routes are so much shorter than the direct following of the parallels of latitude, that the route from Liverpool direct to Greytown, Nicaragua, is only 323 miles, one day's moderate steaming, shorter than the route by way of New York. Norfolk is a common coaling port for vessels passing from the Gulf of Mexico to Europe.

The sailing tracks for this route show how thoroughly this type of transport depends upon the whims of the air. It was found in the old packet days that the journey directly westward to New York was in time 50 per cent. longer than the journey eastward and that a long southern detour on the western voyages was sometimes a benefit from the point of time. The explanation of this as of all the other facts of sailing route location depends upon an understanding of the main fact of the world's wind circulation, which should therefore be briefly stated here.

The combined influence of the motion of the earth and the different temperatures in different latitudes produce a general wind system upon the surface of the earth and with greater regularity upon the oceans than upon land. This wind system is studied by the sailing captain as carefully as the coal question is by the owner of a line of steamers. The winds are most regular and reliable in the hot latitudes. The part of the Torrid Zone receiving the most direct rays of the sun gets hottest and is a region of calms because the highly heated air is rising. This rising air of the zone of calms is replaced by the air that blows in from north and south, the trade winds which sweep regularly over the torrid

Steamship Verdi; Lamport & Holt Line to Brazil and the River Plate.

zone and are deflected from north and south to northeast and southeast winds by the earth's rotation toward the east. In some regions, particularly off the coast of Spain, the trade winds extend to a considerable distance beyond the tropic, but this is unusual. Owing to the apparent northward and southward motion of the sun, the zones of the trade winds and doldrums also move several degrees north each summer and south each winter. In both the temperate zones the prevailing winds are westerly, though not so constant as the trade winds, being more liable to disturbance by cyclonic storms, during which for a day or two the wind blows from all points of the compass in turn.

The sailing routes of the Atlantic illustrate in a striking manner the effects of the prevailing winds. Between the northern states and the English channel the sailing vessel goes before the westerly wind and follows closely upon the steamer route. Returning there are two routes, a southern and a northern. The northern faces the west wind and involves much tacking back and forth. The southern route going southwest to avoid the westerly winds and get into the trades, passes along the coast of Spain, south of the Azores and Bermudas, and crossing in the latitude of Havana comes up northwestwardly to the middle Atlantic states. If the destination is the Gulf of Mexico, the recommended track is still farther south, passing into the Caribbean near Barbados and out through the Yucatan channel into the gulf. In the winter this southern route is made even longer because the vessel must go farther south to reach the trade winds. Even the vessel bound for New York may then go 150 to 200 miles south of the tropic of Cancer. At this season the seas east and northeast of Newfoundland are more favorable to ships because free from ice. The icebergs and ice floes are released from their frozen moorings by the summer thawing and float about the ocean during summer and autumn. The solid freezing of winter holds the next ice crop in place until the succeeding June. During this season vessels returning from North Europe are recommended to follow the northern route. From the North Sea they go around Scotland, those from the channel steer northwest from the Scilly Isles or southwestern Ireland, till latitude 54 deg. is reached, then from mid-ocean a southwesterly route is followed along the coasts of Newfoundland and Nova Scotia. This northern detour is taken to avoid the strong headwinds and storms which often rage during this season with great fury between 45 and 50 deg. north.

The route next in importance to the North Atlantic is the Mediterranean Asiatic trunk route, passing from the Straits of Gibraltar around the continent of Asia to Japan. This route, the great thoroughfare between the east and the west, has many feeders east of Gibraltar, and double termini in the Atlantic, one in the region of the English channel, one in America, chiefly New York, but partly also in the Gulf of Mexico. As it skirts the coast of Eurasia it is fed by a branch from every bay that indents that great land mass, and by other branches from Africa, the East Indies and Australasia. Important contributions come from Barcelona in Spain, Marseilles in France, Genoa and Naples in western Italy, Venice and Trieste on the Adriatic, Smyrna and Piraeus on the Aegean, Constantinople, Odessa and Batum on the Black Sea. At Alexandria the commerce of Egypt is received and at Aden a part of the trade of the Persian Gulf, East Africa and Bombay, the main line going on to Ceylon and Singapore. At Colombo vessels for Calcutta, Madras and Burmah turn northward into the Bay of Bengal and the Australian mail steamers turn southward across the Indian ocean; at Singapore the route, rounding the corner of Asia, sends a branch to Java and on to Torres Strait and east Australia, receives the traffic from Siam, Tonquin, the adjacent East Indian islands and some from Manila. The main route passes on to Hong Kong, Shanghai and Yokohama, Shanghai being the branching off point for the trade of Vladivostok, Port Arthur, Tien Tsin and other ports in North China and Korea, and latterly it is extended even to San Francisco, with more services promised for the Pacific coast of America.

This great route from the west to the east is the creation of the Suez Canal. Before the opening of that gateway of the seas it was entirely unprofitable for steamers to engage in the trade between the Orient and the Atlantic. The trade was then comparatively small, and the greater part of the present traffic is the creation of the new route, which is now as absolutely monopolized by them.

The rocks, reefs, narrow passages, calms and fitful winds of the Red Sea combine with towage and tolls at Suez and poor winds in the Mediterranean to absolutely block this route to sailing vessel traffic.

The Good Hope route is not such a coasting route, nor is it so well supplied with feeders. The peculiar shape of the west African coast, and the scattering character of its commerce, have brought about a duplication of steam routes in the Atlantic west of Africa. The coasting and local route follows the coast, settlement by settlement from Morocco to German Angola. The more important route, the South African route, sweeps boldly around the continent to Cape Town with occasional stopping of ships at the Cape Verde islands for coal. At Cape Verde or to the south of it two branches of it unite to form the route, one connecting with the English channel, one with New York bay. East of the Cape of Good Hope the vessels in the African trade stop at the British South African ports of Port Elizabeth and East London, most of them continuing to Delagoa Bay, but rarely farther. A few pass up the east coast of Africa. African ports are, however, the destination of but a part, less than half, of the vessels traversing the South African trunk route. The others go directly to Australia and New Zealand, often without touching Cape Town. From the United States to Australia the Suez Canal route is practically as long as the Good Hope route, and all the vessels naturally follow the cheaper and more open route around the continent. From England the saving by canal is about a thousand miles, not enough to make its use profitable for any but fast passenger and mail ships. The purely freight lines from Europe use the South African trunk route. The more important lines steer directly from South Africa to Adelaide, Melbourne and Sydney, and sometimes go on to Brisbane. Less important ones run directly to Freemantle, West Australia, to New Zealand, or to New Zealand via Melbourne or Hobart (Tasmania).

The Good Hope route divides with the Cape Horn route the honors of being the heaviest factor in the world's sailing traffic. They are typical sailing tracks. The inbound and outbound tracks differ, and there are also the seasonal variations, but these sailing tracks are more deserving of the title of a trunk route than any others in the world. The equatorial section of the outbound route is followed by all vessels from both Europe and America destined to the coasts of five continents bordering upon the Pacific and Indian oceans. The inbound routes to Europe and America are not at any time united so completely, although they have some of their divisions in common.

The outgoing routes converge in the equatorial section because they cannot safely pass Cape St. Roque without going with the trade wind that blows from the Canaries directly toward the point of South America. European vessels have a direct route from the English channel until they reach the trade winds off the coast of Spain or Morocco, before which they easily ride.

The vessels from the Atlantic coast of the United States would be delayed by the trade wind if they sailed directly toward Brazil. The quicker way for them to reach Cape St. Roque is to go with the west wind eastwardly across the Atlantic toward the Azores, then turn south and go with the trade wind. This route joins the European near the equator. From this point southward to the tropic of Capricorn vessels bound for the Indian ocean proceed directly south to avoid the southeast trade and catch the prevailing west winds which carry them across the South Atlantic to Cape Town and into the Indian ocean.

The inbound routes of the Atlantic are everywhere in different locations from the outbound. In returning from the Indian ocean the southern west winds are a hindrance and the navigator keeps as close to the Cape of Good Hope as possible, and sails northwest into the trade winds and on toward the equator. The American and European routes from the Indian ocean diverge from the Cape; the first named going almost directly to New York, thus crossing the northeast trade at a right angle, and having nearly the same angle to the Gulf Stream and the prevailing westerly winds north of Bermudas. The European routes in crossing the northeast trades are driven so far to the west that they enter the zone of westerly winds in the longitude of eastern Brazil and Greenland, and, passing to the west of the Azores, approach their destination from a westerly direction.

The Good Hope route gathers to itself almost the whole sail traffic of the Indian ocean. These routes have a distribution altogether different from that occurring in other oceans because the wind system of the northern half of the Indian ocean is unlike that of the other oceans, due to the disturbing influence of the continent of Asia. This enormous and largely arid land mass lies just to the north of the trade wind zone, and in summer it becomes so much hotter than the ocean to the south of it that the air rising from over the land draws toward the land an enormous southwest sea breeze blowing continuously from the equator toward Asia—directly reversing the trade wind during the summer months. These winds, bearing the name of monsoons, occupy the latitude of the northern trades, and by their force sweep across the greater part of the usual zone of calms, and in the season of the northern summer they exert some influence several degrees south of the equator. The southern part of the Indian ocean has a normal trade wind at all seasons and the northern part has in the winter months.

The sailing routes of the Indian ocean, the creation of these winds, unlike those of the Atlantic and Pacific, have somewhat the form of trunk lines and branches with separate systems inbound and outbound at the point of Africa. The inbound trunk follows the southern margin of the ocean from west to east. On this thoroughfare the navigator takes advantage of the steady west wind as long as possible before turning northward to the ports of Africa, Asia or the East Indies. Australian vessels complete the voyage before the west wind. Vessels turning toward Asia or the Sunda

Islands can sail by the trade winds directly north to the vicinity of the equator. Here the course, for points beyond the equator, must change to take advantage of the changing monsoons. The summer route to Bombay passes north close to the east coast of Madagascar, and goes with the southwest monsoon across the Arabian Sea. The winter route, avoiding the full force of the winter (northeast) monsoon, goes northward toward Ceylon and then turning northwest follows the west coast of India at right angles to the wind. The return routes for both seasons follow closely upon the latter route as far as the equator, and then, like all the returning routes of the Indian ocean, go west southwest across the southeast trade wind to the point of Africa, avoiding the westerly winds as much as possible. The routes to and from Calcutta show the results of exactly the same principles that entered into the location of the Bombay routes. They do not cover so wide an area because the Bay of Bengal is so much narrower than the Arabian Sea. Sunda Strait, the sailers' gateway to the East Indies, the Philippines and the coasts of East Asia, is below the monsoon zone, and has but one approach directly from the south and one outbound route, a direct line to the point of Africa.

The South American trunk route sweeps around the two longer sides of that continent from Cape St. Roque to Panama and on up the coast of America to British Columbia. Like the other trunk routes it is fed from two sources, Atlantic North America and Europe, the two parent streams uniting at Cape St. Roque. The greatest sources of traffic for this route in eastern South America are the Brazilian coffee from Rio Janeiro and Santos, and the grain and animal products of the La Plata ports. Many vessels, devoted only to the trade of the west coast, call at east coast ports only for coal, but discharge and receive cargo at many ports upon the west coast between Valdivia in southern Chile and Guayaquil, Ecuador. A few steamers continue this semi-coasting trade along the coasts of western Columbia, Central America, Mexico and the United States to San Francisco and Puget Sound. Other steamers round the continent of South America, but have no South American trade. Since 1901 a number of steamers have sailed from the Pacific ports of North America for European ports without doing a coasting trade en route, but all steamers in this trade are an innovation in a trade that has belonged exclusively to the sailer.

Steamship Obidense; Booth Line to Para.

At the Straits of Magellan the traffic of this route is swelled by vessels in the New Zealand trade, particularly those returning loaded toward Europe. With this exception, the South American trunk does not in its steam traffic receive long branches or feeders as does the Mediterranean-Asiatic in rounding the continent of Asia. The difference is more apparent than real. The Asiatic route skirts the heads of peninsulas, and is often hundreds of miles from the ports lying at the heads of the seas indenting the coast. The branch routes to these ports are evident. The coast of South America is so even that any steamer passing around the continent passes comparatively near to all the ports. The real effect of branches is preserved by the division of the territory among the steamer lines. Some call at the ports of one section of the coast and have no freight connection whatever with other districts. Some lines of west coast of South America steamers are as separate from the other traffic of the South American trunk as the Calcutta or Zanzibar steamers are separate from the remaining traffic of the Mediterranean-Asiatic trunk.

The sailing contingent on the South American trunk route keep safely out of sight of the steamer that hugs the coast to save miles. While the steamer creeps through the squally and tortuous Straits of Magellan the sailer puts in another thousand miles in enduring the buffetings of the western fury off Cape Horn. So steady and so strong is this wind that ships sometimes stand for weeks in almost one place and some have given it up and turned about to seek their Pacific destination by going around the world before the west wind that ramps about without ceasing across the antipodean seas.

The sailing routes of the Pacific are shaped by the same forces that operate in the Atlantic. The effect of the prevailing winds is distinctly marked in the north and south tracks. Northward from Cape Horn vessels run comparatively close to the coast and directly across the course of the west winds. When the ships bound for the Pacific coast of the United States reach the southeast trade they follow it to the equator, work as best they can directly north across the zone of calms and then at right angles across the northeast trade until they reach the westerly winds, before which they run directly to the land. This last characteristic is much more pronounced in the route from Australia. The remarkable curves in the northern and southern parts of this route giving it the shape of a letter S, are striking evidences of the value to the sailor of the westerly winds of the temperate zones. The sailing route from San Francisco to Cape Horn goes southward with the northeast trade, turns to the west to get a sailing angle across the southeast trade and then below the tropic gradually swings southeastward to the Cape with the westerly winds. From San Francisco to Australia this route is comparatively direct to the tropic of Capricorn, where a turn to the west is made to avoid the westerly winds until as near the Australian coast as possible.

The captain sailing around Cape Horn into the Atlantic desires to avoid the coastal wind and current that carried this ship downward and inside the Falkland Islands. Inbound, he steers far to the east of the Falklands, keeping in the prevailing west winds as long as possible, and then borne onward by the southeast trades makes a gradual curve toward the equator at mid-ocean. If the destination is America, a northwesterly route is taken at 10 deg. S., and north of the equator, the routes to American and European ports are similar to those from the Indian ocean, described above.

The Pacific ocean is peculiar in that it may in a sense be said to be uncrossed by any present or prospective Great Routes except the one calling at Hawaii. Despite the riches upon its shares, the Pacific may well be called a waste of water. Only upon or near its margin will great and promising trade routes arise, leaving its vast center to silence and to routes of secondary importance. It is difficult to realize that this one ocean embraces nearly one-half of the entire surface of the globe, that between the mainland of the American continent at the equator, in Ecuador and the opposite mainland of Asia, near Singapore, lies the distance of 12,000 miles, or 175 deg., almost half the distance around the world. Between these two equatorial points upon the spherical surface of the globe there are three connecting lines of practically equal length, one following the equator directly across the mid-ocean and two slightly shorter ones following the meridians (great circles) and passing respectively near the north pole and the south pole. As steamer routes follow great circles, the great size of the Pacific causes most of its routes to avoid its middle and skirt its margin. Routes from east to west must, to follow great circles, keep in high latitudes near the margin of the ocean to secure their shortest courses. A glance at Pacific traffic shows it to be on the margins.

The heaviest commerce in the Pacific waters passes up and down the coasts of East Asia and of South America, bound for the exits at Singapore and the Straits of Magellan. By far the most important route entirely upon the Pacific is that connecting North America and Asia, the American-Oriental trunk route. Like the North Atlantic route this is a composite one, and not so compact because of the irregularities produced by the calls of some lines at Hawaii, 2,000 miles below the line of shortest passage between Puget Sound and Yokohama. It is nevertheless proper to consider the North Pacific lines as one trunk route, since all the different courses are close together at the American end, and converge at Yokohama to follow the Asiatic coast to the ports of China or the Philippines. One line now sends steamers to Manila directly from Yokohama, having them call at Hong Kong and Shanghai on the return. It is probable that other lines now sailing no farther than Hong Kong will, if there is increase in Philippine industry, extend their service by making Manila the final destination. This fact of the shape of the earth and the great circle routes show the futility of the hope that Manila might become the Gateway of the East. It is the last port of the row.

On the American side the Asiatic lines have within recent years originated at six places: Manzanillo (Mexico), San Diego, San Francisco, Portland and Puget Sound, and before many years there will probably be other American ports added to the list, although the first two are now discontinued. Lines of vessels start from San

Francisco and call at Honolulu, although it lengthens the voyage more than 800 miles. From all starting points vessels also go directly to Yokohama, and usually by the northern or great circle route. From Puget Sound it is impossible to follow a perfect circle because of the Aleutian Islands, within sight of which the vessels pass in good summer weather. In the winter it is the practice of some captains to steer straight across the ocean or even to go south of the direct route to secure more favorable winds and weather. The great circle route is the one most commonly followed, unless calling at Hawaii, and from all points on the American coast, including Panama, this, the mathematically shortest route to any point in Asia, follows the coast line to California, passes close to San Francisco, closer to Puget Sound than to Hawaii, and thence northward to the latitude of Alaska before turning south and skirting the shore of Japan.

A route of less importance and far less promise than the Oriental is the Pacific coast, Australasian, the last of the steam trunk routes. This route, like the preceding, is composite and more definitely spread out than any other trunk routes. On the east is the course followed by the line plying between San Francisco and Auckland, New Zealand, via Tahiti, Society Islands; on the west that from Vancouver to Sydney via Honolulu and Fiji Islands. By a branching of the route at Honolulu, San Francisco is connected with Sydney, and by other branchings at Fiji and Samoa, British Columbia is connected with New Zealand.

This route across the Pacific has been found by experience to be the quickest mail route from Australia to Europe. The weather in the Pacific is usually reliable and favorable, and when the mail has reached San Francisco by direct steamer, it has the advantage of the fastest long-distance train service in the world to New York, and thence to Liverpool the fastest steamship service in the world. In competition with this is the route followed by the slower steamers crossing the Indian ocean, the Red and Mediterranean Seas, and delivering the mail to the railroad only at Brindisi, Italy, whence, with several days saving of time, it crosses the Alps to Paris and London. There are fundamental traffic reasons, however, why the Pacific coast-Australasia routes lack great promise for the future.

The winds of the North Pacific being essentially like those of the North Atlantic produce a very similar result in sailing tracks, except that all vessels follow the southern track going west.

This brief presentation of the world's ocean routes makes no pretence of being full or complete, but only to point out the main arteries of world commerce, leaving the minor tributaries and distributaries to be worked out by those who may have a special interest in the subject.

The avenues of commerce have been divided off into routes having separate names, but it should not be thought that each is separate from the others. The divisions have been made in part for convenience of description, for the routes are not entirely separate, but connect and overlap at various points into a unified system encircling of the world.

No trunk route with its branches can be considered as an independent unit of circulation with vessels limited to it, and going and coming in even procession with equal numbers inbound and outbound. As no country imports and exports equal quantities of freight, so no route has similar amounts of freight or the requirement for equal number of vessels going and returning. It is usually but not always true that the line steamers go and return by the same route. The irregular element is chiefly furnished by the chartered vessels or tramps which depart from the trunk routes at ports where more freight is imported than exported. They go seeking freight and join other routes at ports that ship more freight than they receive. By this process the Good Hope route is a heavy loser, and the South American and the Mediterranean-Asiatic are gainers. South Africa imports coal, flour, lumber and general manufactures and supplies—all of them being heavy and bulky articles. The leading exports are gold and diamonds, requiring no space worth mentioning. South Africa is, therefore, a dispersing for vessels charged with ballast and seeking freight. Some go to India for grain or jute, others to Burmah for rice, others to Java for sugar, some to Buenos Ayres for wheat, some are even compelled to go to the United States.

In Australia the same conditions are repeated. This commonwealth imports iron, lumber and general manufactures, and exports wool, hides and meat, all of them several times as valuable per ton as the staple imports. Sometimes there is a small export of wheat, but there is usually a large surplus of shipping that must fall back upon coal, which fortunately Australia possesses at Newcastle, 60 miles north of Sydney. With this cargo many vessels go to East Indian and Oriental ports—Batavia, Sourabaya, Singapore, Manila, Hong Kong. After discharging the coal they can sometimes reload directly, but often another though shorter ballast voyage must be made to secure a cargo of Java sugar, Manila hemp, Siam or Burmah rice or even Indian jute, grain and seeds. From Newcastle (Australia) other vessels, usually sailers, depart to Hawaii for sugar or to San Francisco, Portland or Puget Sound for wheat. Others, both sail and steam, carry coal cargoes to northern Chile for nitrate of soda. By these various routes a large proportion, possibly a half, of the vessels that go out on the South African trunk route return to the North Atlantic by another way.

China and Japan are likewise countries with a surplus of outgoing shipping, and Japan is an exporter of coal that is in common use as far south as Singapore, and it is sometimes sent to Hawaii and the Pacific coast of the United States. The surplus shipping of East Asia usually seeks cargo in the Philippines, Java or the United States, some vessels crossing the North Pacific and transferring themselves from the Mediterranean-Asiatic trunk to the South American by way of the American-Oriental.

Triangular voyages are often made in these transfers from route to route. Such a triangle in the North Atlantic is very pronounced.

Brazil exports coffee very largely to the United States, and as the return cargo is light, many of the coffee ships load in American ports for Europe and return thence with European goods to Brazil, completing a triangular voyage. Voyages of a triangle character are often made by tramp vessels, and many of them can be figured out from the examples given above, but none of the many triangular voyages are so plain, so unobstructed and so nearly equilateral or so systematically followed as the Atlantic triangle.

The balance among the routes will be very much disturbed by the opening of the Panama canal, which will give such an added opportunity for vessels to take shorter routes and to switch from route to route as indicated by the accompanying table of distances.

TABLE OF DISTANCES

One of the first of these developments is likely to be the establishment of a new current of round the world traffic for both tramp and liner.

It is now the custom for liners going out from Europe to China to end the voyage at Yokohama. But once in Yokohama, the most economical route for the return is by way of America, provided Panama were passable. The steamers could discharge and receive cargo at Hong Kong and Shanghai, and continue from Yokohama to San Francisco. The freight conditions in this part of the world would favor this practice because the trade from China and Japan toward Europe is much lighter than that going the other way. The steamers at Yokohama are, therefore, in straits for freight, and it would be natural for them to seek the abundant freights of California, and thus adopt the practice that is being, and has been long, followed by many sailing vessels that have discharged cargoes in the ports of East Asia. This prediction is further strengthened by the recent establishment of a line of steamers running from England to China and Japan, and then for the sake of a return cargo going on to Portland and Seattle, securing nearly a full cargo of wheat, returning thence to Asia, where such other cargo as may be secured is added, and the whole carried westward through the Suez Canal to Europe. The Hamburg-America Co. has a service across to San Francisco, and a contract to establish one to Mexico. With the Panama Canal in operation it is scarcely possible that these steamers would return to England by the longer Asiatic route. If the Suez Canal tolls should be as low as those at Panama (which is very unlikely) the use of the American route by regular lines from Japan to Europe would be probable, because the temptation of Pacific coast freight would continue strong and would certainly, as at present, draw many tramp vessels across the North Pacific.

(*To be continued.*)

The American traveler accustomed to make free with uncomplimentary remarks to train and station men must put a bridle on his tongue in Germany. A merchant with a monthly commutation ticket traveled on a certain express train from Duisburg to Bochum. His ticket read "good on all trains for which an extra charge is not made." Now a time-table sold on this line named this train as one on which commutation tickets are good. But when he was leaving the train the gateman held him up for 10 cents. After some heated discussion the passenger allowed himself to say: "You stupid fellow; you don't understand your own business." Now it turned out that the gateman did understand his business; and that it was by an error that this train was named in the time-table as available with commutation tickets. Arrest for insulting a public servant; 20 marks fine.

New Locomotives for the Atchison, Topeka & Santa Fe.

The Baldwin Locomotive Works recently completed an order for 49 locomotives for the Atchison, Topeka & Santa Fe. Seven of these are Pacific engines for passenger service, and 42 consolidation, for freight service. All have single expansion cylinders, piston valves, Walschaerts valve motion and smokebox superheaters. Ten of the consolidation locomotives are equipped for burning coal; the remainder, including the Pacific type engines, are arranged for burning oil.

The Santa Fe has been operating for some time a ten-coupled locomotive with a smokebox superheater, and its successful performance has resulted in the adoption of superheated steam at comparatively low pressure on these later engines.

The Pacific locomotives have 25 x 28-in. cylinders and driving wheels 73 in. in diameter, and, as the safety valves are set at 160 lbs., the tractive force is 32,600 lbs. The boiler is straight top, with sloping throat and back head, and tubes 20 ft. long. The barrel is built up of four rings, which have "Diamond" butt joint seams on the top center line. The firebox is radially stayed, and the front end of the crown is supported by two I-irons. All firebox rivets are countersunk on the inside. Washout plugs are liberally provided in the front tube sheet, back head and water legs; also on the lower center line of the barrel, along the water level, and in the outside sheet just below the firebox crown.

The superheater is the type developed by the Baldwin Locomotive Works, and illustrated in the *Railroad Gazette* of June 7, 1907. The final passage of the steam is through the tubes at the back of the smokebox, where the gases are hottest. The arrangement of the drums and tubes is shown in the engraving. The joints between the tube plates and drums are made tight with copper gaskets.

The cylinders are designed for double front rails, and are equipped with inside admission piston valves 13 in. in diameter. The steam chest center lines are 6 in. outside the cylinder center lines. The valves have a steam lap of 1⅛ in., and an exhaust clearance of ⅛ in. They are set with a constant lead of ¼ in. and have 6¼ in. maximum travel. The relief valves are the style used by the Pennsylvania on its piston valve locomotives. The live steam ports extend up to a horizontal face above the steam chest. The ports are covered by a plate, which, when the throttle is open, is held on its seat by steam pressure acting on its upper surface. Should the pressure underneath become excessive, the plate is lifted from its seat, and communication thus established between the two ends of the cylinder.

The location of the steam chests makes it possible to use a direct form of valve motion with all parts placed in practically the same vertical plane. Each link is supported by two cast-steel bearers which are bolted in front to the guide yoke, and at the back to a suitable support. The valve rod is carried on a bearer bolted to the top guide, and is rectangular in section

The front truck is swing bolster, with cast-steel saddle and three-point suspension links. The rear truck is the Rushton pattern with outside journals. The engine truck and tender wheels are steel-tired with cast-steel spoke centers and were made by the Standard Steel Works.

The tender frame is of 12-in. steel channels with wood bumpers, and the trucks have arch bar frames, cast-steel bolsters and triple elliptic springs. The tank has a water bottom.

The consolidation type locomotives have 24 x 32-in. cylinders, 57-in. driving wheels and 160 lbs. steam pressure, giving them a tractive force of 43,970 lbs. The details are in many respects similar to those of the Pacific locomotives. This is especially true of the cylinders, with their piston and relief valves, valve motion details, and many of the smaller fittings. The link bearings on the consolidation engines are bolted to the guide yoke, which also serves as a support for the reverse shaft bearings. The cast-steel details for both types include frames, wheel centers, driving boxes and spring saddles, cylinder heads, crossheads and foot plates. The

Consolidation Locomotive Built for Atchison, Topeka & Santa Fe, by Baldwin Locomotive Works.

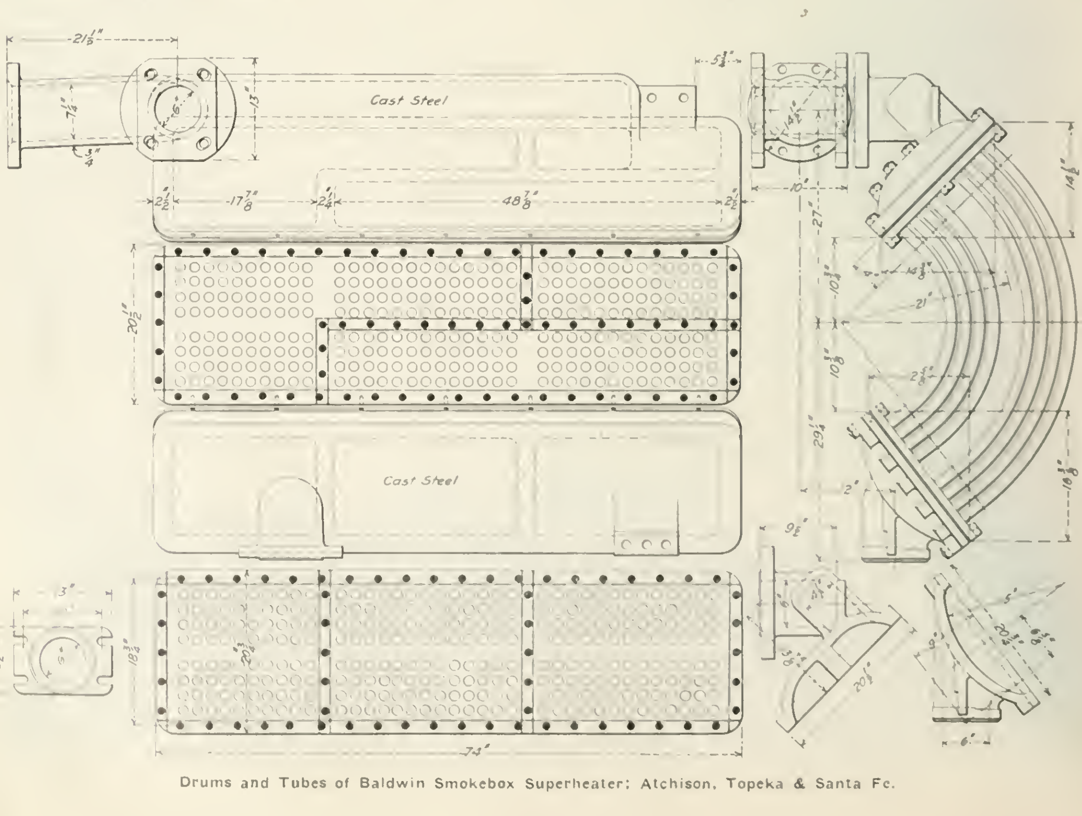
*Per cent.

It is interesting to note that the steam pressure has been cut down from the 180 or 200 lbs. that is the prevailing practice in this country to a figure where boiler maintenance and repairs are more economically effected. This is also nearer the most economical figure for steam consumption as established by the investigations of Prof. Goss, although somewhat below that pressure. In the equating of the tube to firebox heating surface by the Vaughan formula, it will be seen that the figures are almost the same, being within a fraction of a foot, showing markedly the relation between tube length and number of tubes. In this case, the tubes of the Pacific engine are one-third longer than those of the consolidation, while the latter engine has 30 per cent. more tubes. The ratios do not, however, hold exactly, because of the larger diameter of the tubes in the Pacific engine; but the ratio is suggestive of the alternative offered the designer.



Drums and Tubes of Baldwin Smokebox Superheater; Atchison, Topeka & Santa Fe.

GENERAL NEWS SECTION

NOTES.

The Attorney-General of Nebraska has begun suits in the Supreme Court of the state to enforce the Sibley act reducing express rates 25 per cent.

According to a circular recently issued to stockholders in the Chicago Subway Co. the company now has 90 connections with freight producing points.

Western Colorado believes it can grow the finest potatoes in the world, and the Denver & Rio Grande is sending a special train around to give instructions in the art.

R. C. Richards, Claim Agent of the Chicago & North-Western, says that out of 110,000 claims presented last year for loss and damage the road paid 40,000 on the spot.

Proportional rates on grain and grain products from St. Louis to Trunk Line territory have been established by the Wabash, the Clover Leaf, the Alton and the Chicago, Peoria & St. Louis.

Owing to the action of Georgia lawyers in attempting to tie up the funds of the Southern Railway by garnishment and attachments for damage suits, the company has withdrawn its depository funds from the state of Georgia.

Nine railroads in the New England Car Service Association report that 93.6 per cent. of the cars handled in February, 1908, were released within the allowed limit of 96 hours. The proportion for September, 1907, was 92.6 per cent.

The Missouri Pacific has notified the Nebraska Railroad Commission that it will give to shippers of corn and wheat a rate to St. Louis equal to the local rates through Nebraska, and not compel them to ship by way of Omaha at a greater rate.

The Great Western Railway Company, of England, has established an office in the Times building, New York, to afford information to tourists who intend visiting the British Isles and to shippers. T. Kateley has been made General Agent for the United States.

Five special farmers' trains from the East and South came into Winnipeg on March 20. A continuously heavy movement of farming settlers from the United States is reported, most of the settlers coming from Illinois, Ohio, Indiana, Iowa, Nebraska, Minnesota and the Dakotas.

The New York City Public Service Commission on March 19 held that passengers on steam railroads within the city limits of New York need not pay the 10 cents excess fare charged them by the conductors of the train if they fail to purchase their tickets at the ticket office.

The chairman of the Michigan Railroad Commission is quoted as saying that the commission will be lenient for 60 or 90 days and will then be disposed to raise objection to the closing of small stations by railroads in the state in order to reduce expenses under the nine-hour law.

The Canadian Pacific announces that it will grant party rates for parties of ten or more traveling on a single ticket from points in eastern Canada to the Northwest, west of Winnipeg, and to Seattle, Tacoma and Portland on a basis of one fare for the round trip by the all-Canadian route.

The Interstate Commerce Commission has sent a communication to the House of Representatives in which it estimates that the supervision of railroad accounts under the present Interstate Commerce Act will cost the government $750,000 a year. How much it will cost the railroads, it does not estimate.

The Texas & Pacific has advised the Texas Railroad Commission that it will be unable to comply with the Commission's betterment requirements on account of the condition of the money market. Counsel for the road points out that improvements have been ordered which are unnecessary in a period of slight traffic.

The Interstate Commerce Commission has intervened in the controversy between the receivers of the Chicago Great Western and the employees of the road. The receivers have been requested to take no further action until the commission has had an opportunity to use its friendly offices to secure an amicable adjustment.

The Attorney-General of Wisconsin has advised the railroad commission that railroad companies operating in Wisconsin have no authority to charge more than 2 cents per mile for carrying passengers unless they make proper provision for refunding the excess charge. The question was raised by the application of a railroad for permission to require passengers who have an opportunity to purchase tickets, but fail to do so before boarding trains, to pay something in addition to the schedule fare.

Instructions have been sent to the station agents on the El Paso & Southwestern that they will be held responsible for bundles and packages checked from their stations as baggage when they do not come under the company's definition of the term, and that they will have to pay the express charges on such articles if reported by the express companies.

As a result of the ocean rate war, the North German Lloyd Steamship Co. reports annual earnings of $8,174,250, gross, as against $9,829,500 in 1907. The company has declared a 4½ per cent. annual dividend, as compared with 8½ per cent. last year, and has carried forward considerably less than half of the reserve that was carried forward in 1907.

What is known as the Hepburn bill, to amend the Sherman Anti-Trust law, was introduced in the House of Representatives on March 23. The bill provides, among other things, that corporations which file news of contracts and agreements with the proper federal authority are to have immunity from prosecution under the Anti-Trust law if these contracts and agreements are approved.

Following the meeting of the Transcontinental Passenger Association, the Harriman lines and the Atchison, Topeka & Santa Fe have given notice of independent action on tourist rates to the Pacific coast this summer. As against the 2-cent-a-mile basis advocated by the northern lines, the southern lines stood out for a basis similar to that applying to common points in Colorado. From Chicago the round trip rate to coast points between San Diego, on the south, and Vancouver, on the north, will be $72.50.

A bill has been introduced in both houses of the New York legislature to place telegraph and telephone companies and ferry and stage line companies under the jurisdiction of the Public Service commissions. A provision is also inserted in the bill to enable the New York City commission to proceed against the street railway corporations of New York for the forfeiture of rights they claim on certain streets in the downtown section if the commission decides that the corporations are exercising franchises without authority, or have abandoned or do not use all or part of their franchises. Provision is also made for giving the commission the power to audit accounts and to decide, after hearing, how outlays and receipts shall be charged and credited.

Pennsylvania Steel Coaches.

The first one of the 200 all-steel passenger cars ordered by the Pennsylvania last year has just been placed in service between New York and Philadelphia. This coach is 70 ft. long. Aside from the mahogany window sash and seat frames, there is no wood whatever in the coach. It seats 88 persons and weighs 53 tons. It is one of 25 being built at Altoona; the rest of the order was placed with the Pressed Steel Car Co. and the American Car & Foundry Co. These cars were described in the *Railroad Gazette* of June 14, 1907.

President Newman on the Railroad Situation.

The following comments are taken from an advance proof of the current annual report of the New York Central & Hudson River:

The tendency to regulate railroads and the details of their business has been shown in many federal and state laws, either enacted or proposed. The Interstate Commerce Commission and the public service commissions which have been established in a number of the states, have been given indefinite and almost arbitrary power. Hours of labor have been shortened by law, rates of fare have been reduced, liability for accidents has been increased, and in ways too numerous to mention, burdens have been placed on railroad companies which other corporations are not subjected to, and their ability to bear them has been lessened. While the enactment of just and equal laws is of the highest importance to railroads, much of the recent legislation has not been preceded by intelligent study or investigation and has been passed without reference to practical results. Uncertainty as to the effect of these new laws, and doubt as to how far regulation and special legislation as to railroads is to be carried, has without question been one of the causes which have unsettled the value of securities and helped to bring on the present period of depression.

The great expansion of business throughout the country during the period of prosperity which ended in October last brought to this company a rapid increase in the volume of traffic. There has been a continued growth in gross earnings for several years past, but this has been due to increase in the amount of business rather than to an increase in rates. Incident to good times, in order to handle the growing volume of traffic, facilities had to be quickly enlarged at great expense and the number of employees increased. Meanwhile wages and the cost of material rose to a level never before reached in recent years. When, therefore, late in the fall of 1907 depression set in, it was at once felt by this company as well as by all other lines, and gross earnings fell off suddenly and heavily. It was impossible to reduce expenses at once to correspond with the shrinkage in gross revenue.

Minnesota and North Carolina Laws Upset.

On March 23 the United States Supreme Court found the new railroad law of Minnesota and of North Carolina unconstitutional.

In the Minnesota case the controversy arose over the enactment of the 2 cent rate law and the excessive penalties that were provided against the railroads or their officers who refused to comply with its terms—$5,000 fine and five years' imprisonment for each refusal to sell a ticket at the rate named, and over the commodity rates, which were to have gone into effect June 1 last, reducing substantially the rates on certain merchandise and prescribing the minimum weights for carloads. Before that date, however, certain stockholders of the Northern Pacific road brought suit in the Federal Court for the District of Minnesota to enjoin the Attorney-General of the state from putting the rates into effect. That official appeared for the special purpose of objecting to the jurisdiction of the court, contending that it was without authority because the suit was in effect one against a state, prohibited by the Eleventh Amendment. This demurrer was overruled and an order was issued enjoining the enforcement of the rates until it could be determined judicially whether or not they were confiscatory, as claimed by the stockholders.

Attorney-General Young, however, paid no attention to the injunction, but the next day instituted in the state courts proceedings to compel the Northern Pacific to adopt the commodity rates prescribed. When this action was brought to the attention of the Federal Court, the Attorney-General was arrested and after a hearing, in which he again set up his immunity under the Eleventh Amendment, he was adjudged in contempt of the Federal Court, fined $100 and committed to the custody of the United States Marshal until paid and he should purge himself by withdrawing the suit from the state court. Instead he applied to the Supreme Court for a writ of habeas corpus for his release.

Justice Peckham, who delivered the opinion, said that the lower court was given jurisdiction in suits arising under the laws and the Constitution of the United States, and the question really to be determined was whether the acts of the Legislature, if enforced, would take property without due process of law, and the question might incidentally involve a question of fact; its solution, nevertheless, was one that raised a Federal question. The sufficiency of rates with reference to the Federal Constitution, he said, was a judicial question and one over which the Federal courts had jurisdiction, and had been settled by a long line of decisions.

Quoting from prior decisions that a law was invalid where it imposed a remedy so difficult to enforce as to be no remedy at all and that a rate was unconstitutional where the decision of the Legislature or its commission was conclusive as to the sufficiency of the rates, Justice Peckham said that a law which indirectly accomplished a like result by imposing such conditions upon the right to appeal for judicial relief as worked an abandonment of the right rather than face the conditions upon which it was offered or might be obtained was also unconstitutional. He continued:

It may, therefore, be said that when the penalties for disobedience are by fines so enormous and imprisonment so severe as to intimidate the company and its officers from resorting to the courts to test the validity of the legislation the result is the same as if the law in terms prohibited the company from seeking judicial construction of laws which deeply affect its rights.

For that reason the court holds the Minnesota freight and passenger rates to be unconstitutional on their face without regard to the question of the sufficiency of those rates. The Circuit Court, therefore, had jurisdiction and it was its duty to inquire whether the rates permitted by those acts were too low and therefore confiscatory, and if so held that the court then had jurisdiction to permanently enjoin their enforcement. It also had power while the inquiry was pending to grant a temporary injunction to the same effect.

Referring to the affidavits submitted in the case showing that the rates were confiscatory the opinion continues:

We have, therefore, upon this record the case of an unconstitutional act of the state legislature and an intention by the Attorney General of the state to endeavor to enforce its provisions to the injury of the company, compelling it at great expense to defend legal proceedings of a complicated and unusual character and involving questions of vast importance to all employees and officers of the company, as well as to the company itself. The question that arises is whether there is a remedy that the parties interested may resort to by going into a federal court of equity in a case involving a violation of the federal constitution and obtaining a judicial investigation of the problem, and pending its solution obtain freedom from suits, civil or criminal, by a temporary injunction; and if the question be finally decided favorably to the contention of the company a permanent injunction restraining all such actions or proceedings.

This inquiry necessitates an examination of the most material and important objection made to the jurisdiction of the Circuit Court, the objection being that the suit is in effect one against the state of Minnesota and that the injunction issued against the Attorney General illegally prohibits state action, either criminal or civil, to enforce obedience to the statutes of the state.

In the lower court, says the opinion, the case had proceeded on the theory that the rights of the stockholders protected by the Fourteenth Amendment would be violated if the rates were enforced.

A decision in the case, however, did not require a decision of the question whether the adoption of that amendment in any way altered or limited the effect of the Eleventh Amendment prohibiting a suit against a state.

The general discretion regarding the enforcement of the laws when and as the District Attorney deems appropriate is not interfered with by an injunction which restrains the state officer from taking steps toward the enforcement of an unconstitutional enactment to the injury of complainants. In such case no affirmative action of any nature is directed and the officer is simply prohibited from doing an act which he had no legal right to do. An injunction to prevent him from doing that which he has no legal right to do is not an interference with the discretion of an officer.

If the act which the Attorney-General seeks to enforce be a violation of the federal constitution the officer in proceeding under such enactment comes into conflict with the superior authority of that constitution and he is in that case stripped of his official or representative character and is subjected in his person to the consequences of his individual conduct. The state has no power to impart to him any immunity from responsibility to the supreme authority of the United States.

Justice Harlan dissented from the majority opinion, on grounds of states' rights.

Railroad Earnings; July, 1907, to January, 1908.

The report of railroad earnings to the Interstate Commerce Commission do not admit of a comparison with the earnings of previous years, but they are now beginning to be useful as a means of studying developments in the business of transportation for a number of months past. Gross and net earnings of practically all the railroads in the country by months, from July 1 to December 31, are now available, and the figures for January cover the earnings of 183,400 miles of road out of a total of something over 224,000 miles.

For the sake of accurate comparison the earnings have been reduced in the subjoined table to a per mile basis. The January figures are affected more or less by the fact that approximately 19 per cent. of the total mileage of the country is not included, but the portion included is so substantial that the gross and net earnings per mile are probably not far from what the complete figures will show. The net figures given represent the operating income after taxes. The operating ratio represents the proportion of strictly operating expenses, exclusive of taxes, to gross earnings:

	Gross.	Net.	Op. ratio.
January	$770	$153	78.4
December	863	198	73.5
November	983	262	70.1
October	1,117	339	66.8
September	1,048	314	67.0
August	1,079	345	65.2
July	1,022	304	67.2

Gross earnings reached their maximum in October, but net earnings were not at their highest in that month, having been $6 per mile or a little less than 2 per cent. under the net returns of August. Taking the October earnings to represent the high tide of railroad prosperity the falling off in three months, as shown by the January figures, was 31 per cent. in gross earnings and 55 per cent. in net earnings after taxes. The successive operating ratios indicate how slow the railroads were to reduce expenses proportionately to the loss of business.—*Wall Street Journal.*

Passenger Travel on the Great Lakes.

In the eighth inspection district, 11,915,345 passengers were carried by vessels during the season of 1907. The passenger traffic originating at Detroit, which forms a part of the eighth district, embraced 7,805,558 of these persons. The number of passengers carried out of Chicago by water was 1,967,994. The number of persons transported on the ferries enters into the total carried out of Detroit. In the entire district there was the loss of but a single life among passengers, and that was occasioned by the burning of a boat in Lake Michigan.—*Detroit Free Press.*

Report of United States Steel Corporation.

Gross sales and earnings of the United States Steel Corporation in the year ended December 31, 1907, were $757,000,000, against $697,000,000 in 1906. Net earnings were $161,000,000, against $157,000,000 in 1906. The balance applicable for dividends on the common stock or for new construction amounted to $79,000,000, or 15.6 per cent. on the common stock, as against $73,000,000, or 14.3 on the common stock in 1906. The total profit and loss surpluses of the corporation and its subsidiaries on December 31, 1907, was $123,000,000. This surplus stood at $98,000,000 a year earlier. The appropriations for new construction amounted to $54,000,000, as against $50,000,000 in 1906. There were 22,400,000 tons of iron ore mined during the year, as against 20,600,000 tons in 1906. The corporation sold 1,734,000 tons of steel rails in 1907, as against 1,983,000 tons in 1906. The average number of employees in service was 210,180, compared with 202,457, in 1906. The number of blast furnaces was 116, as against 97 in 1906.

Boycott Injunction Made Permanent.

The restraining order and injunction issued against the American Federation of Labor and its executive counsel, their agents, attorneys, servants, etc., at the instance of Buck's Stove and Range Company of St. Louis, by Justice Gould, of the Supreme Court of the District of Columbia in December last, were made permanent March 23 by Chief Justice Clabaugh. The signing of the decree was the result of agreement of counsel for both sides, although an appeal was taken by the Federation as a legal safeguard in case of possible developments in the future.

The decree is practically identical with that signed by Justice Gould in December. It restrains the Federation, its executive counsel, etc., from publishing the Buck's Stove and Range Company under its "We Don't Patronize," or "unfair" list, and prohibits them from boycotting or in any manner interfering with the stove company's business or with the sale of its product or of coercing or attempting to coerce any person, firm, corporation or the public from dealing in an unrestricted manner with the company.

Lectures on Railroad Electrification at the University of Michigan.

C. L. de Muralt, Consulting Engineer and Professor of Electrical Engineering at the University of Michigan, is giving a course of lectures to the senior electrical engineering students at Ann Arbor on the "Electrification of Steam Railroads." During the last term he has taken up such subjects as power station equipment, transmission and working conductors, motor characteristics, etc. He intends to supplement these by discussions of the technical and commercial features of the following subjects: "The General Electrification Problem"; "The Reasons for Electrification"; "The Operating Characteristics of Steam and Electric Locomotives"; "The Choice of Electric Systems"; "An Analysis of the Cost of Operation"; "The Field of Railroad Electrification: the Congested Terminal, the Mountain Grade, and the Trunk Line"; and "Preparation of an Electrification Project for a Particular Road," special attention being directed to such problems as the design of locomotives, the calculation of run sheets, the choice of speeds, study of the peak load, the location of substations, the economics of transmission and other collateral topics.

INTERSTATE COMMERCE COMMISSION RULINGS.

Rate Reduced on Coke from Colorado to Texas.

The Commission, opinion by Chairman Knapp, has announced decision in the case of the Amarillo Gas Co. vs. Atchison, Topeka & Santa Fe et al. The Commission held that defendants' rate of $3.35 per ton of 2,000 lbs. on coke in carloads from the Trinidad coal and coke district in Colorado to Amarillo, Tex., is excessive and unreasonable and should not exceed $2.90 per ton, the rate now in force for the transportation of soft coal between the same points.

Rates on Snapped and Shelled Corn.

The Commission, opinion by Commissioner Cockrell, has announced decision in the case of the Ocheltree Grain Co. vs. Chicago, Rock Island & Pacific. The complaint charged that an unreasonable rate was exacted on shipments of snapped corn, or corn in the shuck, the rate collected being 125 per cent. of the shelled corn rate. It was alleged that snapped corn is less valuable in proportion to weight, 72 lbs. making a bushel, than shelled corn, of which 54 lbs. make a bushel. At the hearing it appeared that the carrier had changed the rate on snapped corn to that on shelled corn. The Commission decided that the carrier, having changed the rate complained of, should keep its present rate on snapped corn in effect for two years.

Poor Location No Reason for Lower Rates.

The Commission, opinion by Chairman Knapp, has announced decision in the case of S. S. Quimby et al. vs. Maine Central and Washington County Railway. The complainants, situated in the eastern part of Washington county, Me., alleged that by reason of their location they cannot take advantage of the milling-in-transit privilege on corn, although their competitors at Bangor and Lewiston, Me., can do so, and therefore allowance of the transit privilege at Bangor and Lewiston constitutes undue discrimination against them.

The Commission declared that the disadvantage under which complainants labor is primarily due to their unfavorable location and that it is not the province of the Commission to overcome disadvantages of this nature by adjustment of transportation charges. If the privilege were denied to complainants and allowed to their competitors, the discrimination so practised might be unlawful; but no such claim was made.

Through Route and Joint Rate Ordered.

The Commission, opinion by Chairman Knapp, has announced decision in the case of the Merchants Freight Bureau of Little Rock, Ark., vs. Midland Valley and Chicago, Rock Island & Pacific. The complainant asked the Commission to establish through routes and joint rates for the transportation of cotton seed in carloads from points on the Midland Valley in Oklahoma, namely, Williams, Panama, Bokoshe, Keota, Stigler, Porum, Warner, Keefeton, Muskogee, Taft, Haskell, Elder and Tulsa, to Little Rock, Ark., via the Midland Valley and the Rock Island. The Commission decided that the failure of defendants to establish such routes and rates unduly discriminates against complainant in favor of manufacturers at Fort Smith, Ark., and Muskogee, Okla., and ordered defendants to establish a through route for the transportation of cotton seed in carloads from such points in Oklahoma over the Midland Valley to Hartford, Ark., and thence over the Rock Island to Little Rock, Ark., and to apply to such transportation joint through rates which as to each of said points of origin shall not exceed the present local charge of the Midland Valley from such shipping point to Hartford plus the present local charge of the Rock Island from Hartford to Little Rock.

Marine Insurance on Lake and Rail Shipments.

The Commission, opinion by Commissioner Prouty, has announced decision in the case of Wyman, Partridge & Co. et al. vs. Boston & Maine et al. This decision is a novel one in that it discusses the question of marine insurance. It seems that prior to the opening of navigation in 1907, shippers provided marine insurance on their rail and lake shipments from New York City to Chicago and Minneapolis, but after that time such rail and lake rates were advanced and the cost of insurance was included in the rates.

The Commission decided that unless a railroad forming part of a lake and rail route sees fit to hold itself responsible for losses arising from perils of the sea, it should tender to the public a transportation contract which leaves shippers free to arrange for their own marine insurance. The bill of lading issued did not show definitely the rights of the shippers. The Commission held that the advanced rates are unreasonable and should be reduced unless the carriers issue bills of lading making them definitely responsible for loss by perils of the sea. The opinion contains a table showing the exact reductions recommended, but no order will be made until May 1, 1908. An order will then be issued putting in the reduced rates above named unless the defendants have previously tendered a contract of shipment under which the shipper receives the same protection which he formerly had under his policy of marine insurance, and make the necessary changes in their tariffs, if any are required.

New Suit Necessary to Get Lower Rate.

The Commission, opinion by Commissioner Prouty, has announced decision in the case of the Merchants Traffic Association of Denver, Colo., vs. New York, New Haven & Hartford and 17 other carriers. The complaint alleged that the all-rail rate on cotton piece goods from New England points to Denver of $1.79 per 100 lbs., in any quantity, is unreasonable, and prayed that Denver be accorded a carload rate on such cotton fabrics. The Commission decided that the application for a carload rating be denied, but that the $1.79 rate is excessive and should not exceed $1.50.

This rate to Denver is not a joint through rate, but is made up of the local rate from New England to St. Louis plus the rate from St. Louis to Denver, or in some cases from St. Louis to Kansas City and from Kansas City to Denver. The Commission said that it might perhaps order a reduction of these several locals to such an extent as to bring the entire rate within the figure named by the Commission; but in that case the Commission would be passing upon a through rate from New England to Denver and no such rate is now in existence. The proper method to follow in cases like this, where no joint rate exists, is to cite before the Commission the proper defendants and pray for the establishment of a through route and joint rate. On a petition of that sort the Commission has power to do justice both to Denver and between the different participating carriers.

The complainant then offered the findings of the Commission and insisted that this ought to be sufficient to establish its right to an order, but the Commission held that the entire matter must be tried *de novo*. As no order could properly be made on the record in this case the complaint was dismissed.

The Commission's Authority in Oklahoma.

The Commission, opinion by Commissioner Lane, has announced decisions in seven cases, namely, A. T. Haines vs. Chicago, Rock Island & Pacific et al.; Kingfisher Mill & Elevator Co. vs. Chicago, Rock Island & Pacific and the Choctaw, Oklahoma & Gulf; Oklahoma Mill Co. vs. the same carriers; Schowalter & Company vs. the same carriers; J. P. Gist vs. the same carriers; Enid Ice & Fuel Co. vs. Chicago, Rock Island & Pacific, Enid Ice & Fuel Co vs. Fort Smith & Western, and W. B. Johnston vs. Chicago, Rock Island & Pacific.

The findings of the Commission in these decisions are: The Commission is the creature of statute and its authority is derived from the act of Congress creating it. Its function is to administer the Rate Law and not to enforce conditions found in federal or other charters. It is not its province to enforce compliance with conditions subsequent, found in railroad charters. Since the admission of Oklahoma as a state the Commission is without power to fix rates to be observed in the future within the present limits of that state.

Rates between points within the present limits of Oklahoma were held not unreasonable at the time shipments in question moved. The present rate of $1.85 per ton on shipments of slack coal from Weir and Midway, Kansas, to Goltry, Okla., is unreasonable and should not exceed $1.50 per ton. Rates between other points outside the present state of Oklahoma and points within that state held not unreasonable.

Coal Rates from Clinch Valley and Pocahontas Fields.

The Commission, opinion by Commissioner Lane, has announced decision in the case of the Raven Red Ash Coal Co. et al. vs. Norfolk & Western. Complainants are engaged in mining coal in the vicinity of Raven, a station in Virginia, on the Clinch Valley division of the Norfolk & Western. The question was whether the rate on coal in carloads from these mines to the eastern seaboard bears a proper relation to the rate charged from what are known as the Pocahontas and Tug River coal fields, which lie along the Pocahontas division of the Norfolk & Western for about 56 miles west of Graham, W. Va., the junction point of the two divisions. To reach the eastern seaboard, the movement from the mines is interstate, the coal being hauled through West Virginia. The rate on coal from mines on the Clinch Valley division to the eastern seaboard is 10 cents per ton more than from mines on the Pocahontas division. Complainants asked that the rate on coal from their mines on said Clinch Valley division to the eastern seaboard should be the same as that of their competitors in the Pocahontas fields, the distances being substantially the same.

The Commission was of opinion that complainants are entitled to the relief prayed for, and that their mines are entitled to the same rate on coal in carloads eastbound as is charged from the Pocahontas-Tug River coal fields, but held that no money damages should be allowed complainants on the shipments made. The Clinch Valley division for purposes of coal rates should be divided into two groups, one extending from Graham to a point 17 miles west of Raven and the other from Graham to Norton.

Joint Rate With Electric Railway Ordered.

The Commission, opinion by Commissioner Harlan, has announced decision in the case of the Cedar Rapids & Iowa City (Electric) Railway vs. Chicago & North-Western. This is a case where the Commission ordered through routes and joint rates to be established between an electric railway and a steam railroad. It appeared on complaint of failure by the steam railroad company to establish through routes and joint rates with the electric line between interstate points, that the shipping communities at points on the electric line between Coralville, Iowa, and Cedar Rapids, Iowa, do not enjoy the benefit of any reasonable or satisfactory through route from and to Chicago and other points reached by the defendant steam railroad.

The Commission held that through routes and joint rates thereover which shall not exceed by more than 10 per cent. the class and commodity rates of defendant between Chicago and common points and Cedar Rapids, should be established and maintained for the transportation of interstate traffic from and to Coralville and on all other points on the electric line intermediate to Cedar Rapids, to and from Chicago and other points on the line of the North-Western via the junction point between the two roads at Cedar Rapids. A former decision of the Commission in regard to the Chicago & Milwaukee Electric Railway was cited and affirmed and the distinction made between the transportation requirements of mere loading points serving one or more farms, as described in that case, and the more extensive requirements of small centers where general merchandising is done and the products of the countryside are concentrated for shipment and coal, lumber and other commodities are brought in to supply local needs.

The Baltic Pool.

The Commission, opinion by Commissioner Lane, has decided the case of the Cosmopolitan Shipping Co. vs. Hamburg-American Packet Co., North German Lloyd Steamship Co., Wilson (Hull) Lines and Scandinavian-American Line. The Commission's own digest of the case is as follows:

1. Complaint alleges that defendant steamship companies transport traffic under through bills of lading between inland points of the United States and foreign ports and are thereby subject to the jurisdiction of this Commission; that such defendants have made an arrangement for the pooling of eastbound export traffic moving by rail to Atlantic ports and thence by steamship lines to points in Denmark, Sweden, Norway, Finland and German points on the Baltic; that this "Baltic pool" arbitrarily determines the ultimate rates from such inland points of the United States to such foreign ports via the North Atlantic ports; and that the Hamburg-American Packet Co. maintains a monopoly of westbound and eastbound traffic forwarded on local and on through bills of lading between Germany and other continental countries and inland cities of the United States. The prayer is that the Commission declare the "Baltic pool" to be an illegal pooling of freights under the act, that the monopoly of the Hamburg-American Packet Co. be declared unlawful, and that general relief be granted. To this complaint defendants demur, on the grounds (a) that this Commission has no jurisdiction of the subject-matter, or power to proceed against defendants, and (b) that the complaint sets forth no matter which is cognizable by this Commission, or which it has been given authority to remedy. *Held*, That for reasons stated in the opinion, the demurrer will be sustained and the complaint dismissed.

2. This Commission has no jurisdiction as to shipments moving from ports of the United States to a foreign country not adjacent, when such shipments are not carried by rail, or by rail and water, from an inland point of origin to a port of transshipment. An inland movement of export or import traffic is a condition precedent to the attaching of jurisdiction.

3. The jurisdiction of this Commission is not to be determined by anything other than the language of Section 1 of the Act, and in this section is found a clear distinction drawn between interstate commerce and foreign commerce to a country not adjacent to the United States; and this distinction saves such foreign commerce from the effect of that provision of the section as to continuous carriage beyond the American seaboard.

4. The Commission may regulate interstate traffic, whether by rail or by a combined rail-and-water route, from point of receipt to point of delivery; but the Commission in its control over foreign commerce is limited to the regulation of such traffic, whether by railroad or by a combination of rail and water carriers, from and to the point of transshipment.

5. The Act provides no machinery by which its provisions can be enforced as to trans-Atlantic steamship lines; the absence of such provision can be explained only by accepting the interpretation that the Commission has no jurisdiction in the premises.

6. The pooling of traffic by water carriers is plainly a matter over which this Commission has no jurisdiction.

7. A rail carrier may control, and connect with, a line of steamships engaged in foreign commerce, with which it may interchange business as freely as with another rail carrier, and it may quote a combined rate for the through movement, the agent of the railroad company acting as the agent of the steamship company in so doing.

8. The Act provides that this Commission shall exercise jurisdiction over the inland portion of the haul, either to or from the foreign country; and it must logically and necessarily follow that the rate which must be filed with the Commission under Section 6 of the Act is the rate governing such movement. On foreign commerce the rate to be published with this Commission should be the rate to the port and from the port—an open rate, which any who desire to do so may use with equal advantage.

9. This position does not conclude the Commission against an examination into the relation which exists between the rail carriers of the United States and the defendant water carriers and condemnation of such arrangement, if the rail carriers to the seaboard are by any means whatsoever disobeying any provision of the Act or omitting to comply with its every requirement.

TRADE CATALOGUES.

Protective Coatings.—F. L. Melville, New York, maker of Anti-Rust, is distributing a circular giving prices and setting forth the advantages of this compound. It is for protecting machinery from rust during shipment. It is semi-liquid and the claims for it are that it is proof against salt water and steam, is always ready for use, will not thin and run off in hot weather, hard rains will not wash it off, it is free from grit, acid and vegetable or animal fats, will not tarnish the most delicate surface and can be removed by simply hard rubbing with waste or rags.

Reamers.—A pamphlet issued by the William J. Smith Co., New Haven, Conn., describes, with price lists, the Smith one-lock adjustable reamer. It is claimed that these can be accurately adjusted in a few seconds, and are as rigid as solid reamers. The blades are made in 14 sizes for reamers from ¾ in. to $3^3/_{16}$ in. in diameter. They are fitted with carbon steel or high-speed steel blades. The price lists include prices of each style and size, and of parts. Full dimensions are also given.

MANUFACTURING AND BUSINESS.

E. H. Rayburn, formerly Manager, in the South, for the Philip Carey Manufacturing Co., Cincinnati, Ohio, is now with the Franklin Manufacturing Co., Franklin, Pa.

Falls hollow staybolt iron, made by the Falls Hollow Staybolt Co., Cuyahoga Falls, Ohio, is to be used in the 30 locomotives being built by the American Locomotive Co. for the Paris-Orleans Railroad, France.

A. Johnston, Jr., for two years with the Van Deventer & Rider Co., Chicago, and before that for a number of years in the engineering department of the Chicago & Eastern Illinois, has opened an office as railroad fencing contractor at 152 East Lake street, Chicago.

D. R. Day, Secretary of the Northwestern Malleable Iron Co., Milwaukee, Wis., for the past 10 years, has been made Manager of the Union Malleable Iron Co., East Moline, Ill. The capacity of this company's plant has recently been doubled. The products include both agricultural and railroad material.

H. S. Moulton, formerly Superintendent of the Allison Car Works, Philadelphia, Pa., and more recently connected with the New York office of the Fitz-Hugh, Luther Co., Chicago, is now with the Empire Steel & Equipment Co., New York, the eastern agents for the Hicks Locomotive & Car Works, Chicago.

Arthur E. Rendle, New York, maker of Paradigm skylights and windows, has a new type of fireproof window, the special feature of which is the material composing the frame and casing. This is asbestos wood, a new building material which has been carefully tested and is said to be especially valuable where lightness combined with durability is desired. These windows are finished to represent any kind of wood and can be treated like any wooden or metal frame window.

The Expanded Metal & Corrugated Bar Co., St. Louis, Mo., has received the following orders: Government of the Philippine Islands, 500 tons of corrugated bars, bought through Paul S. Carter, New York; Hiram Lloyd Contracting & Building Co., contractor for the new high school in St. Louis, 500 tons of corrugated bars; William A. Engeman, contractor for the reinforced concrete retaining wall to be built at St. George ferry landing, Staten Island, N. Y., as part of a plan for municipal improvements in the Borough of Richmond, 600 tons of corrugated bars.

James H. Baker, formerly President of the Solid Steel Tool & Forge Co., Brackenridge, Pa., has established an office at 316 Fourth avenue, Pittsburgh, Pa., as a forging engineer, making specialties of forging development, examination of plants, forging and special machinery, the design of forgings and castings, etc. Mr. Baker has been in the forging business for over 20 years. Last December he resigned from the Solid Steel Tool & Forge Co., which had, before that, absorbed the James H. Baker Manufacturing Co.; the latter has been organized in 1900. Several concerns previously founded by Mr. Baker are now merged in other companies.

Iron and Steel.

The New York Central & Hudson River has ordered 21,000 tons of rails from the Lackawanna Steel Co.

The Philadelphia & Reading is said to be about to ask bids on 16,000 tons of steel for track elevation work in Philadelphia.

OBITUARY NOTICES.

Walter L. Surran, Trainmaster of the Cumberland division of the Louisville & Nashville, with headquarters at Middlesborough, Ky., died on March 21 at Corbin, Ky.

James B. Hill, General Freight Agent of the Southwest system of the Pennsylvania Lines West of Pittsburgh, died on March 21 at Biloxi, Miss., at the age of 67. Mr. Hill was born on March 16, 1840, at Indianapolis, Ind., and was educated at Asbury University at Greencastle, Ind., from which he graduated in 1859. When he was 20 years old he began railroad work in the engineering department of the Atlantic & Great Western, now part of the Erie. He left the engineering for the traffic department and in 1868 became traveling agent of the Star Union Line. From 1877 to 1886 he was agent of the Pennsylvania Lines at Milwaukee and in the latter year was appointed General Western Freight Agent of the Pittsburgh, Cincinnati, Chicago & St. Louis at Chicago. On April 1, 1897, he was appointed General Freight Agent of the same road, a position which he held up to his death.

MEETINGS AND ANNOUNCEMENTS.

(For dates of conventions and regular meetings of railroad conventions and engineering societies, see advertising page 24.)

American Society of Mechanical Engineers.

The next monthly meeting of this society will be held in the Engineering Societies building, New York, April 14. The general subject at this meeting is to be "The Conservation of Our Natural Resources," which is now receiving unusual attention. The President of the United States has sent invitations to the Governors of the several states, and to the presidents of the national engineering societies, to confer in Washington on this important problem. The New York meeting will be addressed by four speakers on "Forest Preservation in its Relation to Water Power, Economy in the Utilization of Fuels, and the Attitude of the Engineer in Regard to These." Dr. Henry S. Pritchett, President of the Carnegie Foundation for the advancement of teaching, will discuss the "Relation of the Engineer to the Body Politic."

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

National Lines of Mexico.—M. M Reynolds, Comptroller, has resigned to go to another company.

New York Public Service Commission, Second District.—Charles H. Keep, Commissioner, has resigned to become President of the Knickerbocker Trust Company in New York City

Operating Officers.

Chicago, Burlington & Quincy.—F. H. Ustick, Superintendent at Aurora, Ill., has been appointed General Superintendent, with headquarters at St. Louis, Mo., succeeding George T. Ross, resigned. A. W. Brown, Superintendent at Ottumwa, Iowa, succeeds Mr. Ustick. Mr. Brown is succeeded as Superintendent by A. W. Newton, general inspector of permanent way and structures.

Delaware, Lackawanna & Western.—Edwin M. Rine, who is now Superintendent of the Morris & Essex division which includes all the New York end of the road and the Hoboken terminals, was born on September 4, 1868, at Brilliant, Ohio. After a school education he entered railroad service at the age of 18 on the Cleveland & Pittsburgh division of the Pennsylvania Lines West, as an operator. He was soon made a despatcher on the Pittsburgh & Western, now part of the Baltimore & Ohio. In 1889 he went to the South Carolina Railroad, now part of the Southern. After a year in the South he returned to Ohio as chief despatcher and later Trainmaster of the Baltimore & Ohio at Cleveland and at Akron. In 1899, the year in which Mr. Truesdale was elected President of the Lackawanna, Mr Rine came to the road as chief despatcher, later becoming Trainmaster, and Superintendent of the Scranton division. On March 1, of this year, he was transferred from the central part of the road to the eastern end.

Missouri Pacific.—William E. Brooks, who is now Superintendent of the Joplin division of the Missouri Pacific, with headquarters at Nevada, Mo., was born on October 9, 1866, at Abingdon, Va. He had no school education and at the age of 14 went to work in a construction gang on the Lexington division of the Chesapeake & Ohio. The next year, when he was 15, he was an operator on that road and the year following went to the Santa Fe as operator. In April, 1884, when he was less than 18 years old he was made despatcher on that road, a position which he held for four years. In 1888 he went to the Kentucky Central, now part of the Louisville & Nashville, as despatcher, and in 1889, also as despatcher, to the Missouri Pacific. Three years after going to this road he was made chief despatcher, a position which he held for 13 years. In March, 1905, he was made chief clerk to the Assistant General Manager, and in April, 1906, Inspector of Passenger Service. From June to September, 1907, he was Superintendent of the Northern Kansas division; from September, 1907, to March, 1908, Superintendent of the Omaha division, and is now, under the recent reorganization of the operating department, Superintendent of the Joplin division of the Missouri Pacific.

W. S. Crane has been appointed Car Accountant, succeeding A. R. Duncan, resigned.

New York Central & Hudson River.—The headquarters of P. E. Crowley, Assistant General Manager, are to be moved from New York to Albany.

Peoria & Pekin Union.—George W. Walliser has been appointed Superintendent, with headquarters at Peoria, Ill., succeeding H. G. Kruse, resigned to go to another company.

Traffic Officers.

Delaware, Lackawanna & Western.—A. S. Learoyd, Division Freight Agent at Newark, N. J., has been appointed Assistant General Freight Agent, with office at New York, effective April 1.

Lake Erie & Western.—See New York Central Lines.

New York Central Lines.—William F. Carter, District Passenger Agent of the Lake Erie & Western, at Lima, Ohio, has been appointed General Agent of the New York Central Lines at Toledo.

Union Pacific.—H. O. Wilson, General Agent of the freight department at San Francisco, Cal., has been appointed General Agent of the freight and passenger departments at Los Angeles. Mr. Wilson is succeeded by S. F. Booth, who will also be General Agent of the passenger department at San Francisco, Cal.

Engineering and Rolling Stock Officers.

Chicago, Rock Island & Pacific.—William A. Nettleton, the new General Superintendent of Motive Power of this company, was born in 1863, at Hannibal, Mo. He graduated from the Sheffield Scientific School of Yale University in the class of 1885, and began railroad service in November of that year on the Kansas City, Fort Scott & Memphis. In 1888 he was a bridge inspector for Morison & Corthell and in the next year was with A. P. Boller as inspector of the bridge of the New York, New Haven & Hartford over the Thames river at New London, Conn. In that same year he returned to the Kansas City, Fort Scott & Memphis as Engineer of Tests, and held this position until 1892, when he served for a year as Superintendent of Terminals. In 1893 he was appointed Assistant Superintendent of Motive Power of this road, and two years later Superintendent of Motive Power, a position which he held for six years or until 1902. In 1902 he went to the Atchison, Topeka & Santa Fe as Assistant Superintendent of Motive Power. In 1903 he was engaged in special work, and in 1904 he went to the railroad which had taken over the road on which his early service was spent, the St. Louis & San Francisco, of which as well as the Chicago & Eastern Illinois he became General Superintendent of Motive Power. After four years service in this position he went to the Chicago, Rock Island & Pacific on March 1, 1908, as General Superintendent of Motive Power, with headquarters at Chicago.

William A. Nettleton.

New York Central & Hudson River.—The headquarters of John Howard, Superintendent of Motive Power, and of F. W. Brazier, Superintendent of Rolling Stock, are to be moved from New York to Albany.

Union Pacific.—George J. Hatz has been appointed Superintendent of Shops at Omaha, Neb., succeeding H. Stovel, deceased.

Special Officers.

Mexican Central.—B. C. Fleming has been appointed Advertising Manager.

LOCOMOTIVE BUILDING.

Butler Bros., Hibbing, Minn., have ordered 30 six-coupled switching locomotives from the Baldwin Locomotive Works.

The New York Central & Hudson River has ordered 136 locomotives of various types from the American Locomotive Co. The numbers of each type have not yet been decided, but included in the total will be 12 electric engines.

The Chicago, Milwaukee & St. Paul is building 30 simple six-wheel switching (0-6-0) locomotives at its Milwaukee shops. The specifications are as follows:

General Dimensions

Type of locomotive	Switching
Weight, total	127,000 lbs.
Diameter of drivers	50 in.
Cylinders	19 in. x 26 in.
Boiler, type	Straight top
" working steam pressure	180 lbs.
" number of tubes	235
" diameter of tubes	2 in.
" length of tubes	12 ft. 5 1/8 "
Firebox, length	7 " 7 1/8 "
" width	3 " 6 "
" grate area	25.8 sq. ft.
Heating surface, total	1,708 "
Tank capacity	4,500 gals.
Coal capacity	4½ tons

Special Equipment

Brake-shoes	Chicago, Milwaukee & St. Paul
Headlights	Adams & Westlake
Journal bearings	Hewitt
Piston rod packing	Edwards
Valve rod packing	Edwards
Safety valve	Richardson
Sanding devices	Leach

CAR BUILDING.

The Chicago Railways Co., as reported in the *Railroad Gazette* of January 10, has ordered 300 double-truck electric cars from the Pullman Co. and 50 cars from the Pressed Steel Car Co.

The Chicago, Milwaukee & St. Paul, as reported in the *Railroad Gazette* of March 13, is building 2,500 stock cars of 60,000 lbs. capacity at its Milwaukee shops. These cars will be 36 ft. 1¼ in. long, 8 ft. 6¾ in. wide and 7 ft. 5¼ in. high, inside measurements. They will have Bettendorf underframes. The special equipment includes:

Bolsters	Bettendorf
Brake-shoes	Congdon
Brasses	Hewitt
Door hangers	Climax
Trucks	Bettendorf

Three hundred cars of this lot will be double-deck, and the rest (2,200) will have water trough arrangement.

The Cold Blast Transportation Co. (Schwarzschild & Sulzberger), Chicago, has ordered 300 stock cars of 60,000 lbs. capacity from Haskell & Barker, instead of 200 refrigerator cars as reported in the *Railroad Gazette* of March 20. These cars are for May and June delivery, and will measure 36 ft. long and 9 ft. wide, inside measurements; they are to be built of wood with wooden center sills. The special equipment includes:

Bolsters	Haskell & Barker
Brake-beams	Haskell & Barker
Brake-shoes	Haskell & Barker
Brakes	Westinghouse
Couplers	Latrobe
Draft rigging	Williams & Priest
Wheels	Haskell & Barker

The Chicago, Milwaukee & St. Paul, as reported in the *Railroad Gazette* of March 20, has ordered 15 passenger coaches from Barney & Smith and three dining cars from the Pullman Co. The coaches will be 60 ft. long, 9 ft. wide and 9 ft. 10 in. high, inside measurements. The dining cars will be 70 ft. long, 10 ft. wide, over frame, and 15 ft. 6 in. high, over all. The special equipment for both will include:

Bolsters (for dining cars)	American Steel Foundries
Brake-beams	"Diamond" special
Brake-shoes	Congdon
Brasses	Hewitt
Curtain fixtures (for coaches)	Forsyth
Curtain fixtures (for dining cars)	Schroyer
Curtain material	Pantasote
Draft rigging (for coaches)	Westinghouse
Draft rigging (for dining cars)	Miner
Paint	Chic., Mil. & St. Paul standard
Vestibules	Pullman
Wheels (for dining cars)	Paige

The Atlantic Coast Line, as reported in the *Railroad Gazette* of March 20, has ordered, for the Washington & Vandemere, 100 felt insulated ventilated box cars of 60,000 lbs. capacity from the South Baltimore Steel Car & Foundry Co., for April 15 delivery. The inside measurements will be 36 ft. long, 8 ft. 6 in. wide and 7 ft. 6 in. high. The over-all measurements will be 39 ft. long, 11 in. wide and 13 ft. 8⅞ in. high. Bodies and underframes will be of wood. The special equipment includes:

Axles	Steel
Bolsters, body	Cast steel
Bolsters, truck	Open hearth, I beam
Brakes	Westinghouse
Brake beams	Pennsylvania
Brake-shoes	Cast iron
Couplers	Tower
Door fastenings	National Malleable Castings Co.
Draft gear	Farlow Twin Spring
Dust guards	Harrison
Roofs	Murphy outside
Springs	Railway Steel Spring
Trucks	Company's standard, arch bar
Ventilators	Company's standard, on ends
Wheels	Maryland Car Wheel Co.

RAILROAD STRUCTURES.

BATTLE CREEK, MICH.—The Grand Trunk, it is said, will put up repair shops here.

BRANDON, MAN.—The Canadian Northern, it is said, will soon begin work on a large station here.

GRAND FORKS, B. C.—The improvements to be carried out here by the Canadian Pacific include a 15-stall roundhouse to cost $70,000, passenger station and office building, $49,000, and yard improvements $40,000.

HOMER, LA.—The Louisiana & Northwest is said to be planning to put up shops and other improvements here to cost about $100,000.

NANAIMO, B. C.—Work on the Esquimalt & Nanaimo includes putting up a steel bridge at Raymond's crossing, two between Duncans and Shawnigan Lake, also one at Chemainus over the Nanaimo river. The present wooden bridge over Cowichan river is also to be replaced with a steel structure.

SAN ANGELO, TEX.—The Kansas City, Mexico & Orient, reports say, will build roundhouses here in addition to the proposed combined passenger station and freight house.

TRENTON, N. J.—Commercial interests of Philadelphia and Trenton, N. J., are opposed to the plans of the Pennsylvania to a bridge over the Delaware river from West Morrisville, Pa., near Trenton, to connect with the freight relief line to be built under the name of the Pennsylvania & Newark, east to Newark, N. J., about 50 miles. The proposed structure is to have 11 spans, each 100 ft. wide, with two draws of the same width over the channel, and a height in the clear of 34 ft., with draws closed. Objection is made that the bridge will interfere with river navigation.

UTICA, N. Y.—The Public Service Commission, Second district, has approved the plans of eliminating the Genesee street grade crossings, in Utica, by putting up a steel viaduct 68 ft. wide over the New York Central tracks at a cost of about $370,000.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

ABERDEEN & TOMBIGBEE VALLEY.—The subscriptions to the underwriting agreement to secure the bonds for building this line in Mississippi has been nearly three times over subscribed. As reported in our Construction Record the line is now being built from Okolona, Miss., southeast to Pickensville, Ala., all surveyed, and grading finished between Okolona and Aberdeen on 17.5 miles, also Columbus to Pickensville, 11.5 miles. W. T. McKee, Chief Engineer, Aberdeen, Miss.

BIENVILLE-QUITMAN.—Incorporated in Louisiana, with $100,000 capital, to build a line from Bienville, La., east to Quitman, 12 miles. D. C. Richardson, President, Bienville. The D. C. Richardson-Taylor Lumber Co., it is said, is back of the project.

BRINSON RAILWAY.—This company, incorporated to build from Savannah, Ga., northwest to Athens, 180 miles, last year finished the first 25 miles from Savannah to Springfield. The company has bought terminal property at Savannah, and will shortly issue bonds to extend the line to Sylvania, 32 miles. G. M. Brinson, President and Superintendent, Springfield, Ga. (March 13, p. 390.)

CAIRO & NORFOLK.—Incorporated in Kentucky, with $500,000 capital, to build a line from Port Jefferson and Bullard county, along the Mississippi river to Bristol, Va. Incorporators include L. W. Goode and E. E. Weston, of New York; F. R. Allen and C. B. Goode, of Mayfield; W. A. Usher, H. C. Neal and E. S. Beaumont.

CANADIAN PACIFIC.—Announcement is made that this company will open its Toronto-Sudbury line for traffic June 15. (March 13, p. 396.)

CANADIAN VALLEY RAILROAD.—Incorporated by residents of Mutual, Okla., with a capital of $2,000,000. Proposes to build from Fort Supply, Woodward county, Okla., southeast through the counties of Woodward, Dewey, Blaine, Canadian and Oklahoma to Oklahoma City, 150 miles. The estimated cost of the line will be $25,000 a mile.

CHEROKEE BELT & INTERURBAN.—Incorporated in Oklahoma with $500,000 capital and office at Tulsa, Okla., and at Kansas City, Mo., the company proposes to build a line from the Midland Valley Railroad to the Missouri, Kansas & Texas, through the counties of Craig, Tulsa, Rogers & Myers. Incorporators include F. O. Montel, of Kansas City; C. W. Butterworth, of Tulsa; and E. Pease, J. R. Caudley and A. E. Leahe, of Collinsville, Okla.

CHICAGO, LAKE SHORE & SOUTH BEND (ELECTRIC).—Work on this line, building from South Bend, Ind., west to Chicago, Ill., 71 miles, has all been finished except 13 miles between South Bend and Michigan City. Announcement is made that this section is to be opened June 13, and the entire line is to be in operation about July 1st. (March 13, p. 390.)

CHICAGO, MILWAUKEE & ST. PAUL.—The Pacific coast line has been extended from Terry, Mont., west to Lombard, about 337 miles, and this section was put in operation March 15. There remains about 118 miles to finish the line to Butte. Track laying, it is said, will be started at once both east and west from Lind, Wash., where the line crosses the Northern Pacific, and shortly thereafter at Plummer, Idaho.

CHICAGO, ROCK ISLAND & PACIFIC.—An officer writes regarding the report that this company has work under way on the entire line from Amarillo, Tex., west to Tucumcari, N. Mex., 110 miles, that track laying was started this month on the first 20 miles, which is all the work planned to be carried out on this line at this time. (Mar. 13, p. 390.)

COAL & COKE.—Rights of way are reported secured and work is to be started at once by this company, on an extension from Gassoway, W. Va., southeast via Sutton to Webster Springs, 40 miles. The plans include a tunnel three-quarters of a mile long through Elk mountain.

CROW'S NEST & NORTHERN.—A bill has been passed by the Canadian Parliament authorizing this company, recently incorporated in Canada with a capital of $2,000,000, to build a line from a point on the Canadian Pacific, just west of Crow's Nest, B. C., north to the summit or divide between the waters of the North Fork of Michel creek and the waters of Grave creek, via the west side of the North Fork of Michel creek to the confluence of the two north branches, thence by both branches to points near the divide. The bill also authorizes the company to build branch lines not more than 10 miles long. Construction work is to be started as soon as the weather permits, and it is the intention of the company to have the line finished before next winter. All the rights of way have been secured and surveys made. Contracts for grading, track laying, bridges, etc., are soon to be let. The line is to be built to market the output of the Crown Coal & Coke Company, and of the Michel Coal Mines, Ltd. The office of the company is to be at Crow's Nest, B. C. R. J. Belden, of the Crown Coal & Coke Company, Spokane, Wash., may be addressed. (March 6, p. 328.)

GRAND TRUNK PACIFIC.—This company has reached an agreement with the British Columbia Government, and plans are now under way to let contracts for additional sections east from Prince Rupert, B. C. A total of 300 miles will soon be under contract on the line between the Pacific and the Rockies. Active work is under way laying out the terminal city at Prince Rupert. Contract for the first 100 miles let to Foley, Walsh & Stewart, it is stated will cost about $10,000,000. This section extends from Prince Rupert to a point on the Skeena river, skirting the Pacific ocean for some 25 or 30 miles. Nearly all the excavation will be through rock and the work must be finished by September, 1909. About 2,000 men will be put to work as soon as they can be secured.

J. D. MacArthur, who has the contract for building 244 miles of line from a point east of Winnipeg east to the junction with the Lake Superior branch, has had 7,000 men at work on this section all through the winter. About 60 per cent. of the construction work is finished. The contract calls for a number of steel and concrete bridges.

LIMA & TOLEDO TRACTION.—See Ohio Electric Railway.

LOS ANGELES & SAN FRANCISCO SHORE LINE.—Incorporated in California, with $441,000 capital, to build a line from Los Angeles north to San Francisco. Surveys are said to have been made which give a line about 80 miles shorter than the Southern Pacific. John Cross, President and General Manager, Los Angeles.

LOS ANGELES HARBOR COMPANY.—See Los Angeles Harbor Railroad Co.

LOS ANGELES HARBOR RAILROAD COMPANY.—A company was recently incorporated in California under this name, also one under the name of the Los Angeles Harbor Company, each having a capital of $2,500,000. Rights of way have been secured for a proposed line from Wilmington, Cal., at Tidewater, to Los Angeles, about 25 miles. A. C. Bird, of Compton, formerly Vice-President of the Gould Lines in charge of traffic, is President of both companies.

MEXICAN ROADS.—The British syndicate which owns extensive coal fields at Furbero, Vera Cruz, is said to have given a contract to build a line from Furbero to Tuxpan, 80 miles. H. S. Armstrong, formerly at Monterey as Resident Engineer of the Mexican Central, is Chief Engineer. J. S. Nickerson, of Mexico, is also interested in the project.

Bids are to be asked for in June by P. O. Pruto, P. O. Box 138, Parral, Chihuahua, to build a line from Parral east to Jimenez, 60 miles.

OHIO ELECTRIC RAILWAY.—Work has been resumed on the Lima & Toledo, building from Deshler, Ohio, north to Toledo, 30 miles. The section from Toledo south to Waterville is almost finished and about 20 miles from Deshler north to Waterville is yet to be built. (March 13, p. 393.)

PECOS & BALMORHEA.—Application is being made by a company under this name for incorporation by residents of Toyah Creek valley to build a line from Pecos, Tex., south to Balmorhea, 50 miles.

Over $50,000 and the necessary lands for terminal facilities have been subscribed.

RUSTON, NATCHITOCHES & NORTHEASTERN.—Incorporated in Louisiana to build a line from Ruston north to Farmerville, about 25 miles. J. C. Nolan, President; E. L. Kidd, Secretary and Treasurer, Ruston.

SAN FRANCISCO & BAY COUNTIES RAILWAY (ELECTRIC).—See San Francisco, Oakland & San Jose Consolidated.

SAN FRANCISCO, OAKLAND & SAN JOSE CONSOLIDATED (ELECTRIC).—Under this name it is reported a company has been formed with a capital of $7,750,000 as a consolidation of the San Francisco, Oakland & San Jose, operating 25 miles of electric line connecting by ferry with San Francisco, Cal., and the San Francisco & Bay Counties Railway. The latter was recently incorporated to build an electric line from San Francisco south to San Jose. E. A. Heron, D. Searls and F. M. Smith are directors.

SAN FRANCISCO, OAKLAND & SAN JOSE (ELECTRIC).—See San Francisco, Oakland & San Jose Consolidated.

SPOKANE, PORTLAND & SEATTLE.—The section which was built last year from Kennewick, Wash., opposite Pasco, west to Vancouver, 220 miles, is expected to be opened by June. The extension to Spokane, 145 miles, is also to be put in operation this year. (March 13, p. 395.)

WESTERN & ATLANTIC.—Residents of Camden county, Ga., agree to furnish the right of way and terminal site at St. Mary for an extension of this road from Atlanta to the deep water harbor at St. Mary. Several counties along the proposed route, it is said, are now taking action to grant the necessary right of way.

RAILROAD CORPORATION NEWS.

BAINBRIDGE NORTHEASTERN.—Col. M. Wilkinson, of Valdosta, Ga., was on March 2 appointed receiver of this company by Judge Speer in the United States District Court at Savannah. The Bainbridge Northeastern is 18 miles long and runs from Bainbridge to within two miles of Swindell, both in Decatur county, Ga.

BRINSON RAILWAY.—The stockholders of this company, which was incorporated in Georgia in May, 1906, and has built 25 miles of road from Savannah, Ga., to beyond Springfield, are to meet on April 6 to authorize a bond issue at the rate of not more than $10,000 a mile for the first 100 miles and $15,000 a mile for the rest of the line. The road, as projected, is 180 miles long. See Railroad Construction column.

BROOKLYN RAPID TRANSIT.—It is reported that the firm of J. P. Morgan & Co. has become interested in the financial management of this company, which controls the elevated lines and most of the surface lines in Brooklyn, N. Y.

CHICAGO, INDIANA & SOUTHERN.—It is reported that the sale of $15,000,000 fifty-year 4 per cent. bonds of this company, guaranteed by the Lake Shore & Michigan Southern, is being negotiated with J. P. Morgan & Co.

CINCINNATI, HAMILTON & DAYTON.—Holders of the $11,558,000 4 per cent. refunding bonds may exchange these bonds at par up to July 15, for the new collateral purchase money notes. (January 10, 1908; p. 74.)

ERIE.—There are $5,500,000 discount notes, issued in April, 1907, which fall due April 8, 1908.

GRAND TRUNK PACIFIC.—This company recently offered $10,000,000 (£2,000,000) 4 per cent. securities in London, of which the underwriters are reported to have had to take between 50 and 90 per cent.

INDIANA, COLUMBUS & EASTERN TRACTION.—See Ohio Electric Railway.

INTERNATIONAL & GREAT NORTHERN.—Gross earnings for the week ended March 21, 1908, were 18 per cent. less than for the corresponding week in 1907.

KANSAS CITY SOUTHERN.—Gross earnings for February decreased 9 per cent.; operating expenses increased 7 per cent., and net earnings after taxes decreased 38 per cent.

LEHIGH & NEW ENGLAND.—See Lehigh Coal & Navigation Company.

LEHIGH COAL & NAVIGATION.—The stockholders of this company have the opportunity to subscribe to the $1,731,500 new stock at par to the amount of 10 per cent. of their holdings. The proceeds will be used for general improvements, which may include betterments on the Lehigh & New England Railroad, which is owned by the Lehigh Coal & Navigation Co.

MEXICAN SOUTHERN.—The narrow (3 ft.) gage line of this company runs from Puebla, Puebla, Mexico, to Oaxaca, Oaxaca, 367 miles, with a 50-mile tramway branch from Tehuacan north to Esperanza. The stockholders have recently been offered $500,000 (£100,000) 4 per cent. "first mortgage debenture" stock at 82. The proceeds are to be used chiefly to convert the tramway into a steam railroad with 3 ft. gage.

NEW ORLEANS TERMINAL.—Potter, Choate & Prentice, of New York, have offered at 98¼, to yield 7¾ per cent., a block of the $2,500,000 two-year 6 per cent. notes due April 10, 1909. These notes are guaranteed by the Southern and by the St. Louis & San Francisco and are secured by $4,000,000 first mortgage 4 per cent. bonds of the New Orleans Terminal Company, which bonds are also guaranteed by these two railroads. Besides its several terminal properties, the company owns 18 miles of belt railroad.

NEW YORK CENTRAL LINES.—The gross earnings, expenses and net earnings of the various New York Central Lines for the month of January, 1908, with the increase or decrease as compared with January, 1907, are shown below. These figures, for purposes of comparison, are compiled on the same bases as in the previous year and differ from those reported to the Interstate Commerce Commission under the present accounting rules.

	1908	Change	
New York Central & Hudson River			
Gross earnings	$6,636,494	Dec	$776,000
Expenses	5,571,069	"	608,221
Net earnings	$1,065,425	Dec	$167,779
Lake Shore & Michigan Southern			
Gross earnings	$2,932,442	Dec	$532,175
Expenses	2,211,044	"	356,158
Net earnings	$721,398	Dec	$176,017
Lake Erie & Western			
Gross earnings	$349,232	Dec	$64,270
Expenses	300,609	"	9,564
Net earnings	$48,623	Dec	$54,706
Chicago Indiana & Southern.

Net earnings	$28,460	Dec	$20,515

OHIO ELECTRIC RAILWAY.—A block of the Indiana, Columbus & Eastern Traction Company's general and refunding mortgage 5 per cent. bonds, due 1926 are being offered at 96. The mileage owned or leased is 115 miles of electric line in Ohio. The Indiana, Columbus & Eastern is itself leased by the Ohio Electric Railway which guarantees interest on these bonds. With connecting lines in Ohio and Indiana controlled by the same interest, the Indiana, Columbus & Eastern forms part of a system of 1,700 miles of electric line.

PERE MARQUETTE.—The First National Bank of Chicago is offering at par $900,000 6 per cent. equipment notes dated March 1, 1908, maturing up to and including 1911. These notes are part of the new issue which has been exchanged for the 5 per cent. equipment notes of the Eastern Equipment Company, which matured March 1, 1908. (March 6, 1908, p. 330.)

PITTSBURGH, CINCINNATI, CHICAGO & ST. LOUIS.—Operating expenses and taxes in February decreased more than gross earnings, so that there was an increase of $13,500 in net earnings.

TEXAS & PACIFIC.—Gross earnings for the week ended March 21, 1908, were 25 per cent. less than for the corresponding week in 1907.

UNITED RAILWAYS INVESTMENT COMPANY.—This company is to issue at least $3,000,000 6 per cent. serial notes maturing yearly up to 1917, as authorized in June, 1907, by the stockholders. The proceeds are to be used to pay the floating debt of the United Railroads of San Francisco.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK
BRANCH OFFICES AT 375 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. *We give in our editorial columns* OUR OWN *opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.*

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette:

CONTENTS

VOL. XLIV., No. 14. FRIDAY, APRIL 3, 1908.

RECENT ELECTRIFICATION WORK.

It has been the practice at the New York Railroad Club for the past few years to devote one meeting of each season to the discussion of electrical matters, especially along the lines of the electrification of railroads that are or have been operated by steam. These meetings have invariably called out a large attendance and have been marked by a much more conservative estimate of the advantages accruing from electrification than has characterized the gatherings where the subject has been discussed by electrical engineers only. The evening of March 20 was devoted to this subject and was no exception to those that had preceded it.

As in the development of any other great work, it is at the point of realization that extravagance of statement and of claims ceases and the promoters are willing to let the results rest upon their merits. At present, as one speaker pointed out, conditions have reached such a point of perfection, and such great works have been executed, that it is merely necessary to refer to them to confirm a proposition. Previous work has been so well done that it has not been found necessary to introduce any very radical changes or improvements on what has been done before in the developments of the last year. Not that the last word has been said, or that, in the installations that have been completed, there has been no trouble—there have been endless annoyances and unlooked for difficulties that have made the lot of the engineers anything but a happy one. But these difficulties have been those of detail and not of fundamentals and principle, so that the way out is clear, and the means of avoiding similar ones in the future are measurably plain. Further than this, work has been carried to such a point that the operation of electric trains of the first-class calls for higher development of power than that in use on heavy traffic high speed steam-operated lines. The Interborough of New York was cited as an instance where, in the subway section, trains were equipped with motors aggregating 2,000 h.p., while for surface work on the electric zone of the New York Central 1,600 h.p. was provided in a single locomotive. The concentration of high powers is, therefore, no longer a thing of promise but an accomplished fact.

In the course of the discussion, with no set paper as a center, and with each speaker acting as a free lance, the old argument was again presented, to the effect that where such great improvements were made as in the case of the New York Central and Pennsylvania works in New York, if it is desired to compare the costs of steam and electric operation, the whole cost should not be charged to the latter, but the estimate should be based on what it would cost to provide for the same service with steam that will be rendered by the electric equipment. Attention was also called to the increased value of the "air" rights when electric operation is provided for. That is to say, in the construction of terminals it becomes possible to build large and high office buildings immediately above the tracks and thus utilize space that would be useless and valueless were steam to be used, with its accompaniment of smoke and gas.

Viewed, then, in the light of present achievement, the electrical engineer need not anticipate that he will have any more difficult problems to solve than those which have already been presented. They will differ, of course, for different conditions will require different solutions, and each installation of an electric plant will have to be governed by local surroundings in the future just as it has in the past. As for the cost of installation and operation the speakers had little to say. The presentation of possibilities had already been made and it was upon the expectation that these would be fulfilled that much of the present day work had been undertaken. Some of these installations were now working out their own salvation, and they promised well for the fulfillment of the prophecies that had been made regarding them. At any rate, they will now be judged solely on their merits, without extravagance of claim.

With the demonstrations that have been made, the electrical engineer is in a position to undertake any project that may be presented. Not all these projects will offer the inducements of commercial success, but when this is assured it is then merely a question of money to secure the plant. The electric traction engineer has the choice of five systems: the third rail, single-phase, three-phase, 1,200 volt direct current and gasolene-electric car.

This was the trend of the discussion, and it differed very materially from that of previous meetings, since it was a recital of things done rather than of claims for future possibilities. It was in view of this array that one speaker expressed surprise that the list of great works done or under consideration was not larger, but attributed it to the great first cost of many of the enterprises that had been proposed. Reduction of first cost is going to be the biggest problem confronting electrical engineers in the immediate future.

As for the great works that have been either completed or decided upon, the array is certainly imposing. There is the electrification of the New York Central and of the New Haven, with its base at the Grand Central Station of New York; the Pennsylvania's terminal well under way; the opening of the extension of the subway beneath the East river to Borough Hall, and the tunnel under the Hudson to Hoboken, with the probability of others to Long Island and Jersey City in the near future. Then there is the electrification of the Rochester branch of the Erie and of the West Shore between Utica and Syracuse; the Cascade tunnel of the Great Northern, and the line over the Bitter Root mountain on the Pacific coast extension of the Chicago, Milwaukee & St. Paul, over which heavy trains are to be hauled on a 1.7 per cent. grade, with a current generated by water power. Yet, with all these possibilities and probabilities of the future, there was not a word in the discussion regarding the demise of the steam locomotive, but it was stated that when the youngest man in the room was old and gray headed the steam locomotive would still be at work, and an estimate was made that if all the electrical manufacturing concerns in the country were to devote themselves exclusively to building electric locomotives for the next twenty years they would not, at the end of that time, have built as many as the number of the steam locomotives now in use.

The meeting was interesting, not only from the statements that were made regarding the achievements of the past year and the absence of all extravagance of claim, but as an exemplification of that broadness of vision that has come to the electrical engineer as the result of his contact with the steam engineer and his increased familiarity with the problems presented by heavy traffic, high-speed work.

HIGH STEAM PRESSURES IN LOCOMOTIVE SERVICE.

The Carnegie Institution of Washington has issued a book of about 140 pages containing the results of the experiments conducted by Prof. W. F. M. Goss at Purdue University on the high steam pressures in locomotive service. As is usual in the documents coming from this authority, the work is of the highest value as indicating the limitations of commercially profitable pressures in locomotive practice. In the summary of his conclusions the author shows that, as there is an increase of boiler pressure, there is a decrease in the amount of water consumed per indicated horse power and this same statement holds in the item of fuel consumption also. This would lead to the natural conclusion that the higher the pressure the more economical the operation. This is not, however, necessarily the case, as was so admirably shown at the meeting of the Master Mechanics' Association last year. As the pressure is increased the saving does not increase in the same ratio, being less for the same increments of higher pressure. Then, too, even that saving that has been indicated "depends upon the degree of perfection attending the maintenance of the locomotive," and the values obtained assume a high order of maintenance. If this is lacking, it may easily happen that the saving which is anticipated through the adoption of higher pressures will entirely disappear. The difficulties to be met in the maintenance both of boiler and of cylinders also increase with increase of pressure.

Dean Goss' results supply an accurate measure by which to determine the advantage of increasing the capacity of a boiler. For the development of a given power, any increase in boiler capacity brings its return in improved performance without adding to the cost of maintenance or opening any new avenues for incidental losses. As a means to improvement, it is more certain than that which is offered by increase of pressure.

As a scale of pressure is ascended, an opportunity to further increase the weight of a locomotive should in many cases find expression in the design of a boiler of increased capacity rather than in one for higher pressures. Assuming 180 lbs. pressure to have been accepted as standard, and assuming the maintenance to be of the highest order, it will be found good practice to utilize any allowable increase in weight by providing a larger boiler rather than by providing a stronger boiler to permit higher pressures. Wherever the maintenance is not of the highest order, the standard running pressure should be below 180 lbs. Wherever the water, which must be used in boilers, contains foaming or scale-making admixtures best results are likely to be secured by fixing the running pressure below the limit of 180 lbs.

A simple locomotive using saturated steam will render good and efficient service when the running pressure is as low as 160 lbs., under most favorable conditions, no argument is to be found in the economic performance of the engine which can justify the use of pressure greater than 200 lbs. The early tests were made with the first locomotive on the plant, but the pressures were limited to a maximum of 150 lbs. and the results are given in Prof. Goss' book on *Locomotive Performance* which was reviewed in the *Railroad Gazette* of May 3, 1907. In the new series the work was done at pressure of 240, 220, 200, 180, 160 and 120 lbs., a range which extends far below and far above pressures which are common in present practice.

As for the difficulties of operating under high pressure, the work with the experimental locomotive has shown that those difficulties which, in locomotive operation, are usually ascribed to bad water, increase rapidly as the pressure is increased. The water supply of the Purdue laboratory contains a considerable amount of magnesia and carbonate of lime. When used in boilers carrying low pressure, there is no great difficulty in washing out practically all sediment. The boiler of the first experimental locomotive *Schenectady No.* 1, which carried but 140 lbs. and was run at a pressure of 130 lbs., after serving in the work of the laboratory for a period of six years, left the testing-plant with a boiler which was practically clean. Throughout its period of service this boiler rarely required the attention of a boilermaker to keep it tight. Water from the same source was ordinarily used in the boiler of *Schenectady No.* 2, which carried a pressure of 200 lbs. or more. It was soon found that this boiler, operating under the higher pressure, frequently required the attention of a boilermaker. After having been operated for no more than 30,000 miles, cracks developed in the side sheets, making it impossible to keep the boiler tight, and new side sheets were applied. In operating under pressures as high as 240 lbs., the temperature of the water delivered by the injector was so high that scale was deposited in the check-valve, in the delivery pipe, and in the delivery tube of the injector. Under this pressure, with the water normal to the laboratory, the injectors often failed after they had been in action for a period of two hours. The interruptions of tests through failure of the injector, and through the starting of leaks at stay bolts, as the tests proceeded, became so annoying that, as a last resort, a new source of water supply was found in the return tank of the university heating-plant. This water was mostly distilled, and its use greatly assisted in running the tests at 240 lbs. pressure.

Probably some of the difficulties experienced in operating under very high steam-pressures were due to the experimental character of the plant, and would not appear after practice had, by a gradual process of approach, become committed to the use of such pressure but the results are clear in their indication that the problem of boiler maintenance, especially in bad-water districts, will become more complicated as pressures are further increased. Since, taking the country over, there are few localities where locomotives can be furnished with pure water, the conclusion stated should be accepted as rather far-reaching in its effect.

The tests developed no serious difficulties in the lubrication of valves and pistons under pressure as high as 240 lbs., though this could not be done with a grade of oil previously employed. With increase of pressure any incidental leakage, either of the boiler or from cylinders, becomes more serious in its effect upon performance.

In concluding this brief review of the difficulties encountered in the operation of locomotives under very high steam-pressures, the reader is reminded that an increase of pressure is an embellishment to which each detail in the design of the whole machine must give a proper response. A locomotive which is to operate under such pressure will need to be more carefully designed and more perfectly maintained than a similar locomotive designed for lower pressure, and much of that which is crude and imperfect, but nevertheless serviceable in the operation of locomotives using a lower pressure, must give way to a more perfect practice in the presence of the higher pressure.

The effect of pressure on boiler performance was a point upon which information was desired. The generation of steam at 120 lbs. involves a temperature of the water which is 50 degrees less than that which must be dealt with in generating steam at a pressure of 240 lbs., and, in general, it has been assumed that any increase in boiler pressure necessarily results in some loss of evaporative efficiency. It has been known that for the small ranges of pressure common in stationary practice, this difference is not great, but the facts have not been established with reference to locomotive performance, or for ranges as great as those covered by the experiments under consideration in any service. The results show that the lowest efficiency is obtained with the highest pressure, and performances under different pressures fall in order inversely with the pressure. The facts thus defined may be stated as follows:

The evaporative efficiency of a locomotive boiler is but slightly affected by changes in pressure.

Changes in steam-pressure between the limits of 120 lbs. and 240 lbs. will produce an effect upon the efficiency of the boiler which will be less than 0.5 pound of water per pound of coal.

Smokebox temperatures increase in all cases as the rate of evaporation is increased. The equations show that the effect of increasing the pressure from 120 lbs. to 220 lbs. is to increase the smokebox temperature 17 degrees; that is, an increase of pressure of nearly 100 per cent. results in an increase of smokebox temperature of approximately 3.5 per cent.

In the preceding statements is to be found an explanation of the constancy in the evaporative efficiency of the boiler under different steam pressures. The fact seems to be that the water in the boiler is about as effective in absorbing the heat of the gases when its temperature is 400 degrees (240 lbs. pressure) as when its temperature is but 350 degrees (120 lbs. pressure).

The data sustain the following conclusions:

1. The smokebox temperature falls between the limits of 590 degrees F. and 850 degrees F., the lower limit agreeing with a rate of evaporation of 4 lbs. per foot of heating-surface per hour and the latter with a rate of evaporation of 14 lbs. per foot of heating surface per hour.

2. The smokebox temperature is so slightly affected by changes in steam-pressure as to make negligible the influence of such changes in pressure for all ordinary ranges.

3. The equation $T = 488.5 + 25.66\ H$, where T is the temperature of the smokebox expressed in degrees F. and H is pounds of water evaporated from and 212 degrees per foot of heating surface per hour, possesses a high degree of accuracy.

Further, pressure has been found to have no effect upon the draft. For example, when the rate of evaporation is 10 lbs. per foot of heating surface per hour, the draft in front of the diaphragm is approximately four inches for all pressures. There is, in fact, no reason why the draft should vary materially with changes in pressure.

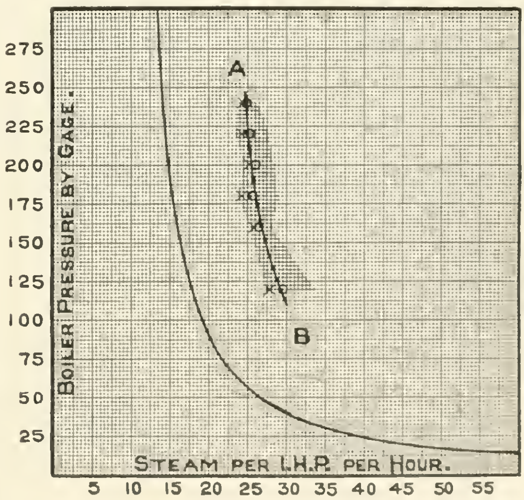
Attempts were made through an analysis of the smokebox gases to explain the variations in the evaporative efficiency of the boiler. The results, however, have not proven entirely satisfactory. That is, where the evaporative performance is abnormal, they do not permit the assignment of a definite cause. They do, however, entirely justify certain general conclusions. They show that the amount of excess air admitted to the furnace is never great, and in most cases it is very small—far below the limits which are thought desirable in stationary practice. They show, also, that the excess air diminishes as the rate of combustion increases. It is apparent, therefore, that the loss in efficiency arising from excess air is under normal conditions smaller than in most other classes of service. Moreover, while the supply of air appears limited, it is significant that the losses from imperfect combustion, as shown by the presence of CO, are also small, the actual amount varying irregularly between limits which are very narrow.

As already indicated in former papers by Prof. Goss, the steam consumption per indicated horse-power is less upon the locomotive than was formerly supposed. For example, it appears that at a pressure of 240 lbs. the engine, when working under a fully open throttle, gave a horse-power hour in return for the consumption of less than 24 lbs. of steam, and under any condition of speed or cut-off for which it was found possible to operate the engine under a wide open throttle the consumption never exceeded 26.3 lbs. At lower pressures involving the possibility of a wider choice in the condition of operating, the range is somewhat increased. Thus, at 120 lbs. pressure the minimum value is 27.5 and the maximum 33.8, a range which, while greater than that just referred to, is nevertheless extremely narrow as compared with the range incident to the operation of other classes of engines.

The most efficient point of cut-off for the lowest pressure is evidently that secured when the reverse lever is in the eighth notch, which is equal to 35 per cent. of the stroke. At 200 lbs. pressure the most efficient cut-off is that represented by the sixth notch, or 27 per cent. of the stroke, and the data do not disclose that a shorter cut-off than this under a full-open throttle is profitable for the engine experimented upon, even though the pressure be raised to 240 lbs.

The effect of speed on steam consumption shows that for all pressures above 160 lbs. the most efficient speed is 40 miles.

For purposes of comparison, the effect of pressure on performance has been defined by a line. In preparing to draw such a line the average performance of all tests at each of the different pressures was obtained and plotted, the results being shown by the circles on the figure. Points thus obtained can be regarded as fairly representing the performance of the engine under the several pressures only so far as the tests run for each different pressure may be assumed to fairly represent the range of speed and cut-off under which the engine would ordinarily operate. The best results for each different pressure, as obtained by averaging the best results for each speed at constant pressure, are indicated upon the diagram with a light cross. These points may be regarded as furnishing a satisfactory basis of comparison in so far as it may be assumed that when the speed has been determined an engine in service will always operate under conditions of highest efficiency. Again, the left-hand edge of the shaded zone represents a comparison based on maximum performance at whatever speed or cut-off. In addition to the points already described, there is located upon the diagram a curve showing the performance of a perfect engine with which the plotted points derived from the data of tests may be compared. This curve represents the performance of an engine working on Carnot's cycle, the initial temperature being that of the several pressures stated, and the final temperature being that of steam at 1.3 lbs. above atmospheric pressure. This latter value is the assumed pressure of exhaust in locomotive service.



Guided by this curve, representing the performance of a perfect engine, a line A B has been drawn proportional thereto, and so placed as to fairly represent the circular points derived from the experiments. It is proposed to accept this line as representing the steam consumption of the experimental engine under the several pressures employed. It is to be noted that it is not the minimum performance nor the maximum, but it is a close approach to that performance which is suggested by an average of all results derived from all tests which were run. Since its form is based upon a curve of perfect performance it has a logical basis, and since it does no violence to the experimental data its use seem justifiable.

An examination of all of the data obtained that are comparable shows that the values, especially if confined to the tests run with the reverse lever in the second, fourth and sixth notches, show but slight variation in the coal consumed per horse-power hour either with changes of speed or with changes in pressure. The fact, also, that the record shows but three out of 46 tests, representing a great variety of running conditions, for which the consumption exceeds

4 lbs., argues well for the efficiency of the locomotive in ordinary service.

The record of coal consumption shows that this performance is affected by variations in the evaporative efficiency of the boiler, due doubtless to irregularities of firing, but which are in fact unaccounted for.

An analysis of the general results obtained is summarized in a statement which may be accepted as a general definition of performance, assuming all irregularities to have been eliminated. Such a summarized statement may be expressed by the equation:

$$E = 11.305 - 0.221\ H$$

in which E is the number of pounds of water evaporated from and at 212 degrees per pound of coal, and H is the number of pounds of water evaporated from and at 212 degrees per foot of heating surface per hour.

It appears, also, from the data that the steam consumed by the cylinders varies for each different pressure with changes in speed and cut-off, and it has been sought to summarize the facts derived from the experiments into a single expression. This appears in the form of the curve A B, which is to be accepted as representing the performance of the cylinders under different pressures without reference to speed or cut off. Combining this general statement expressing cylinder performance with that already obtained covering boiler performance, it should be possible to secure an accurate measure of the coal consumption per indicated horse-power hour, for each different pressure which will represent the results of all tests at that pressure.

The steps in this process are set forth by the table.

Engine Performance Under Different Pressures.

Boiler pressure. 1.	Steam per I. h. p. hour, Values frm curves. 2.	B. t. u. given to 1 lb. steam feed water* 3.	Equivalent lbs. of water: Per I. h. p. hr. 4	Equivalent lbs. of water: Per lb. of dry coal. 5.	Lbs. coal per ind. h. p. hr. 6.	Coal saving, each increment: Pounds. 7.	Coal saving, each increment: P'r cent. 8.
240 lbs.	24.7	1,176.6	30.09	9.10	3.31	0.06	1.8
220 "	25.1	1,174.4	30.52	9.06	3.37	.06	1.8
200 "	25.5	1,172.0	30.94	9.03	3.43	.07	2.0
180 "	26.0	1,169.5	31.48	8.99	3.50	.09	2.5
160 "	26.6	1,166.8	32.14	8.94	3.59	.18	4.8
140 "	27.7	1,163.8	33.38	8.85	3.77	.23	5.8
120 "	29.1	1,160.5	34.97	8.73	4.00	...	...

*Temperature at 60 deg. F.

The values, especially those of columns 2 and 6, are of more than ordinary significance. They represent logical conclusions based upon the results of all tests. Comparisons between them will show the extent to which the performance of a locomotive will be modified by changes in the steam-pressure under which it is operated. They show in the matter of steam consumption (column 2) that—

Increasing pressure from 160 to 180 lbs. reduces the steam consumption 0.6 lb., or 2.3 per cent.

Increasing pressure from 180 to 200 lbs. reduces the steam consumption 0.5 lb., or 1.9 per cent.

Increasing pressure from 200 to 220 lbs. reduces the steam consumption 0.4 lb., or 1.6 per cent.

Increasing pressure from 220 to 240 lbs. reduces the steam consumption 0.4 lb., or 1.6 per cent.

In the matter of coal consumption (column 6) they show that—

Increasing pressure from 160 to 180 lbs., reduces the coal consumption 0.9 lb., or 2.5 per cent.

Increasing pressure from 180 to 200 lbs. reduces the coal consumption 0.7 lb., or 2.0 per cent.

Increasing pressure from 200 to 220 lbs. reduces the coal consumption 0.6 lb., or 1.8 per cent.

Increasing pressure from 220 to 240 lbs. reduces the coal consumption 0.6 lb., or 1.8 per cent.

These values are from actual tests. Those who are inclined to insist upon basing their conclusions upon observed data will perhaps find in them a satisfactory conclusion of the whole investigation. The results show how slight is the gain to be derived from any increment of pressure when the basis of the increment is above 160 lbs. But they do not in fact tell the whole story. In order to secure such results from a single locomotive it was necessary to employ a machine designed for the highest pressure experimented upon. Obviously, for the tests at lower pressure, the locomotive was needlessly heavy for its dimensions. If for the tests under each of the lower pressures the excess weight could have been utilized in providing a boiler of greater heating-surface, the difference in performance with each increment of pressure would have been less than that to which attention has already been called. It is for this reason that the results already quoted, while significant and concise in their meaning, are nevertheless to be accepted as insufficient when regarded as a relative measure of the value of different steam-pressures.

The final test of locomotive efficiency from the standpoint of the operating company is the amount of coal used per dynameter horse-power or, as it is more familiarly expressed, per ton mile hauled. The factor represents the combined performance of the boiler, the cylinders and the machinery of the locomotive. It connects the energy developed in the boiler by the combustion of fuel with that developed at the drawbar. From the data obtained it appears that the coal consumption per horse-power hour at 240 lbs. ranges from 3.35 to 5.01 lbs., while at a pressure of 160 lbs. the range is between 3.79 and 4.78 lbs., conclusions which are of interest from at least two points of view. First, because of the small difference in performances resulting from a relatively large change in pressure, and, second, because of the significance of the values quoted when accepted as a measure of locomotive performance. It is doubtful if any other type of steam engine exhausting into the atmosphere can be depended upon to deliver power from the periphery of its wheel in return for the expenditure of so small an amount of fuel.

From the discussion of the effect of increasing pressures compared with increasing boiler capacity it appears that there is a decided economical advantage in increasing the pressure when the basic pressure is low, but as this latter is raised, this advantage disappears until they are about balanced at 160 lbs., whereas there is no possible excuse for increasing the pressure beyond 320 lbs.

NEW PUBLICATIONS.

Boiler Waters. By William Wallace Christie. New York: D. Van Nostrand Co. 235 pages; 6 in. by 9 in.; 77 illustrations; cloth. Price, $3.00.

This book will be found to be a convenient reference for matters regarding the formation of scale, the corrosion of boiler plates and the foaming of the water. It is a compilation or collection of data on the subject that cover the principal impurities to be found in the usual run of feed waters, their effects upon the boiler and the means to be used to counteract such effects as may be injurious. The work opens with a statement of the impurities that are to be found, and then follows an outline of the methods to be followed in analyzing for them. In this no attempt is made to give instruction in chemistry, but there is a detail of the simple apparatus to be used and the methods to be followed to get quick results. The instructions are clear and concise and are such that a man of ordinary intelligence should, when prospecting for water, be able to ascertain whether that which is offered is fit for boiler purposes or not.

In treating of boiler scale, in the second chapter, there are a number of "awful examples" given of accumulations that have been removed from neglected boilers, and these are followed by a few rules that should be followed for the prevention and removal of such accumulations, with a statement of the effect of various scales on heat conduction and the evaporative efficiency of a boiler. The same method of example, cause and remedy is followed in the treatment of corrosion and foaming. The effects of oil and galvanic action are dealt with for the most part by extracts from other reports in which the results of investigations are summarized. A separate chapter is devoted to hardness, the means used in its determination and removal. There is also a chapter descriptive of the various feed-water heaters that are upon the market, and a closing one in the text on water softening or purification. There can be no summing up of conclusions, but the book opens the field for each individual to make inquiries along the lines of his own requirements guided by the experience of others. The last chapter contains a series of tables of the usual character on the conversion of metric to English measurements, on the properties of water and saturated steam, with a list of the chemical symbols of the substances entering into the subject. The book thus forms, as already stated, a valuable collection of data upon the important topic with which it deals and can be used as a guide by those who are having trouble with the waters used in their boilers.

Track Tanks.

Jersey City, N. J., March 16, 1908.

To the Editor of the Railroad Gazette:

I have read with interest the article on Track Tanks by Mr. Ross in your issue of March 13, and would like to add the results of some trials made on the Pennsylvania Railroad at Atglen, Pa., in October, 1906, under the direction of Frank Goodfellow.

The tanks at Atglen are on a curve and so are not directly comparable to those on tangent. During the trials, runs were made over a standard 19-in. trough and large ones, 29 in., both with and without lips, as shown in Figs. 1, 2 and 3. Trials were also made with a closed and semi-closed deflector and with a modified dipper, i.e., modified from the standard Pennsylvania Railroad dipper, as described in the *American Engineer and Railroad Journal*, November, 1896, and the *Railroad Gazette*, January 8, 1897. The

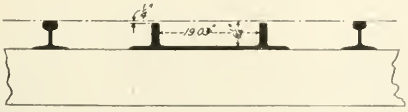

Fig. 1—Standard 19 in. Trough.

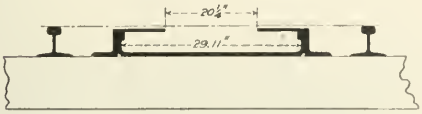

Fig. 2—Trough, 29 in., without Lips.

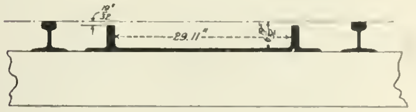

Fig. 3—Trough, 29 in., with Lips.

trials showed poor results or such slight increases in efficiency as to be more than counterbalanced by the increased complication.

Fifteen runs were made over each type of trough with the standard scoop; of these, three were made at each of the following speeds, 20, 30, 40, 50 and 60 m.p.h., and the results averaged, thus getting a fairly accurate figure. The results of the trials of the two 29-in. troughs show that the trough without lips is the more efficient from 32 to 48 m.p.h., while at all other speeds the trough with lips is better. In comparing the 19-in. trough with the results of the 29-in. one with lips, the latter is the better up to 30 m.p.h., while at all higher speeds the 19-in. one gives better results, as will be seen from the efficiency curve, Fig. 4.

From this it would seem to be good practice to install a 29-in. trough with lips on freight tracks, where the average running speed would be less than 30 m.p.h. This would be so from a motive power standpoint considering only the amount of water delivered to tender, but taking maintenance into account this would not do, as a larger quantity of water is thrown on the right-of-way, thus offsetting any gain due to larger tank fulls.

The speed for greatest economy was found to be 40 m.p.h., which makes the minimum splash with a correspondingly large

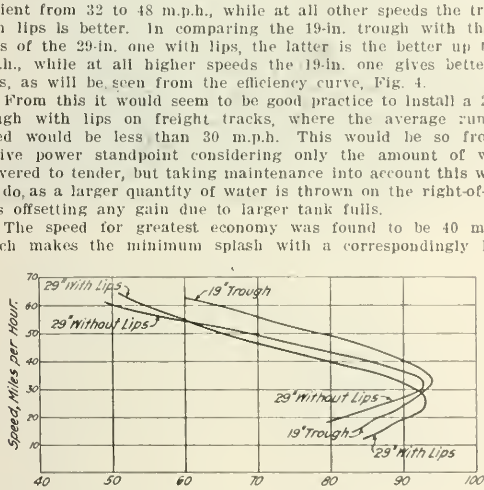

Fig. 4—Water to Tender Efficiency.

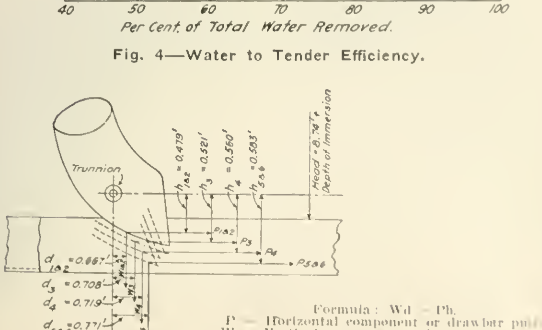

Fig. 5—Position of Dipper for Different Depths of Immersion.

amount to tender per foot of length of trough. A comparison of the results at this speed is shown in table 1.

Table 1.

		With lips,	No lips,
Trough	19 in.	29 in.	29 in.
Speed, miles per hour	40 miles.	40 miles.	40 miles.
Total water removed per lin. ft. of trough	.2892	.3355	.3156
" " to tender per lin ft. of trough	.2655	.2955	.2728
" " spilled per lin. ft. of trough	.0137	.0400	.0428
Per cent. water to tender	96.50	85.25	87.00
Per cent. water spilled	3.50	14.75	13.00

It might be of interest in passing to mention the action of the water in the trough when the dipper is lowered. To make observations of this, the special tender used was fitted with open flooring and a cage hung between the trucks from which an observer could get a good view of the action and, in most of the runs, photographs. At 30 and 40 m.p.h., the writer passed back from around the point of the dipper in a thin sheet about the width of trough, and fell about 5 ft. back of the tender, striking the disturbed water in the trough and splashing out at the sides. This action is not restricted to the trial tender but may be observed on fast passenger trains, the water flying back, at times, far enough to be thrown down by the forward trucks under the first car of the train. At 50 and 60 m.p.h. there was so much splash that the rear truck of tender was hidden from view, while looking down from the top the whole point of the dipper could be seen cutting the water with no appreciable frothing. As the speed diminishes, a wave action is set up in front of the dipper, the water being piled up until it falls over the sides. This wave increases in size up to the point where the velocity imparted to it is less than that necessary to overcome the resistance due to gravity and friction, when, of course, no more water is lifted.

A summary of the results shows conclusively that with the standard type of dipper the 19-in. trough is the more economical when all speeds are taken into consideration.

Some interesting calculations of the load on scoop and the resultant force on the drawbar for different depths of immersion were made from the results of the Bellwood trials in August, 1906.

Fig. 5 shows the positions of the dipper at different depths of immersion, the vertical distances are taken from the point of support or trunnion to the point of impact of the dipper and water, or the point where the water changes its direction and the horizontal distances are from point of impact to center line of trunnion.

From this, the results shown on Table 2 have been calculated from the moment about the trunnion. In the upper portion of the table will be found the calculations based on the weight of water delivered to tender, while the lower portion is based on total water removed from trough.

Table 2

	Calculated							
	From water to tender				From total water removed			
		Component P force at drawbar		Comp. W, load on dipper,		Component P force at drawbar		Comp. W, load on dipper
Test.	Speed, in m. p. h.	Pounds.	D. h.p.	lbs.	Speed in m. p. h.	Pounds.	D. h.p.	lbs.
1....	25.7	557.6	38.21	400.4	25.7	571.9	39.19	410.7
2....	29.3	700.3	54.71	502.9	29.3	791.0	61.80	568.0
3 ...	30.8	904.2	74.26	655.2	30.8	960.3	78.86	695.8
4....	39.9	1,430.2	152.19	1,010.2	39.9	1,487.9	158.14	1,050.7
5 ...	51.9	2,374.0	328.52	1,795.1	51.9	2,764.6	382.60	2,090.5
6 ...	58.3	2,935.5	456.32	2,219.5	58.3	3,494.9	543.22	2,642.5

From this it will be seen that at high speeds, 50 to 60 m.p.h., the load on the scoop is about a ton, while the corresponding calculated dynometer horse-power reaches from 450 to 550, or about one-half of the available horse-power of an Atlantic locomotive at that speed.

It is therefore good policy for enginemen of high-speed trains to slow before taking water and for those of low-speed trains to increase it, if possible, to get the greatest economy.

B. S. MURPHY,
Mechanical Inspector, Hudson Companies

What Are We Going to Do About Accidents?

March 28, 1908.

To the Editor of the Railroad Gazette:

With reference to the letter of "General Manager," which appeared in your issue of Feb. 28, there can be no doubt whatever that the frequency of train accidents is viewed by operating officers with great anxiety, and the necessity of raising the average of efficiency and intelligence in the ranks of employees, by the weeding out of careless and incompetent men, must be universally recognized. "General Manager" attaches considerable importance to surprise checking as a means of exposing carelessness and incompetency, but it should not be overlooked that there must be a moral force acting in support of any such system, which if properly sustained by the executive, over which "General Manager" presides, will induce among the rank and file a sense of personal pride in a service and create a standard of private honor rising very much higher than the principle expressed by surprise checking.

"General Manager" says that "it is unquestionably practicable to lessen the number of train accidents." I quite agree, and I think that the lines along which this is likely to be accomplished is in the direction of raising the moral standard of the men. Much can be done by the influence of example. Rules and precepts discouraging and prohibiting drinking among railroad men hopelessly fail in their effect if they are not supported by good example. The highest officers are concerned in this as well as superintendents and heads of departments, and if they do not realize that some sacrifice in the interest of discipline is necessary on their part, they cannot reasonably expect—taking human nature as it is—compliance with stringent instructions which the men know are based upon precept only and not on practice. I venture to think, for instance, that if the use of intoxicating liquor was abolished from official cars, it would, by the influence of example materially strengthen the efforts of departmental officers in removing the standing menace of drinking, which though happily reduced in every direction, still exists to a dangerous extent.

In every regulation dealing with personal conduct and attitude while an employee is on duty, or in and about the premises of a railroad company, the officers should take a distinct lead and set up the standard which they wish their men to follow on every possible opportunity.

"General Manager" suggests that the record of 100 per cent. of the men who were found obedient to the rules when surprised is false, and this circumstance just serves to illustrate my point. The weakness or strength of the moral fiber amongst men in a large organization will, generally speaking, be a reflex of the principles of general and departmental control. In "General Manager's" case, there is an obvious want of confidence in both departmental officers and men, and I suggest that with this spirit pervading his organization, too much should not be expected as the result of what is merely a mechanical check. Officers, and particularly superintendents, should have greater faith in their men and should more fully appreciate their own responsibility in cultivating a higher morality which is the real basis of efficiency and honest service, and which should make the suspicion which haunts "General Manager's" mind impossible.

Is he satisfied, that in exercising his authority in matters concerning the staff as a whole, he has given adequate consideration to this aspect of his administrative work? If a company stands square before the men who compose its working force, and the principles of control are transparently honest as they should be, there should be no room for suspicion and distrust. Nothing can be so prejudicial to the spirit of individual loyalty as an influence of this kind. Loyalty to a service shows itself in the spontaneous display of interest and energy on the part of employees, and this is the actual source of the general efficiency at which we are all aiming and which can only be successfully developed along the lines of mutuality between the management, departmental officers and the staff. If "General Manager" should quietly check up his departments in this direction, it is not unlikely that the feeling of distrust to which he has given expression would be found to have its source in a lack of co-operation or a laxity of principle for which his own policy may even be directly responsible.

I firmly believe that the great majority of railroad men are not only willing but anxious to strictly comply with the rules of safe operation, and as a general suggestion I would say that the district officers should meet the men more frequently than is the case at present. The nature, cause and prevention of every accident that occurs should be thoroughly explained either by means of printed descriptions or in conference. A man may fail at a critical moment, not as the result of neglect, but because he may be in doubt on some point which has not been made clear to him. The responsibility in such a case extends, I think, to the management. The officers find it necessary to confer frequently, and at a reasonable cost, it would be a sensible and profitable investment to provide facilities whereby the men could meet and discuss problems of everyday railroading assisted by some of the officers. By these means uniformity of practice could be secured and any conflict of opinion as to the interpretation of certain rules would be removed. A healthy individual interest would be excited and a way would be cleared for the subsequent adoption of a system of oral examinations, than which no better means of testing intelligence and efficiency could be devised.

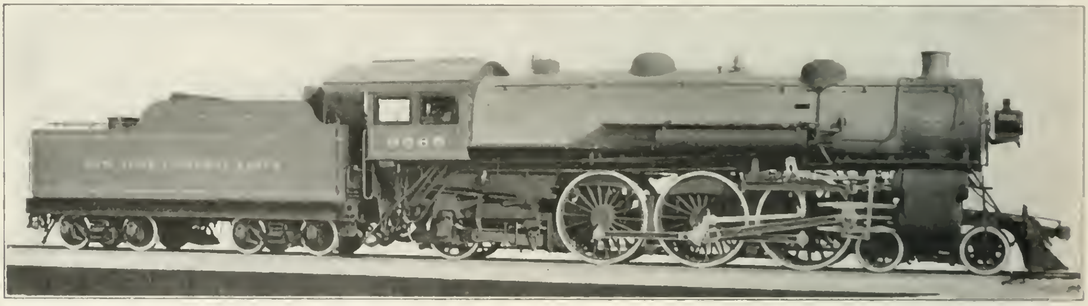
SUPERINTENDENT

Pacific Locomotive for the New York Central.

The Schenectady works of the American Locomotive Co. have recently completed an order of 40 Pacific type locomotives for the New York Central & Hudson River Railroad. These are the heaviest passenger locomotives ever built for this road and will be used in hauling through trains. At the present time these trains are handled by a $21\frac{1}{2}$ x 26 Atlantic type engine, having a maximum tractive power of 23,300 lbs. The reason for adopting the Pacific type in ordering new passenger equipment was that the Atlantic type engine did not provide the necessary adhesive weight for starting purposes to satisfactorily meet the requirements.

In general, the engines here illustrated are duplicate in design of a previous lot built last year by the same builders for the Lake Shore & Michigan Southern, which took the place of the Prairie type as the standard high-speed passenger engine on that road, and are now hauling all their important trains, including the Twentieth Century Limited. It is probable that this new class will become the standard type of heavy passenger power for all the New York Central Lines.

In working order these engines have a total weight of 266,000 lbs., of which 171,500 lbs. is carried on the driving wheels. The cylinders are 22 in. diameter by 28 in. stroke, and with driving wheels 79 in. in diameter and a working pressure of 200 lbs., the engines will develop a maximum tractive effort of 29,200 lbs.

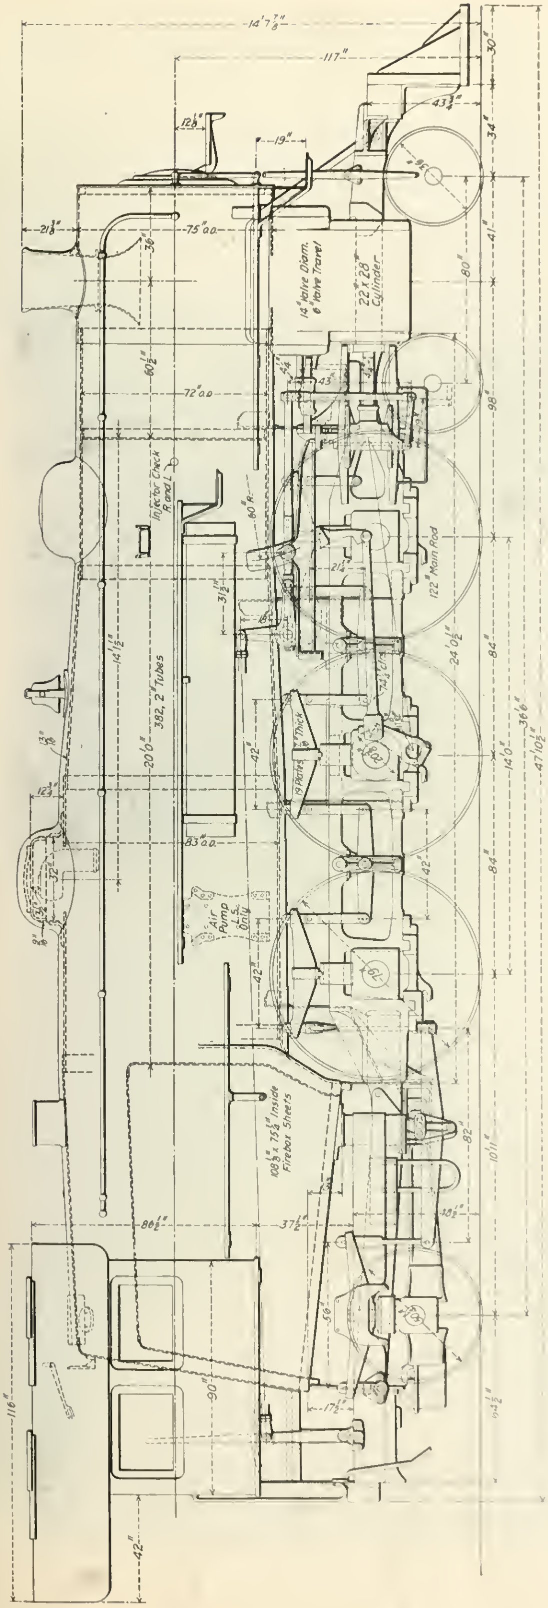


Pacific Locomotive; New York Central & Hudson River.

Especial attention was paid in working out the design to providing a boiler of the highest capacity, and it will be seen from an examination of the principal ratios given below that in this respect the design is considerably above the average Pacific type engine. The boiler is of the radial stayed type with a conical shaped middle ring and the outside diameter of the front ring is 72 in. It contains 382 tubes 2 in. in diameter and 20 ft. long, and provides a total heating surface of 4,210 sq. ft., of which the tubes contribute 3,982 sq. ft. and the firebox and arch tubes the remainder. The firebox is $108\frac{1}{8}$ in. long and $75\frac{1}{4}$ in. wide and has a grate area of 56.5 sq. ft.

In accordance with the present requirements in locomotive design the boiler is raised high above the frames, the top of the front course being 12 ft. $10\frac{1}{2}$ in. above the rails. This cuts down the space available for the dome, which is only $12\frac{3}{4}$ in. above the shell and also drops the throttle down so that its lower opening is about flush with the top of the shell. It will leave about 15 in. between the surface of the water, when it stands at the second gage, and the throttle, and this may be cut down as low as 11 in. with more water and the engine on a grade; while, with the surging of the water, when the engine is in motion the wave crest may come very close to the throttle itself. Attention is called to these points merely to show how allowances that were formerly considered the minimum have been cut down until they have practically disappeared under the stress of the later designs. Compare this clearance with that obtained with the old boilers with a high dome on the wagon top and the difference will be seen to be very marked. In the same way there is a tendency on recent designs to place the injector check well up to the front tubesheet. In this case there is but $8\frac{1}{2}$ in. from the center to that sheet, and this in spite of the protests that have been made that such close proximity tends to leaky tubes. Evidently that claim is not being substantiated.

Part of the engines built on this order have been fitted with



Pacific Locomotive; New York Central & Hudson River.

steel tubes and the balance with charcoal iron. At the firebox end the slope of the side-sheets is such that there is a chance for a free liberation of the steam over the entire surface with a direct rise away from the metal throughout the whole distance from the foundation ring to the crownsheet. The spread of the sheets is 75¼ in. at the bottom, drawing in to 62 in. at the springing point of the curve of the crownsheet. This gives an inward slope of 1 in 7 to the sheet. Again it may be well to contrast the conditions for steam liberation thus obtained with those of the narrow firebox set between the frames, where the waist of the firebox was drawn in as with corsets, and the steam trailed over the side sheets the whole distance from the point of its generation to the space provided for it over the crownsheet. With the wide firebox, the quality of the steam as it enters the steam space must be much dryer than was possible with the old firebox, and thus the necessity for the great height to the throttle no longer exists. Besides this, the film of steam over the sidesheets should be much thinner than before, resulting in cooler sheets and a reduction of the stresses on the staybolts.

In general design the engine embodies no especial novelties and the interest in it lies, for the most part, in its size, the smoothness of its lines and the pleasing symmetry of its proportions. Cast-steel is used for the parts usually made of that material, and the engine is equipped with the ordinary fittings in the way of high-speed brakes, etc. In some of the ratios it will be noticed, as we have said, that the results are somewhat higher than usual. Thus, the ratio of tractive effort to weight is 5.84, which is well above common practice.

The following are some of the principal dimensions of these engines:

Cylinder, diameter	22 in.
Piston, stroke	28 in
Wheel base, driving wheel	14 ft
" total	36 ft. 6 in.
" total, engine and tender	67 " 11 "
Weight on drivers	171,500 lbs
" total	266,000 "
" engine and tender	430,000 "
Heating surface, tubes	3,981.6 sq. ft
" " firebox	199.9 "
" " arch tubes	28.4 "
" " total	4,209.9 "
Grate area	56.5 "
Journals, driving axle	10½ in x 12 "
" engine truck	6½ " x 12 "
" trailing truck	8 " x 14 "
" tender (M. C. B. standard)	5½ " x 10 "
Boiler, diameter, first course	72 in.
Steam pressure	200 lbs.
Firebox, length	108¼ in.
" width	75¼ "
" thickness, crown, side and back sheets	⅜ in.
" thickness tube sheet	½ in.
" water space	4½ in.
Tubes, number	382

The East River Tunnels of the Pennsylvania Railroad.

The four tunnels of the Pennsylvania Railroad under the East river, connecting Manhattan Island at Thirty-third street with Long Island City, have now all been bored through, so that it is possible to walk under the river in any one of the four tubes. It was long the hope of the late Austin Corbin President of the Long Island Railroad, to have rail connection between Long Island and Manhattan but it was left to the great foresight and genius for railroad construction, operation and financing of the late A. J. Cassatt, President of the Pennsylvania Railroad, to carry through such a plan. The Long Island Railroad was bought by the Pennsylvania on the strength of the potentialities of its territory. Mr. Cassatt saw that Long Island, now scarcely profitable to a railroad, held great possibilities for development of traffic when directly connected with Manhattan Island. The tunnel extension to Long Island is part of the comprehensive scheme evolved by him and his right-hand helper in working out these great plans for the New York terminal improvements, Samuel Rea.

The East river tunnels of the Pennsylvania and the great air power plants which furnish the air pressure used in their construction were described in great detail in the *Railroad Gazette* of July 6 and July 27, 1906. The present article is in the nature of a brief general summary of the work, marking the successful completion of all four of the tunnel tubes. The photographs show excavation in rock, the face of one of the shields in rock, the erector at work putting steel plates in the tunnel lining, one of the great caissons, and the floating equipment used in the work.

The Pennsylvania East river tunnels begin in two steel caissons sunk between First avenue and the river front, Manhattan, and continue in a pair of tunnels driven from each caisson under the Manhattan ferry slips of the Long Island Railroad and the East river to a similar pair of caissons sunk on the water front at Long Island City, just south of the Long Island Railroad ferry slips on that side of the river. Thence they continue diagonally underneath the Long Island Railroad tracks, gradually converging and passing under Vernon avenue and meeting in one shaft at East avenue, Long Island City. The total length underneath the river, from caisson to caisson, is about 4,000 ft., and from the Long Island City caisson to East avenue, 2,000 ft. The work was divided into three working sites, 2,000 ft. of four tunnels being driven from each site. The divisions were as follows: 2,000 ft. from the Manhattan shafts to the center of the river, 2,000 ft. from the center of the river to the Long Island City shafts, and 2,000 ft. from the Long Island City shafts to the East avenue shafts. The total length of the four tunnels is 24,000 ft. The outside diameter of each tunnel is 23 ft. The tunnels are lined throughout with cast iron tunnel lining in rings 2 ft. 6 in. long, divided into 11 segments and a key, each ring weighing $11\frac{1}{2}$ tons and each segment except the key weighing about one ton. There were about 100,000 tons of cast iron lining used, and 1,500,000 bolts of $1\frac{1}{2}$ in. diameter used in fastening the segments together. The tunnels are to be lined with concrete 2 ft. thick. The vitrified conduits for carrying electric light and power cables, of which there are 1,000,000 ft., are built in benches on each side of the track. These benches form a sidewalk for passengers in case trains are stalled in the tunnel.

The construction problem presented at the time the plans for these tunnels were made was a new one. Their cost was problematical, and the estimates of the engineers, estimates and nothing more. One bidder on the contract proposed to build the tunnels by the freezing method; another made it clear by his proposal that he had no knowledge of the real nature of the work. The accepted bid was that of S. Pearson & Son, Ltd., of London, who had not only recently successfully driven the Blackwall tunnel with an outside diameter of 27 ft., under the Thames river in England, at that time the most difficult work of this sort ever carried out, but had been the contractors in 1889-1890 for the tunnel under the Hudson river from Hoboken to Morton street, New York, the first sub-aqueous tunnel ever driven by the shield method.

One of the Caissons at Long Island City.

This tunnel, which was on February 25, 1908, opened to travel by the Hudson & Manhattan Railroad, had before 1889, been pushed 2,000 ft. out from the New Jersey shore of the Hudson river, where the heading had been abandoned and the tunnel had caved in. In order to regain the heading of this old tunnel, a great canvas balloon filled with hay and clay was dropped from a floating derrick into the cavity. This kept the water out long enough so that it was possible to regain the tunnel, excavate the silt and build a chamber in which, under an air pressure of 42 lbs. to the square inch, the shield was erected. This, because shield tunnelling was then a new art, was probably the greatest and most daring feat in the history of subaqueous tunnel work. This shield was advanced and cast iron lining built behind it for between 2,000 and 3,000 ft., and it was being advanced at the rate of 10 ft.

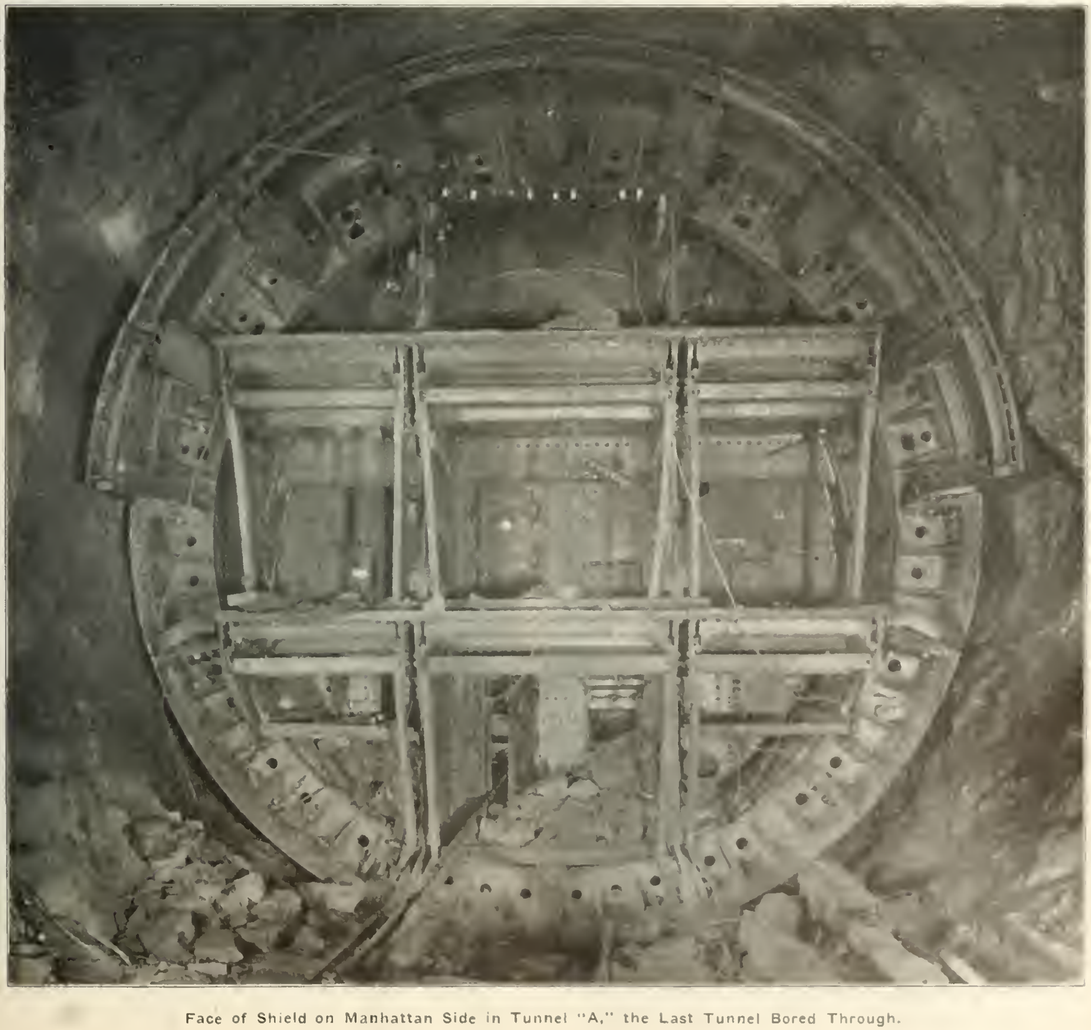
Floating Equipment—Dredge, Tug and Scow.

a day when the company which was carrying on the enterprise failed and the contract was abandoned, to be taken up again in recent years by the Hudson & Manhattan Railroad. The old shield left in the tunnel in 1890 was used to finish the work in 1907. The boring in 1890 was done by E. W. Moir, now Vice-President and Chief Engineer of S. Pearson & Son, Incorporated, which is the name of that branch of the firm which is carrying out the East river tunnel contract. The fact that the wide experience of Mr. Moir and of his firm in subaqueous tunneling was available, as well as the fact that the reputation of S. Pearson & Son, Ltd., as successful contractors—successful both for themselves and for their employers—was generally recognized throughout the world, made this firm the most desirable bidder on this difficult contract.

Excavating in Rock.

In March, 1904, when the contract for the East river tunnels was let, there was only one small tunnel tube under the East river. This was known as the East river gas tunnel and ran under Blackwell's Island, being sunk so deep that it was almost entirely in solid rock, though some seams of soft, decomposed rock were met with, which necessitated the use of very high air pressure. The two Battery tubes of the Interborough Rapid Transit subway to Brooklyn had been well started on the Manhattan side, but as the formation there was entirely rock these had given no experience of the formations to be expected under the main part of the East river. Subsequently the Belmont (Steinway) tunnel was pushed through, advantage being taken by William Barclay Parsons in its construction of the Man o' War's reef, a continuation of the Blackwell's Island reef, on which a shaft was sunk. From this shaft, tunnels were driven in each direction to meet the shields coming from Manhattan and from Long Island, thus virtually cutting in half the time necessary for completion. There was no such favorable formation of which the Pennsylvania tunnels could take advantage.

The trial borings in the bed of the East river showed that the strata on the lines of the tunnels were rock on each side of



Face of Shield on Manhattan Side in Tunnel "A," the Last Tunnel Bored Through.

the river, sloping down so that the tunnels would emerge into a full face of boulders and quick and beyond which would be reached silt and quicksand without boulders. The Man o' War's reef in the middle of the river stands up against the quicksand in such a way that the roof of the tunnels comes sometimes 10 ft. above the reef and sometimes only 1 ft above, but it is seldom that there is sufficient rock in the roof to form a safe cover for the workmen. The problem, therefore, was to tunnel by a shield through a mixture of quicksand and rock and through quicksand alone.

In trying to keep the air pressure high enough to overcome the head of water and quicksand at the bottom of the tunnel, there was a constant risk of blowing off the roof of quicksand and allowing the water to pour in from above. If the pressure was lowered sufficiently to prevent blowouts, the quicksand flowed from under the shield and between the joints of the tunnel lining and allowed the tunnel to settle, and after the pressure was raised high enough to prevent this the roof was blown off and the tunnels flooded.

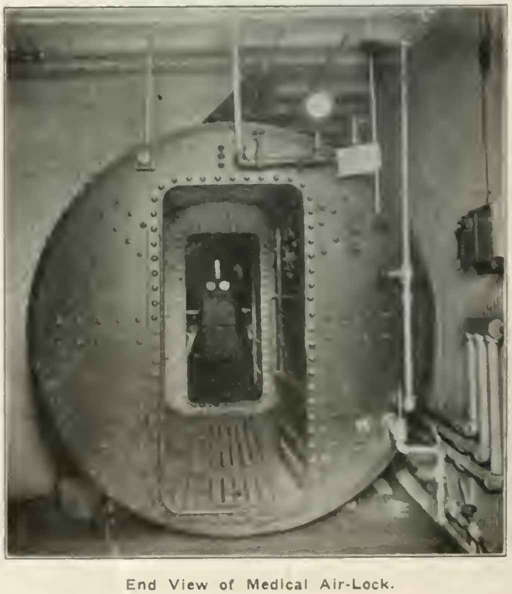
Mr. Moir foresaw and guarded against this danger by specifying that permission should be gained from the War Department for dumping clay in the river bed to a sufficient depth to allow the air pressure to be raised without causing blowouts. The necessity of this can be realized from the fact that at certain points the tunnels have only 7 ft. of quicksand between them and the water of the river. After the full permit was obtained for dumping the clay, no flood of water occurred in any of the eight subaqueous headings. This clay blanket deposited in advance of the shields, combined with the continuous grouting made with a quick setting concrete over the iron lining, did away with many of the dangers of this delicate tunneling work. The clay came from Haverstraw, N. Y., and was dumped from scows whose position was located by transit men in the high towers of the coal unloading plants of the Long Island Railroad on the Long Island shore and of the New York Edison Company in Manhattan. A total of about 500,000 cu. yds. of clay was deposited on this work. Now that the tunnels have been finished, this clay is being dredged off the river bottom and sent out to sea.

As the shield advanced and the iron lining was erected, cement and lime grout was forced out through grout holes in the cast iron lining to fill up the annular space left outside the lining of the shield and also the roof cavities left in the rock excavation where it had been blasted. For this purpose 250,000 barrels of cement and lime were used. The joints between each segment were caulked with lead or rust caulking to make the tunnels water tight before the concrete lining was placed.

One of the accompanying photographs shows the "medical air lock." On March 20, 1908, the workmen and staff of S. Pearson & Son, Inc., presented to Mr. Moir a brass model of this air lock about 2 ft. 6 in. long by 9 in. in diameter, complete in all particulars. This model was inscribed as follows: "Presented to Mr. E. W. Moir, the maker of the first medical air lock on the old Hudson tunnel, 1890, by grateful 'sand hogs' on the Pennsylvania East river tunnels, New York, 1908." The medical air lock is an air pressure hospital where men attacked with the bends (caisson disease) after coming out into the open air may undergo recompression, which has been found to be the only practicable means of

Erecting Plates in the Tunnel Lining; Looking Toward Shield.

Erecting Plates in the Tunnel Lining; Side View.



End View of Medical Air-Lock.

relief. In the building of these tunnels there have been three cases of men who, to all intents and purposes, were dead, but after recompression in the medical air lock fully recovered. There have also been cases of men who were paralyzed but were entirely restored to their normal condition after recompression. There are six of these medical air locks for use of engineers and workmen in the tunnels, each one being fitted with a double chamber so that the doctor in charge can pass in and out to his patients without interfering with or interrupting the air pressure of the inner room with the hospital beds. The air lock has compressing and decompressing valves, thermometers and pressure gages.

The chief engineer of this project for the Pennsylvania Railroad is Alfred Noble, who has been responsible for the design and construction of the tunnels. He has been assisted by a board of engineers appointed by the railroad, which originally consisted, besides himself, of Brig. Gen. Charles W. Raymond, chairman; Gustav Lindenthal, Charles M. Jacobs, William H. Brown and George Gibbs. C. L. Harrison is principal assistant engineer and has had particular charge of the alinement of the tunnels.

One of the accompanying portraits is of Sir Weetman D. Pearson, President of S. Pearson & Son, Inc., and also of S. Pearson & Son, Ltd., London, probably the foremost contractor in the world. The second photograph is that of Henry Japp, Director and Managing Engineer of the New York branch of the firm. He was the first engineer, four years ago, for the contractors on the East river tunnels, and has been constantly in charge of the work ever since. The third photograph is of Mr. Moir.

Electric Night at the New York Railroad Club.

The annual "electric night" of the New York Railroad Club was on March 20. For several years the March meeting of the club has consisted of several short discussions by well-known engineers who have been in charge of important electrical development.

The first speaker was L. B. Stillwell, Consulting Electrical Engineer for the Hudson Companies and the Interborough Rapid Transit Co. He compared the passenger traffic of the Interborough lines with that of steam railroads, showing that the annual passenger mileage in the subway was greater than that on the New York, New Haven & Hartford or on the New York Central, twice that on the Erie, and about the same as that of the Pennsylvania Lines East. The average daily car mileage of the elevated lines and the subway together is 326,357 miles, and the two systems, together, carry an average of 1,519,000 passengers a day. The horse power of the motors on the cars of a subway train aggregate 25 per cent. more than that of a New York Central electric locomotive. Mr. Stillwell then gave some details, illustrated by lantern slides, of the following recently completed under-river tunnels in New York City.

BELMONT TUNNEL.

This tunnel, which is also known as the Steinway tunnel, was built by the New York & Long Island Railroad in the interests of the Interborough-Metropolitan Co. It runs from East 42d street, Manhattan, under the East river to Long Island City. On the Long Island side there is a loop, at which point the cars come to the surface, some of them traveling further east. The operation of this tunnel is to be unique, in that ordinary surface cars are to run through it. For this reason there is a contact rail on the roof of the tunnel. It is a T section, weighing about 20 lbs. to the yard, and is bolted to brackets, which are adjustable. Where the tunnel is tube construction, these brackets are bolted to the flanges of the rings; where the roof is concrete, they are fastened to bolts sunk in the concrete. The rail is supported every 9 ft. A special pantograph trolley is used. This is quite compact, because of limited clearance; it can be compressed so as to be used when the minimum distance between the roof of the car and the contact rail is 8 in. It is similar to that used on the New York Central. On September 24, 1907, the first car was run through the north tube, being only two days after the workers on the tunnel proper had finished their work enough to get out of the way. This was the first car to move under the East river from Manhattan to Long Island under its own power.

EAST RIVER EXTENSION OF THE INTERBOROUGH.

Because of limited space, a special design of third rail is used in this tunnel. It is an inverted U section and is placed 26 in. from the gage line. This distance is criticised because it may not be far enough away to allow cars of other lines to be interchanged in case it is desired, in future, to operate cars of the New York Central, the Long Island Railroad, etc., over the Interborough. [The New York Central distance is $28\frac{1}{4}$ in. and the Long Island $27\frac{1}{2}$ in.] A special design of bonding is used. The slugs of the bonds go through the rail vertically, there being two plugs, arranged tandem, at each rail end.

For pumping out water in the East river tunnel, there are five sumps. There are now six 6-in. pumps, there being two pumps in the sumps at the bottom of the dip, each having 600 gal. capacity per minute. These sumps are in chambers 7 ft. x 14 ft. placed between the tubes. The pumps discharge through individual pipes to sewers in Manhattan and Brooklyn.

The piston action of trains is sufficient for normal ventilation. If three trains were stalled in one tunnel, people in the middle train would not suffer discomfort for an hour. An auxiliary ventilating plant, however, is installed for use in such emergency. There are air flues at each end of the tunnel, through which air is forced in in the direction of traffic at the rate of 43,000 cu. ft. per minute against the assumed normal pressure in the tunnel. However, this rate will probably be affected by the direction of the prevailing winds. The operation of the ventilating system is controlled by the despatcher at Bowling Green. At each manhole there is a telephone, a fire extinguisher and a fire hose, which can be coupled to the water lines running through the tunnel.

HUDSON & MANHATTAN.

The grades in this tunnel run as high as 5 per cent. All the cars used are motor cars (in the Interborough subway, motor cars and trailer cars are alternated in making up a train), and by reversing the motors the cars can be surely held on any grade.

Hugh Hazelton, of the Hudson Companies, described the construction of the Hudson & Manhattan cars (*Railroad Gazette*, June 14, 1907). The Hudson & Manhattan when finished will have 19 miles of track. Of this, six miles are now in operation, and six more are excavated and ready for bench walls, and are expected to be in operation by the end of the current year.

In the Hoboken terminal there are two station tracks for each incoming track, so that one train can come in and discharge passengers as another is being loaded. This will make possible a $1\frac{1}{2}$-minute headway. There are separate loading and unloading platforms in all three terminals. The lights are operated by alternating current direct from the power house, or by direct current from the third rail. This rail, which is similar to that in the Brooklyn extension of the Interborough, is low in manganese and carbon. Its conductivity is one-eighteenth that of copper. The protection over the rail is of jarrah wood, from Australia. The boards are 2 in. x 9 in. x 9 ft. It is heavier and a little harder than oak. Its particular value lies in its fire resisting qualities. It will stand the flame of a blow torch for 11 minutes before burning through, as compared with oak, eight minutes, and pine about two minutes. Also, jarrah wood will not keep on burning after the torch is taken away. The tunnel is lighted by two rows of lamps, spaced 60 ft. apart on each row. They are alternate, so that there is a light every 30 ft. The power house is at Washington and First street, Jersey City. There are two 3,000-k.w. generating units. At present, however, power is being acquired from another source.

J. M. Waldron, Signal Engineer of the Interborough Rapid Transit, described the signal system of the Brooklyn extension. This was described in an article in the *Railroad Gazette* of February 28, 1908.

NEW YORK CENTRAL.

W. J. Wilgus spoke of the advantages of electrification as found from the experiences of the New York Central. Since July 1, 1907, all New York Central trains have been electrically operated to and from Grand Central Station. The system has proved successful from the operating, the engineering and financial standpoints. There are a number of "by products" of the electrification of steam lines. With electric operation, it is possible to make use of the "air rights" of the corporation; that is, to build office buildings over terminal yards. The New York Central property at the Grand Central Station terminal is worth $50,000,000 more under electric operation than under steam operation, taking into account this possibility of erecting revenue producing buildings on it. Under electric operation, also, money is saved in the lighting of yards and terminals. As long as propulsion current is there, it is easy to provide additional current for these other purposes. The New York Central, in this way, will save $200,000 a year. There is also plenty of current available for labor-saving devices at freight terminals; for example, the operation of float bridges, unloading machinery, etc. A power house is designed so that it can take care of peak loads. Between these points of maximum requirements, power for other purposes can be turned out at a cost about equivalent to the cost of burning coal under the boilers. Another advantage is the economy of switching by electricity. Mr. Wilgus knows of one yard in which $114,000 a year was saved in this way. Also, when there is a continuous current-carrying conductor along the road, it is possible to use other devices, such as automatic stops. The use of automatic stops makes it unnecessary to have more than one man at the front end of the train, since in the electric locomotive or the front car of a multiple unit train the second man has nothing to do except stand ready to take the motorman's place in case of trouble. Automatic stops also take the place of surprise checking to correct careless overrunning of stop signals.

NEW YORK, NEW HAVEN & HARTFORD.

W. S. Murray, Electrical Engineer of the New York, New Haven & Hartford, emphasized the fact that the steam locomotive was in no danger of being relegated to the scrap heap. The bases for determining the relative efficiency of different systems of motive power are reliability of service, fixed charges and operating expenses. One pound of coal burnt at the Cos Cob power house is equivalent to two pounds burnt in a steam locomotive. The same ratio applies to the locomotive mileage of steam and electric locomotives. The mistakes in the design of the New Haven electric engine are not fundamental. The troubles the road has had are due to the fact that electrification was only partial, this situation bringing in problems which the New York Central, with its complete electrification, did not have. The company has on file orders for multiple unit cars, but these will not be placed until the electric locomotive has been perfected. A few experimental multiple unit cars have, however, been ordered.

ELECTRIFICATION IN 1907.

George Gibbs gave the following list of what had been done during the year in electrification and other important developments in electric traction: The New York Central began full electric operation in New York City on July 1, 1907, the New York, New Haven & Hartford (the first alternating-current electrification of a steam road in this country) July 22; part of the West Shore, June 15, this being particularly interesting as giving an opportunity to compare the results of direct competition with trolley lines; Rochester division of the Erie, June 18; Belmont tunnel, September 24; Brooklyn tunnel, January 27, 1908; Hudson & Manhattan tunnel, February 25. Other electrification projects definitely decided on are: The Cascade tunnel of the Great Northern, and the line over the Bitter Root mountains on the Pacific coast extension of the Chicago, Milwaukee & St. Paul. This line is 54 miles long and the grades on each side of the summit are 1.7 per cent. Current is to be generated by water power. An advantage of electrification in timbered country is that danger of forest fires is lessened.

Walter C. Kerr, Vice-President, Westinghouse, Church, Kerr & Co., said that he wondered that so little had been done in actual electrification. A deterrent is the great first cost of the electrifications which have been proposed. The electrification of tunnels is particularly attractive. Another field is the electrification at terminals in large cities. Those of this class which have been completed or are under way all connect with tunnels, e.g., the New York Central, the New Haven, the Pennsylvania, etc. The other fields for electrification are branch lines and heavy mountain grades. Everybody admits that electrification is theoretically advisable, but the first cost is the great hindrance. It is now time to reduce costs, not only of electric apparatus, but the other costs entering into such installations. When a new road is built to be operated by electricity, from 15 to 20 per cent. of the cost is for electric material. When a steam railroad is electrified, 75 per cent. of the cost is for electric material. The turbine has cut in half the cost of generating power. Heating and coal handling also cost less than before. These savings are offset by the increased cost of labor and material; and this increase makes still more necessary the economy in handling just mentioned. There has been much technical advancement, what we need now is attention to costs.

ELECTRIC ENGINES OF THE SPOKANE & INLAND.

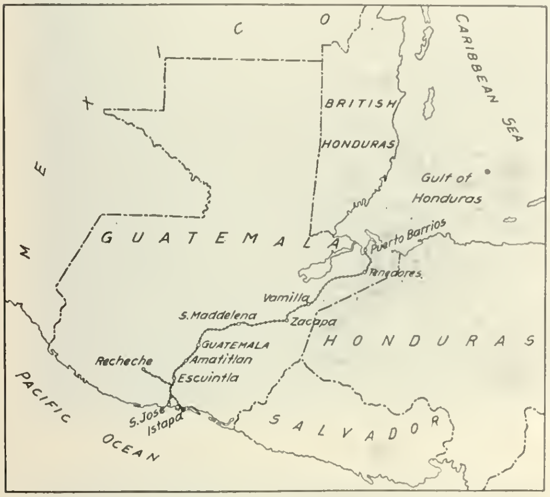
B. G. Lamme, of the Westinghouse Electric & Manufacturing Co., spoke of the freight locomotives of the Spokane & Inland. Direct current is used in Spokane and 6,600 alternating current outside of the city. There is a 2-per cent. upgrade eight miles long leading out of the city. Beyond that the country is level, supposedly, but really so rolling that 40 per cent. of the line is on a 1½ per cent. grade. The first order was for 21 passenger motor cars and eight freight locomotives. The nominal rating of the locomotives was 600 h.p., there being four motors of 150 h.p. one-hour capacity to each locomotive. The engines have two swivelled trucks. The maximum tractive effort is 15,000 lbs., and continuous effort, 7,000 lbs. On the first grade out of the city the motors heated so that their efficiency for overcoming following grades was reduced. On these first locomotives the cooling fans were geared to the motors; on the later ones they were equipped with fans operated separately. In the first locomotives, the fans, of course, moved slowly and supplied less air to the motors at just the times when the motors needed cooling most. At one point on the line the locomotive has to stop for a turnout on a steep grade. The conclusion drawn from the experience with these locomotives was that a one hour rating will not do. So in the later locomotives, the tractive effort rating was made 16,000 lbs. continuous and 25,000 lbs. one-hour or maximum rating. The one-hour rating will not do for long distance hauling. The steam locomotive develops a certain maximum power and keeps it up indefinitely. The electric locomotive has no maximum except the maximum of the power house. Its tractive effort must be adjusted to the heating of the motors. Therefore for freight service the basis of the system should be continuous tractive effort, with an emergency high rating. The new locomotives on the Spokane & Inland are satisfactory; the old ones are also, but they cannot haul such heavy trains. The speaker was recently asked how soon he believed the steam locomotive would be supplanted by the electric locomotive. He therefore did some figuring. He decided that if all the electric companies in the country began now to build nothing but electric locomotives, letting all their other work go, it would take from 10 to 20 years to replace the number of steam locomotives now in service, taking no account of the additional steam locomotives that would be built in the interim.

William McClellan, Consulting Engineer, said that the electrical engineer has shown that electric locomotives and multiple unit cars can do all the work which steam equipment does. The difficulties which have been already surmounted in the tunnels under the North and East rivers, New York, and in the New York Central and the New Haven installations, are worse than any that will be met in the future. Cost prophecies will be fulfilled. Electrification can provide greater capacity than can changes of location, including deep cuts, etc., on steam railroad mountain divisions. Recent progress in steam locomotive design is due in great measure to the competition of electric equipment. The question as to what system to use, i.e., d.c., a.c., etc., as well as the cost, is the reason why more electrification has not been carried out. The systems are as follows: Third rail, single-phase, three-phase, 1,200-volt d.c. and the gasolene electric car. Anyone of these may be best and everybody is afraid to definitely choose one, as it may later prove to be the wrong one. The electrical engineer is likely to be too technical. He needs the broader view which he gets by working with the steam railroad engineer. When the electrical engineer gets broadened, the necessity of which is becoming more generally recognized, much will be done.

The passenger traffic through the Simplon Tunnel has fluctuated greatly and was largest in August, 1906, the third month of its operation. In that month 42,622 passengers were carried through the tunnel. The number fell to 14,545 in November of that year, and to 10,106 in the following January. The largest number in any month since has been 34,500. The freight traffic has grown rapidly but is still small. The largest in 1906 was 5,658 tons in October. For the first five months of 1907 it was about 44,000, swelled by a blockade of the Mont Ceni route. Since May it has been 5,000 to 6,000 tons per month. The first year the gross earnings were $190,000.

The Guatemala Railroad.

The republic of Guatemala has until lately been as far away commercially from Europe and the eastern United States as the Hawaiian Islands, because access to the city of Guatemala, a beautiful city of 100,000 inhabitants, the capital and the center of almost the entire trade of the country, has been possible only from the



Map Showing Location of Guatemala Railroad.

Pacific side. On that coast Guatemala has no harbors, therefore vessels have to lie in the offing and handle freight and passengers to and from the shore by lighters and small boats. The chief commodity exported, coffee, is as yet mostly produced on the west slope of the Cordilleras between the city of Guatemala and the Pacific ocean. This has hitherto been lightered to vessels, then carried 1,000 miles south along the coast to Panama, there transferred to the Panama Railroad and carried across the Isthmus to Colon, two to four weeks being required for this part of the trip. At Colon a transfer to vessels on the Atlantic side had to be made. In addition to the expense of lighterage and transportation there has

Azacuajulla Viaduct; Guatemala Railroad.

been a heavy loss on coffee carried by this route through exposure to water in the numerous transfers and through bleaching and deterioration resulting from its long carriage in a hot climate. A similar disadvantage has attended all of the other business of Guatemala in and out. The only available routes for passengers between Guatemala City and the eastern United States and Europe have been by the way of San Francisco or Panama, and the time involved between Guatemala City and New York has been three weeks at least and usually more.

This unfavorable situation of Guatemala has always been a heavy handicap on development of its trade. With the purpose of bringing the country within easy reach of the world the government of the republic about 35 years ago took steps toward construction of a railroad from the Atlantic side to the capital, nearly 200 miles, and had succeeded up to 1896 in building 134 miles of line from Puerto Barrios, the principal harbor on the Atlantic coast, toward the city of Guatemala. However, when the difficult mountain section was reached, funds gave out and work was suspended. Several unsuccessful attempts were subsequently made to complete the line. Finally in 1904 a concession was granted to Minor C. Keith, Vice-President of the United Fruit Company, and Sir William C. Van Horne, Chairman of the Board of the Canadian Pacific Railway, both of whom had had much experience in building railroads in the tropics, the former in Costa Rica and the latter in Cuba. They

Rock Cut East of Azacuajulla.

associated with them General Thomas H. Hubbard, President of the Guatemala Central Railroad, the 75-mile road which connects the city of Guatemala with the ports of San Jose and Istapa on the Pacific coast, and immediately set about the work of construction. The Guatemala Railroad was finished on January 10, 1908.

The new work was among the summit peaks of the Cordilleras and was attended with many difficulties, among which were numerous deep ravines which had to be crossed by great bridges, some of which are shown herewith. There are also numerous shorter through truss bridges, and masonry arches have been freely used. At many points protection walls of masonry topped by rubble work are built to protect the road against the mountain streams. All tunnels are lined throughout with masonry. The whole work was made permanent throughout no wood was used except the creosoted cross-ties. While the new work was going on, the old section of the line had to be almost entirely rebuilt to bring it, for economy in working, up to the standard of the new section. The railroad is now in operation and Guatemala is relieved of her handicap.

Freights which before required from two weeks to a month to be handled between Colon and the city of Guatemala may now be handled between that city and Puerto Barrios in one day, and passengers may now reach Guatemala City from New York inside

Las Vacas Viaduct, Near the City of Guatemala.

Callejon Viaduct; Guatemala Railroad.

Trapich Fill; Mountain Section of Guatemala Railroad.

Plantation Track of the United Fruit Company on the Guatemala Railroad.

of a week instead of from three weeks to a month. Moreover, new and fast steamers are being built by the United Fruit Company to shorten the time between Guatemala City and New York via New Orleans to four and a half days.

The opening of this new line will give a great impetus to the development of Guatemala, which already has a population of 1,700,000 and great natural resources in its rich soil, its forests and its mines. It is expected that the entire coffee trade of Guatemala will very soon be turned through Puerto Barrios, and the great bulk of the import and export trade will immediately be handled that way.

An important source of revenue to the railroad will be the carriage of bananas, the plantings of which now being made by the United Fruit Company along the road already require 40 miles of plantation railroad tracks. The banana plantation of the United Fruit Company now extends for 28 miles continuously on both sides of the main line of the road. The extent of this industry is realized by few people in the United States. Some idea of it can be conveyed by the statement that the United Fruit Company employs 125 steamships in this trade. The low lands of Guatemala extending back from the coast on the Atlantic side are perfectly adapted to growing bananas, and Puerto Barrios has the advantage of being a day to a day and a half nearer to New Orleans and the other principal distributing markets than Port Limon in Costa Rica, which has hitherto been the chief source of supply.

A branch line to the frontier of Salvador is projected which would pass through the most important mining district in the country, where gold and silver mining has been carried on for nearly a century, although on a small scale owing to the impossibility of bringing machinery across the mountains.

The successful carrying out of Guatemala's great railroad enterprise has been mainly due to the energy, foresight and courage of President Estrada Cabrera, whose keen interest, liberal support and fair dealing are spoken of by the men who built the road in the warmest terms. They state that from the beginning to the end of their work, peace and quiet have prevailed in Guatemala and that the sensational reports which have from time to time been published in the United States and Europe have been almost wholly without foundation. During this time the troubles between some of the other Central American states have made President Estrada Cabrera's position a most difficult one, but with admirable wisdom and tact he has kept his country clear of all complications.

The Attendance at the Maintenance of Way Convention.

Secretary Fritch, of the American Railway Engineering and Maintenance of Way Association, has prepared an analysis of the attendance of the recent convention, which shows it to have been fully representative of the engineering departments of American railroads. The total number of members who registered during the meeting was 281, an increase over 1907 of 70. This figure is larger than that given in our report of the convention last week due to the fact that a number of new members who were voted in during the convention have properly been included in the total attendance. There were present 51 chief engineers, nine assistant chief engineers, 32 engineers maintenance of way, 11 principal assistant engineers, 19 bridge engineers, 26 division engineers, 25 assistant engineers and 15 signal engineers. Ninety-one railroads with a total of 166,429 miles were represented. The following list gives the complete classification of the members in attendance.

Presidents	3
Assistant to president	1
Vice-presidents	3
General managers	3
Assistant to general manager	1
General superintendents	2
Division superintendents	5
Chief engineers	51
Assistant chief engineers	9
Engineers maintenance of way	32
Principal assistant engineers	11
Bridge engineers	19
Division engineers	26
Engineers bridges and buildings	2
Assistant engineers	25
Inspecting engineers	7
Resident engineers	7
Locating engineers	2
Terminal engineers	4
Inspectors of maintenance	2
Engineers of construction	3
Signal engineers	15
Chemists	4
Chief draftsman	1
District engineers	2
Designing engineer	1
Tunnel engineer	1
Superintendent of track and roadway	2
Supervisor of timber preservation	1
Rail inspector	1
Maintenance of way accountant	1
Railroad architect	1
Editors of railroad journals	2
Professors of universities	8
Master carpenter	1
Civil, consulting and contracting engineers	21
Total	281

Re-Lining Long Curves by Running Trial Curves.

BY R. W. WILLIS,

Engineer Missouri District, C., B. & Q.

The following method of re-lining curves takes the place of running out tangent intersections or meandering the curve. It is to be used on long curves. In most offices there are old notes which give the original degree of curve. For the trial curve, use the curve shown in these old notes, unless the degree of curve is such that it should be spiraled. In such a case, the degree of the trial curve should be increased so that the difference between its external and the external of the curve shown in the original notes will be about one and one-half times the offset which would have to be made from the tangents in putting in a spiral. This ratio depends somewhat on the length of the curve.

Take a point on one of the tangents (on an offset tangent if the curve is to be spiraled) as near the P. C. as possible. The curve is very liable to run off the bank after 500 ft. or more have been run; when this happens, measure the distance from it to the center of the track, divide by the sine of twice the deflection angle and move the P. C. ahead or back accordingly as the curve ran off the inside or outside of the track. The trial curve run from the corrected P. C. will not in most cases be more than 3 ft. from the tangent when it reaches the P. T. At the turning points, which should be made every 500 ft., put a tack in a tie either ahead or back of the turning point so that a line to the tack from the turning point will be parallel to the tangent from which the curve was started. By stretching a string from the turning point to the tack, a new turning point, as explained later, can be located without setting up the instrument.

Near the end of the curve, take a line parallel to the track and passing through the last station on the trial curve; the total deflection angle is equal to half the angle between this parallel line and the tangent to the trial curve, added to or subtracted from the deflection angle for the last station, according to whether the central angle of the curve has been increased or decreased.

It usually takes 10 or 15 minutes to get this total deflection angle. The central angle should check to within a minute of the angle which would be found if tangent intersections were run out. The trial curve can usually be run very quickly; that is, as fast as the men can chain accurately and the transitman make deflections. When the P. T. has been set, measure the distance from it to the center of the existing track, or to the offset tangent if the curve is to be spiraled. Divide this distance by the sine of the central angle. The quotient gives the amount which the P. C., the turning points and the P. T. must be moved to be in their true positions. They are moved on lines parallel to the tangent from which the curve was started, and the movement is ahead or back according as the P. T. of the trial curve fell inside or outside the tangent.

This gives points on a true curve every 500 ft., so that in setting stakes it is not necessary to set a stake more than 250 ft. from the instrument. The tacks must be accurately placed in the stakes. The instrument does not have to be set up oftener than if the curve were run by the usual method. If it be found necessary to change the degree of curve so as to fit the track as close as possible, it can be easily and quickly done by figuring exactly how much the external of the trial curve should be shortened or increased. A point is then set for a fore-sight on the external by measuring from the center point on the trial curve, and from the trial curve it is easy to establish the P. C. and P. T.

On very long curves, any desired point can be fixed by the following method: Multiply the radius of the curve by the versed sine of the angle on the trial curve between the central point of the curve and the point to be established; also multiply the radius by the versed sine of the corresponding angle on the existing curve. Taking the difference between these two products, and allowing for the difference in length of the external of the trial curve and of the desired curve, any point can be established by measurements from the trial curve. If a Searles spiral is used, the trial curve should be started at the end of the spiral next to the curve. The point should be found by taking the offset from the tangent for the end of the spiral so that the point would fall slightly inside the center of the track, depending somewhat on the degree of the curve.

The objections to the usual method of re-lining curves are: the time required, and the fact that while the curve will fit the track at the center point, it may not fit it at any other point, at least not to the best advantage. With a great deal of figuring, quarter points can be established which will make the curve fit the track quite closely, but on long curves, where several courses are necessary, this takes an enormous amount of figuring and multiplies the chances of error. A good curve runner, using the trial curve method described, should establish and stake 3,000 ft. of curve a day. I have established and staked 5,000 ft. of curve in a day and had some little time to spare.

Bolt Locking.

BY W. H. ARKENBURGH.

The specifications for mechanical interlocking at present under consideration by the Railway Signal Association provide as follows:

"91. All facing point switches, derails, movable point frogs, on high-speed routes shall be bolt locked with signals governing such route."

"In all cases where switch and lock movements are used, bolt locks shall also be used."

"92. The switch bar on all bolt locks shall have an independent connection to switch point."

"93. The signal bar on bolt lock shall * * * be a part of the line and not lugged or looped in * * *."

A bolt lock is a device whereby a signal governing a route blocks and is locked by any or all switches in the route, that is, a proper position of the switch is made necessary before the signal can be cleared. Generally only facing point switches and high-speed signals are bolt locked.

The necessity for a bolt lock lies in the supposed unreliability of the facing point lock and the switch and lock movements. The former is usually some form of plunger actuated by a lever distinct from the switch lever, designed to pass through and hold in position a rod attached to the first or bridle rod of switch. It is obvious that should the connection between the plunger and the lever break, after the plunger had been withdrawn, the switch could not be locked. Also, with the present almost universal method of using but one plunger which will pass through either of two holes in the lock rod, according as the switch is normal or reversed, if the switch connections should fail, the plunger would relock the switch in the same position as before it was withdrawn. The switch and lock movement is a device for throwing and locking a switch with one lever and line of pipe. If any part of the connection should break the lever could be moved without any effect on the switch.

To provide safety even should any of the above events take place, bolt locking has been resorted to. In general practice a bolt lock consists of a notched bar extending from the bridle rod of the switch and intersecting at right angles a similar bar inserted as an integral part of the signal connections. The notches are so arranged that only when the signal is properly set can the signal bar pass over the switch bar.

There are many so-called bolt locks in use which consist of nothing more than a facing point plunger and casting, the plunger lugged to the pipe line and passing through an ordinary lock rod connected to the switch when the switch is properly set and the signal cleared. Only one hole is provided so that if the switch is not right the plunger cannot enter and consequently the signal cannot be cleared. This sort of construction is wrong in one very important particular. If any of the pins holding the plunger and its connections should fall out or be removed the apparatus is inoperative. In other words a failure of the apparatus produces a dangerous condition. This is what the specification aims to do away with. If two notched bars are used, and the signal bar is made a part of the line, any failure of this bar or its connections will prevent the signal from being cleared.

It has been customary in many cases where the interlocking station is located between a signal and a switch governed, to extend the signal pipe line both ways from the lead out through a double jaw in order to bolt lock the switch. Theoretically this is wrong, for should any part of the line between the lead out and the switch break down a false signal might be given. A strict interpretation of the specification forbids this being done, but careful consideration should be given to the conditions necessary to allow a false signal to be given. First, the switch connections must fail allowing the switch to be in a position not corresponding to that of the lever, or the facing point lock connections must fail, allowing the switch to stand partially open, provided it is sufficiently out of adjustment, with the facing point lock lever reversed. Second, the bolt lock connections between the leadout and the switch must fail. *Both* the first and second conditions must occur at the *same time*. The probability of this combination of circumstances occurring is extremely remote. Now there is no reason why the pipe line from leadout to bolt lock cannot be made absolutely continuous with tang end riveted and screwed connections throughout. The matter of adjustment can be taken care of by a turn buckle and there is no need to insert a compensator, for the expansion and contraction of 1-in. pipe amounts to only .008 in. per 100 in. per 1 deg. F., and this could be provided for in the length of the notch in the signal bar without danger of clearing the signal to such an extent that it would be accepted by an engineman. The only alternative solution of the problem is to run the signal pipe line first to the farthest switch governed, returning thence by means of cranks through bolt locks to the signal. In other words run the line all around the plant. It is perfectly evident that this method is out of the question owing to cost and general complications in plants of any size. It is possible, however, to meet the situation by electrical means. Before describing such it will be well to consider some weak points of present practice which are negatively allowed by the specifications, but are far more dangerous than some of those it condemns.

First, consider the switch bar of a bolt lock and its connections. Almost universally, this consists of a rod at one end of which is the notched bar and at the other a jaw. This rod is attached to the *lug* on the bridle rod or switch point by a *pin* through the jaw secured by a *cotter key*. Lugs are secured to switch point by bolts and nuts. Very often the notched bar is also secured to the rod by a jaw and pin. Suppose a pin falls out or the bolts break or are removed (both have occurred), of what use is the bolt lock? If the rod is fastened to a lug on the bridle rod, there are four more chances of failure; the switch point lug bolts and the two pins holding the bridle rod to the switch point lugs. Sometimes the bolt lock connection to a switch passes across several tracks, through transverse pipe carriers. The failure of one or more of these carriers might very well allow the rod to buckle and produce a dangerous condition. These transverse pipe carriers are not nearly so substantial as the regular pipe carriers.

The specifications require bolt locks only on high-speed signals. Theoretically and practically one signal is just as important as any other at an interlocking plant, and the failure of one end of a cross-over might very well cause a side or head-on collision, through clearing an unboltlocked dwarf signal.

It is a fact that some roads are experimenting with, and to a certain extent, have even adopted rigid switch and lock rod fittings. That is to say bridle and lock rod together with the switch point lug are made all in one piece, except that sometimes a turnbuckle is introduced for adjusting. The same is done with a throw or second rod. Here, of course, the cage must be retained. With this arrangement pins and cotters are done away with in one of the places where they are most dangerous. If this form of construction were carried one step further so as to include the switch connection to the bolt lock, making it a part of the bridle rod, most of the weak points of present bolt locking practice would be eliminated. It seems pertinent to remark in this connection that if the plunger of the facing point lock were attached to the line by means of a riveted tang end joint instead of by a jaw and pin, another source of danger would be removed.

Electrical bolt locking can be accomplished in a number of ways. Where power operated or semi-automatic signals are used, the control circuits for these can be broken through controllers on the various switches. A strict interpretation of the specifications would require a mechanical bolt lock even where a power operated signal is used. This would seem absurd on account of the expense of the pipe line and connections, especially if it would be necessary to run all around the plant. Moreover, any failure of the mechanical bolt lock would not prevent the signal from being cleared. It is really unnecessary, as breaking the control circuit is just as efficient a method. In any electrical scheme, however, the tendency is to locate the battery for all apparatus in the tower and to run, if conditions seem to require it, to one end of the plant and back again through the various instruments past the tower to the apparatus controlled. This is even worse than running both ways from the leadout to reach a bolt lock, unless the wire between the battery and the first instrument is kept absolutely insulated from the rest of the circuits. This is because a loop is established and any break-down of the insulation between the battery feed and another part of the same or another circuit will cut out all intermediate instruments. Every signalman has had experience with nails through trunking, dry and wet rot on the insulation, cracks in the insulation and numerous other phenomena of a similar nature. It is hardly possible that anyone will claim that as much dependence can be placed on the insulation of a wire as on a pipe line for the operation of signaling apparatus. Short circuits to the common return frequently lead to similar results. The safe method is to insulate the main positive and negative feeds from all other circuits either in separate trunking or on a pole line, or put a battery at each end of the plant.

A safer method of electrical control of power operated or semi-automatic signals is to make both the plunger of the facing point lock and the switch itself control the circuits. When this is done assurance is given not only that the switch is properly set but also that it is locked, before a signal can be cleared. This method can be applied also to electric selection of signals by the switch.

Electric locks, controlled by either method described, can be attached to the signal lever latch to lock it normal, unless the route is properly set. This is an efficient method, but is more expensive than breaking the control circuits. It is really the only electric bolt locking feature that can be applied to a purely mechanical plant. If route levers are used, as they sometimes are, especially where extensive approach and detector locking devices are employed, the lock can be applied to the route lever to lock its tappet reversed. Such a scheme would be far more liable to tie up a plant than the former, in case of failure, for the route would be locked as set up. It is, however, always possible to provide a release. The term tappet as here used is meant to include any device actuated by the movement of the lever latch.

Electric locks, however controlled, when used for bolt locking, should not be attached to a facing point lock lever only. For, should the connections between the lever and the lock break down no protection could be secured. As an additional safeguard, to lock the switch with the signal clear, locks on the tappet of the facing point lock lever, as above, might prove very efficient, but would seem unnecessary, especially where approach or route locking is employed. When so applied the circuit would be controlled through a normally closed circuit breaker on the home signal arm.

It would seem that in the present state of the art of signaling the whole subject of bolt locking has an exaggerated importance. There is certainly more room for improvement in facing point lock construction and switch fitting; and this might, in the end, render bolt locks unnecessary. The bolt lock is at best a cumbersome and expensive device. The only excuse for its existence is an attempt to overcome defects in other apparatus which might better be improved.

Locomotive After Derailment.

Hauling a Locomotive Up a Mountain Side.

On February 3, 1908, passenger train No. 604 on the Erie division of the Pennsylvania Railroad, hauled by engine 555, was derailed at the top of the mountain just before entering the village of Frackville. The train was running at 30 miles an hour when the engine suddenly left the track and plunged down the mountain side to a wagon road about 200 ft. below. The engineer was instantly killed; the fireman escaped without injury.

When the engine left the track, the coupling between the tender and the first car broke and the passenger coaches passed safely along the track and stopped a few hundred feet beyond the point of derailment. The tender turned a somersault over the engine and landed beyond it in the wagon road, completely blocking it. The engine stood on its wheels at an angle of 45 degrees with the horizontal, with the pilot buried in the ground.

Track (Upper Right Hand Corner), Engine at Foot of Slope, and Highway.

The mountain side was so steep and the engine so far away from the track that it was very difficult to get it back again. Several attempts to pull it directly back up the slope with two 50-ton steam derricks failed. It was finally decided to lay a track from the wrecked engine about 200 ft. along the public road to an old inclined plane which ran to the top of the slope.

About 80 years ago Stephen Girard built the Danville & Pottsville Railroad, which consisted of stretches of comparatively level track connected by inclined planes up which the cars were hauled by cables. The road was projected from Danville, on the northern branch of the Susquehanna river, to Pottsville, but was built only from Girardville to Pottsville, being used to develop the resources of the Girard estate. No. 5 of these planes is near the point of the Frackville derailment.

After the prostrate locomotive had been turned around by hydraulic jacks, so that it was parallel with the road, it was possible by using long cables attached to the derrick at the head of the plane, to pull it about 200 ft. along the wagon road on the temporary track to the foot of the plane. From this point the difficult and dangerous task of retracking the engine began. The plane was on an angle of about 45 degrees from the horizontal and about 350 ft long. The two steam wrecking derricks, of 50 tons capacity each, were placed at the head of the plane on the main track, each derrick having a line of steel cables strung from it to the locomotive so that each derrick worked independently of the other. This was done so that one derrick could hold the engine in case of accident to the other. On account of the long distance the engine had to be pulled up the plane, five cables, each 50 ft. long, joined together, were used on each derrick.

When everything was ready, the signal was given to each der-

Locomotive at Foot of Plane after Having Been Pulled Along Highway. Telegraph Pole Marked "X" Shows Where Derailment Occurred.

rick to pull and the heavy engine started to move slowly up the plane. After it had been pulled 50 ft. a stop had to be made. While one derrick held the engine, the other took out a section of its cable. The start up the plane was made at 10 a. m., Sunday, February 15, 1908, and at 12:45 p. m. the locomotive was safely alongside of the

Locomotive Being Pulled Up Inclined Plane.

main track at the top of the hill. The accompanying photographs show the locomotive at various stages of this work.

Notwithstanding its long fall the engine was not greatly damaged. The cab and small parts had been stripped from it, but the frame, boiler and wheels were intact, so that after it was retracked it was hauled to the shops on its own wheels, and was soon ready for service again.

The Ocean Carrier.

BY J. RUSSELL SMITH, PH.D.

XIII.

Charter Freight Rates and Attempts at Their Control.

The sea is free, and in a consideration of the principles controlling its freight rates the cast-off theories of land transportation are found to apply to its principal lines of trade. The most pronounced change in the theory of land transportation is the growing recognition of the fact that competition is not the controlling force that it was once supposed to be. Upon the ocean, on the other hand, the theory of free competition still finds application.

The reason for this difference between land and sea transportation will be most easily seen if one considers for a moment what constitutes the unit of transportation by land and by sea. Upon the ocean it is a single ship. Ports are open to all; the ocean is a free and toll-less highway upon which the ships of all nations may and do come and go at will. Upon land the railroad train renders the similar carrying service, but the carrying unit is the railroad itself complete from end to end. The equipment for carrying a ship's cargo 3,000 miles is not 10 per cent. more costly than that of carrying it across a narrow channel. The cost of equipment necessary for supporting a train may be roughly put at 50 to 100 per cent. of the value of the train for every mile it goes. Before a train can be run 3,000 miles there must have been years of labor for the building of 3,000 miles of railroad, requiring the investment of one to two hundred millions of dollars in roadway, terminals, branches, feeders, repair shops, etc. A new competitor for this same 3,000-mile service must expend another hundred or more millions prior to running the first train and, as population increases, the cost of railroad building increases because of higher land values. Equipment for sea carriage, on the contrary, becomes cheaper year by year through the process of invention. Ocean transportation investment requires the ownership of vehicles only—movable capital. Railroad transportation investment is chiefly in the form of fixed capital—roadway, structures and terminals. This heavy investment of fixed capital must earn dividends where it is placed or be an almost total loss. In contrast to this the steamship or sailing vessel capital is the most mobile in the world. The world ocean is open to it, and it can speed away to the shore of any and every maritime country upon the surface of this terrestrial globe.

A discussion of ocean freight rates must be introduced by a brief reference to the two distinct methods of operating ships and carrying on the transportation business: (1) Charter traffic, in which the unit of operation is a single vessel working independently; and (2) line traffic, in which many ships combine to render one service.

1. *Charter Traffic.*—The fact that the sea is an open highway enables any navigator to go where he will and engage singly in the carrying trade, if he wishes to do so. This absolute independence of the single ship has its economic advantages. No costs need be incurred except those necessary for the particular traffic in hand. If the shipper can deal in ship-load lots, he has no need of a liner. He hires a vessel of his own.

The primary object of tramp or charter traffic is cheapness with efficiency. The primary qualifications of line traffic are regularity and speed. These entail costs, and there must be higher freight rates to make line traffic profitable. There is room for both services. The exacting traffic in manufactures and passengers is increasing, and with it the demand for line traffic and corporate organization. Along with this is the growing traffic in cheap and bulky goods requiring the service of unorganized cheapness. The trade of the present comprises many million tons of cheap and bulky raw materials which must be transported in great quantities and at the lowest possible cost. These usually go in ship-load lots as charter traffic.

If steel rails, iron, locomotives or other heavy manufactures are moved in sufficient quantities, as is occasionally the case, they may become charter traffic, but the staple articles for this type of ocean work are grain, lumber, coal, ores, sugar, cotton, petroleum, nitrate of soda, jute, etc. This is absolutely a world trade. The chief market for wheat is Great Britain and the nearby parts of the continent, but this one commodity is shipped from the Atlantic ports of America from Galveston to Montreal, from San Francisco, Columbia river and Puget sound on the Pacific, from the Argentine Republic and India, from Russian ports on the Baltic and Black seas, from the Danube river and sometimes from Chile and Australia. Cryolite comes from Greenland; nitrate of soda from Chile; nickel ore from New Caledonia; iron ore from Arctic Norway, Sweden and tropic Cuba; jute from Calcutta; wool from New Zealand; sugar from Germany, Cuba, Java, Brazil and Peru. There is no ocean, no zone, no continent, no great island that does not contribute its threads to this world mesh of routes including hundreds of ports to and from which sail thousands of ships, each ship operated independently and usually as the result of a particular bargain between the shipper and the carrier. Here competition reigns.

A cargo is in the warehouse and a ship at the anchorage. what shall be the rate if the ship takes the cargo? Both parties are after profits. If there is a cheaper ship in sight, the shipper takes it. If there is a better cargo in sight, the ship takes it. If cargoes are plenty and ships are scarce, the rates will rise to the point where it is cheaper to let the goods lie rather than move them at the increased rate. A 300 per cent. rise in rates has occurred within a fortnight, although plenty of ships were lying idle in the next ocean; but they happened to be 50 days away and the goods had to go within a month. In this case, for that particular traffic the idle ships did not exist, although the next month they were on the spot and rates came down again to their former level. If ships are plentiful and cargo scarce, the ships bid for the cargo and rates go down and down. If profits cannot be made, the manager aims to cover expenses; if not whole expenses, then enough of the expenses to make a small loss rather than a great loss, and he ties his ship up only when his operating losses exceed the loss resulting from absolute idleness with its rapid depreciation and interest and other costs.

The charter rate is a marginal rate. If there are 10 ships and five cargoes, the cheapest ships get the cargo. If there are 10 cargoes and five ships, only the highest paying cargoes can be moved. Fluctuations are, therefore, sharp and there seems to be a present tendency for rate depressions to be prolonged. There are several reasons for this prolongation. One is the appeal that the shipping business makes to the gambling instinct. There are seasons of great profit; ships at times pay for themselves in a year. There are also years when there is only loss, because the great prizes have served as a magnet to draw too many people into the shipping business. Again, it requires no special knowledge. A person needs only some capital and the acquaintance of brokers who will buy him a ship and other brokers who will secure her cargo on commission. A novice with money could begin in an hour after he reached a long distance telephone anywhere in the United States or England.

It is customary in the business, especially in Great Britain, for an enterprising manager to form a stock company and build a few ships which the promoter manages on a salary or commission. The ship builder or the public will often loan money on these ships so that the company has a divided responsibility in stock and bonds much like an American railroad. The greater number of charter boats are apparently owned outright, but when depression strikes the business and there is any tendency toward maintenance of rates the manager of a mortgaged fleet is goaded to desperation by the knowledge that the holders of the bonds and probably of the stock also must have some satisfaction or his ships will be foreclosed and his company and his business wiped out. Thus the mortgaged ship is a rate depresser.

Another factor tending to prolong depression is the cheapness of new ship. When the demand for new ships falls off, the ship builders face the necessity of turning off their men. To prevent this they will build ships at a very low figure and keep their force together for better times. These changes in the price of ships and in the prosperity of the shipping business quickly respond to the state of the carrying trade. In the prosperous year, 1900, the chairman of a British shipbuilding company in addressing his stockholders said, "A ship which four years ago could be built for £70,000 to-day would cost £100,000." In August, 1900, a freight steamer 11 years old brought at auction £30,000. In November, 1901, after a break in rates, the same steamer sold for less than £18,000.*

During periods of cheap ship building the manager of chartered vessels sees a good opportunity to provide himself with some thoroughly modern ships at a low figure and be ready for the hoped-for advance when it comes. If it does not come immediately, his new vessels, possessing all the latest economies and low capital cost, can be operated more favorably than older, less efficient and more costly vessels. The result of this reasoning and of the action which grows out of it is that the amount of building does not readily respond to depressions in rates, and these depressions drag on to great length because ship building continues in spite of them. The low rates which resulted from a number of causes in the spring of 1901 can scarcely be said to have had any relief till the autumn of 1905. Any signs of higher rates brought out idle ships from their moorings, and these ships promptly put the rates down to the dead level.

Why do not the owners of vessels for hire agree upon rates and maintain them? This problem is akin to that of universal peace among nations and really does involve the harmony of many nationalities. Will the Greek, the Turk, the Chinaman and the Hindoo agree with the men of Liverpool and London, New York, Hamburg, Marseilles, Genoa and Christiania, and will they all adhere to the agreement if they make it? What if the agreement leaves a man's ship idle while the other 98 per cent. of the tonnage is busy with profitable voyages at the agreed rate? By the slightest shade of undercutting he can be deluged with cargoes. Will he abide by loss that others may profit? Even if the ship owners of the world should agree, and keep their agreement, there are a thousand other men now in their employ who know the business. Capital awaits investment. Ship builders will build ships for any responsible party in a few months. Ships are always being sold so that you and I may buy some to-day, place them in the hands of a broker or agent whose business it is to find cargoes and manage ships, and behold, there is competition again upon the sea. The biting and absolutely controlling force of this competition lies in this: If 98 per cent. of the shipping should be operated under a maintained rate agreement that gave good profits and there arose any dearth of cargo, the 2 per cent. of independent ships with a rate a shade below the agreement rate would be desperately busy and profitably employed. All the idleness would be with the agreeing ships, the new building would be with the outsiders, the increase of idleness would be with the agreeing ships until their union perforce broke down because of the large number of idle ships in the union and the prosperity outside of it.

The line separating profit and loss seems to set the limit to which charter rates can possibly be raised by agreements among carriers. Above that point there is no need of agreements, since, if cargo is more abundant than ships, rates are high from natural causes and, if there is an excess of tonnage, the rate cannot be upheld for the reasons previously stated. This statement is borne out by the history of attempts at rate control and by the united opinion of ship owners themselves.

The lack of successful rate control by the owners of charter vessels cannot be charged to lack of experience in co-operation. There is a large number of shipowners' associations in all large shipowning countries, and especially in England, where the bulk of this class of shipping is owned. In London alone there at least nine such organizations. These associations exist for nearly all the purposes that can be attained by co-operative action. The annual report of one of the Liverpool associations for 1905, for example, describes efforts to effect favorable legislation in London; to change local harbor regulations; to persuade the government to take action on the policy of various foreign governments toward British shipping; to change charter party forms (form of chartering agreement); to change coal trimming charges at Cardiff; to reduce Suez Canal tolls, etc. One strong and growing association exists only to fight organized labor, and many associations are concerned chiefly with the ever present insurance question. They are often perfectly willing to spend £5,000 sterling in combating a case involving £100 and a precedent. One of these bodies—the North of England Protecting and Indemnity Association—reported that on December 31, 1905, there were enrolled in the association 2,470 steamers with a tonnage equal to about half of the total under the British flag. For some purposes at least the ship owners know how to co-operate.

The recent prolonged depression in freight rates which began in the spring of 1901 produced two serious attempts at charter rate control of an international character, and their results help to show the limitations upon such efforts and their essential futility as producers of profitable rates. The condition of the shipping business in this period was such as to drive men into agreements, if any economic force could produce that result. The shipping journals were full of letters, articles and editorials proclaiming the unprofitable conditions of the trade. The president of the Clyde Steamship Owners' Association declared in his annual address, January 20, 1903, that it was hardly possible to sketch out a round voyage on which a freighter could pay expenses. A British shipowner of much experience stated in March, 1905, that "on the average, British sailing ships of over 3,000 tons (dead weight) have lost about £1,000 each per annum during the last three years and that smaller vessels have fared almost as badly." On December 29, 1904, *Fairplay* summarized the report of 49 tramp vessel owning companies for the year then ending. They had 393 vessels of 1,184,358 gross tons, capital £10,253,752, and debt £3,157,128. Assuming 5 per cent. interest on the indebtedness and the customary 5 per cent. for depreciation, they would have required £140,040 more than their total earnings to avoid a loss even if no allowance be made for income tax and management expenses. A month previous to the publication of the digest of these reports, the same journal had declared editorially that, "taken upon the whole, tramp tonnage is being run at a disastrous loss." At the end of 1903 a similar analysis of 36 companies showed results like those cited above, and six of the 36 had actual cash loss for the year on operating expenses, to say nothing of expenses of management, interest on bonds, depreciation or dividends.

In such times as these anything tending to improve the condition of rates was eagerly snapped at. The French bounty-fed sailing ships, receiving a government bounty that paid almost enough to run them, were in a position to make competition exceptionally ruinous for British and German ships of the same class. There was an international conference of these sailing vessel owners in Paris in December, 1903. It drew up a constitution for the "Sailing-ship Owners' International Union," which was to become operative when subscribed to by the owners of 75 per cent. of the shipping involved. The organization, with headquarters in London, was formally launched in June, 1904, when the first rate committee announced the schedule of minimum rates for the guidance of its membership. The circular sent to the members in June, 1905, states that

> The Sailing-ship Owners' International Union . . . has only to do with vessels of 1,000 tons net register and upwards, and the control of the union is in the hands of an international committee, the members of which are appointed annually by the various nationalities in agreed-on proportions.
>
> Although it is obvious that much good work might be done in many directions by such an international association, the only object of the union for the present is the binding together of sailing-ship owners not to accept less than certain agreed-on rates for freight for the principal homeward voyages in which sailing-ships engage, and members of the union are bound under a penalty not to charter their vessels at a lower rate than the minimum prescribed by the committee of the union for any particular voyage.
>
> The intention of the union is not to push up freights to such an extent as to oppress shippers or check business, but to prevent the ruinous competition which has come into the business and reduced freights to such a point that they could not possibly pay expenses, and in many cases were leaving heavy losses to owners.
>
> The union was originally started on the basis of not less than 75 per cent. of the British, French and German tonnage interest being included, but for 1905 the percentage has arisen to 87 per cent.

By November, 1905, the seventh freight circular had been issued, but most of the rates had remained unchanged, except to permit a small reduction to cargoes of over 2,500 tons. In 1906 the organization was still in healthy existence. Its limitations become apparent when it is noted that it applies only to the longest voyages, namely, the Pacific coast of North and South America, Australia and New Caledonia to Europe, and that it covers only the return voyage, leaving absolute freedom for the outgoing voyage and for all other trades.

A shipowner who had been influential in promoting the union said of it in a letter in December, 1905:

> This Sailing-ship Union would never have come into existence if it had not been for the French sailing-ship bounties and the absurd manner in which these bounties are paid. If the French ships had been competing on level terms, there would have been no need of any union. So far as I know there has been no attempt on similar lines to control sailing vessel rates in the past, and I know of no combination among shipowners which has held together as this one has done. The minimum rates adopted are intended to prevent loss rather than make gain. In most cases they are lower than cost, taking into account the outward rates that have been ruling, and which, of course, come into the calculation for the round voyage. The idea of the union, however, has been, if possible, to steady the freights, interfering as little as possible with the ordinary course of business and the natural fluctuations of the market. At the present time, unfortunately, the only place from

*See *Lloyd's Weekly Gazette*, Oct. 5, 1905, p. 638, and *Fairplay*, Nov. 21, 1901.

which anything in excess of the minimum rate is obtainable is from Australia, the conditions of the markets on the Pacific coast both of North and South America being such that the minimum rate is barely obtainable. The minimum rate applies to vessels of 2,500 tons, and for every increase on this size a slight reduction is allowable, as it was found that the larger ships could not get employment as long as the smaller vessels were available on exactly the same terms.

As far as the members of the union are concerned, the minimum rates have been maintained wherever they have been fixed, say west coast North and South America and Australia. Unfortunately, owing to the want of cargo on the west coast of North America, and the accumulation of tonnage in South America, various union ships have been unable to get the minimum rate and have required to move in ballast to some other part of the world where prospects were better. The small percentage of ships still outside the union, moreover, has at various times caused trouble by cutting in just under the union rate. The prospects are, however, that for next year fewer ships will be outside the union.

An owner with a fleet of vessels in the union, states its advantages thus: "I think you might put it that they provide for a small loss rather than a great loss. This has undoubtedly been for the advantage of sailing-ship owners." The advantages of being among the few outside the union were shown by freight quotations at this time. The San Francisco *Chronicle*, January 28, 1906, stated that "apparently anything willing to take less than combination rates is promptly picked up." On February 18, the same journal stated: "Freight rates continue lifeless to the United Kingdom as well as from the north as from here. Charterers are not willing to pay combination rates, and it makes a deadlock for the present." That deadlock means ships lying idle in the harbor, eating up the owners' bank account. If that were being tried when a 2 per cent. cut on a *profitable* rate would give employment, it is not likely that the union would long survive.

The small scope and importance of this union as a force in the control of world rates appears from considering that it is limited (1) to minimum rates which are on a basis that affords no profit (e.g., wheat 22s. 6d. from San Francisco to Liverpool); (2) to certain long voyages; (3) to returning voyage only; (4) to vessels of certain size only; (5) to sailing vessels only, when sailing vessels all told are not now doing over 6 or 7 per cent. of the work of ocean transportation.

In January, 1907, this organization seemed to be on the verge of final dissolution. Strange to say, or rather, quite naturally, its embarrassment seems to have resulted from a burst of prosperity attendant upon the rebuilding of San Francisco after its destruction in April, 1906. There was a great demand for coal, cement and steel which doubled the out rate from Europe from 15 to 30 shillings per ton. Under the normal conditions of trade, the rate outward from Europe is a by-product rate, a ballast rate. The larger movement of freight is from the Pacific to the Atlantic, and the ships take back anything they can get at any rate they can get, or as alternatives take ballast. That is why sailing vessel-owners made no attempt to control the out rate.

The San Francisco disaster suddenly reversed things. So many ships went out with building material that there was a plethora of shipping seeking return cargo, and having had the unusual experience of making profit on the out freight, they were willing to take a by-product rate home again. This the Minimum Agreement prohibited. "This standard has been circumvented by vessels being fixed on a round freight from United Kingdom or continent or from New South Wales to west coast and home to United Kingdom or continent.*

One week after the above sentence was published in London, the Shipowners' Union sent out on January 11th a new rate circular to members saying that there would be no change in the minimums last announced except that the nitrate rate to the United Kingdom and continent would be suspended from January 14th. This was a very extensive exception, being quite half of all that the union stood for. Lloyd's Liverpool correspondent spoke of friction in the association, of its frequent meetings, of rumors of German withdrawal. "Indeed it is felt," he continues, "in some quarters that its breaking up is only a matter of a very short time. The abandonment of the nitrate rates was apparently the beginning of the end. This, however, proved to be a continuance of life rather than the death rattle, for the organization was still in a normal condition (minus nitrate rate) in February of 1908.

The same conditions of depression that drove the sailing vessel owners of Paris brought about a somewhat similar conference of steamship owners in Copenhagen in February, 1905. The success of the sailing vessel owners was one of the reasons that led to the assembling of those interested in the commerce of the Baltic and White seas. This narrow geographic unit has corresponding to it what might also be called a commodity unity also. The trade is predominantly in wood and lumber, with coal as return freight. The great world markets for oversea lumber are the United Kingdom, Germany, Holland, Belgium and France. This import trade amounts to more than 15,000,000 tons, and less than a fifth of it comes from across the Atlantic. The remainder, or more than 12,000,000 tons, is shipped from Norway, Sweden and Russia. This is one of the greatest items in the world's trade.*

This traffic, while international, is little greater in geographic extent than is the traffic of the American Great Lakes. Some of the leading shipowners, dissatisfied with unprofitable timber carrying, conferred for three days at Copenhagen in February, 1905, and fixed a minimum scale of rates for the various ports, and then went back to their various countries to work up support for the scheme so that it might be put in force at another conference in June. In this they were successful, but only as regards the outgoing rate on lumber. The total vessel tonnage affected by this agreement is only about 1,612,000 divided among 1,048 steamships. Although this Baltic and White Sea agreement is purely local in character it is the most comprehensive among charter steamship owners that has as yet been seriously considered. This organization has had no revolutionary earthquakes to upset its plans and is now entering upon its third year in better shape than the Sailing-vessel Owners' Union, which was its prototype. The Scandinavian winter makes the Baltic trade quite largely a summer season trade. In the season of 1906 the agreed-upon rates were maintained, and on April 12, 1907, there was another meeting at Copenhagen to arrange for the ensuing summer. Much exhortation was given the members to insure their doing nothing that would increase the difficulty of maintaining the rates.

This organization has busied itself much with work of the kind usually taken up by the various shipowners' associations of Great Britain, namely, the establishment of favorable and uniform charter parties. These blank forms or contracts are exceedingly important in such an organization, for by them it would be easy to name a uniform cash consideration and bring about practical discrimination by varying the clauses about measurement, loading, discharge, or insurance of cargo, etc.

These two rate agreements, the small and weakly newborn offsprings of the most profound shipping depression of modern times, seem but to emphasize the controlling force of free competition in deciding the charter rate, which is a world rate. If the agreeing Baltic carriers should push their rate much above the general level, they would probably be greatly embarrassed, and the timber shippers greatly pleased, by the appearance of ships sent in by the hungry and enterprising Greeks, Hindoos and other shipowners from the remotest ends of the earth.

(*To be continued*).

Lloyd's Gazette Weekly, 1907, p. 10 and p. 41.

*American wheat exports amount to from four to seven million tons per year, and sugar (about 2,000,000 tons) is our heaviest import.

Foreign Railroad Notes.

The French in their several colonies in West Africa in the five years since 1902 have built 554 miles of railroad, in addition to the 370 miles then open. Capital has been provided for building 466 miles more. The longest of these roads extends from the River Senegal at Kayes, the head of navigation, which is 320 miles from the mouth, southeastward 345 miles to a navigable part of the Niger at Koulikoro, 420 miles up stream from Timbuctoo, of which the poet says:

If I were a cassowary,
On the plains of Tim-buc-too
I would eat a missionary,
Skin and bones and hymn-book too.

The course of the Niger from Koulikoro to Timbuctoo is northeastward, thence southeast and south more than a thousand miles to the Gulf of Guinea.

The gentlemen who drive their cattle on the tracks in front of trains to recover damages must hide their diminished heads before a Belgian peasant. He had been slightly hurt by a railroad accident and had been paid $75 therefor. Delighted to find that his skin might be a source of income, he loosened a rail on the track about a quarter of a mile from a station, took the first train from that station, and succeeded in being hurt when the train ran off and killed the engineman, wounding five men seriously and others slightly. He insisted on going home, and for some reason was suspected. When a policeman came to search his house he took a gun, ran into the field and shot himself.

The Central Northern Railroad of Argentina was opened on the last day of 1907 from Jujuy northward 176 miles to the southern border of Bolivia at La Quiaca. The new road was built by L. Stremitz & Co. for $6,894,659 gold. Jujuy is 2,133 ft. above the sea; La Quiaca, 11,293 ft. The highest point on the line, however, is 62 miles further south at Tres Cruces, 12,100 ft. above the sea. On the southern 21 miles there are 125 bridges from 7 to 690 ft. long. For six miles Abt cog-wheel engines are used. A section of the line is liable to be covered by mud and rocks brought down by torrents from the mountains. La Quiaca is about 150 miles south of Potosi.

The Metal Tie.*

BY DR. ING. A. HAARMANN,
Geheimer Kommerzienrath

III.

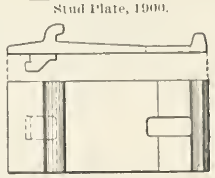
An efficient means of attaching the rail to the tie has always been of material importance in extending the use of metal superstructure. The main considerations in this connection are: Avoiding the bending of ties to secure inclination of rail; efficiently protecting the tie against wear, reducing the number of pieces needed for attaching the rail, increasing the ease of track-supervision, and providing for easy gage adjustments on curves. These considerations led to the introduction of my hook plate fastening on the Prussian State Railroads as early as 1882. The hook plate gives the rail its inclination and distributes the pressure on the tie. By entering into the tie, and by grasping the flange on the outside, it renders additional fastenings at this point unnecessary, and as a result of the uniform spacing of the holes in the ties it makes adjustment of the gage on curves a simple matter.

To be sure, the first hook plate was not perfect, especially was it too small (Fig. 34). But the tie of that date had defects also, prominent among which was too narrow an upper surface. Too much account was made of actual requirements, and too little of the much greater demands of the future that were but dimly appreciated. For the somewhat wider ties of sections 51 and 52 (Fig. 33, *Railroad Gazette*, March 27), the plates could be made longer, but even this size was not sufficient, as was evidenced by the wear of the ties and of the plates. By increasing the width of the plate, and in addition transferring the seat for the clip to the hook plate itself, the hook plate fastening was materially improved. The movements of the rail were, however, still communicated to the hook plate, so that the surface wear of the ties and fractures at the corners still continued. To remedy this, an inside stud was added, and this so-called "stud plate" was in addition provided with a rib having an inclined face for the clip to brace against, thus getting a firmer grasp on the rail. While this arrangement permitted the adjustment of the gage by the use of a single size of clip instead of the four sizes heretofore required, the added stud required that holes be made in the tie differently from the standard. Another arrangement, not open to this objection, was that in which there was only one stud, this being on the outer side of the stud plate, the stud filling the hole but not being provided with a hook. These stud plates represent the transition from the older hook plate to the newer hook stud plate, which, combining the advantages of both, neither requires a perforation of the tie different from the standard, nor lacks the increased safety furnished by the hook. It excels both in the increased surface of contact and in that it provides a cover for the hole receiving the stud, thereby insuring longer life to the tie.

Hook Plate, 1881.

Hook Plate, 1882.

Stud Plate, 1900.



Hook Stud Plate, 1906

Fig. 34—Development of the Hook Plate.

Fig. 35 represents graphically the yearly increase in the number of hook plates. The lower line gives the quantities furnished yearly, the upper line the total number that have gone into service, amounting to 57,000,000, or enough to equip 12,400 miles of track. As regards the hook stud plates, after a preliminary trial in the spring of 1906 on the Württemberg State Railroad (Fig. 36), 25 miles of track have been equipped with them by the Oldenburg State Railroad (Fig. 37). In Württemberg and in Oldenburg the rib ties proposed by me have been adopted. They were first laid on the road between Georgsmarienhütte and Hasbergen; then, since 1900, on a section between Cologne and Hamburg, and, since 1904, on several sections of the Breslau and of the Elberfeld divisions of the Prussian State Railroads. The chief feature of the rib tie consists in two ribs along the upper edge that secure the bearing plates in their position. They have curved sides, a broad base and are easily tamped. The Württemberg specifications require a spacing of 28 in.; the Oldenburg, 28$\frac{1}{3}$ in. The bearing surface of the track is about the same in both cases and exceeds that of the American roads with their well-known close spacing of wooden ties. The Prussian State Railroads have decided to adopt the rib tie with hook plate fastening as a standard. The tie will be the same as before, with the addition of the ribs; the width is 9$\frac{1}{8}$ in., bearing surface 971 sq. in. and weight 137 lbs. (Fig. 38). At the joints the so-called broad-tie, form 66, is to be used. This tie, with two pairs of ribs, has a bearing surface of 2,016 sq. in., and weighs 282 lbs. The hook stud plates are adapted to a 3$\frac{3}{4}$ in. flange (Fig. 39). The illustration (Fig. 40) shows the track of the Georgsmarienhutte Railroad; 300 miles of road will be thus equipped by the State Railroad management. It is perhaps worthy of notice that malicious tampering with this style of track is much more difficult than is the case with one using wooden ties and spikes or chairs and wedges. Whoever has seen a rib tie crack in operation will never be satisfied with one with wooden cross ties.

*Address delivered at the meeting of the "Verein der deutschen Eisenhüttenleute," Dec. 8, 1907, at Düsseldorf. Reprinted from *Stahl und Eisen*, by permission.

In 1880 the late Privy Councillor Grüttefien read a paper at

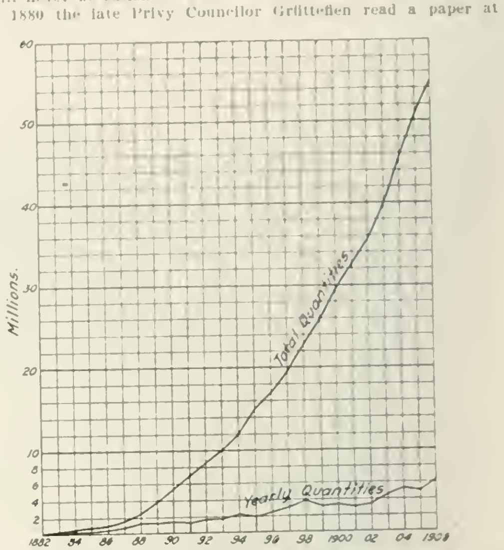


Fig. 35—Total and Yearly Quantities of Hook Plates Used for Permanent Way with Metal Ties.

the meeting of the Iron and Steel Institute at Düsseldorf "On the Results Obtained with Various Systems of Permanent Way in Prussia." At that time it was impossible to foretell that the metal cross tie would be the victor in the contest with the longitudinal tie. It therefore seems irrational to cite against the metal tie, as does the society for furthering the use of wooden ties, the deductions made by Grüttefien 27 years ago, when the development of the metal tie was only beginning. This authority pointed out that the Vautherin tie and the Hilf tie were too weak, too short and too light. But he also said, and this was based on the experience of the Prussian State Railroads with metal ties for only five years, that the eventual success was not doubtful. This opinion he based on the better lasting qualities of the metal ties, the more reliable methods of attaching the rails, the greater uniformity in spacing, the diminished tendency to creep and the quiet and elastic movement of the rolling stock. Citing England and the United States is not to the point, if for no other reason than because the conditions obtaining in those countries are quite different from ours. In England unusually large masses of metal mounted on broad wooden ties are used, and in the United States they are not

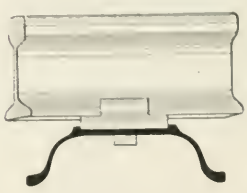

Fig. 36—Rib Tie, Form II; Württemberg State Railroads.

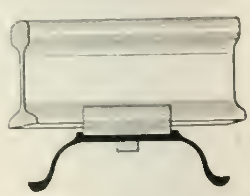

Fig. 37—Rib Tie, Form III; Oldenburg State Railroads.

niggardly in the matter of wooden supports. But that thereby the riding on English or American tracks is more satisfactory than on our own, I deny from personal experience. Even on the well cared for Midland Railway almost every joint is felt, and the jars and oscillations on the line from London to Liverpool, and on that from Liverpool to Manchester, in spite of the careful maintenance of track and the inspection of wedges morning and night, leave nothing to be desired on the score of distinctness. Rather might the riding over some of the American roads be considered superior.

But that is not entirely the result of the close spacing and of the heavier rails, for a material part is due to the many wheeled American trucks, which are excellently equipped with springs and which in combination with the long cars adapt themselves to the track with the utmost ease. On a previous occasion I have called attention to the importance of the truck and I can now only confirm the statement that in regard to it the American roads have the lead. This statement is not incompatible with a weakening of my former enthusiasm for the Pullman cars, that vary considerably in the quality of their accommodation. As to the tracks themselves? There are some main routes, for instance those of the Pennsylvania Railroad, that are treated like parade horses and are cared for and caparisoned accordingly. But there are also other less favored lines owned by the same company, e.g., Buffalo to Harrisburg, that are treated more like cart horses. Opinions concerning English and American railroads must be accepted with some caution. The layman is apt to mix cause and effect. In the United States the opinion is more exalted as having to do with a "great country." One of its railroad magnates, Mr. Gould, a few weeks ago expressed him-

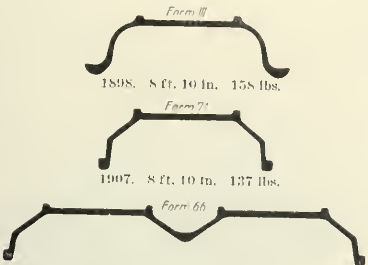

Fig. 38—Rib Tie Sections.

self to the effect that, "Between our railroads and those of Europe there is no comparison. Ours are the best in the world." He did concede that he had seen some pretty fair ones in Germany. In this qualified praise he was about right, for here just as yonder there is a difference between the permanent way and car equipment of main lines and those of branch lines. Perhaps there is another difference; possibly the citizen in Germany protests more loudly if he considers himself unduly neglected in governmental regulations than does the citizen on the other side of the pond. But in making his critical remarks, Mr. Gould should not have forgotten

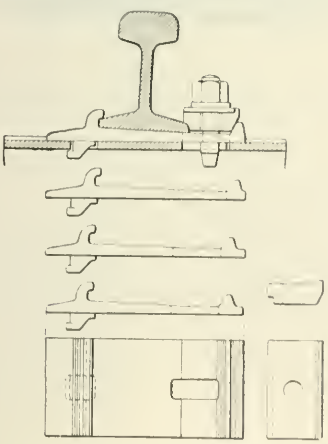

Fig. 39—Hook Stud Plate; Prussian State Railroads, 1907.

that while accidents cannot be avoided entirely, still those recorded in America go far beyond a reasonable average.

Those who defend the wooden tie from principle cannot be reproached with the fact that the perfecting of this tie has not kept pace with the development of the metal tie, because that was a matter beyond their control. Should it be necessary to give this member particular dimensions, a desirable shape or a definite weight, such requirements entail no problems with the metal tie. A case in point is the broad tie for joints, made to meet the requirements of the administration of the Prussian State Railroads. If the demand were made for ties of still greater weight, no rolling mill would declare it impossible. And if specifications called for a tie to have a life of 50 years or more for use on lines with heavy traffic, even this demand the iron and steel industry would meet, furnishing a product of great uniformity both as to shape and quality. In making these assertions I am exaggerating in no way. The old and light Cosyns ties, which, after having stood 40 years' service, can still be used, although laid on a roadbed that cannot be compared with that of the coal regions, have demonstrated the lasting qualities of the material even with unfavorable ballast, and that is the important thing. Surely it is reasonable to expect that a metal tie properly constructed, proportioned and equipped, turned out in accordance with our present experience, will have a still longer life. The comparative behavior, under similar conditions of heavy traffic, of impregnated wooden ties and of metal ties with and without ribs is well shown by samples in the Osnaburg Track Museum. In view of the superior qualities of the metal tie, we iron and steel men are amply justified in placing it prominently in the foreground.

There is no question that the wooden ties have done great service; to deny their importance would be foolish. But is not the producer of wooden ties entirely dependent on the growth of the tree? In regard to dimensions, cross-section and length, resistance and durability, the friends of the wooden tie must be satisfied with the qualities offered by nature in each individual case. As it is impossible to make all the ties of a large order from trees of the same character in respect to age, growth and freedom from knots, we cannot speak of the uniform durability of the wooden in the same sense that we speak of it in the metal tie. The time for the selection of woods is long past, and the best that can be done is to delay its rapid deterioration by impregnation, and so defend it against the attacks of its numerous enemies. If the wooden tie is to reach a higher value for use, the means must be borrowed from the iron and steel industry, and, by equipping it with heavy tie plates or massive chairs, lengthen its life and increase its ability to render service.

In the estimate made to establish the relative economic value

Fig. 40—Permanent Way with Rib Ties, Showing Joint Tie.

of the wooden tie and the metal tie, I have not taken into account as factors the undoubted increase in safety of operation, nor the favorable effect of properly constructed metal permanent way on rolling stock. Furthermore, I have left out of the reckoning the fact that the manufacture of metal ties means a considerable outlay in wages which would inure to the benefit of our country, and would amount to not less than $9.80 per ton.

The basis for the comparison are the specifications laid down by the Prussian State Railroads for the construction of permanent way for fast train service, i.e.:

1. A permanent way with 25 impregnated fir ties supporting a rail of 49 ft. 2½ in. long.

2. A permanent way with rib ties (forms 71 and 66, Fig. 38), 23 intermediate ties and one broad tie for the joint, this last counting for two single ties,* the length of rail being the same.

The cost of rails, splice bars, ballast and maintenance has been assumed to be the same for both systems, although we have sufficient evidence that metal ties, in the long run require less labor for maintenance than do wooden ties. All prices for metal are official. For old material, I assume a loss in weight of 20 per cent and a value of only $10.09 per ton. An estimate presented by me at a meeting of the "Verein für Eisenhüttenkunde," and which has not been controverted, sets forth that every ton of metal ready for use in permanent way represents an income from freight to the railroads transporting the finished or partly finished products, the scrap and the raw materials (coal, coke, pig iron, slag, etc.), amounting to $6.54 and, including the old material, to $7.20. This item cannot be disregarded even though the freight charges do not in every case inure entirely to the benefit of the road purchasing and using the ties. All that interests us is to obtain average values applicable to the large territory served by the Prussian State Railroads. The fact that other roads, on account of their geographi-

*Since this paper was read, new specifications for the standards of permanent way require 24 intermediate ties and one joint broad tie, i. e., one tie more than above.

or economic position, may have to use different values does not change the general accuracy of the proposition. As the wooden ties have also to be transported, I will deduct the freight on the finished metal ties and instead of \$6.51 or \$7.20, place the freight receipts at \$5.45 per ton, thus avoiding any charge of discrimination in favor of the metal tie.

The cost of the impregnated tie is not obtainable from official statistics, as these give only the average cost of the total of wooden ties, making no distinction as to their character, whether impregnated, fir, beech or oak. I shall have to rely, therefore, on my own general knowledge. It would certainly not be excessive if I assumed the cost of the ties ready for laying in the track (including cost of impregnation and planing, but excluding transportation from storage points to place of use) at \$1.20 each. Incidentally, oak ties on the same basis cost \$1.62 and beech ties \$1.80. But I will assume the purchase price of the impregnated fir tie at only \$1.02. It is assumed that the ties remain in use in main track up to the time of their removal, and the value of these old ties I will put at the rather high figure of 30 cents each. This is on the assumption that they will be fit to some extent for use on sidings, although many, probably the most, will be disposed of for fuel at much lower figures.

Next the question of their life. Experience has shown the average length of service for impregnated fir ties on main tracks under heavy traffic to be 10 to 12 years. I will assume 12 years. After what has preceded we might reasonably allow to the rib tie three times as long a life. I will not go so far, however, and will content myself with 20 years as the average length of service for metal rib ties.

In regard to the fastenings, it is known that their renewal generally coincides with the removal of the ties, excepting possibly in the case of the bolts, which often require earlier replacement. Eight years' experience with rib ties furnish the assurance that the carefully designed hook stud plates and the clips, with their large contact surface, will have a length of life equal to that of the tie. This result can be confidently expected, as the hook stud plates are now being worked out of the cold bar by especially designed machines. For the T-bolts I assume an average life of 12 years. As the hook plates of the wooden ties are of generous dimensions, I assume that they will last 18 years, while the small clips and the tie screws will be worn out in main track service in from 10 to 12 years, the same as the ties. Possibly this may be too optimistic for these last, as the repeated tightening and refastening occasion considerable wear. Finally, the cost of the labor of replacements, taking out old ties and putting in new ones, must not be neglected, and for this, whether the ties be of wood or of metal, I will allow 12 cents per tie.

Based on the above data, the following is the calculation in detail of the net cost per mile of the ties with their attachments required by the two systems, credits being allowed for the value of scrap and for the freight earnings accruing from the transportation of material as noted above.

1. *Fir Tie Permanent Way.*

25 ties supporting rails 49 ft. 2½ in. long.

				229
5,369	T bolts, 1.5 lbs. each =	4.027 tons at \$63.27 − 5.45 = \$57.80	\$233	
	Less scrap	3.222 " at 10.90	35	
				198
				\$3,386

The annual amount required to be paid into a sinking fund to cover, by the time replacements are necessary, the above outlays at the rate of 4 per cent. compound interest, is.

1. *For Permanent Way with Wooden Ties*

Wooden ties, clips and screws for ties

$$\frac{(2{,}255 + 151 + 360)\ 0.04}{1.04^{12} - 1} = \$184.44$$

Hook plates for wooden ties

$$\frac{983 \times 0.04}{1.04^{18} - 1} = 38.54$$

\$222.98

2. *For Permanent Way with Rib Ties.*

Rib ties, hook stud plates and clips,

$$\frac{(2{,}212 + 747 + 229)\ 0.04}{1.04^{20} - 1} = \$107.07$$

$$\frac{198 \times 0.04}{1.04^{12} - 1} = 13.18$$

\$120.25

From the above it appears that in a country with an efficient iron and steel industry, wooden ties are at least 85 per cent. more costly than metal ties. If the difference of \$102.73 between the annual payments to the sinking fund is to disappear, wooden ties must become materially cheaper. But these figures do not tell the whole story of the economic superiority of the metal tie. In addition to a

Fig. 41—Permanent Way with Rib Ties.

greater safety in operating, and a saving in wages, there would accrue to the country at large the indirect benefits arising from the regular and steady work that would fall to the share of the metal industry.

I am confident that the time is approaching when, in view of the demonstrated longer life and greater reliability of permanent way with metal ties, even after a very material reduction from present prices, the wooden tie will be regarded as too expensive. We must accustom ourselves to the idea that, as in ship building, house building, bridge building and in other fields, so also in railroad building metal is crowding out wood. When half of the 70 million wooden ties at present lying on 33,000 miles of important lines of main track are replaced by metal ties (which in itself would mean lower costs of operation and of maintenance) the saving in the amount of the yearly contributions to the sinking fund would amount to nearly \$1,700,000, representing the interest on a capital of \$42,500,000, and we iron and steel men would be in position to pay for labor additional wages amounting to over \$26,000,000 yearly.

In this presentation and in the deductions made, I have only, as I believe, set forth clearly incontrovertible facts. If the German iron and steel makers share this belief, it will be their task to champion the metal tie energetically. The choice of the particular metal tie best adapted to given conditions will lie with the proper railroad authorities. I have the utmost confidence that these, both in the engineering department and in that of finance, will recognize the validity of my demonstration. Eventually, in our permanent way, the use of wooden ties will only be justified to the extent that in the interest of domestic forestry it may be tolerated on some branch roads. On the main lines they will have to be given up, and we can confidently hope that before long the entire structural part of the permanent way will be of steel and iron.

The distilleries of the upper Congo are protected against the pauper distilleries of Europe by a freight rate on spirits over the Congo Railroad at the rate of 70 cents per ton per mile, making \$175 per ton, or \$8.75 per 100 lbs., for the 250 miles.

GENERAL NEWS SECTION

NOTES.

The New York Assembly has passed a bill compelling railroads to issue half fare tickets to school children.

According to recent advices the outlook for a big wheat crop this year in the Kansas wheat belt is extremely good.

The Missouri Pacific has asked for a injunction forbidding the Nebraska Railroad Commission from attempting to regulate its traffic or rates.

It is understood that the Atchison, Topeka & Santa Fe has bought 1,200 acres of oil lands in the Midway field in California at a cost of about $2,000,000.

The Indiana Railroad Commission issued an order March 30 reducing express rates between 10 and 12 per cent. The Commission thinks the companies are earning too much.

At a conference between presidents of Missouri and Illinois roads and their general counsel, March 26, it was decided to test the constitutionality of the 2-cent passenger rate laws in those states.

On and after April 1 the Southern Railway will apply the 2½-cent passenger rate on all tickets sold in Tennessee. It will also give an open party rate of 2 cents for parties of 10 or more traveling on one ticket.

The Canadian Pacific has adopted a demerit system of discipline instead of the suspension system. Sixty demerits will be grounds for dismissal. For every year free from demerits, 20 demerits will be deducted.

On April 1, Attorney-General Bonaparte transmitted to United States attorneys information of 28 instances where the Federal Safety Appliance Law is alleged to have been violated. Of the total number, 13 occurred in California.

The Interstate Commerce Commission has reversed its own ruling and will allow transcontinental roads to grant rates to California for April 4 and 5, the occasion of manoeuvers by Admiral Evans' fleet, without insisting on the 30-day provision.

It is understood that the government will bring a test case as soon as possible after May 1 to try out the commodity clause of the Rate Law, and will thereafter not prosecute railroads for failure to comply with this clause, pending a decision of the Supreme Court.

The passenger department of the Southern Pacific announces that between March 1 and March 18 more than 7,000 people entered the state of California, most of the immigrants going to the northern part of the state. The company's tourist travel was 20 per cent. less this winter than a year ago.

The Oklahoma Corporation Commission on March 26 rescinded its former order ousting the Fort Smith & Western Railroad from the state on account of its refusal to do passenger business on a 2-cent basis. The Commission decided after a hearing that the road should be allowed to continue to do business on a 3-cent basis.

Chairman Knapp, of the Interstate Commerce Commission, wrote the Senate committee on interstate commerce March 30, to the effect that the Commission believed that a physical valuation of the railroads of the country could be completed in three years and that the total expense would perhaps be not less than $3,000,000.

Judge Pollock, in the United States Circuit Court at Topeka, Kan., on March 27, enjoined the State Board of Railroad Commissioners and the Attorney-General from putting into effect a new schedule of freight rates on April 1. The railroads alleged that the proposed schedule was confiscatory. The case will be argued on April 14.

Arrangements were made March 30 for the purchase by the city of Winnipeg, Man., of the entire holdings of the Winnipeg Electric Railway, which is a consolidation of the Winnipeg Electric Street Railway and the Winnipeg General Power Co., and operates the entire street railway, gas and electric business of Winnipeg and St. Boniface.

An appeal was made to the employees of the Chicago, Milwaukee & St. Paul last fall to economize in each detail of operating expense in order to avoid the necessity of reducing wages. According to recent advices, $160,000 was saved in January by careful work, about one-fourth of which is attributed to the saving in coal, due to careful locomotive firing.

For 589 railroad stations in the western New York car service district 65,569 cars were reported during February, as against 78,377 cars during the same month last year, a decrease of 29 per cent. The average detention was unchanged. For the eight months ended with February the Pacific northwest car service district reports 574,708 cars; a gain of 19 per cent. for the current commercial year.

A delegation of freight trainmen employed by the Philadelphia & Reading have asked the State Railroad Commission to obtain information for them about the working of the federal 16-hour law. They argue that the 16-hour limit often expires when they are only a few miles from a terminal point, and want to know whether it is their duty to stop work and tie up traffic under such circumstances, or to take the train to the end of the run.

Judge Thomas G. Jones, of the United States District Court, at Birmingham, Ala., made permanent on March 28 the preliminary injunction issued last August directed against certain acts in the Alabama railroad law which sought to prevent the railroads from going to the federal courts for relief. All rate acts are also suspended by the injunction until the justice of the rates can be determined. The opinion followed the general lines of that given by Justice Peckham in the Minnesota and North Carolina cases.

The United States Supreme Court has decided in favor of the company what is known as the Meat Rate case of the Interstate Commerce Commission v. the Chicago Great Western, involving the right of the company to reduce the rate on live stock products without making a similar reduction in the rate on live stock. The Commission found that the change of the rate on one article without a corresponding change on the other was unlawful, but the court reversed this decision.

Judge Calhoun of the United States District Court at Austin, Tex., on March 28 rendered a decision ousting the Western Union Telegraph Co. from Texas and assessing against it back franchise tax fees amounting to $100,000. The question at issue was whether the company had a right to transact a telegraph business between Texas points without first having obtained a domestic charter or a foreign permit to do business in the state. The company is now prohibited from doing any interstate business in Texas, except that for the federal government.

The Ohio Railroad Commission has added another rule governing the loading and unloading of cars and free time. It provides that when a consignee shall elect to work on a fixed standard of receipts his business shall be rated as to daily capacity and thereafter if the cars consigned to him exceed the rating, he shall be charged each day with 1½ times his rated daily capacity, 48 hours being allowed for unloading each day's placing, actual and constructive. The ratings shall be done by the railroad and the consignee shall have the right of appeal to the Commission. All ratings shall be filed with the Commission.

Assistant Postmaster-General McCleary has given his decisions on the questions of fining railroads for delays in handling the mails and of compensation for the so-called "half car line" mail routes, where a car is only needed one way, and the government has hitherto adopted the practice of paying only half the usual compensation for the round trip. Mr. McCleary has decided that the long roads of the West and South shall be divided into divisions of from 200 to 400 miles, and the penalties for failure to observe the schedule shall be exacted on these shorter hauls rather than on the long, continuous route. As regards the "half car lines," the railroads are to be paid for hauling mail cars both ways whether the cars are in actual use both ways or not.

The Eureka Tape Repairer.

A convenient steel tape repairer is being put out by the Chicago Steel Tape Co., 6233 Cottage Grove avenue, Chicago. It is made of thin sheet metal, folded in the shape of a sleeve and coated inside with a combination solder and flux. The heat of a match is enough for soldering the sleeve to the broken ends, making a strong joint. The sleeves are made to fit any width and weight of tape and are very light, a dozen of them weighing less than half an ounce.

Traffic Club of New York.

At a meeting of the Traffic Club of New York on March 31 an address was delivered by Capt. J. W. Miller, Vice-President and General Manager of the New England Navigation Co., who after recalling incidents of his earlier experiences in the Navy, read a paper covering the general subject of Water Transportation. Mr. Miller showed how in the last 30 years the opportunities of the West had turned away the American people from maritime enterprise and predicted that the time has now come when the trend would be the other way and the merchant marine of the United States would be built up. He showed how in the course of development of the West by railroads, rebates and other discriminations had arisen, and pointed out that a new era in transportation is just beginning, in which fair methods must be used and tariffs must be made more simple and understandable.

New England Navigation Company's New York Terminals.

The New York terminals of the New Haven Line and the Bridgeport Line were moved on April 1 to Pier 28, East River, near Catherine street. The steamers of these lines formerly used Piers 19 and 20, East river.

New York City Street Railway Conditions.

Mr. Ivins shows, taking his facts from the petitions of the receivers to the Federal courts and to the State Board of Tax Commissioners, that in 1894 the whole number of revenue passengers carried in Manhattan was 236,012,000, of which 5,306,000 were transfer passengers. In 1902 the total number of passengers had risen to 382,268,000, and the transfer passengers to 134,963,000. In that year gross receipts from operation were $19,739,000. Five years later, for the year ending June 30, 1907, the number of revenue passengers had fallen to 376,629,000, and the number of transfer passengers (transfers required by law) had risen to 194,765,000. The gross receipts at the end of this five-year period had decreased $377,737, and operating cost had risen $1,234,000.

Anybody can see that this is the road to ruin. Yet the responsible men of the Metropolitan system were led to believe, and the people were led to believe, that the universal transfer was a public benefit justifying consolidation of the lines and a liberal policy toward them. The result shows that a corporation can be asked to give too much.

The relation of the special franchise tax to the difficult, and, as it has seemed, insoluble problem of the street railway situation, is made no less clear by Mr. Ivins' calculation of the operating account of the system based upon the receivers' figures. From gross income from all sources of $21,919,692, there are to be deducted operating expenses of $13,172,571, leaving a surplus for maintenance, wage increase, renewal, depreciation, taxes, interest and dividends of $8,747,121. After the deductions for maintenance, depreciation, wage increase, and taxes, exclusive of a special franchise tax, are made, there remains available for interest and dividends the sum of $3,605,743. On the carefully estimated cost of reproducing the system, which Mr. Ivins puts at $106,500,000, this gives only 3.4 per cent. return. There could, of course, be no possibility of any dividends on stock, and the city would lose the $900,000 of special franchise taxes for which no provision could be made.

Mr. Ivins dryly remarks that in these figures "the invitation to private capital is not irresistible." A private corporation would not, the city should not, undertake to carry on a street railway business in New York under conditions and requirements that make this showing inevitable. The private corporation that has hitherto operated the lines has paid rentals and dividends only by starving the maintenance account until the roads are physically as well as financially bankrupt. The franchise tax they have not paid at all. The city has no right to undertake a losing business. The carrying of street railway passengers is not a philanthropy.

The teaching of Mr. Ivins' analysis is precisely the teaching of our present deadlock in subway construction. The lesson the people must learn, though they will be most unwilling to learn it, is the lesson that they and their lawmakers, in seeking to make better terms for the public, have made unbearable and bankrupting terms for the corporations. The stock watering and misdeeds of Metropolitan management are not involved in the problem. Mr. Ivins takes no account of the $240,000,000 of outstanding capital—his estimate is based on production cost. Against the abolition of the general transfer there would be a loud public protest. Against the repeal of the special franchise tax the voices of its original sponsors and of thousands of agitators who have since that time become vocal would be raised. But if transfers are to be given under present conditions, and if the other requirements of the law as it now stands are to be enforced, either surface railway passengers must be carried by the city on a charity basis or they will not be carried at all.

Mr. Ivins deserves the thanks of the community for the opportunity he has given it to look the facts in the face. We regard his utterance as deeply significant, a notable indication of the turning of the tide.—*New York Times.*

Some New Scherzer Bridges.

The New York, New Haven & Hartford, on which several Scherzer rolling lift bridges are in service, is building a number of additional bridges of this type. These include a double-track bridge across the Seekonk river at Providence, R. I., and six-track bridges across the Bronx and Eastchester bay on the Harlem river branch of the New York division. The New York Central is building a double-track Scherzer bridge across Wappinger creek on the Eastern division, which will be ready for service in the near future. Double-track Scherzer bridges for the Lake Shore & Michigan Southern and Chicago, Lake Shore & Eastern railroads across East Chicago canal at Indiana Harbor, Ind., are building, and will be ready for service when the canal is opened. The Norfolk & Western has two double-track Scherzer bridges building across the Southern and Eastern branches of the Elizabeth river near Norfolk, Va., and a single-track bridge is being built for the Seaboard Air Line across Hillsboro bay, Tampa, Fla., as a part of the terminal improvements being made by the Seaboard at that point. Two single-track bridges of the Scherzer type are being built for the Norfolk & Southern across Albemarle sound as the movable spans in a long trestle being built to replace the present ferry service between Edonton and Mackay's Ferry. The double-track Scherzer bridge crossing Coney Island creek for the Brooklyn Rapid Transit system has been in service for several months, carrying the heavy traffic on that line. The single-track Scherzer bridge crossing Rainy river for the Duluth, Rainy Lake & Winnipeg and Canadian Northern railroads is expected to be ready within 30 days. Work is also being pushed on the long span double-track bridge for the San Pedro, Los Angeles & Salt Lake across the San Gabriel river at Long Beach, Cal.

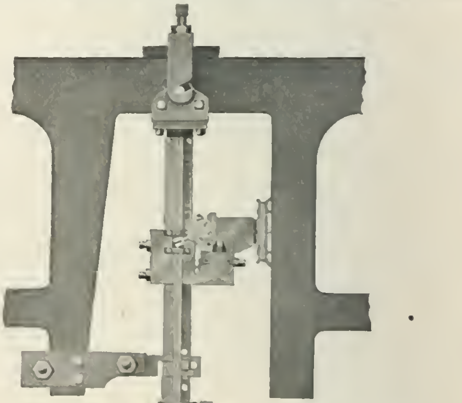
A number of Scherzer rolling lift bridges are being built for both British and Colonial railroad service. It is expected that the combination single-track railroad and highway bridge at Barrow-in-Furness, England, and the two double-track bridges for the Buenos Ayres Great Southern Railway at Buenos Ayres, Argentina, will soon be placed in service, and work is now being pushed on the long span bridge for the Burma Railways near Rangoon, India. Several bridges of the Scherzer type are in operation or under construction in Egypt, and the two railroad and highway bridges for the Tehuantepec Railway Company at Salina Cruz, Mexico, will be completed in the near future.

About fifty Scherzer bridges have been built for electric street railway and interurban service, nearly all being double or multiple track structures.

Facing Pedestal Legs of Locomotive Frames.

The illustration shows a machine for facing pedestal legs of locomotive frames. It is made by H. B. Underwood & Co., Philadelphia, Pa.

At the top of the squared bar is a steel swivel, so that the cutting tools can be placed to work on either leg. There is also a swivel to allow work to be done on the angular side of the shoe. The top of the swivel is a large surface which clamps firmly to the frame and is easily changed, so that the work can be done in narrow spaces. In one side of the squared vertical bar, or slide, for the milling head is a steel square thread feed screw. The milling head has a bronze



Machine for Facing Pedestal Legs of Locomotive Frames.

half nut, engaging the feed screw by a ratchet and pawl for change of feed. The feed is operated by an eccentric on the milling head, driving the vertical shaft. The milling head has two adjustments, to and from the leg and across the face, giving fine and quick adjustments without knocking or loosening any part. At the lower end, universal adjustable clamps hold the device rigidly to the frame.

Power is applied to gears turning the milling spindle. This is threaded to receive the milling cutters, which are made of squared high-speed steel and are removable for grinding and adjusting. Power reaches the gears through a telescopic shaft, having universal tumbling joints at each end. By using this flexible shafting the source of power may be placed in a convenient and out-of-the-way place, and belts are eliminated.

The machine removes a large quantity of metal quickly, making light cuts, but taking only a little time for each cut. The Underwood two-cylinder air or steam motor is recommended for driving this and other portable tools.

Heating and Ventilating the Storage Battery Stations on the New York Central & Hudson River.

In the electrification of the New York Central terminal at New York, an interesting problem was the heating and ventilation of the storage battery stations at Lexington avenue, Yonkers, King's Bridge and Bronx Park. The company installing the storage batteries was willing to guarantee them for 10 years, provided the temperature was maintained at 70 deg. F. This necessitated a heating plant for cold weather and a means of cooling in warm weather, as well as proper ventilation at all times.

Fig. 1—Battery Floor; Kings Bridge Sub-Station.

In charging the batteries, destructive acid fumes are thrown off, which precluded the possibility of heating by direct radiation, as the fumes would attack and destroy the radiators and pipe lines. The blower system was therefore adopted. The heating plant could thus be placed in a detached building, and the air ducts to the battery building are protected against the corrosive action of the acid fumes.

So far five stations have been equipped. The battery room, busbar chambers, corridors, stair halls, controller chambers, etc., are the portions heated and ventilated. The method used for heating and ventilating the King's Bridge sub-station is typical of all stations. The air is circulated through a sectional pipe heater by a steel plate fan driven by a belted motor. Steam is supplied by a small low-pressure boiler, located in an adjacent room. The hot air is distributed by suitable ducts to various points.

Fig. 2—Battery Floor, Looking East; Yonkers Power House.

Two methods of distribution are used. These are shown in the accompanying photographs. One is by carefully protected galvanized iron ducts, as shown in Figs. 1 and 2, this being used only at Yonkers. At the others there is no piping, the air being admitted at one end of the room through tile conduits terminating at registers made of 95 per cent. lead and 5 per cent. antimony. The results have been fully as satisfactory by this method as by distributing air by ducts with branches at frequent intervals. The advantage, so far as appearance is concerned, may be seen in Fig. 3. Furthermore, the ducts are costly to install and require frequent attention to keep them in condition to resist the acid fumes.

The heating system is compact, easily accessible and under control at all times. It is claimed to be moderate in cost, easily installed and economical both in operation and maintenance. It is also very flexible, it being possible to deliver the air at any temperature without diminishing the volume. Thorough ventilation for the battery rooms is therefore assured while the batteries are being charged.

The American Blower Co., Detroit, Mich., designed the systems and furnished the apparatus, which was installed by John Hankin & Brother, heating contractors, New York.

Fig. 3—Battery Floor, Looking West; Yonkers Power House.

American Iron & Steel Institute.

The American Iron & Steel Institute, formed mainly by United States Steel Corporation interests to afford a means of communication between members of the iron and steel trades, has been incorporated in New York. The Directors are: Elbert H. Gary, William E. Corey, Charles M. Schwab, E. O. S. Clarke, W. J. Filbert and John A. Topping, of New York; Howell Stackhouse and F. C. Felton, of Philadelphia, Pa.; Willis L. King, of Pittsburgh, Pa.; Edward Bailey, of Harrisburg, Pa.; J. C. Maben, of Birmingham, Ala.; W. O. Rogers, of Buffalo, N. Y.; J. F. Welborn, of Denver, Colo.; T. J. Drummond, of Montreal, Que., and Samuel Mather, of Cleveland, Ohio. The principal office is to be in New York.

A Newspaper Story.

At Homestead, Pa., Sunday afternoon the locomotive of a fast train tossed John Hastings over the roof of a (one-story) house and into the window of a shoe shop 40 ft. away. "He hadn't a broken bone, a bruise or a scratch," says the reporter. "He was conscious. Two bundles of laundry which he carried, one under each arm, were intact. He said he wanted to go home, and the doctor said he had no objection."

INTERSTATE COMMERCE COMMISSION RULINGS.

Rate on Cameras Upheld; on Motorcycles Reduced.

The Commission, opinion by Commissioner Prouty, has decided the case of Merchants Traffic Assoc. v. Atchison, Topeka & Santa Fe et al. The complaint was that the rates on cameras and camera stands from St. Louis, Mo., to Denver, Colo., and on bicycles and motorcycles are excessive. The Commission decided that while the rate on cameras and camera stands is high, it is not so excessive as to warrant interference; this branch of the complainant's case was not sustained. The rate applied on motorcycles from St. Louis to Denver was held to be excessive, and ordered to be reduced so as not to exceed the rate on bicycles between said points.

TRADE CATALOGUES.

Steam Shovel News.—The current number is a special spring number. The leading article is on "Testing High Explosives," by Waldon Fawcett. The tests referred to are those now being made by Dr. Charles E. Munroe for the United States Government. Other interesting articles are: "Transporting a Steam Shovel," describing the moving of a traction steam shovel through some heavily timbered and swamp country in Minnesota; "Steel Sheet Piling for Cofferdam Construction"; "Steam Shovel Work in the Klondike", "A Scow for Trench Shovel", "Stripping Ore Mines," and "Quarry Economy." There are also descriptions of some new boom and swing engines for heavy-duty shovels, and an electric shovel.

Waterproofing.—The Standard Asphalt & Rubber Co., Chicago, has prepared a pamphlet regarding its waterproofing for foundations and track elevation and other structures. The physical properties and the general method of application are first described, and this is followed by illustrated descriptions of a number of pieces of work done for railroads, large buildings, reservoirs, etc. There is also a list of similar work which has been done or is under way. Another pamphlet is a catalogue and price list of coatings and dips. An effort has been made in this to give a concise and true description of the materials and the work to which they are adapted. The book is 3⅝ in. by 6 in. and has 28 pages.

Signal Construction Materials and Lightning Arresters.—The signal department of The Railroad Supply Co., Chicago, has issued Sections 3 and 4 of Catalogue No. 7. Part 3 shows signal construction and maintenance materials, including battery chutes and receptacles, batteries and battery supplies, channel pins and bond wires, insulated joints and track insulations, insulated and line wires, and miscellaneous construction and maintenance materials. Part 4 shows various styles of lightning arresters, designed for both direct and alternating current. Various lightning arrester applications, ground plates, ground rods and water and fireproof boxes for arresters are included.

J. G. White & Co. have issued an exceedingly interesting pamphlet of 82 pages showing illustrations and brief comment upon their engineering work in every quarter of the world. The pamphlet includes a map on which 115 J. G. White contracts all over the globe are indicated by red dots. It is entitled "At Work Around the World."

London & North Western.—This company has issued a revised list of its picture post cards. There are now 55 sets of these cards, selling at 2d. per packet. Eight million cards have been sold.

Mine Equipment.—A circular issued by The Jeffrey Manufacturing Co., Columbus, Ohio, illustrates 14 of the Jeffrey specialties in mine equipment.

MANUFACTURING AND BUSINESS.

The offices and plant of the Gordon Battery Co. have been moved to Aldene-Roselle, N. J.

The offices of the General Contracting & Engineering Co., 15 Whitehall street, New York, will be moved on or about May 1 to the Hudson Terminal building, 50 Church street.

The receivership of the Westinghouse Machine Co., Pittsburgh, Pa., was vacated on March 31. The company now has no floating debt; it has a large number of orders and about $1,000,000 cash on hand.

Fred K. Potter, for many years connected with the Capell Fan Engineering Co., has been appointed Manager in the Pittsburgh district for the Sirocco Engineering Co., New York. Mr. Potter's office will be in the Keenan building, Pittsburgh, Pa.

The Railroad & Car Material Co., Bessemer building, Pittsburgh, Pa., was recently incorporated to deal in wholesale lumber, railroad equipment and supplies, including castings and forgings. The officers are: President, J. W. Scull, formerly Purchasing Agent of the Pressed Steel Car Co., Pittsburgh, Pa.; Vice-President, C. W. Cantrell, formerly Eastern Manager of the Herman H. Hettler Lumber Co., Chicago; and Secretary, W. H. Coyle.

The net profits of the Canadian Westinghouse Co., Ltd., Hamilton, Ont., for the year ended December 31, 1907, were $427,053, an increase of 23 per cent. Dividends of $215,221 were paid, $200,000 was reserved for depreciation, and $20,000 for inventory. The profit and loss balance carried forward was $391,284. At the end of the year the unfilled orders amounted to $1,136,000. The output of the air-brake department increased 35 per cent.

John C. Sesser, Engineer of Maintenance of Way of the Chicago, Burlington & Quincy at St. Louis, Mo., has resigned to go to the W. K. Kenly Co., Chicago, as Vice-President in charge of the railroad department. Mr. Sesser is a graduate of Lehigh University, having completed the engineering course in 1896. From that year until 1902 he was a construction engineer on the Chicago & North-Western, the Union Pacific and the Chicago, Milwaukee & St. Paul. From 1902 to 1903, he was Chief Engineer of the Au Sable & Northwestern, leaving that road to become Superintendent of Construction of the Burlington. In 1907 he was appointed to the office he now leaves. Mr. Sesser is a member of the Maintenance of Way Association and an associate member of the American Society of Civil Engineers. His new headquarters will be in the First National Bank building, Chicago.

The Westinghouse Electric & Manufacturing Co., Pittsburgh, Pa., has an order from the Dominion Iron & Steel Company, Halifax, N. S. for a 500-h.p. electric generator, which will be used in the operation of one of the company's iron mines on Belle Island, Newfoundland. It is interesting to note that in one of the mining camps at Guanajuata, Mex., the Pinginco mines, 250 Westinghouse motors, ranging in capacity from 5 to 200 h.p., are being operated.

A new company is being formed to take over and continue the publication of Moody's Manual, heretofore published by The Moody Corporation, New York. The manual for 1908 is now ready for the press. Arrangements are being made to supplement the book with a monthly service, thus keeping the manual up-to-date throughout the year. The price of the manual, including this monthly service, will be $10, which has heretofore been the price of the book alone.

The joint convention of the American Supply & Machinery Manufacturers' Association, the National Supply & Machinery Dealers' Association and the Southern Supply & Machinery Dealers' Association will be held at Richmond, Va., May 13-15, 1908. William H. Taft, Secretary of War, is to address the three associations on Wednesday afternoon, May 13. F. D. Mitchell, 309 Broadway, New York, is Secretary-Treasurer of the first named association.

The Quincy, Manchester, Sargent Co., New York, recently closed a competition in which prizes were offered to men in charge of track work for the best answers to certain inquiries regarding the use of, and suggestions for, anti-rail creepers. The judges of awards were as follows: W. M. Mitchell, Manager and Chief Engineer, Kentucky & Indiana Bridge & Railroad, representing the railroads; O. Metcalf, Jr., American Railway Device Co., representing the selling interests of anti-rail creepers, and W. C. McMahon, President of the Belle City Malleable Iron Co., representing the manufacturers. There were 85 competitors, and prizes were given as follows: First prize, W. H. Kofmehl, Roadmaster, Chicago, Milwaukee & St. Paul, Elgin, Ill.; second prize, W. H. Hoyt, Assistant Chief Engineer, Duluth, Missabe & Northern, Duluth, Minn.; third prize, E. J. Boland, Roadmaster, Union Pacific, Cheyenne, Wyo.

John Albert Brill, Vice-President, Director, and one of the founders of the J. G. Brill Company, Philadelphia, Pa., died on March 25, after four years' sickness. The following sketch of his life has been prepared by James Rawle, his life-long friend and President of the Brill company:

Mr. Brill was born in Philadelphia on December 15, 1852, whither his parents had moved from Cassel, Germany, a few years before. Always studious as a lad he received a sound education. At the early age of seventeen his instinct of industry led him into the works upon which he has since stamped his strong individuality and to whose building up he gave the absolute love and devotion of his life. Endowed with great ability, in which keen insight was united with infinite perseverance, he brought to the work of his life the qualities of an inventor of the most valuable improvements in transportation facilities. These embraced nearly every feature of cars and trucks which go to make up the modern electric car. At the outset of his career he did with his whole soul the things which a boy could do—drove the engine, kept the accounts. Gradually he was advanced by the firm to more responsible positions and was soon placed in charge of the department of sales. In this his great abilities found their appropriate sphere. When, in 1887, electric propulsion developed, his genius developed with it, and the present types of electric trucks in universal use are practically those which he invented. He was in every sense of the word a pioneer. He led; others followed. He foresaw by instinct, and usually years in advance, the direction in which electric street railway practice must necessarily develop, and he devoted himself to the task of teaching the railway companies These high in their management

John A. Brill.

recognized his wisdom and sound judgment and constantly sought his advice—sooner or later they always followed it. In 1904 the Franklin Institute awarded him the John Scott legacy premium and medal for meritorious inventions in cars. He had a strong sense of justice, but resented bitterly any treatment which he considered unfair. It is sad to see a man so strong, so worthy and so useful, stricken down by the lingering pain of disease.

MEETINGS AND ANNOUNCEMENTS.

(For dates of conventions and regular meetings of railroad conventions and engineering societies, etc., see advertising page 26.)

The Traveling Engineers' Association.

At the next regular meeting of this association there will be a paper for discussion on the "Use of Steam Heat on Passenger Trains," and at the next annual meeting a paper on "How can Road Foreman of Engines interest Engineers and Firemen in keeping posted on progress in locomotive development including valve gears and steam distribution?"

American Society of Mechanical Engineers.

The semi-annual meeting of this society is to be held in Detroit, Mich., June 23-26. The papers to be presented at this meeting are as follows: Method of Cleaning Gas Conduits, by W. D. Mount; Method of Checking Conical Pistons for Stress, by Prof. George H. Shepard; Clutches, with special reference to automobile clutches, by H. Souther; Gas Power, by Prof. L. S. Marks; Journal Friction Measuring Machine, by Henry Hess, and A By-Product Coke Oven, by W. H. Blauvelt. There will also be a symposium upon machinery for conveying materials, with papers by several authorities. The Society for the promotion of Engineering Education will also hold its annual meeting in Detroit at this time, which will enable members of each society to participate in the sessions of the other.

Iron and Steel.

The Interborough Rapid Transit is in the market for about 1,000 tons of rails of standard section.

ELECTIONS AND APPOINTMENTS.

Executive, Financial and Legal Officers.

Railway Commission of Canada.—Judge J. P. Mabee, of the High Court of Justice of Ontario, has been appointed Chief Commissioner of the Canadian Railway Commission, succeeding A. C. Killam, deceased. Mr. Mabee in 1905 was Chairman of the International Waterways Commission. His appointment to the Railway Commission is for 10 years.

Operating Officers.

Canadian Northern.—A. E. Warren has been appointed Superintendent of the Second division, with headquarters at Winnipeg, having authority over all branch lines out of that city.

Chicago, Rock Island & Pacific.—J. C. Nolan, who resigned as Superintendent of the Louisiana division in October, has been elected President, with office at Ruston, La., of the Ruston, Natchitoches & Northeastern, projected from Ruston, La., north to Farmerville, 25 miles.

Gulf, Colorado & Santa Fe.—The jurisdiction of Oliver Snyder, Superintendent of the Galveston division, has been extended to include the Southern division. The two have been consolidated and are now operated as a single division. His headquarters will be transferred from Galveston, Tex., to Temple. K. S. Hull, Superintendent at Temple, is now Superintendent of the Texas & Gulf, with office at Longview, Tex., succeeding M T Pratt, who returns to the engineering department of the Atchison, Topeka & Santa Fe.

International & Great Northern.—H. W. Clarke, Second Vice-President and General Manager, has been appointed General Superintendent, with office at Palestine, Tex., in charge of the whole road, reporting to the Receiver. J. C. Dailey, General Superintendent, has been appointed Superintendent, with office at Palestine, Tex., reporting to the General Superintendent. The Division Superintendents, Superintendents of Machinery, Chief Engineer, Car Accountant and General Claim Agent will report to the Superintendent.

Louisville, Henderson & St. Louis.—Lucien J. Irwin, General Freight and Passenger Agent at Louisville, Ky., has been appointed General Superintendent, succeeding A. M. McCracken, retired.

New York, Chicago & St. Louis.—G. C. Todd, Trainmaster of the Buffalo division, has been appointed Joint Superintendent of Telegraph of the New York, Chicago & St. Louis and the Western Union Telegraph Company, with headquarters at Cleveland, Ohio, succeeding R. W. Mitchener. J. W. Cantlin has been appointed Trainmaster, with headquarters at Conneaut, Ohio, succeeding Mr. Todd.

Texas & Gulf.—See Gulf, Colorado & Santa Fe.

Traffic Officers.

Cleveland, Cincinnati, Chicago & St. Louis.—Charles Krotzenberger, General Agent of the passenger department at Cincinnati, has been appointed Assistant General Passenger Agent at St. Louis, Mo., succeeding C. L. Hilleary, now General Passenger Agent of the Lake Erie & Western. W. G. Knittle, General Agent of the passenger department at Toledo, Ohio, succeeds Mr. Krotzenberger, with headquarters at Cincinnati. W. F. Carter, Traveling Passenger Agent, with headquarters at Toledo, succeeds Mr. Knittle at Toledo.

Delaware, Lackawanna & Western.—F. P. Fox, Industrial and Advertising Agent, is to resign shortly to go into other business.

Kalamazoo, Lake Shore & Chicago.—W. H. Cochrane has been appointed General Traffic Manager, with headquarters at Chicago, Ill.

Lake Erie & Western.—C. L. Hilleary, Assistant General Passenger Agent at St. Louis of the Cleveland, Cincinnati, Chicago & St. Louis, has been appointed General Passenger Agent of the Lake Erie & Western, succeeding S. D. McLeish.

New York, New Haven & Hartford.—George L. Connor, Passenger Traffic Manager, and Artemus C. Kendall, General Passenger Agent, have both at their own request retired, the former after 40 years and the latter after 41 years of service. Mr Connor entered transportation service in August, 1868, as a clerk in the Treasurer's office of the Narragansett Steamship Co. (Bristol Line), between New York and Boston. In 1873 he was appointed Auditor of Passenger and Freight Receipts of that company, and in 1874 General Passenger Agent. After three months' service as General Passenger Agent he was appointed General Passenger Agent of the Old Colony Steamboat Co. (Fall River Line), a position which he held for 20 years. For six years of this time, beginning in 1887, he was also General Passenger and Ticket Agent of the Old Colony Railroad, until in 1893 it was absorbed by the New York, New Haven & Hartford. In 1893 he was also appointed Passenger Traffic Manager of the New York, New Haven & Hartford and shortly afterward of the Providence & Stonington Steamship Co., controlling the Sound lines to those ports. In June, 1894, his title was changed to Passenger Traffic Manager of the Old Colony Steamboat Co. On July 1, 1898, he was appointed Passenger Traffic Manager of the rail and Sound lines of the New York, New Haven & Hartford, including the New England Navigation Company, a position which he held until April 1, when he was placed on the retired list.

Mr. Kendall entered railroad service in 1861 on the Boston & Worcester, now part of the Boston & Albany, as ticket clerk at Brookline, Mass. In 1863 he was ticket clerk at Boston. In 1867 he went to the Boston, Hartford & Erie, now part of the New York, New Haven & Hartford. For three years he was Ticket Agent of this road at Boston, and for six years General Ticket Agent. In 1876 he became General Passenger and Ticket Agent of the New York & New England, now also part of the New York, New Haven & Hartford. In 1893 Mr Kendall became General Passenger Agent of the Eastern district of the New York, New Haven & Hartford, and on July 1 1905, General Passenger Agent of the entire road.

The office of Passenger Traffic Manager of both the New York, New Haven & Hartford and the New England Navigation Co. has been abolished. Mr. Kendall's successor as General Passenger Agent is A. B. Smith, with headquarters at Boston, Mass. Mr. Smith was born in Boston and entered railroad service in 1880 in the engineering department of the Burlington & Missouri River Railroad in Nebraska, now the western lines of the Chicago, Burlington & Quincy. After working in the engineering and operating departments he was appointed Assistant General Passenger Agent. In 1904 he went to the Northern Pacific as Assistant General Passenger Agent, and in 1907 came to the New Haven as General Traffic Manager of the Connecticut Company, which operates the extensive electric system in Connecticut of the New Haven. He has been promoted from this position to be General Passenger Agent of the New York, New Haven & Hartford and of the New England Navigation Co., in which latter position he succeeds F. C. Coley, who, besides being Assistant General Passenger Agent of the New York, New Haven & Hartford, with headquarters at New Haven, Conn., becomes Assistant General Passenger Agent of the New England Navigation Co., with headquarters at New York

The authority of R. T. Haskins, Freight Traffic Manager of the New England Navigation Co., has been extended to represent the freight traffic interests of the N. Y., N. H. & H., at New York, including such special duties as may be assigned to him. Mr. Haskins will report to B. Campbell, Vice-President.

Pennsylvania Lines West.—M. S. Connelly, General Western and Division Agent, at Chicago, Ill., has been appointed General Freight Agent, with office at Pittsburgh, Pa., succeeding James B. Hill, deceased.

Southern Pacific.—John H. Glynn has been appointed New England Agent in charge of the passenger and freight departments, with headquarters at Boston, Mass., succeeding E. E. Currier, deceased.

Engineering and Rolling Stock Officers.

Chicago, Burlington & Quincy.—John C. Sesser, Engineer of Maintenance of Way at St. Louis, Mo., has resigned to become Vice-President of the W. K. Kenly Co., Chicago. See Manufacturing and Business.

Kansas City Southern.—F. R. Cooper has been appointed Superintendent of Machinery, with headquarters at Pittsburgh, Kan., succeeding R. M. Galbraith, resigned.

Purchasing Agents.

New York, New Haven & Hartford.—J. H. Sanford, Assistant Purchasing Agent, has been appointed Manager of Purchases and Supplies, with office at New Haven, Conn., succeeding A. E. Mitchell, resigned.

LOCOMOTIVE BUILDING.

The Lehigh & New England is said to be in the market for three locomotives. This item is not yet confirmed.

CAR BUILDING.

The Wisconsin & Northern is in the market for three passenger cars.

The Pittsburgh, Shawmut & Northern is asking bids on 1,000 coal cars.

The International Railway, Buffalo, N. Y., is said to be in the market for electric cars. This item is not yet confirmed.

The Third Avenue Railroad, New York, is said to be in the market for electric cars. This item is not yet confirmed.

The New York City Railway is said to be in the market for 150 pay-as-you-enter cars and 100 standard cars. This item is not yet confirmed.

The Oklahoma Railway Co., Oklahoma City, Okla., is said to be in the market for three interurban cars. This item is not yet confirmed.

The Lehigh & New England has ordered 250 forty-ton, all-steel gondola cars from the Cambria Steel Co., and 250 thirty-ton steel underframe box cars from the American Car & Foundry Co.

RAILROAD STRUCTURES.

Acapulco, Guerrero, Mex.—The Mexican government, it is said, has plans under way for harbor improvements here to cost several million dollars. The preliminary work includes a new wharf, for which contract has been let.

Brandon, Man.—Plans, it is said, are being made by the Canadian Northern to put up a new passenger station here.

Empalme, Sonora, Mex.—Work is now under way putting up reinforced concrete shops for the use of the Cananea, Yaqui River & Pacific and the Sonora division of the Southern Pacific here. It is said that over $1,000,000 gold is to be spent for general improvements. Plans call for the erection of 15 buildings, including a tie treating plant to have a capacity of 4,500 ties a day.

Mobridge, S. Dak.—The new steel bridge of the Chicago, Milwaukee & St. Paul, at this place, has been opened for traffic. It is said that the company will put up a new steel bridge at Chamberlain this year.

Port Bolivar.—The Santa Fe, it is said, has spent about $100,000 on improvements here, including a pier, and will spend about $100,000 more to finish the work. Port Bolivar, which is the deep water terminal of the Gulf & Interstate division of the Santa Fe, is five miles east of Galveston on the main land, is being developed into an important port by the Santa Fe. The Gulf & Interstate, which runs from Port Bolivar east to Beaumont, is also to be rehabilitated.

Pottsville, Pa.—The Pottsville Union Traction Co., it is said, will build a bridge at Mauch Chunk street.

St. Johns, N. B.—Bids, it is said, are wanted by William Downie, General Superintendent of the Atlantic division, Canadian Pacific, for the construction of concrete piers and arches for bridges at various points on the road.

Saskatoon, Sask.—The Grand Trunk Pacific and the Canadian Northern, it is said, will jointly put up a passenger station here.

Winnipeg, Man.—Bids are wanted April 15 by M. H. MacLeod, General Manager, Canadian Northern, Winnipeg, Man., for putting up a union passenger station, hotel and terminal shops, here, for the joint use of the Canadian Northern and the Grand Trunk Pacific. The estimated cost of the improvements is $3,250,000.

RAILROAD CONSTRUCTION.

New Incorporations, Surveys, Etc.

Atchison, Topeka & Santa Fe.—Excavation work has been finished on the new double-track tunnel through Raton Mountain, near Raton, N. Mex., to be 5,000 ft. long through solid rock, and 144 ft. below the existing tunnel, and the bore is being cemented. It is expected to have the tunnel in service in July. The Lantry Construction Co., of Kansas City, Mo., contractors. (March 13, p. 389.)

Birmingham & Gulf Railway & Navigation Co.—Incorporated last year in Alabama with $10,000,000 capital, to build an electric line from Tuscaloosa, Ala., northeast via Birmingham to Gadsden, about 120 miles; also to operate a line of steamers and coal barges between Tuscaloosa, Mobile and Gulf points, and Montgomery and Mobile. The company has bought the Tuscaloosa Belt Railway, a 12 mile belt line at Tuscaloosa, which is being electrified. Work is now under way on the 120 miles between Tuscaloosa & Gadsden. Henry S. Thompson, President, New York; J. A. Vandergrift, General Manager, Tuscaloosa.

Canadian Northern.—The city authorities at Winnipeg, Man., it is said, will compel this company to construct a concrete subway under Water street.

Canadian Pacific.—This company, it is said, has given a contract to Janse & MacDonald, of Maple Creek, Sask., to build a new line on the north side of the river from Lethbridge, Alb., west to McCloud, about 36 miles. The old line south of the river which has steep grades, it is said, is to be abandoned. Work is now under way on a large bridge over the Lethbridge river for the new line.

Canadian River Railroad.—See Santa Fe, Liberal & Englewood.

Chicago, Milwaukee & St. Paul.—This company is reported to be ballasting and relaying its extension from Mitchell, S. Dak., to Rapid City, the track from the Missouri west, having been originally laid on a gumbo roadbed, making it almost impossible to operate in wet weather.

Durango & Sombrerete.—Surveys are reported made by this company for a proposed line, from Durango, Durango, Mex., southeast to Sombrerete, Zacatecas, about 100 miles. It is said contracts for building the line will shortly be let. Mining interests of Sombrerete are promoting the line to provide an outlet for the ores from that section.

Grand Trunk Pacific.—Contracts for building 365 miles additional in New Brunswick, Quebec and Ontario, was recently let by the National Transcontinental Railway Commission as follows:

(1) District A. New Brunswick, from a point 58 miles west of Moncton to the crossing of the Intercolonial Railway, 39.7 miles. Grand Trunk Pacific Construction Co.

(2) From last named point to the Tobique river, N. B., 67 miles. Grand Trunk Pacific.

(3) From the last named point to $2\frac{1}{2}$ miles west of Grand Falls, N. B., 31.5 miles. Willard Kitchen Co., Ltd., Fredericton, N. B.

(4) From boundary line between Quebec and New Brunswick west, 52.9 miles. M. P. & J. T. Davis.

(5) From west of Abitibi river crossing, Ontario, west 100 miles. E. F. & G. E. Farquler, Ottawa.

(6) From about $19\frac{1}{2}$ miles west of the crossing of Mud river, near Lake Nepigon, east, 75 miles. E. F. & G. E. Farquler, Ottawa. (Mar. 20, p. 429.)

Foley, Welch & Stewart, who have the contract for building 126 miles from a point six miles east of Edmonton, Alb., west, have sublet some of the work as follows: Chas. Lawrence, six miles; D. Fitzgerald, 12 miles; John Timothy, eight miles, James O'Connor, 11 miles; Fitzgerald & Tompkins, five miles; F. Mann, three miles, and MacDonald & McAllister, 10 miles. Additional sub-contracts will shortly be let by H. J. Fetter, of Edmonton, Alb.

Great American.—Incorporated in South Dakota, with a capital of $15,000,000, by Wisconsin capitalists and nominal headquarters at Pierre, and office at Chicago, and at Lancaster, Wis. The proposed route is from Chicago, Ill., northwest to Winnipeg, thence west to

Medicine Hat, Alberta. The incorporators include A. J. Hyde, Thomas T. Orton, J. C. Brockert, H. L. Moses, Lancaster, Wis., and I. W. Goodner, Pierre, S. Dak.

Illinois Central.—It is announced that regular through freight traffic over the Birmingham extension will be begun on April 19.

Interlake Railroad.—Incorporated in Illinois to build a line from a point on Lake Michigan, in Cook county, Ill., northwest to Fox Lake, in Lake county, about 30 miles. The incorporators include Otto Heper, M. F. Smith, G. S. Melcher, G. H. Coney and F. A. Stuckman.

Lake Shore & Michigan Southern.—On the extension of the Pittsburgh & Lake Erie, from Youngstown, Ohio, to Lake Erie, contract was let last year by the Lake Erie & Pittsburgh to the Carter Construction Co., to build from Mill Creek Junction, near Cleveland, southeast to Kent, 26 miles. Grading and bridge construction will soon be finished. Track laying is to be started early in May and the line from Mill Creek Junction to Kent will probably be ready for operation this fall.

Manistee & North-Eastern.—Surveys are being made by this company for an extension of its eastern branch from Wexford, Mich., northeast toward Alpena.

Mexican International.—Contract is reported let to B. Corrigan, of Monterey, Mex., for building a branch coal line through the Cloete coal fields in the state of Coahuila, connecting with the main line at Sabinas. The contract also calls for building a large bridge over the Santiago Papasquiero river, on the Tepehuanes division.

Mexican Roads.—A system of railroads about 200 miles long, it is said will be built in the state of Zacatecas, Mexico, to connect the various mining districts. The state government has granted a subsidy of $2,000 per kilometer and the right of way across the public lands has also been donated. American Smelting interests headed by R. S. Towne, are reported back of the project.

New York Subways.—The New York Public Service Commission, First district, will begin advertising for bids for building the Fourth avenue subway in Brooklyn April 6. Construction of this subway was approved by the Board of Estimate on March 27. It is to run from the Brooklyn end of the Manhattan bridge under the Flatbush avenue extension to Fulton street, thence to Ashland place, thence to Fourth avenue and under Fourth avenue as far as Forty third street, Brooklyn. The work is divided into six sections and separate contracts will be let for each section. Nothing will prevent one contractor from bidding on all six sections. The estimated cost for the six sections is about $15,000,000. Comptroller Metz opposed the resolution on the ground that the city's finances were not in condition to build the entire subway at the present time, and announces that he will refuse certification of contractors' checks accompanying bids so as to bring the matter into the courts. (March 13, p. 393.)

Northern Dakota.—An officer writes that bids are wanted April 15 for building this proposed line from Edinburg, N. Dak., on the Great Northern, north to a point near Hallson in Pembina county, thence northwest to a terminal not yet named on the Canadian boundary, in Cavalier county, about 21 miles. The work includes a 300-ft. pile trestle. Thos. D. Campbell, President and General Manager; C. H. McFarlane, Chief Engineer, Grand Forks, N. Dak. (March 13, p. 393.)

Rome & Osceola.—This company is to be incorporated to build from Rome, Oneida county, N. Y., north to Osceola, Lewis county, 25 miles. The names of the incorporators are not given.

San Diego & Arizona.—This company, which has some surveys made for its proposed line from San Diego, Cal., east to Yuma, Ariz., 200 miles, and a small amount of grading finished near San Diego, is being promoted by John D. Spreckles, of San Francisco. A concession, it is said, has been asked for by the same interests from the Mexican government to build south on the peninsula of Lower California to Magdalena bay, thence across the peninsula to the port of La Paz. It is proposed to build a line about 700 miles long.

San Juan, Taviche & Oaxaca.—This company is now owned by the Consolidated Metals Co., with headquarters at Oaxaca. It is said that the new owners have given contracts for an extension to the Taviche mining camp, in the state of Oaxaca.

Santa Fe, Liberal & Englewood.—An officer writes that work is under way at various points building this line from Des Moines, N. Mex., east via Hooker to Woodward, Okla., with a branch from Gate, Okla., northeast to Englewood, Kan., a total of 321 miles. The Canadian River Railroad, building from the proposed terminus at Woodward, southeast to Watonga, from which place there are to be two branches, one east to Guthrie and the other southeast to Oklahoma City, is to form part of this line. Very little construction work has been finished on this line.

York (Pennsylvania) Railway (Electric).—This company recently opened for traffic its new line from York Pa. southwest to Hanover, 18½ miles. Plans are reported underway for an extension from York to Harrisburg.

RAILROAD CORPORATION NEWS.

Atchison, Topeka & Santa Fe.—A semi-annual dividend of 2½ per cent. was on April 1 declared on the common stock. This is at the annual rate of 5 per cent., which is a reduction from the 6 per cent. rate, which has been paid for one year. Before April, 1907, the rate was 5 per cent., and from 1902 to 1905, 4 per cent. The first payment on the common stock was made in 1901, when a dividend of 3½ per cent. was paid.

Gross earnings for February decreased 9 per cent. as compared with February, 1907. Net earnings decreased 5½ per cent. There were 166 more miles operated in 1908 than in the previous year.

Birmingham & Gulf Railway & Navigation Co.—This company has bought the 12 miles of belt railroad, formerly owned by the Tuscaloosa Belt Railway, at Tuscaloosa, Ala. This is now being electrified and contracts have been let for a 120-mile extension to Gadsden. George D. Rogers, 12 Broadway, New York, is Secretary and Treasury. (See Railroad Construction column.)

Chicago, Cincinnati & Louisville.—The receiver has applied to the United States Court for permission to issue $1,500,000 receivers' certificates. He says that the road has never been fully completed or equipped. It needs to be reballasted, side tracks must be put in at Cincinnati and other points, the freight-house at Cincinnati must be enlarged, an overhead crossing must be built at the Big Four tracks to avoid threatened suit, an additional telegraph wire from Cincinnati to Chicago must be strung, a roundhouse and other improvements must be made at the Peru shops, a station must be built at Hammond, a station should be built at Converse, coaling stations should be put in at Richmond and at Brighton and other improvements must be made. About $500,000 to $600,000 would cover the foregoing. Furthermore, though a good passenger business is done at night between Cincinnati and Chicago in Pullman cars, the day business is bad because of the poor day coaches; $100,000 should be spent for parlor cars, café cars and day coaches. Not less than $300,000 to $400,000 worth of freight cars are also needed. There are charges against the road by other roads for handling C., C. & L. cars, which, if not paid, will result in the company's being shut off from communication with other roads. There are claims for labor, material and supplies. The receiver thinks that by using $1,500,000 it will be possible to earn not only operating expenses, but enough to meet all fixed charges and so increase the value of the property that when finally sold a price more than $1,500,000 greater than could now be obtained will be received.

Chicago Great Western.—Gross earnings for the six months ended December 31, 1907, decreased 9 per cent., as compared with 1906. Net earnings were $817,000, against $1,500,000 in 1906, a decrease of 45 per cent. There was a deficit of $360,000 after paying interest on the debenture stock and all prior charges, as against a surplus of $520,000 in 1906. Cash on deposit on December 31, 1907, amounted to $2,256, while the company's bank account had been overdrawn $109,715.

Chicago Junction Railway.—See Indiana Harbor Belt.

Chicago Union Traction.—The preferred stock has been assessed $3⅓ a share and the common stock $1 a share, payable on or before May 1, 1908. The present plan of reorganization involves cutting down the $12,000,000 preferred stock to $6,000,000 and the $20,000,000 common stock to $5,000,000.

Colorado & Southern.—Gross earnings for February were $1,083,000, against $1,027,000 in February, 1907. Net earnings were $330,000, against $314,000 in 1907. Owing to an increase of $16,700 in the interest charges, there was a decrease of $1,366 in surplus after charges.

Delaware & Hudson.—This company owns all but one share of the $1,000,000 common stock of the New York & Canada Railroad. This one share has recently been bought by Vice-President W. H. Williams for a price said to be $1,500. The Delaware & Hudson is now asking from the Public Service Commission, Second District, authority to acquire this remaining one share and to absorb the New York & Canada. The New York & Canada runs along the west side of Lake Champlain from Whitehall, N. Y., to Rouses Point, and forms a part of the Delaware & Hudson's through line to the Adirondack mountains and Montreal.

Denver & Rio Grande.—Gross earnings for February were $1,2[illegible], against $1,500,000 in 1907. Net earnings after taxes were $377,000, against $417,000 in 1907. For the eight months ended February 29 net earnings after taxes were $4,69[illegible] in 1908, against $4,636,000 in 1907.

Erie.—This company has been authorized by the Public Service Commission, Second District, to issue $15,000,000 notes dated April 1, 1908, and payable on or before July 1, 1913, secured by general lien 4 per cent. bonds to the amount of $9,157,000 and Pennsylvania collateral 4 per cent. bonds not exceeding $750,000, as collateral. These notes have not, so far as is known, been sold, although the Erie has $5,500,000 discount notes maturing on April 8, besides other pressing obligations.

Grand Trunk Pacific.—The Transcontinental Railway Commission is to buy the Temiscouta Railway for use as part of the line from Moncton, N. B., via Quebec, to Winnipeg, Man., 1,800 miles. The Temiscouta Railway runs from Riviere du Loup via Edmundston Junction to Connors, 113 miles. Only the line from Riviere du Loup to Edmundston Junction, 81 miles, will probably be used as part of the through line.

Great Northern.—The following controlled companies are now owned directly by the Great Northern:

St. Paul, Minneapolis & Manitoba	Montana & Great Northern
Eastern Railway of Minnesota	Billings & Northern
Willmar & Sioux Falls	Spokane Falls & Northern
Park Rapids & Leech Lake	Columbia & Red Mountain
Minnesota & Great Northern	Washington & Great Northern
Duluth, Watertown & Pacific	Seattle & Montana
Dakota & Great Northern	Minneapolis Union
Montana Central	

Gulf & Ship Island.—Net earnings for February were $16,000, against $65,000 in 1907, a decrease of 75 per cent.

Indiana Harbor Belt.—The report of the Chicago Junction Railway for the year ended December 31, 1907, has the following statement in regard to the sale of the outer belt line of the Chicago Junction to the Indiana Harbor Belt:

> That part of the railroad of the Chicago Junction Railway known as the "outer belt," which is the railroad originally belonging to the old Chicago, Hammond & Western, has been sold under the terms of contract dated June 29, 1907, between the Chicago Junction Railway and the Indiana Harbor Belt Railroad, the Lake Shore & Michigan Southern and the Michigan Central. The consideration received consisted of $2,500,000 bonds issued by the Indiana Harbor Belt Railroad. These bonds bear interest at the rate of 2 per cent. per annum for the first five years, 3 per cent. per annum for the second five years, and 4 per cent. per annum thereafter, and the principal is payable July 1, 1957. The bonds are guaranteed as to principal and interest by the Lake Shore & Michigan Southern and the Michigan Central. The so-called "outer belt" was subject to a mortgage executed by the old Chicago, Hammond & Western, to secure an outstanding issue of $2,500,000 6 per cent. bonds, and connected with it were contracts with other railroads which involved constant expenditures for increased trackage and facilities. This mortgage and indebtedness and the performance of these contracts were assumed by the purchasers. As the property would require the immediate expenditure of large sums for necessary betterments and improvements, and increased facilities, the sale upon the terms stated was considered highly advantageous to the Chicago Junction Railway. The result has been to relieve it from liability for the payment of the $2,500,000 of existing bonds and the fixed charge of $150,000 per annum, as well as from the necessity of providing large sums for improvements and for additional trackage under existing contracts.—(Nov. 15, 1907, p. 666.)

Leavenworth, Kansas & Western.—See Union Pacific.

Lehigh Valley.—Gross earnings for February were 10 per cent. less than in February, 1907, and net earnings 50 per cent. less. This is the worst showing which the road has made in any month of the present depression.

Louisiana & Arkansas.—Net earnings for February were 50 per cent. less than in 1907.

Metropolitan Street Railway.—See New York City Railway.

National Railways of Mexico.—On March 28 the public deed of incorporation of the new company, in which are to be merged the Mexican Central, the National of Mexico and other railroads controlled by the Mexican government, was signed by 23 incorporators, headed by Minister of Finance Limantour. (March 6, 1908, p. 330.)

New York City Railway.—Messrs. Joline & Robinson, as receivers of the Metropolitan Street Railway, has been authorized by the United States Circuit Court to issue $3,500,000 one-year 6 per cent. receivers' certificates, no part of whose proceeds may be used except in the improvement, acquisition and maintenance of the property. (March 20, 1908, p. 430.)

Kuhn, Loeb & Co. offer to pay the semi-annual interest coupon, due April 1, 1908, on those of the 4 per cent. refunding 100-year mortgage bonds of the Metropolitan Street Railway, which have been deposited subject to the bondholders' agreement, prior to May 15, 1908. This same firm took similar action in regard to the coupons defaulted January 1 on the 4 per cent. bonds of the Third Avenue Railroad.

Pacific Coast Company.—A quarterly dividend of $1\frac{1}{4}$ per cent. has been declared each on the second preferred and the common stock, making an annual rate on each of 5 per cent., instead of 6 per cent. annually, which has been paid since 1905 on each of these classes of stock. The Pacific Coast Company operates five steamship lines along the Pacific coast from Nome, Alaska, to Mexico, and also owns the Columbia & Puget Sound Railroad, about 50 miles, and the Pacific Coast Railway, with 80 miles of narrow gage line.

Pennsylvania.—Gross earnings of the Lines East, directly operated, decreased 14 per cent. in February, 1908, as compared with February, 1907. Net earnings decreased 17 per cent. For the two months ended February 29 gross decreased 15 per cent. and net 20 per cent.

Shipments of bituminous coal originating on the Pennsylvania Railroad Company's Lines East of Pittsburgh and Erie for the three months from Dec. 31, 1907, to March 28, 1908, were 8,093,033 tons, against 9,196,623 tons in 1907, a decrease of 12 per cent. The coke shipments were 1,718,252 tons, against 3,433,088 tons in 1907, a decrease of 50 per cent.

Philippine Railway.—This company controls the projected railroads on the Philippine Islands other than Luzon, the lines on that island being controlled by the Manila Railway. The Philippine Railway has 10 miles in operation on the island of Cebu and 20 miles more on that island under construction. On the island of Panay, 40 miles are under construction. Its contract with the Philippine government calls for the construction of a total of 95 miles on Cebu, 100 miles on Panay and 100 miles on Negros. The New York Stock Exchange has recently listed $1,500,000 first mortgage 4 per cent. 30-year bonds of 1937, guaranteed by the Philippine government, and has authorized the listing prior to July 1, 1908, of $1,000,000 additional of these bonds.

Reading Company.—Gross earnings of the Philadelphia & Reading in February were $2,600,000, against $3,100,000 in 1907. Net earnings were $770,000, against $889,000 in 1907.

Rock Island Company.—It is reported that plans are under way for the separation of the Chicago, Rock Island & Pacific, the Choctaw, Oklahoma & Gulf, which is the Choctaw division of the Chicago, Rock Island & Pacific, and the St. Louis & San Francisco. Strong protest against the present close combination between these roads has been made by the state authorities of Oklahoma.

Southern.—Gross earnings for February were 16 per cent. less than in 1907. Net earnings decreased 9 per cent. Taxes increased 18 per cent. and net earnings after taxes decreased 15 per cent.

Temiscouta Railway.—See Grand Trunk Pacific.

Texas Southern.—The foreclosure sale of this road, often advertised and postponed, is now set for May 5; the upset price, $375,000. The road, which runs from Winnsboro to Marshall, 74 miles, with four short branches, making a total operated mileage of 109 miles, is said to be in a chaotic state.

Third Avenue Railroad.—Frederick W. Whitridge, Receiver of the Third Avenue Railroad, and of the Forty-second Street, Manhattanville & St. Nicholas Avenue Railway, has been appointed by Judge Lacombe, of the United States Circuit Court, Receiver of the Union Railway, one of the subsidiaries of the Third Avenue Railroad. The Union Railway operates street railways in the borough of the Bronx, New York City.

Tuscaloosa Belt.—See Birmingham & Gulf Railway & Navigation Co.

Union Pacific.—A special meeting of the stockholders will be held on May 5 to ratify the taking over of the physical properties of the Leavenworth, Kansas & Western, which runs from Leavenworth, Kan., to Miltonvale, 166 miles, and has been operated separately, although all of its stock is owned by the Union Pacific; and of the Topeka & Northwestern, which is a cut-off from Menoken, Kan., to Onaga, with an extension under construction to Marysville, in all 69 miles. This cut-off is to connect Kansas City with the main line in Nebraska. The stockholders are also to authorize an issue of bonds on the (about) 1,650 miles of line of the Union Pacific now mortgaged, including the two railroads already named. This bond issue will probably be about $50,000,000, secured by a first mortgage on these lines.

The directors of the Union Pacific have denied the request of certain stockholders that they should sue E. H. Harriman, H. H. Rogers and James Stillman, directors, for personal profits alleged to have been made by them in the sale of stocks held by them to the Union Pacific, and have made the statement that the ownership of the three directors named in certain of the stocks bought during the latter half of 1906 was known to the Board, and that these directors were excused from voting on the matter of purchase, furthermore, that so far as is known by the Board, and it is so informed by Kuhn, Loeb & Co., none of these directors had any ownership in the 105,000 shares of the Illinois Central stock purchased by the Union Pacific from that firm.

RAILROAD GAZETTE

ESTABLISHED IN APRIL, 1856.

PUBLISHED EVERY FRIDAY BY THE RAILROAD GAZETTE AT 83 FULTON STREET, NEW YORK

BRANCH OFFICES AT 375 OLD COLONY BUILDING, CHICAGO, AND QUEEN ANNE'S CHAMBERS, WESTMINSTER, LONDON

EDITORIAL ANNOUNCEMENTS.

THE BRITISH AND EASTERN CONTINENTS edition of the Railroad Gazette is published each Friday at Queen Anne's Chambers, Westminster, London. It contains selected reading pages from the Railroad Gazette, together with additional British and foreign matter, and is issued under the name Railway Gazette.

CONTRIBUTIONS.—Subscribers and others will materially assist in making our news accurate and complete if they will send early information of events which take place under their observation. Discussions of subjects pertaining to all departments of railroad business by men practically acquainted with them are especially desired.

ADVERTISEMENTS.—We wish it distinctly understood that we will entertain no proposition to publish anything in this journal for pay, EXCEPT IN THE ADVERTISING COLUMNS. *We give in our editorial columns* OUR OWN *opinions, and these only, and in our news columns present only such matter as we consider interesting and important to our readers. Those who wish to recommend their inventions, machinery, supplies, financial schemes, etc., to our readers, can do so fully in our advertising columns, but it is useless to ask us to recommend them editorially, either for money or in consideration of advertising patronage.*

OFFICERS.—In accordance with the law of the state of New York, the following announcement is made of the office of publication, at 83 Fulton St., New York, N.Y., and the names of the officers and editors of The Railroad Gazette:

OFFICERS:

W. H. BOARDMAN, *Prest. and Editor*
E. A. SIMMONS, *Vice-President*
RAY MORRIS, *Secretary*
R. S. CHISOLM, *Treas.*
I. B. RINES, *Cashier*
L. B. SHERMAN, *Western Manager*

EDITORS:

RAY MORRIS, *Managing Editor*
BRAMAN B. ADAMS
CHARLES H. FRY
FRANK W. KRAEGER
GEORGE L. FOWLER
HUGH RANKIN
BRADFORD BOARDMAN

CONTENTS

VOL. XLIV., No. 15. FRIDAY, APRIL 10, 1908.

We print in another column a full abstract of the address recently delivered by Arthur Hale to a committee of the Massachusetts legislature opposing a reciprocal demurrage bill. Mr. Hale is always worth listening to, and when he talks about car service he has a way of expressing rather more clearly than anybody else a lot of principles that the average operating man understands but has never really thought out or formulated in his own mind, and that the average state legislator does not understand at all. What Mr. Hale had to say, reduced to its shortest and most impolite terms, was that reciprocal demurrage is not reciprocal, that it is an unfair and unwise principle and that New England has too many detention privileges already; but he put these plain truths in so amiable and convincing a fashion that it must have dispelled any illusions that existed in the minds of his hearers about this rather illusive subject. We are printing a good deal of Mr. Hale's address because we want it to be read in states that need it even more than Massachusetts does.

Although the electric motor is the ideal means for moving draw spans which must be turned by power, an examination of existing practice indicates that its adaptation to the work has not been well understood in the past. For example, a 250-ft. double track swing span weighing 600 tons is equipped with two 50-h.p. railway type motors. The maximum effort required of these motors, according to the ammeter readings, is about 45 h.p. In another case a 350-ft. double track swing span having twice the weight of the first, or 1,200 tons, is to be equipped with two 25-h.p. motors. A third case, a proposed 480-ft. double track span of 1,800 tons, is to have two 40-h.p. motors—three times the weight with four-fifths the power of the first. In the first instance the power provided obviously is excessive. What of the other two, which agree pretty closely? The greatest resistance to overcome in such service is the inertia of the span. Some recent experiments have shown that when the average angular velocity is approximately 1 deg. per second, about 80 per cent. of the effort of the motor is used in accelerating the motion of the span. This requires a large torque at starting and a uniform accelerating effort, conditions that are best met by the characteristics of the direct current series motor. In determining the design and capacity of the motor both the character of service and the maximum requirements are governing conditions, and it is here that advantage may be taken of a peculiar quality in electric motors to secure the most economical installation possible. An electric motor properly designed is capable of sustaining a considerable overload for a short period of time without injurious heating. Therefore where a motor is loaded intermittently and for short periods, with intervals of rest between, it can be made to do work considerably in excess of its normal rated capacity. Furthermore, it may be specially designed for this intermittent loading and therefore be even better adapted to the work than a motor designed for continuous duty. The duty of a drawbridge motor is unique in that the working period covers only a few seconds of time and the cycles of operations may be separated by long periods of rest. For illustration, take the 250-ft., 600-ton span mentioned above. Assume it must be turned 90 deg. in 60 seconds. The demand on the motor is for 45 h.p., increasing from zero to a maximum at the end of 40 sec., say. Assume a rest period of 15 min. At 500 volts the maximum current used is 67 amperes. It can be shown that the equivalent heating effect of this current applied for 40 sec., followed by a period of rest of 900 sec., would be produced by a current of 14 amps., or about 10 h.p. at 500 volts, if continuously applied. Obviously, therefore, even one motor having a continuous capacity of 45 h.p. is too large for the service. What is required is a motor rated on its intermittent capacity of the full horse-power at full voltage for such a length of time as will produce the requisite temperature rise in service.

The "Bureau for the Safe Transportation of Explosives and Other Dangerous Articles" has been in operation since June 10, 1907. The report of Major B. W. Dunn of the United States Army who is Chief Inspector, covering the work of the Bureau up to February 1, 1908, is summarized in another column. This association is a splendid example of the way in which necessary and important results, which it has been proved by bitter experience it would be impossible to get by individual initiative, can be successfully brought about by intelligent co-operation. After the disastrous wreck in 1905 on the Pennsylvania Railroad near Harrisburg, Pa. caused by the explosion of a freight car loaded with high explosives, the Pennsylvania tried for two years through its own special inspectors to secure conformity to the revised rules of the American Railway Association for the transportation of explosives which had been amended as a result of this disaster. This company was successful in carrying out these regulations on its own lines; nevertheless only a small proportion of the dangers from explosives were guarded against, because this one railroad company was powerless to enforce these regulations on connecting lines from which dangerous cars were constantly being received. President McCrea, of the Pennsylvania, was the leading spirit in the formation of the Bureau of Explosives, being chairman of the committee which drew up its constitution and by-laws. The bureau includes such members of the American Railway Association as choose to become members. Expenses are proportioned according to: (a) mileage; (b) gross earnings; (c) number of factories on each line where explosives are made. Its regulations for transportation of explosives were published in the *Railroad Gazette* of November 8, 1907. There are at present 91 railroad companies operating 149,669 miles of railroad which are members. The Baltimore & Ohio, the Chicago, Milwaukee & St. Paul, the Great Northern and the Northern Pacific are large roads which have not yet joined the Bureau. This mileage of nearly 150,000 miles is distributed among 17 local inspectors whose mileage runs from the 4,000 miles in the Indianapolis district to the 23,000 miles in the Kansas City district. The most striking results of the inspections can be summed up in three items from the summary: During the less than eight months covered by the report, the inspectors found 119 magazines with dirty floors stained with nitro-glycerine and 59 magazines with high explosives stored in them in a leaking and dangerous condition. Out of 178 cars inspected in transit or at terminals, the lading in 99 had moved because of improper loading or staying or other conditions such as would easily bring about a dangerous accident. One of these cars, which had cracks in the roof, sides and ends, contained over two tons of dynamite. Light material had been used to brace these packages and the bracing had given way, allowing the packages to slide about the car. As if this were not enough, loose iron pipe and a roll of wire cable in an upright position were loaded in the same car. The car was placarded for explosives on one side only. Here were conditions ripe for a terrible and costly accident. Based on experiences such as these, the fact that in spite of all that has been accomplished only 41 of the 94 railroads which are members of the Bureau had on February 1, received either a "first general inspection" or a "partial inspection," and the further fact that the Bureau is about to issue regulations for transportation of inflammables whose traffic volume is many times that of explosives, Major Dunn makes a strong plea for more inspectors. In his words, "the Bureau has undertaken a work of unsuspected magnitude." Great good has already been accomplished, actually and potentially. The Bureau must either go forward or backward; at the present stage of its development it cannot stand still. More funds are necessary if it is to do its now evident duty. The present is, of course, a difficult time to secure larger appropriations from railroads, but Major Dunn points out that the total of the known losses from the six major accidents from explosives and one large fire from a shipment of inflammable liquid, shown in the records of the Bureau for 1907, was over $500,000 and even this does not represent by any means the total loss. If such losses are to be prevented in future the Bureau must be upheld in its work.

THE REASON FOR THE STEEL WHEEL.

It is a peculiarity of American railroad rolling stock that there is a roughness of finish and a crudeness of connection, not only between stationary parts, but also between parts that have some motion, the one over the other, that is not to be found in cars built in other countries. The reason for this is not hard to find. America was a great, undeveloped, sparsely settled country and the railroad, as a rapid means of intercommunication, was an absolute necessity for the upbuilding of the nation. In order to meet this demand, construction was carried on with great rapidity and pushed through territory where the immediate traffic in sight was very meagre. Consequently the first cost of roadbed and equipment was cut down to the lowest notch that made operation a possibility and so cast iron was substituted for forgings and rough metal for finished parts. Therefore, while the foreign car builder turned to wrought iron for the centers and early tires of his wheels, the American, being in possession of a very superior grade of cast iron that was not only exceedingly strong, but capable of being chilled to great hardness in the mould, used that metal for his wheels with great success under both passenger and freight cars.

Throughout all the middle years of the nineteenth century, cast iron was the only metal used for car wheels in the United States, and during the whole of this period makers were constantly experimenting with mixtures of metals and forms of patterns in order to produce a wheel that would possess some quality that would make it superior to its rivals. The records of the patent office are replete with the work of the designers in this direction. The result of this concentration of energy was the production of a wheel that took a high rank in the records of the time for durability and safety and was known as the charcoal iron wheel. Such a wheel was usually formed of about 85 per cent. of charcoal iron pig and 15 per cent of the scrap iron resulting from this mixture, melted with the old companies' Lehigh coal, and was possessed of a chilled tread of great hardness and durability.

Meanwhile there had been no uniformity of practice in the form of the tread and flange, and other parts of the wheel. Each maker or purchaser had been a law unto himself, with the result that great variations of practice existed in different sections of the country and upon different roads in all of the details of wheel construction. Under the conditions existing at the time, this was a matter of comparatively small importance. The individual railroads were almost isolated, there was a diversity of gages, and interchange of traffic was so small that it was not until after the organization of the Master Car Builders' Association that any systematic effort was made to introduce a uniformity of practice into car wheel construction.

That association originated in a meeting of master car builders brought together to consider the conditions set up by the running of line cars over their respective roads and the rules under which such an interchange of traffic should be carried on. It was quite natural then that the wheel should be among those details that should receive early attention. It was necessary that it should run over tracks that differed slightly in gage; that were laid with rails of widely different pattern, with still wider variation in the methods of track laying and permanent way construction. It was necessary that the tread and flange of the wheel should be so proportioned that it could run over these different conditions of track with ease and safety, and further that the wheel should be of such diameter that the height of the cars and their couplers might be brought approximately to a uniform distance above the rail, a condition that was not realized, however, until many years afterwards.

At the meeting of 1868 an agreement was reached, regarding the width of the compromise tread, and thereafter there was considerable private discussion as to the desirability of a standard tread and flange, but it was not until 1882 that the subject was really brought before the association for action. At that time an agreement was reached regarding the width over all, as well as the diameter and the machinery was set to work to secure a standard form. The next year forms for tread and flange were proposed and these were almost identical with those that were afterwards adopted. In 1884 M. N. Forney read an elaborate paper on the relation of the wheel to the rail, and at the next convention in 1885, a contour was submitted for adoption as a standard, but was rejected as that of 1883 had been. In 1886 another form was submitted in which the tread was made slightly conical instead of cylindrical as in the case of the one presented in 1885, and this was adopted as a standard and has remained such until the present time.

In 1906, it was modified and the modification adopted as recommended practice by the addition of ¼ in. to the thickness of the flange and the changing the taper of the tread from one in twenty-five to one in twenty. It is not probable that any further changes will be made for many years to come other than the abandonment of the old standard and the adoption of the recommended practice of 1906 in its stead.

Turning now to the character of wheels used during these early years we find that, as soon as the weights of passenger cars were increased above those obtaining in the late sixties and early seventies, due to the introduction of sleeping and parlor cars, managers felt a doubt as to the safety of the cast iron wheel for passenger service and the steel-tired wheel was introduced; slowly at first, but later it came into universal use except on a few roads with facilities for making their own wheels, so that they were put in a position of absolute control over methods and materials used.

At first the construction of the steel-tired wheel was somewhat complicated and involved the use of a large number of pieces. This was afterwards simplified to a great extent, and the parts made less. Meanwhile, when the first steel-tired wheels were placed in passenger service the standard capacity of the freight car of the country was 20,000 lbs. with the empty car weighing about as much more. In the later seventies there was a movement to increase the carrying capacity of these cars and in the succeeding fifteen years it rose to 60,000 lbs. Up to this time there had been no trouble with the cast iron wheel and no change had been made other than to increase the thickness of metal in the plates and hub to meet the requirements set up by the heavier load that was to be carried and the larger axle that was to be used. This heavier wheel apparently fully satisfied the requirements of the 60,000 lbs. capacity car, though there were some complaints of the inferiority of the later day wheel as compared with those of twenty-five years before. Whether the wheel was actually inferior or was as good and simply failed oftener because it did not have the same margin of strength as the older wheel is an open question.

Later when car capacities were raised to 80,000 lbs. there was no appreciable shortening of the average car wheel life as compared with those under cars 60,000 lbs. capacity. But when in the late nineties the cars of 100,000 lbs. capacity were introduced a new element was brought into play. Roads equipped with such cars began to have a great deal of trouble with broken flanges.

On level roads the wheels are apparently able to give better service, but on mountain lines where there are long continued applications of the brakes, overheating, checking and subsequent breakage are of common occurrence while the average life of wheels under these high capacity cars is approximately one-half that under cars of 60,000 lbs. capacity. Frequently the heating of the wheel by the brakeshoe sets up such internal strains that a crack will start in the body of the metal where no possible inspection could detect it and then it works outward until, when it reaches the surface, it has developed to such dimensions that the flange breaks without warning with results that are more or less disastrous.

Facing this condition, with doubts, on one hand, about the entire reliability of the cast iron wheel, and with the excessive cost of the built-up steel-tired wheel, on the other hand, rendering these wheels out of the question for freight work, a market has been opened for a cheaper steel wheel than any that has been upon the market.

But the service that has been required and rendered by the steel-tired wheel in passenger car and locomotive work has established a high standard of efficiency, and it is essential that any innovation in the methods of steel car wheel construction and design shall produce a wheel that, so far as the physical properties of the metal composing it are concerned, shall be fully up to the standards already set by the steel-tired wheel. Its chemical composition must be such that its hardness, ultimate strength, elasticity, and wearing qualities should stand in favorable comparison with the best, and this must be done at a price that will make it possible to use such a wheel in freight service at a cost not to exceed the cast iron wheel. This does not mean that the first cost is to be the same, but that, when the renewals are taken into consideration, the ultimate cost of wheels for a series of years shall be no greater with the steel than with the cast iron wheel.

THE PASSENGER AS A REFORM AGENT.

In a city not hundreds of miles from New York situated on a great railroad system there lived a "club man" who on his journeys to and from the metropolis often indulged in the luxury of a parlor or sleeping car. One day not long ago when starting on a long trip and seeking sleeping car accommodation he was, as he asserted, "held up" by the conductor of the car to the amount of $1 as a bit of personal "graft," in addition to the regular charge for the berth. On his return the passenger entered no formal complaint but made club land resound with his wrong. He had been robbed by a highwayman in the railroad company's uniform. The railroad company was not much better when it winked at such graft—and so forth and so on in the familiar terms of epithet of the angered and aggrieved passenger. The complainant, in one of his bursts of eloquence against the railroad, chanced to be overheard by one of the company's officers. The officer quietly started a careful investigation which in effect confirmed the dollar story and then called on the complainant to stand to his guns in a formal statement as basis for discipline of the offending conductor. Then the passenger backed water. He was one of the familiar type of men who are louder in talk than agile in action and who shirk even small responsibility. He refused to make formal complaint and declared that the dollar was but a gratuity pure and simple. And so the inquiry of the company with the improvement of the service as its aim came to naught.

A few weeks ago on one of the branch lines of the same railroad system another passenger was riding in the smoker on a special excursion ticket good on its face for that particular train. In insolent terms he was ordered back by the regular train conductor to three extra rear cars put on for excursionists. The passenger refused to go, showed the face of his ticket and stood successfully on his rights. Fifteen minutes later on asking an apology from the conductor he was refused. A week or two after, the same passenger, who was a lover of fishing, after a day's sport, cumbered with much angling *impedimenta*, reached a flag station of the same company after a toilsome pull at the oars and a hard trudge by highway. The train schedule called for a stop at the station and, by custom for years in the absence of the regular "drop" the stop signal was the waiting passenger on the platform, visible from far down the line. Here the waiting angler stood with two fish baskets, three bait pails and the same number of fishing rods like an animated semaphore. The engineer, afterwards alleging that he "didn't see," ignored the passenger and ran the train by and on. The train happened to be fifteen minutes late.

The outcome in these two cases was far different from the first. The aggrieved passenger followed up instantly each offense with a formal statement to the division superintendent. There was some delay—partly accidental—and cutting of red tape. But, in the end, after a fair investigation the conductor was summoned before the powers, found guilty, warned to exercise better courtesy and judgment and ordered to make apology to the passenger; and, in the case of the engineer, the result was substantially the same. A fair inference based on the rule of human motive and conduct justifies the conclusion that the conductor will hereafter be more heedful of duty and, what is of more importance, will spread his disciplinary experience among his mates to their own and the company's profit; that the engineer will not again run a belated train past a flag station in violation of the schedule; and that, in the earlier instance, the sleeping car conductor will be encouraged to continue his "graft." Incidentally it may be stated that the passenger who complained received official thanks.

These three cases are not fiction or parable. They are actual and recent instances which illustrate an evil and its remedy. Every railroad corporation, if wise, wants good service. It realizes or should realize that its chief point of contact with the public is in that service. It wants to subdue petty graft, to supply good cars, accurate train service, tactful and judicious conductors and faithful engineers and trainmen. Elements such as these are a part, and a large part, of the company's assets that connote public good will and reach up even to legislation. But a railroad corporation is not an Argus. It owns no accurate personal equation of its thousands of officials; and, in the detection of grievance, it must rely on the passenger's moral sense and individual backbone, its own responsibility ending when it offers the mechanism of prompt inquiry and correction. But it is against just such a condition that the average passenger fails to make good. He voices his wrong, real or imaginary, in private outcry, in an anonymous screed to a local newspaper or in "setting up" a sensational reporter with his tale. In not a few cases he swallows the offense in silence and says and does nothing. In his relation to the railroad company he belongs to that large group of citizens who in civic life are neglectful of duties and who would rather have things pleasant than have them right. When the railroad passenger reverses that too common viewpoint, drives his complaint home, reserves his outcry for the time when actual grievance is officially unredressed and recognizes his own *quasi* partnership with the railroad in improved service, then will the evil be minimized and the passenger himself become the advance agent of its reform.

NEW PUBLICATIONS.

Intercorporate Relationships of Railways in the United States, as of June 30, 1906. Prepared by the Division of Statistics and Accounts, Interstate Commerce Commission, Washington, D. C.

The Interstate Commerce Commission has issued its first special report under the amended Interstate Commerce Act. The report covers investigations intended to show the manner in which the railroad corporations have been welded into highly centralized systems, and to present a statement of net railroad capital outstanding in the hands of the public, eliminating all holdings of railroad securities by other railroad corporations. The statistical portion of the report is now in press; the portion at hand is the text only, but it shows, according to the Commission's calculations, that the net railroad securities of the country are on a basis of $58,050 per mile of line. This figure, which is of considerable statistical interest, is the only useful result which appears to have been accomplished by the very great amount of work which must have been spent upon the study. The report is illustrated with a number of diagrams showing the way the more complicated railroad systems have been formed together through the medium of holding companies. Although these diagrams are interesting, it is scarcely clear why the Interstate Commerce Commission should have spent time on them; as the subject matter is all of public record and easily obtained by those who are interested. The principal impression which the reader gains from the advance copy is a feeling of sympathy for the railroads, which had to answer the exceedingly complicated questions addressed to them by the Commission in a series of circulars in order to enable the Commission to bring out a number of well-known facts from original sources.

CONTRIBUTIONS

The Inland Waterways Commission and Transportation.

New York, March 23, 1908.

TO THE EDITOR OF THE RAILROAD GAZETTE:

For years the inhabitants of the Mississippi Valley have asked for such improvements of that stream and its affluents as would abridge either or both, the cost in time and money necessary for assembling and distributing commodities produced, consumed or transported for further increase of value in and about that basin. They labored under the impression that their efforts were impeded or nullified by the able chairman of the House River and Harbor Committee, and that the principle of proclaiming an unincreasable minimum and thus pitting locality against locality, popularly called log rolling, was being used with ability to continue the poverty of localities deficiently supplied with transportation facilities. This feeling led to action which is shown in the commencing sentence of our President's letter of March 14, 1907: "Numerous commercial organizations of the Mississippi valley have presented petitions asking that I appoint a commission to prepare and report a comprehensive plan for the improvement and control of the river systems of the United States. I have decided to comply with these requests by appointing an Inland Waterways Commission."

There follows this the names of his appointees, nine gentlemen, of whom Congressman Burton, chairman of the River and Harbor Committee of the House of Representatives, was at the President's suggestion made chairman of the committee, and by election of the committee Senator Newlands, of Nevada, is vice-chairman, and Dr. McGee, of the Bureau of Soils, is secretary. President Roosevelt seems to have handed those petitioners of the Mississippi valley, who desired cheaper transportation, a lemon. This vulgar and upstart word is used advisably. The classic "Dead Sea apple" has by reputation an inviting exterior. The report contemplates only inaction and delay. The committee contains no expert on transportation. Only one, General Mackenzie, apparently at all connected with transportation, and he, as chief of the United States Engineer Corps, dissents from his colleagues in three out of six items of a "Supplementary Report."

The chairman of the Commission has been highly and continuously praised for his services to the country in connection with River and Harbor bills by all "accelerators of public opinion" owned or employed by our railroad bankers. These services have been generally obstructive. The probable value of contributions to the science of transportation by the Secretary of the Commission may be judged by an extract from his speech at the "Atlantic Deeper Waterways Conference," Philadelphia, November 18-20, 1907. In this, after referring to the pre-revolutionary tax on tea (which Lord Acton said broke up the British Empire) he continued: "We are paying to our tyrant transportation a tax of 30 to 50 per cent. on all that we eat, wear or use in our every day lives. Our forefathers rebelled—why shouldn't we?" All this of the lowest freight rates in the world; substantially one-half those of Holland and Belgium, one-third those of Great Britain.

Vice-Chairman Newlands, at the same conference, referred to "men in our great financial centers who have been accustomed to gather together these fragmented railroads, form them into great combinations, and then force upon the country exaggerated volumes of bonds, preferred stock and common stock that bewilder the imagination." Those who traveled between Buffalo and New York, with four changes of trains to Albany and then ferried at that city, before Corning gathered together the fragmental railroads which he combined into the New York Central, will not particularly regret the combination. Nor will there be regret at the marked decrease in freight rates shortly following the consolidation. The Senator's idea of bonds, preferred stock and common stock being forced upon the country will perhaps not be concurred in by those who have worked early and late to obtain an infinitesimal percentage of the Senator's exaggerated volume. No recommendations of any potentiality in reducing the cost of transportation seem possible from a committee so officered.

President Roosevelt, however, basing his efforts on "the general and admitted inability of the railroads to handle promptly the traffic of the country," rather than on the economic value of capacious channels of exchange, the use of which cannot, without legislative action, be impeded by or to any one, endorses his appointees and their report in a message of transmission, Senate Doc. 325, as follows.

"This report is well worth your attention. It is thorough, conservative, sane and just. It represents the mature judgment of a body of men exceptionally qualified, by personal experience and knowledge of conditions throughout the United States, to understand and discuss the great problem of how best to use our waterways in the interest of all the people. If the report errs at all it is by over-conservatism."

Everyone has read, "that it was unregulated railroad competition which prevented or destroyed the development of commerce on our inland waterways." And there are traces on the public mind of a latent regret that the railroads could not have been so regulated as to make their freight rates as high as in Germany and so conserve the navigation of inadequate waterways. In the report prominence is given to Representative Burton's patent, which is "heartily" endorsed in the message, for impeding internal improvements by demanding an "equitable distribution" of their costs to the communities, etc., "beneficially affected." That is to say, e.g., we should have postponed building the Union Pacific Railroad until the Mormons (who, by the way, would have been starving before three years without it) could have contributed equitably to its cost. There may be some more ingenious way of continuing the poverty of localities whose principal products cannot bear the costs of production and transportation to market.
