2. **Lemon Juice** (*Succus Limonum*, L. [U. S.]).—A slightly turbid, very sour liquor, with a grateful flavour, obtained from lemons by expression and straining. Owing to the mucilage and extractive which it contains, it readily undergoes decomposition, though various methods have been proposed of preserving it. On this account, an *artificial lemon juice* has been proposed as a substitute. The juice, both of lemons and limes (the fruit of *Citrus Lima*, Macfadyen, or *C. acida*, Roxburgh), is extensively imported. In 1839, duty of one halfpenny per gallon was paid on 37,338 gallons of these juices. In the West Indies *lime juice*, is preferred to lemon juice.

According to Proust, *lemon juice* consists of *citric acid*, 1.77; *malic acid, gum*, and *bitter extractive*, 0.72; and *water*, 97.51. *Lime juice* contains the same ingredients, in somewhat different proportions: the quantity of citric acid in it is larger, while that of mucilage, &c. is less.

CITRIC ACID.—(See *ante*, p. 947.)

Lemon juice furnishes a most agreeable and refreshing beverage, and proves refrigerant and antiscorbutic. It is employed for several purposes, as follows:—

a. *In the preparation of refrigerant drinks*.—It may be either added to barley-water, or mixed with sugar and water to form *lemonade*. The latter may be extemporaneously made, by adding two lemons sliced, and two ounces of sugar, to two pints of boiling water, and digesting until cold. A similar beverage is called, by Mr. Brande,² *King's Cup*. These acidulated drinks are exceedingly useful for allaying thirst, and as refrigerants in febrile and inflammatory complaints, and in hemorrhages. In the latter maladies, *iced lemonade* should be preferred. Where there is nausea or a tendency to sickness, *effervescent lemonade* is useful. "Lemonade, as a beverage in putrid diseases, was first introduced by the French physicians in the beginning of the seventeenth century; and about the year 1660, an Italian

¹ Hebreton, *Journ. de Pharm.* xiv. 377.

² *Dict. of Pharm.* 341

from Florence, having learnt a process of freezing confectionery, conceived the happy idea of converting such beverage into ice. This found a ready sale, and was the occasion of so great an increase in the number of sellers of lemonade, that, in the year 1660, the *Lemonadiers* of Paris were formed into a company, and received a patent from the Government.¹

3. *In the formation of the effervescing draught.*—The effervescing draught, made with lemon juice (or citric acid) and bicarbonate of potash, is one of the best remedies we possess for allaying sickness and vomiting. The citrate of potash, which is formed, is a mild diaphoretic and diuretic, and often allays restlessness and watchfulness in fever. It is adapted for lithic acid deposits; but, like other remedies of the same class, is sometimes objectionable in phosphatic deposits. When our object is to determine to the skin, an effervescing draught, composed of lemon juice or citric acid and sesquicarbonate of ammonia, is to be preferred. The relative proportions of the alkaline carbonates, and of lemon juice or citric acid, for the formation of effervescing draughts, is as follows:—

<i>Citric Acid.</i>	<i>Lemon Juice.</i>	<i>A Scruple of the Alkali.</i>
Grains 14	or fʒiiiss	Bicarbonate of Potash.
Grains 17	or fʒiv	Carbonate of Potash.
Grains 24	or fʒvj	Sesquicarbonate of Ammonia.

Effervescing draughts are exceedingly valuable vehicles for the exhibition of other remedies.

γ. *As an Antiscorbutic.*—Lemon juice has long been regarded as an invaluable antiscorbutic; but on account of the difficulty of preserving it, crystallized citric acid is usually substituted. “Those only,” says Sir Gilbert Blane,² “who have made themselves acquainted with the early part of the naval history of this country, or those who have perused the interesting, popular, and eloquent narrative of Commodore Anson’s voyage, can duly appreciate the value of this simple remedy.” Yet, on hypothetical grounds, Dr. Stevens³ ventures to assert that citric acid produces scurvy!

δ. *As an Antidote.*—In poisoning by the alkalies and their carbonates, the vegetable acids are the antidotes; and the most convenient, easily procurable acidulous substances are, in general, vinegar and lemon juice.

ε. *As an Anti-narcotic.*—In poisoning by narcotic substances, as opium, lemon juice may be administered, after the poison has been removed from the stomach, to counteract the effects.

[*In Rheumatism.*—Lemon juice has been recommended as a remedy in acute rheumatism and gout by Dr. Owen Rees, and has been used with success by many practitioners, not only in this country, but in Italy, France, and America. Dr. Rees considers the citric acid to undergo changes in the stomach, and to supply oxygen to such elements as tend to produce uric acid, and thereby to induce the formation of urea and carbonic acid instead.—Ed.]

ζ. *Other Uses.*—Several of the medicinal uses of lemon juice can only receive a passing notice. Such are, the employment of it, with common salt, in *dysentery*, *remittent fever*, *bellyache*, and *putrid sore-throat* as recommended by Dr. Wright;⁴ its use in *cardialgia*, by Dr. Dewees; and in *syphilis*, by Dr. Rollo. *As a topical remedy for uterine hemorrhage*, after delivery, Dr. Evratt⁵ recommends that a cut peeled lemon be introduced into the uterus, and the juice there expressed. It causes uterine contractions, by which the juice is expelled and the hemorrhage stopped. In *hospital gangrene*, Dr. Werneck⁶ applied, with good effect, in the first stage of the disease, either lint soaked in lemon juice, or segments of lemons.

ADMINISTRATION.—The mode of employing lemons will be obvious from the preceding remarks.

⁶ *Dierbach, Neuest. Entd. in d. Mat. Med.* 3te Abt. S. 512, 1828.

1. **OLEUM LIMONUM**, L. E. D. [U. S.]; *Essential Oil of Lemon Peel; Essence of Lemons*.—This oil is usually procured by expression, as follows: the flavedo of the lemons is removed by rasping, and is afterwards expressed in hair sacks. The oil which is thus procured is received in flasks, where it deposits some of its impurities, and is then decanted and filtered.¹ Baumé² says the rasped flavedo is pressed between glass plates. Expressed oil of lemons is somewhat turbid, and liable to undergo change by keeping, owing to the mucilaginous matter which it contains in solution. Oil of lemons may be procured also by distillation; and the oil thus procured is pure, not disposed to undergo change by keeping, and is employed, under the name of *scouring drops*, for removing grease spots from silks and other textures; but its flavour is less pleasant and sweet. The greater part of the oil of commerce is brought from Portugal and Italy; some, however, is procured from France. When quite pure, it is colourless, limpid, and of a fragrant odour, like that of lemons. Its sp. gr. at 70° F. is 0.847. It is soluble in all proportions in anhydrous alcohol, and it boils at about 145° F. When the commercial oil is exposed to a temperature of -4° F. it deposits white crystals, the nature of which is not known; the rectified oil remains perfectly liquid and transparent at this temperature. Oil of lemons is composed of two isomeric oils, one (*citrene*, Dumas; *citronyle*, Blanchet and Sell) capable of forming, with hydrochloric acid, a crystalline compound (composed of $C^{10}H^8 + HCl$); the other (*citryle*) not forming any crystalline compound with this acid. The composition of the oil of lemons is $C^{10}H^8$; *i. e.* it is identical with that of the oil of turpentine, savin, copaiva, bergamot, and citron.³

Oil of essence of lemons possesses the stimulant properties of the milder volatile oils, and is denominated carminative and diaphoretic. In full doses, it is said to be apt to occasion headache and giddiness. Its principal use is for communicating an agreeable odour and flavour to other medicines. It may be taken as a carminative, in the dose of a few drops, on sugar (*elæosaccharum limonum*). As a perfume, it is an exceedingly useful adjunct to sulphur ointment, and to evaporating lotions. To this, as to some other volatile oils (see *oleum rosmarini*), has been ascribed the power of promoting the growth of the hair, and, in consequence, it has been added to pomatum. More recently, it has been employed as a stimulant application in various external inflammations of the eye. It was first used in these diseases by Dr. Worlitz,⁴ who applied it by squeezing the little drops of oil from the rind of the lemon into the eye. He used it with good effect in rheumatic, catarrhal, and serofulous inflammations of the eye, in pannus and pterygium, and in opacity and some other consequences of inflammation of the cornea. It has since been tried by Mr. Foote,⁵ at the Ophthalmic Hospital, who dropped the oil into the eye in the same way that the *vinum opii* is applied. In some cases it caused excessive pain. He thinks it preferable to the *vinum opii*, in all cases where a stimulant is required.

2. **SYRUPUS LIMONUM**, L. E. [*Syrupus Limonis*, U. S.]; *Syrup of Lemons*.—(Lemon juice, strained [and freed from impurities by subsidence, *E.*], Oj; Sugar ßiiss [Rectified Spirit ßiiss, *L.*]. [Boil the juice for ten minutes, and strain; add the sugar to this, and dissolve. Lastly, when the syrup is cold, add the spirit.—The *Edinburgh College* dissolves the sugar in the juice, allows subsidence, skims, and pours off the clear liquor.—The *Dublin College* has now a substitute for this syrup, which is called *Syrupus Acidi Citrici*, made as follows: Citric Acid, in powder, Distilled Water, of each ßiiss; Tincture of Lemon Peel ʒv; Simple Syrup Oij. The acid is dissolved in the water, and the solution added to the syrup and tincture.—*Ed.*] Refrigerant. An agreeable adjunct to diluent drinks, as barley-water, in febrile and inflammatory complaints, and to gargles.—Dose, fʒj to fʒiv.

320. CITRUS AURANTIUM, *Risso, L. E. D.*—THE COMMON OR SWEET ORANGE TREE.

Sez. Syst. Polyadelphia, Polyandria.

(Fructûs; Fructûs cortex exterior; Flores; Oleum è floribus destillatum, *L.*—Distilled water of the flowers; Volatile oil of the flowers, *E.*—Fructûs succus et tunica exterior; Flores; Folia, *D.*)

HISTORY.—It is somewhat uncertain when the sweet orange became known to Europe. The bitter orange, as well as the lemon, was known during the middle ages, but the sweet orange is supposed not to have been introduced until a period after this.¹

Fig. 406.

Citrus Aurantium.

1. Flower. 2. A set of Stamens. 3. Section of Ovary. 4. Section of Fruit.

BOTANY.—**Gen. Char.**—See *Citrus medica*.

Sp. Char.—*Leaves* oval, elongated, acute, sometimes slightly toothed; *petiole* more or less dilated and winged. *Flowers* white, large. *Fruit* orange-coloured, roundish or ovoid, usually depressed, rarely terminated by a small knob; *rind* with convex vesicles of oil; *pulp* sweet (Wight and Arnott).—A great number of sorts is known to gardeners. The *China orange* is the common orange of the markets and of the Portuguese. The *St. Michael's orange* is a small seedless variety. The *blood-red orange* has a reddish-yellow fruit, with a pulp irregularly mottled with crimson.

Hab.—Asia; probably China. Cultivated in the South of Europe, the Azores, and the West Indies.

DESCRIPTION.—*Orange leaves* (*folia aurantii*) are

feebly bitter. Their watery infusion is greenish and somewhat bitter. They contain a fragrant volatile oil, which is procured by distillation, and is called, in the shops, *essence de petit grain*. *Orange flowers* (*flores aurantii seu naphæ*), when fresh, are white. They are sometimes exported from the South of Europe, stratified with common salt in barrels (Risso). Dried orange flowers are yellowish, and have an agreeable odour, which is less powerful than that of the fresh flowers. By distillation, orange flowers yield a fragrant volatile oil (*oleum Neroli*; *oleum aurantii*). The *small green fruits* (*fructus immaturus aurantii*) which fall during the great heats of the summer, are carefully collected and dried. They, as well as the unripe fruit of the next species [*citrus vulgaris*], form the *orange berries* (*baccæ aurantii*) of the shops. Their size does not exceed that of a cherry; their colour

¹ Macfadyen, *Bot. Miscell.* i. 302.

is dark-grayish or greenish-brown; they have an aromatic odour and a bitter taste. They are used for flavouring *Curaçoa*. When smoothed by a lathe, they constitute the *issue peas* of the shops: they are preferred to ordinary peas for keeping up the discharge of an issue, on account of their pleasant odour. An infusion of orange berries is rendered green by the sesquichloride of iron. By distillation these berries yield a fragrant oil (the original *essence de petit grain*). The ripe fruit, or the orange (*aurantium*; *poma aurantiorum*), is imported in chests and boxes, each orange being separately packed in paper. The best come from the Azores and Spain; very good ones are also brought from Portugal, Italy, and other places. The rind is sometimes employed as a substitute for the rind of the bitter orange. It yields, by distillation, a fragrant volatile oil (*essential oil of sweet orange*).

COMPOSITION.—1. **Orange Flowers** were analyzed by Boullay,¹ and found to contain *volatile oil, bitter extractive, gum, acetic acid, and acetate of lime*.

2. **Orange Berries** were analyzed, in 1828, by Lebreton,² who found their constituents to be as follows: *Volatile oil, sulphur, chlorophylle, fatty matter, hesperidin, bitter astringent matter*, with some traces of *gallic acid, citric and malic acids, citrates and malates of lime and potash, gum, albumen, lignin; mineral salts*, and traces of *iron and silica*. Widemann³ obtained a *crystalline substance* analogous to, but yet different from, hesperidin.

3. **Orange Peel** has not been analyzed; but its composition is, doubtless, analogous to that of lemon peel.

4. **Orange Juice** consists of *citric acid, malic acid, mucilage, albumen, sugar, citrate of lime, and water*.

1. **VOLATILE OILS FROM THE SWEET ORANGE TREE.**—The volatile oils obtained from the leaves, flowers, and fruit rind of the sweet orange tree, agree, in their essential chemical characters, with each other, with the corresponding oils obtained from the bitter orange, and with the volatile oil of lemons. They differ principally in their odour.

The oil of sweet orange kept in the perfumers' shops, is obtained by distillation with water from the rind of the fruit.

The other volatile oils of this species are not distinguished in English commerce from those of the next species.

2. **HESPERIDIN.**

3. **BITTER PRINCIPLE (*Aurantiin*).**

4. **WIDEMANN'S CRYSTALLINE MATTER.**—Obtained from unripe oranges. It is distinguished from Hesperidin by its very distinct prismatic crystallization, by its insolubility in water, and by its not forming oxalic acid with nitric acid.

PHYSIOLOGICAL EFFECTS AND USES.—**Sweet Orange Peel** is an aromatic stimulant and tonic analogous to lemon peel, and is occasionally employed as a substitute for the *bitter orange peel*. "Large quantities of it are sometimes productive of mischief, especially in children, in whom colic, and even convulsions, are sometimes induced by it. We have known the case of a child, in which death resulted from eating the rind of an orange."⁴

Orange Juice is a refreshing and grateful beverage, and is extensively used at the table. In febrile and inflammatory complaints, it is a valuable refrigerant;—allaying thirst and diminishing preternatural heat.

321. CITRUS BIGARADIA, *Risso, L. E. D.*—THE BIGARADE, OR BITTER ORANGE TREE.

Sex. Syst. Polyadelphia, Polyandria.

(Fructus cortex exterior, *L.*—Distilled waters of the flowers; Rind of the Fruit; Volatile oil of the flowers, *E. D.*)

HISTORY.—The bitter orange became known to Europe during the middle ages. All the old established orange groves of Spain, as those at Seville, planted by the Moors, are of the bitter orange.⁵

¹ *Bull. de Pharm.* i. 337.

² *Ibid.* xvi. 707.

³ Macfadyen, in *Hooker's Bot. Miscell.* i. 302.

⁴ *Journ. de Pharm.* xiv. 377.

⁵ *United States Dispensatory.*

Fig. 407.

*Citrus Bigaradia.*

BOTANY. Gen. Char.—See *Citrus medica*.

Sp. Char.—Leaves elliptical, acute, or acuminate, slightly toothed. Petiole more or less winged. Flowers large, white. Fruit orange-coloured, roundish, or slightly elongated or depressed; rind with concave vesicles of oil; pulp acid and bitter (Wight and Arnott).

Numerous varieties of this are cultivated. One of these yields the fruit known in the English market as the *Seville Orange*.

Hab.—Asia. Cultivated in Europe.

DESCRIPTION.—The leaves of this species, when rubbed, emit a very agreeable odour. Distilled with water, they yield a bitter, aromatic water, known in Languedoc as *eau de naphre* (*aqua naphæ*). At the same operation is procured a volatile oil, called the *essence de*

petit grain, of finer quality than that obtained from the leaves of the sweet orange. The flowers yield by distillation with water, *orange-flower water* (*aqua aurantii*, Ph. Ed.) and *oil of Neroli* (*oleum aurantii*, Ph. Ed.) of finer quality than the corresponding preparations obtained from the flowers of the sweet orange. The unripe fruits, like those of the sweet orange, are called *orange-berries*, and are employed for the purposes before mentioned. The *Seville orange* is round and dark, and has an uneven, rugged, very bitter rind (*bitter orange peel*; *cortex aurantii*, Ph. L. and Ed.), which is employed for medical purposes as well as in the preparation of *candied orange peel*, and for flavouring the liquor called *Curaçoa*.

COMPOSITION.—The composition of the leaves, flowers, and fruit of the bitter orange is doubtless analogous to that of the corresponding parts of the sweet orange.

1. **OIL OF ORANGE-LEAF**; *Essence de petit grain*.—The term *essence de petit grain* was originally applied to the volatile oil of the orange-berry, which, however, readily underwent decomposition. It is now used to indicate the volatile oil obtained from the leaves both of the bitter and sweet orange. That procured from the bitter orange is of better quality than that from the sweet.

2. **OIL OF ORANGE-FLOWER**; *Oil of Neroli* (*Oleum Aurantii*).—Procured from the flowers of both the bitter and sweet orange; but that from the former is preferred. It is obtained by submitting the flowers, with water, to distillation; and it is found floating on the water in the receiver. It has an aromatic and fragrant odour, somewhat different from that of the flower. "It appears to me," says Soubeiran,¹ "to be a product of the alteration of the natural essential oil. The latter is more soluble than the neroli oil, and remains in solution in the water. Its presence may be demonstrated by agitating the distilled water with ether deprived of alcohol. By spontaneous evaporation, the ethereal solution leaves behind an essential oil, which has absolutely the same odour as the flowers, and which dissolves in water." Oil of neroli, furnished me by one of the most respectable importers as genuine oil, has a reddish colour. I am informed that the *essence de petit grain* is frequently substituted for it.

3. **OIL OF THE RIND OF THE BITTER ORANGE.**—This is sold by perfumers as *essential oil of bitter orange*. It has a considerable resemblance to the oil of the sweet orange.

PHYSIOLOGICAL EFFECTS AND USES.—The rind of the Seville orange being considerably more bitter than that of the sweet orange, is to be regarded as more stomachic and tonic. Its uses are the same. Its principal value is as a flavouring agent.

1. **INFUSUM AURANTII COMPOSITUM**, L. D.; *Infusum Aurantii*, D.; *Compound Infusion of Orange Peel*.—(Bitter Orange Peel, dried, ℥ss [ʒij, D.]. [Lemon Peel ʒij, L.]; Cloves, bruised, ʒj [ʒss, D.]; Boiling [distilled] Water Oj [Oss, D.]. Digest for a quarter of an hour in a vessel lightly covered, and strain [through linen or calico, E.; infuse for half an hour, D.]—An agreeable stomachic. It is

¹ *Novu. Traité de Pharm.* i. 454.

an excellent vehicle for the exhibition of various other medicines, as saline purgatives, ammonia, bitter tinctures, &c.—Dose, fʒj to fʒij.

2. CONFECTIO AURANTII, L.; *Conserva Aurantii*, E. [*Confectio Aurantii Corticis*, U. S.]; *Confection of Orange Peel*.—(Orange Peel, separated by a rasp, ℥j; Sugar ℥iij. Beat the rind in a stone mortar with a wooden pestle; then, the sugar being added, again beat them, until they are thoroughly incorporated, L.—Grate off the rind of bitter oranges, and beat it into a pulp, adding gradually thrice its weight of white sugar, E.)—An agreeable stomachic. Employed as an adjunct to bitter and purgative powders, which are to be formed into electuaries. It is a good vehicle for the exhibition of the sesquioxide of iron.

3. SYRUPUS AURANTII, L. E. D.; *Syrup of Orange Peel*.—(Dried Bitter Orange Peel ʒiiss; Boiling Water Oj; Pure Sugar ℥iij [Rectified Spirit ʒiiss, L.]. Macerate the peel in the water for twelve hours, in a vessel lightly covered; boil for ten minutes, strain the liquor, and proceed as for the Syrupus Althææ, L. [add the sugar, and dissolve with the aid of heat, E.].)—To avoid the volatilization of the essential oil, as little heat as possible should be employed in the process. The *Dublin College* orders as much sugar as may be necessary. An equally agreeable and efficacious syrup may be prepared by adding fʒj of tincture of orange peel to Oj of simple syrup. Syrup of orange peel is stomachic, but its principal use is for flavouring. Dose, fʒj to fʒij.

4. TINCTURA AURANTII, L. E. D.; *Tincture of Orange Peel*.—(Bitter Orange Peel, dried, ʒiiss [ʒiv D.]; Proof Spirit Oij. Macerate for seven [fourteen, D.] days [and express strongly, E.], and filter the liquor. “This tincture may be prepared by percolation, by cutting the peel into small fragments, macerating it in a little of the spirit for twelve hours, and beating the mass into a coarse pulp before putting it into the percolator,” E.) This tincture is an agreeable stomachic, and is principally employed as a flavouring adjunct to decoctions and infusions (tonic or purgative), effervescing mixtures, &c. Dose, fʒj to fʒij.

5. AQUA FLORIS AURANTII, L.; *Aqua Aurantii*, E.; *Orange-flower Water*.—[This preparation is now removed to the *Materia Medica* of the London Pharmacopœia.—Ed.] Orange-flower water is usually imported. That prepared from the flowers of the bitter orange possesses the most fragrant odour, but it is sometimes prepared from the flowers of the sweet orange. It contains free acetic acid, derived from the flowers; hence, if kept in a vessel of lead or copper, it acquires a metallic impregnation. The presence of lead in it has recently been pointed out by Mr. Squire.¹ The following are the characters of the pure orange-flower water:—

“Nearly colourless; unaffected by sulphuretted hydrogen.—*Ph. Ed.*”

Sulphuretted hydrogen produces, with either lead or copper, a dark-coloured precipitate. Orange-flower water is employed in medicine, as well as in perfumery, on account of its agreeable odour.

AQUA COLONIENSIS; *Eau de Cologne*; *Cologne Water*.—A much admired perfume. Two varieties are known in the shops—the *French* and the *German*; the latter fetches the highest price. Both profess to be made by *Farina*. The recipes for making it are numerous. I subjoin one, which is said, by Trommsdorff,² to be followed in the Cologne manufactories: Oil of Neroli; Oil of Citron; Oil of Bergamot; Oil of Orange; Oil of Rosemary: of each twelve drops; Malabar Cardamoms ʒj; Rectified Spirit Oj. Distil. Eau de Cologne forms an agreeable evaporating lotion in headache, fever, &c. It should be applied by means of a single layer of linen.

OTHER MEDICINAL AURANTIACEÆ.

The FERONIA ELEPHANTUM, a large tree growing in most parts of India, yields a gum which is used for medicinal purposes by the practitioners of Lower India. It is an exudation of the

¹ *Brit. Ann. of Med.* for Jan. 1837, p. 13.

² *Journ. de Pharm.* xviii. 79.

stem, and closely resembles gum Arabic.¹ It is not improbable that part of the *East India gum* brought to this country may be the produce of this tree.

ORDER LXXV. TERNSTRÖMIACEÆ, *Lindley*.—THE TEA TRIBE.

Though unable to do more than bestow a passing notice on TEA, I cannot wholly omit all reference to this important and interesting substance. Two kinds of Tea plant are cultivated in our green-houses; the one called *Thea viridis*, or *Green Tea*, the other *Thea Bohea*, or *Black*

Fig. 408.

Thea Bohea.

Tea. Great discrepancy of opinion exists as to whether the different varieties of tea of commerce are obtained from one or from two species.² The well known differences between green and black teas lend great support to the assertions of those who contend that these teas are obtained from different plants growing in different provinces of China. Mr. Reeves's observations on this point³ appear to me exceedingly apposite. In commerce, two principal kinds of tea are distinguished—the *Black* and *Green*; to the first belong *Bohea*, *Congou*, *Campoi*, *Souchong*, *Caper*, and *Pekoe*; to the latter, *Twankay*, *Hyson-skin*, *Hyson*, *Imperial*, and *Gunpowder*.⁴ Frank⁵ analyzed both black and green teas, and obtained the following results:—

	<i>Black.</i>	<i>Green.</i>
Tannin	40.6	34.6
Gum	6.3	5.9
Woody fibre	44.8	51.3
Glutinous matter	6.3	5.7
Volatile matter, and loss	2.0	2.5
Tea	100.0	100.0

Sir H. Davy⁶ also found more tannin in black than in green tea, in the proportion of 48 to 41. But these results are opposed to our daily experience, as derived from flavour, which indicates

¹ Ainslie, *Mat. Ind.* i. 161. ² See Royle's *Illustr.* p. 109; and Hooker, *Bot. Mag.* t. 3148.
³ See Royle, *op. cit.*
⁴ For some interesting observations on *Assam Tea*, see Royle's *Essay on the Productive Resources of India*, Lond. 1840; and Bruce's *Report on the Manufacture of Tea, and on the Extent and Produce of the Tea Plantations in Assam*, in Jameson's *Journal*, xxviii. 126, 1840.
⁵ Gmelin, *Handb. d. Chem.* li. 1253 ⁶ *Phil. Trans.* for 1803, p. 268.

the greater astringency in the green tea, and to the experiments of Mr. Brande.¹ The difference in the quantity of tannin in the two kinds of tea is, however, not very great. A few years ago, Oudry² announced the existence in tea of a crystalline, salifiable base, to which he gave the name of *theina*; but more recently Jobst³ has asserted its identity with *caffein*, already noticed. Dr. R. D. Thomson⁴ has described a fixed oil (*Tea Oil*) obtained from the tea plant. It is composed of *elaine* 75, and *stearin* 25. Notwithstanding the extensive employment of tea as an article of diet, yet it is no easy matter to ascertain correctly its precise effects on the constitution. Its astringency is proved by its chemical properties; and hence tea may be resorted to as an easily accessible antidote in cases of poisoning by substances containing vegetable alkalies, or by emetic tartar. Another quality possessed, especially by green tea, is that of diminishing the tendency to sleep. Hence, like coffee, it is often resorted to by those who desire nocturnal study. Moreover, it may be employed as an antisporific to counteract the effects of opium and intoxicating liquors; and Dr. Clutterbuck⁵ has suggested its application to the relief of the stupor of fever, which he considers to be nearly allied to intoxication. Tea appears to possess a sedative influence with regard to the vascular system; and in this, as well as in the watchfulness which it produces, tea somewhat resembles foxglove. On account of its sedative power, Dr. T. Percival⁶ recommends its use in feverish and inflammatory diseases, and I can speak, from frequent observation, of its good effects in these maladies. To this power should also be referred the relief of headache experienced by the use of tea. In colds, catarrhs, rheumatism, &c. warm infusion of tea is frequently employed as a diluent, diaphoretic, and diuretic. Strong green tea, taken in large quantities, is capable, in some constitutions, of producing most distressing feelings,⁷ and of operating as a narcotic. Dr. Lettsom⁸ found that a strong infusion of tea, introduced into the abdomen of a frog, caused paralysis of the hind extremities of the animal.⁹

ORDER LXXVI. DIPTERACEÆ, Lindley.—THE DIPTEROCARPUS TRIBE.

DIPTEROCARPEÆ, Blume.

DRYOBALANOPS AROMATICA, Gaertner (*D. Camphora*, Colebrooke; *Shorea camphorifera*, Roxb.) is a large tree growing in Sumatra and Borneo. From its stem are obtained a liquid called *Camphor oil*, and a crystalline solid denominated *Sumatra* or *Borneo Camphor*.

1. *Liquid Camphor*; *Camphor Oil*.—Is obtained by making deep incisions into the tree with an axe. The oil gushes out, and is received in bamboos or other convenient utensils.¹⁰ It is occasionally imported into this country in tin canisters. It is sometimes perfectly limpid, transparent, and colourless; but more usually it is more or less coloured, being yellow or brownish. Its odour is somewhat analogous to that of oil of cajuputi, combined with the odour of camphor and cardamoms. Some samples have a strong odour of turpentine. This oil has been analyzed by Martius.¹¹ The mean of three analyses gave him for its constituents carbon, 83.129, hydrogen 11.346, and oxygen 5.25; or $C^{20}H^{16}O^2$.¹ Recently, Pelouze¹² has analyzed it. He regards it as a hydrocarbon, whose formula is $C^{20}H^{16}$. By exposure to the air, it rapidly oxidizes and becomes $C^{20}H^{16}O^4$. Hence, therefore, it would appear that Martius must have analyzed an oxidized oil. Camphor oil has been employed in the preparation of scented soap. Sixty pounds of dark brown oil yielded forty pounds of colourless liquid oil, and twenty pounds of crystalline camphor.

2. *Sumatra* or *Borneo Camphor*. By the natives of Sumatra it is termed *Kapúrbarus* (i. e. *Baroo Camphor*)—It is found in the natural fissures or crevices of the wood, and is obtained by cutting down the tree, dividing it transversely into several blocks, which are split with wedges into small pieces, from the interstices of which the camphor, if there be any, is extracted.¹³ After being separated from impurities, it is packed in *catties*. Being much esteemed by the Chinese, it fetches a very high price. According to Mr. Crawford,¹⁴ its value is 78 times that of Japan camphor! It rarely comes to this country as a commercial article. For some of the samples in my museum I am indebted to the late Mr. Gibson (of the firm of Howard, Jewell, and Gibson, of Stratford), who stated that "they are part of two very small boxes imported about twenty years ago, which were bought by me at the common price of camphor at the time, but which it was afterwards discovered were invoiced at an enormous price. Our firm gave

them up to the importers, reserving samples, and they were re-shipped for India. I never on any other occasion except one saw a small specimen of what I have named *native camphor*.¹

Sumatra or Borneo camphor occurs in small white fragments of crystals. They are transparent, brittle, and have a camphoraceous odour and a hot taste. According to Pelouze, its crystalline form is a prism with six regular faces, and derived from the rhombohedral system. It is lighter than water, very slightly soluble only in water; but is very soluble in alcohol and ether. It is fusible and volatile. Its composition, according to Pelouze, is $C^{20}H^{18}O^2$.

Sumatra Camphor is distinguished from Common or Laurel Camphor by several characters; such as the form of the crystals above mentioned; their greater hardness, so that when shaken in a bottle they produce a ringing sound; they are more brittle, and do not so readily sublime and condense in crystals in the upper parts of the bottle.

Its medicinal properties are probably similar to those of ordinary or laurel camphor. But in the East, especially by the Chinese, the most extravagant virtues are assigned to it, and it is accordingly highly valued. In the *Puntsau* it is called Lung Naou Heang, or "Dragon's Brain Perfume."

ORDER LXXVII. BYTTNERIACEÆ, *De Candolle*.—THE CACAO TRIBE.

Fig. 409.

Theobroma Cacao.

The *THEOBROMA CACAO* is a native of the West Indies and of Continental America.

Its seeds (*nuclei cacao*) when torrefied, and with various additions (sugar, and usually either cinnamon or vanilla), made into a paste, constitutes *chocolate* (*chocolata*), which furnishes a very nourishing beverage, devoid of the ill properties possessed by both tea and coffee, but which, on account of the contained oil, is apt to disagree with dyspeptics.¹ *Cocoa* is another preparation of these seeds. It is said to be made from the fragments of the seed-coats mixed with portions of the kernels. It is somewhat astringent, and is adapted for persons with relaxed bowels.

ORDER LXXVIII. MALVACEÆ, *R. Brown*.—THE MALLOW TRIBE.

CHARACTERS.—*Calyx* of 5 (rarely 3 or 4) sepals, more or less coherent at the base, valvate in æstivation, often with bracts or external sepals forming an involucre or outer calyx. *Petals* as many as the sepals, and alternate with them; hypogynous, equal; spirally contorted in æstivation, generally adnate to (but sometimes distinct from) the lower part of the tube of the stamens. *Stamens* equal in number, or more commonly a multiple of the petals; generally indefinite (rarely definite), hypogynous. *Filaments* united into a tube, and unequal in length, the outer ones being shorter. *Anthers* 1-celled, uniform, dehiscing by a transverse chink. *Ovary* of many carpels, generally verticillated round the axis, and coherent (sometimes free). *Styles* as many as the carpels, either distinct or united. *Stigmas* as many as the carpels, more or less distinct. *Carpels* either 1- or 2-seeded, and dehiscing inward by a chink, or polyspermons, with a loculicidal dehiscence, or having a septum in the middle which bears the seed on the inner side; in some cases nearly free, in others united into a many-celled capsule or an anomalous berry. *Albumen* none. *Embryo* straight. *Radicle* terete. *Cotyledons* twisted like a chrysalis.—*Herbs, shrubs, or trees.* *Leaves* alternate, generally petiolate, and with stipules. (*De Cand.*)

PROPERTIES.—"The uniform character is to abound in mucilage, and to be totally destitute of all unwholesome qualities" (*Lindley*).

¹ For particulars respecting the manufacture of chocolate, see *Ure, Dictionary of Arts*, p. 292; and *Soubbeiran, Traité de Pharm.* i. 447.

322. MALVA SYLVESTRIS, Linn. E.—COMMON MALLOW.

Sez. Syst. Monadelphia, Polyandria.
(Herb, E.)

HISTORY.—According to Dr. Sibthorp,¹ the Μαλάχη χερσαία of Dioscorides² is the *Malva sylvestris*.

BOTANY. **Gen. Char.**—*Calyx* 5-cleft, persistent, surrounded by an involucl of usually 3, rarely 1 or 2, or 5 or 6, more or less oblong or setaceous bracteoles. *Ovary* with many cells, each with 1 ovule. *Styles* as many as the cells. *Carpels* several (rarely only 5), capsular, indehiscent, 1-seeded, circularly arranged around the axis. *Radicle* inferior (Wight and Arnott).

Sp. Char.—*Stem* erect. *Leaves* 5- to 7-lobed, acute. *Pedicels* and *petioles* hairy. (De Cand.)

Root perennial, tapering, branching, whitish. *Stem* 2 or 3 feet or more high, branched. *Leaves* deep green, soft and downy. *Flowers* large, three or four together, axillary. *Petals* obovate, purplish rose-coloured, with deeper veins, combined by the base of their claws.

Hab.—Indigenous; hedges and road sides. Flowers from June to August.

DESCRIPTION.—Common Mallow (*herba malvæ sylvestris*) is odourless, and has merely a mucilaginous herbaceous taste. Its watery infusion is deepened in colour by the sesquichloride of iron, and forms a precipitate with acetate of lead. Dwarf mallow (*herba malvæ rotundifoliæ*) possesses similar properties.

COMPOSITION.—I am unacquainted with any analysis of this plant. The constituents are probably similar to those of *Althæa officinalis*. *Mucilage* is the prevailing principle. *Extractive* also is another constituent. The *colouring matter* of the flower is an exceedingly delicate test of alkalies, which render it green.

PHYSIOLOGICAL EFFECTS AND USES.—Emollient and demulcent. Employed in the form of decoction, in irritation of the alimentary canal, and of the pulmonary and urinary organs. In tenesmus, the decoction is used in the form of enema. In external inflammations, emollient fomentations and cataplasms of mallow are sometimes employed.

323. ALTHÆA OFFICINALIS, Linn. L. E.—COMMON MARSH-MALLOW.

Sez. Syst. Monadelphia, Polyandria.
(Folia; Radix, L.—Leaves; Root, E.)

HISTORY.—According to Dr. Sibthorp,³ this plant is the Ἀλθαία of Dioscorides.⁴

BOTANY. **Gen. Char.**—*Calyx* surrounded by 6- to 9-cleft, involucl. *Carpels* numerous, capsular, closely and circularly arranged round the axis (Wight and Arnott).

Sp. Char.—*Leaves* softly tomentose on both sides, cordate or ovate, toothed, undivided, or somewhat 3-lobed. *Peduncles* axillary, many-flowered, much shorter than the leaf. (De Cand.)

Root perennial, tap-shaped, rather woody. *Stem* 2 or 3 feet high. *Leaves* hoary green, peculiarly soft and downy, with a fine starry pubescence. *Flowers* 3 or 4 together, on axillary stalks, large, pale rose-coloured.

Hab.—Indigenous; marshes, especially near the sea.

DESCRIPTION.—The leaves of Marsh-mallow (*foliæ althææ*) are odourless, and have a mucilaginous taste. The root (*radix althææ*) is long, cylindrical, branched, about the thickness of the finger, plump, mucilaginous, white internally, and covered with a yellowish epidermis. That which is imported from France has been deprived

¹ Prodr. Fl. Græc. ii. 45.

² Prodr. Fl. Græc. ii. 42.

³ Lib. ii. cap. 144.

⁴ Lib. iii. cap. 103.

of its epidermis, and is white (*decorticated root of marsh-mallow*). Its odour is feeble; its taste sweet and mucilaginous. Iodine colours it dark blue. Sesquichloride of iron forms with the concentrated decoction, a brown semi-transparent gelatinous mass.

COMPOSITION.—Marsh-mallow root has been analyzed by Bacon,¹ by L. Meyer,² by Wittstock,³ and by Buchner.⁴ The results of the latter chemist are as follows:—*Fatty oil* 1.26, *glutinous matter* 1.81, *uncrystallizable sugar* and *althein* 8.29, *mucilage* 35.64, *starch* 37.51, *phosphate of lime* 8.29, *vegetable medulla* 11.05, and *woody fibre* 7.50 [excess 11.35].

ASPARAGIN; Asparamide; Althein.—The substance which has been called *althein* is identical with *asparagin*. It is crystallizable, odourless, and almost tasteless. It is soluble in water and alcohol, sp. gr. 0.837; but it is insoluble in absolute alcohol and in ether. It consists of $C^8H^7N^2O^5$. Acted on by the watery solutions of the alkalis, it evolves ammonia, and is converted into *aspartic acid* ($C^8H^5NO^6$); hence it is called *asparamide*, as it is an aspartite of ammonia ($C^8H^5NO^6 + H^2N$), minus an atom of water. It has an influence on the therapeutic properties of the root.

PHYSIOLOGICAL EFFECTS AND USES.—Similar to those of common mallow, already stated. On the continent it is a favourite demulcent. The *pastilles* and *pate de guimauve* are used as pectorals. The powder of marshmallow root is used in France to envelop pills. "The simple decoction is recommended as an injection, to be thrown into the vagina, in cases of difficult labour, arising from rigidity of the soft parts."⁵

1. **MISTURA ALTHÆÆ, E.; Marsh-mallow Mixture.**—(Root of *Althæa* ʒiv; Raisins, stoned, ʒij; Boiling Water Ov. Boil down to three pints; strain through linen or calico, and, when the sediment has subsided, pour off the clear liquor for use.)—An agreeable diluent and demulcent. Employed in visceral inflammation and irritation; as nephritis, calculous affections, gonorrhœa, strangury, &c. From one to three pints may be taken in the course of the day.

2. **SYRUPUS ALTHÆÆ, L. E.; Syrup of Marsh-mallows.**—(*Althæa* Root, sliced, ʒiiss; Pure Sugar lbiiiss; Water [boiling, *E.*] Boil down the water with the root to one-half [strain, *E.*], and express [strongly through calico, *E.*] the liquor when cold, *L.* Set aside for twenty-four hours, that the impurities may subside; then pour off the liquor, and the sugar being added, boil down to a proper consistence.)—Demulcent, employed as an adjunct to cough mixtures, and as a pectoral for children. It readily ferments, and becomes ropy.—Dose, fʒj to fʒss.

324. GOSSYPIUM HERBACEUM, Linn. E.—COMMON COTTON.

Sex. Syst. Monadelphia, Polyandria.
(Hairs attached to the seed, *E.*)

HISTORY.—It is somewhat doubtful who first mentioned cotton. There is some reason for supposing that cotton cloth is referred to in the Old Testament.⁶ Cotton (*βύσσις*), is mentioned by Herodotus;⁷ but he or his translators are in error, in stating⁸ that the Egyptians, in embalming, wrapped the body in cotton cloth; since all mummy cloths are found, on a microscopic examination, to be linen.⁹ Pliny¹⁰ speaks of the cotton plant (*Gossypion*) and of the cloth (*Xylina*) made of the woolly substance which envelops the seeds.¹¹

BOTANY. Gen. Char.—*Calyx* cup-shaped, obtusely 5-toothed, surrounded by a

⁶ *Euterpe*, lxxxvi.

⁷ Dutochet, in Jameson's *Journal*, vol. xxiii. p. 320. This author suggests that the *βύσσις* of Herodotus was the filamentous weavable matter which lint [flax] supplied.

⁸ *Hist. Nat. lib. xix. cap. 2, ed. Valp.*

⁹ For farther historical details, see Royle's *Illustr.* p. 84, *et seq.*

² Gmelin, *Handb. d. Chem.* ii. 1251.

⁴ *Ibid.* für 1832, S. 511.

3-leaved involucrel, with the leaves united and cordate at the base, and deeply cut or toothed irregularly. *Style* simple, marked with 3 or 5 furrows towards the apex. *Stigmas* usually 3, sometimes 5. *Capsules* 3- to 5-celled, 3- to 5-valved at the apex, loculicidal. *Seeds* numerous, imbedded in cotton. Young branches and leaves more or less conspicuously covered with little black dots; nerves below usually with one or more glands (Wight and Arnott).

Sp. Char.—Bi-triennial; *young parts* hairy. *Leaves* hoary, palmate, with sub-lanceolate, rather acute lobes. *Stipules* falcate-lanceolate. *Leaves* of the exterior calyx dentate. *Capsules* ovate pointed. *Seeds* free, clothed with firmly adhering white down under the long white wool (Roxburgh).—*Petals* of a lively yellow colour, with a purple spot near the claw. Dr. Roxburgh¹ particularly distinguishes three varieties cultivated in India—viz., the *Dacca*, the *Berar*, and the *China* cottons.

Hab.—Asia. Cultivated in India, Syria, Asia Minor, the Mediterranean, and America.

DESCRIPTION.—The filamentous substance, called *cotton* (*gossypium*), consists of tubular hairs, which arise from the surface of the seed-coat. By drying, they become flattened; and in this state, if they be immersed in water and examined by the microscope, they appear like distinct, flat, narrow ribands, with only occasional appearances of joints, which are indicated by a line at a right angle, or nearly so, to the side of the tube. Cotton is distinguished (under the microscope) from the vegetable fibre which constitutes linen by the tubes of the latter being in bundles, round, tapering at the extremities, and, when jointed, having oblique articulations. Cotton which has undergone no preparation is denominated *raw cotton*.²

COMPOSITION.—Cotton is a modification of *lignin*, and consists, therefore, of *carbon*, *hydrogen*, and *oxygen*; but the precise relative proportions of its constituents have not been ascertained. In all its essential chemical properties it agrees with ordinary woody fibre. It is completely insoluble in water, alcohol, ether, oils, and vegetable acids. Strong alkaline lyes dissolve it. The strong mineral acids decompose it. With nitric acid it yields oxalic acid.

PHYSIOLOGICAL EFFECTS AND USES.—Raw cotton, or cotton wool, has been employed with apparently good effect in the treatment of burns.³ It allays pain and irritation, apparently by forming, with the discharges, a substitute for the epidermis, under the protection of which the process for the formation of the new cuticle takes place, undisturbed by external irritation. The exclusion of the air seems to be a most important part of the treatment; and, of course, to effect this, many other agents (as lint) will answer in the place of cotton. The following is the method of employing cotton: The cotton should be carded in narrow fleeces, thin enough to be translucent, and applied in successive layers, so as completely to protect the injured parts from the effects of motion and pressure. When the skin is severely scorched, a spirituous or turpentine wash may be applied previously to the application of the cotton. As complete repose of the part is necessary, the first dressing should be allowed to remain as long as possible undisturbed. Raw cotton has also been used as a topical application in erysipelas.⁴

Cotton-wool, impregnated with nitro or chlorate of potash, has been employed as *moxa*.

The well-known superiority of linen to cotton, as a dressing for wounds and ulcers, is usually ascribed to the triangular shape of the cotton fibres, the sharp

Fig. 410.

*Gossypium herbaceum.*

² For much interesting information regarding Cotton, but which is unsuited to this work, consult Royle, *op. cit.*; M'Culloch, *Dictionary of Commerce*; and Ure, *Dictionary of Arts*.

³ Anderson, *Edinb. Med. and Surg. Journ.* xlii. 215, 1808.

⁴ *Lond. Med. Gaz.* Nov. 8, 1839.

angles of which are supposed to cut and irritate the flesh. But this shape of the fibres exists only in the imagination of those who have never examined them by the microscope. Raspail¹ ascribes the superiority of linen for surgical purposes to the hollow condition of the tubular fibrillæ, by which they are enabled to absorb into their interior the blood or purulent secretion. The tubes of cotton, on the other hand, are filled with an organizing substance, and, therefore, can imbibe nothing into their interior.

[**COLLODIUM**, U. S.; *Collodium*.—(Take of Cotton, freed from impurities, and finely carded, half an ounce; Nitrate of Potassa, in powder, ten ounces; Sulphuric Acid eight fluidounces and a half; Ether two pints and a half; Alcohol a fluid-ounce. Add the Sulphuric Acid to the Nitrate of Potassa in a Wedgewood mortar, and triturate them until uniformly mixed; then add the Cotton, and by means of the pestle and a glass rod, imbue it thoroughly with the mixture for four minutes. Transfer the Cotton to a vessel containing water, and wash it, in successive portions, by agitation and pressure, until the washings cease to have an acid taste, or to be precipitated on the addition of chloride of barium. Having separated the fibres by picking, dry the cotton with a gentle heat, dissolve it by agitation in the Ether, previously mixed with the Alcohol, and strain. Collodion should be kept in closely-stopped bottles previously well dried. The first part of the above process produces gun-cotton, which is dissolved in ether. It is a transparent solution, of syrupy consistence and ethereal smell. It is used as an application in surgery to wounds, with the view of producing cohesion of the edges. When applied, the ether evaporates, leaving a film, which is the bond of union. It is sometimes used as a covering to ulcers, burns, and superficial inflammation, as a protection and stimulant. I have used it with advantage in sore nipples.]

ORDER LXXIX. LINACEÆ, *Lindley*.—THE FLAX TRIBE.

LINÆE, *De Candolle*.

CHARACTERS.—*Calyx* 3- or 4, generally 5-sepaled. *Sepals* coherent only at the base, imbricate in æstivation, continuous with the peduncle, and therefore persistent. *Petals* as many as the sepals; hypogynous, unguiculate at the base, slightly united together, and to the ring of the stamens; alternate with the sepals, twisted in æstivation. *Stamens* equal in number, and alternate with the petals, cohering into a monadelphous ring at the base, and having an abortive filament, or tooth, between each. *Anthers* innate, bilocular, bi-rimose. *Ovaries* subglobose, with as many cells as there are sepals, rarely fewer. *Styles* as numerous as the cells of the ovary. *Capsule* globose, crowned by the permanent bases of the styles, composed of carpels having induplicate margins and dehiscing at the apex by two valves, and which are divided into partial cells, by an incomplete dissepiment arising from the centre. Seeds in each cell two inverted. *Albumen* generally none, but in its stead there is a tumid, fleshy endopleura. *Embryo* straight, with the radicle turned towards the hilum.—*Herbs* or *shrubs*, with entire exstipulate leaves. (De Cand.)

PROPERTIES.—The fibres of Linacææ have great tenacity. The seeds abound in oil and mucilage, and are in consequence emollient.

325. LINUM USITATISSIMUM, *Linn. L. E. D.*—COMMON FLAX.

Sex. Syst. Pentandria, Pentagynia.

(Semina; Oleum e seminibus expressum, *L. D.*—Seeds; Meal of the seeds deprived of their fixed oil by expression; Expressed oil of the seeds, *E.*)

HISTORY.—From time immemorial flax has been employed in the manufacture of cloth; and it appears, from our most ancient records, that Egypt was celebrated for its production.² Dutrochet³ asserts that mummy cloth is made of flax.

¹ *Chim. Organ.*

² *Jameson's Journal*, xxii. 221.

³ *Exodus*, ix. 31; Herodotus, *Euterpe*, cv.

BOTANY. Gen. Char.—*Sepals* 5, distinct, quite entire or serrated. *Petals* 5. *Stamens* 5. *Styles* 3 to 5, distinct from the base, or combined to the middle or apex (Wight and Arnott).

Sp. Char.—Smooth, erect. *Leaves* lanceolate or linear. *Panicle* corymbose. *Sepals* ovate, acute, with membranous margins. *Petals* somewhat crenate, larger by three times than the calyx. (De Cand.)—Annual. One or two feet high. *Leaves* distant. *Flowers* large, purplish-blue. *Capsule* globular, about the size of a small pea.

Hab.—Indigenous; cornfields; not unfrequent. Extensively cultivated in this, as well as in other European countries, both for its fibre for making thread, and for its oil obtained from the seeds.

DESCRIPTION.—The seed of the flax, commonly termed *linseed* or *lintseed* (*semina lini*), is small (about a line long), oval, oblong, flattened on the sides with acute edges, pointed at one extremity, smooth, glossy, brown externally, yellowish-white internally, odourless, and has an oily mucilaginous taste. The seed-coat is mucilaginous; the nucleus oily. The *cake* (*placenta lini*) left after the expression of the oil, is usually denominated *oil cake*; it forms, when ground to a fine powder, *linseed meal* (*farina lini*). The best oil cake for the preparation of linseed meal is the English, fresh made. Foreign cake is of inferior quality. The colour of linseed meal is grayish-brown. It abounds in mucilage. The meal prepared by grinding the unpressed seeds yields a considerable quantity of oil.

The substance termed *flax* is prepared from the fibrous portions of the bark of the plant.¹ The short fibres which are removed in heckling constitute *tow* (*stupa*), which is employed both in pharmacy and surgery. Of flax is made *linen* (*linteum*), which, when scraped, constitutes *lint* (*linteum carptum*; *linamentum*), an important agent to the surgeon.²

COMPOSITION.—Linseed has been analyzed by L. Meyer.³ Its constituents he found to be as follows: *Fat oil* (in the nucleus) 11.265, *wax* (in the husk principally) 0.146, *acid soft resin* (in the husk principally) 2.488, *resinous colouring matter* 0.550, *yellow extractive with tannin and salts* (nitre and the chlorides of potassium and calcium) 1.917, *sweet extractive, with malic acid and some salts*, 10.884, *gum* (in the nucleus) 6.154, *nitrogenous mucilage, with acetic acid and salts* (in the husk principally), 15.120, *starch, with salts* (in the husk), 1.480, *albumen* (in the nucleus) 2.782, *gluten* (in the nucleus) 2.932, *husk and emulsion* (?) 44.382. The ashes contained *oxide of copper*.

1. **FIXED OIL.**—(See p. 989.)

2. **MUCILAGE OF LINSEED.**—Has been examined by Bostock,⁴ by Vauquelin,⁵ and by Guerin-Varry.⁶ Resides in the seed coats. Is extracted by hot water. When the solution is mixed with alcohol, white mucilaginous flocks are precipitated. Dicitate of lead forms a precipitate in it. Neither infusion of nutgalls nor chlorine have any effect on it. It is not coloured blue by iodine. It reddens litmus (owing to the free acetic acid). It consists of two parts: one soluble, the other insoluble in water. Its ashes contain carbonates of potash and lime, phosphate of lime, chloride of potassium, sulphate of potash, oxide of iron, alumina, and silica.

Proximate Analysis.		Ultimate Analysis.	
Soluble part	52.70	Carbon	31.50

⁴ *Ann. de Chim.* lxxx. 314.

⁵ *Nicholson's Journal*, xviii. 31.

⁶ *Journ. de Chim. Méd.* vii. 7. 9.

a. *Soluble part* (*Arabine?*) soluble in cold water. Treated with nitric acid, yields 14.25 per cent. of mucic acid, besides some oxalic acid.

β. *Insoluble part*. A nitrogenous substance, not soluble in water, and not yielding mucic acid by the action of nitric acid. Properly speaking, therefore, it is not a gummy substance.

PHYSIOLOGICAL EFFECTS.—Linseed is emollient and demulcent. It also possesses nutritive qualities; for, in the form of a thick mucilage (or jelly, as it is termed), it is employed for fattening cattle. *Linseed cake* is also employed for a similar purpose. *Linseed oil* is a mild laxative.

USES.—Employed, to allay irritation, in the form of *infusion* or *tea*, *expressed oil*, and *meal*.

1. **INFUSUM LINI COMPOSITUM**, L. [U. S.]; *Infusum Lini*, E.; *Linseed Tea*.—(Linseed, bruised, ℥vj [℥ss, U. S.]; Liquorice Root, bruised, ℥ij; Boiling [distilled, L.] Water Oj. Digest near the fire, in a lightly covered vessel, and strain [through linen or calico, E.]—Employed as an emollient and demulcent in irritation and inflammation of the pulmonary and urinary organs, and of the mucous membranes generally: as gonorrhœa, dysentery, alvine irritation, and pulmonary affections. It is rendered more palatable by the addition of sliced lemon and sugar-candy.—Dose, fʒij to fʒiv, or *ad libitum*.

2. **DECOCTUM LINI COMPOSITUM**, D.; *Compound Decoction of Linseed*.—(Take of Linseed ℥j; Liquorice Root, bruised, ℥ss; Water Oiss. Boil for ten minutes in a covered vessel, and strain while hot.)—Ed.]

3. **OLEUM LINI**, L. E. D. [U. S.]; *Linseed Oil*.—To prepare this oil, the seeds are first bruised or crushed, then ground, and afterwards subjected to pressure in the hydraulic or screw press.¹ *Cold-drawn linseed oil* (*oleum lini sine igne*) is paler coloured, less odorous, and has less taste, than linseed oil prepared by the aid of a steam heat of about 200° F. (*oleum lini*, offic.); but, according to Mr. Brande,² it “soon becomes rancid and more disagreeable than that expressed at a higher temperature.” The seeds yield by cold expression 18 or 20 per cent. of oil; but by the aid of heat from 22 to 27 per cent. Linseed oil is usually amber-coloured; but it may be rendered quite colourless. For a fine sample of colourless oil I am indebted to Mr. Whipple. Linseed oil has a peculiar odour and taste; it is soluble in alcohol, but more readily so in ether. When exposed to the air, it dries into a hard transparent varnish. This change is greatly accelerated by boiling the oil, either alone or with litharge, with sugar of lead or with common white vitriol. The resulting oil is called *drying oil* or *boiled oil*. The efficacy of the process is ascribed by Liebig³ to the elimination of substances which oppose the oxidation of the oil. The ultimate composition of linseed oil, according to Saussure, is carbon 76.014, hydrogen 11.351, and oxygen 12.635. Its proximate constituents are *oleic acid* (chiefly), *margaric acid*, and *glycerin*.—Rarely employed internally. Its most ordinary use is for the preparation of *Linimentum calcis*, already (Vol. I. p. 564) described.⁴

4. **FARINA LINI**, E.; *Linseed Meal*.—(The meal of the seeds deprived of their fixed oil by expression, E.)—Emollient. Employed in the preparation of the *linseed meal poultice*. It is a constituent of the *pulvis pro cataplasmate*, D., already noticed. The farina of the unpressed linseed is preferred to the powder of linseed cake, on account of its oleaginous quality. What is usually sold as such has been prepared from recently pressed English oil cake.

5. **CATAPLASMA LINI**, L.; *Linseed Meal Poultice*.—(Boiling Water ℥x; Linseed, powdered, ℥ivss, or as much as may be sufficient. Add the water by de-

greens to the linseed, stirring constantly that a poultice be made.)—A valuable emollient poultice.

326. LINUM CATHARTICUM, Linn. E.—PURGING FLAX.

Sex. Syst. Pentandria, Pentagynia.
(Herb, E.)

HISTORY.—First mentioned by Thalius in the sixteenth century.¹

BOTANY. Gen. Char.—See *Linum usitatissimum*.

Sp. Char.—Smooth, erect. Leaves opposite, obovate-lanceolate. Stem above dichotomous. (De Cand.)

Annual. Stem slender, 2 to 6 inches high. Flowers drooping before expansion, white, small.

Hab.—Indigenous; pastures; common.

DESCRIPTION.—Purging flax (*herba lini cathartici*) is odourless, but has a very bitter taste.

COMPOSITION.—I am unacquainted with any analysis of this plant. Probably its purgative principle is *bitter extractive*.

PHYSIOLOGICAL EFFECTS AND USES.—Cathartic and occasionally diuretic; but somewhat uncertain in its operation. Formerly used in rheumatism. Now almost obsolete. Dose ʒj of the dried plant; or an infusion of a handful of the fresh plant may be employed.

ORDER LXXX. CARYOPHYLLACEÆ.—THE CHICK-WEED TRIBE.

CARYOPHYLLÆ, Jussieu; De Candolle.

CHARACTERS.—Calyx generally persistent, of 4, or oftener 5 sepals, which are continuous with the pedicel, and either free or coherent into a 4- or 5-dentate tube, imbricate in aestivation. Petals as many as the sepals (very rarely 0), inserted on the torus, which is more or less elevated on a pedicel (anthophorus), alternate with the sepals, unguiculate, having the fauces sometimes crowned with petaloid scales. Stamens as many as, or double the number of, the valves inserted in the torus. Filaments subulate, sometimes submonadelphous at the base. Anthers 2-celled. Ovary simple, 2- to 5-valved, inserted at the apex of the torus, and crowned by an equal number of styles. Capsule of 2 to 5 valves, united at the base, dehiscing at the apex, generally 1-celled, sometimes 2- to 5-celled. Septa protruding from the middle of the valves, incomplete or continuous to the axis. Placenta central. Seeds numerous (very seldom few or definite); albumen farinaceous generally central; embryo usually peripheral, more or less incurved (seldom central and straight); radicle directed towards the hilum. Herbs or undershrubs, with opposite entire leaves. Stems jointed. (De Cand.)

PROPERTIES.—Remarkable, for the most part, for their insipidity and consequent inactivity.

327. DIANTHUS CARYOPHYLLUS, Linn.—CLOVE PINK; CARNATION, OR CLOVE GILLYFLOWER.

Sex. Syst. Decandria, Dignia.
(Flores.)

HISTORY.—First noticed by Manfredus de Monte Imperiali.²

BOTANY. Gen. Char.—Calyx tubular, 5-toothed, imbricated at the base with 2 to 4 opposite scales. Petals 5, with long claws. Stamens 10. Styles 2. Capsule 1-celled. Seeds compressed, convex on one side, concave on the other; peltate. Embryo scarcely curved. (De Cand.)

Sp. Char.—Stem branched. Flowers solitary. Scales of the calyx 4, very

¹ Sprengel, *Hist. Rei Herb.* 1. 35.

² Sprengel, *op. supra cit.* 1. 293.

short, ovate, somewhat mucronate. *Petals* very broad, beardless. *Leaves* linear-awl-shaped, channelled, glaucous. (De Cand.)

A *perennial* plant; the origin of the fine carnations of the gardens. *Flowers* pink, purple, white, or variegated; double, semi-double, or single.¹

Hab.—Indigenous. Cultivated in gardens.

DESCRIPTION.—The red or deep crimson gillyflowers (*flores dianthi caryophylli*; *flores caryophylli rubri*; *flores tunicæ*) were formerly employed in medicine on account of their colour. They have a pleasant aromatic smell, and a bitterish sub-astringent taste. They communicate to water their smell and colour.²

COMPOSITION.—I am unacquainted with any analysis of them. They obviously contain a *volatile oil*, *colouring matter*, and an *astringent principle*.

PHYSIOLOGICAL EFFECTS AND USES.—Formerly supposed to have an influence over the nervous system to raise the spirits, &c. Simon Pauli³ recommended them in various nervous and spasmodic affections, and in malignant fever. They have also been used as flavouring and colouring agents; and a *symp* of them was formerly contained in the British Pharmacopœias.

ORDER LXXXI. POLYGALÆÆ, *De Candolle*.—THE MILK-WORT TRIBE.

POLYGALACÆÆ, and KRAMERIACÆÆ, *Lindley*.

CHARACTERS.—*Sepals*, 5, imbricate in æstivation, the two interior generally petaliform, the three exterior smaller; two of them are interior, and sometimes united, the third is posterior. *Petals* 3 to 5 hypogynous, more or less united by means of the tube of the stamens (rarely distinct). *Filaments* of stamens adherent to the petals, monadelphous, divided at the apex into two opposite equal phalanges. *Anthers* 8, 1-celled, innate, dehiscing by pores at the apex. *Ovary* 1, free, 2 celled, rarely 1- or 3-celled. *Style* 1. *Stigma* 1. *Pericarp* capsular or drupaceous, 2- or 1-celled. *Valves* septigerous in the middle. *Seeds* pendulous, solitary, often with a carunculate arillus at the base; *embryo* straight, generally in the axis of a fleshy albumen (or rarely), exalbuminous, in which case the endopleura is tumid. *Herbs* or *shrubs*. *Leaves* entire, generally alternate, articulated on the stem. (De Cand.)

PROPERTIES.—Leaves and roots for the most part bitter and astringent.

328. POLYGALA SENEGA, *Linn. L. E. D.*—THE SENEKA.

Sex. Syst. Diadelphia, Octandria.

(*Radix, L.*—*Root, E. D.*)

[*Senega, U. S.*]

HISTORY.—The root of this plant was introduced into medicine as a remedy for the bites of venomous animals, in the early part of the last century, by Dr. Tennant, a Scotch physician, residing in Pennsylvania.⁴

BOTANY. Gen. Char.—*Sepals* persistent, the two inner ones wing-like. *Petals* 3 to 5, adnate to the tube of the stamen; the inferior one keel-shaped (perhaps composed of two united). *Capsule* compressed, elliptical, or obcordate. *Seeds* pubescent, carunculated at the hilum, destitute of a coma. (De Cand.)

Sp. Char.—*Stems* several, somewhat erect, simple, terete. *Leaves* ovate-lanceolate, the upper ones acuminate. *Racemes* somewhat spiked. *Wings* orbiculate. *Capsule* elliptical, emarginate. (De Cand.)

Root perennial, branching. *Stems* annual, from 9 to 12 inches high, occasionally tinged at their lower part with red or purple. *Leaves* alternate, sessile, or on very short stalks, paler beneath. *Flowers* small, white. *Alæ* of the calyx white, with green veins. *Capsule* small, containing two blackish seeds.

¹ For horticultural information respecting them, consult Loudon's *Encyclopædia of Gardening*.

² *Lewis, Mat. Med.*

³ *Quadrip. Bot. p. 211.*

⁴ *An Epistle to Dr. Mead, 1712.*

Hab.—United States of America; most abundant in the southern and western parts.

DESCRIPTION.—*Senega* or *Seneka* root (*radix senegæ* seu *senekæ*), sometimes called the *seneka-snakeroot* or the *rattlesnake root*, is imported from the United States in bales. It varies in size from that of a writing-quill to that of the little finger; it is contorted, presents a number of eminences, and terminates superiorly in an irregular tuberosity, which exhibits traces of numerous stems; a projecting line extends the whole length of the root. The cortical portion is corrugated, transversely cracked, thick, of a grayish-yellow colour. The central portion (*medicullium*) is woody and white. The taste of the root is at first sweetish and mucilaginous, afterwards acrid and pungent, exciting cough and a flow of saliva; its odour is peculiar and nauseous.

COMPOSITION.—*Senega* root has been repeatedly made the subject of chemical investigation. In the last century it was examined by Burckhard, by Keilhorn, and by Helmuth.¹ In 1804 it was analyzed by Gehlen;² and in 1811 by Fougèron.³ Peschier⁴ also published an analysis of it. In 1826 it was analyzed by Feneuille,⁵ in 1827 both by Dulong d'Astafort⁶ and by Folehi,⁷ in 1832 by Trommsdorff,⁸ and in 1836 by Quevègne.⁹ I subjoin three of these analyses:—

<i>Trommsdorff.</i>		<i>Dulong.</i>	<i>Quevègne.</i>
Volatile oil	a trace.	Volatile oil, traces.	Polygalic acid.
Acrid resin	4.552	Acrid extractive.	Virgineic acid.
Sweetish bitter extractive	33.570	Yellow extractive.	Tannic acid.
Pectic acid	10.444	A substance reddened by sulphuric acid.	Pectic acid.
Wax	0.746	Pectic acid.	Cerin.
Soft resin	5.222	Wax.	Fixed oil.
Mucus	5.968	Resin.	Yellow colouring matter.
Woody fibre	34.316	Gum.	Gum.
Malates, potash, and lime	2.536	Woody fibre.	Albumen.
Dried <i>Senega</i> Root	97.354	Malates of potash and lime.	Woody fibre.
		Mineral salts and iron.	Salts, alumina, silica, magnesia, and iron.
		Senega Root.	Senega Root.

1. **POLYGALIC ACID**, in the impure state, was first procured by Gehlen, who called it *Senegin*. It is the active principle, and resides in the cortical part of the root. When pure it is a white, odourless powder, which is at first tasteless, but afterwards communicates an acrid feeling to the mouth, and a sense of constriction to the fauces. It irritates the nostrils and excites sneezing. It is volatile, and, when decomposed by heat in a glass tube, evolves no ammonia, and hence contains no nitrogen. It is soluble in water and in alcohol, especially when heated by heat; but it is insoluble in ether, acetic acid, and the oils. Its solution forms white precipitates (*polygalates*) with diacetate of lead and pronitrate of mercury. Sulphuric acid has a characteristic effect on polygalic acid; it renders polygalic acid yellow, then rose-red, and afterwards dissolves it, forming a violet-coloured solution, which becomes decolorized in twenty-four hours. The *alkaline polygalates* are not crystallizable. Polygalic acid consists of carbon 55.704, hydrogen 7.529, and oxygen 36.767; or, C²²H¹⁶O¹¹. It has considerable resemblance to esculic acid.¹⁰ Given to dogs in doses of six or eight grains, it causes vomiting, embarrassed respiration, and death in three hours. Two grains thrown into the jugular vein caused vomiting, and, in two hours and a half, death.

5. **VIRGINEIC ACID.**—A volatile, fatty acid, analogous to valerianic, phoenic, and butyric acids. It is an oily liquid, of a reddish colour, a strong, penetrating, disagreeable odour, and an acrid taste. It is soluble in alcohol, ether, and caustic potash, but scarcely so in water.

PHYSIOLOGICAL EFFECTS.—*Senega* possesses acrid and stimulant properties. In small doses it is diaphoretic, diuretic, and expectorant; in larger doses, emetic and purgative. Sundelin¹¹ took a scruple of powdered *senega* root every two hours for six hours; it caused irritation of the back part of the tongue and throat, and gave rise to an increased flow of saliva. These effects were soon followed by considerable burning in the stomach, nausea, and vomiting. The skin became warmer and moister; there was griping pain of the bowels, followed by watery evacuations;

³ Quoted by Goebel and Kunze, *Pharm. Waarenk.*

⁶ *Journ. de Pharm.* xiii. 567.

⁹ *Pharm. Central-Blatt für 1832*, S. 419.

¹⁰ *Journ. de Pharm.* xxiii. 270.

the secretion of urine was increased, and a feeling of heat was experienced in the urinary passages. For some days after, there was gastric uneasiness with loss of appetite. *In larger doses*, it caused burning pain in the stomach and bowels, violent vomiting, purging, anxiety, and giddiness.

It appears to excite moderately the vascular system, to promote the secretions (at least those of the kidneys, skin, uterus, and bronchial membrane), and to exert a specific influence over the nervous system. It has been principally celebrated for its expectorant effects.

In its operation on the nervous system, it has considerable resemblance to Arnica; but its influence over the secreting organs is much greater. It is somewhat analogous to Helenium in its action.

USES.—In this country, senega is comparatively but little employed. It is an exceedingly valuable remedy in the latter stages of *bronchial* or *pulmonary inflammation*, when this disease occurs in aged, debilitated, and torpid constitutions, and when the use of depletives is no longer admissible. It appears to re-establish a healthy condition of the secreting organs, to promote the resolution of the morbid deposits, and to give strength to the system. I usually administer it in combination with ammonia, which appears to me to promote its beneficial operation. Frequency of pulse, and a febrile condition of the system, are by no means to be regarded as impediments to the use of this medicine.

In *chronic catarrh* and *humoral asthma* it has also been used. It has been extravagantly praised by Dr. Archer, of Maryland, as a remedy for *croup*.¹ He represents it as being capable, without the aid of any other means, of removing this alarming disease. Few practitioners, I suspect, would venture to trust it. Yet it might be a useful addition to emetics. As a stimulant and promoter of the secretions, it has been used with advantage in the latter stage of *low fever* accompanied with torpidity. It has also been used as an emetic, purgative, and diaphoretic, in *rheumatism*, as a diuretic in *dropsy*, and as an emmenagogue in *amenorrhœa*. It was introduced into practice as a remedy against the bite of venomous animals, as the rattlesnake.

ADMINISTRATION.—The dose of the *powder* is from grs. x to ℥j. But the *infusion* or *decoction* is the best form of exhibition.

1. DECOCTUM SENEGÆ, L. [U. S.]; *Decoction of Senega*.—(Senega Root ℥x [℥i, U. S.]; Distilled Water two pints [Water Oiss, U. S.]. Boil down to a pint, and strain.)—Stimulating, expectorant, and diuretic. Dose, fʒj to fʒiij, three or four times daily. Ammonia is often a valuable addition to it.

[2. INFUSUM POLYGALÆ, D.—(Polygala Root, bruised, ʒss; Boiling Water ʒix. Digest for one hour in a covered vessel, and strain.)—The product should measure about eight ounces.—ED.]

[3. INFUSUM SENEGÆ, E.; *Infusion of Senega*.—(Take of Senega ʒx; Boiling Water one pint. Infuse for four hours in a covered vessel, and strain.)—ED.]

[4. SYRUPUS SENEGÆ, U. S. *Syrup of Seneka*.—(Take of Seneka, bruised, four ounces; Water a pint; Sugar a pound. Boil the Water with the Seneka to one-half, and strain; then add the Sugar, and proceed in the manner directed for Syrup. Or, take Seneka in coarse powder four ounces; Water a sufficient quantity; Sugar fifteen ounces. Mix the Seneka with four fluidounces of Water, and allow the mixture to stand for twelve hours; then put it into an open apparatus for displacement, and gradually pour water upon it until the liquid passes nearly tasteless. Evaporate the filtered liquor to half a pint, strain, and having added the Sugar, proceed as for Syrup.)—This preparation possesses all the advantages of the decoction, to which, moreover, it is superior, in its acceptability to the patient. It may be employed by itself, or it may be combined with other articles and employed in the form of cough mixture. The dose is fʒi or fʒij.

¹ Eberle, *Mat. Med.*

5. **EXTRACTUM SENEGÆ**; *Extract of Seneka*.—(To make this preparation, a formula has been given by Mr. Procter, in *Am. Journ. of Pharmacy*, vol. xiv. p. 287. Take of Seneka, in coarse powder, ℥xvj; Alcohol Oij; Water Oiv. Mix the Alcohol and Water, and macerate the Seneka in one half of it for two days, place the mixture in a displacement apparatus, and operate with the same menstruum until six pints of tincture are obtained. Evaporate this on a water-bath till reduced to the consistence of an extract. One drachm of this extract dissolved in a pint of water yields a preparation of the same theoretical strength, but greater actual strength than the official decoction. It may be used in the same manner as the preceding, by combination.]

329. **KRAMERIA TRIANDRA**, *Ruiz and Pavon, L. E. D.*—**THE RHATANY.**

Sex. Syst. Tetandria, Monogynia, Willd.
(*Radix, L.*—*Root, E. D.*)

HISTORY.—This plant was discovered by Ruiz and Pavon, in 1779, in South America. It was introduced to notice into this country, as a medicine, by Dr. Reece, in 1808. In 1813, Ruiz's dissertation on it appeared in an English dress.¹

BOTANY.—**Gen. Char.**—*Sepals* 4 or 5, irregular, coloured, spreading, deciduous. *Petals* 4 or 5, irregular, smaller than the calyx, the 3 inner unguiculate. *Stamens* 1, 3, or 4, hypogynous, unequal. *Ovary* 1-celled, or incompletely 2-celled; *style* terminal; *stigma* simple; *ovules* in pairs, suspended. *Fruit* between hairy and leathery, globose, covered with hooked prickles, by abortion 1-seeded, indehiscent. Spreading, many-stemmed *undershrubs*. *Leaves* alternate, simple, entire, or 3-foliate, spreading. *Racemes* simple, spiked (Lindley).

Sp. Char.—*Leaves* oblong, somewhat acute, villous-silky. *Pedicels* somewhat longer than the leaf, bibracteate, forming a short *raceme*. (De Cand.)

Suffruticose. *Root* long, branching. *Stem* procumbent, branching. *Leaves* sessile, covered on both surfaces with long, silky leaves. *Flowers* solitary, lake-coloured. *Stamens* 3. *Drupe* round, beset with stiff reddish hairs.

Hab.—Peru; growing abundantly in Huanuco, Huamalics, and Canta.

DESCRIPTION.—Rhatany root (*radix kramerix seu rhatanix*) is brought from Peru. It consists of numerous woody, cylindrical, long branches, varying in thickness from that of a writing-quill upwards. These pieces consist of a slightly fibrous, reddish-brown bark, having an intensely astringent and slightly bitter taste, and of a very hard, ligneous medullium, of a yellowish or pale red colour. The largest quantity of astringent matter resides in the bark, and therefore the smaller branches (which have a larger proportion of bark) are to be preferred.

Foreign or South American extract of rhatany (extractum kramerix seu rhatanix americanum) is occasionally imported.

COMPOSITION.—Rhatany root has been analyzed by Trommsdorff, Vogel, C. G. Gmelin, and Peschier.²

<i>C. G. Gmelin.</i>		<i>Peschier.</i>	
Tannin	32.3	Dried watery extract	31.25
Sweet matter	0.7	Insoluble matters	68.75
Mucilage	8.2		
Nitrogenous ditto	3.3	Rhatany Root	100.00
Lignin	43.3		
[Loss	0.9]		
Rhatany Root	100.0		
		Tannin	42.6
		Gallie acid	0.3
		Gum, extractive, and colouring matter	66.7
		Kramerie acid	0.4
		Dried Watery Extract of Rhatany Root	100.0

1. **TANNIC ACID.**—To this, as well as in part to a minute portion of gallic acid, rhatany root owes its astringent qualities. It is this acid which enables an infusion of rhatany root to form,

¹ Eckard, *Diss. Inaug. de Rad. Ratanhiæ*, Berol. 1822.

² L. Gmelin, *Handb. d. Chem.* ii. 125.

with a solution of gelatine, a precipitate (*tannate of gelatine*), and with sesquichloride of iron a brownish-gray precipitate (*tannate of iron*). The properties of tannic acid have been already described.

2. **KRAMERIC ACID.**—Peschier ascribes the stypticity of rhatany to this acid, the properties of which are at present imperfectly known.

PHYSIOLOGICAL EFFECTS.—A powerful astringent, and, like other agents of this class, tonic also. (See the effects of astringents, *ante*.)

USES.—Rhatany root is adapted to all those cases requiring the employment of astringents; such as *profuse mucous discharges* (as humid catarrh, old diarrhœas, fluor albus, &c.), *passive hemorrhages* (especially metrorrhagia), and *relaxation and debility of the solids*. It is sometimes used as a *tooth powder* (as with equal parts of orris root and charcoal). Dentists sometimes employ tincture of rhatany diluted with water as an *astringent mouth wash*.

ADMINISTRATION.—The *powder* may be given in doses of from grs. x to ʒss. The *infusion* or *extract* is more commonly employed. *Compound tincture of rhatany* is prepared by digesting ʒiij of bruised rhatany root, and ʒij of orange peel, in Oj of proof spirit. Sometimes ʒss of serpentary root and ʒj of saffron are added. It is an efficacious astringent and stomachic.—Dose, fʒj to fʒij.

1. **INFUSUM KRAMERLÆ, L. D.;** *Infusion of Rhatany.*—(Krameria ʒj [ʒss D.]; Boiling Distilled Water Oj, [ʒix D.] Macerate for four hours [one hour, D.] in a lightly covered vessel, and strain. (The product should measure about eight ounces, D.)—Astringent and tonic. Dose, fʒj to fʒij.

2. **EXTRACTUM KRAMERLÆ, E.;** *Extract of Rhatany.*—(Prepared as extract of liquorice. [A better mode is by evaporation of the displaced infusion.] Astringent.)—Dose, grs. x to ʒj.

3. **TINCTURA KRAMERLÆ, U. S.** *Tincture of Rhatany.*—(Rhatany in powder ʒvi; Diluted Alcohol Oij. Macerate for fourteen days, and strain, or prepare by displacement.)—Used as an adjunct to cretaceous mixtures, or with tonics. The dose is fʒj to fʒij. It may be employed diluted with water as a gargle.]

[4. **STRYPUS KRAMERLÆ, U. S.** *Syrup of Rhatany.*—(Extract of Rhatany ʒij; Water Oj; Sugar lb ijss. Dissolve the extract in the water, and make the solution into a syrup. A pleasant astringent, used in diarrhœas, chronic dysentery, and hemorrhages.)—Dose, fʒj to fʒss.]

ORDER LXXXII. VIOLACEÆ, Lindley.—THE VIOLET TRIBE.

VIOLARIÆ, De Candolle.

CHARACTERS.—*Sepals* 5, persistent, with an imbricate æstivation, usually elongated at the base. *Petals* 5, hypogynous, equal or unequal, usually withering, and with an obliquely convolute æstivation. *Stamens* 5, alternate with the petals, usually opposite them, inserted on a hypogynous disk, often unequal; *anthers* bilocular, bursting inwards, either separate or cohering, and lying close upon the ovary: *filaments* dilated, elongated beyond the anthers; two, in the regular flowers, generally furnished with an appendage or gland at their base, *Ovary* 1-celled, many-seeded, or rarely 1-seeded, with 3 parietal placentæ opposite the three outer sepals; *style* single, usually declinate, with an oblique hooded *stigma*. *Capsule* of 3 valves, bearing the placentæ in their axis. *Seeds* often with a tumour at their base; *embryo* straight, erect, in the axis of fleshy *albumen*—*Herbaceous* plants or *shrubs*. *Leaves* simple, usually alternate, sometimes opposite, stipulate, entire, with an involute *vernation*. *Inflorescence* various (Lindley).

PROPERTIES.—Roots more or less emetic.

330. VIOLA ODORATA, Linn. L. E.—THE SWEET VIOLET.

Sez. Syst. Pentandria, Monogynia.
(Petalum recens, L.—Flowers, E.)

HISTORY.—According to Dr. Sibthorp,¹ this is the *Ἴων πορφύρεον* (*purple violet*) of Dioscorides.² It was employed in medicine by Hippocrates.

BOTANY.—Gen. Char.—*Sepals* 5, unequal, prolonged into appendages at the base. *Corolla* unequal, 2-lipped, of 5 petals, the lower calcarate. *Capsule* bursting with elasticity, many-seeded, 3-valved.—*Herbaceous* plants (Lindley).

Sp. Char.—*Stigma* uncinatè, naked. *Leaves* rounded cordate. *Sepals* ovate, obtuse. *Spur* very blunt. *Capsule* turgid, hairy. *Seeds* turbinate, pale. *Runners* flagelliform. (De Cand.)

Perennial. *Flowers* fragrant, deep purple, often white, occasionally lilac. *Bracts* inserted above the middle of the scape.

Hab.—Indigenous. Flowers in March and April. Cultivated on account of the odour and colour of the flowers.

DESCRIPTION.—Violets (*flores violæ odoratæ*) should be gathered immediately they are expanded, as they subsequently become purplish. Their delightful fragrance is well known. The root of the violet (*radix violæ odoratæ*) has been used in medicine.

COMPOSITION.—In 1822, Pagenstecher³ detected the following substances in an infusion of the flowers: *Odorous principle*, *blue colouring matter*, *sugar* both *crystallizable* and *uncrystallizable*, *gum*, *albumen*, and *salts of potash* and *lime*. Boullay⁴ obtained from the *root*, *leaves*, *flowers*, and *seeds* an acrid principle, which he has termed *violine*.

1. ODOROUS PRINCIPLE.—This has not been isolated. It is supposed, however, to be of the nature of volatile oil. By digesting violets in olive oil, the latter dissolves the odorous matter, and acquires the smell of violets: this preparation is the *oil of violets*, the *huile de violette* of perfumers. The *eau* or *esprit de violette* is nothing more than an alcoholic tincture of the rhizome of the Florentine orris, which has an odour similar to that of the violet.

2. COLOURING MATTER.—It is soluble in water, but not in alcohol. It is changed to red by the strong acids, and to green by the alkalis: hence, the expressed juice and syrup are valuable as tests for discovering the existence of either acids or alkalis. An infusion of violets has been said to contain three kinds of colouring matter; namely, a *blue colouring matter*, not precipitable by the acetate of lead, but which is completely decolorized by sulphuretted hydrogen; secondly, a *bright-red acid colouring matter*, which causes a bluish-green precipitate with the solution of acetate of lead; thirdly, a *violet-red colouring matter*, which does not precipitate the neutral acetate of lead, but throws down a greenish-yellow precipitate with the subacetate of lead.

3. VIOLINE (*Emétine indigène*).—It was at first mistaken for *Emetina*. Its nature requires farther investigation. It is a white powder, of a bitter acrid taste, slightly soluble in water, and insoluble in ether. It is precipitated from its solution by infusion of nutgalls. Its operation is similar to that of emetine.

PHYSIOLOGICAL EFFECTS.—The *odorous emanations* of violets, like those of some other flowers, are said to have occasionally proved dangerous, and in one case were supposed to have brought on apoplexy.⁵ Dr. Lindley⁶ has known them cause faintness and giddiness. Taken *internally*, violets act as laxatives. The *seeds* possess similar properties. The *root*, in doses of from $\zeta s s$ to ζj , proves emetic and purgative.

USES.—Violets are employed in the preparation of the officinal syrup. They are useful as a test for acids and alkalis, and are much sought after for bouquets. The root might be employed as a substitute for ipecacuanha.

SYRUPUS VIOLÆ, L. E.; *Syrup of Violets*.—(Of the Violet $\zeta i x$; Boiling Dis-

¹ *Prodr. Fl. Græc.* 1. 147.

³ Trillel, quoted by Murray, *App. Med.* 1. 178.

⁴ *Lib. iv. cap.* 122.

⁵ *Journ. de Pharm.* x. 23.

⁶ *Flora Medica.*

tilled Water Oj; Sugar ℥iij, or a sufficiency; Rectified Spirit ℥iiss, or a sufficiency. Macerate the violet in water for twelve hours, then express and strain.—Set aside that the dregs subside, and proceed as directed for the Syrupus Althææ, *L.* (Fresh Violets, *L.* ℥bj; Boiling Water Oiiiss; Pure Sugar ℥viiss. Infuse the flowers for twenty-four hours in the water [in a covered glass or earthenware vessel, *E.*]; strain without squeezing, and dissolve the sugar in the filtered liquor, *E.*)—The colour of this preparation is improved by making it in a tin or pewter vessel. No satisfactory explanation of this has been offered. The Edinburgh College, fearful, I presume, of metallic impregnation, direct glass or earthenware vessels to be employed.—Genuine syrup of violets is readily distinguished from any counterfeit by its being reddened by an acid, and made green by an alkali. Hence it is employed as a test.—As a medicine it is used as a mild laxative for new-born infants. Thus, a mixture of equal parts of oil of almonds and syrup of violets is often administered, in the dose of one or two teaspoonfuls, for the purpose mentioned.

Fig. 401.

Root of *Ionidium Ipecacuanha*.

OTHER MEDICINAL VIOLACEÆ.

The roots of several species of *Ionidium* possess emetic qualities, and have been employed as substitutes for our officinal ipecacuanha (*Cephaelis Ipecacuanha*).

The root of *IONIDIUM IPECACUANHA*, a native of the Brazils, is termed *False Brazilian Ipecacuanha*. It yielded Pelletier five per cent. of emetine. The dose of it, as an emetic, is ℥ss to ℥j infused in water.

The root of the *IONIDIUM MICROPHYLLUM*, or the *Cuchunchully*, a native of Quito, possesses similar properties.

Dr. Bancroft¹ speaks favourably of it in Elephantiasis tuberculata. But the specimens which he sent home as *Cuchunchully* are said by Sir W. Hooker to be identical with *Ionidium parviflorum*, Vent. Dr. Lindley,² however, received from the Hon. W. F. Strangways, the "*Cuchunchully de Cuenca*," which was the *I. microphyllum* of Humboldt.

ORDER LXXXIII. CISTACEÆ, Lindley.—THE ROCK-ROSE TRIBE.

CISTI, Jussieu. CISTOIDEÆ, Ventenat. CISTINEÆ, De Candolle.

Fig. 402.

*Cistus creticus*.

The substance called *LADANUM* is a resinous exudation from the *Cistus creticus*, growing, as its name implies, in Crete. In the time of Dioscorides it was collected by combing the beards of the goats which browse on the plant. According to Tournefort³ and Sieber, it is now collected by a kind of whip or rake, with a double row of leathern thongs. With this the countrymen brush the plants, and when the whips are sufficiently laden with the juice, it is scraped off by knives, and made into cakes. Pure ladanum consists of resin and volatile oil 86, wax 7, aqueous extract 1, and earthy matters and hairs 7 (Guibourt). Pelletier found 72 per cent. of sand in it. It possesses stimulant properties, and was formerly a constituent of some plasters. Its use is now obsolete.

ORDER LXXXIV. CRUCIFERÆ, *Jussieu*.—THE CABBAGE OR CRUCIFEROUS TRIBE.BRASSICACEÆ, *Lindley*.

CHARACTERS.—*Sepals* 4, deciduous cruciate. *Petals* 4, cruciate, alternate with the sepals. *Stamens* 6, of which two are shorter, solitary, opposite the lateral sepals, and occasionally toothed; and four larger, in pairs, opposite the anterior and posterior sepals, generally distinct, sometimes connate, or furnished with a tooth on the inside. *Disk* with various green glands between the petals, and the stamens and ovary. *Ovary* superior, unilocular, with parietal placentæ usually meeting in the middle, and forming a spurious dissepiment. *Stigmas* 2, opposite the placentæ. *Fruit* a silique or silicula, 1-celled, or spuriously 2-celled; 1- or many-seeded; dehiscent by two valves separating from the replum; or indehiscent. *Seeds* attached in a single row by a funiculus to each side of the placentæ, generally pendulous. *Albumen* none. *Embryo* with the radicle folded upon the cotyledons.—*Herbaceous* plants, annual, biennial, perennial, very seldom suffruticose. *Leaves* alternate. *Flowers* usually yellow or white, seldom purple (*Lindley*).

PROPERTIES.—Pungent stimuli. They furnish nutritive, condimentary, and antiscorbutic substances. Their pungency depends on an acrid volatile oil, composed of *carbon*, *nitrogen*, *hydrogen*, *sulphur*, and *oxygen*. This oil becomes absorbed, and in some cases is detectable in the secretions. The nutritive properties of cruciferæ arise from their mucilaginous, saccharine, and extractive constituents. *Cakile maritima* is purgative. *Cheiranthus lividus* is said to be dangerous to goats; while *Lepidium piscidium*, we are told, stupefies fish. These statements, however, require farther proof. With these doubtful exceptions, none of the cruciferæ are poisonous.

Fig. 403.

A Silique.

331. CARDAMINE PRATENSIS, *Linn.*—CUCKOO-FLOWER.*Sex. Syst.* Tetradynamia, Siliquosa.

HISTORY.—Brunfels and Tragus are the earliest writers in whose works an undoubted notice of this plant appears.¹

BOTANY. *Gen. Char.*—*Silique* linear, with flat, nerveless valves, which often separate elastically. *Seeds* ovate, not bordered (O=). *Umbilical cords* slender. (*De Cand.*)

Sp. Char.—*Leaves* pinnatisect; segments of the radical ones somewhat rounded—of the cauline ones, linear or lanceolate, entire. *Style* very short, scarcely more slender than the silique; *stigma* capitate. (*De Cand.*)

Root perennial. *Stem* about a foot high. *Flowers* light purple, flesh-coloured, or white.

Hab.—Indigenous; meadows and moist pastures. Flowers in April and May.

DESCRIPTION.—The flowers (*flores cardamines*) are somewhat bitter and pungent, and have a slight odour. By drying they become inodorous and almost insipid. The *leaves* possess a flavour analogous to, though less agreeable than, the common water-cress.

COMPOSITION.—I am unacquainted with any analysis of the plant worth quoting. The pungency depends on *volatile oil*, the bitterness on *extractive matter*. A few experiments on this plant are mentioned by Gronhart.²

PHYSIOLOGICAL EFFECTS AND USES.—The flowers of cardamine are said to be stimulant, diaphoretic, diuretic, and nervine. They were formerly used in epilepsy, especially when it occurred in children, but have now fallen into almost total disuse. They were recommended by Sir George Baker³ in cholera and spasmodic asthma. Dose of the dried flowers, ʒij or ʒiij.

¹ Sprengel, *Hist. Rei Herb.*² *Med. Trans.* i. 442.³ *Spec. Inaug. Resiomonti*, 1785.

332. COCHLEARIA ARMORACIA, Linn. L. E.—HORSERADISH.

Sez. Syst. Tetradymania, Siliculosa.
(*Radix recens*, L.—Fresh root, E.)

HISTORY.—Sprengel¹ considers this plant to be the *μαρανις ἀγρία* of Dioscorides;² and Dierbach³ suggests that it was known to Hippocrates. But these opinions are by no means well established.

BOTANY. **Gen. Char.**—*Silicule* sessile, ovate-globose or oblong, with ventricose valves. *Seeds* many, not bordered. *Calyx* equal, spreading. *Petals* entire. *Stamens* not toothed.—(O=). *Flowers* white. *Leaves* often somewhat fleshy. (De Cand.)

Sp. Char.—*Silicules* ellipsoid. Radical *leaves* oblong, crenate; cauline ones elongated, lanceolate, dentate, or incised. *Root* fleshy, large. (De Cand.)

Root perennial, long, cylindrical, white, very pungent. *Stems* two feet high. *Leaves* much veined. *Flowers* white.

Hab.—Indigenous; extensively cultivated. *Flowers* in May.

DESCRIPTION.—Horseradish root (*radix armoraciæ*; *radix raphani rusticani*) evolves, when scraped into shreds, a highly penetrating acrid vapour. Its taste is very pungent. It is coloured blue by tincture of iodine. An infusion of it is tinged reddish yellow by the sesquisalts of iron.

COMPOSITION.—Horseradish root was analyzed by Gutret,⁴ who found its constituents to be—*acrid volatile oil*, *bitter resin*, *extractive sugar*, *gum*, *starch*, *woody fibre*, *vegetable albumen*, *acetic acid*, and *acetate and sulphate of lime*.

VOLATILE OIL (*Oleum Armoracæ*).—Obtained by distillation without water. It is pale yellow, heavier than water, and very volatile. Its odour is exceedingly powerful, and like that of horseradish. One drop is sufficient to infect a whole room. Its taste is at first sweetish, then burning and acrid. It causes inflammation and vesication when applied to the skin. It is slightly soluble in water, easily so in alcohol. The watery solution yields, with acetate of lead, a brown precipitate (*sulphuret of lead*); with nitrate of silver, a black one (*sulphuret of silver*). [It contains sulphur and nitrogen, but no oxygen. It has lately been shown to be identical with Volatile Oil of Mustard.—Ed.]

PHYSIOLOGICAL EFFECTS.—Horseradish is a well-known pungent, acrid stimulant, capable of producing vesication when applied to the skin, and of causing vomiting when taken, in the form of infusion, into the stomach. Its odorous emanations readily excite a copious flow of tears. On the general system it operates as a stimulant, and promotes both urine and perspiration.

USES.—Scraped in shreds, it is used at the table as a condimentary accompaniment to roast beef. It is not much employed as a medicine. Chewed, it serves as an excellent masticatory. Taken in this way, or in the form of syrup, it may be serviceable in some forms of hoarseness. An infusion of it may be taken to excite vomiting, or to promote the operation of other emetics, as in poisoning by narcotic substances. As a general stimulant, diaphoretic, and diuretic, it has been used in palsy, chronic rheumatism, and dropsy. It is one of the remedies deemed antiscorbutic.

ADMINISTRATION.—Dose, ℥ss or more, scraped into shreds.

1. **INFUSUM ARMORACIÆ COMPOSITUM, L.**; *Compound Infusion of Horseradish.*—(Horseradish, sliced; Mustard-seeds, bruised, of each ℥i; Compound Spirit of Horseradish f ℥j; Boiling Distilled Water Oj. Macerate the root and seeds in the water for two hours in a lightly covered vessel, and strain. Then add the compound spirit of Horseradish).—This preparation soon undergoes decomposition. It is stimulant and diuretic, and has been employed in chronic rheumatism, paralysis, dropsies, and scurvy.—Dose, f ℥j to f ℥ij.

³ *Lib.* ii. 138.

⁴ *Gmelin, Handb. d. Chem.* ii. 1243.

2. SPIRITUS ARMORACIÆ COMPOSITUS, L.; *Compound Spirit of Horseradish*.—(Horseradish, sliced; Dried Orange Peel, of each ℥xx; Nutmegs, bruised, ℥v; Proof Spirit, Cong. j; Water Oij. Mix, and let a gallon distil by a gentle heat).—Usually employed as a stimulating adjunct to other medicines, especially to diuretic infusions. Dose, ℥j to ℥iv.

333. COCHLEARIA OFFICINALIS, Linn.—COMMON SCURVY-GRASS.

Sex. Syst. Tetradynamia, Siliculosa.
(Herba.)

HISTORY.—This plant does not appear to have been known to the ancients.

BOTANY.—*Gen. Char.*—See *Cochlearia Armoracia*.

Sp. Char.—*Silicules* ovate-globose, twice as short as their pedicels. Radical leaves stalked, cordate; cauline ones ovate dentate-angular. (De Cand.)—*Annual*. Stem about a foot high. *Flowers* pure white.

Hab.—Indigenous; on the sea-coast and in watering-places on the Welsh and Scottish mountains. Cultivated in gardens.—Flowers in April and May.

DESCRIPTION.—Scurvy-grass (*herba cochleariæ*) evolves, when rubbed, a somewhat pungent odour. Its taste is penetrating and acrid.

COMPOSITION.—The *inspissated juice* was examined by Braconnot,¹ and the *fresh herb* by Gutret.² The latter obtained from it the following constituents: *volatile oil, bitter resin, bitter extractive, gum, green fecula, vegetable albumen, hydrochlorate and sulphate of ammonia, nitrate and sulphate of lime.*

VOLATILE OIL (*Oleum Cochleariæ*).—This oil is identical with the oil of horseradish (*ante*, p. 1000).

PHYSIOLOGICAL EFFECTS AND USES.—A gentle stimulant, aperient, and diuretic. It has long been esteemed as an antiscorbutic.³ It has also been used in visceral obstructions. It is occasionally eaten with bread and butter, like the water-cress. [Formerly introduced into the Dublin Pharmacopœia, now omitted.—ED.]

334. SINAPIS NIGRA, Linn. L. E. D.—COMMON OR BLACK MUSTARD.

Sex. Syst. Tetradynamia, Siliquosa.

(*Seimen, L.*—Flour of the seeds, generally mixed with those of *Sinapis alba*, and deprived of fixed oil by expression, *E.*—The flour of the seeds, *D.*)

HISTORY.—Mustard (*σάπυ*) was employed in medicine by Hippocrates.

BOTANY. *Gen. Char.*—*Siliques* somewhat terete; the valves nerved. *Style* small, short, acute. *Seeds* in one row, somewhat globose. *Calyx* spreading. (De Cand.)

Sp. Char.—*Siliques* smooth, even, somewhat tetragonal, pressed close to the peduncle. Lower leaves lyrate; upper ones lanceolate, quite entire, stalked.—*Annual*. Stem 3 or 4 feet high. *Flowers* yellow.

Hab.—Indigenous; hedges and waste places. Cultivated in fields, especially in Durham and Yorkshire.

DESCRIPTION.—Black mustard seeds (*semina sinapis nigra*) are small and roundish. Externally they are beautifully veined, and of a reddish or blackish-brown colour, though sometimes whitish. Internally they are yellow. They are inodorous, but have an acrid, bitter, oleaginous taste.

Fig. 404.

a. *Sinapis alba*. b. *Sinapis nigra*.

Simon;⁶ by Bussy;⁷ and by Bouton and Frémy.⁸ From their labours we learn that black mustard seed contains *myronate of potash, myrosine, fixed oil, a pearly fatty matter, gummy matter, sugar, colouring matter, sinapisin, free acid, peculiar green matter, salts.*

1. **MYRONIC ACID.**—So called by Bussy, its discoverer, from *μύρον*, an odorous oil. It is an inodorous, non-volatile, bitter, non-crystallizable acid. It is soluble in water and alcohol; but not in ether. It is composed of carbon, sulphur, hydrogen, nitrogen, and oxygen. The alkaline myronates are crystallizable. Myronate of potash yields no precipitate with nitrate of silver, nitrate of baryta, acetate of lead, corrosive sublimate, or chloride of calcium. The characteristic property of myronic acid is, to yield the *volatile oil of mustard* when mixed with myrosine and water. [This acid in mustard seed is combined with potash, forming myronate of potash, which is identical with the *sulpho-sinapisin* of Henry.—Ed.]

2. **MYROSINE; Emulsin of Black Mustard.**—Bussy called it myrosine, from *μύρον*, odorous oil, and *συν*, with, because it yields, with myronic acid and water, the volatile oil of mustard. It has considerable resemblance to vegetable albumen and emulsin; but as it cannot be replaced by either of these substances, in the development of the volatile oil, it must be regarded as a substance *sui generis*. It is soluble in water; but is coagulated by heat, alcohol, and acids, and in this state it loses the power of acting on the myronates, and of yielding the volatile oil.

3. **SINAPISINE.**—This term has been given, by Simon, to a substance which he procured from black mustard seeds, and which, he states, possesses the following properties: It presents itself in the form of white, brilliant, micaceous, volatile crystals, which are soluble in alcohol, ether, and the oils, but are insoluble in acids and alkalis. When mixed with the albumen (myrosine) of the mustard seed, it yields the volatile oil of mustard. Bussy ascribes this last property to myronic acid. It is highly improbable that two constituents of mustard should possess it. Analogy would lead us to suppose that the oil is generated by non-acid substances. Simon says sinapisine contains no sulphur. Myronic acid contains sulphur.

4. **VOLATILE OIL OF MUSTARD.**—This does not pre-exist in the seeds; but is formed when water is added to the farina, by the mutual action of the contained myrosine and myronate of potash (sinapisine?), just as the volatile oil of bitter almonds is generated by the mutual action of emulsin, amygdalin, and water (see p. 768). Alcohol extracts from the farina no volatile oil; but, by coagulating the myrosine, renders the farina incapable of developing the oil by the

MANUFACTURE OF MUSTARD.—The following method of preparing *flour of mustard* (*farina sinapis*) was kindly furnished me by a manufacturer: The seeds of both black and white mustard are first crushed between rollers, and then pounded in mortars. The pounded seeds are then sifted. The residue in the sieve is called *dressings* or *siftings*: what passes through is *impure flour of mustard*. The latter by a second sifting yields *pure flour of mustard*, and a second quantity of dressings. The *common flour of mustard* of the shops is adulterated with flour (wheaten), coloured by turmeric, and rendered hot by pod pepper. By pressure the dressings or siftings yield a fixed oil (*fixed oil of mustard*), which is used for mixing with rape and other oils. The whole seeds are never pressed. Mustard cake is employed as a manure, being too hot for cattle.

COMPOSITION.—Black mustard seed was analyzed by Thibierge.¹ Some of its constituents have subsequently been examined by Henry fils and Garot;² by Pelouze;³ by Robiquet and Boutron;⁴ by Fauré;⁵ by

⁸ Ibid. xxvi. 39.

subsequent action of water. Sulphuric acid and the other mineral acids, as well as carbonate of potash, check the formation of the oil. But when the oil is once formed, the acids have no power to prevent its effects. Volatile oil of mustard is colourless or pale yellow; it has a most penetrating odour, and a most acrid burning taste. Its sp. gr. at 68° F. is 1.015 (1.03S). It boils at 290° F. It is slightly soluble in water, but readily so in alcohol and ether. By the action of ammonia on this oil, a white, odourless, crystallizable substance (an *amide*?) is produced, which consists of one atom of the oil, and one atom of ammonia, $C^8H^6NS^2 + NH^3$.¹ These crystals are decomposed with the greatest facility by binoxide of mercury.² [Volatile oil of mustard is represented by the formula $C^8H^5NS^2$. According to Wertheim, this oil is the sulphocyanide of allyle ($All=C^6H^5$). This is theoretically consistent with the constitution above given, for $C^8H^5C^2NS^2=C^8H^5NS^2=All,CyS^2$.—Ed.] It is powerfully acrid, rubefacient, and vesicant. It has been proposed as a rubefacient in paralysis, and as a vesicant. The distilled water of mustard has been employed against the itch.³

5. FIXED OIL OF MUSTARD.—Usually procured from the dressings or siftings of mustard above referred to. It constitutes about 28 per cent. of the seeds. Its colour is reddish or brownish-yellow. It has a faint odour of mustard, and a mild oily taste. It does not readily become rancid. It has been used as a purgative and anthelmintic.⁴

PHYSIOLOGICAL EFFECTS.—Mustard is an acrid stimulant belonging to the group of the *volatile pungent stimuli*. It holds an intermediate rank between horseradish and pepper. Its topical action is that of a powerful acrid, and depends on the volatile oil developed by the action of water. The irritant operation, on the eyes, of the vapour arising from a mixture of hot water and flour of mustard, is familiarly known. Mustard cataplasms cause redness and burning pain, which, if the application be continued, becomes almost insupportable. A prolonged application causes vesication, with even ulceration and gangrene. Compared with those of cantharides, the topical effects of mustard on the skin sooner subside when the application is discontinued. When swallowed, mustard evinces the same stimulant operation on the stomach and bowels. Taken in moderate quantities, with the food, it promotes the appetite, and assists the assimilation of substances which are difficult of digestion. In somewhat larger doses (as one or two teaspoonsful) it rouses the gastric susceptibility, and operates as an emetic. In excessive quantities it gives rise to vomiting, purging, and gastro-enteritis. The effects of mustard on the general system are those of a stimulant. It quickens the pulse, and promotes the secretions (especially the urine) and the exhalations.

USES.—The dietetical uses of mustard are well known. It is well adapted for cold, phlegmatic individuals, with a torpid or atonic condition of the digestive organs. It is an excellent condimentary adjunct to heavy and difficultly digestible foods, as fatty matters.

As a medicinal agent, mustard is employed for several purposes. As an emetic it is useful where we want to rouse the gastric sensibility, as in narcotic poisoning, malignant cholera, and some forms of paralysis.⁵ As a stimulant to the digestive organs, it is applicable in atonic or torpid conditions of these parts, with dyspepsia, loss of appetite, and hepatic torpor. As a diuretic it has been employed with some benefit in dropsy.⁶ As a febrifuge in intermittents, it has been employed either alone or in conjunction with cinchona.⁷ But the principal use of mustard is as a rubefacient (see *Cataplasma Sinapis*). Flour of mustard, or bruised mustard seed, is sometimes added to pediluvia.

ADMINISTRATION.—As an emetic, the dose is from a teaspoonful to a table-spoonful of the flour of mustard in a tumblerful of water. As a diuretic in dropsies, and for some other purposes, mustard whey (*serum lactis sinapinum*) is a convenient form of exhibition. It is prepared by boiling half an ounce of the bruised seeds or powder in a pint of milk, and straining; the dose is f̄iiv twice or thrice a day.

¹ This constitution differs from that formerly given by Dumas and Pelouze, *Journ. de Chim. Méd.* ix. 615.

⁷ Bergius, *Mat. Méd.* 2d edit. ii. 618.

CATAPLASMA SINAPIS, L.; *Sinapismus*; *Mustard Poultice* or *Sinapism*.—(Linseed; Mustard seed, of each, powdered, ℥iiss; Boiling Water ℥xj. Add the powders, previously mixed, to the water by degrees, stirring so that a poultice be made.)—Crumb of bread may be often conveniently substituted for linseed meal. Vinegar and other acids check the formation of the acrid oil. Boiling water also has an injurious effect. Hence water whose temperature does not exceed 100° F. is to be preferred for making the mustard poultice. Actius¹ was acquainted with the injurious influence exercised by vinegar on mustard; and he observes: "*Scd et hoc noscendum est: si in aceto maceretur sinapi inefficatus redditur: Acetum enim sinapis vim discutit.*" Several experiments on this subject have been made by Trousseau and Pidoux.² They found that a sinapism made with flour of black mustard and water produced as much effect in six minutes as one made with flour of black mustard and vinegar did in fifty. Curiously enough, however, they state that vinegar did not diminish the activity of English flour of mustard. This, perhaps, is referable to the fact that common English flour of mustard contains pod-pepper, the active principle (*capsicin*) of which is soluble in vinegar. The London College formerly ordered vinegar.—The mustard cataplasm is a powerful local irritant. It readily excites inflammation, and, when allowed to remain applied sufficiently long, causes vesication. It proves, in many cases, a most painful application. In various affections of the brain (as in the stupor and delirium of low fever, in apoplexy, and in poisoning by opium) it is a most valuable application to the feet and ankles. In pulmonary and cardiac diseases it is occasionally applied to the chest with excellent effects. Dr. Blackall³ speaks in high terms of the mustard cataplasm, quickened with oil of turpentine, in typhoid pneumonia. Of course, in all these cases, it operates on the principle of a blister, over which its speedy effect gives it a great advantage. It is applied spread on linen or calico. Great caution is necessary in its application to persons who are insensible to pain; for if it be continued too long, it may occasion ulceration and sloughing, though no pain be manifested. Hence its effects should be examined at short intervals. In one case, death had nearly resulted from the neglect of this caution. Four sinapisms were applied to the wrists and insteps of a female lying in a comatose condition following puerperal convulsions. As no manifestation of pain occurred, the application was continued for three hours. Sloughing followed, which nearly proved fatal.⁴

335. SINAPIS ALBA, Linn. L. E. D.—WHITE MUSTARD.

Sex. Syst. Tetradynamia, Siliquosa.

(Semen, L.—Semina, D.—Flour of the seeds of *Sinapis nigra*, generally mixed with those of *Sinapis alba*, and deprived of fixed oil by expression, E.)

BOTANY. Gen. Char.—See *Sinapis nigra*.

Sp. Char.—*Siliques* hispid, spreading, somewhat narrower than the ensiform beak. *Leaves* lyrate, and, as well as the *stem*, nearly smooth. (De Cand.)

Annual. *Stem* 1 or 1½ foot high. *Flowers* large, yellow. *Beak* longer than the pod.

Hab.—Indigenous; in waste places. Cultivated in both fields and gardens. Flowers in June.

DESCRIPTION.—White mustard seeds (*semina sinapis albæ*) are larger and somewhat less acrid to the taste than the black ones. They consist of rounded-elliptical yellow grains, composed of a yellow nucleus enveloped in a thin semitransparent shell. The hilum is at one extremity of the ellipse.

COMPOSITION.—According to the analysis of John,⁵ white mustard seeds consist of an *acrid volatile oil*, *yellow fatty oil*, *brown mild resin*, *extractive* (very small

¹ *Sermo* iii cap. 181.

⁵ Trousseau and Pidoux, *op. supra cit.* i. 700.

quantity), *gum* (small quantity), *woody fibre*, *albumen*, *free phosphoric acid*, and *salts*.

Robiquet and Boutron,¹ however, have proved that white mustard contains neither volatile oil nor any substance capable of producing it; and that it owes its activity to a *non-volatile acrid substance*, which does not pre-exist in the seeds, but is readily formed in them under certain conditions. Another chemical peculiarity of white mustard seed is, that it contains *sulpho-sinapisin*.² Hence, while sesquichloride of iron strikes a deep red colour in an infusion of white mustard, it merely communicates an orange tint to the infusion of black mustard. Moreover, the thick mucilaginous liquor obtained by digesting the seeds of white mustard in cold water is peculiar to them.³ Simon⁴ has announced the existence of a new principle, which he calls *erucin*.

1. **SULPHOSINAPISIN**.—It was at first supposed to be an acid, and was in consequence called, by Henry and Garot,⁵ *sulphosinapic acid*. But they subsequently established its non-acid properties. It is a white, crystallizable, odourless, bitter substance, soluble in water, alcohol, and ether. Under the influence of various agents (acids, oxides, and salts) it readily yields hydrosulphocyanic acid. To this acid is probably to be ascribed the red colour developed when a persalt of iron is added to an aqueous infusion of white mustard. Its aqueous solution forms, with nitrate of silver, a white precipitate. Boutron and Frémy state that sinapisin [sulphosinapisin], under the influence of emulsion [myrosine], is converted into an acrid substance and hydrosulphocyanic acid. Sulphosinapisin consists of *carbon* 57.920, *hydrogen* 7.795, *nitrogen* 4.940, *sulphur* 9.657, and *oxygen* 19.688; or $C^{24}H^{22}NS^{2}O^7$. [This statement of its composition requires revision.—En.]

2. **NON-VOLATILE ACRID PRINCIPLE**.—This does not pre-exist in white mustard, but is readily developed in it by cold water. As before mentioned, Boutron and Frémy⁶ ascribe its formation to the action of the emulsion of the seed on the sulphosinapisin, by which hydrosulphocyanic acid and this acrid matter are produced. The latter substance is an unctuous, reddish, odourless liquid, which has the pungent hot taste of horseradish. It contains sulphur as one of its constituents.

[From recent researches it appears that myrosine is contained both in black and white mustard; it is found to be precisely similar, and to possess similar properties, in the two varieties of seeds; but the products are different. Thus white mustard does not yield with myrosine and water the volatile oil of mustard, but a pungent oil of a different kind; hence it may be inferred that white mustard does not contain myronate of potash, but some other substance of an analogous kind. This different result on the two seeds is not owing to any peculiarity in the myrosine of white mustard, because when this is added to the residue of black mustard deprived of its myrosine, it yields the volatile oil, just as the emulsine of the sweet almond produces the essential oil of almonds on mixture with the amygdaline of the bitter almond and water. Myrosine acts on amygdaline like emulsine, but the latter cannot develop volatile oil of mustard by its action on myronate of potash.—En.]

3. **ERUCIN**.—A yellowish-white substance, which is very soluble in ether, carburet of sulphur, and turpentine. It dissolves in boiling alcohol, but is insoluble in water and solution of ammonia. It does not redden the salts of iron, and contains no sulphur.

PHYSIOLOGICAL EFFECTS.—Similar to, though milder than, those produced by black mustard. Swallowed whole, the seeds prove stomachic, laxative, and diuretic. But their use in the large quantities in which they have been recommended is by no means free from danger. Gastro-enteritic inflammation of a fatal kind has been induced by them. The danger of their accumulation in the appendix cæci is obvious. Mr. J. L. Wheeler⁷ has known them retained in the bowels for seven weeks.

USES.—Dr. Cullen⁸ first mentions the practice of giving half an ounce, or an ordinary tablespoonful, of entire and unbruised mustard seeds. A few years ago, it was again brought forward, as if new.⁹ It has been advocated in a long list of diseases attended with torpor or atony of the digestive organs; and at one time it was fashionable and popular. Sir John Sinclair¹⁰ recommended mustard seeds for the preservation of the health of old people especially. The seed-leaves of white mustard and of *Lepidium sativum* are used at table under the name of *mustard and cress* or *corn salad*.

Chelidonium majus is another acrid of this order

336. PAPAVER RHŒAS, *Linn. L. E. D.*—COMMON RED CORN POPPY.

Sex. Syst. Polyandria, Monogynia.
(*Petalum* recens, *L.*—*Petals*, *E. D.*)

HISTORY.—Theophrastus³ calls the red poppy *βοιάς*. Dr. Sibthorp³ considers the *μῆραν βοιάς* of Dioscorides⁴ to be the red poppy.

BOTANY. *Gen. Char.*—*Sepals* 2, convex, deciduous. *Petals* 4. *Stamens* numerous. *Style* 0. *Stigmas* 4 to 20, radiating, sessile upon the disk crowning the ovary. *Capsule* obovate, 1-celled, composed of from 4 to 20 carpels inclosed in a membranous production of the thalamus, dehiscing by short valves under the crown of the stigmas. *Placentæ* between the valves, produced internally, forming complete dissepiments. (De Cand.)—*Herbs*, with a white juice. *Peduncles* inflexed at the apex before flowering.

Sp. Char.—*Capsule* smooth, obovate. *Sepals* hairy. *Stem* many-flowered, rough, with spreading setæ. *Leaves* pinnatifid; lobes elongated, incised-dentate, acute. (De Cand.)

Annual. *Petals* rich scarlet. This plant is distinguished from *Papaver dubium* by, 1st, the wide-spreading hairs of the flower-stalks; 2dly, a shorter capsule; 3dly, its stigma of eight to ten rays.

Hab.—Indigenous. A troublesome weed common in fields. Flowers in June or July.

DESCRIPTION.—The petals of the red poppy (*petala rhœados seu papaveris erratici*) have a rich scarlet colour, a slightly opiate odour, and a bitterish taste. By drying they become violet red and odourless.

² *Prod. Fl. Græc.* i. 359.

³ *Hist. Plant.* ix. 13.

⁴ *Lib. iv. cap.* 64.

COMPOSITION.—The flowers of the red poppy have been analyzed by Beetz and Ludewig,¹ and by Riffard.² The latter chemist obtained *yellow fatty matter* 12, *red-coloured matter* 40, *gum* 20, *lignin* 28. It is not improbable that this plant may contain *morphia* in very minute quantity.

RED COLOURING MATTER.—Riffard obtained it, in the impure state, by first macerating the petals in ether to remove a fatty matter, and then in alcohol. By distilling the alcoholic tincture to dryness, a dark-red colouring matter was obtained, which in thin layers was bright-red. It was deliquescent in the air, soluble in alcohol and in water, but insoluble in ether. Acids diminished the intensity of its colour. Chlorine decolorized it. The alkalies blackened it. By the last character it is distinguished from the colouring matter of the red cabbage, &c., which becomes green by alkalies. Sesquichloride of iron gives it a dark violet or brown tinge.

PHYSIOLOGICAL EFFECTS AND USES.—The red poppy is valued medicinally as a colouring ingredient only. It probably possesses a narcotic property in a very slight degree, but which is scarcely sensible in the ordinary doses in which this medicine is employed. Navier³ says that the continued use of the tincture or syrup by dogs gave the stomach a bluish-red tinge.

5. SYRUPUS RHŒADOS, L. E.; *Syrup of Red Poppies; Syrup of Corn Poppy*.—(Of the Red Poppy ℥ij; Boiling Distilled Water Oj; Sugar ℥iij, or a sufficiency; Rectified Spirit ℥iiss, or a sufficiency. Add the red poppy gradually to the water heated in a water-bath [vapour-bath, E.], frequently stirring them; then the vessels being removed, macerate for twelve hours; afterwards [strain and, E.] express the liquor by hand [through calico, E.], and [proceed as ordered for the Syrupus Althææ, L.] [add the sugar, and dissolve with the aid of heat, E.]—Employed only as a colouring ingredient, especially in conjunction with acids, which brighten it. It readily ferments and spoils.

337. PAPAVER SOMNIFERUM, Linn. L. E. D.—THE SOMNIFEROUS OR WHITE POPPY.

Sex. Syst. Polyandria, Monogynia.

(Capsulæ maturæ; Capsulæ immaturæ succus concretus, L.—Capsules not quite ripe; Concrete juice from the unripe capsules, E.—Capsularum succus proprius concretus; Capsulæ maturæ, D.)

HISTORY.—This is one of the most anciently known and described plants. Homer speaks of the *poppy* (μῆκων) growing in gardens;⁴ so that it appears to have been in cultivation even at that early period. It was employed in medicine by Hippocrates, and is mentioned by Theophrastus, Dioscorides, and Pliny. Hippocrates⁵ speaks of two kinds, the *black* and *white poppy*; the former, he says, confines the bowels more than the latter.

It is uncertain at what period *opium* was first known or introduced into medicine. Hippocrates⁶ recommends the μῆκώριον, or *poppy juice*, in a disease of the uterus; and Dioscorides,⁷ on the authority of Erasistratus, tells us that Diagoras (who was contemporary, as is supposed, with Hippocrates) condemned the use of opium. These are, I believe, the most ancient Greek authorities who speak of this substance; and it is impossible, I think, to arrive at any accurate conclusion from their remarks, whether opium had or had not been known long before their time, though Alston⁸ infers, from the little use made of it by Hippocrates, as well as from Diagoras condemning its use in diseases of the eyes, that its virtues were not known long before him. Dioscorides and Pliny⁹ mention that the expressed juice of the heads and leaves is termed *Meconium*, and that it is much weaker than opium. Theodore Zwinger, Sprengel,¹⁰ and others, have supposed that the *nepenthes* (νεπενθίς) of Homer¹¹ was opium. Dr. Royle,¹² however, has suggested that the substance referred

to by Homer may have been a preparation of *Cannabis sativa*, the remarkable effects of which have been recently pointed out by Dr. O'Shaughnessy.¹

The word *opium* is derived from $\delta\pi\acute{o}\varsigma$, *the juice*, and signifies that it is *the juice* par excellence; just as the flower of the rosemary has been called *anthos*, or *the flower*, and the cortex cinchonæ, *the bark*.

BOTANY. Gen. Char.—See *Papaver Rhoëas*.

Sp. Char.—*Capsules* obovate or globose, and, as well as the *calyces*, smooth. *Stem* smooth, glaucous. *Leaves* amplexicaul, cut-repand, dentate, somewhat obtuse. (De Cand.)

An annual *herb*. *Root* white, tapering. *Stem* 2 to 6 feet high, erect, branched, leafy, glaucous green. *Leaves* alternate, sessile, ovate-oblong, glaucous beneath. *Peduncles* terminal, leafless, with bristly hairs. *Seeds* numerous, small, roundish or reniform, oily, sweet, and edible.

There are two well-marked varieties, which, by some botanists, are considered to be distinct species:—

a. nigrum; *P. somniferum*, Gmelin.—*Capsules* globose, opening by foramina under the stigma. *Seeds* black.² *Peduncles* many. *Flowers* usually violet or red, of different tints, though sometimes white.

β. album; *P. officinale*, Gmelin.—*Capsules* ovate globose; foramina under the stigma either none or obliterated. *Peduncles* solitary. *Seeds* and *petals* white.

Hab.—Asia and Egypt. Grows apparently wild in some parts of England, but has probably escaped from gardens. Cultivated in Hindostan, Persia, Asia Minor, and Egypt, on account of the opium obtained from it. According to Dr. Royle, var. *β album* is cultivated in the plains of India; and var. *α nigrum* in the Himalayas. In Europe, the poppy is cultivated for the capsules, either as medicinal agents or for the oil (*poppy oil*) obtained from the seeds, and which is employed in painting. The London market is principally supplied with poppy heads from the neighbourhood of Mitcham, in Surrey.

DESCRIPTION. 1. OF POPPY HEADS.—Poppy heads (*Capsulæ* seu *Capita Papaveris*) are usually collected when quite ripe, as ordered by the London and Dublin Colleges; but they would be more active as medicinal agents if they were gathered while still green; and the Edinburgh College very properly directs the immature capsule to be employed. As met with in commerce, poppy heads vary somewhat in size from that of a hen's egg to that of the fist. Their texture is papyraceous; on the top of them is the star-like stigma. They are yellowish or yellowish-brown, and, if they have been collected before they were quite ripe, have a bitterish taste. When fresh, they have a slightly opiate odour, which they lose by drying. A decoction of the dried poppy capsule is rendered, by the sesquichloride of iron, brownish-red (*meconate of iron*). Nitric acid makes the decoction transparent, and communicates a slightly orange-red tinge, indicative of the presence of morphia.

2. OPIUM. Preparation.—The mode of extracting opium is, to a certain extent, similar in all countries, and consists in making incisions into the half-ripe poppy capsules, and collecting the exuded juice. According to Dioscorides,³ Kæmpfer,⁴ Kerr,⁵ and Texier, this juice is worked up into a homogeneous mass; whereas Bellonius⁶ and Olivier⁷ speak of the juice concreting on the poppy; and the first of these writers describes opium as consisting of agglomerated granules.

Now Guibourt,⁸ by examining the opiums of commerce by means of a magnifier, thinks he has discovered that the Smyrna and Persian (or Trebizond) opium is composed of small agglutinated tears (*opium with a grain*); whereas the Egyptian, and I would add the Indian opium, is a homogeneous mass, and therefore must have been worked up in the manner described by Dioscorides, Kæmp-

fer, and others (*homogeneous opium*). M. Ch. Texier¹ thus describes the process of obtaining opium followed in Asia Minor: "A few days after the flower has fallen, men and women repair to the fields and cut the head of the poppy horizontally, taking care that the incisions do not penetrate the internal cavity of the shell. A white substance immediately flows out, and collects in tears on the edges of the cuts. In this state the field is left for twenty-four hours, and on the following day the opium is collected by large blunt knives. Each head furnishes opium once only, and that to an extent of a few grains. The first sophistication which it receives is that practised by the peasants who collect it, and who lightly scrape the epidermis from the shell to augment the weight. This operation adds about one-twelfth of foreign matters. Thus collected, opium has the form of a glutinous and granular jelly. It is deposited in small earthen vessels, and beat up with saliva. When asked why water was not employed in place of saliva, the answer was that water caused it to spoil. It is afterwards enveloped in dry leaves, and in this state it is sold. The seeds of those poppies which have yielded opium are equally good for sowing the following year."

Some little variation will be found in the description of other writers of the methods practised in other parts of the East. Kæmpfer says that in Persia the incisions are made crosswise by a five-edged knife. Kerr states that, in the province of Behar, "two longitudinal double incisions" are made "upon each half-ripe capsule, passing from below upwards; care being taken that the internal cavity of the capsule is not penetrated.

[The most complete history of the cultivation and preparation of opium in our Indian possessions has been published by Dr. Eatwell. An abstract of his paper was published in the eleventh and twelfth volumes of the *Pharmaceutical Journal*, in 1852. We have selected from this such portions as appeared to possess any interest in reference to the history of this most important article of *Materia Medica*.—ED.]

The cultivation of the poppy in British India is confined to the large central Gangetic tract, about six hundred miles in length and two hundred miles in depth, which is bounded on the north by Goruckpore, on the south by Hazareebaugh, on the east by Dingepore, and on the west by Agra. This large extent of country is divided into two agencies, the Behar and the Benares, the former being presided over by an agent stationed at Patna, at which station is the central or sudder factory of the agency, the latter being under the control of an agent residing at Ghazeepore, which station contains the sudder factory of the Benares agency. Finally, the control of the entire department is vested in the Board of Customs, Salt, and Opium, located at Calcutta. Of the two agencies, the Behar is the larger and more important, sending to the market about treble the quantity of drug turned out by the Benares agency. The Benares agency comprises eight divisions, namely, the Benares and Mirzapore, the Ghazeepore, the Azinghur, the Juanpore, the Selimpore, the Goruckpore, the Cawnpore, and the Futehpore. In these eight divisions, the aggregate amount of land under poppy cultivation, in the season 1849-50, was 107,823 beegahs.²

The lands selected for poppy cultivation are generally situated in the vicinity of villages where the facilities for manuring and irrigation are greatest. In such situations, and when the soil is rich, it is frequently the practice with the cultivators to take a crop of Indian corn, maize, or vegetables off the ground during the rainy season, and after the removal of this, in September, to dress and manure the ground for the subsequent poppy sowings. In other situations, however, and when the soil is not rich, the poppy crop is the only one taken off the ground during the year, and from the commencement of the rains in June or July until October, the ground is dressed and cleaned by successive ploughings and weeding, and manured to the extent which the means of the cultivator will permit. In the final preparation of the land in October and November, the soil, after being well loosened and turned up by the plough, is crushed and broken down by the passage of a heavy log of wood over its surface, and it is in this state ready for sowing. The amount of produce from various lands differs considerably. Under very favourable circumstances of soil and season as much as 12 or even 13 seers (26 lbs.) of standard opium may be obtained from each beegah of 27,225 square feet. Under less favourable conditions the out turn may not exceed three or four seers, but the usual amount of produce varies from 6 to 8 seers per beegah.

The chemical examination of different soils in connection with their opium-producing powers

¹ *Journ. de Pharm.* xxi. 196.

² A Beegah is 27,225 square feet.

presents a field for very profitable and interesting inquiry; nor is the least important part of the investigation that which has reference to the variations in the proportions of the alkaloids (especially the morphia and narcotine) which occur in opium produced in various localities. That atmospheric causes exert a certain influence in determining these variations is probable; that they influence the *amount* of produce, and cause alterations in the *physical* appearance of the drug are facts well known to every cultivator. Thus, the effect of dews is to facilitate the flow of the juice from the wounded capsule, rendering it abundant in quantity, but causing it at the same time to be dark and liquid. An easterly wind (which in this part of the country is always concomitant with a damp state of atmosphere) retards the flow of the juice, and renders it dark and liquid. A moderate westerly wind, with dew at night, form the atmospheric conditions most favourable for collections, both as regards the quantity and the quality of the exudation. If, however, the westerly wind (which is an extremely dry wind) blow violently, the exudation from the capsules is sparing. Whilst the effects of the meteorological phenomena in producing the above results are well marked, their action in altering the relative proportions of the chemical constituents of the juice of the poppy plant is more obscure; and it is highly probable that the chemical composition of the soil plays a most important part in this respect. Dr. O'Shaughnessy is certainly the most accomplished chemist who has ever in India turned his attention to the subject, and he has published the results of his analysis of specimens of opium from the different divisions of the Behar agency, which are worthy of much attention. In the opium from eight divisions of the agency, he found the quantity of morphia to range from $1\frac{3}{4}$ to $3\frac{1}{2}$ grains per cent., and the amount of the narcotine to vary from $\frac{3}{4}$ grain to $3\frac{1}{2}$ grains per cent., the consistence of the various specimens being between 75 and 79 per cent. In the opium from the Hazareebaugh district (the consistence of the drug being 77) he found $4\frac{1}{2}$ per cent. of morphia and 4 per cent. of narcotine, whilst from a specimen of Patna garden opium he extracted no less than $10\frac{3}{4}$ per cent. of morphia and 6 per cent. of narcotine, the consistence of the drug being 87. With respect to this last specimen, Dr. O'Shaughnessy mentions that the poppies which produced it were irrigated three times during the season, and that no manure was employed upon the soil. It is much to be regretted that these interesting results were not coupled with an analysis of the soils from which the specimens were produced, for to chemical variations in it must be attributed the widely different results recorded above. The climate in which the Patna garden opium was produced (and which is equal in narcotic excellence to the best opium of Turkey or Egypt) was precisely the same as that in which the comparatively poor specimens of the eight divisions above alluded to were collected, and therefore could not have exerted any influence in producing the chemical differences which the drug from the different localities presented.

The poppy cultivated in the Benares and Behar agencies is exclusively the white variety (*papaver somniferum album*). In situations favourable to its growth, it vegetates luxuriantly, attaining usually a height of about four feet. The stem is branched, and is terminated by from two to five ovate-globose capsules, averaging in size a duck's egg. The plant takes about three months and a half in reaching maturity, and the time for its cultivation is exclusively the cold season, extending from November to March. It has been found advantageous to change the seed employed in the different divisions every two or three years, and there are certain districts which produce seed of generally acknowledged superiority, and from which the supplies are therefore drawn, and distributed to the cultivators of distant agencies. The soil having been prepared in the manner described above, the sowing is effected by throwing the seed broadcast over the land, and this takes place between the 1st and 15th of November. In three or four days, the plough is again passed over the land to bury the seed; and the soil is afterwards again levelled by means of the log of wood before alluded to. The whole surface is then divided into square compartments, the sides of which are about ten feet in length, and are raised and converted into little channels for the purpose of irrigation. The number of times the plant may require irrigation depends in a great measure upon the nature of the season; if some heavy showers fall in December, January, and February, two irrigations may be sufficient; whereas, if the cold season pass over with little or no rain, the operation may be required to be repeated five or six times. Ten or twelve days are sufficient for the germination of the seed, and after the little plants have attained a height of two or three inches they are carefully weeded and thinned.

In its progress towards maturity, the poppy plant is liable to injury in various ways. It may be nipped by unusually severe frosts, or the plant may become stunted and never fairly reach maturity, owing to the first sowings failing and subsequent late ones being required, or owing to unusual heat and deficient moisture. Portions of cultivation sometimes droop and wither from causes which are not obvious, or are attacked by blight; and finally, considerable injury is frequently inflicted upon the poppy plants by a parasitical species of broom rape (*Orobanche indica*), which, attaching itself to the roots of the plants, causes them to wither. In February, the plant is generally in full flower, and towards the middle of the month, and just before the time for the fall of the petals, these latter are all carefully stripped off and collected. They are then formed into circular cakes from ten to fourteen inches in diameter, and about $\frac{1}{8}$ of an inch in thickness. The manner in which these leaf-cakes are formed is the following: A circular shallow earthen vessel is heated to the requisite degree, by being placed inverted

over a slow fire. A few petals are then spread upon its heated convex surface, and as soon as the glutinous juice which they contain is seen to exude, others are added to the moist surface and are pressed down by means of a cloth. As soon as these latter become moist in turn, they receive a similar addition of petals, and in this manner the cake is extended circularly by successive and continuous additions, until it has reached the required dimensions. Instead of the earthen vessel, a shallow or nearly flat iron cooking utensil is sometimes used. The cakes of petals (known in the department under the name of "leaves"), when they reach the sudder factory at Ghazepore, are carefully sorted and separated into three classes, according to their size and colour. The smaller and dark-coloured "leaves" are used in forming the inner portions of the shells of the opium cakes, whilst the largest and least discoloured ones are kept for furnishing their outside coverings. In a few days after the removal of the petals, the capsules have reached their utmost state of development, when the process of collection commences, which extends from about the 20th of February to the 25th of March.

The mode of collecting the juice is the following: At about three or four o'clock in the afternoon, individuals repair to the fields and scarify the poppy capsules with sharp iron instruments called *nushturs*. The *nushtur* consists of four narrow bars of iron, each of which is about six inches in length, and of about the thickness of the blade of a penknife. At one extremity, each bar does not exceed a quarter of an inch in breadth; but it gradually expands, until it has acquired the breadth of about one inch at the opposite end, where it is deeply notched. The sides of the notch are somewhat curved and ground to sharp edges, and the external angles are brought to sharp points. The four little bars, being placed side by side, are bound firmly together by means of strong cotton thread; and the points, at their cutting extremities, are kept separated from each other, to the extent of about $\frac{1}{8}$ of an inch, by means of the cotton thread which is passed between each pair of contiguous blades. Thus prepared, the instrument presents four pairs of curved, pointed, diverging blades, somewhat similar in shape to the luncet blades of a cupping scarificator. In employing the *nushtur*, only one set of points is brought into use at a time, and the capsule is scarified longitudinally from its base to its summit, the incisions generally passing more or less along one of the longitudinal eminences, observable on the outside of the capsule, which mark the attachment of the internal dissepiments. The scarifications thus made are very superficial, and do no more than traverse the thin pericarp of the capsule. If a horizontal section be made of the capsule of a vegetating poppy plant, the milky juice will after a few seconds be perceived to exude first and in greatest quantity from those portions of the sarcocarp which correspond to the bases of the dissepiments. It does not, however, exude only from these points, but ultimately from the entire surface of the cut sarcocarp. It moreover does not appear in dots as if poured out from longitudinal vessels, but exudes gradually from the meshes of the cellular tissue. If a thin segment of the capsule be examined under a high magnifying power, no longitudinal vessels are observable, but a confused mass of cellular tissue is observed occupying the interspace between the epicarp and endocarp; and opposite to the duplicatures of the endocarp, which go to form the dissepiments, the meshes of the cellular tissue are perceived to be much larger than in other situations; hence the free exudation of juice at these points. It therefore appears that the mode of making the scarifications as actually practised is the most effectual that could be adopted. Each capsule is scarified from two to six times, according to its dimensions; an interval of either two or three days being allowed after each operation.

The capsules having been scarified in the manner above described, the collection of the juice is made at an early hour in the following morning. This is effected by means of instruments called *seetooahs*, which are made of sheet-iron, and resemble concave trowels; and with these the juice is scraped from the surface of the scarifications, until the instruments become filled, when their contents are emptied into an earthen pot which the collector carries by his side. After the plant has ceased to yield any more juice, its utility is still unexhausted. The capsules are then collected, and from the seeds an oil is extracted, which is used by the natives for domestic purposes, both for burning in lamps and for certain culinary purposes. Of the entire seed a comfit is made, resembling in appearance caraway comfits. Of the dry cake remaining after the extraction of the oil, a coarse description of unleavened bread is sometimes prepared by the very indigent, or it is given to cattle, or used medicinally for poultices. The capsules, deprived of their seeds, are still available for preparing emollient and anolyne decoctions, which the natives use both internally in coughs, and externally as fomentations. The stems and leaves are left standing, until they have become perfectly dry, under the influence of the hot winds of April and May, when they are removed, and crushed and broken up into a coarse powder, known, in the department, under the name of "poppy trash," and which is employed in packing the opium cakes. When fresh collected, the juice from the capsules presents the appearance of a wet granular mass, of a pinkish colour, and in the bottom of the vessel which contains it is found collected a dark fluid resembling infusion of coffee, to which the name of *pussawah* is given. The recent juice reddens strongly litmus paper, and acts rapidly upon metallic iron, covering it speedily with an inky crust of meconate of iron. The juice, when brought home by the cultivator, is placed in a shallow earthen vessel, which is tilted to such a degree that all the *pussawah* can drain off; and this plan is persevered in so long as anything fluid will separate. The *pussawah* obtained by this means is set aside in a

covered vessel, and receives no farther attention until taken for weightment to the Ghazeeport sudder factory.

The opium now requires frequent attendance on the part of the cultivator. It is daily exposed to the air, though never to the sun, and is regularly turned over every few days, in order to insure a uniform dryage in the whole mass; and this process is persevered in for the space of three weeks or a month; or, in fact, until such time as the drug may have reached within a few degrees of standard consistence. Standard opium, according to the Benares regulations, is opium which, on being subjected to a temperature of 200° Fah., until everything volatile is driven off, shall leave a residue of 70 per cent. This is the consistence at which the agency puts up the drug for the market, every effort being made to adhere to it as strictly as possible, and this is likewise the standard by which the price paid to the cultivators is regulated. If the cultivator deliver his drug of standard consistence, he receives for it the regulated price; if it be above standard, he receives a pro rata increase of payment; whereas, if it be below standard, he is subjected to a corresponding deduction in price. The opium, on its arrival at the Ghazeeport factory, is turned out of the confined earthen pots in which it is received, and is weighed in wide tin vessels called tagars, care being taken that no larger quantity than 10 seers (20 lbs.) is ever brought to the scale at a time. This weightment is made under the eye of the gomashita (or of his accredited agent) of the kotee to which the opium belongs, and in the case of the neighbouring or "home" kotees, the cultivators attend in person with their produce. This weightment is verified by an European officer stationed at a check-scale in another room, and the tagar with its contents passes on at once to a table, at which are seated the opium examiner, or an experienced sub-deputy agent, and the native opium examiner, called the purkhea. The purkhea now plunges his hand into the centre and to the bottom of the drug, stirs it about, and grasps it in various directions to feel for impurities, and then withdraws a handful, which he manipulates between his fingers, revealing its colour, texture, and mode of fracture, and finally ascertains its aroma.

He then throws upon a plate a small portion as a specimen, and estimates its consistence. This estimate is written down on a ticket by the European officer, and it is sent with the specimen to the laboratory, where a fixed weight of drug is accurately weighed, evaporated to dryness in a plate placed on a metallic table heated by steam, and the weight of the residue carefully determined. It rarely happens that the purkhea's guess differs from the actual assay by more than one or two grains, and it serves to check the actual assay in cases of evident mistake or accident, which occasionally must occur when a multitude of delicate operations are rapidly carried on. The number of specimens which leave the examiner's table daily amounts to little short of two thousand. In the examination which the drug undergoes at this stage, the quantity or pussehah which it may contain is made the subject of special remark; and a pussehah fine or batta, as it is termed, is levied, proportionate to the quantity apparently present in the drug. The reason for this is, that pussehah injures the physical qualities of opium, causing it to look black and liquid, whilst at the same time it gives to the drug a high assay when tested by evaporation.

The *tactus eruditus* possessed by the purkhea is very remarkable; he rarely fails to detect even small quantities of the grosser and more tangible impurities, whilst he is no less delicately alive to the slightest variation in colour and smell. In the event of a specimen appearing to be adulterated, it is at once set aside to be carefully examined by the opium examiner, who makes a special report respecting it for the information of the agent, who, should he see sufficient grounds for doing so, confiscates it, when the whole of the drug is destroyed, and the cultivator gets nothing for it. Should the adulterations be less extensive, and the drug such as to be not altogether useless, it is taken at half price, or is subjected to such smaller penalty as the examining officer may think fit to inflict; and it is employed in making the lewah, or paste, used in forming the shells of the opium cakes. The great probability of detection, and the risk of confiscation, act as very efficient checks to the prevalence of adulteration, and the quantity of opium confiscated yearly is comparatively small. The nature of the adulterations practised by the cultivators is very various.

The grosser impurities usually mixed with the drug to increase its weight, are mud, sand, powdered charcoal, soot, cow-dung, pounded poppy petals, and pounded seeds of various descriptions. All of these substances are readily discoverable in breaking up the drug in cold water, removing the soluble and lighter portions of the diffused mass by decantation, and carefully examining the sediment. By this means impurities of the above nature usually become physically apparent. Flour is a very favourite article of adulteration, but is readily detected; opium so adulterated speedily becomes sour, it breaks with a peculiar short ragged fracture, the sharp edges of which are dull, and not pink and translucent as they should be; and, on squeezing a mass of the drug after immersion in water, the starch may be seen oozing from its surface. The application of the iodine test, however, furnishes conclusive evidence of its presence, or at least of that of some amylaceous compound. The farina of the boiled potato is not unfrequently made use of; ghee and goor (an impure treacle) are also occasionally used, as being articles at the command of most of the cultivators. Their presence is revealed by the peculiar odour and consistence which they impart to the drug. In addition to the above, a variety of vegetable juices, extracts, pulps, and colouring matters, are occasionally fraudulently mixed with

the opium; such are the inspissated juice of the common prickly pear (*Cactus dillenii*), the extracts prepared from the tobacco plant (*Nicotiana tabacum*), the *Datura stramonium*, and the Indian hemp (*Cannabis indica*), &c. The gummy exudations from various plants are frequently used; and of pulps, the most frequently employed are those of the tamarind and of the Bael fruit (*aegle marmelos*). To impart colour to the drug, various substances are employed, as catechu, turmeric, the pounded flowers of the mowha tree (*bassia latifolia*), &c.

In the case of so complex a substance as opium, it is useless to look for a single test which shall reveal at once, with chemical precision, the purity of the drug; morphimetry would be the most accurate test to put in force, but the process would be too tedious and expensive to be of practical utility. Moreover, the colour, aroma, and texture are the commercial criterions of the excellence of the drug; and opium rich in morphia, but deficient in the above qualities from careless preparation, would probably be regarded with suspicion in the market, despite its intrinsic narcotic excellence; and for this reason, whenever the drug is received deficient in the above sensible qualities (as sometimes arises from careless treatment), but not adulterated in any way, it is subjected to a certain fine, and employed only in making lewah. The colour of well-prepared opium is a deep dull brown when viewed in mass, which becomes a bright chestnut brown when a small portion of drug is spread in a thin layer upon a white surface. It adheres to the fingers, and draws out to a moderate extent, breaking with a ragged fracture; should it, however, contain much pussewah, its ductility is much increased, and it is more glutinous.

Its smell is peculiar, and perfectly *sui generis*; it is not unpleasant, and in the recent well-prepared drug somewhat fruity. In cold water it breaks down readily into curdy flakes of the colour of pease soup, which gradually subside, leaving the supernatant liquid of a deep brownish-yellow colour. When broken under water by the hand, the drug adheres moderately to the fingers at first, but is soon entirely diffused. Should it contain gum fraudulently mixed, this latter adheres pertinaciously to the hands, and is with difficulty removed; and in this manner I have frequently detected the presence of a substance similar to birdlime, probably the tenacious juice of the banyan tree (*Ficus indica*). If to a portion of the cold watery infusion in a test-tube, a few drops of a solution of diacetate of lead be added, a dirty gray precipitate (meconate of lead) falls, so copious as to equal nearly in bulk the amount of fluid in the tube. Animonia throws down a very similar and almost equally abundant precipitate, composed of resin and the alkaloids, which, on exposure to the air, speedily assumes a black colour. Tincture of iodine throws down a brick-red precipitate, and tincture of sesquichloride of iron occasions a similar precipitate of somewhat darker colour. These tests may be applied in a few seconds, and the comparative bulk of the precipitates thrown down may enable us to form a rude estimate of the amount of opium contained in a given specimen. In very largely adulterated specimens, the evidence afforded by the above means is sufficiently marked. A solution of gelatine for the detection of tannic acid, and strong alcohol for the precipitation of gum, form the only other chemical reagents likely to be required.

After having been duly weighed into store, the opium receives but little treatment in the factory. It is kept in large wooden boxes, capable of containing about 14 mds (10 cwt.) each, in which it is (if below the manufacturing standard) occasionally stirred up from the bottom, until it has acquired the necessary consistence. Whilst remaining in these boxes, it speedily becomes covered with a thin blackish crust (ulmine), and deepens in colour according to the amount of exposure to air and light which it undergoes. Should the drug be of very low consistence, it is placed in shallow wooden drawers, instead of in boxes, in which it is constantly turned over, until its consistence has approximated to 70 per cent. From the general store or malkhana, the drug is exported daily in quantities equalling about 250 mounds, for the purpose of being manufactured or made up into balls or *cakes*, as they are termed in the department.

In exporting opium for this purpose, the officer who performs the duty selects for the most part opium which is exactly at standard, or very close to it, whilst to compensate for any drug which may have risen higher than the prescribed consistence, a certain proportion of opium of low consistence is exported, the consistences of the various proportions of drugs selected for export being determined by a certain number of test assays. The portions of drug thus selected are then weighed out with exactitude, in portions of 10 seers (20 lbs.) each, and are thrown promiscuously into shallow wooden drawers, in which men mix them up together, rapidly and thoroughly thrusting their arms into the drug and kneading it in various directions. From these drawers the opium is transferred as mixed to boxes, all of which are of the same size, and from each of which a specimen is drawn and assayed. The mean of the assays of these boxes gives the average consistence of the export of the day, and serves as a guide as to whether the drug be of the proper consistence for caking. The above operations are generally completed by about 4 P.M., and before evening the drug is removed from the boxes to large wooden vats, 20 feet long, 3½ feet wide, and 1½ feet deep, situated in the caking-room. In these vats it undergoes a further kneading and admixture, by men who wade knee deep through the opium from one end of the vats to the other, until their contents appear to be of uniform consistence. Two specimens are, on the following morning, drawn from each vat, and assayed; and should the consistence have reached the factory standard, caking immediately commences.

Down either side of the room in which the vats are placed, are ranged the cake-makers, numbering usually about one hundred and ten individuals; each man being seated upon a wooden stand, and being furnished with a brass cup, forming the half of a hollow sphere, and with another tin vessel graduated so as to hold a determinate quantity of fluid. On the previous evening the leaves requisite for forming the shells of the cakes have been weighed out and tied up in bundles of prescribed weight, and have been damped to render them supple. Down the centre of the room are placed a certain number of small scales, at which the quantity of opium intended for each cake is separately weighed; and beside the scales are boxes filled with lewah, for the agglutination of the leaves which form the shells of the cakes. In forming the lewah, all opium of inferior quality is used, and all the pussewah received is also employed for this purpose; but in addition to these, a considerable quantity of unexceptionable drug is also expended. These are broken down in the washings of the various pots and vessels which have contained opium, and a thin semifluid paste is formed, of such a consistence that 100 grains of it, when evaporated to dryness at a temperature of 200° F., shall leave 53 grains of residue.

Matters being thus arranged, the cake-maker receives in his graduated measure from the lewah box the prescribed quantity of lewah for making a single cake, and having by his side a bundle of leaves previously weighed, he rapidly forms in his brass cup the lower segment of the shell of the opium cake, pasting leaf over leaf, until the thickness of half an inch has been obtained, and allowing a certain free portion of the most external leaves to hang down all round over the sides of the brass cup. This accomplished, a boy is in waiting with the opium to be put into the cake, which he has just brought from the caking scales, and which he throws into the shell so far prepared to receive it. The cake-maker, holding the opium away from the sides of the shell with the left hand, then tucks in round the sides leaf after leaf, well smeared with lewah, imbricating one over the other, until he has completed the entire circle; the free edges of the leaves, which had hitherto hung over the sides of the cup, are now drawn up tightly, and the opium well compressed within its bag of leaves.

A small portion at the top now only remains, which is speedily closed by laying on leaf after leaf; and finally the work is completed by the application of a single large leaf, which covers the entire exposed half of the cake. As thus formed, the well-finished cake is a pretty regular sphere, not unlike, in size and appearance, a 24 lb. shot. It is now rolled in a little finely-pounded poppy trash, which adheres to its surface, is at once placed in a small earthen cup, of precisely the same dimensions as the brass mould in which it was made, and is carried out into the open air and exposed to the direct influence of the sun. It is so exposed for three days, during which time it is frequently turned and examined; and if (as is frequently the case) it should have become distended and puffy, it is at once torn open, the extricated gas allowed to escape, and the cake again tightly closed. On the evening of the third day it is placed (still contained in its cup) in the cake-frames, which are formed of open battens, and allow of a free circulation of air about the cakes. The average number of cakes made by a single man in one day is about 70; but there are cake-makers who will turn out as many as 90 or 100 cakes, between 9 A. M. and 3 P. M. The number of cakes made daily in the factory, during the manufacturing season, is from 6,500 to 7,000, and the total number of cakes manufactured, in one season, has been 426,800.

By the end of July the manufacturing is finished, but the cakes still require much attention; they are constantly turned over in their cups, and as mildew collects on their surfaces, it is removed by rolling and rubbing them in dry poppy trash. They are, moreover, individually examined, and those which present weak points are strengthened by the application of extra leaves; and their appearance is moreover improved by the application of a single leaf of the first quality, which being of large dimensions, and carefully and equally made, covers the greater portion of the surface of the cake, and gives to it a smooth and finished appearance.

By October, the cakes have become perfectly dry to the touch, and have acquired considerable solidity; and they are now packed in chests, each of which is furnished with a double tier of wooden partitions, each tier presenting twenty square compartments, for the reception of so many cakes, and in which the cakes are steadied by means of loose poppy trash, with which all the interstices are filled.

It might be supposed that so fragile a structure as the poppy petal would furnish but an insecure packing envelop; but the shells of the opium cakes are possessed of more resistance than might be imagined, and owing apparently to some antiseptic property in the lewah, they are capable (after once being thoroughly dried) of being preserved for a great length of time. For three or four months after manufacture the shells require constant care and attention; and even after being packed, any exposure to damp or moisture subjects them to injury. After a certain lapse of time, however, the opium contained in the cake ceases to yield any more moisture to the shell, and this latter acquires extreme solidity. There are three specimen cakes in the Ghazee-pore factory which are some fifteen years old; they are as solid as balls of wood, and may be thrown from a height upon a stone floor without injury.

The above process of manufacture applies to the opium which is put up for the China market, and which includes the great bulk of the entire provision. With the drug intended for internal

consumption, and called abkaree opium, a different process is followed. The opium intended for abkaree purposes is brought to a consistence of 90 per cent. by direct exposure to the sun, in which state it is as firm and as easily moulded as wax. It is then formed, by means of a mould, into square bricks of one seer weight each, and these are wrapped in oiled Nepal paper, and packed in boxes furnished with compartments for their reception. The opium put up in this way has not the same powerful aroma as is possessed by that put up in balls; but this is its only deficiency, whilst it has the great advantage of containing a large amount of drug in a very limited space, and in a state very manageable for packing.

The manufacture for the season being finally concluded, six cakes are selected promiscuously from the provision, by the magistrate of Ghazee-pore, for examination and chemical analysis. Of these, two are forwarded to the opium examiner at Calcutta, two to the examiner of the Behar agency, and two are reserved for examination by the examiner of the Benares agency.

The examination which these cakes undergo has reference to the following points:—

1. The gross weight of the cake.
2. The weight of the shell, detached as clearly as possible from the contained opium.
3. The weight of the opium contained in the shell.
4. The condition of the shell.
5. The physical character of the drug.
6. Its consistence.
7. The amount of extract taken up from it by cold distilled water.
8. The quantity of morphia present.
9. The quantity of narcotine present.

The following table will show the chemical results of the examination of the opium of the Benares agency from 1845 to 1849:—

Season.	Residue from 100 grs. exposed to a temp. 200° F.	Extract taken up by cold distilled water from 100 grs.	Morphia per cent.	Narcotine per cent.
1845—46.	73	52.33	2.76	5.33
	75	50.26	2.20	5.20
Average . .	74	51.29	2.48	5.26
1846—47.	72	43.25	2.46	4.30
	72	42.25	2.30	4.75
Average . .	72	42.75	2.38	4.52
1847—48.	71	44.43	2.23	5.66
	70	39.26	2.17	5.70
Average . .	70.5	41.84	2.20	5.68
1848—49.	75.5	47.37	2.75	3.85
	75.5	48.62	3.67	4.27
Average . .	75.5	47.99	3.21	4.06

A chief chemical feature which distinguishes Bengal opium from that of Turkey and Egypt, is the large proportion which the narcotine in the former bears to the morphia; and this proportion is shown by the above analysis to be constant in all seasons. It is a matter of importance to ascertain whether the treatment which the juice receives after its collection can influence in any way the amount of the alkaloids, or of the other principles contained in opium. In Turkey it is the custom to beat up the juice with saliva; in Malwa it is immersed, as collected, in linseed oil; whilst in Bengal it is brought to the required consistence by mere exposure to the air in the shade, though at the same time all the watery part of the juice that will separate is drained off and used, as has already been explained, in making lewah.

The following are the results which I obtained from the analysis of fresh juice, collected in February, 1850, and from which none of the pussawah was separated. The analyses have a special reference to the amount of the alkaloids, morphia, and narcotine, present in the drug, no attempts having been made to separate any of the other principles in a state of purity.

I.

Analysis of 2,000 grains of freshly collected juice, subjected to experiment in the day of collection.

	Grains.
Morphia	11.1
Narcotine	32.7
Other matters soluble in alcohol, codeia, narceia, meconic acid, resin, &c. &c.	521.0
Dry marc insoluble in alcohol, lignin, caoutchouc, &c. &c.	225.2
Water and volatile matter separable at a heat of 200° Fah.	1210.0
Total	2000.0

In the following experiment, the juice, instead of being subjected at once in its crude state to analysis, was exposed in an evaporating basin to a temperature of 200° F. until it was judged to have reached about the factory standard consistence; and of the opium so prepared, 1,000 grains were analyzed.

II.

	Grains.
Morphia	24.9
Narcotine	30.9
Other matters soluble in alcohol, codeia, narceia, meconic acid, resin, &c. &c.	546.7
Dry marc insoluble in alcohol, lignin, caoutchouc, &c. &c.	215.0
Water and volatile matter, separable at 200° Fah.	182.5
Total	1000.0

In Experiment III. a portion of freshly collected juice was placed in an open porcelain basin, on the 23d February, and occasionally stirred with a glass rod, until it had acquired solidity, no attempt being made to separate any pussewah from it. On the 7th May it was found to have acquired a consistence of 90.3 per cent. and its analysis gave the following results:—

	Grains.
Morphia	26.1
Narcotine	32.8
Other matters soluble in alcohol, codeia, narceia, meconic acid, resin, &c. &c.	630.4
Dry marc insoluble in alcohol, lignin, caoutchouc, &c. &c.	213.7
Water and volatile matter, separable at a heat of 200° Fah.	97.0
Total	1000.0

In order to be able to compare these results one with another, we will suppose, in each case, the drug to have been reduced to a similar state of dryness, by exposure to a heat of 200° F., when the composition of the three different specimens will appear as follows:—

	I.	II.	III.
Morphia	1.405	3.061	2.890
Narcotine	4.012	3.795	3.632
Matters soluble in alcohol	65.949	66.874	69.811
Dry marc insoluble in alcohol	28.506	26.301	23.665
Total	99.872	100.031	99.998

The agreement of the results in these three sets of experiments is tolerably close, except in the case of the drug subjected to analysis on the day of collection, in which the quantity of morphia present is extremely small; but, as if to compensate for the deficiency to a certain amount, the quantity of narcotine present is larger than in either of the other two specimens. The suggestion which this arrangement naturally prompts is, whether it be possible that narcotine, by parting with a portion of its carbon, hydrogen, and oxygen, during the process of analysis, or during the changes which occur in the juice after its extraction from the plant, can be converted into morphia. The proposition is, however, quite speculative, and could only be satisfactorily demonstrated by a careful set of minute experiments, having reference to the proportions of all the principles entering into the composition of opium, at different periods, from the date of the extraction of the juice until the cessation of all fermentative action, which takes place until the drug has reached a certain degree of spissitude. The results of the second analysis are worthy of remark; they seem to indicate that the employment of artificial heat in bringing the drug rapidly to the required consistence is not detrimental to the narcotic excellence of the resulting opium; on the contrary, the experiment, so far as it goes, appears to indicate the very opposite result. It has already been stated that in preparing the drug the cultivators drain from it all the fluid portion, which of course consists of the most soluble principles of opium, dissolved in dew, or in moisture absorbed from the atmosphere. I now propose alluding more particularly to this fluid, to which the name of *pussewah* is given, and which is brought to the factory in large quantities, of many gallons at a time, and of all consistences, from that of a limpid fluid to that of thick treacle.

Recently collected *pussewah* is a dark fluid, resembling strong infusion of coffee, and having a peculiar smell. It reddens litmus paper strongly; a solution of diacetate of lead causes in it a most copious gray precipitate (meconate of lead), and lime water has the same effect. Ammonia throws down a copious precipitate, of a mottled gray colour, which soon becomes uniformly black; and copious dilution with water likewise occasions in it a deep brown precipitate. I found the specific gravity of some recently-collected *pussewah* to be 1.120, the temperature of the atmosphere being 83°; and 100 grains, on evaporation to dryness, were found to yield 30 grains of a brownish-yellow residue, emitting an odour somewhat resembling that of heated Burgundy pitch. After *pussewah* has become concentrated to about one-third of its original volume, it acquires the consistence of treacle; and, as the process of drying goes on still farther, it gradually becomes solid. During the hot and dry months, this solid residue acquires a resinous hardness, becoming brittle, and breaking with a resinous fracture; but as soon as the weather becomes damp it rapidly absorbs moisture from the atmosphere, becomes jetty black and polished on the surface, and acquires a consistence similar to that of cobbler's wax. *Pussewah* (as might be supposed) contains some of the most valuable constituents of opium; its principal components are meconic acid, resin, morphia, and narcotine. From 500 grains of solid *pussewah*, which on evaporation to dryness left 88.9 grains of residue, I extracted 12 grains of pure narcotine, but only a trace of morphia. I, however, am inclined to attribute this latter result to an accident in the analysis; as in a second analysis of 500 grains of solid *pussewah*, which on evaporation yielded 85.5 grains of residue, I obtained 10.6 grains of morphia, and 16.9 grains of narcotine. In order to form an idea of the precise extent to which the composition of Bengal opium is affected by the practice of draining from it the *pussewah*, it is requisite to ascertain, with some approach to accuracy, the quantity of *pussewah* usually furnished by a given amount of opium. The quantity of standard opium received at the sudder factory of the Benares agency during the season of 1849-50, was 18,191 maunds; whilst the quantity of *pussewah* delivered amounted to 100 maunds, being at the rate of one maund of *pussewah* to nearly 182 maunds of drug, the *pussewah* containing, on an average, say 50 per cent. of solid matter. This *pussewah*, be it observed, although separated from the drug, is not lost to the provision, being employed in the formation of the shells of the cakes; and, as the Chinese form a watery extract of the drug for the purpose of smoking, the whole of the constituents of the *pussewah* are thus recovered on boiling the shells in water, as is practised in China.

Amongst the thousands of individuals, cultivators and employés, with whom the factory is filled during the receiving and manufacturing seasons, no complaints are ever heard of any injurious effects resulting from the influence of the drug, whilst they all remain quite as free from general sickness as persons unconnected with the general establishment; in fact, if anything, more so. It occasionally happens that a casual visitor to the factory complains of giddiness or headache; but the European officers employed in the department, who pass the greater part of the day with the thermometer between 95° and 105° Fah. amongst tons of the drug, never experience any bad effects from it. The native *purkhea* sits usually from 6 A. M. to 3 P. M. daily, with his hand and arm immersed nearly the whole time in the drug, which he is constantly smelling, and yet he feels no inconvenience from it. He has informed me that, at the commencement of the season, he experiences usually a sensation of numbness in the fingers; but I believe this to be more the result of fatigue, consequent upon the incessant use of the arm and fingers, than of any effect of the opium. In the large caking vats, men are employed to wade knee-deep through the drug for several hours during the morning, and they remain standing in it during the greater part of the rest of the day, serving out the opium by *armfuls*, their bodies being naked, with the exception of a cloth about the loins. These men complain of a sensation of drowsiness towards the end of their daily labours, and declare that they are overpowered early in the evening by sleep, but they do not complain of the effect as being either unpleasant or injurious. Infants, of a few months old, may be frequently seen lying on the opium-be-smeared floor under the vats, in which dangerous position they are left by their thoughtless mothers, but, strange to say, without any accident ever occurring. Here are abundant facts to show that the health of those employed in the opium factory, and in the manipulation of the drug, is not exposed to any risk whatever, whilst the impunity with which the drug is handled by hundreds of individuals, for hours together, proves that it has no endermic action, for I am inclined to consider the soporific effect experienced by the vat-traders as produced through the lungs, and not through the skin.

[We subjoin the following remarks, by the late Dr. Pereira, on the cultivation and manufacture of *Patna Opium*, from a paper published by him in the *Pharmaceutical Journal* for Nov. 1851.—Ed.]

The India section of the Great Exhibition contained a most complete collection of specimens, drawings, and implements illustrative of the cultivation and manufac-

ture of Patna opium. Unfortunately, however, no description of the processes accompanied the illustrations, and therefore I have been obliged to obtain information on this subject from various sources. The drawings which were sent over were fifteen in number. Several of them, however, rather illustrated the general processes of agriculture followed in India, than anything peculiar to the cultivation of the poppy. The first of the series represented a native engaged in thinning and weeding the poppy plants. "The poppy," says Mr. W. B. Johnson, "requires a good, rich, dark soil, well prepared with manure, and divided into small oblong plots, of about six by four feet, for the convenience of weeding and patching. The sowings commence early in November. The day the seed is sown, the land is well watered; on the next day, the ryot breaks all the lumps with his *khoorpu*. The plant soon shoots up, and, when about six inches high, it is thinned and weeded; it is kept well watered until the capsules are nearly ripe, and the petals falling off. The watering then depends upon the state of the weather: if mild, the irrigation is continued; if there should be strong winds, it is discontinued, for fear of (the capsules?) being blown off." "The poppy," according to Mr. Impey, "takes three months and a half to arrive at perfection, at least to the transitory and half-ripe state, between the fall of the petal and the dehiscing of the pericarp, which is the period most favourable to the extraction of the juice; and it grows to the height of four feet and upwards when well attended to. Its erect stem is divided into from four to fourteen branches, which strike off at various heights, the lowest usually two and a half feet from the ground. The capsule, in a full-grown state, measures frequently three and a half inches long by two in diameter."

A second drawing represented a native woman pulling off the poppy petals for the purpose of making leaves for the envelop of the opium for the China market. Each cake or ball of opium is calculated to consume five chittacks¹ of these leaves.

Speaking of the cultivation of the poppy in Malwa, Mr. Impey says:—

"The petals and leaves, which are in other districts kept to form the covering for the cakes, are permitted to fall off, and not applied to any purpose, nor even sold by the ryot; but poor people gather them, and when a sufficient quantity is collected and pounded, dispose of them at six rupees per maund to the Buniahs and opium-dealers, who require them for packing and wrapping the cakes."

The next operation is that of tapping or bleeding the poppy capsules. This is effected by making a series of parallel wounds in the exterior surface of the capsule with the instrument called a *nushtur*. This consists of several (three, four, or five) heart-shaped lancets or blades, tied together with some cotton thread. In one of these *nushturs* or incising instruments there were three lancets, while in another there were four, in both cases bound together by cotton. Mr. Johnson says that the wounds in the capsules ought to be made diagonally, in order to prevent the juice falling off in the night, when the dews are heavy; and Mr. Impey states that in Bengal they are made so. But in some cases the incisions are made perpendicularly. Speaking of the *nushtur*, Mr. Impey states that so much only of the points is allowed to protrude "as is actually necessary, so that no discretion or latitude in manipulation is left to the labourer; the length of the point which protrudes externally is one-twelfth of an inch, and the distance between each blade is one-eighth of an inch. The area of the beegah is at this time imaginarily divided into three or four compartments, and the labour apportioned accordingly, the different processes of bleeding or gathering the juice going on separately in each, when the previous one has been finished; three men are employed, and in this way each plot is bled every three or four days. Twelve days are required to complete the operation, so that each capsule becomes wounded three, and occasionally four and six times, if the heads are large; but this is not of frequent occurrence.

"The mode of wounding the capsule is as follows: Being depressed, and held almost horizontally, to admit of greater facility and steadiness in cutting, the inci-

¹ A chittack, or chitak, is equal to 1 oz. 17 dwts. 12 grs. English troy weight.

sions are made longitudinally, and from below upwards, about 3 P. M., or in the hottest part of the day, and after the collections from former incisions have terminated. A small quantity of white milky juice exudes almost immediately upon the incision being made, of the consistence of cream, on the surface of which after a short time a slight pellicle is formed by the power of the solar rays. The object of making the incisions at this hour is to obtain this result. By the continued force of the solar influence, a greater degree of evaporation and inspissation takes place (but not sufficiently to close the orifices of the wounds), which prevents the juice falling off the capsule, although, when the night dews are heavy, or the juice very plentiful, this cannot altogether be avoided. The greatest exudation occurs in the night-time, from the dew washing and clearing the incisions, and favouring the escape of the juice. During the night, the juice continues to ooze out gradually, and in the morning it is fit for removal. By this time it has altered its appearance. Instead of the white milky character which it had before, it assumes a thick gummy consistence, and exhales a powerfully narcotic smell; it is much darker, of a light drab colour, and streaked with deeper shades of the same and red and black striæ, the latter known as *pasêvâ*—a term, as the meaning implies (perspiration or exudation), literally applicable to the whole mass, but used to denote this especial appearance (see *ante*, p. 1017). The nature of the juice is perhaps best understood by the native name applied to it in Central India, viz. (*Anglice*) slime."

A third drawing represented the natives engaged in scraping off the exuded juice. "Scraping, the next process," says Mr. Impey, "is commenced on the following morning at sunrise, and executed with rude blunt iron scrapers, resembling a cleaver in miniature. A small piece of cotton soaked in linseed oil is stuck on the upper part of the blade, and both the thumb and edge of the scraper are occasionally smeared with it, to guard against the glutinous effects of the juice, which would otherwise adhere strongly to the fingers. Towards the point of the scraper the most pure juice is gathered, for there the first scrape is made; the second is done more with the heel of the instrument, near the handle, and the juice is much lighter in colour. It is during this operation that the first sophistication occurs, the scraper being carried heavily over the capsules, taking with it a considerable part of the beard or pubescence. The manner in which scraping is performed is by grasping the capsule between the thumb and forefinger of the left hand, inclining it gently as in bleeding; the thumb of the right hand being then placed on the top of it, the scraper is drawn briskly upwards, almost similar to the making of a pen. This is repeated twice; every head is of course submitted to the process, and each is considered to yield a weight of juice equivalent to about 15 grains troy. In full-grown fruitful fields, each man will collect upwards of half a pound of chick per day, at least, by 10 A. M., by which time this part of the work is over."

Dr. Butter, in his account of the preparation of opium for the China market, observes that "the goodness of the soil, and the management of the irrigation, are circumstances which powerfully affect the strength of the juice at the time of its collection; but a third agent, still less amenable than these to control, now comes into play, the precipitation of *dew* on the surface of the capsule. When a current of wind, or a cloudy sky, prevents the formation of dew, it is found that the scarifications made in the capsule about the middle of the preceding day are sealed up by the slight oozing of juice which had immediately followed the incisions, and the quantity of opium obtained is small. When, again, the dew is abundant, it washes open the wounds in the capsule, and thus facilitates the flow of the milk, which in *heavy* dews is apt to drop off the capsule entirely, and be wasted. But when the dew is in moderate quantity, it allows the milk to thicken by evaporation, and to collect in irregular tiers (averaging one grain of solid opium from each quadruple incision), which on examination will be found to have a greater consistency, and a 'rose-red' colour towards the external surface, while the interior is semifluid, and of a 'reddish-white' colour. This inequality of consistence constitutes the *grain of raw opium*, of which I shall have to speak hereafter.

“In the collection of these drops of half-dried juice, it is very apt to get mixed with the dew, which, in the earlier hours of collection, continues to besprinkle the capsules, and which here does a double mischief—first, by retarding the inspissation of the general mass of the juice; and, secondly, by separating its two most remarkable constituent parts—that which is soluble, and that which is insoluble in water. So little aware, or so reckless, even under the most favourable construction of their conduct, are the *koéris*, of the injury thus caused by the dew, that many of them are in the habit of occasionally washing their scrapers with water, and of adding the washings to the collection of the morning. In Malwa, *oil* is used for this purpose, to the irremediable injury of the flavour of the opium. On examining the juice thus mixed with water, it will be found that it has separated, as above mentioned, into two parts, a fluid, and a more consistent portion; the latter containing most of the resin, gluten, caoutchouc, and other less soluble constituents of opium, with part of the super-meconiate of morphia; and the former containing the gum, some resin, and much of the super-meconiate of morphia, and much of the colouring principle, which, though pale at first, is rapidly affected by light, and acquires a very deep ‘reddish or blackish brown’ colour. Many *koéris* are in the habit of draining off this fluid portion into a separate vessel, and of bringing it, under the name of *paséwá*, for sale, at half the price of opium, to the Benares agency, where it is used as *léwá* (paste for the petal envelops of the cakes). Others, after allowing the soluble principles to become thus changed into an acescent, blackened, sluggish fluid, mix it up with the more consistent part of their opium, and bring the whole for sale in this mixed state; the consequence of which is, that they are subjected to a penalty, called *battá upon paséwá*, and regulated by the estimate of the opium-examiner of the quantity of *paséwá* contained. This penalty is the only efficient check upon this most pernicious practice of the *koéris*, for on the generality of the *gomáshias* it is difficult to impress the necessity of their looking after the *koéris* during the collecting season.”

Mr. Impey, alluding to the practice in Malwa, says: “When the capsules crack and turn brown they are pulled off the stalks, and the seed shaken out; the heads are then thrown away. In poor districts, where the people cannot afford the indulgence and luxury of opium for smoking and chewing, the poppy heads are made into a decoction, and the liquid drunk in its stead. This liquid, from the Persian name of the capsule, is termed ‘Post.’ But another and more useful application of the capsules is also exercised; they are ground into fine powder, and, like the leaves, sold, under the name of *boosa*, to the retailers, and sprinkled over the *buttees* of opium, both to prevent their adhesion and to form a covering for them.

“The seeds are a very useful part of the plant, and very plentiful. From two to five maunds are procurable from a beegah, which obtains ready sale at 12 to 16 seers for a rupee; a very small quantity being required for seed, the rest is converted into oil, which, according to the native mode of expression, gives one-third in weight. According to Dr. O’Shaughnessy, it yields 56 per 100. It is of a pale yellow colour, clear, burns well, but is not adapted for lamps, on account of the smoke and smell which it gives out. The oil is very cheap, selling at eight seers per rupee; and the refuse is an extremely wholesome and nutritious food for cows, termed here *Khari*; it sells at the low rate of eight annas per maund. Lastly, the stalks, which might be made use of for firewood, are left in the ground untouched and unheeded.”

The juice which is scraped off the poppy-heads is collected in shallow earthen pans, and is removed in these from the fields. A fourth drawing represented a native engaged in this operation.

A fifth represented two natives engaged in manipulating the opium, with a view to its introduction into the earthen vessels or bottles (called *gumlahs*). The lower half of each is surrounded with wicker-work, to protect the vessels. The native dealers judge of the consistence of opium by the feel. Dr. O’Shaughnessy says

that the opium brought to the factories contains from 64 to 68 per cent. of solid matter, but that by evaporation it reaches the consistence of 70—the standard of the factory for the Chinese investment.

Dr. Butter observes, that “in the Benares shells the *léwá*, or paste for uniting the poppy petals, remains visibly interstratified with them, dark coloured, and tenacious; while in the *Behar* it is in a great measure absorbed by the petals, which are apparently in intimate contact with each other, and is not to be distinguished from them.” He farther observes that “any strong cheap mucilage or farinaceous paste, or perhaps some indigenous imitation of birdlime, would answer for the inner portion of the shell; and an exterior coating of a resinous, waxy, or oily nature, impervious to water, would defend this from the moisture of the air.” In reference to the shape of the cakes, he says: “The shape ought to be as nearly spherical as possible, that being the geometrical form which, under the smallest surface, contains the greatest quantity of matter, and which, consequently, affords the least scope for the extrication of air, and ultimate injury to the shape of the cake when that air escapes. Greater attention to boring the earthen cups in which the cakes are dried *perfectly* hemispherical, instead of parabolical, as they now are, would contribute to the desired sphericity.”

DESCRIPTION.—In commerce, several varieties of opium are known. The principal kind, however, is that brought from Smyrna. But the recent events which have occurred in China will probably throw a considerable quantity of Indian opium into European commerce.

1. *Smyrna Opium* (*Opium Smyrnæum*).—This is the *Turkey* or *Levant opium* of commerce. It occurs in irregular rounded or flattened masses of various sizes, rarely exceeding two lbs. in weight, enveloped in leaves, and usually surrounded with the reddish capsules of some species of *Rumex* (*R. orientalis*, according to Koch;¹ but *R. Patientia*, according to Merat).² Some of the flat cakes are without the capsules, and somewhat resemble Constantinople opium. When first imported, the masses are soft, and of a reddish-brown colour; but, by keeping, they become hard and blackish. Its lustre is waxy; its odour is strong and unpleasant; its taste is bitter, acrid, nauseous, and persistent. M. Guibourt regards the masses as being made up of agglutinated tears, and on this account as being the purest met with. It is, however, frequently found largely adulterated. From one sample, weighing 10 ounces, I obtained 10 drachms of stone and gravel. Notwithstanding occasional frauds of this kind, Smyrna opium affords the best commercial opium. It yields more *morphia* and *meconic acid* than either Constantinople or Egyptian opium.³ The quantity of *morphia* which can be obtained from it is, perhaps, on the average, about eight per cent. Pelletier,⁴ in an operation on about two ounces of this opium, procured a quantity of *morphia* equal to 7.08 per cent. From a pound, he calculates that eight or nine per cent. could be obtained. On an average 12 per cent. of hydrochlorate of *morphia* may be procured from it. Dr. Christison obtained two drachms of *narcotine* from half a pound of the best Turkey opium; hence, we may estimate the quantity at about four per cent. Hydrochlorate of *morphia*, prepared by Gregory's process from Turkey opium, contains, according to Dr. Gregory,⁵ one-twelfth of codeia. Merck⁶ examined five kinds of Smyrna opium; from the worst he procured 3 to 4 per cent. of *morphia*; from the best 13 to 13.5 per cent. In the latter variety, he found 0.25 per cent. of codeia.⁷

2. *Constantinople Opium* (*Opium Bizantinum seu Constantinopolitanum*).—I am indebted to Professor Guibourt for an authentic sample of this. His description of it is as follows: “There are two sorts of it; one in very large irregular

⁷ [Smyrna opium rasped, then mixed with common filtered water and allowed to remain in the liquor, yields a solution which powerfully retards the putrefaction of any animal matter placed therein. Dr. Pereira, in *Pharm. Journ.* vol. xi. p. 135.—Ed.]

cakes, which are flattened like the Smyrna opium. This is of very good quality. The other is in small, flattened, regular cakes, of a lenticular form, from two to two and a half inches in diameter, and covered with a poppy leaf, the median nerves of which divide the disk into two parts. It has an odour similar to the preceding kind, but more feeble; it blackens and dries in the air. It is more mucilaginous than Smyrna opium." To this account I may add that the cakes are never covered with the *Rumex* capsules, as those of Smyrna opium are. Berthemot describes two kinds of it; one soft, the other hard and brittle. Constantinople opium is inferior to the Smyrna kind, but superior to Egyptian opium. Professor Guibourt says that this kind of opium yields only half the morphia procurable from the Smyrna opium. Berthemot also states that, though it yields more morphia than the Egyptian opium, it gives less than the Smyrna kind. This, however, does not agree with the experience of Mr. Duncan, of Edinburgh, who has never failed to obtain an extraordinary quantity of hydrochlorate of morphia from it. From an experiment of Dr. Christison's, he calculates the quantity of hydrochlorate of morphia obtainable from it at 14 per cent.¹ Merck² procured 15 per cent. of pure morphia, but scarcely a trace of codeia. It is obvious, therefore, that Constantinople opium is of unequal quality. It is probable that opium of unequal qualities, and produced in several parts of the Turkish empire, is carried to the capital, and, being exported from thence, bears the name of Constantinople opium.

3. **Egyptian Opium** (*Opium Ægyptiacum*).—It occurs in round flattened cakes of about three inches diameter, covered externally with the vestiges of some leaf. It is usually very dry. It is distinguished from the two preceding varieties by its reddish colour, analogous to that of Socotrine or hepatic aloes. Some very inferior qualities are sometimes offered for sale, and which appear to the sight and touch to be largely adulterated. By keeping, it does not blacken like the other kinds; its odour is less strong, and somewhat musty. Guibourt says, that by exposure to the air it becomes soft. Egyptian opium is for the most part inferior to either of the preceding kinds; but its quality is by no means uniform. Some kinds become damp by keeping. Guibourt tells us it yields only five-sevenths of the morphia obtained from Smyrna opium. Berthemot also states that it contains less morphia than either of the preceding kinds of opium, and that the morphia is more mixed with narcotine. He farther adds that the morphia which it yields is purified with great difficulty. The watery infusion of Egyptian opium has a distinct odour of acetic acid. Dr. Christison obtained about 10¼ per cent. of pure white hydrochlorate of morphia from it, which, he says, is about the quantity procured from good Turkey opium. Merck³ procured only from 6 to 7 per cent. of morphia, but much meconic acid.

4. **Trebizond Opium** (*Persian Opium*).—Some years since a quantity of opium was imported into this country from Trebizond, in the form of cylindrical sticks, which, by pressure, have become somewhat angular. Their length is about six inches; their diameter about half an inch, a little more or less. Each one is enveloped in a smooth shiny paper, and tied with cotton; its colour is similar to that of Socotrine aloes. It has the opiate odour stronger than that of the Egyptian kind, but less than Smyrna opium, and mixed somewhat with a musty odour; its taste is intensely bitter. It is commonly termed in commerce Persian opium, but the specimens I received came from Trebizond. It is a very inferior kind. Merck⁴ could obtain no morphia from it by the ordinary mode of proceeding. He, however, afterwards succeeded in obtaining about 1 per cent. It gave only a trace of narcotina. There must, I suspect, be some error in these statements, as this opium is certainly richer in morphia than is here stated.

5. **Indian Opium** (*Opium Indicum*).—Three varieties of Indian opium are known in commerce, viz: *Malwa*, *Benares*, and *Patna Opium*. As the two latter

¹ *Journ. de Pharm.* xxi. 547.

² *Op. supra cit.*

³ *Pharm. Central-Blatt für 1836*, S. 491.

⁴ *Pharm. Central-Blatt für 1836*, S. 493.

kinds are undistinguishable, I shall include them under one head of *Bengal Opium*.

a. *Bengal Opium (Benares and Patna Opium)*.—Its preparation is fully described by Dr. Butter.¹ I have been kindly furnished with samples of the Benares and Patna kinds, of the growth of the years 1835—36, and 1837—38, by Mr. Maitland, of the India House.

Bengal opium is imported in balls, each weighing about three lbs. and a half, and packed in chests, each containing about forty balls. The balls are hard, round like cannon-balls, and about the size of a child's head. Externally, each ball is made of poppy petals, firmly agglutinated by a paste called *lewah*, to form a firm but laminated envelop weighing about 14 oz. On cutting through this, the opium is found to be quite soft, homogeneous, apparently quite pure, and to have the consistence of a soft extract. Its colour is blackish-brown. Its odour and taste are strong, and purely opiate. On exposure to the air this opium speedily becomes covered with mouldiness. Both *Bahar* or *Patna* and *Benares Opium* are exported from Calcutta. Bahar and Benares are the only districts of Bengal where opium is produced. Benares is most valued by the Chinese (Butter). Farther experiments are required, ere we can speak with confidence as to the percentage quantity of morphia and narcotina obtainable from Bengal opium. Dr. Smytten² procured only 2½ or 3 per cent. of morphia. But from some experiments which I have made, I consider this quantity to be considerably below the truth. Mr. Morson informs me that Benares opium contains rather more than half the quantity of morphia contained in good average Turkey opium.

Garden Patna Opium.—For a sample of this opium I am indebted to Dr. Christison. It is imported in square cakes (inclosed in thin plates of mica), about three inches in length and breadth, and one inch thick. It has the appearance, as Professor Guibourt describes it, of a well-prepared, shiny, dry, pharmaceutical extract. Its colour is blackish-brown. Its odour is less powerful than that of Smyrna opium.

In the first edition of this work, I described this kind of opium as *fine Malwa opium*. The following extract of a letter which I received from Dr. Christison will explain the cause of this error: "The common ball opium of Patna and Benares (which are all but identical) was long known in India to be inferior in quality. During the inspectorship of Mr. Fleming, of Barrochan, he instituted inquiries, along with his assistant, Captain Jeremie, as to the causes of its inferiority, and, among other reasons, was led to suppose it owed its softness, tarriness, and general low quality, to the 'ryots' storing the juice in bottles till it accumulated to a sufficient extent to be made up, and to fermentation consequently taking place. Means were therefore taken to get this juice before being long kept, and it was made up into square cakes, of which I sent you one under the incorrect name of Malwa opium—the name by which I got it." Mr. Fleming subsequently recognized the cakes in Dr. Christison's laboratory with his official stamp on them. Dr. Christison obtained 9.5 per cent. of muriate of morphia (snow-white) from it, a considerable portion of narcotine, and so large a proportion as one-twelfth or 8 per cent. of codeia.

This I presume is the opium employed by Merck³ under the name of Bengal opium, and which, he says, was inclosed in plates of mica. In 100 parts, he found *morphia* 8, *narcotine* 3, *codeia* 0.5, *thebaina* 1, *meconine* traces, and *porphyroxin* 0.5. Another sample of Indian opium, in round balls of half a pound each, and of the consistence of Calabrian extract of liquorice, yielded him 10 per cent. of morphia.⁴

β. *Malwa Opium*.—A few years since, this ranked among the inferior kinds of

¹ On the Prepar. of Opium for the China Market, in *Journ. Asiat. Soc. of Beng.* v. 105, 1836. [See also the author's account of the manufacture, *ante*, p. 1018.—Ed.]

⁴ *Pharm. Central-Blatt für* 1836, 493.

Indian opium, but it has been gradually rising in value, and is now highly esteemed. I have received two varieties of opium under this denomination. They were brought to me from India by former pupils of mine.

αα. One kind consists of a round flattened cake or ball, weighing ten ounces. It seems to have been packed in a coarse kind of dust, composed of broken poppy petals. Its consistence is about that of moderately firm Smyrna opium. When cut into, it presents a homogeneous texture. Its colour is dark brown; its odour similar to that of Smyrna opium.

ββ. The other kind (described in the first edition of this work as *inferior Malwa opium*) is in flattened cakes without any exterior covering. It is dull, opaque, blackish-brown, externally; internally, somewhat darker and soft. Its odour is somewhat like that of Smyrna opium, but less powerful, and combined with a slight smoky smell. Guibourt says it yields as much extract as Levant opium; but its insoluble residue wants the vinous odour and glutinous consistence of the latter. It furnishes only one-third the quantity of morphia yielded by Smyrna opium. From common Malwa opium Dr. Smytten procured only from 3 to 5 per cent. of morphia; but, from fine samples, from $7\frac{3}{4}$ to 8 per cent.

Mr. E. Solly¹ states that he found "occasional minute cavities full of a pale-yellow oil," in a specimen of Malwa opium. This opium yielded him 80 per cent. of soluble matter.

γ. *Cutch Opium*.—Under this name I have received from Bombay a small cake of opium, rather more than an inch in diameter, and apparently enveloped by the remnants of leaves. Its odour is much less powerful than that of Smyrna opium.

δ. *Kandeish Opium*.—In round flattened cakes, weighing about half a pound each. It is nearly black, is hard, brittle, and presents a gritty or granular fracture. It yielded Mr. E. Solly² 72 per cent. of soluble matter, and about 7 per cent. of morphia.

6. *English Opium (Opium Anglicum)*.—It is in flat cakes or balls, enveloped with leaves. It resembles fine Egyptian opium more than any other kind; its colour is that of hepatic aloes; it has a moderately strong opiate odour.³ Mr. Hennell procured from 700 grains of English opium, prepared by Messrs. Cowley and Staines, 53 grains, or 7.57 per cent. of morphia; while from the same quantity of Turkey opium he obtained only 48 grains, or nearly 7 per cent. of morphia.⁴ Mr. Morson,⁵ from 20 oz. avoird. of the same British opium, procured only 384 grains, or about 4.4 per cent. of morphia, and 222 grains, or about 2.53 per cent. of narcotina. Probably the morphia obtained by Mr. Hennell was not freed from narcotina. Mr. Young declares British opium to be stronger than the commercial opium; six ounces of the former being equal to eight of the latter.⁶

7. *French Opium (Opium Gallicum)*.—I have not seen any samples of this. Pelletier⁷ describes it as being of a deep reddish-brown colour, and brittle when dry. Its taste was somewhat different from that of Smyrna opium. It left a less insoluble residuum than Eastern opium. Pelletier procured more morphia from it than from Smyrna opium. In an experiment on about two ounces of each, he obtained about 10.38 per cent. from the former, and only 7.08 per cent. from the latter. It contained no narcotina. He obtained sensible traces of *codeia*, but none of *narceine*, *meconine*, or *thebaine*, perhaps because the quantity of opium experimented on was too small. The disappearance of one immediate principle (narcotina), and the augmentation of another (morphia), caused by climate, are interesting facts. Petit⁸

got from 16 to 18 per cent. of morphia; and Caventou (quoted by Christison) obtained from 22 to 28 per cent. from French opium; but, I presume, the morphia was very impure.

8. **German Opium** (*Opium Germanicum*).—Biltz, of Erfurt, obtained from indigenous German opium 16½ and even 20 per cent. of morphia, where the opium had been procured from the *P. somniferum*, α . *nigrum*; and between 6½ and 9½ narcotina. But from opium made from *P. somniferum*, β *album*, he got conversely 6.8 per cent. of morphia, and 33 per cent. of narcotina.

COMMERCE OF OPIUM.—The quantities of opium on which duty was paid during six years, were as follows:—¹

In 1834	27,253 lbs.	In 1838	30,824 lbs.
1835	30,398	1839	40,784
1836	32,553	1840	45,589
1837	36,533	1841	37,900

Since August 13, 1836, the duty has been 1s. per lb; previous to that, and from 1828, it was 4s. per lb. Of the above quantities, the greater part was imported from Turkey. The quantity of opium produced in Hindostan is enormous. In Patna and Benares its cultivation is a monopoly in the hands of government; and a revenue is derived from the Malwa opium, by a system of passes on shipment from Bombay. Of the whole quantity raised in Hindostan, it is calculated that about two-thirds have been sent to Canton, and the remainder to the Eastern Islands.² The following table is from Mr. R. Montgomery Martin's *Statistics of the Colonies of the British Empire*, London, 1839 (p. 366).

Estimate of Quantity and Total Value of Indian Opium consumed in China during the years ending in 1832—33.

Years.	Patna.	Benares.	Malwa.	Total.	
	Chests.	Chests.	Chests.	Chests (of one pecul, or about 133½ lbs. avoird.)	Amount in Spanish Dollars.
1827—28	4006	1128	4401	9535	10,425,075
1828—29	4831	1130	7171	13132	12,533,215
1829—30	5564	1579	6857	14000	12,057,157
1830—31	5085	1575	12100	18760	12,904,263
1831—32	4442	1518	8265	14225	11,501,584
1832—33	6410	1880	15403½	23693½	15,352,426

All the world knows that these enormous quantities of opium were smuggled into China (by the connivance of the local authorities) for the purpose of smoking. The vessels anchored at Lintin, about seventy miles from Canton, and delivered the opium to the boats of the Chinese buyers. "Malwa opium is considered by the Chinese as having a higher touch, but not so mellow nor so pleasant in flavour as the Patna opium. The smokable extract, which each quantity of opium contains, is thus intimated by the Chinese—(who use opium as we do wine or spirits): Patna and Benares opium 45 to 50 touch—average 48; Malwa 70 to 75—average 72½; Turkey 53 to 57—average touch 55."³ The smokable extract here referred to, is an aqueous extract of opium prepared by the Chinese. A detail of the important events which have resulted from the active and extraordinary steps taken by this remarkable people to put a stop to the trade in opium, would be out of place in this work. Suffice it to say that, in 1839, no less than 20,283 chests of opium, valued at nearly £3,000,000 sterling, were delivered up to the Chinese, and by them destroyed by immersing the opium in water with lime and salt, and, when the whole had become a fetid mud, allowing it to escape into the river.⁴

COMPOSITION.—Few substances have been so repeatedly submitted to chemical investigation as opium. The mere reference to the different labours which have

¹ Trade List.
² Evid. taken before the Committee of the House of Lords on the Affairs of the East India Company, No. 646, 1830, p. 25.
³ R. M. Martin, *op. supra cit.* p. 306.
⁴ See *Asiatic Journal*, vol. xxx. part. ii. p. 310; also *Parliamentary Reports on the Trade with China*, No. 359, 1840; and *Corresp. relating to China*, 1840.

been bestowed on it, would occupy more space than I can devote to the subject. I must, therefore, content myself with brief notices of the most important epochs in its chemical history, and a reference to some of the analyses which have been made of it.

In 1803 Derosne¹ discovered *narcotina*. In 1804 Sertürner² announced the existence of *meconic acid* and *morphia*. Seguin³ appears to have discovered them about the same time. Robiquet⁴ confirmed these discoveries in 1814. In 1826 *meconine* was discovered by Dublanc Jeune, and again, in 1830, by Couerbe.⁵ In 1832 Pelletier⁶ discovered *narceina*; and, in the same year, Robiquet⁷ announced the existence of *codeia*. In 1837 Merck⁸ announced the existence, in opium, of a new substance, which he called *porphyroxin*; but his statement requires confirmation.

Analyses of opium have been published, in 1800 by Bucholz,⁹ in 1804 by Sertürner, in 1814 by Seguin, in 1817 by Braconnot,¹⁰ in 1818 by Buchner,¹¹ in 1819 by John,¹² in 1823 by Pfendler,¹³ in 1824 by Lindbergson,¹⁴ in 1826 by Merck,¹⁵ in 1826 by Geiger,¹⁶ in 1831 by Biltz,¹⁷ in 1832 by Pelletier,¹⁸ in 1834 by Schindler,¹⁹ and in 1836 by Mulder.²⁰

The following substances may be regarded as the constituents of opium : *Morphia*, *narcotina*, *codeia*, *narceia*, *meconine*, *thebaina*, or *paramorphia*, *pseudomorphia*?, *meconic acid*, *brown acid extractive*, *sulphuric acid*, *resin*, *fat oil*, *gummy matter*, *caoutchouc*, *albumen*, *odorous principle* (volatile oil?), and *lignin*.

1. **Volatile Odorous Principles (Volatile Oil?)**.—The distilled water of opium has the peculiar odour of this drug, and by keeping deposits a rosy substance. Hitherto, however, all attempts to isolate the volatile odorous principle of opium have failed, and its nature, therefore, is as yet unknown. Nysten¹ swallowed two ounces of the distilled water without any sensible effect; and Orfila injected a like quantity of it into the jugular vein of a dog without apparently causing any inconvenience to the animal. The volatile principle cannot, therefore, possess much activity; but Nysten concludes that "the distilled water of opium, strongly saturated with the aromatic principle, is capable of producing drunkenness and sleep, when taken in a strong dose."

2. **Morphia**.—(This will be described hereafter.)

3. **Codeia (Codeine)**.—So called from *κόδων*, a poppy head. It is a white, crystalline solid, soluble in cold, and still more so in boiling water. It is soluble in alcohol and ether. It is insoluble in a cold weak solution of potash. If more codeia be added to boiling water than this liquid can dissolve, the excess melts and forms an oily layer, at the bottom of the vessel; and, by cooling, a crystalline mass is obtained. It reacts as an alkali on test papers, and unites with acids to form crystalline salts. From morphia, codeia is distinguished by its not becoming blue on the addition of a persalt of iron. It is also said not to redden nitric acid like morphia (Turner). All the specimens of codeia which I have met with became orange yellow on the addition of nitric acid. Moreover, ammonia does not precipitate it from its very diluted solution in hydrochloric acid, on account of its solubility in water; and this affords a means of separating morphia from codeia. The separation may be more easily effected by ether, which readily dissolves codeia; or by alkalies (potash or soda), which dissolve morphia, but leave codeia. From meconine it is distinguished by its aqueous solution possessing marked alkaline properties, as manifested by its action on test papers. Tincture of nutgalls produces a copious precipitate (*tannate of codeia*) in solutions of codeia.

[We have, like the author, observed that codeia and its salts acquire an orange yellow colour on the addition of nitric acid, and farther that it decomposes iodic acid like morphia, and sets free iodine. The specimen examined was considered to be pure, although it is possible that traces of morphia may be retained, and account for the reactions observed. Codeia is so soluble in water that the solution has a strong alkaline reaction. It readily yields well-defined prismatic crystals by the evaporation of its aqueous solution. These are larger, but have the same form

¹ Orfila, *Toxicol. Gén.*

under the microscope as those of morphia, viz. quadrangular prisms. When strong sulphuric acid is added to codeia it is somewhat reddened. On dropping into this mixture one drop of a solution of bichromate of potash there is an immediate decomposition, with change of colour, the liquid becoming rapidly green, from the liberation of green oxide of chrome. In this respect codeia resembles morphia. In fact, the chief chemical difference is that pointed out by the author, viz., the non-coloration on the addition of a persalt of iron.¹—En.]

Anhydrous codeia consists of $C^{35}H^{20}NO^5$, Symbol Cd⁺. It, therefore, contains an atom less of oxygen than morphia does. [There is the same relation between the formulæ of Morphia and Codeia as between those of Cinchona and Quina.—Ed.] Its atomic weight is 284. Crystallized in ether it contains no water; but crystallized in water it retains two atoms of water of crystallization.

The salts of codeia have not been much studied. The nitrate readily crystallizes. The *tannate* is insoluble in water. The *double hydrochlorate of morphia and codeia* is the salt at one time sold as hydrochlorate of morphia, by those who prepared it by Gregory's process. Hence it has been termed by the French pharmacologists *sel de Gregory*.

The effects of codeia and its salts have been imperfectly examined by Kunkel, Gregory, Barbier, and Magendie, but the results are very conflicting. Kunkel¹ says it is a local irritant, becomes absorbed, excites the circulation, and produces convulsions; but that none of the animals on which the codeia was tried were either stupefied or paralyzed. Magendie,² however, says it causes sleep, and when exhibited in large doses, stupor. He considers one grain of codeia equivalent to half a grain of morphia; two grains excite nausea and vomiting. Barbier³ also states that it produces sleep. Dr. W. Gregory⁴ says that, in doses of five or six grains, it causes an excitement like that of intoxication, followed in a few hours by depression, nausea, and sometimes vomiting. Magendie proposes to use it as a substitute for morphia, to procure sleep and allay pain, in doses of from one to three grains. A *syrup of codeia* (composed of codeia grs xxiv; distilled water f ℥iv; sugar ℥ viij) has been used in whooping-cough. The dose for a child of about seven years of age is a teaspoonful. It has been given in irritation of the gastric mucous membrane.⁵

4. Narcotina (Narcotine).—So called from *ναρκωτικός*, narcotic. The greater part of the narcotina of opium is in a free state, as it is removable by ether without the aid of either acids or alkalis. It is a white, inodorous substance, crystallizing in prisms, which are fluted or striated—distinguished from morphia by being insipid, very soluble in ether, insoluble in alkalis, by its not becoming blue on the addition of the sesquichloride of iron, by its not decomposing iodic acid, and, when quite pure, by its not yielding a brown colour when treated by chlorine and ammonia. Heated on paper over a candle it gives a greasy-looking stain to the paper. Nitric acid dissolves it, and acquires an orange tint. [Sulphuric acid turns it yellow, and on adding bichromate of potash green oxide of chrome is slowly set free.—En.] It does not affect vegetable colours, and by this character is readily distinguished from both morphia and codeia. It is insoluble in cold water, but dissolves in 400 parts of boiling water—in 100 parts of cold alcohol—or in 24 parts of boiling alcohol. The volatile oils also dissolve it; it is soluble in ether. It consists of $C^{46}H^{25}NO^{14}$. The salts of narcotina have been but little examined. They are more bitter than those of morphia, redden litmus, and are precipitated from their solutions by infusion of nutgalls and by the alkalis. The *hydrochlorate* is crystallizable. Both this and the *sulphate* are very soluble in water.

[Orfila has suggested a test for narcotina, which produces very striking results. If to the mixture of strong sulphuric acid and narcotina, a small fragment of nitrate of potash, or any nitrate, be added, the liquid speedily acquires a deep blood-red colour. Morphia treated in the same way gives a dingy brown or olive green colour. Conversely, a mixture of narcotine and sulphuric acid has been proposed as a test for nitric acid or a nitrate. It is the nitric acid which here operates, and the presence of a trace of nitric acid in sulphuric acid may be often revealed by the fact that when the latter is added to narcotina it acquires a reddish tint.—En.]

Narcotina is extracted from the residue of the opium which has been subjected to the action of cold water. This is treated with water acidulated with either acetic or hydrochloric acid, and to the filtered solution ammonia is added. The precipitate treated with boiling alcohol yields narcotina, which is deposited as the liquor cools. Narcotina may be separated from morphia by ether, which dissolves the narcotina, but leaves the morphia, or by a solution of potash, which dissolves the morphia, but leaves the narcotina, or by the cautious addition of weak acetic acid, which dissolves the morphia, and, unless the acid be greatly in excess, does not dissolve the narcotina.

When narcotina was first discovered, it was said to be the stimulant principle of opium; and Magendie states, a grain of it, dissolved in olive oil, produced the death of a dog in twenty-four hours, while twenty-four times this quantity was given, dissolved in acetic acid, with impunity. Orfila, at one time, declared it was inert, then that it acted like morphia, and subsequently that

³ Journ. de Pharm. xxiv. 144.

⁴ Formulaire, 8me. éd. 87.

⁵ Ibid. p. 219.

its operation was remarkable and peculiar. Bally asserts that, in a solid state, it is inert; for 129 grains may be given, at one dose, without exciting any obvious effect. The truth is, I believe, that narcotina possesses but little activity; and I presume, therefore, that the first experimenters with it employed an impure substance. Dr. Roots gave gradually increased doses of it, up to a scruple, without the least injury. The bitterness of its sulphuric solution led him to employ it in intermittents, as a substitute for disulphate of quina. More recently, attention has been drawn to it in India, by Dr. O'Shaughnessy,¹ as an Indian indigenous substitute for quina; and nearly 200 cases of intermittent and remittent fevers, treated by it with success, have been published.

[The proportion of Narcotina contained in the different varieties of opium is, according to Dr. O'Shaughnessy, for 100 parts of Bengal Opium, 3 parts, the same for Malwah opium, while Turkey opium yields only one per cent. (from notes).—Ed.] One of the products of the oxidation of Narcotine is Opianic acid; of the mode of procuring and properties of which we subjoin the following remarks, from the author's notes.

Opianic Acid.—This substance is most readily obtained, according to Liebig and Wohler, by the oxidation of narcotine in the following manner: Dissolve narcotine in an excess of dilute sulphuric acid, add to the solution finely powdered binoxide of manganese, and apply heat. It will soon assume a yellow saffron-like colour, and evolve carbonic acid gas. Heat to boiling, which is to be kept up until no more carbonic acid gas escapes. Both the manganese and sulphuric acid must be in excess; test for these, and then filter whilst boiling. In cooling, the fluid will nearly wholly congeal, and form a magma of fine needle-like crystals of opianic acid. The mass is to be placed on a filter to allow the yellow-coloured fluid to pass off; wash several times with cold water, press as firmly as possible, and remove impurities by treating with animal charcoal, and repeated recrystallization from boiling water.

Opianic acid crystallizes in very small shining silky prisms of indefinite form. It is but slightly soluble in cold water, but more so in hot; so that a saturated solution, in cooling, nearly wholly crystallizes, like a solution of benzoic acid. It is also soluble in alcohol. It reacts as an acid though it has but a faintly sour and bitter taste. It readily melts, and forms a clear oil, which crystallizes on cooling, but remains amorphous if heated beyond the point of melting. It does not appear to be volatile, although it may be distilled over, a circumstance referable to its adhesion to the sides of the retort. Heated in the air it emits an aromatic odour (similar to narcotine, which it resembles in combustion), with a vivid flame and deposition of carbon. Opianic acid expels carbonic acid, and forms soluble salts, with bases. The salts of silver and oxide of lead crystallize in thin shining prisms and flakes. It contains no nitrogen.²

5. Narceine (*Narceina*).—So called from *νάρα*, stupor. It is a white, inodorous solid, crystallized in long, fine, silky needles, radiating in tufts from a centre, with a slightly bitter, and even somewhat metallic, taste. It dissolves in 230 parts of boiling water, or 375 parts of water at 60°. It fuses at about 198°, and at a higher temperature is decomposed. Narceine has several very striking properties by which it is distinguished from other substances. The first of these deserving of notice is the action of mineral acids on it. Thus the sulphuric, nitric, and muriatic acids, so diluted with water that they cannot alter the elementary composition of narceine, give this substance a fine light-blue colour, immediately on coming in contact with it. This alteration of colour does not appear to depend on any change in the elementary composition of narceine, since, by saturating the acids with ammonia, the narceine is precipitated unchanged. When much water is added, the blue colour disappears. Another peculiar trait of narceine is, that it forms a bluish compound (*iodide of narceine*) with iodine; heat and alkalis destroy the colour. These characters are sufficient to distinguish narceine from all other known substances. In addition, I may add that it does not form a blue colour with the sesquichloride of iron, as morphia does.

Narceine was at first supposed to be a vegetable alkali; but as it does not affect vegetable colours, nor combine with nor saturate acids, it is now regarded as a neutral principle. Narceine is composed of $C^{28}H^{20}NO^{12}$.

Two grains have been several times thrown into the jugular vein of a dog, without producing any appreciable effect. It is presumed, therefore, to be inert.

6. Meconine—So called from *μαίον*, a poppy. It is a white, crystalline, odourless solid. Its taste, which at first is scarcely perceptible, is afterwards sensibly acid. The crystals are six-sided prisms, with dihedral summits. It fuses at 194°, and becomes a colourless, limpid fluid. At a higher temperature it may be distilled. It dissolves in 265 parts of cold water, or in eighteen parts of boiling water. It is soluble in alcohol and in ether. It is distinguished from morphia and codein by its not possessing alkaline properties. From morphia it is farther distinguished by its great fusibility, its greater solubility in water, and its not becoming blue on the addition of sesquichloride of iron. Cold sulphuric acid dissolves meconine, the solution being limpid and colourless. If heat be applied, the liquid becomes dark. If the quantity of sulphuric acid be small in proportion to that of meconine, the liquid assumes a green colour. If chlorine gas be passed over fused meconine, the latter becomes blood-red, and on cooling

¹ Brit. and For. Med. Rev. vol. viii. p. 263.

² Journ. für prakt. Chemie, xxvii. pp. 97, 98.

forms crystals. The compound thus formed is composed of chlorine and some organic base: if the first be removed by oxide of silver, a white acid is obtained, which Couerbe calls *mechloic acid* ($C^{14}H^{10}O^{10}$). By the action of nitric acid on meconine we obtain *hyponitromeconic acid*, composed of one atom of meconine and half an atom of hyponitrous acid. Meconine is remarkable for not containing nitrogen. Its composition is $C^{10}H^{10}O^4$.

A grain dissolved in water, and injected into the jugular vein of a dog, produced no remarkable effect. Farther experiments, however, are required before we can positively declare it to be an inert substance.

7. Thebaina (Paramorphia).—So called from *Thebes*, an ancient city of Egypt. It is a white, crystalline, fusible solid, having an acrid, styptic taste, very soluble in alcohol and ether, but hardly at all soluble in water. It possesses alkaline properties, and dissolves in weak acids. From these solutions it is precipitated by alkalis. An excess of alkali cannot dissolve it, unless, indeed, the alkaline solution be very concentrated. It fuses at 302° , but does not volatilize at any temperature. It is distinguished from morphia by not becoming blue on the addition of the perchloride of iron, and by not forming crystallizable salts with acids. From codeia it differs in not crystallizing in large crystals, and in not forming crystallizable salts. With meconine and narceine it has no analogy, and from them it is distinguished by the want of the peculiar properties which characterize these bodies. It resembles narcotina more than any other substance, but is distinguished by the crystals being shorter or granular, and wanting the pearly brilliancy possessed by those of narcotina; by its acrid taste; by its fusibility at 302° ; by its greater solubility in alcohol; and by nitric acid when dropped on it converting it into a substance like a soft resin, before dissolving it. Pelletier considered it to be isomeric with morphia;—hence he called it *paramorphia*. According to Dr. Kane's analysis, it consists of $C^{25}H^{14}NO^3$; and its atomic weight is 202. Couerbe's analysis gives another atom of oxygen. The last-mentioned chemist says that, by fusion, the crystals lose two atoms of water. Magendie states that one grain injected into the jugular vein, or placed in the pleura, acts like brucia or strychnia, and causes tetanus and death in a few minutes.

8. Pseudomorphia.—This is a substance which Pelletier has occasionally met with in opium. It is a whitish solid, which, like morphia, dissolves in caustic alkalis, is reddened by nitric acid, and made blue by contact with the sesquichloride of iron. But it does not decompose iodic acid, and cannot form salts with acids. It consists of $C^{27}H^{18}NO^{14}$. It is not poisonous; at least, nearly eight grains, given to a rabbit, produced no effect. Pelletier thinks that pseudomorphia must be some combination of morphia, in which this substance has lost its poisonous properties.

9. Porphyroxin?—This name has been given by Merck¹ to a supposed new principle found in Bengal opium. It is described as crystallizable, fusible, soluble in alcohol, ether, and weak acids. Alkalis precipitate it from its acid solution. Farther experiments are required to determine its existence and precise nature.

10. Resin—Brown, insipid, inodorous, softened by heat, insoluble in water and ether, but soluble in alcohol and in alkaline lyes: Nitrogen is a constituent of it.

11. Extractive.—The substance usually denominated the extractive of opium is probably a heterogeneous body. It is brown and acid, and has been supposed to be one of the active principles of opium. The reasons for this opinion are the following: In the *first* place, it has been asserted that after the morphia has been separated from an infusion of opium by magnesia, the filtered liquor gives by evaporation an extract which produces the same kind of narcotic effect that opium does.² *Secondly*, the effects of the known active principles of opium are not sufficiently powerful to authorize us to refer the whole of the active properties of opium to them. Thus, on an average, 100 parts of opium yield from 8 to 10 parts of morphia (the most active of the known constituents of opium), and, therefore, if this alkali were the only active principle, it ought to be 10 or 12 times as powerful as opium is. Now we know that morphia is but little, if at all, more active than opium, and, therefore, this last-mentioned substance either contains some other active principle, or the activity of morphia is surprisingly increased by the principle or principles with which it is naturally in combination. Butter³ says the insoluble residuum possesses considerable narcotic qualities.

12. Fatty Matter.—Yellow or brownish. Probably colourless when pure. It reddens litmus, and unites with alkalis to form soaps, from which acids disengage it apparently unchanged.

13. Meconic Acid.—Hitherto found in the poppy tribe only. It is usually procured from meconate of lime by acting on it, in hot water, with hydrochloric acid. The meconic acid crystallizes on cooling. The formula of the anhydrous acid is $C^{14}HO^{11}$. The crystallized acid contains 9 equivalents of water; and the acid dried at 212° contains 9 equivalents of water. [The symbol of meconic acid is $\bar{M}e$. The formula of the anhydrous acid is $C^{14}HO^{11} = \bar{M}e$; and the acid dried at 212° , $C^{14}HO^{11} = \bar{M}e + 3 aq.$; of the crystallized acid, $C^{14}HO^{11} + 3HO + 6aq = \bar{M}e + 9aq$. It is admitted by chemists to be a tribasic acid.—Ed.] When pure it is in the form of white,

** I have had no opportunity of verifying the statements in this column.

transparent, micaceous scales, which are soluble in four times their weight of boiling water. But at this temperature water decomposes it; carbonic acid is evolved, and a solution of *komenic acid* ($C^{12}H^{20}O^8 + 2 \text{ aq.}$) is obtained. Cold water dissolves a smaller quantity of meconic acid. Alcohol is also a solvent for meconic acid. By the dry distillation of meconic acid it loses carbonic acid and water, and becomes *pyromeconic acid* ($C^{10}H^{20}O^6 + \text{aq.}$).

The characteristics of meconic acid are as follows: 1st. It reddens the neutral sesquisalts of iron, forming the *meconate of the sesquioxide of iron*. Alkalies, protochloride of tin, and nitric acid, assisted by heat, destroy this red colour. A solution of corrosive sublimate, which destroys the red colour of sulphocyanide of iron, does not decolorize a red solution of meconate of iron. 2dly. It forms with a weak solution of *ammoniated sulphate of copper*, a green precipitate (*meconate of copper*). 3dly. It yields white precipitates (*meconates*) which are soluble in nitric acid, with *acetate of lead*, *nitrate of silver*, and *chloride of barium*: The acetates which, like meconic acid, redden the sesquisalts of iron, and might, therefore, be confounded with it, do not occasion precipitates with the salts of lead and of barium. [Besides, the meconate of lead is insoluble in acetic acid.—Ed.] 4thly. It is not reddened by *chloride of gold*, which reddens hydrosulphocyanic acid and the sulphocyanides.

It deserves especial notice that many substances enjoy equally with meconic acid the power of communicating a red colour to the sesquisalts of iron. The following are some of them: the *acetates*, *hydrosulphocyanic acid*, and the *sulphocyanides*, the *saliva of man and of the sheep*, the *urine of man* (frequently), *infusion of white mustard*, *komenic*, *pyromeconic*, and *indigotic acids*, the liquid obtained by the action of hydrochloric acid on detonating silver, the decoctions of *Cetraria islandica* and of *Gigartina Helminthocorton*.

Meconic acid is believed to be an inert substance. Sertürner swallowed five grains of it without observing any effect. Sömmerring gave ten grains to a dog; Fenoglio and Blengini gave eight grains to dogs, crows, and frogs, and four grains to various men; in all cases no effects were observed.¹ Combined with bases it doubtless modifies their action. Meconate of soda, however, is not active, as Sertürner asserted. It is supposed that the effect of the morphia in opium is modified by its combination with meconic acid. I have already mentioned that this acid is said to be an antidote in cases of poisoning by corrosive sublimate. If, however, the statement be true, the fact is of little practical value, on account of the scarcity of the acid; for neither opium nor laudanum can be given in quantity sufficient to neutralize the effect of this salt, without proving deleterious. Moreover, we have other good and easily accessible antidotes. Anthelmintic properties have been ascribed to the acid and some of its salts.

CHEMICAL CHARACTERISTICS.—Litmus paper is reddened by a watery infusion of opium (or tincture of opium diluted with water), owing to a free acid (*meconic*). Sesquichloride of iron gives it a deep red colour (*meconate of iron*). Acetate and diacetate of lead occasion a copious gray precipitate (*meconate and sulphate of lead, with colouring matter*), which, treated by sulphuric acid or sulphuretted hydrogen, yields free meconic acid. Chloride of barium also causes a precipitate (*meconate and sulphate of baryta*). Ammonia renders the infusion turbid (*precipitated morphia and narcotina*). Tincture of nutgalls causes a precipitate (*tannates of morphia and codeia*). Nitric acid communicates to the infusion a red colour (*oxidized ? morphia*). Iodic acid and starch cause, after some hours, a blue precipitate (*iodide of starch*). This last test does not always succeed. Chloride of gold causes a deep fawn-coloured precipitate.

APPLICATION TO MEDICO-LEGAL PURPOSES.—On examining the alimentary canal of persons destroyed by opium, it not infrequently happens that no traces of the poison can be obtained. I have met with several instances of this, and others are referred to by Dr. Christison.² Either, therefore, opium is rapidly absorbed, and its unassimilated parts are thrown out of the system by the excretories, or the constituents of this substance are digestible and assimilable.

The characters available for the detection of opium are twofold, *physical and chemical*.

1. **PHYSICAL CHARACTERISTICS.**—Whether in the solid state, or dissolved in water or spirit, opium possesses three physical properties, by one or more of which it may be frequently recognized. These are, a *more or less brown colour, a remarkable and peculiar odour, and a bitter taste*. Of these the odour is the only characteristic one. In the alimentary canal it is strongest when the stomach is just opened, or when the opiate liquor is just reaching the boiling point. Other odours, however, frequently mask it. The analogy between the odours of lactucarium and opium deserves notice.

2. **CHEMICAL CHARACTERISTICS.**—The chemical tests of opium are those for meconic acid and morphia above mentioned. In a case of suspected poisoning, the stomach and duodenum (cut into small pieces) with their contents, are to be digested in distilled water, and the solution filtered successively through a sieve, muslin, and paper. A little acetic acid added to the

¹ Richter, *Ausf. Arzneim.* Bd. ii. S. 616.

² *On Poisons.*

water coagulates any caseum, and is thought to facilitate the solution of the morphia. Its presence in large quantity is objectionable, on account of the red colour produced by the action of the acetates on the ferruginous salts; this resembles the colour developed with these salts by meconic acid.

a. *Application of Trial Tests.*—To a small portion of the filtered liquid apply the following tests:—

1. A few drops of *tincture of chloride of iron*, which produces a red colour (*meconate of iron*) in an opiate solution.
2. Apply excess of *strong nitric acid*, which also reddens (*oxidizes? morphia*) opiate liquors.
3. Add *iodic acid and starch*, and set aside for twenty-four hours. Blue iodide of starch is sometimes formed if morphia be present (unless, indeed, the quantity be very minute).—The fallacies of these tests have been already stated (see MORPHIA).

The success or failure of these tests is not to be considered as absolutely decisive as to the presence or absence of opium.

b. *Separation of the Morphia and Meconic Acid.*—Add to the filtered liquor a considerable excess of a solution of acetate of lead, and set aside in a tall vessel for the precipitate (*meconate and sulphate of lead, with colouring matter*) to subside, leaving a clear liquor (*acetates of morphia and lead, &c.*). Pour off the latter, and collect the precipitate on a filter. Before adding the acetate of lead, it may be sometimes necessary to evaporate the liquor, in a water-bath, to the consistence of syrup, which is to be digested and boiled in alcohol, and the alcoholic tincture evaporated, and the residuum dissolved in water. To the filtered solution add the acetate of lead. This complication of the process is not usually necessary. Furthermore, by boiling with water, meconic acid is decomposed.

The above-mentioned clear liquor and the lead-precipitate are then to be tested (the first for morphia, the second for meconic acid), as follows:—

Proceeding with the lead-precipitate (meconate and sulphate of lead, and colouring matter).

Suspend the lead-precipitate in water contained in a conical glass, and pass a stream of sulphuretted hydrogen through it, to convert the lead into a sulphuret, which is to be removed by filtration. The clear liquor is then to be gently heated (to expel the excess of sulphuretted hydrogen), and, if necessary, concentrated by evaporation. Or add a few drops of diluted sulphuric acid to the meconate of lead, by which an insoluble sulphate of lead is formed, and meconic acid held in solution. Boiling decomposes the meconic acid. The tests for meconic acid are then to be applied, viz:—

- a. Tincture of chloride of iron.
- b. Ammoniacal sulphate of copper.
- c. Chloride of gold.
- d. Acetate of lead.

2. *Proceeding with the clear liquor* (solution of the acetates of morphia and lead).

Place the clear liquor in a conical glass, and pass through it a stream of sulphuretted hydrogen, to precipitate the lead, and then filter. Then boil the filtered liquor, and, if necessary, concentrate by evaporation. To the clear liquor apply the tests for morphia, viz:—

- a. Strong nitric acid in excess.
- b. Iodic acid and starch (several hours may be necessary for the success of this test).
- c. Tincture of chloride of iron (this test will only succeed with solid morphia, or very concentrated solutions).
- d. Ammonia.
- e. Infusion of nutgalls (this test will not answer if much free acid be in the liquor).
- f. Chlorine, and afterwards ammonia.

Dr. Christison observes, that "It will often happen, in actual practice, that the only indication of opium to be procured by the process consists in the deep red colour struck by permuriate of iron with the meconic acid. Now, will this alone constitute sufficient proof of the presence of opium? On the whole, I am inclined to reply in the affirmative." I regret I cannot agree with him in this conclusion, since several other substances produce the same colour, and three of these are very likely to be met with in the alimentary canal, namely, the acetates (thus acetate of ammonia or acetate of potash administered medicinally), mustard and saliva. [It is also to be remarked that the colour of the acetate of iron is not destroyed by a solution of corrosive sublimate.—Ed.] In regard to saliva, he remarks: "It is seldom possible to procure a distinct blood-red coloration from the saliva, except by evaporating a large quantity to dryness, and redissolving the residue in a small quantity of water; and I question whether it can be separated at all after the saliva is mixed with the complex contents of the stomach." I am sorry again to be at issue with so high an authority, but our results being discordant, it is but right I should state my experience. In a large majority of cases, I find saliva is distinctly and unequivocally reddened by the persalts of iron. In some few cases only have I observed this test indistinct. I have several times obtained from the stomachs of subjects in the dissecting-room a liquor which reddened the salts of iron."

ESTIMATION OF THE PURITY AND STRENGTH OF OPIUM.—Opium is brought into the market of very unequal degrees of purity, in consequence of its having been subjected to adulteration; and partly, perhaps, from the employment of dif-

ferent methods of preparation. Moreover, its consistence is by no means uniform; that of some kinds being quite soft (as the Patna and Benares), and of others quite hard (as some of the Egyptian opium). As this difference depends on the presence of unequal quantities of water, an obvious variation of strength is the consequence. Moreover, the quantity of morphia in good opium of different or even of the same localities is by no means constant. Furthermore, opium, from which the morphia has been extracted, has been fraudulently introduced into commerce.¹ It is highly desirable, therefore, to have a ready, easy, accurate, and precise method of determining the purity and strength of opium. I regret to state that such a method is still a desideratum.

1. OF THE ESTIMATION OF THE WATER.—This will be readily judged of by the consistence, but still better by observing the loss on drying a given weight of the opium at 212°.

2. OF THE DETECTION OF FOREIGN BODIES.—A physical examination of opium will frequently detect impurities (as leaves, bullets, stones, fruit, &c.). If a decoction of the suspected opium be made and strained, various foreign matters are left on the sieve. In this way, I obtained 10 drachms of small stones and gravel from 10 ounces of opium. On another occasion I detected a gelatiniform substance, which was insoluble in both water and alcohol, in an opium (Egyptian?), the tincture of which could not be rendered clear by filtration. A decoction of opium, when cold, should not give a blue precipitate (*iodide of starch*) on the addition of tincture of iodine; if it do, the presence of starch or flour is obvious.

3. OF THE ESTIMATION OF THE QUANTITY OF MORPHIA IN OPIUM. (*Morphiometry*).—This is a subject of no slight difficulty. A remark connected with it, which deserves notice, is that there is no constant ratio between the quantity of morphia in a given sample of opium and that of any other constituent. Berthemat,² however, is of opinion that it is in the ratio of that of the meconic acid. The correctness of this opinion is not borne out by my own observation, and was positively denied by Robiquet.³ It follows, therefore, that the extraction of the morphia is the only true morphimetric method of proceeding. Several methods of effecting this have been proposed.

a. *Process of the Edinburgh Pharmacopœia*.—“A solution of 100 grains, macerated twenty-four hours in two fluidounces of water, filtered, and strongly squeezed in a cloth, if precipitated by a cold solution of half an ounce of carbonate of soda in two waters, and heated till the precipitate shrinks and fuses, will yield a solid mass on cooling, which weighs, when dry, at least 11 grains, and, if pulverized, dissolves entirely in solution of oxalic acid.”—*Ph. Ed.* 1839. This is a modification of the process for procuring disulphate of quina, and of estimating the quality of yellow bark. The fused mass obtained by the process is morphia, narcotine, and resinous extractive. From the trials I have made of this process, I am inclined to speak very doubtfully of its value. Morphia is soluble in a solution of carbonate of soda, and, therefore, variations in the degree of heat applied to the liquor, as well as in the time during which it is subjected to heat, will be attended with corresponding variations in the results. Nay, if the heat be maintained too long, the whole of the morphia will be dissolved! Hence, therefore, to prove successful, this process requires more precautions than the directions of the College would lead one to imagine.

b. *Thiboumarry's process*.—Prepare an aqueous extract of the opium to be examined, and dissolve it in water. Add ammonia to the boiling liquor [taking care not to add much excess], and, when cool, filter. Wash the precipitate on the filter first with cold water, then with proof spirit, and afterwards dry it. Then boil it with animal charcoal in rectified spirit, and evaporate the filtered liquor, by which crystals of morphia are procured.⁴—The following modifications of the process will be found valuable: After the precipitate on the filter has been washed with water, dry it, mix it with proof spirit, and add drop by drop acetic acid until the solution slightly reddens litmus. By this means the morphia, and not the narcotina, will be dissolved. Precipitate the morphia from the filtered solution by ammonia. This perhaps is the best process for determining the goodness of opium at present known.

γ. *Berthemat's process*.—To a filtered infusion of opium add chloride of calcium, boil, filter (to get rid of the meconate and sulphate of lime), and evaporate to the consistence of syrup. The residuum should form a granular crystalline mass (principally hydrochlorate of morphia), which is to be separated from the mother-water, and purified by resolution in water.⁵ This is an application of Gregory's process, hereafter to be described. It appears to be an objectionable method, as a considerable portion of the morphia will be left in the mother-liquor.

δ. *Couerbe's process*.—Boil an infusion of opium with lime (which dissolves the morphia), and filter through paper. Saturate the filtered liquor with an acid, and precipitate the morphia by ammonia. This, perhaps, is the most speedy process for the detection of opium.

[As a summary of the characters of good opium we subjoin the following paragraph, which we find among the author's notes :—

1. Treated with cold water, it ought to completely divide itself. The extractive matter should be dissolved, and the resinoid matter should be separated.

2. The liquor, which is at first turbid, should become clear by repose, and assume a more or less deep brown colour.

a. It should give a wine-red colour with persalts of iron (meconic acid).

b. It should give a whitish precipitate with chloride of calcium by the aid of heat (meconate and sulphate of lime). The supernatant liquor, filtrated and concentrated by evaporation, should deposit crystals of muriate of morphia.

c. It should give with ammonia dropped into the boiling liquor a precipitate, especially after cooling, consisting of coloured morphia mixed with resin, narcotine, and a little meconate of lime.

Some of the peculiar ingredients of opium are not discoverable in the infusion or decoction; such as narcotina, codeia, meconine, narceine, and thebaina.—En.]

PHYSIOLOGICAL EFFECTS. a. *On Vegetables.*—The effects of opium on plants have been principally examined by Marcet' and Macaire.² The latter writer states that the stamens of the barberry (*Berberis vulgaris*) and the leaves of the sensitive plant lost their contractility, and soon died, when the stems of these vegetables were immersed in an aqueous solution of opium. But I have tried this experiment with a different result. I immersed a flowering stem of the barberry in water, to which the tincture of opium had been added. In thirty hours, I could not perceive any effect on the plant. The stamens, even in the overblown flowers, still retained their contractility. Charvet states that he watered a sensitive plant with a moderately strong infusion of opium forty-eight days, without affecting the irritability of the plant. By immersing a portion of Chara in a solution of opium the circulation of this plant becomes slower, is soon suspended, and is ultimately stopped.³

β. *On Animals generally.*—The operation of opium on animals has repeatedly been the subject of physiological investigation. An abstract of a considerable number of experiments made by various individuals has been published by Wibmer.⁴ The most complete and extended series of experiments is that made by Charvet⁵ on the different classes of animals, for the purpose of determining its comparative action. While on all it has been found to act as a poison, its effects are observed to vary somewhat, according to the degree of development of the nervous system.

In the *invertebrated animals* opium causes weakness or paralysis of the contractile tissues, with gradual sinking, and death. Thus, in the *polygastrica* and the *annelides*, it first accelerates the animal movements, but afterwards paralyzes them. Now, in the lower invertebrata, a central nervous apparatus is altogether wanting; while in the higher animals of this class it is not sufficiently developed to exercise that influence over the whole individual which we observe it to possess in the vertebrated classes.

In the *vertebrated animals*, we have a high development of the central organs of the nervous system, and a consequent increase in the number of symptoms caused by opium. Thus, in *fishes*, *amphibials*, and *reptiles*, we observe, in addition to the weakened and paralytic condition of the contractile tissues, convulsions. In fish, the convulsive contractions bend the body laterally; whereas, in the other vertebrata, the superior dorsal muscles are affected, and hence the head and tail are elevated. These differences obviously depend on the disposition of the muscles. Proceeding in the ascending order, we observe in *birds* and *mammals*, besides the paralysis and convulsions, stupor. The last-mentioned symptom, however, is principally manifested in the highest of the mammals, man; that is, in that animal which has the most highly developed brain; while, in some of the lower mammals, as the ruminants, it is scarcely observed; and even in the carnivora, as dogs, it is very slight. It is somewhat remarkable that the stupor is more manifest in birds

¹ *Ann. de Chim. et Phys.* xxix. 20.

² *Ibid.* xxxix. 213.

³ Meyen, *Report on the Progress of Vegetable Physiology during the year 1837*, translated by W. Francis, p. 14, Lond. 1839.

⁴ *Wirk. d. Arzneim. u. Gifte*, Bd. iv. S. 74, et seq.

⁵ *De l'Action comp. de l'Opium*, Paris, 1826.

than in the lower mammals. Moreover, it is not undeserving of notice that the operation of opium on the different races of man is not uniform. On the negro, the Malay, and the Javanese, it more frequently acts as an excitant, causing furious madness, or delirium and convulsions. Are we to ascribe the less frequent occurrence of these symptoms in the Caucasian variety to the greater development of his brain? In conclusion, then, it appears that the effects of opium on the animal kingdom have a relation to the degree of development and influence of the nervous system.

γ. *On Man.*—I propose to examine the effects of opium under three heads or subdivisions: *first*, the effects of one or a few doses employed medicinally; *secondly*, the effects of the habitual employment of opium, either by chewing or smoking it; and *thirdly*, its effects on the different systems of organs.

1. *Effects of one or a few doses.*—We may consider these under three degrees of operation.

First degree of operation.—In *small doses*, as from a quarter of a grain to one grain, opium generally acts as a stimulant, though in this respect the symptoms are not uniform. Usually, the vascular system is somewhat excited, and a sensation of fulness is experienced about the head. Dr. Crumpe¹ took one grain of opium when his pulse was at 70, and the alteration in the number of beats was as follows:—

In 2	5	10	15	20	25	30	35	40	45	50	55	60 minutes.
Pulse beat 70	74	76	76	74	74	74	72	72	70	70	70	70

The excitement in the cerebral vascular system is accompanied by alterations in the condition of the nervous functions. The mind is usually exhilarated; the ideas flow more quickly; a pleasurable or comfortable condition of the whole system is experienced, difficult to describe; there is a capability of greater exertion than usual. These symptoms are followed by a diminution of muscular power, and of susceptibility to the impression of external objects; a desire of repose is experienced, with a tendency to sleep. While these effects are taking place, the mouth and throat become dry, and hunger is diminished, though the thirst is increased; and slight constipation usually follows. Such are the ordinary effects of a small dose of opium on persons unaccustomed to its use. By repetition, however, its influence becomes considerably diminished; and those, therefore, who resort to it for the purpose of producing a pleasurable excitement, are obliged to augment the dose to keep up an equal effect.

Second degree of operation.—Given in a *full medicinal dose* (as from two to four grains), the stage of excitement is soon followed by that of depression. The pulse, which at first is increased in fulness and frequency, is afterwards reduced below the natural standard. The effect of two grains and a half on Dr. Crumpe (when his pulse was beating at 70) was as follows:—²

In 5	10	15	20	25	30	35	40	45	50	55	60	75	90 minutes.
Pulse beat 74	74	74	76	78	80	72	70	64	64	66	70	70	70

The skin becomes hot; the mouth and throat dry; the appetite diminished; the thirst increased; and frequently nausea, or even vomiting, is induced. The symptoms of excitement soon pass away, and a state of torpor succeeds; the individual seems indisposed to exertion; the muscular system appears enfeebled; the force of external impressions on the organs of the senses is diminished; and the ideas become confused. This state is followed by an almost irresistible desire of sleep, which is frequently attended by dreams—sometimes of a pleasing, at others of a

¹ *Inq. into the Nat. and Prop. of Opium*, p. 33, 1793.

² *Op. supra cit.* p. 85.

frightful nature. These effects are usually succeeded by constipation (which may continue for several days), by nausea, furred tongue, headache, and listlessness.

Third degree of operation; poisonous effects of opium.—Dr. Christison has so briefly summed up the effects of a poisonous dose of opium, that I cannot do better than quote his statement: "The symptoms of poisoning with opium, when it is administered at once in a dangerous dose, begin with giddiness and stupor, generally without any previous stimulus. The stupor rapidly increasing, the person becomes motionless and insensible to external impressions; he breathes very slowly, generally lies quite still, with his eyes shut and the pupils contracted; and the whole expression of the countenance is that of a deep and perfect repose. As the poisoning advances, the features become ghastly, the pulse feeble and imperceptible, the muscles exceedingly relaxed, and, unless assistance is speedily procured, death ensues. If the person recovers, the sopor is succeeded by prolonged sleep, which commonly ends in twenty-four or thirty-six hours, and is followed by nausea, vomiting, giddiness, and loathing of food."

2. *Habitual use of Opium.*—Of those who habitually employ opium as an intoxicant, some chew or eat it; others smoke it.

Opium-eating.—The ill effects of opium-eating have been described by most travellers in Turkey and Persia, where this practice is carried to a greater extent than in any other part of the world. In the writings of Dr. Russell,¹ Chardin,² the Baron de Tott,³ Pouqueville,⁴ and Madden,⁵ will be found notices of these effects. The following extract is from one of the latest accounts, that of Dr. Oppenheim:—⁶

"The causes leading to the use of opium are many, and among them may be reckoned the following: long-continued diarrhœa, as a remedy for which opium is used in the first instance, and its use afterwards continued from habit; chronic coughs, in which opium is also used as a popular remedy; habitual drunkards also frequently have recourse to opium as a new stimulus, after they have abjured wine in some fit of repentance. Persons holding high offices or dignities in the state have also recourse to opium, when the preservation of their character forbids them the use of wine; some very strict believers also take opium as a restorative in cases of great exertion, as the *Tartars* (couriers), who travel with astonishing celerity. Opium-eaters generally begin with doses of from half a grain to two grains, and gradually increase the quantity till it amounts to two drachms, and sometimes more, a day; they usually take the opium in pills, but avoid drinking any water after having swallowed them, as this is said to produce violent colic; to make it more palatable, it is sometimes mixed with syrups or thickened juices; but in this form it is less intoxicating, and resembles mead; it is then taken with a spoon, or is dried in small cakes with the words *Mash Allah*, the "work of God," imprinted on them. The effect of the opium manifests itself one or two hours after it has been taken, and lasts for five or six hours, according to the dose taken and the idiosyncrasy of the subject. In persons accustomed to take it, it produces a high degree of animation, which the *Theriaki* (opium-eaters) represent as the acmé of happiness.

"The habitual opium-eater is instantly recognized by his appearance. A total attenuation of body, a withered, yellow countenance, a lame gait, a bending of the spine, frequently to such a degree as to assume a circular form, and glossy, deep-sunken eyes, betray him at the first glance. The digestive organs are in the highest degree disturbed, the sufferer eats scarcely anything, and has hardly one evacuation in a week; his mental and bodily powers are destroyed, he is impotent. By degrees, as the habit becomes more confirmed, his strength continues decreasing, the craving for the stimulus becomes even greater, and, to produce the desired effect, the dose must constantly be augmented. When the dose of two or three drachms a day no longer produces the beatific intoxication so eagerly sought by the Opiophagi, they mix the opium with [corrosive] *sublimat*e, increasing the quantity till it reaches to ten grains a day; it then acts as a stimulant. After long indulgence the opium eater becomes subject to nervous or neuralgic pains, to which opium itself brings no relief. These people seldom attain the age of forty, if they have begun to use opium at an early age. The *fasts* in the month of *Ramazan* are for them fraught with the most dreadful tortures, as during the whole of that month they are not allowed to take anything during the day. It is said that, to assuage their sufferings, they swallow before the morning prayer, besides the usual dose, a certain number of other doses, each wrapped up in its particular paper, having previously calculated the time when each

envelop shall be unfolded, and allow the pill to produce the effects of their usual allowance. When this baneful habit has become confirmed, it is almost impossible to break it off; the torments of the opium-eater, when deprived of this stimulant, are as dreadful as his bliss is complete when he has taken it; to him, night brings the torments of hell; day, the bliss of paradise. Those who do make the attempt to discontinue the use of opium, usually mix it with wax, and daily diminishing the quantity of the opium, the pill at last contains nothing but wax."

For an account of the effects produced on English opium-eaters, I may refer to the well-known confessions of Mr. De Quincey,¹ and of the late Mr. S. T. Coleridge.² Numerous instances of the enormous quantities of opium which, by habit, may be taken with impunity, have been published. Dr. Chapman³ tells us that he knew a wineglassful of laudanum to be given several times in twenty-four hours. "But what is still more extraordinary," says this author, "in a case of cancer of the uterus, which was under the care of two highly respectable physicians (Drs. Monges and La Roche) of Philadelphia, the quantity of laudanum was gradually increased to three pints, besides a considerable quantity of solid opium in the same period." Pinel mentions a lady who required 120 grains of opium to give her ease in cancer of the uterus.

Some doubt has been entertained as to the alleged injurious effects of opium-eating on the health, and its tendency to shorten life; and it must be confessed that in several known cases which have occurred in this country no ill effects have been observable. Dr. Christison⁴ has given abstracts of eleven cases, the general result of whose histories "would rather tend to throw doubt over the popular opinion." A few years ago, a Life-Assurance Company, acting on this general opinion, resisted payment of a sum of money, on the ground that the insurer (the late Earl of Mar) had concealed from them a habit which tends to shorten life. But the case was ultimately compromised. Dr. Burnes⁵ asserts that the natives of Cutch do not suffer much from opium-eating.

In those cases of disease (usually cancerous) in which enormous doses of opium are taken to alleviate pain, I have usually observed constipation produced; but Dr. Christison says, "constipation is by no means a general effect of the continued use of opium. In some of the cases mentioned above, no laxatives have been required; in others, a gentle laxative once a week is sufficient."

In 1841, an opium-eater, aged 26, was admitted into the London Hospital. He was accustomed to take two or two and a half drachms of solid opium daily. He originally began its use to relieve the attacks of angina pectoris. He was now most anxious to leave off this habit; though the difficulty of doing so was extreme. It did not diminish, but, according to his assertion, augmented his appetite; so, after each dose, he ate voraciously. At first, when he commenced its use, it caused dryness of the mouth and throat, and constipation, but latterly his bowels were regular, as before he commenced the use of this drug. His pulse ranged from 88 to 96. His urine was somewhat less than natural. The condition of his skin varied; in general it was dry, but occasionally was covered with profuse perspiration. He described the effect of the opium on his mental faculties as those of calmness, comfort, and serenity. Under its use he was able to support great bodily and mental fatigue. He never experienced the exhilarating and pleasurable sensations described by De Quincey. His feelings, when not under the influence of opium, were most distressing. Mr. Davies (an intelligent pupil) described his condition at this time as follows: Eyes hollow, dark, and sunken; features haggard; hands trembling; voice and manner anxious; mouth parched; appetite wanting; sleeplessness. Unable to sleep for want of his accustomed dose, he used to pace the ward of the hospital at night almost frantic, though quite sensible of his miserable condition, and anxious to abandon the practice.

[There is great reason to believe that the practice of opium-eating is very common in this country among the lower as well as the middle classes. The consumption of opium is very great, and wholly disproportioned to the quantity required for medicinal purposes. From an official report just published (July, 1853), it appears that during the last five months the enormous quantity of 63,354 lbs. of opium have been imported into this country; the quantity for the last month was 9,699 lbs.—Ed.]

Opium-smoking.—I have already referred to the enormous quantities of opium

¹ *Confessions of an English Opium-eater.*

⁴ *Sketch of Hist. of Cutch*, p. 9, Edinb. 1839.

⁵ *Treat. on Poisons.*

consumed in China and the islands of the Indian Archipelago by smoking. The *smokable extract*, called *chandoo*, is made into pills about the size of a pea. "One of these being put into the small tube that projects from the side of the opium-pipe, that tube is applied to a lamp, and the pill being lighted, is consumed at one whiff or inflation of the lungs, attended with a whistling noise. The smoke is never emitted by the mouth, but usually receives vent through the nostrils, and sometimes, by adepts, through the passage of the ears and eyes."¹ The residue in the pipe is called *Tyechandoo*, or fecal opium, and is used by poor persons and servants.

The mode of using the pipe has been depicted by Mr. Davies.² Some details respecting the mode of smoking opium have been given by Dr. Hill.³

In the first edition of this work, I stated that though the immoderate practice of opium-smoking must be highly detrimental to health, yet that I believed the statements of Medhurst,⁴ and others, applied to cases in which this practice was carried to excess; and I observed that an account of the effects of opium-smoking by an unbiased and professional witness was a desideratum. My opinion was founded on the statements of Botta⁵ and Marsden.⁶ The latter, a most accurate writer, observes that "the *Limun* and *Batang Assei* gold-traders, who are an active and laborious class of men, but yet indulge as freely in opium as any others whatever, are, notwithstanding, the most healthy and vigorous people to be met with on the island." This desideratum has been recently supplied by Mr. Smith,⁷ surgeon, of Pulo Penang, whose statements fully confirm my opinion. For though the practice is most destructive to those who live in poverty and distress, and who carry it to excess, yet it does not appear that the Chinese, in easy circumstances, and who have the comforts of life about them, are materially affected in respect to longevity, by the private addiction to this vice. "There are many persons," observes Mr. Smith, "within my own observation, who have attained the age of sixty, seventy, or more, and who are well known as habitual opium-smokers for more than thirty years past."

The first effect of this drug on the Chinese smokers is to render them more loquacious and animated. Gradually, the conversation drops, laughter is occasionally produced by the most trifling causes, and to these effects succeed vacancy of countenance, pallor, shrinking of the features, so that the smokers resemble people convalescing from fever, followed by deep sleep for half an hour to three or four hours. An inordinate quantity causes headache, vertigo, and nausea. The Malays are rendered outrageous and quarrelsome by the opium-pipe.

It is extremely difficult to discontinue the vice of opium-smoking, yet there are many instances of its being done. The continuance of this destructive practice deteriorates the physical constitution and moral character of the individual, especially among the lower classes. Its powerful effects on the system are manifested by stupor, forgetfulness, deterioration of the mental faculties, emaciation, debility, sallow complexion, lividity of lips and eyelids, languor and lacklustre of the eye, appetite either destroyed or depraved, sweetmeats or sugar-cane being the articles that are most relished. "In the morning, these creatures have a most wretched appearance, evincing no symptoms of being refreshed or invigorated by sleep, however profound. There is a remarkable dryness or burning in the throat, which urges them to repeat the opium-smoking. If the dose be not taken at the usual time, there is great prostration, vertigo, torpor, discharge of water from the eyes, and in some an involuntary discharge of semen, even when wide awake. If the privation be complete, a still more formidable train of phenomena takes place. Coldness is felt over the whole body, with aching pains in all parts. Diarrhoea occurs; the most horrid feelings of wretchedness come on; and, if the poison be withheld,

death terminates the victim's existence." The offspring of opium-smokers are weak, stunted, and decrepit.

[Dr. Eatwell's paper on opium contains some remarks on the subject of opium-smoking, which we here subjoin.—Ed.]

"It has been too much the practice with narrators, who have treated on the subject, to content themselves with drawing the sad picture of the confirmed opium debauchee, plunged in the last state of moral and physical exhaustion, and having formed the premises of their argument of this exception, to proceed at once to involve the whole practice in one sweeping condemnation. But this is not the way in which the subject can be treated; as rational would it be to paint the horrors of delirium tremens, and upon the evidence to condemn at once the entire use of alcoholic liquors. The question for determination is, not what are the effects of opium used to excess, but what are its effects on the moral and physical constitution of the mass of the individuals who use it habitually, and in *moderation*, either as a stimulant to sustain the frame under fatigue, or as a restorative and sedative after labour, bodily or mental. Having passed three years in China, I may be allowed to state the results of my observation; and I can affirm, thus far, that the effects of the abuse of the drug do not come very frequently under observation; and that, when cases do occur, the habit is very frequently found to have been induced by the presence of some painful chronic disease, to escape from the sufferings of which the patient has fled to this resource. That this is not always the cause, however, I am perfectly ready to admit; and there are, doubtless, many who indulge in the habit to a pernicious extent, led by the same morbid impulses which induce men to become drunkards in even the most civilized countries; but these cases do not at all events come before the public eye. It requires no laborious research in civilized England to discover evidences of the pernicious effects of the abuse of alcoholic liquors; our open and thronged gin palaces, and our streets, afford abundant testimony on the subject; but in China this open evidence of the evil effects of opium is at least wanting. As regards the effects of the habitual use of the drug on the *mass* of the people, I must affirm that no injurious results are visible. The people generally are a muscular and well-formed race, the labouring portion being capable of great and prolonged exertion under a fierce sun, in an unhealthy climate. Their disposition is cheerful and peaceful, and quarrels and brawls are rarely heard amongst even the lower orders; whilst in general intelligence they rank deservedly high amongst orientals. Proofs are still wanting to show that the moderate use of opium produces more pernicious effects upon the constitution than does the moderate use of spirituous liquors, whilst at the same time it is certain that the consequences of the abuse of the former are less appalling in their effects upon the victim, and less disastrous to society at large, than are the consequences of the abuse of the latter. Compare the furious madman, the subject of delirium tremens, with the prostrate debauchee, the victim of opium; the violent drunkard with the dreaming sensualist intoxicated with opium; the latter is at least harmless to all except to his wretched self, whilst the former is but too frequently a dangerous nuisance, and an openly bad example to the community at large."

4. *Action of Opium on the Different Organs.*—In discussing this subject, it will be convenient to consider the organs arranged in groups or systems devoted to some common functions.

a. *On the Cerebro-spinal System.*—Taken in small or moderate doses, opium first produces excitement of the vascular system of the brain, accompanied with corresponding excitement in the cerebro-spinal functions, as already stated. This state, however, is succeeded by that of depression. The effect of opium-eating and opium-smoking on the intellectual faculties has been already described. In large or poisonous doses the leading symptom is sopor; that is, a state analogous to profound sleep, from which the patient *can* be roused, though with difficulty. In the latter stage of poisoning this symptom is succeeded by coma—that is, profound sleep, from which the patient *cannot* be roused. Sopor is usually accompanied either with actual paralysis of the muscular fibres, or with a diminished power almost amounting to it; both of which states doubtless arise from the same condition of the cerebro-spinal system which produces sopor or coma. This state is usually supposed to be sanguineous (venous) congestion. The pupil is usually contracted—a circumstance deserving of especial notice. In some cases there is delirium in the place of sopor or coma, and convulsions instead of paralysis. These are to be regarded as exceptions to the general rule, and are accounted for, pathologically, by supposing that they depend on a state of irritation or excitement set up in the nervous centres, and which usually, though not invariably, terminates in congestion. Another effect of opium is diminished sensibility. Thus, the whole body becomes less susceptible

of painful impressions; in dangerous and fatal cases, the eyes are insensible to light—the ears to sound. This state has been accounted for by supposing that the functions of the sensitive nerves are diminished or suspended by the congested condition of the brain.

From these effects of opium on the cerebro-spinal system the following inferences may be drawn:—

1. That it is an objectionable agent in apoplexy, phrenitis, and paralysis.¹

2. That under proper regulations it is a remedy which may be used to stimulate the cerebro-vascular system, to promote sleep, to diminish inordinate muscular contraction, to diminish the sensibility of the body, and thereby to alleviate pain.

3. *On the Digestive System.*—The usual effects of opium on the organs of digestion are the following: It diminishes secretion and exhalation from the whole canal; thus it causes dryness of the mouth and throat, and diminishes the liquidity of the stools; it excites thirst, lessens hunger, checks the digestive process (for in some animals poisoned by opium, food which they had taken previously has been found in the stomach unchanged); and in some cases it excites vomiting. Mr. Kerr² tells us that, in the famine which prevailed in the East Indies in the year 1770, opium was purchased by the unhappy sufferers, at extraordinary prices, to allay the cravings of hunger, and to banish the dreadful prospect of death. The Tartar couriers, who travel immense distances in a short period of time, take opium only during the journey, to support them. It diminishes the sensibility and contractility of the digestive organs; hence the difficulty, in severe cases of poisoning, of producing vomiting. The constipation which follows the use of opium depends partly on the same cause, and in part also on the diminished excretion of bile, and diminished secretion from the gastro-intestinal mucous membrane. Spœrgel³ found the choleric ducts of animals, to which opium had been given, filled with bile; yet it had not passed into the intestines, for the feces were scarcely tinged by it, but had the appearance which we observe them to have in jaundiced patients.

From these effects of opium on the digestive organs, we may draw the following inferences:—

1. That in diminished secretion from the gastro-intestinal membrane, in extreme thirst, in loss of appetite and weak digestion, in obstinate costiveness, and in diminished excretion of bile, opium is an objectionable remedy.

2. That under proper regulations opium is an admissible remedy for the following purposes: To diminish excessive hunger; to allay pain, when unaccompanied by inflammation; to diminish the sensibility of the digestive organs, in cases of acrid poisoning, and in the passage of biliary calculi; to produce relaxation of the muscular fibres of the alimentary canal (in colic and diarrhœa), and of the gall-ducts (in the passage of calculi), and to diminish excessive secretion from the intestinal canal, in diarrhœa.

By continued use (as by opium-eaters) this drug frequently ceases to cause dryness of the mouth, to pall the appetite, or to confine the bowels, as I have already mentioned.

γ. *On the Vascular System.*—Opium certainly influences the movements of the heart and arteries; but the effect is by no means uniform, since in some cases we see the pulse increased, in others diminished in frequency; and a like variation is noticed in its fulness. Moreover, these variations occur in the same case at different stages. From Dr. Crumpe's experiments, before referred to, it appears that, after the use of a moderate dose of opium, the frequency of the pulse is first increased, and then decreased. The diameter of the artery, and the force and regularity with which the pulsations are effected, are properties of the pulse, readily, but by no means uniformly, affected by opium. To a certain extent we perceive a

¹ [We subjoin a note by the author in reference to the contraindications for the use of opium in certain forms of hysteria.—Ed.] I have seen, in two cases, serious effects follow the use of small doses of opium in hysteria. Both patients were females at or about the age of twenty, weak and thin, and subject to hysteria. In the first, there was insensibility apparently of an hysterical kind. The patient had several fits. On her recovery from these she complained of headache, and there was great irritability. Only one grain of opium was administered, but this caused sopor and death.

² *Med. Obs. and Inq.* vol. v. p. 321.

³ Quoted by Christen, *Opium hist. chem. and pharm. invest.* p. 66, 1820.

relation between the condition of the pulse and that of the cerebro-spinal functions. Thus, when convulsions occur, we usually have a hurried pulse—whereas, when sopor or coma supervenes, the pulse becomes slower or weaker, or both, than natural. But these conditions are by no means uniform. A frequent pulse, with a feverish condition of the body, are common consequences of the use of small or moderate doses of opium; and in poisoning by this drug, a quick pulse, even though no convulsive movements are observed, is by no means rare. A poisonous dose of opium usually enfeebles the pulse, sometimes makes it fuller, often renders it irregular, and towards death always renders it feeble, and often imperceptible. We can easily believe that the muscular fibres of the heart must experience, from the use of a large dose of opium, a diminution of power in common with other muscular fibres, and hence the contractions become weaker. It is also probable that the contractile coat of the arteries and capillaries equally suffers. Now Wirtensohn¹ supposes that the fulness of the pulse sometimes observed in poisoning by opium, arises from the insufficient power of the heart to propel the blood through this paralyzed or weakened capillary system. The accumulation of blood observed in the large venous trunks and cavities of the right side of the heart is supposed to arise from the obstruction experienced to its passage through the pulmonary vessels.

In attempting to lay down indications and contraindications for the use of opium as a remedy for morbid conditions of the circulation, two difficulties present themselves: *first*, the same condition of the vascular system may be induced by various and even opposite causes, for some of which opium may be an appropriate remedy, while for others it may prove an injurious agent; *secondly*, the effects of opium on the circulation are not uniform, and hence not to be relied on. The following conclusions, therefore, are submitted with considerable hesitation as to the universality of their application:—

1. That in increased activity of the vascular system with considerable power, or with diminished secretions and exhalations, and in morbid conditions of the vascular system with a tendency to sopor or coma, opium is an objectionable remedy.

2. That in vascular excitement with great diminution of power, as after hemorrhage, and in various morbid conditions of the pulse attended with acute pain, spasm, or profuse secretion and exhalation, but without visceral inflammation, opium often proves a serviceable agent.

δ. *On the Respiratory System.*—In studying the effects of opium on the respiration, we must remember that the mechanical part of this function is effected by muscular agency; and as the contractility of the muscular fibre is powerfully influenced by opium, so the respiratory movements are also necessarily modified. Occasionally, the primary effect is a slight increase in their frequency; but the secondary effect is almost always of an opposite kind, the respiration being slower than usual; and when coma is present, the breathing is usually gentle, so as scarcely to be perceived; but in some cases it is stertorous. In fact, a paralytic condition of the respiratory muscles takes place, in consequence of which inspiration becomes gradually more and more difficult, until eventually asphyxia is induced, which is usually the immediate cause of death. Another effect ascribed to opium is, that it checks the arterialization of the blood, by diminishing the supply of nervous agency, without which the decarbonization or oxygenization of this fluid cannot take place. It is difficult, however, to distinguish the consequences of this effect from those of asphyxia produced by paralysis of the respiratory muscles.

The third point of view under which we have to examine the influence of opium on the respiratory system is, its effect on the membrane lining the trachea and bronchial tubes and cells. In the first place, it diminishes the sensibility of this, in common with other parts of the body; and, secondly, it checks exhalation and mucous secretion.

A knowledge of these effects of opium on the organs of respiration leads to the following conclusions:—

1. That this agent is contraindicated in difficulty of breathing arising from a deficient supply of nervous energy, as in apoplectic cases; that it is improper where the venous is imperfectly converted into arterial blood; and, lastly, that it is improper in the first stage of catarrh and

¹ Quoted by Barbier, *Traité Élém. de Mat. Méd.* t. ii. 2me éd.

peripneumony, both from its checking secretion, and from its influence over the process of arterialization.

2. That in cases of poisoning by opium, artificial respiration is indicated to prevent asphyxia.

3. That opium may, under proper regulations, be useful to diminish the contractility of the muscles of respiration, or of the muscular fibres of the air-tubes, as in spasmodic asthma; to diminish the sensibility of the bronchia, in the second stage of catarrh, and thereby to allay cough by lessening the influence of the cold air; and lastly, to counteract excessive bronchial secretion.

ε. *On the Urinary System.*—Authors are not agreed as to the effect of opium on the kidneys; some asserting that it increases, others that it diminishes, the quantity of urine secreted. Thus, Dr. Michaelis¹ asserts that, in giving opium in venereal cases, he has sometimes found the secretion of urine exceeding in quantity all the fluids drank. It cannot, however, be doubted that in most cases a moderate quantity of opium diminishes the excretion, while at the same time it makes this fluid turbid and thick. This does not, however, prove that the kidneys are the parts affected. Sprægel² tells us, that when he gave two scruples of opium to dogs, no urine was passed for two days; and, under the influence of two drachms of this medicine, the urine was retained for three days. But dissection showed that the kidneys had not ceased to secrete urine, since the bladder was found distended with this secretion, and its parietes without the least sign of contractility on the application of nitric acid; so that it would appear the non-evacuation of the urine was referable to the insensible and paralyzed condition of the vesical coats, and not to the diminished urinary secretion. Charvet³ has also noticed in dogs, cats, and hares, that the urinary bladder was distended. As, however, in man, opium usually increases the cutaneous exhalation, while in other mammals this effect was not observed, we must be careful in transferring our conclusions with respect to the influence of opium on one order of animals to another order. But I ought to add that Welper, of Berlin, always found the bladder filled with urine both in man and animals. In some morbid conditions of system, opium certainly checks the urinary secretion. This is decidedly the case in diabetes.⁴

The ureters and bladder have their sensibility and contractility diminished by opium. With respect to the effect on the first of these parts, the statement seems proved by the well-known beneficial influence of opium in cases where calculi are descending along these tubes. The acute pain is frequently relieved, and the ureters relaxed, so that large calculi are sometimes allowed to descend from the kidneys along them.

Besides the observations of Sprægel, before referred to, we have other evidence of the paralyzing and benumbing effect of opium on the bladder. In some cases of poisoning by this substance the bladder has been found to be unable to contract on its contents. In some other instances the sphincter of the bladder has been paralyzed, and in consequence the urine was voided involuntarily.⁵ Barbier has also noticed the same thing, and quotes the experience of Dr. Bally to the same effect. The effect of morphia on the bladder is more marked than that of opium.

These remarks on the effects of opium on the urinary organs lead to the following conclusions:—

1. That in diminished sensibility or contractility, or both, of the ureters or bladder, the use of opium is objectionable.

2. That, under proper regulations, opium may be a valuable remedy to dull the sensibility of the pelvis of the kidney, in cases of renal calculi; to allay pain and produce relaxation of the ureters when calculi are passing along these tubes; and, lastly, to diminish irritation of the bladder, whether produced by cantharides or other causes.

ζ. *On the Sexual System.* αα. *Of Men.*—Opium has long been celebrated as an aphrodisiac; and we are told that the Japanese, Chinese, Indians, Persians, Egyptians, and Turks, use it as such. Among other symptoms of excitement pro-

⁵ See *Lond. Med. and Phys. Journ.* xxviii. e6; xxxi. 193; and *Lond. Med. Rev.* for 1811, p. 371.

duced by the habitual use of large doses of opium, it is not improbable that there may be a heightened condition of the venereal feelings, in consequence of an increased determination of blood to that part of the brain supposed to be devoted to the sexual function, which part the phrenologists assert to be the cerebellum. Moreover, it is said to produce erection; and in support of this statement the following strange story is told: "Turcæ ad Levenzinum, 1664, contra Comitum Lud. Souches pugnantes, opio exaltati, turpiter cæsi et octo mille numero occisi mentulas rigidas tulere."¹ Cabanis² adopts this story, and ascribes the above-mentioned condition to the convulsive movements, which affect the body *in articulo mortis*, and not to an aphrodisiac operation. The effect alluded to, if it really does take place, is probably to be referred to the accumulation of blood in the erectile tissues, arising from a disordered state of the circulation. Impotence is ascribed by some to opium-eating, and is a more probable effect. I am unacquainted with any facts on which to ground any well-founded opinion as to the power of opium to diminish or increase the spermatic secretion.

β3. *Of Women.*—We have little positive information as to the effects of opium on the reproductive organs of women. It is said that the catamenia, lochia, and secretion of milk are unaffected by it, but that it causes intumescence of the nipples. Under its use the milk acquires a narcotic property. Furthermore, at times, it has appeared to have an injurious effect on the fœtus *in utero*.³ Opium appears to act on the uterus as on most other contractile parts of the body; that is, it diminishes the contractility and sensibility of this viscus.

From these observations it follows:—

1. That wet-nurses and pregnant women must employ opium with great caution, as its use by them may endanger the life of the child.
2. That opium may be employed to allay pain, spasm, and morbid irritation of the sexual organs in either sex; and that its use in the female is not likely to be attended with retention of the uterine or mammary secretions.
3. That the influence of opium on the venereal appetite is not sufficiently and satisfactorily determined to permit us to make any practical application of it.

γ. *On the Cutaneous System.*—Considered as an organ of sense, the cutaneous system is affected by opium in an analogous way to the other organs of sense; that is, its sensibility is diminished. But the skin has another function—that of excretion, and which does not appear to be at all diminished, nay, to be increased, by the use of opium; one of the usual effects of this medicine being perspiration, which is in some cases attended with a prickling or itching of the skin, and occasionally with an eruption. In fact, taken medicinally, opium is a powerful sudorific, and often proves so even when acting as a poison. "In a fatal case, which I examined judicially," says Dr. Christison, "the sheets were completely soaked to a considerable distance round the body."

From these remarks it follows:—

1. That opium is not likely to relieve loss of feeling or excessive perspiration; but may, on the other hand, under some conditions of the system, prove injurious.
2. That opium is adapted to the relief of pain or excessive sensibility of the skin, and for provoking perspiration; but the propriety of its use for these purposes must be determined by reference to the condition of the system generally. Experience proves that when the skin is very hot, and especially if it be also dry, opium is seldom beneficial, but often hurtful.

θ. *Topical Effects.*—The local effects of opium are, compared with the general effects, very slight. Applied to the eye, the internal membrane of the nose, urethra, cutis vera, wounds or ulcers, it first causes pain, a sense of heat, and inflammation; but these effects subside, and are followed by a weakened or a paralytic condition of the sensitive and motor nerves. Several physiologists have proved that opium causes a local paralysis of the nerves; and Muller⁴ has shown that the narcotic action is not propagated from the trunk of a nerve to its branches. Crumpe⁵ showed that, at the end of thirty minutes, the eye to which opium had been applied was

¹ Christien, *op. supra cit.* p. 53.

² F. H. Ramsbotham, *Lond. Med. Gaz.* vol. xiv. p. 84.

³ *Op. supra cit.*

⁴ *Rapp. de Phys. et du Morale de l'Homme.*

⁵ *Phys.* by Baly, vol. i. p. 630.

somewhat less susceptible of the action of alcohol. Scarcely any obvious effect results from the application of opium to the ordinary integument, on account of the barrier presented by the cuticle. Employed endermically the effects are much more powerful.

POST-MORTEM APPEARANCES.—The most important appearances are those observed in the nervous system; such as turgescence of vessels, effusion of water or of coagulable lymph, and occasionally, though rarely, extravasation of blood.

Whenever redness of the digestive canal is observed, I believe it is referable to the use of some irritants (such as spirits, ammonia, or emetics) taken either with or after the use of opium.

MODUS OPERANDI.—Under this head, I propose to examine several points not hitherto noticed, which involve the theory of the operation of opium on the system.

1. *The Odorous and Active Principles of Opium are absorbed.*—This assertion is proved by the following facts:—

a. The odour of opium is sometimes recognizable in the secretions and exhalations; thus, it is well known that the opiate odour is frequently detected in the breath of persons poisoned by this drug; and Barbier¹ states it may be also noticed in the urine and sweat.

β. The secretions, in some cases, appear to possess narcotic properties. Barbier mentions the case of an infant who was thrown into a state of narcotism of several hours' duration, in consequence of having sucked a nurse who had previously swallowed a dose of laudanum to relieve a cramp of the stomach.

γ. Barruel asserts that he detected morphia in the blood and urine² of a person under the influence of a poisonous dose of laudanum. As, however, these results have not been obtained by Dublanc or Lassaigue, the statement is not to be absolutely relied on.

2. *The Constitutional Effects of Opium depend in great part, if not wholly, on the absorption of its active principles.*—The facts on which this assumption rests are:—

a. The active principles of opium are absorbed.

β. The constitutional effects of it are found to be proportionate to the absorbing powers of the part.

γ. The effect of opium, when thrown into the jugular vein, is similar to, though more powerful than that produced by its application to other parts of the body.

δ. "The narcotic action does not react from a particular point of a nerve on the brain."³

3. *The Essential and Primary Operation of Opium is on the Nervous System (the Brain and Spinal Cord chiefly).*—This axiom is proved by reference to the already-described effects of opium. An examination of them shows that—

a. The most important effects of opium are direct and obvious lesions of the nervous functions.

β. The other effects of opium appear, for the most part, to be secondary; that is, they arise out of the nervous lesions just referred to.

4. *Opium acts on the Nervous System as an Alterative.*—There are but three kinds of changes, compatible with life, which medicines can effect in the vital actions of an organ; viz. an increase, a diminution, or an alteration of activity. A change in the intensity or energy merely of the vital actions of the nervous system would not give a satisfactory explanation of the effects of opium. We are obliged, therefore, to assume that opium changes the quality of the actions. This is what is meant by the term *alterative*.

The inquiry into the nature and kind of influence exercised by opium over the system, presents an extensive field for speculation and hypothesis. Galen⁴ declared opium to be cold in the fourth degree, and his authority long prevailed in the schools. It was first opposed by the *iatro-chemists*, who declared opium to be of a hot nature⁵. Some, however, adopted a middle course, and asserted that it possessed both hot and cold particles.⁶ The *iatro-mechanists* endeavoured to explain the operation of opium on mechanical principles. By some, expansion, by others condensation of the blood, was supposed to be produced by the mechanical properties of

¹ *Traité Élém. de Mat. Méd.* li. 732, 2d ed.

² On one occasion I at first supposed that I had detected morphia and meconic acid in the urine of a man poisoned by opium; for both nitric acid and the sesquioxide of iron gave a red colour to this secretion. I have since found, however, that the urine of healthy individuals often yields the same results.

⁵ Wedelius, *Opiologia*, cap. vi. p. 26, 1682.

⁶ See Crumpe, *op. supra cit.* p. 91.

the opiate particles acting on the nerves.¹ Dr. Cullen² considered opium to be a sedative, and referred its effects to its power of "diminishing the mobility and in a certain manner suspending the motion of the nervous fluid."³ Several later writers, Barbier,³ for example, also call opium a sedative. Brown⁴ declared it to be a stimulant, and his opinion has been adopted by Crumpe,⁵ Murray,⁶ and Dr. A. T. Thomson,⁷ in this country, and of course by the continental Brunonians, as well as by the partisans of the Italian theory of contra-stimulus.⁸ Fontana⁹ ascribed the operation of opium to changes which it induces in the blood. Mayer¹⁰ declared opium to be both stimulant and sedative; viz. stimulant to the nerves and vascular system, but sedative to the muscles and digestive organs. Lastly, Orfila¹¹ asserts that "opium, employed in strong doses, ought not to be ranked among the narcotics or the stimulants; it exerts a peculiar mode of action, which cannot be designated by any of the terms at this moment employed in the *Materia Medica*." These examples, selected out of many opinions, will be sufficient to prove how little is really known of the real action of opium; and I believe we shall save ourselves much time and useless speculation by at once confessing our ignorance on this point.

5. *The operation of Opium, compared with that of other cerebro-spinants or narcotics, is distinguished by both positive and negative characteristics.*—The symptoms constituting the *positive* characters are relaxation or paralysis of the contractile tissues, a tendency to sleep or stupor, a contracted pupil, and constipation. The symptoms whose absence furnishes the *negative* characters, are tetanic convulsions, delirium or inebriation, dilated pupil, syncope, gastro-intestinal irritation, and topical numbness.

These are the general characteristics of the opiate medication. To some of them, occasional or perhaps frequent exceptions exist.

I have already pointed out the distinguishing effects of hyoscyamus, belladonna, and stramonium. The topical numbness caused by aconite distinguishes its operation from that of opium. Moreover, in three cases of poisoning by this substance, which came under my notice, there was no stupor. Tobacco and foxglove enfeeble the vascular system, causing syncope; and they also produce gastro-intestinal irritation. Farthermore, they have not that tendency to induce sleep which we observe after the use of opium. The speedy operation, short period of influence, and, usually, the presence of convulsions distinguish the operation of hydrocyanic acid. Indian hemp induces a cataleptic state.¹² Vinous liquids cause their well-known peculiar inebriation. Their effects in small doses agree to a certain extent with those of small doses of opium; but they are not equally available as antispasmodics. The peculiarities of the operation of conia have been pointed out.

USES.—Opium is undoubtedly the most important and valuable remedy of the whole *Materia Medica*. For other medicines we have one or more substitutes; but for opium none, at least in the large majority of cases in which its peculiar and beneficial influence is required. Its good effects are not, as is the case with some valuable medicines, remote and contingent, but they are immediate, direct, and obvious; and its operation is not attended with pain or discomfort. Farthermore, it is applied, and with the greatest success, to the relief of maladies of every day's occurrence, some of which are attended with the most acute human suffering. These circumstances, with others not necessary here to enumerate, conspire to give to opium an interest not possessed by any other article of the *Materia Medica*.

We employ it to fulfil various indications; some of which have been already noticed. Thus we exhibit it, under certain regulations, to mitigate pain, to allay spasm, to promote sleep, to relieve nervous restlessness, to produce perspiration, and to check profuse mucous discharges from the bronchial tubes and gastro-intestinal canal. But experience has proved its value in relieving some diseases in which not one of these indications can be at all times distinctly traced.

1. *In Fevers.*—The consideration of the use of opium in fever presents peculiar difficulties. Though certain symptoms which occur in the course of this disease, are, under some circumstances, most advantageously treated by opium, yet, with

one or more of these symptoms present, opium may, notwithstanding, be a very inappropriate remedy. The propriety or impropriety of its use, in such cases, must be determined by other circumstances, which, however, are exceedingly difficult to define and characterize. It should always be employed with great caution, giving it in small doses, and carefully watching its effects. The symptoms for which it has been resorted to are, *watchfulness, great restlessness, delirium, tremor, and diarrhoea*. When watchfulness and great restlessness are disproportionate, from first to last, to the disorder of the vascular system, or of the constitution at large; or when these symptoms continue after excitement of the vascular system has been subdued by appropriate depletives, opium frequently proves a highly valuable remedy; nay, the safety of the patient often arises from its judicious employment.¹ The same remarks also apply to the employment of opium for the relief of delirium; but it may be added that, in patients who have been addicted to the use of spirituous liquors, the efficacy of opium in allaying delirium is greatest. Yet I have seen opium fail to relieve the delirium of fever, even when given apparently under favourable circumstances; and I have known opium restore the consciousness of a delirious patient, and yet the case has terminated fatally. If the skin be damp, and the tongue moist, it rarely, I think, proves injurious. The absence, however, of these favourable conditions by no means precludes the employment of opium; but its efficacy is more doubtful. Dr. Holland² suggests that the condition of the pupil may serve as a guide in some doubtful cases; where it is contracted, opium being contraindicated. A similar suggestion with respect to the use of belladonna was made by Dr. Graves, to which I have offered some objections. When sopor or coma supervenes in fever, the use of opium generally proves injurious. Recently, the combination of opium and emetic tartar has been strongly recommended in fever with much cerebral disturbance, by Dr. Law³ and Dr. Graves.⁴

2. *In Inflammatory Diseases*.—Opium has long been regarded as an objectionable remedy in inflammation; but it is one we frequently resort to, either for the purpose of palliating particular symptoms, or even as a powerful auxiliary antiphlogistic remedy. The statement of Dr. Young,⁵ "that opium was improper in all those diseases in which bleeding was necessary," is, therefore, by no means correct in a very considerable number of instances. The objects for which opium is usually exhibited in inflammatory diseases are to mitigate excessive pain, to allay spasm, to relieve great restlessness, to check excessive secretion, and to act as an antiphlogistic. In employing it as an anodyne, we are to bear in mind that it is applicable to those cases only in which the pain is disproportionate to the local vascular excitement; and even then it must be employed with considerable caution; for to "stupefy the sensibility to pain, or to suspend any particular disorder of function, unless we can simultaneously lessen or remove the causes which create it, is often but to interpose a veil between our judgment and the impending danger."⁶ As an antiphlogistic, it is best given in conjunction with calomel, as recommended by Dr. R. Hamilton, of Lynn.⁷ The practice, however, does not prove equally successful in all forms of inflammation. It is best adapted for the disease when it affects membranous parts;⁸ and is much less beneficial in inflammation of the parenchymatous structure of organs. In *gastritis* and *enteritis* the use of opium has been strongly recommended by the late Dr. Armstrong.⁹ After bleeding the patient to syncope, a full opiate (as 80 or 100 drops of the tincture, or three grains of soft opium) is to be administered; and if the stomach reject it, we may give it by injection. It acts on the skin, induces quiet and refreshing sleep, and prevents what is called the hemorrhagic reaction. If the urgent symptoms return when the patient awakes, the same mode of treatment is to be followed, but combining calomel

⁹ *Ed. Med. Comment.* ix. 191.

with the opium. A third venesection is seldom required. In *peritonitis*, the same plan of treatment is to be adopted; but warm, moist applications are on no account to be omitted. Of the great value of opiates in *puerperal fever*, abundant evidence has been adduced by Dr. Ferguson.¹ In *cystitis*, opium, preceded and accompanied by bloodletting and the warm bath, is a valuable remedy; it relieves the scalding pain, by diminishing the sensibility of this viscus to the presence of the urine, and also counteracts the spasmodic contractions. In *inflammation of the walls of the pelvis of the kidney, and also of the ureters*, especially when brought on by the presence of a calculus, opium is a most valuable remedy; it diminishes the sensibility of these parts, and prevents spasm; furthermore, it relaxes the ureters, and thereby facilitates the passage of the calculus. In *inflammation of the gall-ducts*, produced by calculus, opium is likewise serviceable; but, as in the last-mentioned case, bloodletting and the warm bath should be employed simultaneously with it. In *inflammation of the mucous membranes*, attended with increased secretion, opium is a most valuable remedy. Thus, in *pulmonary catarrh*, when the first stage of the disease has passed by, and the mucous secretion is fully established, opium is frequently very beneficial; it diminishes the sensibility of the bronchial membrane to cold air, and thereby prevents cough. In severe forms of the disease, bloodletting ought to be premised. Given at the commencement of the disease, Dr. Holland² says that twenty or thirty drops of laudanum will often arrest it altogether. In *diarrhœa*, opium, in mild cases, is often sufficient of itself to cure the disease; it diminishes the increased muscular contractions and increased sensibility (thereby relieving pain), and at the same time checks excessive secretion. Aromatics and chalk are advantageously combined with it. In violent cases, bloodletting should precede or accompany it. *Mild or English cholera*, the disease which has been so long known in this country, and which consists in irritation or inflammation of the mucous lining of the stomach, is generally most successfully treated by the use of opium; two or three doses will, in slight cases, be sufficient to effect a cure. When opium fails, the hydrocyanic acid is occasionally most effective. In *dysentery*, opium has been found very serviceable; it is best given in combination with either ipecacuanha or calomel. I have already stated that, in *inflammation of the parenchymatous tissues of organs*, the use of opium is less frequently beneficial, but often injurious. Thus, in *inflammation of the cerebral substance*, it is highly objectionable, since it increases the determination of blood to the head, and disposes to coma. In *peripneumonia*, it is for the most part injurious; partly by its increasing the febrile symptoms, partly by its diminishing the bronchial secretion, and probably, also, by retarding the arterialization of the blood, and thereby increasing the general disorder of system. It must be admitted, however, that there are circumstances under which its use, in this disease, is justifiable. Thus, in acute peripneumonia, when bloodletting has been carried as far as the safety of the patient will admit, but without the subsidence of the disease, I have seen the repeated use of opium and calomel of essential service. Again, in the advanced stages of pneumonic inflammation, when the difficulty of breathing has abated, opium is sometimes beneficially employed to allay painful cough, and produce sleep. In *inflammation of the substance of the liver*, opium is seldom beneficial; it checks the excretion, if not the secretion, of bile, and increases costiveness. In *rheumatism*, opium frequently evinces its happiest effects. In acute forms of the disease it is given in combination with calomel, as recommended by Dr. R. Hamilton—bloodletting being usually premised. From half a grain to two grains of opium should be given at a dose. Dr. Hope³ recommends gr. vij or gr. x of calomel to be combined with each dose of opium. It is not necessary, or even proper, in ordinary cases, to affect the mouth by the calomel; though to this statement exceptions exist. The use of mercury may even, in some cases, be objectionable; and in such, Dover's powder will be found the best form of exhibition. This

¹ *Essays on the most Important Diseases of Women*, Part i. 1539.

² *Lond. Med. Gaz.* xix. 815.

³ *Op. supra cit.* p. 421.

plan of treatment is well adapted for the diffuse or fibrous form of acute rheumatism; but it does not prove equally successful in the synovial forms of the disease. It is also valuable in chronic rheumatism.

3. *In Diseases of the Brain and Spinal Cord.*—In some cerebro-spinal diseases great benefit arises from the use of opium; while in other cases injury only can result from its employment. The latter effect is to be expected in inflammation of the brain, and in apoplectic cases. In other words, in those cerebral maladies obviously connected with, or dependent on, an excited condition of the vascular system of the brain, opium acts injuriously. But there are many disordered conditions of the cerebro-spinal functions, the intensity of which bears no proportion to that of the derangement of the vascular system of the brain; and there are other deviations from the healthy functions in which no change in the cerebral circulation can be detected. In these cases, opium or morphia frequently evinces its best effects. In *insanity*, its value has been properly insisted on by Dr. Seymour.¹ He, as well as Messrs. Beverley and Phillips, employed the acetate of morphia. Its good effects were manifested rather in the low, desponding, or melancholic forms of the disease, than in the excited conditions; though I have seen great relief obtained in the latter form of the disease by full doses. Opium is sometimes employed by drunkards to relieve *intoxication*. I knew a medical man addicted to drinking, and who, for many years, was accustomed to take a large dose of laudanum whenever he was intoxicated and was called to see a patient. On one occasion, being more than ordinarily inebriated, he swallowed an excessive dose of laudanum, and died in a few hours of apoplexy.

In *delirium tremens*, the efficacy of opium is almost universally admitted. Its effects, however, require to be carefully watched; for large doses of it, frequently repeated, sometimes hasten coma and other bad symptoms. If there be much fever, or evident marks of determination of blood to the head, it should be used with great caution, and ought to be preceded by loss of blood, cold applications to the head, and other antiphlogistic measures. Though opium is to be looked on as a chief remedy in this disease, yet it is not to be regarded as a specific. Dr. Law² speaks in high terms of its association with emetic tartar. I have before noticed the use of opium in alleviating some of the *cerebral symptoms which occur during fever*.

In *spasmodic and convulsive diseases* opium is a most important remedy. In *local spasms produced by topical irritants*, it is a most valuable agent, as I have already stated; for example, in *spasm of the gall-ducts or of the ureters*, brought on by the presence of calculi; in *colic*, and in *painful spasmodic contractions of the bladder, or rectum, or uterus*. In *spasmodic stricture* opium is sometimes useful. In genuine *spasmodic asthma*, which probably depends on a spasmodic condition of the muscular fibres investing the bronchial tubes, a full dose of opium generally gives temporary relief; but the recurrence of the paroxysms is seldom influenced by opium. There are several reasons for believing that one effect of narcotics in dyspnœa is to diminish the necessity for respiration. Laennec³ states that when given to relieve the extreme dyspnœa of mucous catarrh, it frequently produces a speedy but temporary cessation of the disease; and if we explore the respiration by the stethoscope, we find it the same as during the paroxysm—a proof that the benefit obtained consists simply in a diminution of the necessity for respiration. That the necessities of the system for atmospheric air vary at different periods, and from different circumstances, is sufficiently established by the experiments of Dr. Prout;⁴ and it appears that they are diminished during sleep, at which time, according to Dr. Edwards,⁵ the transpiration is increased. Moreover, the phenomena of hibernating animals also bear on this point; for during their state of torpidity, or hibernation, their respiration is proportionally diminished.

⁴ *Ann. of Phil.* ii. 330; and iv. 331.

⁵ *De l'Infl. des Agens Physiq.* p. 321, 1824.

In the *convulsive diseases* (*chorea, epilepsy, and tetanus*) opium has been used, but with variable success; in fact, the conditions of system under which these affections occur, may be, at different times, of an opposite nature; so that a remedy which is proper in one case is often improper in another. In *tetanus*, opium was at one time a favourite remedy, and is undoubtedly at times a remedy of considerable value. But it is remarkable that the susceptibility of the system to its influence is greatly diminished during tetanus. I have already referred to the enormous quantities which may, at this time, be taken with impunity. In 128 cases noticed by Mr. Curling,¹ opium in various forms, and in conjunction with other remedies, was employed in 84 cases; and of these, 45 recovered. Notwithstanding, however, the confidence of the profession in its efficacy is greatly diminished.

Lastly, opium occasionally proves serviceable in several forms of *headache*, especially after loss of blood. I have seen it give great relief in some cases of what are commonly termed nervous headaches; while in others, with apparently the same indications, it has proved injurious. Chomel² applied, with good effect, opium cerate to a blistered surface of the scalp, to relieve headache.

4. *In Diseases of the Chest*.—In some affections of the heart and of the organs of respiration opium is beneficial. I have already alluded to its employment in *catarrh, peripneumonia, and spasmodic asthma*. In the first of these maladies caution is often requisite in its use. "In an aged person, for example, suffering under *chronic bronchitis* or *catarrhal influenza*—and gasping, it may be, under the difficulties of cough and expectoration—an opiate, by suspending these very struggles, may become the cause of danger and death. The effort here is needed for the recovery of free respiration; and if suppressed too long, mucus accumulates in the bronchial cells, its extrication thence becomes impossible, and breathing ceases altogether."³

5. *In Maladies of the Digestive Organs*.—I have already referred to the use of opium in *gastritis, enteritis, peritonitis, diarrhoea, dysentery, colic, the passage of gall-stones, and in hepatitis*. With respect to the use of opium in *hepatic affections*, I am disposed to think, with Dr. Holland, that, with the exception of the painful passage of a gall-stone through the ducts, there is scarcely a complaint of the liver and its appendages "where opium may not be said to be hurtful, though occasionally and indirectly useful when combined with other means."⁴ *In poisoning by acrid substances* opium is used with advantage to lessen the susceptibility of the alimentary canal, and thereby to diminish the violence of the operation of these local irritants. Cantharides, all the drastic purgatives, when taken in excessive doses (as elaterium, colocynth, gamboge, scammony, and croton oil or seeds), and *Arum maculatum*, may be mentioned as examples of the substances alluded to. Besides the above-mentioned beneficial operation, opium allays the spasmodic contractions of the bowels, relieves pain, and checks inordinate secretion and exhalation.

In poisoning by corrosives (the strong mineral acids and alkalies, for example), opium diminishes the sensibility of the alimentary canal; it cannot, of course, alter the chemical influence of the poisons, but it may prove useful by allaying the consequences of inflammation.

As meconic acid is said to be an antidote in cases of poisoning by corrosive sublimate, opium, in full doses, may perhaps be administered with some advantage, when other antidotes cannot be procured.

In poisoning by the preparations of arsenic, of lead, and of copper, opium is sometimes found useful.

6. *In maladies of the urino-genital apparatus* opium is a most valuable remedy. It mitigates pain, allays spasmodic action, checks copious mucous secretion, and diminishes irritation. Its use for one or more of these purposes in *nephritis, cystitis, the passage of urinary calculi, and spasmodic stricture*, has been already pointed out. *In irritable bladder* it is an invaluable remedy, especially in conjunction with

¹ *Treat. on Tetanus*, p. 151, 1836.

² Holland, *op. supra cit.* p. 425.

³ *Lond. Med. Gaz.* vol. i. p. 156.

⁴ *Op. supra cit.* p. 429.

liquor potassæ. In irritation and various painful affections of the uterus, and in *chordee*, the value of opium is well known. In the treatment of the *phosphatic diathesis* it is the only remedy that can be employed, according to Dr. Prout, to diminish the unnatural irritability of the system.

Of all remedies for that hitherto intractable malady, *diabetes*, opium has been found to give the most relief.¹ Under its use the specific gravity, saccharine quality, and quantity of urine have been diminished. It has not, however, hitherto succeeded in permanently curing this disease. Dr. Prout has also found it serviceable when there is an *excess of urea in the urine*.²

7. As an *Anodyne*.—To relieve pain by dulling the sensibility of the body, opium is, of all substances, the most useful, and the most to be relied on for internal exhibition. We sometimes use it to alleviate the pain of inflammation, as already mentioned; to diminish spasm and the sensibility of the part in calculi of the gall-ducts, in the ureters, and even when in the urinary bladder; to relieve pain in the various forms of scirrhus and carcinoma, in which diseases opium is our sheet-anchor; to allay the pain arising from the presence of foreign bodies in wounds; to prevent or relieve after-pains; to diminish the pain of menstruation; and, lastly, as an anodyne in neuralgia. As a *benumber* or *topical anodyne* it is greatly inferior to aconite. Hence, in neuralgia, the latter is much more successful than opium. (See *Aconitum*.)

8. In *Hemorrhages*.—Opium is at times serviceable to obviate certain *ill effects of hemorrhages*; as when there is great irritability attended with a small and frequent pulse, and also to relieve that painful throbbing about the head so often observed after large evacuations of blood. In or immediately after *uterine hemorrhage* the use of opium has been objected to, on the ground that it might prevent the contraction of the womb; but where the employment of opium is otherwise indicated, this theoretical objection deserves no weight. In *bronchial hemorrhage* it is at times a valuable remedy, and may be associated with acetate of lead (notwithstanding the chemical objections to the mixture) with good effect.

9. In *Mortification*.—When mortification is attended with excessive pain, opium is resorted to. In that kind of mortification called *gangræna senilis*, which commences without any visible cause, by a small purple spot on the toes, heels, or other parts of the extremities, and which sometimes arises from an ossified condition of the arteries, Mr. Pott³ strongly recommended opium, in conjunction with a stimulating plan of treatment, and experience has fully proved its great efficacy.

10. In *Veneral Diseases*.—Opium is frequently employed in venereal diseases to prevent the action of mercurials on the bowels during salivation; also to allay the pain of certain venereal sores, and venereal diseases of the bones. By some it has, in addition, been employed as an anti-venereal remedy; and, according to Michaelis⁴ and others, with success. Moreover, it is stated by Dr. Ananian, who practised at Constantinople, that those persons who were in the habit of taking opium rarely contracted the venereal disease. But opium possesses no specific anti-venereal powers.⁵ It has appeared to me, on several occasions, to promote the healing of venereal sores.

11. In various forms of *ulcers*, and in *granulating wounds*, the efficacy of opium has been satisfactorily established by Mr. Skey.⁶ Richter⁷ and others⁸ had already noticed its good effects; but their statements had attracted little attention. Mr. Grant,⁹ in 1785, pointed out the efficacy of opium in the treatment of foul ulcers, attended with a bad discharge, and much pain. He ascribed these symptoms to "morbid irritability," which the opium removed. Its use is prejudicial in ulcers

⁹ *Lond. Med. Journ.* vi. 5, and 130.

attended with inflammation, in the florid or sanguineous temperament, and in childhood. But in the chronic or callous ulcer, in the so-called varicose ulcer, in recent ulcers (from wounds), in which granulation proceeds slowly, or in other cases, the efficacy of opium, administered in small doses (as ten drops of laudanum three times daily), is most manifest, especially in elderly persons, and in those whose constitutions have been debilitated by disease, labour, spirituous liquors, &c. It appears to promote the most genial warmth, to give energy to the extreme arteries, and thereby to maintain an equal balance of the circulation throughout every part of the body, and to animate the dormant energies of healthy action.

12. The *external application* of opium is comparatively but little resorted to, and for two reasons: in the first place, its topical effects are slight; and secondly, its specific effects on the brain and general system are not readily produced through the skin. Aconite and belladonna greatly exceed opium in their topical effects. The following are some of the local uses of opium: In *ophthalmia*, the wine of opium is dropped into the eye when there is excessive pain (see *Vinum Opii*). In *painful and foul sores*, opiates are used with occasional good effects. Mr. Grant¹ applied the tincture twice a day, in an oatmeal poultice, to irritable sores. Opiate *frictions* have been employed as topical anodynes, and to affect the general system. Thus, in *chronic rheumatism and sprains*, the opium liniment proves a useful application. In *maniacal delirium*, as well as some other cerebral disorders, Mr. Ward² employed, with apparently beneficial effects, opiate frictions; for example, ℥ss of opium, mixed with gr. iv of camphor, ℥iv of lard, and ℥j of olive oil. In *neuralgic affections*, an opiate cerate, or finely powdered hydrochlorate of morphia, applied to a blistered surface, occasionally gives relief. In *gastrodynia*, it may be applied in the same way to the epigastrium (Holland). In *gonorrhœa and gleet*, opium injections have been used. In *spasmodic stricture, diseases of the prostate gland*, and in *gonorrhœa to prevent chordee*, an opiate suppository is a useful form of employing opium, especially where it is apt to disagree with the stomach. In *nervous and spasmodic affections* (as some forms of asthma), the endermic application of opium or morphia, applied along the course of the spine, is often singularly beneficial, when all methods of depletion and counter-irritation have proved utterly unavailing (Holland). In *toothache*, opium is applied to the hollow of a carious tooth. Dr. Bow³ speaks in the highest terms of the efficacy of the external application of opium in *inflammatory diseases*, but especially *bronchitis* and *croup*.

ADMINISTRATION.—Opium is given, *in substance*, in the form of pill, powder, lozenge, or electuary. The dose is subject to great variation, depending on the age and habits of the patient, the nature of the disease, and the particular object for which we wish to employ it. In a general way, we consider from an eighth of a grain to half a grain a *small dose* for an adult. We give it to this extent in persons unaccustomed to its use, when we require its stimulant effects, and in mild catarrhs and diarrhoeas. From half a grain to two grains we term a *medium dose*, and employ it in this quantity as an ordinary anodyne and soporific. From two to five grains we denominate a *full or large dose*, and give it to relieve excessive pain, violent spasm, in some inflammatory diseases after bloodletting, in tetanus, &c. These are by no means to be regarded as the limits of the use of opium. *Opium pills (pilulæ opii)* may be prepared either with crude or powdered opium. The latter has the advantage of a more speedy operation, in consequence of its more ready solution in the gastric liquor. Employed as a *suppository*, opium is used in larger doses than when given by the stomach. Five grains, made into a cylindrical mass with soap, may be introduced into the rectum, to allay irritation in the urogenital organs.

ANTIDOTES.—In a case of poisoning by opium, the first indication is to remove the poison from the stomach, the second is to neutralize any of it which may be retained in the system, and the third is to obviate its injurious effects.

¹ *Op. supra cit.*

² *Lancet*, March 18, 1837.

³ *Med. and Phys. Journ.* vol. i. p. 440, 1799.

1. **Use of Evacuants.**—Until other and more powerful evacuant means can be obtained, we should have recourse to tickling the throat with the fingers, or with a feather dipped in oil. As domestic emetics, mustard or salt may be exhibited. A dessertspoonful of flour of mustard, or a tablespoonful of salt, may be taken, stirred up in a tumblerful of water. The stomach-pump is, however the best means of evacuating the contents of the stomach, and, when it can be procured, should always be preferred. The emetics usually resorted to are the sulphates of zinc and copper; the first is preferred. It should be given in doses of from one to two scruples. The dose of sulphate of copper is less—from five grains to fifteen. Ipecacuanha or tartar emetic may be resorted to when the other means are not at hand. Clysters containing fifteen or twenty grains of tartar emetic may be administered; or, in extreme cases, a solution of one or two grains of this salt may be injected into the veins, taking care to prevent the introduction of air.

2. **Use of Chemical Antidotes.**—There are no known agents which completely destroy the activity of opium by their chemical properties, and which can be resorted to in these cases. Infusion of galls, however, is regarded as the best, though an imperfect antidote. Magnesia, as well as iodine and chlorine, have also been recommended.

3. **Use of Therapeutical Means to obviate the Effects.**—The following are the principal means which have been found efficacious:—

a. *Rousing the patient*, by exercising him up and down a room between two men. It may sometimes be necessary to continue this for several hours.—β. *Cold affusion*. Cold water dashed over the head and chest is an exceedingly valuable agent. It often assists the operation of emetics. Dr. Boisragon¹ recommends the alternation of impression, with hot or cold water, and at different parts of the surface of the body.—γ. *Irritants*. The application of irritants to the body is also sometimes a useful practice; thus blisters and sinapisms to the feet.—δ. *Venesec-tion*. Bloodletting is sometimes necessary; but it can be safely practised only after the opium has been withdrawn from the stomach. Orfila says that under these circumstances it never increases but in most cases materially relieves the symptoms.—ε. *Stimulants*. Ammonia, camphor, musk, coffee, and other stimulants, are sometimes used with advantage.—ζ. *Vegetable acids*. Orfila has found the vegetable acids to be the best anti-narcotics. For this purpose, drinks of vinegar and water, lemon-juice, or cream of tartar and water, should be given every ten minutes. These agents, however, should not be resorted to till the poison has been evacuated from the stomach.—η. *Artificial respiration*. As a last resource this is on no account to be omitted. Death has on several occasions been apparently averted by it. An interesting case, in which it was successfully practised, was published many years ago by Mr. Whately.² Natural respiration was extinct when it was begun. In another successful case, related by Mr. Smith,³ artificial respiration was kept up for four hours and a half (with an interval of an hour). When it was commenced there was no pulse at the wrist, and only a slight irregular action of the heart, indicative that life was not quite extinct. A third case, also successful, is that of an infant ten days old, which had taken twenty-five or thirty drops of laudanum intended for the mother, and had lost the power of deglutition, was comatose, and had several convulsions. Artificial respiration was sustained for two or three hours.⁴—[θ. *Electricity* and electro-magnetism have also been successfully employed of late years in several cases of poisoning by opium. This agent has been found effectual in keeping roused, children that are labouring under the effects of narcotic poison.—ED.]

PREPARATIONS.—In noticing the preparations of the poppy employed in medicine, I shall arrange them under three heads: 1st, Preparations of poppy-heads; 2dly, Of opium; 3dly, Of morphia.

¹ Lond. Med. Gaz. March 6, 1840.

² Med.-Chir. Trans. xx. 56.

³ Med. Obs. and Inq. vi. 331.

⁴ United States Dispensatory.

a. *Preparations of Poppy-Heads.*

1. **DECOCTUM PAPAVERIS**, L. E. D.; *Decoction of Poppy; Poppy Fomentation.*—(Poppy-heads, sliced, $\bar{\zeta}$ iv; Water Oiv. [Oij, E. D.] Boil for a quarter of an hour [ten minutes, D.], and strain.)—The seeds contribute, by their oleaginous properties, to the emollient quality of the decoction. This preparation forms a common fomentation, which is applied to bruised, inflamed, excoriated, tender, or swollen parts; to the eye in ophthalmia, to the abdomen in enteritis, peritonitis, to tender ulcers, &c. In cancer and other painful affections of the uterus, it is thrown into the vagina as a soothing remedy.

2. **SYRUPUS PAPAVERIS**, L. E.; *Syrup of White Poppies.*—(Poppy-heads, without the seeds, lb. iij [lb. iss. E.]; Sugar [pure, E.] lb. v. [lb. iij, E.]; Boiling Water, Cong. v. [Oxv. E.]; [Rectified Spirit, $\bar{\zeta}$ v, L.] Boil down the capsules in the water to two gallons, and strongly express the liquor. Again boil down the strained liquor to four pints, and filter while hot. Set it by for twelve hours that the dregs may subside; then boil down the clear liquid to two pints, add the sugar and dissolve it; lastly, mix in the spirit, L.—The *Edinburgh Pharmacopœia* directs the poppy-heads to be first macerated in water for twelve hours; then to boil down to five pints, and strain and express strongly through calico. Again to boil down to Oiss, add the sugar, and dissolve with the aid of heat.)—Syrup of poppies, especially if too thin, is very liable to ferment, and then contains spirit or acetic acid, or both, and is of course ill adapted for medicinal use. To check these changes, it should be carefully made with spirit, according to the directions of the London College, taking care that it has the proper consistence, and keeping it in a cool place. Occasionally, a mixture of treacle and laudanum, or of syrup and extract of poppies, has been substituted; but this fraud is highly dangerous, and has on several occasions proved fatal to children.¹ Syrup of poppies is narcotic, sedative, and anodyne, and is commonly employed as the infant's opiate. It mitigates pain, allays spasm and troublesome cough, and promotes sleep. Even in the adult it is sometimes used for these purposes. It forms a useful adjunct to pectoral tinctures. Over ordinary opiates it has the positive advantages of a less disagreeable taste, and the supposed one of being less likely to create nausea and headache. Even when properly prepared, its administration to infants requires the greatest caution, on account of their known susceptibility to the influence of opiates. "I have been informed," says Dr. Montgomery, "of more than one instance in which a teaspoonful has been known to prove fatal to a healthy child."—The dose of it, for an infant of three or four months old, is $f\bar{\zeta}$ ss; for adults, from $f\bar{\zeta}$ ij to $f\bar{\zeta}$ iv.

3. **EXTRACTUM PAPAVERIS**, L. E.; *Extract of Poppy.*—(Poppy-heads, without the seeds, bruised, $\bar{\zeta}$ xv; Boiling [distilled, L.] Water, Cong. j. Macerate for twenty-four hours; then boil down to four pints, and filter the liquor while hot; lastly, evaporate to a proper consistence [by the vapour bath, E.]—Anodyne and soporific. It appears to me to produce effects similar to those of opium, for which it is frequently substituted, on the supposition that, while it allays pain and promotes sleep, it is less liable to occasion nausea, constipation, headache, or delirium. If it be prepared from a decoction, instead of an infusion of poppy-heads, as directed in the pharmacopœias, it will contain a considerable quantity of inert mucilaginous matter.—Dose, gr. ij to $\bar{\zeta}$ j.

b. *Preparations of Opium.*

1. **PILULÆ OPII sive THEBAICÆ**, E.; *Opium Pills.*—(Opium one part; Sulphate of Potash three parts; Conserve of Red Roses one part. Beat them into a proper mass, which is to be divided into five-grain pills.—It is to be observed that this pill contains twice as much opium as the opiate pill of the last Latin edition of this

¹ See the cases referred to by Dr. Montgomery, in his *Obs. on the Dublin Pharm.* 472.

pharmacopœia, *E.*)—Employed as an anodyne and soporific.—Dose, one or two pills (*i. e.* gr. v to gr. x). The sulphate of potash serves to divide the opium. One pill of five grains contains one grain of opium.

2. *PILULÆ SAPONIS COMPOSITÆ*, L. D. [U. S.]; *Compound Soap Pills*.—(Opium powdered; Liquorice, powdered, each ℥ij; Soft Soap ℥vj. Beat them together until incorporated, *L.*—Opium, in fine powder, ℥ss; Castile Soap ℥ij; Distilled Water ℥ss, or as much as is sufficient. Reduce the soap to a fine powder, add the opium and water, and beat the mixture into a mass of a uniform consistence, *D.* [U. S.]—Employed as an anodyne and soporific.—Dose, gr. iij to gr. x. Five grains contain one grain of opium. [Two and a half grains U. S. contain gr. i opium.] The soap enables the pills to dissolve readily in the juices of the stomach. From gr. v to ℥j are sometimes used as a suppository.

3. *PILULÆ CALOMELANOS ET OPII*, *E.* (See Index.)

4. *PILULÆ PLUMBI OPIATÆ*, *E.* (See Index.)

5. *TROCHISCI OPII*, *E.*; *Opium Lozenges*.—(Opium ℥ij; Tincture of Tolu ℥ss; Pure Sugar, in fine powder, ℥vj; Powder of Gum-Arabic, and Extract of Liquorice, softened with boiling water, of each ℥v. Reduce the opium to a fluid extract by the formula [given for extract of opium]; mix it intimately with the liquorice previously reduced to the consistence of treacle; add the tincture; sprinkle the gum and sugar into the mixture, and beat it into a proper mass, which is to be divided into lozenges of ten grains.)—In London, the manufacture of lozenges is practised as a distinct trade. The opium lozenges of the shops usually contain each about one-eighth of a grain of opium. Lozenge-makers employ a much smaller proportion of gum. The tincture of tolu, which they use, is much more concentrated than that of the shops, the spirit of which is objectionable. Opium lozenges are used to allay troublesome cough.

6. *PULVIS CRETÆ COMPOSITUS CUM OPIO*, *L.*; *Pulvis Cretæ Opiatus*, *E. D.*; *Compound Powder of Chalk with Opium*.—(Compound Powder of Chalk ℥viss [℥vj, *E.*; ℥iv, ℥vij, *D.*]; Powder of Opium ℥iv [℥j, *D.*]. Triturate them together thoroughly [and pass through a fine sieve, *D.*]—Astringent and narcotic. Employed in diarrhœa.—Dose for adults, ℥j to ℥ij; for children, grs. ij to grs. x, according to their age. Forty grains of this powder, prepared according to the London or Dublin Pharmacopœia, or thirty-seven of the Edinburgh Pharmacopœia, contain one grain of opium.

7. *CONFECTIO OPII*, *L.* [U. S.]; *Electuarium Opii*, *E.*; *Confection of Opium*; *Philonium Londinense*; *Philonium Romanum*.—(Opium, powdered, ℥vj; Long Pepper ℥j; Ginger ℥ij; Caraway ℥iij; Tragacanth, powdered, ℥ij; Syrup f℥xvj. The London College directs the dry ingredients to be kept mixed in the form of a very fine powder, and the syrup to be added when the confection is to be used. The Edinburgh College adopts the following formula: "Aromatic Powder ℥vj; Senega, in fine powder, ℥iij; Opium, diffused in a little Sherry, ℥ss; Syrup of Ginger lbj. Mix them together, and beat into an electuary.")—Aromatic and narcotic. Employed in flatulent colic and diarrhœa; in the latter complaint usually as an adjunct to the

¹ The ancient philonium was a famous electuary of the opiate kind. It was called Philo's antidote, after Philo, of Tarsus, its inventor, who lived, it is supposed, in Augustus's time. The composition of the Philonium, described in Greek elegiac verses, is preserved and explained by Galen, *De med. comp. sec. loc. lib. ix. 4.* The terms of the receipt are enigmatical, and may amuse some readers; we give the substance: "Take of the yellow and fragrant hair of the divine Crocus, whose blood glitters in the fields of Mercury; as many drachms as a man has senses; of the Eubœan Nauplian, a drachm; of the slayer of Menœtiades, as preserved in the bowels of sheep, the like quantity; add twenty drachms of white flame, and twenty of the bean of the wild animal of Arcadia; a drachm of the root (falsely so called) which grows in the land famous for the Pisaman Jove; take twice five drachms of $\pi\alpha\pi\upsilon$, written with the masculine article prefixed; and mingle all with the production of the daughters of the bulls of Athens." Galen interprets this curious medico-poetical farrago, which, without his aid, would certainly be not a little obscure, as implying the admixture of saffron, pyrethrum, euphorbium, white pepper, hyocyamus, spikenard, opium, and Athenian honey. It is, moreover, stated in the verses, that the pains for which this $\mu\eta\alpha\upsilon\alpha\upsilon\alpha$ was most serviceable, were those of colic, of the liver, dysuria, and stone.—(Dr. Wm. Cummin, *Lond. Med. Gaz.* vol. xvii. p. 900.)

chalk mixture.—Dose, gr. x to ʒj.—The *Dublin* preparation of the older pharmacopœias contained gr. j of opium in about twenty-five grains of confection. The *London* preparation is somewhat weaker, and contains gr. j of opium in perhaps thirty-six grains. The *Edinburgh* preparation is still weaker; forty-three grains of it containing about one grain of opium.—[The *U. S. Pharm.* directs Opium in powder four drachms and a half; Aromatic Powder six ounces; Clarified Honey fourteen ounces. Rub the opium with the aromatic powder; then add the honey, and beat them together until thoroughly mixed. About thirty-six grains contain one of opium.]

8. EMPLASTRUM OPII, L. E. D.; *Plaster of Opium*.—(Extract of Opium ʒj; Prepared Resin of the Spruce Fir ʒij; Plaster of Lead ʒviij; Boiling Water f ʒj. Add the resin of the spruce fir, the opium, and the water, to the melted plaster, and with a slow fire boil down until all unite into a proper consistence, *L.*—The *Edinburgh College* omits the water. The formula of the *Dublin College* is as follows: Of Opium, in very fine powder, ʒj; Resin Plaster ʒix. Melt the plaster by steam or water bath, add the opium by degrees, and mix thoroughly. [The *U. S. Pharm.* directs Opium in powder two ounces; Burgundy Pitch three ounces; Lead Plaster a pound; Boiling Water four fluidounces. The process is similar to the above.]—Employed as a tonic anodyne in rheumatism, lumbago, and neuralgia. Its powers are very slight, or even equivocal.

9. EXTRACTUM OPII, L. [U. S.]; *Extractum Opii*, E.; *Extractum Opii aquosum*, D.; *Extract of Opium*.—(Opium, sliced, ʒiij, *E. D. U. S.*; Water [distilled, Ov, *L.*], [Ovj, *D.*], [Ov, *U. S.*] Add Oijss of the water to the opium, and macerate for twenty-four hours, stirring occasionally with a spatula, then strain. Macerate what is left in the remaining water for twenty-four hours, and strain. Lastly, evaporate to a proper consistence, *L.*—The *Edinburgh College* digests five times successively; each time in a pint of water, and for twenty-four hours each time. Filter the successive infusions as they are made, passing them through the same filter; unite and evaporate them in the vapour-bath to the due consistence. [The *U. S. P.* follows the *Edinburgh.*]—The *Dublin College* digests the water in like manner, but in successive quarts.)—When opium is digested in water, this fluid takes up the *odorous principle*, the *salts of morphia and codeia*, the *narcotina*, the *gum*, the *extractive*, and some of the *resin*. A portion of morphia is frequently found in the dregs. Moreover, a portion of the *oil* is found in the solution. By concentration, the odorous principle is dissipated, and the resin and the oil, combined with and in part saturating the narcotina, are separated. These matters would be more completely got rid of by redissolving the extract in water. The removal of these inert principles, as well as the impurities of opium and the consequent concentration of the active constituents of this substance, must, of course, render the extract a more powerful preparation than ordinary opium. Good opium yields more than half its weight (from 60 to 70 per cent.) of extract, which, therefore, should be at least one-third more active than crude opium. It is usually believed to operate with less disturbance to the general system than the ordinary preparations of opium. It is employed as an anodyne, sedative, and soporific, in cases where crude opium or its tincture disagrees.—The dose of it is from gr. ¼ to gr. iij or gr. iv.

LIQUOR OPII SEDATIVUS.—Mr. Battley, some years since, assured me that the only ingredients employed in the preparations of his *liquor opii sedativus* were opium, water, and heat. It appears to contain somewhat less meconic acid than the ordinary tincture of opium. Probably this and some other principles of opium are got rid of by successive evaporations and solutions. Perhaps an aqueous solution of the watery extract of opium, with the addition of a little spirit to preserve it, would be a convenient substitute.

10. TINCTURA OPII, L. E. D. [U. S.]; *Tincture of Opium*; *Laudanum*.—(Opium, powdered, ʒiij; Proof Spirit Oij; [Diluted Alcohol, *U. S.*] Macerate for seven [fourteen, *U. S.*] days, and filter, *L.* [U. S.]—The proportions used by the *Dublin*

College are also ℥iij of Opium, and Oij of Proof Spirit. The *Edinburgh College* directs—"Opium, sliced, ℥iij; Rectified Spirit Oj and f̄vij; Water f̄xiiiiss. Digest the opium in the water at a temperature near 212° for two hours; break down the opium with the hand; strain and express the infusion; macerate the residuum in the rectified spirit for about twenty hours, and then strain and express very strongly. Mix the watery and spirituous infusions, and filter.—This tincture is not easily obtained by the process of percolation; but when the opium is of fine quality, it may be prepared thus: Slice the opium finely; mix the spirit and water; let the opium macerate in fourteen fluidounces of the mixture for twelve hours, and then break it down thoroughly with the hand; pour the whole pulpy mass and fluid into a percolator, and let the fluid part pass through, and the rest of the spirit without packing the opium in the cylinder, and continue the process of percolation till two pints are obtained," *E*.)—The percolation process of the *Edinburgh College* is unnecessary and troublesome, and will, I suspect, be rarely, if ever, adopted by laudanum preparers. Tincture of opium is of a deep brownish-red colour, with the peculiar odour and taste of opium. Its sp. gr., according to Mr. Phillips,¹ is 0.952. Nineteen minims of it contain about one grain of opium. Proof spirit dissolves the same constituents as water, but it takes up a large proportion of narcotina, resin, and oil. I have repeatedly prepared morphia from the insoluble residue left behind in the preparation of the tincture.

[Some difference of opinion exists respecting the real strength of the Tincture of Opium of the Pharmacopœias. In the translation of the last edition of the *London Pharmacopœia*,² Mr. Phillips states that *nineteen minims* contain, or are equivalent to, one grain of solid opium, and he describes the ordinary dose as from ten to sixty minims. Mr. Squire, in his translation of the three Pharmacopœias, states that the tincture of opium is of the same strength in all, and that "one grain of powdered opium is employed to produce *thirteen minims* of the tincture." Dr. Christison says: "The *Tinctura Opii*, commonly called *laudanum*, is made by all the Colleges with such proportions of the opium and spirit, that about *thirteen minims and a half*, or about twenty-five drops, contain the active part of one grain of opium. But the London tincture may be sometimes sixteen per cent. stronger than the others, as dry opium is directed to be used. The tincture of the shops is very often adulterated. Good tincture should leave, when thoroughly dried up in the vapour-bath, from seventeen to twenty-two grains of residuum for every fluid-ounce; but I have several times found it so low as ten or seven only." The dose, according to Dr. Christison, is from fifteen to forty-five minims.

This question has been recently examined by Dr. Garrod, with results differing from those stated in the text. Dr. Garrod did not find that the undissolved portion, after maceration for the tincture, yielded any morphia. It yielded an abundance of narcotine and meconic acid. The residue, given internally, in doses varying from one to thirty grains, was found to be quite inert. Should traces of morphia be left after the ordinary process of preparing the tincture of the London College, Dr. Garrod does not believe that this would make any appreciable difference in the strength of the preparation. He considers "that the *Tinctura Opii* contains the active matter of the *whole* of the drug used in its formation; and therefore about *twelve minims* of tincture of opium possesses all the activity of *one grain* of crude opium, assuming that it loses only twelve per cent. in the drying. If dry opium is taken for comparison, *one grain* is contained in about *thirteen and a half minims*; and therefore one fluidrachm of *tinctura opii* contains five grains of the drug, or four and a half grains (according as it is compared with dry or moist opium), in place of three grains."

"In the *Edinburgh* preparation, the amount of tincture containing a grain of opium is about *thirteen and a half minims*; for the opium is ordered in the same proportion, but not previously reduced to powder or dried. In the *Dublin* pre-

¹ *Transl. of the Pharm.*

² *Pharm. Lond.* 1851.

paration the opium is ordered to be coarsely powdered, but Avoirdupois weight is used in place of Apothecaries', which makes the strength of the tincture such that *twelve minims and three-quarters* contain one grain of opium."¹

It follows from this statement, that when tincture of opium is properly-made, and the directions of the London Pharmacopœia are strictly carried out, the strength of the tincture is much greater than it has been hitherto supposed to be. One fluidrachm will represent a dose of five grains, instead of three grains of opium, as stated by Mr. Phillips. The purity of the opium, its comparative strength in morphia, the strength of the spirit used as a solvent, and the period of maceration, will, however, materially affect the result. According to our observation, the statement of Dr. Christison, that the quantity of soluble matter taken up is subject to great variation, is correct; and unless it be assumed that the morphia is constantly in the same proportion in every sample of opium, and that the whole of the morphia is invariably taken up by the proof spirit, the tincture must necessarily vary in its strength. A practical solution of this question would be obtained by observing whether the effects of a grain of opium are really obtained by the administration of twelve or thirteen minims of an average tincture.—ED.]

Tincture of opium is a powerful and valuable anodyne and soporific. Its employment is to be preferred to that of solid opium where a more immediate effect is required. Moreover, in administering opiates to children, the facility of adjusting small doses of it presents a great advantage over solid opium. The dose of it, like that of solid opium, must vary according to several circumstances. For an adult it varies from ℥x to fʒj. To children it must be given with the greatest caution. I have seen a powerful effect produced in an infant by one drop. In infants exhausted by illness and of a delicate constitution, one minim might cause death.

[11. TINCTURA OPII ACETATA, U. S. *Acetated Tincture of Opium*.—(Take of Opium two ounces; Vinegar twelve fluidounces; Alcohol half a pint. Rub the opium with the vinegar; then add the alcohol, and, having macerated for fourteen days, express, and filter through paper.)—This preparation was introduced into the pharmacopœia as a substitute for *Black Drop*. The dose is ℥x.

12. TINCTURA OPII CAMPHORATA, U. S. *Camphorated Tincture of Opium. Paregoric Elixir*.—(The formula for this preparation of the British Colleges has been given at page 404, under the name of *Tinctura Camphoræ Composita*. That of the U. S. Pharm. is Opium, in powder, Benzoic Acid, each a drachm; Oil of Anise a fluidrachm; Clarified Honey two ounces; Camphor two scruples; Diluted Alcohol two pints. Macerate for fourteen days, and filter through paper. About two grains of opium are contained in the ounce. For its uses, see p. 405.)]

13. ENEMA OPII, L.; *Enema Opii vel Anodynum, E.; Opium Clyster*.—(Decoction of Starch fʒiv; Tincture of Opium ℥xxx. Mix, L.—The *Edinburgh College* uses ʒss of Starch; fʒss to fʒj of Tincture of Opium; and fʒij of Water. The starch is boiled in the water, and the tincture added when the mucilage is cool enough for use.)—The formula of the London College is, in my opinion, to be preferred to that of the Edinburgh College; but it may be sometimes necessary to double or treble the quantity of tincture employed. In the passage of renal calculi, in nephritis, irritation or inflammation of the bladder, uterus, or prostate gland, in dysentery, and painful affections of the large intestine, the opium clyster is most valuable.

14. LINIMENTUM OPII, L. E.; *Linimentum Opii vel Linimentum Anodynum, D.; Liniment of Opium*.—(Soap Liniment fʒvj; Tincture of Opium fʒij [of each fʒj, D.] Mix, L.—Castile Soap ʒvj; Opium ʒiiss; Camphor ʒiij; Oil of Rosemary fʒxj; Rectified Spirit Oij. Macerate the soap and opium in the spirit for three days; filter, add the oil and camphor, and agitate briskly, E.)—Employed as an anodyne in rheumatism, neuralgic pains, sprains, &c.

¹ See *Pharm. Journ.* for 1851, p. 250.

15. VINUM OPII, L. E. D., U. S.; *Laudanum Liquidum Sydenhami*, Ph. L. 1720; *Tinctura Thebaica*, Ph. L. 1745; *Wine of Opium*.—(Opium ℥ij, *E. D.*) [Extract of Opium ℥iiss, L. (℥ij, *U. S.*)] ; Cinnamon, bruised; Cloves, bruised, of each ℥iiss [℥j, *U. S.*]; Sherry Wine Oij; [Wine Oj, *U. S.*] Macerate for seven, [fourteen, *D. (U. S.)*] days, and filter.—The Dublin College omits the spices. Its effects are similar to those of the tincture of opium, but its taste and smell are more agreeable. It was recommended by Mr. Ware¹ as an application to the eye in ophthalmia; and experience has fully proved its efficacy where there is much scalding pain, lachrymation, and intolerance of light. When first applied, it causes a sharp pain and a copious flow of tears, but these effects soon subside, and are followed by a considerable abatement of the former sufferings.—For internal use, the dose is grt. x to ℥j.

16. TINCTURA OPII AMMONIATA, E.; *Ammoniated Tincture of Opium*.—(Benzoic Acid and Saffron, chopped, ℥vj of each; Opium, sliced, ℥ss; Oil of Anise ℥j; Spirit of Ammonia Oij. Digest for seven days, and filter.)—Employed as a powerful diffusible stimulant and antispasmodic in hooping-cough and other spasmodic affections. Each drachm and a quarter contains about a grain of opium.—Dose, ℥ss to ℥j.

17. ACETUM OPII, E. D. (U. S.); *Vinegar of Opium*.—(Opium ℥iv; Distilled Vinegar ℥xxvj. "Cut the opium into small fragments, triturate it into a pulp with a little of the vinegar, add the rest of the vinegar, macerate in a closed vessel for seven days, and agitate occasionally. Then strain and express strongly, and filter the liquors," *E.*—The *Dublin College* uses one ounce and a half of Opium to one pint of Dilute Acetic Acid; macerates for seven days in a close vessel, with occasional agitation; strains, expresses, and filters.)—Vinegar dissolves all the principles of opium soluble in water, and is better adapted for holding in solution the narcotina and the resinous matter of opium. It cannot, of course, effect any change in the sulphate of morphia contained in opium. Whether any acetate of morphia is formed at the expense of the meconate of morphia has not been satisfactorily proved. The effects of vinegar of opium do not appear to be precisely those of ordinary opium. It is believed to possess the anodyne, sedative, and soporific qualities of opium, without being apt to excite the disagreeable effects (nausea, headache, constipation, and general disorder of system), which sometimes result from the ordinary preparation of this drug. Hill² says that Le Mort observed a very odd effect from this preparation, "which was, that it often brought on suppressions of urine." Dr. Montgomery³ has seen one instance of this effect; and Dr. Thomas Beattie⁴ has remarked the same result from the *Black Drop*. This paralyzing effect on the bladder is doubtless referable to the morphia, which seems to acquire, in this preparation, increased activity. Vinegar of opium is employed as an anodyne, sedative, and soporific. Dr. Montgomery observes that he has found this preparation of opium decidedly superior to every other in relieving the agony of cancer uteri, and procuring rest at night." The same authority states that twenty drops are equivalent to thirty of the common tincture of opium.—Dose, grt. vj to grt. xxx.

[The *U. S. Pharmacopœia* directs *Black Drop (Acetum Opii, U. S.)* to be prepared as follows: Take Opium, in coarse powder, eight ounces; Nutmeg, in coarse powder, an ounce and a half; Saffron half an ounce; Sugar twelve ounces; Distilled Vinegar a sufficient quantity. Digest the Opium, Nutmeg, and Saffron with a pint and a half of Distilled Vinegar, on a sand-bath, with a gentle heat, for forty-eight hours, and strain. Digest the residue with an equal quantity of Distilled Vinegar in the same manner for twenty-four hours. Then put the whole into a percolator, and pass and repass until the liquid is clear. When filtration ceases, pour on Distilled Vinegar to make three pints. Lastly, add the Sugar by means of a water-bath, evaporate to three pints and four fluidounces.—Dose, ℥x.]

BLACK DROP.—*Acetum Opii* may be regarded as the officinal substitute for a celebrated quack medicine called the *Black Drop*, or *The Lancaster* or *Quaker's Black Drop*, the method of preparing which has been described by the late Dr. Armstrong. In this preparation, *verjuice* (juice of the wild crab) is employed instead of vinegar. But there are several sources of uncertainty in the process.

Dr. Porter's *solution of opium in citric acid* has never come into general use.

c. Morphia and its Preparations.

1. MORPHIA, D.; *Morphina*, *Morphine*, *Morphium*.—So called from *Morpheus*, the god of sleep. Wedelius, Fr. Hoffman, and Neumann, speak of a *crystalline salt* obtained from a solution of opium; but they formed no correct notion of its nature. The *magistry of opium*, noticed by Ludwig, in 1688, may, perhaps, have been morphia.

Morphia is peculiar to the poppy tribe. It exists in opium in combination with meconic and sulphuric acids. Doubts, indeed, have been expressed with respect to its independent existence in opium, some chemists having suggested that it is a *product* rather than an *educt*; but it is now satisfactorily proved that there are no grounds for the supposition that it is a product.

[The *Dublin College* alone now admits morphia amongst its pharmaceutical preparations. The directions for preparing it are as follows:—

Take of Turkey Opium, cut into thin slices, ℞j; Distilled Water Ovj; Chloride of Calcium ℥vj; Prepared Animal Charcoal as much as is sufficient. Macerate the opium for twenty-four hours with a quart of the water, and decant. Macerate the residuum for twelve hours with a second quart of the water, decant, and repeat this process with the rest of the water, subjecting the insoluble residuum to strong expression. Let the decanted solutions and expressed liquor be evaporated by a steam or water-heat to the bulk of one pint, and then passed through a calico filter. Pour in now the chloride of calcium, first dissolved in four ounces of distilled water, and then proceed with the evaporation until the solution is so far concentrated that, upon cooling, nearly the whole of it becomes solid. Let this solid matter be enveloped in a couple of folds of strong calico, and subjected to powerful pressure, the dark liquid which exudes being reserved for subsequent use. The squeezed cake is now to be acted upon with about half a pint of boiling water, and the whole being thrown upon a paper filter, the precipitate must be well washed. The filtered solution having been evaporated as before, cooled and solidified, the residue is to be again subjected to expression. If the product be not quite white, this process should be repeated a third time, the liquid forced out during expression being always preserved. Let the squeezed cake be dissolved in six ounces of boiling water, and, if necessary, cleared by filtration through prepared animal charcoal, the portion of it soaked by the filter being carefully washed out of it; and to the solution thus obtained let water of ammonia be added, in slight excess, and let the crystalline precipitate, which forms when the liquor has cooled, be collected on a paper filter, and washed with cold distilled water until the washings cease to give a precipitate upon being dropped into an acid solution of nitrate of silver. Lastly, let the filter be transferred to a porous brick, in order that the morphia it contains may become dry.

The liquids separated by expression from the muriate of morphia in the preceding process, having been diluted with water, so as to occupy the bulk of four ounces, and then supersaturated slightly with ammonia, let the precipitate which forms be collected, after the lapse of six hours, on a filter, and washed with a little cold water. This, if redissolved in dilute muriatic acid, boiled with a little animal charcoal, and filtered, will, upon cooling, afford a crystalline deposit, from which, when pressed, dissolved in water, and supersaturated with ammonia, an additional quantity of morphia will be procured.—Ed.]

The following directions for preparing morphia were given in the former *London Pharmacopœia*. No directions are given in that for 1851.

Take of Hydrochlorate of Morphia $\mathfrak{z}\text{j}$; Solution of Ammonia $\mathfrak{z}\text{v}$; Distilled Water Oj. Add the Hydrochlorate of Morphia, first dissolved in a pint of water, to the solution of Ammonia with an ounce of water, shaking them together. What is thrown down wash with distilled water, and dry it with a gentle heat.

[The *U. S. Pharmacopœia* adopts a method recommended several years ago by Dr. Staples, of Philadelphia. The formula is: Take of Opium, sliced, a pound; Distilled Water, Alcohol, each a sufficient quantity; Solution of Ammonia six fluidounces. The Opium is to be macerated and worked with the water; the infusion evaporated to six pints and filtered; then five pints of Alcohol are to be added, and three fluidounces of Solution of Ammonia mixed with half a pint of Alcohol. Twenty-four hours afterwards the remainder of the Ammonia and the same quantity of Alcohol are to be added. By rest the crystals deposit. The Alcohol serves the purpose of suspending the colouring principles of the Opium, and renders the crystals purer. To purify them they may be dissolved in hot alcohol, and filtered through animal charcoal.]

In this process the ammonia unites with the hydrochloric acid, and the morphia being set free is precipitated.

Pure morphia presents itself under the form of transparent crystals, whose primary form is the right rhombic prism. On turmeric paper, as well as on reddened litmus paper, morphia has an alkaline reaction. Notwithstanding that it is insoluble, or nearly so, in cold water, it has a distinctly bitter taste. Boiling water dissolves a little more than one-hundredth part of morphia. It dissolves in 40 parts of cold anhydrous alcohol, and 30 parts of boiling alcohol; but it is insoluble, or nearly so, in ether. It is soluble in the oils (fixed and volatile), in solutions of potash and soda, and also, but in much smaller quantity, in solution of ammonia; lastly, it readily dissolves in sulphuric, hydrochloric, and acetic acids. When heated, the crystals lose their transparency and water of crystallization; a strong heat causes them to enter into fusion, in which state they form a yellow liquid similar to melted sulphur, and which becomes white and crystalline on cooling. Heated in the open air, it burns like resin, and leaves a carbonaceous residuum.

The following are the chief *characteristics* of morphia:—

1. *Nitric acid* reddens morphia or its salts (the chlorate excepted, according to Dumas), and forms with them an orange-red solution, which is much darkened by excess of ammonia, and which becomes yellow after a little time. By the prolonged digestion of morphia in nitric acid, we obtain oxalic acid.—*Fallacies*. Nitric acid produces a red colour with several other bodies, as brucia, commercial strychnia, several volatile oils (as oil of pimento and oil of cloves) some resinous substances, infusion of cloves or of pimento, &c.

2. *Iodic acid* is deoxidized by morphia, iodine being set free. Hence, when this alkali is added to a solution of iodic acid, the liquor becomes reddish-brown, and forms a blue compound (*iodide of starch*) with starch. *Fallacies*.—Sulphuretted hydrogen, sulphurous acid, phosphorous acid, sulphocyanide of potassium, sulphosinapisin, and some other agents, have a similar effect on iodic acid.

3. *Neutral sesquichloride of iron* dropped on crystals of morphia renders them blue. The same effect is produced on solution of salts of morphia when concentrated. The nature of the blue compound is not perfectly understood. Possibly part of the morphia is oxidized, and the compound thus produced unites with some oxide of iron (*morphite of iron*). If water in excess, or acids, or alkalies, be added to the blue compound, the colour is destroyed.—*Fallacies*. Tannic and gallic acids with a little water, and infusion of cloves or of pimento, also form blue compounds with sesquichloride of iron.

4. The *alkaline carbonates* occasion a white precipitate (*carbonate of morphia*) in solutions of the soluble morphitic salts.

5. *Solution of ammonia* precipitates morphia from its solution in acids. A considerable excess of ammonia redissolves the precipitate. In very dilute solutions, ammonia occasions no precipitate until heat be applied to drive off the excess of alkali.

6. *Infusion of nutgalls*, or a solution of *tannic acid*, causes a precipitate (*tannate of morphia*) in neutral solutions of the morphitic salts. The precipitate is soluble in acetic acid.

7. An alcoholic solution of *carbazotic acid* causes no precipitate in an alcoholic solution of morphia.

8. If a solution of *chlorine* be mixed with a solution of morphia, or its salts, and then ammonia added, a dark brown colour is developed.

[9. If to a mixture of morphia and concentrated sulphuric acid a drop of bichromate of potash be added, green oxide of chrome is set free.—En.]

10. A very sensitive test of the presence of morphia or its salts in solution is, to add a

drop or two of chloride of gold; a yellow precipitate falls, which on shaking is taken up; and if a drop of Liq. Potassæ be now added, it assumes various hues (according to the manipulation) first greenish, then bluish, then violet, and finally purple. The presence of morphia may be detected in a dilute coloured solution of opium, by simply dropping in the gold and potash without disturbing them; in the course of a few seconds, by placing a piece of white paper at the back of the vessel, purple clouds or streaks will be distinctly seen following the gold as it falls; the gold, in each instance, yields up its chlorine and is reduced; sometimes a blue black precipitate (oxide) is formed, varying according to the strength of the solution operated on.

The composition of morphia is, according to Regnault,¹ as follows:—

	Atoms.	Eq. Wt.	Per. Cent.		Atoms.	Eq. Wt.	Per Cent.
Carbon . . .	35	210	71.91	Morphia	1	292	94.2
Hydrogen . .	20	20	6.85	Water	2	18	5.8
Nitrogen . .	1	14	4.80				
Oxygen . . .	6	48	16.44				
Morphia . .	1	292	100.00	Cryst. Morph. . .	1	310	100.00

Formula $C^{35}H^{20}NO^6$: Symbol $\overset{+}{M}$.

The *morphytic salts* are, for the most part, crystallizable. When pure, they are colourless. They have a bitter taste.

The following characters of the acetate and hydrochlorate of morphia are given in the *London Pharmacopœia* for 1851.

Acetate of Morphia (Sal ex Opio præparatus Crystalli).—Soluble in water and in rectified spirit, and, when the spirit is distilled from it, yields crystals, which are totally destroyed by heat. On the addition of Nitric acid, morphia becomes first red, and afterwards yellow. Tincture of sesquichloride of iron gives it a blue colour. Chlorine and [afterwards] ammonia being added to its salts, they are rendered of a brown colour, which is destroyed when more chlorine is added. Morphia is precipitated from its salts by solution of potash, which, added in excess, redissolves it.

[ADULTERATIONS.—Morphia is found contaminated with narcotina, codeia, and the colouring or resinoid matter of opium. Narcotina is best distinguished by the action of solution of caustic potash, which dissolves morphia but does not act on narcotina or codeia. Ether may be substituted, as this scarcely dissolves morphia, whereas it dissolves codeia and narcotina. The colouring or resinoid matter is detected by the colour of the morphia. If ammonia be added to a solution of hydrochlorate of morphia and codeia, the morphia is precipitated and the codeia left in solution. It is obvious that the process adopted by the Edinburgh College yields muriate of morphia contaminated with codeia.—ED.]

The precise relation which the effects of morphia and its salts bear to those of opium, is a point on which the profession is by no means agreed. Some recent writers² declare that, after having carefully compared the effects of the morphia salts with those of opium, they can discover no difference between them; but my own limited observation of the effects of these salts induces me to agree with those who admit the similarity, but not the identity, of the effects of these substances. Charvet³ could observe no difference between them in their action on the *invertebrata*. But on the higher classes of the *vertebrata* there were obvious differences. The effects of morphia on *man* are in several respects different from those of opium, but they appear to want uniformity; that is, the same results have not been arrived at by different experimenters. This may in some cases at least be ascribed to the employment of morphia contaminated with some other principles of opium. In *small doses*, as from a quarter of a grain to one grain, acetate of morphia causes a feeling of distension or fulness about the head, some disturbance of vision, oftentimes headache, giddiness and somnolency, or actual sleep, which, however differs from ordinary sleep, and is often more or less disturbed. The pupils are usually contracted. Orfila says this occurs in nineteen out of twenty cases. However, in some instances dilatation has been observed, and in others the pupil was natural. The pulse is generally slow and small, though sometimes it is more frequent, and

¹ *Pharmaceutisches Central-Blatt für 1838*, S. 486.

² Trousseau and Pidoux, *Traité de Thérap.* i. 161, 1836.

³ *De l'Action Comp. de l'Opium*, 1826.

occasionally is soft and full. Itching of the skin is frequently noticed, or even a cutaneous eruption is by no means uncommon. Grain doses readily excite gastric uneasiness, nausea, and vomiting. One remarkable symptom often caused by acetate of morphia, especially in men, is a difficulty in voiding the urine, and which appears to depend on a weakened or paralytic condition of the bladder. Bally¹ lays great stress on this last-mentioned symptom, especially when a full dose of morphia has been taken. When these effects subside, loss of appetite, muscular feebleness, and constipation are left behind. When the dose is increased, the effects become somewhat alarming. Great cerebral excitement is produced, vision is disordered and obscured, there is ringing in the ears, and the patient, when lying horizontally, experiences sudden convulsive movements, like those produced by the electric shock. When a fatal dose has been swallowed, the stomach sometimes manifests irritation, but this is soon followed by great disorder of the cerebro-spinal system, which ultimately assumes an apoplectic character. The sight becomes dim, excessive weakness is experienced, gradually all consciousness is lost, and coma supervenes, attended usually with contracted, though sometimes with dilated pupils, coldness of the surface, frequent and small pulse, hurried stertorous respiration, and occasionally with convulsions. Before insensibility comes on, as well as when it is subsiding, there is itching of the skin. Difficulty in passing the water is also experienced, in consequence of the paralyzed state of the bladder. Not unfrequently, lividity of skin is observed.

The effects of morphia and its salts appear to be identical in their nature. The soluble salts (as the hydrochlorates) are more constant and certain in their operation than uncombined morphia, in consequence, probably, of the difficult solubility of the latter.

In comparing the morphitic salts with opium, we observe that they are less stimulant, and less disposed to cause sweating, constipation, headache, and dryness of the tongue. The feelings which they excite are less agreeable, and hence they are not adapted to be substituted for opium by the eaters of this drug. They more readily affect the bladder than opium.

USES.—We employ morphia, or its salts, in preference to opium, when our object is to make applications to the denuded dermis (*endermic medication*). They are employed in this way for the purpose of alleviating violent neuralgic pains, and to relieve the excessive endermic operation of strychnia. Gastrodynia and obstinate vomiting are sometimes relieved by the endermic application of morphia to the epigastrium; and violent headache by the application of this remedy to the temples. Occasionally, this mode of administration is adopted when we wish to bring the general system under the calming and sedative influence of morphia, and where from some cause its exhibition by the mouth is objectionable. Some cases of maniacal delirium may be treated with advantage this way.

The morphia salts are given internally in cases where we wish to obtain the anodyne, soothing, sedative, soporific, and antispasmodic qualities of opium, and where this drug is objectionable on account of its tendency to excite certain injurious effects already referred to. In all cases where both opium and the morphia salts are equally admissible, I prefer the former, its effects being better known and regulated; moreover, opium is to be preferred as a stimulant and sudorific, and for suppressing excessive mucous discharges.

ADMINISTRATION.—The salts are given internally, in a substance or solution, in doses of from one-eighth to one-fourth of a grain, or beyond this. I have given in insanity two grains of muriate of morphia at a dose. For endermic use they are to be finely powdered, and applied to the extent of a grain or a grain and a half at a time.

2. MORPHIÆ ACETAS, L. E. D. [U. S.]; *Acetate of Morphia*.—This salt was formerly directed to be prepared by the *London College* as follows:—

¹ *Mém. de l'Acad. Roy. de Méd.* i. 99.

Take of Morphia ℥vj; Acetic Acid ℥ij; Distilled Water ℥iv. Mix the Acid with the water, and pour them upon the morphia to saturation. Let the liquor evaporate with a gentle heat, that crystals may be formed.

In this process, the acetic acid saturates the morphia, and the solution by evaporation yields crystallized acetate of morphia.

The following are the directions of the *Edinburgh College* :—

“ Take of muriate of morphia any convenient quantity. Dissolve it in fourteen times its weight of warm water, and, when the solution is cool, add aqua ammoniæ gradually, and with constant agitation, until there is a permanent but faint odour of ammonia in the fluid. Collect the precipitate on a calico filter, wash it moderately with cold water, and dissolve it by means of a slight excess of pyroligneous acid, in twelve parts of warm water for every part of muriate of morphia that was used. Concentrate the solution over the vapour-bath, and set aside to crystallize. Drain and squeeze the crystals, and dry them with a gentle heat. More acetate of morphia may be obtained on concentrating the mother liquor.”

In this process, the ammonia decomposes the muriate of morphia, and the precipitated morphia is afterwards dissolved in diluted pyroligneous (acetic) acid. In the *Pharmacopœia of the Dublin College* the following process is given :—

“ Take of Morphia, in fine powder, ℥j; Rectified Spirit ℥vij; Acetic Acid of commerce (sp. gr. 10.44) ℥ivss, or as much as is sufficient. Pour the spirit on the morphia, and, applying heat, gradually add the acetic acid until a neutral or slightly acid solution is obtained. Let this be evaporated to the consistence of syrup by a steam or water heat, and then set by for a few days until it solidifies. In operations on the great scale, it will be worth while to remove the spirit by distillation.”

[Morphia (freed from Narcotina) ℥j; Distilled Water Oss; Acetic Acid, a sufficient quantity, *U. S.* Proceed as directed by *L. P.*]

Acetate of morphia is usually prepared by evaporating its solution to dryness by a gentle heat. Obtained in this way, it is amorphous. It is difficult to obtain it pure, as it readily undergoes decomposition, when its solution is evaporated, and is converted into a mixture of morphia, neutral acetate, and the superacetate of morphia. Hence, as met with in commerce, it is imperfectly soluble in water, unless a few drops of acetic acid be added. It is usually slightly coloured. Its crystals, when pure, are colourless and radiating. The following is the composition of this salt :—

	Atoms.	Eq. Wt.	Per Cent.
Morphia	1	292	82.95
Acetic acid	1	51	14.5
Water	1	9	2.55
Acetate of Morphia	1	352	100.00

Crystallized acetate of morphia is

Very readily dissolved in water. Its other properties are such as have been stated of morphia, *Ph. L.*

It is less soluble in alcohol than in water.

The *Edinburgh College* gives the following characters of the purity of this salt :—

One hundred measures of a solution of ten grains in half a fluidounce of water and five minims of acetic acid, heated to 212°, and decomposed by a faint excess of ammonia, yields by agitation a precipitate which, in twenty-four hours, occupies 15 5 measures of the liquid.

The dose of this and the other morphitic salts has been already mentioned.

[3. LIQUOR MORPHIÆ ACETATIS, L.; *Morphiæ Acetatis Liquor*, D.—(Solution of Acetate of Morphia. Take of Acetate of Morphia ℥iv; Acetic Acid ℥xv; Distilled Water Oj; Proof Spirit Oss. Mix and dissolve, *L.* The dose of this solution is from ℥vj to ℥xv.)—[Take of Acetate of Morphia eighty-two grains; Rectified Spirit five fluidounces; Distilled Water fifteen ounces. Having added the spirit to the water, dissolve the acetate of morphia in the mixture; and, if the solution is not quite clear, pass it through a paper filter.—D.]

4. MORPHIÆ HYDROCHLORAS, L.; *Morphiæ Murias*, F. D. [U. S.]; *Hydrochlorate* or *Muriate of Morphia*.—In the last *London Pharmacopœia* this salt is placed in

the *Materia Medica* as *Sal ex opio preparatus Crystalli*. In the former edition, it was directed to be prepared as follows:—

Take of opium, sliced, lb. j; Crystals of Chloride of Lead ℥ij. or as much as may be sufficient; Purified Animal Charcoal ℥iiiss; Hydrochloric Acid; Distilled Water; Solution of Ammonia, each as much as may be sufficient. Macerate the opium in four pints of distilled water for thirty hours, and bruise it; afterwards digest for twenty hours more, and press it. Macerate what remains again, and a third time, in water, that it may become free from taste, and as often bruise and press it. Evaporate the mixed liquors, with a heat of 140°, to the consistence of a syrup. Then add three pints of distilled water, and, when all the impurities have subsided, pour off the supernatant liquor. Gradually add to this two ounces of chloride of lead, or as much as may be sufficient, first dissolved in four pints of boiling distilled water, till nothing farther is precipitated. Pour off the liquor, and wash what remains frequently with distilled water. Then evaporate the mixed liquors as before, with a gentle heat, that crystals may be formed. Press these in a cloth, then dissolve them in a pint of distilled water, and digest, with an ounce and a half of animal charcoal, in a heat of 120°, and strain. Finally, the charcoal being washed, evaporate the liquors cautiously, that pure crystals may be produced. To the liquor poured off from the crystals first separated, previously mixed with a pint of water, gradually drop in as much solution of ammonia, frequently shaking it, as may be sufficient to precipitate all the morphia. To this, washed with distilled water, add hydrochloric acid, that it may be saturated; afterwards digest it with two ounces of animal charcoal, and strain. Lastly, the animal charcoal being thoroughly washed, evaporate the liquors cautiously, that pure crystals may be produced.

Water extracts from opium the *meconate and sulphate of morphia and codeia*; a part of the *narcotina*, of the *meconine*, of the *narceine*, and of the *thebaine*; the brown acid *extractive*; and a part of the *resin*, and of *fat oil*. When chloride of lead is added to infusion of opium, meconate, with a little sulphate of lead, and some resinous colouring matter, are precipitated, while the hydrochlorates of morphia and of codeia are left in solution. A solution of the impure crystals is then decomposed by ammonia, by which the morphia is precipitated, while codeia and hydrochlorate of ammonia are left in solution. The morphia is dissolved in hydrochloric acid, and the solution of the hydrochlorate decolorized by charcoal.

The *Edinburgh College* follows Gregory's process. Their directions for preparing this salt are as follows:—

“Take of Opium ℥xx; Water Oviij; Muriate of Lime ℥j, or a slight excess.—Macerate the opium in fragments for twenty four hours in two pints of water, and separate the infusion, squeezing well the residue. Repeat the maceration successively with two pints more of the water till the whole is made use of. Concentrate the whole infusion over the vapour-bath to one pint, and add the muriate of lime dissolved in four fluidounces of water. Set the whole aside to settle; pour off the liquid; wash the sediment with a little water, adding the washings to the liquid. Evaporate the liquid sufficiently in the vapour-bath for it to solidify on cooling. Subject the cooled mass to a very strong pressure in a cloth; redissolve the cake in a sufficiency of warm distilled water; add a little powder of white marble, and filter; acidulate the filtered liquor with a very little muriatic acid; and concentrate a second time in the vapour bath for crystallization. Subject the crystals again to very strong pressure in a cloth. Repeat the process of solution, clarification by marble and muriatic acid, concentration and crystallization, until a snow-white mass be obtained.

“On the small scale, trouble and loss are saved by decolorizing the solution of muriate of morphia by means of a little purified animal charcoal after two crystallizations. But on the large scale, it is better to purify the salt by repeated crystallizations alone, and to treat all the expressed fluids, except the first, in the same way with the original solution of impure muriate of morphia. An additional quantity of salt may often be got from the first dark and resinous fluid obtained by expression, on merely allowing it to remain at rest for a few months, when a little muriate of morphia may be deposited in an impure condition.

“The opium which yields the largest quantity of precipitate by carbonate of soda, according to the formula in p. 1034, yields muriate of morphia not only in the greatest proportions, but likewise with the fewest crystallizations.”

In this process, the changes are analogous to those before described for the process of the *London Pharmacopeia*, that meconate and sulphate of lime, instead of meconate and sulphate of lead, are produced.

The *Dublin College* gives the following directions:—

“Take of Morphia, in fine powder, ℥j; Pure Muriatic Acid ℥viiss, or a sufficient quantity; Distilled Water ℥iiss. Mix the acid with the water; heat to about 200°, and add the morphia, con-

stantly stirring, so that a solution may be formed having a slightly acid reaction. Set this to cool for 12 hours, and let the crystals, which separate, be drained of the liquor which surrounds them, and dried on blotting-paper. The decanted liquor will, by farther concentration and cooling, give additional crystals.¹

Another, and, as it is believed, a greatly improved method of obtaining morphia has been recently suggested by Mohr.² It consists in adding, to a concentrated infusion of opium, milk of lime, prepared with a quantity of dry lime, equal to the fourth part of the weight of the opium. The mixture is heated till it boils, and is filtered while hot through linen. The filtered liquor has a light brown yellow colour. While still hot, it is mixed with pulverized sal ammoniac in excess; the lime is saturated by the muriatic acid of the sal ammoniac, and the ammonia of the latter is set free, and the morphia precipitated. In this way crystallized morphia may be obtained without the use of alcohol.

Pure hydrochlorate of morphia crystallizes in plumose, acicular crystals. It is colourless, odourless, bitter, soluble in from 16 to 20 parts of cold water, but less of boiling water. When its saturated boiling solution is allowed to cool, it congeals to form a crystalline mass. It is soluble in alcohol. By heat, it is decomposed and totally dissipated. Nitric acid reddens it. Sesquichloride of iron with an alkali colours it blue.

The air-dried crystals are thus composed :—

	Atoms.	Eq. Wt.	Per Cent.
Morphia	1	292	76.24
Hydrochloric acid	1	37	9.66
Water	6	54	14.10
Crystallized Hydrochlorate of Morphia	1	383	100.00

According to the *London College*, crystallized hydrochlorate of morphia should be

Soluble in water and in rectified spirit. What is precipitated from the aqueous solution by the nitrate of silver is not entirely dissolved either by ammonia, unless added in excess, nor by hydrochloric acid, nor by nitric acid. It answers in other respects to what is stated above of the acetate of morphia.

The *Edinburgh College* gives the following characters of its purity :—

"Snow white; entirely soluble; solution colourless; loss of weight at 212° not above 13 per cent.; one hundred measures of a solution of 10 grains in half a fluidounce of water heated to near 212°, and decomposed with agitation by a faint excess of ammonia, yield a precipitate which, in twenty-four hours, occupies 12.5 measures of the liquid."

On the above, I would merely observe that Mr. Sandall³ found that the quantity of water which this salt loses by drying varies from 9.20 to 14.33 per cent. The effects, uses, and doses of this, as well as the other morphitic salts, have been already described.

5. LIQUOR MORPHIÆ HYDROCHLORATIS, L.; *Morphiæ Muriatis Solutio*, E.; *Morphiæ Muriatis Liquor*, D.; *Solution of Muriate of Morphia*.—(Take of Hydrochlorate of Morphia ℥iv; Distilled Water Oj; Proof Spirit Oss. Mix and dissolve, L.—Muriate of Morphia ℥iiss; Rectified Spirit f℥v; Distilled Water f℥xv. Mix the spirit and water, and dissolve the muriate of morphia in the mixture with the aid of a gentle heat, E. D.)—About one hundred and six minims of this solution contain one grain of muriate of morphia.—The dose is from m℥x, gradually increased to f℥ss.

6. TROCHISCI MORPHIÆ, E.; *Morphia Lozenges*.—(Muriate of Morphia ℥j; Tincture of Tolu ℥ss; Pure Sugar ℥xxv. Dissolve the muriate of morphia in a little hot water; mix it and the tincture of tolu with the sugar; and, with a sufficiency of mucilage, form a proper mass for making lozenges; each of which should weigh about fifteen grains.)—Each lozenge contains about one-fortieth of a grain of

¹ *Athenæum* for 1840, p. 772; *Report of the Tenth Meeting of the British Association*, Lond. 1841; and *Berlinisches Jahrbuch*, Bd. xliiii. S. 448.

² *Lond. Med. Gaz.* xxii. 186.

muriate of morphia. The morphia lozenges of the shops usually contain each one-twenty-fourth of a grain of muriate of morphia.—This is an agreeable mode of employing morphia, especially in pectoral affections.

7. TROCHISCI MORPHIÆ ET IPECACUANHÆ, E.; *Morphia and Ipecacuanha Lozenges*.—(Muriate of Morphia ℥j; Ipecacuan., in fine powder, ℥j; Tincture of Tolu ℥ss; Pure Sugar ℥xxv. Dissolve the muriate in a little hot water; mix it with the tincture and the ipecacuan. and sugar; and, with a sufficiency of mucilage, beat the whole into a proper mass, which is to be divided into fifteen-grain lozenges.)—Each lozenge contains about one-fortieth of a grain of muriate of morphia, and one-thirteenth of a grain of ipecacuanha. Useful to allay tickling cough.

8. MORPHIÆ SULPHAS [U. S.]; *Sulphate of Morphia*.—This salt, though not contained in the British pharmacopœia, is occasionally used in medicine. It is crystalline, and readily soluble in water. It consists of 1 atom sulphuric acid=40, 1 atom morphia=292, and 6 atoms water=54. One of these atoms of water is an essential constituent of the salt, and cannot be removed without destroying the salt. The other 5 atoms are the water of crystallization. The dose of it is the same as the other morphitic salts.

9. [THE LIQUOR MORPHIÆ SULPHATIS, [U. S.] *Solution of Sulphate of Morphia* is made in the proportion of one grain to the ounce of water. Dose, ℥j to ℥ij.]

[338. SANGUINARIA CANADENSIS, Linn.—BLOODROOT.

Sex. Syst. Polyandria, Monogynia.
(Sanguinaria, U. S. The Root.)

Gen. Char.—*Calyx* pentaphyllous, deciduous. *Petals* eight. *Stigma* sessile, two-grooved. *Capsule* superior, oblong, one-celled, two-valved, apex attenuated. *Receptacles* two, filiform, marginal (*Nuttall*).

Sp. Char.—*Root* tuberous, horizontal, giving out a reddish and a very acrid lactescent sap. *Leaves* solitary, radical, reniform and lobed. *Scape* naked, one-flowered, sheathed at base. *Petals* variable in number. April. Perennial.

This plant is called *Bloodroot*, from the red colour of its root, which, when wounded, pours out a quantity of red viscid juice. The same issues from the stalks of the leaves and flowers, but to a less amount. It is also known by the name of *Puccoon*. It grows throughout the United States, appearing in open woods at an early period of the spring, which it highly ornaments by its handsome white flowers.

The root is horizontal, from an inch to two inches in length, and half an inch in diameter, thicker at the summit, terminating abruptly as if bitten off (*præmorse*), fleshy, succulent, and beset with slender red fibres or radicles. It is taken from the ground during the summer, and when dried becomes dark-brown externally, contracted, wrinkled, somewhat twisted. It breaks with a short, waxy fracture, presenting an orange-red colour upon the fractured surfaces. Its odour is feebly narcotic, disagreeable, but lost in a measure by drying. Its taste is acrid and bitter.

The powder is grayish-red.

COMPOSITION.—No detailed account of the constituents of this root has been presented, but Dr. Dana of New York has obtained from it an alkaline substance, which is probably the active principle of the root.

SANGUINARINA (Dana).—This principle is obtained by digesting the finely-powdered root in absolute alcohol, and adding to the solution ammonia, so long as a precipitate is thrown down. This is boiled in water with animal charcoal, and filtered; what remains on the filter is digested in alcohol, and dried by evaporation. A white pearly substance remains. It has an acrid taste, renders the yellow of turmeric brown, and changes the infusion of purple cabbage green. It is sparingly soluble in water, but soluble in ether and alcohol. With tincture of galls it affords a precipitate soluble in alcohol, but insoluble in ammonia. It combines with acids and forms salts, which all present some shade of red, crimson, or scarlet of great intensity of beauty. (Smith, in *Journ. of Philada. Col. of Pharm.* vol. iii. p. 95.)

MEDICAL PROPERTIES.—No experiments upon animals have been made with Bloodroot to determine the effect it is capable of producing. It is stated that

farriers sometimes give it to horses, in order to produce sweating, and facilitate the shedding of their hair. (*Downey's Essay*, p. 30.)

On man it produces effects which are characterized by considerable energy. In 1803, Sanguinaria was made the subject of an Inaugural Essay, by Dr. Downey, of Maryland, which appears to be the first attempt to determine its operation. Twenty grains of the recent root, and eight grains of the alcoholic and watery extracts, induced nausea and vomiting, with more or less sensation of warmth and heat in the stomach, acceleration of pulse, and in several experiments, a slight degree of headache. An acrimonious impression was uniformly made upon the fauces, and in several instances it acted on the bowels. The leaves are endowed with similar powers, and the seeds exert a marked power over the brain and nervous system, occasioning torpor, languor, disordered vision, and dilatation of the pupils. These statements have been confirmed by subsequent investigation, and consequently Bloodroot must be regarded as a stimulant, acrid emetic, and narcotic; a diaphoretic effect when produced must be accessory to these effects. In large doses, the "emesis is violent; there is a burning sensation in the stomach, faintness, vertigo, dimness of vision, and alarming prostration." (*United States Dispensatory*.) The disease in which it has been employed are those of the lungs, as pneumonia, catarrh, phthisis, croup, &c. It has also been used in rheumatism and in jaundice, but in the latter disease must be a remedy of questionable propriety. It was known to Dr. Shœff, who speaks of the employment of a decoction in gonorrhœa.

The mode of exhibition is in powder, the dose as an emetic being 20 grains; the form of pill is preferable, on account of the acrimony. As a stimulant and alterant, doses of 5 grains may be given every 3 or 4 hours. The infusion or decoction may be made in the proportion of ʒss to Oj of water.—Dose, fʒss to fʒi.

TINCTURA SANGUINARIÆ, [U. S.] *Tincture of Bloodroot*.—Bloodroot, bruised, four ounces; Diluted Alcohol two pints. Macerate for fourteen days, and filter through paper or prepare by displacement. Dose, fʒss to fʒj. As an emetic, fʒss.]

ORDER LXXXVI. MENISPERMACEÆ, *De Candolle*.—THE COCCULUS TRIBE.

MENISPERMEÆ, *Jussieu*.

CHARACTERS.—*Flowers* (by abortion?) unisexual, usually diceious, very small. *Floral integuments* in one or several rows, each of which consists of three or four parts, hypogynous, deciduous. *Petals* sometimes absent. *Males; stamens* monadelphous, or rarely distinct; sometimes equal in number, and opposite to the petals; at other times three or four times as many; *anthers* adnate, turned outwards, or inserted on the apex of the filament. *Females; ovaries* sometimes numerous, each with one style cohering slightly at the base; sometimes solitary, crowned with many stigmas, internally many-celled, and, therefore, consisting of many carpels soldered together. *Drupe*s usually berried, 1-seeded, oblique or lunate, compressed. *Seed* of the same shape as the fruit; *embryo* curved or turned in the direction of the circumference; *albumen* 0, or small and fleshy; *cotyledons* flat, sometimes lying face to face, sometimes distant from each other, and lying in two cells of the seed!; *radicle* superior, but sometimes appears inferior, when the apex of the fruit is, by the mode of growth, contiguous with the base.—Sarmentaceous flexible tough shrubs. *Leaves* alternate, simple or rarely compound, mucronate. *Flowers* small, usually racemose. (*De Cand.*)

PROPERTIES.—The roots of several species are bitter and tonic; the seeds of some of them are narcotic.

339. COCCULUS PALMATUS, *De Candolle, L. E.*—THE CALUMBA PLANT.*Menispermum palmatum, Lamarck.**Sex. Syst. Diœcia, Hexandria.*(Radix, *L.*—Root, *E. D.*)[Columba, *U. S.*]

HISTORY.—Franciscus Redi,¹ in 1675, is the first writer who mentions the root of this plant; he praises it as an alexipharmic or antidote for poisons. Cartheuser afterwards examined it; but Dr. Thomas Percival² gave the best account of it. This root has been known by various names—such as *Calumba*, *Colombo*, *Colomba*, and *Colomba*. Its native country and history were long involved in obscurity. In 1830, Dr. Hooker³ published a complete description of both the male and female plants. The root was at first supposed to come from Colombo, a town of Ceylon, and from which it was said to derive its name. But it is now known to be the produce of Mozambique. Its English name, Calumba, is derived from the Portuguese word *Kalumbo*, the *o* in which is mute.⁴

BOTANY. **Gen. Char.**—*Flowers* unisexual, (always?) diœcious. *Calyx* of 12 sepals in four series, with 2, 3, or more close-pressed bracteoles. *Males*; *stamens* 6, or rarely 3, opposite to the inner sepals, distinct; *anthers* 2-celled, terminal, dehiscing vertically; *filaments* either filiform with the anther cells horizontal, approximate, and each externally 2-lobed, or thickened at the apex with the cells divaricating downwards, and separated by the connective. *Females*; *ovaries* 3, 6, or numerous. *Drupes* 1 to 6, or numerous, 1-celled, 1-seeded. *Peduncles* axillary or rarely lateral; males usually many-flowered; females generally few-flowered, without bracts, or with very small ones if present (Lindley).

Sp. Char.—*Leaves* cordate at the base, 5- to 7-lobed; lobes quite entire, acuminate, somewhat hairy. *Stems* and *ovaries* clothed with glandular hair. (De Cand.)

Root perennial, of several fasciculated, fusiform, fleshy tubers, with a brown warty epidermis; internally deep yellow, odourless, very bitter. *Stems* annual, herbaceous, twining, beset at the lower part with long glanduliferous hairs: of the males, simple; of the females, branching. *Leaves* alternate, nearly orbicular, wavy on the margin, with long hairy footstalks. *Racemes* axillary, solitary; in the male plants compound. *Flowers* small, green. *Fruit* drupaceous or berried, about the size of a hazel-nut, densely clothed with long spreading hairs, tipped with a black oblong gland.⁵

Hab.—Thick forests on the shores of Oibo and Mozambique, as well as inland for 15 or 20 miles.

PREPARATION OF THE ROOTS.—The natives never cultivate the plant, the spontaneous produce being sufficient. The roots are dug up in March (the hot season), the offsets from the main root are cut in slices, strung on cords, and hung up to dry in the shade. It is deemed fit for commerce when, on exposure to the sun, it breaks short; and of a bad quality when it is soft or black.

DESCRIPTION.—Calumba or Colombo root (*radix calumbæ*) is met with in flat circular or oval pieces, of from half an inch to three inches in diameter, and from one to three or four lines thick. It occurs also in cylindrical pieces of from one to two inches long. The epidermis covering the sides of the pieces is of a yellowish-

Fig. 417.

Cocculus palmatus.
(Male plant.)

¹ *Exp. circa varias res nat.* p. 179.² *Bot. Mag.* 2970—71.³ Bojer, in Hooker's *Bot. Mag.* tt. 2970—71.⁴ *Med. Essays*, vol. ii. p. 3, 1773.⁵ Barry, *Aquatic Researches*, x. 385.

gray or brownish colour, smooth, or irregularly rugous. The transversal surfaces are of a greenish or grayish-yellow colour, depressed in the middle from the great shrinking of the medulla in the drying process, and consist of three or four concentric layers. The outer or cortical portion varies in thickness, but is usually about two or three lines thick. It is separated from the ligneous portion by a dark-coloured layer, not exceeding a hair in thickness. The internal or medullary portion is light, spongy, and shrunk. The odour of calumba is faint, but somewhat aromatic; the taste aromatic, and very bitter. In the larger and thicker pieces small holes are occasionally observed, which have been made for the convenience of drying. On account of the starch which it contains, the root is readily attacked by insects.

I am indebted to Mr. N. B. Ward for a sample of calumba root cultivated at the Mauritius. It is deficient in the bright greenish-yellow tint of the Mozambique calumba.

COMMERCE.—In the year 1838, duty (2*d.* per lb.) was paid on 19,805 lbs., and in 1839, only on 9384 lbs. of calumba.

COMPOSITION.—The more recent analyses of Calumba root are those of Planche¹ and Buchner.²

	Planche.	Buchner.
Bitter matter	13	10 to 12.2
Animal matter, soluble in water and not in alcohol	6	0
Yellow resinous extractive	0	5.0

Vegetable medulla [pectin?]	0	17.4
Woody fibre	39	12.6
Water	0	9.8
Loss		?
Calumba Root	100	100

1. ODOROUS PRINCIPLE (*Volatile Oil?*).—The odour of the root is supposed to depend on a volatile oil, traces of which were procured by Planche. The distilled water of the root possesses the odour of the latter.

2. CALUMBIN (*Bitter Principle*).—A crystallizable, odourless, very bitter, neutral substance, extracted from Calumba root by Wittstock.³ Its crystals are rhombic prisms. It is fusible; very slightly soluble in water, alcohol, ether, and volatile oils. Boiling rectified spirit dissolves about 1-40th of its weight. It dissolves in acids and alkalies, its best solvent being acetic acid. It is unaffected by metallic solutions, and by infusion of nutgalls. Sulphuric acid dissolves it, assuming first a yellow, then a red colour. Its composition, according to Liebig, is carbon 65.45, hydrogen 6.18, oxygen 28.37; or C¹²H⁷O⁴.

Planche describes the active principle of calumba as a *yellow bitter matter* soluble in water and alcohol, and yielding no precipitate either with the salts of lead or infusion of galls.

3. STARCH.—This constitutes about one-third by weight of the root. It renders the root an easy prey to insects. The structure of the starch particles has been described by Payen.⁴ These bodies are remarkable by their gibbosities, and by the hilum being found on the largest part of the particles.

CHEMICAL CHARACTERISTICS.—If the root be moistened with water, and then touched with tincture of iodine, it becomes black. A decoction of the root, when cold, forms with a solution of iodine a blue colour (*iodide of starch*). Sulphate of iron, emetic tartar, and gelatine, produce no obvious change in an infusion of calumba, showing the absence of tannic and gallic acids. Litmus detects no free acid. Infusion of nutgalls causes in the infusion of calumba a precipitate (*tannate of starch?*).

¹ *Bull. de Pharm.* iii. 189.

² *Ibid.* 1830, S. 517.

³ *Pharm. Central-Blatt für 1831*, S. 429.

⁴ *Ann. Scient. Nat. Botany*, July 1838, p. 20.

ADULTERATION.—The root of *Frasera Walteri*, called the *American* or *false calumba*, has been occasionally substituted for calumba root on the continent. Such a fraud would not be practicable in England, at least to any extent, as the appearance of the root is quite dissimilar to that of the genuine calumba. It is distinguished chemically from the latter by three characters: 1st, it undergoes no change of colour when touched with tincture of iodine, showing that it contains no starch; 2d, it becomes blackish-green on the addition of sulphate of iron; 3d, it yields a precipitate with a solution of gelatine. The two last characters indicate the presence of tannic acid.

PHYSIOLOGICAL EFFECTS.—Calumba is an excellent tonic, promoting the appetite, assisting the digestive process, and improving the quality of the secretions from the gastro-intestinal mucous membrane. It is not a stimulant; for Dr. T. Percival took a scruple of it on an empty stomach, but did not observe that it had the least effect on the regularity, fullness, or velocity of the pulse. In another experiment, he swallowed half a drachm; in ten minutes his pulse was fuller and slower by three beats, and continued so for three-quarters of an hour. In consequence of the quantity of starch and gum which it contains, it is sometimes termed a *mucilaginous* or *demulcent tonic*. *Cetraria islandica* and Simaruba bark agree with calumba in this circumstance. But from them, as well as from quassia, it is distinguished by its aromatic properties. In some respects (*i. e.* in its tonic and aromatic qualities) it approximates to rhubarb, but is devoid of the purgative and astringent properties of the latter. Its want of astringency distinguishes it from the astringent tonics (as cinchona). Full doses of it, in the form of powder, given when the stomach is very irritable, cause vomiting. It does not appear either to constipate or relax the bowels. We are not acquainted with the effects of excessive doses of it. Poisonous properties have been assigned to it by Buchner,¹ who states that Härtl, one of his pupils, applied a grain of the ethereal extract of calumba, deprived of wax by repeated solution in water, to a wound in the leg of a rabbit, and that it proved fatal in ten hours.

USES.—Calumba is one of our most useful stomachics and tonics. Its great value consists in its not being apt, like other and more powerful tonics, to create nausea, sickness, febrile disorder, or headache, so that it is tolerated when other remedies of this class would be immediately rejected. Indeed, on many occasions it evinces a positive power of checking vomiting. Schwilgué,² in order to test its anti-emetic qualities, gave it when vomiting had commenced after the use of emetic tartar and ipecacuanha. It frequently arrested the vomiting. He also gave it in conjunction with these emetics, and observed that the vomiting occurred more slowly than usual, and was milder. Probably it owes these valuable properties to a combination of circumstances; such as its freedom from acidity and astringency, the large quantity of starch which it contains (from which it acquires demulcent properties), and the peculiar operation of its bitter principle. The following are the principal uses to which it has been applied:—

1. *In a languid state of the stomach, with general debility*, attended with want of appetite, indigestion, nausea, and flatulence, experience has fully established the value of calumba, and has proved the justice of the encomiums passed on it by Dr. T. Percival. It is of all tonics the least likely to disagree with the stomach. In the stage of convalescence after an attack of fever, the infusion of calumba is an excellent preparative for the more powerful tonics (infusion of cinchona and disulphate of quina). In those forms of dyspepsia attended with great acidity of stomach, it may be given with advantage in combination with bicarbonate of potash.

2. *To allay vomiting*, when not dependent on inflammatory conditions of the stomach, calumba is often highly serviceable; as in bilious vomiting, in the sickness which so frequently attends pregnancy, and dentition. Even vomiting arising from renal calculi or diseased kidney has been somewhat palliated by calumba. I

¹ *Toxikol. S.* 229.

² *Mat. Méd.* ii. 374.

have seen the most satisfactory results from the combined use of infusion of calumba and effervescing draughts (composed of citric acid and bicarbonate of potash) in those occasional attacks of vomiting especially observed in delicate females, and which are commonly termed bilious attacks. By this treatment the violence and continuance of the vomitings have been diminished, and the continued employment of calumba has reduced the frequency and in some cases prevented the occurrence of future attacks.

3. *In diarrhœa and dysentery*, where tonics are admissible, as in the later periods of these diseases, when the inflammatory symptoms have subsided, and in habitual diarrhœa, calumba often proves serviceable. In Germany, it is denominated *Ruhrwurz* (i. e. *dysenteric root*).

ADMINISTRATION.—Calumba is administered in the form of *powder, infusion, or tincture*. The dose of the *powder* is from gr. x to ʒss. The *infusion* is the most eligible form of exhibition.

1. INFUSUM CALUMBÆ, L. E. [U. S.]; *Infusum Colombæ*, D.; *Infusion of Calumba*.—(Calumba, sliced [in coarse powder, *E. D.*], ʒv [ʒss, *E. (U. S.)*; ʒiij, *D.*]; Boiling [distilled, *L.*] Water [Cold Water, *E. D.*] Oj [ʒix, *D.*] Macerate for two hours in a lightly covered vessel, and strain, *L. D.*—"Triturate the calumba with a little of the water, so as to moisten it thoroughly, put it into a percolator, and transmit cold water till fʒxvj of infusion be obtained," *E.*)—The facility with which this preparation undergoes decomposition is ascribed by Planche to the substance which he terms *animal matter*.—Dose of the infusion, fʒj to fʒij. It may be conjoined with alkalies or chalybeates, without injury or obvious change. [Infusion of calumba becomes muddy by allowing it to stand on the dregs.—*ED.*]

2. TINCTURA CALUMBÆ, L. E.; *Tinctura Colombæ*, D.; *Tincture of Calumba*.—(Calumba, sliced [in small fragments; if by percolation in moderately fine powder, *E.*], ʒiij [ʒv, *D.*] [ʒiv, *U. S.*]; Proof Spirit [Diluted Alcohol, *U. S.*] Oij. Macerate for seven days [fourteen, *D.*], and filter.—"Express the residuum strongly, and filter the liquors. This tincture is much more conveniently prepared by the process of percolation, allowing the powder to be soaked with a little of the spirit for six hours before putting it into the percolator," *E.*—An excellent adjunct to bitter infusion and effervescent medicines, when given to check vomiting.—Dose, fʒj to fʒij.

340. ANAMIRTA COCCULUS, *Wight and Arnott, E.*—THE COCCULUS INDICUS PLANT.

Sex. Syst. Diœcia, Monadelphia.
(Fruit, *E.*)

HISTORY.—"According to Sprengel,¹ the fruit now usually called *Cocculus indicus* was introduced by the Arabians, and was described by Avicenna and Serapion under the name of *Maheradsch*."² In my copy, however, of the Latin translation of Avicenna,³ the word *Maheradsch* does not occur, but *Mahezeheregi*, or *Mahezhera*,⁴ is said to intoxicate fish. Nor can I find it in Serapion. *Cocculus indicus* is sometimes termed the *Levant nut*, or *bacca orientalis*.

BOTANY. *Gen. Char.*—*Flowers* diœcious. *Calyx* of 6 sepals in a double series, with 2 close-pressed bracteoles. *Corolla* 0. *Male*: *stamens* united into a central column dilated at the apex; *anthers* numerous, covering the whole globose apex of the column. *Female*: *flowers* unknown. *Drupes* 1 to 3, 1-celled, 1-seeded. *Seed* globose, deeply excavated at the hilum; *albumen* fleshy; *cotyledons* very thin, diverging.—*Twining plants*, with a corky bark. *Leaves* more or less cordate-ovate. *Flowers* in lateral compound racemes (*Wight and Arnott*).

¹ *Berl. Jahrb.* xxiii. 1822, S. 70.

² *Venet* 1564.

³ *Schwartz*, *Pharm. Tabell.* S. 388, 2te Aug.

⁴ *Lib.* 2ndus, tr. 2ndus, cap. 488.

Sp. Char.—The only species.

A strong climbing *shrub*. *Bark* deeply cracked, ash-coloured. *Leaves* stalked, large (from 8 to 12 inches long); petiole a little shorter than the leaves.

Hab.—Malabar, and Eastern Islands, &c. of India.

DESCRIPTION.—As met with in commerce, *Cocculus indicus* (also called *Cocculus levanticus* seu *piscatorius*) has considerable resemblance to the bay berry (*bacca lauri*), but is scarcely so large as the latter. It consists externally of a dried, thin, blackish-brown, rugous, acrid, and bitter layer, which envelops a thin, bivalved, white, ligneous shell (*endocarp*). In the middle of this shell arises a central placenta, which is contracted at its base, but enlarged and divided into two cells superiorly. Between this placenta and the shell is an oleaginous, yellowish, very bitter nucleus (*seed*), of a semilunar form. This nucleus never wholly fills the cavity of the shell—at least in the *Cocculus indicus* of commerce; for by keeping, it gradually becomes atrophied, and in old samples it is not uncommon to find the shell almost empty. This change is observed also in other oleaginous seeds. By this character alone *Cocculus indicus* may be instantly distinguished from the bay berry. The *Edinburgh College* requires that—

“The kernels should fill at least two-thirds of the fruit.”

COMMERCE.—*Cocculus indicus* is imported in bags from Bombay, Madras, and Ceylon. I am not acquainted with any official returns of the quantity annually brought over. From a druggist's private books I find that, in 1834, about 2,500 bags entered; and this probably is much below the quantity imported. The greater part is consumed for illegal purposes—principally for adulterating beer and ale, though this practice is prohibited by the legislature, under a penalty of £200 upon the brewer, and £500 upon the seller of the drug.

COMPOSITION.—*Cocculus indicus* was examined in 1811 by Boullay,¹ and in 1834 by Pelletier and Couerbe.² The results obtained by the last-mentioned chemists were as follows:—

Analysis of the Nucleus.

1. Picrotoxin.
2. Resin.
3. Gum.
4. A fatty acid substance.
5. An odorous matter.
6. Malic acid.
7. Mucus.
8. Starch.
9. Lignin.
10. Waxy matter.
11. Inorganic substances (nitrate and sulphate of potassa, and chloride of potassium), by incineration carbonates of potash, and of lime, manganese, and iron.

Analysis of the Shell.

1. Menispermia.
2. Paramenispermia.
3. Yellow alkaline matter.
4. Hypopicrotoxic acid.
5. Wax.
6. Starch.
7. Chlorophylle.
8. Resinous matter.
9. Gum.
10. Fatty matter.
11. Inorganic substances (as those of the nucleus with the addition of copper).

1. **PICROTOXIN** (*Picrotoxic Acid*).—At first, it was supposed to be an alkaline substance, and was termed *picrotoxin*. It is a white, crystalline, intensely bitter substance, usually crystallizing in needles, but sometimes in silky flexible filaments or transparent plates, or granular crystals. It is soluble in 150 parts of water at 57° F., in 25 parts of boiling water, in a third of its weight of alcohol, and in less than half its weight of ether. It is insoluble in the fixed and volatile oils, but is soluble in acetic acid. It does not combine with acids, but forms combinations with alkalis. It seems, therefore, to be an acid, though a feeble one. It consists of C¹²H⁷O⁹. The poisonous properties of the nucleus (*seed*) of *cocculus indicus* depend on picrotoxin. [Dr. Glover has recently experimented on the properties of this substance, and has published an account of his experiments in the *Lancet*.³ According to the analysis of Dr. Francis, it contains nitrogen, and it consists in 100 parts of carbon 60.26, hydrogen 5.70, nitrogen 1.30, oxygen 32.74.—En.]

2. **MENISPERMIA** (*Menispermia*; *Menispermine*).—This is an opaque, white, crystalline substance, soluble in alcohol and ether, but insoluble in water. It fuses at 245° F., and at a higher temperature is decomposed, leaving an abundant charcoal. It dissolves in, and saturates acids; and from these solutions alkalis precipitate it. Concentrated sulphuric acid has little action on it; hot nitric acid converts it into a yellow resinous substance, and oxalic acid. It is composed,

¹ *Ann. de Chim.* lxxx. 300.

² *Lancet*, Jan. 11, 1831, p. 47.

³ *Ann. Chim. et de Phys.* liv. 161.

according to Gay-Lussac, of $C^{18}H^{12}NO^2$. It does not appear to have any marked action on the animal economy.

3. **PARAMENISPERMIA** (*Paramenispermia*; *Paramenispermine*).—This is a crystalline solid, insoluble in water, scarcely soluble in ether, but dissolving readily in alcohol. It is fusible and volatile, and may be sublimed unchanged. It does not saturate acids, and, therefore, differs in this respect from the preceding substance. Notwithstanding this, however, its composition is the same.

4. **HYPOPICROTOXIC ACID**.—This acid is an amorphous, brown solid, insoluble in water (cold or boiling), insoluble in ether, soluble in alkalies, and precipitable from its solution in them by the mineral acids. It is composed of, carbon 64.14, hydrogen 6.09, oxygen 29.77. This composition approximates to that of picrotoxin.

The yellow alkaline matter of the shell has been scarcely examined.

Boullay¹ mentions a crystalline substance which he calls *menispermic acid*; but its properties require farther examination²

CHEMICAL CHARACTERISTICS.—Iodine colours the nucleus brown. The cold watery infusion of the whole fruit is slightly acid, and produces a dark precipitate with the sesquichloride of iron. Infusion of galls also occasions a precipitate.

PHYSIOLOGICAL EFFECTS. a. *On Vegetables*.—A solution of the aqueous extract of *Cocculus indicus* killed a haricot plant in twenty-four hours.³

β. *On Animals generally*.—It is poisonous to all animals; at least it has been found to be poisonous to dogs, goats, cows, crocodiles, birds, and insects. Goupil⁴ considered it to be a local irritant; but the correctness of this opinion is denied by Orfila.⁵ When introduced into the stomach its irritant effects were confined to the production of nausea and vomiting. It acts on the cerebro-spinal system, causing staggering, trembling, tetanic convulsions, and insensibility. Goupil states that all fish which eat it die—roach being killed very easily, barbel with more difficulty. "The barbel," we are told, "is, of all fish, that whose flesh the most frequently occasions accidents in those animals who eat it; probably because these fish, taking a longer time to die, the poison is longer subjected to the action of the digestive juices, and a considerable quantity of it is consequently absorbed." Orfila says, *Cocculus indicus* acts like camphor on the nervous system, and principally on the brain.

γ. *On Man*.—Its effects on man have not been accurately ascertained. Hill⁶ says, three or four grains of it have brought on nausea and faintings. It is frequently added to malt liquors, for the purpose of increasing their intoxicating powers; but, from some accounts which I have received from an Excise officer, who has been repeatedly subjected to the influence of beer thus adulterated, its action appeared to be rather on the voluntary muscles than on the intellectual powers.

The operation of *Picrotoxine* is analogous to, though stronger than, that of *Cocculus indicus*. Ten or twelve grains, given by the mouth, are sufficient to kill a dog. A grain and a half, injected into the jugular vein of a dog, killed the animal in twenty minutes.

USES.—*Cocculus indicus* is rarely employed in medicine. It has, however, been used as an external application, in the form of powder or ointment, to destroy pediculi (hence the Germans call these fruits *Läusekorner*, or *louse-grains*). It has also been employed in some obstinate skin diseases, as porrigo; but its use requires caution, especially where the skin is not entire, on account of the danger of absorption. Notwithstanding the severe prohibitory statutes against the employment of *Cocculus indicus* in brewing, I have reason to believe that it is extensively used; but being employed in the form of a solution of the extract, the form is not easy of detection. Morrice⁷ gives full directions for its employment. In the manufacture of porter, this author directs three pounds of *Cocculus indicus* to be added to every ten quarters of malt. "It gives," says he, "an inebriating quality, which passes for strength of liquor;" and he adds, "that it prevents second fermentation in bottled beer, and consequently the bursting of the bottles in warm climates."

⁶ Quoted by Orfila, *Toxicol. Gén.*

⁷ *Hist. of the Mat. Med.*

ANTIDOTE.—In poisoning by *Cocculus indicus*, or picrotoxin, remove the poison from the stomach as speedily as possible. No chemical antidote is known, though acetic acid has appeared to give relief. The symptoms must be combated on general principles, no peculiarities in the treatment being known. As a last resource, try artificial respiration.

UNGUENTUM COCCULI, E.; *Ointment of Cocculus Indicus*.—(Take any convenient quantity of *Cocculus indicus*, separate and preserve the kernels; beat them well in a mortar, first alone, and then with a little axunge, and then add axunge till it amounts, altogether, to five times the weight of the kernels.)—Used to destroy pediculi.

Jäger¹ has an *ointment of picrotoxin* (composed of gr. x of picrotoxin and ℥j of lard) in obstinate forms of porrigo.

341. CISSAMPELOS PAREIRA, Linn. E. D.—PAREIRA BRAVA, OR VELVET LEAF.

Sex. Syst. Diœcia, Monadelphia
(Radix, L.—Root, E. D.)

HISTORY.—The root of this plant was first mentioned by Piso² in 1648, under the name of *Caapêba*. It was introduced into Paris, in 1689, by M. Amelot, the French ambassador at Portugal.³

It is usually termed *Pareira* (*Parreyra*) *brava*, which means, literally, *wild vine*, on account of its supposed resemblance to the root of the wild vine. The Germans call it *Grieswurzel* (*i. e.* gravel root), on account of its beneficial effects in stone or gravel.

BOTANY. Gen. Char.—Diœcious. *Male: sepals* 4, in a double series. *Petals* 4, united into a cup-shaped corolla, with usually an entire margin. *Stamens* united in slender columns dilated at the apex, bearing two 2-celled anthers opening horizontally; cells placed end to end, and forming a 4-lobed, 4-celled annulus round the top of the column. *Female: calyx* of 1! lateral sepal. *Corolla* of 1! petal in front of the sepal. *Ovary* solitary. *Stigmas* 3. *Drupe* obliquely reniform; but compressed, wrinkled round its margin. *Seed* solitary uncinately; *embryo* long, terete, inclosed in a fleshy albumen. (Wight and Arnott.)

Sp. Char.—*Leaves* peltate, subordinate, ovate-articulate; silky-pubescent beneath. *Female racemes* larger than the leaf. *Berry* hispid. (De Cand.)

A climbing *shrub*. *Root* woody, branching. *Stem* round, smooth, or with close-pressed down. *Leaves* aristate at the point, when full-grown smooth above, underneath covered with silky pubescence (hence called *velvet leaf*), but not truly downy. *Flowers* small, yellow. *Berry* scarlet, round or reniform, hispid.

Hab.—West India Islands and Spanish Main.

DESCRIPTION.—The root of *Cissampelos Pareira*, commonly termed *pareira brava* (*radix pareiræ bravæ*), is sometimes imported under the name of *abuta* or *butua* root (*radix butæ*). Von Martius says that, in the Brazils, *Cissampelos Pareira* is called *Butua* or *Capêba*. *Pareira brava* occurs in more or less cylindrical pieces, sometimes flattened or bluntly angular. Some of the pieces are as thick as a child's arm—their length often a foot or more. Externally, they are covered with a dark-brown rind or cortex, which is furrowed longitudinally, and wrinkled transversely. The wrinkles have very much the appearance of large, transversely elongated lenticellæ. The surface of the transverse section of the root is of a yellowish-gray colour, and presents a number of concentric circles (the annular layers), traversed by numerous radiating lines (medullary rays); between these lines are triangular bundles of woody fibres and ducts—the latter are large, and being cut transversely,

¹ *Rust's Mag.* B4. xiv. St. i. S. 103.

² *Murray, App. Med.* i. 490.

³ *Hist. Nat. Brasil.* 94.

constitute the numerous holes or apertures presented by the cut surface. The circles or layers occasionally assume a very eccentric appearance.

The number of concentric circles varies with the age of the root. The fracture of the root is coarsely fibrous. The taste is sweetish, aromatic, afterwards bitter and unpleasant. It has no odour.

SUBSTITUTION.—The pareira brava of commerce yields most unequal quantities of extract. This circumstance, as well as some variation in the appearance of the pieces, leads to the belief that the roots (and stems?) of more than one plant, are sold under this name. A sample of a supposed spurious root,¹ yields “only a very minute quantity of the extract; and the decoction prepared from it, according to the usual formula, has only a slightly bitter taste, instead of the strong bitter of the decoctions” of the true root. A piece of this supposed spurious root presents an appearance of medulla, and is covered externally with a lichen; whence it would appear to be a portion of a stem.

COMPOSITION.—Pareira brava has been analyzed by Feneulle,² who found the constituents to be, *a soft resin, a yellow bitter principle, a brown colouring principle, vegeto-animal matter, fecula, super-malate of lime, nitrate of potash, and some ammoniacal and mineral salts.* More recently, Wiggers³ has announced the discovery of a new vegetable alkali, which he calls *cissampelin*, in this root.

1. Feneulle considers the **YELLOW BITTER MATTER** to be the active principle of the root. It is described as being soluble in both alcohol and water. From its solution it was precipitated by tincture of nutgalls as well as by diacetate of lead. In these properties it appears to agree with cathartine; but it is, probably, a mixture of several substances.

2. The properties of **CISSAMPELIN** have not been described. Wiggers says it is a strong, saline base, soluble in ether and in acetic acid. From its acetic solution it is precipitated by carbonate of soda.

CHEMICAL CHARACTERISTICS.—The presence of starch in the root is shown by iodine. An infusion of the root yields a precipitate on the addition of infusion of galls, and is rendered brown by the sesquichloride of iron.

PHYSIOLOGICAL EFFECTS.—I am unacquainted with any experiments made to determine the effects of this root in the healthy state of the body. From its taste, botanical affinities, and effects in diseases, it appears to possess a tonic power, and occasionally to act as a diuretic. Farthermore, its efficacy in certain maladies of the urinary organs induces us to ascribe an almost specific influence to this root over the mucous membrane lining the urinary passages. It certainly does appear to have the power of altering the quality of the urinary secretion. Large doses prove aperient.

USES.—It was originally introduced into medicine as a lithontriptic. Its powers in this way were at one time highly vaunted, and Helvetius even went so far as to assert that calculi, the size of an olive, had disappeared under its use, and that the operation of lithotomy was no longer necessary! We now employ it almost solely *in discharges from the urino-genital mucous membrane.*—It has been used in gonorrhœa, leucorrhœa, and chronic inflammation of the bladder. In the latter of these diseases, Sir B. Brodie⁴ states that he has seen more good done by this root than by the *Uva-ursi*. “I am satisfied,” says this eminent surgeon, “that it has a great influence over the disease which is now under consideration, lessening very materially the secretion of the ropy mucus, which is itself a very great evil, and, I believe, diminishing the inflammation and irritability of the bladder also.” He recommends it to be taken in the form of a concentrated decoction, to which may be added some tincture of hyoseyamus; and in these cases in which there is a deposit of the triple phosphates, muriatic or diluted nitric acid may be added.

ADMINISTRATION.—The *powder* has been given in doses of from half a drachm to a drachm. But the *infusion* or *decoction*, to which some *extract* has been added, is to be preferred. A *tincture* or *essence* has been prepared by digesting one part of

¹ See *Lond. Med. Gaz.* vol. xviii. p. 992; and vol. xix. p. 835.

² *Berl. Jahrb.* xl. 223, 1838.

³ *Journ. de Pharm.* vii. 404.

⁴ *Lond. Med. Gaz.* i. 300.

the root in five parts of rectified spirit. It is reputed diuretic and anticatarrhal. Its dose is fʒj.

1. DECOCTUM PAREIRÆ, L.; *Decoction of Pareira*.—(Pareira, sliced, ʒx; Distilled Water Oiss. Boil to a pint and strain.) [Narcotics, especially hyoseyamus, and alkalies or acids, may be added to this decoction as occasion may require. A stronger decoction than this is recommended by Sir Benjamin Brodie, who employs ʒss of the root to Oij of water, to be gently boiled down to one pint. Eight to twelve ounces of this should be taken daily. This is certainly a more effective preparation than that of the Ph. L.—Ed.]

2. INFUSUM PAREIRÆ, E. D.; *Infusion of Pareira Brava*.—(Pareira ʒvj; Boiling Water Oj. Macerate for two hours in a lightly covered vessel, and strain through calico, E.)—Dose, fʒj to fʒij. It will be advisable to increase the strength of this infusion by the addition of some extract of pareira to it. The Dublin College orders ʒss of the bruised and torn root, to ʒix of boiling water, and macerates for one hour.

3. EXTRACTUM PAREIRÆ, L. E.; *Extract of Pareira Brava*.—(Prepared as Extract of *Hæmatoxylon* [as Extract of Liquorice-root, E.]—Dose, gr. x. to ʒss. It is usually given in conjunction with the infusion or decoction.

OTHER MEDICINAL MENISPERMACÆ.

The student must not confound PAREIRA BRAVA with the PAREIRA BARK belonging to *Strychnaceæ*, and before noticed, nor with the PAREIRA MEDICA, Lindley,¹ a menispermaceous plant, whose root is employed by the Cingalese as a stomachic.

ORDER LXXXVII. MAGNOLIACEÆ, De Candolle.—THE MAGNOLIA TRIBE.

MAGNOLIACEÆ and WINTERACEÆ, Lindley.

CHARACTERS.—All the parts of the flower disposed in ternary number. *Sepals* 3 to 6, deciduous. *Petals* 3 to 27, in many series, hypogynous. *Stamens* numerous, free, inserted on the torus beneath the ovaries; *anthers* adnate, elongated. *Ovaries* numerous, inserted on the torus above the stamens, generally disposed like a spike, monostylous; *styles* short; *stigmas* simple. *Carpels* as many as the ovaries, 1-celled, 1- or many-seeded, capsular, and dehiscing by a superior chink; or capsular bivalved, dehiscing by an inferior chink; or follicular: or somewhat fleshy and indehiscent; or, lastly, samariform, aggregate, or partially united into a loose or dense strobile. *Seeds* attached to the internal angle of the carpels; *albumen* fleshy; *embryo* straight, small, inferior.—Elegant trees or shrubs. *Leaves* alternate, pinnatinerved. *Flowers* conspicuous, often powerfully odoriferous. (De Cand.)

PROPERTIES.—Bark tonic and aromatic. The same properties are possessed by some of the fruits. The flowers by their odour readily occasion nausea, headache, and faintness.

342. DRIMYS WINTERI, De Candolle.—WINTER'S BARK TREE.

Wintera aromatica, Murray.
Sex. Syst. Polyandria, Tetragynia.

HISTORY.—William Winter, captain of one of the ships which accompanied Sir Francis Drake, in the year 1578, to the Straits of Magellan, returning in 1579, brought the bark of some trees, which he had cut down there, to Europe. From this circumstance Clusius² called it *Winter's bark* (*Winteranus cortex*). It was afterwards confounded with *Canella bark*.

BOTANY. *Gen. Char.*—Carpels congested, baccate, many-seeded. *Filaments* thickest at the apex; cells of the anther separate. (De Cand.)

¹ *Fl. Med.* 370.

² *Exot. lib. iv. cap. i. p. 75.*

Sp. Char.—*Leaves* oblong, obtuse, glaucous beneath. *Peduncles* simple, approximated, or very short, divided into elongated pedicels. (De Cand.)

Fig. 418.

*Drimys Winteri.*

A large forest tree. *Branches* often tuberculated from the scars of the old footstalks. *Sepals* 2 to 3, green. *Petals* 7, milk-white. *Fruit* ovate.¹

Hab.—Straits of Magellan, Chili, Peru, New Grenada.

DESCRIPTION.—Winter's bark (*Cortex Winteri* seu *Winteranus*) occurs in quills or rolled pieces, commonly a foot long, one or two inches in diameter, and two or three lines thick. Its colour externally is pale-yellowish, or dull reddish-gray, with red elliptical spots; internally, it is reddish-brown. Its odour is aromatic, its taste warm and pungent. The characters by which it is distinguished from Canella bark have been already pointed out. Its infusion is darkened by the salts of iron.

COMPOSITION.—Winter's bark has been analyzed by M. Henry,² who found its constituents to be *resin, volatile oil, colouring matter, tannin, acetate of potash, chloride of potassium, sulphate of potash, oxalate of lime, and oxide of iron.*

1. **VOLATILE OIL** (*Oleum Corticis Winteri*).—Pale-yellow, lighter than water, with a very hot and acrid taste. By standing it is separated into two parts; one (the most abundant part) a greenish-yellow liquid; the other (heavier, but lighter than water) white, and of a fatty consistence.

2. **RESIN.**—Reddish-brown, and almost odourless. Its taste is at first feeble; then acrid and persistent.

PHYSIOLOGICAL EFFECTS AND USES.—Stimulant, aromatic, and tonic. Its uses are similar to those of cinnamon and canella alba. Winter employed it in scurvy. It is seldom employed.—Dose, ʒss or ʒj.

MAGNOLIA GLAUCA, Linn.

(Magnolia, U. S. Sec. List.)

This is usually a small tree, the height of which varies from 10 to 30 feet, branching, with a smooth, glaucous, whitish bark. The *leaves* are from three to five inches long, and an inch and a half to two inches wide, nearly elliptical, rather acute, sometimes obtuse, shining green above, very glaucous beneath, and when young, the under surface clothed with a glaucous, silky pubescence. *Petioles* three-quarters of

Fig. 419.

an inch long. *Flowers* very fragrant, on thick, clavate, pubescent peduncles, about half an inch in length. *Sepals* oblong, concave, roughish, dotted, as long as the petals. *Petals* white, an inch or an inch and a half long, obovate. *Stamens* numerous; *filaments* short, with the point extending above the adnate anthers. *Ovaries* collected in an ovoid cone; *styles* very short, recurved. *Carpels* opening longitudinally. *Seeds* obovate, covered with a purple fleshy arillus, falling out of the carpels when mature,

¹ See Solander's *Med. Obs. and Inq.* vol. v. p. 41.

² *Journ. de Pharm.* t. v. p. 459.

and hanging for some time by a long filiform funiculus. (Darlington, *Flora Cestrica*.) *Sex. Syst. Polyand. Polygyn.*

This plant is abundant along the Atlantic coast, from Massachusetts to Florida, where it frequents thick swamps and morasses; it does not grow spontaneously in dry and argillaceous ground unless transplanted. It is readily detected when in bloom by the rich perfume of its handsome white flowers; this occurs in May and June. The glaucous leaves and white shining bark at other seasons serve to distinguish it from the trees with which it grows. In the Southern States it is called *White Bay* and *Sweet Bay*. The bark is taken off during the spring and summer. When dried, it is in pieces several inches in length, and an inch or two broad, somewhat rolled, light; ashen, smooth and silvery externally, white and fibrous internally. It has an aromatic odour, which is impaired by time, and a taste warm, pungent, and bitterish. The bark of the root has similar sensible properties, and is regarded as being superior to that of the trunk and branches; it is rough externally. No detailed account has been given of its chemical composition; it is probable that an active principle, similar to *Liriodendrine*, found in the *M. grandiflora*, by Mr. Stephen Procter (*Am. Journ. of Pharm.* vol. xiv. p. 95), is also to be found in this species. Magnolia is tonic and diaphoretic in its effects on the animal economy, and may be used in cases where these effects are available. Its employment has been beneficial in the treatment of chronic rheumatism, and has proved serviceable in arresting the paroxysms of intermittent fever. The dose is $\bar{3}$ ss to $\bar{3}$ j, in powder; or a decoction may be made in the proportion of $\bar{3}$ j to Oj.—Dose, $\bar{3}$ j or $\bar{3}$ ij. An infusion in brandy is sometimes used in rheumatism.

The *M. ACUMINATA*, *Cucumber Tree*, officinal in *U. S. Pharm.*, is a large tree, inhabiting the mountainous districts of the United States; and the *M. TRIPETALA* (*Umbrella Tree*), also officinal, is a much smaller tree. The bark of both affords the official drug in common with the preceding. The uses are the same.

The *MAGNOLIA GRANDIFLORA* is deserving of a similar rank. Mr. S. Procter (*op. cit.*) found the bark to contain *green resin, volatile oil*, and a peculiar *crystallizable principle* analogous to *Liriodendrine*, an acid precipitating the salts of iron green, and *salts*.

LIRIODENDRON TULIPIFERA, Linn.—AMERICAN POPLAR TULIP TREE.

(*Liriodendron*, *U. S. Sec. List.*)

This tree is one of the handsomest peculiar to the United States. Its height varies from 60 to 100 feet, and it is often four or five feet in diameter. In the old trees the branches are spreading at the summit, and frequently of great height without branches; in the young trees the branches are in the form of a cone. *Buds* large, compressed, obovate. *Leaves* three to five inches long, and four to six inches broad, nearly quadrangular in their outline, smooth, shining green above, paler beneath, rounded or subcordate at base, with a short, diverging, acuminate lobe (sometimes two) on each side, and the broad central lobe emarginately truncated. *Petioles* two to three inches long. *Flowers* large, campanulate, each with two caducous bracts at base. *Sepals* obovate-oblong, concave, pale yellowish-green, as long as the petals, spreading, and at length reflexed, deciduous. *Petals* lance-obovate, mostly obtuse, greenish-yellow, stained with reddish-orange below the middle. *Stamens* in a simple series, shorter than the petals; *filaments* with a lance-ovate point extending above the long adnate anthers. *Ovaries* closely imbricated; *stigmas* sessile, recurved. *Carpels* two-celled, samara-like, with a lance-oblong

Fig. 420.

wing at apex, incurved at base, with a prominent internal ridge, imbricated in a cone upon a slender fusiform receptacle; one of the cells frequently obliterated, and both seeds often abortive. (Darlington, *Flor. Cest.*) *Sex. Syst. Polyand. Polygyn.* It is called *Tulip Tree* on account of its numerous large, showy, orange-coloured, tulip-shaped flowers. According to *Michaux*, the northern limit of this tree may be placed at the southern extremity of Lake Champlain, lat. 45°, and it seldom is found east of the Connecticut River. It is found abundantly through the Middle and Southern States, requiring a rich, not too moist, soil.

The bark of the trunk and larger branches is very rough, and covered with dead epidermis, which is very much split and divided; upon the smaller branches it is smooth, and of a deep ashen hue. It is brought into the market in pieces of three or four inches long, deprived of epidermis, and of a yellowish-white colour, light, fibrous, and easily broken; the odour is somewhat aromatic; the taste pungent, aromatic, slightly camphorous, and bitter. The article obtained from the root has similar sensible properties, but browner externally and rougher.

A peculiar principle (*Liriodendrine*) has been obtained from this bark by the late Prof. Emmet, of the University of Virginia (*Journ. of Phil. Col. of Pharm.* vol. iii. p. 5). It is a crystalline solid, bitter and inodorous at 40°, fusible at 180°, and volatile at 290° F. When carefully heated in a glass tube closed at one end, it gives off a white vapour, which condenses again, without signs of crystallization. It is not acid or alkaline. Its discoverer regarded it as a substance analogous to camphor.

The medical properties of *Liriodendron* are those of a stimulant and tonic; in large doses it is diaphoretic, and is also stated to be diuretic. As a febrifuge it has been employed by a number of American physicians; but as it is stimulant, and apt to sicken the stomach, or to act upon the bowels, the condition of the organs is to be strictly inquired into, and the system prepared for its employment. Dr. Young regarded it as also beneficial in hysteria, and as an anthelmintic. The dose in substance is ℞j to ℥ij. In this form it acts with most power. As it yields its virtues to water and alcohol, it may be exhibited either in infusion, decoction, or tincture. There are no official preparations.

OTHER MEDICINAL MAGNOLIACEÆ.

ILLICIAM ANISATUM is an evergreen tree, growing in Japan and Cochin-China. Its fruit constitutes the *star-anise* (*anisum stellatum*) of the shops. It consists of a variable number (usually six to twelve) of hard woody follicles, disposed in a star-like form, each containing an oval reddish seed. It has the odour of common anise (*Pimpinella Anisum*), but somewhat sweeter. By distillation it yields the *oil of star-anise* (*oleum badiani*), which closely resembles, and is often substituted for, the oil of common anise; but it congeals less readily than the latter. Star-anise is aromatic and carminative. Both the fruit and the oil are employed by liqueur-makers. As regards its effects it might be substituted for common anise.

ORDER LXXXVIII. RANUNCULACEÆ, *De Candolle*.—THE CROWFOOT TRIBE.

CHARACTERS.—*Sepals* 3 to 6, hypogynous, deciduous, generally imbricate in æstivation, occasionally valvate or duplicate. *Petals* 3 to 15, hypogynous, in one or more rows, distinct, sometimes deformed. *Stamens* definite or indefinite in number, hypogynous; anthers adnate. *Carpels* numerous, seated on a torus, 1-celled or united into a single many-celled pistil; *ovary* one or more seeded, the *ovules* adhering to the inner edge; *style* 1 to each ovary, short, simple. *Fruit*, either consisting of dry akenia, or baccate with one or more seeds, or follicular with one or more valves. *Seeds* albuminous; when solitary, either erect or pendulous; *embryo* minute; *albumen* corneous.—*Herbs*, or very rarely *shrubs*. *Leaves* alternate or opposite, generally much divided, with the petiole dilated and forming a sheath half clasping the stem. *Stipules* occasionally present. *Hairs*, if any, simple. *Inflorescence* variable. (*Lindley*.)

PROPERTIES.—Mostly poisonous. Acridity is the prevailing quality, conjoined, in a considerable number of instances, with a narcotic quality. Several of the species are topical bennumbers.

343. RANUNCULUS ACRIS, Linn.—UPRIGHT MEADOW CROWFOOT.

Sex. Syst. Polyandria, Polygynia.

BOTANY. Gen. Char.—*Calyx* of 5 sepals; sepals not separate at the base, deciduous. *Petals* 5, rarely 10, with nectariferous scales at the base. *Stamens* and *ovaries* numerous. *Caryopsides* ovate, somewhat compressed, terminating in a short mucro or horn, scarcely larger than the seed, smooth, striated or tuberculated, arranged in a globose or cylindrical head. (De Cand.)

Sp. Char.—*Calyx* spreading. *Flower-stalks* round and even. *Leaves* in three deep-lobed and cut segments; those of the uppermost linear and entire. *Stem* erect, covered with close hairs.¹

Perennial. *Flowers* yellow. *Petals* with a scale at the base.

Hab.—Indigenous; very common in meadows and pastures. *Flowers* in June and July.

COMPOSITION.—Not analyzed. Its *acid principle* is either very volatile, or readily undergoes decomposition, as, by drying, the plant loses its acridity.

PHYSIOLOGICAL EFFECTS.—A powerful acid. Inflammation of the palm of the hand has been produced by pulling it up and carrying it a little distance.² Withering³ says it easily blisters the skin. Orfila⁴ has shown, by experiments on animals, its powers of causing inflammation of the tissues to which it is applied.

USES.—It has been applied as a rubefacient and epispastic, but is far inferior to cantharides and mustard, on account of the uncertainty of its operation.

344. RANUNCULUS FLAMMULA, Linn.—LESSER SPEAR-WORT CROWFOOT.

Sex. Syst. Polyandria, Polygynia.

BOTANY. Gen. Char.—See *Ranunculus acris*.

Sp. Char.—*Leaves* ovate-lanceolate, bluntish stalked. *Stem* reclining. *Root* fibrous. *Seeds* smooth. (Smith.)

Perennial. *Leaves* nearly entire, subserrate. *Flowers* bright gold colour.

Hab.—Indigenous; sides of lakes and ditches abundant.

PHYSIOLOGICAL EFFECTS AND USES.—Similar to those of *Ranunculus acris*.

345. HELLEBORUS NIGER, Linn., L. E.—BLACK HELLEBORE, OR CHRISTMAS ROSE.

Sex. Syst. Polyandria, Polygynia.

(*Rhizoma et radix*, L.—*Root*, E.)

[*Helleborus*, U. S.]

HISTORY.—According to Sprengel,⁵ this is the plant called by the Abbess Hildgard, *Christiana*.

It must not be confounded with the *ἡλιβορος μίρα* (*black hellebore*) of Dioscorides,⁶ which, according to Dr. Sibthorp,⁷ was the plant which he has described and figured under the name of *Helleborus officinalis*. Hippocrates employed hellebore in medicine. Melampus employed it with great success, in the treatment of

³ *Hist. Rei Herb.* i. 320.

⁴ *Fl. Græca*.

⁵ Curtis, *Fl. Lond.* vol. i.

⁶ *Tox. Gén.*

⁷ *Lib.* iv. cap. 151.

madness, 1,400 years before Christ. His use of it is the earliest instance on record of the use of a purgative.¹ It has been called after him *melampodium*—a term which has also been applied to *Helleborus niger*.

BOTANY. Gen. Char.—*Calyx* persistent, of 5 sepals; sepals roundish, obtuse, large, usually green. *Petals* 8 to 10, very short, tubular, narrow, and nectariferous beneath. *Stamens* 30 to 64. *Ovaries* 3 to 10. *Stigmas* terminal, orbicular. *Cap-sules* coriaceous. *Seeds* in a double row, elliptical, umbilicated. (De Cand.)

Sp. Char.—*Leaves* radical, pedatisect, quite smooth. *Scape* leafless, one- to two-flowered, bracteated. (De Cand.)

Rhizome several inches long, tuberculated, horizontal, scaly, blackish-brown externally, white internally, with many dependent, long, simple root-fibres. *Leaves* on cylindrical stalks from 4 to 8 inches long; lobes ovate-lanceolate, serrate near the point. *Scape* shorter than the petiole. *Sepals* ovate or roundish, large, white, slightly tinged with pink, eventually becoming green. *Petals* green, tubular, shorter than the stamens. *Follicles* many-seeded. *Seeds* black, shining.

Hab.—Sub-alpine, woodland regions in the midland and southern parts of Europe.

COMMERCE.—Hellebore root is imported in barrels and bags from Hamburg usually, but sometimes from Marseilles.

DESCRIPTION.—The root met with in commerce under the name of black hellebore root (*radix hellebori nigri*, seu *radix melampodii*) consists of two parts—the rhizome or rootstock, and the fibres which arise from it. The rhizome is half an inch or less thick, several inches long, horizontal or contorted, knotty, with transverse ridges and slight longitudinal striæ. The fibres are numerous, cylindrical, dark brown externally, internally whitish or yellowish-white, with a central paler cord. The odour is very feeble, and scarcely perceptible, but has been compared to that of senega root. Its taste is slight at first, then bitterish, acrid, and nauseous.

SUBSTITUTION.—It is probable that the roots of *Helleborus viridis* and *fetidus* are sometimes substituted for, or intermixed with, black hellebore root. This practice certainly occurs on the continent. The root of *Actæa spicata* (sometimes called *radix hellebori nigri falsi*) is also said to be occasionally substituted for the genuine root; its stronger fibres, when cut transversely, present the form of a cross. As far as I have observed, the roots, sold in this country as black hellebore, have a very uniform appearance, and from this I have not had reason to suspect any intermixture of other roots.

COMPOSITION.—Vauquelin² analyzed the root of *Helleborus hiemalis*. This analysis is quoted by Soubeiran³ as the analysis of black hellebore root. Feneulle and Capron⁴ analyzed the black hellebore root.

Vauquelin's Analysis.

Very acrid oil.
Extractive.
Starch.
Vegeto-animal matter.
Sugar.
Lignin.

Root of *Helleborus hiemalis*.

Feneulle and Capron's Analysis.

Volatile oil.
Fatty oil.
Volatile acid.
Resinous matter.
Wax.
Bitter principle.
Ulm. in.
Gallate of potash.
Ammoniacal salts.

Root of *Helleborus niger*.

ACRID OIL, Vauquelin; *Soft Resin*, Gmelin; *Helleborin*.—This substance is odourless, has an acrid taste, and is soluble in spirit. Vauquelin ascribed the activity of hellebore to it. Feneulle and Capron, on the other hand, ascribe it to a combination of *fatty oil* and *volatile acid*. Probably the two latter correspond to the acrid oil of Vauquelin.

PHYSIOLOGICAL EFFECTS. a. On Animals.—Given by the mouth to the ear-

¹ Le Clerc, *Hist. de la Méd.* p. 27, 1729.

² *Nouv. Traité de Pharm.* i.

³ *Ann. de Muséum*, viii. 87.

⁴ *Journ. de Pharm.* viii. 503.

nivora (as dogs), it causes vomiting, frequently purging and griping. In excessive doses it produces gastro-enteritis. If the œsophagus be tied, to prevent the ejection of the root from the stomach, it causes staggering, weakness or paralysis of the hind extremities, insensibility, and death. Similar effects result from its application to a wound.¹ Orfila states, when the animals survive a few hours, inflammation of the rectum is a constant occurrence; whereas, Vicat² says it causes inflammation of all the intestines, except only the rectum. The latter statement is entirely erroneous.

β. *On Man.*—Black hellebore is a local irritant, drastic purgative, and emmenagogue. Given in *small doses*, it increases the secretion and peristaltic motion of the intestines, and acts as a stimulant to the pelvic circulation, thereby promoting the menstrual and hemorrhoidal discharges, and, by its influence over the portal circulation, contributing probably to increase the hepatic secretion. *Large doses* act as a drastic purgative, and frequently also occasion sickness. They produce a more manifest influence over the pelvic vessels, often cause cold sweats, and lower the strength of the pulse. In an *excessive* or *poisonous dose* it acts as a narcotico-acrid poison, and causes vomiting, purging, burning pain in the stomach and intestines, cramps of the lower extremities, cold sweats, faintness, paralysis, insensibility, and death. The fresh root *applied to the skin* produces rubefaction and vesication.

As a drastic purgative it is allied to colocynth, from which its narcotic operation and its greater influence over the pelvic organs distinguish it.

USES.—Black hellebore, though greatly esteemed by the ancients, is but little employed by the moderns. It is adapted for torpid, phlegmatic individuals, especially when the pelvic circulation is languid. On the other hand, in easily excitable persons, and where any irritation of the pelvic organs (especially the uterus and rectum) exists, it proves injurious.

1. *In affections of the nervous system*, especially mania, melancholia, and epilepsy, it has long been celebrated, and, under the above-mentioned conditions, at times proves serviceable.

2. *As an emmenagogue*, it was greatly esteemed by Dr. Mead,³ and is still much valued by some practitioners. He gave two teaspoonfuls of the tincture in a glass of warm water twice a day. The remarks already made will readily suggest the class of cases to which it is applicable.

3. *In dropsy*, its drastic operation renders it useful. Furthermore, when this disease depends on, or is connected with, a languid state of the portal circulation, black hellebore proves farther useful by the stimulus which it communicates to the hepatic vessels.

4. Lastly, black hellebore has been used in *chronic skin diseases*, and as an *anthelmintic*.

ADMINISTRATION.—The dose of powdered hellebore is from grs. x to ℥j, as a drastic purgative. When we require a milder effect, we may give it in doses of grs. iij to grs. viij. It has also been given in decoction; but the tincture is the most frequently employed preparation.

TINCTURA HELLEBORI, L. [U. S.]; *Tincture of Black Hellebore*.—(Hellebore, bruised, ℥v. [℥iv, U. S.]; Proof Spirit [Diluted Alcohol, U. S.] Oij. Macerate for seven days, and strain.)—Dose, fʒss to fʒj. Principally employed as an emmenagogue.

² *Hist. des Plant. Ven. de la Suisse*, p. 60.

³ *Works*, p. 563, 1762.

346. DELPHINIUM STAPHYSAGRIA, Linn. L. E.— STAVESACRE.

Sex. Syst. Polyandria, Trigynia.
(Semina, L.—Seeds, E.)

HISTORY.—Hippocrates employed stavesacre in medicine. Sibthorp¹ found the plant growing in Crete and Zante, and identified it with the *σταφίς ἀγρία* of Dioscorides.²

BOTANY. Gen. Char.—*Calyx* deciduous, petaloid, irregular; the *sepals* elongated at the base into a spur. *Petals* 4, the two upper appendiculated within the spur. (De Caud.)

Sp. Char.—*Spur* very short. *Bractlets* inserted at the base of the pedicel. *Petioles* pilose. *Pedicels* twice as long as the flower. (De Caud.)

A stout herb, one or two feet high. *Stem* and *petioles* hispid, with soft hairs. *Leaves* broad, palmated, stalked, 5 to 9-cleft. *Racemes* lax. *Flowers* bluish or purplish. *Capsules* 3, large.

Hab.—South of Europe, the Levant, and the Canaries.

DESCRIPTION.—Stavesacre seeds (*semina staphisagriæ* seu *staphidis agriæ*) are irregularly triangular (sometimes quadrangular), slightly arched, blackish-brown, and wrinkled. They contain a white and oily nucleus. Their odour is slight but disagreeable; their taste bitter, very acrid, hot, and nauseous. Iodine colours the seeds brown. Their watery infusion is darkened by sesquichloride of iron. Infusion of nutgalls renders it turbid.

COMPOSITION.—Stavesacre seeds were analyzed in 1820 by Brandes,³ and in 1821 by Lassaigne and Feneulle.⁴

Brandes's Analysis.

Delphinia	8.10

Malate of delphinia.
Volatile oil.
Fatty oil.
Brown bitter matter.
Yellow ditto.
Uncrystallizable sugar.
Gum.
Woody fibre.
Animal matter.
Albumen.
Mineral salts.

Stavesacre Seeds.

1. **DELPHINIA** (*Delphina*; *Delphine*; *Delphinum*).—As usually met with, this is a white odourless powder. Its taste is extremely acrid and very bitter. It fuses at 248° F. It is scarcely soluble in water whether hot or cold, but dissolves in ether, and still better in alcohol. Its alcoholic solution reacts as an alkali on test paper. It is not crystallizable, though its texture is said to be crystalline, when the powder is moistened. It saturates acids, forms salts which are acrid, very bitter, and difficultly crystallizable. From its solution in acids, it is precipitated by alkalis. Its composition is $C^{27}H^{19}NO^2$. Its atomic weight, therefore, is 211. Couerbe⁵ says that, as usually procured, it is not absolutely pure, but contains a resinous matter, and an acrid resin which he calls *staphysain*.

2. **VOLATILE ACID** (*Delphinic Acid?*)—Discovered by Hofschlæger.⁶ It is white, crystalline, volatile at a low temperature, and in small doses is a powerful emetic.

PHYSIOLOGICAL EFFECTS.—The activity of stavesacre seeds depends partly on the delphinia and partly on the volatile acid. The powder of the seeds readily excites nausea, vomiting, and purging. Orfila⁷ has shown that on dogs it acts first as an acrid and afterwards as a narcotic poison. Its operation appears to be similar to cebadilla.

USES.—Stavesacre seeds have been used to destroy pediculi; whence the Germans

⁶ *Ann. Chim. et de Phys.* 1. 2.

term them *Lüusesaamen*, or *louse-seeds*. For this purpose they are employed in the form of ointment or acetous infusion. They have also been administered internally (in doses of from three to eight grains) against worms, and externally in the form of decoction (prepared by boiling $\bar{3}j$ of the seeds in Oij of water) in inveterate itch.

ANTIDOTE.—See *Veratrum album*.

DELPHINIA.—Four grains of delphinia dissolved in a drachm of rectified spirit produce, when rubbed on the skin, a sensation of burning and prickling, with tingling and slight redness. Taken internally, in doses of half a grain, it sometimes acts slightly on the bowels, and increases the flow of urine. In larger doses, as a few grains, it gives rise to sensations of heat and tingling in various parts of the body.¹ The diseases in which it is chiefly successful are neuralgic cases. It has also been used in rheumatic affections with some benefit. It is employed externally in the form of ointment or alcoholic solution. The *unguentum delphinia* consists of $\bar{3}ss$ of delphinia, $\bar{3}j$ of olive oil, and $\bar{3}j$ of lard. The *solutio delphinia*, composed of $\bar{3}j$ of delphinia dissolved in $f\bar{3}ij$ of rectified spirit, is an excellent embrocation. Internally, delphinia is given in the form of pills. The *pilula delphinia* consists of gr. j of delphinia; grs. xij extract of hyoscyamus; and the same quantity of extract of liquorice. Divide the mass into twelve pills, one of which may be taken every three hours (Turnbull).

347. ACONITUM NAPELLUS, Linn., L. E. D.—COMMON WOLFSBANE, OR MONKSHOOD.

Sex. Syst. Polyandria, Trigynia.

(Follum recens et exsiccatum; Radix, L.—Leaves, E.—The Root, D.)

HISTORY.—The ancient history of Aconite is involved in great obscurity. The Greeks make frequent reference to a most virulent poison which they term *ἀκόνιτον*. Theophrastus² is the earliest writer who speaks of it. As *Aconitum Napellus* is a virulent poison, and is a native of Greece, where it is known at the present day as *ἀκόνιτον*,³ it would at first appear probable that our common aconite was the plant referred to by the ancient Greeks. But the characters of it as given by Theophrastus quite preclude this supposition; and I believe no one has been able to identify satisfactorily the plant described by this ancient naturalist.⁴ Dioscorides⁵ has noticed two kinds of *ἀκόνιτον*.

BOTANY. Gen. Char.—*Calyx* petaloid, irregular, deciduous, or withering; upper sepal concave, helmet-shaped. *Petals* 2, superior (nectaries), on long stalks, expanded at the apex into a bag hidden beneath the helmet. (De Cand.)

Sp. Char.—*Flowers* densely spiked or loosely paniced. *Helmet* semicircular, rarely boat-shaped. Bag of the *petals* somewhat conical. *Spur* short, thick, inclined. Whigs of the *stamens* cuspidate or evanescent. Lobes of the *leaves* cuneate pinnatisect. *Ovaries* 3, rarely 5, smooth or pilose. (De Cand.)

Perennial herb. *Root* tapering. *Stem* simple. *Flowers* blue.—This species is subject to great variation in the dense or loose condition of the inflorescence, in the form of the helmet, the colour and size of the flower, the breadth and the number of slashes of the leaves, the downiness of the parts of the plant, and the condition of the stem. De Candolle⁶ admits no less than twenty-nine varieties.

Hab.—Europe. It is placed among indigenous plants, but it is a doubtful native.

The *Dublin College* directs the root to be used.

The *London College* directs the root (*radix*) as well as the leaves (*folia*) to be employed.

The *Aconitum Napellus* is one of the most active species of the genus, and no good evidence

⁶ *Prodr.* i. 62.

has yet been adduced to prove its inferiority to the *A. paniculatum* var. γ *Storkianum*, which Stork published as *A. Napellus officinalis*, and which was formerly adopted as the officinal plant.

Moreover, the roots of *A. paniculatum* are not found in commerce, nor is the plant grown (except in botanical gardens) in this country; so that druggists and apothecaries could not if they would have obeyed the former directions of the London and Dublin Colleges.

DESCRIPTION.—Aconite root (*radix aconiti*), when fresh, consists of a tapering rootstock, placed perpendicularly, or nearly so, in the earth, and of numerous cylindrical fleshy fibres arising from it. At its upper and thickest part the rootstock seldom exceeds the thickness of the finger; inferiorly it is attenuated and filiform. Sometimes two or three rootstocks are conjoined. In the latter case the root has a palmated appearance. Its total length is three or four or more inches. Its colour, as well as that of the fibres, is externally coffee-brown; its odour is earthy. Internally, it is white and fleshy. Its taste is bitter; but after a few minutes a remarkable numbness and tingling is perceived on the lips, tongue, and fauces. By drying, the root shrivels, and becomes darker coloured. The root should be gathered in the spring, just before the leaves appear. The leaves (*folia aconiti*), when chewed, have the same taste, and produce the same feeling of numbness.

COMPOSITION.—No complete analysis either of the root or the leaves of *Aconitum Napellus* has been made. The following are the constituents of the root of *A. Lycoctonum*, according to Pallas:¹ a black oil, a green fatty matter, a substance having some analogy with the vegetable alkalies [impure aconitina?], vegetable albumen, starch, lignin, and some salts.

The leaves of *Aconitum medium Schraderi* were analyzed by Bucholz.²

Both Brandes and Peschier announced the existence of a peculiar alkali (*aconitina*) in aconite. Their statement was confirmed, in 1825, by Pallas,³ and, in 1832, by Geiger and Hesse.⁴ Peschier also asserted that aconite contained a peculiar acid (*aconitic acid*). His assertion has been substantiated by L. A. Buchner, Jr.⁵ It has been since ascertained that the same acid is developed by the action of heat on citric acid. Most chemists have admitted the existence of a *volatile acrid principle* in aconite, but it has not hitherto been isolated.

1. **ACONITINA.**—See *post*.

2. **VOLATILE ACRID PRINCIPLE.**—This principle, though admitted by several chemists, has not been isolated. Geiger⁶ submitted the fresh herb of *Aconitum Napellus*, with water, to distillation, and obtained a liquor having an acrid taste, an unpleasant odour, and whose emanations affected the eyes. May not this volatile principle be the product of the decomposition of aconitina? The following circumstances favour this suggestion: 1st. The fresh herb and root have little odour; 2d. The local effect of aconitina is similar to that of the root and leaves; 3d. Aconitina, when mixed with the other constituents of the plant, readily undergoes decomposition, so that considerable nicety of manipulation is required in the extraction of it; and Mr. Morson tells me he has sometimes failed to obtain it.

3. **ACONITIC ACID.**—In the evaporation of the juice of aconite, octahedral crystals of *aconitate of lime* are frequently deposited. From these L. A. Buchner obtained the acid. The acid also exists in *Equisetum fluviatile*, and may be formed by the action of heat on citric acid. As obtained from aconite it is scarcely crystalline, merely forming warty elevations. It is white, permanent in the air, odourless, very sour, and is very soluble in water, alcohol, and ether. When heated it fuses, and at the same time undergoes decomposition; but does not yield fumaric acid. From the latter acid it is distinguished by its greater fusibility and solubility; from maleic acid by its forming indistinct crystals, and not yielding fumaric acid by heat. The anhydrous acid, as found in aconitate of silver, consists of $C^4H^1O^3$.

4. **FATTY OIL.**—This is extracted from the root by alcohol. It is dark coloured. All the specimens of it, which I have obtained, possess a powerfully benumbing property [from the presence of aconitina?].

PHYSIOLOGICAL EFFECTS.—Hitherto, I have met with no clear and accurate account of the effects of aconite, and some of them appear to me to have been entirely overlooked.

a. *On Animals.*—If a small quantity of the soft, alcoholic extract of the root of aconite be introduced into a wound (as into the cavity of the peritoneum) in a dog,

¹ *Journ. de Chim. Méd.* i. 192.

² *Op. supra cit.*

⁴ Gmelin, *Handb. d. Chem.* ii. 1241.

⁵ *Journ. de Chim. Méd.* x. 464.

⁶ *Ibid.* 1831, 491.

it usually causes vomiting (sometimes of a stercoraceous character), diminishes the force of the circulation, weakens the muscular system so as sometimes to cause the animal to stagger in walking, and destroys common sensibility of feeling, without causing stupor. A dog under the influence of not too strong a dose, will sometimes follow its owner round the room, recognize him by wagging his tail when called, and yet be totally insensible to pinching, pricking with needles, &c. Convulsions do not usually occur until a short period before death, and they are then commonly slight, and rather to be termed spasmodic movements. I have repeatedly demonstrated these effects to the pupils attending my lectures.

The following is a notice of one experiment:—

March 31, 1837. London Hospital. Present, Mr. Adams, and several medical students.—A small portion of alcoholic extract of aconite was introduced into the peritoneal sac of a strong dog, which had been kept fasting for some hours. In a few minutes he was evidently affected. He was less capable of supporting himself, and leaned against a wall. In ten minutes was insensible to the pain caused by the introduction of pins into his legs, paws, body, tail, nose, &c. His sight, however, was unaffected; at least, he winked as usual, when attempts to strike him were feigned. Was not paralytic, for he walked, though not firmly. He recognized several individuals, and wagged his tail when spoken to. He made violent attempts to vomit. He then lay down, became apparently weaker, and died without a single convulsion. At one period, the action of the heart was slower than usual, and the first and second sounds of the heart were unusually clear and distinct. Subsequently, the circulation was quickened. Respiration was not disordered; nor were the bowels affected.

I have subsequently found that, if a large quantity of alcoholic extract be used, the loss of feeling is not so well marked; for death succeeds in so short a period of time that the loss of feeling, as distinguished by the insensibility immediately preceding death, is not well observed. For the same reason, rabbits do not answer well for demonstrating these effects; and the weakness (paralysis?) of the hind extremities, and spasmodic movements, are much more marked in them than in dogs. I can distinguish no difference between the effects of *Aconitum Napellus* on rabbits, and those of *Aconitum ferox* on the same animals.¹ On opening the bodies of dogs killed by aconite immediately after death, no pulsations of the heart are visible.—Want of space compels me to abstain from entering into any details respecting the experiments made on animals with aconite by Wepfer,² Sprægel,³ Viborg,⁴ Brodie,⁵ and Orfila.⁶

β. On Man.—The topical effects are peculiar, and most remarkable. If a leaf or a small portion of the root be chewed, or a few drops of the alcoholic tincture of the root be applied to the lips, there are produced in a few minutes numbness and a remarkable tingling sensation. These effects endure for many hours. If the quantity taken into the mouth be somewhat larger, the palate and throat are affected. To me, the sensation appears as if the velum and soft palate were elongated, and rested on the dorsum of the tongue. To relieve this, frequent attempts are made to swallow.

When *small and repeated doses* of the alcoholic tincture of the root are taken internally, they cause a sensation of heat and tingling in the extremities, and occasionally a slight diuresis.

The extract of aconite of the shops is but little to be relied on. Many samples produce neither numbness nor tingling when rubbed on the lips and gums. Störck⁷ states that it acts as a diaphoretic and diuretic. These symptoms, however, are by no means constantly produced, and, when they occur, are not always clearly referable to the aconite used.

In *poisonous doses*, the effects of aconite are most remarkable. The following details of the effects produced on a family of three persons were furnished me, a

¹ See the results of my experiments on the latter plant, in the splendid work of my friend Dr. Wallich, *Planta Rariores Asiaticæ*; also, a detail of my experiments in the *Edinb. Journ. of Nat. and Geogr. Science*, July 1830, p. 235.

⁷ *Phil. Trans.* for 1811, p. 178.

few days after the accident, by one of the sufferers (Mrs. Prescott), and her account was confirmed by a very intelligent neighbour who witnessed the progress of the symptoms:—

In December, 1836, Mr. Prescott, aged 57, residing in the City Road, planted in his garden a few pieces of horseradish. On February 5, 1837, he observed some green shoots, which he supposed to be those of horseradish. He dug up three of them. The roots (samples of which were given, and have yielded me thriving plants of *Aconitum Napellus*) were tap-shaped and small. Perhaps a very small walnut would exceed in bulk that of the whole root. These roots were washed, scraped, placed on a plate with some vinegar, and eaten at dinner (at 2 o'clock), with roast beef, by Prescott, his wife (aged 57), and a child (aged 5). It was remarked at dinner that the root was very mild, and had not the pungency of horseradish. After the family had dined, about one root was left; so that two had been eaten at dinner, the greater part (perhaps one or one and a half roots) by the husband. About three-quarters of an hour after dinner, Mr. Prescott complained of burning and numbness of the lips, mouth, and throat, and which soon extended to the stomach, and was accompanied with vomiting. The matters ejected were first his dinner, and afterwards a frothy mucus; but at no time was any blood brought up. The vomiting was very violent and constant for an hour, and continued more or less until within half an hour of his death. An emetic was swallowed at a quarter past 4 o'clock; and, therefore, the subsequent vomiting may be ascribed, in part at least, to this. His extremities were cold, but his chest was warm; the head was bathed in a cold sweat. His eyes, to use the expression of his neighbour, were "glaring." He complained of violent pain in the head, and trembled excessively. The last symptom might, perhaps, be in part owing to his terror of the mistake he had committed. The lips were blue. His mental faculties were not disordered; on this point I made particular inquiry, and I was assured that he was neither delirious nor sleepy, but was quite conscious until within two minutes of his death. He had no cramp, spasm, or convulsion; the only approach to it was trembling. He frequently put his hand to his throat. Though exceedingly weak, he did not lose his power over the voluntary muscles; for, within a few minutes of his death, he was able, with the assistance of his neighbour, to walk to the water-closet. His bowels were acted on once only after dinner, and that on the occasion just mentioned, which was about an hour after he had taken the emetic and some castor-oil. His breathing was apparently unaffected. On his return from the water-closet he was put to bed, and within a few minutes expired, apparently in a fainting state. Death occurred about four hours after dinner.

Mrs. Prescott was affected in a similar way. She had the same burning and numbness of the lips, mouth, throat, and stomach, and violent vomiting. She experienced a curious sensation of numbness in the hands, arms, and legs; and she lost the power of articulating, so that she was unable to tell the address of her son. Her attempts to speak were attended with unintelligible sounds only. She experienced great muscular debility, and was unable to stand. In this respect her condition differed from that of her husband, who could both stand and walk. She felt stiffness of, and difficulty in moving, her limbs. She had no cramps, spasms, or convulsions. The only approach thereto was the stiffness of the muscles when she attempted to put them in action, as in her attempts to wipe her face. Some of the external senses were disordered; thus, to use her own expression, though her eyes were wide open, her sight was very dim, and surrounding objects were seen indistinctly. The hearing was unaffected. The sensibility of the body was greatly impaired; her face and throat were almost insensible to touch. She felt very giddy, but was neither delirious nor sleepy. For the most part she was conscious, but at times scarcely knew what was passing around her. Her body and extremities were cold. She was frequently pulling her throat about, but she knew not why. Five or six hours after dinner she began to recover, and her natural warmth returned. The remedies employed were an emetic, castor-oil, pediluvia, rum and water, and some "warm" medicine given her by a neighbouring practitioner. The child was similarly but more slightly affected, except that she evinced a slight tendency to sleep. Like the others, she was constantly putting her hands to her throat.¹

Mr. Sherwen² has published a most interesting case of a female poisoned by the alcoholic tincture of the root. About five minutes after swallowing it, she was seized with a pricking and tingling down her arms and fingers, and a painful numbness across the wrists; the tongue and mouth next felt the same, then the legs and feet; and in less than ten minutes her face seemed to her feelings to be swelling, and the throat growing tight. She felt sick, and made many efforts to vomit. Her legs failed, she was almost blind, but was conscious of her plight.

¹ [In *The Times* of Nov. 4, 1842, is a brief report of another case of poisoning by aconite root taken by mistake for horseradish. The patient was sensible, but died. Dr. Geoghegan has published some valuable remarks, on this form of poisoning, in the *Dublin Journal of Medical Science*, vol. xix. page 403.—Ed.]

² *Lancet*, March 25, 1837, p. 13.

When seen by Mr. Sherwen, her eyes were fixed and protruded, with *contracted* pupils; countenance livid; jaws and fauces rigid; arms and hands quite cold and pulseless; the legs and trunk much in the same state; breathing short, imperfect, and laborious; while the heart fluttered feebly. She was sufficiently sensible to tell how the accident occurred. In an attempt to administer an emetic a strong convulsion occurred. Copious vomiting afterwards took place. Five hours after she had taken the poison the pulse was becoming full, only 58 per minute, and intermitting. There was less oppression at the præcordia, and the pupils were larger. She eventually recovered. These cases agree with the one detailed in the *Philosophical Transactions*.¹ Pallas (quoted by Christison) and Degland² have published cases in which violent vomiting, purging, colic, and abdominal tenderness, are said to have been produced by aconite [?].

In comparing the operation of aconite with that of other cerebro-spinants, we observe that its most characteristic topical effect is *numbness and tingling*. Applied to the eye it causes *contraction of the pupil*. When the root or its tincture is swallowed, the most marked symptoms are *numbness and tingling of the parts about the mouth and throat, and of the extremities, vomiting, contracted pupil, and failure of the circulation*. The heart appears to be weakened or paralyzed, and a state approaching to asphyxia is produced. *Convulsion or spasm* is not constantly present, and, when it does take place, is probably a secondary effect arising from the incipient asphyxia. In neither of the cases which I have above detailed, nor in that of Mr. Sherwen, did *stupor* occur. Yet in some recorded instances it has happened. In such it probably depends, as Mr. Sherwen suggests, on the congested condition of the venous system of the brain brought on by the failure of the heart's action, and the consequent accumulation of blood on the right side of the heart.

USES.—A knowledge of the physiological effects of aconite suggests the therapeutical uses of this medicine. A benumber is obviously the physiological remedy for increased sensibility (pain) of the nerves. As a *topical remedy*, aconite is most valuable for the relief of neuralgic and rheumatic pains. In *neuralgia*, no remedy, I believe, will be found equal to it. One application of the tincture produces some amelioration, and, after a few times' use, it frequently happens that the patient is cured. In some cases the benefit seems almost magical. In others, however, the remedy entirely fails to give any permanent relief. Though the pathology of this disease be but little understood, yet we know that the causes of it, and the conditions under which it occurs, are by no means uniform. We are, therefore, easily prepared to believe that while in some cases aconite may prove beneficial, in others it may be useless. I do not think that in any it proves injurious. The causes of neuralgia are, however, usually obscure, and therefore we are in most cases not able to determine *a priori* the probability or the reverse of the beneficial agency of aconite. Hence its employment must be, for the most part, empirical. I have observed that, when it succeeds, it gives more or less relief at the first application. When the disease depends on inflammation, aconite will be found, I think, an unavailing remedy. In a painful affection of the nerves of the face, arising from inflammation of the socket of a tooth, it gave no relief. In *rheumatic pains*, unaccompanied with local swelling or redness, aconite is frequently of great service. In painful conditions of the intercostal and other respiratory muscles, occurring in rheumatic individuals, I have found this remedy most valuable. In one case of *sciatica* it gave partial relief; but in most cases in which I have tried it, it has failed. In *lumbago*, I have not tried it. Dr. Turnbull³ states that a lady was cured of this disease by the aconite ointment. In *acute rheumatism*, its application has not proved successful in my hands; but I have been informed of cases occurring to others in which it has been of great service.

¹ Vol. xxxviii. p. 27.

² See his *Treat. on Pain, and Nerv. Dis.* 1837.

³ *Journ. de Chim. Méd.* iii. 311.

Aconite has been administered *internally* in various diseases, principally on the recommendation of Störck.¹ It has been employed as a narcotic (anodyne) sedative, sudorific, resolvent, and diuretic. The diseases in which it has been employed are *rheumatism, gout, scrofula, phthisis, syphilis, some skin diseases, scirrhus and cancer, intermittents, dropsies, paralysis, epilepsy, amaurosis, uterine affections, and hypertrophy of the heart*. In the large majority of these maladies scarcely any practitioner now believes in its efficacy. Fouquier gave it very extensive trials without obtaining much relief from it, except as a diuretic in *passive dropsies*. In *rheumatism*, it has frequently proved serviceable when combined with a sudorific regimen. I have seen it give great relief in rheumatic pains. In *hypertrophy of the heart* it has been recommended by Dr. Lombard,² on account of its decidedly sedative effects.

ADMINISTRATION.—The only preparations of aconite, whose activity may be relied on, are the *tincture of the root* (made with rectified spirit), the *alcoholic extract*, and Morson's *aconitina*. The *powder* is given in doses of one or two grains, gradually increased, until some effects are produced; but no reliance can be placed on it. When of good quality, it causes numbness and tingling of the lips and tongue a few minutes after its application to these parts.

ANTIDOTES.—See the treatment for poisoning by tobacco. In Mr. Sherwen's case³ great benefit was obtained by the abstraction of ten ounces of blood from the jugular vein.

I. TINCTURA ACONITI, L.; *Tinctura Radicis Aconiti*, D. [*Tinctura Aconiti Radicis*, U. S.]; *Tincture of Monkshood* [*Tincture of Aconite Root*, U. S.].—(Root of Aconite, recently dried and coarsely powdered, ℥xv; Rectified Spirit Oij. Macerate for seven days and strain.)—This formula is very nearly that given by Dr. Turnbull.⁴ Its dose is five drops three times a day. It should be employed with great caution. As an embrocation in neuralgia and rheumatism it is invaluable. It is applied by means of a sponge tooth-brush, or a small piece of sponge attached to the end of a stick. Mr. Curtis, of Camden Town, has suggested to me the use of an aconite plaster, prepared by spreading the soft alcoholic extract (obtained by evaporating the tincture) on adhesive plaster, in neuralgia.—[The *Dublin College* gives the following formula for the tincture: Take of Aconite Root, dried and cut small, ℥x; Rectified Spirit Oj. Macerate for fourteen days, strain, express, and filter.

The following are the directions of the *U. S. Pharm.*: Take of Aconite Root, well bruised, ℔j; Alcohol Oij. Macerate for fourteen days, express strongly, and filter through paper. This tincture may also be prepared by the process of displacement in the following manner: Take of Aconite Root, in powder, a pound; Alcohol a sufficient quantity. Mix the aconite root with a pint of alcohol, and allow the mixture to stand for twenty-four hours; then transfer it to a percolator, and pour alcohol gradually upon it until two pints of filtered liquor are obtained.]

[*Fleming's Tincture of Aconite* is a more powerful preparation. As this has acquired some repute, and has already occasioned several deaths, we subjoin the formula: Take of Root of Aconitum Napellus, carefully dried and finely powdered, ℥xvj, troy; Rectified Spirit f℥xvj. Macerate for four days, then pack into a percolator; add rectified spirit until twenty-four ounces of tincture are obtained. It is beautifully transparent, of the colour of sherry wine, and the taste is slightly bitter. Dose, as an anodyne and antineuralgic, five minims three times daily. The dose should be cautiously increased.⁵ A revenue officer lately lost his life from merely tasting this tincture, under the supposition that it was wine, or a flavoured spirit.—Ed.]

[Mr. Redfern has communicated to the author a case of poisoning by tincture of

¹ *Essay on the Internal Use of Thorn-Apple and Monkshood*, 1763.

² *Treat. on Painf. and Nerv. Dis.* p. 91, 1837.

³ *Brit. and For. Med. Rev.* i. 249.

⁴ *Lancet*, March 25, 1837.

⁵ *An Inquiry into the Medicinal Properties of the Aconitum Napellus*, by A. Fleming, M.D.

aconite, in which the tincture was probably that which is known as Fleming's tincture.—Ed.] "The patient was a young man of the age of 21, who had been suffering from acute articular rheumatism for some days previous to his admission. He took five drops of the tincture, three times a day, for two days, without marked relief. On the third day this dose was increased to six drops, and was ordered to be taken with the same intervals between the doses as formerly. Unfortunately, however, these directions were not adhered to, for the first dose of six drops was administered at nine o'clock A. M., and the second at eleven. At twelve o'clock, the hour of visit of the physicians, the man was found in a state of extreme restlessness, and complaining of great pain in various parts of his body. To use his own expression, 'he felt as though his skin were too tight for his body.' In imploring relief, he described his sensations as most intolerable. At this time there was much frothing at the mouth, with violent retching at intervals. The surface of the body was cold, and bathed in profuse perspiration, which ran down his face in streams. The pulse, though at first 150 in the minute, fell to between 50 and 60 in a few minutes, and was so small and compressible as scarcely to be felt at the wrist. Brandy and water was ordered to be given internally in repeated doses, and warmth was also applied to various parts of the surface. In six hours afterwards the man had almost wholly recovered, and had lost all his rheumatic pains, which never returned. It may be stated that in this case, as well as in three others in which the same tincture was administered, the dose of four or five drops almost invariably produced decided effects, viz. tingling and numbness of the limbs, and very generally relief of the pain."

2. [TINCTURA ACONITI FOLIORUM, U. S.; *Tincture of Aconite Leaves*.—Take of Aconite Leaves ζ iv; Diluted Alcohol Oij. Macerate for fourteen days, express, and filter through paper. This tincture may also be prepared by thoroughly moistening the aconite leaves in powder with diluted alcohol, allowing the mixture to stand for twenty-four hours, then transferring it to a percolator, and gradually pouring upon it diluted alcohol until two pints of filtered liquor are obtained. This preparation is weaker than the preceding.—The dose is gr. x—xx.]

3. EXTRACTUM ALCOHOLICUM ACONITI [*Extractum Aconiti Alcoholicum*, U. S.]; *Alcoholic Extract of Monkshood*.—(Prepared by distilling the spirit from the tincture, until the consistence of an extract has been obtained.)—It has been employed internally in doses of one-sixth of a grain every three hours. It should be given in the form of pills (*pilulæ aconiti*) made of liquorice powder and syrup. It may be also employed externally in the form of ointment (*unguentum aconiti*), composed of one part of the extract and two parts of lard (Turnbull), or spread on adhesive plaster.

[The formula of the *U. S. Pharm.* is as follows: Take of Aconite Leaves, in coarse powder, lbj; Diluted Alcohol Oiv. Moisten the powder with half a pint of the diluted alcohol, and, having allowed the mixture to stand for twenty-four hours, transfer it to a percolator, and add gradually the remainder of the diluted alcohol. When the last portion of this has penetrated the powder, pour in sufficient water from time to time to keep the mass covered. Cease to filter when the liquor which passes begins to produce a precipitate as it falls in that which has already passed. Distil off the alcohol from the filtered liquor, and evaporate the residue to the proper consistence.]

4. EXTRACTUM ACONITI, L. E. [U. S.]—(Fresh Aconite Leaves lbj. Bruise the leaves in a stone mortar; then press out the juice, and evaporate it, unstrained, to a proper consistence, *L.*—"Take of the leaves of monkshood, fresh, any sufficient quantity; beat them into a pulp; express the juice; subject the residuum to percolation with rectified spirits, so long as the spirit passes materially coloured; unite the expressed juice and the spirituous infusion; filter; distil off the spirit, and evaporate the residuum in the vapour-bath, taking care to remove the vessel from the heat so soon as the due degree of consistence shall be attained," *E.*)—An uncertain

preparation. When of good quality it causes numbness and tingling, within a few minutes after its application, in the mouth and lips. The tincture or alcoholic extract are, in my opinion, greatly to be preferred to this variable preparation.—Dose, one or two grains at the commencement, and to be gradually increased until some obvious effect is produced.

5. **ACONITINA**; *Aconitine*.—The following directions for making this alkaloid were given in the former *London Pharmacopœia*. The alkaloid is now, however, altogether excluded:—

“Root of Aconite, dried and bruised, ℞ij; Rectified Spirit, Cong. iij; Diluted Sulphuric Acid; Solution of Ammonia; Purified Animal Charcoal, each as much as may be sufficient. Boil the Aconite with a gallon of the Spirit for an hour, in a retort with a receiver adapted to it. Pour off the liquor, and again boil the residue with another gallon of the Spirit, and the Spirit recently distilled, and pour off the liquor also. Let the same be done a third time. Then press the Aconite, and, all the liquors being mixed and strained, let the Spirit distil. Evaporate what remains to the proper consistence of an extract. Dissolve this in water, and strain. Evaporate the liquor with a gentle heat, that it may thicken like a syrup. To this add of dilute Sulphuric Acid, mixed with distilled water, as much as may be sufficient to dissolve the Aconitina. Then drop in solution of Ammonia, and dissolve the Aconitina precipitated in diluted Sulphuric Acid and water, mixed as before. Afterwards mix in the Animal Charcoal, frequently shaking them during a quarter of an hour. Lastly, strain, and solution of Ammonia being again dropped in, that the Aconitina may be precipitated, wash and dry it.”

Aconitina exists in the plant in combination with a vegetable acid (aconitic acid?). Alcohol extracts this salt with some other matters. The alcoholic extract yields this salt to the water, and on the addition of sulphuric acid a sulphate of aconitina is formed, which is decomposed by ammonia, and the aconitina precipitated. It is then again dissolved by sulphuric acid, the solution decolorized by charcoal, and the aconitina again precipitated by ammonia. As prepared by Mr. Morson, this substance presents the following properties: It is a white, odourless solid, either dull and amorphous or somewhat sparkling, and apparently crystalline. As it is usually described as being uncrystallizable, I have carefully examined a supposed crystalline mass with the microscope, but I could not detect distinct crystals. The fragments appeared like thin plates of chlorate of potash, and, though they varied greatly in shape, the triangular form seemed predominant. Heated in a tube, aconitina readily fuses, and forms a pale amber-coloured liquid; and at a higher temperature it is decomposed. It is not volatile. Heated on platinum foil, over a spirit-lamp, it is speedily and entirely dissipated. It is soluble in alcohol, ether, and the acids. From its acid solution it is precipitated by ammonia. A minute portion of it mixed with lard, and applied to the eye, causes *contraction* of the pupil, as I have repeatedly seen. Geiger and Hesse state, that the aconita which they obtained produces *dilatation* of the pupil. Mr. Morson's aconitina is so powerful that one-fiftieth of a grain has endangered the life of an individual. It is the most virulent poison known, not excepting hydrocyanic acid.

The following notes were formerly appended to it in the *London Pharmacopœia*:—

“An alkali prepared from the leaves and root of aconite. It is very soluble in sulphuric ether, less in alcohol, and very slightly in water. It is totally consumed in the fire, no salt of lime remaining. This substance, possessing strong power, is not to be rashly employed.”

A spurious aconitina is found in the shops. It is imported from France, and bears the stamp and label of a celebrated French chemical firm. Its colour is grayish-yellow. It is inert, or nearly so; at least I have taken one grain of it without perceiving the least effect of it on the tongue or otherwise. It is not completely soluble either in ether or alcohol. When burnt on platinum foil, it leaves a calcareous residue. The only genuine aconitina which I have met with is that manufactured by Mr. Morson, of Southampton Row; and Dr. Turnbull informs me that he has found none other to possess any medicinal value. Mr. Skey also found this to be the case.¹

¹ See *Lond. Med. Gaz.* xix. 185.

The effects of this alkaloid are similar to those of aconite root, but, of course, much more powerful. If the ointment, or an alcoholic solution of this substance, be rubbed on the skin, it causes intense heat, tingling, and numbness, which continue for more than twelve or eighteen hours. A minute portion of an ointment, composed of a grain of the alkaloid to two drachms of lard, applied to the eye, causes almost insupportable heat and tingling, and contraction of the pupil. This last effect was shown me by Dr. Turnbull, in some amaurotic cases of several years' standing; the pupils underwent no change when the eye was exposed to strong daylight. In very minute doses it has caused heat and tingling upon the surface of the body, and sometimes diuresis; but it cannot be administered internally with safety. In one case (an elderly lady), one-fiftieth of a grain had nearly proved fatal. Satisfied that great insecurity attends its internal use, Dr. Turnbull tells me he has long since ceased to employ it in this way, as the slightest inattention on the part of the dispenser may be attended with fatal results. The enormous cost (3s. 6d. per grain!) of Morson's aconitina limits its use. I believe that the alcoholic tincture is a perfect substitute for it; and the experience of others confirms my own observation. Of the great efficacy of aconitina in neuralgic and rheumatic affections, no one can entertain any doubt who has submitted the remedy to trial.¹ The following are Dr. Turnbull's formulæ for using aconitina externally:—

1. *Unguentum Aconitinae; Aconitine Ointment.* (Aconitine gr. xvj; Olive Oil ℥ss; Lard ℥j. Mix.)—It is employed by friction with the finger during several minutes.

[Dr. Fleming recommends for external use the following preparation: Take of Aconitina gr. xvj; Spir. Rectif. ℥ xvj; Lard ℥j. Rub together and make an Ointment. One or more drachms of the tincture may, according to Dr. Fleming, form an excellent substitute for the ointment in external use; but, when there is any abrasion of the skin, the use of any of these preparations is attended with danger.—Ed.]

2. *Solutio Aconitinae; Aconitine Embrocation.* (Aconitine, gr viij; Rectified Spirit ℥ij. Dissolve.)—Used by friction-sponge (as a sponge tooth brush). Care must be taken not to employ it where the skin is abraded.

[348. CIMICIFUGA RACEMOSA.—BLACK SNAKEROOT.

Sex. Syst. Polyandria, Monogynia.
(Cimicifuga, U. S.—The Root.)

BOTANY. Gen. Char.—*Sepals* four to five. *Petals* (or rather staminodia) three to five, concave or unguiculate, sometimes by abortion few or none. *Stamens* numerous; *anthers* retrorse. *Style* short; *stigma* simple. *Carpels* one to eight, follicular, many-seeded. *Perennial herbs.* *Leaves* two to three ternately divided, segments incisely serrate. *Flowers* in virgate racemes, white. (Torrey and Gray, *Flor. of North America*).

Sp. Char.—*Racemes* very long; *leaflets* ovate oblong, incisely toothed; *staminodia* slender, two-forked (*Ell. Sk.* ii. p. 16). *Root* thick and knotted, with long fibres. *Stem* three to eight feet high, glabrous, furrowed, leafy near the middle. *Leaves* three, ternate; *leaflets* two to three inches long. *Racemes* branching, six to twelve inches long; *pedicels* three to four lines in length, bracteate. *Flowers* very fetid. *Sepals* caducous, greenish-white, concave. *Staminodia* four to eight. *Carpels* globose ovate, glabrous. *Seeds* seven to eight, compressed and angular. De Candolle states that the flowers are sometimes digynous, but we have never observed more than a single ovary in a flower (T. and G. *op. cit.* vol. i. p. 36).

Hab.—This plant is known by the names of *Tall Snakeroot*, *Black Snakeroot*, and *Rich Weed*. Its size and the long white racemes of flowers make it a conspicuous ornament of our woods.

It is abundant in open woods and on hillsides throughout the United States, from Canada to Florida. It flowers in June and July.

The root as found in the shops is composed of a rough tuberculated head and

¹ See Dr. Turnbull, *op. supra cit.*; Mr. Skey, *Lond. Med. Gaz.* vol. xix. p. 151.

numerous radicles, seven inches long, of a black colour externally, white internally. The radicles are extremely brittle and liable to be separated. The odour is feeble and earthy; the taste bitter and astringent, leaving an impression of acrimony upon the palate. The sensible properties depend upon the time when the root is collected, and the mode of drying and preserving it. It should be collected late in the summer, or in the autumn.

COMPOSITION.—An analysis made by Mr. Tilghman, resulted in the detection of the following substances: *Fatty matter, gum, starch, resin, tannin, wax, gallic acid, sugar, oil, black colouring matter, green colouring matter, lignin, and salts of lime, iron, magnesia, and potassa.* The experiments, however, led to no decided conclusion as to the nature of the active principle. "The peculiar bitterness and nauseating properties of the plant seemed more fully developed in the ethereal extract than in any other form." (*Am. Journ. of Pharm.* vol. vi. p. 20.)

MEDICAL PROPERTIES.—Considerable variance of opinion has existed with regard to the influence this medicine is capable of exerting upon the animal economy. By the late Professor B. S. Barton, it is stated to be astringent; he farther informs us that "in a putrid sore throat, which prevailed many years ago in Jersey, a strong decoction of the roots was used with great benefit as a gargle." Dr. Mears, who tried the medicine upon himself, reports a decided impression upon the brain, evinced by a distressing pain in the head and giddiness; it also increased the force and fullness of the pulse, and produced a flushed condition of the face; uneasiness of the stomach, and violent efforts to vomit were also among the symptoms experienced by him (*Phil. Monthly Journ. of Med. and Surg.* Sept. 1827). Dr. Garden had previously mentioned the tendency to affect the brain, which is compared to digitalis; this writer also states that it operates powerfully upon the secreting organs and absorbents, and that, when exhibited in large doses, nausea, vertigo, anxiety, great restlessness, pains in the extremities, &c. were occasioned (Togno and Durand in *Translation of Manual of Edwards and Vavasseur*, p. 339). Dr. Chapman, speaking of this article, informs us that he has never been able to discover the astringent action in any great degree, but that it is "expectorant, narcotic, antispasmodic, diaphoretic, and in large doses emetic. Given so as to affect sensibly the system, we find, first, some nausea, followed by greater freedom of expectoration, and more or less relaxation of surface, with slight nervous tremors and vertiginous affection. The pulse during this state is considerably lowered, and is apt to remain so for some time." (*General Therapeutics.*) In addition to these views with regard to the medicine, it may be farther stated that it has been regarded as having a control over the uterus. The diseases to which it has been applied are as diversified as the effects just referred to. Dr. Garden thought highly of it in phthisis pulmonalis, but that the diagnosis was strictly accurate cannot be assumed; the probability is that it proved beneficial rather in simulative cases. It is not difficult to understand how service can be obtained in humoral asthma, catarrh, and analogous affections, in which it has been recommended, by a stimulating impression upon the mucous membrane, and the promotion of healthy expectoration. The evidence of a favourable action in rheumatism is of a decided character. In the wards of Professor Dunglison, at the Philadelphia Hospital, it has been used with benefit. He informs us that "when pushed so as to produce catharsis, and even slight narcosis, it certainly appeared to be of service in the acute forms." (*General Therapeutics and Mat. Med.* vol. ii. p. 194.) In the chronic form, we should expect much more to be accomplished by it.

In chorea, it is highly spoken of. Several years ago, Dr. Young (*American Journ. of Med. Science*, vol. ix.) brought cimicifuga before the profession as a remedy in this disease, and his results have to a certain extent been verified by other physicians. Professor Wood found that a case under his care yielded to it, after the failure of purgatives and metallic tonics. The latter author also exhibited it satisfactorily in a case of convulsions occurring periodically, and connected

with uterine disorder. In these cases, however, its precise mode of operation is obscure.

Black snakeroot may be given in powder, in doses of half a drachm, two or three times daily.

The decoction is made by boiling for a few minutes $\bar{3}j$ of the contused root in Oj of water. The dose is $\bar{3}j$ or $\bar{3}ij$, two or three times daily. This is a better form than the powder.

The tincture may be made with $\bar{3}iv$ of the bruised root, and Oj of Diluted Alcohol. The dose is gtt. xx to $f\bar{3}j$, two or three times daily. This preparation is adapted to rheumatic cases.

349. COPTIS TRIFOLIATA, *Salzb.* — GOLDEN THREAD.

Sex. Syst. Polyandria, Polygynia.
(*Coptis*, U. S.—The Root.)

BOTANY. *Gen. Char.*—*Sepals* 5 to 6, petaloid, deciduous. *Petals* 5 to 6. *Stamens* 15 to 25. *Follicles* 5 to 10, on long stipes, somewhat stellately diverging, membranaceous, ovate oblong, pointed with the style, 4- to 8-seeded. *Herbs* with radical, divided, subcoriaceous leaves, and very slender, extensively creeping roots.

Sp. Char.—*Leaves* 3-foliolate; *leaflets* cuneiform-obovate, crenately and mucronately toothed, obscurely 3-lobed; *scape* 1-flowered. *Roots* consisting of long bright yellow fibres, intensely bitter. *Leaves* evergreen; *leaflets* about an inch long. *Scape* slender, three to five inches high. *Sepals* 5 to 7, oblong, obtuse, white. *Petals* much shorter than the sepals, yellow at base. *Carpels* acuminate with the persistent style. *Seeds* oblong, black, and shining; *raphe* very indistinct. (Torrey and Gray, *Flor. of North Amer.* i. 28.)

Hab.—This plant is found in mountain bogs, from Greenland and Labrador to Pennsylvania.

The root, which is the official portion, is brought into the market in the dried state. It is filamentous, threadlike, and of a deep golden-yellow colour, very brittle. The fibres are usually commingled with the leaves of the plant. By the Shakers, the whole plant appears to be compressed into the square form. It has no odour; the taste is bitter without astringency.

This article of the *Materia Medica* is ranked among the pure bitters, as its medicinal properties appear solely to depend upon a bitter extractive matter. It may be employed as a tonic under circumstances calling for the exhibition of such remedies, and may be ranked with *sabattia* and that class of articles, acting as a stonachic, improving the appetite, &c. It is not as powerful as gentian, quassia, and other pure bitters. In the treatment of aphthous sore mouths of children, it has been used as an application in New England.

The mode of employment may be in the form of *infusion*, which may be made in the proportion of $\bar{3}ss$ to Oj of Water.—Dose, $\bar{3}j$ to $\bar{3}ij$.

A *tincture* is made by macerating $\bar{3}j$ of the Root in Oj of Alcohol.—Dose, $f\bar{3}j$ to $f\bar{5}ij$.

The dose of the powder is gr. xx to $\bar{3}j$. An extract might be prepared.

OTHER MEDICINAL OR POISONOUS RANUNCULACEÆ.

1. The leaves of *HELLBORUS FORTIDUS* are emetic and purgative. They have been employed as a vermifuge against the large round worm (*Ascaris lumbricoides*).

2. *HELLBORUS VIRIDIS* possesses similar properties.

3. *ACONITUM FEROX* is, perhaps, the most violent of the ranunculaceous poisons. It is a Nepaul plant, and constitutes the *Bish* or *Bish* poison of that country. Several years since, I undertook, at the request of Dr. Wallich, to examine the effects of this plant on animals. My

experiments were made with plants which had been ten years in Dr. Wallich's possession, and which, therefore, had doubtless lost part of their activity; yet their effects were most energetic (Wallich's *Plante Asiatica rariores*; and the *Ebinb. Journ. of Nat. and Geogr. Science*, July, 1830, p. 235), but of the same nature as those of *Aconitum Napellus*.

The *DELPHINUM CONSOLIDA* is officinal in the *U. S. Pharmacopœia*.

ORDER LXXXIX. PODOPHYLLÆ.—*Lind.*

ESSENTIAL CHARACTER.—*Sepals* 3 to 4, deciduous or persistent. *Petals* in 2, 3, or more rows, each of which is equal in number to the sepals. *Stamens* hypogynous, 12 to 18, arranged in two, three, or more rows; *anthers* linear, oval, turned inwards. *Stigma* somewhat peltate. *Fruit* succulent or capsular, 1-celled. *Seeds* indefinite; *embryo* small.

Herbs.—*Leaves* broad-lobed. *Flowers* radical, solitary, white (Beck).

PODOPHYLLUM PELTATUM, *Linn.*—MAY-APPLE.

Sex. Syst. Polyandria, Monogynia.
(*Podophyllum*, *U. S.*—The Root.)

BOTANY. Gen. Char.—*Sepals* 3. *Petals* 6 to 9. *Stamens* 12 to 18. *Stigma* large, subsessile, peltate. *Berry* somewhat fleshy, not dehiscent. *Seeds* many.

Sp. Char.—*Stem* erect, 2-leaved, 1-flowered; *fruit* ovate.

The common names by which this plant are known are *May-Apple* and *Hog-Apple*. It has a large, horizontal, creeping, perennial root; the stem is from eight to twelve inches high, naked, with sheathing stipules at the base, dichotomous at the summit, dividing into two petioles two to four inches in length, each bearing a peltate leaf. The leaf is large, hanging, divided into five to seven lobes, cuneate, oblong, dentate, and often bifid at the apex. Flower solitary in the axil of the petioles; peduncle recurved, white. The fruit is an oval berry, an inch and a half long, smooth, yellowish when mature, succulent, and pulpy, having a mawkish sweet taste, edible, but not agreeable.

Hab.—*May-Apple* is common throughout the United States, in moist woods and shady situations along the banks of rivulets. It flowers in May.

In the dried state, the root is found in pieces several inches in length, the thickness of quills; some of them are knotty and swollen at intervals (jointed), and beset with the remains of the radicals, somewhat corrugated and wrinkled; externally the colour is deep brown or blackish; internally dingy white. The fracture is short. The entire root has little odour; the taste is sweetish, bitter, and somewhat acrid.

The powder is grayish; it has somewhat the odour of *ipecauanha*.

CHEMICAL COMPOSITION.—*Podophyllum* has been examined with the view to determine its constituents. Dr. E. Staples found it to contain resin, starch, and a peculiar vegetable substance crystallizable in white silky tufts. (Togno and Durand, *Translation of Edwards and Vavasour's Manual*.) Mr. Hodgson obtained from it also a peculiar principle. To this the name *Podophylline* has been given.

PODOPHYLLINE. (*Hodgson*.)—When dry, this substance is in pale brown scales of considerable lustre; is easily pulverized, is unalterable in the air, and has a strong bitter taste. It is copiously soluble in strong alcohol, and much more so in boiling than in cold water, the aqueous solution retaining when cold about a grain to the ounce. It is soluble to some extent in sulphuric ether. It is readily separated from water by muriatic acid, is coloured red by nitric acid, and becomes first olive or green, and subsequently purple by sulphuric acid. Exposed to heat it fuses, blackens, and dissipates in black smoke. (*Journ. of Phil. Col. of Pharm.* vol. iii. 275.) It has not as yet been determined whether this or the resin is the active principle.

MEDICAL PROPERTIES.—*May-Apple* root is an active cathartic, resembling jalap in its action upon the bowels. It stimulates the muciferous glands and exhalants, and occasions watery discharges; in too large quantities, giving rise to tormina. It is highly spoken of by many eminent writers, who have tested its efficacy. Dr. Eberle (*Mat. Med.*) says he very frequently gave it instead of jalap, and always found it active and safe in its operation. Dr. Burgon regarded it as slower in its

operation than the article mentioned, but as leaving the bowels longer in a lax and soluble condition. (*Med. Recorder*, iii. 332.) The cases to which it is adapted are of an inflammatory character, especially at the commencement, where brisk purging is required. In bilious fever and intermittents, it has been much used throughout the country. Combination with calomel or cremor tartar increases its certainty, and at the same time moderates its drastic action. In overdoses, it occasions tormina and tenesmus, and hypercatharsis with muco-bloody discharges; it also nauseates the stomach and induces emesis.

The leaves of the plant and young shoots are said to be highly poisonous.

The dose of the powdered root is from ten to twenty grains.

EXTRACTUM PODOPHYLLI, U. S. This preparation is made in the same way as the Extract of Jalap. It has the advantage over the crude medicine of being given in smaller bulk, and may be substituted for it, or for the extract of Jalap.—Dose, ten to fifteen grs.]

ORDER XC. JUGLANDEÆ.—*De Cand., Lind.*

ESSENTIAL CHARACTER.—*Flowers* diclinous. *Sterile flowers* in an ament. *Perianth* scaly, oblique, irregularly lobed. *Stamens* inserted on the receptacle, indefinite (three to thirty-six); *filaments* short, distinct; *anthers* thick, two-celled, bursting longitudinally. *Fertile flowers* with a single or double perianth, the outer four-parted, the inner (when present) of four pieces. *Ovary* inferior, one-celled; *ovule* solitary, erect; *styles* one to two, very short or none; *stigmas* large, either two and lacerated or discoid and four-lobed. *Fruit* drupaceous, one-celled, with four imperfect partitions. *Seed* four-lobed; *embryo* large; *albumen* none; *cotyledons* fleshy, two-lobed, wrinkled; *radicle* superior.

Trees.—*Leaves* alternate, unequally pinnate (Beck).

JUGLANS CINEREA, Linn.—BUTTERNUT.

Sex. Syst. Monœcia, Polyandria.

(*Juglans*, U. S.—The inner Bark of the Root.)

BOTANY. Gen. Char.—Monœcious. *Sterile flowers*; ament imbricate, scales mostly five-parted. *Perianth* five to six-parted. *Stamens* eighteen to thirty-six. *Fertile flowers*; *perianth* double, each four-parted. *Styles* one or two. *Drupe* partly spongy; *nut* rugose and irregularly furrowed.

Sp. Char.—*Leaves* pinnate; *leaflets* numerous, lanceolate; serrate rounded at the base, soft pubescent beneath; *petioles* villous; *fruit* oblong ovate, with a terminal projection, viscid and hairy, on a long peduncle; not oblong, acuminate, conspicuously sculptured (Beck, *Botany of North. and Mid. States*, 335).

This plant is the *J. cathartica* of Michaux. The common names by which it is known are *White Walnut* and *Butternut*. In some situations it is a large tree, with numerous branches and a smooth cinereous bark. The fruit is less rank and strong than the black walnut, but by age becomes rancid and unpleasant; it abounds in oil. Early in the spring, if the bark be pierced, there exudes a saccharine juice.

Hab.—Butternut abounds in Canada and the northern and middle sections of the United States, in rich bottom lands and along streams. It flowers in May, and the fruit ripens in September and October.

The inner bark, when first separated from the tree, is of a pure white colour, but soon begins to change, and by the time it becomes dry, is of a deep brown colour. It comes into the market in pieces, which have a fibrous fracture. If the epidermis has not been removed, they are smooth externally. The inner bark is the officinal portion; that from the root is most active. When in the fresh state a rubefacient effect is stated to be made upon the skin. The period for collecting it is in May. The odour is feeble, and the taste is bitter and pungent.

COMPOSITION.—Mr. S. Wetherill found in this bark *fixed oil*, *resin*, *saccharine matter*, *lime*, and *potassa*, a *peculiar principle* (*extractive*?), and *tannin*. (*Unpub-*

lished Essay). Dr. Bigelow did not find tannin by the action of gelatine. Mr. Wetherill, however, found a precipitate afforded by standing.

EXTRACTUM JUGLANDIS, U. S. *Extract of Butternut.*—This is the officinal preparation, which is mostly used. It is made by displacement from the bark, in coarse powder, by means of water, and evaporating the solution. It is of a black colour, having a caramel-like odour, and bitter astringent taste. It is a pretty certain mild cathartic, operating without pain or irritation, and evacuating the alimentary canal without depletion. For a long time it has been employed as a purgative throughout the country, and is one of the articles to which Dr. Rush directed attention. Dr. Barton, in his *Collections*, also speaks highly of it. By all the subsequent writers upon *Materia Medica*, it is noticed as one of the most valuable of our indigenous productions. The cases to which it is adapted are, fevers, with disturbance of the liver and congestion of the abdominal organs, habitual costiveness, and dysenteric affections. By combination with a mercurial, as blue pill or calomel, its powers are increased. The dose is 10 to 30 grains, in pill. The extract which is brought in from the country, and made by decoction, is objectionable, from the little care taken in its preparation.

A decoction is sometimes used, but the taste and the quantity required render it inferior to the officinal preparation.

ORDER XCI. GERANIACEÆ, *De Cand., Linn.*

ESSENTIAL CHARACTER.—*Sepals* five, persistent, more or less unequal, with an imbricate aestivation; sometimes saccate or spurred at the base. *Petals* five (or by abortion four, rarely none), unguiculate. *Stamens* usually monadelphous, hypogynous, twice or thrice as many as the petals. *Ovary* composed of five pieces, placed round an elevated axis, each one-celled, one-seeded; *ovules* pendulous; *styles* five, cohering round the axis. *Fruit* formed of five carpels cohering round the axis, having a membranous pericarp and terminated by an indurated style, which finally twists and carries the pericarp, along with it. *Seeds* solitary, pendulous; *albumen* none. *Embryo* curved; *radicle* pointing to the base of the cell; *cotyledons* foliaceous, convolute, and plaited.

Herbs or shrubs.—*Stems* tumid and separate at the joints. *Leaves* either opposite or alternate (Beck).

GERANIUM MACULATUM, *Linn.*—SPOTTED GERANIUM.

Sex. Syst. Monadelphia, Decandria.

(*Geranium, U. S.*—The Root.)

BOTANY. Gen. Char.—*Sepals* five, unequal. *Petals* five, equal. *Stamens* alternate, fertile ones larger, and with nectariferous scales at the base. *Carpels* with long awns, at length separating elastically from the summit to the base; awns smooth internally (Beck).

Sp. Char.—*Root* perennial, irregularly gibbous and horizontal, brownish, mottled with green externally, and greenish-white internally. From the root spring a number of radicle leaves and one or more stems; these are erect and terete, of a green colour, and furnished with reflexed hairs. At the height of six, eight, or ten inches from the ground, the stem becomes forked; and at the point of division is furnished with two large petiolate leaves, which are generally reflexed. *Leaves* on the upper part of the stem either with very short petioles or sessile. The peduncles arise from the dichotomous divisions of the stem, and support two flowers on short pedicles. The calyx consists of five oval, lanceolate, ribbed, cuspidate segments, plumosely ciliate at their outer margin, and membranous on the other; sometimes three of the segments only are ciliate. *Petals* five, obovate, not emarginate. *Stamens* ten, furnished at the base with glands, and terminated by oblong, convex, deciduous anthers of a purple colour. Germ ovate. *Style* persistent, the length of the stamens at first, but afterwards elongated. *Stigmas* five. *Capsule* containing five seeds, which,

when mature, becomes detached by the elasticity of the awns (Griffith, *Am. Journ. of Pharm.* vol. iv. p. 90).

The common names for this plant are *Crowfoot* and *Crane's bill*. It is a handsome plant, of which there are several varieties, varying in the form of the foliage and colour of the flower; these depend upon soil and situation. The most usual colour of the flower is lilac.

Hab.—The *geranium maculatum* is common throughout the United States, growing in hedges and borders of damp woods. It flowers in May.

In the dried state, the root presents itself in pieces an inch or two in length, and three to four lines thick, corrugated, wrinkled, and rough, with a few fibres attached; externally the colour is brown, internally dingy white. It breaks with a short fracture. The odour is feeble, the taste astringent and bitter. The powder is gray.

CHEMICAL COMPOSITION.—From Dr. Staples's analysis, it appears that *Geranium* contains *gallic acid* in large quantity, *tannin*, *mucilage* in a small proportion, *amadin*, *red colouring matter*, principally in the external covering of the root, *resin* in small quantity, and a crystallizable vegetable substance (*Journ. of Phil. Col. Pharm.* i. 171).

MEDICAL PROPERTIES.—*Geranium* is an astringent of some power, and the therapeutical uses to which it has been put, are based upon this action. It early attracted the attention of those who were inquiring into the remedial value of indigenous plants, and has been uniformly spoken of by all subsequent writers upon the same subject. In its effects and range of application it differs not from others of the same class; more powerful than some, and less so than others. In hemorrhages and bowel affections, under the appropriate pathological conditions calling for their exhibition, *geranium* may be administered with advantage. As a local application in chronic inflammation, ulceration, &c., benefit may equally be expected from it, as for instance in the form of a gargle where the throat is involved, and in that of injection in gonorrhœa and leucorrhœa. The forms of exhibition are varied.

If the powder be used, the dose is from 10 to 30 grains. The *decoction* is made by boiling an ounce of the bruised root for a few minutes in a pint of water. Dose, ℥ʒj to ℥ʒij. An *infusion* may be prepared in the same manner. A *tincture* and an *extract* may be prepared from it.

ORDER XCII. CORNACEÆ, *De Cand.*—THE DOGWOOD TRIBE.

ESSENTIAL CHARACTER.—*Calyx* adherent to the ovary; *limb* four to five-toothed, minute or four to five-lobed, with a valvate aestivation. *Petals* distinct, equal in number to the teeth of the calyx, and inserted alternately with them into the margin of the hypogynous disk, broad at the base; *aestivation* valvate. *Stamens* four to five, inserted with the petals, and alternate with them; *anthers* introrse, mostly cordate. *Ovary* one-celled, with solitary pendulous ovule in each cell; *styles* single. *Drupe* baccate with a one to two-celled nucleus, crowned with the remains of the calyx. *Seeds* anatropous. *Embryo* nearly the length of the fleshy albumen; the radicle shorter than the oblong cotyledons.

Trees or shrubs, rarely herbaceous, with a bitter bark. *Leaves* opposite (or rarely somewhat alternate), mostly entire, exstipulate, pinnately veined. *Flowers* cymose; the inflorescence sometimes capitate and involucrate, rarely diocious. *Hairs* centrally affixed. (Torrey and Gray.)

CORNUS FLORIDA, *Lin.*—DOGWOOD.

Sex. Syst. Pentandria, Monogynia.
(*Cornus Florida*, U. S.—The Bark.)

BOTANY. Gen. Char.—*Limb* of the *calyx* four-toothed, minute. *Petals* oblong, spreading. *Filaments* filiform. *Style* subclavate; *stigma* obtuse or capitate. *Drupe* not connate into a syncarpium. *Leaves* entire, minutely scabrous, with the appressed bicuspitate hairs. *Flowers* white, rarely yellow. (T. and G.)

Sp. Char.—*Leaves* of the involucre four, obovate, or with a callous notch at the apex; drupes oval; *leaves* ovate acuminate.

Fig. 421.

*Cornus Florida.*

Dogwood is a small tree, varying in height from 15 to 20 or 30 feet, rarely attaining more, with an irregular growth. The branches are numerous and expanded. It is a conspicuous ornament of the forest in the spring of the year, when the large leafy involucre are expanded and resemble showy white flowers diffused in every direction. Within the involucre are the flowers, in clusters, rather inconspicuous, greenish-yellow. The leaves are developed after the flowers. In the fall of the year they become deep red. The drupe or berry is bright red when mature.

Hab.—This plant is common throughout the United States, growing in open woods in moist soil from Canada to Florida and Louisiana. Its growth is modified by the climate; to the south it attains its extreme size. In the northern sections of the country the time of flowering is May, but in the southern it is during March and April.

The bark of the tree constitutes the officinal portion; that from the root is regarded as most efficacious. It is brought into the market in pieces slightly quilled, several inches long, half an inch to two broad, and two or three lines thick, of a grayish-red colour, breaking with a short fracture, and exposing lighter-coloured surfaces, mottled with red and white. The pieces from the root are rougher externally and more frequently destitute of epidermis. The odour is feeble; the taste bitter and astringent, with a little aroma. In the fresh state the taste is a little acid.

CHEMICAL COMPOSITION.—Dr. Walker, who analyzed the bark, announced that it contained *gum, resin, tannin, and gallic acid*. To these have since been added, by Mr. Cockburn (*Am. Journ. of Pharm.* vol. vii. p. 114), *oil, fatty matter, a crystalline substance, bitter extractive, wax, red colouring matter, lignin and potassa, iron, lime, and magnesia*. From his experiments, it appeared that the bitterness alone resided in the extractive matter, from which the crystalline substance was obtained.

A principle, to which the name *cornine* was given, was several years since announced, but has not been subsequently obtained by analysis.

MEDICAL PROPERTIES.—The article under consideration is a decided roborant, and hence has been placed by systematic writers in the list of tonics. By Dr. Walker it was found to augment the force and frequency of the pulse and to increase the heat of the body. It also has an astringent effect. An analogy has been supposed to exist between its mode of operation and that of cinchona, but it does not seem to be possessed of more than a general invigorating effect. As a substitute for bark or its preparations, dogwood has been employed in the treatment of intermittent fever, and in domestic practice is much used. Advantage has also been derived from it in the hands of regular practitioners. The objection to its use, however, is the large doses required, which disorder the stomach. As a mere tonic it is applicable to the same range of cases as other of its congeners. The recent bark is apt to disagree with the stomach and produce pain.

Dogwood bark may be given in powder, infusion, decoction, or extract. The dose in substance is ℥j to ℥j.

DECOCTUM CORNUS FLORIDÆ, U. S.; *Decoction of Dogwood Bark.*—(Take of Dogwood, bruised, an ounce; Water a pint. Boil for ten minutes in a covered vessel, and strain the liquor while hot.)—Dose, f℥j to ℥ij.

Two other species of CORNUS, the *C. CIRCINATA* and *C. SERICEA* have been placed in the secondary list of the *United States Pharmacopœia*. Both of these are shrubs. The bark is in the quilled form. The medical properties are nearly similar to those of the *C. florida*. They are employed in the same way and for the same purposes.—J. C.]

II. The Animal Sub-kingdom.

Division I. Invertebrata.—Invertebral Animals.

CHARACTERS—Animals destitute of a *vertebral column* and an *internal skeleton*. *Skin* sometimes ossified, and thereby forming an *external skeleton*. *Nervous system* not always evident.

SUBDIVISION I. ACRITA, Macleay.

Nervous system indistinct, diffused, or molecular (Owen).¹

Class I. Poriphera, Grant.—Poripherous Animals.

CHARACTERS.—Simple, soft, aquatic *animals*, with a fibrous *axis*, without perceptible *nerves* or *muscular filaments*, or *organs of sense*, or any *circulating* or *glandular organs*. Their body is composed of a soft gelatinous *flesh*, traversed internally with numerous ramose, anastomosing canals, which commence from superficial minute *pores*, and terminate in larger, open *vents*.²

350. SPONGIA OFFICINALIS, Linn. E.—THE OFFICINAL SPONGE.

(Sponge, E.)

HISTORY.—Aristotle³ was acquainted with the sponges, and notices the popular but erroneous opinion of their shrinking when attempted to be plucked.

ZOOLOGY. Gen. Char.—Body soft, very elastic, multiform, more or less irregular, very porous, traversed by numerous tortuous canals, which open externally by very distinct vents (*oscula*), and composed of a kind of subcartilaginous *skeleton*, anastomosed in every direction, and entirely without spicules (De Blainville).⁴

My friend, Mr. J. S. Bowerbank,⁵ has recently shown that spicula do exist in the keratose or horny sponges of commerce. They are imbedded, to a greater or less extent, in the substance of the fibre, and are mostly to be observed in the larger flattened portions of the fibre, and not in the finer anastomosing threads. Mr. Bowerbank has also shown that the fibre of the true sponges is solid, and not tubular, as commonly supposed.⁶

Sp. Char.—*Masses* very large, flattened and slightly convex above, soft, tenacious, coarsely porous, cracked and lacunose, especially beneath. *Vents* round, and for the most part large (Lamouroux).⁷

These characters are insufficient to distinguish the officinal sponge from numerous other allied species; and it is tolerably clear, from Mr. Bowerbank's discoveries, above alluded to,

¹ *Cyclop. of Anat.* art. *Acrita*.

² *Hist. d. Anim.* lib. i. cap. ix. p. 16, Tolosm, 1619.

³ *The Microscopic Journal*, i. 5.

⁴ The only tubular sponge known to Mr. Bowerbank is *Spongia fistularis*. This, however, he proposes to separate from the genus *Spongia*, and to give it the generic name of *Fistularia*.

⁵ *Hist. des Polyp. Corall.* p. 20, 1816.

⁶ *Grant. Brit. Annual* for 1839, p. 267.

⁷ *Man. d'Actinol.* p. 529, 1834.

that the naked eye is incompetent to distinguish species of this curious genus, and that the microscope must be principally, if not wholly, relied on for ascertaining specific characters. Mr. Bowerbank has recognized three distinct species in the sponges of commerce.

The animality of sponge is by no means universally admitted; indeed, a considerable number of the naturalists of the present day regard it as of vegetable origin; and its position, in a natural classification of plants, it is said, should be between Algæ and Fungi.¹ But the recent observations of Mr. Bowerbank appear to me to be conclusive as to its animality. In one species of sponge he detected a branched vascular system, with globules in the vessels analogous to the circular blood-disks of the higher animals. Now, nothing analogous to this has hitherto been detected in plants. The sponge derives its food from the fluid in which it lives. The water (containing the matters necessary for the existence of the animal) enters by the superficial pores, circulates through the anastomosing canals, and is expelled by the fecal orifices or vents, carrying along with it particles which separate from the sides of the canals.²

Sponge adheres to rocks by a very broad base. When first taken out of the sea it has a strong fishy odour. Its colour varies from pale to deep brownish-yellow. It often contains stony or earthy concretions (*lapides spongiarum*), which Bley³ found to consist principally of the carbonates of lime and magnesia. Shells also are found in sponges. Various marine animals pierce and gnaw it into irregular holes.

Hab.—In the Red and Mediterranean Seas. Chiefly collected about the islands of the Grecian Archipelago.

COLLECTION.—The inhabitants of the Greek islands collect sponge by diving for it. In their submarine operations, they carry with them a knife. Practice enables them to remain a considerable time under water.⁴ As soon as the sponge is brought on shore, it is squeezed and washed to get rid of the gelatinous matters; otherwise putrefaction speedily ensues.

DESCRIPTION.—Commercial sponge (*spongia*) is the dry skeleton of the animal, from which the gelatinous flesh has been removed, as just mentioned. When deprived of stony concretions, &c. found in the interior of the mass, it is soft, light, flexible, and compressible. When burnt, it evolves an animal odour. It absorbs water, and thereby swells up. Nitric acid colours it yellow. Liquor potassæ dissolves it; the solution forms a precipitate on the addition of an acid. The finer sponges, which have the greatest firmness and tenacity, were formerly called male sponge; while the coarser portions were denominated female sponge.

In 1841, duty (6*d.* per lb., with an additional 5 per cent. on the duty) was paid on 58,931 lbs. of sponge.

In English commerce⁵ two kinds of sponge are met with, which are respectively known as Turkey and West Indian.

a. Turkey Sponge.—This is imported from Smyrna, and constitutes the best sponge of the shops. It occurs in cup-shaped masses of various sizes. Its texture is much finer than the West Indian kind. Mr. Bowerbank, by the aid of the microscope, has discovered that it consists of two species of *Spongia*, not distinguishable from each other by the naked eye. One of these is characterized by the presence of a beautiful, branched, vascular tissue, which surrounds, in great abundance, nearly every fibre of its structure, and is inclosed in an external membrane or sheath. In the other and most common kind of Turkey sponge, no vascular tissue has yet been discovered. The common variety is called *honeycomb* sponge.

β. West Indian Sponge.—The principal source of this is the Bahama Islands; whence it is commonly known as *Bahama Sponge*. Its forms are more or less con-

¹ See Hogg, in the *Linn. Trans.* vol. xviii. pp. 363 and 368; also, Johnson's *History of British Zoophytes*, ed. 1835.

² Grant, *Outlines of Comparative Anatomy*, p. 310, Lond. 1836.

³ *Pharm. Central-Blatt für 1834*, S. 273.

⁴ Savary, *Letters on Greece*, p. 109, Lond. 1788. [Dr. Lefevre, of Rochefort, found that among the Navarino sponge divers, accustomed as they were to the practice of diving, there was not one who could sustain entire submersion of the body for two consecutive minutes. The average period of entire submersion was seventy-six seconds.—Ed.]

⁵ On the continent, a considerable variety of sponges are known. See Baudrimont, in the *Dict. de l'Industrie*, t. iv. art. *Eponge*; and Dr. T. W. C. Martius's *Lehrbuch der Pharmaceutischen Zoologie*, Stuttgart, 1838.

vex, with projecting lobes. Its fibre is coarser. Its tissue has but little cohesion, and hence this kind of sponge is commonly regarded as rotten. Mr. Bowerbank states that it consists of one species only of *Spongia*.

COMPOSITION.—Well-washed sponge, freed as much as possible from earths and salts by dilute acids, was analyzed, in 1828, by Hornemann,¹ who found it to consist of a substance similar to osmazome, animal mucus, fat oil, a substance soluble in water, a substance only soluble in potash, and traces of chloride of sodium, iodine, sulphur, phosphate of lime (?), silica, alumina, and magnesia. Mr. Hatchett² found sponge to consist of *gelatine* (which it gradually gave out to water), and a thin, brittle, membranous substance, which possessed the properties of *coagulated albumen*.

According to the experiments of Posselt,³ the substance of sponge is peculiar, and stands near the horny substance, from which, however, it is distinguished both in composition and properties. It, nevertheless, is not a proteine compound, nor does it contain a trace of such a body.

USES.—The extensive economical uses of sponge are familiar to every one. To the surgeon it is of great value on account of its softness, porosity, elasticity, and the facility with which it imbibes fluids. Its use at surgical operations and for checking hemorrhage is well known.⁴ It has also been applied to wounds and ulcers for imbibing acrid discharges.⁵ The *sponge-tent* is usually made of compressed sponge impregnated with wax (*spongia cerata*), and which is called *prepared sponge* (*spongia præparata*). It is prepared by dipping sponge into melted wax, and compressing it between two iron plates till the wax hardens. It was formerly much used for dilating sinuses and small openings, but it is seldom resorted to now.

SPONGIA USTA; *Pulvis spongiæ ustæ*; *Calcined or Burnt Sponge*.—Formerly in the Dublin Pharmacopœia, and directed to be prepared as follows: Having cut sponge into pieces, beat it to free it from little stones; burn it in a closed iron vessel until it becomes black and friable, and reduce it to powder. Preuss⁶ calcined 1,000 parts of sponge: of these, 343.848 parts were destroyed by heat. The residue consisted of carbon and siliceous insoluble matters, 327.0; chloride of sodium, 112.08; sulphate of lime, 16.430; iodide of sodium, 21.422; bromide of magnesium, 7.570; carbonate of lime, 103.2; magnesia, 4.73; protoxide of iron, 28.720; and phosphate of lime, 35.0.—Burnt sponge, if good, should evolve violet fumes (*vapour of iodine*) when heated with sulphuric acid in a flask. It has been employed as a resolvent in bronchocele, serofulous enlargement of the lymphatic glands, &c.—Its efficacy is referable to iodine and bromine. Iodine is now almost invariably substituted for it.—Dose, \mathfrak{z} j to \mathfrak{z} ijj. It is given in the form of electuary or lozenges (*burnt sponge lozenges*; *trochisci spongiæ ustæ*.) [A decoction of burnt sponge is, when filtered, colourless. When treated with starch and chlorine, it strikes a blue colour, showing the presence of an iodide.—Ed.]

Class II. Polypipera, Grant.—Polypiperous Animals.

The polypiperous animals have received their name from the circumstance of their bearing tubes called *polytes*. They consist of two parts, a skeleton and a fleshy portion. The skeletons

⁶ *Pharm. Central-Blatt für 1837*, 169.

Fig. 422.

*Corallium Rubrum.*

vary in their consistence, and also in their position relative to the soft parts. They are soft and flexible, or hard and calcareous. They are external and tubular, or internal and solid. The *fleshy portion* may be, with respect to the skeleton, either external or internal. It gives origin to fleshy tubes (*polytes*), each of which, at its external orifice, is surrounded by *tentacula*.

The calcareous internal skeleton of *CORALLIUM RUBRUM*, Lamarck (*Isis nobilis*, Pallas; *Gorgonia pretiosa*, Ellis), is the *Red Coral* of the shops. It consists of carbonate of lime principally coloured with oxide of iron. *Prepared Red Coral* (*Corallium rubrum præparatum*) was formerly used in medicine, but it presents no advantage over chalk. Its powder, obtained by levigation, or an imitation of it, is still kept in the shops, and is occasionally employed as a dentifrice. [According to Witting, 100 grains of red coral yield the following constituents:—

Carbonate of lime	83.25
Carbonate of magnesia	3.50
Oxide of iron	4.25
Animal gelatine and sand	7.75
Loss	1.25
	100.00

SUBDIVISION II. RADIATA, Lamarck.—RADIATE ANIMALS.

CHARACTERS.—*Nervous system* distinct, composed of filaments and rudimentary ganglia; the filaments arranged circularly around the buccal orifice (*Cyclo-neura*).

No officinal substance is obtained from the Radiata.

SUBDIVISION III. MOLLUSCA, Latreille.—MOLLUSKS OR SOFT ANIMALS.

MALACOOZA, Blainville.—CYCLO-GANGLIATA, Grant.

CHARACTERS.—Inarticulated animals with a soft not annulated *skin*. *Cerebral ganglia* arranged circularly around the œsophagus.

Class III. Conchifera, Lamarck.—Conchiferous Mollusks.

CHARACTERS.—Acephalous, aquatic mollusks, with a bivalve or a multivalve *shell*. *Organs of respiration* 4 pectinated laminæ. *Heart* simple. *Impregnation* effected without the assistance of a second individual.

351. OSTREA EDULIS, Linn.—COMMON EDIBLE OYSTER.

(The shells burnt, of former Ph. Lond.)

[Testa, U. S.]

HISTORY.—Oysters were greatly admired by the Romans as a most delicious article of food.¹ Those of Britain were much esteemed; though they were said to be inferior to those of *Cyzicena* (Pliny).²

ZOOLOGY. Gen. Char.—*Body* compressed, more or less orbicular. Edges of the *mantle* thick, non-adherent, or retractile, and provided with a double row of short and tentacular filaments. The two pair of *labial appendices* triangular and elongated. A subcentral bipartite *muscle*. *Shell* irregular, inequivalved, inequi-

¹ Pliny, *Hist. Nat.* lib. xxxii. cap. 6, ed. Valp.

² Juvenal, *Sat.* iv.

lateral, coarsely laminated. *Left or inferior valve* adherent, largest, and deepest; its summit prolonged, by age, into a kind of keel. *Right or upper valve* smallest, more or less operculiform. *Hinge* oral, toothless. *Ligament* somewhat internal, short, inserted in a cardinal pit, growing with the summit. The *muscular impression* unique and subcentral (Blainville).

Sp. Char.—*Valves* ovate-roundish or obovate; the upper one flat. *Lamellæ* of both valves imbricated and undulated (Brandt).¹

Brandt² has given an elaborate account of the anatomy of the oyster, to which I must refer the student interested in these details.

Hab.—European and Indian seas. Our own coasts furnish some of the finest kinds.

OYSTER FISHERIES.—Oysters are caught by dredging. In order to improve their flavour and size they are laid on beds in creeks along shore, where they rapidly improve. Colchester and other places of Essex, as well as some parts of the coast of Kent, are the nurseries or feeding-grounds for the metropolis.³

DESCRIPTION.—The officinal parts of oysters are the *shells (testæ ostreæ)*. The hollow halves are preferred, as they contain more carbonate of lime. When calcined, oyster-shell yields a quicklime, formerly much esteemed as a lithontriptic.

COMPOSITION.—*Oyster-shells* have been analyzed by Bucholz and Brandes,⁴ and by Rogers.⁵ The *flesh of the oyster* has been analyzed by Pasquier.⁶

<i>Bucholz and Brandes's Analysis.</i>		<i>Pasquier's Analysis.</i>	
Carbonate of lime	98.6	Osmazome	} 12.6
Phosphate of lime	1.2	Gelatine	
Alumina	0.2	Mucus	
Albuminous matter	0.5	Albumen	
	—	Fibrine	
Oyster Shells	100.5	Water	87.4
		Flesh of the Oyster	100.0

The dietetical properties of oysters have been before noticed.

TESTÆ PREPARATÆ, Testæ Ostreorum Præparatæ [Testa Præparata, U. S.]; *Prepared Oyster-Shells* of former *London Pharmacopœia*.—Wash the shells, first freed from impurities, with boiling water; then prepare in the same manner as directed for chalk. The mode of preparing chalk by elutriation has been already described. After oyster-shells have been washed, boiled, and crushed, they are dried and ground to an impalpable powder previous to elutriation. In the shops the substance sold as prepared oyster-shells is in small conical masses. The principal constituent of prepared oyster-shells is carbonate of lime, and they therefore possess the same medicinal properties as chalk, already described, and which is usually substituted for them.

Class IV. Cephalopoda, Cuvier.—Cephalopods.

CHARACTERS.—*Body* inclosed in a bag (*mantle*). *Head* protruding from the bag, crowned with inarticulated arms, furnished with cups or suckers, and surrounding the mouth. *Eyes* two, sessile. *Mouth* with two horny mandibles. *Hearts* three. *Sexes* separate.

¹ *Med. Zool.*

² *Ibid.* *Bl.* ii.

³ For details respecting the treatment of oysters in beds, see Spratt's *History of the Royal Society*, p. 307. "In the fish-shops, the oysters are laid with their flat sides uppermost; they would die were it otherwise. The animal breathes and feeds by opening its shell, and thereby receiving a new portion of water into the concavity of its under-shell. Oysters, when packed in barrels, should be laid in the same position. "Geologists can tell whether oysters were overwhelmed in their native beds, or rolled away and scattered as shells, by determining their position." (*Paley's Theology*, by Bell, vol. ii. pp. 220—221.)

⁴ *Gmelin, Handb. d. Chem.* ii. 1477.

⁵ *Sullivan's Journal*, vol. xxvi. p. 361.

⁶ *Gmelin, op. supra cit.*

352. SEPIA OFFICINALIS, Linn.—COMMON CUTTLE-FISH.

The substance called *os sepia* or *cuttle-fish bone* is an oval or oblong calcareous bone (sometimes termed a *shell*) deposited in the mantle of the animal. The common species of *sepia* is *S. officinalis*, Linn.; but *S. elegans*, Blainville, also yields part of the cuttle-fish bone of the shops.¹

Os sepia has a cellular texture, and is so light as to float on water. It is cast in considerable quantities on the shore, and is collected for commercial purposes. It was analyzed by John, who found the constituents to be as follows:—

	Hard upper or outer Portion.	Porous Part.
Carbonate (with a trace of phosphate) of lime	80	85
Non-gelatinous animal matter, soluble in water with some common salt	7	7
Gelatinous membrane not soluble in water	9	4
Water, with a trace of magnesia	4	4
	100	100

Reduced to powder it is used as a dentrifice. It is employed for several purposes in the arts, as for polishing, for forming moulds for small silver castings, and as a pounce.

SUBDIVISION IV. ARTICULATA, Cuvier.—ARTICULATED ANIMALS.

CHARACTERS.—*Skin* annulated. *Muscles* attached to the inner surface of the skin. *Nervous system* of two cords extended along the ventral surface of the body, with ganglionic enlargements at intervals (*diplo-neura*); the anterior ganglion (brain) placed over the œsophagus.

Class V. Annulosa, Macleay.—Annulose Animals.

ANNELIDES seu ANNELIDA.

CHARACTERS.—*Body* more or less elongated. *Skin* soft, segmented and annulated. *Articulated members* and *wings* absent. *Blood* red.

353. SANGUISUGA, Savigny.—BLOODSUCKING LEECHES.

Iatrobdella, Blainville.

HISTORY.—We have no accurate knowledge of the exact period when leeches either became known to, or were employed by, man; but this deficiency of information is not necessarily referable to their discovery preceding the date of our historical documents. It is true that in the common version of our most ancient record, the Bible,² this passage occurs: "The horseleech hath two daughters, crying, Give, give;" but critics are not agreed as to the correctness of this translation. The word "*Olukeh*," or "*Aluka*," here interpreted "*horseleech*," means, according to Bochart, destiny or fate, either of which terms should, according to this writer, be substituted for that of horseleech; the daughters alluded to being Eden and Hell. But the Vulgate, Greek, and Lutheran translations are all against his opinion. Brandt³ has entered into a very elaborate discussion of this subject, from which it appears that, in Arabic, the term *Aluka* indicates a leech, while *Aluk* signifies fate; the latter being derived from *Alaka*, to attach or hang to, because every man's fate is supposed to be appended to him, just as a leech affixes itself to the body; so that from this it appears probable the word "*Olukeh*" of the Old Testament really refers to the leeches. Nay, I think there is some reason for suspecting that the *Sanguisuga ægyptiaca* is the species referred to. The leeches referred to by Herodotus,⁴ are *Bdella nilotica* (Savigny).

¹ Brandt and Ratzeburg, *Med. Zoolog.* ii. 599.

² *Med. Zool.* ii. 231.

³ *Prov.* xxx. 15.

⁴ *Euterpe*, lxviii.

But admitting that these animals were known at this early period, it does not appear that they were employed in medicine: for Hippocrates makes no mention of them, though he notices other modes of drawing blood. Aristotle also is silent with regard to them. In the extracts which Cælius Aurelianus has made from the writings of Diocles, Praxagoras, Herophilus, Heraclides, Asclepiades, and other ancient physicians, who lived between the time of Hippocrates and Themison, no mention is made of the employment of leeches; a remarkable fact in favour of the opinion that they were not at this period in use. In fact, the founder of the Methodic sect, Themison, is the first person in whose works we find mention of leeches being employed therapeutically.¹ However, it does not follow that he was the first who prescribed them, though our documentary evidence fails in tracing back their use beyond his time.

In the Latin and Greek languages, the animal has received its name from its sucking or drawing qualities. Thus, the Greeks called it βδέλλα, from βδέλλω, to suck; the Romans *hirudo*, probably from *haurio*, to draw out; or *sanguisuga*, literally signifying "bloodsucker," from *sanguis* and *sugo*. It would appear, however, that the latter of these two Latin terms is the more modern; for Pliny,² in speaking of elephants, says: "Cruciatum in potu maximum sentiunt, hausta, hiru-dine, quam sanguisugam vulgo cœpisse appellari adverto."

ZOOLOGY. Gen. Char.—*Jaws* with two rows of pointed, numerous *teeth*, which are mutually inclined at an acute angle (Brandt).³

Body elongated. *Back* convex. *Belly* flat. *Extremities* somewhat narrowed, furnished with disks or suckers; the anterior extremity somewhat narrower than the posterior one. *Rings* from ninety to a hundred. *Eyes* represented by ten blackish points. *Mouth* tri-radiate. *Jaws* cartilaginous, armed with numerous cutting teeth. *Anus* small, placed on the dorsum of the last ring.

Cuvier⁴ includes all leeches in the genus *Hirudo*; but later naturalists have found it necessary to arrange them in several genera. The leeches employed in medicine have been formed into a distinct genus, called by Blainville⁵ *Iatrobella* (from *ιατρος*; and *βδέλλα*, a leech), by Savigny,⁶ *Sanguisuga*. The latter classical term, so expressive of the bloodsucking properties of the genus, I have adopted. All leeches, it appears, are not provided with an apparatus for perforating the skin of vertebrate animals. In consequence of the numerous complaints addressed to the Préfet de Police, in 1825, that of the leeches sold in Paris some would not bite, while others caused painful and obstinate wounds, he consulted the Council de Salubrité, who deputed MM. Pelletier and Huzard fils, to inquire into the accuracy of the statements. One of the results of the investigation was, that the animal called in France *horseleech*, and which had been particularly charged with causing painful wounds, could not perforate the human skin, the teeth of the animal being quite blunt.⁷ The horseleech referred to, the reporters declared to be *Hæmopsis sanguisorba*, Savigny; but Blainville says it was *Hæmopsis nigra*.

Species.—1. *SANGUISUGA OFFICINALIS*, Savigny; *Hirudo provincialis*, Carena, Mem. della Reale Accad. di Torino, xxv. 282; *Sanguisuga meridionalis*, Risso, Hist. Nat. de l'Europe mérid. t. iv. p. 428; *the Green Leech*.—*Back* greenish or blackish-green, with six rusty-red band-like [longitudinal] stripes. *Belly* olive-green, unspotted (Brandt).—South of Europe. Those brought to England come from Bordeaux, Lisbon, and Hamburg.

Moquin-Tandon⁸ admits three varieties:—

- a. Dorsal bands interrupted at intervals.
- β Dorsal bands reduced to blackish spots.
- γ. Dorsal bands united by transverse ones.

2. *SANGUISUGA MEDICINALIS*, Savigny; *Hirudo medicinalis*, Linn. L. D.; *True English or Speckled Leech*.—*Back* greenish or olive-green, with six rusty red longitudinal stripes, which are mostly spotted with black. *Belly* greenish-yellow, spotted with black (Brandt).—*Spots* very variable in size and number; in some cases they are but few; in others, are so numerous as to form the almost

⁸ *Monogr. de la fam. des Hirud.* p. 112.

prevailing tint of the belly, the intervening spaces appearing like greenish-yellow spots.—Europe, especially the northern parts. A native of England, but rare. Imported from Hamburg.

Several varieties of this leech have been described and figured. One of the most remarkable of these is the *flesh-coloured medicinal leech* (*Sanguisuga medicinalis carnea*) described by Guillez of Paris. The anterior half of its body is flesh-coloured; while the posterior half is of the usual colour. The *spotted* or *piebald leech* is flesh-coloured, with olive-green spots.¹

These are the only species employed in medicine in this country. Others have been described and figured by Brandt.² The following is a short sketch of the *anatomy* of the medicinal leech:—

The **CUTANEOUS SYSTEM** of the animal consists of a transparent *epidermis* (which is thrown off from the body every four or five days) and the *corium*. The latter consists of condensed cellular tissue, composed, according to Brandt, of globules. Like the epidermis, it shows the partitions into rings. It contains a number of *globules* impregnated with a pigment varying in colour in different places, and which is the source of the colours presented by the surface of the animal.

It is asserted that the predominant or base colour is, in part at least, owing to the colour of the soil in which the animals are found. Dr. J. R. Johnson³ says: "Mr. Baker, a man of some intelligence, residing in Glastonbury, and who for the last twenty years has been in the habit of collecting large quantities of leeches for sale, informs me that, at the Black River, near Glastonbury, they are black, from the peat being of that colour; at Cook's Corner, they are of a reddish cast from the red peat; while at Auler Moor, where, from a deficiency of peat, they penetrate the clay, they are yellow."

The **MUSCULAR SYSTEM** has been elaborately described by Brandt, but can scarcely be comprehended without the aid of drawings. The muscles of the trunk are arranged circularly, longitudinally, and obliquely; of these, the circular fibres are the most external, and the longitudinal ones the most internal.

The **DIGESTIVE SYSTEM** consists of a mouth, alimentary tube, anus, salivary glands, and liver. The *mouth* is placed in the middle of the oval or buccal disk; its shape is triradiate; that is, of three equidistant lines or rays meeting in the centre. Within it are three white sublenticular *jaws* (*dentiferous tubercles* or *piercers*), which in appearance are cartilaginous; but Brandt says they consist of a strong firm skin, inclosing a muscular mass. On the free-curved sharp margin of each jaw are about sixty small, finely-pointed *teeth*. The *œsophagus* is a muscular tube, and dilates as it approaches the stomach; but at its termination it contracts into a small circular aperture, its whole length not exceeding a quarter of an inch. The *stomach* occupies two-thirds of the length of the animal, and is divided into about eleven compartments or cells, each of which, from the second to the eleventh, gives off on each side a *sacal sac*, those of the last cell being by far the largest, and extending down by the side of the intestine as far as the commencement of the rectum. The stomach consists of three coats, a cellular, a muscular, and a mucous coat. Its eleventh cell terminates by a funnel-shaped projection in the intestine. The *intestine* is about an inch in length; at its upper orifice is a valve, and at its lower end a sphincter; on either side of it, for the greater part of its length, is one of the sacs for the last compartment of the stomach; on its inner surface are several folds. It is divided into *small* and *large intestine*, the lower part of the latter being called a *rectum*. The *anus* is not, as we might anticipate, in the posterior disk, but on the dorsal surface of the last ring. *Salivary organs* have been described; they consist of whitish granular masses placed around the *œsophagus*, into which tube the common salivary duct opens. De Blainville, Carus, and Brandt, speak of a *liver*. It is a brownish mass placed on the alimentary canal, the ducts opening into the stomach and intestine. The best mode of displaying the cells of the stomach is to immerse a leech, fully gorged with blood, for a week in a saturated solution of corrosive sublimate.

² *Treat. on the Med. Leech*, p. 42, 1816.

³ *Med. Zool.* ii.

The **VASCULAR SYSTEM** consists of four great pulsating vessels, giving off numerous ramifying branches; but without any heart, commonly so called. Two of these are placed laterally, a third in the median line of the dorsal surface, and a fourth on the abdominal surface. All these vessels pulsate (Johnson). We know very little about the manner in which the blood circulates. Brandt thinks that the lateral vessels must be arteries, on account of their very distinct transverse and longitudinal fibres; the dorsal and venous vessels he terms veins.¹ Does not the dorsal vessel correspond to the vena cava, and the abdominal vessel to the vena porta, of higher animals? Grant,² however, terms the dorsal vessel of the annelides an artery.³

The **RESPIRATORY SYSTEM** consists of small apertures (called *stigmata* or *spiracula*) arranged in two rows on the abdominal surface, and occurring at every fifth ring. They lead into little cavities lined by mucous membrane, and which have been called *air sacs*, *pulmonary vesicles*, *mucous bags*, *cryptæ*, or *lateral vesicles*, containing usually a whitish fluid. They are placed on each side of the alimentary canal, in the spaces between the cæcal sacs of the stomach, and are usually regarded as organs of respiration. Brandt, however, asserts that the respiratory function is effected solely by the skin, and that these vesicles are, in fact, receptacles for mucus secreted by a neighbouring glandular apparatus, which has a whitish appearance, and in form represents a folded intestine. This notion, however, is not new, but was held by De Blainville and Johnson.

The **NERVOUS SYSTEM** consists of two parts: *one* (which we may compare to the *cerebro spinal axis* of the vertebrata) consists of a chain of ganglia (usually about twenty-three in number) occupying the mesial line of the abdomen, and connected by a double nervous cord; the first ganglion (*brain*) is placed on the œsophagus, and supplies the eyes and neighbouring muscles. The *second* part of the nervous system is that lately discovered by Brandt, and may be regarded as a kind of *sympathetic system*. It consists of three ganglia (connected to the brain by filaments, and supplying the jaws), and a single nerve connected to them, and running along the abdominal surface of the stomach in the mesial line.

Of the **EXTERNAL SENSES**, three only have been recognized; *feeling*, which resides in the external surface of the body; *taste*, apparently indicated by the fondness of leeches for certain fluids (as blood, milk, &c.); and *vision*, effected by ten eyes (in the form of black spots) arranged in a crescent form at the anterior or cephalic extremity of the animal.

The **SEXUAL SYSTEM** is double; that is, each animal is androgynous, or possesses both male and female organs. There is, however, no power of self-impregnation (the contact of two individuals being requisite, each acting to the other in a double capacity of male and female). The **MALE ORGANS** consist of several pairs of *testicles*, *two vasa deferentia*, *two vesiculæ seminales*, *two ejaculatory ducts*, and a *penis* surrounded at its base by what some have termed a *prostate gland*. The penis projects from the abdominal surface at about one third distant from the anterior extremity. The **FEMALE ORGANS** consist of *two ovaries*, *two oviducts* (which subsequently unite into one), a hollow organ (*uterus*), which opens by a contracted aperture (*vagina*) externally at about the twenty ninth ring, or five rings below the penis.

That leeches are essentially oviparous admits of no doubt; and we have now an admirable account of their development by Professor Weber.⁴ It appears that soon after copulation an unusual activity pervades the ovaries, in consequence of which some ova (termed by Weber *germs*, by Carus *yelks*) are separated, and pass along the oviduct to the uterus, where they stop, in order to obtain the matters necessary for their development, and their proper coats. They here become invested with a serous like membrane, on the inner side of which is produced (either by secretion from the uterine cavity, or from the membrane itself) an albuminous whitish mucus, serving in part for the nourishment of the ova, and which is regarded as a kind of *liquor amnii*. Subsequently, a glutinous fluid is deposited on the outside of the serous coat. When the ova are expelled from the uterus, part of this fluid gives a coating to them, while part is expelled before and after them. But this coat seems now distended with air-vesicles, and

has the frothy appearance of well-beaten white of egg, produced by the violent contraction of the uterus.

The animals usually deposit their ova (in their own native waters) in holes or moist places on the shore, from May to the end of September. When first expelled, they are somewhat cylindrical in form, and have a brownish appearance. The frothy layer adheres very slightly; but, after lying in the water for a quarter of an hour, the outer surface becomes somewhat hardened, forming a kind of pellicle or fine skin. After some days, a portion of this frothy covering is converted into a spongy tissue (*spongy coat of the cocoon*), covering the capsule of the ova (*cocoon*) wholly or partially. In this state, the cocoon has a brownish, fibrous appearance, similar to fine sponge, and varies somewhat in its size and weight; its longest diameter being from six to twelve lines, its shortest from five to eight, and its weight from twenty-four to twenty-eight grains.¹

The ova or germs, which have a lenticular form, evince vital movements; and very soon we perceive a funnel-shaped tube, extending from their surface inwards, and which appears to absorb the albumen of the cocoon. The ovum goes on enlarging, and becomes somewhat elongated, and subsequently the young leech begins to be developed on the exterior part of the ovum, the aperture of the funnel being the spot where the mouth of the young animal is observed. The abdominal surface is the first, the dorsal the last to be developed. When the young leeches have attained a considerable size they pierce their cocoon.

DISEASES OF LEECHES.—The natural duration of the life of leeches is not easily determined; but judging from the slowness of their growth, and the length of time full-grown leeches have been preserved, we may necessarily infer that they are long-lived animals. Dr. Johnson thinks that, in their native waters, if they can always meet with an abundant supply of food, they may live at least twenty years. But they are subject to several diseases, some of which are epidemic, and of a very destructive kind. Although the study of the pathology of this animal is of considerable interest in a commercial and even scientific point of view, yet no practically useful results have hitherto been arrived at, in regard to the prevention and treatment of the diseases of leeches. Dr. J. R. Johnson mentions three diseases as common to this animal: 1st. An ulcer, seated in various parts of the body, but more generally affecting the side. It destroys life in a few days. 2d. A rigidity and narrowing of one part, whilst another portion is studded with tumours of putrid coagulated blood. 3d. A flaccid appearance of the whole body, except the lips, which are hard, swollen, purple, and frequently bloody. These diseases are particularly prevalent during the summer months. Brostat² describes three epidemic disorders.

COLLECTION AND COMMERCE OF LEECHES.—Leeches may be caught with the hand, or by a kind of net (described by Derheims), or by the gatherers going into the ponds with naked feet, to which the leeches adhere; or by baits, especially the liver of animals. The two latter methods are objectionable; one, because it is not free from danger to the gatherers, and the other because it is apt to injure the health of the animal. An interesting and graphic account of the leech fishery at La Brenne, and of the miserable appearance of the fisherman who collects the leeches,

¹ See figures of the cocoon, in Dr. J. R. Johnson's *Farther Observations on the Medicinal Leech*, 1825.

² Brandes's *Archiv*, Bd. v.

by allowing them to attach themselves to his legs and feet, has been published in the *Gazette des Hôpitaux*. A translation of this paper is given in McCulloch's *Dictionary of Commerce*. Leeches are largely imported from Hamburg. The Hamburg dealers draw their supplies from the Ukraine. "Having exhausted all the lakes of Siberia, Bohemia, and other more frequented parts of Europe, the buyers are now rolling gradually and implacably eastward, carrying death and desolation among the leeches in their course, sweeping all before them, till now they have got as far as Pultava, the pools and swamps about which are yielding them great captures."¹ Leeches are sometimes imported in bags, but more usually in small barrels, each holding about 2,000, the head being made of stout canvas to admit the air. The best vessels for preserving these animals are unglazed brown pans or wooden tubs. The dealers have a notion (and possibly a correct one) that the leaden glazing is injurious. These pans should be very little more than half-filled with soft water (pond, river, or rain water). This does not require changing so often as is commonly supposed. In very hot weather, or when the water has become bloody, or otherwise much discoloured, it should be changed every day or so; otherwise, in summer, every four or five days, or a week; in winter, once a month is believed by large dealers to be sufficient.

The *consumption of leeches* must be enormous. Some years ago it was stated that four principal dealers in London imported, on the average, 600,000 monthly, or 7,200,000 annually.² Feé³ says: "It is estimated that 3,000,000 are annually consumed in Paris; and, as the population of Paris is to that of the whole of France as one is to thirty-three, it follows that, independently of exportation, 100,000,000 are consumed annually, which is equivalent to three leeches annually for each person. Now, if we estimate the average price at fifty francs per thousand, we shall have the enormous sum of five millions of francs paid for this one article of our materia medica."

MODE OF BITING.—Having fixed on a suitable spot, the animal applies his oval disk, and firmly fixes it (at first, perhaps, by atmospheric pressure; then by intimate contact), so that the anterior end forms an angle with the other portions of the body. The three cartilaginous jaws bearing the sharp teeth are now stiffened and protruded through the triradiate mouth against the skin, which they perforate, not at once, but gradually, by a saw-like motion. Dr. Johnson⁴ says: "The jaws are carried from side to side in an oblique direction;" and adds, "their action may be seen by presenting to the leech a coagulum of blood, and when the leech is in the act of suction, cautiously removing it. For a few seconds it appears unconscious of its removal, which presents a fair opportunity of observing the oscillatory movement of each piercer." The wound is not produced instantaneously, for the gnawing pain continues for two or three minutes after the animal has commenced operations. Thus, then, it appears that the leech saws the skin; hence the irritation and inflammation frequently produced around the orifices. The flow of blood is promoted by the suction of the animal, which swallows the fluid as fast as it is evolved. During the whole of the operation the jaws remain lodged in the skin. In proportion as the anterior cells of the stomach become filled, the blood passes into the posterior ones; and when the whole of this viscus is distended, the animal falls off. On examination, it will be found that not a particle of blood has passed into the intestine.

¹ Bremner. *Excurs. in the Interior of Russia*, vol. ii, p. 408, 1809. [In some parts of England, more particularly in the feony districts of Cambridgeshire and Lincolnshire, the trade in leeches forms a valuable branch of business. The manner in which the leeches are taken is this: Two or three persons, furnished with long poles, enter the marshes with their shoes and stockings off, and continue beating the weeds and rushes for some time. The leeches being disturbed by this proceeding, are aroused from their wonted lethargy, and, impelled by hunger, the effect of long abstinence, seize with avidity the first animal object they meet with. The feet and ankles of the leech-catchers being exposed to them, the same are freely fastened upon by the leeches, and they are thence removed and deposited in a basket carried for the purpose of receiving them. When taken home, they are washed in a weak solution of salt and water, and when purified are carefully packed in wet linen cloths, and in this manner are dispatched to the different leech merchants and the various medical establishments throughout the country.]

PHYSIOLOGICAL EFFECTS.—There are two classes of phenomena observed in all modes of drawing blood; one of which has been termed *local*, the other *general*. In phlebotomy and arteriotomy, the first is trifling, and of no therapeutic value; and we resort to these operations only as means of affecting the general system. On the other hand, we obtain topical effects, both powerful and useful, from cupping and leeching; hence these are termed *local*, while the former are denominated *general* bloodlettings. It must, however, be remembered, that constitutional or general effects are also frequently obtained from both cupping and leeching.

1. *Constitutional or general effects of leeching* are the same in kind as those caused by the loss of blood from other means. A moderate quantity of blood may be abstracted without any obvious effects on any of the functions; but, if the amount taken be increased, syncope results. The quantity necessary to produce this varies, however, considerably, and will depend on the mode of drawing it (whether rapidly or otherwise); the position, constitution, and age of the patient; the nature of the disease; and many other circumstances not necessary to enumerate. It is well known that a small quantity will, if taken rapidly, and the patient be in the erect posture, cause this effect; whereas, a considerably larger amount may be abstracted, if taken gradually, and the patient in the recumbent position, without giving rise to it. The usual explanation of this is, that when blood is drawn faster than the vessels can contract, the circulation is temporarily stopped, and fainting ensues. Several reasons, however, lead me to doubt the sufficiency of this explanation. Leeching, then, as being a slower mode of abstracting blood, is less likely to cause syncope than venesection, or even cupping. As the patient recovers from the fainting state, hysterical symptoms sometimes manifest themselves. Throbbing headache, and sleeplessness, are by no means uncommon consequences of the loss of blood. In some cases I have seen febrile excitement, of several hours' duration, brought on by bloodletting.¹

Dr. Marshall Hall² has directed attention to the disorder of the cerebral functions (marked by convulsions, delirium, or coma) caused by bloodletting. I may observe, that convulsive movements are by no means uncommon in syncope from general bloodletting, and I think are not always to be considered as denoting that the remedy has been used beyond the safe degree. I have on several occasions been told by patients about to lose blood, that they are apt to faint and struggle when bled; and I have, in consequence, been requested to prevent them from injuring themselves. Delirium and coma are less frequently met with. Great depression of the vascular system, followed by sudden dissolution, is another occasional effect of loss of blood.³

As might be expected, an operation so powerfully affecting the vital functions cannot be passive in its influence over morbid action; but the phenomena vary so much in different diseases, and even in the same disease under different circumstances, that it becomes extremely difficult to offer any general results. That loss of blood is sometimes beneficial, at other times hurtful, is well known. Its immediate beneficial effects are best seen in pneumonia and ophthalmia. In the first of these diseases the respiration sometimes becomes easier, and the pain removed, while the blood is flowing; and from this time the amendment progresses. In ophthalmia, the redness of the conjunctiva disappears during the syncope from bloodletting, and sometimes never returns with equal intensity. A tendency to hemorrhage has been thought by some experienced practitioners to be engendered or increased by the application of leeches. Thus, the return of the menses, the aggravation of menorrhagia, hæmoptysis, and apoplexy, have been found to follow, and apparently to result from, the employment of leeches.⁴

¹ For farther details respecting the effects of loss of blood, see Dr. Clutterbuck *On the Proper Administration of Bloodletting*, 1840.

² *On the Morbid and Curative Effects of Loss of Blood*, 1830.

³ See an illustrative case in the *Lancet*, vol. xi. p. 94.

⁴ See the observations of Laennec and Sir James Clark, in Forbes's translation of Laennec's *Treatise on Diseases of the Chest*, p. 193, 1827.

The effects of bloodletting are considerably influenced by disease. Every practitioner is acquainted with the fact that in certain morbid conditions patients bear the loss of larger quantities of blood than in others. I need only mention apoplexy, inflammation of the serous membranes, peripneumony, and phrenitis, as examples of increased tolerance; while chlorosis and cholera may be cited as instances of diminished tolerance. On this point there cannot be, I think, two opinions.

I confess I am not prepared to assent to the inferences Dr. Hall has drawn from these facts, nor to the rules he has laid down in the diagnosis and treatment of disease founded on the circumstances just mentioned. The susceptibility to syncope is so great in some persons, that we should, I suspect, be often led into error, if we were to infer the absence of inflammation merely from the occurrence of fainting after the loss of a few ounces of blood. Besides, it not unfrequently happens that a patient faints on the first, but not on the second or third bleeding. I have more than once seen this. Neither do I think it would always be safe to bleed *ad deliquium*, even if we were satisfied that inflammation be present; for in some it is difficult to occasion syncope, although the quantity of blood lost be so great as to endanger the safety of the patient. The practice of Dr. Hall, however, is much to be preferred in this respect to that of Mr. Wardrop;¹ for, although both recommend bleeding to syncope in inflammation, the former places his patient in the erect, the latter in the recumbent posture. And here I cannot help remarking, that the practice of ordering patients to be bled to syncope in the recumbent posture appears to me a highly dangerous one. That fainting will sometimes occur in the erect position, before a sufficient quantity of blood has been drawn, we all know; and, to prevent this occurrence, it is frequently proper to bleed in the recumbent posture; but I must protest against bleeding patients to *syncope* in this position.

I have yet to notice another class of the general effects of the loss of blood, which may be denominated secondary or remote, and which are in no way useful in the treatment of disease. In some cases excessive reaction occurs, attended with throbbing of the vessels of the brain, pain and disorder of the cerebral functions. Examples of this are seen in women who have suffered severely from uterine hemorrhage. Exhaustion, with insufficient reaction, is another remote effect of loss of blood. In two cases of infants, I have seen this effect, consequent on hemorrhage after a leech-bite, terminate fatally. Other secondary or remote effects of bloodletting are mentioned; they consist principally in disorder of the sensorial functions, marked by delirium, coma, or even amaurosis.²

Having hitherto described the consequences of bleeding generally, I must now refer more particularly to leeching. The constitutional or general effects caused by the application of leeches are best observed in children and delicate females—more especially the former. I have, on several occasions, seen infants completely blanched by the application of one or two leeches. Pelletan mentions the case of a child, six years old, who died from the hemorrhage occasioned by six leeches applied to the chest. Leeching, then, is here, to all intents and purposes, a mode of general bloodletting, arising in part from the powerful influence which a small quantity of blood produces in infants; and secondly, because one leech will cause the loss of more blood in them than in adults, owing to the greater vascularity of the cutaneous system. It is apparent, therefore, that in the diseases of infants, leeching may, in most cases, be substituted for venesection. But in disorders which are rapidly fatal, as croup, opening the jugular vein is undoubtedly to be preferred, since it is necessary to produce an immediate and powerful effect. As children advance in years they become capable of bearing larger evacuations of blood; and, therefore, leeching excites a less influential effect. It is quite impossible to say at what age venesection ought to be substituted, or, in infancy, what number of leeches should be applied; since they take away such unequal quantities of blood. These are points

¹ On Bloodletting.

² Dr. M. Hall, *op. supra cit.*

which must be decided by the practitioner in each case. Here is a tabular statement of the amount of blood which Dr. James Blundell¹ has taken from children at different ages:—

Ages.	Quantities.
2 months	1 ounce to $1\frac{1}{3}$ ounces.
4 "	$1\frac{1}{2}$ " to 2 "
8 "	2 " to 3 "
12 "	3 " to 4 "
18 "	4 " to 5 "
3 years	8 " to 10 "
6 "	10 " to 12 "

But these quantities are exceedingly large, and in most instances greater than it will be found prudent to abstract. Guersent says that, in infants up to two years of age, we ought never to draw more than three or four ounces of blood in twenty-four hours.²

2. *The local effects of leeching* must now be noticed. The jaws of the leech may be compared to three saws, each armed with sixty teeth. It is, therefore, not surprising that pain and afflux of blood to the wounded part should be occasioned by the laceration of the skin by a single leech. I have sometimes seen one of these animals produce intense redness to the extent of an inch around the bite. This is best observed when the skin is delicate, as that covering the mammæ of the female. Now when a number of these animals are applied, their united local effects must have some influence over a neighbouring disease. There are also certain topical effects which occur subsequently, such as ecchymosis; the irritation and inflammation of the mouths of the punctures; the diffused redness and the soreness in the parts intervening between the bites, which cannot be without influence over morbid action. They act on the principle of counter-irritation. In taking into consideration the beneficial influence of leeches, we must, therefore, not forget these, nor the fomentations and poultices subsequently employed.

When leeches are applied to the temples, especially if they fix close to the external canthus, a diffused swelling frequently arises, similar to that caused by erysipelas. This is not referable to any noxious qualities of the animal, for it happens when the finest and most healthy are employed; nor to the teeth of the animal being left within the wound, since I have seen it when the leech has fallen off spontaneously.

In concluding these remarks on the local effects of leeches, I have only to add that, independently of the local irritation caused by the puncture, I believe the evacuation of blood from an inflamed part may be more beneficial than the same quantity taken by the usual operation of venesection. In other words, I am disposed to admit what were formerly termed the *derivative* effects of local bleeding. The amount of benefit obtained by the application of leeches to parts that have been injured by falls, &c., as in fractures and dislocations, has frequently appeared to me much greater than could be referred to the combined influence of the quantity of blood lost, and the local irritation of the punctures; so, also, with respect to the good effects of leeching hemorrhoidal tumours. Mr. Wardrop thinks more benefit is in some cases obtained by the application of leeches at a distance from the affected organ, constituting what has been termed a *revulsive* operation.

I trust the remarks now offered will be sufficient to prove that, in estimating the therapeutic influence of leeches, the quantity of blood drawn is not the only element in the calculation; and I think, in practice, constant proof will be found that leeching is more beneficial than can be accounted for by the mere quantity of blood drawn.

USES.—The following are some of the uses of leeches:—

1. *In children and delicate adults (as females and aged persons) leeches often form an excellent substitute for general bloodletting*, when the object is not to occasion

¹ *Lancet*, Sept. 20, 1828, p. 773.

² On the sensible effects of leeches on man, see Vitet, *Traité de la Sangs. Méd.* 1809.

any immediate or sudden effect on the disease. In children, it is necessary to avoid applying them to the neck, or other parts where compression cannot be conveniently made.

2. In local determinations of blood, unattended with febrile symptoms, local bloodletting, when it can be resorted to, is generally, though not invariably, preferred to phlebotomy. The advantages of leeching over cupping are, the less pain, and the ease with which blood may be procured; for it is evident that in swelled testicle, in inflammation attending fractured limbs, and in acute inflammation of the mammary gland, patients could not, in most cases, bear the necessary pressure of the cupping-glass; and in some parts of the body, as the abdomen, blood can only be procured from cupping by a very dexterous manipulation.

3. In internal and other inflammatory affections, accompanied with constitutional disorder, the rule is to employ general in preference to local bloodletting. But circumstances occasionally render the reverse practice justifiable and proper, as where the disease is not active, and the patient delicate and weak. In many instances it will be found most advantageous to combine both modes of drawing blood; for example, in *abdominal inflammations*, the application of leeches, preceded by venesection, will sometimes do more good than the same quantity taken by the lancet alone. During the progress of *fever* with determination of blood to the brain, the application of leeches to the temples, after the use of bloodletting, is often attended with the best effects.

4. There are some diseases in which no substitute of equal efficacy can be found for leeches. Such, I conceive, are *hemorrhoidal tumours*, and *prolapsus of the rectum*. In these cases, general is not equal to local bloodletting, and cupping is out of the question.

5. In various organic diseases leeches will often be found an exceedingly useful palliative means. I would particularly mention, as examples, affections of the heart and lungs.

6. Dr. Crampton¹ recommends the application of leeches to the internal surfaces; as to the conjunctiva in ophthalmia, to the tonsils in cyanche tonsillar, and to the internal surface of the nostrils in epistaxis. The mode of applying a leech to the tonsils is as follows: pass a single thread of silk through the body of the leech, and make fast the ligature to the finger of the operator; then apply the leech to the part.

There are few diseases in which loss of blood is required, where leeching is positively objectionable; indeed, erysipelas is the only one that can be named. Here it has been supposed that the local irritation caused by leeches would add to the severity of the malady; but I believe that, even in this case, the objections are more imaginary than real. There are, however, numerous instances in which leeching is negatively objectionable; in some, the quantity of blood drawn by these animals is insufficient to make much impression on the disease, as in visceral inflammation of robust persons; in others, where the disease is very rapid and fatal, the effects of leeches are too slow, as in croup. Venesection is the remedy in all these instances.²

MODE OF APPLYING LEECHES.—Let the part be well cleansed (sometimes it may be necessary to shave it); then dry the leeches, by rolling them in a clean linen cloth; place them in the lid of a pill-box, and apply to the affected part. This is a preferable method to applying them by the fingers, or in a wineglass. A narrow tube (called a *leech-glass*) will be found useful when we wish to affix one of these animals to the inside of the mouth, or any particular spot. [By grasping the body of the leech gently in a dry cloth, its head may be directed to any part where we wish it to be applied; and by gently withdrawing it as its head reaches the skin, we compel the animal to fix its head to the spot, and insert its teeth.—Ed.]

¹ *Dublin Hospital Reports*, vol. lii, 1822.

² For a more extended account of the uses of leeching, see Dr. R. Price, *Treatise on the Utility of Sanguisuction*, 1822.

Several circumstances influence the fixing of leeches; as the condition of the animal, whether healthy or otherwise; the nature and condition of the part to which it is applied: thus, leeches will not readily attach themselves to the soles of the feet, or the palms of the hands, or to the hairy parts—the presence of grease, vinegar, salt, and some other substances, will prevent them from biting; whereas, milk, sugared water, and blood, are said to have the contrary effect. Scarifying the part promotes their attachment. The condition of the patient also affects the fixing of the animal. Derheims¹ says that leeches will not bite those under the influence of sulphur, on account of the evolution of sulphuretted hydrogen by the skin. The effluvia or vapours of the room, as the fumes of tobacco, sulphur, vinegar, &c., will prevent them biting, or even cause them suddenly to fall off.

The quantity of blood a leech is capable of drawing varies considerably. I believe four drachms to be the maximum. On an average, I do not think we ought to estimate it at more than one drachm and a half. Of course this has no reference to that lost after the animal has fallen off; and which varies according to the vascularity of the part; in children being oftentimes very considerable. When the leech has had sufficient it drops off; but it is said that if the tail be snipped the animal will continue to bite, the blood passing out posteriorly as fast as it is taken in by the mouth. I have tried several, but they usually let go their hold the instant the tail is cut. H. Cloquet² has made the same remark. In order to disgorge the leech of the blood, the usual practice is to apply salt to its body; but it is objectionable (if you wish to preserve the animal), since the surface is frequently thereby blistered, and several days elapse ere the creature regains its former activity. Some advise squeezing the blood out by the mouth; others, the application of diluted vinegar to the head. If no kind of emetic be employed, the blood remains for a considerable time in the stomach of the leech undigested, but without putrefying.

AFTER-TREATMENT.—When leeches have fallen off, it is generally desirable to promote the sanguineous discharge. This is best done by the use of warm fomentations or cataplasms; or even, in some cases, by cupping-glasses. Great caution is necessary in the case of children. Some years since, the application of a leech was ordered to the chest of a child labouring under pneumonia; it was at the same time mentioned that the bleeding should be encouraged. The directions were literally fulfilled—the discharge of blood was assiduously promoted—until so large a quantity had been lost that death was the result. No attempt was made to stop it, nor notice sent to the Dispensary, in the practice of which the case occurred. The child being illegitimate, and the mother evidently careless of its recovery, led some to suspect that this did not take place through mere ignorance. In another instance two leeches were ordered for a child aged about eighteen months, suffering with pneumonic inflammation, a consequence of measles. The following day the poor little creature was found in a fainting, or rather dying state, with face and lips completely blanched. On inquiry, it appeared the leech-bites were still bleeding, and no attempt had been made to stop the discharge, the mother thinking it would be beneficial, more especially as the pneumonic symptoms had considerably abated. As predicted, the little sufferer died within twenty-four hours.

In some persons, there appears to be an hereditary predisposition to hemorrhage, so that very slight wounds are attended with serious and even fatal effects. Mr. Wilson, quoted by Mr. Wardrop,³ has related the case of a child where one leech had nearly caused death, by the serious hemorrhage. When about three or four years old, this child bit its tongue, and, notwithstanding that every attempt was made to stop the discharge, death took place from the loss of blood.

I have been called to many cases of hemorrhage after leech bites, and have never failed in stopping it by compression. Sometimes mere exposure to the air will be suf-

¹ *Hist. Nat. et Méd. des Sangs.* p. 134, 1825.

² *Op. supra cit.* p. 13.

³ *Dict. de Méd. art. Sangsue,* p. 83.

ficient; or, if this fail, we may apply a dossil of lint and a bandage. In other instances, this will not succeed. I usually employ compression, thus: roll a piece of lint into a fine cone, and introduce it into the bites by means of a needle or probe; over this lay a compress and bandage. Sponge may be substituted for the lint. Various other modes have been proposed; some, I think, exceedingly cruel, since I do not believe them ever necessary. I allude, now, to the application of a red-hot needle; and to passing a needle through the orifice, and wrapping thread round, just as a farrier stops the discharge of blood from the vein of a horse. Some employ absorbing powders, as gum arabic; or styptic washes, as a saturated solution of alum. One very effectual means is to apply a stick of lunar caustic scraped to a point, or powdered nitrate of silver. Sir Charles Bell, in one case, stitched up the wound.

ACCIDENTS FROM LEECHES IN THE MUCOUS CAVITIES.—The ancients were very apprehensive of the ill consequences likely to arise from swallowing leeches. That their fears were not groundless is proved from the following circumstances, related by the celebrated Baron Larrey. When the French army entered upon the deserts which separate Egypt from Syria, the soldiers, pressed by thirst, threw themselves on their faces, and drank greedily of the muddy water, and which, unknown to them, contained leeches (*Sanguisuga ægyptiaca*), having the form of a horse-hair, and the length of a few lines only. Many of them felt immediately stings, or prickling pains, in the posterior fauces, followed by frequent coughs, glairy spots, slightly tinged with blood, and a disposition to vomit, with a difficulty of swallowing, laborious respiration, and sharp pains in the chest, loss of appetite and rest, attended with great uneasiness and agitation. On pressing down the tongue of the individual first attacked, a leech was discovered, which was with difficulty removed by the forceps. Little or no hemorrhage followed, and the patient recovered. Those which had attached themselves to the posterior fauces were removed by the use of gargles composed of vinegar and salt water. The Chief of Brigade, Latour-Mauberg, commander of the 22d regiment of chasseurs, swallowed two in the deserts of St. Makaïre, a day's journey from the Pyramids, which so much weakened him, that his convalescence was long and difficult.

Derheims¹ relates a case where a young man, who had leeches applied to his anus, was so unfortunate as to have one enter his rectum unnoticed. The animal made several punctures, and was not expelled until some hours after, when salt-water injections were used. The wounds caused by the bites, however, did not heal for several months, during which time the patient suffered considerably, and constantly passed blood with the feces.

Whenever practicable, salt-water injections should be resorted to. In the following cases related by Derheims² this practice could not be adopted. Two small leeches were applied to the gums of an infant during the period of dentition, and by the inattention of the nurse they fixed themselves at the back part of the mouth, and, becoming gorged with blood, caused great difficulty of respiration. The infant, by strongly closing the jaws, prevented the removal of the animals, who only ceased their hold when they were filled with blood. The hemorrhage continued for two hours.

Ill effects have resulted from swallowing leeches. A lady accidentally swallowed a leech she was applying to her gums. Acute cardialgia soon came on, with a feeling of erosion and creeping in the interior of the stomach; sometimes convulsive movements in the limbs and muscles of the face; frequency and irregularity of the pulse; universal agitation and paleness of the countenance. The physician who was called in, recollecting the fact ascertained by Bibiéna, that leeches could not live in wine, administered half a glass every quarter of an hour. The symptoms were soon alleviated; and the fourth dose caused vomiting, by which the dead leech

¹ *Op. supra cit.* p. 140.

² Page 140.

was evacuated, with much glairy matter, mixed with clots of black blood. By a proper subsequent treatment, the patient recovered in eight days.¹

[The following case occurred within our knowledge: A lady was directed to apply a leech to the septum of the nose. By some accident the animal insinuated itself into the nasal cavities, and, reaching the posterior nares, the patient was irresistibly compelled to swallow it. No uneasiness was felt, probably owing to the leech having already drawn much blood. A moderately strong solution of chloride of sodium was administered at short intervals. The leech was not discharged by vomiting, and it did not pass by the bowels. The patient suffered from no unusual symptoms, probably owing to the rapid administration of the solution of salt.—ED.]

Class VI. Insecta, Goldfuss.—Insects.

CHARACTERS.—Articulated animals with 6 feet (*hexapoda*), one pair of *antennæ*, a dorsal vessel for circulation, respiring by *tracheæ*, and undergoing *metamorphosis* (being successively *ovum*, *larva*, *pupa*, and *imago*). Head distinct from the thorax.

ORDER I. COLEOPTERA, Linnæus.—BEETLES.

CHARACTERS.—4 wings, of which the two upper or anterior *elytra* or (*wing cases*) are horny or leathery, united down the back by a straight suture; lower or posterior wings folded longitudinally. Mandibles and jaws for mastication.

354. CANTHARIS VESICATORIA, Latreille, L. E. D.—THE BLISTER BEETLE, OR SPANISH FLY.

Lytta vesicatoria, Fabricius; *Meloë vesicatorius*, Linnæus.
(The whole fly. E.—*Cantharis*, U. S.)

HISTORY.—Hippocrates employed in medicine an insect which he calls *καρθαρις*, whose effects were similar to those of our *Cantharis vesicatoria*. Hence, it has been erroneously inferred by some writers that our blistering beetle is identical with that employed by the ancients. That this inference is incorrect is proved by the following facts. In the first place, many beetles agree in their effects on the system with those of *Cantharis vesicatoria*; secondly, the word *καρθαρις* merely signifies a *small beetle* or *scarabæus parvus*; thirdly, both Dioscorides² and Pliny³ refer to several kinds of *cantharides*, but remark that the most powerful are those with transverse yellow bands on the wings, and that those which are homogeneous in colour are weak and inert. It is tolerably clear, therefore, that neither of these ancient writers was acquainted with *Cantharis vesicatoria*. Now the characters assigned to the ancient blistering insect agree precisely with those of two species of *Mylabris*. Burmeister⁴ suggests that *Mylabris Füsselini*, a native of the south of Europe, was the species used by the ancients. *Mylabris Cichorii* is employed as a blistering beetle at the present day in China and some parts of Hindostan, and may, perhaps, have been used by the Greeks and Romans.

ZOOLOGY. Gen. Char.—*Antennæ* elongate, simple, filiform. *Maxillary palpi* with terminal joint somewhat ovate. *Head* large, heart-shaped. *Thorax* small, rather quadrate, narrower than the *elytra*, which are as long as the abdomen, soft, linear, the apex slightly gaping. *Wings* two, ample (J. F. Stephens).⁵

Sp. Char.—Bright glossy brass-green or bluish, glabrous; beneath more glossy, with a few hairs. *Breast* densely pubescent, finely punctured. *Head* and *thorax* with a longitudinal channel. *Elytra* with two slightly raised lines. *Tarsi* violaceous. *Antennæ* black, with the basal joint brassy (J. F. Stephens).

¹ *Recueil périodique*.

² *Hist. Nat.* l. b. xxix. cap. 30, ed. Valp.

³ *Man. of Brit. Coleopt.* p. 334, 1839.

⁴ *Lib. ii.* cap. 65.

⁵ *Man. of Entomol.* by Shuckard, p. 562, 1836.

Form elongated, almost cylindrical. *Length* six to eleven lines. *Breadth* one to two lines. *Colour* brass or copper green. *Odour* nauseous, unpleasant. *Body* covered with whitish-gray hairs, which are most numerous on the thorax. *Head* large, subcordate, with a longitudinal furrow along its top. *Eyes* lateral, dark brown. *Thorax* not larger than the head, narrowed at the base. *Elytra* from four to six lines long, and from 3-4ths to 1½ lines broad; costa slightly margined. *Wings* ample, thin, membranous, veined, transparent, pale brown; tips folded. *Legs* stout, from four to six lines long, the hinder ones longest; *tibiæ* clavate, in the female all terminated by two small movable *spurs*; in the male, the two hinder pairs of extremities alone have this arrangement, the anterior ones having but one spur; last joint of the *tarsi* with a pair of bifid claws. *Abdomen* soft, broadest in the female. In the female, near the anus, are two articulated, caudal appendages.

Fig. 426.

Cantharides.

The *internal organization* of these animals has been elaborately studied by Audouin¹ and by Brandt² THE NERVOUS SYSTEM consists of a cerebro spinal axis, and a double and single sympathetic system. The *cerebro-spinal axis* consists of a double nervous cord, and nine ganglia (two cephalic, one of which is the brain, three thoracic, and four abdominal). The *single sympathetic system* commences at the brain by two branches, which unite at the ganglion frontale, from which a single nerve proceeds along the œsophagus to the stomach, where it divides into two, forming at its division a small ganglion. The *double sympathetic system* consists of four ganglia placed on the œsophagus, two on either side of the single nervous cord just described,

with which, as well as with the brain, they are connected by nervous twigs. THE VASCULAR SYSTEM consists of a simple pulsating dorsal vessel, which extends from the head to the extremity of the abdomen. THE RESPIRATORY SYSTEM consists of ten pair (three thoracic, seven abdominal) of stigmata, which open into the tracheæ. THE DIGESTIVE SYSTEM consists of the mouth, which terminates in the pharynx. The latter contracts into a long muscular œsophagus, which ends in an elongated fusiform stomach. The latter is marked transversely by bands formed by the

² Med. Zool. ii.

muscular coat. Between the stomach and intestine is a *valve* (pylorus) formed by four small floating, kidney-shaped bodies. The *small intestine* forms two curvatures, and then proceeding directly backwards, terminates in the swollen *cæcum*, which ends in the very short narrow *rectum*. The *biliary vessels* consist of six very long, filiform, convoluted tubes, which terminate anteriorly at the stomach near the pylorus, and posteriorly at the intestine near the *cæcum*. THE SEXUAL SYSTEM of the MALE consists of a pair of spherical *testicles*, having externally a granulated appearance; two *vasa deferentia*, which have a ringed appearance; three or four pairs of tubes (*seminal vesicles* or *epididymoid vessels*), the functions of which are imperfectly known; a *common spermatic duct*; and a *penis*, which has three barbs or *hooks* at its extremity, and is enveloped by a *sheath*. THE FEMALE ORGANS consist of two large, hollow, egg-shaped *ovaries*, the cavities of which are called *calyces*. On their external surface is an immense number of pyriform *egg-tubes*. From each ovary or calyx arises an *oviduct*, and the two oviducts by their junction form the *common oviduct*, the lower portion of which is called the *vagina*. Into the common oviduct passes a *tube* from a vascular bag, called *spermatheca* (*vesicula copulatrice*, Audouin), and also from other *appendages* (*sebaceous glands*, Audouin).

I must refer to Audouin's paper for an amusing account of the amours of these animals.

HAB.—Europe. Originally, perhaps, a native of the southern parts, especially Italy and Spain. Now found in France, Germany, Hungary, Russia, Siberia, and England. With us they are rare. In the summer of 1837, they were abundant in Essex and Suffolk.¹ They are found on species of *Oleaceæ* (as the ash, privet, and lilac), and of *Caprifoliaceæ* (as the elder and Lonicera).

MODE OF CATCHING CANTHARIDES.—In the south of France these animals are caught during the month of May, either in the morning or evening, when they are less active, by spreading large cloths under the trees, which are then strongly shaken or beaten with long poles. The catchers usually cover their faces, and guard their hands by gloves.² Various methods have been recommended for killing the insects; such as exposing them to the vapour of vinegar (the practice mentioned by Dioscorides), or of hot water, or of spirit of wine, or of the oil of turpentine. Geiger states that, if destroyed by dropping oil of turpentine into the bottle in which they are contained, they are not subject to the attack of mites; but I believe they are more frequently destroyed by immersing the cloths containing them in hot vinegar and water, and then drying on hurdles covered with paper or cloths.

PRESERVATION.—Cantharides should be preserved in well-stoppered bottles, and to prevent them from being attacked by mites (*Acarus domesticus*), a few drops of strong acetic acid should be added to them. I have found this a most successful mode of preservation. (Besides mites, they are subject to the attacks of a moth (*Tinea flavifrontella*), and two coleopterous insects (*Anthrenus muscorum* and *Hoplia farinosa*).

COMMERCE.—Cantharides are imported from St. Petersburg, in cases, each containing 160 or 170 lbs.; and also from Messina, in barrels or cases, holding each about 100 lbs. They are principally brought over towards the end of the year. In 1839, duty (1s. per lb.) was paid on 16,376 lbs.

The cantharides from St. Petersburg are the largest and most esteemed. They are somewhat more copper-coloured than the French or English varieties, which have rather a brassy than copper tint. Sir James Wylie³ states that they are very abundant in the southern provinces of Russia.

CHARACTERISTICS FOR MEDICO-LEGAL PURPOSES.—There are no *chemical tests* for cantharides, to be relied on. Orfila⁴ has published an account of the effects of various reagents on tincture of cantharides; but they are unimportant. Cantharides are rarely met with in a sufficiently perfect form to enable us to recognize them by their *zoological characters*. Their *physical characters* are much more important. In all powders of cantharides golden green particles may be distinguished; these may be separated from the other contents of the stomach by immersing them in boiling water; the fatty matter rises to the surface, while the cantharides powder falls to the bottom. Orfila has recognized these particles in a body nine months

¹ Westwood, *Intr. to the Mod. Classif. of Insects*, vol. i. 1839.

³ Richard, *Dict. des Drog.* i. 550.

⁴ *Toxicol. Gén.*

after interment; so that they do not readily decompose, even when mixed with decaying animal matters. [A portion of the suspected substance spread in a thin layer should be allowed to dry on a piece of glass. When dried, either by the naked eye or by the aid of a lens, the green and copper-coloured particles of the wings may be seen, if cantharides be present, on one or both sides of the glass.—Ed.] Some other insects, however, have the same golden-green colour, but are without vesicating properties; and *vice versa*, there are many insects which vesicate, but which have not a golden-green colour. The physical characters of the particles, aided by their *physiological effects*, together form tolerably conclusive evidence of the presence of cantharides. To judge of the effects of cantharides, and their preparations, we should proceed as follows: If the suspected matter be a liquid, evaporate it to the consistence of an extract; then digest in repeated quantities of sulphuric ether. The ethereal solutions are to be mixed, and allowed to evaporate in the air; the vesicating properties of the residuum may be determined by applying it to the inside of the lip or to the arm. If the suspected matter contain solid particles, these are to be digested in ether, and the concentrated tincture applied to the inner surface of the lip.¹ Dr. Hastings² has published an interesting fatal case of inflammation of the alimentary canal and urinary organs. The symptoms simulated those caused by excessive doses of cantharides; but the moral and other evidence seemed to negative the suspicion that insects had been taken.

ADULTERATION AND GOODNESS.—The goodness or quality of cantharides may be recognized by their odour, and freedom from other insects, especially mites. Sometimes the powder, but more commonly the plaster, is adulterated with powdered euphorbium. I have been informed, by persons well acquainted with the fact, that it is a common practice, amongst certain druggists, to mix one pound of euphorbium with fourteen pounds of powdered Spanish flies.

COMPOSITION.—Cantharides were analyzed in 1803 by Thouvenal,³ in 1804 by Beaupoil,⁴ and in 1810 by Roubiquet.⁵

Thouvenal's Analysis.	Beaupoil's Analysis.	Roubiquet's Analysis.
Watery extract . . . 37.50	Black matter, insoluble in alcohol, but soluble in water 12.04	1. <i>Cantharidin</i> .
Subsequent alcoholic extract 10.42	Yellow matter, soluble in water, alcohol, and ether 12.94	2. Green fatty oil, soluble in alcohol.
Subsequent ethereal extract 2.08	Green oil, soluble in alcohol and ether 13.99	3. Fatty matter, insoluble in alcohol.
Insoluble residuum . . 50.00	Parenchyma, salts, and oxide of iron 60.13	4. Yellow viscid substance, soluble in water and alcohol (osmazone?).

	Total 100.00	6. Yellow matter, soluble in ether and alcohol.
		7. Free acetic and uric acids.
		8. Phosphate of lime, and phosphate of magnesia.
		Cantharis vesicatoria.

1. **CANTHARIDIN** (*Vesicatorin*; *Cantharides-Camphor*).—Has been found in *Cantharides vesicatoria*, *Lytta vittata*, *Mylabris Cichorii*, and other vesicating insects. Probably exists in all the blistering beetles. To procure it, concentrate an alcoholic tincture (prepared by percolation) and set aside; the cantharidin slowly crystallizes. It is purified by washing with cold alcohol, and boiling with alcohol and animal charcoal. Its properties are as follows: It crystallizes in the form of micaceous plates, which are fusible, forming a yellow oil, which by a stronger heat is vaporizable, forming white vapours; these subsequently condense into acicular crystals of cantharidin. Dana regards it as an organic alkali, but without any just grounds; for it will not restore the blue colour of litmus paper reddened by an acid. Gmelin's opinion, that it is a solid volatile oil, seems to be correct. When isolated, it is not soluble in water, but becomes so by combination with the other constituents of cantharides; the yellow matter probably being the principal agent in rendering it so. This, then, is the reason why an aqueous infusion of the insects contains cantharidin in solution. Cold spirit, digested on cantharides, extracts cantharidin; which it can only do by the agency of some of the other principles of the flies. It is easily soluble in ether, oils (volatile and fixed), and hot spirit of wine; and from the latter it separates as the liquid cools. Concentrated boiling sulphuric acid dissolves cantharidin; the

¹ See *Ann. d'Hygiene Publique*, 1835, xiii. p. 455.

² *Trans. of the Provin. Med. and Surg. Assoc.* vol. i. p. 402.

³ *Ann. de Chim.* xlvii. 230.

⁴ *Ibid.* lxxvi. 302.

⁵ *Ibid.* xlviii. 29.

solution is slightly brown; when diluted with water it deposits small needle-like crystals of cantharidin. Boiling nitric and hydrochloric acids dissolve it without changing colour; the solutions, by cooling, deposit it. Cantharidin is dissolved by potash and soda; but when concentrated acetic acid is added to the solution, the cantharidin is precipitated. Ammonia is without action on it. According to Regnaud, it consists of carbon 61.68; hydrogen 6.04; and oxygen 32.28.

Robiquet thus describes the effects of cantharidin: The 1-100th part of a grain, placed on a slip of paper and applied to the edge of the lower lip, caused, in about a quarter of an hour, small blisters. A little cerate being applied, served only to extend the action over a larger surface, and both lips were in consequence covered with blisters. Some atoms of cantharidin, dissolved in two or three drops of almond oil, were rubbed over a small piece of paper, and applied to the arm; in six hours the blister was formed, the size of the paper. The volatility of cantharidin at a comparatively low temperature, and the action of the vapour on the conjunctival membrane, are shown by the accident which happened to one of Robiquet's pupils, who was watching its crystallization, and felt acute pain in the conjunctiva, which was followed by inflammation, accompanied with small phlyctenæ, and loss of sight for several days. Robiquet, who was not so near the liquid, suffered but slightly. I have suffered once in preparing this substance. I applied one drop of an ethereal solution of impure cantharidin to the inside of the lower lip; but immediately afterwards, repenting of my temerity, I wiped it carefully off. In about an hour a blister had formed on the inside of the lip, and it was five or six days before the part had completely healed. Bretonneau, in his experiments on animals, has not found any marked aphrodisiac effect produced by cantharidin. He found that it rendered the circulation slower, and caused fatal lethargy.

2. VOLATILE-ODOROUS OIL?—Orfila asserts that volatile odorous oil is one of the constituents of the insects. The distilled water of cantharides is strongly odorous and milky; and its vapour affects the eyes and kidneys like cantharides.

The active and odorous principles of cantharides reside principally in the sexual organs of the animals. Both Farines and Zier tell us, that the soft contain more active matter than the hard parts. It appears, also, that the posterior is much more acrid than the anterior portion of the body; and Zier says the ovaries are particularly rich in this active matter. If so, it is evident that we ought to prefer large female to male insects. It is a well-known fact, that the odour of these animals becomes much more powerful at the season of copulation than at other periods; and that persons sitting under the trees in which these insects are found, at this season more particularly, are very apt to be attacked with ophthalmia and ardor urine.

PHYSIOLOGICAL EFFECTS. *a. On Animals.*—The principal experiments with cantharides on animals (dogs) are those of Orfila¹ and Schubarth.² It results from their investigations, that these insects cause violent inflammation in the parts to which they are applied, and an affection of the nervous system (spinal cord, principally). Injected into the jugular vein, the oleaginous infusion caused tetanus; introduced into the stomach, the œsophagus being tied, the tincture produced insensibility (Orfila). Inflammation of the inner coat of the bladder was observed when the poison had remained in the stomach for a few hours before death.

β. On Man.—The topical effects of cantharides are those of a most powerful acrid. When these insects are applied to the skin, the first effects noticed are, a sensation of heat accompanied by pain, redness, and slight swelling. These phenomena are soon followed by a serous effusion between the corium and epidermis, by which the latter is raised, forming what is commonly termed a blister, or, in the more precise language of the cutaneous pathologist, an *ampulla* or *bulla*. The effused liquid has a pale-yellow colour, with a very feeble taste and smell. Two analyses of it have been made:—

Analysis by Dr. Bostock.		Analysis by Brandes and Reimann.	
Albumen	6.00	Albumen	5.75
Uncoagulable matter	0.14	Animal matter, with muriate of ammonia, potash salts, carbonates, lactate, muriate, and sulphate of soda	0.26
Salts	1.00	Water	93.99
Water	92.86		
	100.00		100.00

If the cuticle be removed, the subjacent corium is seen intensely reddened, and, by exposure to the air, oftentimes becomes exceedingly painful. If irritants be applied, a secretion of pus takes place, and sometimes a whitish-looking false mem-

¹ *Toxicol. Gén.*

² Wibmer, *Wirk. d. Arzneim. u. Gifte*, Bd. iii. S. 262.

brane is formed. Long-continued irritation occasionally causes tubercular granulations. Not unfrequently I have noticed ecchymatous pustules around the blistered surface; and in one remarkable case, which fell under my notice, the whole body, but more especially the pectoral region (to which the blister had been applied), was covered with them. Sometimes the vesicles of eczema occur. Ulceration and gangrene are not uncommon; the latter effect is occasionally observed after exanthematous diseases, especially measles. I have seen death result therefrom in two instances. The constitutional symptoms frequently produced are excitement of the vascular system (as denoted by the increased frequency of pulse, heat of skin, and furred tongue), and irritation of the urinary and genital organs (marked by heat and pain in passing the urine, which is usually high coloured, or there may be complete suppression). It not unfrequently happens that the part to which a blister has been applied remains considerably darker coloured than the surrounding skin. Rayer states that the disappearance of these discolorations is hastened by the use of sulphurous baths.

When swallowed, cantharides act topically on the *gastro-intestinal membrane*; in poisonous quantities they excite inflammation of the mucous lining of the alimentary canal, with constriction and difficulty of swallowing, which is sometimes so great, that not a particle of fluid can be got into the stomach without the most inexpressible anguish; violent burning pain, nausea, vomiting, frequently of bloody matters, sometimes with flakes like the inner lining of the alimentary tube, and great tenderness to touch. These phenomena sufficiently indicate the gastric inflammation. Ptyalism is not an uncommon occurrence. The enteritic symptoms are, abundant and frequent evacuations, sometimes of blood, with horrible griping and burning pain, and exquisite sensibility of the abdomen.

The *volatile odorous matter* evolved by these insects is a local irritant; for it causes itching and even inflammation of the eyelids and conjunctiva, irritation of the air-passages, marked by epistaxis, convulsive sneezing, &c. If it be inhaled, as is done when persons sit under trees on which the animals are found, or by breathing the vapour of decoction of cantharides, an affection of the urinary organs may be brought on. The same remote effects may also be excited by blisters, by handling the insects, by applying them to wounds, by swallowing them, or by injecting solutions of their active principle into the veins. We may classify the *remote effects* of cantharides into those observed in the urino-genital, the nervous, and the vascular systems.

aa. Action on the Urino-genital System.—The pain in the loins, and the alteration in the quantity and quality of the urine, are the symptoms indicative of the inflamed condition of the kidneys. The burning pain and tenderness in the hypogastric region, and the constant desire to pass the urine, with the inability of doing so except drop by drop, are evidences of the vesical inflammation. The action on the genital organs in the male is proved by priapism, which is sometimes accompanied by satyriasis, sometimes not; and by the occasional inflammation and mortification of the external organs. In the female, the action on the sexual system is shown by the local heat and irritation, and by the occasional occurrence of abortion.

bb. Action on the Nervous System.—The affection of this system is proved by the pain in the head, disordered intellect, manifested in the form of furious or phrenitic delirium, convulsions of the tetanic kind, and subsequently coma. It is deserving of especial notice, that sometimes several days elapse before the nervous symptoms show themselves: thus, in a case related by Giulio, they appeared on the third day; in another instance, mentioned by Graaf, on the eighth; and in a case noticed by Dr. Ives, they were not observed until the fourteenth day.¹

cc. Action on the Vascular System.—The pulse becomes hard and frequent, the skin hot, and the respiration quickened; diaphoresis is occasionally observed.

The susceptibility to the influence of cantharides is by no means uniform. Werl-

¹ See Christison, *Treatise on Poisons*

hoff mentions the case of a lad who used to be attacked with priapism and involuntary emission by merely smelling the powder. Amoreux says, in one case a pinch of the powder caused death; while in another a spoonful occasioned only slight heat in the throat, and ardor urinæ. Dr. Hosack has mentioned an instance in which a man took nearly six ounces of the tincture with the view of self-destruction, yet no dangerous symptoms followed. In contrast with this, I may instance a case that came within my own knowledge, where one ounce of the tincture produced serious symptoms. Orfila has seen twenty-four grains of the powder prove fatal.

1. *Action in small or medicinal doses.*—In very small quantities there are no obvious effects. If we increase the dose, a sensation of warmth is felt in the throat, stomach, and respiratory passages, with increased secretion from the alimentary tube. By continued use, a tickling or burning sensation is experienced in the urethra, with frequent desire to pass the urine, which may or may not be altered in quality and quantity. In some cases diuresis is observed, in others not; in the latter the urine is generally higher coloured than usual. Occasionally the sexual feelings are excited.

2. *Action in larger doses; Subacute Poisoning.*—The symptoms are heat in the throat, stomach, intestines, and respiratory passages; pain in the loins, burning sensation in the bladder, with frequent desire to evacuate the urine, which is sometimes bloody, and passed with difficulty. Painful priapism, with or without satyriasis. Pulse more frequent, skin hot, and the respiration quickened; the nervous system is frequently excited.

3. *Action in still larger doses; Acute Poisoning.*—The symptoms observed are, in part, common to other irritant poisons; in part peculiar to the vesicating insects. Violent burning in the stomach, with exquisite sensibility and constant vomiting; extreme thirst, dryness, and fetid odour of the mouth, and not unfrequently ptyalism. Burning pain and spasmodic contraction of the bladder, giving rise to the most excruciating agony. Notwithstanding the incessant desire to void urine, nothing but drops of blood are passed, and with great pain. The constriction of the throat and difficulty of deglutition are most distressing and alarming; the unfortunate sufferer is constantly tormented with violent gripings, purging, generally of blood, extreme tenderness of the whole abdominal surface, faintings, giddiness, convulsions, and an almost hydrophobic aversion to liquids, with delirium terminating in coma.

The mode and immediate cause of death are various; sometimes the nervous symptoms kill before gangrene makes its appearance; but more usually the patient dies from inflammation and subsequent mortification of the alimentary tube or of the genital organs.

POST-MORTEM APPEARANCES.—On opening the bodies of persons poisoned by cantharides, inflammation and its consequences have been observed in the alimentary tube, and the urinary and genital organs. The cerebral vessels have been found in a congested state. It is deserving of notice that inflammation of the urino-genital organs is more likely to be met with in patients dying within a few days after poisoning.

USES.—Hippocrates used vesicating insects (under the name of cantharides) internally; but the practice was subsequently regarded as dangerous; and, so lately as the year 1693, the President of the College of Physicians committed Dr. Groenvelt to Newgate for daring to employ them!¹

1. *Local Uses.*—Cantharides are frequently used as topical agents; sometimes as stimulants, sometimes as rubefacients, at other times as vesicants.

a. *To stimulate topically.*—Tincture of cantharides with water (in the proportion of three or four drachms of the tincture to a pint of water) has been employed to stimulate ulcers; more especially sinuses and fistulous sores. It is said, on the same principle that stimulant and irritant applications are made to the eye in oph-

¹ Groenvelt, *De tuto Cantharidum in medicinâ usu interno*, 12mo. Lond. 1698; Greenfield, *Treatise on Cantharides*, translated by Martin, 1706.

thalmia; that is, to excite a new action, which shall supersede the old one. Matthew's once celebrated injection for fistula *in ano* is a wash of this kind.¹ In *alopecia* or *baldness*, when this is not the result of old age, unguents of cantharides have been employed to promote the growth of hair. Powdered cantharides have been advised as an application to the *parts bitten by rabid animals*.

β. To produce Rubefaction.—For this purpose the tincture may be mixed with soap or camphor liniment; or when it is desirable to limit the effect to a particular spot, and especially if friction be objectionable, the common blistering plaster may be applied, allowing it to remain in contact with the part for an hour or two only. Rubefacient liniments are employed to *excite the sensibility of the skin in numbness and paralysis*; as also to *promote local irritation in neuralgic and rheumatic pains*. In the *inflammatory affections of children* it will be occasionally found useful to employ the plaster as a rubefacient merely.

γ. To excite Vesication.—A considerable number of substances (mineral, vegetable, and animal) cause vesication when applied to the skin. Horseradish, meze-reon, liquor ammoniæ, and acetic acid, may be mentioned as examples. To these may be added heat, applied in the form of hot water, or a hot metallic plate. For facility of application, certainty of effect, and slightness of pain, no agents are equal to cantharides, and these are now almost solely used.

It was formerly supposed that the efficacy of blisters was in proportion to the quantity of fluid discharged. But the truth is, that the therapeutic influence is in proportion to the local irritation, and has no more relation to the quantity of fluid discharged than that the latter is frequently (not invariably) in the ratio of the former. Stoll's axiom is, therefore, correct: "Non suppuratio sed stimulus prod-est." As to the precise manner in which blisters, or, indeed, any remedies, influence diseases, we are quite in the dark. We are accustomed to refer their operation to the principles of counter-irritation. I must refer those who feel interested in the question whether blisters ought to be applied in the neighbourhood of, or at a distance from, the affected part, to a paper by Barthez, in the *Recueil de la Société Médicale de Paris*. In this country, we generally apply them near to the morbid part; to which practice Barthez assents, with some exceptions.

We employ blisters in inflammatory diseases, both acute and chronic; in the former, however, preceding their use by bloodletting. In chronic inflammatory disease we often employ what is termed a perpetual blister; that is, the cuticle is removed, and the blistered surface dressed with savine or cantharides ointment. This practice is advisable in chronic diseases of the chest, of the joints, of the eyes, &c. Blisters are sometimes used in erysipelas; thus to localize the disease when disposed to spread, and as a revulsive, applied to the feet, in erysipelas of the head. A blister to the perineum has been sometimes found beneficial in gleet.

It is hardly safe to apply blisters to children immediately after exanthematous diseases, sloughing being not an unfrequent result. If it be required to produce in them counter-irritation, the best plan is to dilute the common blistering plaster, by mixing with it three times its weight of soap cerate. I have seen this compound frequently employed, but never observed any unpleasant results from it. Another plan, sometimes adopted, is to apply a common blister, for an hour or two only, so that it shall merely produce rubefaction.

2. Remote Uses.—These will require examination under distinct heads, according to the particular object we have in view in employing cantharides.

a. To act specifically on the Urinary Organs.—In *dropsy*, they have been used to excite diuresis, though they frequently fail in producing this effect. In *diabetes*, cantharides have been employed, but without apparent benefit. In *paralysis of the bladder* they are frequently useful, when there are no marks of local irritation. Two opposite conditions may be the result of paralysis of this organ; namely, retention or incontinence of urine. The latter condition is not unfrequently met

¹ Dr. Paris, *Pharmacologia*.

with in children, and is very likely to be relieved by cantharides. It is usually stated they are particularly serviceable in that species of incontinence which occurs during sleep only; but I have seen them cure the disease during day, and fail in giving relief at night. The case alluded to was that of a boy, 14 years old, who had been subject to incontinence of urine since his infancy. He was a robust lad, and apparently in the most perfect health. I put him under the influence of gradually increased doses of cantharides, and within two months he was enabled to retain his urine by day, but it still passed involuntarily at night; and, though he continued the remedy for a considerable time, no further benefit was obtained. In incontinence of urine which occurs after lingering labours, from the long-continued pressure of the child's head, cantharides are sometimes serviceable. But their use must not be commenced until all the symptoms of local irritation have subsided.

β. *To act on the Organs of Generation.*—In consequence of the specific stimulus communicated by cantharides to the bladder, it has been supposed that the same influence might be extended to the uterus; and thus these insects have been employed as *stimulating emmenagogues*, in some cases with apparent benefit, but frequently without any obvious effect. Abortion has occasionally happened from their employment, as I have myself witnessed in one case.

Cantharides are also employed as an *aphrodisiac*, both in man and other animals (as horses, heifers, and asses). In man, if given in sufficient quantity to excite the sexual feelings, they endanger the patient's safety. Most of the cases in which we are requested to administer aphrodisiacs, will be found, on examination, to require moral rather than pharmacological treatment. In *discharges from the genital organs*, beneficial effects are frequently obtained by the internal use of cantharides. In gleet, they have been often found serviceable. Mr. Robertson¹ explains their efficacy by saying that they excite a mild inflammatory action on the urethra (shown by the discharge becoming thick, opaque, and puriform), which supersedes the previous morbid one. I have frequently found equal parts of tincture of chloride of iron and tincture of cantharides a successful combination in old-standing gonorrhoeas. The dose is twenty drops at the commencement.

γ. *In Chronic Skin Diseases.*—Pliny states that cantharides (*Mylabris*) were employed in a disease which he terms lichen. At the present time, tincture of cantharides is not unfrequently employed in *lepra psoriasis*, and *eczema*. Having found other remedies very successful in lepra and psoriasis, I have rarely had occasion to try cantharides; but Rayer² says: "Of all the energetic and dangerous remedies that have been used in lepra, the tincture of cantharides is, perhaps, that which has the most remarkable influence over the disease. The great objection to its employment is its liability to excite inflammation in the digestive organs and urinary passages, especially among females, which necessitates the immediate suspension, and occasionally the entire abandonment, of the medicine." Bielt has found it successful in chronic eczema, as well as in the scaly diseases.

δ. *In diseases of the nervous system*, cantharides were at one time in great repute. The cases in which they were employed were hydrophobia, epilepsy, chorea, tetanus, and mania. Experience has shown that they deserve little attention in any of these complaints.

ε. *In obstinate sores*, Mr. Robertson recommends cantharides on the same principle that he uses them in gleet.

ADMINISTRATION.—Powdered cantharides are not unfrequently employed internally. The dose is one or two grains in the form of pill. The *tincture* is the safest preparation, and should, therefore, always be preferred.

ANTIDOTE.—In poisoning by cantharides, remove the poison as speedily as possible from the stomach. If sickness have not commenced, the removal may be effected by the stomach-pump, emetics, or tickling the throat (see treatment of

¹ *Practical Treatise on the Powers of Cantharides*, 1806.

² *Diseases of the Skin*, translated by Dr. R. Willis.

poisoning by OPIUM, *ante*). Assist the vomiting by mucilaginous and albuminous demulcent liquids—as linseed-tea, milk, white of egg, with water, &c. No chemical antidote is known. Oil was at one time thought to be an excellent remedy; but since the discovery of its being a solvent for the cantharidin, suspicion has been entertained that it is calculated to increase, rather than decrease, the patient's danger. This theoretical and plausible objection, first broached, I believe, by Pallas, seems supported by experience. Orfila found that cantharides macerated in cold oil, and afterwards given to dogs, killed them in a few minutes; and Dr. Christison says, "the case mentioned in the Genoa Memoirs was evidently exasperated by the use of oil." I confess, however, I think farther experience is required to determine the hurtful consequences of employing oil; for—as the editors of the *Dictionnaire de Matière Médicale* very properly observe—on the same principles that oil is prohibited, mucilaginous drinks ought also to be prescribed, since cantharidin, aided by the yellow matter, dissolves in water; and on the other hand, oil, in some cases, has appeared to be beneficial. To counteract the effects of cantharides, bloodletting, both general and local, opium, and the warm-bath, must be resorted to. Camphor was at one time highly esteemed for counteracting the effects of cantharides. Oleaginous and mucilaginous injections into the bladder are recommended to relieve the vesical symptoms.

1. ACETUM CANTHARIDIS (*Epispasticum*), L.; *Acetum Cantharidis*, E.; *Vinegar (epispatic) of Cantharides*; *Acetum Cantharidis*, D.—(Cantharides, rubbed to powder, ℥ij; Acetic Acid Oj. Macerate the cantharides with the acid for eight days, occasionally shaking; lastly, express and strain, L.—"Cantharides, in powder, ℥ij; Acetic Acid f℥v; Pyroligneous Acid f℥xv; Euphorbium, in coarse powder, ℥ss. Mix the acids, add the powders, macerate for seven days, strain and express strongly, and filter the liquor," E.—Spanish Flies, in fine powder, ℥iv; Strong Acetic Acid f℥iv; Acetic Acid of commerce (sp. gr. 1044), f℥xvj. Mix the acids, and, having added the flies, macerate in a close vessel for fourteen days; then strain through flannel with expression, and filter, so as to obtain a clear liquid, D.)—Not fitted for internal employment. Applied to the skin as a convenient and prompt vesicant. In the formula of the London College, eight times as much cantharides are employed as in the tincture.

2. TINCTURA CANTHARIDIS, L. E. D. [U. S.]; *Tinctura Lyttæ*; *Tincture of Cantharides*.—(Cantharides, in powder, ℥iv; Proof Spirit Oij; [Spanish Flies, bruised, ℥j; Diluted Alcohol Oij, U. S.] Macerate for seven [fourteen, D., U. S.] days, [strain and express strongly the residuum, E.] express, and filter, D. "This tincture may be obtained much more conveniently and expeditiously by percolation, provided the cantharides be reduced to coarse powder, and left with a little of the spirit in a state of pulp for twelve hours before the process of percolation is commenced," E.)—The strength of this preparation is now uniform in the three British Pharmacopœias. Dose, ℞x, gradually increased to ℥j. Its effects on the bladder must be carefully watched. It should be given in some demulcent liquid, as barley water or linseed tea. It is sometimes employed externally as a rubefacient.

3. CERATUM CANTHARIDIS, L.; *Unguentum Cantharidis*, E.; *Cerate of Cantharides*.—(Cantharides, in very fine powder, ℥j; Spermæci Cerate [Resinous Ointment, E.] ℥vj. [℥vij, E.] Add the cantharides to the cerate, softened by heat, and mix.)—This preparation must not be confounded with the next one, than which it is more irritant. The uses of the two are the same. From the greater activity of the cerate, more danger of the absorption of the active principle of the cantharides is to be apprehended. When this occurs, the bladder becomes affected, and, in some cases, inflammation of the absorbents, and fever, are produced.

4. UNGUENTUM INFUSI CANTHARIDIS, E.; *Unguentum Cantharidis*, L. D. [U. S.]; *Ointment of Cantharides*.—(Cantharides, in very fine powder, ℥ij [℥ij, U. S.]; Distilled Water f℥xij [Oss, U. S.]; Resinous Cerate lbj [℥vij, U. S.]. Boil the

water with the cantharides down to one-half, and strain. Mix the cerate with the strained liquor, then evaporate the mixture to a proper consistence, *L.*—"Cantharides, in moderately fine powder, Resin, and Beeswax, of each ℥j; Venice Turpentine and Axunge, of each ℥ij; Boiling Water ℥v. Infuse the cantharides in the water for one night, squeeze strongly, and filter the expressed liquid. Add the axunge, and boil till the water is dispersed. Then add the wax and resin; and, when these have become liquid, remove the vessel from the fire, add the turpentine, and mix the whole thoroughly," *E.*—Liniment of Spanish Flies ℥viiij; White Wax ℥iij; Spermaceti ℥j. Melt the wax and spermaceti in the oil with a gentle heat, and stir the mixture constantly until it concretes, *D.*)—A milder and less certain preparation than the preceding. Used to excite a purulent discharge from blistered surfaces, and to stimulate issues and indolent ulcers.

5. *EMPLASTRUM CANTHARIDIS*, *L. E. D.*; *Emplastrum Lyttæ*; *Plaster of Cantharides*; *Blistering Plaster*.—(Cantharides, in very fine powder, ℥bj; Wax, Lard, of each ℥viiss; Resin ℥iij; Lard ℥vj, *L.*—Cantharides, in very fine powder, Resin, Beeswax, and Suet, of each ℥ij, *E.*—Cantharides, in very fine powder, ℥vj; Yellow Wax, Resin, and Lard, of each ℥iv, *D.*)—"Liquefy the fats, remove from the heat, sprinkle in the cantharides in very fine powder, and stir briskly, as the mixture concretes on cooling."—[The *Ceratum Cantharidis*, *U. S.* Cerate of Spanish Flies, *Emplastrum Epispasticum*, is the same as this. It is made as follows: Take Spanish Flies, in very fine powder, ℥bj; Yellow Wax, Resin, Lard, each ℥viiij. Melt the wax, resin, and lard, and stir in the Flies until cool.] Dishonest druggists sometimes omit a portion of the cantharides here ordered, and substitute powdered euphorbium. In making blistering plasters, care must be taken not to add the cantharides while the melted lard is quite hot, as the heat greatly injures the vesicating power of the insect. For a similar reason the plaster should be spread by the thumb, a heated spatula being objectionable. To prevent the blister moving after its application to the skin, its margin should be covered with adhesive plaster. In order to guard against any affection of the urinary organs, place a piece of thin book-muslin or silver (tissue) paper between the plaster and the skin. The efficacy of the blister depends on the fatty matter dissolving the cantharidin, and transuding through the muslin or paper. Some recommend the paper to be soaked in oil, which is supposed to dissolve the cantharidin. Now oil, not being miscible with the blood, is not readily absorbed; and hence, it is supposed, arises its protective influence. The usual time requisite for a blistering plaster to remain in contact with the skin is twelve hours; the vesicle is then to be cut at its most depending part, and dressed with spermaceti ointment. When the irritation caused by these plasters is excessive, it is sometimes necessary to substitute a poultice for the ointment. When we wish to make a perpetual blister, the cerate of cantharides is employed as a dressing; or if we wish to excite less irritation, and prevent the possibility of the urinary organs being affected, the cerate of savine. The danger of applying blisters to children after exanthematous diseases, especially measles, has been already noticed (see p. 1125).

6. *EMPLASTRUM CANTHARIDIS COMPOSITUM*, *E.*; *Compound Plaster of Cantharides*.—(Venice Turpentine ℥ivss; Burgundy Pitch and Cantharides, of each ℥iij; Beeswax ℥j; Verdigris ℥ss; White Mustard Seed and Black Pepper, of each ℥ij. Liquefy the wax and Burgundy pitch, add the turpentine, and, while the mixture is hot, sprinkle into it the remaining articles previously in fine powder, and mix together. Stir the whole briskly, as it concretes in cooling, *E.*)—"This is supposed to be an infallible blistering plaster. It certainly contains a sufficient variety of stimulating ingredients."¹

7. *EMPLASTRUM CALEFACIENS*, *D.* [*Emplastrum Picis cum Cantharide*, *U. S.*]; *Warming Plaster*.—(Plaster of Cantharides ℥bss; Burgundy Pitch ℥bvss. Melt

¹ Duncan, *Edinburgh Dispensatory*.

them with a steam or water-bath, and, withdrawing the heat, stir constantly until the mixture stiffens.) [The formula of the *U. S. P.* is as follows: Take of Burgundy Pitch lbijss; Cerate of Spanish Flies lbss. Melt them together by means of a water-bath, and stir them constantly till they thicken on cooling.] Stimulant, rubefacient, and, in some cases, vesicant. Used in catarrh, local pains, &c.

8. **PANNUS VESICATORIUS**; *Blistering Cloth*; *Taffetas Vesicant*.—(Digest powder of cantharides in sulphuric ether. Let the ethereal tincture be submitted to distillation, and the residue evaporated, by means of a salt-water bath, until ebullition ceases. The oily mass which remains is to be melted with twice its weight of wax, and spread on cloth prepared with waxed plaster,¹ *Henry and Guibourt*.²)—Employed as a substitute for the ordinary blistering plaster, than which it is a more convenient and elegant preparation.

The *Tela vesicatoria* or *Blistering Tissue*, and *Charta vesicatoria* or *Blistering Paper*, are analogous preparations.

The *Papier épispastique*, or *Epispatic Paper* of Henry and Guibourt, is prepared as follows: Take of white wax 8 parts, spermaceti 3 parts, olive oil 4 parts, turpentine 1 part, powder of cantharides 1 part, and water 10 parts. Boil slowly for two hours, constantly stirring it. Strain the fatty mixture through a woollen cloth, without expression, and spread on paper.

OTHER COLEOPTEROUS VESICANTS.

In Europe, the ordinary vesicating insect is the *Cantharis vesicatoria*; but in some other parts of the world other blistering insects are employed. Thus, *Cantharis vittata*, or the *Potato-fly*, *C. atrata*, *marginata*, and *cinerea*, are used in North America. In the Brazils, *C. atomaria* has been employed. *C. ruficeps*, a native of Sumatra and Java, is said to possess extraordinary blistering properties. *C. gigas* (*Lyttacarulea*, Pfaff) is a native of Guinea and the East Indies. *C. violacea* (*Lytta gigas mas*, Buchner) is a native of the East Indies. In Arabia, *C. syriaca* (*Lytta segetum*) is said by Förskal to be employed. *Mylabris Cichorii* is used in China and some parts of the East Indies. *Meloe proscarabeus* is an indigenous vesicating insect, which has in two instances caused death. *M. majalis*, or *true Mayworm*, possesses similar properties.

ORDER II. HEMIPTERA.—*Linnaeus*.

CHARACTERS.—2 wings covered by *elytra*. Mouth formed for suction; the *rostrum* composed of a tubular articulated sheath, including four scaly setæ, in place of mandibles and jaws. *Elytra*, in some, crustaceous, with the posterior extremity membranous; in others, almost similar to wings, but more extended, thicker, and coloured (Stark).³

355. COCCUS CACTI, *Linn. L. E. D.*—COCHINEAL INSECT.

(Coccus, L.—The entire insects, E. D.)

HISTORY.—The Spaniards, on their first arrival in Mexico, about the year 1518, saw the cochineal employed (as it appears to have been long before) by the native inhabitants of that country, in colouring some part of their habitations and ornaments.⁴

ZOOLOGY. **Gen. Char.**—*Tarsi* with 1 joint, and terminated by a single hook. *Male* destitute of a *rostrum*, with 2 wings covering the body horizontally; abdomen terminated by 2 setæ. *Female* apterous, furnished with a *rostrum*. *Antennæ* of 11 joints, filiform, and setaceous.

Sp. Char.—*Male* very small, with the *antennæ* shorter than the body; *body*

¹ The *Toils préparés à la cire*, used by the French pharmacologists, is prepared by spreading the following mixture on cloth: white wax 8 parts, olive oil 4 parts, and turpentine 1 part (Henry and Guibourt).

² *Pharmacopée Raisonnée*, 3me édit. p. 470, Paris, 1841.

³ *Elements of Natural History*, ii. 318.

⁴ Bancroft, *Experimental Researches*, i. 413; and Beckmann, *History of Inventions*, ii. 192.

elongated, of a deep red, terminated by 2 long diverging *setæ*; wings large, white, crossed above the abdomen. *Female* nearly twice as large as the male, bluish-red, covered with a white farina; *antennæ* short; *body* flattened below, convex; *feet* short.

Fig. 429.

Cochineal Insects (male and female).

- a. Male, with the wings expanded.

 d. Impregnated female (natural size).

Fig. 430.

*Opuntia Cochinitifera.*

the second the young females also are collected; and in the third both old and young ones, and skins, are collected indiscriminately. Before the rainy season commences, branches of the nopal plant, loaded with infant insects, are cut off and preserved in the houses of the Mexicans, to prevent the animals being destroyed by the weather.

COMMERCE.—In 1839, the quantity of cochineal on which duty (1s. per cwt.) was paid, was 489,998 lbs. In 1838 it was only 204,748 lbs. It is said that, on the average, one pound of cochineal contains 70,000 dried insects.

DESCRIPTION.—Cochineal (*coccus*; *coccinella*) consists of the dried female insects, which are about one or two lines long, wrinkled, of an irregular figure, convex on one side and flat or somewhat hollow on the other. They are inodorous, have a bitterish warm taste, tinge the saliva violet red, and yield a dark red powder. In

Wings of the male beautifully snow white. The females fix themselves firmly on the plant, which serves them as a habitation, and never quit this spot; here they couple, and increase considerably in size. Each insect lays several thousand eggs, which proceed from the body through an aperture placed at the extremity of the abdomen, and pass under the belly to be there hatched. Death then ensues; the body of the mother dries up; its two membranes become flat, and form a sort of shell or cocoon, in which the eggs are inclosed, and from whence the little cochineals soon proceed. The female only is of commercial value.

Hab.—Mexico.

CULTIVATION.—The cochineal insects feed on the *Nopal* (*Opuntia cochinitifera*).¹ Mr. Ward² says, the plantations are confined to the district of La Místeca, in the state of Oaxaca, in Mexico. The animals are domesticated and reared with the greatest care. Plantations of these are cultivated for the nourishment of the insects. Here the impregnated females are placed; this operation being denominated *sowing*. Young ones are soon developed; and some months afterwards, when the females have become fecundated and enlarged, the harvest commences. The insects are brushed off with a squirrel's tail, and killed by immersing them in hot water, and afterwards drying them in the sun, or by the heat of a stove. Three harvests are made annually; the first being the best, since the impregnated females alone are taken; in

the second the young females also are collected; and in the third both old and young ones, and skins, are collected indiscriminately. Before the rainy season commences, branches of the nopal plant, loaded with infant insects, are cut off and preserved in the houses of the Mexicans, to prevent the animals being destroyed by the weather.

¹ *Cactus cochinitifera*, Linn., is without spines, and is called *Spineless Cochineal*; this does not produce the best Mexican Cochineal. De Candolle has given as *C. coch.* the *C. Tuna* of Linnæus—a plant totally distinct. *Cactus Tuna* yields the cochineal of Mexico. *C. cochinitifera* also yields *Opuntia maxima*.—Sloane, vol. ii. p. 152, t. 8, f. 1 and 2.

² Mexico in 1827, i. 84.

burning they evolve an animal odour, and leave a grayish-white ash. By infusion in water they swell up, show their ringed character, and even their feet, giving the liquid a red colour. Both the Honduras and Vera Cruz kinds are distinguished into the silver and black varieties. *Silver cochineal* (*cochinilla jaspeada* of the Spaniards) has a purplish-gray colour; but in all the furrows and depressions we observe a whitish powder, which, examined by the aid of a lens, appears like fine wool. *Black cochineal* (*cochinilla renigrada* or *grana nigra* of the Spaniards) is reddish or purplish-black, and devoid or nearly so of the silvery character. *Granilla* (*cochinilla sylvestre* or *grana sylvestria*) consists of very small cochineal insects, and smaller, wrinkled, globular, or ovate masses (cocoon and new-born insects?), somewhat like fragments of the cochineal insect.¹

An extensive system of adulterating cochineal, by a mercantile house in London, was discovered a few years ago. The genuine article was moistened with gum-water, and then agitated in a box or leather bag, first with powdered sulphate of baryta, then with bone or ivory-black, to give it the appearance of black cochineal. By this means the specific gravity of the cochineal was increased from 1.25 to 1.35, and 12 per cent. of worthless heavy spar sold at the price of cochineal.² Powdered talc and carbonate of lead have been used to give the silvery appearance. But a lens will readily distinguish these powders from the real wool, which gives the true silvery character.

COMPOSITION.—Two analyses of cochineal have been made; one by John,³ the other by Pelletier and Caventou.⁴ The latter chemists found the constituents to be *carmine*, *peculiar animal matter*, *fatty matter* (composed of *stearine*, *olein*, and an *odorous acid*), and *salts* (viz. phosphate and carbonate of lime, chloride of potassium, phosphate of potash, and a salt of potash, containing an organic acid).

COCHENILLIN (*Carmine*)—Obtained by digesting cochineal in ether, to extract the fatty matter, and then in alcohol, which dissolves the carmine. This colouring matter is a brilliant purplish-red substance, with a granular or crystalline appearance; unalterable in the air, easily soluble in water and alcohol, but insoluble in ether. It fuses at 112° F. Chlorine renders it yellow. Acids change its colour. The concentrated mineral acids decompose it. Alkalies render the watery solution of carmine violet. Lime-water forms a violet precipitate with it. The affinity of hydrate of alumina for it is most remarkable; the compound formed by their union is called a *lake*. [*Cochenillin* contains nitrogen, but its formula has not yet been determined. According to Preisser, the red colouring matter of the insect, which he calls *Carmine*, is derived by oxidation from the colourless crystalline compound called by him *carmine*—Ed.]

The pigment sold in the shops as *carmine*,⁵ and which is one of the most valuable colours employed by the painter in water colours, is a compound, of which cochenillin is one of the constituents. Pelletier and Caventou regard it as consisting of cochenillin, animal matter, and an acid.

PHYSIOLOGICAL EFFECTS AND USES—Diuretic, diaphoretic, antispasmodic, and anodyne qualities have been assigned to cochineal, but without the least evidence of their existence. A mixture of carbonate of potash and cochineal is a popular remedy for hooping-cough. The only real value of cochineal is as a colouring matter, and as such it is used both in powder and solution. In the arts, it is extensively employed in dyeing scarlet and crimson, and in the manufacture of *carmine* and *lake*.

MANUFACTURE OF CARMINE.—[We subjoin the following note by the author on the manufacture of carmine, evidently the result of his own observation of the process pursued.—Ed.]

Carmine is prepared from *black cochineal*. A decoction of the insect in water is made. The residue is called *carmine grounds* (used by paper-stainers). To the decoction is added a precipitant—say bichloride of tin. Alum will not answer, as the colour is very different. The decoction to which the bichloride has been added is put into wash-hand basins, and allowed to stand. Slowly, a deposit takes place. It adheres to the sides of the vessel, and the liquid being poured off, it is dried. Artificial heat cannot be used, as it changes the colour of the

¹ See *Granillo*, in Bancroft's *Experimental Researches*, 1. 433.

² *Ure*, *Dictionary of Arts and Manufactures*, pp. 305-6.

³ *Gmelin*, *Handb. der Chem.* ii. 1474.

⁴ *Ann. de Chim. et de Phys.* viii. 250.

⁵ *Carmine*, sold by the perfumers as *Rouge*, is very different from jeweller's *rouge* (oxide of iron). The carmine sold for theatrical performers must be largely diluted, as it has been sold at 10s. per ounce, when carmine, properly so called, was worth £3 or £4 per ounce.

deposit; neither can solar light be employed, for the same reason. This precipitate when dried is *carmine* [the liquor is called *liquid rouge*]. It can only be made in certain states of weather. If the weather be too hot, the liquids soon become sour, and the deposit is redissolved; yet fine weather is necessary, or the precipitate will not dry; flies also injure it. If carmine be not dry, it is apt to become mouldy.

The decoction from which the carmine has been precipitated yields a farther precipitate on the addition of more of the precipitant; but the product thus obtained is darker coloured, and is sold to the colour-makers as *lake*. It varies considerably in its tint.

Carmine is quite soluble in ammonia. Its colour should be remarkably bright. It should be also in the form of a light powder. These are the best tests of its goodness. *Carmine* is used for velvet painting, for pattern drawing for waistcoats, for water-colour painting, and as a face paint. Lady Dungannon's composition is composed of carmine, with a little water and ammonia. According to Bateaman, *rouge for the face* is made by mixing ʒss of levigated French chalk and 2 oz. of fresh carmine.

Six drachms of carmine may be obtained from 1 lb. of cochineal.

Cochineal is sometimes used for colouring pickled cabbage.

[Cochineal colouring for jellies, &c. is prepared by adding cream of tartar to a decoction of cochineal, and filtering. The pink saucers sold in colour shops are made up with a mixture of carmine, gum, and ammonia.—Ed.]

TINCTURA COCCI CACTI, D.—(Take of Cochineal, in fine powder, ʒij; Proof Spirit Oj. Macerate for fourteen days, strain, express, and filter.)

[The author has recommended the following preparation for the tincture of cochineal: Cochineal, in powder, one part; Rectified Spirit eight parts. Macerate for eight days, then filter.—Ed.]

ORDER III. HYMENOPTERA, *Linnæus*.

CHARACTERS.—4 naked veined *wings* of unequal size. *Mouth* composed of jaws, mandibles, and 2 lips. *Lip* tubular at its base, terminated by a labium, either doubled or folded in, and forming a kind of sucker. *Females* with a compound ovipositor or sting at the anus (Stark).

356. APIS MELLIFICA, *Linn. L. E. D.*—THE HIVE BEE, OR HONEY BEE.

(1. Humor florum in favo repositus despumatus, *L.*; Saccharine secretion, *E. D.*—2. Cera, Favus preparatus; Cera alba, idem dealbatus, *L.*; Cera flava, Waxy secretion, Cera alba, Bleached beeswax, *E.*; Cera alba, Cera flava, *D.*)

HISTORY.—This animal was very anciently known, and is frequently referred to in the Old Testament. In all ages it has been an object of admiration and attention, on account of its industry, curious economy, and policy.

ZOOLOGY. Gen. Char.—*Labium* filiform, composing with the jaws a kind of *proboscis*, geniculate, and bent downwards. First joint of the posterior *tarsi* large, compressed. No spines at the extremity of the last two *legs*. Upper *wings* with one radial and three cubital cells (Stark).

Sp. Char.—Blackish. *Abdomen* of the same colour, with a transverse grayish band, formed by the down at the base of the third and following segment (Stark).

The honey bee lives in societies, called *swarms*, consisting of from fifteen to thirty thousand individuals. Each swarm is composed of three classes of individuals—viz. a female, males, and neuters. The female, called the *queen bee*, is narrower and longer than the others. The males, termed *drones*, are smaller than the females, and are devoid of stings. In each hive there are from 800 to 1000 drones. Towards autumn, when they can be of no farther use, they are destroyed by the neuters. The neuters are termed *working bees*, and are by far the most numerous, since in each hive there are from fifteen to thirty thousand. They are in reality females, whose ovaries are not developed, in consequence, as some have supposed, of the nature of the aliment with which they are supplied while in the larva state.

The DIGESTIVE SYSTEM of the animal consists of highly developed *salivary organs* communicating with the proboscis, of an *œsophagus* (which enlarges at one part, forming the *crop*, *sucking-stomach*, or *honey-bag*), a *proper stomach*, *small and large intestines*, and *biliary vessels*. The latter open into the alimentary canal immediately behind the stomach. The SEXUAL SYSTEM, in the male, consists of a pair of *testicles*, each having a *vas deferens*, which terminates in a *vesicula seminalis*. From the conjoined extremities of the vesiculae proceed a *common duct* terminating in a *penis*. The female genital organs consist of two ovaries made up of tubes, each containing about twelve ova; the two oviducts from these ovaries terminate in a *vagina*, into which also opens a duct from a *roundish vesicle*. The POISON APPARATUS is found in the females and neuters only. It consists of two thin convoluted *secreting organs*, opening into a *pyriform receptacle*, from which a *small duct* passes to the *sting*, which consists of two portions placed side by side, barbed at the extremity and contained in a sheath. The *poison* is said to be hot and acrid to the taste. The consequences produced by the sting of a bee are pain, redness, swelling, and hardness of the part; and might prove fatal if a swarm were to attack an individual. The removal of the sting (if left within the wound), and friction with saliva, or with oil and harts-horn, is all the treatment usually required.

Hab.—Old continent (Latreille). In a state of nature they reside in hollow trees; but they are almost universally domesticated, and are preserved in *hives*. Curtis¹ has described and depicted a remarkable instance of the nest of some hive bees attached to the arm of a tree. It was discovered in 1838, by Lord Malmesbury, in his plantation near the River Avon.

Bees furnish two products useful in medicine—viz. *honey* and *wax*.

a. HONEY. PRODUCTION.—Honey (*mel*) is secreted by the nectariferous glands of flowers, and is collected by the working or neuter bees, who take it by suction or lapping, and pass it into the dilatation of the œsophagus, denominated *crop*, *sucking-stomach*, or *honey-bag*; beyond which, we presume, the honey does not pass, as it has never been found in the true stomach. When the animal arrives at the hive, the honey is disgorged by a kind of inverted peristaltic motion, and is probably somewhat altered in its properties by the secretions of the crop. It is used by the animal as food.

PHYSICAL PROPERTIES.—Honey varies in its taste and odour according to the age of the bees and flowers on which they have fed. A hive which has never swarmed is considered to yield the best, which is therefore called *virgin honey*. The flavour of Narbonne honey, which is so much admired, is said to arise from the labiate flowers on which the animals feed; to imitate this, a sprig of rosemary is sometimes added to the honey obtained from other places.

PURITY.—Flour, it is said, is now and then mixed with honey. This adulteration may be readily distinguished by its insolubility in cold water, and by the blue colour produced by the addition of iodine.

The London College directs that honey—

Is not to be employed without being despumated. Dissolved in water, iodide of potassium and acid being added, it does not become of a blue colour.

CHEMICAL PROPERTIES.—The constituents of honey vary somewhat according to the food of the bees, the season, the age of the animals, the mode of extracting it from the combs, &c. It must, however, be regarded at all times as a concentrated solution of *sugar* mixed with *odorous, colouring, gummy, and icaary matters*. The saccharine matter is of two kinds: one crystallizable, and analogous to the sugar of grapes; the other uncrystallizable, and similar to the uncrystallizable brown syrup of the sugar-cane. Guibourt has found also mannite, which differs from sugar in not fermenting when mixed with water and yeast.

PHYSIOLOGICAL EFFECTS.—Honey is emollient, demulcent, nutritive, and laxative. When fresh it is apt to occasion indigestion and colic. Collected from poisonous plants it has been found to possess deleterious qualities. The honey of Trebizond has long been notorious for its deleterious qualities. Mr. Abbott² says it causes violent headache, vomiting, and a condition like that of a tipsy man. A larger dose produces deprivation of all sense and power for some hours afterwards. These

¹ *British Entomologist*, xvi, pl. 700.

² *London and Edinburgh Philosophical Magazine* for October, 1834, vol. v. p. 313.

effects agree with those assigned to this honey by Xenophon,¹ in his account of the "Retreat of the Ten Thousand." Pliny² also speaks of this poisonous honey. Tournefort³ ascribes its venomous properties to the bees feeding on the *Azalea pontica*. Many other instances of poisonous honey are on record.⁴

USES.—Mixed with flour, and spread on linen or leather, it is a popular application to promote the maturation of small abscesses and furunculi. It sometimes forms a constituent of gargles, partly on account of its taste, partly for its emollient operation. It is also used as a vehicle for the application of other more powerful agents to the mouth and throat, especially in children. It is occasionally employed as an emollient and demulcent in inflammatory affections. In troublesome coughs, barley-water, mixed with honey, and sharpened with slices of lemon, and taken warm, forms a very agreeable and useful demulcent to allay troublesome coughs.

1. MEL DEPURATUM, D.; *Clarified Honey*.—(Melt the honey in a water-bath, and strain it while hot through flannel.)—The object of this process is to deprive honey of certain impurities which render it apt to ferment; but the flavour and odour of the honey is somewhat injured by the operation.

2. OXYMEL.—See p. 947.

β. WAX. SECRETION OF BEESWAX.—Beeswax (*cera*) was at one time supposed to be merely the pollen of plants elaborated by bees. Bonnet, however, so early as 1768, asserted it to be a secretion from the ventral scales. Hunter⁵ and Huber have subsequently proved the correctness of this assertion. The latter writer, indeed, proved that the pollen is not at all essential to the production of wax, for bees fed on honey and water equally secreted it, and formed the usual waxy cells. With this wax they construct the *comb* (*favus*), the cells (*alveoli*) of which are hexagonal with angular bottoms.⁶ The substance called *Propolis* is collected by the bees from the buds of trees. It is of a resinous nature, and is used for lining the cells of a new comb, stopping crevices, &c.

Fig. 431.

Cicada limbata.

Other animals secrete wax. Thus the larva of the *Cicada limbata* or *white wax insect* of China is covered with a waxy powder, which is communicated to the trees upon which these insects are found, and is collected by the natives, who esteem it highly as a medicinal substance.⁷

Wax is also a product of vegetables; but *vegetable wax* is not employed in this country. *Myrtle wax* is obtained from the berries of the *Myrica cerifera*, a native of the United States of America. These are boiled in water and pressed. The wax exudes, floats on the water, is skimmed off, and is remelted. This kind of wax has a greenish-yellow colour. By saponification it yields stearic, margaric, and oleic acids, along with glycerine, so that it is rather fat than wax.

PREPARATION.—Wax is extracted from the comb, partly by allowing the latter to drip, partly by subjecting it to pressure. The comb is then melted in water, by which the impurities subside, and the wax is allowed to cool in moulds.

PROPERTIES OF YELLOW BEESWAX.—Yellow wax (*cera flava*) has a remarkable and peculiar odour; its colour is more or less yellow, but varying in degree; its specific gravity varies from 0.960 to 0.965. [It melts at 145°—ED.] It is said to be sometimes adulterated with suet, which gives it a fatty and disagreeable taste. Resin may be recognized by its solubility in cold alcohol; bean or pea meal, by its insolubility in oil of turpentine.

WAX BLEACHING.—This is effected by melting yellow wax (either in a copper vessel, or in a large vat or tub, by means of steam), running it off, while in a melted

state, into a trough, called a *cradle*, perforated at the bottom with holes, and placed over a large water-tank, at one end of which is a revolving cylinder, almost wholly immersed in water. By this means the wax is solidified, converted into a kind of ribbon, and conveyed on the surface of the water to the other end of the tank. These ribbons of wax are here lifted out, and conveyed in baskets to the bleaching-grounds, where they are exposed to the air one or two weeks (according to the state of the weather), being turned every day, and watered from time to time. The wax is then remelted, reribboned, and rebleached; it is subsequently refined by melting in water acidulated with sulphuric acid.

PROPERTIES OF WHITE WAX.—White wax (*cera alba*; *cera dealbata*) is yellowish-white; I have never met with pure wax perfectly white. The circular cakes of commerce, as well as wax candles, always contain spermaceti, which the dealers add to improve the colour. Pure wax is solid, brittle, inodorous, or nearly so, insipid, fusible, and at a much higher temperature decomposable. Its specific gravity varies from 0.8203 to 0.965. [It melts at 158°, and congeals at 149°.—Ed.]

COMPOSITION.—According to John, wax is a compound of two other substances;—the one called *cerine*, the other *myricine*. [The former is soluble in alcohol, the latter is comparatively insoluble.—Ed.] These have been examined by Boudet and Boissenot.¹

1. **CERINE.**—This constitutes at least 70 per cent. of wax. It fuses at 143½ F. It dissolves in 16 parts of boiling alcohol. By saponification with potash it yields margaric acid, a minute portion of oleic acid, and a considerable quantity of a non-saponifiable fat called *ceräine*.

2. **MYRICINE.**—It fuses at 149° F. It dissolves in 200 parts of boiling alcohol of sp. gr. 0.833. It is not saponifiable by potash. Etting² says that cerine, ceräine, and myricine are isomeric, and composed of C¹⁹H¹⁹O. More recently, Hess³ asserts that pure wax is homogeneous, and possesses the properties of myricine; its composition being C²⁰H²⁰O. The difference between cerine and myricine he ascribes to the presence of *ceric acid* formed by the oxidation of myricine.

[Mr. B. C. Brodie has made an extensive series of researches into the constitution of wax, and has assigned formulæ to sixteen different constituents or products of the decomposition of wax. He applies the name cerotic acid to cerine, and represents its formula as C⁵⁴H⁵⁴O⁴. Pure myricine he considers to be represented by C²²H²²O⁴.⁴ It is remarkable that in nearly all the varieties of wax, as well as in the products obtained from this body, the carbon and the hydrogen are in equal equivalents.

Beeswax varies much in the proportions of cerine and myricine which it contains. Wax is obtained from the vegetable kingdom. *Myrtle wax* is derived from the *Myrica cerifera*. From the action of potash it appears to be more analogous to the fatty bodies than to wax. Its formula is C³⁶H³⁶O². The *Chinese* and *Japan wax* is the produce of *Rhus Succedaneum*. It is white and crystalline, resembling spermaceti. Formula=C³⁶H³⁶O². The *sugar-cane wax* has been called *Cerosine* by Dumas. It is a wax-like substance, deposited in fine light pearly scales on the surface of some species of sugar-cane. It melts at 180°, and is not saponified by potash. Its formula, according to Dumas, is C⁴⁴H³⁶O².—Ed.]

PHYSIOLOGICAL EFFECTS AND USES.—Wax is an emollient and demulcent. It has been administered internally, in the form of emulsion (prepared with melted wax and soap, yolk of eggs, or mucilage), in *diarrhœa* and *dysentery*, especially when ulceration of the alimentary canal is suspected. In these cases it has been used by Hufeland and Wedekind. It has sometimes been employed as a *masticatory*; but its action is mechanical only. Its principal use, however, is *externally*, sometimes as a mild sheathing or protecting application, sometimes as a basis for the application of other agents. It is a constituent of all *cera*, which take their name from it. The vapour evolved from wax placed on redhot iron has been inhaled in phthisis.

3. **LINIMENTUM SIMPLEX, E.**; *Simple Liniment*.—(Olive Oil *four parts*; White Wax *one part*. Dissolve the wax in the oil with a gentle heat, and agitate well as the fused mass cools and concretes.)—Differs from the *Unguentum simplex* in its greater liquidity. Used to soften the skin, and to promote the healing of chaps.

OTHER HYMENOPTEROUS INSECTS.

The tribe of hymenopterous insects, called *Gallicolæ* or *Diplolepariæ*, contains the insects which produce those excrescences on plants commonly denominated *galls* (see *Nutgall*, and *Bedeguar*). Latreille¹ comprehends all the insects of this tribe in one genus—viz. *Cynips*.

Class VII. Crustacea, Cuvier.—Crustaceans.

The dietetical properties of the Crustaceans (Lobsters, Crabs, Cray-fish, Prawns, and Shrimps) have been noticed in a former part of the work.

Fig 432.

Astacus fluviatilis.

1. **ASTACUS FLUVIATILIS.**—In the stomach of the *Crayfish* are found, at the time the animal is about to change its shell, two calcareous concretions, commonly called *Crabs' Eyes* or *Crabs' Stones* (*Lapilli Cancrorum*), which were formerly ground and employed in medicine, as absorbents and antacids under the name of *Prepared Crabs' Stones* (*Lapilli Cancrorum preparati*; *Lapides Cancrorum preparati*; *Oculi Cancrorum preparati*).² They consist of carbonate of lime and animal matter principally, with a little phosphate of lime. Their use is now obsolete. In the shops, imitations of them (prepared with chalk and mucilage, or size) are still met with.

2. **CANCER PAGURUS.**—The *Black-clawed* or *Large Edible Crab* was at one time an official animal. Its *Claws* (*Chelæ Cancrorum*), when prepared by grinding, constitute the *Prepared Crabs' Claws* (*Chelæ Cancrorum preparatae*) of the shops. Their composition and uses are similar to those of prepared *Crab's stones*. I have already given an account of the effects and uses of carbonate of lime.

¹ In Cuvier's *Régne Animal*, v. 291, 1829.

² "Those animals which are ready to moult, have always two stony substances, called *crabs' eyes*, placed in the stomach, which, from the experiments of Reaumur and others, appear destined to furnish the matter, or a portion of it, of which the shell is formed; for if the animal is opened a day after its moult, when the shell is only half hardened, these substances are found only half diminished; and if opened later, they are proportionably smaller." (Kirby, *Bridgewater Treatise*, vol. ii. p. 55; quoted by Bence Jones, p. 79.)

Division II. Vertebrata.—Vertebral Animals.

CHARACTERS.—Animals furnished with a *skull* and *vertebral column* for the protection of the brain and spinal marrow.

Class VIII. Pisces.—Fishes.

CHARACTERS.—Vertebrate animals with cold red *blood*, respiring by *gills* or *branchiæ*, and moving in the water by the aid of *fins*.

No article of the *Materia Medica*, contained in the British pharmacopœias, is derived from this class of animals; but the important uses of *isinglass*, and the extraordinary efficacy, in various diseases, ascribed by some writers to *cod-liver oil*, render it necessary to notice both of these productions.

357. ICHTHYOCOLLA.—ISINGLASS.

HISTORY.—Ichthyocola (*ἰχθυόκολλα*, from *ἰχθύς*, a fish; and *κόλλα*, glue) is mentioned by both Dioscorides¹ and Pliny.² The latter of these writers ascribes its invention to Dædalus.

ZOOLOGY.—Isinglass is obtained from various fishes, some only of which have hitherto been ascertained. The finest kinds are procured from different species of *Acipenser*. Several other genera—as *Silurus*, *Morrhua*, *Gadus*, *Otolithus*, *Lota*, and *Polynemus*, also yield it.

The organ from which isinglass is usually procured is the *air-bag*, or *swimming bladder*, sometimes termed the *sound*. It is a membranous sac filled with air (containing from 69 to 87 per cent. of oxygen), and placed under the spine, in the middle of the back, and above the centre of gravity. In most fish it communicates with the œsophagus, or stomach, by the *ductus pneumaticus*. In others, it is an imperforate sac. Occasionally there are two sacs, which communicate with each other. In the *Acipenser stellatus*, according to Brandt,³ the bag is composed of three membranes: an external, silvery one, derived from the peritoneum; a middle, membranous (*hautigen*) one; and the most internal, very vascular, and, as it were, pulpy membrane. The latter, he states, yields the fish gelatine. But unless the sound of this fish differs considerably from that of other fishes, there must be an error in this statement. I have examined all the purse and pipe isinglass of commerce, and find the internal to be an insoluble membrane. In the cod, the innermost membrane is very thin, and is perhaps analogous to the epithelium. Externally to this is a highly vascular thin coat, and still more externally is the gelatinous coat, which appears devoid, or nearly so, of vessels.

PREPARATION.—The mode of preparing the swimming-bladder for sale as isinglass, varies in different countries. Sometimes the bag is dried unopened, as in the case of the *purse*, *pipe*, and *lump* isinglass of the shops. At other times it is laid open, and submitted to some preparation; being either dried unfolded, as in the *leaf* and *honeycomb* isinglass; or folded, as in the *stuple* and *book* isinglass; or rolled out, as in the *ribbon* isinglass. When it arrives in this country it is *picked* or *cut*. Formerly, it was picked into shreds by women and children, but it is now usually cut by machines worked by steam.

DESCRIPTION.—Many varieties of isinglass are imported; the Russian kinds are the most esteemed; but the Brazilian, on account of its cheapness, is very extensively used.

¹ Lib. iii. cap. 109.

² *Hist. Nat.* lib. vii. cap. 57; and lib. xxxii. cap. 94, ed. Valp.

³ Brandt and Ratzeberg's *Medicinische Zoologie*, p. 27, Berlin, 1833.

1. Russian and Siberian Isinglass.—The isinglass produced in the Russian empire is principally obtained from the sturgeons. These cartilaginous fishes constitute the genus *Acipenser*.

The following are the generic characters of *Acipenser*: Body elongated and angular, defended by indurated plates and spines, arranged in longitudinal rows; snout pointed, conical; mouth placed on the under surface of the head, tubular, and without teeth (Yarrell¹). The species are badly determined. Brandt² has described and figured eight. *Acipenser Sturio*, or the *Common Sturgeon*, is occasionally caught in the River Thames. The species from which ISINGGLASS is procured are the following:—

1. *A. Huso*, Linn. The *Beluga* or *Bielaga*.—Inhabits the Caspian Sea and its tributary streams. Its roe (ovary) is esteemed as *caviare*. Its swimming-bladder, when properly prepared, yields *leaf isinglass* of three qualities, *fine firsts*, *firsts*, and *seconds*.

2. *A. GULDENSTADTI*, Brandt and Ratzeburg. The *Ossetr* or *Osseter*.—Inhabits the Caspian and Black Seas and their tributary rivers. *Caviare* is prepared from its roe (ovary). From its swimming-bladder are obtained both *staple* and *leaf isinglass*. The varieties of the *staple* are the *Patriarch Astrakhan*, and *Astrakhan firsts*, *seconds*, and *thirds*. The *leaf* varieties are *firsts*, *seconds*, and *thirds*.³

3. *A. RUTHENUS*, Linn. The *Sterlet*.—Inhabits the Black and Caspian Seas and their tributary rivers; and the Arctic Ocean. Its roe yields *caviare*. *Leaf* and *book* (*first* and *second*) *isinglass* are obtained from the swimming-bladder.

4. *A. STELLATUS*, Pallas. The *Seuruga*.—Inhabits the Caspian and Black Seas and their tributary rivers. Yields *caviare* and *leaf isinglass*.

[WE subjoin some remarks by the author on the swimming-bladders of several species of *Acipenser* from the Volga. These were published in the *Pharmaceutical Journal*.⁴—ED.]

Professor Ludewig kindly sent me the dried air or swimming-bladders of three species of *Acipenser*, namely, the *A. Huso*, *A. Guldensadtii*, and *A. stellatus*. I had been for some time anxious to possess specimens of these swimming-bladders, in order that I might farther satisfy myself of the real nature and position of the isinglass membrane.

In the second edition of my *Elements of Materia Medica*, pp. 1859 and 1861, I have stated that the innermost layer of the swimming-bladder is insoluble in boiling water, and is not the gelatigenous or isinglass membrane. I came to this conclusion from a careful examination of the sound of the codfish, and of the unopened pipe and purse isinglass of commerce, all of which I found to be lined with an insoluble epithelium. In the leaf isinglass, imported from Russia, this membrane has been removed, probably by rubbing with a cloth; and as in some species of *Acipenser* this layer is exceedingly fine, its presence is apt to be overlooked. But in the swimming-bladders of some other fishes it is much thicker, and its non-removal in them considerably deteriorates the commercial value of the isinglass which they yield. The insolubility of the inner lining of the Hudson Bay purse isinglass is well known to the dealers.

Dr. Edward Martiny, the learned author of the *Naturgeschichte der jur die Heilkunde wichtigen Thiere*, published at Darmstadt last year, has, however, denied the accuracy of my account of the gelatigenous or isinglass membrane. He describes these bladders as consisting of two membranes (*Hauten*), an *outer*, strong, shining, and fibrous membrane, and an *inner* soft mucous coat. The outer membrane is covered by a peritoneal coat. "The inner membrane, namely, the mucous membrane, is the so-called isinglass." To this sentence he has appended a foot-note, of which the following is a translation:—

"Pereira (*Elements of Materia Medica*, vol. ii. 2d ed. p. 1861) erroneously regards the middle coat as yielding gelatine."

This statement, emanating from so high an authority as Dr. Martiny, induced me to re-examine the subject, and the result is the confirmation of the accuracy of my former statement. I have now examined the swimming-bladders of four species of sturgeon, and in all find their inner coat, or lining, to consist of an epithelium insoluble in water. In some, however, it is so exceedingly delicate as to require very careful microscopic examination to detect it. In the spring of the present year, I obtained the swimming-bladder of the common sturgeon (*Acipenser Sturio*) caught in the Thames, and found its lining membrane to be a very delicate, but insoluble epithelium. I gave a portion of it to my friend Mr. John Quekett, of the Royal College of Surgeons, and requested him to examine it, and the following is the reply which he sent me:—

"I have carefully examined the sections of air-bladder, and I find that, commencing with the inner coat, you have—

"1st. An epithelial layer; then,

"2dly. The membrane to which the epithelium is attached (basement-membrane); then,

¹ *History of British Fishes*, ii. 360.

² T. W. C. Martius, *Lehrb. d. pharm. Zool.* S. 76, 1838.

³ *Med. Zool.* ii. 1 and 349.

⁴ Vol. vii. No. 10, April, 1848.

"3dly. Some flaky spindle-shaped bodies, which give the silvery appearance; then.

"4thly. Some fibrous tissue, arranged principally in two directions, probably the muscular or elastic coat; then,

"5thly. Some areolar tissue; and,

"6thly. Lastly of all the serous coat.

"I have not tried the solubility of these layers in boiling water, but should think it must be the middle or thick substance which is the gelatinous coat."

On the receipt of the air-bladders of the three species of *Acipenser*, sent me by Professor Ludewig, I resolved to submit them to a careful microscopic examination, in order to ascertain in them the existence or absence of an inner epithelial or insoluble layer. I have detected it in all of them.

a. *Acipenser Huso*.—This fish, called by the Russians the *Bieluga*, yields the isinglass known by the name of the *Bieluga* (or *Eeluga*) leaf. The dried air-bladder is a pyriform bag about the size of a small pig's bladder. Its length is about eleven inches, its greatest diameter about five inches. The opening of the ductus pneumaticus is near the larger extremity.

b. *Acipenser Guldenstadti*.—From this fish is obtained both *staple* and *leaf* isinglass. The dried pyriform swimming bladder, now laid before the Society, is of the kind called in commerce the pipe. Its length is about ten inches, and its greatest diameter about three inches. The opening of the ductus pneumaticus is at the larger extremity.

c. *Acipenser Stellatus*.—This yields *leaf* isinglass. The pyriform swimming-bladder of this fish, which I have received from Professor Ludewig, is also of the pipe kind. Its length is eight inches, and its greatest diameter two and a half inches.

But in Russia the acipenser is not the only genus from which isinglass is obtained, for it is also procured from *Silurus Glanis*,¹ which Dr. Royle² suggests may be the source of the *Samovey*³ isinglass of commerce.

Brandt⁴ thus describes the preparation of Russian isinglass. The swimming-bladder is cut open, washed, and then exposed to the air with the inner silvery membrane turned upwards. The latter is then stript off and placed in damp cloths or left in the outer covering, and prepared or kneaded. It is then taken out of the cloths, and either merely dried (*leaf isinglass*) and twisted or folded in a serpentine manner, between three pegs, into the shape of a horseshoe, heart, or lyre (*long* and *short staple*), or folded in the manner bookbinders fold printed sheets of paper (*book isinglass*). Jackson⁵ has given figures to illustrate the manner in which the staple and book isinglass are made to retain their shapes by skewers. Several kinds of *leaf isinglass* are imported from Russia. The finest kind is that from Astrakhan, of which one kind is said to be obtained from the Beluga (*Acipenser Huso*). These are imported from St. Petersburg. The *Samovey leaf* is an inferior kind brought from Taganrod. *Sisane leaf* is the produce of a small fish; each leaf measuring only about $2\frac{1}{2}$ inches each way, and weighing about a drachm; it looks like pieces of dried bladder, marked by two fibrous or muscular bands. *Kroski isinglass* I have not seen; but I am told it is in small, circular, membranous disks. *Long staple isinglass* is of fine quality. It is the produce of the Oural. [It is usually imported loose—at times strung on ropes. The latter kind is preferred.] Of *short staple* three kinds are known; the finest is from the Oural, and is distinguished by the name of Patriarch, but it is very scarce. The *Astra-*

¹ Pallas, *Reise durch verschiedene Provinzen des russischen Reichs*, Th. i. S. 130, Petersb. 1771.

² On the Production of Isinglass along the Coasts of India, with a Notice of its Fisheries, p. 29, Lond. 1842.

³ This word is sometimes written *Samovey* or *Simovey*. I have been unable to trace its derivation. Dr. Royle's suggestion appears to me probable, since the Russian name for the *Silurus Glanis* is *Som*, while Albertus Magnus calls it *Somus*. The Polish term is *Saum*.—(Brandt and Ratsburg, *op. supra cit.* li. 31.) Moreover, Martins says that staple, leaf, and book isinglass are produced from this fish. Now these are the three forms of the *Samovey isinglass*. [A note addressed to the author confirms this view. The isinglass in question comes from the Russian fish *Som*. The Russians having no article, make an adjective of *Som* by adding "ov." They pronounce it *Samovey*, although they spell it *Somovey*. There is another kind called *Leshony*, from the fish *Lesh* or *Leshoksh* (Bream). It is more soluble than the *Samovey* kind, but scarcely of equal strength.—Ed.]

⁴ Though the account above given by Brandt agrees with the statements of Pallas, Gmelin, Georgi, and Tooke, there must be some inaccuracy in it. I have before stated that the innermost membrane of the swimming-bladder is insoluble—but according to Brandt's statement, the innermost is the gelatinous membrane. The account which T. W. C. Martius (*Lehrbuch d. pharmaceut. Zoologie*, p. 71, Stuttg. 1839) gives of the preparation of isinglass in Russia confirms my views. The swimming-bladders, he observes, are first placed in hot water, carefully deprived of adhering blood, cut open longitudinally, and exposed to the air, with the inner delicate silvery membrane upwards. When dried, this fine membrane is removed by beating and rubbing, and the swimming-bladder is then made into different forms.

⁵ Royle, *op. supra cit.* p. 21.

khan short staple is one of the best kinds. The *Samovey short staple* is of inferior quality. Two kinds of *book isinglass* are met with. That from the Oural is of excellent quality. *Samovey book* is an inferior kind. *Siberian purse isinglass* is of moderately good quality, and is in general demand. [A small kind on strings, in a necklace form, is sometimes imported.]

2. **Brazilian Isinglass.**¹—This is imported from Para and Maranhão; but it has not hitherto been ascertained from what fishes it is procured; though it is obvious, from a superficial examination of the commercial specimens, that they must have been obtained from at least several species or genera. Mr. Yarrell² suggests the genera *Pimelodus* and *Silurus* as the source of it. It comes over in the form of *pipe*, *lump*, and *honeycomb*. *Pipe Brazilian isinglass* must have been procured from a large fish. It is prepared by drying the swimming-bladder unopened. In some cases this bladder is imported distended with air. The dried bladders, or *pipes*, as they are called, are from ten to twelve inches in length, and two or two and a half inches broad. Their weight is about five ounces. Their shape is somewhat conical, tapering at one extremity and broader at the other, where, on either side, is a conical caecal prolongation. It is devoid of smell. *Lump Brazilian isinglass* consists of two swimming-bladders placed side by side, considerably separated at one end, and communicating at the other extremity with each other. When perfect, each lump somewhat resembles in shape a torpedo. Its size varies. A perfect, though not very large specimen, measured eight inches in length, and, at the broadest part, five inches in breadth. Its weight is six ounces and a half. It consists of three portions, separated by constrictions. The largest portion is five inches broad, and three inches and a half long; flattish in front, rounded posteriorly. It consists of two sacs, placed one on either side. The middle portion is oblong, three inches long, and two inches broad; it consists of two sacs, which communicate with those of the preceding portion. The third portion is oblong, one inch and a half long, and three-quarters of an inch wide. It consists of one sac only, into which both the sacs of the middle portion open. *Honeycomb Brazilian isinglass* appears to be the largest portion of the lump kind split open. The lump variety is sometimes softened, and rolled out into thin ribbons, in this country. On account of its deeper colour and inferior solubility, Brazilian isinglass is not in demand for domestic use; though, as it is sold in the cut state, it is probably largely intermixed by shopkeepers with the finer kinds of Russian isinglass, and sold as such. As it is moderately cheap and soluble, it is in extensive use for fining by brewers, who are the principal consumers of this kind of isinglass. [When digested with boiling water, it leaves a very large proportion of undissolved white residue of a starchy consistence.]

3. **New York Isinglass.**—Occasionally, *ribbon isinglass* is imported from New York. It is in thin ribbons of several feet long, and from an inch and a half to two inches in width. It is but little used in this country. It is less soluble than the Russian, and affords a dark-coloured solution.³ Dr. J. V. C. Smith,⁴ author of a work on the fishes of Massachusetts, states that it is obtained from the air-bladder of the common Hake (*Gadus merluccius*), which is thrown into water to macerate for a little while, and is then taken out and pressed between two iron rollers, “by which it is elongated to the extent of half a yard and more. It is then carefully dried, packed, and sent to market. The common cod (*Morrhua vulgaris*) yields a poorer kind of isinglass; but the hake only is known to the extensive manufacturers as fit for their purposes.”

4. **Hudson's Bay Isinglass.**—I have been unable to ascertain from what fish this isinglass is procured.⁵ It comes over in the *purse* form. A specimen in my

¹ Sometimes called *Cayenne Isinglass* (Guibourt).

³ *United States Dispensary*; also *Journal of the Philadelphia College of Pharmacy*, vol. iii. pp. 17 and 92.

⁴ In a letter to Dr. S. W. Williams, of Deerfield, Massachusetts, from whom I received the above information.

⁵ Richardson, in his *Fauna Boreali-Americana*, part iii. says, that the sturgeons of North America are equally numerous with those of Asia, but that their sounds and roes are utterly wasted.

possession measured twelve inches in length, and three inches and a half in diameter; its weight is one ounce and a half. It is of a light yellow colour, translucent, and free from taste and smell. The inner lining of the sac, which may be readily stripped off, is insoluble in water; the remaining membrane dissolves in boiling water.

5. East India Isinglass.—It appears that, for a long period, this has been exported from Calcutta to China, but it has only recently occupied the attention of Europeans. It is probably the produce of a species of *Polynemus*.¹ But the fishes called by Dr. Buchanan, *Bola*, and several species of *Silurus*, especially *Silurus raita*, also yield isinglass (Royle). Most of the specimens of Indian isinglass which I have examined have an unpleasant fishy odour, which renders them totally unfit for domestic use, and greatly deteriorates their commercial value. A specimen of *East India purse isinglass* which I examined consisted of an unopened swimming-bladder, flattened and dried. Its shape is oval-oblong; its length nine inches; its breadth three inches and a half; its weight seven ounces and a half. It has a strong fishy smell, and a dark colour.

Another kind (*East Indian leaf isinglass*) is merely the sac laid open and dried. It is eight or nine inches long, six or seven inches broad, and about three-tenths of an inch thick. A third kind (*East India rolled leaf isinglass*), which I have received from Dr. Royle, appears to have been formed by rolling out the preceding kind into thin plates. One specimen was about eighteen inches long, three inches and a half wide, and one-tenth of an inch thick. Some of the sheets are covered with a thin film of chalk.

Picked East India isinglass, kindly furnished me by Dr. Royle, is in small shreds, two or three inches long, and tapering at the extremities. It is hand-picked in India by the natives. The composition of this isinglass has been ascertained by Mr. Solly, and will hereafter be stated.²

Manilla Isinglass.—A variety under this name has been recently imported. It is called *thin cake*. It is white and clean. It is equal in quality to Brazilian or Samovey book. The fish which yields it is found in the River of Manilla, and on the coasts of the Phillipines, Luconia. Chief mart, Manilla. Price four shillings per pound. It is smaller than the Brazilian; but it greatly resembles the lump Brazilian, and the fish is probably an allied species.³

6. Cod Sounds.—Cod sounds, in the dried state, are brought from Scotland, and used as a substitute for foreign isinglass. They are, however, usually preserved soft by salting, and dressed for the table.

PURITY.—When isinglass is reduced to small shreds (*picked* or *cut isinglass*), it is scarcely possible to distinguish, by the eye, some of the inferior from the finer kinds. The best criteria are its whiteness, freedom from unpleasant fishy odour, its solubility in water, and translucency of the jelly obtained on cooling from its hot solution. [No sample even of the best isinglass (Beluga or Astrachan leaf) is completely soluble in boiling water. There is always some undissolved residue (albuminous membrane); but this is small in proportion to the goodness of quality. In Beluga, it may form one per cent.; in some kinds of Brazilian, as much as twenty per cent. The reader will find some good remarks by Mr. Redwood on the adulteration of isinglass, in the *Pharmaceutical Journal* for May, 1850, p. 503.—ED.]

SUBSTITUTION.—Hartshorn shavings and sole-skins (when clean, sweet, and well

¹ Mr. McClelland (*Journal of the Asiatic Society of Bengal*, viii. 900) states that Indian isinglass is yielded by *Polynemus Sole* of Buchanan. But, inasmuch as he obtained only sixty-six grains of isinglass from one of these fishes, while some of the specimens of *ommuretes* weigh from half to three-quarters of a pound, it seems tolerably clear that the Indian isinglass of English commerce cannot be obtained from *P. Sole*, but must be procured from some larger fish. It may be the produce of *Polynemus teria*, Buchanan, or the new species of *Polynemus*, referred to by Dr. Cantor (*Journal of the Royal Asiatic Society*, v. 100, London) as the *Sallina* or *Saccolia*.

² For farther details respecting East Indian isinglass, see Dr. Royle's work, *On the Production of Isinglass along the Coasts of India, with a Notice of its Fisheries*, London, 1842.

³ Metcalfe, December 1842.

prepared) are sometimes substituted for isinglass in fining. For domestic uses, *patent gelatine* is frequently employed as a substitute for isinglass.

Fig. 433.

False Isinglass from Para (natural size).

7. Para Isinglass.—A substance has lately been imported under the name of Isinglass, which, on examination, proves not to be isinglass, but the dried ovary of a large fish.

Two boxes were imported; they did not contain more than 14 or 16 lbs. A similar article has been before imported into London. It consists of bunches of the size and shape of the subjoined figure. They somewhat resemble a bunch of grapes; and consist of ovoid or rounded masses, attached by peduncles to a central axis; by immersion in water, this axis is found to consist of a convoluted membrane, to one side only of which these ovoid masses are attached.

A very superficial examination of this so-called isinglass proves that it is neither the swimming-bladder of a fish, nor is it gelatinous; but it is in reality the ovary of some large fish, and is of an albuminous nature. When soaked in water, its fishy odour becomes very obvious.

The ovid masses are *ova*. They are highly vascular on the surface, and are filled with an animal substance of a yellow colour. In general appearance they resemble the vitellus of a shark or ray.

The *Sudis Gigas*, a large osseous fish, upwards of six feet in length, is found at Para. Its flesh is dried, salted, and eaten by the lower classes; and its swimming-bladder constitutes one of the kinds of Brazilian isinglass imported into London. It is probable, therefore, that the ovary of this fish constitutes the false isinglass in question. If not from this fish, it is probably obtained from some allied genus (as *Amia*) of highly organized osseous fishes.¹

¹ [It was during his visit to the Museum of the College of Surgeons for the purpose of examining the preparation to which the preceding plate refers, that the late Dr. Pereira met with the serious accident

GELATINE.—Gelatine may be extracted from bones, by boiling them in water under pressure; or, more readily, by employing bones which have been previously digested in hydrochloric acid to extract the phosphate of lime. In this way a nutritious soup is prepared in Paris for the hospitals, and other pauper habitations.¹ Gelatine has even been extracted from fossil bones. A soup was prepared from one of the bones of the Great Mastodon, by the Prefet of one of the departments of France.

Nelson's Patent Gelatine is obtained from glue pieces, freed from hair, wool, flesh, and fat.² It is probable that inferior kinds of isinglass are also employed. Two kinds of this patent gelatine are made up: the best (called *gelatine of the first quality*) is opaque; it is, by preference, made from the cuttings of the hides of beasts, or from the skins of calves; the inferior kind (called *gelatine of the second quality*) is transparent; it is made from non transparent glue pieces. Both kinds are sold, cut somewhat in imitation of picked isinglass.

French gelatine is sold in cakes, marked like those of common glue, with the nets on which they have been dried. They are either uncoloured, or coloured red, green, or blue. [Some of this patent French gelatine is made at Paris, from the cuttings of skins used for making white kid gloves.—Ed.]

[A very pure form of gelatine is now extensively sold under the name of *Swinburne's Patent Refined Isinglass*. It is procured from the skins of calves cut into very thin slices, and treated simply with water at or about 200°. No chemical substance whatever is used in its preparation. The skins are treated with successive quantities of water until all the gelatine is extracted. The common sorts of isinglass are treated in the same way, and a very pure kind of colourless gelatine is thus obtained from them, the residues being subsequently boiled up to make glue. The gelatine of the first quality thus procured is white, inodorous, and tasteless, entirely free from acidity or alkalinity. If previously soaked in cold water, it is entirely dissolved without leaving any residue on the addition of a small quantity of boiling water, and the solution on cooling, if not over-heated, sets into a firm transparent jelly. The properties are the same, whether it be procured from calves' skins, or from isinglass. The process simply deprives the isinglass and skins of their insoluble albuminous portions.

The test of the goodness of gelatine is this: When boiling hot water is poured upon it, it should not form a yellow gluey-looking mass of an offensive odour, but it should be colourless, of a thick consistence, and entirely free from smell. The French gelatine is generally run into very thin sheets, in order to conceal the yellow colour. It has no smell when dry, but is very offensive when treated with warm water in the manner above described. A pink or red colour is sometimes given to it in order to conceal its bad quality. The principle, gelatine, is deteriorated by any chemical substance used for its extraction. Gelatine thus prepared, has found its way into the market, and has tended to give an evil reputation to this substance as an article of food and as an economical substitute for isinglass. But it is a well-known fact that isinglass owes its chief properties to *gelatine* alone, and chemistry and the microscope show that when this principle has been once extracted either from skins or fish-bladder, its properties are identical, provided they have not been changed by any chemical process in the extraction. Swinburne's gelatine of first quality is not to be distinguished from the gelatine separated from the air-bladder of the sturgeon. The latter, weight for weight, yields a much larger proportion than the skin of the calf, and the process of extraction is more easy, but the principles are the same; they have the same properties and are adapted to the same uses.

The term *Isinglass* is probably an English corruption of the German *Hausenblase*—bladder of the Sturgeon. To apply the term isinglass to gelatine extracted from skin is, therefore, not only a misnomer but a mistake. All kinds of isinglass may be regarded as gelatine plus certain impurities or adventitious substances. Gelatine, however, is not isinglass, but the true animal principle separated from these impurities.

Much absurd discussion has arisen as to whether gelatine is to be regarded in the light of a *product* or *educt* of the tissues. It is an educt of the swimming-bladder of the sturgeon, and is properly described by the author (*infra*) as a *constituent* forming from 86 to 93 per cent. of isinglass. If an educt of the air-bladder of the sturgeon, it must be equally an educt of the skin of young animals, as of the calf, i. e. it exists in the skin as such, and is not produced from it by the action of boiling water any more than starch is produced from grain by a similar process. The tissue of the skin is closer than that of the air bladder; hence it requires a longer continuance of the action of water to separate the gelatine from the other principles. Acetic acid will, however, dissolve gelatine from the skin in the cold, and tannic acid (in tanning skins) com-

which confined him in his bed, and from which he was just recovering, when he was suddenly seized with fatal illness. The above was written while he was confined to his bed, and it was one of the last articles from his pen. It therefore possesses an interest beyond that of the subject to which it relates, and for this reason we have extracted the paragraph from the *Pharmaceutical Journal* for January 1827, in which it was published.—Ed.]

¹ See D'Arceet, *Recherches sur les Substances Nutritionnelles que renferment les Os*, Paris, 1829; also Edwards, *Recherches Statist. sur l'Emploi de la Gelatine*, Paris, 1835; and *Quarterly Journal of Science*, April, 1827.

² See the specification of his patent in *The Mechanic and Chemist* for 1840.

bines with the gelatinous tissue in the cold to form leather. These facts show correctly and truly that gelatine exists in the skin as an-independent principle, like albumen.—Ed.]

COMPOSITION.—Isinglass of fine quality was analyzed by John,¹ who found the constituents to be *gelatine* 70.0, *osmazome* 16.0, *membrane* insoluble in boiling water 2.5, *free acid* (lactic?), with *salts of potash* and *soda*, and some *phosphate of lime*, 4.0, and *water* 7.0. These results, however, can scarcely be accurate; for dried flesh, as Berzelius² observes, does not contain more than 8 per cent. of osmazome; and if isinglass contained 16 per cent. it could not be kept dry when exposed to the air.

Mr. E. Solly, jun.³ examined three specimens of Bengal isinglass, and found the constituents to be *gelatine*, *albumen*, a small portion of *saline* and *earthy substances*, *osmazome*, and a minute trace of *odorous oil*. The quantities of gelatine in three specimens were respectively 86.5, 90.9, and 92.8 per cent.; while those of albumen were 13.5, 9.1, and 7.2 per cent.

For the following table of the different kinds of isinglass known in the London market, I am principally indebted to Mr. James Metcalfe, wholesale dealer in isinglass, of No. 20, Artillery Place, Finsbury Square.

Country.	Place of Produce.	Place of Export.	Name and Character.	Prices per lb. English.		REMARKS.	
Russia	The Oral (Ural)	St. Petersburg . . .	Long Staple Ural, 1st and 2d . . .	14 6	13 6	Very choice and dear. These are the sorts which yield the cut. Refuse of the above. Seldom imported. Seldom inquired for. Used for finings. In great demand. Seldom imported. In good esteem. A thin insoluble membrane lining the inside. Not in use. In general demand. Not in much repute. Used perhaps for mixing. Objected to on account of its fishy smell and imperfect solubility. When carefully prepared, it may equal the Brazilian kind.

² Royle, *On the Production of Isinglass*, p. 40, Lond. 1842.

³ *Traité de Chim.* vii. 668.

EFFECTS AND USES.—The *dietetical* properties of gelatine have been already noticed. Considered *medicinally* it is an emollient and demulcent. It is employed, dissolved in water or milk, and rendered palatable by acid and sugar, as a nutritious substance for invalids and convalescents.

A solution of isinglass, with tincture of benzoin, is brushed over black sarcenet to form *Court* or *Black Sticking Plaster*. *Liston's isinglass plaster* consists of oiled silk coated with isinglass.¹ The preparation of *Gelatine Capsules* has been already described.

Isinglass is also employed as a clarifying or fining agent, (for coffee, wines, beer, &c.) Some of the constituents of these liquors unite with the gelatine, and form soluble compounds, which precipitate, and in the act of precipitation the gelatine incloses within its meshes the matters which rendered the liquid turbid. The great consumers of isinglass are the brewers,² who employ principally the coarse Brazilian variety.

358. OLEUM JECORIS MORRHUÆ.—COD-LIVER OIL.

(*Gadus Morrhua*, L.—*Morrhua vulgaris*, D.)

[*Oleum Morrhue*, U. S.]

HISTORY.—The oil obtained from the livers of the Common Cod, and various other allied species of fish, appears to have been for a long period a popular remedy, in various countries of Europe, for rheumatism, and some other diseases, though its use by medical practitioners is comparatively recent. In 1782, it was strongly recommended in chronic rheumatism, by Dr. T. Percival,³ and in 1807, by Dr. Bardsley,⁴ who states that it was in high repute in Lancashire.

ZOOLOGY.—This oil is principally procured from the common cod (*Morrhua vulgaris*; *Gadus Morrhua*), formerly called *Asellus major*;⁵ also from allied species, as the Dorse (*Gadus callarias*), the Coal-fish (*Gadus carbonarius*), the Burbot (*Lota vulgaris*), the Ling (*Lota molva*), and the Torsk (*Brosmius vulgaris*).⁶

Some of the fish-oils⁷ of commerce are obtained exclusively from the liver, others are procured from the adipose tissue diffused through the body of the animal generally. In the former, therefore, we are prepared to find bile-constituents, which are not obtainable from the latter. In fishes, properly so called, the distribution of oil in the body of the animal is not uniform. In the *Gadidæ* or Cod-tribe (common cod, dorse, coal-fish, pollack, turbot, ling, torsk, &c.), in the *Squalidæ* or Sharks, and in some other fishes, almost the whole adipose tissue of the animal is concentrated in the form of oil contained in the liver.⁸ On the other hand, in the salmon, herring, sprat, and wolf-fish, the oil is more diffused through the body of the animal, and the liver is, comparatively speaking, devoid of it. The oils obtained from the livers of the different species composing the tribe *Gadidæ*, appear to be very similar in their physical and chemical qualities, and there is good reason for believing that they agree in their medicinal properties. To all of them the term

¹ *Pharmaceutical Transactions*, i. 145.

² Full particulars respecting the mode of fining beer are given by Jackson, in his *Essay on British Isinglass*, Lond. 1765.

³ *London Medical Journal*, lii. 393.

⁴ *Medical Reports*, p. 19.

⁵ See Schoneveld, *Ichthyologia*, p. 18, Hamb. 1681. Pinn (*Hist. Nat. lib. ix. cap. 38. ed. Vulp.*) mentions two kinds of *Asellus*; namely, a smaller kind called *callaris*, and a kind termed *baccii*, caught in deep water only.

⁶ See Dr. J. H. Bennett's *Treatise on the Oleum Jecoris Aselli*, p. 17, Lond. 1841.

⁷ I use the term *fish-oils* in its popular and commercial acceptation, and include under it not only the oils obtained from fishes properly so called, but also those procured from other aquatic animals, as the *catenes* and seals.

⁸ Professor Owen in his *Lectures on the Comparative Anatomy and Physiology of the Vertebrate Animals* (Part I, *Fishes*, p. 344, 1846), observes, "that the myriads of deep-sea captured and seasonally rejected on our coasts, show that the fishermen have not yet taken full advantage of this anatomical fact, which exposes to them an abundant source of a pure and valuable oil."

oleum jecoris aselli,¹ *oleum jecoris gadi*, or *cod-liver oil*,² is indiscriminately applied, though it is commonly used, especially in this country, to indicate the oil procured from the liver of the common cod. (*Gadus morrhua*, Cuv.) It would be better, therefore, to employ the term *oleum jecoris morrhue*, or simply *oleum morrhue*, when it is intended exclusively to designate the latter oil. De Jongh, in his *Disquisitio comparativa chemico-medica de tribus olei jecoris aselli speciebus*, published at Leyden, in 1843, states that the Bergen (Norwegian) oil is principally obtained from three species, viz. the dorse (*Gadus callarias*), the Coal-fish (*Gadus carbonarius*), and the pollack (*Gadus pollachius*), but chiefly from the first.

PREPARATION.—In different countries the mode of preparing the oil varies somewhat. The cod-oil met with in the London market is the produce of Newfoundland, where, according to Pennet,³ it is thus procured: "They take a half tub, and, boring a hole through the bottom, press hard down into it a layer of spruce boughs; upon which they place the livers, and expose the whole apparatus to as sunny a place as possible. As the livers corrupt the oil runs from them, and, straining itself through the spruce boughs, is caught in a vessel set under the hole in the tub's bottom." "At Newhaven, near Edinburgh, the fishermen simply boil the livers in an iron pot, and then filter it [the oil] through a towel containing a little sand." (J. H. Bennett.)

DESCRIPTION.—Among the London dealers, I have met with but one kind of cod-liver oil. Its colour is chestnut-brown, and its odour is like that of boiled cod's liver. It is the *Cod Oil* of commerce, the *oleum jecoris aselli fuscum* of continental pharmacologists. It is extensively used by curriers in dressing leather.

In general, continental writers distinguish three varieties of cod-liver oil; one white or pale-yellow, a second brownish-yellow, a third dark-brown. But between the finest pale-yellow or almost colourless oil, and the dark-brown cod-oil used by curriers, there is an almost infinite variety of shades, so that no absolute difference can be founded on colour only. De Jongh made, in Mulder's laboratory, a very elaborate analysis of three kinds of cod-liver oil, the properties of which he thus describes:—

Three kinds of cod-liver oil are admitted and described by the writer just quoted. These are *pale*, *pale-brown*, and *brown*.

1. *Pale cod-liver oil*.—Golden yellow; odour not disagreeable; not bitter, but leaving in the throat a somewhat acrid fishy taste; reacts feebly as an acid; sp. gr. 0.923 at 63°.5 Fahr. Cold alcohol dissolves from 2.5 to 2.7 per cent. of the oil; hot alcohol from 3.5 to 4.5 per cent.; in either it is soluble in all proportions.

2. *Pale-brown cod-liver oil*.—Colour that of Malaga wine; odour not disagreeable; bitterish, leaving a slightly acrid fishy taste in the throat; reacts feebly as an acid; sp. gr. 0.924 at 63°.5 Fahr. Cold alcohol dissolves from 2.8 to 3.2 per cent. of it; hot alcohol from 6.5 to 6.8 per cent. Ether dissolves it in all proportions.

3. *Dark-brown cod-liver oil*.—Dark-brown, by transmitted light greenish, in thin layers transparent; odour disagreeable, empyreumatic; taste bitter and empyreumatic, leaving behind in the fauces an acrid sensation; reacts feebly as an acid; sp. gr. 0.929 at 63°.5 Fahr. Cold alcohol dissolves from 5.9 to 6.5 per cent. of it; hot alcohol from 6.5 to 6.9 per cent. of it. In ether, it is soluble in all proportions.

¹ Pliny (*Hist. Nat.* lib. iv. cap. 28) states that there were two kinds of fishes called *aselli*, one smaller, termed *callaria*, the other found in deep water, and denominated *bacchi*; the latter were preferred to the former. Varro (*Opera Omnia*, p. 21, Durdrechtii, 1619) says that these fishes derived their name *aselli* from their resemblance in colour to the ass. By some later writers the term *asellus* has been extended to several species of the cod tribe—thus, the common cod is called *asellus major*; the ling, *asellus longus*; the coal-fish, *asellus niger*; the whiting, *asellus albus*; the dorse, *asellus striatus*; the pollack, *asellus haifingo*, &c. A few years ago, a writer in one of the medical journals, mistaking the meaning of the word *asellus*, gravely announced that "oil of the liver of the ass" had been introduced as a remedial agent into Germany from Sweden.

² The term *cod-liver oil* is here used to indicate the oil obtained from the livers of any of the cod tribe. In this sense it is about equivalent to the Latin term *oleum jecoris aselli*.

³ *Arctic Zoology*, iii. 305, 1792.

COMPOSITION.—Cod-oil has been analyzed by several chemists. The following is the analysis of Marder.¹ In 200 grains of the oil he found the following substances:—

<i>In the Clear Oil.</i>		<i>In the Burnt Oil.</i>	
Green soft resin	0.104	(brown resin)	0.130
Brown hard resin	0.026	(black resin)	0.156
Gelatine	0.312	0.036
Oleic acid	111.833	95.000
Margaric acid	20.625	8.000
Glycerine	16.832	18.000
Colouring matter	11.500	25.000
Chloride of calcium	0.1040	0.2002
Chloride of sodium	0.1179	0.1883
Sulphate of potash	0.0361	0.0614
	161.4006		147.6809

Since the above analyses were made, *iodine* and *bromine* have been detected in this oil.

De Jongh found the principal constituents of these oils to be *oleate* and *margarate of glycerine*, possessing the usual properties. But they also contained *butyric* and *acetic acids*, the *principal constituents of the bile* (bilifellinic acid, bilifulvin, and cholic acid), *some peculiar principles* (among which the substance called *gaduin*) and not quite one per cent. of *salts*, containing *iodine*, *chlorine*, and traces of *bromine*. Moreover, he found that the oil always contained *free phosphorus*.

The following table shows the proportions of the constituents in the three kinds of oil:—

<i>Constituents.</i>	<i>Pale Oil.</i>	<i>Pale Brown Oil.</i>	<i>Brown Oil.</i>
Oleic acid (with <i>Gaduin</i> and two other substances)	74.03300	71.75700	69.78500
Margaric acid	11.75700	15.42100	16.14500
Glycerine	10.17700	9.07300	9.71100
Butyric acid	0.07436	—	0.15875
Acetic acid	0.04571	—	0.12506
Fellinic and cholic acids, with a small quantity of mar- } garine, oleine, and bilifulvin	0.04300	0.00200	0.29000
Bilifulvin, bilifellinic acid, and two peculiar substances	0.26800	0.44500	0.87600
A peculiar substance, soluble in alcohol	0.00600	0.01300	0.03800
A peculiar substance, insoluble in water, alcohol, and ether	0.00100	0.00200	0.00500
Iodine	0.03710	0.04060	0.02450
Chlorine, and traces of bromine	0.14880	0.15660	0.08400
Phosphoric acid	0.09135	0.07890	0.05365
Sulphuric acid	0.07100	0.08505	0.01010
Phosphorus	0.02125	0.01136	0.00754
Lime	0.15150	0.16780	0.08170
Magnesia	0.00880	0.01230	0.00380
Soda	0.05340	0.06810	0.01790
Iron	—	—	a trace
Loss	3.00943	2.60319	2.56900
Cod-Liver Oil	100.00000	100.00000	100.00000

By reference to this table, there will be observed some slight differences in the composition of the three kinds of oil. Whether these are constant or accidental, farther investigations are required to determine. But from De Jongh's analyses, it would appear that the *pale* oil is richest in oleic acid and glycerine—that the *brown* oil contains the largest amount of margaric, butyric, and acetic acids, and of the substances peculiar to cod-liver oil—and, lastly, that the *pale-brown* oil is richest in iodine and saline matters.

I now proceed to notice in detail some of the substances which enter into the composition of this oil.

1. *Of Gaduin.*—For the discovery of this substance in cod-liver oil we are indebted to De Jongh. It may be obtained as follows: Saponify cod-liver oil by means of caustic soda, and decompose the soap thus obtained by means of acetate of lead. The resulting lead soap is to be treated with ether, which takes up oleate of lead and gaduin, and leaves undissolved the margarate of lead. The ethereal solution is dark brown. If it be decomposed by sulphuric acid, brown oleic acid is set free. The brown colour of this acid is owing to the presence of gaduin. To separate the latter, add excess of caustic acid to the oleic acid, by which oleate of soda is formed. This is insoluble in the excess of caustic soda. It is to be dissolved in alcohol, and the alcoholic solution cooled below 32° Fahr., by which the oleate of soda separates, leaving for the most part the gaduin in solution. By the addition of sulphuric acid the gaduin is precipitated from its solution. Gaduin is a brown substance which is soluble in alcohol, but is rendered insoluble by evaporating its solution to dryness. The alcoholic solution yields, on the addition of neutral acetate of lead, a copious precipitate, composed of $C^{25}H^{22}O, PbO$. If this lead salt be

¹ Pharm. Central-Blatt für 1857, p. 536.

digested with carbonate of soda, it is decomposed, and a soda salt is obtained in solution, from which sulphuric acid precipitates a brown acid. This, when dried at 285° Fabr., was found to have the following composition: $C^{35}H^{22}O^9$. Gaduin is odourless, tasteless, and of a dark brown colour. It is completely insoluble in water, but is for the most part soluble in both ether and alcohol. Its insoluble portion augments every time the solution is evaporated. When dry, it is brittle and pulverizable. It is insoluble in both nitric and hydrochloric acids. In sulphuric acid it dissolves, and acquires a blood-red colour; but from this solution it is precipitated both by water and alkalis. It is soluble in alkalis. Diffused through water and treated with chlorine, it becomes decolorized. In burning, it yields an odour, first of acetic acid, afterwards of cod oil, and leaves behind a small quantity of ash.

The *insoluble modification of gaduin*, to which allusion has already been made, is blackish-brown, pulverizable, insoluble in water, alcohol, ether, and diluted sulphuric acid; but by concentrated sulphuric and hydrochloric acids it is converted into a black powder, without freely dissolving; in hot nitric acid, it gradually and completely dissolves. It dissolves in alkalis, forming a red coloured solution. In burning, it evolves the odour of acetic acid, and leaves about 0.822 per cent. of ashes. When dried at 238° F. its composition is $C^{39}H^{26}O^{12} = C^{35}H^{22}O^8 + C^4H^3O^3 + HO$; that is, gaduin ($C^{35}H^{22}O^8, HO$) combined with acetic acid ($C^4H^3O^3$). But De Jongh's formula scarcely agrees with his experimental result. He says that analysis gave him 7.04 per cent. of hydrogen, whereas his formula indicates about 7.3 per cent.

Berzelius states that, when he read De Jongh's account of gaduin, he was struck with the analogy of the reactions of this substance with those of bilifulvic acid, and he tells us that he was disposed to think that gaduin is primitive bilifulvic acid, and that the reddish-brown substance, insoluble both in alcohol and water, which he (Berzelius) separated from bilifulvin by long and numerous operations, is only the insoluble modification of gaduin. This point, however, at present remains undetermined.

Gaduin is contained in all the three varieties of oil examined by De Jongh. At first, it is yellow, but under the influence of atmospheric air it acquires a brown colour.

2. *Fatty acids; margaric and oleic acids.*—These acids, as obtained from cod-liver oil, do not appear to differ in their nature and composition from the same acids procured from other sources. De Jongh analyzed them in the form of margarate and oleate of lead. The results were as follows:—

Margarate of lead	$C^{34}H^{20}O^3, PbO$.
Oleate of lead	$C^{44}H^{28}O^4, PbO$.

3. *Glycerine.*—This was obtained by saponifying cod-liver oil by caustic soda. The residual lye was decanted from the soda-soap, saturated with sulphuric acid, and the sulphate of soda prepared by crystallization. The residual glycerine was compared with glycerine procured from olive-oil and lead, and found to be darker coloured. All these kinds of glycerine were decolorized by adding basic acetate of lead to the glycerine solution, though they again became coloured when submitted to evaporation.

4. *Bile constituents.*—When cod-liver oil is shaken with water, an emulsion is obtained from which the oil slowly separates. The aqueous liquid becomes clear by filtration. That which had been obtained by shaking the brown oil with water was coloured and empyreumatic; but the other kinds of oil did not colour the water. The liquid invariably had a slightly acid reaction, and the oil which had been shaken with it was clearer, had a feebler odour, and reacted less powerfully as an acid. By boiling the oils with water, the same results were obtained. By evaporation, the aqueous fluids from all the three kinds of oil yielded a reddish-brown extract, which, softened by heat, was slightly soluble in water, was more soluble in ether, and completely so in alcohol. Alkaline solutions dissolved it, and acids threw it down again in the form of a reddish-brown flocculent precipitate. The extracts had a peculiar odour and a bitterish taste. The quantities obtained from the different kinds of oil were as follows:—

	With cold water.	With hot water.
Pale oil	0.607 per cent.	0.513 per cent.
Clear brown oil	0.590 " "	0.549 " "
Brown oil	1.288 " "	1.256 " "

When successively treated with ether, alcohol, and dilute spirit, all these extracts yielded the same results.

By ether, a reddish-brown, transparent, glutinous extract was obtained, which melted by heat, stained paper, and had the odour and taste of bile. After some time, small crystals made their appearance in it. It was slightly soluble in water, but readily so in ether as well as in alcohol. A solution of carbonate of ammonia being added to its ethereal solution caused the separation of the mixture into two layers; an upper turbid layer, which by evaporation yielded some drops of *olein*, some crystals of *margarin*, and a *brownish mass* which was identical with that procured by the evaporation of the lower layer. This brown mass had a bitter taste, was separated by water into a soluble and insoluble portion, and consisted of *fellinate* and *cholate of ammonia*.

The extract which had been exhausted by ether yielded to alcohol a blackish-brown, odourless, bitter, shining, hygroscopic mass; which dissolved with difficulty in water, and consisted of *biliverdin*, *bilifulvin*, and *bilifellinic acid*.

Dilute spirit removed from the residual extract a black, shining substance, soluble in alkalis, concentrated sulphuric acid, and hot acetic acid, but insoluble in nitric and hydrochloric acids. From its alcoholic solution, baryta-water and acetate of lead precipitated it of a brown colour. It left no residue by burning.

The residue of the aqueous extract, left after the action of the three above-mentioned solvents, contained an *organic substance* (whose nature has not been determined) and *inorganic salts*, in which chlorine, phosphoric and sulphuric acids, lime, magnesia, and soda were found, but no potash or iodine.

5. *Iodine, bromine, and chlorine*.—Considerable, though, as I conceive, unnecessary, importance has been given to the fact that cod-liver oil frequently or usually contains both iodine and bromine. To the presence of one or both of these substances has been ascribed the whole or part of the remedial efficacy of the oil. A little consideration, however, would be sufficient to prove that their therapeutical agency in the oil must, if any, be exceedingly small. The proportions in which they exist in the oil is inconstant, though in all cases very small. Moreover, beneficial effects have been produced by the use of the oil, which neither iodine nor bromine is capable of producing.

Some chemists have failed to detect *iodine* in cod-liver oil. De Jongh says that it is present in every genuine oil, but that the only certain mode of detecting it is to saponify the oil, and carbonize the resulting soap. He confirms Stein's remark, that neither by immediately carbonizing the oil, nor by saponifying it, and then decomposing the soap by acids, can the iodine be detected. It follows, therefore, that iodine exists in the oil neither in the free state nor in that of metallic iodide, but probably in organic combination, perhaps as an iodic fatty acid. De Jongh determined the proportion of iodine by forming iodide of palladium; every 100 parts of anhydrous iodide of palladium were considered equivalent to 70.34 parts of free iodine.

The largest amount of iodine found in genuine oil is less than 0.5 per cent. If the amount obtained be larger than this, fraud may be suspected. It is said by Dr. Martiny¹ that some dishonest druggists have introduced iodine into the oil for the purpose of augmenting its commercial value. Nay, it is stated that an artificial cod-liver oil has been made by combining iodine with common fish or train oils.

De Jongh detected *bromine* in the oil by Balard's process. The carbonized soap was digested with alcohol, and the alcoholic extract treated with chlorine gas and ether. Its proportion was estimated in conjunction with that of chlorine, as the quantity was too small to admit of accurate separation.

The *chlorine* was determined by precipitating it as chloride of silver from the watery extract of the carbonized soap.

6. *Phosphoric and sulphuric acids*—*Phosphorus*.—De Jongh determined the presence and quantity of these ingredients in the following way: The oil was saponified by potash, and the soap thus obtained decomposed by hydrochloric acid, by which the fatty acids were separated. From the solution the phosphoric acid was precipitated by a nitrate of iron (whose proportions of oxide was known) and ammonia, and the sulphuric acid by means of nitrate of baryta.

In order to determine the presence and quantity of free phosphorus or sulphur, a given quantity of oil was decomposed by concentrated nitric acid, and the quantity of phosphoric and sulphuric acids in the oxidized liquid ascertained by the above-mentioned method. More phosphoric acid was procured from the oxidized than from the unoxidized liquid, and the proportion of phosphorus was calculated from the excess of acid.

7. *Acetic and butyric acids*.—De Jongh separated these volatile acids from cod-liver oil by adding sulphuric acid to the soda-soap, and distilling the liquid thus obtained. The distilled product had a peculiar odour. It was saturated with barytic water, and evaporated to dryness. One portion of the residue was insoluble in alcohol, the other was soluble. The insoluble salt was acetate of baryta with two equivalents of water ($=C^4H^6O^2, BaO$); the soluble salt was butyrate of baryta. The soluble salt obtained from the pale oil gave the formula $2(C^4H^6O^2), BaO, 6H^2O$; that procured from the pale-brown sort gave the formula $C^4H^6O^2, BaO, HO$.

Rancid cod liver oil emits an odour like common fish, or train-oil, and we might, therefore, expect that phocenic acid would be a constituent of cod-liver oil. De Jongh did not detect it; but thinks that phocenic acid may perhaps be resolvable into acetic and butyric acids—a supposition somewhat improbable, seeing that phocenic acid contains considerably more carbon than either butyric or acetic acid. Berzelius observes that the presence of acetic acid in cod-liver oil, in a form which is not extractable by water, is remarkable, because it leads to the supposition that it is contained in the form of a peculiar fat, which would be the acetate of lipula. It will be unnecessary to enter into any details with respect to the other constituents of the oil.

ADULTERATION.—The characters by which we judge of the genuineness, purity, and goodness of the oil, are partly physical, partly chemical.

¹ *Naturgeschichte der für die Heilkunde wichtigen Thiere*, Darmstadt, 1847.

The physical characters which are usually employed are principally colour, odour, and flavour. The finest oil is that which is most devoid of colour, odour, and flavour. The oil as contained in the cells of the fresh liver is nearly colourless, and the brownish colour possessed by the ordinary cod-oil used by curriers is due to colouring matters derived from the decomposing hepatic tissues and fluids, or from the action of air on the oil. Chemical analysis lends no support to the opinion, at one time entertained, that the brown oil was superior, as a therapeutical agent, to the pale oil. Chemistry has not discovered any substances in the brown oil which would confer on it superior activity as a medicine. On the other hand, the disgusting odour and flavour, and nauseating qualities of the brown oil, preclude its repeated use. Moreover, there is reason to suspect that, if patients could conquer their aversion to it, its free use, like that of other rancid and empyreumatic fats, would disturb the digestive functions, and be attended with injurious effects.

Of the chemical characters which have been used to determine the genuineness of cod-liver oil, some have reference to the iodine, others to the gaduin or to the bile constituents. I have already stated that some fraudulent persons are said to have admixed iodine (either free iodine or iodide of potassium) with train-oil to imitate cod-liver oil. The presence of this substance may be readily detected by adding a solution of starch and a few drops of sulphuric acid, by which the blue iodide of starch is produced; or the suspected oil may be shaken with alcohol, which abstracts the iodine.

But though we may thus readily prove that the suspected oil contains no artificially added iodine, the iodine which is naturally contained in, and more intimately combined with the oil, may be frequently recognized by another process. Marchand¹ gives the following directions for detecting it: Saponify the oil with soda, carbonize the soap thus obtained, digest the coal in distilled water, add a drop of starch paste, and subject the mixture to the action of a voltaic battery, the positive pole being placed in contact with the starch paste, the negative pole with the solution. If iodine be present, the starch becomes blue. Marchand states that by this test the iodine can be detected in the urine of a patient soon after he has taken the oil. This, however, is certainly not always correct; for I submitted the urine of a young gentleman, who, for several weeks, had taken with great benefit a tablespoonful of cod-liver oil thrice daily, to the action of a galvanic battery of fifty pairs of plates for several hours, without obtaining the slightest evidence of the presence of iodine.

Sulphuric acid has been employed as a test for cod-liver oil. If a drop of concentrated sulphuric acid be added to fresh cod-liver oil, the latter assumes a fine violet colour, which soon passes into yellowish or brownish-red. Some samples of oil produce at once the red colour, without the preliminary violet tint. Goble,² who noticed this reaction in the case of oil of the liver of the ray, says, that oil which has been prepared by ebullition in water does not possess this property, but yields with sulphuric acid a clear red colour. This, however, is an error, at least with respect to cod-liver oil. It has been erroneously supposed by some persons that this violet colour was due to the evolution of iodine by the action of the acid on an alkaline iodide contained in the oil. If that were the case, the presence of a little starch-paste would be sufficient to convert the violet into an intense blue colour; which is not the case. The coloration, in fact, depends on the action of the sulphuric acid on some one or more organic constituents of the oil, and the following facts lead me to infer that it is in part due to the presence in the oil of one of the constituents of the bile.

It is well known that, in 1844, Pettenkofer³ pointed out a new test for bile. If to a liquid supposed to contain bile about two-thirds of its volume of oil of vitriol be added, the liquid kept cool, a few drops of a solution of cane-sugar (four or five

¹ *Lehrbuch der Physiolog. Chemie.*

² *Journal de Pharmacie*, 3me sér. v. 308. 1844.

³ *Ann. der Chemie und Pharmacie*, B. lii. S. 90, 1844; also Simon's *Chemistry*, translated by Dr. Day, ii. 193.

parts to one of sugar) be added, and the mixture shaken up, a violet-red colour is produced, provided bile be present. This test succeeds very well, if we dissolve a little extract of ox-bile in water, and test the solution with sugar and oil of vitriol. The colour developed agrees with that produced by the addition of oil of vitriol to cod-liver oil, which De Jongh has shown contains the essential constituents of the bile. Pettenkofer remarks that the presence of a very great excess of chlorides will change the violet-red colour into a brownish-red. This fact is deserving of notice, because it may aid in accounting for the fact that some specimens of cod-liver oil strike a brownish-red, not a violet-red colour, with oil of vitriol. Strecker¹ confirms Platner's observation that both cholic and paracholic acids produce the same colour with sugar and oil of vitriol, as bile does; so that Pettenkofer's test doubtless acts on one or both of these acids. Now De Jongh has shown that cholic acid is contained in cod-liver oil, and we have, therefore, good reason for believing that it is in part by the action of oil of vitriol on this acid that the violet-red colour is produced in cod-liver oil.

But it is well known that for the development of this colour in bile it is necessary to use, besides oil of vitriol, a third agent (sugar). Pettenkofer observes that for cane-sugar we may substitute grape-sugar or starch; in fact, any substance which can by the action of oil of vitriol be converted into grape-sugar. No such substance has hitherto been detected in cod-liver oil, and, therefore, it may be said the necessary ingredient to produce this characteristic reaction of oil of vitriol on cholic acid is wanting. Strecker has recently supplied the wanting link. In his valuable paper, to which I have already referred, he observes that acetic acid may be substituted for sugar. To the liquid supposed to contain bile add a few drops of acetic acid, and then concentrated sulphuric acid, when a magnificent purple-red colour is developed. If the quantity of bile be small, it may be necessary to use heat. Now, as cod-liver oil contains acetic acid, we have the requisite agent to enable the oil of vitriol to act on the cholic acid, and the development of the purple or violet-red colour is then readily accounted for. I have already noticed the red colour produced by the action of oil of vitriol on gaduin (supposed by Berzelius to be derived from the bile). Here, then, is another source for the red colour caused by the action of sulphuric acid on cod-liver oil.

It follows, therefore, from what has been now stated, that oil of vitriol is a test for liver oils. It does not distinguish one liver oil from another, for it reacts equally with the oil of the liver of the ray and with oil of the liver of the common cod. Neither does it distinguish good cod-liver oil from bad, for it produces its characteristic reaction both with common brown cod-oil, and with the finest and palest qualities. But it serves to distinguish oil procured from the liver, from oil obtained from other parts of the animal.

[The experiments of De Jongh go to prove that the active principle of the cod-oil is a substance called by him gadin. Dr. Winckler considers the efficacy of the oil to depend on the presence of oxide of propyle, a substance existing also in ergot of rye, and in the liquor in which herrings are pickled.—Ed.]

Mr. Beasley communicated to the late Dr. Pereira the subjoined method by which he detected iodine in cod-liver oil: To detect iodine in the liquor which accompanies the oil from the liver of codfish, it is sufficient to put a portion of it into a porcelain capsule with a little starch, and add a few drops of a fresh and rather dilute solution of chloride of lime. The characteristic colour manifests itself either immediately or after standing a short time.

The detection of the iodine in the oil was thus effected: $\frac{3}{4}$ iss of hydrate of potash was triturated in a wedgewood mortar with about $\frac{1}{2}$ vj of warm water, and $\frac{1}{2}$ ij of the oil. The mortar was set in a warm place, and triturated occasionally until the combination appeared complete. The soapy mass was thrown, by portions, into a crucible heated to redness in a common fire, and the heat continued till the soap was calcined. The residuum was triturated with $\frac{1}{2}$ ij or less of water, and the mixture thrown on a filter. A portion of the clear lixivium was placed on a capsule with a little starch and nitric acid, moderately diluted, gradually added.

¹ *Ann. der Chemie und Pharmacie*, Bd. lxx. 8. 15, 1848.

A considerable effervescence takes place, and as soon as the point of saturation is passed the mixture becomes coloured. A considerable excess of acid, however, destroys the colour.

PHYSIOLOGICAL EFFECTS.—At the commencement of its use cod-liver oil frequently causes nausea, disagreeable eructation, and occasionally vomiting. In the dose of a tablespoonful it acts as a laxative, diaphoretic, and diuretic.¹ But Taufflied² declares that, in doses of from two to four spoonfuls a day, he never found it “exert any appreciable influence upon the urine or perspiration, or produce any disturbance in the economy.” The disagreeable flavour of the oil sometimes creates nausea and sickness, but when habit has surmounted the repugnance to it, these effects cease. In several cases it has proved emmenagogue;³ and on some occasions it has given rise to a cutaneous eruption.⁴ Dr. Bardsley found that most persons were disposed to get fat under its use.

USES.—Though it has been used more or less successfully in a considerable number of diseases, the cases in which it has proved most successful are those of a gouty, rheumatic, or scrofulous nature, [and especially in phthisis.—Ed.] But even in these it requires a very long-continued use to prove successful. The most recent writer on its employment observes that its use must be continued long, “at least a month, often six weeks, and sometimes for years.” As the oil contains iodine, and as it proves most successful in those maladies in which this element proves successful, it has been suggested that iodine is its active principle. Taufflied, however, denies this, and asserts that the properties of the two are not identical, for the one succeeds where the other fails. Is bromine the active agent?⁵ [It must not be forgotten that iodine and bromine are combined organically with some of the constituents of this oil, and in such manner that they are not to be immediately recognized by the ordinary tests. This fact may perhaps tend to develop a peculiar action of iodine and bromine, and endow them with an efficacy not otherwise attainable.—Ed.]

The oil is best adapted for relaxed, torpid, and phlegmatic temperaments, and for scrofulous subjects. In plethoric habits, and where irritation of the stomach and bowels, or inflammation, exists, its use is contraindicated.

Rheumatism, *scrofula*, and *phthisis* are the diseases in which it has proved most successful. In *rheumatism*, it is indicated in the chronic forms of this disease, where the muscles and tendons are rigid, and the joints nearly inflexible. In chronic *gout* it is said not to be so efficacious. In *scrofula*, it has proved successful in most of the forms of this disease, but especially when it affects the bones (as in rickets, caries, &c.), and in *tabes mesenterica*. In the latter intractable form of the disease, its efficacy has occasionally been most surprising. [The experience of the profession at large appears now quite to have established the fact that cod-liver oil is one of the most efficacious of all remedies in arresting the progress of pulmonary phthisis; that it enables patients to struggle on longer against the inroads of the disease, and thus enables them sometimes to obtain cicatrization and contraction of cavities which otherwise must have produced speedy death.—Ed.]

The oil has also been employed in some other diseases, with more or less success. In *chronic skin diseases* attention was drawn to its use, some years since, by Dr. Marshall Hall.⁶ In *tinea favosa*, *impetigo*, and chronic *eczema*, it has been found efficacious as a topical application. In *chronic ophthalmia*, especially of a scrofulous kind, it has been given internally, and, in some cases, applied to the eye with benefit. In *paralysis*, also, it has been found beneficial by Schuppmann.⁷

ADMINISTRATION.—For an adult, the dose at the commencement is a tablespoonful, which has sometimes been increased to six times this quantity (!) This

¹ Schenk, *Hufeland's Journal*, Bd. xxii. 1822.

² *London Medical Gazette*, Feb. 28, 1840.

³ Bennett, *op. supra cit.* pp. 46 and 47.

⁴ *Ibid.* pp. 16 and 47.

⁵ For an account of Ascherson's speculations on the *modus medendi* of this oil, see Dr. Bennett's *Treatise*, before cited, p. 53.

⁶ *London Medical Gazette*, x. 796.

⁷ For farther details respecting the therapeutic uses of this oil, the reader is referred to Richter's *Ausführl. Arzneim.*; *Dierbach's Newest. Entd. in d. Mat. Med.* p. 270, 1828; and *Ibid.* i. 352, 1837; also D. Bennett's *Treatise*, already quoted.

dose is to be repeated two, three, or four times a day for several weeks, or even months. One patient consumed thirty-six lbs. of oil in two years and a half!! (Taufflied.) Dr. Bardsley gave from $\bar{3}$ ss to $\bar{3}$ iiss twice or thrice a day in warm table beer. For children of twelve months or under, the dose is a teaspoonful night and morning. The addition of some aromatic oil (as of lemon, peppermint, cassia, or anise) partly covers the unpleasant taste and smell. It is sometimes taken in the form of an emulsion. Peppermint water and lozenges have been recommended for covering the unpleasant taste of the remedy. [A minute portion of common salt, taken both before and after the dose of oil, will sometimes enable the stomach to bear this remedy when all other devices fail.—ED.]

Class IX. Aves.—Birds.

CHARACTERS.—Vertebrated animals, with red and warm *blood*, respiring by *lungs*, and the young of which are produced from *eggs*. Body covered with *feathers*, and general conformation organized for flying.

ORDER I. GALLINÆ, *Linnæus*.—GALLINACEOUS BIRDS.

CHARACTERS.—*Bill* short, convex, in some genera covered by a *cere*. Upper *mandible* bending from its base or only at the point; nostrils lateral, covered by a membrane, naked, or feathered. *Tarsus* long. Three *toes* before, united at their base by a membrane; hind toe articulated on the tarsus above the junction of the anterior toes.

359. GALLUS BANCKIVA var. DOMESTICUS, *Temminck*.—THE DOMESTIC COCK AND HEN.

Phasianus Gallus, *Linn. E.*

(*Ovi albumen*; *Ovi vitellus*, *L.*—The egg, *E.*—Ovum, *D.*)

HISTORY.—No mention is made of this animal in the Old Testament. Both the male and female are referred to in the New Testament.¹ Aristotle² calls the cock ἀλεξτροων,—the hen ἀλεξτροπις.

ZOOLOGY. **Gen. Char.**—*Bill* of medium size, strong, base naked. Upper *mandible* arched, convex, bent towards the point. *Head* surmounted by a crest or plume. *Ears* naked. Three *toes* before, united to the first joint; the hind toe raised from the ground. *Tarsus* with a long and bent *spur*. Middle *feathers* of the tail arched. *Wings* short.

Sp. Char.—*Comb* dentated. *Throat* wattled. *Feathers* of the neck linear and elongated. *Body* variegated with beautiful colours. *Tail* compressed and ascending. *Comb* and *wattles* of the female less than those of the male.

Some doubt exists as to the origin of our domestic cock and hen. *Sonnerat*³ affirms that all the varieties originate from the *Jungle Fowl* (*Gallus Sonnerati*); while *Temminck* refers them to the *Javan Fowl* (*Gallus banckiva*).

STRUCTURE OF THE OVARIUM AND DEVELOPMENT OF THE EGG.—The **OVARIUM** (*racemus vitellorum*) or *egg-organ*, consists of a cluster of ova, in a hen beginning to lay, about 500 in number. The stalk by which each ovum is attached to the ovarium is called the *petiolus*. The size of the ova is exceedingly various; when quite ripe, they are as large as the yolk of an egg; the smaller ones are white, the larger ones yellow. Each ovum, when ripe, is composed of a *calyx*, the *yolk-bag*, and the *yolk*. The *calyx* constitutes the outer coat or covering of the ovum, and consists of two layers—an outer one, derived from the peritoneum, and an inner one, which is somewhat thicker. Between these two coats the vessels ramify. The *petiolus* is merely a prolongation of the calyx; it is studded with a number of small ova resembling vesicles. On that part of the calyx of a ripe ovum which is opposite the petiolus is a whitish curved stripe,

¹ *Matthew*, xxiii. and xxvi.

² *Voyage aux Ind. Orient.* ii. 148.

³ *Hist. de Animal.*

called the *stigma*, indicating the spot where the calyx bursts, to allow the escape of the yolk. The *yellk-bag*, or *membrana propria vitelli*, is within the calyx, and closely invests the yolk. It is a flocculent, delicate, fine coat. In the early stage of the ovum, the yolk is constituted of a pellucid fluid lymph, and is hardly distinguishable from the *vesicula cicatriculæ*. It then becomes whitish, and subsequently yellow, globules of oil making their appearance. In a ripe ovum, it is viscid, tenacious, and of an orange yellow colour; and lies in the calyx, with its long axis towards the petiolus. It is composed of three layers, the middle one having the deepest colour; the innermost inclosing a white fluid called the *albumen centrale* (or *substantia alba vitelli*), from which passes a *little canal* to that part of the surface of the yolk called the *cicatricula*.

The internal surface of the yolk bag is lined with a very thin stratum of globules, in form and figure like those of the blood, but arranged organically. The *cicatricula* or *tread* (as it is improperly called), is formed by an accumulation of these globules forming a mamiform heap, the convexity of which is towards the centre of the yolk, and is usually situated nearer the petiolus than the stigma. In the top of this is the so called pellucid *poze*, which is occupied by a small vesicle discovered by Purkinje,¹ and called by him the *vesicula germinativa*, or *vesicula cicatriculæ*. It is found in all the ovarian ova, and seems to be a natural organ, since it is found in the ova of fowls which have never had access to the male. When the yolk falls into the infundibulum, this vesicle disappears. THE OVIDUCT has some resemblance to a convoluted intestine. It is situated on the left side of the animal. Its superior expanded free extremity is called the *infundibulum*, the edges of which are fimbriated. Inferiorly, the oviduct opens into the cloaca. It is attached to the spine by the *mesometrium*. The *infundibulum*, or expanded portion of the tube, receives the ovum as it escapes from the calyx of the ovarium. The upper part of the ovum is lined by a fine villous membrane, covered with follicles secreting the albumen, or glaire, and thrown into a number of longitudinal folds. The first layer of albumen which the ovum receives forms the *membrana chalazifera* of Dutrochet; at either end of which is a soft, pellucid, albuminous nodule, which may be regarded as the *rudimentum chalazarum*. During the descent of the ovum in the oviduct, it receives fresh deposits of albumen; and, as it undergoes spiral rotations in its passage, the above-mentioned processes become curved spirally, and in the perfect egg constitute the *chalazæ*, *grandines*, *appendices albuminis*, or the *poles* or *treadles*. From one chalaza to the other are observed, in many eggs, one or more white striæ, formed by a thickening of the *membrana chalazifera*. Vicq d'Azyr called this appearance the *zona albicans*.

The *albumen*, *glaire*, or *white* of the egg, is not uniform in its consistence. The thickest portion is that which is first deposited around the yolk. Proceeding from without inwards, the three layers of albumen are denominated *albumen primum*, *a. secundum*, and *a. tertium*. Just before the egg arrives at that part of the oviduct called the uterus, it receives its outer coat, the *pellucula ovi*. In the middle, or so-called uterine portion of the oviduct, is formed the *calcareous shell*. Some eggs are expelled without it; these are termed *oon eggs*. The chalk is first deposited in small polygonal pieces, having a crystalline appearance; but, when the deposit has attained a certain thickness, all traces of crystallization are lost.

Hab.—Domesticated in all the four quarters of the globe.

DESCRIPTION.—Eggs (*ova*) are too well known to need much description. Their specific gravity varies from 1.080 to 1.090. By keeping they become lighter, by the evaporation of a portion of the water. Dr. Prout² found that in two years an egg had lost $544 \frac{2}{10}$ grains. The relative weights of the different parts of the egg are, according to the same authority, as follows: *shell and membrane*, 106.9; *albumen*, 604.2; *yellk*, 288.9; total, 1,000. By boiling in water, an egg loses two or three per cent.

1. **EGG-SHELL** (*Testa Ovi*; *Putamen Ovi*).—This consists, according to Prout, of *carbonate of lime*, 97; *phosphate of lime and magnesia*, 1; *animal matter*, with traces of sulphur and iron, 2. The chalk renders the egg absorbent and antacid; hence its use to neutralize the acidity of wines.

2. **PELLUCULA OVI** (*Membrana Putaminis*).—An albuminous membrane which lines the shell. It is soluble in alkalies, and from its solution is precipitated by acids. It weighs about 2.35 grains (the whole egg being supposed to be 1,000 grains). At the larger end of the egg it forms the *follicula aeris*; the air of which, according to Bischoff, contains 23.475 per cent. of oxygen.

3. **WHITE OR GLAIRE** (*Albumen seu Album Ovi*) consists of two or three laminae, which are not homogeneous, as two parts at least are discernible, viz. a solid, probably organized albumen, having the appearance of a very fine delicate membrane, forming a series of cells, in which is contained the liquid albumen. Glaire or white of egg consists, according to Gmelin, of *albumen* 12.0, *mucus* 2.7, *salts* 0.3, and *water* 85.0. According to Dr. Bostock,³ *white of egg* consists of

¹ *Symb. ad ovi avium histor. ante incub.* Lipsiæ, 1830.

² *Philosophical Transactions* for 1822, p. 377.

³ *Nicholson's Journal*, ii. 246.

water 80.0, albumen 15.5, uncoagulable matter 4.5=100.0. The coagulability of albumen by heat, and its incoagulability by acetic acid, distinguish it from caseine. Albumen or glaire (or ovalbumen) is distinguished from albumen of the serum of the blood (*seralbumen*) by its being coagulated by ether. The membranous tissue in which the liquid albumen of eggs is contained is said by Couerbe to be devoid of nitrogen; he calls it *albumenin* or *oonin*.

4. **YELK** (*Vitellus Ovi*) is a kind of yellow emulsion, consisting of oil suspended in water by means of albumen, and inclosed in a sac called the *yelk-bag*. On its upper surface is seen the cicatricula. At the extremities are the twisted flocculent *chalazæ*. The yelk consists, according to Dr. Prout, of *yellow oil, with crystallizable fat* 28.75, *albumen containing phosphorus* 17.47, and *water* 53.8. Dr. Prout¹ says, the yelk of egg consists of *water* 170.2, *albumen* 55.3, *yellow oil* 91.0=316.5. The yellow oil (*oleum ovi*) may be obtained by boiling the yelk hard, and digesting in ether or alcohol, which dissolves the oil. By distilling off the alcohol from the filtered tincture, the oil is left behind.

PHYSIOLOGICAL EFFECTS AND USES.—Both the glaire and the yelk are highly nutritive; the latter, on account of the oil which it contains, is somewhat less easy of digestion than the white. Both are more readily assimilated when in the soft state than when hardened by heat. Considered as medicinal agents, they are emollient and demulcent. The glaire is a valuable agent in the treatment of poisoning by bichloride of mercury, sulphate of copper, and the bichloride of tin. Its efficacy in these cases depends on the combination of the albumen with the oxide or chloride of the metal. [The yelk, as well as the white, exerts antidotal powers, and may therefore be freely used.—Ed.] The glaire is also used as a demulcent or sheathing agent in all cases of corrosive or acrid poisons. The yelk is a constituent of the *mistura spiritûs vini gallici*. It is also used for preparing emulsions. Its oil has been applied to cracked nipples. The white or glaire is employed as a clarifying agent for wines and some other liquids. Its efficacy depends on its coagulation, by which it entangles in its meshes the impurities with which it either rises to the surface or precipitates. When the liquid to be clarified does not spontaneously coagulate the albumen, it is necessary to apply heat. Bookbinders use the glaire as a varnish.

Class X. Mammalia, *Linnaeus*.—Mammals.

CHARACTERS—*Vertebrated animals with red and warm blood, breathing through lungs, viviparous, and suckling their young with milk formed in their breasts or mammæ.*

ORDER I. CETACEA, *Linnaeus*.—THE CETACEANS.

CHARACTERS.—*Body pisciform, terminated by a caudal appendage, cartilaginous, and horizontal. Two anterior extremities formed like fins, having the bones which form them flattened and very soft. Head joined to the body by a very short thick neck. Two pectoral or abdominal mammæ. Ears with very small external openings. Brains large. Pelvis and bones of the posterior extremities represented by two rudimentary bones lost in the flesh.*

360. PHYSETER MACROCEPHALUS, *Lind. L. E.*—GREAT-HEADED CACHALOT.

(Concretum in propriis cellulis reperiuntur, *L.*—Cetine nearly pure, *K.*—Cetaceum, *D.*)

HISTORY.—Cuvier² is of opinion that this animal is perhaps the *Physeter* of Pliny³—the *Orca* of some other Latin writers.

ZOOLOGY. Gen. Char.—*Inferior teeth* eighteen to twenty-three on each side of the jaw. *Upper jaw* broad, elevated, without teeth, or with these short and con-

¹ *Philosophical Transactions*, 1822.

² *Hist. Nat.* ix. 3, and *axil.* 63, ed. Valp.

³ *Rech. sur les Ossements Foss.* v. 328.

cealed in the gum; *lower jaw* elongated, narrow, corresponding to a furrow of the upper, and armed with thick and conical teeth entering into corresponding cavities in the upper jaw. *Spiracular orifices* united at the upper part of the snout. A *dorsal fin* in some species, a simple eminence in others. *Cartilaginous cavities* in the superior region of the head, filled with *oily matter*.

Sp. Char.—*Lower teeth* twenty to twenty-three on each side, recurved and pointed at the extremity. Small conical teeth concealed in the upper gums. *Tail* narrow and conical. *A longitudinal eminence* on the back above the anus. Upper part of the body blackish or slate blue, a little spotted with white. *Belly* whitish. *Length* forty-five to sixty feet.

The *snout* of the cachalot, notwithstanding its prodigious length, is formed only by the maxillæ on the sides, by the intermaxillæ towards the median line, and by the vomer on this line. The intermaxillæ project to form the anterior part of the snout. Posteriorly, the right one ascends higher than the left. The *spout-hole* is single (in most cetacea it is double), and directed towards the left side, so that whenever the animal spouts water, it is to that side only.

SEAT OF SPERMACETI.—Spermaceti is found in several parts of the body of the animal, mixed with common fat. The head, however, is the grand reservoir for it. Here it is found (mixed with oil) in a large excavation of the upper jaw, anterior to, and quite distinct from, the true cranium which contains the brain. Mr. Hunter¹ states that the spermaceti and oil are contained in cells, or cellular membrane, in the same manner as the fat in other animals; but that besides the common cells there are larger ones, or ligamentous partitions going across, the latter to support the vast load of oil, of which the bulk of the head is principally made up.

There are two places in the head where this oil lies; these are situated along its upper and lower part; between them pass the nostrils, and a vast number of tendons going to the nose and different parts of the head. The purest spermaceti is contained in the smallest and least ligamentous cells. It lies above the nostril, along the upper part of the head, immediately under the skin and common adipose membrane. These cells resemble those which contain the common fat in the other parts of the body nearest the skin. That which lies above the roof of the mouth, or between that and the nostril, is more intermixed with a ligamentous cellular membrane, and lies in chambers whose partitions are perpendicular. These chambers are smaller the nearer to the nose, becoming larger towards the back part of the head, where the spermaceti is more pure.

Mr. Hunter discovered about the nose, or posterior part of the nostril, a great many vessels having the appearance of a plexus of veins, some as large as a finger. On examining them, they were found loaded with spermaceti and oil; and some had corresponding arteries. They were most probably lymphatics, whose contents had been absorbed from the cells of the head.

Hab.—Pacific Ocean, Indian and Chinese Seas. Especially off New Guinea and parts adjacent, Timor, Australasia, Polynesia, Peru, &c.

EXTRACTION OF SPERMACETI.—In the right side of the nose and upper surface of the head of the whale is a triangular-shaped cavity, called by the whalers “the case.” Into this the whalers make an opening, and take out the liquid contents (oil and spermaceti) by a bucket. The dense mass of cellular tissue beneath the case and nostril, and which is technically called “junk,” also contains spermaceti, with which and oil its tissue is infiltrated.² The spermaceti from the case is carefully boiled alone, and placed in separate casks, when it is called “*head matter*.”²

PURIFICATION.—The substance called “*head matter*” consists of spermaceti and sperm oil. Its colour is yellow. Its consistence varies with the temperature. In cold weather it consists of a congealed mass (spermaceti) surrounded and infiltrated by oil. To separate the latter as much as possible, it is put into filter bags. The solid thus obtained is then submitted to compression in hair bags, placed in an hydraulic press. It is then melted in water, and the impurities are skimmed off. Subsequently, it is remelted in a weak solution of potash. It is then fused in a tub by the agency of steam, ladled into tin pans, and allowed slowly to concentrate into large, white, translucent, crystalline masses.

PROPERTIES.—Commercial spermaceti (*cetaceum*; *sperma ceti*) usually contains

¹ *Philosophical Transactions*, lxxvii. 390.

² Beale, *Natural History of the Sperm Whale*, p. 186, 1839; also, F. D. Bennett, *Narrative of a Whaling Voyage round the Globe*, from the year 1833 to 1836, ii. 153 and 228, Lond. 1840.

a minute portion of sperm oil, which is best removed by boiling in alcohol. [The Cetine or pure spermaceti is dissolved, and is deposited on cooling in a crystalline mass. This process should be repeated so long as the alcohol extracts any oil.—ED.] Absolutely pure spermaceti (called *Cetine*) is a white lamellated substance, without taste, and almost odourless. By the addition of a few drops of alcohol or almond oil, it may be reduced to powder. [It is crystalline, has a bright pearly lustre, and melts at 120°. At 670° it is sublimed unchanged.—ED.] It is insoluble in water, and slightly soluble only in alcohol, even at a boiling temperature. [When distilled at a high temperature it is converted chiefly into ethalic or cetylic acid, and *cetène*, a liquid hydrocarbon having the formula $C^{30}H^{50}$. By carefully regulating the temperature these two products alone are formed. When saponified by fusion with caustic potash, it yields cetylate of potash and *ethal* ($C^{30}H^{30}O$) or hydrated oxide of cetyle. No oleate or margarate of potash is produced, as was formerly supposed. According to L. Smith, purified spermaceti or cetine is a cetylate of oxide of cetyle, the oleic acid formerly found being derived from a portion of sperm oil adhering to the spermaceti.—ED.]

COMPOSITION.—The ultimate analysis of pure spermaceti or cetine was made by Chevreul.¹ The proximate composition of the same substance has been ascertained by Dumas and Peligot.²

<i>Chevreul's Analysis.</i>		<i>Dumas and Peligot's Analysis.</i>	
Carbon	81.600	Margaric acid	2
Hydrogen	12.562	Oleic acid	2
Oxygen	5.479	Cetène	3
		Water	3
Cetine	100.000		
		Atoms.	Atoms.
		Cetine	1

or

Margarate of cetine	2
Binoleate of cetine	4
Water	3
	1

[The researches of L. Smith and others have shown that the analysis of Dumas and Peligot must have referred to an impure specimen of spermaceti, i. e. a specimen from which the oil had not been entirely separated. The formula of cetine or pure spermaceti, on Liebig's authority, is $(C^{64}H^{94}O^4)$. This corresponds to one equivalent of oxide of cetyle ($C^{30}H^{30}O$) and one equivalent of cetylic acid ($C^{30}H^{31}O^3$). This formula at once explains the products obtained by its saponification and distillation. By distillation at a high temperature, the ethal ($C^{30}H^{30}O$) loses 1 equivalent of water and becomes cetène, while the cetylic acid takes up the equivalent of water, and is distilled over as hydrated cetylic acid.—ED.]

PHYSIOLOGICAL EFFECTS AND USES.—Emollient and demulcent. Internally, it has been employed in irritation and inflammation of the alimentary canal (as diarrhoea and dysentery) and of the bronchial membrane (catarrh); but its internal administration is now nearly obsolete. Its principal medicinal use is in the preparation of cerates and ointments.

ADMINISTRATION.—When employed internally it is generally exhibited in the form of an emulsion (*spermaceti mixture*) made with the yolk of egg. Or it may be made with mucilage.

1. CERATUM CETACEI, L. [U. S.]: *Ceratum simplex*, E.; *Unguentum Cetacei*, D.; *Spermaceti Cerate*.—(Spermaceti \bar{z} ij; White Wax \bar{z} viiij; Olive Oil Oj, L.—Olive Oil 6 parts; Bleached Beeswax 3 parts; Spermaceti 1 part, E.—White Wax lbs; Spermaceti lbj; Prepared Hogs' lard lbij, D. "Heat the oil gently, add the wax and spermaceti, stir the whole briskly when it is fluid, and continue the agitation as it cools," E. [Spermaceti \bar{z} j; White Wax \bar{z} iiij; Olive Oil f \bar{z} v, U. S.]—If cold oil be added to the wax and spermaceti, the preparation is apt to be somewhat lumpy. As the white wax of commerce is always largely mixed with spermaceti, this preparation has never the precise composition intended by the College. Practically, however, this is of no consequence. The preparation is employed as a mild and simple dressing for blisters and excoriated surfaces.

¹ Gmelin, *Handb. d. Chem.* ii. 440.

² *Ann. de Chim. et de Phys.* lxxii. 5.

2. UNGUENTUM CETACEI, L.; *Spermaceti Ointment*.—(Spermaceti $\bar{\zeta}$ v; White Wax $\bar{\zeta}$ xiv; Olive Oil Oj. Having melted them together with a slow fire, stir assiduously until they become cold.)—A softer preparation than the preceding, but used in the same cases.

AMBERGRIS.—The substance called Ambergris (*Ambra grisea*) is procured from the Cachalot or Sperm Whale.¹ In this country it is used as a perfume only; on the continent it is employed in medicine. It appears to be the indurated feces (perhaps somewhat altered by disease) of the animal. Mr. Beale² collected some of the semifluid feces, and found that the dried mass had all the properties of ambergris. It is a solid, opaque, grayish, striated substance, having a pleasant musk-like odour, and which is supposed to be derived from the Squid (*Sepia moschata*) on which the animal feeds; and in support of this opinion it must be mentioned that the horny beaks of this animal are found imbedded in the masses. Its sp. gr. is 0.908 to 0.92. John analyzed it, and found it to consist of a peculiar non-saponifiable fat (*ambreine*) 85, sweet balsamic alcoholic extract, with benzoic acid, 2.5, aqueous extract, benzoic acid, and chloride of sodium 1.5. *Ambreine* is soluble in alcohol, and by the action of nitric acid furnishes a peculiar acid called *ambreic acid*. The effects of ambergris on the system are said to be analogous to those of musk. In the shops is kept an alcoholic tincture (called *essence of ambergris*), which is employed as a perfume only.

ORDER II. RUMINANTIA, Cuvier.—RUMINANTS.

PECORA, Linnæus.

CHARACTERS—No incisors in the upper jaw; in the lower, usually eight; a vacant space between the incisors and molars, but in which, in some genera, are found one or two canines. Molars twelve in each jaw, the crown marked with two double crescents of enamel, of which the convexity is outwards in the lower jaw, and inwards in the upper. No clavicles. Extremities disposed for walking. Two toes furnished with hoofs; metacarpal bones united. Four stomachs; intestines long. Two or four inguinal mammae. Horns in the males, and often in the females of most species.

361. MOSCHUS MOSCHIFERUS, Linn. L. E. D.—THE MUSK ANIMAL.

(Concretum in folliculo præputii repertum, L.—Inspissated secretion in the follicle of the prepuce, E. D.)

HISTORY.—Aristotle, Pliny, Ælian, and Oppian, make no mention of this animal. Ætius³ is the earliest writer who notices the perfume. None of the etymologies hitherto given for the word *Musk* (*μόσχος*) are satisfactory.

ZOOLOGY. Gen. Char.—Incisors $\frac{0}{8}$. Canines $\frac{1}{1}$ — $\frac{1}{1}$. Molars $\frac{6}{6}$ — $\frac{6}{6}$ =34. Canines wanting altogether in the females; superior canines large in the males. Ears long, pointed. Body slender. Feet with hoofs, separated and enveloping the last phalanges. Tail very short. Two inguinal mammæ.

Sp. Char.—Fur of a gray-brown; hair coarse. A pouch before the prepuce of the male, filled with an unctuous musky substance. Size of the roebuck.

The absence of horns and the presence of canine teeth distinguish the animal from the Deer (*Cervus*). The *Stylocerus moschatus* is the connecting link between the deer and the musks. It has the horns of the one, and the canine teeth of the other.

The most interesting part of the musks is the *preputial musk sac*. Cuvier⁴ says no other species of *Moschus* possesses a musk sac; but this statement is not correct. *M. Altaicus*, Eschscholtz (*M. Moschiferus Altaicus*, Brandt), *M. Napu*, and *M. Javanicus*, are also said to possess musk sacs.

³ Op. supra cit. p. 135.

⁴ Règne Animal, nouv. édit. i. 259, 1829.

Fig. 434.

Belly of *Moschus moschiferus*.

(From Pallas.)

a. Tail. b. Anus. c. Scrotum. d. Preputial orifice. e. Abdomen. f. Orifice of the musk sac.

Its hairs are stiff but smooth, and disposed in a circular manner around the external musk orifice.

2. *Muscular coat*.—This consists of two strata of fibres which surround the sac in a circular form. Pallas¹ states that they arise from the groin, and unite anteriorly with the panniculus carnosus. He regards them as the compressors and retractors of the follicle and of the prepuce when the genital organ is thrust out. The same naturalist has described two retractors of the penis.

Between the two strata of muscular fibres is placed the *penis*, which is remarkable from the circumstance of the urethra projecting beyond the extremity of the glans. In its usual state the penis lies rolled up within the belly.

On the inner surface of the muscular fibres is a number of small oblong or roundish *glands*, compared by Pallas to the Meibomian glands of the palpebræ.

3. *Fibrous coat*.—This is the most external of the proper coats of the musk sac. On its inner surface are numerous depressions or cells, surrounded by ramifying folds, within which the bloodvessels ramify. This coat is continuous (through the musk orifice) with the corium.

4. *Pearly coat*.—A soft delicate membrane, shining like mother-of-pearl. It lines the cells, and covers the folds of the fibrous coat.

5. *Epidermoid coat*.—It is the inner lining of the sac. Its external layer is silvery white; its internal one yellowish or reddish brown.

6. *Musk glands*.—In each of the depressions observed on the internal coat of the musk sac

Fig. 435.

*Moschus moschiferus*.

ANATOMY OF THE MUSK SAC.—The sac is peculiar to the male animal. If he be supposed to be laid on his back, and the belly examined, we observe behind the navel, and immediately in front of the preputial orifice, a small aperture (*external aperture of the musk sac*) leading into the *musk canal*, which terminates in the cavity of the *musk sac*. The aperture is about half an inch from the umbilicus, and usually about a line, or a line and a half, from the preputial orifice. In some preparations in my possession the distance is much greater. The preputial orifice is somewhat more prominent, and has a number of longish hairs projecting from it, in the form of a brush or hair-pencil; whereas, the external musk aperture is placed in a depression, and is smooth.

The *musk sac* is of an oval form, rather broader at the anterior than at the posterior part. It is flat and smooth above, where it is in contact with the abdominal muscles, but convex below (supposing the animal standing). Its breadth is from $1\frac{1}{2}$ to $1\frac{3}{4}$ inches; its length from 2 to $2\frac{1}{2}$ inches; its depth varies, being greatest anteriorly, where it is about one-half or three-fourths of an inch. The *external aperture* of the musk sac is placed in the median line, but nearer to the anterior than the posterior extremity of the sac. The *musk canal* is about 1 or $1\frac{1}{2}$ lines long, its diameter being about one line. The *internal aperture* of the musk sac is surrounded by fine hairs, which readily fall off, and are found in the musk of commerce. The following are the parts of which the musk sac consists:—

1. *Outer or hairy coat or skin*.—This is a continuation of the hide, and covers the convex portion of the sac.

are found two or more irregular-shaped bodies of a yellowish or reddish brown colour. These bodies consist of a central brownish mass (supposed to be glandular), covered by a fine membrane.

7. *Contents of the Musk Sac.*—Pallas found that, in young animals, the sac was empty and contracted. In the adult animal it contained about a drachm and a half of musk, and in old animals more than two drachms. But these quantities must be below the average, since the dried pods of commerce contain on the average more musk than this. Mr. Campbell¹ describes the musk found in the sac as soft, reddish-brown, granular, and having the appearance of soft gingerbread.²

Hab.—Asia, between 16° and 58° north latitude, and 92° and 155° of east longitude. Especially on the Atlas and Himalayan ranges. China, Cochinchina, Tonquin, Tartary, and Siberia, have all been celebrated for the musk. The animal is timid, and dwells in cold mountainous districts, where coniferous plants abound.

CAPTURE OF THE ANIMALS.—Various methods of catching the animals are adopted. Sometimes they are taken by snares or gins, sometimes by pitfalls, sometimes by shooting them. The Tungouses, one of the native tribes of Siberia, employ the bow and arrow only.

DESCRIPTION.—Three kinds of musk are described, viz: *China*, *Russian* (or *Kabardine*), and *Bucharian*. I am acquainted with the first two only.

1. **China, Tonquin, or Thibet Musk** (*Moschus tunquinensis seu tibetanus*).—This is imported in small rectangular boxes (*catties*), about 7¾ inches long, 4¾ inches broad, and 4½ deep; covered externally by silk, and lined with sheet-lead and paper. These boxes contain about twenty-five sacs or pods, each wrapped separately in paper. On the outside of the lid of some of the boxes is marked *Lingchong Musk*; and on the inside of the lid is a rude Chinese representation of the musk hunters, some shooting the animal, others cutting out the musk bag. On the paper, which envelops each pod, are similar rude representations in blue or red ink.

Pod musk (*moschus in vesicis*) consists of roundish or somewhat oval pods, which are generally broader at one end than at the other. The hairs are brownish-yellow, or grayish or whitish, bristle-like, and stiff; arranged in a concentric manner around the orifice of the sac. A careful examination will always discover the remains of the penis. The pods are about 2½ inches long, and 1¾ inches broad. The weight of each pod, as well as of the contained musk, is very variable. I am indebted to Mr. Noakes, druggist, of Snowhill, for the following account of the weight of six pods, and of the grain musk obtained therefrom:—

<i>Pods of Musk.</i>	<i>Weight.</i>	<i>Contents.</i>
1	5½ drachms 0 grains	} Grain Musk 16 drachms 15 grains.
1	4½ " 0 "	
1	8 " 37½ "	
1	9 " 47½ "	
1	5 " 20 "	
1	3½ " 0 "	
Total . . 6	37 " 15 "	16 " 15 "
Average 1	6 " 12½ "	2 " 42½ "

Grain musk (*moschus in granis*; *moschus ex vesicis*) is granular, unctuous to the feel, mixed with hairs, of a dark reddish-brown colour, a bitter aromatic taste, and a strong, remarkable, very persistent smell (*musky odour*). Its odour can scarcely be called peculiar, since it is common to several animals and vegetables. Thus, the musk-ox and the musk-cat evolve it. The submaxillary gland of the crocodile secretes an unctuous musky substance. Among plants, *Erodium moschatum*, *Malva moschata*, and *Centaurea moschata*, may be referred to as possessing a musky odour. When mixed with other scents, musk has the remarkable property of augmenting and improving their smell, without much imparting its own; hence it is extensively used by perfumers. A few drops of potash added to musk increases its odour, by setting free, it is supposed, ammonia.

¹ *Journal of the Asiatic Society of Bengal*, vi. 119, Calcutta, 1827.
² For further details respecting the structure of the musk sac, consult Brandt and Ratzeburg, *Med. Zool.* Bd. i.

2. **Siberian, Russian, or Kabardine (Caberdine) Musk** (*Moschus sibiricus, rossicus* seu *cabardinus*). This is an inferior kind. The pods are said to be more oblong or oval than those of the China kind; the hairs longer and whiter. But I have examined large quantities of Siberian musk, the pods of which are not distinguishable from those of the China by any of these characters. The only invariable distinction I have observed is in the scent, which is remarkably different; it is much less powerful, and more nauseous and disagreeable, being somewhat empyreumatic. Geiger says, it is sometimes accompanied by an odour somewhat similar to that of the sweat of a horse. This kind of musk is imported in wooden boxes, and all the pods that I have examined were in a good state of preservation; but frequently, I am told, this is not the case.

BUCHARIAN MUSK (*Moschus bucharicus*) is described by some pharmacologists, but I have never met with it. The hairs are said to be yellowish or reddish-brown. The musk has a weak odour, and is of very inferior quality.

ADULTERATION.—The great sophisticators of musk are the Chinese. I have seen several *artificial* pods of musk which had been imported from Canton. T. W. C. Martius¹ calls this artificial kind *Wampo Musk*, and says that, for some years past, it has been extensively introduced into commerce. The hairy portion of the sacs is formed of a piece of the skin of a musk animal (readily distinguishable by its remarkable hairs), coarsely sown at the edges to a piece of membrane, which represents the smooth or hairless portion of the sacs. These pods are distinguished from the genuine ones by the following characters: the absence of any aperture in the middle of the hairy coat; the hair not being arranged in a circular manner; and the absence of remains of the penis (found in every genuine musk sac). These false sacs, as well as the genuine ones, are sometimes enveloped in papers marked "*Musk collected in Nankin by Jung-then-chung-chung-kee.*" The odour of the musk of the false sacs is ammoniacal.

Grain musk is sometimes imitated by dried blood, and perhaps by other substances. The fraud is to be detected by a careful examination of the appearance and odour of the particles, and by their chemical characters. An infusion of genuine musk gives *no* precipitate with a solution of bichloride of mercury, but does with tincture of nutgalls, and acetate of lead. By incineration, genuine musk leaves behind a grayish-white ash, whereas blood yields a reddish one. *Artificial musk* is said to be prepared by rubbing in a mortar dried bullock's blood with caustic ammonia, and mixing the half-dried musk with genuine musk.

COMMERCE.—At an average of the three years ending with 1832, the imports of musk from all places eastward of the Cape of Good Hope, with the exception of China, amounted to 4,965 ounces a year.² In 1839, duty (6*d.* per ounce) was paid on 2,389 ounces.

COMPOSITION.—In 1803, Thiemann³ analyzed musk. In 1805, Bucholz⁴ examined it. In 1820, Blondeau and Guibourt⁵ published an analysis of it. Afterwards, Westler,⁶ Buchner,⁷ and Geiger and Reinmann,⁸ submitted it to chemical investigation.

ODOROUS PRINCIPLE.—Has not hitherto been isolated. The strong and diffusive odour of musk would lead us to expect that its odorous matter was highly volatile. Yet such is not the fact; for we cannot deprive musk of its peculiar odour by distillation, though the distilled liquid has a musky smell. As it is destructible by heat, it is obviously organic. It is not peculiar to musk, since many other substances exhale an analogous odour. Some have suggested that it is the result of putrefaction of one or more of the constituents of musk; and in support of this statement it is asserted that, by Leslie's method of desiccation, musk may be dried and rendered odourless. I have repeatedly performed this experiment with every care, but without obtaining odourless musk. Robiquet was of opinion that many odorous substances owed their odour to a certain quantity of ammonia, which, being disengaged, carried off with it substances not otherwise volatile, which masked the ammoniacal smell. In applying this hypothesis to musk, it must be admitted that it harmonizes well with several of the circumstances observed. Thus, musk evolves ammonia; water distilled from musk contains ammonia; and potash added to a solution of musk heightens its odour (by facilitating the evolution of ammonia?).¹

PHYSIOLOGICAL EFFECTS.—Musk disturbs the functions of the stomach, acts as a stimulant to the vascular system and brain, and afterwards proves narcotic. Jörg² and his pupils submitted themselves to its influence in doses of from 2 to 15 grains in water, or mixed with magnesia. Its primitive effects were eructation, weight at the stomach, diminution or increase of appetite, dryness of the œsophagus, heaviness of the head, vertigo, and headache. The secondary effects were more marked on the encephalon than on the digestive canal; disposition to sleep, faintness, and a feeling of heaviness in the whole body. Lastly, deep and long-continued sleep. In very large doses, the action on the nervous system was very marked; trembling in the limbs, and even convulsions, were observed. The pulse was increased in frequency, and somewhat fuller. These effects show that musk belongs to the cerebro-spinants. It is a stimulant to the nervous and vascular systems, and an irritant to the stomach. Its effects are by no means uniform. Trousseau and Pidoux³ suffered from its use neither excitement of the vascular system nor sleep. Its influence is more manifest in some constitutions (those, for example, commonly termed nervous, in whom there is a very sensible or excitable condition of the nervous system), than in others (as the phlegmatic). Moreover, its effects are more marked in some morbid conditions of the cerebral functions (of the hysterical kind), than in the healthy condition of these functions. In some persons the nervous system appears to be peculiarly susceptible of the odour of musk; for it is reported that headache, giddiness, and even fainting, have been induced by it. When the digestive apparatus is previously in a state of irritation, musk increases the local disorder, giving rise to pain, nausea, vomiting, and diarrhoea. Sometimes the stimulant influence of musk is directed to the sexual organs. Trousseau and Pidoux⁴ experienced from it "une assez vive excitation des organes génitaux." In the

¹ Even after a century, musk, if originally good, retains its odour. The author examined some, in the possession of Mr. Ince, of the date of 1745, i. e. 100 years old. It was in small cohesive masses, and had a powerful and delightful odour. Is this the kind described as being scarce, and which the animal is said to squeeze out by pressure against stones? Mr. Ince has also some sixty years old—this is very inferior.

² *Material zu einer Arzneimittell.* Leipzig, 1825; and *Lond. Med. Gaz.* xxvi. 952.

³ *Traité de Thérap.* i. 25.

⁴ *Op. supra cit.*

female it has occasionally provoked the catamenial discharge. In persons disposed to epistaxis it has at times appeared to bring on the hemorrhage. Occasionally, diaphoresis or diuresis has seemed to result from its use.

The odorous principle of musk is absorbed, and subsequently thrown out of the system by the excretories. Barbier¹ observes that the urine and the sweat of persons who have taken this substance are powerfully impregnated with its odour—now and then so strongly, that the hand, applied for the purpose of feeling the pulse, retains its odour for some time. On *post-mortem* examination, the brain, and the cavities of the chest and abdomen, in those who have taken it during life, sometimes emit a strong smell of musk. Tiedemann and Gmelin² recognized the odour of musk in the blood of the mesenteric, splenic, and portal veins; but they failed to detect it in the contents of the lacteals. Trousseau and Pidoux mention that, in their experiments, the excretions acquired a feeble odour of musk. Jörg, however, denies that the excretions of those who have taken musk have the smell of this substance.

USES.—The effects of musk, already alluded to, show that it is a remedy which will be useful where we want to excite the nervous system; and, *vice versâ*, that it will be hurtful where there exists a determination of blood to the brain, and in those constitutions denominated plethoric. The cases in which experience seems to have shown that musk is sometimes useful, are the following:—

1. Those diseases which are attended with convulsive movements, and which, therefore, are called *spasmodic*. Such, for example, as hysteria, epilepsy (especially of children, and where the disease does not depend on organic changes, or on plethora), chorea, and even in some cases of tetanus. The employment of musk here has led to its denomination of antispasmodic.

Dr. Cullen,³ on whose practical information I place great reliance, says: “I maintain that musk (when genuine) is one of the most powerful antispasmodics that we are acquainted with. I have found it, with Dr. Wall, to be a powerful remedy in many convulsive and spasmodic affections, and in some of a very peculiar kind. I had once a gentleman affected with a spasm of the pharynx, preventing deglutition, and almost respiration. This, when other remedies had failed, was relieved by the use of musk, which often showed its power; for the disease continued to recur at times for some years after, and was only obviated or relieved by the use of musk.”

2. In *low fevers* which are accompanied with delirium, twitchings of the muscles, a small contracted pulse, and convulsions, musk has been occasionally employed, and with benefit. Like opium, its use in these cases is always uncertain; in one instance relieving, in another increasing the malady, though the cases may be to all appearances parallel.

3. In *retrocedent gout*, as where gout attacks the stomach or the head, giving rise to headache or delirium, musk has been found beneficial. Cullen relates a case where immediate relief was obtained by the exhibition of fifteen grains of genuine musk.

4. In the *delirium* which sometimes occurs in pneumonia, but which bears no relation to the intensity of the latter, and is accompanied with adynamia, Recamier⁴ has found it beneficial.

5. Lastly, during the severe visitation of *malignant cholera*, musk was one of the remedies tried. I saw it employed several times, but without obvious relief. The experience of others was various; but the result is, that the profession has formed a very low estimate of its power in this disease.

ADMINISTRATION.—Musk should be given in *substance*, either in the form of boluses, or suspended in water by means of saccharine or mucilaginous substances.

¹ *Traité Élém. de Mat. Méd.* 2d edit. li. 143, 1804.

² *Vers. üb. d. Wege auf welch. Subst. ins Blut gelang.* S. 63, 69, 71, 73, 1800.

⁴ Jacquet, *Biblioth. Méd.* lix.

³ *Mat. Méd.*

Its dose is from eight to fifteen grains. In children, it may be sometimes used in the form of enema.

ESSENCE OF MUSK, used as a perfume, is ordinarily prepared from the musk pods from which the grain musk has been extracted. The following formula has been furnished me, as one in common use: Grain Musk ℥xiv (or Musk Pods ℥vij); Boiling Water Oss. Digest until cold; then add, of Rectified Spirit Ovjss; Carbonate of Potash ℥ss. Digest.

362. CERVUS ELAPHUS, Linn. L. E.—THE STAG.

(Cornu, L.—Horn, E.)

HISTORY.—Both the hart and the hind (the male and female stag) are repeatedly mentioned in the Bible.¹ The stag is also noticed by Hippocrates, Aristotle, Pliny, Galen, and Avicenna.

ZOOLOGY. Gen Char.—*Incisors* $\frac{9}{8}$, *canines* $\frac{9}{8}$ — $\frac{9}{8}$, or $\frac{1}{6}$ — $\frac{1}{6}$, *molars* $\frac{6}{6}$ — $\frac{6}{6}$ =32 or 34. *Canines*, when they exist, compressed and bent back. *Head* long, terminated by a muzzle. *Eyes* large, pupils elongated transversely. *A lachrymal sinus* in most. *Ears* large and pointed. *Tongue* soft. *Body* slender. Four inguinal *mammæ*. *Horns* solid, deciduous, palmated, branched, or simple, in the males; females, with one exception, without horns.

Sp. Char.—*Horns* with three anterior antlers, all curved upwards, the summit forming a crown of snags from a common centre. *Lachrymal sinuses*. *Fur* red-brown in summér, brown-gray in winter. *A pale disk* on the buttocks.

The stag usually begins to shed his antlers in February or March, immediately after which their reproduction begins, and by July he has completely renewed them.² The first sensible phenomenon of the formation of these parts is the vascular excitement about the frontal bone. The arteries are observed to be enlarged,

Fig. 436.

Skull and Antlers of *Cervus Elaphus*.

a. Crown of the antlers with the velvety covering.

and to pulsate more strongly than usual; the heat is increased, and, in fact, all the symptoms of active inflammation come on. Very soon we perceive two cartilaginous tubercles, one on each side; these enlarge and elevate the skin, by which

¹ Deut. xiv. 5; and Psalms, xviii. 33.

² The temporary existence of the antlers shows that they are for a temporary use. The period of their existence, and the stoppage of their growth by castration, points to the sexual functions for their use. No sooner are they fully formed than the males engage in the most deadly fights for the females. In the College of Surgeons are two fine heads with the antlers interlocked—the animals died starved.

they acquire, from the distension of the latter, a velvety covering. These tubercles are soon converted into real bone; but the deposit of ossific matter does not stop here; it continues around the base of the antlers, thus giving rise to what has been usually termed the *burr*. These osseous prominences, the antlers, are supplied with two sets of vessels—an external or cutaneous, which is the most efficient, and an internal. By the pressure made on the former by the burr, they are obliterated; the covering of the antlers no longer receiving a supply of blood, soon ceases to live, dries up, and falls off. The internal vessels continue to keep up the life of the bone for a few months longer, when death takes place. This occurrence may be in part owing to the imperfect nutrition, and partly, perhaps, to the exposure of the bone to the air without any envelop; but it arises principally from some unknown changes in the vital actions. The antlers being now dead, nature soon sets about their separation. To effect this, the living parts at the base are rapidly absorbed, so that the antlers being left but slightly adherent to the frontal bone, readily fall off by a gentle knock. A few hours only elapse before the irregularity on the surface of the os frontis is covered by a thin pellicle, and shortly afterwards the formation of a fresh pair of antlers is commenced. Castration stops the growth of the antlers.

Hab.—Europe, Asia, and North of Africa.

DESCRIPTION AND COMPOSITION—The antlers of the stag are commonly called *hartshorn* (*cornu cervi vel cornu cervinum*). Though simply designated *cornu* (*horn*) in the London and Edinburgh Pharmacopœia, their composition is very different from that of the horns of the ox or the sheep, and which are sometimes called *true horn*. The latter consists principally of coagulated albumen; whereas, hartshorn has the same composition as bone. According to Merat-Guillot,¹ it consists of *soluble cartilage (gelatine)* 27.0, *phosphate of lime* 57.5, *carbonate of lime* 1.0, *water and loss* 14.5.

Hartshorn shavings or *raspings* (*rasura velamenta cornu cervi*) readily give out their gelatine by boiling in water.

PHYSIOLOGICAL EFFECTS AND USES.—Decoction of hartshorn is nutritive, emollient, and demulcent. It has been used in intestinal and pulmonary irritation. It is generally taken flavoured with sugar, lemon, or orange juice, and a little wine.

Hartshorn shavings are directed to be used in the manufacture of *Antimonial Powder*, but manufacturers generally substitute bone sawings.

Brewers sometimes employ decoction of hartshorn for fining beer and other liquors. It is preferable to isinglass on account of its cheapness. The gelatinous matter of bones being less soluble than that of antlers, bone sawings or shavings do not answer as a substitute for hartshorn.

CORNU USTUM was formerly a preparation of the Ph. L., but is now removed to the *Materia Medica*, and designated "*Calceis phosphas e cornu igne comparata.*"

363. OVIS ARIES, Linn. L. E.—THE SHEEP.

(Sevum [U. S.]; Adeps preparatus, L.—Fat, E.)

HISTORY.—The sheep is one of the anciently known animals. It is mentioned by Moses,² by Herodotus,³ Aristotle, and other ancient writers.

ZOOLOGY.—**Gen. Char.**—*Incisors* $\frac{2}{2}$, *canines* $\frac{2}{2}$, *molars* $\frac{2}{2}$ —32. *Horns* common to both sexes, sometimes wanting in the female, thick, angular, wrinkled transversely, pale-coloured, turned laterally in a spiral form. *Ears* small. *Legs* slender. *Hair* of two kinds. *Tail* more or less short. *Two mammae*.

Sp. Char.—[*O. Musimom.*]—*Horns* very strong, arched backwards and curved downwards, and towards the point. *General colour* fawn, more or less brown, white

¹ Quoted by Berzelius, *Traité de Chim.* vii. 643.

² *Thalía*, cxiii.

³ *Genesis*, iv. 2.

on the face and legs, and under the belly; a darker streak on the dorsal line, on the flanks, and often black about the neck.

Fig. 437.

Ovis Ammon.

Fig. 438.

Ovis Musimon.

The immense number of races of this animal in cultivation are well known; and it is now difficult, perhaps impossible, to determine its native condition. Modern zoologists, however, ascribe our domesticated sheep to *Ovis Ammon*, called the *Argali* of Siberia, or to *Ovis Musimon*, termed the *Mouflon* or *Mufston* of Sardinia.

Hab.—Domesticated everywhere.

DESCRIPTION.—Mutton suet (*sebum*; *adeps præparatus*) is the fat from the neighbourhood of the kidneys of the animals. It is prepared (*sebum præparatum*) by melting it over a slow fire, and straining through linen or flannel in order to separate the membranous portions.

COMPOSITION.—The *ultimate* analysis of mutton suet has been made by Chevreul and by Bérard.¹ The first of these chemists also ascertained its *proximate* composition.

Ultimate Analysis.			Proximate Analysis.	
	Chevreul.	Bérard.		
Carbon	78.996	65.0	Stearine	} principally.
Hydrogen	11.700	21.5	Elaine or Oleine	
Oxygen	9.304	13.5	Margarin, a little.	
Mutton suet	100.000	100.0	Hircin, a little.	
			Mutton Suet.	

PHYSIOLOGICAL EFFECTS AND USES.—Like other fatty bodies, mutton suet is nutritious, but difficult of digestion. Its local effects are emollient and demulcent. In medicine it is used as a basis for ointments, cerates, and some plasters; being preferred, in some cases, to hogslard, on account of its greater consistence.

364. BOS TAURUS, *Linnaeus*.—THE OX.

(Lac.)

HISTORY.—An animal very anciently known and highly valued. It is repeatedly mentioned by Moses.

ZOOLOGY. Gen. Char.—*Incisors* $\frac{9}{8}$, *canines* $\frac{9}{8}$ — $\frac{0}{8}$, *molars* $\frac{6}{8}$ — $\frac{6}{8}$ = 32. *Body* large. *Members* strong. *Head* large; forehead straight; muzzle square. *Eyes* large. *Ears* generally funnel-shaped. A fold of the skin, or *dew-lap*, on the under side of the neck. Four *mammæ*; tail long, tufted; horns simple, conical, round, with different inflections, but often directed laterally, and the points raised.

Sp. Char.—*Horns* round, lateral arched, with the point turned outwards. *Face* flat, or a little concave. *Occipital crest* in the same line as the base of the horns.

¹ Gmelin, *Handb. d. Chem.* ii. 439.

Mammæ disposed in a square form. *Hair* fawn-coloured, brown or black, not sensibly longer at the anterior than the posterior parts. About seven feet long.

MAMMARY GLANDS two, placed close together, and constituting the *udder*. Each gland consists of a number of *lobes*, made up of *yellowish* or *reddish soft granules*, which consist of very fine bloodvessels, nerves, and the commencement of the *milk* or *lactiferous ducts* (*ductus galactophori*) which unite to form 8 or 10 principal ducts, which open into the *large duct*, or *duct of the teat*. This tube is conical, and has a number of folds on its internal surface.

Hab.—Domesticated everywhere.

DESCRIPTION.—Milk (*lac*), or to be more precise in our description, *cows' milk* (*lac vaccinum*), is an opaque, white, emulsive liquid, with a bland sweetish taste, a faint peculiar odour, and a sp. gr. of about 1.030; the latter property is subject to considerable variation. When recently drawn from the animal it is slightly alkaline. Subjected to a microscopical examination, milk is observed to consist of myriads of *globular particles* floating in a serous liquid. These globules are exceedingly minute; according to Raspail¹ the diameter of the largest does not exceed in size the 0.0003937 (about 1-2500th of an inch). They instantly disappear by solution on the addition of a drop of caustic alkali. Both Donné² and Sir A. Cooper³ have separated the globules by repeated filtration; the filtered liquor was transparent. The milk globules consist essentially of *butter*. Donné denies that they contain any caseum, since they are soluble both in alcohol and ether, which do not dissolve caseum. Being specifically lighter than the liquor in which they are suspended, they readily separate by standing. They therefore rise to the surface, carrying with them some caseum, and retaining some of the serum; thus forming what is called *cream*. The milk from which the cream is separated is termed *skimmed milk*.

Cream (*cremor lactis*; *flos lactis*) has a variable sp. gr. The average, perhaps, is 1.0244. The upper stratum of cream is richest in butter, the lowest in caseum. By agitation, as in the process termed *churning*, the fatty globules unite to form *butter* (*butyrum*); the residue, called *buttermilk* (*lac-butyratum*), consists of caseum, serum, and a little butter.

Skimmed milk, like cream, has a variable sp. gr.; perhaps the average may be taken at 1.0348. If left to itself it readily acquires acid properties, while white coagula, commonly termed *curds*, separate from it. If an acid or rennet (an infusion of the fourth stomach of the calf) be added to it, this change is immediately effected. The curd separated by the rennet is called *caseum*. But after rennet has ceased to produce any more coagula, acetic acid will cause a farther quantity to be formed. The curd thus separated by the acid is termed *zieger* or *serai*. The *whey* (*serum lactis*) left after the separation of the caseum and serai, yields on evaporation, sugar of milk, one or more nitrogenous substances, lactic acid, and some salts.

COMPOSITION.—Milk has been the subject of repeated chemical investigation.⁴ The recent analysis of several kinds of milk, published by MM. O. Henry and Chevallier, has been already stated.

The following table shows the composition of several domestic preparations of milk :—

		CONSTITUENTS.			
MILK	Cream	Butter	solid fat	} 1. Stearine. 2. Butyrine. 3. Oleine.	
		Buttermilk	liquid fat		
	Buttermilk	caseum	} 4. Caseum.		
	Matters coagu- lable	serum or whey		} 5. Zeiger or Serai. 6. Sugar of Milk.	
	Skim- milk	Matters coagu- lable	not by rennet		not by rennet, but by acetic acid
			saccharine matter	azotized matter	} 8. Alkaline and earthy lac- tates and phosphates. 9. Alkaline sulphate and phosphates. 10. Earthy and ferruginous phosphates.
		Whey or serum	soluble in alcohol	soluble in water, not in alcohol	
			salt	insoluble in water	

¹ *Chim. Organ.*

² *On the Anatomy of the Breast*, 1840.

³ *London Medical Gazette*, xxv. 302.

⁴ See Berzelius, *Traité de Chim.* vii. 583.

1. **CASEUM** or *Casein*; *Albumen of Milk*; *Lactalbumen*.—An albuminous substance distinguished from the albumen of the egg and of blood by its not coagulating when heated, by its being coagulated on the addition of acetic acid, and by the products of its spontaneous decomposition. When dried it is yellowish and transparent, like gum; it is odourless, and has a very slight taste. It is soluble in water. If its solution be boiled in contact with the air it becomes covered with a white pellicle insoluble in water. The acids unite to form with it, when they are in excess, insoluble compounds. Various salts (as sulphate of copper, bichloride of mercury, nitrate of silver, bichloride of tin, &c.) form insoluble compounds with it. Its composition has been already stated.

2. **BUTTER**.—This well-known substance consists of three fatty bodies, *stearine, elaine* or *oleine*, and *butyrine*. The latter substance is characterized by yielding, by saponification, three volatile, odorous, fatty acids, viz. *butyric, capric, and caproic acids*. A small quantity of these acids exists in ordinary butter, especially when it has been exposed to the air, and gives butter its peculiar odour.¹

3. **SUGAR OF MILK**; *Lactin*; *Saccholoactin*.—Obtained from whey by evaporation. As used in commerce it occurs in cylindrical masses, in the axis of which is the cord which serves as the nucleus for the crystals. It is extensively made in Switzerland. Mr. Hess² has shown that, under certain conditions, sugar of milk is susceptible of fermentation, as was before inferred from the fact that the Tartars prepare a vinous liquid, called *Koumiss*,³ from mares' milk. It is gritty under the teeth, and is very slightly soluble in alcohol. It is much less sweet, and less soluble in water, than common sugar. By the action of nitric acid it yields, like gum, saccholactic or mucic acid; so that it forms, as it were, a connecting link between sugar and gum. The composition of it, according to Prout, has been already stated. The formula of crystallized sugar of milk is $C^{24}H^{19}O^{19}$ —5 aq. [Owing to its presence, the oxide of copper is reduced by Trommer's test on boiling milk with sulphate of copper and potash.—Ed.]

4. **LACTIC ACID**—This, though stated by Berzelius to be a constituent of milk, is probably a product of its decomposition.

5. **SALTS**—Some of these are soluble in alcohol, as the lactates of potash (principally), soda, ammonia, lime, and magnesia; others are soluble in water, but not in alcohol, as sulphate of potash and the phosphate of potash and soda; lastly, the salts insoluble in water are the phosphates of lime, magnesia, and iron. The latter are held in solution in milk by the caseum principally. Berzelius says by the lactic acid also.

CHARACTERISTICS OF GOOD MILK.—The changes produced in the quality of the milk by diseased conditions of the cow has attracted considerable attention in Paris, owing to the prevalence of a malady called the *cocote*, among the cows in that capital.⁴ The following are the essential morbid changes which have been recognized in milk: want of homogeneousness, imperfect mobility or liquidity, capability of becoming thick or viscid on the addition of ammonia, and presenting, when examined by the microscope, certain globules (agglutinated, tuberculated, or mulberry-like, mucous or pus-globules) not found in healthy milk.⁵ Hence, then, good milk should be quite liquid and homogeneous; not viscid; and should contain an abundance of spherical transparent globules, visible under the microscope, soluble in alkalis and ether; should not become thick when mixed with ammonia; and should form a flocculent precipitate with acetic acid, but not be coagulated by heat alone. The relative quantity of cream afforded by milk is estimated by a graduated glass tube called a *lactometer*. [The test for the purity and goodness of milk is the microscope. By this instrument the number, size, and form of the oil-globules may be determined.—Ed.]

I have repeatedly submitted the milk supplied to me by a respectable dealer in this metropolis, to examination by the lactometer, but the results have been most unsatisfactory, as the quantity of cream which I procured varied from 5 to 23 per cent by measure. I have usually found the afternoon's milk to yield less cream than the milk supplied me in the morning. On one occasion, I found 11.5 per cent. of cream in the morning milk, but only 5 per cent. in the afternoon milk. The milk of an Alderney cow yielded 17.5 per cent. of cream.

PHYSIOLOGICAL EFFECTS.—The dietetical properties of milk have been already noticed. As a medicinal agent it is regarded as a demulcent and emollient.

⁴ See *Journ. de Pharm.* xxv. 301—318.

⁵ *Recherches microscopiques sur divers laits obtenus de vaches plus ou moins affectées de la maladie qui a régné pendant l'hiver de 1825 à 1830, et désignée vulgairement sous la dénomination de Cocote*, par M. Turpin, in the *Mémoires de l'Académie Royale des Sciences de l'Institut*, t. xvii. Paris, 1840.

USES.—The *dietetical* uses of milk have been already noticed.

As a *demulcent*, milk is an exceedingly valuable substance in irritation of the pulmonary and digestive organs. It is an excellent sheathing agent in poisoning by caustic and acrid substances, and in some of these cases it acts as a chemical antidote; for example, in poisoning by bichloride of mercury, sulphate of copper, bichloride of tin, the mineral acids, &c. Milk is farther employed on account of its demulcent qualities in the preparation of the bread and milk poultice, which requires to be frequently renewed on account of the facility with which it undergoes decomposition, and acquires acrid qualities.

Milk is a constituent of the *Mistura Scammonii*, E.

Whey is an excellent diluent and nutritive, *Wine whey* (*serum lactis vinosum*) taken warm, and combined with a sudorific regimen, acts powerfully on the skin, and is a valuable remedy in slight colds and febrile disorders. I have already referred to the uses of *cream of tartar whey*, *alum whey*, and *tamarind whey*.

1. **LACTIC ACID.** $C^6H^5O^5 + Aq.$ Symbol= \bar{L} . This acid has been introduced into medicine by Magendie.¹ As it is one of the constituents of the gastric juice, he proposed its use in dyspepsia, and as it is a ready solvent of phosphate of lime, he suggested its employment in phosphatic deposits in the urine. An Italian physician² has more recently recommended it in gout, in consequence of its being a special solvent of the freshly precipitated phosphate of lime. It has been exhibited in the form of lozenges, or in solution in water flavoured with sugar.

2. **OX BILE** (*Fel Bovinum seu Tauri*). Formerly extract of ox bile (*fel tauri inspissatum*) was employed in medicine as a tonic, and it has been recently reintroduced by a few practitioners in dyspeptic cases and biliary derangement. The dose of it is a few grains in the form of pills.

ORDER III. PACHYDERMATA, Cuvier.—THE PACHYDERMS.

ESSENTIAL CHARACTERS.—Three kinds of *teeth*. Four *extremities*, with the toes variable in number, and furnished with strong *nails* or *hoofs*. No *clavicles*. *Organs of digestion* not disposed for ruminating.

365. SUS SCROFA, Linn. L. E. D.—THE HOG.

(Adeps præparatus, L.—Fat, E.—Adeps sullus, D.—Adeps, U. S.)

HISTORY.—The hog is an animal very anciently known. By the Levitical law the Jews were forbidden to eat its flesh;³ on account of either the filthy habits of the animal, or its supposed tendency to engender skin and other diseases, more especially leprosy. The Mahometans are also interdicted from eating it.

ZOOLOGY. **Gen. Char.**—*Incisors*, $\frac{4}{4}$ or $\frac{8}{8}$; *canines*, $\frac{1}{1}$ — $\frac{1}{1}$; *molars*, $\frac{7}{7}$ — $\frac{7}{7}$; = 42 or 44. *Canines* bent upwards and laterally; *molars* tuberculous; lower *incisors* bent forwards. Four *toes* on all the feet, the two middle ones only touching the ground, armed with strong *hoofs*. *Nose* elongated, cartilaginous. *Body* covered with bristles. Twelve *teats*.

Sp. Char.—*Tusks* strong, triangular, directed laterally. No *protuberance* under the eyes. *Colour* blackish-gray in the wild animal, but varying much in the domesticated races.

The varieties of this animal are almost innumerable. They are most conveniently reduced to the following:—

Fig. 439.

Skeleton of *Sus Scrofa*.

a. Foot with five hoofs.
b. Undivided hoof.

¹ *Formulaire pour la préparation et l'emploi de plusieurs nouveaux médicaments*, Paris, 1835

² *British and Foreign Medical Review*, ix. 330.

³ *Levit.* xi. 7.

a. *S. Scrofa ferus*. The wild hog, or wild boar.

β. *S. Scrofa domesticus*. The domesticated hog, which varies in its form and colour.

γ. *S. Scrofa pedibus monungulis*. The hog with solid and undivided hoofs. This variety was noticed by Aristotle and Pliny.

Hab.—The temperate parts of Europe and Asia; the northern parts of Africa; America; the Islands of the South Sea, &c.

PREPARATION.—The fat of the animal is employed in medicine. That about the loins being firmer and denser than the fat of the other parts of the animal, is selected for medicinal use. In order to separate it from the membranes in which it is contained, it is melted over a slow fire, then strained through flannel or linep, and poured while liquid into a bladder, where it solidifies by cooling (*adeps præparatus*). Occasionally salt is added to preserve it; but unsalted lard should be employed for medical purposes. By melting in boiling water, lard may be deprived of any salt which may have been mixed with it. While solidifying, lard should be kept stirred, to prevent the separation of stearine and elaine.

PROPERTIES.—*Hogslard* (*adeps suillus vel porci*) or *axunge* (*axungia*, so called from the use anciently made of it, namely, greasing the axle of a wheel—*unjuendi axem*) is at ordinary temperatures a white or yellowish-white solid. Its melting-point varies from 78.5 F. to 87.5° F. In the liquid state it should be perfectly clear and transparent; but if it be intermixed with water it has a whitish or milky appearance. It should have little or no taste or odour. By exposure to the air, however, it acquires an unpleasant odour and acid properties. In this state it is said to be *rancid*. This condition is induced by the oxygen of the air, part of which is absorbed, while a small portion of carbonic acid is evolved. As stearine does not become rancid in the air, while elaine does, the rancidity of lard is referred to the latter constituent. But it has been found that the purer the elaine the less readily does this change occur; whence it is assumed that some foreign substance in the elaine is the primary cause of rancidity, either by undergoing decomposition or by acting on the elaine.

COMPOSITION.—The *ultimate* composition of lard was ascertained by Chevreul,¹ as well as by Saussure and Berard. The first of these chemists also made a *proximate* analysis of rancid lard; and Braconnot determined the composition of fresh lard.

<i>Ultimate Analysis.</i> — Chevreul.	<i>Proximate Analysis of</i> <i>Fresh Lard</i> —Braconnot.	<i>Proximate Analysis of Rancid Lard</i> —Chevreul.
Carbon 79.098	Stearine } 38	Stearine and elaine.
Hydrogen 11.146	Margarine } 38	Volatile non-acid matter having a rancid odour.
Oxygen 9.756	Elaine or Oleine . . 62	Caproic (?) acid.
Lard 100.000	100	Another volatile acid.
		Oleic, margarie, and perhaps stearic acids.
		Yellow colouring matter.
		Non-acid, non-volatile matter, soluble in water.
		Rancid Lard.

PHYSIOLOGICAL EFFECTS.—Lard, like other animal fats, is nutritious, but very difficult of digestion. Its topical effects are demulcent and emollient. Both the flesh and fat of the hog have been long supposed to dispose to cutaneous disease; but it is no easy matter either to prove or disprove this opinion.

USES.—In medicine, lard is principally employed as a basis for unguents. It has been used, by friction, as an emollient; but the practice is now obsolete. In pauper establishments it is sometimes employed, as a substitute for spermaceti ointment, to dress blisters; but the salt which lard sometimes contains, as well as the facility with which this fat becomes rancid, are objections to its use. I have seen it occasion considerable irritation.

¹ Gmelin, *Handb. d. Chem.* ii.

ORDER IV. RODENTIA, *Cuvier*.—THE RODENTS.GLIRES, *Linnaeus*.

ESSENTIAL CHARACTERS.—Two large incisors in each jaw, separated from the molars by a vacant space. No canine teeth. Molars with flat crowns or blunt tubercles. Extremities, the posterior longest, terminated by unguiculated toes, the number varying according to the species. Mamma variable in number. Stomach empty. Intestines very long.

366. CASTOR FIBER, *Linn. L. E. D.*—THE BEAVER.

(Castoreum; Folliculi præputii proprio humore repleti, *L.*—A peculiar secretion from the preputial follicles, *E. D.*)

HISTORY.—Castoreum was employed in medicine by Hippocrates, who considered it to have the power of acting on the uterus. It was an ancient opinion that the castor sacs were testicles, and that when closely pursued by the hunter, the animal tore them off, leaving them behind as a ransom.¹ This absurd notion [which is carried out in old plates on beaver hunting] seems to have been long ago disbelieved; for Pliny² tells us that Sextius derided it, and said it was impossible the animal could bite them off, since they were fastened to the spine. Thus was one error confuted by another; the truth being, the testicles are so placed in the inguinal region, on the external part of the *os pubis*, that they are not discernible until the skin is removed. Moreover, female beavers also have castor sacs.

ZOOLOGY. **Gen. Char.**—Incisors $\frac{3}{3}$, canines $\frac{0}{0}$, molars $\frac{4}{4}$ — $\frac{4}{4}$ = 20. Molars composed of flat crowns, with sinuous and complicated ridges of enamel. Five toes on each foot, the anterior short and close, the posterior longer and palmated. Tail broad, thick, flattened horizontally, of an oval form, naked, and covered with scales. (Stark.)

Sp. Char.—Fur consisting of two sorts of hair, one coarse and brownish, the other downy, more or less gray. About two feet long.

The ordinary colour of the animal is brown; but yellow, black, spotted, and white beavers, are met with. The two latter are very rare. Richardson³ has never seen either of them, though he has met with black beavers, which were kept as curiosities. The tail is remarkable for its scaly appearance. Its great breadth (oftentimes 5 inches) depends, not on the width of the caudal vertebræ, but on numerous strong tendons inserted into these vertebræ. Incisor teeth smooth, orange-coloured anteriorly, white posteriorly.

¹ Juvencul, Sat. xii. v. 34.² Fauna Boreali-Americana.³ Hist. Nat. lib. xxxii. cap. xliii. ed. Valp.

There is some reason for supposing that the European and American beavers are distinct species. The former are *burrowers*, the latter are for the most part *builders*.¹

ANATOMY OF THE CASTOR SACS.—It has been before stated that both male and female beavers are furnished with castor sacs; hence it will be convenient to consider them in the two sexes separately.

1. *Of the Male Castor Sacs*—If the animal be placed on his back, we observe, near the tail, a hollow (called by some a *cloaca*) inclosed by a large wrinkled, somewhat hairy, cutaneous protuberance, which, according to Perrault,² is easily contracted and dilated, not only by a sphincter, as the anus, but simply like a slit. In this hollow the anus, the prepuce, and the oil sacs open.

When the skin of the abdomen is removed, four eminences, covered by their appropriate muscles, are brought into view. They are placed between the pubic arch and the so called cloaca. The two nearest the pubes are the *castor sacs*, while those next the cloaca are the *oil sacs*. Between the two castor sacs, in the male, lies the *penis* with its bone (*os penis*); it is lodged in a long *preputial canal*, which terminates in the cloaca, and has some analogy to a vagina; so that there is some difficulty to determine, until the skin be removed, whether the individual be male or female.

The penis points towards the tail, not towards the navel, as in the dog. Its surface is covered with longitudinal wrinkles and pits; in each of the latter is found a dark-coloured warty-like body. The *testicles*, *vasa deferentia* and *vesiculæ seminales*, present nothing remarkable. There is no *scrotum*. Like most other Rodentia, the beaver has *vesiculæ accessoriae*, or blind ducts, which open into the urethra near its commencement. Just at that point where the urethra joins the penis are observed *Cowper's glands*. The *castor sacs* open by a common aperture into the preputial canal. This aperture is about one inch in width, and is placed opposite the extremity of the *glans penis* in the relaxed condition of the organ, and about one inch from the orifice of the prepuce. Between this common orifice of the castor sacs and the glans penis is a semilunar fold. There is also a second, similar, but thicker fold covering the rectum. The *castor sacs* are pyriform and compressed. They communicate with each other at their cervical portion; but their funnels diverge outwards and towards the pubes. Each castor sac is composed of an *external* or *cellular* coat which incloses *muscular fibres*. The latter are a continuation of the panniculus carnosus; their function appears to be to compress the sac. Within these fibres lies a very *vascular coat*, which covers the scaly or glandular coat, and sends processes in between the convolutions of the latter. The *scaly or glandular coat* forms numerous folds or convolutions, which are largest and most numerous in the fundus of the sac. Externally, it is shining, silvery, and iridescent. Internally, it presents numerous, small, lanceolate, oblong or semilunar scales, which are mostly toothed at their margin, and envelop each a *brown body*, supposed to be a gland, and which is lodged in a small cavity. The inner surface of the castor sacs is lined with *epithelium* (a continuation of the epithelium of the prepuce), which invests the glands and scales of the scaly or glandular coat. In the cavity of the castor sac is found the *castoreum*, which, when recent, is thin, fluid, highly odorous, yellow or orange-coloured, becoming deeper by exposure to the air. The quantity of this secretion is liable to great variation. The *oil sacs* are conglomerate glands, placed one on each side between the castor sac and anus; their ducts terminate in the cloaca. The secretion of these sacs is a fatty matter, having the consistence of syrup or honey, a peculiar odour, and a yellowish colour. It was formerly used in medicine under the name of *pinguedo seu axungia castoris*.³

2. *Of the Female Castor Sac.*—We are less perfectly acquainted with the anatomy of the female than of the male beaver. Indeed, I am acquainted with three dissections only of the former, viz. one by Gottwaldt, a second by Aegse,⁴ and a third by Mortimer.⁵ The subjoined description is from the memoir of the last-mentioned authority. He says the animal had two *ovaria*, and an *uterus* dividing into two horns (*uterus bicornis*) as in the bitch. The *bladder* lay exactly over the body of the uterus. The *meatus urinarius* ran upon the *vagina* above two inches in length. Just below the *os pubis*, on each side of the *vagina*, above the *meatus urinarius* (supposing the animal laid on her back), a pair of *pyriform bags* were found, about 1½ inch long, and 1 inch broad, diverging at their funnels or broad ends, but approximating most closely at their necks or narrow extremities, which were canals communicating with the adjoining glands. The membranes which formed these bags were tough, wrinkled, and furrowed, of a livid dirty colour. They were hollow, and capable of containing about an ounce of water. Upon opening them, a small quantity of dark brown liquor, like tar, was found, having an odour like castoreum, and in addition a smell of ammonia. It is probable that the emptiness of the sacs, and the unusual quality of their contents, arose from the youth of the animal. About an inch lower, on each side of the *vagina*, were a pair of *glands* (*oil sacs*), each about 1½ inch

¹ See some remarks on the distinctions between the burrowing and building beavers, in *Jameson's Journal*, xxviii. 68.

² *Mem. for a Natural History of Animals*, p. 65, Lond. 1701.

³ For further details respecting the structure of the castor sacs, consult Brandt and Ratzeburg, *Med. Zool.* i.

⁴ Both referred to by Ratzeburg, *op. supra cit.*

⁵ *Philosophical Transactions*, xxxviii. 1735.

long, and $\frac{1}{2}$ inch broad. Their form was oblong but irregular, and having several protuberances externally; their colour was pale flesh, like the pancreas. They seemed to communicate with the castor sacs, the sac and gland on each side opening externally by one common orifice, around which were long black hairs.

Hab.—North America, from 67° or 68° to about 33° north latitude; Europe, from 67° to 36° north latitude, but becoming very scarce. It appears to have been indigenous.

CAPTURE OF THE BEAVER.—The beavers are caught in various ways; sometimes in traps; sometimes in nets; but the usual method is to break up the beaver houses when the animals retreat to their bank holes, where they are easily taken.

COMMERCE.—Castoreum is imported from North America by the Hudson's Bay Company. The greater part of that brought over is sold for exportation. In 1839, duty (6*d.* per lb.) was paid on 801 lbs.

DESCRIPTION.—Two kinds of castor (*castoreum*) have long been known, viz. Russian and American. The latter, however, is the only one now met with in English commerce.

1. **American Castor** (*Castoreum Americanum*).—It usually consists of two isolated sacs, frequently wrinkled, and which are connected so as to form two parts, like a purse, or like two testicles connected by the spermatic cords. The size of the sacs is liable to considerable variation; they are elongated and pyriform. The penis or the oil sacs, or both, are sometimes attached to them. The colour and other external characters are variable. In December, 1834, I examined between three and four thousand pounds of castoreum, which was offered for sale by the Hudson's Bay Company. A considerable quantity of it was covered externally with a bluish white mouldiness, while the remainder was of a brownish colour. The brown colour, however, varies considerably; sometimes being dark, in some cases yellowish, or even reddish. Some castor sacs are found nearly empty, and present, in their dried state, a very fibrous character; these are of inferior quality. Others are found gorged with unctuous matter, and, when quite dry, break with a resinous character, presenting no fibres until they have been macerated in spirit of wine. In many well-filled sacs the castoreum is quite soft.

In English commerce, two varieties of American castoreum are made; one called the *Hudson's Bay*, the other the *Canadian*. Both are imported by the Hudson's Bay Company. The *Hudson's Bay castoreum* is usually considered the finest variety. The specimens of it which I have examined at the house of the Company, in December, 1834, came from Fort York and Moose River. The finest samples were superior to any of the Canadian kind, though the average quality was much the same.

2. **Russian Castor** (*Castoreum rossicum*).—This is exceedingly scarce. When met with it fetches a very high price. I have paid for a museum sample £2 per oz., while American castor fetched only twenty shillings per lb. There are at least three kinds of castor sold as Russian. *Chalky Russian castor* occurs in smaller and more rounded sacs than the American kind.¹ The specimens of it which I had seen had neither penis nor oil sacs attached. The colour is ash-brown. Its odour is peculiar, empyreumatic, and readily distinguishable from that of the American kind. Under the teeth it breaks down like starch, has at first little taste, then becomes bitter and aromatic. It is readily distinguished from all other kinds by dropping it into diluted hydrochloric acid, when it effervesces like a lump of marble. I have seen another kind of castor from Russia, which may be termed *Resinous Russian castor*. The sacs were large, well filled with resin, did not effervesce with hydrochloric acid, and had an odour very similar to that of American castor. The *Russian castor described by Guibourg*² appears to have been subjected to some preparation.³ [Among the frauds connected with the sale of castor, the author mentions that he examined a pair of "fictitious castor sacs," but found them to be real sacs

¹ See *London Medical Gazette*, xvii. 206, fig. 41.

² See *London Medical Gazette*, xvii. 297, fig. 42.

³ *Journ. de Chém. Méd.* viii. 602.

emptied of their natural contents and stuffed with hay. The coats were thin and membranous.—Ed.]

COMPOSITION.—Castoreum has been subjected to chemical analysis by several chemists. Those whose results deserve especial reference are Bonn¹ and Brandes.²

<i>Brandes's Analyses.</i>			
Volatile oil	1.00	Volatile oil	2.0
Resin	13.85	Resin	58.6
Castorin	0.33	Cholesterine	1.2
Albumen	0.05	Castorin	2.5
Osmazome	0.20	Albumen	1.6
Carbonate of lime	33.62	Gelatine	10.4
Other salts	2.52	Osmazome	2.4
Mucus	2.30	Matter soluble in alcohol	1.6
Animal matter like horn	2.30	Carbonate of lime	2.6
Membrane	20.00	Other salts	2.4
Moisture and loss	22.83	Membrane	2.0
		Moisture and loss	11.7
Canadian Castor	99.30		
		Russian Castor	99.0

These analyses do not agree with my experiments and observations. The quantity of carbonate of lime assigned to Canadian castor is much too large. By incinerating 60 grains of American castor in a platinum crucible I found only 1.2 gr. of ashes, which, if the whole were lime, would be equal to little more than 3.57 per cent. of chalk.

1. **VOLATILE OIL OF CASTOREUM.**—This is obtained by distilling the same water several times with fresh portions of castor. It is pale yellow, and has the odour of castor, with an acrid bitter taste. Bonn says he obtained 34 per cent. of oil; but there must be some error in this statement.

2. **CASTORINE; Castoreum Camphor,** Gmelin.—A crystalline, fatty, non-saponifiable substance. It is fusible, and in the liquid state floats on water. When pure, it is quite white. It is soluble in ether and boiling alcohol. By long ebullition with nitric acid, it is converted into a yellow crystallizable acid, called *castoric acid*. The super-castorate of ammonia is crystallizable, and forms white precipitates with the salts of silver, lead, and protoxide of iron, and a green precipitate with the salts of copper. Castorine is obtained by boiling castor in alcohol; the castorine is deposited when the liquor cools. Scarcely any can be got from American castor.

3. **RESIN.**—This is dark brown, has an acrid and bitter taste, and a slight odour of castor. It is insoluble in pure ether, but dissolves readily in alcohol. Water precipitates it from its alcoholic solution.

[In reference to the chemical constitution of Castor, Dr. Pereira made the singular discovery that the aqua castorei contained the hydruret of salicyle. His paper on the subject was published in the *Pharmaceutical Journal* for November, 1851.—Ed.]

In the year 1844, Wöhler³ remarked that carbolic acid strongly resembled in odour fresh castoreum, and suggested that the volatile oil of castoreum was probably nothing but carbolic acid; and added, that, like the latter substance, it became black by its reaction with chromic acid. Soon after this observation, I endeavoured to verify it by subjecting *aqua castorei*, freshly prepared from good American castoreum, and in which were floating globules of *oleum castorei*, to the action of a solution of chromic acid; but I failed to produce any blackening effect, even at a boiling temperature. It occurred to me, therefore, that probably carbolic acid was not an invariable constituent of castoreum.

In 1848, Wöhler⁴ announced the existence of both carbolic acid and salicine in Canadian castoreum. By subjecting this to distillation with water, he obtained a clear distillate in which small drops of oil were floating, and which possessed a strong odour of castoreum. With sesquichloride of iron it gave distinctly, though feebly, the characteristic reaction of carbolic acid; it became violet, which colour again disappeared in a short time, with a whitish cloudiness precisely like carbolic acid. It was not coloured yellow by ammonia, as is the case with hydruret of salicyle (salicylous acid). In the liquid which was left in the retort, Wöhler detected, after filtration, a benzoate and salicine. On mixing it with muriatic acid, it became turbid, and, in the course of a day, deposited small crystals of benzoic acid. It was also observed that the mother-liquor separated from these crystals contained hydruret of salicyle, for it gave, with sesquichloride of iron, first a deep violet-blue colour, and only afterwards the white cloudiness produced by benzoic acid. In the muriatic solution, from which the benzoic acid had separated, Wöhler detected salicine by the action of chromate of potash and sulphuric acid, which converted it into hydruret of salicyle.

I had occasion to examine the *aqua castorei*, prepared from American castoreum, and was surprised to find that it had acquired the very agreeable odour of the distilled water of the

¹ Quoted by Gmelin. *Handb. d. Chem.* ii. 1449.

² *Ann. d. Chem. u. Pharm.* B. xlix. S. 360, 1844; also *Pharm. Journ.* iv. 186, 1844.

³ *Ann. d. Chem. u. Pharm.* B. lxxvii. S. 360, 1848; also *Chemical Gazette*, vii. 11, 1849.

⁴ *Ibid.*

flowers of meadow-sweet (*spiræa ulmaria*). It no longer contained any traces of volatile oil. On testing it with sesquichloride of iron, it gave at first a violet colour and afterwards a whitish cloud (*benzoate of iron*). With ammonia it became feebly yellow. It was obvious, therefore, that it contained hydruret of salicylc, which must either have been originally obtained by distillation from the castoreum, or have been produced in the *aqua castorei* by some other principle. That it was not originally obtained from the castoreum I have strong grounds for believing; because the *aqua castorei*, when first prepared, had not that agreeable odour which it now possesses, but had the usual castoreum smell, and contained abundance of globules of volatile oil of castoreum. For several years past, in my lectures, I have noticed and described it, and have remarked that, unlike another specimen of *aqua castorei*, which I prepared in 1833,¹ it appeared to me to be losing its proper castoreum odour, and to be acquiring a more agreeable one. During the last twelve months, however, the change of odour has been more marked and rapid than it had been previously, the hydruret of salicylc having been gradually formed in the *aqua castorei*.

As the *aqua castorei*, in which it was formed, was obtained by distillation, it is obvious that the hydruret of salicylc must have been produced from some volatile substance. Now as the water originally contained globules of *oleum castorei*, which have gradually disappeared, and become replaced by the hydruret of salicylc, this oil would seem to be the real source of the last-mentioned substance. However this may be, it can scarcely be doubted that both the hydruret of salicylc and carbolic acid (which Wöhler declares to be identical with *oleum castorei*) are derived from salicine (the presence of which in castoreum has been before stated). As the beaver feeds on the bark of the willow and poplar, we have a ready explanation of the source of the salicine.

Salicine by oxidation readily yields hydruret of salicylc (as by the action on it of a mixture of chromate of potash and sulphuric acid). When it is swallowed, it suffers oxidation, and is excreted in the form of hydruret of salicylc. Professor Liebig informed me that *Chrysomela Populi*, a coleopterous insect which feeds on the leaves of the willow and poplar, excretes hydruret of salicylc; and if allowed to crawl over paper moistened with a persalt of iron it produces a violet-coloured stain. In the human subject, also, salicine suffers a similar change, and is converted into hydruret of salicylc, which passes out of the system in the urine, in which fluid it may be detected by a persalt of iron, which strikes a violet colour with it. Laveran and Millon assert that salicylic acid is also produced, but this is doubtful; for Wöhler and Frerichs found that hydruret of salicylc did not become changed into salicylic acid in its passage through the system. Hitherto, I believe that carbolic acid has not been detected in the urine after the use of salicine; but its presence is by no means improbable, as it is one of the products of the decomposition of the alkaline salicylates.

But to return to the origin of the hydruret of salicylc in *aqua castorei*. It by no means follows that it should be derived from the carbolic acid, but more probably from some other volatile product of the oxidation of salicine. As carbolic acid is a constituent of castoreum, and as it is a powerful agent on the animal economy, it follows that it must be one of the active principles of castoreum. Wöhler and Frerichs found that rabbits, guinea-pigs, and dogs, to which a few drops of carbolic acid diluted with water were administered, constantly died in convulsions in the course of one quarter of an hour; but no important anatomical lesion was discovered in the bodies after death. As castoreum contains but very minute quantities of carbolic acid, it is obvious that should its medicinal activity be found to depend on the latter, a cheap and more effective substitute for castoreum would be found in carbolic acid obtained from coal tar. And here I may observe that carbolic acid and creosote are closely related, if indeed they be not identical, as Laurent and some other chemists suspect.

As the odour of *Hyræum* (see p. 1178) closely resembles that of castoreum, the presence of carbolic acid may be suspected, but no evidence of its presence can be gained by the action of the sesquichloride of iron on either a watery infusion of *hyræum*, or on the distilled water of this substance.

PHYSIOLOGICAL EFFECTS.—Castor is usually denominated a stimulant and anti-spasmodic. Since the time of Hippocrates it has been regarded as endowed with a specific influence over the uterus.

In 1768, Mr. Alexander² took it in various doses to the extent of two drachms; and the only effect he experienced from it was disagreeable eructations. In 1824, Jörg and his pupils, males and females,³ submitted themselves to its influence; but the only effects were a slight uneasiness in the epigastric region, and disagreeable eructations having the odour of castor, and which were not allayed by breakfast or dinner, and only ceased at night when sleep came on.

¹ This specimen also contains minute traces of the hydruret of salicylc, as shown by the action of the sesquichloride of iron, as well as of ammonia.

² *Experimental Essays*, p. 83.

³ *Material. zu einer kunft. Arzneimittell.* Leipzig, 1824; *London Medical Gazette*, xxvi. 952.

These facts seem to show that castoreum possesses but little medicinal power; yet Dr. Cullen¹ declares that on many occasions it is certainly a very powerful antispasmodic. Its odorous particles become absorbed, for they have been recognized in the urine by their smell.

USES.—Castoreum was formerly in great repute in those affections of the nervous system denominated *spasmodic*; such as hysteria, epilepsy, and catalepsy; more especially when these diseases occurred in females, and were attended with uterine disorder. In those kinds of fever called *nervous*, this medicine has also been recommended. In the northern parts of Europe it is used for its supposed *uterine influence*, to promote the lochial discharge, and the expulsion of retained placenta. It is, however, little employed, partly, perhaps, in consequence of its disagreeable taste and smell, its variable quality, and its high price; but for the most part, I believe, because practitioners consider it an almost inert remedy.

ADMINISTRATION.—It is best given in substance, either reduced to powder or in the form of pill. The dose should be at least ℥ij.

1. **TINCTURA CASTOREI**, L. E. [U. S.]; *Tincture of Castor*.—(Castor, bruised, ℥iiss; Rectified Spirit Oij. Macerate for seven days, then press and strain. "This tincture may be prepared either by digestion or percolation, like the tincture of Cassia," E.)—Rectified Spirit, used by the London and Edinburgh Colleges, is a better solvent for castor than proof spirit. The quantity of castor used in the processes is much too small. A fluidounce of the Edinburgh tincture contains three-fourths of a drachm, while the London preparation contains only half a drachm; so that to give a medium dose of castor (℥j), it would be necessary to administer f℥ij of the tincture (rectified spirit) of the London Pharmacopœia! Dr. Paris² says the dose of this tincture is ℥xx to f℥ij.—[The U. S. Pharm. directs Castor, bruised, ℥ij; Alcohol Oij. Macerate for seven days, express and filter through paper.] The tincture of castor made with American castor has a very different odour, is of a much paler colour, and yields a much smaller amount of precipitate on the addition of water, than the tincture of Russian castor.

2. **TINCTURA CASTOREI AMMONIATA**, E.; *Ammoniated Tincture of Castor*.—(Castor, bruised, ℥iiss; Assafetida, in small fragments, ℥x; Spirit of Ammonia Oij. Digest for seven days in a well-closed vessel; strain, and express strongly the residuum; and filter the liquor. This tincture cannot be so conveniently prepared by the method of percolation, E.)—Stimulant and antispasmodic. Spirit of Ammonia is a good solvent for both castor and assafetida.—Dose, f℥ss to f℥ij.

367. Hyrax Capensis.—The Cape Badger.

(Hyraceum, a proposed substitute for Castoreum.³)

HISTORY.—I have received from my friends, Messrs. August Faber and Co., of London, a small sample of this substance, with a note, stating that Hyraceum was a new article, intended as a substitute for castoreum in medicine. They inform me that they believe all that has been imported into Europe as yet, is a dozen tins, of about one pound and a half each, which were sent from the Cape of Good Hope (the place of production) to Hamburg, and there sold at about eight shillings each. The tins were of a cylindrical shape, and the hyraceum contained in each was in one mass, adhering to the tin without any other protection. As this substance is a very remarkable one, and is scarcely known even by name in this country, I subjoin a short notice of it, and of the animal which yields it.

The name *hyraceum* was first applied to this substance by Dr. Edward Martiny,⁴ in 1847. It is derived from *Hyrax*⁵ (the generic name of the animal yielding this substance), and bears the same relation to this latter word that castoreum does to castor. By the Dutch colonists, this substance has been erroneously called *Dassen-piss*, under the mistaken notion that it was the urine of the *Dasse* (the name by which the animal is known at the Cape).

¹ *Mat. Med.*

² From a paper by the author in the *Pharmaceutical Journal*, September, 1850.

³ *Naturgeschichte der für die Heilkunde wichtigen Thiere*, p. 119.

⁴ The word "hyrax" is derived from ὑραξ, which Nicander (*Alexipharmaca*, 37) uses to signify the shrew-mouse.

⁵ *Pharmacologia*.

ZOOLOGY.—The animals referred by zoologists to the genus *Hyrax*, and called by French zoologists *Damans*, possess remarkable interest to the naturalist, on account of the importance of anatomy to the accurate determination of their position in a natural classification. For a long period they were placed among the *Rodentia*, to which in size and general appearance they bear some resemblance. But Cuvier showed that, by their organization, they really belong to the *Pachydermata*, being, with the exception of the horn, little else than rhinoceroses in miniature; at least, they have quite similar molars, but the upper jaw has two stout incisors, curved downwards, and, during youth, two very small canines, the inferior four incisors, without any canines. The dental formula of the genus, therefore, is as follows: incisors $\frac{2}{2}$, canines 0, molars $\frac{3}{3}$ — $\frac{3}{3}$ =34. The animals have four toes to each of their fore-feet, and three to the hind-feet, all, excepting the innermost posterior, which is armed with a crooked and oblique nail, terminated by a kind of very small, thin, and rounded hoof. The body is covered with thick hair, and beset here and there with erinaceous bristles. They have a simple tubercle in place of a tail, short muzzle and ears, and six teats, two pectoral, and four ventral.

The *Hyrax capensis*, Cuvier, the *Cavia capensis* of Pallas, and some other writers, was considered by Cuvier to be identical with the *Hyrax Syriacus*—the *Coney* of Scripture.¹ It is about the size of a large rabbit; with soft hairs, grayish, or ashy-brown above and paler beneath. Along the back is a dark band or stripe, with a blackish spot in the middle. The head is thicker, and the mandible or lower jaw higher than in other species. Vertebrae from forty-eight to fifty. Ribs twenty-one to twenty-two. Space between the incisor and molar teeth small. Interparietal bone large and three-angled.

Thunberg² alludes to the popular notion at the Cape, that these animals menstruate. "In the crevices of the mountains, a great number of *dasses* (*Cavia capensis*) were found, which were generally supposed to have the menstrual flux." In another passage,³ he says he "was shown a kind of bitumen, which the country people supposed to be the inspissated urine of the great mountain rat (*Cavia capensis*) that is found there. I was informed," he adds, "that this bitumen was to be found in great abundance in the cracks and crevices of the mountain, especially at one large projecting *krants* or summit."

Sparrman⁴ notices the animals which the natives call *dasses* or *badgers*. "These creatures," he observes, "which have some affinity with the ordinary marmots, and are about the same size, are eaten by many people, who look on them as a delicacy. They are likewise easily made tame, and are found in many other places in the African mountains. The little *Dassen islands* on the western coast of Africa take their name from them. On these places in the mountains where these creatures dwell, there is found a substance, called here, *dassen piss*. It resembles petroleum, or rock oil, and by many that have seen it is actually considered as such. It is likewise used by some people for medical purposes, and by them is supposed to have greater powers than is consistent with any degree of probability. Finding that this substance did not stand the same proofs as petroleum, and at the same time that it was found only in places frequented by the *dasses*, I had sufficient reason to conclude that it proceeded from this animal, and that it is most probably the menstrual excretion of this creature, as observations made on tame females of this species have given room for such a suspicion; and as, besides, the *dass's* excrements are often found in this substance, and seldom anywhere else."

Professor Lichtenstein informed Schrader, that "this substance is found in small separate pieces on rugged mountainous declivities, chiefly in those districts where the *Hyrax capensis* is most frequently found. The colonists collect these pieces, which, when fresh, are soft and somewhat glutinous, and press them together in large masses, in which state the volatile constituents are better preserved. They employ it medicinally, either in the form of powder, or infused in wine, in many diseases, especially in hysterical complaints, in which it frequently acts in a surprisingly beneficial manner."

"The Hottentots," says Buffon,⁵ "highly prize a kind of medicine, which the Dutch call *badger's urine* (*pissat de blaireau*). It is a black dry substance, which has a very bad smell, and is found in the crevices of the rocks, and in caverns. They say it is derived from the urine of these animals, who always pass it in the same spot. The urine deposits this substance, which, becoming dry by time, acquires some consistence. This," adds Buffon, "is very probable; for the animal at Amsterdam, almost always passed his water in the same corner of the cage in which he was confined."

In the published accounts of the dissections of this animal, no glandular structure, such as we must suppose would be required for the secretion of hyraceum, is mentioned. Mr. Quekett writes to me that, having examined a portion of the specimen which I gave him, he believes it "to be composed entirely of excrement, and not, like castoreum and musk, the secretion of a gland; for I find," he adds, "that the *hyrax capensis* has no anal or other glands."⁶ But it deserves to be especially noticed that dissections of *male* animals only have been published; while the remark of Sparrman would lead us to suspect that the secretion is peculiar to the female.

¹ *Leviticus*, xi. 5; *Psalms*, ciii. 18.

² *Travels in Europe, Asia, and Africa, between the years 1770 and 1779*, i. 165.

³ *Ibid.* i. 166.

⁴ *Voyage to the Cape of Good Hope*, i. 309, 1768. ⁵ *Histoire Naturelle*, Supplement, t. vi. p. 250, 1782.

⁶ [Mr. Quekett could detect no trace of any glands likely to produce the hyraceum.—ED.]

Farther observations respecting the anatomical structure of the animal are required ere we can arrive at any satisfactory conclusion respecting the origin of hyraceum. My friend, Mr. Thomas Bell, Sec. R. S., who some years since had in his possession a living full-grown male animal (the one which was subsequently dissected by Professor Owen), tells me that his specimen had no peculiar smell, nor did he perceive any peculiar gland on examination after death.

Pallas¹ notices, as unusual and anomalous in the structure of the animal, the mode of insertion of the ureters into the fundus of the bladder. Professor Owen notices, and somewhat corrects this description.² For what purpose this structure is designed in the hyrax, or whether the urine undergoes any change in consequence of it, Mr. Owen could not conjecture, but he alluded to the alleged medicinal qualities of this secretion.

Sparman's opinion receives no support from the physical and chemical examination of the specimen in my possession.

Dr. Krauss, of Stuttgart, who resided for a long time at the Cape, says, that most of the colonists regard it as a secretion which appears with the catamenia.

Dr. Edward Martiny,³ who reports this, adds, "that its occurrence at the rutting season gives great weight to this opinion. I regard hyraceum," he continues, "as a secretion connected with the sexual functions, and produced by highly developed preputial and probably also vaginal glands, as in the beaver; but with this difference, that while in the beaver we know not whether this secretion is at times evacuated, in the hyrax it is very probably actually excreted. For we find it in considerable quantities in those places where the animals are met with; a fact explained by the circumstances that the animals at the Cape usually live in herds. Dr. Krauss writes to me, that it is especially found in the fissures of the variegated sandstone of many mountains in the colony, especially in Kokmansklof and Franche Hoek, and may be collected there in extraordinary quantity. In proof of this, it may be mentioned that, some years ago, Professor Pöppig, of Leipzig, received from the Cape some bird-skins, stuffed with hyraceum, to preserve them. So that it must be met with in considerable quantity, and at a low price, and might, therefore, be obtained as an excellent substitute for the more costly castoreum."

PROPERTIES.—Hyraceum, such as I have received it, is a tolerably hard solid substance, which breaks with considerable difficulty; and has a blackish brown colour, a glistening or resinous appearance in places, which have a somewhat glutinous feel. It has a moderately strong odour, which greatly resembles that of Canadian castoreum. In taste, also, it is like the latter substance. [Its specific gravity is from 1.422 to 1.5.] When heated in the flame of a candle, it evolves a castor-like odour, swells up, burns, and leaves behind a spongy coal, with a whitish ash on the apex. From the yellow colour which it communicates to the outer cone of the flame, it manifestly contains sodium or soda, and from the intense white light which the ash on the apex of the coal evolves, it obviously contains lime (?). Water dissolves a considerable portion of it. Boiled in alcohol, it communicates a feeble colour to this liquid. By boiling in water, it evolved a smell similar to that of castoreum, and yielded a decoction which was of a dark yellowish-brown colour, and very feebly restored the blue colour of reddened litmus paper. When submitted to dry distillation in a test-tube, it evolved, first, an odour of castoreum, then a dense white empyreumatic smoke, which communicated a blue colour to reddened litmus paper, thereby indicating the presence of ammonia. Hyraceum has been submitted to a careful microscopic examination by myself as well as by my friends Dr. Sharpey and Mr. John Quekett. Vegetable tissues (epidermis, cellular tissue, woody fibre, ducts and spiral vessels), animal hairs, and siliceous sand, have been found in it. Mr. John Quekett observes that "spirit and caustic potash appear to have little or no action on it; but they bring out a few epithelium scales, principally of the scaly variety." I could detect no blood disks. Dr. Sharpey also observes that he "saw nothing which could for a moment be taken for blood particles or the remnants of blood particles." He observed globular particles, perhaps, either resinous or oily; and at least two kinds of vegetable epidermis, one apparently from a gramineous plant. The animal hairs were short fragments, very fine, and by no means numerous.

As the hyraceum which I have received contains vegetable remains, and probably, therefore, is contaminated with the excrement of the animal, I was anxious to know what kind of fecal matter is discharged from the bowels. Pallas says that the "scybala in ultimo intestino erant moleculosa, fusco-lutea." Dr. Andrew Smith, author of the *Illustrations of the Zoology of South Africa*, tells me that the feces are in little balls, something like rabbit's dung. He also informs me that, in the places where the animals live at the Cape, the feces occur in heaps, while the hyraceum is found in the crevices of the rock, as if it had run off in a liquid state, from which he inferred that it was a product of urine and excrement.

COMPOSITION.—Schrader⁴ submitted hyraceum to chemical examination, and found its constituents to be as follows:—

¹ *Spicilegium Zoologicum*, t. i. fasc. ii. p. 16, 1767.

² *Op. ante cit.*

³ *Proceedings of the Zoological Society*, 1832.

⁴ *Berlin. Jahrb. für d. Pharmacie*, 1818.

Stearine (Talgsubstanz)	1
Green resin, soluble in absolute alcohol	2
Odorous yellow substance, soluble in ordinary alcohol and in water	38
Brown substance, soluble in water	25
Insoluble residue (vegetable fibre, quartz sand, &c.)	34
	100

From his experiments, Schrader concluded that hyraceum was for the most part of an animal nature, very probably an excretion, and that its medicinal properties resided in its odorous yellow constituent, which dissolved both in spirit and in water. Its colour did not arise from the presence of blood, for he left a decoction of hyraceum exposed to the air for some weeks, without finding that it underwent putrefaction or any change of odour. It still retained the smell of Canadian castoreum, and had scarcely any effect on reddened litmus paper. By distillation with water, a distilled liquor was obtained, which had a feeble, faint, somewhat resinous odour, but no reaction on test paper. The minute quantity of urine, therefore, which it contained, must be regarded, like the sand and the vegetable substances, as an accidental impurity, although it is not impossible that these substances may be due to the admixture of animal excrement.

According to Paffe, it is produced by the uropoietical system. The hyrax drinks very seldom, if ever; and its urine, like that of the hare, is thick and glutinous. The animals secrete the urine at one spot, and by evaporation the tenacious extract sticks to the root. The fresh urine is reddish-coloured. Lehmann regards it as solid excrement. Reiche¹ analyzed hyraceum, and obtained twenty different substances, including castorin, uric acid, urea, as well as benzoic and hippuric acids; but Fikentscher says that he could not detect either of the last four substances; and he gives the following as the results of his analysis:—

Matter soluble in ether	11.5
Matter soluble in spirit of wine	38.0
Matter insoluble in both	19.1
Inorganic salts	31.4
	100.0

TINCTURA HYRACEI (Martii).—R Hyraceum, powdered, ℥ij; Distilled Water ℥xviiij. Digest at from 86° F. to 100° for eight days, frequently shaking. Filter, and to the solution add: Water, sufficient to make by weight, ℥xxj; Rectified Spirit ℥ij. Mix and filter. Dose, ℥xx to ℥j.

With regard to the medicinal qualities of hyraceum I have very little to say. My sample is too small to enable me to make any experiments with it. I believe it to be inert and useless; but it has been supposed to resemble castor in its nature, odour, and medicinal qualities. "The action of hyraceum," says Dr. Martiny, "is exactly the same as that of American castor, for which it may be substituted." But to say that hyraceum is equal to castor in medicinal properties is, I believe, to say little in its favour; for, in my opinion, there is no valid evidence that castor possesses any medicinal power whatever. Considered in an anatomical and physiological point of view, both castor and hyraceum possess some interest, but as therapeutical agents they are worthless. The remedial use of sexual and anal secretions and of excrements (e. g. castor, musk, civet, ambergris, album græcum, and hyraceum) belongs to the superstitious and absurd practices of a former age, and the administration of such disgusting and useless substances should be banished from scientific medicine.

It has been used in the form of powder, or of tincture.

[We subjoin an extract from an inaugural dissertation at Erlangen on this substance, by Fikentscher, found among the author's papers.—Ed.]

"In 1848," he says, "a selected specimen of the hyraceum was sent from the Cape to Professor Martius, who placed a part of it at the disposal of the Royal Hospital at Erlangen. Professor Canstatt, the distinguished theoretical and practical physician, submitted it to a careful trial, administering it to a great number of patients in the hospital, and obtained the best results. Professor J. Vogel reported that at the hospital of the University of Giessen, an application of this medicament had been made, at first, in small doses, without obtaining the results aimed at, but which failure was remedied by the administration of greater doses. As regards my own experience, I have already treated, in a space of two years, thirty three persons [the history of these cases the author has annexed in an appendix], thirteen of whom were hysterical persons, thirteen were subject to gastralgia, and one was an inveterate hypochondriac. Seven of them were treated with the tinct. hyrac. conjointly with other medicines; and twenty-six were treated with the tinct. hyrac. pure; all but eight of the latter were restored. The constricting pains in the region of the stomach, which ordinarily followed every use of food or of liquid—the headache, loathing, and vomiting—were diminished, and the appetite was restored. Other hysterical symptoms, as spasms, the peculiar globus hystericus, the nervous headache, palpitation, trembling of the members, to which thirteen individuals were before more or less subject, disappeared after the use of the tinctura hyracei, except in three persons.

"To these, my own observations, I will add those of two of my friends: 'Dr. Wintrich, docent and assistant physician at the Policlinik at Erlangen, has applied the tinctura hyracei (in doses of from one-half to one teaspoon) in cases of spasm, palpitation, hysteria, gastralgia, as well as in nervous excitements of irritable persons, altogether in thirty cases, and obtained good results. Dr. Meinel, at Roth, reported that he has made use of the tinct. hyrac. in cases of hysteria and of chlorosis, where a peculiar irritability of the nerves existed, and obtained very favourable results.'

"Finally, we conclude that the Tinctura Hyracei deserves to be recommended in most cases of irritability of the nervous system, in hysterical affections, and in gastralgia, *in doses of from one-half to one teaspoonful*. Every medical man knows well the difficulties which are presented in the treatment of hysterical persons: sometimes one is compelled to make use of the whole series of the so-called anti-spasmodica, nervina, and anti-hysterica, in order to calm the patient; consequently, it must be satisfactory to be able to make use of a medicine which has been found to be efficacious in most, if not in all cases of this description."

[Since this was written, experience has not confirmed the very favourable description of the new drug here given. We are inclined to put the same value on it as that assigned by the author to album græcum, and other excrementitious articles. They are the relics of the superstitious practices of a bygone age.—Ed.]

APPENDIX.

THE METALLIC CYANIDES.¹

368. AURI TERCIANIDUM.—TERCIANIDE OF GOLD.

Formula AuCy³. Equivalent Weight 277.

THE directions for preparing this salt, in the French Codex, are somewhat diffuse. The process consists essentially in very carefully adding a solution of pure cyanide of potassium to a solution of chloride of gold, until a precipitate (*cyanide of gold*) ceases to be formed. The chloride of gold, prior to solution, should be deprived of all excess of acid by heating it in a salt-water bath.

Cyanide of gold is a yellow powder, which is insoluble in water. It has been used in venereal and serofulous affections, both externally and internally. The dose is from one-fifteenth to one-tenth of a grain, made into a pill with some inert powder.

369. HYDRARGYRI PERCIANIDUM.—PERCIANIDE OF MERCURY.

Formula HgCy. Equivalent Weight 126.

HISTORY.—This salt was discovered by Scheele. Its real nature was first pointed out by Gay-Lussac in 1815. It has been known by various appellations, as *Prussian Mercury (Hydrargyrum Borussicum)*, *Prussiate*, *Hydrocyanate*, *Cyanuret*, *Cyanide* or *Bicyanide of Mercury (Hydrargyri Prussias, Hydrocyanas, Cyanuratum, Cyanidum seu Cyanodidum)*.

PREPARATION.—There are two methods of preparing this salt; one recommended by Proust, the other by Winckler. Proust's process was formerly adopted in two of the British Pharmacopœias.

The *London College* formerly ordered, of Percyanide of Iron [*Prussian Blue*] \mathfrak{z} viij; Binoxide of Mercury \mathfrak{z} x; Distilled Water Oiv. Boil them together for half an hour, and strain. Evaporate the liquor that crystals may be formed. Wash what remains frequently with boiling distilled water, and again evaporate the mixed liquor that crystals may be formed. The *Dublin College* employed of *Prussian Blue six parts*; *Nitric Oxide of Mercury five parts*; *Distilled Water forty parts*.

In this process the cyanogen of the Prussian blue combines with the mercury of the nitric oxide, while the iron unites with the oxygen of the oxide. Pure percyanide of mercury may be more economically prepared by Winckler's process. This consists in saturating hydrocyanic acid with red oxide of mercury. The solu-

¹ [It was announced by the author, in the preface to Vol. I of this edition, published in 1849, that the description of the various metallic cyanides should follow that of hydrocyanic acid. Since the announcement was made, the cyanides have been struck out of the London and Dublin Pharmacopœias. Nevertheless, we have thought it advisable to retain the author's account of these preparations, and we have therefore placed them in the Appendix.—Ed.]

tion is to be filtered and allowed to crystallize. In this process double decomposition takes place, the resulting products being water and percyanide of mercury.

PROPERTIES.—The crystals of this salt are square prisms. They are heavy, white, colourless, transparent or opaque, inodorous, and have a strong metallic taste. They are soluble in water, both hot and cold, and very little, if at all so, in alcohol.

Fig. 442.

Fig. 443.

General Form of Crystals of Bicyanide of Mercury.

Crystals with Modified Planes.

CHARACTERISTICS.—Perfectly dry percyanide of mercury when heated yields metallic mercury and cyanogen gas. The latter is known by the violet or bluish-red colour of its flame. Heated with hydrochloric acid it evolves hydrocyanic acid. It is not decomposed by nitric acid or the alkalis. Its solution throws down a black precipitate with hydrosulphuric acid, and white pearly crystalline plates (*hydrargyro-iodo-cyanide of potassium*) with a concentrated solution of iodide of potassium.

[COMPOSITION.—Its composition is variously stated, according to the number assumed for the equivalent of mercury. The greater number of British chemists now consider it to be constituted of a single equivalent of each element, and therefore represented by the formula HgCy . The term Percyanide is given to it, in order to keep the nomenclature in conformity with that adopted by the author in the mercurial preparations of the first volume. There is no other cyanide of mercury known.—ED.]

PURITY.—When prepared from ferrosesquicyanide of iron (Prussian blue), the crystals are usually yellowish, from the presence of some oxide of iron. The following tests of its purity were published in the previous edition of the London Pharmacopœia:—

Transparent and totally soluble in water. The solution, when hydrochloric acid is added, emits hydrocyanic acid, which is known by its peculiar smell; and a glass moistened with a solution of nitrate of silver and placed over it, gives a deposit, which is dissolved by boiling nitric acid. By heat it emits cyanogen, and runs into globules of mercury.

PHYSIOLOGICAL EFFECTS. *a. On Vegetables.*—It acts on plants like perchloride of mercury.¹

β. On Animals.—Coulon² found that it acted on dogs, cats, sparrows, frogs, snails, &c. like hydrocyanic acid. After death, inflammation of the stomach was observed. Ollivier d'Angers³ tried its effects on dogs. Seven grains, dissolved in water, killed a small dog in ten minutes, under attempts to vomit, general convulsions, and exhaustion, manifested alternately; respiration and circulation were at first accelerated, and afterwards diminished. Similar effects were produced by applying the salt to the cellular tissue, or injecting it into the veins. Tiedemann and Gmelin⁴ detected mercury in the blood of the splenic vein of a horse to which the percyanide had been administered.

¹ Goepfert, in De Candolle, *Phys. Vég.* 1834.

² *Traité sur l'Acide Prussique*, quoted by Wibmer, *Wirk. d. Arzneim.* iii. 30.

³ *Journ. de Chim. Méd.* i. 269.

⁴ *Versuche üb. d. Wege auf welch. Subst. aus d. Magen u. Darmk. ins Blut. gelang.*

γ. *On Man.*—Taken in *small doses*, it very readily excites nausea and vomiting. Parent¹ says it does not produce the epigastric pain which the perchloride of mercury readily occasions. Continued use causes salivation. In one case, one-eighth of a grain twice a day caused ptyalism in three days.² Mendaga³ says it acts directly on the skin and bones, and hence it sometimes very speedily allays the pain of and disperses nodes.

In *large doses*, especially in very susceptible persons, it affects the nervous system, and causes fainting, anxiety, and cramps. Twenty-three and a half grains in one instance⁴ caused death in nine days. The most remarkable symptoms were: obstinate vomiting; mercurial ulceration of the mouth, and abundant ptyalism; contractions of the heart, which at first were very strong, but became successively slower and more feeble; the abdomen was yielding, and not tender, notwithstanding the constant tenesmus; suppression of urine; semi-erection of the penis, and ecchymosis of this organ, as well as of the scrotum; and, ultimately, convulsive movements.

USES.—It has been employed as an *antivenereal* medicine, and was first used as such by Brera.⁵ Parent⁶ administered it as a substitute for the perchloride of mercury, over which it has several advantages. Thus, being more soluble, it ought to be more readily absorbed; it does not give rise to epigastric pain; and lastly, it is not so readily decomposed; for alkalis, several salts, and many solutions of organic matters, which decompose corrosive sublimate, have no effect on it. It may be applied in the form of aqueous solution or ointment to venereal sores.

It has been employed in induration of the liver, in some chronic skin diseases, in obstinate headache, and in other maladies, as an antiphlogistic.

Its principal use in this country is as a source of hydrocyanic acid and of cyanogen gas.

ADMINISTRATION.—Internally, it may be employed in doses of one-sixteenth of a grain gradually increased to one-half of a grain. It may be administered in the form of pills (made with crumb of bread) or in alcoholic solution. It will be frequently advisable to conjoin opium, to prevent nausea or vomiting. When used as a *gargle* or *wash*, we may employ ten grains to a pint of water. An *ointment* may be prepared of ten or twelve grains to an ounce of lard.

ANTIDOTE.—I am unacquainted with any antidote for it. Albumen does not decompose it. Perhaps ammonia might be found serviceable, to diminish the effect on the nervous system. Opium relieves the vomiting. Our principal object must be to remove the poison from the stomach, which is to be effected by the stomach-pump, emetics, tickling the throat, &c.

370. ARGENTI CYANIDUM.—CYANIDE OF SILVER.

Formula AgCy. Equivalent Weight 134.

HISTORY.—This compound, sometimes called *Hydrocyanate*, *Cyanuret*, or *Cyanodide of Silver*, or *Argentum zootinicum*, has been studied by Scheele, Ittner, and Gay-Lussac.

PREPARATION.—In the *London Pharmacopœia* it was formerly directed to be prepared as follows:—

Take of Nitrate of Silver $\mathfrak{z}\text{ij}$ and $\mathfrak{z}\text{ij}$. Diluted Hydrocyanic Acid, Distilled Water, each Oj. Dissolve the Nitrate of Silver in the Water, and add to them the diluted Hydrocyanic Acid, and mix. Wash what is precipitated with distilled water, and dry it.

In this process, one equivalent or 27 parts of hydrocyanic acid react on one equivalent or 170 parts of nitrate of silver; thereby generating one equivalent or

⁴ *Journ. de Chim. Méd.* i. 210.

⁵ *Journ. de Chim. Méd.* viii. 473.

⁶ Richter, *op. cit.*

134 parts of cyanide of silver, and one equivalent or 9 parts of water, and setting free one equivalent or 54 parts of nitric acid.

PROPERTIES.—When first thrown down it is a curdy precipitate, which by drying becomes pulverulent. It is insipid, insoluble in water, but dissolves in caustic ammonia. It is decomposed by hydrochloric and hydrosulphuric acids, both of which develop with it hydrocyanic acid. It combines with other metallic cyanides to form the *argento-cyanides*. By exposure to the atmosphere and solar rays it slowly assumes a violet tint. It is slowly decomposed by mixture with neutral vegetable substances.¹

CHARACTERISTICS.—It is insoluble in cold nitric acid, but soluble in the boiling acid. When carefully dried and then heated in a glass tube, it yields cyanogen gas (which is readily known by its combustibility and the bluish-red colour of its flame) and a residuum of metallic silver. The latter is recognized by the before-mentioned tests for this metal.

COMPOSITION.—The following is the composition of this substance :—

	Atoms.	Eq. Wt.	Per Cent.
Silver	1	108	80.60
Cyanogen	1	26	19.40
Cyanide of Silver	1	134	100.00

PHYSIOLOGICAL EFFECTS AND USES.—I am unacquainted with any experiments made to determine its effects on man and animals. Serre, of Montpellier,² gave it in syphilitic maladies, in doses of one-tenth and even one-eighth of a grain, without the least inconvenience. It was introduced into the London Pharmacopœia, at the suggestion of Mr. Everitt, as a source of hydrocyanic acid, but it has been excluded from the last edition.

371. ZINCI CYANIDUM.—HYDROCYANATE, CYANIDE, OR CYANURET OF ZINC.

Formula $ZuCy$. *Equivalent Weight* 58.5.

This salt was introduced by the German physicians, as a substitute for hydrocyanic acid. It is prepared by adding recently-made oxide of zinc to hydrocyanic acid; or by adding a solution of sulphate of zinc to a solution of cyanide of potassium. It is a white powder, insoluble in water or alcohol. If a strong mineral acid be added to it, hydrocyanic acid is developed, and a soluble salt of zinc obtained. The latter is recognized by the tests before mentioned for a solution of zinc. It consists of one equivalent or 32 parts of *Zinc*, and one equivalent or 26 parts of *Cyanogen*.

Its effects have not been carefully ascertained, but they are supposed to be similar to those of hydrocyanic acid. It has been used principally in affections of the nervous system, as epilepsy, hysteria, and chorea. It has also been employed in cardialgia and cramps of the stomach, and as an anthelmintic in children. The dose is a quarter of a grain to a grain and a half, three times a day. It may be taken in the form of powder mixed with calcined magnesia.

372. RADIX SUMBUL.—SUMBUL ROOT.

SUMBUL,¹ SAMBUL, MUSK-ROOT.(Racine de Sambola ou Sambula, *Guidouri*.²—Moschna-wurzel of the Germans.)

This drug was introduced into Germany from Russia about the year 1840; more recently, it has been brought under the notice of the medical profession in England.³

The botanical origin of Sumbul root is involved in obscurity; from a resemblance which it bears to Angelica, there is reason to think it is afforded by some nearly allied umbelliferous plant. It has been supposed a native of Persia; but we think there is greater reason to conclude that it is produced in some of the more remote regions of Central Asia. Dr. Granville states that it is brought into the Moscow drug-market by way of Kiakta.

Two varieties of Sumbul have appeared in English commerce, viz:—

1. **Russian Sumbul Root** (*Radix Sumbul Muscovitici*).—The Sumbul imported from Russia occurs in nearly circular pieces, formed by the transverse section of a large root; these pieces, which have a dirty, somewhat worn appearance, are from about 2½ to 5 inches in diameter, and from ¼ of an inch to 1½ inches in thickness at the edge, which, owing to unequal contraction in drying, is thicker than the central portion. On the outer edge they are covered with a dusky, brown, rough bark, frequently beset with short bristly fibres; the interior consists of a spongy, coarsely fibrous, dry, yellowish-white mass, of a somewhat farinaceous appearance. Some pieces, constituting the crown portion of the root, are covered with a papery bark. The root has a pure musky odour. Its taste is rather bitter, and very slightly acid.

2. **Indian Sumbul Root** (*Chinese Sumbul Root* ?); *Radix Sumbul Indici*.—A second variety of Sumbul root has been imported into England from Bombay. It is stated to be of closer texture, firmer, denser, and of a more reddish tint than the Russian sort. Some of the pieces are said to bear a slight resemblance to inferior rhubarb. In odour it is perhaps less powerful than the Russian.⁴

Sumbul root has also been brought to England *via* China. A sample in our possession, said to have been thus obtained, is in smoothly cut slices, having the cut surface of a dusky yellow or reddish-brown, surrounded with a paler zone. The external thin bark has been mostly peeled off, leaving visible a pale yellow inner bark. The pieces, which, from their regular edges, appear to have been cut from a *dried* root, are smaller than those of the Russian sumbul, denser, and sometimes of an almost unctuous aspect. The odour resembles that of the Russian sumbul, though rather weaker; the taste is bitter, and slightly suggestive of ammoniacum. Judging from the description of Indian sumbul root given in the *Pharmaceutical Journal*,⁵ this variety is identical with it.

Sumbul root has been analyzed by several German chemists,⁶ the results of whose investigations show it to contain a volatile oil; two balsamic resins, one soluble in ether, the other in alcohol; wax, starch, &c. In addition to these, a crystallizable acid has been obtained in minute quantity by Dr. Reinsch, and named by him *Sumbulic acid*.

Sumbul root may be administered, in substance, in doses of from grs. iij to grs. viij; in tincture, made by digesting for seven days ℥ij of the root in ℥xvj of proof spirit.⁷ An ethereal tincture is likewise employed, as may be also, according to

¹ The Arabic word, *Sumbul*, signifying an *saw* or *spike*, has been applied to several odoriferous drugs, as, e. g. to the true spikenard, *Nardostachys Jatamansi*, De Cand., the *Sumbul Hindes* or *Indian Sumbul* of the East; see Sir William Jones *On the Spikenard of the Antients*, in the *Asiatic Researches*, ii. 405, iv. 111, Lond. 1799; also Richardson's *Persian, Arabic, and English Dictionary*, word *Sumbul*, l. 544, Lond. 1806.

² *Hist. des Drogues*, 4ème édit. iii. 195.

³ See *The Sumbul, a New Asiatic Remedy*, by A. B. Granville, M. D. Lond. 1830.

⁴ *Pharmaceutical Journal and Transactions* for Feb. 1832, xi. 339.

⁵ Vol. xi. p. 358.

⁶ *Pharmaceutical Journal and Transactions*, xi. 144.

⁷ Quoted in *Journ. de Pharm.* xix. 278, 1851.

Dr. Granville, an aqueous infusion, decoction, or extract. The alcoholic tincture may be given in doses of from ℥xx to ℥lx.

[NOTE.—We subjoin a list of some papers published by the author in the *Pharmaceutical Journal* since the previous edition of his work. They will be found to contain many subjects of interest in addition to those noticed in these volumes.]
