Well, after reading the above important suggestion, it linked idea after idea within me until my blood was fired with enthusiasm, for I thought of taking a scene in Hyde Park, or in the City—where the ceaseless stream of life is never ending—by the machiue camera one day, and produeing, in the course of a few hours, a paper whieh could be delivered to the public, showing true to nature all the movements of life, or auything that may be of interest whieh was photographed at the time. So you can gather from this something of the vastness of what it may be possible to aecomplish by the aid of the printing machine which I am about to show you, doing away with all the tedious sketehing and the troublesome bloek proeess whieh oeeupies so much time and costs so mneh. A well-kuown person's photograph, with his letter, conld be eopied by photography and printed by light mueh more quickly than you could set up the type for the letter, let alone making a bloek—whieh wonld take days—for the likeness, and then not so perfect as it would come ont when printed by light alone, for you eould not equal the texture and detail by the bloek process as you could by the other. Then, as regards the letter, you could have a *fac simile* without setting up any type, and read each individual's own handwriting.

I find in this age of speed that it is no good to have ideas if you do not put them into practice, so this maehine, which is the invention of myself and Mr. Varley, was soou begun, and eight months elapsed before the first band was printed: it seems ridiculous, when you look at the machine, that it should have taken so long. I could not finish it before. I will show you the first band printed by it; after that band was developed I saw the possibility of carrying out all the ideas, which, if I am spared, I intend to do, and the Bath Photographie Soeiety shall be the first to see them, for there is a link of affection attaehing me to the Society, being one of its founders. I will pass round the first band with forty to fifty pietures upon it, and I hope that before long you will see the first complete newspaper.

The most important feature of the machine is that the moment the exposure is given the paper must be still, and pressed to the negative. The results which you see before you are printed by gaslight, but of course the eleetrie light will be nsed in the future. I have also brought you a band with 400 pictures upon it, taken at the rate of three to four a second. I have brought the eamera whieh I took them by for you to see, and you will notice that the movements are the same as in the printing maehine, so with the two eombined I eould take a string of pietures in Milsom Street one day, and have them in a newspaper the next.

It would take too long to explain the maehine and camera in detail this evening, but, no doubt, soon a deseription, with blocks illustrating both, will be published in one of the papers.

* Read at the Bath Photographic Society.

THE PREPARATION OF THIOSINAMINE FOR POSITIVE DEVELOPMENT.

BY A. PERCY SMITH, F.I.C., F.C.S.

1. Preparation of allyl sulphocyanate or oil of mustard, C_3H_5CyS. Take blaek mustard seeds, bruise and maeerate for twelve hours in five parts of water. Distil till no more oil passes. Separate the oil, and use the aqueons distillate, whieh contains some oil in solution, for maeeration of fresh seed.

The crnde oil is dehydrated by ealcium chloride and redistilled till eolourless. It boils at 145° to 150°. The distillation should be effected in a draught eupboard, or other means be taken to avoid contact with the vapour of the oil, whieh has a very unpleasant effect upon the nose and eyes.

2. Saturate the oil with ammonia gas, or mix it with three to fonr times its volume of strong aqueons ammonia. Set aside until it crystallises, and filter. The mother liqnor should be boiled to expel ammonia, and then evaporated.

Thiosinamine, or allyl sulphoearbamide, $N_2CS.C_3H_5.H_3$, is in shining, white, inodorons prisms, having a bitter taste. It melts at 70° to 74°, and is readily soluble in hot water, aleohol, or ether.

SIXTY-FOUR of Mr. H. P. Robinson's photographs were on view in the rooms of the Society of Amateur Photographers of New York uutil September 27th, on which date they were sent for a month to the Photographie Soeiety of Philadelphia.

THE LARGE LENS.—A dispatch from Cambridge, Mass., says:—Yesterday the glass for the University of Southern California teleseope was unpaeked by Alvin G. Clark. Among those present were Judge R. M. Widney, president of the University Bank of Los Angelos, and a trustee of the University of Southern California, George Clark, and Robert Widney. When the lid of the big box was removed Clark tenderly lifted away the exeelsior fibre which eovered the preeious lens. The glass measures about 10ft. in eireumferenee, or 4ft. 4in. in diameter. Although it is 2½in. thick at the eentre, and 1½in. at the edge, it was as transparent as a bit of thin plate glass. Clark's hands fondled it as he would a baby while he murmured: "What a beauty it is. No one ever saw its like before." It is nearly five iuehes wider in diameter than the Lick teleseope glass. Clark says that its eurve on one side is almost perfeet, as he aseertained by the aid of a spheroid, but that the other will stand a great deal of eutting down. He has not yet deeided whether he will have the work done at his manufaetory in Cambridgeport, or put up a new plant to complete it near the scene of its future home in California.—*Invention.*

APPARATUS AT THE PHOTOGRAPHIC EXHIBITION.

V.

In the present Exhibition there is another camera, in addition to the one previously described, so made that it can be extended and used within its case. Messrs. Shew and Co. exhibit their well-known and popular "Eclipse" hand-camera inside a leather case, which case is no larger than an ordinary sling cover. It is represented closed in fig. 14, with the ends of the two straps.

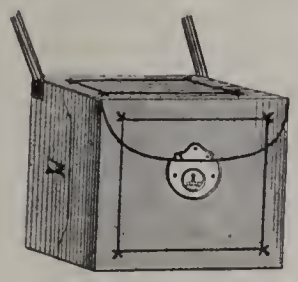

Fig. 14.

Fig. 15 represents the case open ready for use. The right hand is in the position for starting the shutter, and the left supporting and helping to steady the camera. The removable finder is held in grooves on the top of the leather case. To open the slide, the side tuck-pocket is turned back, and allows the slide-shutter to be withdrawn. The removal of the slide to reverse the back is done through a small opening opposite the end of the slide on the other side of the case, through which the operator pushes his thumb, and then seizes the slide with the other hand.

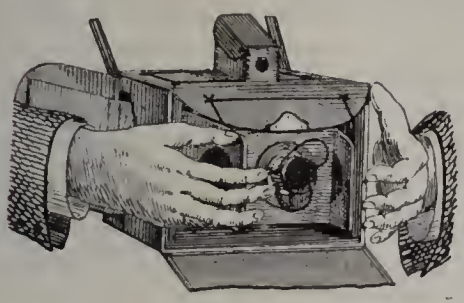

Fig. 15.

The case contains the camera, three double backs, and the finder, all so closely packed that there is no waste space. For large sizes it will be specially advantageous, because the case and strap help to give support and to steady the camera. In fig. 15 a portion alone of the folding flap of the case is represented.

Fig. 16.

Another exhibit, by the same firm, is a double-ribbon magnesium lamp, smaller than those hitherto made to drive the ribbons in pairs. The ribbons emerge side by side through separate small tubes.

The Fry Manufacturing Company exhibit photographs on some handsomely embossed and stamped sheets of celluloid, made in close imitation of ivory; they are of elegant appearance, and a general idea of them may be gathered from fig. 16. The use of celluloid in photography is of comparatively recent date. So far no objections to it on the score of durability have been discovered, although in some instances specimen photographs on it have been exposed in street show-cases for about a year.

The same firm exhibits the Hibbard repeating flash-lamp, represented in fig. 17, and as Messrs. Fry and Co. sent us one of them about a year ago, we have had occasional experience in its use. A good point about the lamp is that it is held in the hand, and can be made to give two or more flashes in quick succession, so that, if the lamp be moved a little forward between each flash, the light is somewhat diffused, and harsh shadows more or less avoided. Pleasing portraits of sitters may thus be obtained by its aid in private drawing-rooms; we have not tried it upon groups, but only upon one sitter at a time. The pneumatic chamber is held in the hand like the handle of a pistol, and the little spirit lamp projects in front. The cut represents the various adjuncts sent out with the lamp.

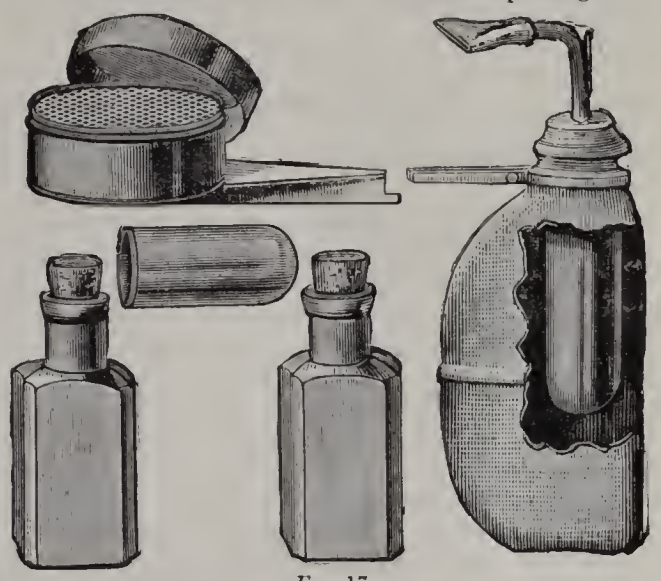

Fig. 17.

With all lamps in which powdered magnesium is blown through a flame, some of the metal usually escapes unburnt. The nature of the sample of the metal bought has much influence over the amount of this waste. Some samples are coarse, like filings; others are fine, like flour. The latter give a rapid and more brilliant flash. Possibly in them the metal may sometimes be purer, because pure magnesium is a "rotten" easily-powdered metal, but, when toughened by the admixture of zinc, it may be more difficult to get into a state of fine division, and its affinity for oxygen is lowered. Fine powders ignite more rapidly than coarse ones, all other conditions being equal; in fact, some metals, when reduced to an abnormally fine state of division, will spontaneously ignite by mere exposure to the air.

WANTED, A WORD.

BY THE REV. F. C. LAMBERT, M.A.

TECHNICAL terms, of the right kind, are among the most useful of scientific aids; but alas! many technical terms are far from being appropriate, much less self-explanatory. Two photographic technical terms of very recent birth are far from satisfactory—viz., "orthochromatic" and "isochromatic." These two terms are both applied to those plates which are supposed to render negatives of coloured objects in the true value of the luminosity of their colours. It seems that these terms are applied indifferently, and it is only fair to add that they are about equally inappropriate.

The former of the two (orthochromatic), if it means anything, can only be applied to photographic plates in the sense of their rendering a negative in right or proper *colour*; compare *ortho* in orthography, orthodoxy, and orthoepy.

The second term (isochromatic), in turn, can only, in this connection, be construed to mean equal or average colours—*i.e.*, all colours equally; compare *iso* in the compound isobaric, isothermal, isoclinal. (N.B.—Nuttall defines isochromatic as "having the same colour.") Thus, as I have elsewhere previously pointed out, neither of these popular terms conveys any hint that their meaning includes the idea of *proportional brightness*, and I have already suggested that the word "metriolamprotic" would have met the requirements of the case. Possibly my suggestion came too late, or, possibly, the conservative "cussedness" of the English in general, and photographers in particular, made them stick to a blunder, having once made it. However, now that the advocates of the production of photographs by means of the so-called pinhole are about to separate themselves, by all means let us have a term which is something more like civilised language than the mongrel term "pinhole-photograph"—a term about on a level with cablegram.

I have failed to find any Greek word which corresponds exactly with pinhole, and the nearest approach to this is the word τρῆμα (*trema*, with the *e* long—*i.e.*, pronounced treema), meaning, "that which is pierced through," a hole; *e.g.*, eye of a needle; holes or pips of dice. Thus, we may compound a word "tremagraph" (*e* long) without offending against reasonable sound and sense, and, furthermore, there is another argument which, with many people, is of paramount importance—viz., it is *two syllables shorter* than the mongrel "pinhole-photograph."

It may be urged that the word means simply a writing or drawing made by means of a punctured hole, and does not include the notion of light being the active agent in the production of the picture. To this objection nothing can be said beyond the advice to add our old and well tried "photo;" thus, the new child in all the honour and glory of its birthright will be "photo-tremagraph," but for common and vulgar use to be shortened into "tremagraph."

Most of us can remember the old story (with a grammatical moral) concerning the little boy who asked his uncle "how long he'd been an *antiquarian?*" and the answer of the uncle to the effect that "he never remembered being an adjective, and preferred to be called by the noun *antiquary*."

If ever the things we call photographs should speak, they would begin their remarks by asking us why we call them verbs and not nouns, and would, with justice, point out that if we used the word "cryptogram," "telegram," and even that bar-sinister term "cablegram," we were treating them unjustly in not applying to them the term "photogram."

PICTORIAL DEFINITION.*

BY A. COLLIER.

I FEEL, somehow, drawn to this subject, in spite of the hesitation one feels in constantly making oneself heard at these meetings. It is difficult, no doubt, to stick to the title of the paper.† I thought so when the reader of it held up a book and challenged another member to read the title on the back. Were we not pretty close on telescopic definition instead of pictorial?

Whatever may be the outcome of this discussion, it will end, no doubt, in each of us having our own ideas of what definition ought to be, and quite right too; is it not entirely a matter of taste whether we make this, that, or the other the sharpest bit in our photograph, guided by one's common sense, just as much as choosing the point of view? We all agree, I suppose, that many good pictures can be made of a good subject from different points of view—in fact, you will seldom find two painters agree which is the best point of view. In that respect I have little or nothing to say about it. It is when others—if only a few, fortunately—differ widely from our own preconceived notions of definition, that we seek to know the reasons, and if not good and sufficient, reject them. I do not myself care for extreme sharpness, and detest hardness as much as the most enthusiastic pin-hole photographer going. It is the other extreme—describe it as you will—and the pretentions of the pin-hole, naturalistic or fantastic school, that I intend having a tilt at, and that from an artistic point of view only. One feels tempted here to ask the question: What constitutes a school? The schoolmaster and another!

These naturalistic photographers would have us believe they are for nature, nature before anything, and hang conventionality. Just as if, by *only* going to nature, you can avoid it. Where, may I ask, can you find a better example of conventional treatment than Emerson's "Hay Cart" from nature? And as to their idea or impression of what nature is can only be properly rendered through a pin-hole, or lens out of focus—of the two, I would rather have the pin-hole definition than the "judicious use of the stop" as shown by Emerson. We have here a wandering of the focus with a vengeance. Mr. Everitt, the other night, thought these prints were entitled to be considered pictures or works of art, because they recalled scenes with which he was familiar. Now, this is a mistake. If he seeks for no higher quality in art than this, his standard must be a very low one indeed. The artists on the pavement will produce something which will recall scenes; but perhaps Mr. Everitt considers these pictures and works of art. The roughest blot or slightest sketch will do this and more; your imagination is at once called upon to fill up what is wanting in the sketch. No one will contend that the sketch is a picture or work of art because you feel a certain charm in exercising your imagination. Therein lies the charm; it is not in the sketch, and certainly is not in these prints. The charm to a painter is what he feels he could do with

* Read at a meeting of the London and Provincial Photographic Association.

† "Pictorial Definition," by Mr. P. Everitt; read Sept. 4th, 1890.

the subject; it is suggestive because it has lost the hardness one usually finds in photographs. But fuzziness, or whatever term you may use to describe want of definition, is not in itself artistic, or yet a quality in art, any more than smoothness or softness.

The impressionists tell us, Mr. Everitt told us the other night, was Emerson's theory; if you are painting the middle distance, and only conscious of the foreground, why paint it? Quite so; if the foreground is of no importance, why paint it, even as you are only conscious of it? But no, the foreground is too important to be left out, and, as none but impressionists understand these things, they get over the difficulty easily enough by painting it as they are only conscious of it.

Now, I contend that if you look at the foreground as you do the middle distance, you ought in common honesty—there is such a thing as honesty in art—I say in common honesty you ought to render the one in relation to the other as you see it. To say you are only conscious of what you ought to study and endeavour to render truthfully, is nothing but mere affectation; and shirking the difficulties of painting just where they begin, and in a less degree shirking the photographic difficulties of rendering the definition, with an eye to atmosphere and movement, is not a proceeding to be commended.

One may well ask if they have ever seen this nature they imagine they are looking down upon from their lofty pinnacle, condescending to look at a bit at a time, conscious, no doubt, that more than an angle of nine degrees is too much for a weak brain. If they will but study what they confess they are only conscious of, they will in time feel less inclined to cackle about it as they do. So far they are only trying to imitate a few who call themselves naturalistic painters. Do the photographic imitators imagine there is nothing more in the work of this so-called naturalistic school than haziness of outline? One would think so, seeing that is as near as they have got to it, or may ever hope to get. If they had any real artistic feeling in them they would know how utterly hopeless it was to attempt it. There is something more in some of the work of this new school of painters difficult to express without examples, and still more difficult to find in much of the so-called impressionist or naturalistic work one sees about.

It is the mind and soul, as it were, of the man showing in his work that is the backbone of all true art work; without it, it is nothing but a meaningless daub. Where we find this quality we tolerate the slovenly execution or want of definition, as we tolerate the mannerisms of an actor or musician if he appeals to us, or touches a responsive chord in our nature; just as the indifferent manipulation of Rejlander was tolerated at a time when a "clean plate" was thought more of than now, when he gave us something with a little thought in it.

Is it not, then, an insult to one's common sense to be told of the characteristics of the photographs used as examples by Dr. Emerson and Mr. Everitt, that these points are all that one could desire, and that the other is just as it should be, when they are nothing but an out-of-focus transcript of the scene before them at the time of taking the cap off the lens?

An Association of Professional Photographers is being formed, of which Mr. C. P. Richards, of Barrow-in-Furness, is the secretary.

Specifications Published.

17,744. *November 7th*, 1889.—"Machinery for Cleaning Glass Plates." William John Wilson, 6, Malden Road, Watford, Herts, Chemist.

To carry out my invention, I use rollers made of metal or other suitable rigid substance, and coated with a softer elastic material, such as vulcanised india-rubber. These rollers are arranged in pairs, one roller over the other, and caused to revolve in such a way that a plate of glass placed between them is gripped and carried forward in a horizontal plane. Before the plate is entirely passed through, its front edge is gripped by another pair of rollers, which continue its motion forwards, and successive pairs of rollers are arranged so as to carry the plate onwards as far as may be necessary. As the glass passes, along its upper and under surfaces are both brushed by pairs of brushes moving between successive pairs of rollers, the brushes have a rapid oscillatory motion in a horizontal plane, and in a direction at right angles to that in which the glass is moving. The brushes and glass are kept wet by suitably arranged jets of water or other cleansing fluid, and the cleaned glass may be delivered by the machine either in a wet state, or dried by passing between dry rollers, or pads, or squeegees. The brushes, or some of them, may be replaced by pads of leather, sponge, felt, or other suitable material, and a dry powder may be supplied to them instead of the liquid, so that the glass is polished dry instead of or after being washed.

20,661. *December 23rd*, 1889.—"Heating Glass Rooms." John Poat, St. Sampson's, Guernsey.

Whereas it is frequently the case that furnaces used for steam boilers or other purposes already exist in close proximity to green-houses, and from which the heat from the furnace, in order to create a strong draught, is allowed to pass away from the flues at a high temperature, I now, under my invention, propose to utilise this waste heat to create a hot water circulating system to be applied to an adjacent green-house or similar building. In the flues of the said furnace, or immediately in connection with the furnace itself, I employ water tubes, forming the heating surfaces for an independent hot water circulating system for the heating of an adjacent green-house. I may carry fire-tubes of smaller diameter than the water tubes through the centre of the latter, so as to present both an internal and external heating surface to the water tube; or I may introduce such special water heating tubes, with a distinct connection to a green-house hot water system, into, through, or amongst any boiler shell or tube boiler which may itself be used for other distinct purposes.

18,826. *November 23rd*, 1889.—"Cameras." Clifford Lawrance, 27, Martin's Lane, Cannon Street, London, E.C., Manufacturer.

My invention consists in an improved method of arranging and changing plates or films in a detective camera-box, and also in mechanism for working the shutter thereof.

According to this invention, I arrange the plates or films in book form, each plate or film being retained in zinc or other frames, being bound or hinged together at one of their sides or ends, preferably at one side, in such a manner as will allow them to fold over freely and be exposed respectively. This book, containing the plates or films, is provided with an outside

cover, as an ordinary book. The book containing the plates or films in the camera is supported on a partition or other support, with their bound or hinged sides resting on the support. These zinc or other frames are pressed against four or more clips or stops in the camera by means of a spiral or other spring. In the opposite ends of these said zinc frames I cut alternate slots corresponding with the said four or more clips or stops. These clips or stops are connected by means of liners or rods to a knob or thumb-piece, operated from the outside of the camera. When it is desired to change a plate or film, the thumb-piece or knob is moved, which, operating the levers or rods, brings the four or more clips or stops opposite the corresponding slots in the zinc frames, and, owing to the pressure of the aforesaid spring on the said frames, one plate folds over and exposes a fresh surface plate or film. This is continued until all the plates have been exposed and the book exhausted. I provide suitable springs, which are fixed in the body of the camera, so as to break the fall of the plates as aforesaid, and prevent same from folding back if the camera should be inverted. The lens may be covered by a circular or suitable flap, which is attached to a rod which is pivotted at one end, the other end being attached to a thumb-screw or small milled head. This circular or other flap is for the purpose of covering the lens, and excluding light from the interior of the camera when required; a suitable spring is provided in order to keep the flap closed or open, as may be required. The shutters are actuated, according to my invention, by means of a cam actuating a rod attached to a sliding-piece, which in turn is connected to two more rods, the said rods actuating the shutter. I employ an ordinary clock spring or its equivalent to actuate the same. These shutters or wings are operated from the outside of the camera by means of a push connected by means of two rods to a catch-piece or short rod operating on a stop affixed to the said cam. I may also provide a similar stop for the purpose of keeping the shutters or wings open when required, by means of a lever and short rod operating on the said stop affixed to cam.

13,054. *August 20th*, 1890.—"Magnesium Flash-Lamps." GEORGE ADOLF SINSEL, Plagwitzerstrasse No. 9, Leipsic, Saxony, Manufacturer.

These improvements relate to magnesium flash-lamps, and consist in the arrangement with the lamp of a reservoir for containing a supply of the magnesium powder, and in the construction and arrangement of an adjustable piston moved by pneumatic pressure, by means of which the quantity of powder to be fed to the flame of the lamp or burner can be exactly regulated. The current of air which operates the piston also serves to eject the powder.

The inventor claims:—

1. A magnesium flash-lamp constructed, arranged, and operating as described and illustrated in the specification.

2. In a magnesium flash-lamp, the combination and arrangement of a cylinder and piston, the piston being arranged to be pressed against the end of an adjustable hollow rod by means of a spring, and the cylinder having an air bye-pass, substantially as hereinbefore described, and as illustrated by the accompanying drawings.

3. In a magnesium flash-lamp, the construction and arrangement of a piston having passages therein, and its combination and arrangement with a tube as described and illustrated in the specification.

4. In a magnesium flash-lamp, the construction and arrangement of the cylinder having an air bye-pass, as and described and illustrated.

13,191. *August 22nd*, 1890.—"Improvements in the Dusting-on Process." GEORGE WILLIAM WOOD, 3, Askew Road, Gateshead-on-Tyne, County Durham, Clerk.

My invention refers to improvements in or relating to the "dusting-on" process of producing pictures by photography. In the production of positive pictures by what in photography is known as the "dusting-on" process, the support, which is generally a plate of glass or opal glass, is coated with a deliquescent organic matter intermixed with bichromate of potassium or ammonium. These mixtures are sometimes termed "photogenes," and as such will hereinafter be referred to.

After drying, the support is placed under a diapositive, and exposed to the action of daylight, and after exposure the image is developed by dusting on some suitable black or dark coloured matter in the shape of a fine powder, the result being a reproduction of the image of the diapositive employed.

It will thus be seen that if it be desired by this process to make a positive from any given negative, it is necessary, in the first place, to make by some other process a diapositive or transparent positive from it (the negative).

The object of my invention is to provide a "dusting-on" method or process for producing positive images or pictures direct from the negative, and I effect this as follows:—

A support, generally a sheet or plate of any suitable black or dark coloured material—such as ebonite, or vulcanite, or ferrotype plate or glass coated with black or dark coloured varnish or enamel—is, after being well cleansed, coated with a "photogene" such as the following:—

Gum arabic	... 30 grains
White loaf sugar	... 30 ,,
Ammonium bichromate	... 20 ,,
Distilled water	... 1 ounce

This formula works very well, although any of the other well-known "photogenes" will answer the same purpose.

After drying, the support is placed under a negative, and exposed to daylight for a time dependent on the density of the negative and the strength of the light, generally from five to twenty minutes, but an actinometer should be used as in carbon printing. The image is next developed by "dusting-on" some suitable lustrous substance, such as the white, gold, or other light-coloured bronze powders obtainable commercially, or aluminium, magnesium, zinc, tin, silver, or other suitable metal or alloy reduced to powder may be used. It is obvious, also, that any suitable light-coloured, or white, or nearly white substance, such as ivory dust, white marble, or sulphate of barium, may be employed, but substances possessing a metallic lustre, on account of the superior brilliancy of the images produced therewith, are preferred.

Good results may be obtained by reducing salts of silver to the metallic state by precipitation with a suitable reducing agent, *e.g.*, a fifty-grain solution of silver nitrate is precipitated by adding to it a solution of ferrous nitrate and ferrous sulphate intermixed and slightly acidified. The standard developer employed in the "ferrotype" or collodion positive process answers well. The precipitate, after being well washed, is dried, passed through a fine lawn sieve, and may then be used as above set forth. After "dusting-on" is complete, the plate or support is coated as usual with collodion well washed, and finally varnished as a protection against oxidation or other injury.

The above procedure may, if desired, be varied by taking as the support a sheet of plain glass or other transparent medium, coating with photogene, drying, exposing, developing, and finally "backing up" the support with black varnish or printers' ink on paper as in the collodion positive process on glass.

What I claim is:—

1. The use of a light-coloured or white, or nearly white substance for "dusting-on," a dark coloured or black, or nearly black support prepared and applied in the manner and for the purposes substantially as here described.

2. The improved process of producing positive images or pictures direct from the negative, substantially as and for the purposes herein described.

A GOOD PASTE.—A paste which will stick anything is said by Professor Winchell to be made as follows:—Take two ounces of clear gum-arabic, one and a-half ounces of fine starch, and half an ounce of white sugar. Dissolve the gum-arabic in as much water as the laundress would use for the quantity of starch indicated. Mix the starch and sugar with the mucilage. Then cook the mixture in a vessel suspended in boiling water until the starch becomes clear. The cement should be as thick as tar, and kept so. It can be kept from spoiling by the addition of camphor or a little oil of cloves.

Correspondence.

MR. DEBENHAM AND SPHERICAL ABERRATION.

Sir,—I feel bound to reply to your correspondent's letter of last week, and to enter a protest against such inferences as may be drawn from the first and final paragraphs. The only excuse your correspondent has is *ignorance*. Due respect to the conventionalities has alone prevented me from insisting on this before, but there is such palpable evidence of it in the remaining portion of the letter that it speaks for itself.

Mr. Grubb, at any rate, understood that the introduction of spherical aberration altered the disposition of rays as compared with those of an aplanatic lens. Mr. Duner is only unfortunate in the *title* of his paper, "On the Diffusion of Focus," which is evidently all that your correspondent could understand of it, for the paper has *nothing whatever to do with transversal measurements as applied to lenses with spherical aberration!* At the Parent Society, early in 1888, your correspondent being present, I was the first to give formulæ for "depth of focus" when referred to transversal measurement of circles of indistinctness in out-of-focus planes for *aplanatic* lenses, where *they are of value*.

As to the third paragraph, I am prepared to prove myself right, in the *cases I cited* against your correspondent, to any scientific man or meeting interested in the subject, and to explain those cases where readjustment is necessary.

As to the fourth paragraph, my reply should be sufficiently understood from the quotation from my Camera Club paper. A careful experimentalist would see in the subject chosen the reason for the *missing* outwards on the *inside* of the focus tending to reversal, but for the best focus of minute structure, the visual and early stages of development would show Nos. viii. and xv. decidedly better than xi. and xvi. in the negatives.

My reasons are evident for declining farther waste of time in this argument with your correspondent.

25, *Newman Street, London, W.* Thos. R. Dallmeyer.

The first paragraph of the above letter, and the concluding paragraph of Mr. Debenham's letter last week, are rather strong. The long discussion must end here.—Ed.

EYEPIECES FOR FOCUSSING.

Sir,—I observe in a paper by Mr. W. H. H. Clark, read before the American Convention, and printed in your issue of Oct. 24th, a repetition of a statement implying a not uncommon optical error, a correction of which may be useful to those photographers who use magnifiers for the direct examination of the optical images produced by their lenses—an aid which I have found very useful.

It is stated, concerning the great Lick telescope, that "it is now supplemented by a remarkable piece of mechanism—an eyepiece, which has just been completed—out-rivalling anything of the kind before made; the largest before in use being not over two inches in diameter, while the new piece measures over three inches." Further, that "the light from the heavenly bodies seen through the Lick telescope and this new eyepiece will be 2,000 times as great as that seen with the naked eye"—apparently implying that the larger eyepiece transmits somehow more light. As to its phenomenal size, perhaps jealous Britons may find comfort in knowing that—as I myself saw some thirty years ago—an eyepiece of no less than *six* inches in diameter was in use with the Earl of Rosse's gigantic reflector. I remember being shown also the great plane speculum, six inches across its smaller diameter, and, therefore, just capable of reflecting pencils enough to illuminate the whole field of view of this huge eyepiece. But I believe the eyepiece itself was never thought worthy of special mention, being used mostly as a sort of finder, and necessarily unable to convey to the eye the full light of the telescope. According to the following explanation, the eye could only admit from it the light reflected from a portion of the great speculum of, perhaps, 14in. to 18in. in diameter; the full aperture being 72in. The new large eyepiece for the Lick telescope, assuming its focal length to be, as is usual, about equal to the diameter of its field-glass—3in.—appears, on the other hand, to be judiciously planned for observing purposes. It may well be, too, that improvements have been made in the optical construction, an account of which would be of real interest. The serious optical error in the description given is, however, that an actual advantage in the total amount of light received from a heavenly body is supposed to be obtained by its unusual dimensions; and this is impossible. Indeed, as with the great Rosse telescope, the effect of using an eyepiece of large dimensions, and, consequently, of low power, may often be to diminish the light which reaches the eye, and can never be to increase it.

For it follows necessarily, from the accepted optical theory, that the diameter of each pencil of rays, as it emerges from an eyepiece—whether employed with a telescope or with a photographic objective—must always be equal to the aperture of the object lens, divided by the linear magnifying power obtained; this magnifying power being defined as the focal length of the objective, divided by that of the eyepiece; and if this resulting diameter be greater than that of the pupil of the eye, part of the light is necessarily wasted. Part is usually wasted with a binocular glass, the power of which rarely reaches five diameters; while the aperture often exceeds 2 inches. And, under such conditions, the diameters of the lenses of an eyepiece have no more to do with the amount of light from a given object available for vision of it, than the diameter of the lenses of a wide-angle doublet have to do with the intensity of the lens; this intensity being determined not by the size of the lenses, but by the aperture of the stop. For the width of this opening of the pupil of the eye, varying continually as it does through the sensibility of the visual organ to varying intensity of light, averages generally not more than from about $\frac{1}{6}$ to $\frac{1}{8}$ of an inch (Quain gives 0.14), and, with a magnifying power of 5 diameters, a pencil of rays of $\frac{1}{6}$ to $\frac{1}{8}$ inch diameter at the eye corresponds to one of $\frac{5}{6}$ to $\frac{5}{8}$ in. at the object lens; all apertures greater than this ratio going to increase, not the brilliance of the image, but the extent of the field of view.

By the same rule, if we wish to examine directly with an eyepiece the image formed by a portrait lens of, say, 12 inches focus and 3 inches aperture ($f/4$), we must use—that we may judge of the full aperture—an eyepiece not less powerful than from $\frac{2}{3}$in. to $\frac{1}{2}$in. focus, the more powerful eyepiece being required for so bright a light as would cause the pupil to contract to $\frac{1}{8}$ in. If our eyepiece is of lower power, we may as well stop down the lens in the same proportion.

By the same rule, again, the Lick telescope of 49ft. focus and 36 inches aperture would require an eyepiece only just over 2 inches focus for the eye to admit all the light from a really bright object; but from a very faint one, in looking at which the pupil might dilate to 0·18 in., the eye could receive all the light transmitted through one of just under 3 inches focus. Thus, the size and power of the new Lick eyepiece seem eminently judicious; but it is absurd to claim for it the advantage of transmitting more light. Not that the light transmitting power is exaggerated. Far from it—indeed, I should estimate the light received from the telescope as nearer thirty thousand times than two thousand times that received by the naked eye.

As regards the practical employment of such magnifiers in focussing photographic lenses, the use of a powerful eyepiece on a lens of great intensity is very difficult, from the extreme nicety of adjustment required; while, as we have seen, a weak eyepiece is deceptive, except with a small stop. So that a good focussing screen, with or without a magnifier, is most generally convenient. But, when focussing dark interiors, or paintings, which demand a small stop and a long exposure, I find it a great comfort to dispense with ground glass (except in adjusting for position), and to use a plain glass focussing screen with an eyepiece of low power and very large field. I have one of my own construction, of about $2\frac{1}{2}$ inches diameter and focus, so adjusted that when in contact with the screen the other side of the glass, corresponding in position with the sensitive film, is in focus. By this means the faintest detail may be accurately seen with a very small stop, and the position of best focus promptly determined. W. H. Wheeler.

106, *High Street, Oxford.*

WATKINS' EXPOSURE METER.

SIR,—In your careful and appreciative notice of my exposure meter there is a statement which requires explanation, or it may lead to misapprehension. You say that the adjustment of one of the rules is left to the judgment of the observer, and may be known as the "judgment ring." This might naturally lead to the idea that a correction has to be made by the photographer in order to make amends for the shortcomings of the method adopted. Certainly this is not the case. The adjustable scale in question is to express the photographic value of the subject (quite independently of the light), and this value depends chiefly upon its colour, a quality which obviously can only be estimated by means of the eye. The value of the subject varies within well defined limits, the extremes being 25 for white objects, and 300 for exceedingly dark non-actinic ones, and 100 is the average or standard subject number used in four cases out of five.

Regarding the sensitive salts to be used in the construction of an actinometer, the requirements are very different to those for which Bunsen and Roscoe worked, and Captain Abney gives a decided opinion upon the merits of chloride *versus* bromide (or bromo-iodide) for this purpose. He says :—"If a photometer is to be used for any photographic purpose it should be a rigorous rule—a law of the Medes and Persians, in fact—that whatever sensitive salt is employed in the process, the same should be used, in as nearly as possible the same condition, in the photometer." I have made a very large number of experiments in order to find a formula for a suitable sensitive paper, and I do most emphatically assert that the darkening of the paper sent out with the instrument is in exact relation to the sensitiveness under varying lights of an average commercial plate.

I fix upon the standard tint by exposing the paper to a standard amount of light—equal to two seconds' exposure to the strongest possible sunlight in England.

After all, the important point is whether the instrument, as a whole, *does* accurately estimate exposures under all possible circumstances, and I prefer to deal with this in your advertising columns.

Photographers are not slow to give information to each other, and as some hundreds of my instrument have gone into use, its value is now being weighed in the balance.

Hereford, Nov. 1st. ALFRED WATKINS.

A PROPOSED CAMERA CLUB FOR SOUTH LONDON.

SIR,—For some time past the North Surrey Photographic Society has been making efforts to establish a Camera Club in South London.

A scheme has now been formulated which promises to be an entire success, provided we can obtain a fair amount of support and co-operation from amateurs residing in the neighbourhood.

It is proposed to take premises which shall include a large meeting room, commodious dark rooms, library, enlarging rooms, &c., with arrangements for the supply of refreshments and eatables.

A club founded on these lines, while offering all the advantages of a social club, would also provide for the carrying on of photographic work by members who wished to take advantage of it; while its promoters believe, from very careful estimates, that the whole expenses will be met by a guinea subscription.

The districts included in the scheme would be Norwood, Dulwich, Brixton, Herne Hill, Streatham, Sydenham, &c., the site of the premises to be as central as possible.

May I request any gentlemen willing to co-operate in such a scheme to communicate with me, so that a meeting may be called to set the matter in motion.

HAROLD SENIER, *Hon. Sec. N. S. P. Soc.*
88, *Norwood Road, London, S.E.*

[PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—On Tuesday, November 11th, at the Exhibition, 5A, Pall Mall East, at 8 p.m., the medals awarded will be presented; reports made of the Society's new premises and the proposed Photographic Institute; and a paper will be read on "Density Ratios as Affected by Development," by Mr. Chapman Jones, F.I.C., F.C.S.

Proceedings of Societies.

THE CAMERA CLUB.

ON Thursday, October 30th, an exhibition of lantern slides was held at the Camera Club, and members and friends brought over 200 slides for the occasion. A varied exhibition was the result. Mr. Williams contributed landscape scenes; Mr. White and Mr. Lardeur, microscopic subjects; Mr. Griffiths, some effective subjects taken in East Anglia; Mr. Howlett, pictures including an excellent view of the Houses of Parliament; and Mr. Chaug, hand-camera views; other slides were contributed by Messrs. Laurie, Greene, Sands, and Wellington.

The subject on Thursday, November 13th, will be a demonstration of the primuline process by Messrs. Green, Cross, and Bevan.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

October 30th.—Mr. A. HADDON in the chair.

The HON. SEC. announced the receipt of a prospectus of a Photographic Exhibition, to be held in Vienna during the months of April and May next, under the direction of the Vienna Club of Amateur Photographers.

Mr. C. J. ALDHAM showed some photographs of Indian life and scenery.

Mr. W. E. DEBENHAM read a paper entitled "The Unnaturalness of Naturalistic Focussing" (see page 862), and illustrated his remarks by diagrams on the black-board.

Mr. P. EVERITT said that by using an $\frac{1}{8}$-inch stop, as advocated in the paper just read, a different picture was obtained from that seen by the eye; the aperture of the eye was not used for definition, but to limit the quantity of light. He contended that Mr. Debenham had approached the subject from an optical point of view only, which was likely to lead to error and confusion.

In reply to Mr. Debenham, a paper was read by Mr. A. COLLIER (see page 870).

Mr. T. BOLAS said that, in estimating the merits of a photograph, the judgment should not be influenced by the size of the diaphragm used when taking the picture. Fine art was the absolute manifestation of the perfectly unfettered mind; it ceased to be fine art when conventionalism or commercialism stepped in. Emphasising the leading feature in a picture rendered it more pleasing, and was the aim of the artist. Remarking upon the quickness of accommodation of the eye to give maximum sharpness in various planes, he proceeded to draw a comparison of the performance of a lens and that of the eye.

Mr. EVERITT contended that the parallel referred to, between the lens and the eye, was not complete. He produced a piece of thin card with a pinhole pierced in it; by placing this close to the eye the print of a newspaper was rendered visible at a very close range.

Mr. NEWMAN said that the artistic mind frequently had a difficulty in reconciling optical laws and rules; generally it was the aim and practice of a photographer to give definition in all the planes of his picture.

An animated discussion followed, in which many of the members took part.

It being past the usual hour for closing the meeting, it was decided to continue the discussion at the next weekly meeting.

THE LANTERN SOCIETY.

AT the second meeting of this Society, held on Oct. 27th, Mr. LOUIS FAGAN gave a lecture on "Wood Engraving." Speaking of its history, he said it was known in very early times in the East, and was probably first practised by the Chinese. The epoch of its introduction into Europe was unknown, but it was probably introduced by the Saracens. One of the earliest uses to which it was put was in the manufacture of playing cards, and there were shown on the screen slides of some remarkable cards which were cut by a French artist, and which were discovered in Peterborough Cathedral. Several slides were then shown of early specimens of wood engraving; amongst them was one of St. Christopher carrying the

infant Jesus across an arm of the sea, by a German artist, dated 1483, and a most superb specimen of the celebrated Psalter of Faustus, which was printed from blocks on vellum, and of which only seven copies are known. The lecturer then proceeded to explain the method of "cross hatching," showing a magnificent example from the frontispiece of a book published in Mentz in 1486. Slides of chiaroscuro drawings were next shown, and the method of printing from different blocks to obtain the finished result explained. Speaking of Albert Durer, Mr. Fagan observed that he transformed the art of wood engraving, and several very fine specimens of his work were shown on the screen. Two very remarkable slides were shown of the frontispiece of the "Great Bible," printed by order of Henry VIII. The first of these has on it two coats of arms, one of them being that of Cromwell; in the second, the arms of Cromwell have been removed, leaving a white patch on the picture, he having been charged with treason during the interval between the publishing of the first and second blocks. Mr. Fagan concluded by showing examples of the work of Holbein, including some beautiful slides of the "Dance of Death," the finest work of art of its period.

Yarmouth and Eastern Counties Photographic Society.

The first monthly meeting of this Society was held in No. 3 Room of the Friendly Society's Hall, Middlegate Street, on Tuesday evening last. The President (Mr. Arnott) occupied the chair.

The first business was the confirmation of the action taken by the Secretary in securing the room in which the meeting was then held. Such a course had become necessary in consequence of the high charge made by the Corporation for the use of the supper-room in the Town Hall.

After several new members (including Sir Henry Tylar, M.P.) had been proposed and elected, the President read a paper entitled, "Elementary Photography," in which he not only touched upon points necessary for a beginner to know, but upon others with which the more experienced amateur should be familiar. A good discussion followed.

It was agreed that the meeting to be held on the 2nd of December should be devoted to the exhibition of lantern slides prepared by members only.

The Bath Photographic Society.

The first ordinary meeting after the recess was held in the new lecture hall of the Royal Literary and Scientific Institution on October 29th, Mr. W. Pumphrey in the chair.

Mr. F. J. Saunders was elected a member of the Society, and the election by committee of Miss Pearcey and Mr. A. Hinton Jones was confirmed.

Mr. Friese Greene then read a paper on the subject of a new machine for rapidly printing by means of photography (see page 868). The machine and the work done by it were examined with great interest.

Mr. Friese Greene also exhibited two novel forms of flash-lamps, in which successive charges of magnesium were fired with ease and certainty. Whilst Mr. Greene was speaking, a member photographed the auditory during one of the flashes.

The Chairman thanked Mr. Greene for his paper and trouble in bringing the machine down from London that evening. He (the Chairman) was amazed to hear that positives might shortly be obtained therewith from positives.

The secretary (Mr. W. Middleton Ashman) asked the lecturer the speed value of the films, and the light used in producing the pictures shown. He also wished to know how primuline compared in sensitiveness with the silver haloids, prepared for a high degree of sensitiveness to light.

Mr. Greene used gaslight for printing the band, and the sensitive surface was most rapid. Primuline was vastly less sensitive; perhaps what he obtained with silver bromide in a fifth of a second would, with primuline, require thirty seconds or more.

Mr. C. H. Talbot showed some early specimens of his father's work previous to despatching same to the Edinburgh Society. He also presented a copy of Fox Talbot's "Photogenic Drawing" to the Society.

The Chairman handed two handsomely bound volumes of a photographic journal to the secretary as a contribution to the Society's library.

Messrs. J. Dugdale and Davis then showed, by means of the oxy-ethyl limelight, a large number of transpareucies. The disc was about 11 feet in diameter. The subjects included a small series of local pictures, negatives and transpareucies, made by Mr. H. P. R. Wells, on bromide plates; a series of wet collodion transparencies, made by Mr. Dugdale, from negatives taken at the Society's outings during the past summer; also a series of Mr. Dugdale's slides (plain and coloured), illustrating places at a distance. Altogether about 170 slides were shown in little more than an hour.

The Sheffield Camera Club.

A lecture on Norway was given, under the auspices of this Society, on the 29th of October, in the rooms of the Club, by Mr. W. Lamond Howie, F.C.S., of London. The subject was entitled, "Ten Days on the Hardanger." The lecture was illustrated with a series of views photographed by Mr. Howie, and exhibited by a powerful oxy-hydrogen light, and embraced street scenes, many examples of the grander scenery—glaciers, valleys, mountains, waterfalls—as well as characteristic native costumes, and also interiors of dwellings and customs of the inhabitants of the Land of the Midnight Sun. A number of slides illustrating the journey to the Vozingfos reproduced vividly the difficulties of travel on these rugged valleys, and culminated in a view of the rainbows which form in the spray of the great fall.

The Oldham Photographic Society.

The following are the officers of the above Society for 1890-91, elected at the annual meeting held October 31st, in the Oldham Lyceum:—*President*—Mr. Tom Heywood; *Vice-President*—Mr. Wallace Thompson; *Treasurer*—Mr. William Schofield; *Committee*—Messrs. James Brooks, John Chadwick, Edward H. Dixon, John Fullalove, John Greaves, Jun., and William Jackson; *Librarian*—Mr. James H. Prestwich; *Hon. Secretary*—Mr. Thomas Widdop, 16, Burnaby Street, Oldham; *Assistant Secretary*—Mr. William A. Nash, 23, Queen's Road, Oldham.

The twenty-third annual report was read. The treasurer's account showed a balance in hand of £16 12s. 7d. During the past year each member has been presented with a 15 by 12 platinotype print, entitled "My Mammy," the work of Mr. Winter, of Derby. The average attendance at twelve monthly meetings has been about thirty-five members. The Society, during the past year, has lost one of its oldest members, Mr. George Hall, who, during his twenty-three years' membership, occupied the various offices of president, treasurer, and secretary, and was one of the founders of the Society in 1867.

The Liverpool Amateur Photographic Association.

A meeting was held on the 30th of October in the Club Rooms, 3, Lord Street. Mr. Paul Lange presided. Messrs. Robt. Thomson, Alex. Sinclair, A. Quayle, and Rev. W. Smith were elected members, making in all forty-six new members this year.

Mr. John Howson then read a paper on the working of "Alpha Paper," in which he treated on the following points: Objections to developing papers disproved; choice of colours and choice of surfaces of papers; necessity for care in exposure; permanency; latitude, modifications to produce best results from certain negatives; hints on toning; and concluded with a demonstration, in which a number of prints was made from various negatives. Mr. Howson stated that many people said that half-tones were lost with this paper, but the productions that evening had proved that this was not so. The emul-

sion on paper and plates was the same, and any colour could be obtained in the toning, which was with the ordinary alpha paper touing bath. Exposure should be made by scale, and not by guesswork. The burner used was an argand two-light at a distance of ten inches. After developing, the prints were placed in an acid bath without previous washing, then thoroughly washed and toned, and fixed in the combined bath such as used for aristotype papers.

The proceedings closed with the exhibition of the new Boston (U.S.A.) Camera Club's set of slides, entitled "A Ramble in and about Columbus" (Ohio), the lecture being given by Mr. J. A. Sinclair. A set of slides taken on alpha plates was thrown on the screen, and Mr. Paul Lange's "Channel Fleet" studies ended the show.

THE PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

A MEETING of the Society was held on Wednesday evening, October 1st; the president, Mr. JOHN G. BULLOCK, occupied the chair.

It was resolved that the agreement heretofore existing between the Society of Amateur Photographers of New York, the Boston Camera Club, and the Photographic Society of Philadelphia, to hold annual joint exhibitions of photographs, be hereby cancelled, and in place thereof it is agreed that each organisation will hold a public exhibition of photographs, open to all photographers of the world, every third year. These exhibitions are to be held annually in rotation in each of the three cities, as before, but each exhibition will be under the entire control and management of the society holding the same, and under such rules at it may adopt. Each society further agrees that it will not hold any public and open competitive exhibition except in its regular turn, as above, without the consent of the other two societies.

Mr. STIRLING, for the executive committee, reported the receipt of a fine collection of photographs, the work of Mr. H. P. Robinson. The pictures had been hung on the walls of the meeting room, where they would remain on exhibition throughout the month of October.

The PRESIDENT mooted the subject of a communication which had been received from the Syracuse Camera Club, about the holding of a convention of amateur photographers. After a brief discussion, Mr. Coates moved to refer the matter to the executive committee, with power to act.

Mr. CARBUTT gave a brief account of his recent trip in Europe. He had given most of his attention to sight-seeing. In London he had noticed that the tendency in cameras seemed to be towards hand-cameras rather than stand cameras. He had seen several cameras to hold plates in magazines in London, and several on the Continent. He had brought two or three home, and would show them at some future meeting. In Scotland, the work he saw by professionals in Glasgow and Edinburgh was remarkably fine. A great deal of attention was being given to the production of pictures in platinum. In Edinburgh the pictures by Lafayette were among the very best in photographic and artistic excellence. The pictures were no doubt worked up with India ink, but there was a softness, yet force, about them rarely seen in photographic prints. In London he did not see much in the way of improvements in pictures. Platinum was being used there to a considerable extent. The technical quality of the work did not come up to the best class of work in America. The pictures in Paris, Geneva, Vienna, and Berlin portrayed a great deal of artistic feeling in the drapery and models. Many, in producing these, do not give the same care to the technical parts of their pictures as Americans. On the journey from Paris to Munich he had encountered rain all the way. At Lucerne he made an exposure in the rain while his son held an umbrella over him. He went up the Rigi, and made one or two exposures of the shivering mortals who were there waiting for the sun to rise. In Vienna he made a few exposures among the markets. The amateur photographers in Vienna have a very large, flourishing society, and are doing a great deal of investigating work. They meet once a month for regular work, and have a social meeting every Saturday night.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

B. G.—*Permanence of Diazotype Prints.* This point was discussed at the meeting of the Society of Chemical Industry on Monday last, but the evidence is not yet quite conclusive. There seems to be good reason for believing they are fairly permanent, but one of the members brought up a specimen to show that, under some circumstances, they were affected by light. With the new developers improved results have been obtained, and it will now be necessary to try these also; the winter season is not, however, a favourable time for such trials. We have not seen the article to which you refer.

REX.—*Studio Particulars.* The size, 18 by 7 feet, is rather small, and the district surveyor may require you to limit these dimensions still further by keeping a certain distance within the party walls. Of course, your apparatus and lenses must be in proportion, and backgrounds of the simplest character. We can hardly give you an estimate off-hand, but, with a trade catalogue, all the needful accessories could be priced so as to get a rough idea of cost.

J. P. (Oxon.)—*Sulphite as Preservative.* When you add nitric acid to sodium sulphite, an equivalent quantity of sulphurous acid is undoubtedly liberated, and this will act as a powerful preservative. The best condition would be insured by adding the acid in such proportion that not the whole of the sulphite, but only part of it, should be decomposed.

W. J. (Bolton)—*Vignetting in the Camera.* To take a portrait negative bearing its own vignette, the method of exposing with a movable screen in front of the sitter has been sometimes resorted to. The flat surfaces should be painted black and white, so that it may be turned round to get different effects, and always kept slowly moving when in use.

B. PHILLIPS.—*Black Tones in Printing.* These may be got as easily with the borax or acetate bath as by any other formula. The whole point consists in pushing the toning process beyond the chocolate stage, either by using a full dose of gold, or allowing a longer time. Twenty grains of acetate of soda, and one grain of chloride of gold, in about eight ounces of water, are the usual proportions.

L. T.—*The Photographic Exhibition.* Wednesday next, 12th inst., will positively be the last day for visiting the Pall Mall Gallery. It is quite worth a journey to come up and see it, if you have any regard for your art education.

PAT.—*The Kodak in Court.* It was not so much the use of the camera, as the attendant circumstances, which gave offence. Write out your views and send a communication to the Editor. There was no need for the counsel to take the portrait, but anyone near him could have done so. We cannot very well discuss it in this column.

H. S.—*Chemical Formula.* They are the same substance although expressed by different formulæ; you must remember that the atomic weights of oxygen, sulphur, &c., have been doubled.

LIVERPOOL PHOTOGRAPHIC EXHIBITION.—The arrangements for the triennial Exhibition are reported to be making good progress. The Exhibition will be held in the Walker Art Gallery, the use of which has been granted by the Liverpool Corporation, the same suite of five rooms as was used in 1888 having been secured. The opening is fixed for Friday, March 6th, 1891. Full particulars will be duly advertised. The judges will be Capt. Abney, Messrs. J. Gale, H. P. Robinson, A. W. Pringle, J. P. Gibson, and Watmough Webster.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1680.—*November* 14, 1890.

CONTENTS.

PHOTOGRAPHIC AIDS TO SCIENCE.

A LETTER in another column from Mr. Osmund W. Jeffs, secretary to the committee of the Geological Section at the British Association at Leeds, forms one among many other examples which can be brought forward of the daily increasing demand for photographic aid in scientific research and scientific teaching. This fact was never more prominent than at the Leeds meeting of the British Association, when that organisation gave more time to photographic subjects than it has ever devoted before.

In the Geological Section, throughout the week of the meetings of the Association in Leeds, an exhibition of geological photographs was open to the members, and it was probably the first exhibition of the kind which has ever taken place. The movement was started by the Yorkshire Naturalists' Union, which formed a section, with Mr. J. E. Bedford as secretary, to take the work in hand. Yorkshire contributed about one hundred of the photographic views of geological subjects, all of which were on view in the Exhibition. Other contributions were sent in from other counties, and Mr. Jeffs was particularly energetic in the promotion of the work. The idea is to obtain pictorial records of temporary geological sections, which sections may be lost by falling in, or by getting covered with herbage, or by removal—as in the example, for instance, of stone quarries. About two hundred geological photographs altogether were on view, mostly of somewhat large size; a few of them had been turned out by the collotype and other permanent processes. One of the most remarkable consisted of the broken stems of large trees fossilised, which had been laid bare by excavation. The upper parts of the trees had all been cut off ages ago by some of the forces of nature, but the remainder of the stony park is now open to the light of day. The late Lieut. Frederick Ruxton, who passed much of his time in the Wild West with trappers, all in constant danger of their lives from attacks by hostile Indians, narrates how one of the trappers, Black Harris, was not noted for veracity, and in narrating his adventures to a lady in civilised regions, added: "And scalp my old head, marm, but I've seen a putrefied forest!" "La! Mr. Harris," was the rejoinder; "did the leaves and the trees smell badly?" "No, marm," said Mr. Harris, condescendingly; "would a skunk stink if he was froze to stone?" Had Mr. Harris seen the tree stumps represented in the photograph, he would have been nearer the truth than was his intention.

The Geological Committee wants photographic societies to aid it in its work, but so far has not received much assistance from them. The Leeds Photographic Society, and the Thoresby Society (Antiquarian) have appointed a joint committee to photograph old houses in Yorkshire; some step of the same kind might be taken for the production of pictorial geological records.

In the new Observatory near the top of Mont Blanc, the meteorological conditions of that high region are, during the summer months, registered by self-recording mechanical instruments, which can be visited occasionally by assistants. Photographic self-recording instruments are not used, we learnt at the British Association, because they are so costly in the first instance; it is admitted that they do slightly better work than the others. The Observatory was constructed at Chamounix, and put together on the mountain. It cost only £32, but other expenses brought it up to £400. The apparatus it contains will go on working by itself for fifteen days, thereby recording information as to what meteorological changes go on there at an elevation of three miles. Mr. Rankine, the founder of the Blue Hill Observatory in America, has taken several photographs of the Observator near the top of Mont Blanc.

Professor Rowlands, of the United States, exhibited to the Physical Science Section of the British Association a photograph of the spectrum twenty feet long, the length of the original negative. He has been for some time working on the spectrum, chiefly in relation to exact measurements of the solar lines, and he publicly stated that the presence of silicon in the sun had been determined chiefly by photography. There is silver in the sun, and beryllium has quite recently been discovered there; it is doubtful whether uranium is present.

One morning, in the Physical Science Section, Dr. J. W. L. Glaisher, the president, drew attention to some large photographs on opal plates by Mr. Friese Greene, representing the sun and clouds; he said that the photographs were of an exceedingly beautiful description. Mr. Glazebrook stated that the direct negatives of the sun had been taken through yellow glass, and Mr. Symons said that they were equal to the best photographs he had seen. He stated that once an exceedingly curious photograph had come under his notice; the roof of a house had been raised by the wind, and the end of a flapping window-blind then came between the top of the house-wall and the raised roof; the latter fell back into its place, and the end of the window-blind was left sticking out between the top of the house-wall and the bottom of the roof. This result was photographed.

As a closing instance of the increasing use of photography to science, as exemplified at the last British Association meeting, it may be stated that the Committee of the Physical Science Section recommended the managers of the Association to appoint a Committee on Astronomical Photography, and this, we think, has since been done.

SENSITISED PHOTOGRAPHIC SILK.

A LITTLE paragraph recently published in these pages about the introduction into the market of some photographically sensitised silk, brought forth a number of letters of inquiry, in some of which the writers stated that, for several years past, they had been unable to purchase any anywhere. Years ago it was obtainable. Last week we received specimens of the prepared silk from the makers in Paris, and we believe that it is now sold by several English dealers. The manipulations of the prepared silk in the printing operations are so much the same as those of printing upon ordinary ready-sensitised paper, with the exception that the toning bath is of half strength, that there is really nothing to say about them. The results we have obtained with the silk are good, and elegant in appearance.

The manufacturers of the prepared silk, on "the Tisseron system," now under notice, say that, if protected from light and moisture, it can be preserved several months. It is of three colours—white, light blue, and pink—and the back of each piece is marked with pencil. The prints are fixed in a one in ten parts newly-prepared solution of hyposulphite of soda, in which the prints are left for ten minutes. They have next to be washed for some hours in water, and left to dry; then to be damped and gone over with a hot iron. When it is desired to paint the resulting prints with water-colours, the latter should be used with five parts of alum dissolved in a thousand parts of water.

The silk is said to print more rapidly than ready-sensitised paper. The samples sent to us do not do so to a noticeable extent; but comparative experiments might, perhaps, indicate a difference.

LANTERN SLIDE MAKING.

ALL men have their own theories and pet methods of working, and among photographers the rule certainly holds good, for very few among them will agree upon the precise formula by which development, or any other operation, is best brought about. In no department of photography, perhaps, is there greater divergence of opinion than there is concerning the best process for producing transparencies for the optical lantern. Old workers will—perhaps naturally—pin their faith to the wet process, and will assert that no other method will give such uniformity and certainty of result, and as proof of what they say they will point to the circumstance that the best known producers of commercial lantern slides hold fast to the old process. This does not necessarily prove that the wet process produces the finest results, although it is strong evidence that it is so reliable and certain in its practice that the work can be left to assistants who are rule-of-thumb men rather than experts.

The collodio-bromide process has also a large number of worshippers, and it must be at once conceded that this process is capable of the very finest work in the way of lantern slides. It is, however, a far more difficult process to work than the wet collodion method, and involves so many operations and so much care, that the printing of a dozen slides by its aid is quite a serious undertaking, involving the expenditure of much time. In making this statement, we are supposing that the worker has his emulsion ready-made, but that he edges, coats, dries, exposes, and develops his plates. The old albumen process also has its votaries, and it certainly possesses advantages which are not common to other photographic methods, in that the finished film is as clear and nearly as hard as glass, and is practically imperishable. A worker with this process whom we know told us that he once tried the experiment of submitting a gold-toned albumen slide to the heat of a muffle, with the result that the image was actually burnt into the glass. But no one can attempt to make slides in albumen unless he is an ardent experimenter, and is content to make his own plates, from the cleaning of the glass to the finished picture. Their beauty and lasting qualities are undeniable, as anyone is aware who has in his possession some of the orginal stereoscopic pictures by Ferrier, of Paris, which had such a large sale about a quarter of a century back.

But we are all in such a hurry in these more modern days, that we are apt to lose patience unless we can see results rapidly growing under our hands. The old type of experimental worker is well nigh defunct, and his place knows him no more now that every want is met so rapidly by our energetic manufacturers. It seems only the other day, although it is quite eight years back, that a small controversy had arisen round the question whether it were possible to produce a good lantern slide on a gelatine plate. A few ardent workers who made plates for themselves of the right quality answered this question unhesitat-

ingly in the affirmative, and proved, by the excellent pictures which they exhibited, that they were right. But the great majority who tried what could be done with ordinary plates made for negative work showed only dull and flat pictures with dirty high lights, and at once said that gelatine was no good for this class of work. At last the demand for a good lantern plate put the makers upon their mettle, and plates for lantern slides began to be an article of commerce, for which an enormous sale was at once secured. Hundreds of workers have since proved that these plates will give beautiful pictures, but they require care and common sense in their manipulation. They are certainly the very best plates for those who only want to make a transparency occasionally, for they can be purchased ready-made, and their exposure and development are very rapid affairs.

Two sorts of lantern slide plates are now in the market, one being coated with a bromide of silver emulsion, and the other with chloride. The makers do not all state by which process their plates are prepared, but there is no difficulty in distinguishing the chloride plate by its translucent film, and by the orange colour which it has by transmitted light. We ourselves prefer this description of plate to the other, as we believe that it is, on the whole, easier to manipulate, while by altering the developer a wonderful range of tones can be obtained in the finished picture. But it will only yield the best results if the exposure be made to daylight, for the emulsion is very insensitive to artificial light. Chloride plates are also unsuitable for copying work in the camera, when a larger negative has to be reduced to lantern plate size. For these reasons the bromide lantern plates have by far the larger number of admirers, especially among amateurs who have no daylight to devote to the making of lantern slides. The work has a great fascination about it, and there is no cause for wonder that it should have become so popular. Not only are the manipulations full of interest, but the finished result, when projected by the lantern on a screen, shows off the beauties of the original negative in a manner with which no other printing method can compete.

The Year-Book.—We have to thank the numerous friends who have kindly sent us articles for the Year-Book for 1891, now in the press. So many articles of good quality, by the best writers connected with photography, have been received that the number of pages of literary matter in the book has been considerably increased. Among the illustrations is a picture of the developing room at the Royal Institution; some of the others are produced by recent improvements in certain photo-mechanical processes.

The Decimal System in London Schools.—Some time ago a memorial on the decimal system was presented to the London School Board by the Decimal Association. The Board have now informed the Association that, on the recommendation of the School Management Committee, they have asked the Education Department to modify Schedule I of the new Code, so that decimal fractions shall be taught in the fourth standard at latest, and the metric system of measurement and weight be included in the teaching of the fourth and upper standards. The School Management Committee of the Board have also decided that models, illustrating the metric system, shall be added to the Board's requisition list in the event of the Education Department accepting the proposal of the Board.—*Nature*.

THE PRODUCTION OF STEREOGRAMS ON GLASS.

BY H. E. GUNTHER.

At the present time, when the stereoscopic picture, a most beautiful and realistic reproduction of nature, is being revived and rendered popular again, a few words on the making of stereoscopic slides, or a communication of what has been found the most satisfactory and reliable mode of working by some of our ablest and most skilled workers in this branch of photography, will not, I am sure, be deemed out of place.

Two remarkable communications on the above subject have been published of late, the one being a description of some of the best processes, by Dr. Miethe, the other a paper read before the Berlin Photographic Society by Captain P. Kiss. On these two publications, which are most exhaustive, the following remarks are based.

The negatives are taken on gelatino-bromide plates of ordinary sensitiveness: for landscapes, however, erythrosine plates are used. They should be coated as cleanly as possible on not too thin glass plates, so that they can be easily cut with the diamond. The size of the plates used is 13 by 18 centimetres. The negatives should not be too hard, but it is of no consequence if they are slightly fogged.

As is generally known, the negatives are to be cut for printing; this is done in the usual manner, the two halves being then labelled with "right" and "left," so that in printing they cannot be changed. For printing the stereoscopic negative, gelatino-chloride plates with development are preferred by Dr. Miethe to the printing-out plates of the same kind, and the following formula, due to Professor Eder, is recommended by him as excellent and thoroughly trustworthy:—

Solution A.

Sodium chloride (dry)	14 grammes
Gelatine (hard)...	25 ,,
Water	200 c.c.

Solution B.

Nitrate of silver	30 grammes
Water	50 c.c.

Solution C.

Gelatine	25 grammes
Water	200 c.c.

Solution C is, at 122° F., poured quickly into solution B, solution A being then added at once. The emulsion is then vigorously shaken, and poured into a dish for setting. It is important that the emulsion sets quickly, this leading to a warmer tone in development, and, consequently, to a richer gold tone. A warm tone may also be obtained by adding to the emulsion from 10 to 20 grammes of citric acid. After setting, the emulsion is, as usual, squeezed through canvas, very thoroughly washed for at least two hours in running water, and filtered at 104° F. The whole mass is then poured on, at 122° F. Although, if poured on transparent glass, the emulsion looks exceedingly thin, it gives good density. The plates are printed by lamplight for forty to sixty seconds at a distance of one foot from an average paraffin lamp, or for two minutes by candlelight. The longer the plate is exposed, the redder will be the final tone, and, at the same time, the image becomes softer. The best developer for these plates is the following:—

Hydroquinone...	2 grammes
Sodium sulphite	8 ,,
Carbonate of soda	8 ,,
Water	500 c.c.
Sodium chloride	5 to 8 grammes

Fixing is done in a solution of hypo from 1 : 10 to 1 : 15. The plates are then again washed, and toned. For toning, the following method is recommended by Dr. Miethe as the only one giving good results:—

Water	... 1,000 c.c.
Ammonium sulphocyanide ...	... 20 grammes
Hyposulphite of soda	... 1·5 ,,
Chloride of gold solution, 1 : 50	10 to 15 c.c.

If the toning proceed too slowly a little more gold chloride may be added, but care should be taken not to add too much, because, in this case, an uniform purple tone is hardly to be obtained. The above toning bath keeps well. After toning, the plates are rinsed, dusted off with a soft brush, allowed to dry, and rubbed in with a rag on which a drop of linseed oil has been given. This renders the shadows of the image more transparent.

Of the above-described printing process with gelatino-chloride plates, Dr. Miethe says that it is as beautiful as it is convenient and reliable, and, from our own experience, we can confirm this. Captain Kiss, who prints his negatives also on gelatino-chloride plates with development, mentions that, in preparing the above-described emulsion, he takes two-thirds of soft and one-third of hard gelatine, which he soaks in distilled water for about one hour, then washing it in three or four changes of water; finally in distilled water. To 30 grammes of silver nitrate solution he adds 5 drops of diluted nitric acid (1 : 10 water). Before melting the emulsion, he adds 5 drops of diluted hydrochloric acid (1 : 5 water) to 30 grammes of silver nitrate.

During coating, the plates should be warmed up to 77° or 86° F. A plate of 8·5 by 17 centimetres requires 6 c.c. of the emulsion. Kiss observed that the prepared plates do not keep for any long time: after a lapse of a fortnight fog made almost always its appearance at the edges of the plates.

An original method of developing the gelatino-chloride plates has been worked out by Captain Kiss. In employing it, the toning process, which is always a rather tedious and difficult operation, may be entirely omitted; besides, it gives absolutely clear whites. This is of importance, inasmuch as, by the slightest trace of fog, the pictures will considerably lose in appearance. The formula recommended by Kiss is the following:—

Solution A.

Citric acid	... 60 grammes
Carbonate of magnesium ...	... 8 ,,
Carbonate of ammonia (in pieces)	... 26·5 ,,

are put in a glass cup, and covered with distilled water. This combination forming a freezing mixture, it is well to place the cup in luke-warm water. The solution of the ingredients, during which carbonic acid escapes, being complete, distilled water is added to make 240 c.c.

Solution B.

Sulphate of iron	... 28 grammes
Distilled water	... 96 c.c.

Citric acid, a small crystal 5 to 7 millimetres large.

Solution C.

Sodium chloride	... 5 grammes
Water...	... 150 c.c.

Solution D.

Hyposulphite of soda ...	... 1 gramme
Water	... 20 c.c.

To develop the stereoscopic picture, mix—

Solution A	... 45 c.c.
Solution B	... 15 ,,
Solution C	... 3 ,,
Solution D	... 1 drop

The addition of a very small quantity of hypo solution (solution D) has been found absolutely necessary in order to obtain an uniform tone; no good result is obtained without it. The resulting tone depends, however, as is known, much upon the time of exposure given, a short exposure leading to darker tones, a long exposure to brownish ones. If the developer is poured into a well-stoppered bottle directly after use, from four to five pictures may be developed in it in succession. Fixing is done in a hypo solution of 1:6 to 1:10. The plates are then washed for twelve hours in from five to six changes of water.

Plates of ground glass are usually employed in making the stereograms, the emulsion being applied to the smooth surface of the ground glass. As, however, it is difficult to procure well-ground, thin glass plates, at least unless a comparatively high price be offered, and other glasses, as, for instance, opal glasses, take off too much light, it occurred to Capt. Kiss to impart to the gelatine film of the stereograms a matt surface by squeezing them on to rough paper, rubbed in with talc powder, in the same manner as prints on gelatino-chloride paper may be rendered matt by squeezing them on talced ground glass.

The paper used for this purpose is a stout paper coated with a carbonate of calcium emulsion. It is rubbed in with talc powder, placed under water on the picture, and slightly pressed against it; after drying it comes off spontaneously, leaving the gelatine film with a matt surface. The paper can be used repeatedly. The following are the working details of the process.

Preparation of the Carbonate of Calcium Emulsion.—A. Soda Solution.—In 35 c.c. of water 37 grammes of chemically pure crystallised soda are dissolved, and the solution is gradually added with constant stirring to 21 grammes of gelatine (half soft and half hard) dissolved warm in 115 c.c. of water. B. Chloride of calcium solution.—9 grammes of gelatine (half hard, half soft) are dissolved warm in 50 c.c. of water, and 27 grammes of dry chloride of calcium are added to it and dissolved. The solutions A and B are allowed to cool down as much as possible, taking care, however, that they remain fluid. Solution A is then poured in small portions into solution B, the mixture being emulsified by shaking. After the scum has settled the emulsion is poured in a glass dish, and the latter is placed in cold water.

One of two methods may now be used. If a very fine grounding is desired, the emulsion, after setting, is freed from the adhering scum, then it is melted and filtered through a double layer of moistened cambric, which is tied up in the form of a pledget 2 centimetres wide, to a glass funnel. A part of the filtered emulsion is poured in a crystallising dish of about 12 c.m. diameter, the greater part remaining in a discharging pot. Both are placed on a warm plate. In the crystallising dish is put a flat brush about 9 centimeters broad. Meantime plates of finely ground glass have been rubbed in on the matt surface with talc powder and used hand-warm. In coating the ground surface of these plates with the emulsion, the flat brush full of emulsion is at first passed slightly over the plate, so that it is covered thinly, but all over, with emulsion, then the required quantity is quickly poured on, giving thereby to the cup a circular motion over the plate. The emulsion is then evenly distributed by inclining the plate, and the latter placed on a levelled marble or slate plate for setting. After setting, the plates are placed perpendicularly in a plate washing box, and, by repeatedly

changed water, freed from the salts contained in the emulsion.

According to the second method, the emulsion, after setting, is pressed to threads, and the latter are washed as usual, thoroughly dried, melted, and filtered, and coated as described above. After the plates have set, and after washing them, they are covered with the above-mentioned paper. For a plate of 13 by 18 cm., a sheet of mask paper measuring 20 by 25 cm. is taken; it is soaked in water, placed between blotting paper to free it from the superfluous water, and then gradually placed on the plate, beginning at one end, and taking care that air-bubbles are avoided; finally, it is slightly pressed against the glass plate with the squeegee. The projecting sides of the paper are folded on the back of the plate, and the plate is dried lying flat. When dry, the paper comes off spontaneously. The stereoscopic slide, after being sufficiently freed from hypo, is placed on a glass plate of 13 by 21 cm., and together with it laid in a trough filled with water. The paper, after being cut to the size of the glass plate, is rubbed with talc powder, well dusted, soaked in water, and under water placed on the stereoscopic picture, after the air-bubbles which might have formed have been removed by means of a hair brush. The glass plate, together with the stereogram and the paper, then being removed from the bath, the paper is slightly pressed against the stereoscopic slide by means of an india-rubber squeegee, and the sides of the paper projecting over the slide are fixed to the glass plate by laying strips of glass on the paper, and pressing them close to the glass plate by means of printing clips. The stereogram is then dried *lying* and at a place free from draught. After drying, the paper comes off, and the stereogram shows a mat surface. It is then provided with a covering glass plate and bound up as usual. The pictures produced by this process have the characteristic property that they appear equally sharp whether they are examined from the front or from behind.

I trust these few hints derived from the papers of Dr. Miethe and Capt. Kiss will be of use to those who, like the writer, are equally enthusiastic votaries of the stereoscope.

Impurities in Alcohol.—Pure alcohol is desirable for various operations in photography, and Dr. E. Walker, in the *Journal of the American Chemical Society*, has pointed out a hitherto unsuspected source of impurity. He finds that if it be kept for some time in tin cans it slowly reacts on the tin, giving after a while a cloud of oxide of tin so fine that it cannot be filtered out. Vessels of stoneware or glass should therefore be employed for storing alcohol.

The Liverpool Amateur Photographic Association.—The tenth ordinary meeting of the twenty-seventh session opened yesterday at the Association's club rooms, Crescent Chambers North, 3, Lord Street, Liverpool, when Mr. John Howson read a paper on the working of alpha paper. As regards the Association's prize competition for 1890, prizes consisting of silver and bronze medals will be awarded at the annual meeting in November for best and second best series of six pictures, without restriction as to choice of subject, for sizes half-plate and under, and over half-plate respectively; for best and second best series of two enlargements; and for best and second best series of six lantern slides. All work must have been taken during the year preceding the adjudication, and the negatives, development, printing, toning, and clouds (if any) must be the *bonâ fide* work of the competitor. For full rules, see the annual report. The following is the prospective programme of practical demonstrations on lantern slide making:—Nov. 12th—Mr. Isaac Knott, wet collodion process; Nov. 26th—Mr. Paul Lange, printing-in of clouds in slides; Dec. 10th—Mr. W. P. Christian, toning of lantern slides.

IS BLURRING DESIRABLE IN A PHOTOGRAPH?*

BY W. E. DEBENHAM.

In the paper on "The Unnaturalness of Naturalistic Focussing," read last week, it was pointed out that the desirability, as a matter of taste, whether occasionally or generally, of representing objects in the camera with the blurred definition of a lens out of focus, is a point that may be fairly argued, even though it may be demonstrated that such blurring does not represent the image of nature impressed upon the retina.

The question arises, What are the advantages, real or supposed, to be obtained by means of blurring the picture in whole or in part? A claim which has been put prominently forward is that, by placing all but the principal object in a picture out of focus, attention is attracted to that object, and it is recognised as the leading feature. Now, as a matter of fact, does the fineness of detail in any part of a picture cause that part to strike the spectator with the prominence implied by this argument? It does to some extent, probably; but the idea that fine detail is so potent in attracting attention, causing the part where it is present to be recognised as the leading feature of the composition, is probably due to the confounding of fine detail with decision of outline or harshness, both happening to be described by the word "sharpness;" photographers understanding detail by the term, whilst painters use it in the sense of decision of outline. If the part of the picture which is the sharpest photographically—being in best focus, that is—is thereby really made so predominant, we must take it that in Dr. Emerson's "Barley Harvest," the corduroy trousers and hobnailed boots of the sitting figure constitute what Mr. Everitt calls the *motif* of the picture. The sharp contrast between the faces of the figures and the sky will, I think, be generally felt to lead the eye to that part of the photograph rather than to the boots, although the faces are not, photographically speaking, so sharp—not so finely detailed, that is—as the hobnailed soles of the boots.

The difference between the two senses in which the word "sharpness" is used, which was pointed out in the previous paper, is illustrated in this photograph. The corduroy trousers of the sitting figure close to the boots are in good focus, finely defined, and, therefore, what a photographer calls sharp. The upper part of the figures and the scythe stand out sharply, as a painter would say, against the sky; and although not in the best focus, and, therefore, photographically not so well defined or "sharp" as the trousers, are more immediately striking as the leading theme of the picture.

A real gain that may arise in some special cases from the use of such a large diaphragm as to throw part of the picture out of focus, is when some foreground object has its outline obscured by lines in the background. Suppose the case of a horse with foliage behind. In nature we have the help of colour to enable us to separate the one from the other, but in the photograph the leaves and twigs are in places so much of the same depth of tone, that the outline of the animal is either partly lost, or, at all events, requires to be looked for. Now there are several artificial means which may be adopted quite legitimately to separate more distinctly the foreground object which we wish to represent from the background. One plan is to light a fire where the smoke will blow between the two planes, and thus dim the lines of the background.

---

* A communication to the London and Provincial Photographic Association.

Another artifice that may be employed is to use the so-called naturalistic focussing—to use, that is to say, a stop large enough to put the background much more decidedly out of focus than it is seen by the eye to be. This method, indeed, will most likely be employed without the special intention mentioned when photographing anything so restless as animal life.

Other cases where advantages may be claimed for an out-of-focus representation, are where it is desired to idealise, as, for instance, in portraits or studies from the life, when the irregularities and asperities commonly existing on the skin are felt to be blemishes that it would be better not to include in the picture. There is no doubt, too, that we often see these skin marks more prominently in the photograph than in nature. The more perfect is the photograph in lighting and half-tone, the less will such asperities obtrude themselves, and it is, of course, open to argument that the crudeness and harshness due to imperfections of the photograph are more objectionable than the absence of the fine definition seen in nature, and that if losing the detail will enable us to obscure the harshness, it is legitimate to do so. The use of orthochromatic methods, and greater perfection in the photographic registration of half tones, will help to overcome the objection to detail, although, of couse, where it is desired to idealise, and to obscure what are considered to be defects in the original, artificial means of some sort must be resorted to, and throwing the image out of focus is one such means. In subjects of a portrait character, we find that artists more frequently avail themselves of the licenses both to use a certain amount of blurred definition in the subject, and a good deal of indistinctness in the background, than is customary in landscape and other paintings.

A departure from perfect definition of an opposite character to that implied by differential focussing was introduced by Professor Petzval in 1859. He showed how, by separating the components of the back lens of one of his combinations, the sharpness of the focal plane was destroyed by the spherical aberration thus introduced, and that out-of-focus planes not having sharp ones to contrast with, the blurring that existed in them did not strike the eye so prominently. He was careful, however, to describe this quality, which he called depth of focus—using the expression, however, with a different meaning from that of increased definition now generally understood by it—as an imperfection of the lens, and gave no countenance to the idea that there was any real gain of detail in the out-of-focus planes, but only an apparent gain by absence of contrasting sharpness anywhere. This line of argument has also been adopted by Mr. W. K. Burton and others.

Pinhole photography is another way—quite opposite to differential focussing—of obtaining a blurred effect. If the pinhole is small, the blurring is small also, and in a large photograph may be scarcely noticeable at all. A good deal may be said in favour of pinhole photography, particularly on the ground of the equality of definition all over the picture, and absolute freedom from distortion. An objection, of course, exists in the length of exposure necessary, but this does not come into the present discussion.

With respect to the image given by the pinhole, Mr. T. R. Dallmeyer, in a paper read at the Camera Club Conference, started a very strange proposition to the effect that the image given by it tended to exaggerate foreground objects. Dr. Emerson, in "Naturalistic Photography," had very justly observed that "the drawing of pictures taken in such a way would obviously be correct." He now appears, however, to have assumed that there was some foundation of scientific fact for Mr. Dallmeyer's proposition, for in *Photography* of August 21st last he writes that "the 'pinhole' picture is inadmissible, because the smallness of the aperture falsifies modelling and perspective."

When we are told that the details in all but one plane of the picture are too finely defined in photographs generally, and that it is more artistic to have them decidedly out of focus, we are naturally led to look to the works of recognised artists—painters and draughtsmen—to see how they represent nature. We then find that, with the exceptions before mentioned, painters generally give us a fineness of detail throughout the picture which we cannot in most cases rival in the photograph except near to the focal plane, simply from the fact that the use of such a small stop as would be required to imitate in this respect the handiwork of the painter would necessitate too long an exposure.

Take as examples familiar to photographers the photogravures of paintings now on exhibition at the Pall Mall Gallery. In the "Al Fresco Toilet," by Luke Fildes, we see not one face, but all the faces and figures, and not merely these, but the background, and even the vine leaves in the corner, so well defined that, if a photographer were to try to get equal definition in a study of figures similarly arranged, he would have to use such a small diaphragm that the lengthy exposure would almost certainly involve movement of some of the subjects. Take the painting of "Diana or Christ?" by Edwin Long, R.A. Will any one pretend that if he had a group of figures and natural background—the living scene, in fact—thus arranged, he could use a small enough stop in his lens to get the figures throughout so well defined as they are in his painting? Then look at the landscape by R. W. Leader, A.R.A., and see whether the definition throughout is more like that of the "naturalist" or of the photographer who tries to get as good focus as he can throughout the picture. These paintings are not exceptional in respect of detail, but represent the great majority of work of the best painters—subjects of a portrait character excepted—as before mentioned. If, therefore, Dr. Emerson is right in condemning the photographers who get what definition they can throughout the picture, he also condemns the painters whose work we naturally look to as ideals for photographers to imitate artistically. It is not to the point to say that photography will define more minutely than artists paint. This argument only applies to the part in focus, and does not apply to the great part of the picture, which, according to "the naturalist" contention, should be more or less out of focus. Moreover, although at the one plane the representation may be more minute in detail than the painter would think it worth his while to imitate, the difference in this respect is not necessarily either an objection, or even noticeable at ordinary viewing distance.

The fine definition of details in parts not desired to be prominent is often spoken of as though prominence was mainly due to the presence of fine detail. This is not necessarily so, and it is, indeed, generally speaking, due to the character of lighting or amount of exposure rather than to focus that details become objectionably prominent.

Criticism of particular pictures is distasteful and not conclusive, because a principle may be right or wrong,

independent of the character of individual results. Dr. Emerson, however, so challenges criticism by such statements as this is just as it should be, that one may be excused for specifying what seem to us to be faults in the models he puts before us. With regard to the photograph, "Where Winds the Dyke," one of our members, at a former meeting, remarked that if the lower part of the picture were covered, it could not be told what that which does duty for a tree was intended to represent. With such criticism possible, it certainly seems to be juggling with words to say that out-of-focus effect must be used, but not to the extent of interfering with structure. The "Marsh Pastoral" is certainly a pleasing picture, but rather, I think, in spite of that out-of-focus characteristic of one side of the picture than in consequence of it. If the sheep to the right of the picture had been in better focus, I believe the picture would be better, and certainly more like paintings such as those of H. M. B. Davis, for instance. Taking the work of painters generally, do not the photographs of Gale, England, and Bedford more nearly resemble them in general definition than do such productions as we are now bidden to look upon as the embodiment of the picturesque? Do they not also enable us to see better what exists in nature? If on both hands the answer is that they do, let us, at all events for general work, not abandon the old models for those now attempted to be set up.

A preference for the representation of the details of nature, as a general rule, does not involve a denial of beauty of its own kind as belonging to such works as those of Mr. G. Davison and the series of large head studies shown last year by Mr. Lyonel Clark. How far this special kind of beauty is esteemed in comparison with the beauty of the more fully expressed details of nature as seen in a finely focussed photograph, must be very much a matter of individual taste, and in any case we may admire the artistic power displayed in the selection and treatment of a subject, even if holding the view that a smaller pinhole would have yielded a result still more gratifying to one's own taste.

Don't use or be misled by catch words. "Pictorial definition" is an expression that has been taken up on the assumption that some sort of definition other than that recognised as being in focus, is entitled exclusively or particularly to the designation pictorial. "Biting sharpness," as applied to photographic lenses, is another catch word. The expression will not bear analysis, but it suggests something unpleasant in connection with fine detail, which may lead away the judgment of the casual hearer to the idea that unpleasantness is inherent in finely detailed work.

There are subjects and occasions, as has been stated, where a loss of detail may be desirable, but these are, in my view, the exception. With these exceptions, and with the understanding that "sharpness" is used in the photographic sense of fine detail, and not the painter's sense of accentuated outline, I believe that Captain Abney's proposition is thoroughly sound—that photographs should be sharp all over, and that a near object should be as sharp as a far-off one.

The next meeting of the Newcastle-on-Tyne and Northern Counties Photographic Association will be held in the Mosley Street *Café*, Newcastle, on Tuesday, the 18th inst., at 7.30 p.m. A demonstration of the platinotype process, by Messrs. M. Auty and J. Pike, will be given.

THE FOCUS QUESTION.

BY GEORGE DAVISON.

The focus question is now attracting a great deal of attention, perhaps more than it relatively deserves. It is just one of those points upon which every photographer feels he is qualified to express an opinion, whether this be based upon prejudice, or science, or artistic feeling. It is only this year that, owing to the prominent exhibition of some marked examples, any wide popular interest has been expressed on the subject, or that any merits in diffusion and out-of-focus treatment have been discussed and recognised by the rank and file of the body of photographers.

Of the importance of the subject I am convinced, but it seems to me that the bearing of merely optical phenomena upon the question has been over-estimated and too exclusively considered. The investigation of these phenomena is of great interest, but, after all, one is brought back to the conviction that the treatment in an artist's work is a matter of feeling, the result of complicated mental impressions, reactions, and analysis. He can be bound by no one limiting rule as to what he must do in all cases. What he may *not* do may be very clear, and doubtless, as in other matters in art, there may be found a principle which will forbid some particular method or methods of treatment. The one and the only broad contention I should feel inclined to make in this matter of focus in pictorial work, where the feeling and character of a subject are to be poetically given, is, that there must be no such detailed definition as the photographic lens can give. If photographs are to be presented as pictures, and not as scientific diagrams, they must not, under any circumstances, be detailed or sharp; and for the reason that no one ever succeeded in giving a fully spirited and pathetic rendering of a scene or subject, and, at the same time, troubled about the small particulars. In pictures the letter must be sacrificed to the spirit. No one has ever reconciled the two attitudes of the scientific investigator and the artist. Many painters paint somewhat sharp edges or limits to objects, but none of any note try to give the local facts definitely, as they could do if they wished. Those that have prided themselves upon their execution are of little repute in respect of the greater matter of feeling. Painters and photographers may begin by fine literal work, but the cultivated tendency is to broader treatment. As I have already suggested, it does not seem to be, even with impressionist painters, a matter of focus (this has not greatly entered into their study), but of suppression of definite detail throughout. They paint equally sharply or the reverse in representing all planes, but all, with one accord, use a broad treatment in order to drop out the commonplace and to ensure seizing the spirit and character of the subject. For this same purpose treatment by focus is the photographer's only means, and this is to me the great and leading application of the function. I do not say that painters' practice is to be taken universally as a guide. Focussing is one of those points which photography brings into prominent consideration, and painters may yet find many new lessons to be learned from photography, which shall materially affect their general practice.

Passing from this broad contention to the exact treatment by focus, my conviction is that this must be left to the artist, and must be determined by the attitude that the subject in hand compels—in some cases, differential focussing, in

others general diffusion, being felt to be preferable. To limit our methods of treatment without more knowledge concerning the operations of the mind, and a better demonstration of the necessity than at present has been put forward would, I think, be a mistake. Diffusion and differentiation have been made a subject for contention as to which is the truer on optical grounds. I do not see the necessity for an universal application of either. The artist may treat a subject, of which his impression will be vivid concentration of interest on one incident or object, or one in which the impression gained is of the general character and beauty of a landscape. Neither will be all truth, even on optical grounds; both may be representations as spirited and natural as are possible to a limited art. In differential focussing, that which settles the question as to which plane or portion is to be made the sharpest, *is the mental decision of the artist*, his feeling and selection. Similarly, it is his mental attitude which must decide whether to diffuse the focus or to differentiate it.

It has been contended by Dr. Emerson and Mr. Dallmeyer that differential focussing can be the *only* true, and therefore naturalistic, method of treatment, and that diffusion is inadmissible. I have, however, not been able to see that they have proved their case in either respect. Indeed, it would appear that the application of the term "natural" or "naturalistic" to the question of focussing is liable to lead to confusion. Most photographers seem to have the idea that naturalism means simply want of focus and nothing more. Taking into consideration, however, the application of mental focus, one kind of treatment may be argued to be as natural, though not necessarily as artistic, as another. Scientific investigators say it is a natural impression with them that everything is sharp. Such an impression may, no doubt, be registered on the mind by examination and the exercise of memory, and the mental picture be all over as sharp as the eye can see. This, it seems to me, may not unfairly be termed "natural." At the same time, it is not the attitude possible to the artist. It is the scientist's view of a scene, a catalogue in which all the items are minutely enumerated.

But, leaving this as a small matter, and looking at the question from the artistic standpoint, if I were tied merely to what could be demonstrated concerning optical phenomena, and if, at the same time, I were to decline to use any forced expedient for simulating the effect of binocular vision, I should feel compelled to work much sharper than I do, and with only a slight difference of focus in the planes, mourning the impossibility of using any natural and true means of giving the appearance of solidity upon a flat surface. If purely scientific principles are to govern us in respect of focus, then ought our pictures to be as Mr. Dennis Taylor has contended, namely, such as are given with an aperture of about $\frac{1}{8}$ inch, for I cannot see that differential focussing is anything but an expedient, a false way of rendering the effect of binocular vision. The inferior definition given by the eye as compared with the lens does not affect this point. On the other hand, our methods of representing natural scenes on a flat surface must be more or less compromises and artifice, and marked differential treatment may be held to give as near approach to stereoscopic relief as is possible in our art. It may be in that way an expedient for representing the artist's impression or mental focus of some subjects, but certainly I cannot see that binocular vision and contrast of focus can be claimed scientifically to be interchangeable effects. As a minor matter, it may be remarked that the contrast of focus which is forced upon the photographer in using the longer focus aplanatic lenses with large apertures is, as those lenses are at present made, often exaggerated and untrue, to say nothing of the frequently unpleasant character of the definition in the out-of-focus planes. I still think we want a lens to meet this difficulty.

In regard to the question of diffraction photographs, or pinhole pictures, Dr. Emerson objects to them on the ground that they falsify modelling, perspective, and tone. I favour them as giving the most pleasing softened quality of definition of any means as yet employed in photography, and because such diffusion seems to me fairly to give the impression as regards focus which the mind selectively receives from many subjects. There is an appreciable time required for focussing and refocussing different points, and in those cases where the impression is general, photographs of equally soft focus throughout may, I think, be accepted as giving the natural effect. I may say that the best pure landscape photographs of which I have any knowledge are photographs with diffused focus. I do not think there is any falsification of perspective in pinhole photographs, nor any appreciable falsification of tone. As regards modelling, it must be classed with the majority of lenses as used at workable apertures. It is merely a matter of degree between them. The quality of the definition is, in my opinion, of far greater importance than is generally given to it, and in this respect I find nothing to give such æsthetic pleasure as diffraction photographs.

Mr. Dallmeyer, in some of his admirable papers, goes, in my opinion, too far when he claims to have proved pinhole photographs to be inartistic. As already suggested, there is something more to be be considered than the optical phenomena attending the case of an eye fixed upon one point of sight. The question of art can hardly be settled in so direct and easy a way as that. At the same time, Mr. Dallmeyer gives some consideration to "mental focus," and I have found some difficulty in reconciling his statement made in one place that "if a scene is of uniform interest it should be recorded as such," with that in another paragraph that "pinhole photographs must be failures artistically." I have probably failed to understand Mr. Dallmeyer's exact meaning, but I can hardly believe he would contend that a landscape whose beauty lies in its general character cannot possibly form the subject of an æsthetically pleasing picture. He has said that "to portray a subject as the eye sees it, the chief plane of interest (why the plane?) should be better defined than the others." But *who* selects and decides which is "the chief plane"? The artist, of course; and, as I have already said, if he, from his mental analysis, finds the character and the interest general or uniform, to seize and express that best he may apply uniform softness of focus.

THE SOCIETY OF ARTS.—Among the lectures to be delivered during the coming session is the following:—Dec. 17—George Davison, "Impressionism in Photography"; and among the papers for which no dates have as yet been fixed:—"Methods and Processes of the Ordnance Survey," by Colonel Sir Charles Wilson, K.C.B.; "Fast and Fugitive Dyes," by Professor J. J. Hummel; "Photography in Aniline Colours," by Messrs. A. G. Green, C. F. Cross, and E. J. Bevan. Among the courses of Cantor lectures to be delivered on Monday evenings at eight o'clock, is one by Professor R. Meldola, F.R.S., "Photographic Chemistry"; three lectures—March 9, 16, 23.

NATURALISTIC DEFINITION.*

BY PHILIP H. NEWMAN.

Naturalistic definition cannot be in a greater degree a question for photographers than for the professors of any other graphic art which aims at the gratification of the sentiments through the organ of vision. Therefore, I cannot conceive of the question being conclusively settled on any parallelism between the human eye and photographic lenses, and it is matter of considerable satisfaction to find the subject removed this evening from the field of optics to its more legitimate one, that of æsthetics.

In considering this question of naturalistic definition, it will be well to clear the ground of all useless surroundings, and as it is before all things a fine-art subject, it is desirable to determine, if possible, what are the purposes of fine art. In the art of portraiture it is the endeavour of the artist, and within the possible scope of his art, to appeal to the beholder, not only with the more or less truthful representation of his sitters, but also of their mental as well as their physical characteristics. It must be quite understood that in saying this I am merely repeating accepted axioms based on the works and customs of the most celebrated portraitists of all times. If these axioms be accepted now, and the works I have alluded to be studied in relation to the question before us, it will generally be found that every other object or accessory in the portrait but the person represented is duly subordinated to it. That the result has often been admirably effected by photographers goes without saying; and I suppose this success has not a little depended on the possibility of adjusting their greatest powers of definition to the features of their sitters, letting other and subsidiary matters remain more or less out of focus.

Now I think it must occur to most of us contemplating this question of definition from the æsthetic standpoint, that a parallelism to the rules applying to portraiture must be looked for to some extent as holding good in the treatment of other subjects in art. Let us take, for instance, a group of figures, presupposing, of course, that these have been selected and posed with some regard to linear harmony and composition. It would seem that the first consideration is to represent them as in relation to one another in a contributory sense to some action or sentiment. If this be allowed, it follows, as in the case of portraiture, the environment, though contributory to the general effect desired to be produced, must be of secondary import, and not necessarily so well defined as the figures themselves. Indeed, the importance of the group is really emphasised, not by the actuality of the surroundings, but by their suggestiveness. Of course, one is not prepared to say that this has been invariably the mode of treatment adopted in all artistic representations at all times, but I think it must be allowed that the purposes of illustration are best served by filling the mind of the spectator with the main subject of the pictorial drama, rather than equally with the accessories, as much is gained by telling the story, whatever it may be, with directness. If this principle of due subordination has not been adhered to in the methods of all painters, it must be borne in mind that circumstances alter cases, and the pictorial is not suited to all purposes of art, and it is enough for us to remember that it is the principle invariably followed and adhered to in that most important school of *genre* painters to which photography, in scale and general range of subject, may be most naturally affiliated—I mean the Dutch school.

In the treatment of pure landscape there are, and always will be, those who ignore art altogether, and insist that the physical fact is of the same or greater importance than the mental aspect. With these we happily have nothing to do. We will rather deal with those who, not content with subordinating the receding planes in deference to an agreeable ærial perspective and the custom of the greatest landscapists, would, by means of a pinhole or other blurred focus, make the entire work accessory, so to speak, to a plane of greater or less definition in the beholder's brain. This may be conjuring, but it can scarcely be called fine art, whose highest attribute is to call up sympathy between the beholder and the creative or interpretative spirit. The class of works I am alluding to are called "impressionist," and besides their not being in general convincing to the spectator, cause him frequently to doubt whether they truly reflect the conviction (if any) of the artist himself, so that that sympathy I have stated as a characteristic attribute of fine art rarely, if ever, can have effect. It has always seemed to me that the laws of harmony in the graphic and glyptic arts are as inexorable as those which govern that of music; and it may justly be observed that the aim of the greatest composers, however variable in their harmonies and instrumentation, have held the end constantly in view that their greatest art is in contributing and giving value to thematic expression. Neither Beethoven, Schubert, Mendelssohn, nor Wagner blurr their main idea or motive, but strive to impress it on the ear and mind by the judicious background of contributive harmony.

Whether photographers will continue to take notice of the erratic works that have brought about this discussion, or allow themselves to be seriously influenced by them, is for the photographers to decide; but the aspects of the question to the outside public, if worth consideration, are simply these:—In the first place, whether the highest aim of one art can be allowed to be the more or less feeble imitation of another? (I refer here to some recent public exhibits); and, secondly, whether photography is properly understood by photographers whose foreground definition is so suggestive of fog? Also, whether they are not throwing away the substance for the shadow who, parting with that legitimate charm of photography, and wherein it must excel any of the other graphic arts—*i.e.*, in definition and detail—are not falsifying their art and stultifying themselves in the unstopping of their lenses, or discarding them altogether for the blurred focus of a larger or smaller pinhole?

* A communication to the London and Provincial Photographic Association.

A New Material for Paper.—The South American papers report that a new factor is likely to enter the market of the paper manufacturers. It has been proved, they say, that the banana plant contains a greater quantity of pure fibre than any other of the numerous vegetable products used in this manufacture. During the first twelve months of its vegetation the banana plant only produces a single bunch of fruit, after which it dies; but from its roots four to ten young plants shoot up. The adaptation of the plant to commercial purposes will, we are told, revolutionise the market for paper material, and largely affect that industry. The banana plant is easy of cultivation; its fruit is already somewhat largely consumed in Europe, and is prized by some for its slightly laxative properties, and the wandering tribes of Central America have long made use of the banana in a variety of manners.—*Burgoyne's Monthly Magazine.*

Notes.

What is known in the trade as the "lamp season" has now commenced, and in various shop windows may be seen paraffin lamps of almost every shape and form which the wit of man can devise. Such lamps are frequently used in photographic work, so it may be advisable to point out that the great majority of them waste a considerable amount of the light emitted by the flame, in consequence of the employment of glass shades of unscientific design. Commonly enough, the shade is of somewhat the form of a tulip, with its orifice open to the ceiling; such shades let light pass freely, and reflect it freely, to the ceiling, where it is not required, but quench a heavy percentage of the rays which would otherwise reach the table on which the lamp stands. Gas globes which will absorb at least fifty per cent. of the light they receive are not at all uncommon. No part of a gas globe should so come between the flame and the table as to prevent the direct illumination of a considerable area of the latter; even the intervention of colourless unground glass will cut off a little of the light by two reflections. Metal cisterns and supports to paraffin lamps are better than those of glass or other fragile substances liable to accidental breakage. That class of paraffin lamp which has an air-passage up the centre, and gives a tulip-shaped flame, emits a large amount of light as compared with the quantity of paraffin consumed. A paraffin lamp is more safe when the cistern is full of oil than when it is partly full, and with good oil possessing the qualities demanded by law, there is little danger at any time; moreover, there are good "safety lamps" in the market. The main points demanding attention when purchasing a lamp are, firstly, that it shall be made of metal wherever possible; and secondly, that its shade shall permit the rays from the flame to come freely downwards rather than upwards. Much depends, in all cases, upon the quality of the wick.

A new application of light is in use in Illinois. In a large printing office wires from the counting boxes of the machines run to the superintendent's office in another part of the building, and there actuate electric lamps, so that by the flashing of the lamps as the sheets of paper are printed, it can be told whether the machines are going too fast or too slow, or whether they are at a standstill. In each counting box is a make-and-break commutator which sends the electrical pulsations.

Some photographers will not use bromide paper for positive printing because the proofs cannot be toned in the usual way. Dr. Miethe overcomes the difficulty by first transforming the image into chloride of silver by means of a bath composed of the following "parts":—Water, 1,000; alum, 20; bichromate of potash, 10; hydrochloric acid, 20. After a few minutes' immersion in this bath the proof is washed with care, then exposed to light for about two minutes, and then re-developed with the "citric acid developer," which we presume to be the ferrous citrate developer. This usually gives a print of good tone; if not, the print can finally be put in an ordinary toning bath.

Dr. A. Miethe has been trying experiments with films of mica coated with gelatino-bromide of silver, as made by a firm in Görlitz, which firm exhibited negatives upon them at the Congress of the Friends of Photography in Berlin. He says that mica is twenty-three times lighter than glass; that the coated mica plates show no tendency to bend when placed in the dark slides; that they sink in the developing solution, but move to and fro as they sink; that the films have somewhat a tendency to leave the plate, and that to lessen this danger an alum bath may be used. The finished negative is somewhat liable to damage at the edges, over which it is judicious to paste a binding of strong paper. They can be printed through from either side, and are little liable to damage from a fall.

We have all heard and read stories concerning the wonders achieved by itinerant jugglers in India, which quite eclipse the most successful tricks of European wizards and conjurors—feats which are not accompanied by elaborate apparatus, but are usually performed with the simplest articles, and as the juggler or fakir sits on any convenient spot in the open air and in the full light of day. One of the commonest tricks is to scatter a few seeds in a little loose earth, cover the whole with a cloth, and after a few seconds to remove that covering and display a mango or other tree in full growth and about two feet high. The cloth is laid aside, and presently something is seen moving beneath it. The fakir again lifts the covering, and a live baby is seen squirming about on the ground. Back goes the cloth, and the fakir slashes it through and through with a knife in such a way that the little creature beneath must infallibly be cut to pieces. But presently it is shown that no baby is there.

This performance was recently witnessed by two gentlemen who had previously resolved to test a theory which they had suggested to explain these marvels. One was an artist who, armed with pencil and sketch-book, made rapid pictorial notes of what he saw, and the other, a photographer, was prepared with a kodak to take instantaneous shots at the exhibition in detail. These gentlemen, Messrs. Lessing and Ellmore, have published their strange experiences in an American paper, and they give as the locality in which the exhibition occurred a place called Guya, which is a town south of Dinapur.

In addition to the tricks already named, the fakir who was the performer in the present instance accomplished another feat of a still more remarkable character. Holding the end of a ball of twine between his teeth, he cast the rest of it in the air, and it ascended in a straight line skyward, the little crowd which surrounded him watching it as it rose. When their

eyes again sought the fakir he was no longer alone, for a boy stood by his side. This boy, at a gesture from his master, rapidly ascended the twine, like Jack did the beanstalk, and presently with it disappeared in space. Each detail of this wonderful performance was sketched and photographed as it proceeded, and the two gentlemen afterwards compared notes. The sketch-book duly showed everything which the operators had seen; but in the photographs, although the image of the fakir was there, mango bush, baby, and boy were quite invisible.

The result of their experiment justifies, so the authors think, the theory that they had formulated, which is, that by some subtle means these fakirs have the power to hypnotise or mesmerise those who look upon their performances, and that the essential parts of the tricks exist only in the imaginations of the onlookers. But they have not yet learnt how to hypnotise a photographic camera, which refuses to reproduce anything which has no objective reality. This theory is a plausible one, but does not make the juggling less wonderful. The most marvellous part of the business is, that men possessing such powers should not rise above the position of mendicants who are eager enough to send round the hat after each exhibition. A man with the power of mesmerising an audience in this way could soon make his fortune in any European capital.

Photography seems likely to be the science which will add most to our at present very slight knowledge of other worlds. The latest photographs of the planet Mars, by Professor Pickering (which he publishes in the *Siderial Messenger*), are full of interest for unscientific people as well as for astronomers. These photographs were fourteen in number, seven being taken on the 9th of April, and seven on the following day. Care was taken to photograph the same face of the planet on each occasion, and on each of the proofs can be recognised quite distinctly the geographical configurations; but in those of the second day, the white polar spot which marks the south pole is much larger than in those of the first day. It has for some time been known that the stretch of these polar spots varies with the seasons of Mars; diminishing with the summer, and enlarging during the winter. But it is the first time that it has been possible to register the precise date of a considerable extension of these snows, as he and many others believe them to be.

"The visible stretch of these snows," writes Mr. Pickering, "is really immense, because they cover 2,500 square miles." On the morning of April 9th these polar snows were faintly marked, as if they had been veiled by a fog, or by small bodies separated, too faint to be individually reproduced; but on the 10th April the entire region was very brilliant, equalling in brilliancy the snow of the north pole. The date of this event corresponds with the end of the winter season of the hemisphere south of Mars.

On board the Atlantic steamers there is a perfect shoal of amateur photographers; in fact, the camera appears now to be an indispensable adjunct to every traveller's luggage. Some of the photographic mementos of a passage across the Atlantic are no doubt very amusing; but in more than one instance an attempt to take a photograph secretly of some particular scene resulted in some disagreeable consequences. The photographic "cad" is not a nice person to travel with, and it is to be feared there are too many of these gentlemen about. All the more need, therefore, we repeat, for a code of manners.

There is a good deal in Professor Herkomer's recent lecture on portraiture which photographers might study with advantage. The difficulties which photographers and portrait painters experience are the same, and Professor Herkomer touched upon the various points in a manner which every photographer will recognise as something approximate to his own experience. The difficulty of pleasing the sitter, and at the same time doing justice to one's self, is at times insurmountable. Professor Herkomer's portrait of the late master of Trinity College, Cambridge, he regarded as one of his best, but the sitter was dissatisfied with the result. He tried to paint Wagner, and as the latter would not sit, he at last in despair roughly and rapidly painted from memory a portrait of the great musician. When Wagner saw it, he was so pleased that he consented to sit, and at once put on that expressionless, characterless look which so worries photographers. Professor Herkomer has found it a good plan to allow the sitter's family to watch the picture in progress; for the sudden confronting of a man's relations with the finished portrait, generally in a light in which they had never seen the subject, was often disastrous.

Here, again, the experience of the photographer comes in, for he can only give one expression, while the sitter's friends and relatives are familiar with a hundred, and not only with a hundred, but with some out of these hundred mingled together, the combination of which makes up their general idea of a particular face. But Professor Herkomer scarcely does photographers justice when, in speaking of the necessity for an artist to be *en rapport* with his sitters, he says: "If he did not sympathise with his subject he became a mere photographer, who pressed people into set positions." This may be true as regards certain commercial work, but the condition of sympathy is one which the artist-photographer of the first rank invariably tries to establish. As for pressing people into set positions, he would never attempt anything of the kind. Professor Herkomer's words might have been of general application thirty years ago, but they are no longer so.

THE PROPOSED PHOTOGRAPHIC INSTITUTE.*

A TALK WITH SIR H. TRUEMAN WOOD.

PHOTOGRAPHY within the last few years has forged ahead with remarkable rapidity. Clumsily handled, and ill-understood by the men who first essayed to employ it, it has been reduced in these later days to the level of a science, and exalted to the dignity of a fine art. New process has followed new process, as wave follows wave, until the photographic artist has become a veritable Alexander, protesting that the fields of discovery are all but exhausted. There are, in all likelihood, a few surprises still in store for him, but there will be more, say the friends of the science, if photography has but its chartered institute. It has its learned societies, with their love of technical lectures; its amateur associations, preferring an ounce of their own practice to a pound of anybody else's theory; its conventions, its congresses, and its exhibitions. Yet it is not content. It is argued that this widely-distributed and varying force must be focussed, or it will be largely wasted, and that an institute in London is the thing that will focus it. Sir Henry Wood, who courteously gave one of our representatives some information as to the project, is, it will be observed, not altogether sanguine about the matter; but the idea is obviously one that, once planted in the photographic mind, will, in all likelihood, take root vigorously.

THE PROMOTERS.

"So photography, like every other science, is presently to have its Institute?"

"Yes," said Sir Henry Wood, "that is what we are aiming at. As yet, however, we are only on the threshold. The idea was first brought forward by Dr. Lindsay Johnson. He pointed out to the Council of the Photographic Society that Berlin and Vienna have Photographic Institutes, and urged that something of the same kind was very desirable in this country. The Council was impressed with the suggestion, and formed a small committee, consisting of Mr. Glaisher, the president, Mr. Bird, the treasurer, Captain Abney, Mr. Kenrick Murray, Dr. Lindsay Johnson, Mr. Gale, and myself, to formulate a scheme. In the meantime, Dr. Lindsay Johnson had secured the good offices of the Lord Mayor, who has kindly promised to convene a public meeting at the Mansion House when the proposal has assumed definite shape. We may, I think, say that we have now reached that point."

WHAT THE INSTITUTE COULD DO.

"Will you give me an idea of what the scheme is?"

"I think I may do so, even at the risk of being considered somewhat premature. We had naturally to look at the question from various standpoints. First of all, as regards the science of photography. It appeared to us that a photographic institute could very properly encourage the discovery of new processes and the farther development of the existing uses of photography. It might either undertake researches through its own staff, or provide suitable laboratory accommodation for its members, and encourage the successful by grants of money. It would, in any event, make provision for the careful testing of photographic apparatus and materials. From an artistic point of view, it would probably arrange for the holding of exhibitions, both national and international, and would aim possibly as high as the convention, now and again, of an International Congress. As to the commercial aspect of photography, it would provide assistance and information on a great many points, and in matters of copyright and patent should be especially able to safeguard the interests of those engaged in various branches of the photographic industry."

A CENTRE OF PHOTOGRAPHIC EDUCATION.

"But the educational influence of such an institute would alone give it a good claim to support?"

"Yes. One of the chief aims would be to furnish the student with the opportunity of perfecting himself in every branch of photographic knowledge. Lectures would be arranged, classes established, and a regular course of instruction in the technical details of photography would be provided. The institute would hold examinations, and grant diplomas to those who attained the requisite standard of efficiency. Such certificates would not be without their value to young men seeking employment in the many branches of photography. Travelling and other scholarships might be founded if sufficient funds were forthcoming. The institute would naturally aim at establishing a first-class photographic library, and a museum which should be at once historical and scientific."

A BOLD SCHEME.

"You would, of course, seek a charter of incorporation?"

"Yes, and probably it would not be refused us. The difficulty does not lie in that direction so much as in the matter of funds. To carry on the work of a really comprehensive institute would require extensive premises, fitted up for the particular purpose in view. There must be an exhibition gallery, a conference or lecture room, a library, a museum, class rooms, laboratory, studios, dark rooms, and printing rooms. There must be rooms fitted up for the carrying out of collotype, Woodburytype, and various photo-typographical processes. Such building, with the requisite offices, would, it is calculated, involve a capital expenditure of some £10,000 to £12,000, and the scheme itself would cost, roughly, from £4,500 to £5,000 a year. Against this, you would have to set the subscriptions of members and affiliated societies, fees from students, charges for experimental work, and donations and bequests. You will see that the project is one which cannot be developed in a day."

IS IT NECESSARY?

"The point that suggests itself to me is, whether many of the ends you have in view could not be obtained by means of the existing photographic associations?"

"Well, as regards the Photographic Society, its principal work is to hold an annual exhibition. That work it does extremely well. In fact, it would be difficult to do it much better. It is true, it has meetings once a month during the winter season, when papers are read and discussion takes place with reference to various matters connected with photography; but that part of its work has not, I think, been done so well as it ought to have been done. In this respect the Photographic Society does not take the same position in relation to photography as the Chemical or the Physical Society do in respect of their particular branches of work. Of course, to a certain extent, much of the educational work proposed by the institute is already done. At King's College, for example, they have for a long time had a photographic department, in which instruction is given by Professor Thompson. In the Finsbury Technical Schools similar instruction is given by Professor Meldola. Probably this educational work is as good as the proposed institute could arrange for; but for all that, it would be eminently desirable that it should be extended in the way suggested."

PROFESSIONAL JEALOUSY.

"You presume that the professional and the amateur photographer could dwell together in unity?"

"I see no reason," said Sir Henry Wood, "why they should not. They work together very harmoniously in the existing institutions. Take the Photographic Society as an instance. It was formed twenty-five or thirty years ago, in what I may call the early days of photography. All the principal photographers have been and still remain members of the Society, though, as amateur photography has developed, amateurs have joined our ranks. For the amateur the old photographic societies are a little bit too high and dry. They deal with questions, perhaps, from a too exclusively scientific standpoint, with the result that there is little to interest the general amateur. He wants something a little more popular. I do not think there is really much antagonism between the amateur and the professional element. It is true there are a few of the smaller photographers who look upon the amateur with a jealous eye. They may possibly have suffered through him, but not to any extent, because there are few amateurs who can take a decent portrait. If you want a good photograph, you must go to a man who has the knowledge, the experience, and the requisite facilities. You cannot put a man up against your garden wall and take a good picture of him unless you are very clever. But put him in a properly lighted studio, and almost anybody can produce a more or less decent photograph."

* From *The Oracle*.

THE AMATEUR OF TO-DAY.

"Is it a fact that the greater part of the improvements in photography must be credited to amateurs?"

"Yes, I think that is true, but it was more true a few years ago than it is now. The average amateur now takes up photography as an amusement, whereas the old amateur was a scientific man, who was more interested in the science of photography than in picture-making. You may say, however, that almost every improvement has come from the amateur, from the days of Daguerre until a very recent period. Too many professional photographers are content to this day to go on with the art as they find it, without themselves seeking to advance it. My own impression is, that the proposed Institute would find its principal work in regulating the photographic industry, and that the amateurs would form only a small, though by no means an unimportant, portion of it."

ONE STEP AT A TIME.

"You are not absolutely sanguine as to the immediate success of your scheme?"

"I am not, personally. It is rather a large proposal, but the committee thought it their duty to take a comprehensive view of the matter. If the scheme can be carried out in its entirety, we think it will be greatly for the advancement of photography. On the other hand, we may have to be content with a small beginning, and, starting from a modest basis, leave the institute to branch out in the directions which experience suggests. With the great interest now manifested in photography, and the considerable number of photographic societies there are in existence, there ought to be no difficulty in getting funds, at all events for a reasonable scheme. With every year the chance of perfecting the institute would increase. We could scarcely expect to burst full-blown upon the world. We have submitted what we think is the best scheme, and we shall try and work up to it as far as circumstances allow."

PRIMULINE PRINTING PROCESSES.

Recognising the importance of processes arising from the photographic sensitiveness of the primuline derivatives, the *Photographisches Wochenblatt*, in the last two numbers, gives a summary account both of the method of Messrs. Green, Cross, and Bevan, which recently attracted so much attention here, and that of Herr Feer, in which the developing agent is present along with the sensitive compound, so that, as we understand, no proceeding subsequent to exposure is required, except simple washing to remove the unacted-on salts and fix the image. It is also to be remarked that in Feer's process the printing is direct from the negative instead of from a positive, and the ground is free from the yellowish tint which at present, according to the Green, Cross, and Bevan process, remains in the paper or fabric when the operations are finished.

Dr. Otto Von Witt, in *The Wochenblatt*, from which we extract the following account, points out, amongst other matters, that the sensitive sulphonic compound of diazo primuline that is exposed to light in the direct process is not liable to explode. He says:—

When contemplating the general position of photography at the present time, we find a general concensus of opinion with regard to the method and application of the negative processes, a proof that they are in a state giving general satisfaction, but it is otherwise with the positive process. In this department we find methods of the most various kinds wax in favour, only to wane and disappear. We see the same photographer take up now one and now another process, without finding sufficient reason to continue its use. This fact is a proof that each of the processes hitherto practised has certain defects either in the complication of the proceedings, or the defective character of the results. The following account does not profess to describe a new process of universal application; it deals rather with two processes yet in their infancy, but which, nevertheless, promise to be of general interest, because they point to completely new paths.

If we consider the numerous methods of positive printing hitherto known, we find one universal characteristic in all of them; the basis support, in conjunction with starch, gelatine, albumen, gum, &c., is in every case an organic body—in fact, a carbon compound; whilst the image is in every case of an inorganic nature, for it consists of finely divided metals, metallic compounds, or, in the pigment process, of finely ground carbon and other pigments.

In the case of the new processes which are about to be described, organic compounds are chosen for forming the image, and, indeed, bodies belonging to the aromatic series, a series which has been known and celebrated as yielding coloured products in abundant variety. Generally speaking, all organic colouring materials, both natural and artificial, belong to this series. Synthetical chemistry gives us an abundance of reactions by which coloured substances can be formed from others which do not themselves possess tinctorial qualities. In fact, both the positive processes about to be described involve reactions of this kind, with the additional provision that they are brought about and completed by the action of light. This consummation by the influence of the luminous rays is common to both processes; common to them, also, is the circumstance that the colouring bodies produced belong to the same class, namely, the azo-colours. However, in the method and fashion in which the two proceedings arrive at their end, they differ diametrically.

In the case of Feer's process, which, indeed, is the older of the two, light acts on a colourless material, with the result that a coloured body is formed; the proceeding is therefore analogous to most other printing processes, such as the silver, platinum, and the cyanotype process. It produces a positive print from a negative, or from a diapositive it produces a negative.

The primuline process, discovered by Green, Cross, and Bevan, depends upon the presence of a body which can be changed into a coloured substance by a very simple proceeding, but by the action of light it loses this capability of being so changed. The consequence is, that only those parts which are protected from the action of light take on colour. In other words, this method gives a copy of the same character as the original—a negative from a negative, a positive from a positive.

Each proceeding has its own characteristic merit, but their difference indicates separate uses and applications. We will now proceed to give particulars of each process in greater detail, and we will commence with the simpler of the two primuline processes.

All those who have a special study of organic chemistry are aware of the fact that there is a numerous class of bodies called primary amines, and that these, as far as they belong to the aromatic series, are very readily acted upon by nitrous acid, and converted into the corresponding diazo derivatives. These diazo bodies all decompose readily; indeed, in the dry state they are actually explosive, and therefore they ought never to be preserved in such a condition, but as they are required for use they should be prepared by treating the corresponding primary amines with nitrous acid in aqueous solution. If we bring such freshly prepared aqueous solution of a diazo-compound into contact with another amine, or with cer-

tain bodies belonging to the class of phenols, there is an immediate formation of an abundant coloured precipitate —one of the so-called azo colours—amongst which we find yellow and orange in various shades extending towards red, up to scarlet and carmine. The list of tints also includes violet and, indeed, blue.

Almost all diazo bodies decompose gradually under the influence of light, and thereby lose the property of forming azo-colours by uniting with amines and phenols. The merit of Messrs. Green, Cross, and Bevan consists in having found a diazo body which is so quickly decomposed by light as to allow a photographic process to be based upon this circumstance. The photographic application is much facilitated by certain characteristics of the diazo derivative of primuline towards primary amines, and from primuline, therefore, the process takes its name.

Primuline is the sulphonic acid of a previously known yellow primary amine, dehydro-thio-paratoluidine, and it was discovered by Green about two years ago. He also noticed its remarkable peculiarity of being absorbed from its aqueous solution by cellulose and other fibres. If cotton or paper be immersed in an aqueous solution of primuline it is quickly dyed yellow, and the primuline fixed in this way upon the fibre can, like other primary amines, be diazotised. When paper or cloth dyed with primuline is immersed in a solution of nitrite of soda acidified with acetic acid, the colour is changed, and we have upon the paper or cloth the diazotised primuline. The material may now be dried without change, and if it be immersed in a solution of an amine or a phenol, an azo-colour is formed, this remaining thoroughly incorporated in the fibrous material. Diazotised paper or cloth of this kind can be coloured yellow by immersion in a solution of carbolic acid, orange in a solution of resorcin, brown in a solution of phenylendiamine, carmine red by a solution of beta-naphthol, and deep violet by a solution of alpha-naphthylamine.

The diazotised materials are in the highest degree sensitive to light; when they are acted on by light they give off nitrogen, and lose the capability of becoming coloured in the above solutions.

From the above facts the primuline photographic process naturally arises. The diazotised and dry primuline paper or cloth is exposed under a positive, if a positive image is required, for about two minutes in sunlight, or half-an-hour in diffused daylight. It is then immersed in one of the above mentioned solutions, when the image immediately appears.

The whole process is remarkably simple. Its principal application is likely to be as a copying process for plans and drawings. The disadvantage that the prints have no pure whites, but that the ground remains of a yellowish colour, is of secondary importance, and is abundantly counterbalanced by the possibility of obtaining prints of various colours by painting the requisite developing solutions on different parts of the print. Another advantage is the possibility of preparing plans and drawings on cotton fabric which can be readily washed when soiled. Moreover, the primuline process ought to open up a new industry in the production of pretty coloured decorations on textile fabrics.

We hear that the inventors propose to bring coloured fabrics and papers into the market, and that the process is patented in all countries. The purchase of the paper or cloth from the inventors will, therefore, become the license for the use of the quantity so obtained.

Feer's patented process depends upon quite another principle. All diazo compounds will unite with sodium sulphite to form the so-called diazo-sulphonic salts, bodies that crystallise easily, and in which the peculiarities of the diazo-compounds are completely masked. They are very permanent, not liable to explode, and do not react with amines and phenols to form coloured bodies. When the above mentioned sulphonic compound is mixed with amines and phenols in solution, colourless liquids are obtained which can be spread upon paper, and this paper can be dried without change in the dark. When, however, it is exposed to the light, the diazo-sulphonic salt is decomposed, and the free diazo body is again formed, and reacts instantly with the phenol or amine present, and intense azo-colours are thus visibly produced under the action of light. In this case we use a negative when we wish to produce a positive print.

According to Feer's process, any azo-colour can be thus formed by the action of light; hence we are in a position to produce any required tint. Particularly striking are the scarlet-red images which are obtained when the diazo-sulphonic salts of pseudo-cumidine is mixed with beta-naphthol in a solution made alkaline with caustic soda. The paper coated with this solution is dried and exposed. If, instead of taking beta-naphthol, we employ alpha-naphthylamine, violet prints are obtained, and with resorcin the prints are orange in colour. Prints by Feer's process show brilliantly white lights, but the image sinks rather deeply into the paper, and is consequently flat, a disadvantage which should be easily remedied. The future of Feer's process rests in the preparation of copies of any required colour from negatives.

As to the practical value of these two processes, the future must decide. In any case, they strike out entirely new paths, and merit the profoundest consideration.

JAPANESE PHOTOGRAPHS IN GOLD.

PROFESSOR W. K. BURTON closes an article in *The Photographic Times*, of New York, about Japanese photographic work in an exhibition, thus :—

I have reserved for the last notice of what is an exhibit perhaps the most interesting of any, because it is quite new. The exhibitor is A. H. Mizuno, of Yokohama, and what is shown is a series of photographs in *gold* on dark coloured lacquer. The intention is to produce, photographically, the equivalent of hand-done pictorial work in gold in lacquer—one of the fine arts in which Japan far excels any other country in the world. The effect, considered decoratively, is very pleasing. The process has, as yet, been kept secret. One thing the exhibition shows is the much higher level that photography has reached in the metropolis (Tokio) than in any other part of the country.

I predict that, in ten years or less, Japan will be able to produce an exhibition of photographs that will compare favourably with any that can be shown in any other country. They have all the necessary qualifications in the keenest intuitive artistic taste and in a wonderful degree of manipulative skill. The great drawback at the present time is the comparative difficulty in gaining technical knowledge.

A good deal of apparatus is shown, chiefly cameras. Seeing that the Japanese have only taken at all extensively to camera making within the last couple of years, the work shown is very creditable. In fact, the skill of the Japanese in all kinds of wood-work is so great, that I cannot doubt they will soon come to excel in camera work if they stick to it; that is to say, at least, so far as construction goes. So far they have only copied cameras of English design.

Specifications Published.

17,318. *November 1st*, 1889.—"Photographic Cameras." FRANK MIALL, 13, Shelgate Road, Battersea Rise, Surrey, Manufacturer of Photographic Apparatus.

The mode of using the camera is:—After the plates, by the withdrawal of the several lids, are transferred bodily and in a mass from the store box which is temporarily fixed to the discharging box in a horizontal position to the axis of the lens, they are then conveyed by the action of the transversing carriage to the vertical position, and placed in the front of the receiving box, which retains them ready for exposure; and such action to be repeated plate after plate until all be transferred from the discharging box into the receiving box, and can then be removed from thence into the store box.

The inventor claims:—

1. In photographic cameras, the use of a store box to convey sensitive plates or films into the camera, and to receive them after exposure, these several operations to be performed in the open air and without the aid of a dark room.

2. In photographic cameras, the removal or reversal of a sensitive plate or film from the horizontal into the vertical position, by means of projections or pivots, which are formed on the carriers containing the sensitive plates or films.

3. In photographic cameras, the use of a hinged or pivoted bottom to a receptacle containing sensitive plates or films, whereby a plate or film can be removed from beneath a number of others.

4. In photographic cameras, the use of a traversing carriage actuating a hinged or pivoted bottom of a plate receptacle.

5. In photographic cameras, the use of a carrier to contain sensitive plates or films, having formed on its sides or ends studs, projections, or pivots.

19,975. *December 12th*, 1889.—"Lime-light Jets." ALFRED SUITER, 2, Como Road, Forest Hill, Kent, Mechanical Engineer.

Lime-lights, as ordinarily constructed, require a separate jet—or, at any rate, separate nozzles or burners—for each kind of light, such as "blow-through," "mixed," and "ethoxo;" although different nozzles or burners are sometimes used on the same jet, they constitute loose parts, and are apt to be lost or mislaid.

In the lime adjusting portion of the apparatus the revolving motion is much too fast, and when the central screw is of sufficiently sharp pitch, it runs itself down by the least touch or joggle; and when a worm-wheel working on a central screw and worm are used, although it gives the proper speeds, it, at the same time, is complicated and costly.

The object of this invention is to combine the different kinds of jets in one, so that the same jet can be used for either a "blow-through," "mixed," or "ethoxo" light or others, and that there shall be no loose parts; also to give a proper adjustment of the lime by a more simple and effective mechanism than has been employed heretofore.

In carrying out my invention, I introduce between the nozzle or burner of the jet a four-way valve, piston, screw-down, or other valve, communicating on the one side with the separate gases, and on the other with the openings in the nozzle or burner; the passages in the four-way or other valve are so arranged that, when the four-way or other valve stands in one position, there are clear ways through for the separate gases to pass to their respective openings in the nozzle or burner, thus forming a "blow-through" light, and upon a movement of the four-way or other valve, one gas is diverted from one opening in the nozzle or burner into the other passage containing the other gas, thus forming "mixed" and "ethoxo" lights.

To regulate the size of the opening in the nozzle or burner, as required by different lights, the four-way or other valve can be formed in the burner itself, and so arranged that the action of adjusting it, for either kind of light, has the effect—by suitable screw or other motion—of withdrawing from or introducing into the opening in the nozzle or burner a tube or liner, or loosely fitting plug, so either enlarging or diminishing the area of the opening.

For adjusting the lime I mount the pillar for supporting the lime upon a suitable bracket or central pin, the pillar being free to turn on its axis and move vertically; upon this pillar is cut a spiral groove provided with teeth or cogs; into these a worm engages, which is fitted on the spindle that extends to the back end of jet. Upon turning the worm, the lime pillar receives a rotary and a vertical motion at the same time, owing to the worm being capable of a rotary motion only; the amount of rise and fall of lime pillar (per revolution) being dependent upon the pitch of the aforesaid toothed spiral groove.

Correspondence.

LONG-FOCUS LENSES FOR PORTRAITURE.

SIR,—In Mr. Debenham's paper, printed in your last, he says (page 863), "I have heard the question put thus: 'If I take a full-length figure on a quarter-plate with, say, a 7-inch focus lens, I can get the accessories and background defined to an extent that is sufficient. Why, then, if I use a lens of double the length of focus, and a stop of the same proportion or rapidity, can I not get the same amount of general focus as in the former case?'" He explains that "to get this equal amount of definition, the law referred to (that the definition of out-of-focus planes is dependent on the absolute size of the diaphragm, independent of the focal length) shows us that a diaphragm of equal diameter—not proportionate to the focal lengths—is required, involving an exposure four times as long as in the other case."

Waiving the question whether Mr. Debenham's generalisation is entitled to be called "a law," it is important to notice that a serious practical error might be supposed to follow from it, namely, that a short focus lens gives more "depth" than a long focus one for a portrait *on a given scale*. I fear that as it is, operators are but too ready to use short-focus lenses, and to place themselves at short distances from the sitter, with the injurious results as to perspective and "drawing" so severely stigmatised long ago by Mr. Hamerton.

Now, as it is a fact that if, in using a long-focus lens instead of a short one, we do not attempt a larger scale, but simply increase our distance from the sitter in proportion to the longer focus of our lens, the long-focus lens will allow of just as great intensity, and give at the same time just as great "depth," as one of shorter focus. Would it not be far better to say at once that depth of focus depends simply on the scale of the picture and the intensity of the lens, irrespective of its focal length? Then we make no mistake, and use a correct generalisation.

To test the accuracy of this rule by an example, I have cal-

culated the conjugate foci for nose and ear respectively for two lenses; the one of 9 inches, the other of 18 inches focus. I have supposed the 9-inch lens to be placed at a mean distance of 72 inches; reckoning the nose at 70 inches, and the ear at 74 inches. In like manner the 18-inch lens has a mean distance of 144 inches; reckoning the nose at 142 inches, and the ear at 146 inches. Thus, the scale of both images is the same. The results are as follows:—

	Conj. Focus of Nose.	Conj. Focus of Ear.	Difference.
9-inch lens... ...	$10\frac{20}{61}$	$10\frac{16}{25}$	$\frac{324}{3965}$
18-inch lens... ...	$20\frac{19}{31}$	$20\frac{17}{32}$	$\frac{324}{3968}$

I have brought the fractions of an inch representing the difference of foci to the same numerator, so as to show more clearly how minute is the difference between the two lenses. But that the 4 inches between nose and ear bear a larger ratio to the nearer distance of the 9-inch lens than to the more distant one of 18 inches focus, the result would be absolutely the same. The difference is far less than a hair's breadth; but, such as it is, is in favour of the longer focus lens.

Thus, the difference of conjugate foci being the same, the intensity may also be the same; and we may acquire, with a longer focus lens, not only the unmixed advantage of greater covering power, but also the far more important one of better perspective and "drawing." It is, in fact, the *right use* of lenses referred to in the Presidential Address to the Conference.

I would not wish, however, for it be supposed that in making this practical correction of Mr. Debenham's somewhat hasty generalisation, I am finding fault with his main contention as against so-called "naturalism." The limits of a letter, or, indeed, of a single article, are quite insufficient to show what I believe to be the radical misconceptions of physiological and psychical processes in natural vision which pervades Dr. Emerson's impressionist theory. And it is but fair to remark that, although the conditions of ordinary natural vision differ so much from those of the vision of a photograph imaged by a lens as to render their comparison difficult and sometimes misleading, such comparison appears to be, in Mr. Debenham's argument, a just and reasonable meeting of Dr. Emerson on his own ground. As regards the necessity for using very small stops to obtain really good definition all over a large plate, I may, perhaps, venture also to add, that what is probably an unusual experience in very large plates, as well as theory, has shown me that the advantage, and indeed the necessity, for using very small stops, wherever practicable, in photographing on a large scale, is in no way over-rated in the paper referred to. Indeed, it is rather under-rated than otherwise.

106, *High Street, Oxford.* W. H. WHEELER.

SPECIAL RAILWAY FARES FOR PHOTOGRAPHERS.

SIR,—At a meeting of the Council of the West London Photographic Society, held on Friday last, a discussion arose as to the desirability of getting special rates for photographers, from the railway companies, travelling for the purposes of the art, and I was directed, as president of the above Society, to write to you with a view of ventilating the subject.

It has been a practice for some time past for railway companies to grant special cheap tickets to *bonâ fide* anglers. To obtain this privilege, all that is necessary is that the applicant for such a ticket should be a duly credited member of an angling club, and have a pass or certificate to that effect issued by a central angling society. Anglers must carry a rod and the usual implements of the craft, and actually be on fishing bent. Anglers may go in bodies or singly, just as they please, and previous notice to the railway company is not necessary. I do not know the number of established angling clubs, or the number of their members, but they are very numerous, and the cheap ticket is extensively patronised.

I venture to think that photographers are an ever-increasing body, and as much entitled to the benefit of a cheap railway ticket as the angler. The anglers travel entirely for their own pleasure, while the photographers bring home pictures that afford pleasure to others besides themselves, and by their publicity advertise the line of railway on which they are taken. I believe cheap tickets are granted to photographers by some railways, but the privilege is considerably discounted by the fact that the travellers must go in bodies of not less than eight or ten, I believe, and must give, some days prior, notice of their intentions. What I would suggest is, that all the leading photographic societies should combine in a representation to the railway companies on this matter. The West London Photographic Society would cordially co-operate with older societies who would take the matter up, or would, if supported and desired, approach the railway companies themselves in the common interests of their brother photographers.

Any information on the matter would be gratefully accepted by myself or by our indefatigable hon. sec., Mr. John Hodges, 87, Chancery Lane. WALTER ADAM BROWN,

President of the West London Photographic Society.

PASTELS AND PHOTOGRAPHY.

SIR,—I observe in the last number of the NEWS, in an article on "Pastels and Photography," the following sentence: "We see no reason why, in the near future, a new branch of art should not arise in which coloured chalks or pastels should be employed for working upon a photographic base."

I should not have thought it necessary to notice this had it not been for the assumption that it would be a "new" thing for enlargements to be finished in coloured pastels. As I have used pastels for finishing enlarged photographs in colours more than twenty years back, I may be excused for objecting to the idea that it would be a "new" style of work for this purpose. I have also a distinct recollection that the late Mr. Faulkner exhibited a very boldly finished bust of a lady in coloured pastels at one of the early exhibitions of the Photographic Society, held, I think, in the Suffolk Street Galleries.

There is no more pleasing method of executing enlargements in colours, but it requires, in my opinion, more skill than other methods, if successfully carried out. Your own remarks on the Pastel Exhibition show that it is not everyone who may profess artistic skill that is successful. Why this method of finish has not been more patronised may be difficult to say for certain. I think one cause has been the uncertainty as to the permanence of the base on which time and money would have to be expended, and the necessity of employing more skilful aid than is commonly given to the finishing of photographs.

November, 1890. AN ARTIST.

THE GEOLOGICAL PHOTOGRAPHS COMMITTEE.

SIR,—I am desired to invite your valuable aid and co-operation in furthering the work of this Committee, which has been appointed to arrange for the collection, preservation, and systematic registration of photographs of geological interest in the United Kingdom.

At the meeting of the British Association held in Leeds in September last, the Committee were enabled to exhibit, as the result of their first year's operations, a collection numbering upwards of 270 photographs, many of which illustrated geological sections and other features of considerable scientific interest. A catalogue of these views will appear in the report of the Leeds meeting.

So far as the work has yet proceeded, however, only a small proportion of the counties in the British Islands have been represented, and the Committee would respectfully urge upon geologists the desirability of further assisting the scheme, with the object of forming, eventually, a national collection of photographs, illustrating the geology of our own country, which will ultimately be deposited in a centre where the collection will be available for purposes of study and comparison.

I shall be glad to receive copies of suitable photographs, which will be duly numbered and registered, or to be favoured with the following information, viz.:—

1. Lists and details of photographs of geological character already in existence.

2. Names of local societies, or persons, who may be willing to further the objects of the Committee in their own district.

3. Particulars of localities, sections, boulders, or other features which it may be desirable to have photographed.

In order to secure uniformity of action, and as a guide to those who are willing to assist in the scheme, a circular of instructions has been drawn up, copies of which will be supplied on application.

Osmund W. Jeffs, *Secretary to the Committee.*
12, *Queen's Road, Rock Ferry, Cheshire.*

DISSOLVING VIEWS IN CHURCH SERVICES.

Sir,—It is indeed true that one-half the world does not know what the other half is doing. You note in your last issue a dissolving view service, as if it were a new departure and a startling novelty. Why, sir, I should say that hundreds, if not thousands, of such services have been held during the last few years, though generally in mission chapels, &c. More than a year ago, I took part in one such, when the clergy were habited in the usual surplice, and when the ordinary evening service was used; but the hymns were thrown on the sheet, and the text of the discourse consisted of pictures of incidents in the life of our Lord. So numerous and popular are these services that, with the intention of holding one last Good Friday, I sent to the optician several weeks before to hire slides, but I found I was already too late, as every suitable slide had already been booked for many weeks. All this is worthy of record in the Photographic News, because it is, of course, only by photography that it has become possible to have these really beautiful and impressive sacred pictures. The caricatures of sacred things presented by the old hand-drawn slides would have inevitably dissipated every feeling of reverence and devotion if the thing had been attempted in the old days; whereas the solemnising effect produced by some of the latest pictures is very striking, and paves the way for the exhortations of the preacher. Henry Geary.

St. Thomas' Vicarage, 16, Somerset Street, Portman Square, London, Nov. 8th.

Proceedings of Societies.

The Photographic Society of Great Britain.

At the meeting of this Society held on Tuesday evening last, the 11th inst., the chair was occupied by the president, Mr. James Glaisher, F.R.S.

Captain W. de W. Abney read two letters from Colonel Waterhouse relating to some experiments on the reversal of the photographic image by the use of carbamide in connection with the eikonogen developer. These were accompanied by prints illustrating the method, which will be laid before the next technical meeting of the Society. The colours obtainable were reddish brown and purple, and, with the addition of ammonia, a yellowish tinge. He had found a great advantage from the use of a 5 per cent. solution of nitric acid, or of a 3 or 4 per cent. solution of bichromate of potash used as a preliminary treatment before development. Great clearness resulted from this mode of working. Still greater clearness, such as required for line work, can be obtained by treating the plate before development with bromide of copper. A small trace of bichromate in the development also worked well. As for exposure, he found he could scarcely give short time enough.

The medals awarded at the recent Exhibition were then presented, and votes of thanks having been passed to the judges and hanging committee, a paper on "Density Ratios as Affected by Development" was read by Mr. H. Chapman Jones. The paper was principally in reply to the statement by Messrs. Hurter and Driffield, that "the photographer has no control over the gradations of the negative, the ratios of the amount of silver deposited on the film being solely dependent upon the exposure." Mr. Chapman Jones's contention was to the effect that considerable variations in the proportions of the density of the different grades in the negative can be brought about by variations in development, and this he illustrated by experimental plates, and enforced by a series of tabulated results shown upon the black-board. He added that he did not seek to detract from the value of Messrs. Hurter and Driffield's experiments, but that he had endeavoured to show that, in one or two specific cases, their assertions were in error. At the same time, he expressed his thanks to them for the trouble they had taken in making so many estimations of density for him.

A written reply by Messrs. Hurter and Driffield to the paper just read, an advance slip of which had been forwarded to them some time previously, was also put before the meeting.

Mr. W. E. Debenham said that the power to regulate the character of the negative by variation of development was accepted almost as an elementary proposition by photographers generally. It did occur, however, in photography that propositions might be accepted largely without sufficient basis, and it was well, therefore, that they should come up for examination, that their soundness might be put to the test. Captain Abney had long since defined the principal weakness of photography as absence of true gradation at the two ends of the scale. It was of great importance to know whether anything could be done, and he believed that a great deal could be effected towards reducing this evil by particular methods of development. That Messrs. Hurter and Driffield's view of the powerlessness of the photographer to effect any variation in the density ratio after exposure was mistaken was, he thought, evident from the power which photographers certainly had reason to believe they possessed, of preventing the reversal of image in a plate which, with normal development, would have given reversal from over-exposure. Then, at the other end of the scale, he thought it could not be denied that a very different image was obtained from a plate when the development was stopped early, before the details of the shadows were visible in the dark room, and density was obtained by treatment subsequent to fixing, from the image produced by developing until the details in the shadows were brought out to the fullest extent.

Captain Abney said that Mr. Chapman Jones had proved in his paper the points that he, Captain Abney, had maintained. He thought that the results obtained by Messrs. Hurter and Driffield, and which differed from his own, were due to the use of logarithmetic calculations. Almost anything might be cloaked under logarithms. If they had used other logarithms, the results would have come out differently. An error of one place in logarithms makes a very great difference in the actual number. Mr. Debenham had shown that the fact of reversal of image being remediable within certain limits proved the capability of affecting the gradation by development. Some of his own work in photographing mountain scenery had required special development in order to produce gradation. In Switzerland, if you do not over-expose for the lights, you do not get a picture. You have to expose for the details in the shadows, and control the lights by judicious development. If there was no control over the gradation of density, the photographic world had been lying under a delusion for over forty years.

Mr. Valentine Blanchard stated that we had all had experience of the power of development to control gradation. Some time since, he had had some plates that had been exposed by a distinguished artist, brought to him for development. If treated in the ordinary way, they were hopelessly over-exposed, but after the first plate had shown this, the rest were saved by treatment with bromide, and development with a very small quantity of ammonia.

Mr. Chapman Jones said that Messrs. Hurter and Driffield, in the reply which had been read, did not appear to attempt to meet any of the arguments that he had brought forward. He failed to see that the fact that his investigation had been experimental rather than mathematical had anything to do with the truth or falsity of the statement that development cannot influence density ratios.

The Camera Club.

On Thursday, November 6th, Mr. Gale read a paper entitled "Country Rambles with a Camera." Mr. Frank Howard occupied the chair.

Mr. Gale commenced his address with notes concerning

some of his favourite counties, and then proceeded to urge the necessity for observation on the part of the photographer. The heads of his subject were: cottages in landscape, their styles, and the material used in their construction; river scenery; country ponds, commons, ploughing, and harvesting. The questions of figures in landscape and lightiug were also discussed, and illustrated on the screen, and the lecture throughout was adorned with extracts from the poets. The lantern pictures exhibited on the screen by Mr. Gale were of singular beauty.

The CHAIRMAN remarked that they had been present at what might be called a "one-man lantern exhibition," and had been looking upon the labour of a life-time. The pictures showed that each country district had its special characteristics; for instance, in corn districts the cottages were exceedingly picturesque, because of the abundance of straw for thatching.

Mr. HUSSEY considered that Mr. Gale had printed-in clouds in lantern slides iu an admirable manner.

Mr. HUMPHERY had been with Mr. Gale on some of his photographic expeditions, and had been struck by the admirable way in which he managed to get sheep into the positions he desired.

Mr. WILKINSON remarked that Mr. Gale obtained such nice groups of human figures because of his kind way of speaking; he did not order them about.

Mr. W. A. GREENE stated that he had found it difficult to get figures into Alpine views, because the men usually would not staud still for the purpose when they were out on an expedition, and that it was useful to have figures in such views, to show the proportions. With a hand-camera the difficulty is less; but the best effects are obtaiued by louger exposures.

Mr. GEORGE DAVISON, in the course of his remarks, said that nearly all the photographs contaiuing figures specially "introduced" into landscapes had been failures.

Mr. MASKELL stated that Mr. Gale, in his paper, had not spoken of the power of photography to represent values. He (the speaker) had never seen, in true values, a photographic representation of a cornfield, or of gorse.

Mr. GALE, in reply, said that he had been in the midst of the gorse commons when they were in their glory, and that to his disappointment be found that in the photographs the gorse materially detracted from the appearance of the landscape; the yellow flowers came out darker than the greens. He was not using orthochrouatic plates. When the corn was ripening he thought that it could be rendered in its true value.

The subject on Thursday, November 20th, will be "Some Old Processes of Making Lantern Slides," when Mr. Pringle will read a paper.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 6th.—Mr. T. BOLAS in the chair.

Mr. J. STEWART (Glasgow) showed two photographic lenses he had recently received from Jena, manufactured by Zeiss. They differed materially iu their construction. He had only been able to try the smaller one of 10¼ in focus, using a stop equivalent to *f*/10; this gave a negative 18 by 15 quite sharp to the edges. The focus of the larger of the two lenses was about uine inches; the front lens had a diameter of one inch, that of the back lens, hemispherical in form, about two inches.

A question was asked whether any of the known varnishes effectually protected a plate from damp?

The CHAIRMAN suggested that after a perfect washing the film should be quite thoroughly dried previous to being coated with varnish.

Mr. W. E. DEBENHAM recommended gold size; he believed no varnish to be thoroughly impervious to wet.

Mr. J. STEWART passed round a negative which had been coated with a varnish recently made by him. It had been allowed to remain out in the wet for a fortnight attached to a sheet of silver paper, without any stain or markings having set up iu the film. In using collodion varnish, a negative would become spotty sometimes in a few hours.

The adjourned discussiou of the previous week was resumed by Mr. W. E. DEBENHAM, who contributed an additional paper, which he read (see page 881).

Mr. P. H. NEWMAN followed also with a paper on the subject (see page 885).

Several of the members took part in the discussion which followed.

Mr. GEORGE NEWMAN said:—It seems to me that the power of artistic expression in photography is one of the subjects of interest most talked about in the present day, and even at this meeting the difference of opinions is, on the surface, very great. Honestly, are we uot all just a bit tired of it, and anxious to be at something else? Viewing the matter as an outsider, one can hardly help thinking that there must be something very wrong somewhere—so wrong that, even after a whole fortnight's careful study, one of the leading photographic societies of the world cannot decide how a photograph should look when done. The old story of the big-endians and the little-endians, but the simile, like the subject, is just a little stale now. One photographic prophet tells us, in cold blood, the all-detail in a picture is to be of equal sharpness. It necessarily follows from that statement that every object on the print may be converted into the principal motive at pleasure. What becomes of the fundamental rules of harmony with this happy starting-point? Then the other prophets at the opposite end of the stick—the pinhole and brown paper gentlemen! There certainly is harmony of a sort in their productions—of the blurred and smudgy sort. Then another sect, the naturalistic photography artists, the feeble imitators of artists of the Millet school, are they to be treated seriously? Well, even they also do not seem to be entirely approved of here, or, for that matter, in many other places. So, where is one to choose where so many staudards of infallibility are raised, each one with a terribly long-winded written warranty attached? Starting with the assumption that to be a photographer oue must be able to take photographs, one would have thought that upwards of fifty years would be ample time to settle all disputes as to the best method of taking them. But here we are at the beginuing! I, for one, am certain that most of the so-called art talk that goes on week after week, month after month, does harm, not good, aud is but a hindrance to good work coming to the front. An objection was made here last week to smart remarks in general, but I cannot help thinking that they are very useful things to intensify with, and that they are perfectly legitimate weapons when used, as they were then, to bring to ridicule faddists and seekers of cheap notoriety. "If familiarity can breed contempt, certainly art, or what is taken currently for it"—by these worthies—"has been brought to its lowest stage of intimacy." I say this because I mean it, apologisiug to no one. To the school who will have nature and nothing but it, and say that nature is to be taken as she is, I quote from the work of a man to whose gifts few can attain, and he says:—"That nature is always right is an assertion artistically as untrue as it is one whose truth is universally taken for granted. Nature is very rarely right to such an extent even that it might almost be said that nature is usually wroug; that is to say, the condition of things that shall bring about the perfection of harmony worthy a picture is rare, and not common at all." How little this is understod, and how dutifully the casual in uature is accepted as subliine, may be gathered from the unlimited admiration produced by a very foolish sunset. The prophets whom, for convenience, I have called the feeble imitatory school, would not need noticing but for one thing, and that is the fact of their writings being powerful because accepted of the timid ones *sans question*, and so becomes, self-elected, their preacher appointed! "He stands iu high places, harangues and holds forth." Sage of the universities, learned in many matters, and of much experience in all, save his subject; exhorting, denouncing, directing; filled with wrath and earnestness; briuging powers of persuasion and polish of language to prove—nothing; torn with much teaching—having naught to impart; impressive, importaut, shallow; defiant, distressed, desperate; crying out and cutting himself—while the gods hear not. Gentle priest of the Philistine withal, again he ambles pleasantly from all points and through many volumes, escaping scientific assertion—"babbles of green fields." Why do we seek after new masters? Is not the story of the beautiful already complete? What is there to learn that the precepts hewn in the

Marbles of the Parthenon will not ever repeat? With a multitude of new teachings surely we must be blinded.

Mr. W. E. Debenham, replying in support of his views, instanced the pictures of Luke Fildes. Pictures by this artist and others showed good definition throughout.

The Photographers' Benevolent Association.

On Friday evening, the 7th inst., the Photographic Exhibition at Pall Mall was, following the usual kindly custom, allowed by the Photographic Society of Great Britain to be open for the benefit of the Photographers' Benevolent Association. Owing, no doubt, to the inclemency of the weather, the attendance was smaller than on some previous occasions. At a quarter to nine, an admirable selection of slides was shown on the screen by means of the optical lantern; the contributors were Messrs. H. D. Atkinson, Carpenter, F. P. Cembrano, W. Davey, W. Farrington, T. E. Freshwater, H. M. Hastings, Liddle, Poulton & Sons (J. S. Rolfe), J. B. B. Wellington, and J. B. Wollaston.

In the course of his opening remarks, Mr. W. Bedford, Chairman of the Committee of the Photographers' Benevolent Association, said that during the past year more calls had been made on the funds of the Association than in any previous year of its existence, more than £100 having been granted in relief. This might be considered a matter for congratulation, as it showed that the Association and its objects were becoming better known. It was to be regretted, however, that the institution was not more widely supported by those who, at some future time, might be in such a position that they might be glad to avail themselves of its assistance. The minimum subscription was fixed at two shillings and sixpence per annum, so that the humblest might subscribe without taxing his resources. In conclusion, he asked for a hearty vote of thanks to the Photographic Society of Great Britain for having placed the Exhibition at their disposal, and to those friends who had allowed their slides to be used. This was accorded by acclamation.

All persons connected with photography are eligible to subscribe, and, in time of need, to receive assistance from the Photographers' Benevolent Association. Full particulars may be obtained on application to the hon. secretary, Mr. H. J. Beasley, 65, Chancery Lane, E.C.

The South London Photographic Society.

The meeting on Friday, November 7th, was for the purpose of hearing Mr. Banks (the hon. treasurer) recount his experiences of a "Tour in the Channel Islands." He illustrated his remarks by a number of his own views, shown by means of the triple lantern, also lent by him.

Mr. Ransom brought to the notice of the members an old device in the way of focussing screens. It consisted of finely-ground glass, in the centre of which was a transparent spot. On the application of a focussing glass to this spot, that part of the image could be sharply focussed.

The Enfield Camera Club.

The ordinary meeting of the above Club was held on the 5th inst., Mr. D. G. Pinkney, president, in the chair.

The attraction of the evening was an inspection of "Travelling Studentship" prints.

Dr. F. Cresswell and Mr. H. F. Knight were elected members of the committee.

The Sheffield Photographic Society.

The ordinary monthly meeting of the above Society was held at the Masonic Hall, Surrey Street, on Tuesday evening, November 4th, Mr. R. J. Shields in the chair.

After the election of two new members, the judges' award was announced for the annual competition; Mr. T. H. Roberts was awarded the medal for the best six pictures, also the gold medal for the best single picture—a view of Filey Beach.

Messrs. Beck and Charlesworth then gave the first of a series of "two-man lantern slide exhibitions."

Dundee and East of Scotland Photographic Association *November 6th.*—General meeting.

Mr. Peter Feathers gave a paper on "Light and Colour."

Mr. W. E. Boxer exhibited a printing-frame which he had designed for making lantern slides from quarter-plates. The front of the frame has an opening of three and one-eighth inches square. The negative, when placed in the frame, could be moved longitudinally till the part desired was opposite the aperture. The back consists of three flaps, two narrow and faced with rubber; these are at either side of the opening, and, when shut down, keep the negative in position, and are secured by a turn-button, leaving a space between them of three and a-quarter inches for the sensitive plate, which is screened from light by the third flap.

The Oxford Photographic Society.

On November 4th an exhibition of fifty lantern slides, kindly lent by the editors of a photographic newspaper, was made. After these, two sets, the Forth Bridge and the Alhambra Palace, Spain, were shown by the President, as also were some slides made by some of the members. Judging by the applause, the slides were appreciated by the twenty-six members and about eighty visitors present. Unfortunately, the night was wet. Mr. A. F. Stanley Kent, M.A. (Magdalen College), and Mr. J. R. Benson, were elected members.

The meetings of the Society are held in the Wesleyan Lecture Room, New Inn Hall Street, Oxford, and the following is the programme for the present year:—November 21st—Demonstration by Mr. H. M. Smith (Eastman Company); December 2nd—Subject not settled; December 16th—"White Mountain" slides (U.S.A.).

The officers of the Oxford Photographic Society are:—*President*—Mr. E. A. Ryman-Hall; *Vice-Presidents*—Mr. C. C. Cole, Mr. French, Mr. A. F. Kerry, Mr. John Salter; *Hon. Treasurer*—Mr. J. Minn, 15, Leckford Road; *Hon. Secretaries*—Mr. W. Davis, 73, Banbury Road, Mr. F. A. Bellamy, 82, Southmoor Road (4, St. John's Road after November); *Committee*—Messrs. B. J. Franks, W. King, W. H. Payne, H. M. Phillips, A. Robinson, G. Smith, and Rev. W. H. Price.

The Leeds Photographic Society.

On November 6th the members of the above Society held their annual exhibition of lantern slides in the Albert Hall of the Mechanics' Institute; the Exhibition was open to members and their friends. About 230 slides were exhibited, consisting of scenery in Yorkshire—on the Wharfe, Ure, Swale, and Tees; Bolton, Rievaulx, and Whitby Abbeys. The views of scenery taken farther away from home were instantaneous marine pictures from the Isle of Man and other places. The Lake district was well represented, and the castles of Kenilworth, Raglan, Warwick, Tintern Abbey, and other similar places, had received careful attention by some of the exhibitors, and some fine pictures of Continental and Norwegian scenery were exhibited.

The president of the Society, Mr. T. W. Thornton, in a few opening remarks, convinced the assembly that the Society had made much progress during the year. It had secured a lecture hall replete with convenience for experiments and general work, and the public exhibitions of the Society had been so successful that further efforts of a like character had been invited.

Mr. C. H. Bothamley, of the Yorkshire College (vice-president of the Society), announced the titles of the various slides as they appeared on the screen, and the lantern was under the charge of Mr. A. A. Pearson and Mr. S. A. Warburton, the hon. secretary of the Society.

The intervals were filled up by a selection of music performed by the Leeds Private Orchestral Society; Mr. Staniland Hall conducted.

The following are the names of the members who showed lantern slides during the evening:—Messrs. H. P. Atkinson, Godfrey Bingley, C. H. Bothamley, H. Denison, W. Denham, Dr. Jacob, A. A. Pearson, G. H. Rodwell, T. W. Thornton, S. A. Warburton, W. Wright, D. Waddington, E. H. Whitaker, and T. H. Walker.

THE NOTTS AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE hundredth ordinary meeting of this Association was held on Wednesday evening at the Society's rooms, Cavendish Chambers, Market Street. There was a large attendance of members and friends, and this was the first lantern night of the season.

The CHAIRMAN, in introducing the lecturer, referred briefly to his subject, "Hand-Camera Work," and spoke upon the important position the hand or detective camera had attained in the short time it had been before the public. Considering the portability and the ease of manipulation, he thought that, for pleasant reminiscences of journeys, their adaptability would be universally acknowledged.

The lecturer, Mr. WALTER D. WELFORD, of Birmingham, said that hand-camera work had received a large proportion of his attention. He had tried its adaptability upon every subject, including street views, incidents, characters, marine studies, wave catching, animal studies, athletics, country scenes, landscapes, cloudland, Newcastle and Torquay trips, the fair, the fête, and *genre* studies. The lecture was illustrated by 150 views, shown by the oxy-hydrogen limelight, and the lecturer described the incidents and characters depicted on the screen. Street incidents appeared to be his especial *forte*. All the well-known typical characters had been secured—the arab, the lounger, the drunkard, the scavenger, and the rogue. Views obtained by "shots" taken from a train travelling at the rate of fifty miles an hour were shown. Other views were shown taken from the centre of a crowd. Views and incidents can thus be secured which, with the ordinary camera and tripod, it would be utterly impossible to obtain.

MR. N. C. DUNER writes that his recent article ought to have ended with the sixth line (formula X) on page 829. He did not intend the remainder to be printed.

THE PHOTOGRAPHIC CLUB.—The annual dinner will be held on Nov. 19th at 7 promptly. Nov. 26th, monthly lantern meeting; Dec. 3rd, collodio-bromide processes.

LITHOGRAPHY IN THE UNITED STATES.—*The Lithographic Art Journal*, of New York, says that there is a very great demand all over the country for artists, transferrers, and pressmen, and that it is very difficult for lithographic establishments to secure the necessary help; this is a most satisfactory sign of the prosperity of the craft.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—A meeting was held on the 29th of October, with Mr. W. Bedford in the chair. Two appeals for assistance were granted. Messrs. Jauley, Tayler, Hoverden, and Pask were elected as subscribers. Votes of thanks were passed to Mr. F. A. Bridge for conducting the concert on the 24th of October, and to the friends who gave their services; also to the proprietor of Anderton's Hotel, Mr. Freshwater, and the Photographic Club.

THE ROYAL INSTITUTION.—At the last general monthly meeting Sir James Crichton Browne, M.D., F.R.S., presided. Mr. Viriamu Jones, M.A., Mr. C. N. Nicholson, M.A., Mr. John Hartley Perks, and the Hon. Sir James Stirling (Justice of the Supreme Court) were elected members of the Royal Institution. The managers reported that they had elected Mr. Victor Horsley, F.R.S., Fullerian Professor of Physiology for three years, from Jan. 12th next.

THE SPHERICAL ABERRATION CONTROVERSY.—It has been suggested that our note at the foot of Mr. Dallmeyer's letter in last week's NEWS showed concurrence with the contents of that letter. Any such idea is a mistake. As most of our readers know, Mr. Debenham is not ignorant of subjects on which he writes, has a keen analytical intellect, and a large acquaintance with photographic optics. Neither do we approve Mr. Debenham's letter of the preceding week, for there is no doubt that when Mr. Dallmeyer, who is an honourable man, says that he had performed an experiment under certain conditions, he had done what he said. We thought that two very good men were getting much too heated and strong in expression over the controversy, and that it was necessary that it should close.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and or the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

PHOTOS.—*Sodium Thiosulphate* is the new chemical name for hyposulphite of soda, but, on the principle of brevity, this salt is likely to be better known, for many years to come, as "hypo." So with common alum, which is ammonium aluminium sulphate.

19TH CENTURY.—*Mr. Frederic Harrison's "New Pompeii."* The idea of a grand National Safe for the reception of works of art, select engineering models, portraits of eminent persons, and records of a century, being buried beneath Stonehenge for the benefit of future generations, implies that the stronghold, or cellar of concrete, would be a more suitable place for their custody than in the possession of ordinary mortals and government officials. Fancy Mr. Gladstone's latest portrait, or Sir John Millais' "Chill October," however well encased, being buried for years, as suggested, in a dark chamber loaded with moisture and fungoid spores! The remarks about permanent photographs, or enamels, are more to the point, but even these would be better preserved in the British Museum. The appeal may do good by paving the way for the formation of a grand national depôt, in the event of the Imperial Institute failing to take up this work.

W. T. M. D.—*Instruction.* Make enquiries at the Polytechnic Institute, Regent Street, or People's Palace, Mile End.

W. T. W.—We have seen the gentleman named in your letter, and he undertook to give you an immediate reply.

A. P.—*Hard Solder.* You have, by your experiment, merely confirmed a well-known observation that zinc and lead will not fuse together and make a uniform alloy. Two parts of lead to one of tin are the usual proportions for hard solder, and there is no advantage in employing any zinc, which would raise the melting point and serve no good purpose, although it might cheapen the cost of production.

L. F.—*Silver in the Whites of Gelatino-Chloride Prints.* By moistening the paper with ammonium sulphide, and allowing to dry in the air, you will see at once, by a dark stain, whether there is any silver locked up in the whites, as is always the case with albumenised prints.

M. T.—*Self-Vignetted Portraits.* Read again the answer to W. J. (Bolton) last week. Your scheme of introducing a cut diaphragm fixed half-way (out of focus) in the camera would have the effect of producing a negative with a *clear* margin, which would print black. This is not what is required, but the reverse. The exposed plate might be covered with a shaded oval, then held up to a gaslight for a few moments, and finally developed; but it would be difficult to get the image centred, or nicely vignetted, in all cases, by thus working in the dark.

T. B.—*Primulines.* It is of little use beginning a course of experiments on the permanence of the different qualities of developed primuline at this season of the year. Our samples were put out all day on the 5th inst. without undergoing any change, but the sunshine came to them at a low angle, as must always be the case in November. The exposed and protected halves were undistinguishable.

COLONEL WATERHOUSE.—Your reversed negatives and specimen prints were exhibited by Captain Abney at last Tuesday's meeting. See report. The requisites asked for are all now on their way to you. Try the primuline with eikonogen developer.

J. SHAW & Co.—*New Designs.* We will enquire farther, but the account states that the matter is only in the experimental stage at present.

J. DICKINSON.—One size registered would cover the copyright of all.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1681.—*November* 21, 1890.

CONTENTS.

THE POISONOUS INFLUENCE OF CERTAIN DEVELOPERS.

RECENTLY two examples illustrating the poisonous action of certain developers by absorption through the skin of the fingers into the rest of the body, have been brought under our notice. In each instance the sufferer was a well-known photographer, so that there is no question as to the authenticity of the cases.

Recently we called upon Mr. Pricam, one of the chief photographers in Geneva, who, for the credit of his establishment, turns out nothing but carbon prints, so that they shall shine in albums in their beauty when the silver photographs alongside, taken by others, shall have faded into the sere and yellow leaf. He pointed out that his fingers had broken into sores all round the edges of the nails, and said that this was due to the constant use of eikonogen in developing operations, he having used it since it was first introduced into the market, and having been in the habit of lifting the plates from the solution with his fingers. He now uses mechanical lifters.

The other case was brought under our notice last week, by the well-known photographer, Mr. Turnbull, of Edinburgh, who says that in regard to the poisonous effect of pyrogallol in the alkaline developer, he has had painful experience. He says that as an old wet plate worker, he had used the acid iron developer, cyanide of potassium, also pyrogallol with citric acid and silver for intensifying. He had also done much collodio-bromide work with pyrogallol and carbonate of ammonia, and without any ill effects. In 1878, however, on taking exclusively to gelatino-bromide, with pyrogallol and ammonia development, he began to suffer. At that time, the most convenient place he had for a dark room had not water laid on; he had, therefore, to use water carried up to it. At that time, also, the method of developing, holding the plate in the left hand, as when wet plates were used, was common, and as the time of development is much longer with gelatine than with wet plates, the developer was more liable to run down the fingers and hand. The first notice he had of anything wrong was a feeling of itching on the knuckle of the little finger of the left hand, whence the developer often used to drip, and, as he was frequently interrupted at work, he sometimes left the room without his hands being washed, consequently the waste developer partly dried on them. The itching gradually spread over the back of the hand and fingers, then slowly extended up the arm. The other hand and arm next became affected, and small pimples, which became moist, spread until the whole surface of his hands and arms was nearly covered. The face and neck also became affected, principally at the backs of the ears, the sides of the nose, the skin above the eyelids and under the eyes and chin.

In the course of a few weeks the complaint spread to the legs, the inside of the thighs and knees being worst. He had the best of medical advice, and although the various doctors agreed that it was some particular form of eczema, he had no permanently beneficial treatment from any of them. For five years he was more or less ill—so ill, that at one time he was a perfect wreck. By entirely giving up development, by keeping himself interiorly in good order, by plain living, by avoiding much imbibition of stimulants, and by taking much out-door exercise, the disease abated. He indulged in cycling in summer and walking in winter, and he now finds himself in good health, though when he at any time develops with pyrogallol and ammonia, the old symptoms of heat and irritation reappear.

That pyrogallol has an adverse effect upon the health of certain individuals has long been known; whether all persons are equally liable to such attacks is doubtful. Pyrogallol is a more dangerous substance than is generally recognised; indeed, Mr. Vincent Elsden, in his table in our YEAR-BOOK about the poisonous properties of certain photographic chemicals, says that two grains of it will kill a dog, and that the symptoms are like those produced by phosphorus. Questions relating to the poisonous action of photographic chemicals are of general interest, so perhaps some of our medical readers and others will help to throw additional light upon these subjects.

ON PHOTOGRAPHING INTERIORS.

At this season of the year, when out-door work is becoming less and less possible and desirable, the attention of photographers may conveniently be directed to the production of negatives of interiors. In the brilliant summer time one is often tempted to put off such work to a more convenient season—for photographs of interiors mostly mean long periods of exposure—and in the time thus occupied, one is apt to argue, three or four landscape studies might be secured. The more convenient season is obviously found in the fall of the year, when the trees are shorn of their foliage, and when nature wears a sombre hue generally. Certainly, under such conditions, the long exposure necessary becomes longer; but when we remember that interior photography is possible even in rainy weather, we are willing to sacrifice a little extra time in consideration of the fact that we are able to work at all.

In no department of photography, perhaps, is greater advance shown than in pictures of interiors, and it is only natural that this should be the case; for in the days of wet plates—in spite of many ingenious plans for keeping the film moist—the photographer was always nervous about the condition of his plate, and would be apt to cap his lens long before it had had time to do its full work. The result was seen in those hard contrasts—black shadows against white windows—which characterised interior photographs of a by-gone era. Things are very different now. We know that in the case of an interior, however long the time may be for which we leave the gelatine plate exposed to the action of the light in the camera, it cannot very well be spoilt, some workers going so far as to say that a negative of a dark interior cannot be over-exposed. This statement, of course, requires a little of the proverbial grain of salt before it can be literally accepted; but we may go so far as to say that the limit of over-exposure of such subjects is a very wide one.

There is no doubt that the gelatine plate has, beyond the lasting property already referred to, other advantages which commend it for use for interior work, and the chief of these is the wonderful gradation of tones which it is capable of affording. In a good interior photograph of a modern drawing-room, for instance, where textile fabrics of different kinds enter so largely into the decoration of the place, it is possible to say which is velvet and which silk. Still more is the beauty of the process brought out in the delicate shadows which are found on crumpled satin, and the pearly tones on almost any material which is white, or approaching white, in brightness. In our opinion the wet collodion process under the best conditions could not render these delicate tones so well, and this is especially observable in the case of snow. Compare a wet plate negative of a snow scene with a similar picture taken on a gelatine plate, and the difference in the half-tones will be seen to be quite remarkable. This wonderful softness of effect possible with a gelatine plate is unconsciously recognised by certain old stagers who are occasionally heard to hanker after the "vigorous negatives" which they used to obtain with wet collodion.

Interior photographs are by no means difficult things to take, for the element of movement is, of course, eliminated. Provided that great care be taken in choosing the point of view, and in levelling the camera, and focussing it, success is sure to follow. In church interiors the windows used to be the stumbling blocks, especially if they were not filled with stained glass, for, in spite of the precaution of backing the plate, halation was sure to show itself more or less. By using a plate with a ground glass back, or a film, this fault is almost altogether obviated, while in the case of coloured windows, the use of an isochromatic plate is at once indicated. It will thus be seen that the worker of to-day has all kinds of advantages in photographing interiors which were undreamt of a few years back.

But the photographer is not confined to interiors of churches or public buildings, for in this age of luxurious living the interiors of private houses often afford the most exquisite pictures. Our forefathers knew little of this lavish domestic decoration, and what there was of it was confined to palaces and large mansions. The upper middle class were content to have everything solid and good, and these terms were too often synonymous with inteuse ugliness. Now, however, it is the fashion for a rich man to spend a large sum on the adornment of his house, and a new trade has arisen to minister to his wants. Modern decoration does not so much depend upon the upholsterer as of yore. Ceilings are painted, walls are freseoed, or perhaps hung with modern tapestry which vies with that of the famous looms of the past, and the richest hangings give completeness to the whole. Photographers would do well to hang in their reception rooms a few photographs of such domestic interiors as these, in order that their wealthier patrons may be tempted to have their homes depicted in the same way. A new branch of work might thus be initiated, which, as we have pointed out, can be carried through at a time when other photographic operations are wont to go slow.

Derby Photographic Society.—The monthly meeting of the above Society was held at Smith's Restauraut, Victoria Street, on Tuesday; Mr. Richard Keene presided. Mr. H. M. Smith, of the Eastman Dry Plate and Film Company, exhibited their products. A collection of enlargements on their bromide paper was exhibited, together with the Kodak cameras, and a lecture was given by Mr. Smith on enlarging on bromide paper, with a demonstration.

A Wire Screen Background.—This is a most useful little device which we recently saw in use by Mr. Hodges and Mr. Harley, while photographing an assortment of cut flowers in some orthochromatic experiments. It consisted of a light wooden frame of about three feet square, with a couple of cross-pieces to serve as feet, so that it could stand upright on a table or bench. Over this was stretched a piece of wire gauze, such as is employed for window screens; and, of course, it was the easiest possible thing to fix the sprays in any desired position on the wire. A background of any required shade could be placed behind, or light reflected through the gauze at any desired angle. The convenience was great and the effect beautiful. Many other uses will suggest themselves to the ingenious photographer for this simple addition to the studio.—*The Beacon.*

THE INTERNATIONAL PHOTOGRAPHIC EXHIBITION IN EDINBURGH.

Last Friday an International Photographic Exhibition was opened at Edinburgh in a suite of rooms in the home of the Royal Scottish Academy of Paintings, Sculpture, and Architecture. This building is in the centre of "Modern Athens," as Edinburgh is appropriately and commonly enough called; it is on a piece of ground which, at a fair elevation, spans the valley which cuts the city into halves, and from its terraces the views are picturesque in all directions. The Academy building is of the Ionic order of architecture, and harmonises admirably with its surroundings. It was founded in 1826, and the Academy received a royal charter in 1838. Its meetings were held in the Royal Institution of Edinburgh at the outset, and subsequently in Waterloo Place. In 1850 the foundation stone of the present building was laid by the late Prince Albert, and the edifice contains the rooms of the Royal Scotch Academy and of the National Gallery. The whole building is now much too small to meet all the demands upon its space for artistic purposes. Its public rooms, including those in which the Photographic Exhibition is held, are all octagonal in shape, and that shape is not the best for the hanging of pictures. The president of the Academy is Sir William Fettes Douglas, and the secretary Mr. George Hayes.

The Photographic Society of Edinburgh, under whose auspices the Photographic Exhibition is held, was founded in 1861, and has now over 400 members. It was preceded by the Photographic Society of Scotland, founded about 1849, and composed of influential members, some of them of considerable celebrity. Sir David Brewster was one of its members, and read some of his papers on optics at its meetings. It held some exhibitions, and occasionally some good papers were read before it, but gradually fell into a lethargic state and faded away like a summer cloud, without anyone being able to say that it died at a particular moment. Before its death, and in the year 1861, the Photographic Society of Edinburgh was founded by a few active spirits, including Mr. J. G. Tunny and Mr. J. Traill Taylor; Mr. John Nicol, now editor of *The Beacon* at Chicago, was also among the founders. The new Society did excellent work, as proved by the photographic journals of the time, and it held occasional exhibitions. One of its features was the giving of lantern entertainments to members and their friends; these began in 1864 in the small hall of the Royal Society of Arts, and became so popular that, about 1867, they had to be removed to the larger Queen Street Hall, which holds about 900 persons. Three or four of these lantern entertainments are given there every winter. Among the public lectures given under the auspices of the Society was one by Professor Piazzi Smythe about the photographing of the interior and the exterior of the Pyramids.

One of the founders of the Society, the late Mr. Tunny, died three or four years ago; he claimed to have acted upon Le Gray's suggestion, published in 1849, and to have used collodion in photography before Archer. However that may have been, he has no public claim in the matter, because he did not make the method known. The albumen process survived in Edinburgh some years after the introduction of collodion, and in 1851 Ross and Pringle, of Edinburgh, obtained a medal at the Exhibition in Hyde Park for photographs on albumen. A story is told that at one time Tunny taught the collodion process as a trade secret, and a man came over from Fife, and paid to be initiated into the mysteries thereof; upon his return home he wasted gallons of chemicals, but could obtain no trace of a picture, whereupon he drew conclusions not complimentary to his teacher. Mr. Tunny went to Fife to see about the matter, and found that his pupil had followed his instructions faithfully—except that he never drew the shutter of the dark slide!

The following are the members of the Executive Council of the present Photographic Exhibition.

President—*Hippolyte J. Blanc. *Vice-Presidents*—*Dr. Drinkwater, F.C.S., and *W.T. Bashford. *Council*—Hugh Auld, *Alex Ayton, Jun., *Andrew H. Baird, James C. H. Balmain, *Herbert W. Bibbs, Hugh Brebuer, *James Crichton, *William Dougall, Alex. M. Forbes, *William Forgan, William Hume, Alexander A. Inglis, *James Jameson, *G. G. Mitchell, *W. B. Mitchell, *F. P. Moffat, *John Stewart Smith, *John M. Turnbull, *T. Wardale. *Treasurer*—*James M'Glashan, 60, Dalry Road, Edinburgh. *Secretary*—*Thomas Barclay, 180, Dalkeith Road, Edinburgh. *Assistant Secretary*—James R. Roddick, 13, Mentone Terrace, Edinburgh. Honorary members of the executive council, the secretaries of photographic societies in Great Britain.

The following medals will be awarded to the more meritorious exhibitors:—

A Gold Medal for the Picture which possesses the highest degree of merit, irrespective of Size or Subject.—One Silver and one Bronze Medal will be given in each of the under-noted Classes:—Class I. Landscape, 8½ by 6½ ins. or under. Class II. Landscape, above 3½ by 6½ inches. Class III. Portraits, below whole-plate size, in sets of twelve direct prints. Class IV. Portraits, 8½ by 6½ up to 10 by 12 inches, in sets of six direct prints. Class V. Portraits, above 10 by 12 inches, in sets of six direct prints. Class VI. Single Figure Studies, not to exceed 15 by 12 inches, direct prints. Class VII. Combination Printing. Class VIII. Genre Pictures. Class IX. Instantaneous Pictures. Class X. Architecture and Engineering. Class XI. Scientific—Micro-Photography, Botany, Astronomy, Geology, Surgery, &c. Class XII. Landscapes, half-plate and under, confined to Amateurs. Class XIII. Landscapes, above half-plate, confined to Amateurs. Class XIV. Photographs, any subject, confined to Amateur Members of the Edinburgh Photographic Society, Class XV. Pictures which have previously obtained a Prize. Class XVI. Lantern Slides, in sets of six. Class XVII. Reproduction of Pictures by any Process not Mechanical. Class XVIII. Vitreous Enamels. Class XIX. Photo-Mechanical Prints. Class XX. Enlargements, which must be accompanied by Original Negatives. Class XXI. Apparatus, Materials, Processes. Three Silver and Three Bronze Medals to be awarded according to the discretion of the Judges.

The previous great photographic exhibition—for there have been several small ones—was held under the auspices of the Society in 1876.

In addition to the artistic aspects of photography, attention is given in the Exhibition to the following subjects:—

History of Photography.—Specimens of the earlier processes.

* Members of Council of the Edinburgh Photographic Society.

Views, and portraits of eminent characters by such process ; of the inventors themselves if available. Optical and mechanical appliances used in working the earlier processes. Daguerreotype, heliotype (Niepce), photogenic drawings, calotype, collodion positives, &c. Specimens of miniature painting on ivory, and silhouettes in vogue immediately before and during the early days of photography.

Applications to Science.—Astronomy—Photographs of the sun, moon, stars, nebulæ, comets, eclipses, photo survey of the heavens, spectroscopic observations. "The Revelations of the Microscope" photographed in any branch of study. Meteorology—Specimens of daily records, natural phenomena, lightning, rain, clouds, sunsets, rainbows, halos. Physical phenomena photographed in the laboratory, or in nature. Geological, botanical, and zoological specimens photographed. Medicine and surgery. Anthropology and archæology. Engineering and architectural—Photographic records of works in progress. Plans ; blue and black processes (white lines on blue, blue lines on white).

Technology.—Applications to the printing and illustrating trades—Photogravure, litho, zinco, collotype, autotype, Woodburytype, stannotype, helio-chromo, &c., &c. Appliances for the production of these, when not too massive for transport. Books and periodicals illustrated by means of these processes.

The Exhibition was opened last Friday night, and the appended report of the proceedings is quoted from the *Scotsman* of last Saturday :—

The International Exhibition of Photography, promoted by the Edinburgh Photographic Society, was opened last Friday with a conversazione in the Royal Scottish Academy Galleries, at which the Lord Provost delivered an inaugural address. A large and brilliant company was present, and during the greater part of the evening the Galleries were uncomfortably crowded. Though the opening ceremony was announced to take place at eight o'clock, it was nearly nine when the president of the Society, Mr. Hippolyte Blanc, mounted a temporary platform in the central octagon in company with the Lord Provost.

In introducing his Lordship, Mr. Blanc took occasion to explain that the Edinburgh Photographic Society was an association of about four hundred members, which had existed and carried on successful work in photography for about thirty years. The objects of the Association were to discuss whatever pertained to photography, and to propagate a knowledge of the art. This was not the first exhibition held in the city, for in 1876 the Edinburgh Photographic Society ventured a similar exhibition, but under much less favourable conditions. The result was highly satisfactory. There had been an excellent surplus, and upon that surplus the present exhibition had been floated. But in 1876 they were not able to present to the public the manifold items of interest such as were displayed on the walls that evening. Photography, although well advanced, was really only in its dawn at that time ; it was the photography of portraiture. Now they had the application of photography in every field of art, literature, and science. It had been desired that the Exhibition should not be merely a show place for pictures and material appliances for photographic purposes, but that it should at the same time have an educative aim, whereby all who had the slightest shadow of an idea of photography might learn how that shadow could become a living and intelligible substance. During the course of the Exhibition, there should, therefore, he said, be a series of lectures in which the technicalities of photography would be dealt with by gentlemen well qualified to take up the respective subjects. He concluded by presenting his Lordship, on behalf of the Executive, with a copy of the catalogue and a couple of season tickets—one for himself, and another for Mrs. Boyd.

The Lord Provost compared the galleries, illuminated with a brilliant light, adorned with sun pictures, and peopled with ladies and gentlemen wearing the sunflower, to a temple of the sun. From the extreme east to the far west, he said, there were traces of the sun worship. In the sculptured stones of Nineveh and the pyramids of Egypt, in the temples of Greece and Rome, the circles at Stonehenge and Steunis, the cromlechs of Scotland, and the monoliths, sculptured and unsculptured, they had traces of that old sun worship which pervaded the whole face of the globe. It was interesting, too, to think how these traces were still to be found in the shape of our churches, and how they came still more home to us in the Yule log, the May morning celebrations, and the mistletoe bough hung up at the close of the year. As vestiges of the old worship so prevalent in the early stage of the world's history, it all came home to them. Proceeding, his Lordship expressed the pleasure it gave him to assist at such a ceremony. He had been told that there were about 1,200 frames in the Exhibition, and as many frames included a large number of specimens, the display, it would be seen, embraced a collection indicative of much labour and industry on the part of those who practised photography. They had to thank the Association for their arrangement of the treasures committed to them, so that visitors might learn the progress which photography had made from year to year since its commencement half a century ago. He did not know that any more pleasant occupation for one's leisure hours in the country could be found than photography, and he was quite sure it had served not only to give a great deal of pleasure to those who had practised it, but it had been of immense value in connection both with science and with art. They had far more to expect from photography in the future than they had to congratulate themselves on receiving in the past. It was hoped that they might some day be able to photograph colour as well as form, but in the meantime they might congratulate themselves that so much had been done, and do all in their power to encourage the study of the art.

On the motion of Dr. Drinkwater, a vote of thanks was awarded to the Lord Provost, after which the company spent some time examining the collection. A string band of the Queen's Own Cameron Highlanders played selections during the evening.

Five octagonal rooms and a vestibule are devoted to the purposes of the present Exhibition; the central room is the largest. About 1,200 photographs altogether are on view.

The apparatus on view includes the cantilever enlarging lantern exhibited by Mr. Hume, the nature of which may be explained by the aid of figs. 1 and 2. At the rear is a duplex paraffin lamp, in which the tops of the flames are inclined towards each other to obtain more light. The flat sides of the flames are turned towards the condensing lenses. The distance of the flames from the condenser may be adjusted by means of a large metal cone, which will move backwards and forwards within the large annular metal adjunct represented in fig. 1. Diaphragms with circular apertures of various diameters may be inserted in front of, and not far from, the flame. A small ruby window at the back of the lamp permits the flames to be seen, and transmits a light suitable for use when developing. For half-plate negatives a condenser 8¼ inches in diameter is used; all the condensers are strongly mounted in brass cells. In the midst of the apparatus the condensers are firmly seated in the stout mahogany frame on which the other essential parts are hung. A leather bellows of suitable length permits convenient adjustment for focussing the picture when different sized enlargements are being made. The bellows, being mounted upon mahogany frames, are easily removable for their better preservation, and also to adapt the stage of the lantern for the projection of physical experiments, as in fig. 2, in which a voltameter is represented with its battery attached. The voltameter is so placed that an image of the two glass tubes, with their con-

tents, can be projected on the screen. The sliding adjustment in fig. 1 is effected by means of polished and well-fitting brass tubes, which give an easy motion, and furnish a ready means of finding the correct position for the intended picture.

Mr. Hume also has on view some prints produced on various fabrics by means of the diazotype process, which prints have been sent to him from London, at his request, by the inventors. Those on cotton and woven fabrics are mostly of inferior quality, not likely to create opinions in favour of the process by their public exhibition. In some frames upon the walls of the rooms are three or four better specimens.

Mr. J. M. Turnbull exhibits miscellaneous apparatus, including several specialities of his own, in the devising and construction of which much thought and care have been exercised. For instance, in his hand-camera, he tries to meet the published requirements of several

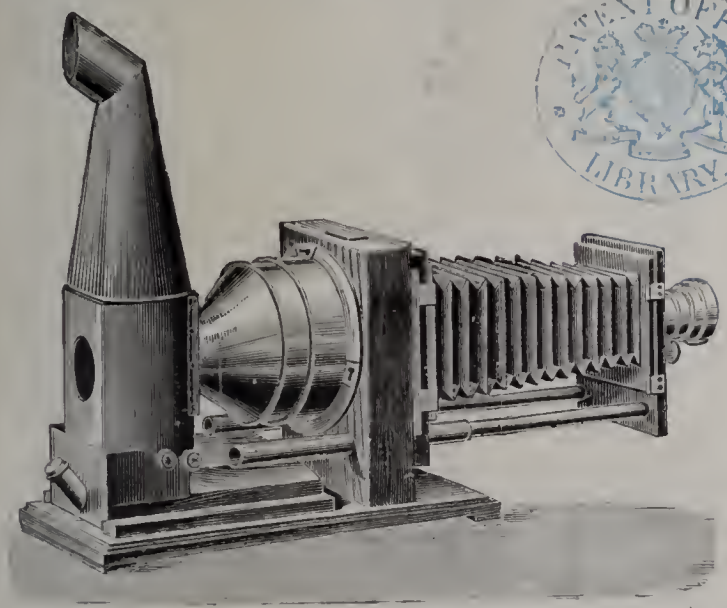

Fig. 1.

photographers. This camera is represented in fig. 3. It has a plain leather-covered case, with no projections outside, for quarter-plate. It is $8\frac{3}{4}$ inches in length, $4\frac{5}{8}$ inches in breadth, and 6 inches in height, and is carried by a small leather handle; it weighs, without slides, $1\frac{3}{4}$ pounds, and with six double slides is 3 pounds 2 ounces; it is supplied of $\frac{1}{4}$-plate, 5 by 4, or $\frac{1}{2}$-plate

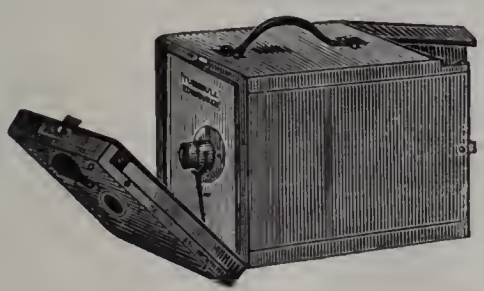

Fig. 3.

size. It opens at the ends only; one end opens to the lens and shutter, and the other end to admit the slides. When not required for shutter work, it can be screwed on a tripod and used as an ordinary camera. Two small finders are attached to the camera. A focussing screen is also supplied, but is only required when the camera is used on a tripod for time exposures. An advantage in this camera is, that it is either a hand-camera of plain and unobtrusive appearance, or, after placing it on a stand and putting in the focussing glass, the image can be seen in the usual way; it is, in fact, a hand-camera and an ordinary camera in one, and can be fitted with six of Turnbull's film slides, half the thickness and weight of plate slides, or with Eastman's roller slide. The lens used with this camera is a rapid rectilinear of six inches equivalent focus, stated to cover the plate well with the full aperture of *f*/8. It has an adjustment for focus, and is marked for 12, 20, 30, and 40 feet, and farther or intermediate distances

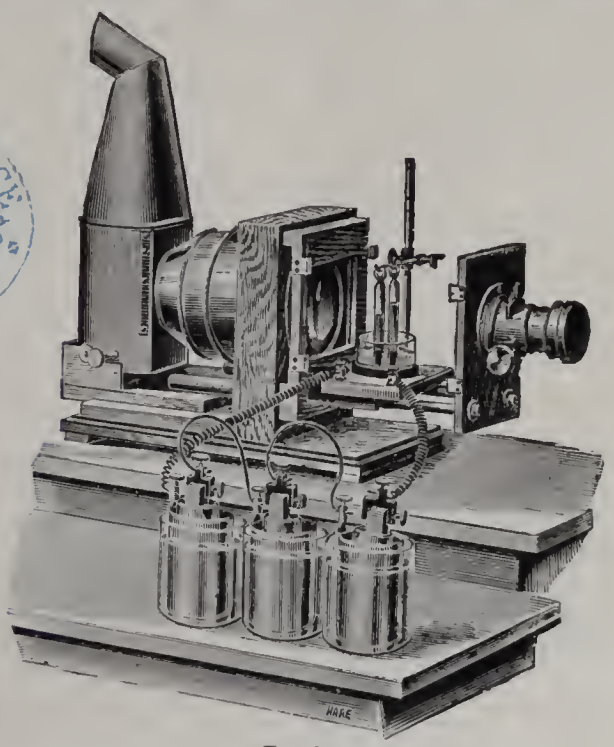

Fig. 2.

A set of standard stops is supplied with the lens. The shutter is the "Waverley Express Shutter," which opens and closes from the centre, and has a speed regulator. The slides are of the American type, with ebonite or celluloid shutters, which pull entirely out when exposing the plate.

One of the most ingeniously devised things in the Exhibition is Mr. Turnbull's walking-stick stand made, all but the case, of peculiarly shaped tubes of thin metal; the metallic legs are hollow at all parts. How they will resist wear and tear we know not. When the legs are first pulled out of the wooden walking-stick case, they look like a walking-stick themselves, being each in horizontal section in form like the segment of one-third of a circle. Each of these tubes contains two other hollow tubes, connected at their lower ends; the section of each of these smaller tubes resembles that of one-sixth of a circle. These smaller tubes bend outwards to form the fork of the upper part of each leg, for connection with the triangular head of the stand in the usual way; greater height is thus obtained than usual with walking-stick stands. All stands of the walking-stick class are more useful when there is little

or no wind. The legs just described are made of specially drawn, thin, hard telescope tube.

Mr. Turnbull also exhibits a folding developing-room lamp for tourists, made on correct principles. It is of rectangular form, and neither of its four sides is opaque; all of them are covered with translucent red cloth. Such lanterns should never have an opaque side, because, if the light be safe which emerges from the window nearest to the developing dish, the same kind of light from the other windows cannot do any harm, and serves to illuminate the room. By the time the rays from these other windows have reached the walls of the room and been partially reflected therefrom, they are far too weak to do any harm. The lamp is small—too small for a candle to be conveniently used inside—so Mr. Turnbull issues with it some specially made "night-lights" of paraffin, in the central wick of which is a fine wire. Mr. Turnbull also has some film carriers on view.

For a time we turn aside from the commercial exhibits, to deal with an interesting collection of pieces of apparatus of historical interest, displayed upon one of the tables near the entrance to the Exhibition.

Among these is a very old portrait lens by Voightlander, made for the firm of Ross and Pringle, of Edinburgh. The lens is so long that it has a special support in front; it has a working aperture of 3¼ inches, and the focus is but 2¼ inches from the back element of the combination. For many years this lens was in use in Edinburgh, chiefly for the taking of portraits of children by the wet collodion process. The lens has no stops. It is placed on public view by Mr. Thomas Pringle.

An old camera of very small size, constructed about 1856, is exhibited by Mr. Turnbull. It has a flap shutter, and a magazine for carrying and sensitising four wet plates of the size of the glasses of mounts for the microscope—3 inches by 1 inch. The plates are exposed inside the nitrate of silver bath; each plate faces a glass window in the bath, and the exposures are made through the windows. By means of a camera of somewhat the same type, arranged to expose but one instead of four plates in a bath, Professor Piazzi Smythe photographed the interior of the great pyramid about twenty years ago. Like the "kodak," this camera has lines upon its exterior to indicate the angle of view. Mr. Turnbull also exhibits one of the old pantascopic cameras, still in good working order.

Mr. E. Lennie exhibits Sutton's panoramic camera, with its lens and its curved glass plates; also its beautifully made curved printing frames, and some photographs taken with the instrument some fourteen or fifteen years ago. One of the views contains the likeness of Mr. Burns, a photographer well known to the past generation in Edinburgh.

Mr. J. Mackean, of Leith, exhibits Aird's original hand-camera, with its magazine of plates held in sheaths, constructed, we are told, in 1872, and fully described with drawings at a meeting of the Edinburgh Photographic Society in March, 1875. The instrument consists of an upper and a lower box; the upper one forms the camera, and each sheathed plate is drawn up in turn for exposure, displacing the focussing screen when it reaches the upper box. When exposed, the plate is lifted from the front and dropped into position at the back. Collodio-bromide emulsion dry plates were used with this camera.

Several curious old-fashioned stereoscopes and monoscopes are on view, dating from 1856 to 1859.

(To be continued.)

PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

The French Photographic Society—New Developer—Experiments with Eikonogen—Photo-Chronographic Researches—Universal Camera—Property in Photographic Work—Photographic Congress of 1889—Progress of Collography—Death of M. Gaillard.

The French Photographic Society.—The Photographic Society of France had its opening meeting on November 7th. The proceedings in the first place were for the refilling of the presidential chair, vacated by the death of M. Peligot. The Society, on my proposition, elected by acclamation M. Janssen, of the Institute. The post belonged, so to say, by right to the illustrious astronomer, who was one of the first to make such a remarkable application of photography to the purposes of astronomy. M. Janssen has never ceased to interest himself in the progress of photography, and to follow it closely. It was he who designated the photographic objective by the words "the retina of science of the future." The Photographic Society could not place itself under higher patronage, or under more learned and intelligent direction.

Yxol Developer.—A new developer has made its appearance. It is called yxol by its inventor, M. Lacoste Delperier. The formula has not been given, and the presentation has, therefore, only a modified interest. It remains to be seen what we have to expect from this reducing agent. Later experiments will show.

Experiments with Eikonogen.—M. Reele gives a conscientious summing up of a set of experiments made to compare eikonogen with hydrokinone. According to him, the latter product possesses a powerful reducing action considerably exceeding that of eikonogen. Relying upon the exact proportion of the divers elements necessary to the preparation of a rational developer, he has prepared one which he names "Lightning," the merits of which he highly extols. Samples of this compound were distributed to the members.

Photo-Chronographic Researches.—Mons. Marey, member of the Institute, is pursuing his photo-chronographic researches. He has brought to perfection an apparatus which serves to photograph two distinct views at intervals of time of very small separation. He is now easily enabled to adapt to it pellicular bands of sensitised film, by means of which he can obtain as many as fifty different views of the same moving object within the space of a single second. The apparatus is endowed with extreme rapidity; the band is unrolled with a continuous movement, but a grip, which comes into action just before a periodic exposure, regulated according to the number of impressions that it is desired to obtain, causes a sort of halt, which suffices to establish regular intervals between each image. M. Marey arranges his sensitive bands on an axis, around which they roll. The two ends of the

band are continued by black or red paper, thus permitting the change of reels to be made in a full light. This arrangement—or rather, this collection of improvements—adds to the greater precision of the images suitable for studying the movements of animals.

Universal Camera.—Messrs. Gilles Brothers have completed a universal camera conformably to the specifications adopted by the Photographic Congress of 1889. The instrument is very well made, and responds to all possible requirements.

Property in Photographic Work.—The President has given an account of what passed at the Congress held in London relative to property in photographic work. M. Bulloz, of the firm of Braun, and M. Davanne represented at this Congress the photographers of France. On their proposition the Congress supported the view that photography ought to be treated, in so far as the protection to be awarded to it goes, on a level with the other graphic arts. In this manner the question of pure art is avoided, and artists are no longer irritated and chafed by asking them to assimilate photographic productions to works of art; photography is thus put in the same category with engraving, lithography, and drawing in general. It remains to see this proposition sanctioned by the Congress at Berne, where already the question has been treated with less favour. Perhaps, this time, a better result may be arrived at.

Congress Documents. — Monsieur Pector, Secretary-General of the Congress of 1889, has deposited at the Bureau a collection of reports and documents relative to the Congress. This volume is very well arranged. We find in it models and drawings of the tickets, marks, and coloured scales traced by divers apparatus, and inscriptions conformable to decisions of the Congress. This last publication, edited with great care by Messrs. Gauthier-Villar and Sons completes the first parcel of the "Procès Verbaux and Resolutions," published by the National Printing Office. We have in this collection everything relating to the Congress of 1889.

Progress of Collography.—M. Gravier showed albums sent by Messrs. Lorilleux as evidence of the quality and variety of colours of their inks. The Lorilleux inks are in great demand for photo-collography, and, thanks to them, we may obtain proofs fit to rival the most beautiful engravings.

Obituary.—M. Gaillard (Paul), one of the oldest and most distinguished of photographic amateurs, founder of a prize of 500 francs for improvements to be introduced into pellicular photography, has just died. He had been one of the Committee of Administration of the French Photographic Society from its commencement.

Photographic Society of Great Britain.—Technical meeting, Tuesday, November 25th, at 5A, Pall Mall East, at 8 p.m. ; open at 7 for reading journals.

Douglas (Isle of Man).—An amateur photographic society has been formed in this town in connection with St. Thomas' Church Guilds. The Society has been named the Douglas (Isle of Man) Amateur Photographic Society. Mr. J. M. Nicholson was elected president, and Mr. R. W. Killey, 16, Sydney Street, Douglas, Isle of Man, hon. secretary.

Photographers' Benevolent Association.—At the meeting held on the 14th inst., Mr. W. Bedford in the chair, three applications for assistance were considered, two of which were granted. Messrs. Arthur Weston, E. C. Boucher, H. P. Collins, and H. R. Hume were elected subscribers. The result of the Photographic Club entertainment was £10 18s. 10d. profit.

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Ferrocyanide of Potassium in the Quinol Developer—Film Stripping—Gelatine Dry Films on Mica—Two Novel Modes of Intensifying—Combined Pyro and Quinol Developer.

Ferrocyanide of Potassium in the Quinol Developer.—As an outcome of many careful experiments with quinol and its variations, I find the following formula with ferrocyanide of potassium, which addition was recommended some time ago by Capt. Himly, to be one giving most satisfactory results, more especially in the case of portraits. It gives more brilliant light lights and softer half-tones than any other developer which I have tried. I make up the following solution :—

Quinol	...	...	...	25 grammes
Sodium sulphite	...	...	...	200 ,,
Distilled water	...	...	...	750 ,,

The quinol is dissolved in the water, then the sulphite is added, and dissolved also by shaking. The solution is then filtered, and finally there are added to the same :—

Carbonate of potassium	...	...	300 grammes

With this developer I begin development, and as soon as the first details are out, I add to 100 c.c. of the above developer 5 to 10 drops of a solution of :—

Ferrocyanide of potassium	...	...	...	10 grammes
Water	...	...	...	100 c.c.

Development then proceeds quickly, so that the exposure may be considerably shortened. The resulting negative is splendid.

Stripping the Film from an Ordinary Gelatine Plate.—As a trustworthy method of stripping the film from an ordinary gelatine plate, the following plan is recommended in the *Deutsche Photographen Zeitung.* Before stripping, the negative must be freed from the varnish, which is done best with methylated alcohol, or with a solution of 1 gramme of caustic potash in 100 c.c. of ordinary alcohol. The negative is then placed on a levelling stand, and coated over its whole surface with a rather thick film of two per cent. plain collodion ; after setting, the plate is thoroughly rinsed with water, until all greasiness of the film disappears. The plate is then placed in a solution of ten drops of hydrofluoric acid in 100 c.c. of water ; the solution should not be used stronger, as otherwise the film would probably frill. In order to avoid this failure entirely, it is well to add to two parts of the above weak hydrofluoric acid solution one part of alcohol or spirit. As soon as the film begins to loosen at the edges, the plate is removed from the bath and rinsed carefully, but thoroughly. After washing the plate is, with the film side up, placed on a soft support (a few sheets of moistened blotting paper), covered with a moistened (not wet) smooth piece of good letter paper, and the latter slightly pressed by means of the ball of the thumb or by an india-rubber squeegee. The paper is next very carefully stripped off, together with the film ; if this is done skilfully the film will adhere well to the paper ; the latter should have been cut a little larger than the film. In order to remove the paper from the film, and at the same time to give to the latter a suitable support, a well polished glass plate, a little larger than the stripped picture, is well-rubbed with tale powder, then coated evenly with collodion, rinsed with water, and placed aside for

about five minutes to drain. The still moist plate is then coated with a twenty per cent. gelatine solution, and completely dried on a levelling stand. Such plates keep well, so that they may be placed in stock. After drying, one of these plates is placed in a dish with cold clean water, and at the same time the paper together with the film is placed in the water; the whole is then brought in contact under water, and without producing air-bubbles; the plate is next removed, and is once more squeegeed and the paper stripped off while still moist. After drying, a sharp knife is passed through the edges, and the film, which has become a rather strong and flexible film, will easily leave the glass, and may then at once be used for printing.

Mica as a Support for the Gelatino-Bromide Film.—The firm of Oswald Moh, of Görlitz, has introduced an interesting novelty consisting of gelatine plates coated on mica in place of glass. This mineral, known as potash mica or muscovite, is found at some places in considerable dimensions and quantities, so that large films of mica, up to one square foot in size, may be obtained at a comparatively low price. If cut to thin plates this kind of mica is almost colourless; besides, it is very light, twenty to forty pieces weighing only as much as a glass plate of the same size and of average thickness. Dr. Miethe, who has tried these new plates, states that the prepared mica surface is twelve to twenty-three times lighter than a prepared glass surface. It may be exposed in any dark slide, and neither during development, nor in any other liquid, do the films show tendency to roll up; on the contrary, they remain perfectly flat, sticking slightly to the bottom of the developing dish, so that when the latter is rocking they remain still. The finished negatives are equal in appearance to glass negatives, and they may be bent and warmed during varnishing without fear of damage. They may, of course, be printed from both sides.

Two Novel Modes of Intensifying Gelatine Negatives.—The following original method of intensifying is suggested by R. E. Liesegang. If a finished negative is placed, after drying, once more in a water bath, a slight relief is produced on the film, the darkest parts of the image lying deepest. The relief remains also after the negative has been dried. If it be now rolled up with an easily drying red or black ink, like a collotype plate, the ink will adhere fastest to the darkest parts, while it is rejected by the unexposed parts of the film. By this method a very strong intensification is obtained. Dr. Stolze describes another method of intensifying, which depends on the behaviour of the bichromated gelatine. The negative is treated for a minute with a four per cent. solution of bichromate of potassium, and then dried. After a rather long exposure from the back it is thoroughly washed and again dried. If the negative be now placed in an aqueous solution of Indian ink, the latter will be absorbed by the unexposed and soluble parts of the film, which are intensified by it, while the exposed parts of the film are not affected by the solution. Liesegang remarks that this method has proved very successful in his hands in cases where but a slight intensification is required.

Combined Pyro and Quinol Developer.—Dr. C. Schleussner, of Frankfort-on-Maine, one of our most eminent gelatine plate manufacturers, recommends the following developer, which, as I may state, gives excellent results, at least with plates of the above-mentioned factory. It gives fine details and high lights, and quick-printing negatives of beautiful colour. The following stock solutions are made up:—

Solution A.

Quinol	20 grammes
Distilled water	... 2,000 c.c.

Solution B.

Carbonate of potassium ...	100 grammes
Distilled water	500 c.c.

Solution C.

Distilled water	400 c.c.
Sodium sulphite	60 grammes
Diluted sulphuric acid	10 to 20 drops
Pyrogallol	20 grammes

At first the sodium sulphite should be dissolved and acidulated with sulphuric acid, then the pyrogallol added. For use, mix:—

Solution A	40 parts
Solution B	10 ,,
Solution C	10 ,, .

It is well to begin development with an old solution, and to replace it by a fresh one as soon as the high lights have been brought out.

THE PHOSPHORESCENCE OF LITHIUM COMPOUNDS *IN VACUO*.

BY E. E. BROOKS.

Having noticed the great brilliancy with which certain lithium compounds phosphoresce when examined by Mr. Crookes's method in the negative discharge *in vacuo*, it may be of some interest to state the results obtained.

Lithium sulphate gave a bright lilac-blue glow.

Lithium phosphate was equally brilliant, the colour being a light Cambridge blue.

Lithium Chloride.—Pale lavender-blue; only moderate brilliancy.

Lithium Fluoride.—Very light flesh-coloured glow, about equal to the chloride in brilliancy.

Lithium Silico-fluoride.—Deep blue, with darker spots, but not so brilliant as the somewhat similar phosphorescence of the sulphate.

Lithium phosphate fused with sodium carbonate gave a bright emerald-green glow, which existed unchanged for a second or two after circuit was broken, and then faded quickly away. The other salts above-mentioned appeared to have no residual glow.

The nitrate, carbonate, and hydrate did not show any signs of phosphorescence.

Some lithium nitrate was fused and partly volatilised *in vacuo*, and the glass in contact with the fused salt received an opaque, enamel-like coating, apparently unaffected by water or acids; and, when the tube was again exhausted, this white coating exhibited a distinct phosphorescence, similar to, but more yellowish than, the normal phosphorescence of the German glass tube.

Of the lithium minerals, I believe spodumene is the only one mentioned by Mr. Crookes. This gives a golden yellow glow.

Lepidolite phosphoresces with very great brilliancy. The colour is a deep red, with traces of blue.

Petalite is also exceptionally brilliant, glowing with a rich yellow, like a live coal.

The spectra of all the above salts and minerals are continuous, only showing a concentration of light in certain parts of the spectrum.

Rubellite and indicollite did not phosphoresce, and amblygonite gave only slight traces of a whitish glow.—*The Chemical News.*

PHOTOGRAPHY IN RUSSIA.

BY C. T. CHESTERMAN.

PHOTOGRAPHY IN THE IMPERIAL THEATRE AT ST. PETERSBURGH—THE IMPERIAL RUSSIAN TECHNICAL SOCIETY—THE NEXT EXHIBITION IN ST. PETERSBURGH—THE NEXT INTERNATIONAL PHOTOGRAPHIC CONFERENCE AT BRUSSELS—DOUBLE GLASS STUDIOS—THE CHOICE OF PHOTOGRAPHIC LENSES.

A PHOTOGRAPHIC studio has been erected on the premises of the Imperial Marian Theatre in St. Petersburgh, and will shortly be opened.

Up to the present time Mons. Bergamasco has had the exclusive privilege of photographing the *artistes* of the Imperial theatres in costumes belonging to the Crown; now it is the intention of the Imperial Theatrical Direction to take these photographs, as well as scenic views, costumes, and theatrical accessories, and to publish copies of them for the benefit of provincial lessees.

According to the *St. Petersburgh Listok*, the studio and suite of rooms in connection therewith are superbly furnished, and the sum of 15,000 rbls. annually has been assigned for carrying out the plans of the Direction. Nevertheless, it will be some time before such an expert photographer as Mons. Bergamasco will be found to fill the post of Imperial Theatrical Photographer. There is a certain amount of skilled routine necessary to be able to turn out pictures such as the establishment of the above photographer has done for over a quarter of a century.

The Marian Theatre has a complete electric light installation, and some scenes have already been successfully photographed there by Mr. A. Smiruoff, the superintending electrical engineer of the theatre.

The V Section of the Imperial Russian Technical Society has elected His Excellency M. M. Deschevoff, president, and Mr. Leon Levitsky, Jun., vice-president of the Society. The members of council for the ensuing year are: Messrs. V. Gratschoff, N. Indoutny, J. Kovalsky, B. Kourdumoff, A. Lavroff, P. Olkhin, G. Schulz, A. Smirnoff, V. Tressnefsky, S. Vroblevsky, and C. T. Chesterman. Acting secretary, Mr. L. Zverintzoff.

It is proposed to give the next exhibition a scientific-educational character; there are hundreds who are at a loss to distinguish between one process and another. It will be the aim of the committee to arrange systematic collections of apparatus and appurtenances to illustrate the various branches of the art, and at stated times competent persons will explain these to the visitors. Besides the above, there will be the ordinary exhibition of photographs and novelties.

The Society proposes to send a delegate to the International Congress, to be held at Brussels in 1891. Here in St. Petersburgh, where all the houses are furnished with double doors and windows, your proposition of a glass studio within a glass jacket is rather the rule than an exception. In severe weather the moisture between the glasses freezes on to the outer panes unless all crevices be closed up round the inner frame. A space of 8 inches is sufficient between the frames; care should, however, be taken to putty the parts where the panes overlap each other in the roof. Inattention to this would soon make itself evident, as the soot of a town atmosphere would find its way through, and, settling upon the under frame, cause a disagreeable state of affairs.

A Russian newspaper, commenting upon the mineral riches of the Ural Mountains, states that platinum is found in no other part of the globe (?) From 1827 to 1845 coins of platinum were struck here, and upon these being withdrawn from circulation the price of the metal fell rapidly; fifteen years ago it was not more than 200 to 500 rbls. per pood, or about 17s. to 44s. per pound, so that its exploration fell rapidly. The present increased demand for it for technical purposes should create a larger supply. In reality, however, there are only 300 poods extracted annually in the Ural, and that is disposed of at the low figure of £13 per pound to agents of an English firm who are engaged to collect the metal in Ekaterinburg. There is a large amount of platinum along the River Ecsou, near the Katschkanar Mountains, where no notice is taken of the alluvial soil containing less than 8 ounces of metal per hundred tons of *dèbris*.

A translation of Mr. Dallmeyer's pamphlet, "On the Choice and Use of Photographic Lenses," has lately been published here by a Mr. Karpoff.

THE Photographic Society is advertising for an assistant secretary.

MR. S. W. GARDINER sends us a reproduced copy, on bromide paper, from a small negative of the large poster announcing the exhibition of the South London Photographic Society, to be held to-day and to-morrow in Hanover Hall, Hanover Park, Peckham.

REDUCTION OF SILVER NITRATE BY OIL OF BITTER ALMONDS.—E. Le Noble.—This reduction takes place under a variety of conditions. The author concludes that benzoyl hydride behaves like the aldehyds, reducing silver oxide, and passing to the state of benzoic acid.—*Journal de Pharmacie et de Chimie.*

PHOTOGRAPHY AND PAINTING.—The more one looks at exhibitions of photographs, the higher becomes one's estimate of painters. For securing portraits of one's friends photography is a fairly adequate and remarkably cheap expedient, and as such is a boon to humanity, though it usually fails in cases where the features of the sitter are very marked or characteristic, as it almost always exaggerates the special character. But look at the composed groups under different titles in the Exhibition of the Photographic Society (now open at the Society of Water-Colours rooms); at the rustic pair reading at their cottage door, for instance, under the title "In the Evening there is Light." This is intended for an idyllic picture such as we frequently find in the Society's galleries in water-colour time; but look at the hopeless vulgarity and inexpressiveness of this old couple set to pose for an idyll. That is realistic art, of which the camera is the true exponent; and what is it worth? A painter would have taken the same two figures, perhaps, just as models for costume and position, but would have put the light of feeling and sentiment into the faces; not such as could not exist in nature, but such as we do not find in the average man and woman, which is the material photography has mostly to deal with. There are various other scenes in which real figures play a part, but they all point the same moral. Take the absolute realism of ordinary men and women, and there is little to make a picture of; it is the artist who makes the picture; the living figures are only the raw material. Landscape is equally a failure in pure photography. Look at the two large Goupil-gravures exhibited by Messrs. Boussod, Valadon, and Co.; they are worth more as pictures than any of the pure photographs. There is one branch of work only in which photography has a value beyond that of any other process, viz., in the representation of architecture, and it is just this which is neglected. There are hardly more than half-a-dozen architectural subjects in the whole collection. The photographs of racing yachts are interesting, as recording the actual movement of the vessels and set of the sails. The photographs of clouds are interesting and valuable. But the bulk of the Exhibition strikes those who are accustomed to go to that room to look at pictures, as an illustration of what photography cannot do. It can *not* produce landscapes, and it can *not* make figure pictures. It only gives the prose of human life; we have to go to the artist for the poetry.—*The Builder.*

Notes.

A Camera Club is about to be established in Brussels, on the same lines as those laid down in other of the European capitals. It will be furnished:—1. With a luxurious studio, and the apparatus necessary for artistic photography, enlarging, and lantern projections. 2. Well-fitted laboratories, replete with every convenience. 3. A library and reading-room, containing photographic and artistic books and journals, a reception room, an exhibition room, and a "bodega." It will be established in the centre of Brussels, and foreigners as well as Belgians may become members. M. Cremers, of Rue de l'Ecuyer 31, Brussels, is working actively in this matter.

Rapid collodion dry plates are matters of interest to photographers, and, as already announced, Herr Gaedicke, of Berlin, has been trying to solve the problem of making collodion dry plates as rapid as gelatine dark plates. Recently he stated to the Society of Amateur Photographers at Berlin that he had succeeded in making them so as to equal in rapidity average gelatine plates, that they are unchanged by keeping for six months, that they may be developed six or eight weeks after exposure, and that the film is thin and rich in silver. The development is effected in an old quinol bath to which one-tenth its volume of a new quinol bath has been added. The plate is soaked in water for one minute, then is submitted to the action of the developer; the image appears in from eight to fifteen seconds, according to the length of exposure, and in one or two minutes the development is complete. About one minute's immersion in the hyposulphite of soda bath is stated to be sufficient for fixing; it is next washed for five minutes, dried, and varnished. He states that it is difficult to over-expose these plates.

M. Jules Breton has been trying experiments, as others have done before him, with hydrosulphite of soda as a developer; the usual way of making it is to add zinc filings to bisulphite of soda, but it oxidises so rapidly that, practically speaking, it must be used at once. He therefore prefers to produce the hydrosulphite directly in the bath, at the bottom of which he places a plate of zinc, and he surrounds the gelatine plate with a band of the same metal; then he pours upon the whole the solution of bisulphite of soda. The solution must be sufficiently weak to prevent any precipitation of the double sulphite of sodium and zinc, which is also formed by the reaction; he says that if any such precipitate be thrown down on the plate, it is easily washed off by water. Sulphurous acid may be used in place of bisulphite of soda, but its smell is suffocating. When the development is normal the images are of a fine black colour; when the development is too prolonged the images have a yellow tinge, which can partly be removed by means of an alum bath.

The season is now upon us when, in British large towns, the smoke and fog demons may be expected to do their worst. It is a strange thing that the British should be so careful about the drainage of towns and the cleansing of the streets, yet let more filthy air pass down their throats and into their lungs than, perhaps, any other people in Europe. Public buildings are blackened by the dirty air, and the photographic industry is impeded by the same influence. Leeds is often concealed from the vulgar gaze of those approaching it by its mantle of smoke. Cannot all the bright intellects in the Yorkshire College of Science do something to chase the smoke demon out of this country, as St. Patrick drove the snakes out of Ireland?

The Stereoscopic Company is "running" somewhat an innovation in connection with photography and electricity by way of advertisement. In the front of its new premises in Regent Street is a sheet of ground glass, measuring about eight feet by seven feet. This, during the daytime, forms a handsome window, prettily draped, and in the evening is a brilliantly illuminated lantern screen, on which are exhibited pictures of the most popular people of the day. The lantern itself is the outcome of a considerable number of troublesome experiments; it is fitted with most delicate adjustments, and gives a light of 6,000 candles. An assistant can switch on the current at will, and pass the slides through night after night. This form of advertising may do a business house a great amount of good; it certainly tends to popularise public characters. Each slide is properly titled, so that should some of the passers-by not be familiar with the face of the latest beauty, or the most popular man, they are at once informed by the name underneath. Possibly we may hereafter give an illustrated description of the lantern.

The phenomenon known as phosphorescence is one of those scientific puzzles which remain unsolved. Theories have been formulated, but no one has yet satisfactorily explained why light without any apparent heat should be so common in nature. The glow-worm, which has furnished poets with many a pretty simile, shines in our hedgerows as brightly as ever it did, but why it shines, and where it gets its luminosity from, no one has yet told us, although many naturalists have done their best to solve the problem. The luminosity of the sea has been traced to a minute organism called the *Notiluca Miliaris*, but there our knowledge stops, and we know no more about the cause of the beautiful light than we do about the secret of the glow-worm. So it is with other phosphorescent things in the animal, vegetable, and mineral divisions of nature; we know very little about them, although it is easy enough to produce a chemical compound which will exhibit the same curious property; and, as our readers well know, such a compound has been introduced commercially of late years under the name of Balmain's luminous paint.

But all chemical preparations of a phosphorescent quality, from the famous Bologna Stone discovered three hundred years ago, to the so-called luminous paint of to-day, sink into nothingness when compared with the brilliant light emitted by the *elateridæ* or fireflies of the West Indies, which are there used for lighting up rooms, and occasionally in lieu of diamonds in ladies' head-dresses. The light given by these creatures is evidently far greater than that emitted by any organism in this country, and it is not strange that they should have been chosen as representative insects of their class for certain investigations which have lately been conducted by Professor Langley and Mr. Verey at the Allegheny Observatory, Pennsylvania.

These investigators, by means of delicate apparatus, have succeeded in measuring the amount of light given out by the firefly of Cuba (*Pyrophorus Notilueus*). This insect is about an inch and a-half long by half an inch in breadth, and it possesses three light reservoirs, two in the thorax and one in the abdomen. These enquirers have calculated that to produce the amount of light emitted naturally by the firefly—that is to say, to get its equivalent by artificial processes—a temperature of 2,000° Fahr. would have to be employed. They have further calculated that nature, in the case of this insect, produces the cheapest light at about 1-400th part of the cost of the energy which is expended in a candle-flame.

Photographers are interested more than ordinary mortals in the question of light, both natural and artificial, and many of them will be wondering, in common with other thoughtful members of the human family, whether the secret of this marvellous source of natural illumination is really beyond the power of science to unravel. Is this light so wedded to vital processes that such a discovery would be equal to mastering the secret of life itself? We think not, because, as we have already pointed out, phosphorescence is present as a result of certain chemical combinations. It is, therefore, not too much to hope that some day the real source of this wonderful flame which burns—if it may be said to burn—with the expenditure of such a trifling amount of energy may be discovered. When that day comes, both the gas companies and the electric light corporations will find their shares at a considerable discount.

The fallacy of Professor Herkomer's dictum, that photographs were useless as representing the sitter as he or she really is, is clearly disproved by examples taken from the works of artists. There is Frank Holl's portrait of Sir Herbert Stewart, for instance. This picture was painted from a photograph, and the result was so striking a likeness that when the picture was first seen in the mess-room, some of the brother officers of the deceased soldier declined to credit the circumstances under which it had been produced. In this year's Academy there was a portrait of a lady by Mr. F. Goodall, R.A.; this was also painted from a photograph, and was considered a most extraordinarily able performance. Another photographic painting was his portrait of Sir Moses Montefiore, on seeing which his friend Dr. Adler exclaimed with astonishment, "It is Sir Moses himself, *wie er liebt und lebt.*" It is needless to say that in all these instances the painter had never seen the original.

The photographer is an indispensable adjunct at almost every function. His services, we note, are especially called into requisition when any patent to be afterwards exploited by means of a limited company is shown. It looks well, we suppose, to be able to produce a picture in which the representatives of the press are pictured in great numbers. The latest instance of this kind of thing was seen at the exhibition of a patent dredging machine at one of the south coast watering places. Two photographs of the guests were taken as they sat at luncheon, but as the exposure was at least one minute, and as the photograph occupied the place of a grace, we have some doubts as to the perfection of the result—a minute to hungry men is a long time. The time may come when some sturdy person of great strength of character will resist this enforced ceremony. He may say that he does not desire to be photographed, and, instead of sitting still, will commence to ply his knife and fork.

The hat-camera, which has been referred to from time to time as one of the curiosities of photography, is, according to the *New York Evening Sun*, of very ancient date. The credit is given to a Parisian who made a small camera which he concealed in his head-covering. A shutter in front was cleverly arranged so that the joint could not be seen. At first he used wet plates, but he soon saw the disadvantages he was labouring under. About the time the lightning photos were put upon the market the Frenchman's hopes rose high; he could take his hat anywhere with him, and no one at a glance would suspect its double purpose. Placed on a table facing the person to be taken, the little button at the back could be pressed and the exposure made. In some respects the hat-camera was immeasurably superior to the toys now in the market. A characteristic of photography is that no sooner does somebody discover a novelty than somebody else discovers that the novelty is very old, and that the germ was suggested five-and-twenty, or thirty, or more years ago. Probably the first instantograph which obtained a picture without the knowledge of the sitter was Skaife's pistolgraph, a quarter of a century ago largely advertised as the best apparatus with which to take babies.

This may fairly claim to be one of the eccentricities in the way of photographers' advertisements. It is from a show-card in a shop window in the Boulevard Sebastopol, Paris, and runs as follows:—"If you will picture have after photographs, you can yourself for five francs taken have, and your wife for three francs painted have with oils all over."

THE REPRODUCTION OF POSITIVES AND NEGATIVES.*

BY ERNEST J. HUMPHERY, M.A.

BEFORE I enter upon the principal subject of my paper, I should like to show you a few of the results of methods of reproduction which are not very frequently used, but are well worth very careful study.

The first is a transparency on platinotype paper, made in the ordinary way by contact, the print being fully printed, and then rather over-developed in order to sink the image, after which the paper is rendered more transparent by the aid of paraffin, which, amongst its other qualities, has the very valuable property of not turning yellow with age. You will notice, in looking at this transparency, that when looked at by reflected light it appears dull and flat, but when held up to a strong light it is as transparent and almost as brilliant as a transparency on glass.

And now I come to the main point of my paper, viz., the reproduction of positives direct from positives, and negatives from negatives. The process is so simple and so fascinating that I trust you will all give it a trial, and that in the hands of some of you who have more leisure than I have, experiments may be carried out which will give you a perfect mastery over the methods of development necessary to obtain the best possible results.

I do not propose to go into the theory of the subject, as that has been so ably discussed already by Captain Abney and others; but merely to give you the practical results of my experiments with varying exposures and different developers.

The method which I have used is this. The negative, in contact with a sensitive plate, is exposed in the printing frame to diffused daylight for a few seconds, and then developed with a very weak developer.

The developers which I have used are eikonogen, hydrokinone, and pyro and soda.

The first negative which I wish to show you is of more than common interest, inasmuch as in the original negative the central figure was seated on a common Windsor or kitchen chair, in a room containing, as far as my memory serves me, a kitchen clock and two other wooden chairs. The whole of the background was very skilfully worked out. I think you will allow that the present surroundings of heather, rock, mountain, lake, and sky make the picture rather more pleasing than the somewhat incongruous furniture of the original. To obtain the reversed negative, which I will hand round for your inspection, the negative was placed in the printing frame in contact with an Ilford ordinary plate, and given twelve seconds' exposure to diffused daylight at 3.45 p.m. on Saturday last, when, as you will remember, the light was rather poor.

The developer used was eikonogen, Marion's instantaneous.

Formula
- 5 parts sodium sulphite
- 2 parts carbonate of potassium
- 1 part eikonogen
- 30 parts water

Diluted with eight times its bulk of water.

Development takes place in the ordinary way, except that, instead of a positive, a negative image gradually appears, and continues until development is complete, which, in this case, was about fourteen minutes.

* From *The Journal of the Camera Club.*

The second plate from the same negative had twenty-five seconds' exposure to diffused daylight at 4.7 p.m. on the same day; and in this case development was continued for sixteen minutes.

The third plate was given an exposure of twenty-five seconds at 4.45 p.m. of the same day, but in this case hydroquinone was used; I cannot give you the exact constituents of this developer, but it is known by the truly scientific name of hintoquinone, mixed in the following proportions:—Hintoquinone, 1½ drams; water, 8 oz. Time of development, thirty-five minutes.

It will be interesting to compare this with the eikonogen developed negative.

The fourth plate is a transparency, produced in exactly the same manner as the former, but from a paper transparency. I will hand round the transparency and the reproduction in order that you may compare them. This was given a two minutes' exposure at 5 p.m., when the light was, of course, very feeble; developed in eikonogen in the same proportions as before, and development was continued for twenty-five minutes.

The fifth, negative of bridge and trees, 20 seconds' exposure at 4.20, light dull.

Developer, eikonogen, 1 in 8.

Time of development, 15 minutes.

The sixth, exposure 8 seconds, 12.30 p.m., light good.

Developer, 60 minims S.P.

20 grs. carbonate of soda
40 grs. sulphite
8 oz. water

Development, 10 minutes.

This seems to give very good results. There is good detail in the high lights, and, perhaps, better gradation throughout.

The seventh, exposure 2 seconds, 12.55.

Developer same as No. 6, but with the addition of 2 oz. water.

Exposure is evidently insufficient. The high lights in the negative partake evidently of both the positive and negative image. The shadows show plenty of detail, as the exposure for shadows was probably about correct.

The eighth exposure was made in a different manner; the first object being to avoid halation, the second to delight the "new sort of lunatics" who believe in the destruction of detail. The plates were placed in the printing-frame back to back. In this case it will be noticed that the evil effects of halation are greatly diminished, and the gradation appears to me much better than in the other examples I have shown.

This leads me very strongly to the opinion that far better results than I have shown would be produced by backing the plates, or by the use of films.

In the quarter-plate reproduction, which I now pass round, I would particularly draw your attention to the margin; this, although entirely protected from light by the rebate of the printing-frame, is black. If you compare this margin with that of the transparency, you will notice that whereas the margin of the negative, which was exposed to no direct light, is black, the margin of the transparency, which was fully exposed to the direct light without any protection, is simply slightly fogged.

Unfortunately, my time for experimenting has been so short that I have not been able to try the effect of backing the plates to prevent halation; but I am inclined to think that this would be very advantageous. Probably, also,

films would give very satisfactory results; but these will have to be the subject of further experiment.

I am at the present moment experimenting with a view to producing enlargements direct from the negatives, but at present have not carried them far enough to obtain perfect results from them. If, however, I succeed, as I hope to do, the advantage of this method of producing enlarged negatives is so great, that it will probably be found to be the most important branch of the subject.

A COLLISION BETWEEN A PHOTOGRAPHER AND A COUGAR.

From a long narrative in *The Detroit Free Press*, we learn that the other morning, in the city of Seattle, the people in the vicinity of Sixth and Pike Streets turned out and joined in the excitement of a genuine hunt after a cougar.

About nine o'clock, as Judge Wood was crossing the vacant lot on the north side of Pine Street, he noticed an immense mountain lion trotting along leisurely across the lot. He watched it as it disappeared in the Kentucky stables.

The appearance of the wild beast caused a big commotion among the horses. The uproar brought one of the men down; he saw the lion quietly taking in the situation. He hurried upstairs, and caused a stampede with his report. Mr. Bishop, owner of the stables, hurried to get his rifle, while the men cautiously took a look at the brute. He was trying to catch a chicken which was in the stable, and succeeded in killing one. He soon found out that the men were watching him, and he made a dive through the window. Mr. Bishop came up just as the animal sprang, and he fired a shot at him, catching him in the hips as they disappeared through the window.

The lion gave a howl of pain, and leaped to the sidewalk, ten feet above, and started down Sixth Street towards Pike on a dead run, screeching and yelping. Pedestrians scattered in every direction, and gave the beast a clear track.

Mr. Munsen, the photographer, was out in the street adjusting his camera preparatory to taking a view of the power house. He had the cloth over his head, and was deeply interested in his work, when the cougar came flying along and ran square into the photographer from behind, turning him and his camera over in a succession of confused revolutions. The cougar righted himself and trotted away, gazing at the astonished photographer as he sat amid the wreck of his apparatus.

On reaching Pine Street, the cougar jumped the fence into Dr. A. P. Cole's yard, and crouched down on the ground. Several children were on the porch, but were too frightened to move. The lion made a spring for them, but was weak from loss of blood, and fell short.

At this point Eugene Chapin rushed out from his store flourishing a big 44 six-shooter, and opened up a brisk cannonade upon the crouching cougar. A good shot from the revolver dropped him as he sprang from the ground.

The dead animal weighed 160 pounds. It probably wandered in from the timber sometime in the night, and could not find its way out in daylight.

The London and Provincial Photographic Association.—November 27th, demonstration of Messrs. Varley and Greene's Magazine Camera, also paper by Mr. Friese Greene; December 4th, "The Primuline Process," demonstration by Messrs. Green, Cross, and Bevan; December 11th, lantern night.

THE ARC LIGHT FOR PROJECTION.*

BY DR. L. H. LAUDY.

A general adoption of the electric arc light for purposes of projection is not far distant, and, having devoted some time to the subject, following it up from the days in which the current was produced from batteries until to-day, when we have on tap a current of electricity as we have gas or water supplies, it seems most fitting that my experience should be given to the members of this Society, and my object in inviting you here this evening is to give you some experimental facts, and ask your verdict as to their application for lantern projections.

Our usual method has been to make use of incandescent lime. This was a great advance from the oil lamp, and to-night we take probably the last step in this direction of improved illumination, and make use of the most intense artificial light known to science.

Artificial light is generally produced by raising some body to a high temperature. If the temperature of the body be greater than that of the surrounding atmosphere, it parts with some of its energy in the form of radiation, and at a high temperature this radiation becomes sensible to the eye, passing from red, yellow, green, to blue and violet. At the present time, for all artificial illumination the radiant body is some form of carbon, either incandescent or combining with the oxygen of the air.

The electric light is the outgrowth of the experiments of Sir Humphry Davy, made at the Royal Institution, London, in 1801, when he used 2,000 cells, with which he decomposed Na and K, and separated their metallic bases. These experiments were repeated and extended, and by using charcoal points as terminals an intense and dazzling light was produced, to which the name voltaic arc was given. Foucault used a more dense form of carbon for his newly-invented lamp or regulator, producing a more steady and uniform light.

The arc light, when produced from a battery, brilliant as it is, was confined to the lecture-room or an occasional outdoor display. The fatal difficulty was the labour and cost of the electrical energy, and it was not until the discovery of induced currents by Faraday that this obstacle was removed.

It was many years before any practical application was made of this most important electrical discovery, and it required the combined forces of Nollett, Von Maldern, Holmes, Wilde, Ladd, and Siemens to produce by mechanical means, direct from motion, a supply of electrical energy that would equal that produced from the battery. Even as late as 1870 this did not seem possible, for the best dynamos at that time yielded only a small amount of electrical energy.

In 1871 Gramme presented to the Academy of Science a description of a new form of magneto-electric machine possessing new features, which were so remarkable as to astonish all the world. Gramme conceived the idea of using a ring, and rotating this between the poles of a magnet in such a way as to prevent reversals in the armature. Many ridiculed this idea; nevertheless, it produced in practice a machine which yielded large currents at much less cost, and laid the foundation of our present system of electric lighting.

From whatever source the electricity is supplied to produce light, it is necessary that the current meets with a resistance, and this condition is best fulfilled when two

* Read before the American Society of Amateur Photographers.

pieces of carbon are made to touch and are then slightly separated. The current, in passing between the space, so increases the resistance as to produce light of great intensity, and is called the arc light.

That a constant resistance may be maintained favourable to the production of light, some mechanical device which will separate and regulate the distance of the carbons is essential. Such an apparatus is called a regulator or arc lamp. There are few inventions on which so much ingenuity has been expended as on arc lamps. The number is already very great and is on the increase, and every bulletin of the patent office is sure to contain several inventions of this kind.

Between the better lamps there is not much to choose for ordinary illumination, but for special purposes, as in the case of lantern projection, some points are of vital importance, for the success will depend mainly upon the steadiness, good behaviour, and the excellence of the automatic feed, quality and position of the carbons, together with a uniform action of the dynamos.

At present arc lights are run both by continuous and by alternating currents, *i.e.*, in some cases the current is steadily in the same direction, while in others the current consists of pulses, alternately positive and negative, succeeding each other at the rate of from 200 to 300 per second.

The first lamp for regulating the position of the carbons was devised by Thomas Wright, of London, in 1845. A few years later Le Molt, of France, devised a clock-work regulator which kept the light steady for several minutes at a time, but the flickering was too great to make it of any practical value. These were followed by Archereau, Lacassagre, and Garlfe, each lamp an improvement on the other, which brought the standard of regulators near to practical application.

In 1849 Foucault devised a clock-work regulator which differed in many details from the ones before used, and gave comparative satisfaction. It was extensively employed for scientific purposes, and, in fact, was the only lamp that was suitable for lantern projection, and is today used in many physical laboratories in preference to other lamps.

The next advance was by Serrin, whose regulator kept the carbons exceedingly steady, and maintained them in their relative positions. This lamp has been used for light-house illumination, and still maintains that position, for, like the Foucault, it is a focussing lamp, the function of which is to maintain the carbons at a central point. To produce this effect the carbons are so arranged that a different motion is imparted to each, that the wearing away may be compensated by a more rapid movement of the positive pole with only a gradual waste of the negative carbon. By this simultaneous approach of both carbons, the positive moving through double the distance of the negative, the arc preserves its normal length, and its position is maintained in space. This is accomplished by an ingenious mechanical device, actuated either by clock-work or electric magnets.

The regulation of the length of arc that shall produce the most intense light with the least current is confined to very narrow limits, and the mechanical construction of the lamp which will yield satisfactory results must be most perfect. In many of the lamps this regulation is still wanting, and lamps lacking the above essentials, which are put together without regard to any electrical laws, with the hope that chance may make them work, produce a hissing and hammering noise that is disagreeable when silence is required, and are not to be recommended for any purpose.

However good the regulation, due to the electrical and mechanical part of the lamp, they cannot regulate the minute accidental variations in the structure of the carbons, which cause a shifting of the arc or chasing, and as the arc flies around, the direction of maximum emission will change with it. These fluctuations produce immense variations in the intensity of the light, changing back and forth from 400 to 2,000 candles. Great improvements have been effected in the homogeneity of the carbons, and the time is not far distant when the flickering will be entirely removed.

The mechanical and electrical regulating devices are all that could be desired, and at present the light is not too irregular to be adopted for purposes of projection. With any good regulation, results may be obtained that far exceed in brilliancy any of the old methods employed. This matter of increased intensity is of great importance, especially in large public halls, where in many cases the picture is enlarged many hundred times, without regard to the diminished light produced by means of the oxyhydrogen light.

In considering the application of the electric light as a source of illumination, it is very important to notice just what position the carbon poles must occupy in relation to certain requirements.

For outdoor illumination the axes should coincide, that the crater formed in the upper carbon may act as a reflector, and thus produce an increased downward illumination. Advantage is taken of the crater-like reflection to cast the rays at variable angles in a given direction.

To obtain the best effects for lantern projections, the carbons are arranged that the axis of the upper carbon coincides with the edge of the lower carbon farthest from the condenser. In this position of the carbons the light will be concentrated upon one side and radiate freely in front, and will be cut off from behind, with little escape at either side. From this it follows that many different results can be obtained, depending upon the position of the carbon.

It is more or less difficult to make a classification of arc lamps in their present state, or divide them into a few distinctive types. The old classification divided them into monophotal and polyphotal. In the former the electro-magnet system, which produces the adjustment of the distance of the carbons, is traversed by the main current and is adjusted for a constant current. This prevents a number of lamps being placed in series, as the approach of the carbons is produced by mechanical means independent of the current. Polyphotal lamps are adjusted for a constant resistance of the arc. This is effected by placing the regulating apparatus in a shunt of the main current, which is also supplied with a cut-out device to short-circuit the lamp in the event of a disconnection in the arc. The objection to this classification is that one would be transferred to the other by an alternation in the winding of the coils. The better or later division is to class them either as series or parallel, which is dependent upon electrical conditions rather than mechanical. We may again subdivide them as a matter of convenience into : 1, hand regulation ; 2, actuated by a spring (clock-work) ; 3, train of wheels and gravity ; 4, differential and gravity ; 5, clutch and dash pot ; 6, electro

motor; 7, focusing; 8, electro magnet and dash pot; 9, lever movement.

The most important consideration is simplicity of construction and sensitive motion of carbons, with speed to allow of instantaneous adjustment. These conditions are changing at each variation of resistance, which alters with the change of temperature in the conductor, and this again varies the potential, so that it is impossible to keep the arc constant. For any increase in the current the wire coils are heated with an increase of resistance in the lamp. To regulate these variations, and to secure the proper proportions, we meet with colliding difficulties, and are confined to narrow limits in order to reconcile them. The necessary features in construction of a lamp are: 1, striking mechanism or separating the carbons; 2, feeding; 3, replacing, to put in new carbons (trimming); 4, moderating, to prevent carbons striking or hammering; 5, change over for two carbons; 6, cut-out; 7, clamps for carbons; 8, driving power, which may be clock-work, gravity, weights, electro magnets, and electro motors.—*The American Amateur Photographer.*

Patent Intelligence.

Specifications Published.

16,778. *October 24th*, 1889.—"Photographic Cameras." Samuel Dunsieth McKellen, 3, Chapman Street, Manchester, Photographic Apparatus Manufacturer.

The first part of the invention has for its object an easy means of carrying any convenient number of plates in one storage box, so that they may be exposed one after another, and an easy means of transferring the exposed plate from its position in the storage box into a separate receptacle.

A chamber or magazine is provided at that end of the camera which is opposite to the lens. This chamber is made to contain any convenient number of plates, preferably one or two dozens, which are placed therein face to back, the sensitive films being towards the lens. The plates are pressed forward against a frame (afterwards to be described) by suitable springs, which exert sufficient pressure at the back of the plates to ensure that the front one shall be always kept in proper register. The transferring of the front plate, after exposure to the receiver, may be effected in the manner described in detail in the patent.

"The second part of my invention is to provide a cover for cameras of all kinds which have to be carried about. This cover is intended to dispense with the use of a carrying case. For this purpose I employ any material of which camera cases are usually made. I cover the base-board of the camera with the material attaching it by means of studs placed in a convenient position, or by any convenient means. I make an opening in the centre of the material corresponding in size to the turn-table in my cameras, or large enough to allow a triangle to be screwed to the base-board, or with only a small hole through which a base-board screw may pass. I make this material of such size and shape that it will fold over and cover all of the camera when it is folded up. It can then be fastened by buckles, or in any convenient way, so as to appear as if the camera were in a case. The advantage of this cover is that the camera can be mounted on its legs, and, the cover being unfastened, the camera can be opened, leaving the cover still attached to the base-board. The camera, cover, and legs attached, can thus be carried about, when photographing, from one point of view to another much more easily, as there is no empty camera case to handle.

"The cover may be attached to the under side of the camera if preferred, but the action is the same. A handle may be fixed to the cover, or the handle of the camera itself may be used by having an opening in the material through which it projects to allow of its being grasped by the hand. If the cover is attached to the under side of the camera, the base-board apertures may be omitted, and in that case the cover would be unfastened before placing the camera on the legs."

The inventor claims:—

1. The use of sheaths or frames with side projections for the purpose described.

2. The method of removing the front exposed plate from its position by sliding the containing sheath or frame along the rails till the projections pass through the notches in such rails as described.

3. The use of a receiver, which is caused to close up against the face of the magazine to enable the exposed plate to fall into it.

4. The use of gripping cushions or racks to firmly grip the sheaths when in the receiver.

5. The combined arrangement of magazine, sheaths with projections, receiver, and gripping racks for the purpose described.

6. The combined arrangement of magazine, sheaths, pinion, or shaft with catch, receiver, and gripping racks.

7. The use of a constantly attached cover with ordinary cameras to take the place of the usual carrying case.

17,548. *5th November*, 1889.—"Cameras." Francis Beauchamp, Hope Cottage, Chadwell Heath, Essex, Engineer.

This invention relates to a camera for photographic purposes, which may be used either on the tripod stand or for detective work, and is made to carry any suitable number of plates. The said camera is divided with partitions for the purpose of forming dark chambers; one chamber has a ground glass for focussing purposes; the plates are held up to an adjustable face by springs. Each plate is provided with a frame which has an arm attached—each arm has a hole in—which is threaded on to a rod or a piece of tube for the purpose of working thereon; each arm is provided with a notch which comes in contact with a push piece from the outside of the camera for the purpose of lifting the said frame, which holds the plate up or down for exposure, through a slot provided with a cover; the frame has a spring tension for clutching the plate firmly. The camera is so arranged that it can be drawn in or out by hand, or by a rack-and-pinion working in a tube which acts as a guide for focussing purposes. As the front of the camera for carrying the lens works telescopically by tubes working in each other, or springs at each corner of sufficient strength for supporting the covering, which may be of any suitable material for excluding the light in the movable part of the camera, I sometimes employ two chambers for the plates, one for the exposed plates, and one for the unexposed. The plates are held by a spring frame in the same manner as before described, but in this case the ground glass is not used, as it has a fixed focus, and a finder is required.

17,773. *November 7th*, 1889.—"Improvements in Photography." Ernest Howard Farmer, of the Polytechnic School of Photography, 309, Regent Street, London, Photographer.

The so-called chromium processes in photography are based upon the property possessed by light of decomposing bichromates and other reducible compounds in the presence of gelatine or other colloid substance; whereby in the gelatine (or other colloid) are induced both chemical and physical changes—chiefly that they are rendered insoluble in their usual solvents.

I have discovered that the like changes take place when bichromates, or chemically similar reagents, are brought into contact with silver surrounded by gelatine or other colloid; that is to say, more or less of the gelatine or other colloid is rendered insoluble in proportion to the quantity of silver present.

I prefer to proceed as follows:—I prepare dry gelatine films in all respects in the ordinary manner, except that I do not add any hardening material to the gelatine, as is sometimes done. I expose these films in the usual way, either in a camera or under a negative or positive, and if only an invisible image has been impressed the picture is developed also in the usual way—I prefer the iron developer. Then the plate or surface carrying the film with the silver image upon it is immersed in a strong solution of bichromate of ammonia, a suitable formula being—

Pure bichromate of ammonia ... ... 4 ounces
Water ... ... 20 ,,

The time of immersion may be one minute. The plate or surface is then washed and dried, when it becomes suitable for use in the various ways in which plates with exposed chromated films are now employed.

For example, the plate or surface may be used in the following well-known processes :—

1. The plate may be of copper and may be etched ; the etching fluid will act least where the plate is most protected by insoluble matter. A copper printing plate is thus obtained.

2. The plate or surface may be treated with hot water, and then used for printing by pouring a suitable ink on the surface, laying a paper thereon, and expelling the superfluous ink by pressure.

3. The plate or surface may be used direct for printing by rolling a greasy ink upon it ; the ink adheres to the insoluble parts, and is repelled by moisture which the unchanged parts retained ; the inked plate is then pressed against the paper to be printed.

4. The plate or surface may be charged with greasy ink, and after washing the image may be transferred to a lithographic stone or surface, which may then be used in printing in the well-known manner.

In the preparation of the plate, chemically similar reagents may be used in place of the bichromate of ammonia, and organic bodies similar to the gelatine (gum, starch, albumen, and the like) can be used in place of or in conjunction with it. The bichromate or similar reagent may be placed previously in the film or developer, and react on the gelatine at the same time as the developer sets free the metallic silver, but the method above described is preferred. It will be seen that in this process the chemical reducing properties of silver are employed, the silver image, acting with the aid of the bichromate, to render the gelatine film insoluble. In this process the metallic silver forming the image acts in the place of the light in causing chemical change in the film.

The inventor claims :—

1. The employment in photography, substantially as described, of the reducing powers of the silver image produced by light in rendering insoluble gelatine and like colloid films.

2. In the production of photographic pictures substantially as described, the process consisting in obtaining a photographic image on a sensitised gelatine or like film, exposing and developing the said image, whereby silver is liberated in the film, and further causing the film so treated to be acted upon by bichromate of ammonia or similar reagent, whereby the film is rendered insoluble more or less in different parts, and proportionally to the varying action of the light upon the sensitised film.

19,319. *December 2nd*, 1889.—"Reducing-Cameras for Lantern Slides." ARTHUR PEARSON, 5, New Station Street, Leeds, Yorkshire, Dealer in Photographic Instruments.

My invention has reference to reducing cameras for lantern slides, and consists,

1. In constructing the end of the camera (where the negative is placed) so that the said negative can be adjusted in its position either horizontally, vertically, or diagonally. To enable me to do this I preferably employ flat springs, one arranged at each corner of the camera, for the purpose of holding the negative in any required position, and when more or less of the picture is required to be exposed, the negative can readily be adjusted or moved from one position to another, which cannot be done with the present construction of camera ; consequently a long felt want is supplied. Instead of employing the flat springs for holding the negative, other equivalent devices may be substituted.

2. In the present construction of cameras, there is always some difficulty in getting access to the lens. To obviate this I divide the camera into two parts, connected together by a suitable form of slide, between which parts there is a space left, giving free access to the lens. The space left between the divided camera is covered over by the focussing cloth for the purpose of darkening the camera, rods or projections being employed to suspend the said focussing cloth. The reducing end of the camera is also lessened in size, and made to the size of plate to be used, the object being to economise room, reduce the cost, and make the camera more portable.

19,618. *December 6th*, 1889.—"Boxes for Changing Photographic Dry Plates." GEORGE BRAMLEY and GEORGE BUTTERWORTH, Clay Cross, Derbyshire, Foundry Manager and Foreman of Mechanics respectively.

The improvement is in the means adopted to ensure the delivery into the dark slide of a single plate.

The inventors claim :—

Constructing changing boxes with a reciprocating frame movable from the outside of box, and a particular combination therewith of a lever and latch, substantially as herein described.

5,860. *April 17th*, 1890.—"Photographic Cameras." HARRY RANSOM, 122, Newington Butts, London, Photographer.

This invention relates to improvements in photographic hand or detective cameras, whereby a number of plates may be successively exposed in a simple and convenient manner.

In carrying out my invention, I provide a rotating shaft or cylinder, to which is hinged a number of sheaths or holders in which the sensitive plates or films are placed. The cylinder is adapted to be rotated in a suitable case or box, and is advantageously formed with as many sides as there are plate-holders, say twelve, for example ; the sheaths or holders are flexibly hinged to the cylinder, and a suitable ratchet arrangement is provided to allow of the cylinder being rotated one-twelfth of a revolution, each movement bringing a plate in a proper upright position opposite the lens and against a flexible frame, which helps to retain the plate in a rigid position during exposure, but allows the sheath or holder with the plate to be passed through it when the cylinder is turned, whereupon the plate by its own weight falls down clear of the lens, bringing the next plate into position for exposure.

In practice, I find it advantageous to form my sheaths or holders so that they shall act as springs to clip the plate firmly, and to form them in parts adapted to slide one upon the other, so that they may be used for different sized plates. I employ a drop shutter with suitable arrangements for operating the same.

In some cases I adopt an auxiliary lens outside the case adjusted and working with the operating lens, whereby I am enabled to accurately focus the object to be photographed.

13,381. *August 26th*, 1890.—"A Photographic Posing Chair." JAMES MCKENZIE DOW, Ogdensburg, in the County of St. Lawrence, and State of New York, Photographer.

My invention relates to posing chairs, more especially adapted for photographers, although equally adaptable to other purposes, and it consists in part of the combination with a suitable seat, of a series of adjustable parts, rest supports, and braces, adapted for varied and independent adjustments for the head, back, arms, &c. ; also in the construction and arrangement of said head, back, and arm rests, combined with other parts, whereby an independent vertical and lateral adjustment may be had ; and thirdly, in the construction and combination of the several parts, whereby such chairs may be utilized with a greater degree of efficiency than when otherwise constructed.

The object of my invention is to provide such chairs with such parts and adjustments, that the subject to be operated upon may be posed more properly, and to the desire of the photographer or other person, posing, or being posed, than by any other means, and at the same time insure the greatest amount of comfort to the person posed.

8,647. *4th June*, 1890.—"Focussing Arrangement for Photographic Cameras." JAMES CHAPMAN SHENSTONE, 13, High Street, Colchester, Essex, Chemist.

My invention relates to a device for attaching a focussing cloth to a camera, and it has for its object attaching the cloth in such a manner that it may be easily attached to or removed from the camera, and it is so firmly attached as to need no control on the part of the operator.

I attain this object in the following manner :—I take an

ordinary focussing cloth, and on one edge I attach a clip designed to embrace the camera on the top and two sides, just in front of the back frame, or at any other conveuient poiut. The clip may be made in a variety of forms, and may either be made adjustable to fit a camera of any size, or it may be made non-adjustable to fit a camera of a given size.

The clip consists essentially of a bar, adapted to lie across the top of the camera, and of two spring arms or their equivalents at each end, adapted to embrace the sides of the camera.

In an adjustable clip the bar is made telescopic, or otherwise, so that its length may be varied either automatically by a spring or springs, in which case the arms at the ends may be rigid, or by meaus of any suitable locking arrangement, iu which case the arms at the euds would be formed as spriugs. In a non-adjustable clip I make the bar of one given leugth, and I attach the spring arms to the end of the said bar. In all cases I prefer to attach the arms to the bar by means of knuckle joiuts or their equivalents, so that they may be folded to lie against the bar, thus euabling the focussing cloth to be folded up into the smallest possible space.

Correspondence.

INSTRUCTIONS FOR USE OF OPTICAL LANTERNS.

Sir,—Numerous enquiries are made as to how to obtain the maximum amount of light from the lamps supplied with optical lanterns.

We venture to enclose advance proof of matter at present in the press on this subject, thinking you may consider the hints it contains useful to many of your readers.

Perken, Son, and Rayment.

Instructions.

Wipe the frout and condensing lenses with a piece of soft silk free froin every particle of dust.

Thoroughly dry the new wick before putting it into the lamp ; let the wick be saturated with oil before lighting.

The best paraffiu oil gives the brightest light ; Diener's A1 safety oil, and Strauge's A1 crystal oil, also the Vascline Co.'s Luxor, are specially recommended.

The best quality of wick is indispensable to brilliant illumination. Cheap wicks and cheap oils are false economies, answerable for very mauy failures and disappointments when exhibiting the lantern. A large and strong pair of scissors should be used to trim the wicks, or preferably the "Optimus" patent wick trimmer, as a perfectly straight and even edge to the cotton is necessary for the avoidance of an uneven flame aud smoke. Cut off the protruding corners to allow the flame to draw evenly upwards.

Light the lamp with wax vestas or tapers. The heads of matches or charred paper are liable to fall into the air passages between the wick tubes, so impeding complete combustion.

When lighting the lamp, do not turn the wicks high immediately, but raise them little by little at intervals of a few minutes. This system, besides improving the flame, gradually warms the condensing and front lenses ; if suddenly heated they are likely to crack. Cold air being allowed to blow on a heated condenser will also certainly cause unequal contraction, *i.e.*, a cracked glass.

The oil reservoir and other exterior parts of the lamp should be wiped *perfectly* dry, otherwise the oil about them will vapourise and fill the apartment with a most unpleasaut odour.

The wicks should be trimmed prior to each exhibition, aud when not burning should be turned one-eighth of au inch below the top of wick tubes, so that they may be permeated with oil.

A plentiful supply of pure air is an imperative necessity for perfect combustion or perfect illumination. In crowded rooms, opening a window or door will greatly improve the light of the lamp ; insufficieucy of air ensures a bad light and an unsatisfactory exhibition. Like ourselves, the lamp gives its best results when it enjoys pure air, clean surroundings, and pure food (oil).

LANTERN SLIDE MAKING.

Sir,—In your article on the above subject in last week's issue, yon say, "chloride plates are also unsuitable for copying work in the camera when a larger negative has to be reduced to lantern plate size." A paragraph or two above this you say, "the makers do not all state by which process their plates are prepared, but there is no difficulty iu distinguishing the chloride plate by its translucent film, and by the orange colour which it has by transmitted light."

Judged by this standard, as well as by the variety of tones obtaiuable, alpha lantern plates are undoubtedly chloride plates, and yet I have within the past three weeks produced several dozen lantern slides on them by daylight reductiou iu the camera from whole-plate negatives, using a RR. lens of 6 inch focus with *f*/11, and an average exposure of 60 seconds.

When I further tell you that an experienced (professional) lanteruist a few days since projected some of these on a disc 18 feet in diameter by limelight, and pronounced them equal to the best slides he had seen produced by the gelatine process, aud much better than the great majority, I think you will agree that it is time it was knowu that chloride plates are equally amenable with bromide ones to camera reduction or copyiug, a longer exposure merely being required.

Plymouth, November 18th. E. H. Micklewood.

PHOTOGRAPHS OF METEOROLOGICAL PHENOMENA.

Sir,—At the Leeds meeting of the British Associatiou, a committee consisting of Mr. G. J. Symons, F.R.S. (Chairman), Professor Raphael Meldola, F.R.S., Mr. John Hopkinson, and myself, was appointed to report npon the applicatiou of photography to the elucidation of meteorological phenomena, and to collect and register photographs of such phenomena. The success with which these instructions can be carried out necessarily depends iu a great measure upon the voluutary co-operation of others.

Will you, therefore, allow us to appeal to photographers through the medium of your columns, and to ask all who have in their possession negatives of clouds, lightning, hoar-frost, hailstones, or any other meteorological phenomena, or of damage done by whirlwinds, tornadoes, or storms, to communicate with me. We shall be grateful for copies of any such photographs, but shall especially welcome offers of future assistance in the shape of photographs taken in accordance with some simple instructions which will be supplied on application.

Arthur W. Clayden.

Warleigh, Tulse Hill Park, London, S.W., November 18th.

Photographic Society of Ireland.—At the technical meeting on November 27th, Mr. J. Carsou will give a demonstration of lautern work.

Herefordshire Photographic Society.—December 2nd, the subject of "Bromide Enlargements" will be opened by the Hon. Secretary.

Indexing Photographic Literature.—In these days of a rapidly iucreasing photographic literature, a systematised index is a necessity to him who wonld have his photographic store of knowledge within easy reach. It is not always easy to lay one's hand on this or that article which was casually glanced over the other day, but which to-day is just what one wants if he can only find it. Even the most modest photographic library is the better at command through an index. Some hiuts from one who is fortunate in the possession of a photographic library of over two hundred volumes, and to whom some thirty periodicals briug the photographic news of the day, may be of value. The first thing is to purchase a small blank book indexed from beginning to end. In this are entered the titles of all the leading articles in the periodicals as they come to hand, the chapter headings of all new books, and references to formulæ and wrinkles. When this book is full, its contents are transferred by subjects to a larger Index Rernm, where they form a condensed *resumé* of photographic matters. In this way the systematic and thorough study of auy subject is simplified, and anxious inquirers are referred to competent authorities.—*American Amateur Photographer.*

Proceedings of Societies.

The Camera Club.

On Thursday, November 13th last, at a meeting of the Camera Club, Capt. W. de W. Abney, president, occupied the chair.

Dr. C. S. Patterson exhibited a printing frame for transparencies, one of the features of which was that no light could get from the sides and pass under the edges of the plates to cause fog.

Mr. Bevan then gave a demonstration of the diazotype process of Messrs. Green, Cross, and Bevan. He gave various particulars, which have been previously published in these pages, and he stated it to be a curious fact that the diazotised primuline itself is almost inseusitive to light, even after exposure to daylight for several hours; only in contact with the matter of the fibre does it become sensitive, and the amount of sensitiveuess differs with the kiud of organic substance with which it is iu contact. On cotton or paper it is more sensitive than upou wool or silk; on cotton it is quicker than the blue ferro-prussiate process, and rather quicker, he thought, than ordinary ready-sensitised albumeuised paper. The sensitive compouud, placed under water and exposed to light, gives off bubbles of nitrogen gas, which can be collected in the usual way iu au inverted bell-jar or test-tube. When the colour of a diazotype print does not please, it can be recouverted into the sensitive substance by suitable treatment, and then be brought out of another colour by the application of a suitable developer. The inventors had exposed pieces of sensitised cloth under glasses of different colour, and under yellow glass, such as might be used in developing rooms, there was a powerful action. Through the kindness of Mr. Norman Lockyer they had been enabled to make spectrum exposures, and fouud the maximum place of actinic power to be different from those given by silver salts, aud apparently somewhere in the orange, but it was difficult to get a maximum; the D-lines were distinctly visible. The speaker then exhibited some lantern slides priuted by the process, with gelatine as the vehicle; they were rich in fine detail, and in one of them the image was of a green colour.

Mr. Davison asked what were the industrial applications of the process?

Mr. Elder remarked that this was not the first process in which the substance sensitive to light was a purely organic body, for at the very dawn of photography Niépce de Châlons nsed bitumen, which was of organic origin, although a mineral substance. When diazo-primuline was decomposed by light, was the substance left the corresponding phenol?

Mr. Bevan replied that it was too soon to say much about industrial applications, but it was hoped that amateurs would take it up for purposes of decoration, and he believed that some silk manufacturers were about to use it in a practical way. He had overlooked the fact that the bitumen process depended entirely upon the sensitiveuess to light of an organic substance of mineral origin. In the decomposition by light of diazo-primuline, he thought that the corresponding pheuol was not produced.

In reply to Dr. Pattersou, he farther stated that the diazo-primuline is rather more sensitive when wet. Paper prepared with it will not keep long after the diazotising; it should be used almost at once, and developed as soon after printing as possible. On gelatine the substance is about one-tenth less sensitive than upon cotton, and the exposed gelatine plates will keep for about a month. He thought it to be cheaper than any photographic process with which he was acquainted. He thought that the process could be applied to wood; so far as they had tried it the image had a sunk-in look ou wood, but means might be adopted to keep it on the surface. In reply to auother speaker, he stated that when the purple developer was used the image must not be washed after coming out of the tartaric acid bath; it must remain acid. The temperature of the developers has little influence.

Mr. Maskell asked whether it had been tried in the camera.

Mr. Bevan replied that by two hours' exposure in the camera they had obtained a weak positive image. With gelatine plates it was impossible to tell when the image was properly exposed; their plan was to expose small test pieces under the same conditions, and every now and then to drop one of them into the developer; it is possible to over-expose, and thereby to weaken the image.

Mr. Elder asked if other amido bodies had been tried.

Mr. Bevan replied that many of them were sensitive to light, but he thought that primuline was the only one which could be successfully applied to practical purposes; all the others are difficult to fix on the fabric, and the results wash out. They were inclined to think that the quicker the printing, the brighter were the colours produced.

Mr. Dallmeyer had read that green could not be produced by the process. How had they produced the greeu image iu oue of the lantern slides?

Mr. Bevan replied that they had only obtained it lately under uncertain conditions with gelatine, while developing a blue colour; it passed through the greeu stage first, so that he could not give any definite information on the subject. Wheu they could mix the developers they could vary the colours, but some would not mix. An exceediugly nice effect was obtained by developing the maroon colour first, and then putting the print in the purple developer. They had found that they could print by an arc electric light of 2,000 candle power at a distance of two feet; the exposure then required was ten or fifteen minutes. In reply to another question, Mr. Bevan said that he did not think that they should charge for a licence to use the process; still, they naturally expected some returu for the invention, and should probably hand the matter over to somebody more versed in business matters than they were.

The President remarked that wherever light was absorbed work must be done, and Mr. Bevan had said that in this process yellow light was largely absorbed, so he was curious to learn the spectrum value of the substance; he expected that its solution would give a spectrum with a baud in the orange. Wheu aniline is acted upon by bromine an orgauic bromide is obtained, and this, when sensitised with nitrate of silver, yields silver bromide, and a compound of a yellow colour, which gives the power of photographing a considerable distance iu the red below the A line of the spectrum. He (Captain Abney) had found that the same effects could be produced by changing the molecular form of ordinary bromide. The dye was very sensitive in the orange, and on examining the spectrum of the said organic substance he had found that it gave a band in the orange. If Mr. Bevan were willing to come at any time to his laboratory at South Kensington, he could give him facilities for carrying on spectrum experiments, and without being dependent upon sunlight. The sensitiveness of the new substance seemed to be very great, and the whole process exceedingly beautiful, to the extent that it ought to be commercially and artistically useful. He thought that it was one by meaus of which a lady would like to make beautiful curtains from her own designs, especially as it is the fashion now to consider yellow to give artistic effects. On behalf of the Camera Club, he would say that the Club was much obliged to Messrs. Green, Cross, and Bevau for showing its members the beautiful process, which, he hoped, would soon becoue beneficial to the photographic world at large.

Mr. Bevan replied that he should be glad to avail himself of the favour of so carrying on his spectrum experiuents, and that, instead of his demonstration being a favour to the Club, he thought that the obligation was the "other way round."

The London and Provincial Photographic Association.

November 13th.—Mr. A. Cowan in the chair.

The eveuing was devoted to judging slides sent in by members for competition; the whole of the members present acted as judges. The trausparencies were made from four negatives; the subjects were, "Cottage at Shere," "Miller's Dale," "Matlock Bath," and "Girl at Well." This set of negatives had beeu handed in succession to those members who had previously signified their intentiou of competiug. Two siugle lanterns were employed, projecting discs side by side on the screen. The process of judging was as follows:—A slide was inserted in the carrier of each of the lanterns, and the pictures

carefully compared on the screen as to detail, transparency of the shadows, colour, and other matters which go to make a good slide. The picture voted to be the best was allowed to remain on the screen until displaced by one that was decided to be of greater merit. The competition was an exceedingly close one, and in several cases only decided by very narrow majorities. Each slide had a distinguishing mark or motto ; corresponding marks were enclosed in envelopes, together with the name of the competitor. The result of the competition was as under :— 1st—"Miller's Dale," "Matlock Bath," T. E. Freshwater ; "Cottage at Shere," A. C. Pemberton ; "Cottage at Shere" G. W. Atkins ; "Girl at Well," P. Everitt. 2nd—"Miller's Dale," "Matlock Bath," H. M. Hastings ; "Girl at Well," A. C. Pemberton ; "Cottage at Shere," C. H. Cooke.

The processes employed were wet collodion, Mr. T. E. Freshwater; wet collodion toned with gold, Mr. G. W. Atkins ; gelatine lantern plates developed with hydrokinone and carb. ammonia, Mr. A. C. Pemberton ; collodio-bromide, Mr. C. H. Cooke.

The Chairman, at the conclusion, spoke about the high quality of all the slides exhibited, and said that it was the best competition that had been given by the Association, and that the task of judgiug not an easy one.

Subsequently a number of slides was projected on the screen contributed by Messrs. G. Newman, W. H. Summers, and J. B. B. Wellington.

West London Photographic Society.

A meeting was held on the 14th inst., at Broadway Lecture Hall, Hammersmith, Mr. W. A. Brown in the chair.

Mr. Jones (Platinotype Co.) gave an account of the platinotype process, and illustrated his remarks by practically demonstrating its working.

In the discussion which followed, Dr. Low said expense need not deter anyone from taking up platinotype ; a spirit lamp or gas stove and an enamelled iron dish from the ironmonger were all the apparatus required. He considered the hot bath process the easiest, cheapest, and most satisfactory of all printiug processes, providing the negative was a good one. The temperature of the solution was not very important ; anything above 120° Fah. gave good results. As to printing, he could do nothing with a thin negative, but with a good one he found the strouger the light the better the print. The "D" salts, as used in the cold bath process, gave much better results thau the plain oxalate solution.

Mr. Blackmore said that the sepia process was the one he preferred. He had sometimes been troubled with small black spots. He had not had time to puzzle the matter out, but thought they might be caused by small particles of calcium getting ou the paper. A curious experieuce had happened to him recently ; he had been under the impression that it was not possible to reduce a platinum print, but on putting a very much over-exposed sepia print in the developer it flashed up immediately very dark and dense, then on transferring it to some strong hydrochloric acid, considerable reduction took place, and the print became quite passable. He would like to know whether the black process was susceptible of reduction in the same way.

Mr. Whiting expressed dissatisfaction with the colour of platinum priuts. He pointed out that there were many shades of black, and he himself preferred a warm black. Would the use of "D" salts give a softer image or a differeut colour? It was rather unfortunate that we could not modify the developer to meet the exigencies of under and over-exposure.

Mr. Hodges agreed with Dr. Low and others that platinum was one of the easiest processes to work, the only difficulty being in the exposure. Unless the prints were carefully watched while printing, it was difficult to detect over-exposure. The negative need not be very dense, but must be full of gradation to produce a good result. He preferred a negative developed with plain pyro of a yellowish hue, but not stained, to one developed with sulpho-pyro. Like Mr. Whiting, he admired the warm black colour, but could rarely produce it. He had tried the addition of bichloride of mercury to the developer, but, although the colour obtaiued was warmer, the lights suffered as a rule. Very much over-exposed prints could be entirely saved if developed in quite cold solution. It was very necessary to remove all traces of iron by using a sufficient number of acid baths—four or five in some cases would be required. If the operation were not thoroughly performed the prints would turu yellow.

Mr. Jones replied that it was better to print a thin negative in a weak light, but a vigorous one would print just as well in the sun. When he spoke about the light, he referred to examining the print. The black specks were caused by minute particles of metal, either in the paper or from the tin. Calcium would produce white spots. The strong acid would reduce a black print just as it did the sepia one, but would rot the paper. Old paper would tend to give warm toues, and a very hot developer would also give a brownish black.

At the next meeting, November 28th, Mr. Andrew Pringle will give a demonstration on "Bromide Printing."

Hackney Photographic Society.

A meeting was held on the 13th inst., when Dr. Roland Smith presided.

The Secretary aunounced that this was the last day for receiving prints for the competition, and that Mr. Henry Crouch had promised to give a lens as one of the prizes.

There is to be an exhibition of the Society's pictures (competition) and lanteru slides on December 11th next, at St. Andrew's Hall, Well Street.

The members had their slides put through the oxy-hydrogen lantern by the Secretary. A good number was shown.

Birmingham Photographic Society.

At the ordinary meeting of the above Society, held at the club rooms on the 13th inst., Mr. J. P. Stone in the chair, Mr. J. H. Pickard gave a practical paper on "Film Photography," and illustrated his remarks by passing a stripping film negative through all the stages, and thus making an enlargement from half-plate to 12 by 10 inches.

The Secretary anuounced that Mr. R. Keen, of Derby, had offered to place any negatives he had of Warwickshire at the service of the Survey Council.

Glenalmond Photographic Club.

The fortnightly meeting was held on Nov. 15th, when the president, Mr. A. S. Reid, M.A., F.G.S., took the chair.

It was resolved that a lantern slide competition should be started, open to members of the Club ; and, after discussing other busiuess, the usual exhibition of members' photographs and apparatus took place.

At a previous meeting six new members were elected.

Mr. C. F. Scobell gave a description of the Kodak and its working, with special demonstrations of its parts, and specimens of work doue by him.

Glasgow Photographic Association.

The first general meetiug was held on November 6th in Bath Street : Mr. William Lang, jun., occupied the chair.

The Secretary's report for session 1889-90, as also the treasurer's, were read and adopted. Office-bearers for current session were theu elected as follows :—*President*—Mr. William Lang, jun. : *Vice-Presidents*—Messrs. J. Craig Annan and Archdeacon Watson ; *Council*—Messrs. Johu Annan, Robert Gardner, William J. Mellwrick, Andrew Mactear, George Mason, and John Morrison ; *Treasurer*—George Bell ; *Secretary*—Percy Rowden.

A vote of thauks was given to the retiring secretary, Mr. J. Craig Annan, for the work he had done for the Society during the time he had held office. Fifteen new members were then elected.

Dr. Emerson's book (presented to the Society), "Life iu East Anglia," was shown to the members, and Mr. J. Craig Annan read a paper in connection therewith. A lively discussion followed.

Specimens of diazotype printing were exhibited, and several series of transparencies were afterwards passed through the Society's lanteru.

THE PHOTOGRAPHIC SOCIETY OF IRELAND.

AN ordinary meeting of this Society was held in the rooms, 15, Dawson Street, Dublin, on Friday evening, 14th inst., Mr. HERBERT BEWLEY in the chair.

A number of questions was read from question box, and one inquiring whether collodiou alone or collodion with a surface of gelatine gave the best results in enamelling excited a discussiou, the general opinion being that gelatine was unnecessary except as a protector to the collodion filu.

The CHAIRMAN then called on Professor J. Alfred Scott to give his paper on "Toned Photo-Micrographs."

In the course of his remarks, Professor SCOTT said that iu 1889 he was shown some beautiful photographs, on Liesegang's aristotype paper, of the spinal cord, taken by Dr. Ringrose Atkins, of Waterford. They were of such a brilliant tint as to give a correct idea of the original specimeus when treated by some staining agent. Dr. Atkius kindly explained the process he had adopted. Prof. Scott made a few modifications in the process, adaptiug it specially for lantern slides, and then found that the process could be extended into other colours. Dr. Atkins' process consisted in touing the silver image with ferrocyanide of uranium. The completed slide, well washed in alum to remove the sodium thiosulphate from the gelatine, was placed in a bath composed of equal parts of a 1 or 2 per cent. solution of potassium ferridcyanide ($K_6 Fe_2 CN_{12}$) and a 6 per cent. solution of uraniuu nitrate. According to the length of time the plate is immersed, the tone passes from a brown to a red. The process would appear to be that silver and potassium ferrocyanides are formed, and the latter is subsequently decomposed, formiug uranium ferrocyanide, the silver salt remaining and giving rise to the opacity mentioned. At this stage the colour can be heightened and rendered more transparent by placing the slide in sodium thiosulphate, which dissolves the silver salt, and leaves an image formed solely of uranium ferrocyanide. The next step was an easy one. Given that the actiou of a 2 per cent. solution of potassium ferridcyanide ($K_6 Fe_2 CN_{12}$) is to form a pale, whitish image of silver ferrocyanide, then let the plate be well washed to remove the free ferrocyanide from the gelatine, and afterwards flood it with a solution of ferric chloride. The image will then turn to au opaque blue, which can be rendered transparent if the silver chloride is dissolved out iu sodium thiosulphate. This latter method gives an image in Prussian blue, but the method is more easily worked for lantern slides thau any hitherto described.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

A MEETING was held in the Mayor's Parlour, Old Town Hall, on November 12th, Mr. S. S. PARTRIDGE iu the chair. Two members were elected, and the details of the forthcoming conversazione ou the 26th inst. were communicated to the members.

Mr. H. SMITH, of the Eastman Co., gave the members some instructions in the development and general treatment of bromide paper, also practical hints as to the details of the process, such as focussing, vignetting, and the several after treatments. Mr. Smith then proceeded to give a practical demonstration of enlarging on bromide paper, aud produced a 15 by 12 enlargement on bromide paper from a Kodak circular negative of $2\frac{1}{2}$ inches diameter.

THE VIENNA PHOTOGRAPHIC SOCIETY.

Mr. FRITZ, technical manager of the State Printing Office, read a paper on the "Auastatic Printing Process," and gave a description of all the different methods employed, also of the method used at the State Printing Office. He exhibited specimens iu which prints twenty, fifty, and more years old were reproduced. The conclusion of Mr. Fritz's paper noticed the new patented process invented by Bartos, in which the sand-blast takes the place of the network used to get half-tone zinc etchings.

Mr. LAINER spoke on "Anhydrous Sodiochloride of Gold."

Dr. J. M. Eder showed some new coloured prints by Veres, of Klauseuburg. Dr. Emerson's photogravures were exhibited, and studies of female models by O. Anschütz, of Lissa.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

FONTAINE.—By referring to the indices of the last ten volumes, we find uo meution of such a machine. Mr. Acworth's exposing apparatus is figured on page 569 of the NEWS for September 7th, 1888.

H. W. N.—*Blisters on Albumenised Prints.* This is a very common complaint of late. We should advise you to fumigate the silvered paper dry, instead of adding ammonia to the sensitisiug bath, which always teuds to loosen the adhesion of the albumeu filu. The paper is a well-known brand, approved in other quarters, and you may be able to use it in this manner, employing the precautious already takeu.

VARNISH.—*Difficulties Encountered.* 1. We do not think it possible that the varnish, even if applied too hot, should clear off the retouchiug peucil marks from one side of the face without affectiug the other. Your experience points to the desirability of inspecting the negative, in future, before applying the varnish. 2. If overheated in this process we should expect to sce little blisters or bubbles formed within the gelatiue film. 3. Examine with a magnifier to look for traces of black lead on the off side of the face, and this will show you whether the heat applied has been too great. In damp weather always give time and gentle temperature for slow dryiug of the film before warming up to the point of varnishiug.

L. E.—*Husbands' Papyrotint.* A short accouut of this process was given some years ago in the *Photographic Society's Journal*, with au illustration of Rochester Cathedral; but full working details will be found in Mr. W. T. Wilkinsou's "Manual of Photo-Eugraving," &c., page 106.

A MEMBER.—*The Photographic Society's New Premises.* As soon as the arrangeuents are completed the ordinary and techuical meetings of the Society will be held at 50, Great Russell Street (opposite the eutrance to the British Museum), where it will be easy to provide for the holding of small periodical displays, but the annual exhibition will be held at one of the West End picture galleries as heretofore. There are rooms now being fitted up for library, stores, and working laboratory, accessible to members under regulated conditions, and open during the daytime as well as certain eveuings of the week.

ANXIOUS ONE (Kendal).—*Transferotype Paper.* Enquire of Messrs. Morgan and Kidd, who used to supply a bromide-coated canvas, and with this there would be no reversal of the iuage.

F. P.—*Photography in Colours.* The whole subject was very fully treated of in the last YEAR-BOOK, fourteen pages being devoted to it by the Editor. Since theu there is little or no progress to record, unless you include under this headiug the two primuline processes, which give coloured priuts, it is true, but not withiu the meaning of what is commonly understood by photography in colours. We know of no other novelty in this counection.

C. H. COLLINGS.—A full report of the matter to which you refer appeared in the *Newcastle Weekly Chronicle* of Saturday, the 8th iustant.

A. M. S.—*The Quadrant Hand-Camera.* In this apparatus the holders have a couple of projecting pins, which enable the plate to be swung into position for exposure from the horizontal magazine at top to a vertical receptacle at the back of the camera, passiug through an arc of 90 degrees or quadrant—hence the name.

M. A.—*South London Photographic Society.* Under the old name a new society has been constituted which bids fair to do useful work. Besides this, there is a proposal for a South London Club to be formed on the lines indicated in Mr. Harold Senior's letter on page 874. See the NEWS of 7th instant.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1682.—*November* 28, 1890.

CONTENTS.

A STANDARD LIGHT IN PHOTOGRAPHY.

A few days ago, the full report of the late International Congress of Photographers was published at Paris in the form of an illustrated and interesting volume. In it full details about the accepted amyl-acetate lamp to produce a standard light for photographic use are given, and on the next page we reproduce the working drawings for the construction of the lamp, in the hope that a sorely-felt photographic want will soon be met in commerce. The standard selected is inexpensive in first cost of apparatus and in use, and the decision of the Conference to adopt an amyl-acetate lamp was a wise one.

The lamp, it will be noticed, differs but little from the ordinary benzoline lamps commonly selling in shops at a few pence each, except that it is much better made, and to accurate measurements; moreover, it has extra adjuncts, and twin screws to regulate the wick. In use, the outside of the lamp must be kept clean, otherwise the amyl acetate (pear oil) will diffuse an aroma throughout the room, and the wick must be kept low enough in the tube not to itself enter into combustion. Whether petroleum spirit or benzoline would not answer practically if not theoretically as well as pear oil, or whether it cannot be specially prepared to answer the purpose, is a question for the future; at all events, Professor Leonhard Weber, of Breslau, once used a benzoline flame as a standard in photometric apparatus.

The Standard Light Committee of the Photographic Congress reports that the standard of light it recommends is produced by means of a lamp with a metallic reservoir and a non-projecting wick, burning acetate of amyl or amylacetic ether. This lamp is represented in figs. 1 to 5. It is made of nickel-coated brass, and consists of a cylindrical reservoir with a flange forming the base of a dome carrying a wick-tube and its screws. The base of the wick-tube is furnished with a fillet upon which slides the extremity of a cap, which is placed there to prevent the evaporation of liquid when the lamp is not in use.

The same wick-tube receives, when the lamp is in use, a screen formed of a thin plate of blackened brass, pierced with a horizontal aperture, and furnished behind with spring clip which adheres to the tube by friction, and permits the screen to be fixed at any height whatever.

The system of screws to regulate the wick is formed of two fluted cylinders placed parallel to each other on opposite sides of the wick-tube, and of which the teeth penetrate to the inside of the tube through two lateral cuts. Two toothed wheels, mounted on the axes of these cylinders and gearing into each other, cause them to work simultaneously. The axis of one of the cylinders is prolonged to the exterior, and terminates in a milled head which is turned to regulate the height of the wick.

The wick is of cotton, plaited cylindrically; its diameter is five millimetres.

This system permits the regulation of the wick, without exterior openings permitting the escape of vapour of ether.

The principal dimensions of the lamp are as follows:—

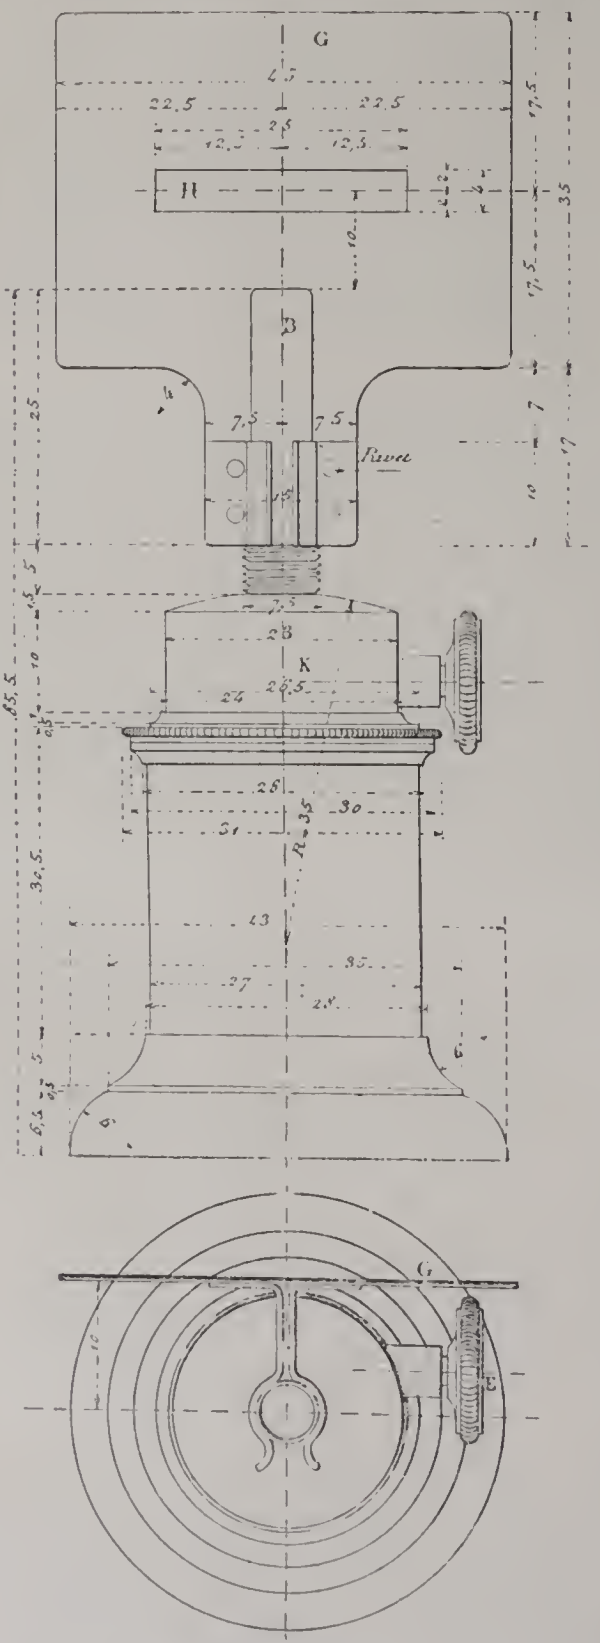
Interior diameter of the wick tube		5	mm.
Total length of the wick tube		58*	,,
Height of the end of the wick tube above the dome		30	,,
Total height of this extremity of the wick-tube above the base of the lamp		85	,,
Approximate contents of the reservoir to the base of the dome		10	c.c.
Dimensions of the rectangular part of the screen	Breadth	45	mm.
	Height	35	,,
Dimensions of the opening in the middle of the height of the screen	Breadth	25	,,
	Height	4	,,
Distance from the plane of the screen to the axis of the wick		10	,,

The acetate of amyl used with this lamp is a colourless liquid, very volatile and odorous, of well-defined chemical composition, and easily procured pure. It is an ether obtained by treating a mixture of acetate of soda and sulphuric acid with amylic alcohol or potato spirit. It is employed by perfumers and confectioners

* The great length of the tube notably reduces the length and brightness of the flame, but it prevents the heating of the reservoir, and assures the constancy of the lamp. The height of the flame should be so regulated as to leave the wick in the interior of the tube to prevent it from being burnt.

under the name of essence of pears, and serves notably to give an aroma to the sweets called "English bonbons," but for this use it is nabitually diluted with alcohol.

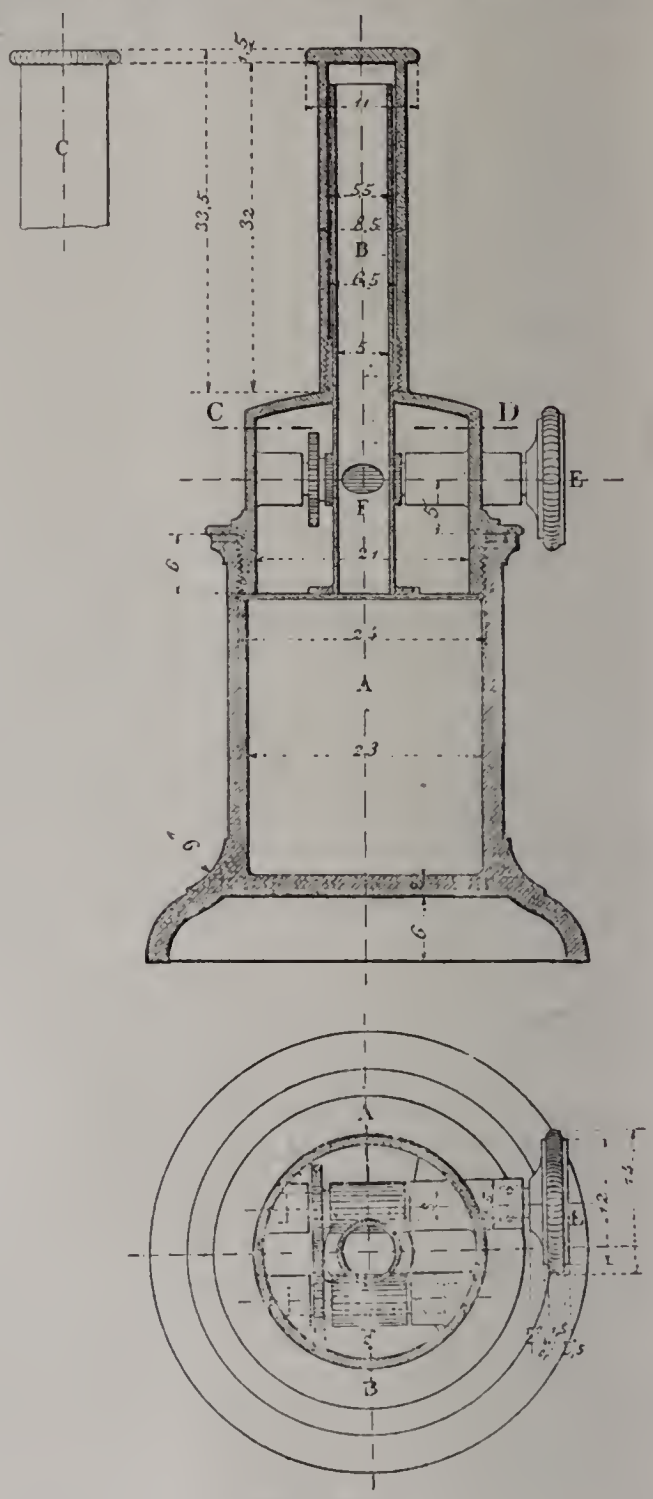
Pure acetate of amyl has a density of 0·87; its



Figs. 1 *and* 2.

boiling point is 125° C., and its price in France is from ten to twelve francs a kilogramme.

To prepare to use the lamp: after having unscrewed the dome, the reservoir is to be filled with amyl acetate almost to the screw thread, and the dome is replaced after making sure that the wick is in good condition,



Figs. 3 *and* 4.

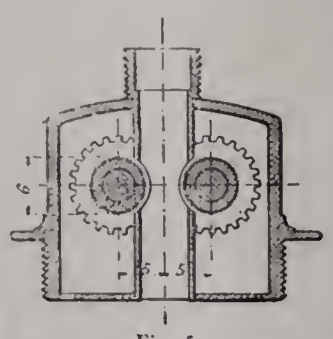


Fig. 5.

and long enough to pass into the liquid when its upper end is at the upper orifice of the wick-tube. The aperture of the screen will then be opposite the most luminous part of the flame, and, placing oneself in front of the screen with the eye at the level of the aperture, a luminous section of the flame will be seen, having the whole

breadth of the flame, and a height of four millimetres, therefore presenting a luminous surface equal to one-fifth of a square centimetre. In working with the lamp, it is sufficient to make sure that the flame burns regularly and keeps itself sensibly at the fixed height.

An improvement in the report would have been a complete specification as to the nature of the wick to be employed. Another improvement would have been a full acknowledgment that the original pear oil lamp was devised by a German, Hefner-Alteneck, whose name is but once incidentally introduced, and then not as the inventor. Hefner-Alteneck's lamp was not of the same dimensions as the one adopted at the Paris Conference.

Herr von Hefner-Alteneck, in his paper describing his lamp, read before the Electrotechnical Society of Berlin, stated that the wick-tube is of German silver, 25 millimetres high, 8 millimetres internal diameter, and 8·2 millimetres outside diameter. The height of the flame is 40 millimetres from the edge top of the wick-tube to the top of the flame. He says that the light should not be used for measurement until it has been burning at least ten minutes. The proper height of the flame is shown by a gauge-rod fixed to the lamp, and carrying two horizontal sights with which the point of the flame must be in line. The wick is a strand of cotton yarns with fifteen or twenty separate threads laid together straight until the wick-tube is filled without squeezing; a slight inaccuracy in this is not of practical consequence. It is essential that the wick should be cut quite level at the top. The quantity of amyl acetate in the lamp is immaterial so long as all the ends of the wick are immersed. The illuminating power of the flame is only normal when it is burning in free air—that is to say, without a chimney—but when draughts cannot be avoided a cylindrical glass chimney may be used, eighty millimetres high, and fifty-five millimetres internal diameter; it is carried on a clip on the rod which also carries the sights. When the chimney is put on, the flame drops slightly; if it be again brought up to the standard height, the illumination is about two per cent. less than when the flame burns in free air.

The Paris report refers to Mr. Bothamley's modification of the pear oil lamp published in the Photographic News, and adds that the labours of the Committee of the Conference were finished before that article was printed.

Le Touriste Photographe, of Bordeaux, has, Japanese fashion, its title-page at the end. It is edited by M. P. Sivan, and on its premises is a developing room for amateurs.

Photographs for an Indian Exhibition.—Mr. H. P. Robinson has sent the following platinum-toned prints to our Exhibition:—(1) "A Strange Fish;" (2) "Against the Wind—A Race with Gran'dad;" (3) "Stalking a Trout—Sunlight through Mist;" (4) "What Sport?" (5) "Over the Hedge;" (6) "What is it?" (7) "Sunny Hours;" (8) "Shades of Evening." I shall defer describing these pictures until after the exhibition, as they have been sent for competition; but there is a unanimity of opinion here that never before has Mr. Robinson sent so good a collection.—*The Journal of the Photographic Society of India.*

DRAWINGS FOR PROCESS BLOCKS.

During the past few years newspapers and periodicals of all kinds have blossomed into illustrated publications, and we know that this is due to the ease with which a printing-block can be produced, without the intervention of an engraver, by the photo-zincographic or one of the allied processes. There has, therefore, sprung up a demand for draughtsmen who are capable of executing the kind of drawings which are alone suitable for this quick method of reproduction as a printing-block ready for the press, and schools are being started where the necessary education for such work can be obtained.

Among photographers generally, there are many who are adepts with their pencils—practical artists who have been tempted to join the photographic army because of the attractive features of such work, and also because they knew that they could bring to bear their art knowledge upon it, and so hope to achieve something in the way of portraiture rather above the average. From such men have our best photographers sprung, while there are not a few who, although they have not been able to reach the topmost rung of the ladder, are sufficiently clever with their pencils to work up enlargements, and to do much in other ways to help them in their daily practice. To photographers having such artistic tastes, a knowledge of the best means of executing a drawing from which a printing-block can be made should be most valuable, and we propose to give in the present article a few hints upon this important subject, and, for the sake of simplicity, we will only deal with the method of producing a line drawing in ink for the zincographic process.

It is a necessity of this process that the drawing shall consist of lines or dots, or the two combined, and that the various half-tones, or *tints*, as an engraver would call them, shall be made up of such dots or lines placed nearer or closer together, according to the depth of tint required. The zinco process is essentially a black-and-white method, which admits of no half-tones, as a photographer would understand that term, these half-tones being made up of the juxtaposition of lines as just described. We would advise anyone who has never done any of this sort of work to study a collection of drawings of the kind as a preliminary operation. He will have no difficulty in obtaining such a collection, for it has for some time been the very commendable custom to issue illustrated catalogues of our chief picture exhibitions, both oil and water-colour. In these catalogues, rough, and in some cases highly finished, sketches of the principal pictures are reproduced by the process under consideration, and as these sketches are furnished by the artists who have painted the original works, they are, as a rule, executed in a masterly manner, and, so far as is possible in such a medium, the peculiarities of touch are faithfully reproduced. The same remarks apply to Mr. Blackburn's admirable "Academy Notes," and we should also recommend the student to get the French publication, containing nearly three hundred pictures, entitled

"Catalogue Illustró du Salon," which can be obtained through any foreign bookseller. After careful examination and dissection of such pictures with a good magnifying glass, the student will learn how the different effects are produced by different hands, and will be tempted to try himself what he can do in the same direction.

The materials are of the simplest. Bristol board of good quality is the basis to work upon, while the best ink to employ is "Stephens' Ebony Stain." Ordinary indian ink rubbed up in a saucer will, after a short time, thicken, clog the pen, and refuse to flow with ease, but the medium which we recommend has none of these faults, while, at the same time, it gives an intensely black line. Some artists prefer to work upon a chalk-faced card, which is manufactured for the purpose, for the reason that the lines inscribed upon its smooth surface are more perfect in outline than is possible on Bristol board. We should, however, advise the tyro to begin, at any rate, on the latter material, and to try the other when he has had a little practice.

It is the invariable rule to draw the original picture a good deal larger than it is intended to be when finished in the form of a printing-block, for, by this artifice, the general work is rendered finer. It would be next to impossible, indeed, for the finest pen to trace lines so delicate as those represented in several of these process pictures. But the amount of reduction which is allowable is a question that requires very careful consideration. We once saw a very beautiful pen and ink drawing measuring about twenty-four inches in length, which was executed by one of our first artists. It was required to reproduce this in block form, but, in the process, the original was reduced to about half-plate size, with the result that the details seemed to be all reduced to a uniform, flat, ineffective grey. The best rule to follow is to ascertain first the size which the future block is desired to be, and then to make the drawing not more than about twice its length and breadth —that is to say, four times the area that the picture is subsequently to be.

In such work there is always a temptation to overelaborate by filling in every atom of space with an assemblage of fine lines. This is a mistake, for the beauty of a drawing does not depend upon the amount of work which it contains, but rather upon the disposition of its lines.

THE EDINBURGH PHOTOGRAPHIC EXHIBITION.*

BY WM. LANG, JUN., F.C.S.

IF one were disposed to be hypercritical, the term "international," which has been applied to the interesting exhibition now within the walls of the Royal Scottish Academy National Galleries at Edinburgh, might perhaps be considered as somewhat overstating the case. The contributors from abroad are, perhaps, not more than six in number; this fact, however, only brings out in strong relief how largely and extensively the photographic art has been developed in our own country, when a collection so varied in character can be brought together without the aid of foreign contemporaries. The Edinburgh Photographic Society deserves to be complimented in this attempt, as we are told in their original prospectus, "to direct attention to the development, in recent years, of photography, and to stimulate further advances by encouraging artistic skill and invention." That the Exhibition will tend to increase public interest in the photographic art there can be no gainsaying. There are to be found what may be termed all the various phases of photography. The oldest practical processes—Daguerreotype and Talbotype—are represented; also the most recent—the primuline. The aid rendered to science by photography is well brought out by the spectrum photographs, the lunar photographs, photographs of various solar eclipses, and so on, displayed on the walls. What the microscope can show of the infinitely little, the photographic plate—"the retina which never forgets"—duly records for us.

In the various photo-micrographs exhibited, the one which should, perhaps, evoke the greatest interest at the present moment, in view of recent investigations, is the bacillus of tuberculosis. To the popular mind, which, to a large extent, considers that photography has only to do with the making of pretty pictures, the scientific applications of photography to which reference has been made should come as a revelation. In meteorological observations photography will yet come to play a most important part; as a forecast of work to be done in this direction, special interest attaches itself to the cloud pictures which have been sent in for exhibition by the Scottish Meteorological Society. Then, again, as showing how photography enters into the daily affairs of our ordinary life, a significant example is to be found in the exhibit forwarded by the proprietors of *The Daily Graphic*. The original sketch of the scene to be reproduced in the example shows the appearance presented by the railway disaster at Taunton; the negative taken therefrom, the type blocks which have been secured by its means, the corresponding composition mould, and finally, the cylindrical form the actual printing surface is made to assume—all form not only an interesting but a highly educational exhibit.

For the purposes of the wood-engraver, the production of a silver print on the wood block itself presents obvious advantages. Several instructive examples of blocks prepared in this manner are to be seen in the Exhibition. Photo-engraving and photo-etching processes are well represented by the finished pictures scattered over the walls of the various rooms, while collotype reproductions have not by any means been overlooked. Specimens of photo-relief printing—or, to give it its more lengthy designation, photo-zincography—are shown, which illustrate well the nature of the process and its applications.

It was intended originally by the executive that the various classes should be apportioned off by themselves; but the wealth of material that was forthcoming was such, that this idea had to be abandoned. Consequently, the classes are all intermingled, and although this arrangement may give a little more trouble to the jurors when they enter upon their labours, it has the advantage that there is a freedom from monotony, which might otherwise have arisen. This was the plan adopted in the Photo-

* To make way for this general description of the Exhibition by Mr. Lang, we postpone the publication of the conclusion of our description of the apparatus there until next week.—ED.

graphic Section of the Glasgow International Exhibition of 1888, and met with general approval there.

From the fact that the writer has been appointed one of the judges, it would scarcely be in accordance with the fitness of things that he should criticise individual competitive pictures, but a few remarks in a more or less general way will not surely come amiss. It was intended that all the pioneers of the photographic art should be represented, as far as it was possible, by enlargements. This has only been in part accomplished. A very interesting enlargement by Moffat, of Edinburgh, of Fox Talbot is to be found in the first room on entering the Exhibition. This picture was taken in the year 1865, and a note in the catalogue states that it was the only time our English pioneer sat for his portrait. Daguerre—an enlargement from Mayall's picture by Nadar, of Paris—is to be found in close proximity to Talbot. Herschel's lineaments are well presented to us by Mrs. Julia Cameron's head-study of the famous astronomer and philosopher. Becquerel and Niepce de St. Victor—the latter produced by Nadar—are duly represented; but this would seem to exhaust the list. It is unfortunate that the Council could not have gone farther, and given the whole of the illustrious founders, as they had proposed. The Exhibition is particularly rich in specimens of Rejlander's work. There is, of course, the somewhat disappointing *magnum opus* of the Dutchman, "The Two Ways of Life," a composition picture made up from a great number of single negatives. The copy shown, which presents a somewhat faded appearance, belongs to the Edinburgh Photographic Society. "Catching—Caught," "Mental Distress," "Oh! Missus," "Baby," "She's looking at me, the dear creature," &c., &c., all indicate a power possessed by Rejlander of making up a picture from slender materials which has never yet been surpassed by any subsequent worker.

One has also to remember that there were no rapid plates in Rejlander's day. What might not have been done by him had he worked under present conditions? Glancing at some of the calotype prints produced by D. O. Hill, the slowness of the sensitive material is brought before us very palpably by the strained appearance of the sitter, and one can see that strong sunlight has been streaming down on the poor unfortunate's face. Many of D. O. Hill's pictures were taken among the tombstones in Greyfriar's Churchyard. Apart from the long exposure under the conditions aforesaid, the surroundings were such that a cheerful aspect was scarcely to be expected. Several frames of D. O. Hill's work are to be found in the Exhibition, and very many of the portraits consist of men famous in their day and generation; sufficient, perhaps, to note the following:—Sir David Brewster, John Murray, James Ballantine, David Roberts, Dr. John Brown, the author of "Rab and his Friends."

Before bringing to a conclusion the somewhat fragmentary observations herein recorded, a special reference should, perhaps, be made to the catalogue which has been issued in connection with the Exhibition. It is a tasteful compilation, and has interspersed throughout its pages several very artistic pictures produced by various photo processes. Several pages are devoted to an historical *resumé* of photographic progress, and many of the more important processes are given in outline. During the time the Exhibition is to remain open arrangements have been made for lectures to be given bearing on photographic matters.

TRANSFERRING GELATINO AND COLLODIO-CHLORIDE PRINTS TO GLASS.

BY HERMANN E. GUNTHER.

In making transparencies as lantern slides or prints on opal glass by the gelatino-chloride process, the emulsion may be poured upon glass plates, and these exposed in the printing frame in quite the same manner as gelatino-chloride paper. In this case, however, plate glass must be used for the negative as well as for the print, since, ordinary glass being uneven, the prints would otherwise be somewhat wanting in detail and half-tones. Furthermore, especially constructed printing frames are required, allowing the watching of the progress of the impression without disturbing the negative.

A much simpler method, yielding transparencies and lantern slides of equal beauty to the printing-out process, consists in transferring an ordinary print on gelatino or collodio-chloride emulsion paper directly to glass.

In the case of gelatine-chloride paper, the following method may be used. After drying, the print is immersed once more in water, and, after removing it from the water bath, it is squeegeed on to a glass plate, allowed to dry, and then steamed over hot water, or put into a dish containing hot water. From time to time a pin or the point of a knife should be passed beneath a corner of the paper, to try to loosen the paper without the picture; if you succeed, strip the paper off the picture, and rinse the latter, which rests upon the glass plate, with cold water.

According to L. Imperatori, the same method may be employed in the following manner:—

The glass plate should first be well washed, dried off, rubbed off with some acetic acid, and then coated with an aqueous solution of gelatine or glue, and dried. The prints to be transferred should not be allowed to dry after washing, or, if that has been done, should be soaked for at least two hours in cold water. They should then be laid on the prepared glass plates, picture side down, in the same way as the prints are squeezed on ebonite or ferrotype plates in order to render them glossy, carefully avoiding all air-bubbles. One corner of the print is then carefully lifted, and the gelatine film separated from the paper at this corner; two sheets of blotting paper are next placed upon the print, a glass plate over these, and the whole allowed to dry under pressure. The print should be exposed to the hot water vapour, but not before it has been perfectly dried. For this purpose water is heated up to the boiling point, and allowed to cool down to 150°F. The print is then held over the vapour from the water for about four to eight minutes, and when the film has become soft, the corner of the paper which has been separated from the gelatine film earlier is carefully lifted up, and the paper carefully peeled off, leaving the glass plate together with the picture exposed to the vapours of the hot water during this manipulation. To give the picture an extra gloss, Imperatori recommends the immersion of it in a warm water bath of about 90° F. after it has stood some twenty minutes in the air. This softens the gelatine film without dissolving it. The picture is next allowed to dry spontaneously, and is then varnished.

Though exceedingly fine results may be obtained by this process, I have found that it is rather complicated, and not entirely trustworthy. When the print on gelatino-chloride paper is exposed to the vapour of the hot water, it oftentimes happens that in spite of all care a part of the gelatine film is stripped off along with the paper, the print

remaining on the glass plate, consequently, often being a weak one. Much more trustworthy is the process involving the use of collodio-chloride paper, by which process I have produced a large number of lantern slides of great beauty. The method I employ is the following:—In a test-tube I heat 10 c.c. of distilled water, in which I dissolve 12 grammes of silver nitrate. The hot solution is poured into a vessel containing 40 c.c. of alcohol, which should be violently shaken to prevent the silver salt crystallising out. The mixture is then added to 320 c.c. of plain collodion of 2 per cent. Also, I dissolve 1 gramme of citric acid and 1·2 gramme of chloride of lithium in 20 c.c. of alcohol, which I add to the collodion and silver solution after filtering. This collodion emulsion should be kept in the dark in a well-stoppered bottle. With it I twice coat a thickly gummed baryta paper (kept in stock by the firm of Ed. Liesegang, of Dusseldorf, under the name of "Abzich-Papier C."), then dry it quickly before the fire. After drying, I float the paper for about one minute on an ordinary silver bath of 10 per cent., dry it again quickly before the fire, fasten the paper, by means of drawing pins, to a piece of pasteboard, and allow it to dry for at least two days in the dark. The reason for the repeated silvering of the paper is that only by the use of this second silver bath is it possible to produce prints of sufficient vigour and uniformity.

Printing is done as usual, but in the case of the production of transparencies it is well to slightly over-print until the lights show a light-brownish tint; for opals the time of printing is as usual.

Toning may be done with the acetate of soda bath, as in the case of albumenised paper, but the hypo solution may be used much weaker than for ordinary silver prints. Good results are also obtained by the use of one of the combined toning and fixing baths, as recommended for gelatino-chloride prints, but without alum. The print is allowed to remain in it until it appears violet by transmitted light. The print may be transferred to the glass plate in the following manner: A glass plate is coated with a 10 per cent. gelatine solution and allowed to dry. The print is immersed in cold water; also the prepared glass plate upon which the picture is laid under water. The whole is then taken out of the water and an india-rubber squeegee passed over it. After a short time it will be found possible to strip off the paper, leaving the picture adhering to the gelatinised glass plate. The picture is then fixed in hypo solution, thoroughly washed, and dried.

Another method of transferring, recommended by W. Kranzhoff, is the following:—

After toning and fixing, the print is thoroughly washed and squeegeed on to the glass plate, which has previously been cleaned with water. It is then, picture downwards, laid upon a table and allowed to dry. After the lapse of about fifteen minutes the paper may be loosened by means of the vapour of hot water. An ordinary coffee-kettle is well suited for this purpose. The water is heated up to the boiling point, and the glass plate, together with the adhering print, is passed with a circular motion through the vapour escaping at the outlet-pipe. After two or three seconds the paper falls down, leaving the picture adhering to the glass. To thoroughly clean the picture this operation may be repeated a few times, when the picture should be rinsed and allowed to dry. After about five minutes the picture will be perfectly dry, and quite finished.

THE TUNBRIDGE WELLS PHOTOGRAPHIC EXHIBITION.

LAST Wednesday the Tunbridge Wells Photographic Exhibition opened under disadvantageous circumstances, for the weather was bad, and the snow lying upon the ground there five or six inches deep. For the last two days snow has been falling in the district to the south of London, but none worth mentioning in London itself; the dirty atmosphere of the town checks the radiation of heat into space; the heat from the chimneys tends also to raise the temperature, and these combined influences may have had something to do with the phenomenon. Yesterday the snow at Dover was eight or nine inches deep.

Such weather thinned the attendance at the Exhibition, but those who were present seemed highly pleased with the lantern entertainment given to them by Sir David Salomons. The lantern employed was good in its design and construction. The projection lenses used on Wednesday were of twelve inches focal length, and, by means of brass framework fixed upon the base-board, their mounts receive support at the outermost ends as well as at the flanges; when lenses of shorter focal length are employed they, by suitable carrying tubes, receive the same support from the framework. The lenses are made to register from the front, on releasing screws on the bed-plate. All the registering arrangements for the limes and the traversing table are governed from the outside of the lantern. The gas supply system has complete cut-offs, so that it is not necessary to disturb the regulating taps after they have been once adjusted; there is also an arrangement for dissolving with the top and bottom of the lanterns without disturbing the one in the middle.

The condensers are of good design, and consist each of a meniscus and double convex lens; the hollow side of the former is turned towards the lime-light, but between it and the source of light is a piece of plate-glass to protect the condenser from the sudden action of heat. At the bottom of the lantern is a metallic tray to catch dust from the limes. The gas bottles are held by a wooden framework found to be of considerable convenience, devised by Sir David Salomons, who also had the lantern made from his own designs, and one of them includes a device for getting a true optical axis to the system in each lantern. He has also devised an improved reading lamp for use during lantern exhibitions. This is the tenth or twelfth lantern he has built, so it is the outcome of long experience. The manufacturer was Mr. J. H. Steward.

Among the photographs which Sir David Salomons projected on the screen last Wednesday, was one of the Royal Scottish Academy, in which the Edinburgh Photographic Exhibition is now being held. He exhibited high-class slides including widely divided classes of subjects; some of the slides were delicately coloured. He exhibited a picture of a house by night, in which the windows suddenly became lighted up, and initiated the uninformed as to the method of producing the effect; in so doing, he incidentally remarked that in the days of old, when photographic lantern slides were unknown, it was impossible to secure such accurate register as is now the case with the two slides used in producing the result. Such work is difficult to perform by hand-painting on glass.

The Exhibition, held under the auspices of the Tunbridge Wells Amateur Photographic Association, contains a pleasing collection of photographs to the number of 604 altogether, produced by about sixty exhibitors, and

it will close to-morrow night. The names of the officers and members of the Exhibition Committee we published a few weeks ago. The Tunbridge Wells Amateur Photographic Association was founded in 1887.

The following is the list of awards by the judges—Sir David Salomons, Bart., Mr. H. P. Robinson, and Mr. C. W. Hastings:—

Sir David Salomon's medal—F. G. Smart.

Other medals—Silver, Joseph Chamberlain; Bronze, Daniel Howard.

Class 1 (architecture)—Silver, Joseph Chamberlain, "Norman Doorway"; Bronze, F. G. Smart, "Interior of St. Cross." Class 2 (interiors)—Silver, Joseph Chamberlain, "Drawing Room"; Bronze, H. T. Wood, "Four Interiors." Class 3 (landscape)—1st, A. W. Pierson, "On the Medway"; Bronze, Daniel Howard, "At Fedsay." Class 4 (instantaneous)—Silver, F. G. Smart, "Fishing Boats in Whitby Harbour"; Bronze, W. B. Cassingham, "Feeding Chicken." Class 5 (genre)—Silver, F. G. Smart, "Fishermen Mending their Net"; Bronze, A. W. Pierson, "Carting." Class 6 (lantern slides)—Silver, A. W. Pierson; Bronze, Alfred Cornell. Class 7 (transparencies)—Silver, withheld: Bronze, Joseph Chamberlain. Class 8—withheld.

Open Classes for Amateurs.—Class 9 (landscape or seascape)—Silver, John Naylor, "Sunshine and Shadow;" Bronze, Ernest Beck, "Off to the Banks." Class 10 (genre)—Silver, John E. Austin, "The Love Letter;" Bronze, Alex. M. Morrison, "A Duet." Class 11 (lantern slides)—Silver, J. E. Austen; Bronze, E. G. Lee. Class 12 (architecture)—Silver, C. Court Cole, "Choir, Christ Church, Oxford"; Bronze, John Naylor, "Fountain's Abbey."

Professional Classes.—Silver, Percy S. Lankester, "Picture of Lady"; Bronze, Clarence James, "His First Model." Class 13 (landscape or seascape)—Silver, J. P. Gibson, "The Woods of Tyne"; extra Silver medal, Lyd. Sawyer, "The Smoky Tyne"; Bronze, C. P. Castine, "Village Scene in Kent." Class 14 (genre)—Silver, S. N. Bhedwar, "The Feast of Roses"; Bronze, Percy S. Lankester, "Picture of a Lady." Class 15 (lantern slides)—Silver, G. W. Wilson and Co.: Bronze, Percy S. Lankester. Class 16 (portraits)—Silver, Percy S. Lankester, "Mrs. Albert Barker"; Bronze, Clarence James, "His First Model."

THE SOUTH LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.

When the Peckham and East Dulwich Photographic Society assumed the name of the well-known association of photographers that, after a long and honourable career of usefulness, was incorporated with the Photographic Club in 1887, some natural fears were expressed as to the result of comparison between the old and the new South London Photographic Societies. If, however, the promise of the exhibition on Friday and Saturday last in the Hanover Hall, Peckham, be fulfilled, all misgivings may be set aside, for there can be no doubt that the young Society, founded about eighteen months ago, has established its claim to high rank among suburban photographic associations. It already numbers over one hundred members.

At the first exhibition last year, held at Shawbury Hall, there were ten exhibitors, but on the present occasion there were about thirty-five, principally amateurs, who contributed a creditable collection of photographs.

On the opening night there was an attendance of 250 visitors, and on the following evening there was such a crowded assembly as to make the viewing of the pictures a matter of great difficulty.

The proceedings on each evening were opened with a programme of vocal and instrumental music by local artistes, followed by an exhibition of lantern slides by Messrs. Banks (treasurer), Boydell, Edwards (president), Gardiner (secretary), Palmer, Ransom, Rice, Walford, and Whitby. The lantern, a powerful triple oxy-hydrogen, with mixed jet, was lent by the treasurer, and the slides were passed through by the secretary.

The following were the awards of the judges, Messrs. A. R. Dresser, J. Traill Taylor, and Leon Warnerke (honorary member of the Society, a former member of council of the old South London):—

Class A—For best general work—(1) W. Rice, silver medal; (2) T. C. Kirby, bronze medal.

Class B—For best six pictures taken at the Society's excursions—(1) J. F. Kelly, silver medal; (2) H. E. Farmer, bronze medal.

Class C—For the best set of six local views—F. W. Webb, bronze medal.

Class D—For the best series of lantern slides—(1) W. Rice, disqualified by award Class A; (2) H. E. Farmer, disqualified by award Class B; (3) E. Boydell, bronze medal.

The hon. secretary also contributed a large frame of lantern slides, many of which slides were meritorious.

Some of the slides were from photographs taken with the Society's 12 by 10 camera, completely fitted, which is hired out to members.

The best general collection shown, but not for competition, was that of the president, Mr. F. W. Edwards, and consisted of photographs of silver shields and plaques, large landscapes and other views, and copies of old engravings, together with the beautiful transparencies which have already been distinguished at the Crystal Palace. Dr. Munyard was also an exhibitor whose works were not in competition.

Among the limited display of apparatus, Mr. H. Ransom showed his new ground glass focussing screen. The glass is finely ground, perfectly flat, and has a transparent spot in the centre which, while not interfering with focussing for views, forms a base over which an eye-piece may be placed, thus enabling the photographer to convert his camera into a telescope.

ASTRONOMICAL TELESCOPES.*

BY A. A. COMMON, F.R.S., TREASURER TO THE ROYAL ASTRONOMICAL SOCIETY.

Before speaking of the enormous instruments of the present day, with their various forms and complicated machinery, it will be well to give some little time to a consideration of the principles involved in the construction of the telescope, the manner in which it assists the eye to perceive distant objects, and, in a brief and general way, to the construction and action of the eye as far as it affects the use of the telescope, all as a help to consider in which way we may hope to still further increase our sense of vision.

* A lecture delivered at the Royal Institution.

I will ask you to bear with me when I mention some things that are very well known, but which, if brought to mind, may render the subject much more easy. Within pretty narrow limits the principles involved in the construction of the telescope are the same, whatever form it ultimately assumes. I will take as an illustration the telescope before me, which has served for the finder to a large astronomical telescope, and of which it is really a model. On examination we find that it has, in common with all refracting telescopes, a large lens at one end and several smaller ones at the other; the number of these small lenses varies according to the purpose for which we use the telescope. Taking out this large lens, we find that it is made of two pieces of glass; but as this has been done for a purpose to be presently explained which does not affect the principle, we will disregard this, and consider it only as a simple convex lens, to the more important properties of which I wish first of all particularly to draw your attention, leaving the construction of telescopes to be dealt with later on.

Stated shortly, such a lens has the power of refracting or bending the rays of light that fall upon it; while they are passing through the lens the course they take is altered; if we allow the light from a star to fall upon the lens, the whole of the parallel rays coming from the star on to the front surface are brought by this bending action to a point at some constant distance behind, and can be seen as a point of light by placing there a flat screen of any kind that will intercept the light. For all distant objects the distance at which the crossing of the rays takes place is the same. It depends entirely on the substance of the lens and the curvature we give to the surfaces, and not at all upon the aperture or width of the lens. The brightness only of the picture of the star depends upon the size of the lens, as that determines the amount of light it gathers together. If, instead of one star, we have three or four stars together, we will find that this lens will deal with the light from each star just as it did with the light of the first one, and just in proportion to the angular distance they are apart in the sky, so will the pictures we see of them be apart on our screen. So if we let the light from the moon fall on our lens, all the light from the various parts of the moon's surface will act like the separate stars, and produce a picture of the whole moon—in the photographic camera the lens produces in this manner a picture of objects in front of it, and this picture we see on the ground glass. When we attempt to get pictures of near objects that do not send rays of light that are parallel, we find that as the rays of light from them do not fall on the lens at the same angle to the axis, the picture is formed further away from the lens. The nearer the object whose picture we wish to throw upon the screen is to the lens, the further the screen must be moved. If we try this experiment we shall find, when we have the object at the same distance as the screen, the picture is then of the same size as the object, and the distance of the screen from the lens is twice that which we have found as the focal length; on bringing the object still nearer the lens, we find we must move the screen further and further away, until when the object is at the focus the picture is formed at an infinite distance away, or, what is more to our purpose, the rays of light from an object at the focus of a convex lens after passing through the lens are parallel, exactly as we have seen such parallel rays falling on the glass come to a focus, and this holds good in other cases where we take the effect of reflection as well as refraction.

We can also produce pictures by means of bright concave surfaces acting by reflection on the light falling upon them. Such a mirror or concave reflecting surface as I have here will behave exactly as the lens, excepting, of course, that it will form the picture in front instead of behind. The bending of the rays in the case of the convex lens is convergent, or towards the axis, for all parallel rays; if we use the reverse form of lens—that is, one thicker at the edge than in the middle—we find the reverse effect on the parallel rays; they will now be divergent, or bend away from the axis; and so with reflecting surfaces, if we make the concavity of our mirror less and less, till it ceases and we have a plane, we shall get no effect on the parallel rays of light except a change of direction after reflection. If we go beyond this and make the surface convex, we shall then have practically the same effect on the reflected rays as that given to the refracted ray by the concave glass lens.

As regards the size of the picture produced by lenses or mirrors of different focal length, the picture is larger just as the focal length is greater, and the angular dimension is converted into a linear one on the screen in due proportion. Now, as we shall assume that the eye sees all things best at the distance of about nine inches, we may say that the picture taken with a lens of this focal length gives at once the proper and most natural representation we can possibly have of anything at which we can look. Such a picture of a landscape, if placed before the eye at the distance of nine inches, would exactly cover the real landscape point for point all over. A picture taken with a lens of shorter focal length, say four inches, will give a picture as true in all the details as the larger one, but if this picture is looked at at nine inches distance, it is not a true representation of what we see; in order to make it so, we must look at it with a lens or magnifier. With a larger picture one can look at this at the proper distance, which always is the focal distance of the lens with which it was obtained, when we will see everything in the natural angular position that we have in the first case.

But if, instead of looking at this larger picture, which we may consider taken with a lens of, say, 90 inches focal length, at a distance of 90 inches, we look at it at a distance of 9 inches, we have practically destroyed it as a picture by reducing the distance at which we are viewing it, and we have converted it into what is, for that particular landscape, a telescopic picture; we see it, not from the point at which it was taken, but just as if we were at one-tenth of the distance from the particular part that we examine. A telescope with a magnifying power of ten would enable us to see the landscape just as we see it in the photograph when we examine it in the way I have mentioned.

Having thus seen how a lens or mirror acts, we will turn our attention to the eye. Here we find an optical combination of lenses that act together in the same way as the single convex lens of which we have been speaking. We will call this combination the lens of the eye. It produces a picture of distant objects which, in the normal eye, falls exactly in focus upon the retina. We are conscious that we do see clearly at all distances beyond about 9 inches. *(To be continued.)*

PHOTOGRAVURE is drawing the attention of Indian amateurs.

THE PROGRESS OF PHOTOGRAPHY.*

BY SIR RICHARD WEBSTER, M.P., ATTORNEY-GENERAL.

The progress of photography can be traced step by step in the records of the Society of Arts. The year 1839 was signalised by the discoveries of Daguerre, viz., that a highly-polished silver plate could be rendered sufficiently sensitive to the effect of light to retain the image or impression refracted upon it. In 1847 we find M. Claudet reading a paper on the Daguerreotype process before the Society. He had then recently propounded the theory, which later researches in connection with electricity are thought by some to go far to verify, that the principal agent in photography was an emanation from the sun, something which is not light, nor yet heat, and he had to admit that the most skilful operator was only an empiric who obtained his results without knowing their cause. M. Claudet seemed to have arrived at the conclusion that no increase in the rapidity of photographic processes was required, and that if we could find a substance which permitted an exposure of half the time —I may mention that a Daguerreotype portrait could then be taken in about twenty seconds—it would be desirable to use a lens which would operate with half the speed. As a matter of fact he was not very far wrong, having regard to the conditions under which he was working.

Later on in the year 1852 Roger Fenton read a paper shortly after the Society had held its first exhibition of photographs (which exhibition, I may note, resulted in the formation of the Photographic Society), and in that paper Fenton spoke of the collodion negative as the *ne plus ultra* of photographic excellence. The application of this phrase to a process which is now, to a large extent at least, obsolete, shows how slow we should be to apply such a term to any known scientific process. Though Mr. Fenton seemed to be satisfied with what we should now consider the very limited power then placed at the command of the photographer, he had a sufficiently clear notion of what might be done in the future. He suggested the application of photography to astronomy—an interesting prophecy, now that the heavens are being so elaborately mapped by photographic means—and to the microscope, and he quoted, as an instance of the application of photography to scientific and geographical research, the fact that photographic apparatus had been supplied to the Arctic expedition under Sir Edward Belcher, and to another exploring expedition sent into the South Pacific under Captain Denham. In the following year, 1853, Mr. Kingsley described before the Society a method of photographing microscopic objects on a large scale, which, though considered at the time a great development, would now be regarded both as clumsy and inefficient. From that time down to the present we have had continual reference to the progress of photography, and descriptions of its various applications, until of late years we find its present condition admirably described in the papers and lectures given by Captain Abney, Mr. Bolas, Mr. Burton, Mr. Spiller, and others.

Nor is it to pure photography, apart from its applications, that this observation applies. The first practical method of producing a printing-block by photographic means, Pretsch's process of photo-galvanography, was described here by the inventor in 1865, and in 1869 Mr. Davenport predicted that at no remote period engraving, like miniature painting, would, owing to the progress of photography, become practically obsolete. If this prediction has not been realised as regards engraving proper, it has very nearly been fulfilled as regards wood-engraving, which has been seriously affected as a profession by the various photographic processes on which illustrated journalism is now so largely dependent. We shall look forward with much pleasure to the latest information on this subject in the paper promised us by Mr. Carmichael Thomas on "Illustrated Journalism."

Few speculations possess more interest than that of the probability of our succeeding in the production of photographic pictures in their true or local colours. For more than half a century this problem has engaged the attention of many experimenters, although originally pronounced to be an illusion by so great an authority as M. Biot. In February, 1840, Sir John Herschel succeeded in procuring upon photographic paper a coloured image of the solar spectrum, and he regarded this result as bringing near the hope that coloured photographs might be obtained. In 1857 Robert Hunt, the well-known pioneer in scientific photography, detailed various experiments in which he had obtained pictures of the spectrum by means of Daguerreotype tablets, prepared in a peculiar way with iodine, on which he stated that the colours had softness and brilliancy. Daguerre himself had remarked that, when he had been taking the picture of any red-brick or any painted building, the photograph assumed a tint of that character. From these facts Robert Hunt expressed the opinion that the possibility of our being able to produce coloured photographs was decided—the probability brought infinitely nearer; and he alludes in the same publication to some experiments of M. Niepce de St. Victor, which, when first produced, were alleged to be perfectly coloured. I am not sufficiently in the secrets of those who have recently been in active pursuit of the same object to express any opinion as to whether or not these hopes are much nearer fulfilment, but if rumour be correct, we shall, before long, have an announcement of great progress in the same direction; and I trust that the members of the Society of Arts will have an opportunity of themselves judging of the processes by which those results have been achieved.

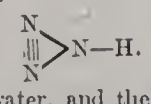
It is, moreover, interesting to note that the subsequent theories of Clerk Maxwell with regard to electricity, and the experiments of Professor Oliver Lodge and Sir Archibald Campbell, may verify the somewhat crude suggestions of M. Claudet as to the real agency which operates in producing a photographic image.

* A portion of the Presidential Address to the Society of Arts last week.

The Photographic Club.—The subject for discussion on December 3rd will be "Collodio-Bromide Processes;" December 10th, "Experiences with Hydrokinone."

Wilson's Photographic Magazine for November contains about the best photograph of the Daguerre Memorial at Washington yet published, and the more one sees of that memorial, the worse it looks. The young woman carved in front thereof, with her stiff wooden legs, chignon, and other prominent characteristics, is, presumably, intended to represent Fame.

A New Gas, Azothydric Acid.—Prof. Curtius, of Kiel, has obtained a compound, N_3H, for which he proposes the constitutional formula—



It is very soluble in water, and the solution dissolves zinc, copper, and iron, with evolution of hydrogen and the formation of nitrides, in which the metals are substituted for the hydrogen set free.—*Chemical News.*

Notes.

Perhaps nothing more illustrates the power of mind over matter than the commercial influences which result for generations from the utterances of poets. Had Scott never written of seeing "fair Melrose aright" and of the grave of Michael Scott, to what extent would the number of hotel-keepers now in the adjacent village have been reduced? Likewise, had Byron not written of Chillon, where would now have been the desecrating electric railway carrying visitors from Vevey to its gates? The Castle of Manfred has had the same glamour of poesie thrown over it, attracting thereunto the photographic amateur who, otherwise, would intelligently have let it alone, because of its unsuitable foreground, and being too high above any possible level of the lens to yield a picture artistic on its own merits. Such is the situation of the Castle of Unspunnen, of which Byron wrote:—

> You red cloud, which rests
> On Eigher's pinnacle so rested then—
> So like that it might be the same; the wind
> Was faint and gusty, and the mountain snows
> Began to glitter with the climbing moon.
> Count Manfred was as now within his tower,
> How occupied we knew not, but with him
> The sole companion of his wanderings
> And watchings—her whom of all earthly things
> That lived, the only thing he seemed to love—
> As he, indeed, by blood was bound to do,
> The lady Astarte.

An amateur recently sent a negative of Manfred's Castle to a commercial firm to enlarge on bromide paper, and one of their intelligent workmen seems to have been operating on negatives by the dozen, and pushing all of them for the same times into the same dish preparatory to leaving, in a few minutes, for his Saturday half-holiday. A nice, flat print, with lights and shades approaching the same density, was the result, the negative being thin and full of detail, so requiring different treatment to that given to average images. The irascible amateur, having made smaller but much better prints himself, said to the firm, "Why is this thus?" and sent some of his own results. The attention of the superior authorities being thus drawn to the matter, they resolved to return a decent enlargement, but took their revenge out of the amateur by writing sarcastically on the wrapper enclosing the returned negative their instructions to their particular workman: "*Replace*, and see that same brilliancy is obtained as in contacts. *Never mind them being chalky.*" The amateur, however, having obtained what he required, was satisfied, and, as said at the end of novels, they all were happy ever afterwards, and had large families.

French opinion about the ugly Daguerre monument at Washington is of interest. The *Moniteur de la Photographie*, after quoting our recent remarks about the monument, says:—"In publishing the preceding extracts we nevertheless recognise the respect paid by the United States to one of our illustrious countrymen, to one of the fathers of photography. We are among those who believe that Daguerre was but the outcome of Nicéphore Niépce. It may, however, be asked whether, without the discoveries of Daguerre, photography would now have arrived at its actual position. We owe to the kindness of M. Schwier, of Weimar, the block of the accompanying engraving representing the monument erected to Daguerre at Washington. The design is in effect sad, disgraceful, but that is of little moment; the work of the committee at Washington none the less deserves our gratitude. We need not look at the outer form, but can attach ourselves to the spirit of the act. We have not waited for the authority of the committee at Washington to print a picture of this monument, being convinced that giving increased publication to its work will have its entire approbation."

Lantern slides produced by the diazotype process, with gelatine as the vehicle, have a long range of gradation and are full of fine detail, but are of gorgeous colours as compared with ordinary lantern plates; therefore, for most subjects, not so pleasing in effect. A delicate emerald green colour has recently been obtained by special development; the green appears in the early stage of the development of a blue picture, so we suppose that some of the yellow compound sensitive to light is then unacted upon by the developer, and the mixture of blue and yellow produces the green. If so, these green prints are unstable.

The Company which was formed many months ago to take the portraits of any of her Majesty's subjects who could be persuaded to forego their customary penny-in-the-slot chocolate or butter Scotch in favour of photography, have not as yet made any great installation of their patent machines; and although it has been stated that such machines are in use, we have not yet had a chance of contributing the sum of one penny; for, truth to tell, we do not know where they are. However, we wish the Company every success in its endeavour to still more popularise our already popular art. But unless the Company looks sharp and takes possession of all the best sites for their operations, they will be eclipsed by a new device of the same kind, which has been contrived in America, and which is sure to make its way across the Atlantic if it is as successful in operation as it is said to be.

It is, of course, only natural that an American invention should altogether outstrip its English prototype; but at present we can only refer to promises, not performances, for the patent is not yet complete. A pretty full description of the contrivance, however, is published in that excellent periodical, the *Scientific American*, and from this description we can get a good idea of what the new device is expected to do. Its grandest feature seems to be that it will work quite independently of daylight, for paucity of light is the initial difficulty with which the English machines—at any rate, those placed in London—will have to contend. At the moment of exposure a charge of magnesium is ignited by an incandescent platinum wire, and the sitter is photographed by flash-light.

The incandescent wire savours of electricity, and, as a matter of fact, the whole of the necessary movements, after the impetus is given by the falliug coin, are carried through by the electric current. The sitter takes his place after having dropped a quarter dollar into the slot, and he theu gives a slight pull to a cord in front of the case. This uncaps the lens, and causes the magnesium flash to take place, and in two and a-half minutes the finished photograph, on a little sheet of flexible celluloid, is preseuted to him. The celluloid, it appears, is carried through the developing and fixing fluids by means of rubber tapes, and "the necessary chemicals are each supplied separately, from an air-tight reservoir, and the flow regulated by a dial apparatus to correspond with the temperature of the atmosphere and the strength of the chemicals."

This last sentence, which we have quoted literally from the published description, will cause a flutter of expectation in the bosoms of those amateurs who like to photograph with the least trouble to themselves. We have heard of gentlemen of this description who do absolutely nothing towards the production of their pictures but selecting the view and uncapping the lens. The mere mechanical work of developing and priuting is carried out by professional hands, and pictures produced in this manner, we are told, have actually more than once taken a medal at an amateur exhibition. Now, if these easy-going amateurs can only secure this marvellous dial apparatus described above, to correspond with the temperature, &c., they will be still more happy. But, perhaps, perfect bliss will not be attained until someone else invents an automatic device which shall select the view and uncap the lens for them.

The balloon, just now, is a subject of great anxiety to military authorities on the Continent. It is strongly suspected by the German War Office that enterprising French balloonists are in the habit of hovering over certain forts on the frontier, and taking photographs of the defences. The difficulty which the commanding officers of the forts in question are in is, that they don't know whether to fire at the balloon or not. If they do take this course, the result would certainly be fatal for the daring aeronaut, and if it should happen that no evidence of his suspected photographic work were discovered, it might prove rather awkward for the commandant. He probably knows sufficient of photography to be certain that only on the negatives taken being developed would any proof or not of the supposed spy be forthcoming, and as in all probability the apparatus and the plates would be smashed when the balloon came in contact with the earth, one feels that the experiment is rather risky.

Mrs. Fawcett is probably a student of physiognomy, or may be she has been studying Mr. Francis Galton's composite photographs of criminals. In a lecture she delivered last week on General Booth's scheme, she thought there was a process of selection which would weed out drunken, lazy, and half-witted individuals, and that photography might be employed in getting to know bad and unsatisfactory characters. This is all which is reported of Mrs. Fawcett's words on the subject, and we certainly should like to know a little more about her views. How is photography to be employed? Will it be necessary to take what Mr. Galton would call a type of face, and compare with it people of supposed demoralised character, or is the camera to be used to take photographs of such persons, so that they may be studied at leisure, and traits of character discovered which, invisible to the naked eye, are revealed by photography?

The ingenuity of photographers is limitless. Hundreds, nay thousands, of persons have noticed the effect when standing between two mirrors, that their reflections are multiplied infinitely. A clever photographer, M. Paboudjian, of Constantinople, has succeeded in photographing this curious multiplication of a single face, and a reproduction of one of his photographs appears in *La Nature*. To obtain this photograph, Mr. Paboudjian took two glasses placed parallel to one another, and separated by about sixty centimetres. In the space between the two glasses he placed the subject to be photographed; and the difficulty he had to solve was how to take the photograph without being seen one's self with the apparatus. This was easily managed by one of the glasses being shorter than the other, and by placing the apparatus on the top of the shorter one, a little inclined towards the floor. The glasses must be unframed, for the frames being reflected would give a very bad effect.

The experiment may be made more complicated by three large glasses placed in the form of a prism, reflecting sides beiug turned inwards; three or four persons are posed in the interior, thus giving the impression of an enormous crowd. A similar effect may be seen just now at the Royal Aquarium, Westminster, where, with only two or three persons, quite the impression of an enormous throng moving to and fro in a garden is produced by a series of mirrors. The illusion is really a very pretty one, but whether the idea is taken from M. Paboudjian's photographs we are unable to say.

It is to be hoped that Mr. Alcott, the naturalist on board the Indian Marine Survey steamer *Investigator*, is also a photographer. This steamer left Bombay on the 18th of October, and in the course of its dredging operations brought up some large prawns. One night, a prawn lying in a bucket of sea-water on deck was observed to be shining brightly, and when seized gave out such a volume of phosphorescence that by its light Mr. Alcott was able to see the details of the interior of the bucket and his own hands. Here was a splendid chance for securing photographic evidence of this luminosity. The light probably might not have been sufficiently sensitive to have taken a photograph of the prawn itself, but it certainly would have secured an impression of the phosphorescence.

AMERICAN AMATEURS' EXPENSES IN PHOTOGRAPHY.

BY CATHERINE WEED BARNES.

How many people know much, if anything, of the expense required to manage an ordinary portrait studio? Does the average sitter consider that a dozen sittings cost the operator any more than one? I speak not only to the amateur, but to the general public, in saying that there is much unconscious ignorance on these and other points in photography which a few words may serve to make clearer. I am often asked if it is not possible to clean an exposed plate so as to use it again, and as regards proofs or prints, they are usually considered as of little, if any, value. It seems to be a positive revelation to one who is not familiar with photographic processes to be told that every sheet of paper must be silvered, and requires pure gold to tone and render the picture permanent; that simple printing will not do this. One very important point is, that the ordinary sheet of silvered paper is 18 by 22 inches. Calculate how many cabinet pictures can be cut from it, and also how much has to be wasted if larger sizes are desired; unless, indeed, one follows the example of some photographers, and cuts the wrong way of the paper, making the long faces broad and the latter still broader. This simple explanation will account for many so-called "poor" pictures. It is usual with professionals to silver every day what paper they estimate will be needed, and, if any is left over, or there is a sudden change in the weather of long-continued dark days, there is a deficit when the books are reckoned up. The general public finds it also hard to understand why, if a negative can be made in stormy weather, it is impossible to make albumen prints.

Many amateurs are deterred from any but the simplest work because some one else has a finer lens, and "of course, there is no use in my trying to do such work," is the ready excuse for careless manipulation, leaving the lens uncovered, wiping the glass with any cloth that happens to be at hand, working with soiled graduates or trays, and generally neglecting the absolutely important rules of neatness and order. Lenses are made now at prices to suit any purse, but it is well to make up one's mind first what kind of work is to be done. It is utterly impossible to make ordinary portraits, landscapes, groups, large heads, interiors, and snap-shots with the same lens. I have done quite good work with a 4 by 5 lens—camera and lens costing twenty dollars—but only outdoors and in the best of light. Do not, in such cases, ask for absolutely sharp outlines clear to the corners, or a soft, well-lit face with everything in focus. Of course, an expensive lens is best for the best work, else why should men spend so much care in devising them? but it is not necessary that an amateur should attempt to cover the whole photographic field. It is much better to select some particular branch, and learn to do that as well as possible. The cheapest work is that done with a small view lens, and using such cameras as the Kodak, Turnover, P. D. Q., &c. I do not think the film rolls have really helped the art side of photography, for, with so many chances to work quickly, one is tempted to make many useless exposures, and not take time to thoroughly study the view before exposure. I was in California once with a friend who had a kodak camera, and he must have made six or seven pictures to my one, but his were two and a-half inches, and mine 5 by 7 in size. His camera had cost twenty-five dollars, and mine, an Anthony "Climax," nearly one hundred and forty dollars. His was always ready and no weight, while mine was heavy, and required much trouble in filling holders and packing exposed plates. I had used a R. R. Dallmeyer lens (6½ by 8½), and, though the results were smaller in quantity, I was not ashamed of them in quality.

The lens is the first thing to be considered as regards expense, for the camera and tripod can be home-made. So, where expense is an important consideration, get as good a lens as you can afford, and fill up the deficiencies in your outfit with brains. My first outfit (5 by 8) cost less than thirty dollars, but, as my great ambition was interior work, I soon disposed of it for an 8 by 10 camera and a fine wide-angle lens, of course at a much greater expense, the latter costing over sixty dollars. As this worked more slowly than my long-focus lens, it was not possible to use it for portraits, which was my next temptation. So a hundred-dollar portrait lens was bought and did very well, using only side light, but added experience made me critical, and then my attic studio was built. Before this, an ordinary view camera on a tripod had been used for portraits, but with the studio a regular portrait camera and stand were needed. Then, as ambition grew, a lens for large heads was required, which cost 164 dollars, and all sorts of accessories. The room being short and full-length, figures being called for, a wide-angle group lens joined the collection. This, being expected to do fine work, was expensive, costing nearly ninety dollars, and when I found certain work could not be done with the lenses on hand, I looked for what would do it. I do not believe in straining a lens, and would prefer buying one rather larger than is actually required. But lenses, and good ones too, are becoming more reasonable in price, and I have one now, a W. A. Euryscope (Voigtländer) covering a 5 by 7 plate with full opening and an 8 by 10 with the smallest stop. Certain kinds of lenses do special work better than others, and I do not believe in pinning one's faith to any one make, although confessing my preference for Voigtländer's and Dallmeyer's for portraits and interiors.

There are several good ones for instantaneous work, but I have had best success with the Dallmeyer and Hermagis. It is curious that one person will succeed where another fails with the same lens or developer. Try for yourself, and decide which is your "particular vanity." If possible, test your lens before buying one; no two, even of the same make, are exactly alike, no matter who tells you so. But the main point settled, then comes the camera, and early in camera work I learned one very useful "point." If you have more than one camera, screw your flange on the front-board of the smallest, and slip that board, when necessary to use a larger plate, tightly into a frame on the larger front-board. By this device one lens can be used on several cameras. One reason for using high-priced lenses is, that often several of the same make fit into the same flange, rendering only one front-board necessary. Tourists will appreciate this necessity for travelling close-reefed. In my reducing camera I use for 8 by 10 negatives a wide-angled Dallmeyer, and for 11 by 14 a R. S. Ross lens. In the former case, put the lens inside the camera, and in the latter put it in the sliding front-board. I have a 5 by 7 Universal camera, and usually carry a 6½ by 8½ Dallmeyer R. R. lens with Prosch shutter, and into the same flange fits a 10 by 12 Dallmeyer W. A. With this outfit it is

possible, with separate front-boards, to carry a 5 by 7 Dallmeyer W. A. and also a Voigtländer W. A. Euryscope, which has a longer focus than my small Dallmeyer; but circumstances govern cases, and it is not generally necessary to take four lenses on short trips. This fitting one front-board on another I utilise for the studio, for interiors, and landscapes. It is especially useful when using a drop shutter, and I have the Green, Low, and Prosch shutters; the first two are not expensive, and are quick enough for the studio, but not for view work. The Prosch is the most expensive, and the quickest for closely accurate work.

As regards cameras, they can cost comparatively nothing, or a great deal. For portraits they should be heavy and rigid, with sliding front, double swing-back, and every other movement which can be devised to secure uncertain sitters. Remember, however, that this means added expense. The stand should be firm and easily controlled. My two portrait cameras cost about one hundred dollars, and my stands, for there are two, cost respectively fifteen dollars and twenty-five dollars. Tripods are comparatively inexpensive, but should be thoroughly trustworthy, and one can well bear an extra weight in outdoor work if sure they will not suddenly give way and bring wreck and ruin in their path. In truth, there is too much demand nowadays for light outfits, while strength and solidity are being sacrificed. People want a good picture, but without its costing them much expense, time, or trouble, and they will not get it.

In studio work one needs backgrounds and various other articles, and the expense of these is limited only by the condition of the operator's purse. Those who have studios are always altering them, as I can testify, and the more one learns, the more chances offer themselves for such alterations.

The landscape worker is spared this, and his expenses must be in the line of plates, lenses, and chemicals. Plates cost all sorts of prices, increasing, of course, with the larger sizes. There is not much difference between those of a size. Cut films are somewhat more costly, but have many advantages, more so, I believe, than the film rolls, while 4 by 5 plates cost about sixy-five cents per dozen; 8 by 10's, 2.40 dollars; 11 by 14's, 5 dollars, and so upwards. Considering the possible risk of defective plates and uneasy sitters, plates are quite a heavy item of expense, especially with weak negatives, when to the cost of development is added that of intensification. With portraits comes the expense of retouching, which ought only to be done by an experienced worker, and this requires a long and severe apprenticeship, besides good eyesight, a steady hand, and endless patience. It should not be attempted by the average amateur, and never done on interiors or landscapes unless under very exceptioual circumstances.

A good negative becomes such only by development with certain chemicals, and their names and combinations are legion. The simpler formulæ are the best, unless you wish to show what you *can* do, and if you get a good one do not change quickly. Pyro costs about six dollars per pound, and both carbonate and sulphite of soda are cheap. There is no better developer for portraits than this combination, while for lantern slides I use eikonogen, which is growing cheaper, in place of pyro, with, generally, sulphite of soda and bromide of potassium. The new acid sulphite is excellent for keeping the pyro bath clear, and can easily be made by Lanier's formula. T. C. Roche uses it in the pyro developer, but I have not tried that. A little sulphuric acid in the alum bath is also a cheap and easy way to clear negatives and slides. It is claimed that one should not use acid with eikonogen, but I have no trouble with it. —*The American Amateur Photographer.*

PHOTO-CHEMICAL INVESTIGATIONS.*

BY FERDINAND HURTER, PH.D., AND V. C. DRIFFIELD.

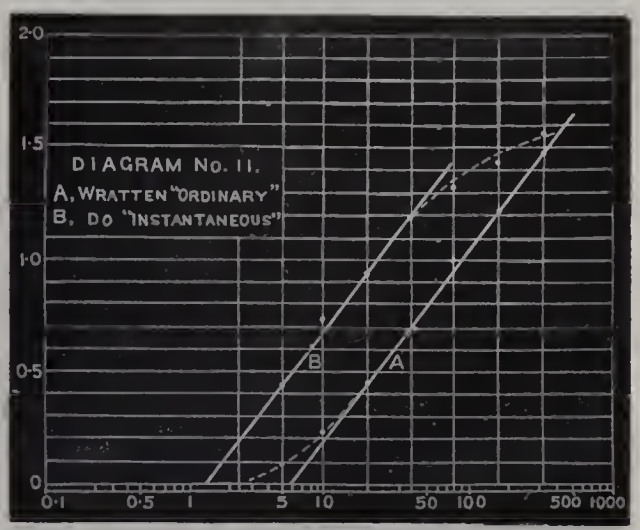
THERE is a theoretical possibility that a plate may be rapid to one developer and slow to another, so as to require different exposures according to the developer used. If silver bromide be reduced to metallic silver, 22,700 units of heat must be supplied to replace the heat of combination. Of this amount of heat, the developer in the act of development supplies a portion. Ferrous oxalate, for instance, would probably supply 12,900 units, so that the light need only supply the difference, viz.,9,800 units. But if another developer could supply more than 12,900 units, then the light clearly need not supply quite so much, and, in that case, the plate would be faster to one developer than to another.

We have not paid such close attention to this question yet as to enable us to decide it finally, but, as far as our experiments have gone, we have found very little difference, if any, between the various developers, and we do not feel justified in assigning to the small differences we have observed any great importance.

If a developer could be found which would render a plate materially faster, that developer would strike a serious blow at the hypothesis that the latent image consists of sub-bromide of silver.

We append a number of interesting diagrams representing our graphic method of determining the inertia of a plate.

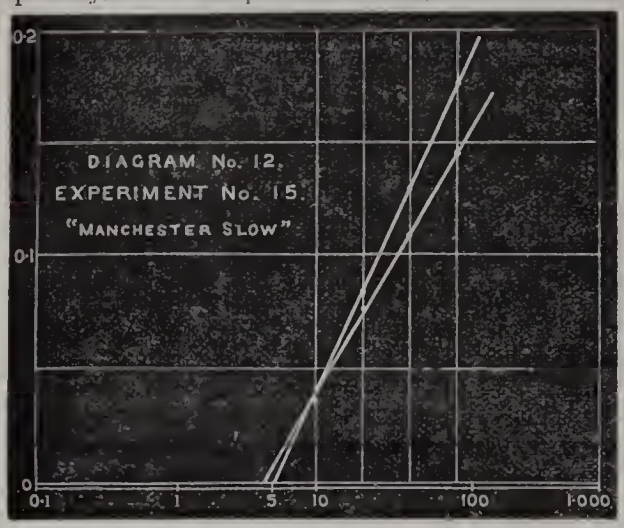
Diagram No. 11 shows the general arrangement we adopt for finding graphically the value of the inertia. An ordinary "slide rule" furnishes the mode of subdividing the scale, the distances of the numbers being proportional to their logarithms. The two curves are the curves of



Wratten and Wainwright "ordinary" and "instantaneous" plates. It will be noticed that the "instantaneous" plate shows, within the given exposures, a portion of the period of over-exposure, whilst the "ordinary" shows a portion of the period of "under-exposure." The inertia of the one is 1·4, that of the other 5·5, and, in round numbers, the one plate is four times as fast as the other.

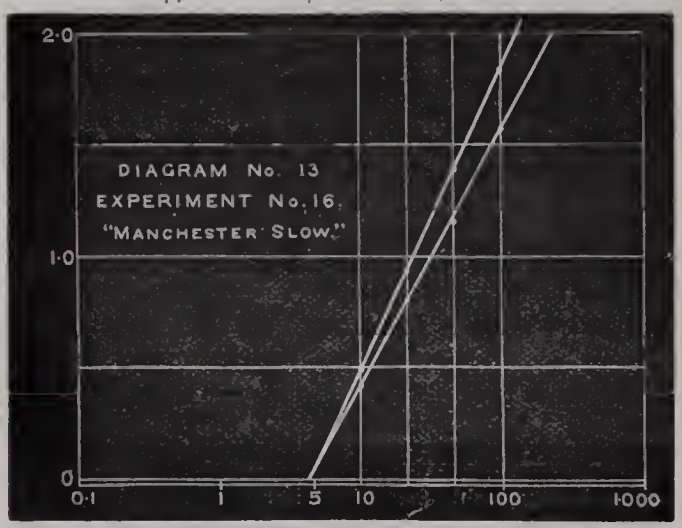
* Concluded from p. 842.

Diagram No. 12 shows the results of experiment 15 graphically, for the purpose of showing that variations in

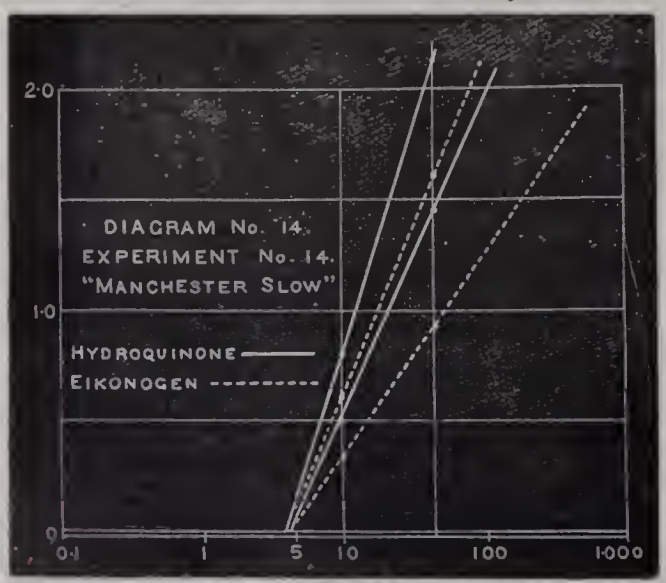


the mode of development do not influence the determination of the inertia, the densities of the two modes of development being different; yet the straight lines practically converge to the same point.

Diagram No. 13.—This diagram represents another variation in pyro development, viz., in the amount of



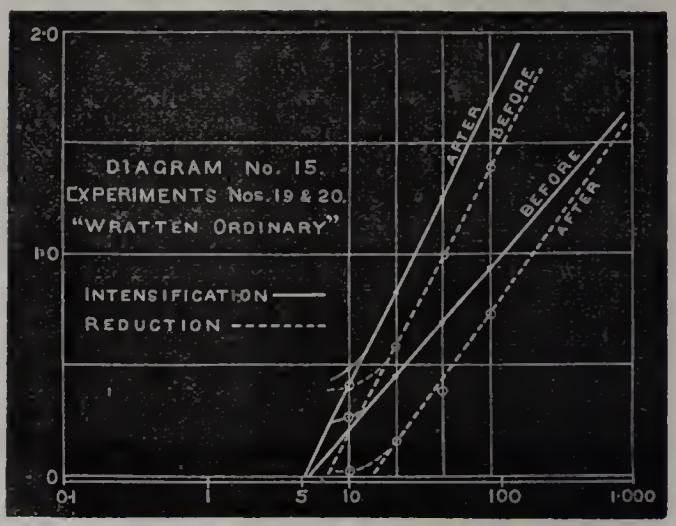
bromide (experiment 16). It will be again seen that the values of the inertia are almost identical, in spite of a con-



siderable difference in the composition of the developer and the time of development.

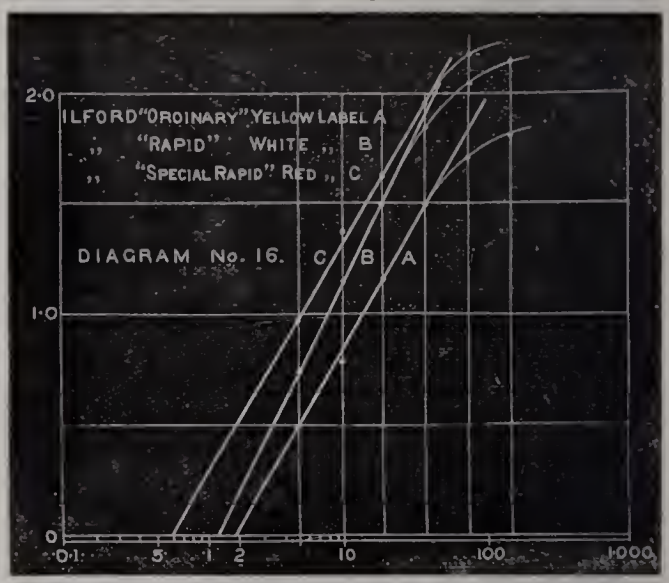
Diagram No. 14 shows four determinations of the inertia of one plate (see experiment 14), two determinations being made with eikonogen and two with hydroquinone, the duration of development being different for each determination; yet the results of all four determinations are practically identical.

Diagram No. 15 shows that the inertia of a plate can be determined after intensification, *but not after reduction*. It



is, therefore, better to develop too little rather than too much. We clearly must not resort to reduction, but we may intensify if the trial plates have been under-developed. (Experiments 19 and 20.)

Diagram No. 16 shows the determination of inertia of the Ilford plates, "ordinary," "rapid" and "special rapid" (red label). Their inertias are respectively 2·0, 1·4, and 0·56, and their speeds are relatively as



1 : : 1·41 : 3·5. The "red label" plates are the most rapid plates we have so far investigated, but we found it very difficult to ascertain their true speed in the camera, on account of the difficulty in securing adequate density.

When the inertia of the plate is known, it is possible to time the exposures in the camera so that the densities of the gradations are almost exactly proportional to the logarithms of the light intensities which produced them. By this means negatives can be produced which satisfy very nearly the definition we gave of a theoretically perfect negative. It must be borne in mind, however, that such a negative is not necessarily true to nature. The optical density after development differs from the density

of the latent image. If the negative is to be true to nature, a plate must be used which is richly coated, the exposure must be carefully timed, and the development must be carried only so far that the value of the development constant γ is numerically equal to 1. Experiments which we have made indicate that for the production of artistic effects on ordinary silver chloride paper, it is necessary to exaggerate the densities, *i.e.*, to prolong the development until γ is greater than 1, and nearly reaches the value 2. This requires further investigation; suffice it to have pointed out that what Captain Abney terms "photographic untruth" is not necessarily inherent in photography, since the photographer has it in his power to decide the degree of exaggeration.

The exposure to be given in the camera can be found by means of the actinograph. when the inertia of the plate is known.

The "actinograph speed" of the plate is found by means of the formula $S = 34\,i$, where S is the speed and i the inertia in candlemeter seconds. We find, for instance, the speed of the Ilford plates from their inertia (as shown on Diagram 16).

		Speed.
Ilford "ordinary"	$= \frac{34}{2}$	$= 17$
Ilford "rapid"	$= \frac{34}{1\cdot01}$	$= 24$
Ilford "special rapid"	$= \frac{34}{0\cdot56}$	$= 60$

This method of referring the sensitiveness of the plate to the candlemeter second as unit will, we believe, greatly promote progress both in the preparation of the plates and in their application. We flatter ourselves that we have supplied one of the greatest needs of plate makers and photographers in general, by enabling them, for the first time, to ascertain accurately the sensitiveness of different plates, and, by means of the actinograph, to apply this information in practice.

The above is the main practical result which has accrued from our investigations, but identically we have shown the fallacy of many popular views on the subject of development, and the paramount importance of correct exposure.

From a purely scientific point of view, perhaps, the most interesting result of our labour is the elucidation of the numerical relation between the exposure and its effect on the sensitive film, and the simple explanation of these relations, based upon the optical properties of the unexposed sensitive film. It would not have been difficult to extend these considerations so as to include in them the reversing action of the less refrangible rays. This would not, however, have served any practical end at present, and it would have complicated the formulæ very considerably. We reserve for a future communication this extension of the law which we have discovered.

THE LANTERN SOCIETY.—On Monday, November 24th, at an exhibition of lantern slides for members and their friends, a selection of about ninety slides was shown on the screen, and several lantern attachments were then shown practically, in operation; namely, the kaleidoscope, pandiscope, cycloidotrope, and vertical attachment. The curious effects capable of being produced by some of these instruments appeared to be somewhat in the nature of a revelation to many of those present.

GELATINE IN PLACE OF GLASS FOR STEREOSCOPIC SLIDES.*

BY CAPT. KISS.

I HAVE already detailed my experience in the preparation of stereoscopic slides on glass plates. In spite, however, of their unquestionable advantages, they have two great faults; they are heavy, and easily broken. If, in order to decrease the weight, the thinnest possible glass is selected, the fragility is increased; if thick glass is used, the weight becomes enormous. These evils stand in the way of the production of stereoscopic slides on glass. Who buys when travelling, an occasion when—at least it is so with me—money is more freely spent than at home, these heavy, unportable pictures? Very few, even when they are to be found in commerce; but in order that their preparation may be profitable to the photographer such rare sales are insufficient. I have, therefore, recently occupied myself with experiments having for their end the replacement of glass by gelatine, and have obtained some very gratifying results, even if the process cannot be considered quite perfected. For the preparation of gelatine stereo-transparencies I employ the same chloride of silver gelatine emulsion as when working on glass; but instead of coating it on plain glass it is poured upon the cleaned, and not too finely ground, side of ground glass. These plates are first thoroughly cleaned by washing. The matt side must appear quite even, without lighter spots, greasy patches, or finger-marks. The plates are then well rubbed on the matt side with talc by means of a linen cloth, and then thoroughly dusted with a soft brush. A linen cloth is then moistened with alcohol of ninety-six per cent., and the edges of the plates are cleaned with it so that the talc is removed to form a border of 7 to 8 mm. (about one-third of an inch).

The coating of plates thus prepared is certainly somewhat more difficult than ordinary, for the emulsion does not flow smoothly on the talced surface, but with the pipette formerly described it goes, after a little practice, very well. The emulsion is poured on in pretty good quantity, about 12 cm. for a plate of 10 by 18 cm. In drying, the use of warm air must be avoided.

Upon these plates, as with glass stereograms, the picture is produced by contact printing and development. The developed plates are washed and placed in an acidified chrome alum solution of two per cent. After drying and retouching the border is cut round, and the film with the picture easily removed. The film is matt on the side which was next the glass to the same extent as was the glass plate itself; the other side bears the picture. Gelatine films obtained in this way are naturally very thin, about the one-fifteenth of a mm. They can, however, easily be strengthened by the process given in *Eder's Ausführliches Handbuch der Photographie*, on page 345 of the third part, 1890 edition. The collodion coating may be omitted, and the plate, warmed to blood heat, coated direct with 20 cm. of a ten per cent. gelatine solution to which some glycerine has been added. For spreading the solution upon the levelled plate, a brush of about 25 mm. (about an inch) in width dipped in warm water, and then pressed out, serves exceedingly well.

If the negative has been divided, as in printing glass stereograms, so that the prints are in their proper positions and do not require to be transposed, the film is cut with sharp scissors to the stereoscopic size, and is laid between

* Translated for the PHOTOGRAPHIC NEWS from *The Photographisches Wochenblatt*.

two films of commercial sheet gelatine, and these again between two thick paper mounts, such as are generally used for coloured paper stereograms. The whole is cemented together, and we have a gelatine stereogram which, viewed as a transparency, resembles a glass stereogram, but is neither so fragile nor so heavy. If either of the protecting gelatine films should suffer damage it can easily be replaced. The picture film lies protected between two other films, and, except by violence, can scarcely be damaged.

If the negative has not been divided, the picture film must be cut and the corners cemented with wax to one of the protecting gelatine films; the other film is then laid upon it, and the whole enclosed between the two paper mounts.

If the picture film, without strengthening, is placed between the two transparent sheets of gelatine, the operation is simplified to that extent. My own collection of stereograms is prepared with the strengthened films laid between two paper mounts with no further protection. This is certainly not a complete safeguard, but, with careful treatment, films thus prepared will last a long time.

THE PLATINOTYPE PROCESS.*

BY JOHN PIKE.

I INTEND merely to give a brief description of the process, for there are certain points which deserve notice, and I am wishful also to enlarge somewhat the scope of the title, and refer to platinum toning generally. Most of the older photographic text-books contained formulæ for platinum toning, designed, I imagine, for use with ordinary albumenised paper. Personally, I never met with any success whatever with such formulæ. The error, or failure, arose from using the chloride of platinum, or chloro-platinic acid, as some prefer to call it; but with platinic nitrate or sulphate a successful toning bath may be made, and this bath was introduced so far back as 1859. It is noteworthy that the gentleman who devised this formula also used chloro-platinite of *sodium*, a salt closely analagons to the platinum toning salt in use at the present time. The same gentleman, Mr. Burnett, also at nearly the same period recommended, as developers of the images formed by his ferric and uranium printing processes, salts of gold, *platinum*, and palladium; and here we have foreshadowed many years ago the platinotype process of the preseut day.

No member of our Society should forget the share taken in experiments of this kind fifty years ago by Sir John Herschel, the distinguished relative of our own distinguished late president. The fact that the action of light reduced the ferric salts to the ferrous was one of the earliest known in photographic chemistry. It was also known that the ferr*ous* compounds would throw down gold and silver from their soluble salts, while the ferr*ic* salts would *not*. Sir John Herschel was aware of this, and devised his chrysotype process. In this process paper was washed over with a solution of a salt of iron, dried, and exposed; it was then toned with a solution of gold chloride, made as neutral as possible, and a picture obtained formed of *purple oxide of gold*. If for gold we substitute platinum, we do not get a precipitate; and here we come to the experiments of Willis, who discovered that the addition of a *soluble oxalate* would cause such a precipitate. Willis also used a platin*ous* salt, viz., the chloro-platinite of potassium, and was enabled thus to get a double deposition of platinum.

The method of obtaining prints by Willis's process depends, firstly, on the fact that ferr*ic* oxalate is reduced by the action of light to ferrous oxalate; secondly, that the ferrous oxalate, when dissolved in a hot solution of potassic oxalate, instantly reduces the metallic platinum from chlorides and other salts, more particularly when in the platinous state; for instance, a solution of a platinous salt—*i.e.*, the chloro-platinite of potassium—is mixed with one of ferr*ic*-oxalate. A properly sized and prepared paper is floated upon this solution and carefully dried; on exposure to light the *iron* salt is affected, being changed to ferrous oxalate, and the particles of this salt will be in close contact with those of the platinum salt. Float this paper upon a hot solution of potassic oxalate; the ferrous image is at once dissolved by the potash salt, but at the moment of solution is reduced also *in situ* some or all of the *platinum*, and the result is a picture in pure *platinum* black. This, the hot-bath process, Mr. Auty will demonstrate first. The advantages of this process of Willis's are the replacing of all the iron salt by one of platinum, and not forming an alloy with that metal; the disadvantages are the faintly visible appearance of the picture during printing, and the numerous precautions to be observed against damp.

So far we have been getting nothing but black tones; hence farther experiments to meet the desires of those who were wishful for the warm tones of the silver print. With the matt surface of the platinotype the Platinotype Company issued a special solution to be added to the hot bath for the production of sepia tones. This solution is believed to contain a salt of mercury, probably the chloride.

In the cold-bath process, which we also propose to demonstrate, Willis's paper is coated with a solution of ferric oxalate and a small quantity of mercury salt; on exposure to light the ferric salt is reduced as before to the ferr*ous* state. The exposed prints are developed—or, rather, toned—in a cold solution of potassic oxalate, say 50 grains to the ounce, to which has been added 6 or 8 grains to the ounce of chloro-platinite of potassium (the toning salt of the Platinotype Company). With a strong solution of oxalate of potash *cold* tones are obtained; with a weak solution warm tones. There are some advantages claimed for the use of cold-bath paper. Prints made by this method are more transparent in the shadows. This may be because the toning is produced by *application*, so to speak, of the platinum salt to the surface of the paper, and not precipitated in the body of the paper, as in the hot bath method. Another important characteristic is the greater purity of the *whites;* this is because the paper is coated with iron only.

The developed prints are placed *at once* in a bath of acidified water, one part of hydrochloric acid to fifty of water, for ten minutes, and then transferred to a second and third acid bath, by which time all traces of *iron* should be removed; a final wash in clean water follows, and this completes the operations.

You will observe that the cold-bath platinum method is essentially a toning process, and by all accounts it admits of many modifications and various ways of application. My own work is generally done by floating. The solution may be applied by means of a brush or flannel roller, or a spray producer may be used.

* A communication to the Newcastle-on-Tyne and Northern Counties Photographic Association.

So far we have been using paper and referriug to paper containing a basis of an iron salt; when we come to use silver we are able at once to secure a greater variety of tone, platinum being well known to form alloys with silver. Blanchard's paper has a basis of silver, and the other matt-surface papers sold for platinum toning are also sensitised on a silver bath. The name of Mr. Lyonel Clark is, of course, very intimately associated with fine work in this direction, and priuts prepared by his method are, iu my opinion, a distinct advance in photographic work. Mr. Clark recommends home-prepared sensitised paper, and some pithy remarks of his on the relative merits of ready-sensitised and home-prepared aud selected paper are well worth quoting. He says:—"With the advantages that ready-made paper brings, it has also its concomitant disadvautages; we are more or less bound to one quality of paper, slightly thicker or slightly thinner in substance, perhaps, or of a more or less hideous tint, but still always the saiue texture or surface, and ou this are indiscriminiately printed the bold outlines of large heads, or grand landscapes, or the exquisite details of stereoscopic work, or the micrographical fidelity of nature's minutest organisms."

Mr. Clark therefore suggests wisely that the paper be selected to fit the subject, and it naturally follows that the tone or colour should also be obtained which more accurately represents the idea to be carried out. I am glad to say our Society has not been altogether behind-hand in experiments with Lyonel Clark's processes aud methods. Mr. Parry, Mr. Sawyer, and Mr. Goold have all, I believe, followed the lines laid down, though I am not sure that platinum has been in all cases in the toning salt used. Possibly one or all of these gentlemen will, if present, favour us by remarks on this subject.

In conclusion, let me remark that years ago, on the walls of our exhibitions were to be seen nothing but the glossy surface of the prints and warm tones; now-a-days we seem to have fallen into the opposite extreme of all matt-surface papers and *cold tones*. Abolish the albumen surface if you will, but let us at least show some idea and sense of fitness in the matter of colour, and remember that variety is pleasing.

THE JURY OF THE NEXT INTERNATIONAL EXHIBITION AT VIENNA.

A Vienna correspondent writes that sooner than was anticipated, the jury of this exhibition has been formed. Hitherto no photographic exhibition has been able to show a jury like this. Artists of the first rank, free from every prejudice, have declared themselves ready to join it and exercise the office, which is by no means free from trouble. By these means the exhibition acquires an importance unsuspected before. Englaud, it is to be hoped, will induce her best men to help to carry out the ideal ou which the exhibition is founded; this is all the more to be hoped because, probably, she is destined to take the highest place there. A few words may be added as to each member of the jury.

Henry von Augeli—Professor at the Imperial and Royal Academy of Fine Arts, Vienna, a celebrated painter whose name is as well known iu England as on the Continent.

John Benk—A sculptor renowned for his sculptures for the House of Parliament, for his Clythia, and other works.

Julius Berger—Professor at the Imperial aud Royal Academy of Arts in Vienna; a great master, who is now engaged in executing a commission to decorate the walls and ceiling of the Historical Art Museum with frescoes.

K. Karger—Professor at the School of Art Industry, Vienna. Recently the city of Vienna entrusted him with the difficult task of painting, for the new Town Hall, a picture representing the *Corpus Christi* procession, and containing portraits of the Emperor and a great number of those about him.

Augustus Schæffer—Director of the Imperial Picture Gallery, Vienna, who, in his own department—landscape paintiug—enjoys a reputation not inferior to that of the others.

Fritz Luckardt—Professor, to whom was given the task of selecting the members of the jury, and whose efforts have succeeded in iuducing the celebrated artists here named to agree to serve. He has declared his readiness to take part in the labours of the jury as a photographic expert, and to draw up its report.

Literary Notices.

Sun Artists. No. V. (*London: Kegan Paul, Trench, Trubner and Co., October.* 1890.)

This is, perhaps, the most interesting number of the excellent periodical, *Sun Artists*, yet issued, for it contains photogravure reproductions of four of the best pictures produced by Mrs. Cameron, the founder of what is now unfortunately called the "Naturalistic" school of photography. In gazing at these beautiful photographs, it seems strange that critics should have existed who showered public abuse upon her head for their production. Mrs. Cameron, however, took no notice of the vulgar outcry, and reviled not in her turn. She was too cultured and refined to indulge in more than silence or gentle speech about her worst adversaries, a moral characteristic which stamps a great mind.

Sun Artists also contains an essay, relating to Mrs. Cameron and her work, written by Dr. P. H. Emerson, from which we learn that Julia Margaret Pattle, daughter of an Indian civil servant, was born in Calcutta on June 11th, 1815. Her father was a Scotchman, and her mother French. In 1837 she married Mr. Charles Hay Cameron, successor to Lord Macaulay as fourth Member of Council of Calcutta. In 1860, some years after their return to England, Mr. and Mrs. Cameron settled at Freshwater Bay, and here Mrs. Cameron found in photography an all-absorbing pursuit. One of the portraits she took here was that of her neighbour, Mr. Alfred Tennyson, a photogravure reproduction of which forms one of the four illustrations which are accompanied by the essay. Another is a splendid portrait, artistically excellent and technically faulty, of Sir John Herschel, which will be valued not alone for its high order of merit, but in remembrance of the work of Herschel as one of the greatest pioneers of photography in its early days. The other two illustrations are "The Kiss of Peace" and "The Day Dream."

Mrs. Cameron's first out-of-focus portrait was a "fluke," as she called it, but, with deep original insight unfettered by man-made conventionality, she saw a beauty therein invisible to the many, so thereafter pursued intentionally a course which had been initiated by accident.

Mrs. Cameron died in Ceylon in 1878. Her photographic period of production extended over ten years, 1865 to 1875.

This patent cannot be adequately described without the aid of diagrams. It contains twenty-six claims.

Correspondence.

THE UNNATURALNESS OF NATURALISTIC FOCUSSING AND LONG FOCUS LENSES FOR PORTRAITURE.

SIR,—Mr. W. H. Wheeler points out what was an accidental omission in my paper on "The Unnaturalness of Naturalistic Focussiug." The sentence should read, "If I take a full-length figure on a quarter-plate with, say, a 7-inch focus lens, I can get the accessories and background defined to an extent that is sufficient. Why, then, if I use a lens of double the length of focus *for an image of double the size on a whole-plate*, and a stop of the same proportiou or rapidity, cau I not get the same amount of general focus as in the former case?" The words in italics, which—or the equivalent of which—I intended to include in the sentence as representing the question actually put, were inadvertently omitted, and I am thankful to have the omission pointed out so that I can take the earliest opportunity for correcting it.

I certainly did not iutend to imply an objection to the use of long focus lenses for portraiture. I have, indeed, both practised aud advocated for this purpose and for copying, the use of as long focus a lens for a given size of plate or scale of picture as the circumstances will permit, aud this not only for the reasons mentioned by Mr. Wheeler, but on account of the curvature of field acting so much more injuriously as the focus is short in proportion to the size of the plate.

The choice of focal leugth for a given size of image which we have in copying and portraiture—limited, however, by the length of the studio, aud sometimes by atmospheric conditions—does not generally exist with regard to other subjects, whether landscape, architectural, or interior.

When we have once decided on the amount of subject to be included, and the best available standpoint—and generally speakiug, a change of standpoint involves a change in the scene itself—we have no longer any choice, but must use a lens of some particular focus for any given size of image.

I aun glad to have Mr. Wheeler with me in advocating the necessity for usiug very small stops to obtain really good definition all over a large plate, and am not surprised to find that he would go farther iu this directiou thau I have iudicated in my paper. The curvature of field that has been referred to, and the desirability of recognising the capacity of the eye for adjustment to various focal planes, would indicate a still greater limitation of the size of the diaphragm, but I did not wish to introduce matters upon which a reasonable argument could be produced on the other side, and the main issue thereby obscured; and, therefore, as waiviug the adjustment argument still left aunple basis for the refutation of the "uaturalistic" conteutiou, I was content in the paper to go no farther than I did.

Mr. Wheeler's views ou the relation of the physiological and psychical processes of uatural visiou to the impressiouist theory would, I am sure, be of great interest and commaud considerable attcution at the preseut time, and I trust that he may be prevailed upon to lay theun before your readers whilst the subject is so much to the front. W. E. DEBENHAM.

London, November 17th.

THE CLUB OF AMATEUR PHOTOGRAPHERS AT VIENNA.

SIR,—Appended I have the pleasure of giving you a list of the gentlemeu who will form the jury at the International Photographic Exhibitiou to be held here next spriug.

H. von Angeli, Professor at the Imperial and Royal Academy of Fine Arts, Vienna, Painter.

J. Benk, Sculptor.

J. Berger, Professor at the Imperial and Royal Academy of Fine Arts, Vienna, Painter.

K. Karger, Professor at the Art Industrial School at the Austrian Museum, Painter.

F. Luckardt, Professor, Imperial Couucillor, Photographer to His Imperial aud Royal Majesty, the Emperor.

A. Schaeffer, Director of the Imperial Picture Gallery at Vienna, Painter. CHARLES SRNA, *President.*

November 16th, 1890.

DIAZOTYPE PRINTING PROCESSES.

SIR,—In your article headed "Primuline Printing Processes," in the issue of this journal of November 14th, you have fallen into an error which we take the liberty of pointing out. Feer's process is not a primuline process, although it is a diazotype process. The author of the article, Dr. Witt, connects them iu the latter aspect only, as may be seen by refereuce to the origiual article.

Feer's method depends upon the sensitiveness of a class of compounds known as the diazosulphonates, which result from the interaction of diazo compounds with the alkaline bisulphites. By the action of the light there uudergoes a decomposition, by which the diazo group is set free, and in the presence of an amine or phenol (the developer), re-acts with these to form colouring matters. In this case the light is the colour-producing agent. In the primuline process the diazo derivative is destroyed by the light—which, therefore, becomes a colour destroying agent.

The one is therefore a "negative"; the other—*i.e.*, the primuline process is a "positive" method.

GREEN, CROSS, and BEVAN.

4, *New Court, Lincoln's Inn, W.C., November 24th.*

DR. KASSLER, of Breslau, has discovered a new method of obtainiug oxygeu. Water is poured upon a mixture of peroxide of bariuu and ferricyanide of potash, and oxygen is giveu off. The oxygen thus obtained is said to be of great purity.

EIKONOGEN.—Au article by M. Georges Robert, in *Le Progrès Photographique* just received, says that M. Pétry, of Bar-sur-Seine, has made known that powdered eikonogen can be preserved by mixing with it a small proportion of powdered bisulphite of potash. M. Robert raises the question whether the latter salt is present in recent samples of eikonogen sent from Germany.

Proceedings of Societies.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AT the technical meeting of this Society held on the 25th inst., the chair was taken by Mr. W. BEDFORD.

Mr. CHAPMAN JONES noted an assertion that had been made to the effect that strong hydrochloric acid reduced the strength of platinum prints. In one quarter it was stated that the sepia prints were particularly affected in this way; whilst the Platinotype Company made that statement with respect to the black prints. He (Mr. Chapman Jones) did not think that any solution of platinum took place, but that if there was a change of colour, it was analogous to what occurred in a negative when treated with acid, and no one inferred a solvent action in that case.

The CHAIRMAN enquired whether it could be stated with certainty what was the difference between the deposit on a sepia and on a black toned platinum print.

Mr. CHAPMAN JONES said that Mr. Willis considered that the sepia deposit was due to an oxide of platinum, but he (Mr. Chapman Jones) did not think that possible. As to the method of securing a sepia-toned image, that was supposed to be a secret, but if cupric chloride or mercuric chloride were added to the platinum solution before coating the paper with it, the sepia effect was produced. As little as one part of mercuric chloride to 500 of the solution was sufficient to produce a very marked effect. The change of colour produced by hydrochloric acid upon a negative was so great that two photographers unacquainted with each other had informed him that that was their regular way of reducing intensity, and that they were obliged to be careful not to carry the action too far, or the negative would be made too thin.

The CHAIRMAN said that the reduciug effect of acid upon a negative only showed itself where there was colour in the deposit. With a grey deposit, such as was obtained with sulphite in the developer, no reduction resulted from the use of acid.

Mr. MACKIE said that he could uot find any effect of changing the colour of deposit to result from the additiou of sulphite to the developer for collodio-bromide plates. If slides of the characteristic red colour were treated with acid, would the colour be thereby altered?

Mr. A. COWAN said that in some cases the colour would not be at all altered. Even treatment with perchloride of iron did not effect much change of colour.

Negatives and prints sent by Col. Waterhouse to illustrate the process for producing reversed images, of which a description had been sent to the Society for the last ordinary meeting, were then laid on the table. The plate treated with bichromate in addition to thiosinamine added to the eikonogen developer, was much more complete in reversal than that in which the bichromate had not been used. The plate developed with phenyl thiocarbamide was also complete in reversal.

The CHAIRMAN said that some time ago he had tried the process introduced by Mr. T. Bolas for obtaining a reversed image, in which the plate was treated with bichromate, and then, after a suitable exposure, developed with iron. He had never succeeded quite to his mind, and had not obtained clearer images than in the examples now shown.

Mr. W. H. HARRISON observed that Captain Abney had stated that the presence of an oxidising agent in the film made it easy to obtain a reversed image. He had some years since endeavoured to obtain thiosinamine, thinking that it should be useful in development, but could not get it. The nearest he could get would be to order sinamine from Germany, and complete the manufacture of the thiosinamine himself. He therefore had abandoned the idea. With regard to coal-tar dyes, a paper had been read not long since by Professor Hummel, of Leeds, in order to do away with the prevailing impression of their very fugitive character. He had, indeed, found many of them fade, but not in greater proportion than those of other origin. Eosine colours were particularly evanescent, as proved by results exhibited by Professor Hummel.

THE CAMERA CLUB.

ON Thursday, November 20th, Mr. ANDREW PRINGLE gave an address on "Some Old Processes of Making Lantern Slides." Mr. H. M. ELDER, M.A., occupied the chair.

Before the lecture, Count PRIMOLI, of Rome, handed round a large and excellent series of instantaneous photographs and larger work of his own production. An exceptionally interesting one represented an indoor function with the Pope seated in full ceremony. This had been given ten seconds' exposure; the figures during the time had not moved. Count Primoli has made over 30,000 exposures in the last two years or so, and sets his photographic account for that period at £2,000.

Mr. PRINGLE commenced by gainsaying assertions to the effect that lantern slide pictures did not come within the domain of art. He insisted on a high scale of lighting, clear shadows, and warmth of colour. He sportively suggested that the screen pictures could easily be made as naturalistic or as definite as the spectator liked by varying his distance from the sheet, and if rough surface was the aim, then all that had to be done was to use a good fuzzy travelling rug as a screen. He then proceeded to give the formula, working details, and distinctive characteristics of several old processes, dry collodion, wet collodion, and collodio-albumen, and he illustrated his remarks by exhibitiug on the screen comparative slides by the several processes. Most of his remarks related to the production of washed collodio-bromide emulsion plates without a preservative, and to the old collodio-bromide process with a preservative.

Mr. HUSSEY said that the collodio-bromide plates gave better results than gelatine plates, for the latter tended to yield hard shadows, due, he thought, to the appreciable thickness of the gelatine film. He thought the best varnish for slides to be shellac dissolved in alcohol.

Mr. W. ENGLAND stated that in the rapid gelatino-chloride plates the gelatine is so thin that the results are as good as with collodion plates, and that the images are quite clear in the shadows. A solution of seed-lac is better than a solutiou of shellac.

Mr. J. B. B. WELLINGTON remarked that if the glass plates be cleaned with a weak solution of gelatine and hydrochloric acid the films will not slip off in the developing or other operations.

Mr. HUMPHERY said that the collodio-bromide process is easy when a large number of plates is prepared at one time.

Mr. F. de P. CEMBRANO had found the chief difficulty in the collodio-bromide process to be the obtaining of a suitable cotton. Mr. Wellington's plan of cleaning plates sometimes resulted in spots. Mr. Brooks did not like hypo for fixing collodio-bromide slides, and preferred weak cyanide of potassium; the plates required less washing afterwards.

Mr. PRINGLE thought that there was no necessity for obtaining "bunged-up" shadows with gelatine, but the tendency was that way; with under-exposure and over-development the shadows were sure to be blocked. The use of mineral acids for cleaning plates was dangerous; a trace of chrome alum in the gelatine might answer as well as hydrochloric acid. Failures were often caused by impurities in the bromides used in making emulsions; when bromide of zinc is used it must be dry. His experience was that the stronger the developer, the less easy it is to get warm tones.

On Thursday, December 4th, Mr. Henry Sturmey will read a paper on "Rollable Transparent Films."

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

ON Tuesday, the 18th inst., the monthly meeting was held in the Mosley Street Café, Newcastle, Mr. J. P. GIBSON in the chair. The subject for the evening was a demonstration of the platinotype process by Messrs. M. Auty and J. Pike.

Mr. PIKE then read a paper on "The Platinotype Process" (see page 932).

Mr. AUTY demonstrated the hot-bath process, developing a large number of prints in view of the members.

Mr. PIKE afterwards showed the working of the cold-bath

process, and referred especially to its greater range of tones as compared with the older method.

The HON. SECRETARY announced that over £15 had been subscribed by the members towards the purchase of a new optical lantern for the Association.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 20th.—Mr. F. A. BRIDGE in the chair. Mr. George was elected a member of the Association. On the subject of collodio-bromide, Mr. J. NESBIT said that he had had considerable experience with this emulsion, and in his opinion it was the easiest and best of all the processes for making lantern slides.

Mr. TEAPE had been using an intensifier from a formula published by Mr. H. Farmer:—

Ferricyanide	¼ ounce
Uranium	¼ ,,
Water	1 pint

using one dram of this solution to 10 ounces of water. He found that if the plate after intensification was washed for four or five hours, the density would be considerably reduced. This raised a question in his mind as to the action of the ferricyanide and uranium on the silver image. He read an extract from Mr. H. Farmer's "Notes" on this subject as follows—"The metallic silver reduces the potassium ferricyanide to ferrocyanide, and with the potassium ferrocyanide uranium forms an insoluble double cyanide which becomes precipitated on the image." This, Mr. Teape said, did not agree with his experience.

Mr. W. E. DEBENHAM, for reducing purposes, originally used ozone bleach and chrome alum: he now gave preference to the following formula:—

Sat. sol. chloride lime	3 parts
Sat. sol. common alum	1 part

Mr. TEAPE said he had been successful with the following:-

Bichromate of potash	1 dram
Sulphuric acid	1 ,,
Water	4 ounces

using 2 drams to 1 ounce of water.

THE BRIXTON AND CLAPHAM CAMERA CLUB.

ON November 20th, Mr. A. R. DRESSER demonstrated the process of "Slide Making," exposing and developing a number of plates from various members' negatives. The printing-in of clouds by vignetting was fully explained and shown, also methods of local development and reduction. This being a popular subject, an interesting discussion followed. A copy of Mr. Dresser's pamphlet on the subject was laid upon the table, together with samples of Wormald's slide masks and binding strips.

At the next meeting, on Dec. 4th, a paper will be read by Mr. E. J. Wall.

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting was held in the Rooms, 180, West Regent Street, on November 17th, the president, Mr. ARCHD. WATSON, in the chair. After the election of twelve new members, a paper on "The Development of Negatives" was read by Mr. W. GOODWIN, followed by a discussion.

A number of transparencies by Mr. Miller, illustrating a tour in Holland with the hand-camera, was shown on the screen by means of the limelight lantern. These were followed by a number of other transparencies by various members.

J. F. SASCHE.—A letter to you, somewhat fully addressed, has been returned by the American postal authorities, with the remark that the name of the "Post Office" was not stated. The papers were posted to you.

A LARGE envelope with an American postage stamp on it has been received by us, with the remark by the London postal authorities that it had been found without contents in a London pillar box.

Answers to Correspondents.

All Communications, except advertisements, intended for publication should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

ANXIOUS ONE (Kendal).—Observing our answer to you last week, the Fry Manufacturing Company have written to say that the article you are in search of is described at page 12 of their trade catalogue; and Messrs. Appleton and Co., of Manningham Lane, Bradford, are prepared to supply Eastman's transferrotype paper.

C. J. K.—*Spots on Unmounted Prints.* The cause of these white spots is often very perplexing. There is no dark nucleus, such as would indicate metallic particles in the paper reducing the silver nitrate, neither are they due to hypo splashes on the finished print, as was at first supposed. Are they caused by some impurity taken up from a blotting pad, or do you use chloride of lime for washing the hands, in which case a touch might injure the prints? Our material is exhausted, so we cannot make any more experiments. We found the prints had been thoroughly well washed.

J. E. D.—*Royal Academy Pictures*, 1890. Under this title a series of reproductions was published by Messrs. Cassell and Co. in three monthly parts, forming a kind of supplement to the *Magazine of Art*. The original price was one shilling each, but owing to the great demand they were soon out of print, and are now only procurable, if at all, at an advanced price. Thanks for your second letter duly received.

F. B.—*Borax in Fixing and Toning Baths.* 1. We can see no objection to the use of borax in the fixing bath to maintain alkaline conditions, and it may even prove superior to ammonia as a remedy against blisters. 2. As regards the use of this salt in the toning bath, and its need for renewal, you must remember that each successive addition of gold chloride destroys a certain amount of borax, so that the same solution cannot be used indefinitely; it must be changed occasionally, or fortified by the addition of a freshly made borax-gold bath.

H. H. (Richmond).—*Athletic Studies.* Enquire of Mr. Auty, of Newcastle, Messrs. Marsh Brothers, of Henley, and Mr. A. R. Dresser, of Bexley Heath. M. Lugardon, and Messrs. Hill and Saunders exhibited a fine series of vaulting figures some years ago; Mr. Muybridge also. Mr. F. M. Sutcliffe's "Water Rats" may show action enough for your purpose, likewise Mr. W. M. Malby's "Tug of War."

T. E. (Dover).—*Munktell's Paper.* We have often used the close-textured Swedish filtering paper bearing the name of Munktell, but never yet heard of a quality of paper suitable for photographic purposes being turned out by this firm. B. K. Rives is a well-known brand of starch glazed paper very suitable for albumenizing.

R. (Witham).—*Mercury Intensifier.* Use half a dram of hydrochloric acid per pint of saturated solution of mercury chloride. This prevents the formation of the chondrin compound, which by subsequent action of ammonia necessarily clouds the clearer portions of the picture. Like albumen locks up silver, so does gelatine the mercury, unless acid be added.

M. B.—*Meteorological Photographs.* Although not coming under the definition of "whirlwinds, tornadoes, or storms," your records of earthquake damage may be acceptable to the British Association Committee. At any rate, you might offer your photographs to Mr. Clayden, whose letter (with address) appeared last week.

HYDROGEN is greatly superior to coal-gas for lime light work, but there are conveniences in using the latter whenever the distance to be traversed happens to be great, and a sufficient supply of coal-gas can be had on the spot

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1683.—*December 5*, 1890.

CONTENTS.

THE DIAZOTYPE PROCESSES.

PERHAPS it is hardly recognised as yet what a considerable influence the diazotype processes may have upon photography with the lapse of time. They give a power of obtaining colour in direct photographic prints never before seen, and, in cases in which the particular developer chances not to be costly, they are usually rather inexpensive to work.

They naturally divide themselves into two great classes: in the one class positive prints are produced from negatives; in the other, positive prints are produced from positives.

The first of these classes—in which positive prints of colours varying according to the mode of preparation of the sensitive surface—is a printing-out system which was discovered by Dr. Adolf Feer, of Lorrach, and its principle, according to Dr. Vogel, is that "a positive paper picture can be obtained from a photographic negative with every diazo compound capable of forming a sulpho-acid, if brought together with sulphite of soda into aqueous solution. If paper be impregnated with this, adding at the same time an amine or phenol, and the dried papers be exposed to light, the sulpho-acids will return to their original compounds—free, simple, diazo compounds and sulphite of soda. The free diazo compounds form now with the amine or phenol present the desired azo colour. These pictures possess one defect; they are more on the inside of the paper than upon the surface, the solution applied having to be alkaline, and alkali attacks the size of the paper, thus allowing the penetrating of the liquid." Dr. Witt states that the azo bodies are capable of producing about two thousand colouring agents, from which we deduce that the proportion thereof likely to be utilisable in photographic work will probably form a wide field for photographic research.

As regards the second of the classes, that discovered by Messrs. Green, Cross, and Bevan, about which much has been published in these pages, the colour obtained is likely to vary with every new developer as it is discovered; moreover, the operator is not limited to primuline as a starting point. Then, again, what are called "developers" in this process are not developers in the full sense of the term, for the images are previously visible, and what are now called "developers" produce the colours by chemical reactions. Should substances be found which will develop upon diazotised bodies photographic images previously invisible, another large field for photographic research will be opened.

According to Dr. Witt, the colours produced by these processes can be generally designated as "fast." We suppose dyers call certain colours fast because they will not move. Messrs. Green, Cross, and Bevan have found that some of the colours produced are so stable that the fabrics dyed by them will bear boiling in soap and water without fading. The influence of light upon them may be different, but such a great number of colouring compounds is obtainable by the process that, with time and experience, it will be possible to separate the stable from the unstable.

Just at the time when these remarkable methods of producing positives from positives have been born into the world, comes the discovery of Colonel Waterhouse, of a method of rapidly producing direct positives in the camera, and with short exposures. Some of his results were exhibited at the last meeting of the Photographic Society, and from among them a selection might have been made which would have answered well if employed to give diazotype pictures by direct printing.

The uses of azo compounds in orthochromatic photography have yet to be unveiled, but several good experimenters, who are also investigators, are engaged in the research.

These facts tend to show that fields of photographic research which it will take years to explore have just been opened.

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section).—The next meeting will be held in the theatre of the Chemical Laboratories, on Wednesday, Dec. 10, when the following papers will be read by Ferd. Hurter, Ph.D., and V. C. Driffield:—(1) "The Sector and Grease-spot Photometers and their Results"; (2) "The Relation between Photographic Negatives and Positives." Both papers will be illustrated by diagrams and experiments.

PHOTO-MICROGRAPHS.

The art of taking photographs of microscopic objects has of late years progressed with leaps and bounds, the advance being due to the large number of amateurs who have taken up this branch of work, to the introduction of improved apparatus to meet their wants, and more than all, perhaps, to the conveniences afforded by the gelatine dry plate. The application of photography to microscopic work is by no means new, although the term photo-micrography being freshly coined might lead some to suppose that it represents a new art. The new word became necessary because of the existence of those miniature photographs—now generally associated with ivory charms and toys—which had taken possession of the title "micro-photograph." To avoid ambiguity, the term *photo-micrograph* was invented to distinguish the enlarged photograph of a microscopic object from the photograph which had been taken from a large object by means of the instrument itself.

The opinions concerning the value of photo-micrographs for purposes of study have not always agreed, some observers advocating them, and others denouncing them as not being so serviceable as drawings. So recently as the beginning of the present year, in a paper read before the Natural History and Microscopical Society of Birmingham, the author went so far as to say that, "although photo-micrography is very popular as a means of transferring pictures of microscopic objects to lantern slides, painting is, in many respects, superior to it." In this case, the word "painting" was understood to mean the method of drawing with pencil and brush on ground glass which was introduced some years back by Dr. Dallinger. But the reasons given why a painted slide should be better than a photograph do not seem to us to be very convincing, for at their head this author states that a well-painted slide *looks* better than a photograph. This, surely, is a very poor reason to advance when the best means of studying an object is in question. Another reason given is that you cannot, in photographing an object, get every part of it in satisfactory focus at the same time. This is, of course, true of some objects, but that it is untrue of others is evidenced by the beautiful examples of photo-micrography which have been exhibited year after year at Pall Mall and elsewhere, and which have more than once met with acknowledgment at the hands of the judges.

Of course, photo-micrography, like everything else, has its disadvantages and imperfections, but we venture to say that drawings of microscopic objects have far more. To begin with, an artist, however skilful, cannot avoid impressing upon his work a certain amount of individuality. It is quite inseparable from his handywork, and he cannot help it, and is as necessary a part of it as the unconscious *character* which every man gives to his handwriting. Picture-dealing would be a lost art were it not for this unconscious mannerism on the part of an artist, which at once stamps his work with being his, and his only. But when this individuality is introduced into a picture of a microscopic object, where correct detail is the chief consideration, it becomes no longer an advantage, but a flaw. Another reason why drawings are untrustworthy is found in the fact that a skilled artist—*i.e.*, one who is used to drawing microscopic objects—will know what peculiarities a certain preparation should exhibit, and will be apt to draw according to preconceived notions rather than from what is actually before him. We need say little concerning the tiring of the eye by long examination during the making of such drawings, for it is obvious that this too is apt to lead to faulty results. We feel quite sure that if two or three skilled draughtsmen were instructed to draw a copy of any particular microscopic object, the resulting pictures would differ from one another to a great degree.

A photo-micrograph, as we know, is subject to none of these failings, but yet it has disadvantages which have given its opponents opportunities for speaking unkindly of it. Many of these having attempted to obtain photographs of stained specimens, and having failed to get good results, have at once placed on record the impotence of photography, without waiting for the antidote for this defect, which afterwards appeared in the form of colour-sensitive plates. Dr. Koch, whose name has lately been on everyone's lips in connection with his alleged cure for consumption, was the first to apply the photographic method to the delineation of Bacteria; and he employs, we understand, isochromatic plates, in conjunction with coloured screens for filtering the light. So high is his opinion of the value of photography for this work, that he considers that, under certain circumstances, a photograph is more valuable than the original object from which it was taken. For the truth is that no two observers see an object in the microscope in the same way, and consequently they draw different conclusions from it. A slight alteration in the focussing arrangements or in the lighting will make an object take to itself quite a different appearance, and thus faulty manipulation may easily lead to false records. A good negative of an object will, on the other hand, yield impressions which are all exactly alike, and details which it is difficult for different eyes to quarrel about.

Devon and Cornwall Camera Club.—The following particulars are forwarded respecting this Club, which possesses the facilities of a lecture hall, library, dark room, and studio in the Athenæum, Plymouth. The president is Mr. J. D. Pode, J.P.; the vice-presidents are Messrs. Robert Murray, C.E., and W. Gage Tweedy, B.A.; council—Major Robert Barrington-Baker, Messrs. David Roy, E. H. Micklewood, Chas. Aldridge, M.D., J. S. Hawker, J.P., S. Weekes, Mus.B., R. Hansford Worth, C.E., A. Reginald Norrington; the hon. secretary is Mr. Robert Burnard, 3, Hillsborough, Mannmead, Plymouth; hon. treasurer—Mr. Arthur A. Carnell, Bedford Villa, Plymouth. Frequent excursions are held during the summer, and in winter, meetings are held every alternate Monday for lantern displays, demonstrations, reading of papers, and discussions. There is a postal branch in connection with the Club. Two photographs are contributed four times a year. Medals and the album itself are offered as prizes on each occasion. The hon. secretary of this department is Mr. J. D. Pode, J.P., Slade, Ivy Bridge, S. Devon; the hon. critic and judge is Mr. Audrew Pringle, F.R.M.S.

THE INTERNATIONAL PHOTOGRAPHIC EXHIBITION AT EDINBURGH.*

Among the various pieces of apparatus on view at the Exhibition, is a large camera made on American lines by Mr. McGhie, and Balwin's baby-holder. Mr. A. H. Band exhibits a detective camera of his own design, and a balance for weighing small quantities of chemicals rapidly. It is made on a steel-yard system, and has a sliding weight; it is mounted on a brass rod stand, and is a neat little instrument. Messrs. Duncan and Sons exhibit prints mounted on smooth paper. Messrs. Arundel and Marshall place on view parcel post tubes and boxes, for the enclosure and protection of goods, also light-tight metallic grooved boxes for plates.

Mr. J. T. Leighton's patent prize medal photographoscope, manufactured by Messrs. Perken, Son, and Rayment, is also on view, and is represented in the accompanying cut. The object of this invention is to provide a means of displaying photographs or other pictures, whereby the necessity for handling is avoided, and the deleterious effects of dust and exposure to the

atmosphere prevented. The pictures are entirely protected from damage by rubbing together, so destructive to valuable prints. The apparatus is neat in appearance, and the designs are suited for the drawing room or library, or for the studio or saloon of the photographer. While the old-fashioned album may be allowed to be on the table unopened and uncared for, this prominent apparatus at once attracts attention. By turning a small side knob or handle, the pictures appear one after the other in endless succession. The number of prints is limited only by the size of the apparatus.

One of the exhibits on view attracts much attention. It consists of the *Daily Graphic* original sketches of the railway accident near Taunton, the zinc block produced therefrom, the flexible stereotype mask taken from the block, and one of the curved stereotype castings as prepared to go upon the cylinder of the machine. All these were in Edinburgh within a day or two after the accident occurred, showing the rapidity with which newspaper work is carried on in these days.

* Continued from p. 902.

Some carbon transparencies of a greenish colour, half-plate size, by Mr. Andrew Swan Watson, form an attractive feature of the exhibition, and they are well mounted and illuminated for public inspection. They chiefly represent sky effects at Tyree, and include beautiful cloud and water effects.

Messrs. George Mason and Co. exhibit a new burnisher of French origin, fitted with apparatus to gauge the various thicknesses of mounts, and that, too, without loss of time. By means of a lever motion, each card is pinched, and its thickness at once indicated. Supposing the gauge to give the number seven, regulators at each end of the roller have to be set at number seven; the burnisher is then ready for use. It is heated by gas, and has a thermometer to show the temperature of the bar.

The same firm also exhibits an enlarging lantern with back as well as front bellows, to permit the light to be withdrawn to any given point. The half-plate lantern has an eight-inch condenser and an achromatic objective. The same firm also exhibits a camera screw with plumb attachment, to give all levels, and the photographer using it can see at once when his camera is level, or how much, and in what direction, it is inclined to the plane of the horizon.

Some good photographs upon wood-blocks, ready for use by the engraver, are placed on view by Mr. A. Nichol, who, however, does not state the method of their production.

In relation to the Kinnear cameras in the Exhibition, and all the world over, it may be of interest to our readers to know that Colonel Kinnear is a native of Edinburgh, and resides there still. He is an active amateur worker in photography still; he looks after all modern improvements, and works with films of the latest make.

Messrs. Wray and Sons exhibit, in a glass case, some of their well-known photographic lenses.

The absence of attendance at some of the stalls is a bar to obtaining information about some of the photographic apparatus on view in the Exhibition.

The photographs in the Exhibition will form the subject of later notices in these pages; meanwhile it may be stated that the display in Edinburgh equals any which has been seen in this country for many years, and is worth a journey of some little distance to inspect. From London and the midland districts the comparatively new route to Edinburgh by the Midland Railway passes through some picturesque districts of interest to photographers, although the beauty of the section between Carlisle and Settle has been grossly exaggerated in print. In Melrose and the surrounding district there is plenty of photographic work to be done. In the burying-ground adjoining Melrose Abbey is the tomb of Sir David Brewster, who gave much attention to photography and photographic optics in his day, and it bears the following inscription:—

"Sacred to the memory of Sir David Brewster, K. H., born 11th of December, 1781, died at Allerby 10th of February, 1868. Also of Dame Juliet Macpherson,

his beloved wife, who died at St. Andrews 27th of January, 1850, aged 63. Also of James Brewster, B.C.S., their eldest son, who died at Dheyrah Door, Bengal Presidency, 19th of November, 1851, aged 39. Also of Charles Macpherson Brewster, their second son, who was drowned in the Tweed 28th of June, 1828, aged 13. 'The Lord is my Light.'"

Literary Notices.

WILD LIFE ON A TIDAL WATER. By P. H. Emerson. Illustrated by P. H. Emerson and T. F. Goodall. (*London*, 1890: *Sampson Low, Marston, Searle, and Rivington.*)

THIS richly illustrated book contains many photo-etchings by Dr. Emerson, and one photo-etching from Mr. Goodall's large painting of Great Yarmouth, "The Last of the Ebb," exhibited at the Royal Academy of 1888. As regards Dr. Emerson's pictorial work therein, it is calculated to give pleasure to all observers, especially to those of an imaginative disposition, who can read sermons in stones, trace castles in the clouds, and see faces in the glowing coals. The photographs have a beauty of their own which all are likely to recognise, whether they approve or otherwise the tenets of the "school" in which Dr. Emerson holds so prominent a place. Recognition of one class of beauty by the observer does not necessarily imply incapacity to appreciate beauty of another class; there is one glory of the sun, and another of the moon, and occasionally abundance to admire in photographs sharp all over. There is also great force in the argument that photography should not always quit its own field of art, to imitate the methods of sculptors or painters.

Dr. Emerson has learnt photo-etching, and in future intends to etch his own plates; he has been experimenting with printing papers to see from which he can obtain the best results, and he has set up a press of his own. Printing from photo-etched plates is about the dirtiest and most troublesome work in which any man can engage, and if Dr. Emerson has enthusiasm enough to go on with this unpleasant part of the work, he should issue a photograph representing himself engaged in the act, with a full view of the palms of the hands and the apron.

Unfortunately, we cannot reproduce one of his etchings as an illustration of the high character of the work now under notice, but we quote the following piece of descriptive writing from the book, to show the literary genius and power of the author:—

DR. EMERSON AND THE CRABS.

'Twas a beautiful evening; the tide was ebbing, yet the water in our drain appeared quite smooth, although a warm, light, southerly breeze was blowing. The course of the drain was clearly defined by this smooth water-way. Indeed, this highway wandering past our door was marked out by lines of foam, outside of which the shallow water on the flats dauced in an endless turmoil of wavelets, shifting, glistening, shimmering, and moving restlessly in the soft sunshine. As the water cleared off the flats I hid myself behind a box on the stern of the house-boat to watch the green crabs, for they are very sharp-eyed. Already the weed had grown round our sides, and hung at low water in festoons from the slimy timbers. I had baited the mud at the water's edge with shrimps, and now awaited anxiously my guests. I had not long to wait; they soon came scrambling up the mud, and running in and out of the sea-weed hanging to the boat. I could hear their hard claws and bodies clattering on the planks. A few had gathered round the shrimps, but I picked out conspicuous groups for study. A duel on a lump of mud first attracted my attention. Two lusty crabs were fighting for a shrimp's tail. They placed four inches of mud between themselves, the happy possessor of the cause of war fighting on the defensive. He opened his claws wide apart, and brandished them in challenge. His opponent raised his right claw high in the air, rushing at his enemy with fiery onslaught. But the knight in possession stood firmly, crouching down on his hairy legs to receive the attack. They closed, and the clash of armour as their carapaces struck together was quite audible from my coign of vantage. Directly they closed the right-armed champion made a dive with his right claw and seized the piece of shrimp from beneath the maw of the crab in possession; but, after a little sparring, he dropped it and retired to the back of the ring preparatory for a second round. Again the right-handed knight made a valiant rush, but he was met by a fence which nearly toppled him into the mud. Then they closed and grappled with each other, but without apparent satisfaction to either warrier. This manœuvre was repeated several times, so the God above, who was getting bored, interfered, and touched each one with a long stick lightly on the back; quick as lightning they crouched their dwarfish bodies in the soft mud, and began to work themselves silently out of sight. In a very short time they were invisible.

I saw at a distance a little crab eating a piece of shrimp with his left arm whilst keeping off an importunate enemy with his right claw. Some of these greedy adventurers would crawl straight up from the water to the bait, seize a piece, scurry off, and hide behind a lump of mud, where, feeling secure, they would crouch in their hateful way and devour their prey. I once saw an octopus at Naples hug a crab under one arm whilst he ate his brother with another. They are fit company, these terrible monsters, and it is their human-like actions that make them so loathsome.

Joey had cast a few bloater-heads on to the mud, and two or three large crabs—the largest I saw were four inches across the greatest diameter of the body—were actually stalking these heads. They advanced in a body, marching in open order, seeking cover, like riflemen as they skirmish, in the depression of gunners' footsteps left in the mud. They evidently did not know what those herring-heads were, and they approached them cautiously, fearing an ambush. It was very funny to watch these pigmies dodging swiftly over hummocks and creeping through hollows, until the leading crab—all these adventurers were old and scarred—drew near to the advance guard of herring-heads, when he stood twitching his claws nervously for a moment, then making a dash he came off triumphantly with a bloater's head. Beating a hasty retreat to the water's edge, he crouched down and began to tear and eat it in his repulsive and even human manner. I have caught some of these loathsome creatures, and taken them on to the dry, hard flat. Placing one on the slub, he would run for a little way, and, seeing that all paths of escape were shut off, he would suddenly turn on to his back, spread his feet and claws out loosely, and feign death. They will keep up this ruse for hours, if necessary, until the flood comes to their rescue. At times I have seen them eat pieces of bad fruit, and it seemed to me that afterwards I saw them sitting in melancholy attitudes along the water-side with their claws on their stomachs, but I will not vouch that they suffered much, and that this was not a flight of the imagination. I have seen a crab hugging a half-shrimp under its arm, the shrimp's feelers sticking up in the air and looking for all the world as though the shrimp were the crab's baby, and the crab the shrimp's nurse. The young crabs seem to go sideways as a means of progression far oftener than the older crabs, who rarely go aslant, unless to dodge an enemy. They look loathsome as they half swim, half crawl through the shallow water; it adds a new terror to their appearance. Altogether they are a green-brown, filthy family, hateful to behold.

More of them have gathered round the shrimps now, and they drag themselves through the noisome mud, carrying titbits to their horrid maws with their claws. One old brown crab, fearful in aspect as he waded through the shallow water on the flat waving his arms, which looked like human stumps,

so graceless and clumsy were his movements. As he neared the morsel of shrimp lying on the mud, he arose in his footsteps and darted out one of his stumps upon the shrimp, clutching it with greed, the greed of the miser. 'Twas a terrible picture! Another ghoul of full growth came and rested on the ooze quite close to me. I was fascinated by his bestial actions, so human were they in movement and sentiment. He fixed his claws into a sole's eye and tried to tear it from the socket; when that attempt failed, he neatly *dissected* and removed the sclerotic with his sharp, razor-like claw; then, holding the sole's head with one claw, he attempted to tear out the eye with the other. It was a ghastly sight! Being a superficial anatomist, he had not thought of the remaining attachments. Still nothing daunted, like an ogre, he grasped the eye tenderly in both claws, and, crouching, fixed his fearful maw into the luscious morsel, sucking its juices like a guilty thing. When he was satisfied he drew himself up to his full height, and stood contemplating the rest of the head. Then I could plainly see the cold, cruel, triangular, inhuman face, with eyes set wide apart, with cruel hairy mandibles and chinless face, the whole expression being one of brutal lust, without one ray of light to illumine the dreadful countenance. Methinks had old Æschylus drawn a giant-crab plucking at the vitals of Prometheus, everyone would have trembled as they read. No hideous monsters of man's imagination will ever be so hateful as the crab and octopus. This dreadful ugliness is not noticed by the casual observer, but it is there. The beauty and ugliness of nature lie side by side, and the artist finds both, though he does not always speak of them.

INSTANTANEOUS PHOTOGRAPHY.

BY JAMES MEW.

Archbishop Trench, in his chapter on the Morality of Words, and especially in that part of it which treats of their degeneration, might, if he has not done so, have treated of many expressions which have fallen away from their original and proper meaning, in consequence of that dilatoriness and tendency to procrastination which disfigures morally a large section of mankind.

Our own language testifies against us. *Directly, presently, in a moment, in an instant*, even *at once*, have a latitude of meaning far removed from their real and etymological signification. The word *instantaneous*, as used in photography, is equally vague, uncertain, and elastic. It may, in fact, mean any lapse of time, from a cap on-and-off exposure of about half a second, to exposures by mechanical shutters occupying a ten-thousandth of that unit of time. Only a twenty-thousandth was, it is said, used by M. Janssen, the French astronomer, in his celebrated picture of the sun. But just as the word *photograph*—instead of which, from the analogies of *telegraph* and *telegram*, we should suppose *photogram* ought to be substituted—has prevailed over and utterly routed its correctly shaped but less fortunate congener, so *instantaneous* is little likely to be now ousted from its time-strengthened dominion, and its linguistic singularity is overlooked in the nearer consideration of its practical convenience. A little after the time of its birth, however, fault was found with it by an Algerian photographer called M. Penne, for the somewhat remarkable reason that it did not, for him, represent sufficient fastness. He accordingly christened an invention of his own by the name *Francaise-extra-rapide*, by which, the public were assured, could be taken a "perfectly instantaneous" photograph—a marvel, indeed, to the mathematical mind.

"There is nothing new," says an ancient and respectable authority, "under the sun." It is well known to most folk fairly skilled in this branch of science that instantaneous photography, which has been regarded as the crown and perfect flower of the photographic art, was what the French call a *fait accompli* half a century ago. In an old number of the *Art Journal* for 1851, a number printed at a date very nearly corresponding with the death of Daguerre, the public is informed that this great artist many years since stated that he had succeeded in copying a moving procession and a crowded market-place with every image faithfully impressed. The surfaces so highly sensitive to solar radiation upon which these pictures of motion were delineated were silver plates prepared with iodine and bromine under "certain forms of manipulation" with which the reader is not made more nearly acquainted. The preparation seems never to have been sufficiently certain and definite for general application. As an instance of occasional success on paper, the representation of a man's foot was exactly transferred in the *camera obscura*, as it was then commonly called, during the process of lifting it from the ground and returning it again, so high a degree of sensibility was then attained. But an experiment made at the Royal Institution about the same period by Mr. Fox Talbot seems exceptionally interesting when we remember the antiquity of its time. On a wheel moving with great velocity a printed paper was affixed. The *camera obscura* was properly adjusted with an albumenised glass plate, and the room darkened. An exposure was then made at the exact moment the printed paper was illuminated by a light obtained by the discharge of a Leyden jar. Then, notwithstanding the velocity of the wheel and the speed of the light, a picture of the print without a blur was obtained on the sensitive tablet.

This sensitive surface was, says the *Art Journal*, produced by a "modification of two processes already well-known, the addition of a hydrocarbon compound being, in all probability, the quickening agency." But in the London *Athenæum* of December, 1851, Mr. Fox Talbot himself gives the whole process of preparing the plate, a process involving ten distinct operations, with which any curious reader who will may become acquainted.

It was seen clearly by Mr. Fox Talbot that all which was wanted to produce the marvels of the present was increased sensibility of the plate, and an augmented intensity of the light. It was, moreover, stated by him that the iodide of iron, an important factor in the result, must be in a "peculiar or definite chemical state," and that an exact adjustment of the proportions of the several ingredients in his recipe was absolutely necessary. Without this no exalted sensibility could be attained, nay, scarcely any photographic result would be produced.

Instantaneous positive paper has also been supposed a comparatively recent invention, yet how far this supposition is exact may easily be discovered by any reader who will trouble himself to read a communication by H. Claudet, published in *La Lumière* in the month of March in the year 1855. Only, however, since the introduction of gelatine plates has instantaneous photography become largely important.

The detective camera has been said, perhaps without sufficient accuracy, to be a misnomer, because the external form of the camera must be concealed in order to constitute it a detective. So, it might be urged, that excellent constable Z000 is not a detective when attired in the ordinary raiment of the policeman. But it seems clear that Z000 is no less a detective in his ordinary raiment than when clothed in the unwonted apparel of a market

gardener or a city clerk. In the former case the detective business could not, indeed, be so satisfactorily accomplished, just as the revelation of the camera would certainly startle an artistically stalked head of game. It would, of course, be desirable that this instrument should put on one of those many shapes which have been suggested by ingenious individuals to disguise it. It might be in the shape of a hat, an oppressive burden in the dog days; a foot ball, which could not well be introduced into general society; a boot, only available, unfortunately, where the operator has a club foot; or a bundle of books from Mudie's, tied round with the regulation strap, probably the least inconvenient suggestion of them all.

As to the collapsible umbrella, and the vest or button camera, the trouble of the one lies in the fact that the machine will not work till the umbrella be put up—a somewhat ridiculous operation under cover or on a fine day; and with regard to the other, however ingeniously covered by the special stiff leather waistcoat fastened by black tape round the body, and however carefully the projection of the lens-tube may be disguised under the semblance of a button, some little suspicion must surely be aroused about any gentleman, with whom an acquaintance has been previously established, by his sudden and alarming accession of fatness. A lady might possibly bear about, to midnight dances and the public show, a detective camera undetected, by the simple device of substituting it for what is known among the secrets of the feminine toilet as a dress-improver, an ingenious though hardly honest contrivance designed to produce the appearance of a bounteous mammillary development in a cachectic subject as flat as the proverbial pancake. Still, whatever form a camera may assume—whether it come in the questionable shape of a bag, or hat, or ball, or boot, or book, or umbrella, or buttoned vest, or dress-improver—it seems to have no more right to the title of a detective camera than the pure and simple instrument undisguised, if used for detective purposes.

(To be continued.)

ARTIST PHOTOGRAPHER—A CLAIM FOR LIBERTY.*

BY HENRY E. DAVIS.

You have been good enough to honour me with an invitation to read a paper before your Society, and I am glad to do my mite of assistance at your proceedings, although it is with a fear that the few sketchy ideas which I am about to mention will hardly be worthy of an association of teachers and students of science and art.

The remarks which I am about to address to you relate to a question which has, for some year or two, perturbed the photographic world; whether with adequate profit or not, those who have followed its perhaps too ample discussion will either have formed already their view, or if not will, in all probability, be so fogged by the various statements and arguments *pro* and *con* that they may do anything but bless the day when the various photographic societies and journals first encouraged the discussion of the topic. You have no doubt already guessed that my subject is the position of the artist photographer.

In recent years a small clique of self-appointed prophets has arisen in photographic circles yclept naturalistic photographers, and one might suppose that it would be correct to assume that if there is any meaning in the name, it should indicate a desire to reproduce nature in its form as it appears to us. It is difficult to ascertain exactly what their tenets are; but anyhow, it is plain, from what can be ascertained from their writings or examples, that such an assumption would be decidedly incorrect. This school appears to have had its origin with a gentleman whose lubrications would intimate a large consumption of works on art criticism, and perhaps a very omnivorous inspection of art examples, without the power of discriminating between the wheat and the chaff, and so jumbling up ideas on art matters that, as a teacher, he seems to me to be pretentious and apparently free from technical ar knowledge, without which it is impossible for him to estimate the rightful position of the artist photographer.

Let us start our view of the matter from the purely photographic side. When I say the purely photographic side, I mean the position indicated as the result of using optical instruments, apparatus, chemicals and preparations, all of the highest excellence that science can provide, with full ability to utilise to the utmost all their respective merits. I think I may take the lens as being the most important member of the outfit, and it has ever been the aim of its producers to improve it for various purposes, so that it should give the clearest and sharpest definition when used to its utmost advantage. On the other hand, photographers have encouraged such improvement by preferring and readily paying for the objectives which best succeed in accurately registering the most minute definition as result of their use; and so much has this been sought after that "photographic," as a colloquial term, has established itself in all civilised languages as an equivalent for minute exactitude of detail in other things than that to which it originally attached.

As a reproductive science in the foregoing sense, photography has proved of inestimable value to the world, and will continue to be so for purposes of science and the arts generally. For such purposes its exact registration can be depended on only provided its workers are thoroughly conscientious practitioners, fully skilled in making the highest practicable use of the best procurable tools. So much for pure photography.

Now let us examine the other phase of photography claimed as an art. It is here that the misapplication of a term has assumed for a vehicle of expression the attributes of such expression. The position of the artist photographer seems to me to be this: He must be as fully informed, and as capable in the practice of photography, as the reproductive practitioner previously referred to—in fact, more so; he ought to study all new processes, especially printing processes, and produce his pictures in that one best suited to his subject. Being well informed in the technics of photography, what is he to do with his apparatus and knowledge? He is to do the same as the painter does with his oil or water colour, or the sculptor with his clay, of the manipulation of which each has technical knowledge: he is to use photography not as the be-all and end-all of his study, but simply as a vehicle for the exposition of his artistic powers; it should occupy in his mind no higher position than the other media which he might use for the same purpose. He will have high-class apparatus and the technical knowledge for making a first-class photograph, which he will use with his best capacity, just as he would go to a first-class manufacturer for the best colours and canvases, and use them with brains, with the

* A communication to the University College Photographic Society.

same ultimate object. He must, having his materials for work and a proper artistic judgment, be left as entirely untrammelled as the artist painter, to produce in his own manner the ultimate outcome of his imagination in the style best adapted to his view of his subject. It is a huge presumption of any man or set of men to come to him and say, "You shall execute all your pictures with the utmost reproductive exactitude," or "You shall execute all your pictures blurred or out-of-focus in whole or in part." Where has any acknowledged art instructor given to the world any such binding axioms?

(*To be continued.*)

LANTERN SLIDE MAKING WITH THE CAMERA.

BY ELLERSLIE WALLACE.

It would be no very difficult matter for us to enter upon a lengthy disquisition here as to the merits of the rival processes of lantern slide making by contact and by the camera. This it is not our purpose to do, however; but we shall simply give some practical points in connection with the latter method which we have found valuable in our own working, and which, we hope, will likewise be of value to our readers. One thing greatly in favour of this method of working is the fact that different sizes of negatives may be utilised for slide making with little or no modification of the apparatus; while in contact printing, of course, the negative must be of the same size as the slide to be made.

In arranging the apparatus for slide making by the camera, it almost goes without saying that daylight is used; whether full sun or diffused light will depend upon the situation and frontage of the work-room. Which of the two is to be preferred is not easy to say. Most operators prefer the even, diffused light of a northern sky; but, in our own practice, necessity compelled us to use a southern exposure, and, after a little experience, we became decidedly fond of it.

To make the difference in working with the north and south light plainer, we will at once proceed to describe the arrangement of the apparatus. In the first place, any small camera, with a plate-holder so arranged as to carry a plate 3¼ by 4¼ inches, is mounted with a good lens of, say, six to nine inches focus. Another camera of any convenient size is arranged to hold the negative in the place usually occupied by the ground glass. If the negatives happen to be just the size of the ground glass, all that is necessary is to remove the latter from its frame and insert the negatives instead, keeping them in position by a few small tacks or pins. If the negatives are of a smaller size, a piece of thin wood is cut to the proper size, and rabbetted so as to hold the negatives, the whole being then inserted in the ground glass frame and kept there by pins—or, better, by a couple of pieces of clock-spring an inch long confined by a small screw run through a hole in one end, the other end being left free to press the negative carrier firmly into position. As many of these carriers should be prepared as there are negatives to be worked with. The lens and front panel of the camera holding the negative are dispensed with.

A stout, flat board, from five to eight feet in length, is now provided with cross-legs at one end, so that it can be rested on the window-ledge by the other end, and be firmly supported. If a southern exposure be used, it will be found most convenient to place the board as mentioned, with a large sheet of ground glass or white tissue paper behind the second camera in the window. The board holds both cameras, the one used for exposing the plates being inside, or nearest the operator, while the other, which holds the negative, is set quite near the white paper to the window, so that the negative receives a full and equable illumination from the paper. The exposing camera is now brought near enough to give an image of the proper size on the ground glass, and care taken that the exact centre of the image falls on the centre spot of the ground glass. A sliding front on the exposing camera will greatly facilitate correct centreing; though if the cameras differ much in size, it may be necessary to elevate one or other of them on a block of wood. If this be done, see that everything is steady before uncapping the lens to expose; any tremor or jarring would be fatal to good results; so both cameras ought to be firmly screwed or clamped down to the board.

There will now be a space intervening between the lens of the exposing camera and the front of the carrying camera, unless the lens be of such short focus that it can be inserted into the latter. This will seldom happen. The space intervening should always be darkened by throwing a cloth over both cameras, supporting it by two sticks at each side to keep it from encroaching upon the field of the lens. The object of this is to prevent any stray light from entering the lens, and thus to utilise only the light that passes through the negative.

It will not be amiss for us to repeat in this connection some advice which we gave when speaking of mechanical aids to increase brilliancy of image. The principle we have just enunciated—of utilising only the light that goes directly to the formation of the camera image—is tacitly admitted by all careful photographers; but, in practice, we rarely find it attended to as it deserves to be. If it was worthy of regard in the days of wet collodion, when plates were of low sensitiveness, it is far more so now, when things are so much improved. Slide making depends greatly upon a clear, brilliant image on the ground glass. Unless we have this to start with, the best chemicals and manipulations will be thrown away.

The arrangement of cameras we have just been describing is very practical and inexpensive; but, inasmuch as the whole apparatus *faces the light*, there will often be reflections from the sides of either camera that will interfere seriously with brilliancy of image. Now, as we mentioned in the article previously referred to, if a large diaphragm of blackened cardboard—or, better, card covered with black velveteen—be placed a few inches in front of the sensitive plate, it will cut off these stray lights and be of great value. It will sometimes be worth while to have such a diaphragm in each camera; they are easily made, and as easily adjusted.

Supposing that a north light be selected instead of a south, it will generally be found more convenient to elevate the end of the board carrying the negative camera, so that the sky itself may act as the illuminant, thus filling the function performed by the white tissue paper in the case of the south exposure. As the sun in the south exposure shines upon the paper, it gives, of course, a very brilliant light, far more so than the blue sky in the north, and the exposure will be much shorter. It is open to the objection that when clouds pass over the sun the strength of the light varies very greatly; but this same objection holds true to a great extent with the north light, except that,

in the latter case, the exposures will be much shortened when a white cloud drifts into that portion of the sky towards which the apparatus is directed.

When the south light is used, we should recommend that the apparatus be kept horizontal, and the white paper screen be set rather close to the negative, at a distance of, say, four or six inches. This will allow room for the hand to pass between, and so facilitate the shading down of special portions of the negative that are too transparent and print too quickly.

The exposure should be made by uncapping the lens, care being always taken to wait until the tremor caused by drawing out the door of the plate-holder has quite subsided.

The question whether to use gelatine or collodion plates we leave to our readers to decide for themselves. We ourselves prefer collodion; but excellent results may be obtained on slow gelatine plates, particularly if developed with hydrokinone or ferrous oxalate.

The matter of exposure must be settled by experiment, but we must caution our readers never to over-expose plates intended for lantern slides. No restraining or tinkering with the developer will make up for over-timing, and the disagreeable muddiness which it produces. —*American Journal of Photography.*

THE BATH LITERARY AND PHILOSOPHICAL ASSOCIATION.

LAST Friday, according to *The Bath Gazette*, the Bath Literary and Philosophical Association invited the Bath Photographic Society to arrange a photographic evening. This took the form of a conversazione, and drew a large attendance. One of the chief features was the collection of photographs on exhibition, which included a large number illustrating some of the grandest scenery in North and South America; they were of large size, printed direct, and not enlargements from small negatives. The lender of this series was Miss Ashley; they were produced by American publishers. A great attraction was the fine collection of transparencies shown by the President of the Photographic Society, Mr. W. Pumphrey. These, between 100 and 200 in number, included exquisite specimens, especially in the way of instantaneous work. Mr. Pumphrey also exhibited an interesting series illustrative of places mentioned in the Old and New Testaments. Mr. A. F. Perren contributed a collection of pictures produced by the platinotype process; they were chiefly "bits" round Bath. A fruit and flower series was placed on view by Mr. E. C. Peacock, and views of Norway by Mr. Bristow. Mr. H. G. P. Wells' principal picture was an enlargement of a small negative illustrative of farmyard life, and an "instantaneous" of the well-known Weymouth swans. Mr. W. Middleton Ashman exhibited some fine bromide enlargements; amongst them was Widcombe Old Church, and a splendid portrait of the President. Photographs were also sent by the Rev. E. A. Purvis, Messrs. W. Gibbs, C. Cloakley, F. J. Saunders, G. F. Powell, E. J. Appleby, B. Williams, R. C. Bush, E. Pitman, W. Howe, Hippisley, Collins, Pitt, Menduin, Peyton, and others.

The President of the Photographic Society, Mr. W. Pumphrey, took the chair, and read a paper giving a brief history of photography from its earliest stages. Its chief point of interest was the claim it made that Mr. Henry Fox Talbot, of Lacock Abbey, should have precedence over Daguerre as the true progenitor of the modern art of photography. The actual MS. of his paper read before the Royal Society in 1839 was handed round, it having been presented to the Bath Society by his son; and some reproductions of his pictures, obtained from the some source, were similarly exhibited. At the same time was shown a specimen of Daguerre's process, and it was explained that whereas Mr. Talbot's could be reproduced, thus being a true prototype of the modern process, Daguerre's photographs could not be copied except in the same way. Mr. Pumphrey made special allusion to the revolution in the art brought about by the introduction of substitutes for the old wet plate system, and observed that the tendency is to still farther reduce the impedimenta by taking small negatives, and if required, enlarging.

Mr. W. Middleton Ashman, secretary of the Photographic Society, exhibited and explained old and the new apparatus. The contrast between the cumbrous box which formerly served the purpose of a camera, and the handy, compact form of the most recent contrivances, set forth clearly the great developments of the art in recent years, and some of the newest adaptations, such as the pin-hole and detective cameras, and the Thornton-Pickard shutter, were also explained.

In the course of Mr. Ashman's address, flash-light pictures were taken with the assistance of Mr. Wells, and immediately carried to the dark room, developed, and transparencies made for subsequent exhibition.

Mr. A. F. Perren gave a description of the platinotype process.

Subsequently the company settled down for an exhibition of lantern-slides. These, for the most part, dealt with show places well known to Bath tourists.

THE SOLAR CLUB will meet on Monday night next at the Café Royal to celebrate the twenty-fifth anniversary of the Club. Several of the founders of the Club will be present, and a considerable number of guests is also expected.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—On Tuesday next, December 9th, at 5A, Pall Mall East at 8 p.m., a paper will be read on "Photography Applied to Astronomy," by E. W. Maunder, F.R.A.S. A discussion will take place on the suggestions which have been made with regard to the proposed Photographic Institute.

MR. GAMBIER BOLTON had the honour of attending at Windsor Castle on Saturday last, and exhibiting before the Queen and H.R.H. the Princess Beatrice his series of animal and bird studies from life, which were highly praised; and Her Majesty accepted seven large studies in bromide of the lion cub lately presented to her by the Sultan of Sokoto, Africa.

FLASH-LIGHT PHOTOGRAPHY.—Last Monday and Tuesday evenings, Mr. R. Slingsby, of Lincoln, gave a demonstration in the studio of Messrs. Marion and Co., Soho Square, London, of taking portraits by the magnesium light. There was a large attendance of professional photographers. Mr. Slingsby exhibited some improved appliances of recent date; he used six flash-lamps and gave rapid shutter exposures; the pneumatic arrangement released the shutter and actuated the lamps the moment the ball was pressed. Messrs. Marion and Co. have introduced into the market special apparatus for this class of work, and Mr. Slingsby used it at the two meetings mentioned.

THE NEW PREMISES OF THE CAMERA CLUB.—The *Journal of the Camera Club* says:—"As most people are aware, the removal of the Club from its present quarters to the new premises in Charing Cross Road will take place at Christmas. Although a portion of the new building will be ready for occupation, the whole of it will not be out of the workmens' hands, and had it been possible to have remained for a month or so longer in the rooms which have served us for the last five years, it would have been desirable to do so. But the present rooms have been let to others, and the committee have been unable to effect any arrangement to retain them after quarter day. Possession of these new premises was confidently promised at Michaelmas last, and therefore, even allowing for a lack of punctuality which is common to the professors of the building art, the committee had reason to hope that at a reasonable time before Christmas the building would have been handed over to them ready in all respects for occupation. That hope has not been realised, and as our present lease expires at Christmas, we must then take possession of what is ready for us in the new building, and leave the formal house-warming to a future occasion."

THE APPLICATION OF NAPHTHALIN DERIVATIVES AS PHOTOGRAPHIC DEVELOPERS.*

BY J. F. SACHSE.

Dr. M. Andressen, of Berlin, the inventor and manufacturer of eikonogen, has lately patented ten new combinations obtained from napthalin, viz., diamidonaphtalinsulfo-acid and amidonaphtolsulfo-acid, which, it is claimed, will work a still greater revolution in photographic development. It is stated that the reducing power of these new compounds is so varied and controllable that in the near future a negative may be developed rapidly or slowly, dense or weak, according to the wishes of the operator—a property which will prove of the greatest practical value in the various branches of the photographic art. These various derivatives are described as follows:

1.—*Dioxynaphtaline.*

Theoretically there are ten combinations of dioxynaphtaline possible; of these nine are known, six of which appear to be of great value, as they bring out the photographic image rapidly and strongly, and, in the opinion of the inventor, are especially valuable for instantaneous exposure and gallery work, viz:—

1.—α Naphto-hydrochinon.
2.—β Naphto-hydrochinon.
3.—α_1 α_3 Dioxynaphtalin.
4.—α_1 β_3 Dioxynaphtalin.
5.—α_1 β_4 Dioxynaphtalin.
6.—β_1 β_3 Dioxynaphtalin.

2.—*Dioxynaphtalinmonosulpho-Acids.*

Of the various compounds obtained, either by oxidation and subsequent reduction of amidonaphtolsulfo-acids, or by the fusion of naphtoldisulfo and naphtalintrisulfo-acids with caustic alkali, or by the sulphuration of dioxynaphtaline, resulting in dioxynaphtolmonosulfo-acid, β naphtohydrochinonmonosulfo-acid was the only compound which has proved of practical use.

3.—*Dioxynaphtalindisulfo-Acids.*

The experimental trials of the dioxynaphtalindisulfo-acids obtained by the different methods has shown that both of the dioxynaphtalindisulfoites described in D. R. P., No. 49857, have special claims as photographic developers, as they cause the image to come up slowly but with great strength, a property which makes the compounds of especial value in landscape photography.

4.—*Amidonaphtole.*

Of the different amidonaphtoles, which are obtainable by the reduction of nitrosonaphtole, nitronaphtole, or from the azo-colours from naphtole, or by the fusion of the naphtylaminsulfo acids, the three following derivatives show extraordinapy power and rapidity when used as a photographic developer:—

1.—α_1 Amido, α_2 Naphtol.
2.—α_1 Amido, β_1 Naphtol.
3.—β_1 Amido, β_3 Naphtol (obtainable by the fusion of β naphtylamin and β sulfo-acid).

5.—*Naphtylendiamine.*

The naphtylendiamines require dilute alcohol as a solvent, to combine with an alkaline solution. The two following derivates are said to act rapidly and strongly in developers:—

1.—α_1, β_1 Naphtylendiamin.
2.—α_1, α_2 Naphtylendiamin.

Together with the advices of above new reducing salts for photographic developers, comes the welcome announcement that the manufacturers of eikonogen have at last succeeded in finding a means of entirely preventing this substance from becoming brown and decomposed. The substance by the aid of which the eikonogen is rendered permanent is kept secret. It is merely stated in the circular that a small quantity of the preserving substance is added, and that the eikonogen will in future be manufactured in the form of a white, absolutely permanent powder, for the use of which as a developing agent the formulæ remain the same as hitherto. This improvement will no doubt be welcomed by all those who have tried the eikonogen developer, and appreciate its valuable qualities.

* Translated from Liesegang's *Photographisches Archiv* for the *American Journal of Photography*. We leave the German terms in this article unaltered.

OPTICS AT THE EDINBURGH PHOTOGRAPHIC EXHIBITION.

On Thursday, last week, there was a large attendance in the Edinburgh Photographic Exhibition on the occasion of the weekly lecture. The speaker was Professor James Hunter, of the Royal Dick Veterinary College, and the Heriot-Watt College, and the subject was "Photographic Optics." Professor Hunter spoke of the relation between mathematics and optics, and of the advance made not so long ago, when mathematical principles began to be employed in the manufacture of lenses; then he gave an exhaustive description of the differing properties of lenses of different construction. Even at the present day, he said, the best lens is but a compromise between spherical aberration and sharpness of image, but he was satisfied that lenses are now as perfect, at least for photography, as they ever will be, while at the same time the lenses used are too good for the rest of the apparatus. Speaking of lenses to give atmospheric effect in a picture, he said that the lens which would probably be selected by an artist with that object would be one in which there would be several errors. He did not wish to decry artistic work, but a photograph was a different thing from a picture. The extreme minuteness of detail is one of the elements of the value of photographs. He showed that no single lens would ever bring light to a focus, entered into an explanation of total refraction, the aberration of the leus and the optic centre, and demonstrated the advantages of the diaphragm—the sheet anchor in all photographic instruments. He regretted that diaphragms were almost invariably incorrectly placed, and showed how their proper position could be readily ascertained. He also explained several trade terms, such as fixed focus, roundness of image, true perspective, and atmospheric effect; and with the aid of a lantern showed the effect of passing a beam of light through different descriptions of lenses. Dr. Hunter also illustrated his lecture by projecting the images of slides through lenses entirely home made, and formed of spheres of glass, or portions of spheres, with, in some cases, flat portions of glass cemented to them, thus forming vessels which were filled with water, and by which means he illustrated the various forms of lenses, also their defects, and the means employed for correcting them.

These operations were actually done in the presence of the observers, and it was extremely instructive to see the sharpening of an indistinct image, the correcting of barrel-shaped lines, and so on. He also employed an admirable set of diagrams specially drawn for the occasion, with geometric exactitude, thus avoiding the mysteries of x and y, and lucidly explaining what are often great difficulties to the layman.

Newcastle-on-Tyne and Northern Counties Photographic Association.—The next monthly meeting will be held in the Mosley Street Café, on Tuesday, the 9th of December. This will be a lantern evening, and the Association's new lantern will be in use for the first time.

Manchester Amateur Photographic Society.—At the next meeting, to be held at the Manchester Athenæum on Tuesday, December 9th, Mr. G. Wheeler will read a short paper on "An Hour's Bromide Printing," with examples; and a demonstration will be given by Mr. H. M. Smith of "Enlarging and Contact Printing on Bromide Paper."

Notes.

The Attorney-General, in his presidential address to the Society of Arts, was somewhat inaccurate in his remarks, published in this journal last week, in relation to the history of photography in natural colours. He spoke of Sir John Herschel's experiments in 1840 as if they were the first in connection with the subject; as a matter of fact, the first photograph in natural colours was taken by Dr. Seebeck, of Jena, who communicated his method to Goëthe, and the latter published the details of the experiment in 1810 in his *Farbenlehre*. Then, again, Sir Richard Webster said nothing about Becquerel, who did far more than any other living man in successful research in relation to photography in natural colours; no better results have ever been produced than by his processes. In the third place, the President of the Society of Arts called attention to work of Niepce de St. Victor in heliochromy. In nearly all his work upon this subject Niepce de St. Victor—who must not be confounded with the great founder of photography, Niepce de Châlons—was a mere imitator of Becquerel; he adopted the methods and processes of Becquerel without acknowledgment, and some alleged discoveries of his own in the matter yet want confirmation by the experiments of others. A paper from his pen was read before the Academy of Sciences at Paris; Becquerel pointed out that this paper contained practically only that which he himself had discovered and published years before, and gave chapter and verse for this accusation. The Academy published this protest from Becquerel, and thenceforth published nothing from the pen of Niepce de St. Victor. We have read the original memoirs of both writers in relation to this subject in the order of their dates of publication, and know that Niepce stands nowhere by the side of Becquerel in relation to the subject of photography in natural colours. The Attorney-General had been consulting Hunt's book, and had probably been misled by some faulty and slipshod historical utterances therein.

On the 30th of March next, the last Congress of Astronomers, preparatory to the execution of a photographic map of the stars, will be held in Paris. Meanwhile, instruments for the purpose have been constructed, and trials have been made of some of them at various observatories. Admiral Mouchez has exhibited at the Academy of Sciences a magnificent photograph of the nebula in Lyra, obtained at the Observatory at Algiers. The print had been enlarged to sixty-four times the size of the original negative, and is said to have possessed remarkable sharpness under the circumstances, thanks to the purity and stillness of the air when the negative was taken. This photograph, also, is one of those which here and there shows that there are objects in the heavens which photography can reveal, but which are invisible to the eye, even when aided by the most powerful teleseope.

If one wants to guage the popularity of any particular hobby or pastime, there is no better method than a glance through the columns of that useful journal, the *Exchange and Mart*. We are thus enabled to judge whether postage-stamp collecting is declining or flourishing, and whether fowls, rabbits, dogs, or silkworms are at present the most favoured pets. An entire column is devoted to photography, which speaks well for the popularity of the art, considering the season of the year; but the articles offered in exchange by would-be photographers are sometimes curious as well as amusing. Thus, one person wants a good rectilinear lens, in exchange for which he will give a new black melton overcoat, which will fit anyone who is five feet nine inches in height, and who measures forty inches over his waistcoat. Another advertiser owns a thorough-bred collie dog five months old, which he is willing to exchange for a 10 by 8 camera. It is evident that this latter advertiser rates his animal somewhat highly, for, according to other advertisements in the same column, the average value of such a pup is one pound, and no one can, with any conscience, expect to buy a camera of that size so cheaply.

Most things, from pills to aniline dyes, can now be had by the penny packet, and a vast convenience they afford to persons whose purses are not too well lined. Among the recent introductions of this kind is one which is of great use to those who, like photographers, have to deal with delicate apparatus—with its liability to fracture. We allude to the penny packets of powdered glue which are now sold by most oilmen. The making of serviceable glue, except to a carpenter, is, under the ordinary condition of things, a matter of serious import. A glue-pot of some kind must be found, the glue must be broken up, and when all that is necessary to do has been done, the resulting compound is either too thick or too thin, lumpy or stringy, or in some other way unsatisfactory. The powdered material sprinkled into a little boiling water contained in a tin canister, and placed in a saucepan, makes in one minute a small quantity of excellent glue, which will do to mend cameras and printing frames, and which will act as an excellent mountant, either used by itself, or as an addition to other materials. It is not cheap intrinsically, for a penny packet does not hold much more than half-an-ounce; but the form in which it is presented, and the opportunity it affords of making a small quantity of trustworthy material almost instantaneously, make it cheap indeed to the busy worker.

In the suburbs it is not uncommon to find photography allied with some other business, and very often we fancy as an attractive bait with which to secure customers for that other business which is considered the more important of the two. This would seem to be the case with an enterprising tobacconist whose premises we passed the other day. By means of a poster outside his shop, he announces that with every ounce of tobacco bought, he will give the purchaser a

voucher, a certain number of which will entitle the holder to have his portrait taken for nothing. The plan, we were told, worked exceedingly well, the farther copies of the portrait which were generally ordered making the method a profitable one.

An addition to the almost limitless list of instantaneous shutters was described at the last meeting of the *Societé Francaise de la Photographie*, which, as it embodies a novel principle, is worth describing. As M. Chameau, who brought it before the Society, said, to call it a shutter is somewhat of a misnomer, as it forms an integral part of the camera, or rather, of the lens. The invention consists of a system of iris diaphragms containing twelve blades, which are put in motion by a handle placed on the outside. The handle has only to be pushed from right to left to enlarge or contract the diaphragm. The movement is so gentle, and the working so easy, that the opening may be modified even during the moment of exposure. M. Chameau's opinion is that, up to the present, such a result has not been obtained with equal facility.

The case of Sternberg *v.* Thaddeus, held this week before Mr. Justice Day, exemplifies the extreme difficulty, familiar enough to photographers, in judging of the fidelity of a portrait. In the case in question, the issue was narrowed to the difference between an engraving and the original picture, yet the evidence of the experts was extremely contradictory. Mr. Sternberg, an engraver, was employed by Mr. Thaddeus, a painter, to execute a mezzotint engraving of a picture of Sir Richard Owen, painted by the defendant. The result did not please Mr. Thaddeus, and he refused to accept the engraving. On the minor facts of the case we need not dwell. The point of importance is that, while Mr. Algernon Graves, the well-known engraver, Mr. Arthur Lucas, the art publisher, and other experts, said the engraving was excellent, Sir Frederick Leighton, Mr. Lehmann, and Mr. M'Lean thought the reverse; Mr. Lehmann's opinion being that the nose was like a potato. The value of Sir Frederick Leighton's evidence was certainly weakened by the fact that he had only compared the engraving with a photograph of the painting, and not with the painting itself. Unless a painting is painted specially with a view to being photographed, it may be that the actinic values of the colours represented in monochrome may give a totally false effect, enlarging or diminishing the shadows as the case may be. In view of such discrepancies, the jury gave the verdict for the plaintiff, as, whatever the result may have been, he certainly had done the work. There is some justice in this. To please everybody in regard to a likeness is a most impossible task. Not infrequently, as photographers know well enough, the opinion of the critic is slightly biassed by the opinion he has of the original; and, so far as photographs are concerned, they often flatter or caricature according to the likes and dislikes of the person criticising.

The well-known animal painter, Mr. Swan—an interesting biographical sketch of whom appeared in an evening paper the other day—without being a photographer, follows the lines of study which instantaneous photography would suggest to most artists. Mr. Swan's habit, when engaged on a great animal picture, is to take repeated sketches of the animal he is painting until he has succeeded in entirely mastering it and understanding it, and is able to put it on paper in any pose he may think fit. This is the method of the Japanese animal painters, whose patience is inexhaustible in the study of nature. What is a succession of studies but a series of instantaneous photographs? Although the painter may take some time in putting his idea into form, the idea itself is, practically, an instantaneous impression of some attitude. In the works of those artists who study nature intently, extremes meet—the fidelity of the instantaneous photograph together with a suggestion of the variety of movements which only the trained eye and hand of the artist can combine.

We have on more than one occasion suggested the desirability of some school of art which shall interest itself entirely in the production of drawings intended to be reproduced by photography for books and periodicals. At the present moment, artists have to find out what is required of them by photography as best they may. There are no fixed principles laid down beyond black ink and Bristol board. Mr. Henry Blackburn has met this want by starting a class for "Instruction in Drawing for the Press." Mr. G. A. Sala, who is an artist himself, in referring to Mr. Blackburn's enterprise, spots a weak point of which all those who have to do with illustrated papers are fully conscious. Mr. Sala says:—"I apprehend that Mr. Blackburn is ambitious to teach students—especially young lady pupils—how to draw clearly, firmly, and neatly in pen and ink, so that their performances, when reproduced, may come out like workmanlike etchings, and not like ragged, raw, blurred, clumsy scrawls."

The work of lady artists is seldom adapted for photographic reproduction. They cannot see the necessity for drawing a line firmly and with solidity. The scratchy, fine-line method which looks so pretty on paper, comes absolutely to grief when it is reproduced. In the old days, the wood-engraver made up with his burin for the hesitancy of the artist; but the camera is unfeeling in regard to all shortcomings. Another mistake which artists frequently make is that light and shade, represented in the drawing by a light stroke and a dark stroke, will be the same in the reproduction. This, of course, is a mistake. Photography takes notice only of differences in thickness, not differences in tint; hence a light line and a dark line will come out exactly the same in the reproduction. It is a common thing to see drawings—otherwise good—muddy and heavy, say in the shadowed side of the face, simply from neglect of these elementary principles.

THE CYANOTYPE REPRODUCTION OF SEA-WEEDS.*

BY WILLIAM LANG, JUN., F.C.S., PRESIDENT OF THE GLASGOW PHOTOGRAPHIC ASSOCIATION.

THE two volumes which it is my privilege this evening to bring before the members of the Philosophical Society are unique in character, whether they be regarded from a photographic or from a natural history point of view. We have here a series of the British Algæ reproduced photographically, and that by a process which may be reckoned as one of the older photographic methods. The blue process, to give it its more familiar title, dates as far back as the year 1842, and was devised by Sir John Herschel. He it was who first demonstrated that light acts on the more highly oxidised iron salts, known as *ferric*, reducing them to a lower state of oxidisation, to what is termed the *ferrous*; and, as these reduced products manifest with certain reagents a different series of reactions from what the original substance gives, he was enabled to show, in a very pronounced manner, the effect produced by exposure to light. Herschel brought forward many methods for printing with salts of iron, but that particular process with which we are more especially concerned this evening received from him the name of the cyanotype. The iron salt which is generally employed in the production of this class of pictures is the ammonia-ferric citrate, and a solution of it may either be brushed over the paper *per se*, and, when dry, exposed to light under the object to be copied, and afterwards, by immersing the print in a solution of potassium ferricyanide, we find that where the light has acted there will be formed a blue product; or the potassium-ferricyanide solution may be mixed along with the ferric-citrate solution in the first instance, when a simple immersion in water is sufficient to bring out the picture. The process remains in use to the present day, and is employed by engineers and draughtsmen for the reproductions of drawings, plans, &c. Specimens of prints obtained according to the method indicated you see here, the lines of the original being reproduced in white on a blue ground. By a modification of the foregoing process it is possible to reproduce the lines of the drawing blue on a white ground. Both papers are prepared commercially. A specimen of the results obtainable by the paper last described is to be seen on the wall. It is generally known as Pellett's paper.

Regarding the permanency of the cyanotype process, we have in the two volumes before us sufficient evidence that prints produced by the blue process are lasting and enduring. Although it is more than thirty years since these impressions were obtained, the brightness and freshness, nay, in some cases, the vividness of their character, would almost induce us to believe that the prints had been but recently produced.

It may be interesting to give the following particulars regarding the volumes and their contents. Opening the first volume, we find the initial page has the title "British Algæ, Vol. I.," printed in white on a blue ground. Obviously the lettering had, in the first instance, been printed on a white sheet of paper with ordinary ink, and, this being superimposed on the sensitive paper, the printing was done in a manner similar to that employed when dealing with the ordinary photographic negative. The following page has the inscription "Photographs of British Algæ—Cyanotype Impressions." The third page explains the purport of the work, and is a facsimile of the handwriting of the producer. It reads as follows:—

"The difficulty of making accurate drawings of objects so minute as many of the Algæ and Confervæ has induced me to avail myself of Sir John Herschel's beautiful process of cyanotype to obtain impressions of the plants themselves, which I have much pleasure in offering to my botanical friends.

"I hope that in general the impressions will be found sharp and well-defined, but in some instances, such as the Fuci, the thickness of the specimens renders it impossible to press the glass used in taking photographs sufficiently close to them to ensure a perfect representation of every part. Being, however, unwilling to omit any species to which I had access, I have preferred giving such impressions as I could obtain of these thick objects to their entire omission. I take this opportunity of returning my thanks to the friends who have allowed me to use their collections of Algæ on this occasion.

"The names refer to Harvey's Manual of British Algæ. I have taken the tribes and species in their proper order when I was able to do so, but in many cases I have been compelled to make long gaps from the want of the plants that should have been next inserted, and in this first number I have intentionally departed from the systematic arrangement, that I might give specimens of very various characters as a sample. "A. A."

The fourth page takes the form of a dedication—"To my dearest father this attempt is affectionately inscribed." Then follow 192 plates of the various specimens reproduced, each one having its botanical name affixed.

The second volume contains 107 plates, to which there fall to be added 80, which have apparently been put in as an appendix, making in all 187. The number of plates in the two volumes is therefore 379. In a note at the end of Vol. II. are the following remarks:—

"Should any of the plants which are omitted, or of which the impressions are from poor specimens, be obtained, a supplementary part may at some future time be added to this work.
"H. P., September, 1859." "A. A."

Through the kindness of Mr. James Britten, Department of Botany, British Museum, I am enabled to give a few details regarding the authorship of these volumes. "A. A." were the initials of Mrs. Atkins, who lived for many years at Halstead Park, Kent, and died there in June, 1871. She was the daughter of John George Children, assistant librarian—*i.e.*, keeper of the zoological department—of the British Museum from 1816 to 1839. On his retirement, he lived with his daughter at Halstead. He died January 1st, 1852, and a memoir of him by Mrs. Atkins was privately printed in 1853. Mrs. Atkins had a large collection of British plants, which at her death was bequeathed to the British Museum, and is now incorporated in the British herbarium there.

How many copies of these cyanotype impressions were issued by Mrs. Atkins I have no means of knowing. From the great labour entailed in their production, it is obvious that only a very few could possibly have been got together. Mr. Britten informs me that there is one in the British Museum. The number of impressions is, however, 411, against 379 in the present volumes, but the introductory prefatory matter is wanting. My informant is of opinion that a set is also to be found at Kew.

The remaining point to be noticed in connection with the cyanotypes shown this evening is the fact that they originally belonged to the late Robert Hunt, F.R.S. In his early days, Hunt worked assiduously at photography, and it is extremely probable that he received these impressions direct from the author. To Hunt we are indebted for the use of iron sulphate as a developer in the collodion process.

* A paper read before the Philosophical Society of Glasgow.

THE CAMERA AND ITS VARIOUS MOTIONS.

BY PROFESSOR W. K. BURTON, C.E.

Chapter II.—General Form of Camera Adjustment for Focussing.

It is not necessary here to take into consideration at all any other kind of camera than that known as the "bellows-body." Wooden "sliding-body" cameras held their own for stereoscopic work long after they had been given up for all other kinds of landscape work, but even for that they have now long been superseded by the bellows-body camera.

Cameras of modern style might be classified in any of various ways, but perhaps we may first of all divide cameras into those in which the adjustment for focussing is done by moving the *back* of the camera—the front, with the lens, remaining fixed—and those in which the back remains fixed, but the front, with the lens, is racked out or in.

The first of the two forms may be typified by Meagher's older form of camera, one that was a favourite with nearly all photographers for a very considerable time, and that

Fig. 1.

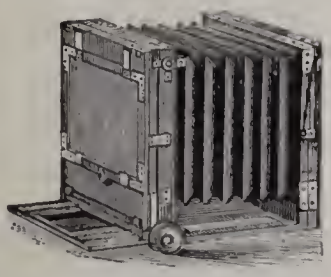

Fig. 2.

is liked by many even now. The objections that there are to this kind of camera in its simplest form are, that it does not very readily lend itself to any great extension, and that the tail-board comes in the way in focussing when a short focus lens is used.

On the other hand, it will be found that, where it is wished to make a photograph of any object whatever on a large scale—say from quarter size upwards—and especially when it is necessary to make it to any *exact* scale, a camera in which the lens is fixed and the back moves is infinitely more convenient than one in which the lens moves. In fact, with the latter, it is nearly impossible to do accurate large scale work. The superiority of a camera with the back moving will be found in the case of any kind of portraiture in which the size is such that the head comes to measure more than about two inches from the chin upwards. Further than this, the camera with the back racking along the base-board is generally very stiff.

The camera with moving front and lens is now the general favourite for landscape work. The chief reasons are the following. Such a form of camera lends itself well to portability and lightness, combined with a long extension, and a fair amount of stiffness, even when extended; there is no tail-board to get in the way in the case of focussing; and, unless a very unusually heavy lens be used, the centre of gravity of the whole camera is less changed by racking out than when the back moves.

The only objection that I know of in connection with this form of camera, besides that already mentioned of its ill-adaptibility to large scale work, is the fact that, in the case of some modifications, the tail-board, or rather base-board, is liable to appear in the picture when a very wide-angle lens is used. The reaction against the use of very wide-angle lenses makes this objection less than it otherwise would be.

I believe the once so well-known "Kinnear" camera (I used one for several years, and found it not to be despised) was the first of the kind at present under discussion; but I think that to Mr. George Hare may be given the credit of being the pioneer of the modern camera with

Fig. 3.

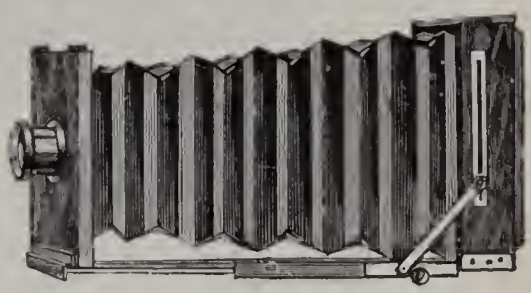

Fig. 4.

adjustment by movement of the front. I illustrate his camera here. Its essentials have been reproduced in nearly every camera that has been introduced since it was patented in 1882. The newer cameras have, many of them, movements not to be found in the camera here illustrated, and doubtless these movements are, for some kinds of work, useful, as will be explained hereafter; but this camera may perhaps be taken as typical of a camera that has all the most essential motions, and that is as light and portable as is compatible with great strength and durability.

Any camera worthy the name is so made that a picture can be taken with the length either horizontal or vertical, and cameras might be classified according to the way in which this is brought about. Roughly, there are two ways. The camera itself is made so that it can be turned bodily on its side, or the camera is made square, with a back so constructed that it can be turned through an angle of 90°. An American invention, whereby the main parts of the camera—that is to say, the back with the bellows, and the front—can be revolved whilst the base-board remains stationary, may be said to come between the two.

The common form of "reversing back" is so made that it is removed entirely to change its position from vertical to horizontal, or *vice versa*; but recently a "revolving back" has been introduced. The back revolves without taking it from the camera at all. This is certainly a convenience in many cases, and a minor advantage is that

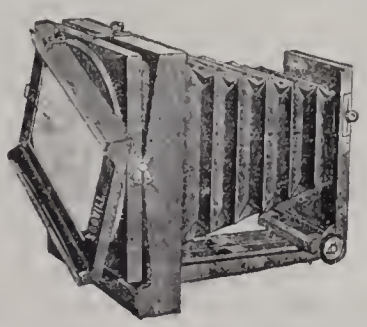

Fig. 5.

if, as sometimes happens, after focussing it is found that the camera has been put in so cramped a place that the shutter of the slide cannot be drawn, the back may be revolved through a right angle, the shutter drawn and turned back, and the back revolved back to its original position.

The revolving back is, I believe, an American invention. I illustrate it here. It may be said that the camera that has

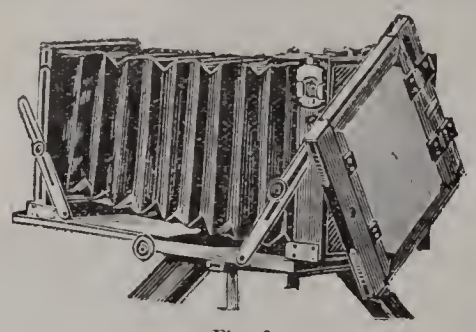

Fig. 6.

to be bodily turned on its side to change the picture from horizontal to vertical has practically been entirely replaced by the camera with a reversing or revolving back.

Focussing Adjustment.—The origin of the "rack-and-pinion" of lenses was the common construction of the older forms of cameras, which had "sliding bodies" with no finer adjustment than was given by pushing or pulling by hand, so that it was nearly impossible to focus accurately with them. Rough focussing was then done by hand, and finer focussing with the "rack-and-pinion." The universal adoption of a comparatively fine form of adjustment of the camera itself has entirely done away with the necessity or desirability of a rack-and-pinion for the lens itself. They persist now, to a certain extent, merely through the inertia of custom. A curious illustration of this is to be found in the fact that I have seen recently made lenses with rack-and-pinion, the focus of the lenses so long that the milled head of the pinion could not possibly have been reached from the place of focussing. I think it likely that the partial persistence of the rack-and-pinion on lenses is due rather to the photographer than to the optician. The former has a sort of idea that there is something of gorgeousness about a rack-and-pinion, and the latter has no objection to provide it at a cost that must allow him a handsome profit.

A screw of coarse pitch running the length of the camera, with bearings fixed to the base-board, and a nut fixed to the moving part of the camera, or a pinion at right angles to the length of the camera, running in bearings fixed to the base-board, and actuating racks fixed to the moving part of the camera, constitutes the common adjustment for focussing.

The chief difference between them is that the handle for turning the screw is always at the extreme back end of the tail-board; the milled head for turning the pinion is always at one side, generally at the outer end of the base-board. The position of the screw handle, just under the chin whilst focussing, is very inconvenient. On the whole, the rack-and-pinion arrangement is to be preferred. It is not, however, in its usual form, and in its common position—at the extreme outer end of the tail-board—adaptable to cameras of a size over 15 by 12 inches, as it is not possible with these to reach the milled head of the screw. Cameras larger than 15 by 12 are, however, so comparatively seldom used for landscape work, that some special arrangement may be adopted where they are. Thus, I have seen a camera for plates 24 by 18 with a longitudinal shaft with bevel wheels, for communicating motion from a position conveniently under the right hand to the further end of the tail-board.

I think one of the most absurd things I ever saw was the manipulation of a camera that would take plates of about 4 feet by 3 feet, constructed on the Hare pattern. One man did the focussing by turning a handle, such as that of a coffee mill or a barrel organ, whilst another shouted instructions from under a black cloth the size of a blanket.

A very good arrangement, adopted in the case of some American cameras specially adapted for portrait work, in which the *back* moves, is to have a coarse focussing arrangement by hand sliding, after which the back can be clamped down and a farther fine adjustment be given by hand. This saves time, especially in the case of large sizes.

One thing to be observed, whatever nature of focussing adjustment be used, is that it should not be too fine. It might appear, at first sight, that, except in the matter of time taken, the finer the adjustment the better; but experiment shows that the adjustment may very well be too fine. I believe that, in practice, every one focusses by racking the ground glass once or twice, first on one side, then on the other of the best focus, and then striking a mean. It will be found impossible to do this with a very fine adjustment.

I remember deciding to fix a screw adjustment to an ancient sliding body ($8\frac{1}{2}$ by $6\frac{1}{2}$) camera that I possessed, and accordingly I made a $\frac{5}{16}$ inch screw of common Whitworth pitch (eighteen threads to the inch). I was much disappointed to find that I could not focus as well with the new screw as I used to be able to do by hand!

A lever is used in some American cameras for giving the final adjustment. I have no experience of this arrangement; but, considering it theoretically, it seems to me that it ought to be both an efficient and an expeditious means of adjustment.

FIGURES IN LANDSCAPE.

THE writer of a letter in *The Journal of the Photographic Society of India* on the above subject says:—"I do not feel convinced by the passage from Ruskin quoted in the last number of the Journal. If a scene is beautiful as you look at it, though no figures appear, surely it does not cease to be beautiful when photographed because no figures have been introduced. If a story has to be told figures are necessary, but it cannot be necessary to drag figures into every landscape under the penalty of being told if you do not that 'where humanity is not, and was not, the best natural beauty is more than vain.' Why should we not admire 'herbage and stone?' Take the Taj at Agra. You have there both herbage and stone. Will a picture of it be improved by the introduction of such figures as would ordinarily be available—the photographer himself, say, or a guide with a torch? If you are an artist, and can imagine and put on canvas the scene when Mumtaz Mahal was buried, do so by all means; but what can the ordinary photographer do in the way of human figures which will not look poor beside the building? Again, take the illustration you gave in one of the earlier numbers of a view of a mountain peak. You think that the introduction of the climbers in the foreground, as if ready for the ascent, would lend an interest to the picture. If the group is artistically posed, yes; but it would be very easy to spoil a fine view by an inartistic group. When we admire a view it is, I think, as a rule, the view alone, and the human figure does not often add to the pleasure we have in looking at the picture. I have been looking through some old numbers of the Academy and Grosvenor Notes and of the Salon, and find many specimens of pure landscape without figures. I cannot help thinking that, where the view is landscape, it is, as a rule, better not to try and bring in figures."

THE NEW PREMISES OF THE PHOTOGRAPHIC SOCIETY.

AT a recent meeting of the Photographic Society Mr. W. S. Bird said:—In obedience to the powers and authority conferred by a special council meeting, it was determined to try to put in practice, as far as possible, a project which has been long before us—to provide something like a home for the Society. A special committee was appointed first to find, and then to recommend, rooms which they thought suitable. They found some premises in Great Russell Street which, it was considered, would give the comfort and accommodation required, certainly in some limited degree, but sufficient for the present. The premises being viewed and reported on to the council, the committee were authorised to enter into negotiations for the premises, with the result that they have been taken for three years at a rent of £115 per annum; the sum originally asked was £125; in addition to the rent, a sum of 5s. weekly to be paid to an attendant as messenger, and so on. The new quarters are in a fine building of considerable architectural pretension, and exactly opposite the centre of the British Museum, a locality which is fairly central. The rooms are now being furnished, gas provided, and all will be ready for occupation at the end of this month, or the beginning of the next. The only objection to the rooms is the fact that they are on the third floor, but the staircases are broad and easy. The premises consist of one large room capable of holding about sixty persons; a smaller room suitable for a library; a good dark-room; and a smaller one for a similar purpose, with entry and lavatory. The general accommodation is such as will add to the comfort of the members and to the utility of the Society. At present we are waiting the appointment of a new assistant-secretary, and we desire to obtain the services of a young man who could fairly represent photography, and who should have a knowledge of general science, and be master of another language beside his own. He should also have some acquaintance with chemical science, have a taste for art, and be disposed to stick to the Photographic Society. We have two or three candidates in view, but the council desire to announce the vacancy publicly, so as to get the best man available. The duties of the new secretary will comprise attendance on the premises, which will be opened a certain number of hours each day, so as to afford facilities to the members who may desire to use the library or the dark-room, and also have the benefit of consulting the assistant-secretary, who would possess sufficient photographic skill to be of use. We have practically launched into the experiment, but in doing so have been liberally supported by the members, who have subscribed to a guarantee fund to carry out the work without loss to the Society. The guarantee fund now amounts to £147 a year for three years; quite enough, it is believed, to secure the Society from loss during the three years of the experiment.

The President then remarked:—As the treasurer has referred to the new assistant-secretary, I might say that Mr. Cocking had, at the time when it was decided to make the experiment, already sent in his resignation, because attendance being constantly required he felt that it would be impossible for him to be in London every day. Since then, however, he has sent another letter stating that it would be possible for him to attend the Photographic Exhibitions in the future as heretofore.

THE PHOTOGRAPHIC CLUB.—Subject for discussion on December 10th, "Hydrokinone Experiences"; December 17th, "Photographic Playthings."

THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—At the meeting held on November 28th (Mr. Bedford, chairman) three applications for assistance were granted, and two new members—Messrs. J. D. Napi and Herbert Rapson—were elected.

NEXT Monday evening, at half past seven, the second annual exhibition of the North Middlesex Photographic Club will be opened at the Jubilee Hall, Hornsey Rise, near London, and not far from Hornsey Road railway station. There will be music and refreshments during the evening, and at nine o'clock a lantern display.

Specifications Published.

134. *January 3rd*, 1890.—"Azo-colouring Matters." RICHARD JOHN FRISWELL, a Director of Brooke, Simpson, and Spiller, Limited, of Atlas Works, Hackney Wick, Middlesex, Aniline Dye Manufacturers, and ARTHUR GEORGE GREEN, a Chemist to the same firm.

The object of our invention is to effect the preparation of azo-colouring matters from oxyazotoluidine of melting point about 212° Centigrade (see *Limpricht Berichte*, vol. 18, page 1405), by acting on it with nitrous acid, or with a salt of nitrous acid, and an acid, and combining the diazo compound so formed, with amines or phenols, or their sulphonic or carboxylic aids.

The following is an example of the practical operation of our process. 25·6 kilos. of oxyazotoluidine, of melting point 212° Centigrade (*Limpricht*), or an equivalent quantity of the sulphate, or other suitable salt, is suspended or dissolved in water containing a free mineral acid, and diazotised by the addition of 14 kilos. of sodium nitrite (98 per cent. $Na\,No_2$).

The solution of the diazo compound thus obtained is poured into an aqueous solution of 49.2 kilos. of the sodium salt of (1—4) alpha naphthol sulphonic acid (corresponding to naphthionic acid), and kept alkaline until the formation of the dyestuff is complete. The colouring matter is then filtered off and dried.

What we claim is:—

1. The preparation of azo-colouring matters by the diazotisation of oxyazotoluidine, and the combination of the diazo

compound with amines, phenols, or their sulphonic or carboxylic acids, substantially as herein set forth.

2. As new articles of manufacture, the azo-colouring matters, prepared in the manner substantially as herein set forth.

401. *January 9th*, 1890.—"Producing a Flash Light." THEOPHILUS HORNE REDWOOD, Bryn Coed, Crescent Road, Chingford, Essex, Analytical Chemist.

My invention relates to improvements in means or apparatus for producing a flash-light more especially applicable to photography, but also intended for other uses, such, for example, as the production of stage effects.

In apparatus of this class, as ordinarily constructed, magnesium, or other suitable powder, was projected into the flame of a spirit or other lamp in a concentrated stream, and whilst some of the powder failed to become ignited, the remainder, being in a concentrated form, failed to produce a flash of any considerable area.

Now, according to my invention, I cause the powder to enter the the flame in a well separated or diffused condition, and I so arrange the lamp that the complete ignition of the powder is effected.

For this purpose, I employ a tray, or container, for the spirit, or other suitable flame-producing material, and I by preference provide this container with a cover, or grating, of wire gauze, or other suitable material, as is well understood, and, if necessary, with a cone, or like device, to cause an increased draught of air adjacent to the flame.

Starting from the back of, and projecting slightly over, the container, and rising vertically above the grating, I arrange a plate or wall of sheet metal, wire gauze, or asbestos, so that the flame issuing from the grating will be attracted by, and caused to lick, the vertical plate, and thus form a thin wall of fire of considerable area.

If desired, I may employ any other suitable form of lamp in conjunction with the vertical plate in lieu of that form of lamp hereinbefore described, and I may employ coal or other gas as the flame-producing material.

At a suitable angle to the vertical plate, I mount upon a standard a projector, consisting of a nozzle or diffuser, provided with a chamber for the reception of the charge of powder, and I connect this nozzle or diffuser by means of a flexible pipe, with a mouthpiece to enable the operator to blow out the charge, or with an india-rubber ball or small bellows, or other suitable air-holding device capable of easy compression.

By suddenly blowing through the mouthpiece, or compressing the air-holder, the powder will be projected from the nozzle, and by reason of the angular position of the diffuser, in relation to the vertical plate of the lamp, the charge of powder will be distributed over the wall of flame, the vertical plate preventing the escape of unignited particles, and a flash of considerably increased area will thus be produced with but the same expenditure of material as heretofore.

If desired, the powder may be projected upon an intervening deflecting plate, and by that directed into the flame.

What I claim is:—

1. In an apparatus for producing a flash-light, the combination of a lamp or burner, a vertical plate or wall located over, or adjacent to, such burner, and a suitable projector or diffuser for the powder.

2. In an apparatus for producing a flash light, the combination of a lamp or burner, a vertical plate or wall located over, or adjacent to, such burner, a suitable projector or diffuser for the powder, and an intervening deflecting plate for directing the powder into the flame.

3. In an apparatus for producing a flash-light, the combination of a lamp or burner, a vertical plate or wall located over, or adjacent to such burner, and a suitable projector or diffuser provided with a chamber to contain the charge of powder.

10,145. *July 1st*, 1890.—"Photographic Enlargements." MARCUS GUTTENBERG, 232, Oxford Street, Manchester, Photographic Artist.

This invention relates to a novel mirror photo-enlargement or decorating process, whereby photographic, and especially photographic portrait enlargements, coloured or otherwise, can be produced in combination with a mirror background, giving an ornamental and pleasing effect in portrait or landscape photography hitherto unattainable.

In carrying out my invention, I make an enlargement of a negative on a transfer of any kind, either transferrotype-paper or by carbon or other transferring process. The image from the enlargement must be cut out, laid face downwards on the mirror, and the outline of the enlargement be marked thereupon with any desired colour. I then take white or coloured paint or varnish, and paint the surface inside the line and allow the same to dry. This done, I wet the enlargement perfectly in water, and transfer it to the painted surface in the usual manner. I then strip the transfer paper, which now lies uppermost, away from the painted surface, leaving the film adhering to the said surface, and when dried it is ready for painting, either in oils, water colours, monochrome, or it can be decorated according to taste.

It will be obvious that the portrait or picture may be produced upon the mirror either by photography, or painted thereupon by the assistance of photography, say by means of a transparency or negative, either through a lantern or otherwise.

What I claim is:—

1. The improved mirror photo-enlargement process, substantially as hereinbefore described.

2. The improved mirror decorating process substantially as and for the purpose hereinbefore described.

Correspondence.

DIAZOTYPE PRINTING PROCESSES.

SIR,—In reply to the letter of Messrs. Green, Cross, and Bevan, it may be admitted that "Diazotype Processes" is, strictly speaking, a better generic title than "Primuline Processes" under which to include their process and that of Feer, seeing that the latter is not confined to the use of the diazo derivative of primuline, but is applicable to diazo bodies generally.

With regard to their contention that Feer's printing process should be called a "negative" one, and their own "positive," it should be remembered that the ordinary silver printing method for obtaining positives direct from negatives are known to photographers as "positive printing processes," and are found so described as far back at all events as the time of Hardwich. Feer's process, resembling in this respect silver printing, would therefore be understood by photographers as a positive printing process, whilst methods which, like the powder process, and the primuline process of Messrs. Green, Cross, and Bevan, requiring a transparent positive to be produced from the negative before a positive can be obtained from it, should have some special designation. The kind of result, negative or positive, obtained by each process, is, as may be seen, clearly pointed out by Dr. Witt. THE TRANSLATOR.

CHEAP RAILWAY TICKETS FOR PHOTOGRAPHERS.

SIR,—I am glad to find that the photographic press organs, the most powerful guardians of our interests we possess, have taken this matter up, and I feel satisfied that with their assistance, and with the co-operation of the principal camera clubs, the desired end may be obtained. Perhaps the best course to pursue would be to present to the railway companies a petition signed by as many societies as possible, in favour of the cheap ticket system, and showing some real grounds for the desired concession. Railway Companies are business people, and while they are willing to meet the public, they expect some return for all favours granted. It would be desirable to get the number of camera or photographic societies throughout the kingdom, and the total number of their members, with other information that would strengthen our position. The West London Photographic Society would gladly leave the lead in this direction to one of the older societies, if one of them would undertake it; but, failing this, would be prepared to undertake the prepara-

tion of the petition if the other societies would sign it. A united petition, with the Camera Club at its head, would carry great weight, and would no doubt succeed in obtaining similar privileges to those now enjoyed by our brothers of the "gentle" art.

Any information on this subject will be gladly received by our Hon. Sec., Mr. John A. Hodges, 87, Chancery Lane, London.

W. A. BROWN,
President of the West London Photographic Society.

THE UNNATURALNESS OF NATURALISTIC FOCUSSING.

SIR,—In acknowledging Mr. Debenham's courteous recognition of my letter, I am glad to see we are essentially in agreement.

In answer to his invitation to lay before your readers my views on the way in which it appears to me that a just theory of the relations of mental and physical processes in natural vision conflicts with the "naturalistic" theory, I would willingly endeavour to do so, so soon as leisure permits, if you thought it likely to be acceptable to them.

I certainly do not think Dr. Emerson sufficiently recognised how little our distinct visual perception confines itself to that which is—at any given instant—within the area of distinct vision; believing that, in natural vision, it always includes much that has been centrally seen during *successive* instants; only being *supported in the memory* by our less perfect sense of it, while also less perfectly imaged away from the central area of distinct vision. I do not believe in even an "impression" being entirely confined to one indivisible instant of time—and, if not, what hinders a distant perception of the whole scene over which we have cast our eyes? It varies, indeed, in its vividness, or mental distinctness, as the varying direction of our attention calls into both mental and physical action the selecting and emphasizing faculties. So I would willingly take a part in endeavouring to controvert what has already been happily termed the "unnaturalness of naturalistic focussing."

It seems, too, to me to be a wilful throwing away of that delicate beauty of definition—neither sketchy nor laboured—which painters would willingly secure if they could, in deference to an entirely mistaken idea that delicately accurate definition of details is incompatible with their due subordination. Mr. Debenham has well pointed out the misconception arising from the different senses in which the phrase "sharp definition" is understood by painters and photographers respectively; and few misconceptions have been more persistent or more injurious.

Perhaps, however, it is to some extent our own fault. We have so striven after speed, pushed to instantaneity even for still life, and have so accustomed ourselves either to small sizes, for which the softness of contrast which pleases us in a large picture is unsuitable, or else to enlargements, in which its combination with true delicacy of definition is unattainable, that few, even among photographers, adequately appreciate the effect which may be produced in a really large direct photograph which is everywhere delicately and accurately defined, yet so duly subordinated that no undue sharpness of contrast seems to emphasise irrelevant detail. Such effects are to be obtained from a suitable subject with a good lens, a small stop, and a sufficient exposure. But how rarely are they obtained! Some ten or twelve years since, I was asked to take a life-size portrait of a young lady after death. Of course the photograph was sacred, and could be shown only to the sorrowing father. But my memory of the delicate detail, obtained through the small stop permitted by an exposure of forty-five minutes in a good light, on a wet collodion plate which needed no forcing, is one that casts into the shade all I have seen of the efforts of enlargers or retouchers. Such untouched delicacy of detail in a large picture is really truth to nature, and I think it would be so regarded by Dr. Emerson himself.

High Street, Oxford. W. H. WHEELER.

P.S.—Please allow me to correct an error in my last. The conjugate focus of the car for a 9-inch lens at 74 inches distance should be $10\frac{1}{32}$ inches, not $10\frac{2}{32}$. The differences, however, are correctly stated.

Proceedings of Societies.

THE PHOTOGRAPHIC SOCIETY OF IRELAND.

THE usual technical meeting of this Society was held at the Rooms, 15, Dawson Street, Dublin, on Thursday, the 27th ult., with Mr. HERBERT BEWLEY in the chair.

Mr. JAMES CARSON, C.E., gave a demonstration of lantern work, in the course of which he exhibited a number of regulators. He stated, for the benefit of those who might be nervous about using compressed gas cylinders, that the Scotch and Irish Oxygen Company subjected their cylinders to some severe tests, and in addition they had them constructed respectively with right and left threaded screws, thus rendering it a matter of impossibility for a careless workman to fill an oxygen cylinder with hydrogen, or *vice versa*.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 27th.—Mr. T. E. FRESHWATER in the chair.

Mr. F. H. VARLEY read a paper on the "Magazine Camera," invented jointly by himself and Mr. Friese Greene. Subsequently Mr. Varley explained the mechanism of the camera by the aid of the blackboard. The camera is capable of making fifty exposures per second, but five per second were found to be a very good average; 400 exposures had been taken on one band of tissue.

Mr. FRIESE GREENE showed a roll of bromide paper which had been printed at the rate of five per second. Mr. Greene also explained a process, yielding an imitation of opal printing. Plain glass plates are coated with an emulsion containing kaolin and baryta. The plates are developed and fixed in the ordinary way. When finished they have the appearance of opal glass.

The CHAIRMAN passed round Mr. Andrew Pringle's new work on the "Optical Lantern," published by the Scovil Manufacturing Company, New York.

THE WEST LONDON PHOTOGRAPHIC SOCIETY.

AN ordinary meeting of the above Society was held at the Broadway Lecture Hall, Hammersmith, on November 28th; the president, Mr. WALTER ADAM BROWN, occupied the chair.

Mr. PRINGLE gave an address on "Bromide Printing." The lecturer, after describing the details of the manufacture of the paper, proceeded to say what a bromide print ought to be. Experience shows that many do not know what constitutes a perfect bromide print. The best test of the quality of a bromide print is that it shall look like platinum at its best. The great advantage of the process is, that whereas a special quality of negative is required for platinum and for silver, a negative unprintable by other methods will yield a passable result with bromide. Other advantages are that the process can be worked at night, therefore light and exposure are under perfect command. In regard to exposure, no definite rule can be laid down, owing to the want of a standard light. Working with a normal developer, a black and white print means under-exposure, and if the finished print be of a greenish or muddy tone, the developer had not time to act properly. Ninety per cent. of failures are due to too rapid development consequent upon over-exposure; the great point to aim at is the control of development. A long exposure tends to yield softness, and if carried too far to fogginess; chalk and soot mean under-exposure. With a thin negative a sub-normal exposure should be given; if hard, super-normal exposure should be given. A developer strong in iron means strong blacks. If the print is from a thin negative, the exposure should be short and the developer strong, and *vice versa*. It is hard to find a better developer than ferrous oxalate. He could not speak so well of pyro or eikonogen, but quinol gives good results. Both the iron and the oxalate solutions should have slightly acid reaction. His method of making iron developer was as follows: Before mixing, acidify the water with sulphuric acid, and then add the iron to saturation, but do not boil. The oxalate solution is

also to be saturated and acidified with oxalic or acetic acid. As to proportions, for a strong developer, 1 iron to 4 oxalate ; medium, 1 to 6 ; a good strength being 1 to 8. He did not recommend diluting the developer with water, as it engendered graininess. As to the use of free bromide, half a grain of it to an ounce of water was a usual quantity, and he advised that. As to quinol, he recommended Thomas's or any standard formula. In regard to manipulation, the paper should first be soaked in clean water, then sweep over the developer, and keep moving. The test of proper exposure is the regular appearance of the image ; by the time the details show in the high lights the shadows should be plucky. With rough paper, development should not be carried too far, as the print, when dry, looks darker. Thorough washing should follow the use of the acid bath. It is important to keep the hypo alkaline by the addition of a little ammonia, as there is a great tendency for the bath to become acid. If blisters appear, a little salt in the first washing water overcomes the difficulty. He recommended the use of a squeegee under a rose tap, which is more efficacious than prolonged soaking in a washer. Mr. Pringle concluded his remarks by practically demonstrating the process.

The next meeting, which will be a lantern night, will take place on December 12th.

The Hackney Photographic Society.

The thirty-sixth ordinary meeting of the above Society was held on the 27th ult.

The Hon. Sec. reminded members of the Exhibition on December 11th. The awards in the competition, with Messrs. J. Traill Taylor and H. P. Robinson as judges, were :—Best picture taken at a Society excursion—Dr. Gerard Smith ; 2nd, Bronze medal—Mr. W. G. Linadell. Best Seascape—Prize (Mr. Crouch's donation of a lens), Mr. W. Wesson. Architecture—Silver medal, Dr. Roland Smith ; Bronze, Mr. F. H. Evans. Beginner's Prize—Bronze medal, Mr. F. W. Cock. Lantern Slides—Microscopical, Dr. W. A. Kibble ; Artistic, Mr. J. Carpenter. Isochromatic Prize—Given by Messrs. B. J. Edwards and Co., Dr. Gerard and Dr. Roland Smith. Nearly 200 pictures were sent in, and 66 entries were made. The gold medal or championship of the Society was won by Mr. Walter Wesson, for a fine picture of "On the Wye." There were some good pictures entered : the judges were pleased with the efforts of this young Society.

A subscription was set on foot to purchase a lantern. It is expected that the new lantern will be ready for use at the Exhibition. The hon. sec. presented the Society with a book on "The Lantern," by Chadwick, and the president gave a lime-light jet.

Some work having been shown by Messrs. Gosling and Dean, the Chairman (Mr. J. O. Grant) called on Dr. Roland Smith for his demonstration on "Kallitype Paper."

Dr. Smith said that the paper is similar in appearance to platinotype paper, but is more under control, as the development can be stopped in any part or at any moment easily. It is, he said, quite a permanent process, and yields prints in about a quarter of the time which silver paper takes. The paper does not require any special way of keeping ; it is, however, desirable that the fingers should be kept off it, as much as possible, whilst developing, or stains might result.

Leicester and Leicestershire Photographic Society.

On Wednesday, November 26th, the first conversazione was held at the Co-operative Hall, High Street, when several of the members showed selections from their work.

Among the photographs exhibited were those of Mr. G. Bankart, a collection of autotype and platinotype prints, of which "The Old Corporal" was specially worthy of note. Mr. T. Scotton, of Derby, showed a number of splendid views in the engine works of the Midland Railway, taken direct on the largest sized plates manufactured, and a good negative of one of the locomotives was exhibited. Mr. F. G. Pierpoint, in addition to prints, had several exhibits of interest, including transparencies, lantern slides, photographic lamp shade, and sets of apparatus. He also displayed a fine bromide enlargement (40in. by 30in.) of a view near Matlock, Bath. An interesting collection of figure studies was displayed by Captain Adcock, of Melton Mowbray. The other exhibitors were Messrs. S. S. Partridge (president), J. S. Cooke (vice-president), aristotypes and bromides ; B. Ellis, F. Joliffe, Woodcock, J. Porritt, enlargements ; A. Wilson, W. Taylor, S. Squire, and Frank Brown. Mr. Weatherhead also placed on view a selection of works of art, antiquities, and objects of interest in foreign manufacture.

During the evening a lecture was given by Mr. Walter D. Welford on "Hand-Camera Work," illustrated by a large number of slides from instantaneous exposures on almost every kind of moving object. The views were of a novel character, illustrating every form of hand-camera work, and they were shown by a bi-unial oxy-hydrogen lantern worked by Mr. Pierpoint.

Birmingham Photographic Society.

The sixth annual meeting was held at the Club Rooms, Colonnade Hotel, Birmingham, on the 27th November, Mr. J. B. Stone, J.P., in the chair.

The Secretary read the report of the Council, from which it appeared that steady progress has been made by the Society during the year 1890. Notwithstanding the removal of eighteen members' names, owing to resignations and non-payment of subscriptions, the register roll has increased from 171 in 1889 to 176 in 1890, twenty-three new members having been elected during the year 1890. The Annual Exhibition of 1889, unavoidably postponed till January, 1890, and held in the Temperance Hall for two days, was a great success, nearly 400 photographs, the work of the members, all taken during the year, and prepared specially for competition at this Exhibition, being shown on the walls. The attendance was large. A number of the competing photographs shown at this local exhibition were forwarded to the Crystal Palace Exhibition, held in March, 1890, to compete in the "Society Competition for the All England Challenge Cup," and the prize was awarded by the judges to the Birmingham Photographic Society. On February 7th, 1890, Mr. S. G. Mason offered a gold medal for special competition, the prize to be given for the best set of six photographs of cottages and river scenery in Warwickshire (the negatives to be at the service of the County Photographic Survey Council), and the council in addition offered a silver medal for the second, and Mr. A. Constantine a bronze medal for the third best set. The photographs were forwarded on July 10th, 1890, to Mr. George Bankart, of Leicester, who was elected judge by the council, and he gave his awards as follows :—Gold Medal, B. Karlese ; Silver Medal, A. J. Leeson ; Bronze Medal, W. J. Harrison. The Photographic Survey of Warwickshire, particulars of which have been given from time to time in these columns, was also referred to at length in the report of the council.

The Librarian's Report showed that members have made good use of the library during the past year, and the Curator of Lantern Slides reported that the stock slides had been fairly well distributed during the year, having been issued to about fifty members, and selections lent to the Camera Club, London, and to the Coventry and Kidderminster Societies. The Society has acquired a first-class bi-unial lantern and accessories.

The Chairman, in moving the adoption of the report, said that if the Society had only done one thing, viz., placed the Photographic Survey of Warwickshire on a firm basis, it could certainly congratulate itself. He was looking forward to the Exhibition to be held in December, when a good number of the survey prints would be shown. He believed in intercourse amongst members, and wished to encourage the publication of receipts and results of the experience of members who knew the best ways of doing things. It would be a good thing if the best results were made more common in the Society. Trade interests would not suffer, but it would facilitate trade interests, as traders would then know what to provide. There were, too, many matters the Birmingham Society could congratulate itself upon, one of the foremost being the winners of the National Challenge Trophy, which, with specimens of the

work which gained the cup, was placed in the Birmingham Municipal Art Gallery.

Mr. Karleese seconded the adoption of the report, which was carried unanimously.

The following officers were then elected:—*President*—Mr. J. B. Stone, J.P., F.L.S., F.L.S.O.; *Vice-Presidents*—Messrs. W. J. Harrison, F.G.S.; E. H. Jaques; B. Karleese; *Hon. Treasurer*—Mr. T. Taylor; *Hon. Librarian*—Mr. W. S. Horton; *Hon. Secretaries*—Messrs. J. H. Pickard and A. J. Leeson.

The Liverpool Amateur Photographic Association.

The 27th annual meeting was held in the Association's Club Rooms, 3, Lord Street, Liverpool, on Thursday evening, 27th November. The President, Mr. Paul Lange, occupied the chair, and there was a crowded attendance of members.

The following were elected members of the Association, viz., Messrs. A. Hutschauney, Harold King, Alexander Watt, R. P. Gilbertson, W. Stone, E. L. Marriott, Howard Arnold, M.D., T. S. Pardy, and W. B. Hellor. The Hon. Secretary's report showed that during the past year the addition to the roll of membership had been the largest in the history of the Association with the exception of the year when the club rooms were opened, and that fifteen members had retired from various reasons, and additions of fifty-five new ones had to be recorded, making a total of 279. The sucess attending the practical demonstrations, of which there had been eleven, was encouraging, the average attendance being about forty. There had been eleven monthly and three optical lantern meetings, also five outdoor excursions, all of which had been well attended.

The report was unanimously adopted.

The Hon. Treasurer's financial statement showed that the total expenses in the year's working had been £224 1s. 1'd.; the income had been £207 16s. 2d.; there was, however, a balance of £361 18s. 11d. to the credit of the Association.

After a discussion on some minor points, the statement was adopted. The Council submitted the following nominations for officers, &c., for 1891:—*President*—Mr. Paul Lange; *Vice-Presidents*—Mr. Wm. Tomkinson, and Mr. Joseph Earp; *Hon. Secretary*—Mr. L. M. Tunstall; *Hon. Treasurer*—Mr. P. H. Philips; *Librarian*—Mr. J. Macdonald Bell; *Auditor*—Mr. Arthur Bradbury; *Trustees*—Messrs. Paul Lange, Joseph Earp, and A. W. Beer; the following to fill the place of retiring members of the Council—Messrs. A. F. Stanistreet, Henry Lupton, F. B. Illingworth, B. Boothroyd.

The Enfield Camera Club.

A meeting of this Club was held on the 19th ult., Mr. D. G. Pinkney, president, in the chair.

Mr. H. F. Knight read a paper on "Exposure." He regarded correct expasure as not secoud to correct development. Without trespassing upon the ground which belongs more properly to development, he pointed out that the two things were closely allied. You may give a laudscape an exposure of a second, and, with similar conditions in every respect, you may give three seconds, or even ten, yet develop the plates in such a way that the negatives shall, in all cases, be practically alike. The operator should know beforehand what the correct exposure for the subject should be, aud that it should not much exceed in duration the time quoted for the shortest of the three exposures. Many people systematically over-expose their plates, and use a highly restrained developer weak in alkali, thus, practically, taking away with one hand what they give with the other. Mr. Knight differs *in toto* from such a method, and believes that the proper course for the landscape photographer is to adopt such a means of development as will enable him to get equally good results as to the value and toue with rapid exposures. Many, if not most, pleasing effects in nature are more or less fleeting or restless. The sea is moving incessantly; the breeze is often sporting amongst the foliage; cattle are seldom stationary for long. Many of the figures one sees artistically introduced into landscape photographs are the result of quick exposures, such as that obtained with an ordinary drop shutter; therefore, given a rapid plate and an energetic developer, and being prepared to give a quick exposure, it is more than ever necessary that the exposure soould be correctly timed. He advised, according to his own practice, to aim at what may be called the shortest possible adequate exposure, and not to trust, as many do, more or less, to haphazard in exposure to rectification in development. He said that broadly speaking, there were three ways of arriving at correct exposure for a given subject under certain conditions, and they are: 1st, by experience; 2nd, by tables; 3rd, by a judicious mixture of the two. Many photographers abuse tables in theory, and it is the way of some beginners to abuse them in practice; for instance, an amateur, who, having set up his apparatus to take a view of the interior of Tiutern Abbey (a roofless ruin), turned to his tables and found two minutes down for a well lighted interior. The exposure was given, but the result did not come up to the expectations of the would-be photographer; therefore acquire experience, and use it together with your tables. There are seven different factors which help to determine the length of an exposure, viz.: lens, stop, plate, time of day, time of year, nature of subject, and light, whether cloudy or otherwise. Mr. Knight examined the seven factors in detail, and proposed to endeavour to express them in figures. For this purpose he adopted a unit, and the unit selected is that the exposure for an open landscape in sunshine at 12 o'clock in June, with a stop marked *f* 10, and a collodion wet plate, is one secoud. For the purposes of exposure the factors of lens and stop can be dealt with together, aud represent theu by figures which shall be universally applicable, *f* 10 representing the figure 1, *f* 8 will be represented by $\frac{2}{3}$; *f* 16 by $2\frac{1}{2}$; *f* 22 by 5, and so on. In a series of stops as usually supplied with the lens, each size smaller requires double the exposure of the next one to it. The next factor is the plate used: it is better for the purpose of experiment to take some well-known plate as a standard instead of wet collodion. Thus Ilford ordinary are twenty times as rapid as the unit. Mr. Knight invariably uses Messrs. Wratten and Wainwright's drop shutter plate, which he considers a fifty-time plate, and is two and a half times faster than an Ilford ordinary. The uext factor is time—time of day, and time of year. The reader went on to say that it would be neeessary to conduct some experiments here, except that it has all been done effieiently for us by Dr. J. A. Scott, and is set out in his well-known table, which he produced:—

Dr. J. A. Scott's Table.

Time.

Hour.		June.	May. July.	April. Aug.	Mar. Sept.	Oct. Feb.	Jan. Nov.	Dec.
12		1	1	$1\frac{1}{4}$	$1\frac{1}{2}$	2	$3\frac{1}{2}$	4
11	1	1	1	$1\frac{1}{4}$	$1\frac{1}{2}$	$2\frac{1}{2}$	4	5
10	2	1	1	$1\frac{1}{4}$	$1\frac{3}{4}$	3	5	6
9	3	1	$1\frac{1}{4}$	$1\frac{1}{2}$	2	4	12	16
8	4	$1\frac{1}{2}$	$1\frac{1}{2}$	2	3	10		
7	5	2	$2\frac{1}{2}$	3	6			
6	6	$2\frac{1}{2}$	3	6				
5	7	5	6					
4	8	12						

Mr. Knight had had considerable experience with the above table, and believes it to be very reliable, and must have been the result of very large experience, and said that anyone who trusts to his eyesight to determine the intensity of light in preference to adopting such a table as the above, puts himself to a considerable disadvantage. The last two factors—viz., nature of subject and quality of light—without reference to the time, are left open to be judged by experience. He advised the taking of the subject and the light together, and to accustom oneself to decide upon the ratio or number required for any subject that may present itself. Thus, an ordinary landscape subject with strong foreground lighted up by the sun should be taken as four. If the light were good, but not actually sunshine, he would double the figure and take it as eight, and so on. If one gets a little bit shut in by trees, the length of exposure required rapidly increases, and you quickly get to ten, or even twenty or upwards; whilst if you have a river scene or open landscape, one or two

would be sufficient, aud for clouds or sea a half or even a quarter. Mr. Knight was only referring to laudscape and outdoor photography, aud said that tables are not of much use for indoor work, or for copying, and went on to say that there are different ways of putting his theory into practice; for instance, supposing he were going to photograph Old Chingford Church at 10 o'clock on a sunny January morning ou a Wratten drop-shutter plate, and as there are tombstones, and so forth, in the foregrouud, which it would be desirable to have pretty sharp, he would use *f*/22, a stop requiring five times the exposure of the unit, viz., *f*/10. The plate, being a fifty-times oue, will require fifty times the exposure of the unit wet collodion. For the time of day, he refers to Dr. Scott's table, and finds five given; then, taking the last two factors together, subject and light, there is a strong foreground, and a bit of a dark yew tree in the middle distance, and four would be the proper ratio to take, or four times what would be required for the unit of open landscape; put in the form of fractions, the figure for the plate being the denominator, and the others numerators, it would be $\frac{5}{1} \times \quad \times \frac{5}{1} \times \frac{4}{1} = 2$ seconds. He had a much simpler way of goin[5] to work. He had prepared a table which, for one quality of plate, and one size of aperture, meets all cases without much calculation.* Mr. Knight ended with saying that the appearance in the focussing screen may, and ought to, be useful iu determining the ratio for subject aud light, and even au actinometer might be used by those who are addicted to such things. For his part, he found a minimum of experience and common sense, which is all he can lay claim to, quite sufficient for what is required.

The evening closed with a unanimous vote of thanks to Mr. H. F. Knight.

THE GREAT YARMOUTH AND EASTERN COUNTIES PHOTOGRAPHIC SOCIETY.

THIS Society held its secoud monthly meeting on Tuesday evening last, at the Friendly Society's Hall, Great Yarmouth. There was a good attendance of members and friends.

After the ordinary busine·s had been transacted, and several new members elected, an exhibitiou of lantern slides (prepared by members only) was proceeded with, and about sixty slides were projected upon the sheet. Each member described his owu slides, aud explained the method of preparation.

THE NOTTS AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE 101st ordinary meeting of this Association was held on Monday evening, Dec. 1st, at the Society's Rooms, Cavendish Chambers, Market Street, Mr. S. WELLS, president, in the chair.

The followiug new members were elected:—Messrs. Zalasiuski, Marsdeu, and George Turner.

Mr. BURROWS gave notice of motion that the sons of members under eighteen years of age be admitted as members at a reduced subscription.

Mr. H. M. SMITH, of the Eastman Compauy, gave a practical demonstration on bromide enlarging, and exhibited a folding camera.

The Society is about to enter into possession of more commodious rooms, which are undergoing thorough decoration.

H. P. ROBINSON.—Your letter is based upon an erroneous impression. The names of yourself aud Mr. Whartou Simpson were not mentioned in our notice of *Sun Artists* last week, nor even for a moment thought of in connection with the matter.

THE PHOTOGRAPHIC NEWS "YEAR-BOOK."—Our YEAR-BOOK for 1891 is now out, and contains many more pages of literary matter and informatiou relating to photography than did its predecessor; it also contains much informatiou about the diazotype processes, and about other discoveries made during the past year. Some of the engravings in it are of exceptional interest, and it contains some tables of figures likely to be useful to photographers.

* This table of figures has been received indistinctly written, so that it cannot be printed without the introduction of errors.—ED.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

G. D. (*Paris*).—Received your letter, which shall have our best attention, and you may expect an early reply by post.

J. C. M.—*Corroded Lens-Mount.* The black stain caused by long contact with a vulcanized rubber ring is sulphide of copper formed by the slow action of sulphur upon the surface of the brass mount. This kind of corrosion will not yield to anything short of buffiug and re-lacquering.

MET.—*The Cold Weather.* During the last week of November, a sharp transition from very mild and genial weather to hard frost occurred, and the thermometer, which had been standing at about 60° F. on Sunday, 23rd ult., made a sudden descent to 20° F. There was a heavy fall of snow, in London, on Friday, 28th, which covered the ground, and remained on the roofs for many days. Such severe weather, early in the season, has not been known since 1879.

U. P.—*Instantaneous Shutters.* For use between the lenses you have the choice of several good patterns, but these must, as you say, act as diaphragms of constantly varying apertures.

AMICUS.—*Want of Rigidity.* There are two methods, either of which may be employed. Your tripod top should be covered with leather, or a stout leather washer used on the clamping screw, as metal to metal often fails to give the requisite degree of stability. On other points, see Professor W. K. Burton's article on page 840 of the NEWS for the end of October.

A correspondent would be glad to know where he can procure Parts I. and II. of "Royal Academy Pictures, 1890," which are now out of print.

L. E. D.—*Plate Mark Boards.* These can be had in various tints, and all sizes, from any of the dealers. The lithographed ground is likely to preserve rather than injure the photograph mounted thereon. Platinotypes are undoubtedly permanent, and good silver prints should last for twenty years, or longer, if kept in a dry place.

T. SEARE.—We cannot very well undertake to give advice about investments. Make your own enquiries of the secretary of the company, about dividends paid during the last few years, amount of reserve fund if any. Ask for a list of directors, last report, and then use your own judgment on all the facts of the case.

A. G.—The date is too recent to permit of your getting a sight of the patent specification.

LUTON.—*The New Institute.* The details of the proposed Photographic Institute are open to discussion at the December meeting of the parent society, but the time given to it must be short, for on the same evening a paper is to be read on "Astronomical Photography. When the charter of incorporation is obtained, an examination will admit to the title of F.I.P., or F.R.I.P. If you cannot attend the next meeting, you might still be able to send on a few suggestions or criticisms to the secretary.

IRIS.—*Barton's Buttons.* These are getting rare and scarce. The catalogue of the effects of the late Dr. Percy made mention of two or three of them, but they were withdrawn before the day of auction sale. Messrs. Murray and Heath and Mr. Ackland were at one time collectors.

F. G.—*Engraving a Portrait.* In a recent action at law, instead of bringing the President of the Royal Academy and other eminent artists into court, to say whether the nose and mouth in Professor Owen's engraved portrait were faithfully reproduced, it would have been easy to take photo-transparencies of the original painting and engraved copy, and see whether they would fairly overlap. Such evidence would have been admissible.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1684.—*December* 12, 1890.

CONTENTS.

THE PROPOSED PHOTOGRAPHIC INSTITUTE.

PARTICULARS about the proposed Photographic Institute have already been published in these pages, and last Tuesday night the subject was again brought under the notice of the Photographic Society, as recorded to-day in another column. The main fact seems to be that, if photographers band together, and through existing organisations, or otherwise, show interest in the matter, and will contribute adequately towards the carrying out of the scheme, upon which the Lord Mayor looks with favour, it is likely that donations amounting to about ten thousand pounds will be forthcoming in the city of London.

A lamentable difference between first-class scientific educational establishments in England and those in some of the other European nations, is the high cost to the students of the teaching which they receive. In Brussels, the walls are sometimes placarded with bills, announcing a course of free lectures on photography in the Old Museum, to be given by the State Professor of Photography, and pointing out the use of the acquirement, and stating that all those who wish to attend can do so after merely signing their names and addresses in a book. If some of them afterwards wish to go more deeply into the subject, they are allowed the use of costly apparatus on the premises, on condition that they make good any damage they may do to the said apparatus, which includes a photo-spectroscope of great cost, and appliances for high-class scientific, as well as ordinary, photographic work. The theory is, that what belongs to the nation is for the use of the nation, and not almost exclusively for the use of a few salaried officials in the shape of professors.

In Switzerland, at the Government Polytechnic Institute at Zurich, for the sum of one hundred francs a year, or four pounds, the students who can pass the preliminary examination can attend for three years for full instruction in one of the learned professions, such as engineering, architecture, forestry, or chemistry; that four pounds is calculated to about cover the cost of the materials they use. Dr. Lunge, one of the greatest authorities on alkali manufacture in Europe, is the professor of chemistry there, and much in relation to photography necessarily falls within his department. Switzerland spends a larger proportion of its revenue in education than does any other nation in Europe; consequently, when its young men go abroad, say to the Far West of America, they can often get employment when their Anglo-Saxon competitors fail. All other things being equal, the best educated nation will be the most powerful nation, and in the good education of the people rests most of the great strength of foreign competition.

In Germany and Switzerland, a young man is not thought to be at all well educated unless he can speak two or three foreign languages. One effect of this is the comparative ease with which Germans can get employment in England, against those natives of this country who are unable to do the work. Education is of more real value to the individual than money. It also causes a vast reduction in crime, as already proved in England during the last twenty or thirty years, since the nation began to do something in the way of the general instruction of the population.

Government aid in relation to the proposed Institute in London will, of course, not be obtainable. There is much to be said for and against the Government taking up such schemes, and Professor Huxley once expressed at Norwich his opinion that science and its branches should not be fossilised by being largely placed under the control of a State Department. All who took part in the discussion, both for and against Professor Huxley's view, agreed that in such a Department there would be "jobbery," but his opponents thought that it would be better to have the jobbery than to go without the State Department. The proposed Photographic Institute, however, can scarcely be included in the subject of the endowment of science; it is more one of the series of questions relating to the education of the people.

THE London Chamber of Commerce is now taking active steps in the matter of copyright law. Those interested should write to the secretary.

COPYING BY ARTIFICIAL LIGHT.

PHOTOGRAPHERS are often called upon to copy drawings, prints from books, old documents, and things of a kindred nature, and they naturally depend upon daylight for executing the work. But in these dull wintry days it is often impossible, in London and large towns especially, to command sufficient daylight for the purpose, and even if it be not foggy, and the atmosphere should for a time lose its yellow colour, the light is so uncertain from minute to minute, that many plates are lost in the endeavour to get that precise exposure which is so necessary for the production of a negative of the black and white order. The work, too, is generally wanted in a hurry, so that it cannot be put aside for a more convenient season, and particularly is this the case when the negatives are required, as they constantly are at this time of year, for lantern slide production.

Last week was a good sample of dull depressing weather in London, and it so happened that we required a number of diagrams reproduced in the form of lantern slides. Seeing the impossibility of producing the necessary negatives by daylight, as morning after morning turned out to be foggy, we resolved upon making a few experiments with artificial light, a brief account of which may prove useful to those who find themselves in a like dilemma, or who have little opportunity for such work until after sundown.

The diagrams which we had to copy were of two kinds, one set being bound up in an octavo volume, and the others (loose) of quarto size or thereabouts. We resolved to commence on the first, and determined to try paraffin lamps as the source of light. We used a quarter-plate camera, which was placed on a board travelling between grooves in front of the upright easel against which the open book was fastened, and we employed slow plates rich in silver. The lamps, with cardboard screens, which served both as reflectors and shields to prevent the direct light from the flame entering the lens, were placed one on each side of the open book, and as close to the page to be copied as possible. The lens employed was of the portable symmetrical type, stopped down sufficiently to give a sharp image to the corners. Focussing was effected without difficulty with the aid of a magnifier, and an exposure of three and a half minutes gave a negative which showed lines of clear glass on a dense background. One after another the negatives were copied from the book with such certainty that the work became somewhat tedious from the mechanical regularity with which they were turned out.

We next tried the effect of illuminating the diagrams with batswing gas burners, and found that the exposure required was a trifle longer. But the gas presented a great convenience in the readiness with which the two burners—fed from one source by means of a T-piece—could be turned up and down, for development was conducted in the same room as the exposure. In using the paraffin lamps, the light could not be turned low enough without the constant risk of extinguishing the flame altogether. We found that by using gas lamps fitted with albo-carbon burners the exposure was immediately reduced by about thirty per cent., but there was no other advantage in their use.

We next had to deal with the larger diagrams, and to get a sufficiently sharp image the lens had to be fitted with a smaller stop, and as the negative had to be reduced to the same size as those already made, the camera had to be moved to about double its former distance from the easel. The greater size of the diagrams also necessitated increased separation of the two burners. The illumination of the image on the ground-glass screen was, under these conditions, very poor indeed; moreover, the centre was not so well lighted as the sides, a fact that was registered by the first negative which we made. We at once saw that the plan which had served well for the small work would not do for the larger diagrams, and we determined to look for a better luminant.

With a little trouble, another T-piece was connected with a bottle of oxygen fitted with a regulator, and two blow-through lime jets were made to replace the gas lamps. After one or two trials, the right exposure was found to be thirty seconds, using the same lens and stop which we had attempted to employ just before, and the whole of the diagrams were now very quickly reproduced on glass. Having a spare plate in one of our dark slides after this work was done, we tried the experiment of photographing one of the large diagrams with a single lime jet. We did not alter the position of the jet, but let it remain at one side of the copy. To the eye it seemed as if the diagrams were well and evenly illuminated, so bright did it seem in the flood of white light that proceeded from the incandescent lime. But the negative taken told a different tale altogether, one side of it being dense, and that density gradually falling off towards the other side, which was far too thin to yield a good print. A better proof of the truth of the well-known law that the intensity of illumination on a surface is inversely as the square of its distance from the source of light could hardly be demonstrated.

THE ROYAL INSTITUTION.—The following are the lecture arrangements before Easter:—Professor Dewar, six Christmas lectures to juveniles on "Frost and Fire"; Professor Victor Horsley, nine lectures on "The Structure and Functions of the Nervous System" (Part I. "The Spinal Cord, and Ganglia"); Mr. Hall Caine, three lectures on "The Little Manx Nation"; Professor C. Hubert H. Parry, three lectures on the "Position of Lulli, Purcell, and Scarlatti in the History of the Opera"; Professor C. Meymott Tidy, three lectures on "Modern Chemistry in relation to Sanitation"; Mr. W. Martin Conway, three lectures on "Pre-Greek Schools of Art"; Lord Rayleigh, six lectures on "The Forces of Cohesion." The Friday evening meetings will begin on January 23rd, when a discourse will be given by Lord Rayleigh on "Some Applications of Photography"; succeeding discourses will probably be given by the Lord Justice Sir Edward Fry, Professor J. W. Judd, Professor A. Schuster, Dr. E. E. Klein, Mr. Percy Fitzgerald, Dr. J. A. Fleming, Dr. Felix Semon, Professor W. E. Ayrton, and others.

THE DIAZOTYPE PROCESS.

The latest news about the diazotype process, as made known last week at a meeting of the London and Provincial Photographic Association by Messrs. Green and Bevan, who in turn addressed the meeting, is that by means of facilities given to them by Captain Abney in his laboratory, it has been found that the maximum intensity of the action of the spectrum upon diazotised primuline nearly corresponds with the blue lithium line. Nevertheless, the action is strong in the yellow, and this permits the printing by light to a great depth in fabrics; on one occasion they had printed an image by one exposure through six superimposed pieces of sensitised cotton cloth; of course the images decreased in intensity and quality in the lower layers. The fact that the printed image does not interfere much with the passage of light to the sensitive substance below, they consider to be a valuable feature of this new mode of printing. They have not yet succeeded in getting a white background, but hope to do so hereafter; they have, however, discovered a means of changing the pale primrose colour of the background to pale green, and this, they think, may be of use for certain artistic purposes. When they want to "undevelop" a developed image, so that, by means of another solution, it may be brought out a second time, but of a different colour, they soak the print in a hot solution of hydrosulphite of soda, made by pouring a hot solution of bisulphite of soda upon zinc filings, and then giving a good shaking to the containing vessel. At the meeting, they demonstrated the effects of over-exposure by showing that the brilliant displays of colour obtained when the exposure has been right are almost entirely absent when the action of light has continued too long.

INSTANTANEOUS PHOTOGRAPHY.*

BY JAMES MEW.

The exact and proper length of exposure in instantaneous photography is indeterminate. The clear indication of objects in motion depends mainly on the rate of motion. Persistence of vision is found to be variable in different subjects. It may be taken generally to amount to one-eighth of a second. It has been argued from this that an exposure should not be shorter than that quantity of time. The argument is invalid, because the motion of the eye is not taken into the reckoning; but it has been stated on very excellent authority that an exposure of one-eighth to one-tenth of a second is the most suitable for the majority of so-called instantaneous manipulations.

Mr. C. Benuett, in 1878, photographed successfully a bouquet of flowers after it had been watered. In this picture the falling drops from leaf and bloom were distinctly perceptible.

An interesting series of instantaneous photographs of a lance thrower was published in the Photographic News of August in the previous year, which had been taken from the *Photographische Correspondenz*. And in the next year is an account of fourteen negatives taken in San Francisco during the progess of a back-somersault. The pictures of the lance thrower, which were the work of Ottomar Anschutz, are twelve in number, and are full both of scientific and artistic interest. They show the muscular action of the human body under severe strain, and form a pleasing group for the contemplation of the painter. But as a rule, positions in which animals never appear to the sight of the public are to be avoided by artists. This was conclusively demonstrated by the series of extraordinary shapes published some few years back by Mr. Muybridge, of San Francisco. They were actually representations of a trotting horse, Occident—his name is worthy of record—moving at the rate of thirty-six feet in a second, but the difference between the real and actual, and the conventional and ideal movements of this animal was deep and wide. The horse did not, indeed, resemble, as was said by an imaginative critic, "a monster and chimera dire." The outlines remained still exact, but instead of the fore legs being extended more or less horizontally, they were commonly collected and involved in knots of considerable intricacy, and suggested not so much a trot as a fall through the air, a painful colic, or a sudden attack of the staggers. The pictures of the Californian artist showed a marvellous succession of weird and convulsive leaps, though at no time of the transit were all the four legs of the beast lifted together from the ground. The exposure of the negative was less than one thousandth of a second. The photograph was retouched. Had painters and sculptors accepted these attitudes of the horse, however consistent with the eternal veracities, their arts would have become revolutionized with a fell and uncanny result.

In the superior classes of police offices there exists, we are told, a peculiar picture gallery, representing the portraits of the varied criminals known to the force. Evil-doers, from the petty thief who filches a turnip to satisfy his hunger, to the parricide who assassinates, with circumstances of peculiar atrocity, the mother who has sold all her having to supply his needs—sinners who stand on precisely the same footing according to the stoic creed—are, without respect of persons, assembled and gathered together here. To supply the needs of this Nigaristan of felony, instantaneous photography may be fairly used. It is difficult, in fact, without a device of this kind, to take the portraits of these people, although at the expense of their country, and for their country's good. You shall have a naughty person assume—supposing him to be aware that the eye of the camera is upon him—as many forms as the sea god Proteus.

Every reader is probably acquainted with that funny picture of Luke Fildes entitled "The Bashful Sitter," in which a brawny prisoner is held down by a posse of warders and police constables, in order to obtain from him a recognisable portrait. In a case of this kind the instantaneous process comes as a boon and a blessing to the vexed officials. It adds, without any appreciable loss of time, or labour, or money, a capital likeness to the pinacotheca of public scapegoats. But instantaneous photography is not always justified of her children. Where, for instance, it is applied to the detection of a lover's kiss—strictly a private concern—or to the unveiling of the disposition, as shown by the features of a respectable member of the cloth struggling with a refractory and fractured umbrella on a day of wind and rain, and to the subsequent publication of both these incidents of our social life and manners, it seems to desert its proper and

* Concluded from p. 942.

legitimate field of action, and to trespass upon that of those fashionable journals which batten upon the private affairs of a family as communicated by the scullery-maid, to whom they have been whispered by the cook, who has received them as a sacred deposit from the footman, and do what lies in their power to vitiate the taste of a backsliding people, which it should be their highest pleasure, as it is their bounden duty, to raise and to reform.

Instantaneous photography is a commonly attractive bait. Whether it be that the operation is easy, or whether it be a consequence of the desire which is said to animate the minds of the present generation of doing everything in a hurry, may be left for the speculative philosopher to determine. The cause is latent; the fact remains. And yet, though the general arrangement of this business is expeditious, the particular details are not easy. Expense, labour, and inconvenience increase with the size of the picture in a compound ratio. A good apparatus is primarily necessary; then a lens of the best quality; then the calculation of the exposure is by no means simple; then comes the treatment of the plate, concerning which a series of articles contributed by M. Sahler to the *Bulletin de la Société Francaise* should be carefully studied; and then last, but not least, there is that little matter of the shutter. The shutter must be able to give an exposure brief, and variable; it must be simple to work, and of a material to withstand alike heat and cold, moisture and dryness; it must be so constructed as not to shake the camera; it may be large or small, or drop, or flat, or rotary, and every one of these forms has a list of arguments to show its superior advantage. Probably there is no photographic appliance over which more ingenuity and labour has been spent than the shutter. Shutters of curious variety have been manufactured and sold for blank pounds, and other shutters, said by their inventors to answer all the purposes legitimately required of a shutter, for as many pence. The fortunate individual who should receive a sovereign for every shutter that has been invented would be able, in the inelegant but forcible language of our time, to *go a buster*.

In spite of these spectres of the threshold, dear is instantaneous photography as remembered kisses after death to the amateur, for it is the amateur, and not the professional, who chiefly favours this branch of their common art. Your amateur takes pictures, more or less imperfect, of all the moving things on land, on sea, and in air. Breaking waves and rolling clouds are more to him than butcher's meat, or his Sunday excursion to Brighton, or his bank holiday at Wormwood Scrubbs. Occasionally he attempts other things than these: a diving duck and a lazy steam-launch he has considered worthy of his skill; but he commonly leaves the lightning flash, the racing yacht, and the London streets, boxers, cricketers, and tennis players, pigeons, storks, swans, and swallows, and many other varieties of moving life, to more experienced and professional hands, and, in favour of these, he resigns a hardy attempt to amuse and instruct his generation by means of the pheuakistoscope, which, being interpreted, means, as we are informed by the learned, an instrument of optical deception.

Most economical of all photographic processes in the matter of light—the fountain of all their energies—is instantaneous photography. Possibly it is for this reason that it is especially grateful to the sun artist. Whether his light be natural or artificial, he uses the least quantity of it to effect his purpose. The modicum which is next to none at all is sufficient for him. But, like an epicure at a feast, though he wants not much, what he has must be of the best quality. He desires it not long, but he desires it strong. Only when there is none at all procurable will he cry with the world in general, and the poet Martial in particular, whose praise of the life of the aged Antonius Primus, in the tenth book of his Epigrams, has furnished its motto to the PHOTOGRAPHIC NEWS, "*Nulla recordanti lux est ingrata.*"

THE CHICAGO INTERNATIONAL EXHIBITION OF 1892.*

BY JAMES DREDGE.

THE suggestion that a great International Exhibition should be held in the United States two years hence appears to date from the summer of 1889, when the rumour spread that Americans, incited by the brilliant results achieved in Paris, determined that a similar celebration, but one that should surpass in extent and grandeur the Centennial Exhibition of the French Republic, should be held on the other side of the Atlantic. The year 1892 was selected because it will be the four hundredth anniversary of the modern discovery of the New World, or rather, of some of its detached outposts lying to the south-east of Florida. It was on August 3rd, 1492, that Christopher Columbus sailed from Andalusia; on October 12th following he took possession, in the name of Spain, of the Bahama Isles, and two weeks later of Cuba. It was not, however, until nearly six years later, and in the course of his third voyage, that he discovered the American Continent; and in this discovery he had been anticipated by Sebastian Cabot, who had been sent out on an exploring expedition by Henry VII. of England, and who was the first to set foot on the American mainland; this was on June 24th, 1497. The choice of dates was therefore at the option of the organisers of the new scheme, and probably for some reasons it would have been preferable to have delayed the celebration until 1897 or 1898; that, however, would have been to dismiss the undertaking to a rather remote and uncertain future, and it was decided, therefore, that it was the first discovery of Columbus which must be celebrated, and that 1892 should be the year during which the commemoration should be held.

What was only a vague rumour floating over the Champs de Mars last year speedily took serious shape, and it became evident that, on or about the date first spoken of, an International Exhibition would be held in America. There can be no doubt that such a scheme is an eminently practical and useful one. Sixteen or seventeen years will have passed since the great Centennial Exhibition had been held in America; and this long period has been marked by a development of resources, a growth of population, an increase in industry and in riches to which history can offer no parallel.

The President of the United States has not yet issued the invitations of participation to foreign countries, because the financial conditions prescribed by the Act of Congress have only been very recently complied with; but it is expected that they will be delivered within a few weeks.

As regards the Art Section of the Exhibition, two dis-

* A portion of a paper read last week before the Society of Arts.

tinct questions would arise: the first having reference to an art collection worthy of this country, and consisting chiefly of pictures lent for the occasion. Such a course was followed at the Philadelphia Exhibition of 1876 with very satisfactory results; it is obvious that this class of collective exhibit has no reference whatever to commerce, and can only be carried out at a very heavy cost, which may be justified by the desirability of maintaining the credit of British art abroad. The other class of art exhibits has a more commercial object; there are many painters of excellence in this country who find it difficult to obtain and keep so large a number of clients as they desire, and these would undoubtedly find new purchasers in America in spite of the heavy tariffs imposed on paintings. Such an exhibit certainly may not be a representative one, but it would doubtless have the advantage of bringing to many struggling artists in this country a rich and liberal *clientèle*.

THE MAGIC LANTERN IN HOSPITALS.

The following is culled from the *Magic Lantern Journal*:—"We are about to suggest a new method whereby many of those who are, from various causes, cut off to a certain extent for a time from the outer world, may have their burdens lightened. We refer to convalescent patients in hospitals. The intended plan is to give the patients an occasional pleasant evening in the form of a lantern entertainment. Imagine the pleasure with which a person will welcome this exhibition who may have, for a long time, been laid up on a bed of sickness owing to disease or accident, to which all are liable. It is proposed that two or three complete lantern outfits be obtained, exclusively for the use of metropolitan hospitals, in which exhibitions could be given at frequent intervals. We feel assured that there is sufficient liberality and kindly feeling among manufacturers to contribute apparatus for this purpose, which could be placed in the hands of trustees; and we feel equally assured that among the large body of lantern exhibitors many would be only too glad to devote an evening, and conduct an occasional exhibition. It would also be a chance for young exhibitors acquiring experience in the conducting of exhibitions before larger and, perhaps, more critical audiences. A considerable number of slides would be required in order to give diversity to these entertainments; but after once started, we have no doubt that many of our readers would be very pleased to devote two or three slides for such a praiseworthy object. The selection, of course, would be left to the donors, but some suited for the amusement of children should be included." The editor asks for expression of opinion from his readers, so as to be able to announce in his next issue that action has been taken in the matter. The offices of *The Magic Lantern Journal* are at Dorset Works, Salisbury Square, London, E.C.

Action of Borax in Alkaline Developing Baths.—P. Mercier.—Sodium borate is generally considered as retarding the development, yet, as it presents an alkaline reaction, it ought to act solely as an accelerator. The explanation of this apparent anomaly may be found in a research by M. Ang. Lambert, published in the *Comptes Rendus*, and on the action of borax upon the polyatomic alcohols and phenols, and especially upon pyrogallol, hydroquinone, and pyrocatechin. It appears that boric acid combines with the primary polyatomic alcohols and certain polyatomic phenols to give rise to certain boro-conjugated acids. Thus, borax added in small quantities to pyrogallol converts it into a true acid which reddens litmus. It is the same with tannin and pyrocatechin, so that with these substances the addition of an alkaline borate is equivalent to the addition of an acid, the salt in this case causing retardation. But this reaction is not produced with the isomers of pyrocatechin, *i.e.*, hydroquinone and resorcine. Neither is it produced with the ether developing agents now in use. Here borax does not give rise to any acid, and acts merely by its alkaliuity.

PHOTOGRAPHY IN AUSTRIA.

Nomenclature in Photo-Mechanical Printing Processes—Schools of Photography—Orthochromatic Photography.

If one undertakes to write for an English technical journal one must, first of all, keep in mind the difference in the technical terms, for your countrymen often, with the same word, designate things quite different from that which we mean. For example, in all Germany half-tone zinc-etching is called autotype ("autotypie"). This expression was chosen by Meisenbach, discoverer of the reversible liniature, and the term still passes current here, just as the term "autotype" is used in England for the carbon process of pigment printing. The use of the Latin and Greek languages for forming new technical terms has the advantage that these expressions, being internationally intelligible, are more readily adopted than newly formed words in any modern language.

Recently an attempt was made to introduce purely German terms for all photo-mechanical printing processes. The credit of this attempt belongs to Mr. Dietrich Schultz-Hencke, first assistant at the Royal Polytechnic at Charlottenburg, Berlin.

Last spring, at the time of the Easter mass, there was a pretty exhibition at Leipzig. All those firms that occupy themselves with photo-mechanical printing, and who have an interest in bringing their productions to the notice of publishers, took part in it. More and more the illustrating of books devolves on photo-mechanical processes. Often, however, booksellers have but little knowledge of the manner in which the illustrations are produced, and so this exhibition was intended not only to show the best work executed in Germany and Austria, but also to explain the processes, to call attention to the half-finished manufactures, and finally, in the catalogue to give an exact account of of the processes which, when finished, produce pictures which are the delight of the beholder.

Mr. Dietrich Schultz-Hencke edited the popular explanation of the different photo-mechanical printing processes, and gave the following clear summary of them all.

I. *Flachdruck.*—Printing from a plane surface: (*a*) from stone, photo-lithography: (*b*) from zinc, without true deep etching ("Chemigraphie"): (*c*) from glass, with the use of the hygroscopic properties of chrome gelatine, which process is commonly known in Germany as "Lichtdruck," whereas in France and England it is now called collotype; (*d*) from glass, by pouring the chrome gelatine direct on to the negative. This is an imperfect method long since given up.

II. *Hochdruck.*—Printing from an image in relief, by means of the book printing-press: (*a*) from a line drawing, zinc etching phototype, just as the expression typography is used for printing, so the word "typus" has been assigned to those methods which produce forms for book printing. This is called photogravure in France. (*b*) Half-tone zinc etching; printing forms produced by means of a net-work. This is called "Autotypic" in Germany.

III. *Tiefdruck.*—Printing from an image in intaglio: (*a*) "Heliographie," printing with greasy ink from a copper-plate which has been prepared from a pigment relief by means of galvanoplasties. This is suitable for line drawing. (*b*) Woodburytype or relief printing; (*c*) heliogravure, half-tone intaglio etching on a copper-plate, with the help of a gelatine relief, or so-called pigment print.

IV. *Farbendruck.*—Colour printing; can be produced either by collotype I. *c*, or phototype II. *b*.

The special advantage of the catalogne is its intelligibility for laymen—to use that word in its index sense: its disadvantage consists in an impossible attempt at inharmonions word-formations, *e.g.*, instead of heliogravnre, the author expects us for the future to say "Licht Aetzton tief Druck," which, to one of the Latin race, must seem like an expression borrowed from the Chinese.

I had intended to write to you about Vienna, but have been so occupied with the Leipzig exhibition. Vienna has only three great photographic societies: the Photographic Society of Vienna (the oldest and largest of them), the Club of Amateur Photographers in Vienna, and the Union of Assistants, which last is unable to conceive of photographic training without beer. These societies have at their side *Die Photographische Rundschau*, *Die Photographische Correspondenz*, and two monthly organs, Moll's *Notizen*, and Lechner's *Mittheilungen*. These last two are published by business men, who have found out that any printed matter published under the name of a newspaper may be sent at the cheap book-post rate.

There are, farther, three great government institutions at work ennobling photography, and spreading a knowledge of it. Those institutions are the Court and State Printing Office, under the management of Colonel Ottomar Volkmer, an authority in electrotechnics: the Teaching and Experimenting Institute of Photography, under the direction of the learned Dr. J. M. Eder; and the Military Geographical Institute, which, in its photographic department, possesses several coryphenses, of whom Mr. Emmanuel Mariot, Baron Hubl, Mr. Rudolph Maschek—director of heliogravure—and Mr. Francis Fiek long ago won for themselves a name in literature.

For to-day I will confine myself to calling your attention to an excellent article by the above-mentioned Baron Hubl in vol. ix. of the *Mittheilungen* of the Institute, containing an account of all the photo mechanical printing processes, and especially of the orthochromatic process. This excellent chemist arrives at the same conclusion as that so clearly proved by Captain Abney, namely, that the expression "optic sensitisers" is an altogether unsuitable one. Dr. Eugen Albert, of Munich, has made a hole in the absorption theory by using yellow ammonia salts of picric acid in collodion emulsion, which, it is true, absorb the blue rays, but do not thereby sensitise the plate for blue, but, on the other hand, almost annul the blue action. At least, to a man's common sense, it is thus made clear that the sensitising for single colours does not depend on the absorption of the ray of light by the colours added, but that the colour must be so decomposed as to act chemically on the silver bromide. This fact is very bad for the adherents of the opposite view; but, clever as they are, they have found a way out of the trap, and assert that the colouring materials act sensitisingly with certain coloured rays only if used homœopathically, and, at the same time, mixed with the emulsion; if put on the plate in greater concentration they act as a screen. The fact therefore appears to be that optic sensitisers, as soon as they act optically, are no sensitisers, but the very opposite. Styx.

Camera Club Notices.—Monday, Dec. 15th, dark room closed from this date, dismantling for removal; Thursday, Dec. 18th, 5.45 p.m., general meeting to consider alteration of rules. No meetings will be arranged for between Dec. 18th and Jan. 8th. No smoking concert on Jan. 5th.

PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

Meeting of the Permanent Commission of the International Congress—French Photographic Society: Installation of M. Janssen in the Presidential Chair—Damoizeau's Panoramic Apparatus—Photographic Cravat—Development with Hydrokinone by M. Balagny—Pusset's Hand Apparatus with Rapid Change—Cutting Board for Glasses—Re-opening Meeting of the Photographic Club of Lyons.

The permanent committee of the International Congress of Photography, which includes Messrs. de Bloehouse (Belgium), the Prince de Molfetta (Italy), Gylden, Sweden (hon. president), Janssen (president), Davanne, Marey, Wolf (French vice-presidents), Drs. Vylder (Belgium), and Petterson. Denmark (foreign vice-presidents), Pector (general secretary), Leon Vidal, Londe (French secretaries), Wada (Japan), and Skinsievitch (foreign secretaries), Gen. Sebert, A. Martin Cornu, de Villechole, Bordet, Perrot de Chamenx, Warnerke, and Fabre (members), held a meeting on the 5th December, 1890. At this meeting there were present, amongst others, Messrs. de Bloehouse, Warnerke, and Wada, foreigners. The object of the meeting was to arrange for placing in the hands of the Belgians the works resulting from the labours of the Paris Congress, for the purpose of the new international congress which is to be held at Brussels in August, 1891. It is to be hoped that many persons authorised to represent England, Germany, Austria, Russia, and other countries will then be present.

I have never thought that the decisions of the first Congress could be taken as without appeal, and I have reason to think that at Brussels there will be a revision of the decisions that up to the present are provisional. We must not hide from ourselves that there are points on which accord will be difficult: nevertheless, some greater progress will be made in the direction of a more important and far-reaching community of understanding.

At the meeting of the French Photographic Society held on the 5th inst., M. Janssen, the elected president, inaugurated his occupation of the presidential chair with a speech as eloquent as witty, in which he broadly traced the work already accomplished by, and the future of photography. He passed in rapid review the services rendered by it to science and art. To science, it constitutes an admirable means of control, of observation, and of registration. To art, it plays not only a documentary part, but produces really artistic work, worthy of forming a new class amongst those the assemblage of which constitutes what are known as the fine arts.

The discourse, which was much applauded, leads us to hope for the active assistance of the worthy M. Janssen to the French Photographic Society. Messrs. Warnerke and de Bloehouse have been invited to accept places in the bureau.

An interesting communication has been made by M. Damoizeau relating to a panoramic apparatus, capable of including upon a single pellicular film, by a combined movement, the whole circle of the horizon. The motor is a clockwork movement acting on the end of the camera and the pellicle cylinder in such a manner that these two movements are synchronous. The pellicle may have a

length of from five to ten metres, but the apparatus may be used either for the entire range of the horizon, or for any desired fraction of it. The band is perforated by a set of teeth actuated by an outside handle, to show how far it has been exposed, and a register shows how much of the pellicle is left upon the cylinder for future use. This apparatus supplies a perfect solution of the problem of panoramic photography. The bulk is inconsiderable, and panoramic views are obtained by it of three metres by fifty centimetres. Remarkable specimens have been shown by M. Damoizeau on "cristallos" pellicular bands.

The apparatus may be reduced to very small dimensions for views of nine centimetres in height. We think that science and art will derive an advantage from an apparatus so ingeniously combined. Let us add that the rolls of pellicular band may be changed in the open light, thus adding to the practical utility of the apparatus. The movement is capable of working at varying speeds, allowing us to give longer or shorter exposures, according to the sensitiveness of the film and the intensity of the light.

A photographic curiosity has been presented by M. Block under the title of photo-cravat. This apparatus is rather a toy than an instrument of importance, but it is ingenious, and proves that something else may be done besides the photo-gibus (hat) and the photo-waistcoat. Soon we shall have all the parts of the costume utilised, and for the ladies there will be photo-brooches, photo-bracelets, &c., and for men there will be photo-canes (or umbrellas), photo-portfolios, &c., not forgetting the old photo-opera-glass. But to return to the photo-cravat. The lens is fitted in a pin having the form of a horse-shoe; the focus is two centimetres; the shutter is worked by a pneumatic ball hidden in one of the trouser pockets; a button serving to change the plate passes through one of the button holes of the waistcoat; and now we may work the apparatus at a distance of one or two metres, provided that we have not a beard, which would mask the lens, and that we have not too prominent a chest, so as to point the camera towards the celestial regions.

M. Balagny, who is for France the hydrokinone made man, for it is he who has, so to say, introduced it there, although it was known elsewhere—notably in England—for a long time before, thinks the moment opportune for returning to the question, now that ideas are clearly formed as to the action of this developer. He recognises that the means of having a developer which does not become darkened in colour is to employ the caustic alkalies, ammonia, soda, and potash, in place of using alkaline salts, such as the carbonates of ammonia, soda, or potash. He prepares his baths with two solutions, one containing hydrokinone, sulphite of soda, and water, and the other containing caustic potash. He adds to the developer bromide of ammonium and also yellow prussiate of potash. If, says he, two baths are prepared, one with carbonate of potash and the other with caustic potash, the first will be seen to redden, and afterwards turn black, whilst the second will remain perfectly uncoloured. One quantity of solution serves to develop many negatives in succession, all endowed with great softness. He showed about forty, of 24 by 36 centimetres, on pellicular films that were very remarkable. The ideas put forth by M. Balagny are in agreement with those expressed by Mr. Reel, and to be found in a little work just published by the house of Ganthier-Villar and Son.

Again new hand apparatus, this time by M. Pusset, very ingenious, and in which the change of plates is effected with incredible rapidity.

It is at the present time with hand-cameras as it was recently with exposure shutters—each day brings forth a new pattern.

We have a multiplication of apparatus intended to realize the first solutions proposed by the International Congress. Messrs. Gilles Brothers have just presented a cutting-board for reducing, for instance, a plate of 13 by 18 centimetres to 12 by 18, the size adopted by the Congress. Of a truth the method is not new, and we have for a long time past known similar cutting-boards made by Mr. A. Cowan.

The Photographic Club of the South East at Lyons had an important re-opening meeting on the 15th of last month. A great Conference was organised, at which more than 500 persons assisted. The member of the Conference whose name heads this article selected as a theme "Photography and Colours." Projections in stereoscopic relief were shown; then a demonstration was given of the diazotype process, accompanied by a description. A superb banquet was offered to the writer. It is gratifying to see photographic emulation excited to so high a pitch in the most important, after Paris, of the French cities.

THE SOLAR CLUB.

Last Monday a dinner of the Solar Club, to celebrate its twenty-fifth anniversary, took place at the Café Royal, Regent Street, London, under the presidency of Mr James Glaisher.

The members of this luminous club call each other "rays." Ray Mill, vice-chairman, responded to the toast of "Success to the Solar Club," by saying that Rejlander, who was his predecessor in the "seat of Vice," used to be the great man of the Club; he was the Landseer of photography. The toast of "The Old Members of the Club" was coupled with the names of Messrs. Francis Bedford, Frank Howard, William Eugland, H. P. Robinson, Valentine Blanchard, and John Spiller, several of whom responded. Then, in impressive silence, "The Memory of Departed Members" was received by those present, all standing up; the names of those given were J. H. Dallmeyer, Samuel Fry, Jabez Hughes, O. J. Rejlander, and G. Wharton Simpson. Next the toast of "The Press" was responded to by Messrs. Harrison, Hastings, and Pearce.

The toast of "The Guests" was responded to by Mr. Barr, Major J. F. Nott, and Mr. Frank Howard. Mr. Barr complained of the gorgeous costume, in the shape of evening dress, he had been compelled, as he thought, to put on, to attend that dinner. He knew that English shirt studs were of no use, so had bought two before he left New York. One of them had a kind of spiral, which first had to be screwed into the bosom of the shirt, and then with a pricking sensation screwed itself into the bosom of the wearer thereof; he could compare that stud to nothing but conscience, and he had a bad one. The other stud was in two pieces, one of which had to be inserted in the linen from the front, and the other from behind. They would have known something of his sufferings had they seen him and a gentleman in the same compartment of a Metropolitan Railway carriage searching about the floor of that carriage with lighted vestas to find the two halves of the stud. When found, the problem was to restore them to their proper position in the shirt; the part that had to go into the front was right enough, but as to the part which had to go in from behind, when in a train which pulled up at a platform every two minutes—there came the difficulty. At each stopping place a little knot of observers began to gather on the platform opposite their window. He did not think that the Solar Club did its duty; for the last two months he had not seen the sun, and the club ought really to buckle to its duties, and attend more industriously to the working of the solar system.

After an impressive speech from Mr. Tom Archer, the Chairman said that he would not follow the subject of shirt studs, and that when he was in New York he truly got plenty of sunlight, but when he looked at the photographs in the windows he saw that the strong light often caused plenty of loss of half-tone not usually seen in English photographs, and in that city there was a bitterness of cold in the winter not experienced here. Their "chancellor for the dinners" had given them some sunlight that evening; he would propose his health. To this Ray William England responded.

Ray John Proctor had heard the proverbial remark about the heads of Scotchmen and the surgical operation; it was

not generally known that it was not the business of Scotchmen to laugh at bad English jokes, but to make good ones for the world at large. He then fired off several humorous Scotch anecdotes.

Mr. Glaisher then had to leave, and Mr. William Clark took the chair. Songs, music, and recitations of good quality at the beginning, and better quality as time wore on, then

enlivened the company; those who took part in this form of entertainment were Messrs. Wilson, Proctor, Blanchard, Pearce, Fitzgerald, Protheroe, Cadett, and Seamell.

The above cuts represent two Solar Rays as they appeared last Monday night. One of them is a speaker of great dramatic power, the other a brilliant foreign *savant*, admired and beloved by all who know him.

THE PHOTOGRAPHIC CLUB.—Subject for discussion on December 17th, "Photographic Plaything"; 24th, no meeting; 31st, lantern night.

CHLOROPHYLL AND LEAF GREEN.*

BY W. N. HARTLEY.

THE author refers to the numerous memoirs on chlorophyll of Stokes, Sorby, Chautard, Timiriaseff, Pringsheim, Reinke, and of Russell and Lapraik and Schunck. Having been occupied at various times during the last seven years in an investigation of the different colouring matters described under the name of chlorophyll, he has deemed it advisable to present his results to the Society without awaiting the further development of the research. The subject matter may be conveniently arranged under the following heads:—

a. Observations on the spectrum of chlorophyll contained in living tissues.

b. The spectrum of chlorophyll as seen in dried leaves.

c. Mode of extracting leaf-green unchanged, and separating the blue from the yellow chlorophyll.

d. Measurements of the spectra of the chlorophylls.

1. Living tissues which are fresh and young, and which, therefore, contain the leaf-green unaltered, exhibit no trace of a band in the yellow close to D, such as is usually attributed to chlorophyll, and there is no indication of one in the green. Complete absorption, just beyond *b*, extends through the ultra-violet.

2. *Yellow chlorophyll* has a distinct absorption band in the red differing from that of *blue chlorophyll*. It has likewise a distinct fluorescence.

3. When light is concentrated on living tissues, the absorption spectrum of the green colouring matter is soon altered.

4. Separation of *blue* from *yellow chlorophyll*. The *blue chlorophyll* may be extracted from minced leaves by cold absolute alcohol, and may be precipitated by addition of baryta. The *yellow chlorophyll* is not so precipitated, or not precipitated so readily.

A warm solution of boracic acid in glycerine, mixed with a little alcohol, liberates the unchanged blue chlorophyll from the dried barium compound.

5. The *blue chlorophyll* exhibits two absorption bands in the red, close together; in the less refrangible region of rays one overlies B and the other overlies C. There is a feebler band near D.

6. Concentrated solutions of *yellow chlorophyll* in benzene are brownish in colour, and exhibit a magnificent red fluorescence.

When *blue* and *yellow chlorophyll* are separately treated with formic acid and ether, there are produced two new substances showing absorption bands in the green. It is believed that when these bands have been observed, either in preparations of chlorophyll or in living tissues, that the chlorophyll has been altered by oxidation of formic aldehyde in the plant. The oxidation could be caused in living tissues by an excessive degree of illumination, which causes the destruction of the tissues, and otherwise by exposure of the contents of the plant cells to air or oxygen. An excessive illumination causes an exceedingly great activity in decomposing carbonic acid, and probably oxygen cannot be respired sufficiently rapidly; hence there may be a reverse action, or an oxidation of formic aldehyde to formic acid.

The leading characteristics of unaltered leaf-green are those of *blue chlorophyll*, namely, an intense absorption in the red, stronger even than in the violet or ultra-violet.

* The *Chemical News* abstract of a paper read before the Chemical Society.

FIGURES IN LANDSCAPE.

BY J. GALE.

How often we see photographs of charming scenery marred and spoiled—in some few cases by the introduction of figures at all; in others, by figures of inappropriate character; in others, again, by figures occupying ridiculous and impossible positions.

In the old days of slow plates, when the making of a negative involved a considerable amount of care and pains and trouble, particularly with the most rapid of the processes then worked (I mean wet collodion), photographers thought twice before introducing figures into their landscapes, and running the risk of the plate being spoiled by their movement, possibly by their walking altogether out of the picture during the exposure.

I have had many opportunities of observing how uninterested the modern worker is in photographs taken in those times; it is not owing altogether to the fact that he will not admit that anything good can have been done by his predecessors, nor to the fact that they are printed in silver, and consequently have faded, and present a worn-out and seedy appearance, but largely to the circumstance that there are no figures, or, if they do appear, that they do not form a conspicuous feature in the landscape.

Now, there are some kinds of landscape, comparatively few, however, where figures have no right to be.

> "There is a pleasure in the pathless woods,
> There is a rapture on the lonely shore,
> There is society, where none intrudes,
> By the deep sea, and music in its roar;
> I love not man the less, but Nature more."

But even this implies the presence in the scene of the poet himself. How lucky the photographer would be if he could only catch him—Lord Tennyson, for instance, with his cloak and slouch hat! He would be quite worth 6d. an hour as the model.

Most landscapes which can be rendered by photography may be improved by the introduction of a figure or figures. There may be some subjects where it is open to question whether figures are admissible or not. For instance, in "the lonely shore," would the loneliness be the less intense by the appearance of a wrecker gathering up the flotsam and jetsam after the storm? The poet, in his endeavour to impress us with the intensity of stillness, introduces several distinct noises.

* * * * *

> "And all the air a solemn stillness holds,
> Save where the beetle wheels his droning flight,
> And drowsy tinklings lull the distant folds.
>
> "Save that, from yonder ivy-mantled tower,
> The moping owl does to the moon complain
> Of such as, wandering near her secret bower,
> Molest her ancient solitary reign."

Would the solitude of the wild common, all snow-and-hoar-frost-bound, be less intense by the presence of yon old hag gathering up her bit of firewood? Again, the poet has his "all but" in describing the desolateness of the deserted village:—

> "For all the bloomy flush of life is fled:
> All but yon widow'd solitary thing,
> That feebly bends beside the plashy spring;
> She, wretched matron—forced in age, for bread,
> To strip the brook with mantling cresses spread,
> To pick her wintry faggot from the thorn,
> To seek her nightly shed, and weep till morn,
> She only left . . . ."

The mountain stream, wild and impetuous, should not have the cockney companion of your travels sitting perched on a rock staring into the camera—an unpardonable blunder often perpetrated; but a fisherman, suitably apparelled, dropping his fly in the pool at the tail of the rapid, would probably not detract from the wildness of the scene. Nor would the Matterhorn lose in vastness, majesty, and impressiveness by a group of roped and axed climbers in the foreground, on the very edge of a yawning crevasse.

On the other hand, it is not open to question that there are places where it would be worse than a blunder not to have figures. What should we think, now, of a photograph of the Bank of England or London Bridge figureless, or occupied by one policeman with nobody about to "run in" but the photographer? These busy haunts must be represented as we daily see them, teeming with the stir and animation of countless crowds; and yet it is not so very long ago that the photographer had to get up at five o'clock in the morning to avoid the crowd and do his work unmolested. In rural scenes, also, surely the costume must be considered; and the faultless garb of Hyde Park and Rotten Row be omitted if possible.

If the photographer *is* to introduce figures, let him beware of placing them where nobody but a lunatic would stand—in the middle of a bog, or risking his neck poised on a rock. There can be no question that round about a cottage is the normal and natural place for figures; and when and where figures are usually to be met with, then and there we cannot be wrong in including them in our view, provided they are of the right type, and not got up in their best clothes for the occasion. The placing of them must be left to the individual taste and fancy of the operator, but let there be an apparent motive for the placing. A skilled grouper will allow them sometimes to drop down haphazard, and then arrest them so that their position shall contribute to the composition of his picture; but he will generally find it necessary to carry out his already-formed ideas, and carefully group them in his own way.

Some children—and, for all that, children of a larger growth too—cannot, and cannot be made to, sit or stand easily and naturally when it is expected of them. Give them a penny to go away and buy some lollipops in the village, for a figure with a look conscious of the presence of the camera will spoil the view. Be very careful as to allowing even one figure of the group to look at the camera. Nothing can, now-a-days, be considered to be *even in the direction of* a picture where a whole lot of figures are gaping into the lens. It is scarcely admissible to find such a state of things in a group *other* than human, and it is better to avoid it in one's studies of sheep, cattle, and other animals irrational.—*The Journal of the Camera Club.*

Improving Poor Negatives.—To improve a poor negative and modify extremes of light and shade, cover the whole of glass side of the negative with any ordinary negative varnish in a cold state. Scrape off as much of this coating opposite the densest parts as is necessary, and if there are any very thin spots in the negative, a little Prussian blue water-colour may be brushed over the varnish to still farther soften the printing through these parts. Of course this dodging has to be done with judgment, or the resulting print will be wanting in those very qualities of which it had an excess before. If the first experiment in this direction is not successful, the whole coating may be cleared off by methylated spirit, and done again.—*Scraps.*

Notes.

According to an American Journal, *The Picture and Art Trade*, the demand in the United States for high-class works of all kinds is steadily on the increase, and has been growing rapidly for some years past. It is said that the chief studios of France, Germany, Italy, and Spain are almost emptied. All the old work, particularly of the Barbizan school, which was in the hands of dealers or in the possession of collectors of small means, has been bought up, and the living painters whose canvases are in demand have orders for work beyond their power of turning it out for a long time to come. The demand is not confined to paintings; rare etchings and engravings are also sought after. As the Americans grow more wealthy the taste of many of them is turning in the direction of high art, which is a good sign, as first-class pictures have a refining influence.

The London Chamber of Commerce is now exerting itself in relation to the improvement of home and international copyright laws, in which subject four of its sections are interested, including the one devoted to photography. These four sections keep in communication with each other by means of two delegates appointed by each of them, making eight delegates in all. At present, the chief points of interest are the prohibitory enactments of the American Copyright Bill. In France, activity prevails about similar subjects. The Minister of Foreign Affairs, at the request of the Russian Government, has asked the Syndicate for the Protection of Literary and Artistic Property to furnish a precise enumeration of the facts relating to the illicit reproduction in Russia of French works of art of any kind, to the injury of the rightful owners, since the abolition in 1887 of the arrangement about literary and artistic property made between the two nations in 1861. The Syndicate has specially mentioned photographic piracies as one of the subjects about which it desires information from those who have suffered. The general secretary to the Syndicate is M. Germond de Lavigne.

Haze is a subject of interest to photographers, especially at this time of year, when fogs so much interfere with photographic work in the studio. Mr. Aitken has given the Royal Society of Edinburgh his experiences on this subject. The formation of haze depends much upon the condensing power of the dust in the air, so Mr. Aitken's plan was first to collect some of this dust from different situations upon glass plates, and afterwards to find at what temperature above the dew point the special kind of dust condensed the vapour of water in the air. He found that magnesia dust has small affinity for water vapour; that gunpowder smoke has great condensing power; that dust collected in a smoking room has greater power of condensing vapour than dust from the outer air. He came to the conclusion that there is no definite line of demarcation between hazy and clear air, and that the air is never entirely free from mist. Whenever the air is dry and hazy at the same time, it always contains a considerable amount of dust.

The first Friday evening lecture of the session at the Royal Institution will be delivered by Lord Rayleigh, on "Some Applications of Photography," and is sure to be of interest. Lord Rayleigh is well versed in photographic optics, the properties of lenses, and is a high authority on the subject of light. One curious fact which he discovered, and proved experimentally, is that, by the suitable admixture of the pure green and the pure red of the spectrum, a bright yellow colour can be produced. He has also sometimes charged water with certain salts until the colourless solution had the same effect upon light as glass, so that a glass rod became invisible throughout the length of it immersed in the liquid.

At the complimentary banquet which was given last week at the Hôtel Métropole to Mr. W. L. Thomas, the originator of the *Graphic*, to signalise the coming of age of that paper, there were gathered together nearly three hundred guests, among whom were many of our leading artists and literary men. The speeches were necessarily much about art, and, of course, photography came in for its share of recognition as an aid to those who wield pencil and brush. Prof. Herkomer, the chairman, in giving an interesting retrospect of his career, alluded to the time when he was so "hard up" that he found a difficulty in scraping together the sovereign which he paid for his first block of wood twenty-one years ago. At that time, he reminded his hearers, the artist had to draw direct on to the wood, and, in the process of engraving, his work as a drawing was necessarily destroyed. Now it is different; the artist draws on paper or cardboard, and the image of the drawing is photographed on to the wood block. The original thus remains intact, and retains a value which is measured by the status of the artist.

This power of preserving drawings intended for book or newspaper illustration is one of the boons which photography has conferred upon artists and publishers. The first can point out that after their drawing has been transferred to wood it will still remain a valuable property, and on that ground can command a better price for their work. The importance of the matter from the publishers' point of view may be estimated by the circumstance that every year Messrs. Cassell hold a "black-and-white" exhibition, consisting of works which have been executed by well-known artists for their various publications. These are offered for sale at a price varying from one to twenty or thirty guineas.

At the same banquet photography came in for recognition in another field of usefulness. Colonel Fitz George, in replying to the toast, "The Army and Navy and Auxiliary Forces," took occasion to pay a tribute of admiration to the courage shown by special

correspondents and artists, who have often followed the fortunes of a campaign and have shared its dangers. He prophesied that the war artist of the future would depend more upon the camera than the pencil, and ventured to parody Tennysou's poem by speaking of the troops as having "Kodaks to right of them, kodaks to left of them, &c." Another speaker thought that artists and photographers would be unnecessary in future warfare, because means would be found to telegraph the images of passing events direct to the editors at home. This last sentiment met with so much cheering that it was evident that there were not many practical photographers present among the guests.

We have had the opportunity of examining a few of the portrait negatives taken by flash-light by the apparatus designed by Messrs. Slingsby, and made by Marion and Co. These portraits show no trace of movement or uneasiness about the eyes, and indeed cannot be distinguished from ordinary daylight negatives. The secret of success seems to lie in using a quick shutter attached to the lens, in conjunction with a battery of flash lamps, in such a manner that the exposure is terminated before the flash is over. By this arrangement the sitter has not time to be startled, or surprised, or to signalise his feelings by a wink before the image has been secured and the lens shut up. It would seem that the magnesium flash is like that of lightning, far slower than it was supposed to be, and this device of the auxiliary shutter successfully copes with the difficulty.

M. Marey will shortly have very few worlds to conquer in regard to the photographing of the animal world in motion. He has already conquered the beasts of the field, the birds of the air, and he is now assailing the fishes of the deep. In other words, he has succeeded in photographing the movements of an animal under water, taking pictures at the rate of fifty in a second, with exposures of from $\frac{1}{2000}$ to $\frac{1}{3000}$ of a second. A set of twelve photographs gives all the phases of the undulations which the medusa impresses upon its umbrella of a locomotor apparatus. Another series exhibits a squid leaping out of the water. A ray has been taken in profile while waving the edges of its flat body; and the curious mode of progression of a cometula has been taken. We shall next hear of him photographing the rapid fluttering of the wing of a dragonfly.

Of late, the art of photographing from a balloon has advanced very much, and the results now obtained leave little to be desired so far as detail is concerned. *La Nature*, in its current number, reproduces an excellent plate of a view of Nice, taken at three hundred yards distance by M. A. Weddel in the captive balloon of M. Louis Goddard, at the commencement of the present year, in March, 1890. The apparatus is suspended from the neck with a strap, leaving the hands free; then, by a screw arrangement, the camera can be turned in any direction, and, when turned towards the subject to be secured, whether it be a neighbouring cloud or a town beneath the balloon, there is nothing left to be done but to use the shutter at the given moment.

The *Daily News* endorses the opinion expressed in these columns more than once, and repeated last week, that "many of our artists have not yet learned the technique which best suits processes." Our contemporary is of opinion that the reason why our foremost novelists do not have their books illustrated, as used to be the case in the days of Dickens, Thackeray, Lever, and Trollope, is to be found in the present methods of illustration. To replace engravings in copper, steel, and wood, we now have "processes"—photographic or otherwise—which too often produce the most hideous and undesirable results. By one method, all creation is made out to exist in various shades of "shepherd tartan" black and white checks. By another, pen drawings "come out" painfully scratchy. This, as we have before pointed out, is unfortunately true. There is certainly need for some artistic and unconventional genius to set a new fashion in drawing for photographic reproduction.

It is only natural that the *Undertaker*, the organ of Mr. Mould and his colleagues, should rush to the defence of the practice of placing photographs on gravestones. It joins issue with another journal which prints a paragraph to the effect that the method of having photographs over graves is not a new one. The paragraph goes on to say: "In Hungerford Churchyard there has been for eight or nine years a gravestone upon which is placed the photograph of the person interred beneath." On this the journal in question comments to this effect: "We think the less this idea spreads the better. There is a coarse realism about it which is, we think, not in good taste." We must confess we coincide with the *Undertaker*, that it is rather difficult to see where the coarseness comes in. The only exception we would take to the practice is where the photograph is of such a fleeting nature that, when faded and discoloured, it gives what an imaginative mind would conceive to be a very realistic resemblance of the person buried. As to the date when the practice first came in vogue, we fancy that it extends to a much earlier period than eight or nine years ago.

Printing in colours by a single operation is as much of a will-o'-the-wisp to the printing enthusiast as is photographing in natural colours to the photographic enthusiast. Processes are continually being discovered, only to be rapidly left alone. The latest invention is that by a young Wisconsin man, A. P. Hanson by name, who is now a resident of Copenhagen. He calls his invention a colourgraph. By it two or three or even more colours can be printed on the same paper at one impression. As yet it has not been adapted to printing.

ARTIST PHOTOGRAPHER—A CLAIM FOR LIBERTY.*

BY HENRY E. DAVIS.

If the artist is a man whose efforts are likely to be of any worthiness, if he really has any artistic perceptions of any value, he will know that dogmatism in art is absurd and an impertinence, and only to be broached by enthusiasts who have lost their heads over a fad to which they are so far committed that they are bound to *see it through*, however disastrous the end of such pretensions may be to themselves. But, unfortunately, they have disciples among those who mistake eccentricity for merit, and, having really no artistic perception whatever, think that, by following the beckoning of some "Sir Oracle" more or less misinformed, they can be manufactured into artists. The true art student quietly pursues his joyful path, while these pretenders to exclusive taste have all, more or less, the *cacoethes scribendi* and *loquendi*, and fill the societies' meetings and the journals with their twaddle, founded chiefly on the perusal of Ruskin and kindred authors, whose best points they miss in their desire to imitate, at a great distance, a style generally grandly eloquent, but frequently deficient in sound reasoning. I often wonder what John Ruskin would say in reply to a demonstration of the views of a naturalistic photographer. My impression is that he would recommend him to attend an elementary art school for a month as a preparation for studying his "Elements of Drawing."

What do the naturalistics require from the artist photographer? They apparently agree on one point, viz., that excessive hardness of detail is not conducive to artistic effect; here, with occasional exception, the painter will be generally with them, but they propose to obtain softness by putting the picture wholly or in part out of focus. This is the weak point of their claim for recognition. The fact is that, with all their study of art and art criticism, they have ignored what is generally the principal factor in the production of a picture—colour, and the media with which it is used—whereas the artist photographer is limited to monotint executed by a printing process. They have not perceived that much of what they see exhibited depends for the effect which they wish to secure, not on being painted with varying focus, which no true artist would do, but on the technical training of the artist ensuring the use of his vehicles in such manner that the heavier detail of his picture sinks in more or less, according to his style or the requirements of the occasion, and that he is able to strengthen or lower the effect of his picture in parts by retouches of colour or other mechanical means. This is a method of proceeding exceedingly difficult for the artist photographer. If retouching a photograph is once allowed, it is impossible to limit the extension of the practice, and such treatment carried to excess would eventually result in what would virtually be a painting.

Nevertheless, there are, to the accomplished photographer, many legitimate ways of dodging and modifying his results, which give him considerable latitude in the manipulation of his pictorial effects. Nor must the facility of improvement by the use of isochromatic plates and tinted screens be forgotten.

The naturalistics, having concluded that everything should for their purposes be more or less out of focus, a further discussion has arisen among their disciples as to what limitation is to be put to this out-of-focus system, and it is actually a subject of debate among them whether or not a circle of confusion of one-hundredth of an inch is the allowable limit or not. Shade of Appelles! Only imagine an intention to regulate artistic execution by minute mathematical calculation.

In fact, what the naturalistics want to do for us poor suffering photographers, is to establish a fixed style for the worker, in which only he is to exhibit the pictorial exposition of his artistic conceptions. But what should we say of an art critic who picked out the highly finished but occasionally somewhat hard style of Landseer, any one of the varying styles of Turner, the plucky impasto of Constable, the minute execution and delicacy of Meissonnier, or the fanciful imaging of a Whistler, and declared that that one he pointed out, and that one only of all these varying styles of execution, is "the only correct and genuine one, all others are counterfeit. N.B.—See the name on the frame"? Would such a teacher meet with encouragement elsewhere than in a farce? And yet the naturalistics have received attention from photographers.

The object of art is to secure admiration and sympathy; its factitious regulation by a narrow-minded clique is impossible. I claim freedom in his work for the artist photographer from these attempts on his liberty of style. If photography is to be used for pictorial purposes, the performer of the work should be left free to adopt his own method for his ultimate object. It would then be that after a time the more able of the artist photographers would gradually form styles each more or less individual, so that it would be possible for a visitor to a photographic exhibition to point to a good picture and say at once, "This is a Smith, or a Jones, or a Jenkins," as the case might be, in the same way that a visitor to the Royal Academy Exhibition can point out a Millais, a Leighton, or a Long. I wish it may in the future truly be said, "By their works ye shall know them."

There has been within the last two or three years a great advance in the manipulation of photography for art purposes, but if the producer of good work is to be trammelled by quack ordinances, then the result will be that, though much good work may continue to be done by lovers of art for its own sake, it will be seen only in the homes of the artists, and will not be sent for public exhibition until there is evidence that the naturalistic craze has ceased to influence the hanging and judging committees.

Art conception is the property of no set of men. The failure to have received any technical education may, in a multiplicity of cases, prevent its expression, but we find it permeating "all sorts and conditions of men." The hard-worked mathematician or banker may find relief in picking out beautiful subjects from the glorious scenes of nature, and feel himself refreshed and ennobled by the ideas which his selections may induce; nor are men of more humble standing, even the illiterate, debarred from the enjoyments of such imagination. Oftentime, wandering away from home, we meet with a humble labourer, to whom has been vouchsafed the capacity for the mental elimination of the special beauties of his loved country side. This man will show you the most lovely bits, the quaintest prospects, for miles round his lowly abode, and his enthusiasm for the beautiful, perhaps roughly expressed, will ensure the artist appreciating in him a brother who truly "Finds tongues in trees, books in the running brooks, sermons in stones, and good in everything."

Literary Notices.

LANTERN SLIDES BY PHOTOGRAPHIC METHODS. By Andrew Pringle, F.R.M.S. (*New York: The Scovill and Adams Co., 423, Broome Street.*)

THIS book is of special interest at the present season, when so many persons are engaged in lantern slide work. The principle upon which the author has acted, is to select a few of the best processes for making the slides, and to describe them minutely, for beginners in any process are frequently at a loss when working from instructions in books, in consequence of the authors having omitted to state useful little points of detail. At the present time, this is likely to be the case in relation to lantern slide making by any of the collodion processes, so many individuals having been born into the photographic world since the advent of gelatine dry plates. Another good point about the book is, that Mr. Pringle writes about those processes alone in which he has had personal practical experience, and photographers in this country know him to be a safe guide in such matters.

As to the artistic value of lantern slides, he expresses the following opinion:—

We see it asserted in a book professing to teach art to photographers that a lantern slide must be outside the domain of art. The writer of this book says nothing whatever in defence of this position of his: he bases it simply on his authority, which, to many minds, will not be enough to condemn slide making. As a matter of fact, an image projected on a screen through a slide may be just as good or as bad from an artistic point of view as a paper print. Practically, such an image is a print on paper, cloth, or in *fresco*; but it is large, and is not persistent. That the ordinary run of slide images are incorrect in "values," wanting gradation, false in "tonality"—whatever that may be—is possible; but that these defects are inherent in and inseparable from slides is a ridiculous and false assumption.

That Mr. Pringle is right in his contention seems to be proved by the circumstance that on rare occasions a lantern picture excites the feelings of the observers—for instance, the Camera Club journal once printed that a picture of the St. Gothard Tunnel had been so projected, and that it had a "weird" effect. Among the photographs brought home from Iceland recently by Dr. Reynolds, and printed as lantern slides, is one in which two men in a dark, shadowy region are seen entering the cloud of steam rising from a boiling spring in the mountains; it might well serve to pictorially represent one of Dante's descriptions of places in the infernal regions. The modern costume of the two individuals somewhat detracts from the romance of the scene, but that could be altered another time; moreover, no Act of Parliament has yet been passed exempting British-born subjects of the present time from entrance into those regions. If a collection were made of the exceedingly small minority of slides which excite the feelings of the observers, the minor points of technical detail might be discussed to see to what extent the lantern slides of the future can be made to meet artistic requirements. There are some weird scenes about the St. Gothard Tunnel, especially near its third and disused entrance near Airolo. The tunnel has three entrances; the third, now closed to traffic, was chiefly used during the construction of this great monument of human skill. The said disused entrance on a wet and wintry day, with the deserted and rotting houses once used by the workmen; the rank weeds springing here and there from the otherwise barren soil, and the dark rocks rising above, formed a few years ago a striking scene of desolation. Whether it presents that aspect now we know not, as the intention then was to utilise this entrance in the way of fortification. The Swiss have made abundant preparations for defending the tunnel, and blowing up the bridges near its entrances, in case of war. Mr. Pringle's antagonist, whoever he may be, is probably right in relation to the great majority of lantern slides.

The author gives the following as the characteristics necessary in a good slide:—

A slide, to be perfect, must have:—1. A high scale of lighting. 2. A continuous scale of gradation. 3. A pleasing tone. To put it otherwise, a slide must have:—1. Clear highest lights. 2. Secondary lights well furnished with detail. 3. Middle tones. 4. Transparent shadow details. 5. A good general colour of image.

As to merits of some processes of production, he says:—

The quality of *clearness in the highest lights* is certainly most easily obtained by the collodion processes; these are followed more or less closely in order by the gelatine-chloride process, the gelatine-bromide process standing last in this respect.

The quality of *opacity in juxtaposition with absolute clearness*, which is so valuable in such slides as are copies of engravings, is most easily obtained by collodion with or without intensification, by gelatine-chloride, and then by gelatine-bromide used in a special manner.

A long *scale of gradation* is a branch of excellence wherein gelatine-bromide stands first. The other processes we cannot place in any order of merit, except that we are inclined to place wet collodion last. The qualities of *half-tone* and *transparence of shadow* may be taken as synonymous or equivalent, and may follow the same order; but of all the transparent shadows we have ever seen produced by pure photography, none could match with those produced by Mr. A. L. Henderson's "argentic stain."

Warmth of tone may, to a certain extent, be achieved by any of our processes; but warmth combined with excellence in other respects is certainly the province of dry collodion. With gelatine organo-chloride plates we can with ease produce a very long range of colours, from scarlet to the coldest blue; but there is a something lacking in the other qualities of plates treated so as to give the warm tones.

The gelatino-bromide process for lantern slides has a long array of advocates in its favour among practical photographers who are experts in this class of work.

Another process mentioned by Mr. Pringle is not much in use, and from his description of it the method seems to deserve more attention than it has received; it was devised by Mr. A. L. Henderson, and we cannot better close our notice of Mr. Pringle's useful book than by quoting what he has to say about the "argentic stain" in relation to lantern-slide printing:

By a process published some years ago by Mr. A. L. Henderson, and used experimentally by the writer, results were obtained more decidedly fulfilling certain desiderata than any other process we have ever seen. The image seems really to consist of a stain rather than of a molecular precipitate of a metal; but, of course, it is a reduction and not a stain. The process is one of printing-out and subsequent toning, and we give it as a good example of processes which might be classed under that one head.

No. 1.

Soak, and then dissolve at low temperature—

Gelatine	240 grains
In—	
Water	10 ounces
Add—	
Sodium acetate	46 grains

No. 2.

Silver nitrate	170 grains
Water	10 ounces

No. 3.

Sodium citrate	30 grains
Sodium chloride...	20 grains
Water	1 ounces

Add No. 2 to No. 1 ; then add No. 3, all the solids being, of course, dissolved, and the temperature low. Lastly, add 2 ounces of dry, hard gelatine, see that all is dissolved, make up with water to 30 ounces, and coat the plates rather thickly. Dry in a drying press or closet in the usual way. Print deeply by contact in daylight ; the printing will be rather slow. Do not wash the plates after printing, but place them directly in the toning bath which is recommended by Mr. Henderson as follows :—

Gold chloride	2 grains
Sodium acetate	20 ,,
Sodium chloride...	20 ,,
Water	10 ounces

Neutralise the acidity with chalk, filter out the chalk, and then add 3 minims of acetic acid. The plate is treated with this solution till it takes a suitable tone ; it will go through various changes of colour during the operation, and the longer the action is allowed to continue, the colder will be the tone. The writer toned plates produced by this formula with the sulpho-cyanide bath, and got very good results.

Ammonium sulpho-cyanide	140 grains
Sodium phosphate	140 ,,
Sodium tungstate	100 ,,
Water	24 ounces

Dissolve, and allow to stand for a day or two ; then add—

Chloride of gold...	15 grains
Water	4 ounces

This bath is apt at first to act unevenly, especially if used too new. After toning by either of these methods and washing, fix the slides in weak hypo thus : sodium hyposulphite, 1 part ; water, 10 parts. Thereafter wash thoroughly, dry, and varnish with clear varnish. A strong point of this process is that combination printing of clouds, &c., is very easy.

THE PICTURES AT THE EDINBURGH PHOTOGRAPHIC EXHIBITION.—I.

THE great exhibition held in Edinburgh in 1876 was remarkable as standing out with distinctly the best collection of photographs, truly international in character, that had up to that time been brought together ; and, as representing the best work of the best workers in the world, has not been surpassed anywhere since. In some instances, the pictures then exhibited would hold their own in the present day, but on the whole it is impossible not to recognize the great advance in general excellence that marks the present exhibition. With but few exceptions the work shown is of a high order of merit, but unfortunately the strong point of the 1876 exhibition, its international character, is wanting in this. The display now on the walls of the Royal Scottish Academy is in reality a high-class exhibition of home productions in which local work is prominent, whereas the local work in 1876 was by no means so.

On first entering the noble suite of rooms, one is struck with surprise that photographs can clothe the walls with such a satisfying effect ; the eye is gratified by the well-filled appearance and general arrangement, and these first favourable impressions prepare the visitor to anticipate satisfaction while examining the details ; nor will he be disappointed.

Of course the large works first catch the eye, and among them will be found portrait studies so perfect in *technique*, so feelingly executed, so tender in tone, so full of character in pose, expression, treatment, that the spectator cannot fail to ask himself if the addition of colour could possibly improve them ; nay, it may so happen that some who will visit these rooms next February may regret that a few of the canvases could not be replaced by some of the charming monochromes now on view.

The major portion of the Exhibition consists of large pictures in pigment, platinum, and gelatino-bromide, while the small prints are nearly all in matt-silver, gelatino-chloride, or albumen—principally the latter ; nor is this to be wondered at.

There are probably more people with half-plate cameras than any other size—except, perhaps, the toys—and as those who use them are in most diverse situations, and the negatives produced vary so greatly in quality, it is natural to expect each operator will employ a printing process that will give the best average results with the least amount of trouble. Albumenised paper is easily obtainable and is most generally understood, while, if judiciously used, it will make passable prints from almost any kind of negative. Besides, small pictures are examined closely, and the highly-glazed surface lends itself particularly to the rendering of minute detail, not only in the high-lights and delicate half-tones, but also in the shadows, which latter are rich and transparent. While making these remarks, I bear in mind that one of the most exquisite landscapes I ever saw at an exhibition was also one of the smallest, and was printed in platinum. The picture referred to was by Berkeley, at the Dundee Exhibition some years ago, and, as far as can be remembered, received no recognition by the judges. Doubtless the negative was peculiarly suitable for platinum printing, and would also have produced charming results in any other process ; but there is no doubt that many negatives will produce more satisfactory prints on albumenised paper than on anything else.

On page 899 will be found the various classes under which exhibitors were invited to compete, and in each of the twenty-two classes one silver and one bronze medal are offered.

CLASS 1. *Landscape, 8½ by 6½ inches or under.*—(As there are about 220 pictures entered in this class, it is impossible to criticise them individually ; we propose only to single out those which appear the most prominent.)

Charles Digby Jones exhibits a number of 5 by 4 prints in platinum, representing Continental views from negatives that must be of exceptionally fine quality. His work is alike admirable in composition and general treatment. In No. 615 the dark pine trees and snow fields are beautifully rendered, while the five views in No. 654 are exceedingly picturesque, the central one being specially so ; in this the sky and interesting middle-distance and foreground are exquisitely rendered and it is well balanced in all its parts.

R. Keene, No. 681. Six whole-plate platinotypes, illustrating "Derbyshire Dales." These also are exceptionally beautiful, the perspective most effectively rendered. They are charming in composition, and have a sufficiency of light and shade, without the meaningless masses of heavy, opaque shadows occasionally seen. A fine artistic scene, with the controlling hand of a master in technique, all combine to produce results that are eminently satisfying.

Ralph W. Robinson sends a number of his well-known pictures. They are generally simple landscapes in which one or more figures are introduced. They are all characterised by a feeling of naturalness, without any appearance of straining after effect, or the posing of the model. "A

Little Truant" is an instantaneous view of a quiet stream on which are floating a number of ducks, while on the bank stands the "truant," all happily caught at the right moment. "Frozen Out"—a pretty rendering of a simple subject, in which a peasant woman is seen breaking the ice with an axe in order to procure water.

W. Stewart, L.R.C.P., No. 726. Five half-plate alpine views (printed on gelatino-chloride paper) of great beauty, that of the "Dent du Midi" being particularly fine. In this, from the snow-field in the immediate foreground, the crevasse in the middle-distance, to the cloud-enwreathed distant mountain, all is depicted in the most tenderly delicate manner, while the quiet sky is in most admirable keeping. Very beautiful also, are the other four pictures in this frame.

W. Mansfield, No. 241. Four street views in platinum, noticeable for the fine rendering of the elm trees. His views of St. Mary Cray are soft, yet brilliant in lighting; one, a quaint old church seen in an arborescent framing, has the character of the trees well portrayed.

G. G. Mitchell, No. 148. Thirteen landscapes; these are successful attempts to combine figure and landscape, some being exceedingly picturesque.

C. P. Cameron, No. 504. Two whole-plate views, one representing an avenue of trees in which the perspective is finely indicated, the other a very effective picture in which a fine-foliaged tree occupies two-thirds of the subject, while through its bending boughs appears a beautiful peep of sun-lit landscape—a distant hill with a village and its church.

J. Patrick and Son, 127, "Bits by the Way." Thirteen interesting rural scenes—a placid pool with water-lilies, a country lane with children, storm-worn cliffs, and rock-encumbered stream.

R. S. Webster, "Astonished." This represents some cows reposing in a meadow at the head of a lovely valley. The animals apparently have just discovered that they are being photographically interviewed. "The Avenue" (692): a pretty effect of light breaking through the trees, and a charming rendering of detail.

A. S. Watson, 142. Three evening studies taken facing the sun: effective cloud and water.

R. H. Pearman, 91. Pleasing woodland views, and a charming rendering of hoar-frost in a country lane (404).

J. Pettigrew. Eighteen 5 by 4 pictures on aristotype paper, very varied in interest and subject, one or two somewhat under-exposed: the others are particularly bright and effective.

Sydney Keith. Views in the Tyrol, Innsbruck, Wales. These are crisp and brilliant photographs, in one or two of which the foliage appears somewhat heavy. This remark by no means applies to No. 160, which is harmonious.

James Crighton, No. 173. Nine views of quiet rural, prettily chosen bits, nicely treated and tastefully mounted.

H. Little, No. 7. Eight seascapes with rugged rock and surf-beat shore.

S. N. Bhedwar, No. 777. "Washing Day," a pretty little picture, representing two children at play, and naturally illustrating the title.

Miss G. J. Waterson, "Pine Woods," No. 1,038. A very successful rendering of the subject with characteristic effect.

W. Kenworthy, "Evening in the Mediterranean," No. 848. This whole-plate platinum print represents an expanse of quiet, reposeful sea, with setting sun and beautiful cloudscape.

P. Ewing, No. 999. Nine whole-plate views. These are distinctly meritorious, from which may be singled out "A View on the Devon," "Loch Achray," and "A Pass in the Trossachs," as worthy of special notice.

Karl Gregor exhibits six pleasing rural views—wooded landscapes and running streams, with cattle and sheep successfully introduced.

J. P. Gibson shows particularly good work on matt silver paper. No. 226, "A Queen among the Roses," is a pleasing composition; so also is "The Ford."

A number of platinum prints is also exhibited by Marshall Wane; they are good average work, and the same may be said of the pictures about Gosford by Jamieson and Co., the pictures by Alexander Nicol, and the Rev. R. H. Blake. Of the pictures by Charles Reid, "Bothwell Castle" seems the most satisfactory: it has a capital rendering of foliage.

The majority of exhibits in this class appear to have been taken in the half-plate camera, and, as indicated above, are mostly printed in silver; a few—principally 8½ by 6½—are in platinum. X. Y. Z.

THE NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

THE following are the minutes of a meeting held at the Grand Hotel, Manchester, on Thursday, November 27th, 1890, with Mr. R. Slingsby, of Lincoln, in the chair.

Present.—A. Lafosse, Manchester; Warwick Brookes, Manchester; E. A. Myers, Manchester; G. Higginson, Bowdon; S. Birtles, Warrington; R. P. Gregson, Blackburn; S. Storey Davis, Halifax; R. Jennings, Blackburn; Donald MacIver, Leeds; H. Graham Glen, Leeds; H. J. Whitlock, Birmingham; John E. Shaw, Huddersfield; D. Bordley, Stafford; F. H. Waley, Doncaster; W. H. Marks, Prestwich; John Grnsby, Pendleton; C. Pettingall, Liverpool; Hubert Henry, Haslingden; F. Sharples, Blackburn; Percy Knott, Bolton; H. J. Godbold, St. Leonards; William Gill, Colchester; J. E. Eddison, Barnsley; Frank M. Sutcliffe, Whitby; W. Roxby, Leeds; Robert Broadhead, Leeds; E. Greaves, Halifax; Brooke Brookes, Bradford; J. H. Amley, Sheffield; Jamson Bros., Liverpool; A. Seaman, Chesterfield; J. W. Tattersall, Accrington; Jeffery Dimsdale, Dewsbury; Thomas Heap, Sowerby Bridge; R. Whitehouse, Manchester; J. H. Crosby, Rotherham; D. Battersby, Manchester; and Chas. P. Richards, Barrow-in-Furness, hon. secretary.

Telegrams from Messrs. Elliott (Elliott and Fry), London; Eason, Dalston, London; Sirdle Brothers, Swansea; McLardy, Oswestry; Fall, Baker Street, London; Ramsay, Bridge of Allan; Dickerson, Sheffield; Bara, Ayr; and letters from Messrs. Chevalier, Tunbridge Wells; McLean, Hunstanton; Phillips, Biggleswade; Burrow, Camborne; Lang Sims, London; Smart, Stirling; Hicks, Glasgow; Midwinter, Bristol; Forrest, Pontypridd; Pratt, Greenock; Ford, Lincoln; Dew, Coventry; Weston, London; Marshall, London; Moffatt, Edinburgh; McKean, Leith; Fieldwicke, Brighton; Hogg, Kendal; Evans, Swansea; Hart, Ashbourne; Tomlinson, Rochdale; Hoggard, Redcar; Bliss, Grantham; Child, Leeds; Faulkner, Woolwich; Brightwell, Wellingboro'; Middleton, South Shields; Becket, Saltcoats; Broadhead, Leicester; Walmsley, Liverpool; Hubert, Hackney; J. P. Clarke, Bury St. Edmunds; Pinder, Marsden; Law, Isleworth; Talbot, Hastings; Yeoman, Barnard Castle; Valentine and Sons, Dundee; Foster, Croydon; Laing, Shrewsbury; Turnbull and Sons, Glasgow; Simmons, London; Bailey, Shrewsbury; Glaisby, York; Partridge, Andover; Robinson, London; O'Shea, Limerick; Norval, Dunfermline; Erwin, Ballymena; Watson, Ripon; Archer Clarke, London; Findlow, Warwick; Berry, Aberdare; Evans, Pwllheli; Fisher, Filey; Clarke, Bethesda; and Byrne, Richmond.

The Chairman said: "Gentlemen, it gives me great pleasure to see such an important gathering as this in response to the invitation sent out to you throughout the length and breadth of the United Kingdom, an invitation, gentlemen, initiated at a gathering of a few kindred spirits three weeks ago at the important centre of Leeds, where a number of us met and discussed the necessity for forming ourselves into an association for the purpose of looking after the interests of those engaged in photographic art as a means of livelihood, and also to attempt an improvement of the social status of the members of the profession. Grievances have arisen, and those matters are only to be met by combined action on the part of the profession generally in order to effect a remedy. A committee was formed, as you are doubtless aware, and the requisite funds were forthcoming to cover the preliminary expenses incurred in announcing to the large body of professional photographers the objects of this meeting."

The minutes of the meeting held at Roundhay Park Mansion, Leeds, were then read, and adopted by the meeting unanimously, and signed by the Chairman.

Mr. Slingsby then said: "Gentlemen of the photographic profession, you have not been invited here to assist in the formation of a Society antagonistic to the parent Society—the Photographic Society of Great Britain—or any similar Society which meets and discusses the prospects of the art of photography in its scientific aspects; neither to act as a Society for the distribution of medals or awards at exhibitions; but to form yourselves into a powerful combination, so that you can deal in a proper manner with matters appertaining to the business difficulties which have arisen, and are likely to arise in the future; such difficulties can only be met by a properly constituted association, having a powerful membership, and a good balance at the bankers. The various anomalies which exist in the practice of photography as a business do not exist in other businesses—the publication of manufacturers' price lists, which do not treat the profession with justice. It is my opinion, and I feel certain it is yours, that manufacturers and dealers would gladly work with you to abolish these anomalies. Then, gentlemen, I think this Association should be established on a broader basis than at first proposed, and that we should invite all concerned to join with us, and to make it a national society, and call it, instead of the Professional Photographers' Association, the National Photographers' Association, which would, in my opinion, be a higher and a nobler title to usefulness, and would take away from it any idea of one-sided selfishness. The *raison d'être* of its existence should be the adjustment of difficulties that arise, and to deal with them as a body instead of the onus being thrown upon an individual. Take, for instance, the various Copyright Acts which have been before Parliament at one time or another. Had the last one of its kind become law it would have been very awkward for professional portraitists in general. Any intended future Copyright Act should be discussed, and any injurious clauses to the detriment of the profession be mitigated by the action of the council of such a Society as this. Then, again, we have the question of the ownership of the negative now and again cropping up. When I tell you that I once stood as defendant, and prepared to contest this some fifteen years ago in the court of Queen's Bench, you will admit this question is an important one. You have, again, the improvement of the status of the profession, and I feel sure you will agree with me that if a photographic artist could put after his name "Member of the N.P.A.," it would stamp him as being a trustworthy member of our craft, deserving the patronage of the public. I would suggest that the subscription should not be less than 21s. per annum; that you should have a president, vice-president, and a council; also a secretary with a salary sufficient to make it worth his while to devote part of his time to the work of the Society; also that the meetings of the council be held quarterly, or as circumstances will admit. An annual gathering of the members of the Society should take place at different important centres, as done by other organised societies. At these meetings matters of interest and papers relating to the business of the profession might be read and discussed, and the action of the Society agreed upon. This would bring individual members into closer relationship, and promote a better feeling amongst those engaged in the pursuit of our art. Again, as we are growing in numbers, the rank and file of our assistants are increasing, and the question of suitable hours of labour and of proportionate payment may have to be adjusted to the interests of both employers and assistants. Likewise, gentlemen, you may, in some degree, ameliorate the very low prices that some work under, and by your recommendation remedy the effects of cutting down prices between rival photographers in the same locality. These are some of the lines of usefulness I have sketched out, and in the event of this Society being successfully carried on, the advice and assistance of its council would be asked when any important measure was being brought before Parliament, as to the means of putting in accord with the feelings of those engaged in the pursuit of the art."

A discussion took place upon the speech, and several resolutions were proposed and carried, amongst which was one that the title of the Society be the National Association of Professional Photographers, proposed by Mr. Lafosse, seconded by Mr. Whitlock.

A committee of twenty was proposed, elected to frame rules and bye-laws, and to report upon the same to a general meeting to be held in Birmingham early in the ensuing year; the hon. secretary to announce the date by advertisement in the photographic journals.

The following are the members of the committee:—Messrs. Slingsby, Lafosse, Richards, Sutcliffe, Warwick, Brookes, Whitlock, Crosby, MacIver, Gill, Elliott, Fall, Shaw, Gregson, Davis, Whaley, Pattingall, Moffat, Birtles, Eddison, Barry.

PRESIDENTIAL ADDRESS TO THE GLASOW PHOTOGRAPHIC ASSOCIATION.

BY WILLIAM LANG, JUN., F.C.S.

GENTLEMEN,—Before touching upon more general matters, my first duty is to return you my warmest thanks for your renewed confidence in me in having so spontaneously and generously continued me in the highest office which it is in the power of this Association to bestow. It is now more than five years since I became your President, and it is most satisfactory and gratifying to myself that the Glasgow Photographic Association, one of the oldest societies in the kingdom, finds itself at the present moment in a state of flourishing activity. Our membership is now continually being added to, and I see no reason why we should not be still stronger numerically. One of your office-bearers remarked to me the other day that he could not understand why such and such an one engaged in photography commercially did not countenance our work as an Association by becoming members. My reply was, let them alone; our duty as an Association is to keep going on in the even tenor of our way, by bringing before the Society all matters appertaining to photography, whether they may bear on the scientific or on the art side of the question; by the exhibition of novelties as they appear from time to time in the photographic world; by keeping ourselves posted in the work of our contemporaries, and bringing forward their published results. Surely all this, if it be continued in, as I hold it has been for the last few years, will ultimately awaken interest and sympathy in those who perhaps may hold aloof from us, and by-and-by, unsolicited and unasked, they will join our ranks. I feel a certain pity for the superior individual who, when spoken to as to his becoming a member of the Glasgow Photographic Association, gives answer in tones which are intended to convey loftiness and superiority—"I do not believe in Associations." I think, gentlemen, such an one with views so biassed, and, shall I also add, so small, would not be any credit to us; therefore I say let him alone. Then, again, I would like to refer to another phase of indifference to the work done by us as an Association, and here we have to find fault with the action of certain actual members, those who pay their subscriptions, but who never honour us with their presence. We want the subscriptions, certainly, but we would like the subscriber himself—sometimes, at all events. I offer these criticisms,

gentlemen, in no unfriendly spirit. I do so because I think all should contribute their little to the furthering of the aims and purposes of our Association; and I do not for my part see how members who are conspicuous always by their absence can be said truly to promote the said aims and purposes. Before I pass on to the consideration of topics more photographic than the preceding, I would simply in a word wish to congratulate you on the council which has just been appointed. I feel sure that it is what may be termed a true working council. The remarks I have made with reference to the non-attendance of the ordinary members would surely apply in still stronger force to members of council. Last year two members were, from some cause or other, made members of council who never once attended a single council meeting. This is not as it should be. I therefore look forward to increased help this session, for from what I know of each one of the members of the council, they all have that interest in the affairs of the Association which is absolutely necessary for its present and future welfare. We all know that a certain game of cards can be played with a dummy, but I have yet to learn how the affairs of a society can be managed on similar lines.

As you are aware, those who practise photography may be broadly classed as amateurs and professionals. The Glasgow Photographic Association, as you know, embraces both sections; there is, therefore, need that both interests be provided for. The council returned contains, I think, a happy admixture of both elements. Some may think that the millennium cannot be far off—that is, the photographic millennium—when the lion and the lamb thus come together; but the true spirit which should imbue all of us, be he amateur or be he professional, is the advancement and development of that ever-wonderful and fascinating art-science of ours, now known and practised over the whole civilised world.

A sign of the times of the great interest which is everywhere evoked by photography may be cited in the great number of exhibitions which take place one after the other in the various centres of Great Britain. There was the Crystal Palace Show in the spring; another one was held in the Drapers' Hall, London, in the month of June; Newcastle had a most interesting and exhaustive exhibition; while there has been but recently opened in the Scottish National Art Galleries in Edinburgh one which promises to be a success all round. The annual Pall Mall collection has, as usual, been held in the customary place. Then, again, in the People's Palace to be presently formed in the east end of our own town there will be a photographic collection which should command attention.

The Photographic Convention of the United Kingdom held their fifth meeting in Chester during the month of June; Mr. C. H. Bothamley, of Leeds, was the President. The gathering was a success in every way. Perhaps the most notable or most ambitious attempt was a magazine camera, brought forward by Friese Greene, to take ten photographs a second of the various phases of motion by simply turning a handle; these, when recombined and projected on a screen, show again the original motion. An important contribution was also given by an honorary member, Mr. Andrew Pringle, on "Photo-Micrography." I was not able to be present myself at Chester, but our Association had a good representative in Mr. Mason. The next meeting is to be held in Bath, which may be denominated classic ground, for Fox Talbot lived in its vicinity, and many of the subjects to be found there have been secured by the illustrious pioneer.

(*To be continued.*)

THE Pope, it is said, has re-established the Observatory at the Vatican. The Pope's astronomers will take part in the making of the great map of the heavens now being prepared by means of photography. The constellation of the Lion is the part which has been allotted to the Vatican Observatory.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—December 18th, ordinary meeting, which will be the last meeting at Masons' Hall Tavern; January 1st, 1891, opening meeting at the new quarters, at the Champion Hotel, Aldersgate Street, close to the G.P.O. Visitors are invited.

AT the Solar Club dinner last Monday night, Mr. Slingsby took several photographs, by the magnesium flash-light, of those present.

THE TUNBRIDGE WELLS PHOTOGRAPHIC EXHIBITION.—At the opening of this exhibition, Sir David Salomons said that unless he were mistaken, their previous exhibitions had been largely to encourage local art by a friendly pat on the back, and the judges awarded medals more as a matter of encouragement. Fortunately, as was proved by the exhibition that day, the Society had passed that stage; this was a more extended exhibition, with excellent work from all parts of England. The next step to the pat on the back in the way of encouragement was the slap in the face. Some of the exhibitors who had fairly expected to again take medals had not done so, and might be a little disappointed. Their exhibits were, however, meritorious; but people at a distance had done better work, and that must also encourage other exhibitors to go on and do better on another occasion. It was a matter for congratulation to see so much good work, and to see that from a handful of about half a dozen amateurs this very considerable Society had arisen, and affiliated itself with the greatest photographic society in the world, the London Camera Club, and was not only taking up its own position, but standing well in respect to the other societies of England.

RECEIVED.—From the Thornton-Pickard Manufacturing Co., a plumb-indicator to assist in levelling the camera. It is represented in the accompanying cut, and is a serviceable adjunct, neatly made, easily fitted on the camera by anyone, and well "finished," so as to present no sharp edges or corners.——From Mr. Walter Tyler, a neatly made printing frame, by means of which nearly the whole of the print can be raised for examination, while the other part, by means of a special device to prevent slipping, is held firmly in position on the negative.——Mr. Freshwater's fleas are well known to London photographers, especially the one as large as a house when it was seen on the screen at a meeting of the Photographic Convention. His fleas and other of his insects and parasites—we mean, of course, his excellent micrographic slides of them—are fully described in a pamphlet just published by Messrs. Newton and Co.

Correspondence.

THE PLATINOTYPE COMPANY.

SIR,—In your report of a meeting of the Photographic Society of Great Britain, held on the 25th November, Mr. Chapman Jones is reported to refer to the Platinotype Company as having stated that strong hydrochloric acid reduced the strength of black platinum prints. There must be some mistake in this reference; certainly we have no recollection of having made such an assertion, which, indeed, would involve what is contrary to experience, for we have never yet succeeded in reducing the strength of a black image by any length of treatment with this acid. PLATINOTYPE CO. (E. J. H.)

29, *Southampton Row, High Holborn, W.C., December 4th.*

PHOTOGRAPHIC TRADES PROTECTION SOCIETIES.

SIR,—I am pleased to learn that there is a probability of a Trade Protection Society for professional photographers; for the last twenty years I have felt the necessity of such a combination.

We could then agree to deal only with those firms which, in the first place, pay the carriage on their goods, or deliver them by their own vans free of charge, at all events within the London radius, according to the custom of all other trades.

In the second place, I think that manufacturers should be held responsible for bad and carelessly prepared plates, paper, mounts, and other goods.

With regard to ourselves, I think the question of uniformity of prices better left alone; like the eight hours movement, it is a very ticklish matter with which to cope. I trust that we shall soon have a large meeting in London, and that my professional brothers will rouse up and shake off their usual apathy.

AUGUSTUS W. WILSON.

13, *Dalston Lane, Kingsland, London, December 9th.*

THE CAMERA AND ITS VARIOUS MOTIONS.

SIR,—In your last issue under the above heading, it is stated that Meagher's form of camera, in its simplest form, does not very readily lend itself to any great extension, and

Fig. 1.

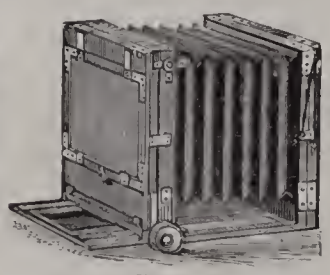

Fig. 2.

that the tailboard comes in the way in focussing when a short focus lens is used.

Fig. 1 shows the camera closed, Fig. 2 shows the camera partly extended, and Fig. 3 shows the camera with front extended. The advantages of this camera are, that it allows of considerable expansion, the half-plate focussing from $3\frac{3}{8}$ inches to 20 inches, and is quickly adjusted for long or short focus lenses; that it is perfectly rigid when extended, and there is no projection of the baseboard in front of the lens. The bellows being parallel, it is available for use with the shortest focus wide angle lens. It can also be fitted with centre partition for stereoscopic work, or with repeating front for one or more pictures on the plate. There are no loose screws required in fixing the camera, and the time occupied in unpacking and fitting the camera on the tripod stand is thirty seconds.

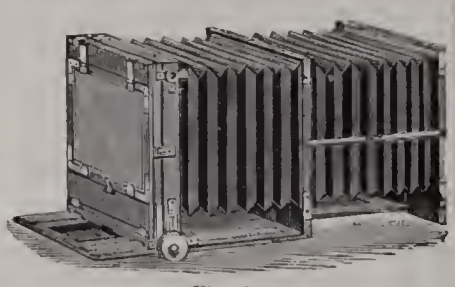

Fig. 3.

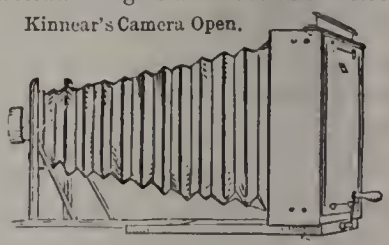
The focal lengths given above apply to a camera with rack adjustment. If fitted with screw adjustment, the focal length would be about 2 inches less.

Fig. 2, as extended, shows the position of the camera when in use with an ordinary half-plate view lens, say of 7 inches focus. With a lens of 3 inches shorter focus there would be no difficulty in focussing. In the early sixties I made a large number of the Kinnear cameras. I give an illustration here similar to what appeared in my catalogue of that time; but one defect in that form of camera is, that the folds of the bellows body, after a little use, are apt to bend inwards, thus cutting off a portion of the field when long focus or short focus wide-angle lenses are used. It is difficult to make this form of camera rigid when extended, and this difficulty is increased if an instantaneous shutter is used on the lens.

Kinnear's Camera Open.



P. MEAGHER.

21, *Southampton Row, W.C., December 8th*, 1890.

[Mr. Meagher has exhibited to us his extension camera described in the above letter; it is of sturdy and durable make, quickly put up, and remarkably rigid when extended. His statement that it can be put up in thirty seconds is accurate.—ED.]

THE NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

SIR,—I have received so many letters in reply to the circular I issued calling a meeting in Manchester, I find it impossible to reply to each.

May I trespass upon your space to call the attention of those gentlemen who ask for information as to the objects of the Association, to the report of the proceedings, a copy of which I enclose for insertion in the current issue, and also to the fact that it is proposed to hold a general meeting of the profession at Birmingham early in the ensuing year, of which due notice will be given by advertisement in the photographic journals.

At this meeting the committee appointed will submit a proposed code of rules and bye-laws for the approval or otherwise of the profession. I therefore hope all photographers will make an effort to be present.

The need of such an association is evident from the tone of the letters I have already received from all parts of the United Kingdom, and, with a combined effort, I feel sure the Society can be established upon a firm and permanent basis, and will be of great service to its members.

CHAS. P. RICHARDS, *Hon. Sec. pro. tem.*

Cavendish Studio, Barrow-in-Furness, Dec. 3rd.

Proceedings of Societies.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AT the ordinary meeting of this Society, held on Tuesday evening, the 9th inst., the chair was occupied by the president, Mr. JAMES GLAISHER, F.R.S.

A paper on "Photography applied to Astronomy," by E. W. Maunder, F.R.A.S., was to have been read at this meeting, but as it was found the oxy-hydrogen light necessary for the lantern illustrations could not be used in the Water Colour Society's Gallery during the continuance of their exhibition, the paper had been deferred until the January meeting, to be held at the Society's new premises.

The honorary treasurer, Mr. W. S. BIRD, briefly explained what had been done by the committee appointed to make arrangements with regard to these premises, situated at 50, Great Russell Street, and members were invited to express opinions concerning the hours at which they should be opened for their use. It was decided that the hours should be from 2 till 9.30 daily, but that there should be a vacation to occupy the whole of the month of August. When necessary, and on special occasions, meetings would be held as heretofore at the Pall Mall Gallery, which was also engaged for the Society's

exhibition ; but in the general way the meetings, both ordinary and technical, would be held in the new premises. As they now had room for a library, and for a nuclens of a photographic museum, the premises committee was prepared to accept gifts of books and other articles.

Mr. LEON WARNERKE thought that arrangements should be made for a more complete supply of foreign periodical photographic literature than the Society now possessed.

The TREASURER referred to the announcements concerning the proposed Photographic Institute which appeared in the Society's Journal. The proposals there put forth included a large scheme as well as a smaller one. The Society might act as nursing-mother to the larger scheme, which he looked upon as belonging to the future. He thought that some of the accumulated funds of the City Corporations might be expected to be used largely in aid of the proposed Institute, provided its practicability and utility could be sufficiently demonstrated ; but they must begin at home if they were to have any chance of success. The Institute, if sufficiently supported, would be a most valuable one. In England we must help ourselves, and must not look for State aid such as is furnished to the Photographic Institute in Berlin.

It was moved by Mr. T. SAMUEL that the project be submitted in the form of a circular letter to the different provincial societies, to elicit the opinion of the photographic public generally on the scheme submitted by the committee.

Mr. H. CHAPMAN JONES seconded the motion, and said that there were a great many societies that might be expected to help in the foundation of the Institute. Such help might be looked for from those societies which were rather of a scientific than of a social character.

Mr. W. BEDFORD thought they should not look for very much assistance from societies, and should not be much influenced by the amount they would be likely to get in this way. Photography was certainly an art and science that should receive aid from some of the accumulated wealth of the City.

The motion was put and carried.

Messrs. J. E. Austin, L. C. Bennett, B. Yorke Bevan, Louis M. Biden, Shapoor N. Bhedwar, F. C. Cembrano, L. E. Clift, H. Cooper, J. H. Craigie, Captain H. Curties, J. C. Douglas, D. T. English, F. M. Gowar, C. F. Hayward, Lieut. S. G. Johnson, W. F. Kimberley, Major H. G. Kemhardt, Lieut. W. G. Leslie, A. Maskell, L. Mitchell, H. Sandilaud, E. Seamell, E. Spencer, J. Wiltshire, L. E. Westrop, H. H. Schultz-Young, Miss W. P. Arnott, and Mrs. E. G. Wrigley were elected.

THE CAMERA CLUB.

ON Thursday, last week, at the ordinary meeting of the Camera Club, Mr. A. MASKELL presided.

Mr. H. STURMEY read a paper on "The Rollable Transpareut Film," and stated that the makers have now got rid of the occasional markings, due to electrical action, which had proved so troublesome in the earlier specimens. A mark like a join appeared in each roll, and this the makers did not seem as yet to have been able to abolish. The speaker described the mode of manufacture of the film, and how he developed, fixed, and dried the negatives.

The CHAIRMAN exhibited some film negatives taken by Major Nott, who is one of the ablest workers on films in this country.

A discussion followed, in which several members took part.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

Mr. EDGAR CLIFTON in the chair.

Mr. A. MACKIE drew attention to some lanteru plates coated with collodio bromide, the films of which were more or less covered with transparent spots. He said that a discussion had been raised whether each spot proceeded from a nuclens. To test this he coated several plates, and before they were quite dry allowed some dust to settle on them ; after the plates were thoroughly dry the dust was blown off, and a plentiful supply of spots was the result. He next coated some plates with an emulsion which had not hitherto produced spots after coating ; these were dusted as in the previous case, but it had no detrimental effect upon the plates. Mr. Mackie contended that this proved it was only certain emulsions that were susceptible of being damaged from the above cause.

A demonstration was given of the diazotype process by Mr. BEVAN, of the firm of Messrs. Green, Cross, and Bevan. The process can be used either for dyeing fabrics or for positive printing by means of the diazo derivative of primuline. Primuline is a yellow coal-tar dye, discovered in 1887 by Mr. A. G. Green. To demonstrate the process Mr. E. J. Bevan took several pieces of fabric ; these were immersed in a bath of water, heated by means of a Bunsen burner to boiling point, a little of the primuline powder having been previously sprinkled into it. A few minutes sufficed to dye the pieces of cloth a permanent bright yellow colour. Primuline itself is not sensitive to light, but a diazo compound is formed by allowing the pieces of material, after dyeing, to remain a few minutes in a bath of nitrous acid. This bath is prepared by dissolving 30 grains of sodium nitrite in one pint of cold water, adding 50 grains of oxalic acid dissolved in one ounce of cold water. The pieces of fabric are, by immersion, rendered sensitive to light and capable of producing photographic prints of a novel character and in various colours. A peculiar feature of the process is that it gives a positive from a positive. Printing may be done in an ordinary printing frame, or the sensitised material may be spread on a board, and the subject to be copied placed on it and pressed flat by means of a glass plate. In this way fronds of ferns, leaves, and other objects can be arranged so as to form very pretty designs. After exposure the materials are transferred from the printing frame to a bath of a weak solution of a phenol or amine, producing colour where the ground has not been decomposed by light, the colour produced depending upon the phenol or amine employed. After washing and drying the print is fixed ; linen, silk, wool, paper, and all materials of this description can be used in this process. In the case of gelatine plates the primuline is incorporated with the gelatine before coating. Some pieces of silk on which designs were printed in various colours were passed round.

A pretty application of the process was shown by Mr. Bevan. A piece of white calico which had been sensitised and exposed during the day under some fern-fronds was locally developed with a brush, several developers being used, producing various colours, but feeble on this occasion from over-exposure.

Mr. W. H. HARRISON asked if isolated diazotised primuline were not explosive.

Mr. A. G. GREEN said that all the diazo compounds were explosive, but diazotised primuline was somewhat stable, and could safely be kept in a bottle. He remarked that these compounds were stable to heat, although so readily decomposed by light. The diazo compounds were all sensitive to light, being about twice as sensitive as ordinary sensitised albumenised paper—the proportion being much greater with yellow light.

In reply to questions, Mr. BEVAN said that other acids beside oxalic could be used with nitrite in the production of nitrous acid, the strength not being important provided sufficient acid was added. He was unable to explain the nature of the chemical change produced by light ; the fact that nitrogen was set free was proved by placing an exposed gelatine film in water, when the image could be traced by the bubbles of nitrogen that were given off. He had collected this gas in order to determine the amount of nitrogen given off, but this was a matter more of scientific than practical interest.

The CHAIRMAN asked if it were possible to get a black image, and whether it could be toned.

Mr. BEVAN said the nearest approach to a black colour they had been able to obtain was a very deep purple ; various tones could be produced by stopping development and using another developer for producing another colour. They had not been able to get a pure white background. Even results were more likely to be obtained when weak solutions were used. The image was capable of being redeveloped to any colour *ad infinitum*. For copying engineers' plans and drawings, he thought diazotype would supersede the old blue process.

A vote of thanks to Messrs. Green, Cross, and Bevan, proposed by the Chairman, brought the meeting to a close.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION. *December 4th.*—Mr. J. D. Cox (president) in the chair.

The principal business of the evening was a lantern slide competition, in which thirteen members took part; each contributed a set of six slides. The competition was decided by the votes of the members present. On the voting papers being scrutinised, the following were declared the prize winners:—First, H. S. Wybrants; second, D. Ireland; third, A. Stewart.

A number of slides by the members, and a series of fifty from the Paisley Photographic Society, were then exhibited.

Messrs. Lowdon, Reform Street, sent for exhibition a set illustrating the Stanley expedition for the relief of Emin Pasha.

THE PHOTOGRAPHIC SOCIETY OF JAPAN.

A MEETING was held on October 11th, at the rooms of the Geographical Society, Tokyo.

There was an exhibition of work done by members during the holidays; it included a pretty fair collection of pictures, but it is to be regretted that more members were not represented. Probably the fact that only some seven or eight exhibited is due to the very unfavourable weather that there has been during nearly the whole of the summer.

Mr. KAJIMA SEBI showed a number of remarkably fine flower studies, and some coloured prints on "aristotype" paper.

Mr. C. D. WEST had a set of prints, of which two of the ss. *Omaha*, taken from the yacht *Daimyo* whilst both vessels were in motion, were remarkable.

Mr. J. B. RENTIERS and Mr. A. J. HARE each showed a set of fine landscapes.

Prof. W. K. BURTON had a number of pictures of children bathing, taken at Misaki. Some of these were printed both in the ordinary way, and on drawing paper with platinum toning, and were also enlarged on bromide paper, so that there was an opportunity of comparing notes as to the effects of different processes.

Captain W. H. HARDY showed a print of a life boat, which attracted attention on account of its representing all that was left of the steamship *Musashi Maru* after the late lamentable accident.

Mr. S. OYAMA brought a fine collection of copper-plate engravings, and of photo-engravings.

There was on show the apparatus with which certain professors of the University had made attempts, more or less successful, at deep sea photography during the summer holidays, and which had resulted eventually in an explosion.

A short business meeting was held, at which the following were elected:—Mr. W. Mann, Mr. S. Oyama, and Mr. H. A. C. Boner. After this the meeting resolved itself into a conversazione.

IDEALISTIC PHOTOGRAPHY.—The London and Provincial Photographic Association has recently heard a great deal about the focus question—"Pictorial Definition," read by Mr. A. Collier; "Is Blurring desirable in a Photograph?" by Mr. Debenham; and "Naturalistic Definition," by Philip H. Newman. One would have thought it would have had an alternation of papers by readers of opposite opinions. "Hear all sides" implies a spirit of justice, and where there is prejudice the search for truth is vain.—*The Photographic Art Journal.*

CHEMISTRY IN THE DARK ROOM.—A lecture on "Chemistry in the Dark Room" was delivered last Saturday at the Photographic Exhibition, Edinburgh, by Dr. Drinkwater, Lecturer on Chemistry at the Edinburgh School of Medicine. There was a large attendance. Having explained the difference between physical and chemical change, the lecturer showed the composition of white light, throwing the spectrum on a screen, and further pointing out the different properties of each end. He demonstrated the invisibility of light by itself, and the effect of passing it through coloured glass. The chemical nature of the spectrum was then treated of, and the lecturer exhibited its power of acting on photographic salts by darkening a piece of sensitised paper by exposure to magnesium light. The nature of the various chemical changes in photography was shown and carefully explained.

Answers to Correspondents.

All Communications, except advertisements, intended for publication should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

C. J. K.—*Hot Rolling Press.* The "Fernande" burnisher ought to meet your requirements, being suitable both for mounted and unmounted prints according to adjustment, and can be used hot or cold.

E. E. M.—*Gelatino-Chloride.* The advantages of Obernetter, celerotype, and other forms of gelatino-chloride paper are asserted to be greater brilliancy and rapidity, combined with better rendering of the details in shadow. You will find formulæ for toning baths, and directions for making gelatino-chloride emulsions, in the new YEAR-BOOK (see pages 99, 134, and 187). Be sure and use an alum bath before toning the prints.

PARATOLOID.—Your question has no bearing on photography, and it is impossible to say more than that the similarity of name would seem to indicate that Dr. Koch's cure—the so-called "Paratoloid"—is a preparation of paratolnidine, the body that serves as a starting point for the manufacture of primuline base.

R. S. D.—*Lens for Enlarging.* The lens mentioned as being already in your possession ought to do all the work you require of it, even to enlarging from whole-plates.

H. J. C. (Lewisham).—*The Journal of the Society of Chemical Industry* (30s. per annum) is to be had of Messrs. Eyre and Spottiswoode, East Harding Street, E.C. The separate monthly copies are only supplied to members. By joining the Society you would gain certain privileges besides getting the journals. We shall be happy to propose you for election.

PHOTARGUS.—1. Instead of using hydrofluoric acid for stripping gelatine films from glass, a mixture of dilute sulphuric or hydrochloric acid and fluoride of sodium will answer equally well. 2. Gelatine skins are still commonly employed, or the films may be reversed and received upon the original glass plate. Celluloid is apt to curl up in the process. 3. You are right, it is a common practice; use slow landscape or chloride plates. 4. Aniline dyes for spotting have not the needful opacity, nor has the soluble black any special affinity for albumen. By using a little gum water with the pigment the points touched become equally glossy with the rest of the surface.

WANTED, a lecture experiment to show manifold changes of colour in the same solution. Probably the following set of reactions would be suitable:—Copper wire or filings dissolved in strong nitric acid give a greenish-blue solution, and red gas; hydrochloric acid added turns bright green; diluted with water, pale blue; ammonia in excess, deep azure blue; cyanide of potassium, colourless; sulphide of ammonium, black. If this will not do, you might ring the changes on permanganate; from purple, green, colourless, to flesh-coloured sulphide.

W. AFRICA.—1. You are free to employ the Woodburytype process, but the cost of hydraulic press and general plant is, of course, rather expensive. 2. Details have appeared in the photographic journals, but there does not seem to be any book of instruction solely devoted to it.

L. F.—*Warming the Studio.* The gas stove you mention is very efficient, and serves to ventilate the room by the introduction of warm, fresh air. We have, however, known the gas flame to be blown out in gusty weather; this should be provided against by having one jet of larger size in the compound ring burner.

RECEIVED.—Mathews' plates illustrating a geometric system of personal identification by photography; also Webster's "Benzene Nucleus" india-rubber stamps.

Other correspondents in our next.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1685.—*December* 19, 1890.

CONTENTS.

THE PHOTOGRAPHIC SOCIETY.

AT the beginning of the new year the Photographic Society will move into rooms of its own in Great Russell Street, and, at the same time, a new era in its existence will begin. This old and honoured Society was inaugurated in January, 1853, at a meeting held in the great hall of the Society of Arts, with Sir Charles Eastlake, president of the Royal Academy, in the chair. He was elected as the first president of the Photographic Society, and the first vice-presidents were Earl Somers, Sir William J. Newton, and Sir Charles Wheatstone. The members of council appointed at the outset were Dr. Becker, Mr. L. Berger, the Rev. G. Bridges, Dr. H. Diamond, Mr. Roger Fenton (hon. sec.), Mr. Peter Le Neve Foster, Mr. P. W. Fry, Mr. T. M. Goodeve, Mr. Robert Hunt, the Rev. C. Jones, Mr. J. D. Lewellyn, Mr. Neville Maskelyne, Mr. A. Maconochie, the Count de Montizon, Mr. H. Owen, Dr. John Percy, Mr. A. Rosling (treasurer), Captain Scott, Mr. G. Shaw, Mr. Charles Vignolles, and Sir Thomas Wilson. For some years it was a fashionable society. After a time it ceased to bear this aspect, and, in course of years, fell into anything but a prosperous state commercially. The amount of the salary which it paid to its permanent secretary had much to do with the reversal of its fortunes. Of late years it has become more prosperous, and has been leading a sedate jog-trot kind of life, displaying activity chiefly in the holding of an excellent annual photographic exhibition.

When a great photographic society is without a library, without a reading room, practically, if not absolutely, without a supply of foreign photographic periodicals, and lives apparently cut off from communication with all the photographic societies in foreign countries, it is clear that a time must come for the awakening from this state of blissful repose.

Some years ago the Belgian Photographic Association tried to hold an International Congress of Photographers, and it fell through simply because so many photographic societies in other countries had not the politeness to answer the letters sent to them by the Belgian Association on the subject. At the time of the last Paris Exhibition the French took up the idea of an International Congress, and the responses from photographers in other nations were not so numerous as should have been the case; however, the International Photographic Congress was held in Paris, and did most useful work, especially in the matter of selecting a standard unit of light for photographic purposes, and in setting forth methods of testing lenses. Either our Photographic Society did receive communications from the Belgians and the French in these matters, or it did not. If not, our Continental neighbours were lacking in courtesy; if they did send such communications, how is it that not a word on the subject, if we mistake not, has ever been uttered at an ordinary or extraordinary meeting of the Photographic Society? A few questions might well be asked as to how it is that, for years past, the Society seems to have been so entirely cut off from communication with organisations of the same kind in other parts of the world.

However, the Society is now beginning to show more signs of activity. Perhaps the time may be at hand when it will be impossible to reasonably put such questions as those just formulated, and probably the Photographic Society may be about to start afresh on lines of action fully in harmony with its historical standing and its honourable name.

MAKING PAPER TRANSPARENT.—The following method of making paper transparent for copying drawings is adopted by the Austrian Hydrographic Bureau:—The sheet of paper, having been placed over the drawing to be copied, is lightly rubbed with a ball of cotton saturated with pure benzine. The tracing can then be readily made, owing to the transparency produced, and the benzine, on evaporating, leaves the paper opaque, as before, and perfectly odourless. To secure satisfactory results, however, absolutely pure benzine must be used.

THE PRICE OF PLATINUM.—As good news to photographers, it may be mentioned that a fall has taken place in the price of platinum, a new source of supply having been discovered in Australia. Dr. Edison is said, in the newspapers, to have hopes of manufacturing a substitute for platinum; this, necessarily, must mean a non-oxidising alloy for electrical contacts, and not anything chemically the same as platinum, but if the latter metal were not required by electricians, it would become cheaper to photographers.

PHOTOGRAPHY IN ITS RELATION TO COMMERCE.

IN the eagerness of photographers, both professional and amateur, to keep themselves posted up with the details of new processes, and the thousand and one things that attract the attention of those interested in the art, the very important part which photography has now assumed in the commercial world is apt to be forgotten. If the chief workers in photography were, as of yore, professional portrait takers, the industries partly or wholly dependent upon it must have been small industries, or, at any rate, affected by the wants of photographers to only a limited extent. But now that the art has assumed the character of a craze or hobby in which many thousands in every country take an active interest, the number of persons who directly or indirectly owe their daily bread to sun-painting is enormous, and, of course, the industries in which they are engaged benefit to a similar degree.

There are a few semi-scientific pursuits which have, in by-gone days, had their worshippers among amateurs, but none can compare with photography in the enthusiasm with which it has been taken up of late years by all classes. Perhaps the hobby which came nearest to it in this respect was the art of electro-plating, which numbered many hundreds of amateur workers very soon after its discovery. It would seem that any new industry which has a taste of the marvellous or magical about it, at once appeals to the imagination of ordinary folk, for we are all more or less superstitious to a certain extent; and it seemed almost akin to magic when a sealing-wax or plaster mould placed in a chemical solution in connection with a battery circuit became covered, in a short time, with a shell of solid metal. The art of photography presented a still more wonderful change brought about by such an intangible thing as light, and in the marvels of the new art the attractive features of the older one were forgotten.

It is certainly good for anyone to have a hobby—some occupation whereby thought can be rendered active, and which is as different as possible from the ordinary occupation of the individual. But the hobby rider will have still more satisfaction with his choice when he remembers that his pastime is one that brings harm to no one, does not—as many pastimes unfortunately do—bring pain and death to lower animals, and which, at the same time, affords the means of living to many thousand workers among the human family. That this is true of photography there can be no question. Besides, there is a farther advantage in the practice of the fascinating art which, perhaps, is not readily recognised. We feel certain that many workers have first been attracted to the study of optics and chemistry by the necessary knowledge of those subjects which the practice of photography entails; and who knows what results may accrue to science from the attention of one or two good brain-workers being thus started on a particular track?

It would be a very difficult matter to estimate with any approach to correctness the number of those who minister to the wants of the photographic world. First, we have a very important new industry established in the manufacture of dry plates. In association with such factories, we find that the glass worker is called upon for an enormous quantity of material. At one factory we were told, on good authority, that the bill for glass alone amounted to more than two hundred pounds monthly. The account for silver and other chemical salts, and for gelatine, would, it is evident, add up to no insignificant amount at such a factory. Then reams of packing paper must also be taken into account, as well as thousands of gross of boxes of various sizes, in which the plates are packed before they are ready for market. At most of our large plate factories other work is also carried on, such as the preparation of albumenised, bromide, and chloride papers, besides a host of incidental productions which need not be mentioned in detail. We may be reminded here that the paper maker shares in the general work of photography, not only in the manufacture of suitable material to serve as the basis for our pictures, but also in the making of tons of paper to satisfy the requirements of the photographic newspapers, and to help in the production of the many books which deal with different phases of the art.

At no time in the history of photography was so much apparatus turned out as is the case to-day. Camera-making engages the services of a host of skilled cabinet workers, who call upon the wood merchant for the finest woods in his store, upon the leather dealers for the best skins, and upon the metal-workers for the most highly-finished brass. We must not forget those without whom the photographer would be powerless, unless, indeed, he were content to represent nature in the fuzzy garb peculiar to the employment of a pin-hole. We, of course, mean the lens manufacturers, who have done so much to bring the photographic art to its present pitch of perfection. We thus see that the large and increasing army of photographers has in its train a huge band of camp-followers. But these, instead of proving a nuisance and encumbrance to the main body, as such congregations of men have often been known to be, support and nourish it. The army, in fact, could not exist without them.

HALATION.—A. and L. Lumière show, in the *Bulletin Belge*, that part of the halo is due to diffusion of light in the sensitive film, and part to the passage of luminous rays through the film. By covering the sensitive plate with a screen, pierced with an opening exactly the size of the luminous image, it was found that the halo formed was so small that it might be ignored. When, however, the film was protected from the image by a black screen the exact size of it, an ordinary halo was obtained. Consequently, the authors conclude that the halo is due to two causes—the support and the lens. From a study of the influence of the support, the authors find that the halo disappears entirely when the illuminated portion of the film exceeds a certain limit, depending upon the index of refraction of the supporting medium, and upon its thickness. The lens also assists in the production of the halo. When the lenses are clean and well polished, it is at its minimum, but a layer of dust augments it considerably.

PHOTOGRAPHY IN AUSTRIA.

Instantaneous Pictures by Angerer—Sitting of the Photographic Society, December 2nd — Lantern Evening of the Club of Amateur Photographers.

Instantaneous Pictures by Angerer.—Among the new publications in circulation here, Victor Angerer's street scenes are really charming. They are instantaneous photographs, 19 cm. by 12·5 cm.; but they are not of that kind in which one sees that the photographer has subjected the plate to the most exquisite torture in order at last to obtain a passable picture. They are fully ripe pictures, in which the figures move with as much grace and ease as if copied for the purpose. M. Angerer, one of Vienna's best photographers, is extremely fond of mountaineering. Recently, on an excursion in Hungary, he caught his foot in a withy springe, and, in falling, so hurt his right foot that he will hardly be able, for a time, to complete his collection of instantaneous photographs. This accident took place shortly after he had favoured the Photographic Society with a description of his manner of taking these beautiful pictures. The camera consists of a simple box, 25 by 20 by 24 cm., for plates 16 by 21 cm. The objective is so placed as to be scarcely noticeable; just as little observable is the instantaneous shutter, as it is placed behind the objective. As the objective has a wide angle (made by Français, of Paris), and makes objects appear pretty sharp, even at a distance of seven metres, more distant objects being all the sharper; and as the focus of the objective is adjusted for the infinite, no special adjustment is needed when using the apparatus. If one wishes to take pictures, one inserts a dark slide in the apparatus, winds up the instantaneous shutter with a key, opens the dark slide, and is then immediately ready to begin taking. With this detective camera no view-finder is used, as with others, because it is often only a hindrance in taking street scenes. Without such an arrangement, one can better judge if the moment is suitable for exposing. In developing the pictures, an oxalate of iron developer is used, with the addition of the well-known accelerator. This consists of—

Hyposulphite of soda	1 gramme
Bromide of potassium...	6 grammes
Water	60 cms.

Of this solution take 8 c.m. to one litre of prepared oxalate solution. If it be wished to develop a plate, take three parts of oxalate solution mixed with the accelerator. This developer is to be recommended when it is a question of shortening the exposure, for it acts with double the force of the ordinary iron developer. Angerer lays it down as the first rule that the same scene should never be taken twice, as the public immediately loses its enthusiasm. As all exposures must be made holding the apparatus, which is tolerably large, in the hand, it is best to hold the camera between the chest and chin, which, naturally, cannot remain unobserved. His pictures form the most charming mirror of life, and it is striking that the groups, almost without exception, look as picturesque as if sketched by an artist.

At the beginning of December, two photographic events took place on one evening. The one was a lantern evening given by the Club of Amateur Photographers for a charitable purpose. It was held in the largest hall in Vienna, which was crowded. Thus the greatest pecuniary success was achieved. The sheet was more than 10 metres square. As the pictures were taken by the members of the Club, whose friends were among the audience, the applause was such as, otherwise, is heard only at a *dilettante* theatre. How trifling seems the imperfection of some of the slides when compared with the joy of the unfortunate people to whom the proceeds will go!

Sitting of the Photographic Society.—The other event was the sitting of the Photographic Society. A sensation was created by some enlargements in the room exhibited by Marion and Co. Particularly the technics of retouching—or rather, the suitableness of the paper for artistic retouching—was pointed out. Also the same firm's opals are a novelty here, at least as to their perfection. Red pigment pictures by Falkner, and photographs on platin paper by Thompson (pictures of children), excited enthusiasm. A little intermezzo took place concerning the rapid developer in use in Paris, and known by the name of "Cristallos." Mr. Putz declared that the musk smell that is added to it is only meant to mislead the purchaser as to its composition. Professor Eder said he had found ferrocyanide of potassium in this developer, but reserved more detailed communications for another time. The ferrocyanide developer was recommended by Jennings in 1885, on page 211 of your journal; and in another form, and in different company, excited attention.

The year 1704 was made celebrated by the battle of the books, but the year 1890 is to be remembered in the annals of photographic glory by the battle of the eosin plates. A clever amateur, Mr. Einsle, went into the Styrian Alps to photograph the glaciers. His outfit consisted of Vogel-Obernetter eosin plates, the fame of which has been so much trumpeted abroad in Germany. The result, however, was a melancholy one; cloudy edges and spots on the plates disfigured his pictures. In his first disappointment he published his sad experiences. The poor photographers had a feeling as were a thunderstorm about to burst forth. Vogel's adherents exhibited hundreds of really excellent pictures, with admirable orthochromatic effect, and of the largest size, in order to give evidence of the excellence of the Vogel-Obernetter plates.

In consequence of the eosin demonstration, nearly 300 pictures adorned the walls of the Imperial Academy of Science. Who knows what irrevocable utterances might have been made had not Professor Luckhardt, after reading Dr. Vogel's assertions and his opponent's semi-declaration of honour, moved that, for the Society, the controversy be ended? But whether the strife between such embittered foes will be continued in Siberia, your correspondent does not venture to prophesy. Certainly, in that case the duty of reporting will not fall to the lot of

STYX.

To Increase Sensitiveness. — A sensitiveness five times greater may be given to gelatino-bromide plates by steeping them in a mixture of 100 c.c. of alcohol at 80 per cent., from 1 to 2 c.c. of a solution of nitrate of silver in water (1 : 15), and 10 c.c. of ammonia. They are allowed to remain in this bath from three to five minutes, dried, and used immediately. —*Der Amateur Photograph.*

The German Language.—*The Photographisches Wochenblatt*, No. 35, of Berlin, thus comments upon our late caution to photographers about to visit the Fatherland, which has been copied in various journals at home and abroad, viz., "We rejoice ourselves that our newly article out of the 'teutschen Glashaus' also beyond the canal and the oceau, happiness excited has. He is with manifold gocose additions in English and American journals uptaken. One periodical appears entirely almost believed to have, that our fellow-laborer earnestly these propositions had made."—*The American Journal of Photography.*

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

TONING BATH FOR YELLOW-STAINED NEGATIVES—DEVELOPERS FOR DETECTIVE CAMERA NEGATIVES—URANIUM INTENSIFIER—COLOURED PHOTOGRAPHS BY TONING—READY-SENSITISED ALBUMEN PAPER—NEW TONING BATH FOR GELATINO-CHLORIDE PAPER.

Toning Bath for Yellow-Stained Gelatine Plates.—To those who use gelatino-chloride paper—more especially Liesegang's aristo paper—for printing yellow-stained negatives present simply the difficulty that the printing takes a little more time than with clear negatives, whereas they possess the advantage that with this paper they yield prints of special softness and beauty. In many cases, however, it will be desirable to remove the yellow stain, caused generally by the prolonged development with pyro or with quinol, and, in such cases, the following method, which has been suggested by a correspondent of *Der Amateur Photograph*, may prove useful. To a solution of 1,000 grammes of hyposulphite of soda in 4,000 c.c. of water, 120 grammes of sulphocyanide of ammonium and 30 grammes of pulverised alum are added, and the milky solution is allowed to stand for some days with repeated stirring; then 150 c.c. of a solution of chloride of gold (1 : 200) are added to it. After the clear liquid has been decanted from the sediment, the yellow-stained negatives are placed in it for about half-an-hour, at the end of which time they will show a beautiful blackish-violet to greyish-blue colour.

Uranium Intensifier.—Mr. L. Schrank, editor of the *Photographische Correspondenz*, recommends the following intensifier as thoroughly trustworthy, especially in the case of negatives destined for zincography, and for the platinotype process:—

Solution A.

Nitrate of uranium	7 parts
Glacial acetic acid	7 ,,
Water	280 ,,

Solution B.

Ferricyanide of potassium	7 parts
Glacial acetic acid	7 ,,
Water	280 ,,

The solutions are poured over the plate in succession. The negative treated with this intensifier acquires a brownish-red colour, which is of great covering power.

The Production of Coloured Photographs by Toning.—I have made of late some curious experiments, which, though they have nothing to do with heliochromy, have given results very similar to those pictures which I have received from M. Veress. It will be remembered that Capt. W. de W. Abney stated some time ago that a process of producing photographs in natural colours, *based upon development*, would be impossible. In reading his lucid and interesting paper, it happened to me to try if it be possible to obtain a heliochromic effect by treating a photographic print, parts of which were printed under various circumstances, by different toning baths. It is well-known that the time of printing, the temperature during the printing process, the degree of density of the negative, the composition and temperature of the toning bath, and other conditions, materially affect the resulting colour of the print. I obtained nice effects in the following manner:—The negative—a cabinet portrait of a gentleman with a black coat, light hair, and light beard—was printed as usual on albumen paper. The print, as soon as it had been removed from the frame, was well washed. Meantime, I prepared two solutions:—

A.—Chloride of gold	1 gramme
Acetate of soda	10 grammes
Water	100 c.c.
B.—Hyposulphite of soda	20 grammes
Water	100 c.c.

They were kept separately in two wide-mouthed glass bottles. Besides, I used two dishes, and a few sheets of blotting paper. After washing, the print was placed between the blotting-paper, and slightly pressed, in order to take away the superfluous water, and then placed flat on a well-cleaned glass plate. I then took a fine brush, dipped it in solution A, and passed it over the whole picture, with exception of the face and the hands of the portrait. The solution was allowed to act until a black tone was obtained, which took about half an hour; the print was then washed for ten minutes, and fixed in solution B; finally, it was washed in the usual manner. The longer the gold solution is allowed to act, the blacker will be the resulting tone. So an orange-coloured neckcloth will be obtained within one minute, a coffee-brown upper coat within five minutes, a violet vest within ten minutes, and a black coat within about half an hour. The face, the hair, and the hands obtain their corresponding colour in the hypo solution. The effect is very nice.

Ready-Sensitised Albumen Paper.—There are many formulæ for the preparation of ready-sensitised albumen paper, but the following one, which is recommended by Fr. Wilde in the *Wochenblatt*, seems to be of special trustworthiness, and deserves the attention of the practical photographer. The paper is floated for two or three minutes on a solution of—

Nitrate of silver	100 grammes
Citric acid	100 ,,
Water	1,200 c.c.
Alcohol	100 ,,

After each sheet has been sensitised, 10 c.c. of the following solution are added to the bath:—

Nitrate of silver	20 grammes
Citric acid	12 ,,
Water	200 c.c.
Alcohol	20 ,,

When removed from the bath, the paper is drawn over a glass rod, and, after draining, placed with the sensitised surface on chemically pure botting-paper. It is then covered on its back with a sheet of stout paper, and well and evenly wiped off by powerful rubbing and pressing. Finally, it is dried spontaneously in the dark. If placed between preserving paper it will keep for from six to eight weeks in summer, and for months in winter. The preserving paper consists of soft, very thick, unsized blotting-paper of white colour, which should be entirely free from wood, chemically pure, and saturated with carbonate of soda. It should be used in rolls of from five to six metres length, and kept, together with the sensitised paper, in pasteboard or tin boxes.

New Toning Bath for Gelatino-Chloride Paper.—According to the *Archiv*, G. Bani recommends the following bath:—

Well water	150 c.c.
Benzoate of soda (produced from the acid)	20 grammes
Caustic potash	0·1 gramme

To this solution is added 50 c.c. of—

Solution of brown gold chloride	1 gramme
Water	150 c.c.

The solution should be stirred, and allowed to stand for two hours. After this time the bath will have become rose-coloured, when it may be used for toning. It is said to give tones similar to those obtained with the platinum toning bath.

Literary Notices.

THE OPTICAL LANTERN. By Andrew Pringle, F.R.M.S. (*New York: The Scovill and Adams Co.*, 1890.)

THIS book, useful at all times, is particularly of value to photographers at the present season, when out-door work is nearly at a standstill. The volume gives plenty of information about the optical or magic lantern; we prefer the old name of the instrument to that on the title-page of this book. There are plenty of optical lanterns which are not used for the projection of images on to screens—railway signal lamps, for instance; also the bull's-eye carried by the friendly or unfriendly policeman.

Considerable experience in his subject is displayed by the author in the information he gives about the construction of oxy-hydrogen jets, and all the other apparatus necessary for the production of the lime-light. More might have been said in the work about the employment of oil lights of different kinds, and the amount of illumination of the screen they will give under stated conditions. Such matters are treated with brevity in the book, yet it is probable that the majority of persons who buy magic lanterns do so for use in their own homes, and avoid the use of compressed gases, the manipulation of which it is not desirable to leave to unskilled members of the home circle.

Mr. Pringle speaks as follows about a form of lantern condenser recommended by Mr. John Traill Taylor:—

This form consists, as will be seen from figure 7, of a plano-convex or slightly meniscated lens in close proximity to a double convex. Mr. Taylor then rightly points out the loss of light certain to arise with this form of condenser unless the focus be long, which will entail loss of intensity, and he proceeds with his usual ingenuity to suggest the interposition of a third

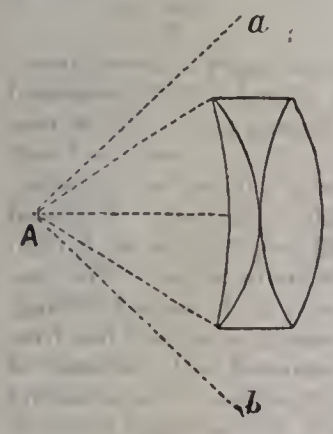


Fig. 7.

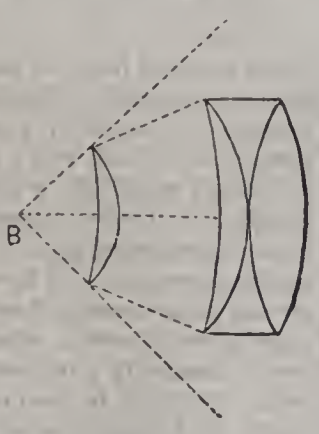

Fig. 8.

lens of plano-convex or menisens form between the light and the doublet combiuation previously representing the entire condenser. The figures are Mr. Taylor's, and almost explain themselves.

In A, *a b* represent rays that are lost, while in B (fig. 8) they are refracted and utilised by the addition of the third and smallest lens. Mr. Taylor therefore concludes in favour of triple condensers.

Our experience is confined to the form first figured (fig. 7) and the part of Mr. Taylor's figure A; of these we prefer the two plano-convex glasses, fig. 1.

The amount of light gained by Mr. Taylor's plan is so great that the advantage gained thereby deserves much stronger emphasis than it has received in Mr. Pringle's book. By the use of the third lens it is true that two additional reflecting surfaces are introduced, causing a slight loss of light so far as the illumination of the screen is concerned, but this is but giving a sprat to catch a whale. In fig. 8, if the area of the ring (otherwise lost) of light be measured which the small lens throws into the larger lenses, and then the superficial area of the circle of light which the larger lenses will collect by themselves be measured, probably it will be found that the use of the small lens causes the amount of light collected by the condenser to be nearly doubled. Possibly, however, fig. 8 is drawn solely for the purpose of illustrating the principle, and that in the practical working the paths of the rays would not form exactly the same angles as those represented in the diagrams. Yet, in any case, the gain in light is great, and why Mr. Pringle should go without the additional light collected by the third lens is a mystery requiring explanation. In fig. 7 the concave surface of the lens nearest to the jet enables it to collect more light than would a plane surface, since near the edge of the plano-convex lens the rays fall more nearly at a grazing angle, consequently more of them are reflected back into the lantern, the diameters of the condensers being the same in both cases.

BOOK ILLUSTRATION.—A correspondent of the *Gutenberg Journal* has drawn attention to the large and bewildering number of appellations under which different processes employed for the illustration of books are now designated. There are:—Tissiérography, zincography, paniconography (or gillottage, after the name of its inventor, Gillot), photogravure, photo-zincography, heliogravure, heliography, heliotype, helioehromotype, hélioglyptie, phototype, hélioplanography, photoglyptie, phototypography, photochromo, pantotype, Woodburytype, panotype, albertype, typochrome, collotype, antotype, diaphanotype, chrysogypy, gelatinography, téténotype, leneography, and chaotype.

PHOTOGRAPHING A WILD BEAR.—Henry H. Ragan, the lecturer, was out in the Yosemite not long ago looking up material. Like the modern traveller, he carried his camera wherever he went. He concluded, records the Chicago *Tribune*, that he would like to photograph a wild bear. This wish was communicated to a hotel clerk, who, like his more easterly brother, signified his willingness to furnish the bear. *Oberon*, king of the fairies in "A Midsummer Night's Dream," boasted that he knew a bank. The Yosemite hotel man, with equal felicity, said that he knew a bear. It came down from the fastnesses at certain hours and approached civilisation, gazed at it, and returned to its cave. Since the Government allows no hunting of game in National Park, Bruin roamed unmolested. But how to get the bear in position for a snap-shot from the camera was the question. The clerk solved this. At a certain hour the clerk took a large portion of meat from the cook's box and left it at a point at which the bear was frequently seen. Ragan followed with his camera. In due time the bear came down from its retreat. The clerk was a safe distance away when the bear appeared, but Ragan stood his ground. The bear stood its ground until the odour of the meat was wafted its way, when it made for the luncheon, picked it up greedily, and then, as if grateful for the feast, reared on its haunches and remained in that attitude for a minute, a sufficient time for a "sitting." A moment later the bear turned in another position, as if trying to accommodate the artist, and the latter obtained another view. The bear then rolled away in the direction whence it came. The artist, on returning, found the hotel clerk and a few guests secreted near his position, heavily armed, ready for a fray if the occasion had arisen.

PHOTOGRAPHY IN THE UNITED STATES.

BY CHARLES S. PATTERSON, M.B.

A National Association of Amateur Photographers—The New York Camera Club—"Stalls" for Developing Rooms—Photo-Micrography—The "Enoch Arden" Prints.

The news of the week is mainly concerning the convention which is to be held on Thursday, December 4th, at the rooms of the Society of Amateur Photographers of New York, at 113, West 38th Street. Twenty-eight delegates from fifteen of the principal photographic clubs of the United States will meet to consider a number of propositions, the principal of which is the advisability of forming a National League of Amateur Photographers. I enclose the prospectus.

I was yesterday shown over the rooms of the New York Camera Club, also those of the Society of Amateur Photographers. These, indeed, put to the blush our moderate ideas. Both premises are fitted throughout with the Swan-Edison incandescent light, and have magnificent brush lights for bromide enlargement.

Each worker in the dark room has a stall to himself, having a passage-way common to all running behind him. There are no doors to this passage, the light being excluded by the entrance, making two turns. The advantages of this arrangement are cool dark rooms, perfect ventilation, and thorough control over the light without incommoding any other worker.

I was shown drying rooms and enlarging rooms—daylight and electric—also rooms for isochromatising and storing plates, and for printing and mounting both paper and lantern slides. In fact, to know what it is to work under perfect conditions, one must enjoy the hospitality of an American photographic club.

While in the Camera Club, I had the pleasure of meeting Dr. Henry G. Piffard, one of the veteran photo-micrographers of the United States. His first photo-micrographic work was done in 1874, to illustrate his well-known work on "Diseases of the Skin." The plates were produced by Bierstadt by the gelatine line process. The source of illumination was a slowly moving heliostat. Now he has replaced his heliostat by a 100 candle-power incandescent lamp, a change he had not been able to make previously, owing to his inability to procure a light of that power. He is inclined to pooh-pooh our photo-micrographic work, and, indeed, for detail and quality his electric-lit negatives will compare very favourably with the best English productions. I have in my possession prints which I shall be delighted to forward for your inspection. Dr. Piffard has also been doing some beautiful microscopic photography of subjects lit by the magnesium flash-light. He uses the form which he invented, and with which his name is so intimately associated. He is certainly master of this method of illumination—detail, light, and shade being all harmoniously blended, and the usual staring character of the flash-lit subject is conspicuous by its absence.

En passant, I may say that the "Enoch Arden" pictures which took the grand prize at the Washington Convention this year are on view at the rooms of the Society of Amateur Photographers. They are three well-printed albumenised silver pictures to illustrate "Enoch Arden." In silver they look common and poor, but would, I think, be more than passable if printed in platinum or sepia. I hope to be able next month to forward full particulars of the fourth annual combined Exhibition of the Boston Camera Club and the Photographic Societies of Philadelphia and New York. The prospectus is now out. It will open on May 28th, 1891.

New York, December 2nd, 1890.

THE NATIONAL ASSOCIATION OF AMERICAN AMATEUR PHOTOGRAPHERS.

The following is the circular mentioned by Dr. Patterson, as having been sent to all the amateur photographic societies in the United States of America, and which seems likely to induce practical results:—

Sir,—The Syracuse Camera Club, by resolution dated August 8th, 1890, authorised the issue of a brief address to the amateur photographic societies and clubs of America, calling their attention to the desirability of a national organisation of those interested in photography, either practically or in its purely scientific relations. No farther reference was made to the special objects of such a national association, but the circular was thrown out as a germ thought, around which might crystallise the suggestions, objections, or assents of the organisations to which it was addressed. A large number of clubs and societies has responded favourably to this address.

The Syracuse Camera Club authorises the publication of the following:—

It may be well in this call for a meeting to effect the preliminary organisation which this numerous favourable response authorises, to herein enumerate some of the purposes that fall naturally within the scope of such a convention, as suggested in the many answers to the circular.

1st. The stimulus to study, invention, theoretical and technical knowledge that result from personal touch with those devoted to the many-sided science called photography, and to dignify a beautiful art which is in danger of being belittled by aimless practice.

2nd. That those objects are best served by an annual conference, preserving its organisation from year to year, and governed by a Council or Executive Board with its officers elected annually or otherwise, as may be determined at the preliminary meeting.

3rd. In connection therewith annual exhibitions of photographs, photographic appliances, and apparatus, and thus secure excellence of work and inventive activity.

4th. To promote the application of photography to the sciences, arts, and professions, among which we may mention astronomy, mineralogy, geology, botany, biology, medicine, pathology, microscopy, surveying and mechanical engineering, geographical and historical photography, medico-legal photography, submarine and spectroscopic photography.

5th. To preserve the scientific papers and inventions presented at the meetings in an annual volume of transactions, and thereby encourage men to prepare papers upon chemical, optical, and other collateral sciences embraced in the field of photography.

6th. To secure arrangements with foreign Custom Houses, through the Government, for the safe transmission of undeveloped plates and apparatus belonging to members of the national organisation, and to arrange with national, State, and local authorities the privilege to photograph in public parks, buildings, and on public occasions under the protection of his badge or membership card.

7th. To secure conveniently arranged dark rooms in all the hotels throughout the country, and special rates for the members of the league; also the preservation of a photographic directory of each locality, relating to the objects of historical and scenic interest, and the best time of day to photograph.

8th. To secure from the general government the free interchange of negatives and slides between the various club societies and members, represented in the national league or conference, and foreign photographers or societies.

This is only a partial enumeration of the important subjects that await the action of such an annual conference, and to

establish which your co-operation is earnestly solicited. The board of directors of the Society of Amateur Photographers of New York, at a meeting held on the 23rd of September, kindly granted the request of the Syracuse Camera Club for the use of the Society's rooms for a meeting of delegates to perfect the preliminary organisation.

You are, therefore, invited to send one or more delegates from your organisation to meet at the rooms of the Society in New York City, No. 113, West 38th Street, on the 4th day of December, 1890, at 10.30 a.m. An answer as early as convenient is requested, together with the names of the members who may be delegated to attend. Wallace Dickson, *Secretary.*

Box 173, *Syracuse, New York.*

SOME OF THE TENDENCIES IN PHOTOGRAPHIC ART.*

BY PHILIP H. NEWMAN.

To observe and comment on some of the present tendencies in photographic art, one is of necessity bound to notice its exhibitions, and although opinions may be divided as to the merits or demerits of the Photographic Society of Great Britain, and however one may be disposed to quarrel now and then over the justice of its awards in particular instances, or to question the advisability of its making any awards at all, one must, I think, allow, if indeed it does not almost go without saying, the exhibition in Pall Mall is usually fairly representative. That of this year being no exception to the general rule, I shall make no apology for drawing your attention to it as the basis of the critical remarks I have the honour to address to you this evening; premising, however, that criticism from my point of view is not necessarily fault finding, and where fault must be found, it is in no carping spirit, but after full conviction, and for that which I conceive to be of the very highest importance, viz., the true interest of art.

Now, at first sight, it may appear a very easy thing to make remarks on a photographic or any other exhibition; you have simply to go and look at the works, see which you like best, stamp them with your approval, slate all the others, and there you are. Of course one has to give some reason for one's likes and dislikes, but if this is wrapped up enough in technical phrases, bristling with plenty of the art-jargon current, one may sufficiently mystify an audience, and one's voice be none the less divinely authoritative because it comes from a cloud. But as I do not like this sort of thing at any time, and have too much respect and sympathy with my audience, in the present case, to veil my own ignorance by relying upon theirs, I grapple with the fact that it is not such a very easy thing after all to give a clear and useful opinion on the great variety of works comprised in the recent show in Pall Mall.

In the first place, the photographic journals have already had much to say on the subject, often dealing with the works exhibited seriatim, and pretty exhaustively; how, then, am I to drag you over this ground again, and tell you that Mr. So-and-So "surpasses himself in the true æsthetic way,"—whatever that may mean—or that Mr. Somebody-else is "very much befogged," and ought not to have been hung at all? Now, however necessary this sort of criticism may be thought to be in the management of a photographic journal, it cannot be said to be of much service to the amateur, so that if we are to talk profitably for an hour on the exhibition, it must be on other lines than these.

Now I am not a photographer, scarcely an amateur, but very much an outsider, and I think it not unlikely that your sagacious president, when he favoured me with your invitation to read a paper, thought there might be some hope in this; at any rate, it gives me hope that in looking at things quite in an outside sort of way, I may be able to point out more in the landscape of general interest, than if I groped for it in the dark room or through the camera. By the way, what an awful thing it seems to have to put one's head in a bag to look for the right combination of art and nature to make a successful picture. Woe unto those who have continually to do so, and cannot see a picture in the camera of their eye before they focus it in that of wood and brass. I fancy sometimes, when I talk to some photographers, or look upon their works, that they have never got their heads out of the bag from the first moment of their focussing career; art and nature both being to them thenceforth but darksome ways illuminated only by weird and flickering lights, leading them to the valley of the shadow of artistic death. If not so, how is it that the walls of our exhibitions are often smothered by lines of frames enclosing befogged inanities representing nothing in nature or art truly; perpetrations of people who are not, and never can be, either photographers or artists; or if they should happen to excel in one direction, are so blinded that they persist in thinking they must necessarily excel in another; obstinately exhibiting caricatures of portraits, when their *forte* is landscape; or whom, though their portraits may be tolerable, maintain the idea—as shown in their works—that aerial perspective in general landscape justifies indistinctness in every plane? Let us get our heads out of the bag, at any rate, and look at this recent exhibition in Pall Mall in the light of clear and wholesome day if possible, and without a sniff of the dark-room about us; and let us see what are our impressions, or depressions, as to questions of art.

Firstly, it seems to me that this exhibition was an epoch-making one, because it emphasised new departures in several directions, which the next exhibition must advance, or stultify itself as to its present leading. These new departures are principally in reference to printing processes. The old albumen silver print is becoming rapidly a thing of the past; it lingers here and there, unmedalled, on the walls; and it may not be prophesying too much to say that in the next exhibition it will be extinct, and that, for better or for worse, platinum and bromide will hold its place. Another new departure that undoubtedly will be more greatly in evidence in the next exhibition than even in this, is rough surfaced paper, as used in most of the new processes. Again, the carbon process seems not only to hold its own, but is gaining in interest as affording opportunity for a genuinely artistic alliance with hand work, as evidenced in some prints showing dry point finishing. There are on the walls many excellent examples of photo-etching and photo-gravure, but I only allude to them in passing; it would take far too long to enter into their merits and progress particularly, or to more than mention the highly interesting diazotype printing, based on the application to the art of the new coal-tar colour, primuline.

While speaking of photo-gravure, it must be remarked as subject of regret that the processes whereby it is endeavoured to produce engraved blocks for stereotyping, or to be used with ordinary letter-press type, are in a most unsatisfactory state—at least, for all commercial

* Read before the members of the West Kent Amateur Photographic Society.

purposes where an artistic result is desired ; the monotony of tone, or mere smudginess, being in most cases very disappointing. A great field is open here for photographers to invent a really artistic process to serve the purposes of the ordinary wood blocks. I may be forgiven for dwelling upon this if it does not arise naturally from the exhibition so much as from my own personal feelings and experience in regard to a series of illustrations "processed" from very tolerable negatives of my own, the prints being far, however, from all one could desire.

The exhibits of photo-micrography show, if anything, an advance ; in their direction, the painstaking labour of those who devote themselves to this less picturesque portion of the art is evidently bearing most desirable fruit in the general application of their results to purposes of study. If your worthy President does not make what is generally known as an artistic exhibit with his bacilli and dry bones, it must be allowed that he has succeeded in getting such a range of tones in the printing of these anatomical illustrations that, in an artistic point of view, some of the landscapists may envy him.

(To be continued.)

A PHOTOGRAPHIC EXHIBITION AT LOUTH.

IN order to give a stimulus to the art of photography amongst the amateurs of the town, the members of the Louth (Lincolnshire) and District Photographic Society decided to have an exhibition of their work in the Council Chamber, and this was held last week on Thursday afternoon and evening. In the afternoon admission was by ticket, and the leading gentry of the town and neighbourhood were present. The Mayor (Ald. James Fowler), who was accompanied by the Mayoress, opened the exhibition. The exhibits of the Louth members were supplemented by some from Mr. Gale, of London, and Mr. Armitage, of Nottingham. Mrs. Clarke showed illustrations of the application of photography to silk for domestic decoration, and some specimens of wall pockets and hand screens made of photographs on silk. Amongst the general exhibits of Mr. and Mrs. S. F. Clarke there were frames of lantern slides for which Mr. and Mrs. Clarke have been awarded several silver and bronze medals, micro-photographs which were awarded a diploma at Vienna, a certificate at the Crystal Palace International Exhibition, and two bronze medals, a picture entitled "What love hangs by," which received a medal at London, and the first prize at a Belfast competition, a picture entitled "Fortune Telling," awarded first prize at Belfast. In the group was a pretty picture entitled

"There is nothing half so sweet in life
As love's young dream."

This is, Mr. Clarke considers, his best picture, and although it did not take a prize, it commanded great attention. Mr. Clarence James is a large exhibitor, and amongst his specimens were a number of portraits taken on rough drawing paper. In his group were three landscape views which were awarded a silver medal at Kidderminster last March, a snow scene, awarded a bronze medal at London in 1888, and a portrait entitled "His First Model," awarded two medals a fortnight ago at Tunbridge Wells. A series of excellent pictures was sent by Mr. Armitage, of Nottingham ; a frost scene was admired by all present. Captain Ranshaw showed some photographs taken thirty years ago. The pictures sent by Mr. Gale, of London, were very handsome ; "A Moonlight Effect" and "A Misty Afternoon" were especially charming. Amongst the other exhibitors were the Rev. C. W. Whistler, of Theddlethorpe (president of the Society), the Rev. H. W. Everingham, of Trusthorpe, Mr. Alfred Plaskett, Mr. John W. East, the Rev. J. M. Coates, Mr. W. P. Willey, Mr. Henri Perron, Geneva, and formerly at the Louth Grammar School, and Mr. G. H. Formau, the latter three of whom showed the productions of their "first year's work." The photographs consisted of bromides, platinotypes, and a few silver prints.

The Mayor said that it gave him great pleasure to open this exhibition of amateur photography. He thought he was right in saying that the Society in Louth was the only one in existence in the whole county of Lincoln, and this was the first exhibition of the Louth Society. Over two hundred pictures were exhibited by the members of the Society, some of which had been shown for competition and won nineteen awards. After looking round at the exhibits, he thought that there was one word which might have been left out of the circular, and that was the word "amateur," for on carefully looking at their views, which were of such high character and good quality, the public might conclude they had before them the work of professionals rather than of amateurs. When they thought of what photography is, and what its namesake was fifty years ago, they could see what great strides had been made in the art. The Mayor then spoke of the advance in the science of photography of late years, and mentioned a picture, a frost scene, Mr. Armitage's collection, which, he thought, was one of the most beautiful photographs he had seen. There were many of local interest, which brought before them small parts of the neighbourhood, with which many people were unacquainted. People at a distance were apt to suppose Lincolnshire to be one flat morass, and that nothing good could come out of it, but on looking round he thought they had convincing proof that there are places of beauty and interest in the county near Louth. He hoped that the exhibition would not be the last ; he also hoped that it might set other towns in the county a little on fire for such a purpose, and that they might form local associations and have exhibitions. The Mayor picked up a picture from Mr. C. James' collection, and pointed out to all present how a picture could be made from a mere nothing ; the view was simply a disused brick pit with a marvellous sky.

Afternoon tea was served between the hours of four and five o'clock by Mrs. S. F. Clarke.

MIXED QUINOL HYDROQUINONE DEVELOPER.—H. Haberlandt recommends—

Sodium sulphite	... ...	100 parts
Eikonogen	... ...	16 ,,
Hydroquinone	... ...	4 ,,
Water	... ...	1,000 ,,
Potassium carbonate	... ...	40 ,,

THE LIGHT OF THE AURORA.—Professors Liveing and Dewar, in a paper recently read before the Royal Society, show that fine dust suspended in gas does not become luminous with its characteristic spectrum in an electric discharge, and they conclude that if the spectrum of the aurora is due to adventitious matter from planetary space, rather than to the ordinary constituents of the atmosphere, such matter must be brought into the gaseous state before it can become luminous in an electric discharge.

PHOTOGRAPHY IN COLOURS.—Dr. Miethe gives an account of the experiments he has made in photography in natural colours. He used collodio-chloride of silver containing an excess of nitrate. He exposed this collodion to a strong light for several hours, agitating it from time to time ; a brown precipitate is formed. After having decanted the clear portion, he coated with it some paper which rather rapidly reproduced the colours. Fixing is done with the aid of a solution of chloride of magnesium to which three per cent. of alum has been added. Unfortunately, at the end of a short time the colours fade. To obtain good results it is necessary to intercept the ultra-violet rays by a special screen. Dr. Miethe makes use of a plate coated with :—

Gelatine	... ...	2 grammes
Glycerine	... ...	2 ,,
Water	... ...	25 c.c.
Heseuline of Schuchardt	... ...	0·05 gramme.

By combining this plate with another coated with the same preparation, but containing, instead of the heseuline, 0·02 grammes of fluorescein, the absorption of the ultra-violet rays is almost complete. It is better to place these two plates with the film sides in juxtaposition.—*Photo. Wochen.*

SOME HINTS ABOUT NEGATIVES.

BY JULIUS F. SACHSE.

With the present month the out-door season of the amateur and tourist photographer draws to a close. The days have again become short, the trees leafless, the hill-sides bleak, and the romantic valleys cheerless, and there is little to tempt any but the pronounced enthusiast to wander forth with his tripod and camera. The great proportion of the outfits will be laid aside and neglected, with, perhaps, an occasional exception when they are brought forth from the shelf and set up for a few flash-light effects, after which they are set back until the zodiacal Taurus once more reigns supreme. Of course this does not allude to the photographic student or enthusiast, for to him the winter season brings the most interesting work of the year, viz., lantern slides, together with the opportunity for experiment and research in every department of the photographic art.

Strange as it may seem, the most neglected branch of amateur photography of the present day is the care and use of the negatives after we have them. The tourist, as well as the general amateur, during the season, exposes plate after plate, develops and fixes them, examines them, is pleased or dissatisfied with the results, as the case may be, after which the negative is put on the shelf along with many others in some out-of-the-way closet, box, or drawer, and the creator of the "latent image" soon forgets all about them, his mind becoming engrossed with new and different subjects, which are in turn destined to fall into the same groove. It is true that, occasionally, a few prints are made from a few of the negatives, but this represents but a small proportion of the whole number of the negatives taken. The great majority are soon forgotten, and at the next semi-annual house-cleaning find their way into the ash-bin.

Independently, it would be an interesting fact to know what proportion of the hand-camerists' "button pressures" ever see the light of day in a printing-frame; we here allude to the perfect negatives, not the failures. But, to return to our subject, we would suggest to all amateur and photographic tourists, now that the long evenings are at hand, to gather all of their photographic results, and put their negatives in envelopes, such as made for the purpose, classify and number them, and, during the coming months, have at least one print made from each and every negative, good, bad, or indifferent; have these mounted on a plain, white card, leaving at least a two-inch margin around the print—this will give ample room for notes or references for the future. These notes should give the exposure, stop, development, and lens, also the date, and, if a view or building, where located, and anything of interest connected with the special view. If the picture contains portraits or figures, add the names and the occasion. This work will be found to be an interesting occupation; in fact, the tourist will go over his trip once more, while, photographically, the comparison of the various prints will prove an instructive lecture for the future.

The prints may then be sorted out according to the subject, and if not bound into a volume can be placed in pasteboard boxes the size of the mounts, a separate box being used for each variety of subject; this is probably the best plan where there are many pictures of different subjects. Where the factor of expense becomes an item, and the amateur cannot do his own printing, we refer him to the excellent paper on "Artistic Blue-Prints" from an esteemed contemporary, which is re-published in the present *Journal*. But, no matter which plan you adopt, get the prints, and preserve and classify your negatives; you never know when any special negative will become of value, and, unless you employ a system, it is just then that you cannot find the one you want.

We were never more impressed with this necessity of a proper classification than on an occasion early last spring. We applied to a prominent member of our photographic society for a negative of a historic subject, which was wanted for an illustration. He had the negative, and wanted to loan it to us, but could not find it. He was certain that he had it; but there, it was somewhere among hundreds of others, all piled helter-skelter in a closet, one on top of the other, with a piece of newspaper between them; many were ruined, some broken, others spoiled by the dampness of wall. In reality, the work of this amateur, which represented years of labour and hundreds of dollars, was really valueless for the want of proper care and classification of the negatives after he had made them.

In our own practice, we put each negative in an envelope, and stand them on end in a strong pasteboard box made for the purpose, and which holds fifty plates. We number the box on the outside—say, 800-849, 850-899, &c. We then index the plates in a book under the proper subject, and any plate in our collection can be found in half a minute, and they are safe from dampness, dust, and interference. Where many subjects are treated, it will be found to be an advantage to reserve a different box for a special subject. Quoting again from our own practice, say the 100's are historic landmarks; 200's, revolutionary subjects; 300's, colonial churches; 800's, experiments with growing plants; 900's, microscopical subjects, &c.

In conclusion, we will say that, if we can afford to make negatives, we should also afford, or be willing, to take care of them, bearing in mind that, with the various changes which fleeting time brings, we never know how soon some negative in our collection may be in demand, and amply repay for the little extra trouble it takes to preserve and classify them.—*American Journal of Photography.*

THE LONDON CHAMBER OF COMMERCE.

A largely attended meeting of the representatives of the various trades interested in American copyright was held on December 11th, at the offices of the London Chamber of Commerce, Botolph House, Eastcheap; Mr. R. K. Causton, M.P., presided. The meeting proceeded to consider what action should be taken in connection with the American Copyright Bill. After discussion, in which Messrs. Edwin Ashdown, James Bowdon (Ward, Lock, and Co.), W. C. Knight Clowes (Wm. Clowes and Sons, Limited), C. J. Drummond (Secretary of the London Society of Compositors), R. W. Routledge (George Routledge and Sons, Limited), A. C. Trench (Kegan Paul, Trench, and Co.), and others took part, it was unanimously agreed that a committee, representative of all interests concerned, be appointed to consider the whole question and report to a future meeting as to what steps they would propose should be taken. It was also suggested that the London Chamber should communicate again with the Board of Trade on the subject.

A petition in favour of the appointment of a Royal Commission to inquire into the desirability of introducing the decimal system of currency, weights, and measures into this country is being circulated by the Decimal Association. Copies of the petition lie for signature at the London Chamber of Commerce, Botolph House; at the office of Mr. J. Emerson Dowson, C.E., 3, Great Queen Street, Westminster; and at the offices of Messrs. Cridland and Nell, 27, Bedford Row, London.

Notes.

When eikonogen first came into market, it appeared in a powdery form and of a chocolate colour, reminding one speaker at a public meeting of "road sweepings"; after a time it became purchasable in nearly white crystals. Dr. Elliott recently informed the New York Society of Photographic Amateurs that he had learnt from German sources that the transformation had been effected by making a saturated solution of the crude eikonogen in hot water, then adding some tartaric acid; the latter seizes the soda of the betanaphtholsulphonate of soda, and sets the acid of the eikonogen free in a flocculent form. The flocculi settle, and the liquid is poured off; the former are then dissolved in sulphite of soda, and from the solution the present eikonogen crystals of commerce are formed. A French authority says that the present powdered and "permanent" variety of eikonogen is made by grinding in with the changeable eikonogen a small proportion of metabisulphite of potash: too large a proportion of the latter salt will slow the developer. The statements are all based upon various assertions printed in foreign journals, and the hints may, perhaps, be useful to those who feel inclined to take up the work of verification.

The duty to be paid at the American Custom House for imported albumenised and sensitised papers has, under recent legislation, been raised from fifteen per cent. to thirty-five per cent., and great is the outcry among American professional photographers. Most of the albumenised paper used in the United States is sent there from Dresden, nearly all home attempts at competition with it having failed. The protective legislation is estimated by Messrs. Anthony & Co., of New York, to impose a tax upon American professional photographers of about one hundred thousand dollars a year.

The method recently employed by Dr. Scholbeuf, of Antwerp, of showing lantern pictures stereoscopically upon the screen, is attracting much attention on the Continent, the advantage of the method being that somewhat complicated synchronous mechanical contrivances are not necessary to produce the effect, and that each observer has but to look through two pieces of glass of different colours, one of which transmits most of the coloured light from one of the pictures on the screen, and the other most of the light from the second picture. Carefully selected green and red glasses are used to give the effect of stereoscopic relief. M. Davanne has made a communication to the Paris Society for the Encouragement of Industry, in which he says that the invention is not new, and that in Poggendorf's Annals for 1853 Herr Rollman, a German physician, describes an experiment of the same kind.

There are some curious photographic studios in the world. A popular photographer, Cook Ely, of Oshkosh, Wisconsin, has one so large that it will accommodate a dancing party of sixty, and a musical band. Says the *Oshkosh Times*:—"When the guests had all arrived, they crossed the yard to the studio. The spacious skylight room, with its fine, hard wood floor, capable of accommodating five sets at once, was illuminated by dozens of Chinese lanterns suspended overhead, the effect being very pretty. The Arions, being stationed at one end of the room, with music that always inspires, soon enticed the merry guests to float in the dreamy waltz, or join in the airy steps of 'McGinty.' The floral decorations in the studio parlour were arranged by Nelson, the grate and mantel being banked with potted chrysanthemums, and a variety of foliage and blossoming plants."

The cheaper production of aluminium is, from a photographic point of view, of so much importance, that we are glad to record any advance which promises progress in that direction. The metal has so many advantages that it may be regarded as the one which will in the future be more used by manufacturers of photographic apparatus than any other. Its high price is at present the sole bar to its extended employment, but of late years the cost of production has been reduced enormously, and we now learn that in the near future the metal will be obtainable at a price less than that of copper.

Many reports to the same effect have before been circulated, but this time the information bears the authority of a well-known name, so that we may have some confidence in it. Mr. E. H. Cowles is one of the directors of the Cowles Electric, Smelting, and Aluminium Company, of New York, and he therefore is able to speak with authority. He is reported in the *New York Times* to have discovered a totally new process for the extraction of the white metal from common clay—a process which, he says, is "ridiculously simple in operation, and almost theoretically perfect." The extraction of the metal from the clay is effected without the use of the electric furnace, and alterations are being made at the Company's works to produce it on a large scale. It is also said that capitalists in New York are preparing to build immense works for the production of the metal by this simplified process, and that one of these establishments will probably be at Niagara Falls, where about 12,000 horse power will be required for its operations.

It seems a pity that photographs do not, like rare etchings and engravings, increase in value with age. Were this the case, some collectors would be able to command a small fortune. But there is no reason why, when permanent prints are the rule instead of the exception, that photographs should not become more valuable as they get older. The chief obstacle would seem to lie in the difficulty of ascertaining whether the original negative is still in existence, for, if it is, of course the possibility of unlimited reproduction must

prevent any great value attaching to a single positive. In one or two London shops photographs of actors and actresses of the last generation are on sale; but, seeing that they only realise sixpence each, we cannot say that any great value is attached to them. They are, however, printed on the ordinary albumenised paper, and show the defects usually exhibited by prints due to that process at the end of a certain—or, rather, uncertain—period of time.

The Parisian paper *l'Illustration* lately contained a number of pictures reproduced from photographs of Dr. Koch, his laboratory, and enlargements from microscopic preparations of those bacilli with which his name is associated. The reproductions are remarkably well done, and place before the public pictures of undoubted accuracy illustrative of a matter about which the most extraordinary interest centres. We learn from the same source that Dr. Koch employs the camera largely in his work, taking photographs of his cases from day to day in order to show the gradual process of healing under his tuberculosis cure.

There is no knowing what photographic treasures the amateur may not pick up in his walks abroad. A Lisbon photographer has just presented to the *Societé Francaise de la Photographie* an enlargement of a photograph of a specimen of the marsouin, a singular fish, remarkable for being able to travel on the surface of the sea. The photograph was taken by one of the first detective cameras made by Goldmann, of Vienna, and had no range-finder. *Apropos* of unexpected photographic "finds," if any amateur photographer had his camera with him on Sunday night at a quarter to ten, he would have had an opportunity of securing photographic evidence of a very remarkable meteor which was visible in London. This meteor shot through the eastern portion of the sky, and at the end of its journey gave out an immense volume of light equal to that produced by a flash of lightning, but of a much paler colour. We have not seen any mention made of this phenomenon having been seen in London, although it appears to have been witnessed at Ramsgate, where, says the *Globe*, the whole town was illuminated, and therefore all the more reason to hope that a picture of it has been secured. Though, of necessity, occupying but a very brief period, there was yet time for a nimble photographer to have taken a snap-shot at it.

The activity shown all over the world in regard to astral-photography is most encouraging. The latest addition to the list of first-class observatories is that which is to be built in Catania, on the Mountain Consueno, near Bagheria. Several years ago an observatory was built on Mount Etna at a height of 3,000 metres, and this observatory is to be combined, so far as the work is concerned, with the new one. This new observatory is intended chiefly for the study of celestial photography, for meteorology, and for seismology. In the garden adjoining will be placed an instrument specially devoted to the photographing of the stellar spectra. With these appliances the new observatory will take its part in the international scheme of preparing photographic charts of the skies. The organisation seems to be of the most complete character, as, in addition to the studies already mentioned, there will be an apparatus by Dr. Huggins for photographing of the solar corona. Prof. Riccò has been appointed regular Professor of Astronomical Physics in the University of Catania, and Director of the two observatories. He is a member of the international committee for photographing the stars.

Mrs. Langtry finds sitting for her photograph more tiring than playing as Cleopatra. For her sixty photographs taken by Mr. Van der Weyde she sat four hours a day for three days. It seems a small thing to sit for one's portrait, but, somehow, it takes a good deal out of one. The effort of concentrating one's self upon nothing at all is unpleasant in the first instance, and becomes positively irksome as time goes on. Some patent has yet to be devised which, while keeping the sitter perfectly still, will yet afford sufficient amusement to sustain the pleasant expression which is so desirable. We imagine, however, that in Mrs. Langtry's case the pictures consisted of costume portraits, and required specific attitudes. Naturally, this would add to the arduous nature of the sitting.

Luke Sharp, of the *Detroit Free Press*, is nothing if not photographic. His Christmas story, which divides with Mr. Rudyard Kipling's "Badalia" the special number, has photography for its basis. To put the matter briefly, a gentleman offends a lady by taking her photograph, as she supposes. She insists upon it being destroyed, and he calmly refuses. Later on, as the plot is unravelled, and as the former enemies grow to be friends, he explains that the photograph which she saw him taking did not contain her portrait at all, although the camera was pointed towards her. The scene of the adventure is in the neighbourhood of the Niagara Falls, and he further explains that it was a picture of the Falls which he was taking, and that the exposure necessary to make a good negative of the Falls was of such a short duration that her figure, being dark, would not appear at all.

"But," objects the lady, "I have seen photographs of people with the Falls as a background." "Yes," replies the gentleman, in effect; "but such pictures are made up from two negatives. People are fond of being photographed standing with the Falls behind them, and they imagine that the picture which they buy is that which was taken; but, as a matter of fact, the photograph of a person is printed on to a photograph taken previously of the Falls, simply because the exposure of the first must be at least ten times that of the second." Luke Sharp's story is, perhaps, not the most successful of his efforts; but it serves to show how useful photography can be when an original plot is wanted.

PRESIDENTIAL ADDRESS TO THE GLASGOW PHOTOGRAPHIC ASSOCIATION.*

BY WILLIAM LANG, JUN., F.C.S.

I DO not know that anything very startling has been brought forward during the six months which form our recess. Perhaps the primuline process may be cited as the most original contribution to photography during that period. As we had at our meeting last month specimens of the colours produced by this method of light printing, I need not enlarge on the subject. Colour photography is always cropping up now and again. The most recent contributor to this vexed question was an Hungarian, Herr Verescz, but experts who have seen the results assert that no real advance has been made on what was done many years ago by Becquerel, Nièpce de St. Victor, and others.

Hand-camera work has really been the principal rage during the past season. I fancy it must have been a good time for the plate maker. Plates have been spoiled indiscriminately, and the amateur has fired away at all "sorts and conditions" of subjects, whether they happened to be sufficiently lighted or not. We have heard a good deal of the part played by the detective camera in the politics of Ireland; how that a picture was secured in open court of one of the witnesses under the very nose, so to speak, of the presiding magistrate. I have here for your inspection some enlargements of Kodak pictures illustrative of shadowing. I am not sure but that the indiscriminate use of this handy instrument (I see that I have perpetrated a joke without meaning it) may lead to mischief. A picture in the periodical *Pick-me-up*, of November 8th, will bring this home better to you than anything else. The letterpress going with the picture is as follows:—"From a lady's letter—'Yes, dear, there was only one thing that spoiled my trip in Scotland, and that was Nellie's meanness. Fancy, while I was making an innocent inquiry of one of the guards at Holyrood, she actually 'mapped' me off with that horrid demon camera of hers, and sent the picture to Bob, and you can't think how disagreeable he has been ever since. Nellie and I don't speak now.'"

I have the picture in question with me, which can be studied afterwards.

Photographing is entering more and more into the everyday occurrences of our ordinary life. Take any of the prominent illustrated papers, and a good percentage of the pictures shown will be found to be produced by some of the photo-block processes. I was very much impressed with an exhibit in the Edinburgh Exhibition forwarded by the proprietors of the *Daily Graphic*. First of all there was the original sketch by the artist with the negative taken therefrom, then the type blocks, which in turn had been prepared from same, and the corresponding composition mould, and, finally, the cylindrical form the actual printing surface had been made to assume. The scene depicted was that of the Tannton disaster, and the illustrations had appeared in the number for the day preceding that of the opening of the exhibition. In our own town collotype, as most of you are aware, is a photo-mechanical method being more or less developed—I speak advisedly when I say that I know of work being turned out equal to what is done on the Continent, which was originally the home of collotype.

I may with advantage, I think, refer to the literature of photography, which has greatly multiplied of late. While the two oldest journals in the country—*The British Journal of Photography*, and the PHOTOGRAPHIC NEWS—have reached their thirty-seventh and thirty-fourth volume respectively† (the contents of one year constituting a volume), the interest in everything appertaining to photography is now so great that publishers are found entering the field with new ventures, and each one is trying his best to give the fullest possible value at the minimum of cost. Witness *Photography*, the *Practical Photographer*, *Photographic Answers*, &c. The latter is a marvellous pennyworth; each number contains an excellent collotype, which I don't think could, *per se*, be produced at the money.

In Mr. Stead's magazine, the *Review of Reviews*, a new departure was inaugurated in the number for the month of August. A compilation of the more important photographs which have appeared since the publication of the previous number is now given in each issue. Productions of the more important add to the interest of this classifying of the photographs of the month. Here again we find photography lending a helping hand, for the reproductions are invariably photographic blocks. In the August number already referred to, portraits of Mrs. Stanley, Millais, and Leighton are given. In the September number, portraits of the Duchess of Teck, Princess Victoria, and the Bishop of Winchester appear. In October, Carmen Sylva, Queen of Roumania, and several portraits of the Ober Ammergau Passion Play are figured; while the most recent, that of November, contains two reproductions of portraits, and eight detective shots at the recent Tipperary trials, taken by Mr. Hindley, the principal of Fallowfield & Co., with his "Facile" hand-camera.

A purely art collection has recently been issued under the title of "Sun Artists." It has now reached its fifth number, and the photographic productions of such men as Gale, H. P. Robinson, Lyd Sawyer, R. Robinson, are reproduced in photogravure. The last number is devoted to the work done by the late Mrs. Julia Cameron.

Then, again, there has been running for some time a publication appearing monthly, published by Cassell's, and entitled *Cabinet Portrait Gallery*. With each number three excellent Woodburytype illustrations are given of celebrities of the day with appropriate letterpress. I have the number published with me this evening, and you can inspect them afterwards. A very interesting work by Werge, of London, having as title "The Evolution of Photography," appeared not long ago. It appeals, however, more directly to those interested in the history of our art. Some portraits are therein reproduced of the pioneers of photography that I have not seen anywhere else, notably Archer, Reade, Kennett, and Goddard; they are collotype, and, although somewhat small, convey a great deal. The book is here for your inspection.

Enough has been said to show how very actively on all sides we find photographic literature extending. Surely this is a testimony, if testimony be needed, that our art is advancing by leaps and by bounds, that it is in very deed becoming part and parcel of the daily life. As an Association it is our high privilege to take part in the general advancement of photography which we see going on all around us. We surely would not be true to the purposes and aims of this Association of ours if we did not feel—if each one of us did not feel—a glowing enthusiasm for that art which may truly be said to have wrought wonders in the past, and which, I may safely venture to affirm, has a still greater future before it. The possibilities of photography are in no sense to be limited and confined, and he would be a bold man who would assert that the highest pinnacle of photographic discovery and photographic utility has now been reached. I think the lines of exhortation in the well-known poem of Longfellow appeal no less strongly to us as a corporate body than they do to the individual:—

"Let us then be up and doing
With a heart for any fate,
Still achieving, still pursuing,
Learn to labour and to wait."

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical meeting on Tuesday, December 23rd, at 8 p.m., at 5A, Pall Mall East.

THE DEATH OF J. VAN NECK.—Joseph Van Neck, amateur photographer, and brother of M. Louis Van Neck, manufacturer of photographic apparatus at Antwerp, while on his way to Egypt, was washed by a great wave off the bridge of the *Tang-Seké*, and was drowned. On more than one occasion Joseph Van Neck has been rewarded by the Belgian Government for saving others at the peril of his life, and he was much respected in Brussels and Antwerp.

---

* Concluded from p. 973.

† The consecutive number of the PHOTOGRAPHIC NEWS to-day is 1,685, and that of the *British Journal of Photography*, 1,598. See also the PHOTOGRAPHIC NEWS of August 23rd, 1889, page 557.—ED.

NATURALISTIC PHOTOGRAPHY.*

Mr. R. B. Lodge began his paper on naturalistic photography by saying that it appeared to him that people start with the assumption that what the human eye is capable of seeing is what the photographer should strive to represent. Apart from the fact that probably no two persons see a landscape really the same, it is impossible to represent on a plane surface—such as a piece of paper or canvas—all the infinite variety and detail seen in any given landscape, and give not only all the detail, but the relative strength, beginning at the distance, and the result would be that the middle distance would be so strong that the foreground would not tell out against it.

The reader then referred to the older art of painting, and said that artists would find it useless attempting to paint the distance as strongly as it could be seen; they merely suggest the distance, and keep the full strength for the foreground, by that means giving the effect of atmosphere to the rest.

Mr. Lodge then proceeded to criticise the plates in Dr. Emerson's "Pictures of East Anglian Life," some of which he considered perfect, but regretted that many subjects were spoilt by an undue striving after tone—although tone and breadth are excellent and necessary qualities in a picture as long as they contribute to the truthfulness of the effect. Many of the prints are completely wanting in atmosphere: the distance looks as near as the foreground, there being no attempt at daylight.

Mr. Lodge agreed with Dr. Emerson's writings, but disapproved of many of his published photographs; he considered great good had been done to photography by his causing others to turn out better proofs of the truth of his principles than he can himself.

The reader then referred to Mr. Davison's work, which obtained the medal at the Pall Mall Exhibition, and said that there was breadth, tone, atmospheric truth, forming a most beautiful picture without any undue sharpness anywhere, yet nothing painfully out of focus, which is a great defect in many of Dr. Emerson's works.

Mr. Lodge concluded by saying that it is impossible to make hard and fast rules about focussing a composition, and treatment generally of a subject; it entirely depends upon circumstances; in some cases sharpness and all possible detail are necessary, in others they would be fatal to success. Generally speaking, he himself has a strong preference for a subject which depends upon composition and effects for its beauty, not upon intricate detail, and pointed out that sharpness and detail are the easiest things to obtain, but granted that in the right place they help to make a picture; they are not the chief points to strive after; on the other hand, it is extremely difficult to subordinate the distant parts of a picture so as to obtain the desired breadth, and to give prominence to the foreground.

Belitzki's Durable Reducer.—This reducer is prepared by dissolving in the order given—

Ferric potassic oxalate	10	grammes
Sodium sulphite (neutral)	8	,,
Oxalic acid	...2½ to 3	,,
Sodium hyposulphite solution (1 : 4)	50	,,
Water	200	,,

This solution keeps well in the dark, and may be used at once after fixing.

* Abstract of a paper read before the Enfield Camera Club.

THE PICTURES AT THE EDINBURGH PHOTOGRAPHIC EXHIBITION.

Class II.—Landscapes above 8½ by 6½.

Between sixty and seventy pictures are entered under this class, and if they were all arranged in such a way that the eye could take a general survey of the whole, the attention would be at once attracted by No. 605, as being distinct in character from all the rest. This is due to the fact that No. 605 consists of three pictures printed in a red-brown colour on very rough-textured drawing-paper, whereas all the rest are tones of grey and black upon ordinary smooth—generally matt—paper. The three pictures entitled "Penzance Harbour," "Autumn Sunset," and "Torbay" are by Colonel W. L. Noverre, and, apart altogether from the special features referred to, are exceedingly picturesque. The rough paper lends itself admirably to enhance the effect of light and shade, particularly aiding the reflections in the water, and giving richness, force, and an imagined detail to what might otherwise have been hard and, perhaps, uninteresting. Two of the pictures each represent a vessel on a slightly rippled sea, with bright sunny sky, the distance being a town, and a low, wooded shore respectively, each in thorough keeping, and duly retiring. The immediate foregrounds are simply the quiet sea, just broken by the glancing light on the ripples, very translucent, the reflections admirable, the whole combining to make exceptionally beautiful results. But it is probable the central picture will have even more admirers; it is a sunset effect, the main light falling on the sea at the horizon, immediately behind a black rock, which materially adds to its intensity. The lines of light in a particularly fine sky all converge to this focus, while the foreground completes a harmonious whole that is exceedingly satisfactory.

H. P. Robinson is specially strong in this class, and we do not remember to have seen him to better advantage. There are a simplicity and truth about his work that are peculiarly pleasing. No. 645, "The Moorhen," is one of the gems of the Exhibition. It is a beautiful composition, and an admirable example of Robinson's characteristic work. The subject is a simple landscape with two figures, exactly in the right place, peering between the branches of trees growing on a bank; the girls are evidently looking down on the moorhen's nest below. The three masses of light are most happily situated, and, altogether, its naturalness, completeness, and beauty lead one almost to forget the thought, the arrangement, design, and art necessary for its production, until reminded of it while considering where and how such another could be produced. No. 631, "Selecting Flies," is another capital picture, and, doubtless, many will think it quite equal to the one above alluded to. No. 632, "Waiting for Gaffer," is somewhat different in treatment and subject from the rest of this exhibitor's contributions. It is a rich and brilliant platinum print representing a grey and brown horse standing in a quiet lane, with a fine mass of foliage as a background. The beautiful, quiet light on the animals, which are most felicitously placed, the feeling of "waiting" so distinctly apparent, and so in keeping with the title, cause many an exclamation of pleasure from the visitors. Other works by Mr. Robinson also command attention, such as "Honeysuckles," "Baby's First Harvest," Sweet Spring-Time" (a couple of lovers, a grand old windmill, and a glorious sky). "Reflections" and "Ferrying Them Over" are characteristic works and charming pictures.

J. R. Gibson sends several carefully treated subjects, notably No. 179, "The Woody Banks of Tyne," which is a capital rendering of foliage in sun and shade, with a good foreground of rocks; also an effective picture entitled "From the Mill Dam." A grand rock occupies almost the whole of the middle distance, but allows a charming peep at a sun-lit distant landscape, while the foreground is occupied by curious waterworn, fissured rocks in the bed of a stream.

A. Williamson exhibits three views on Park Loch, Aberdeenshire. There is a quiet reposefulness about these that is very pleasing. In one with two ladies in a boat there is not a ripple on the water, each single reed has its own unbroken reflection, and the beautifully luminous sky, almost without any defined cloud, is eminently suggestive of peace. Another (No. 18) indicates an approaching sun-set, and expresses silent loneliness; both these are fine compositions, and show a highly cultivated taste.

R. C. Mossman sends a platinum print of the observatory on the summit of Ben Nevis. This also is eminently suggestive of silence and solitude, but totally different in character. Here we have a sombre sky unbroken even by a cloud, a dreary expanse of snow without a foot-print, and a conical mass of snow which, from its shape, we know contains the observatory. The utter solitude is accentuated by smooth snow between the meteorological instruments, which, with dogged perseverance, receive their visits at rigidly fixed intervals, both by day and night; no other sign of life. It is a suggestive picture.

J. Macmahon exhibits some capital views about Aberdeen. Two views of "Old Machar Cathedral" and "King's College" are worthy of notice; and his "Auld Brig o' Balgownie" is particularly fine, while "Aberdeen from the Harbour" is remarkable for its crisp, sharp detail.

J. R. G. Stroud sends some fine views in Jersey; they are printed in carbon; one is specially noticeable, an avenue with beautiful dappling lights and fine perspective.

Andrew S. Watson exhibits a quiet sunset with cloud and water, and a rocky foreground; it is very pleasing; also three brilliant views, "At St. Fillans," the central one by far the best.

George Bruce is represented by "Blanwearie Woods." This shows the entrance to a pine wood with a winding path. It is a difficult subject well treated.

Dr. Drinkwater is well represented by a frame of Scotch views. "On the Ardoch" is a pleasing picture of an old water-mill and trees, with a sun-shot stone-encumbered stream, lighting up the foreground and giving balance to the whole.

Mr. Harding Warner, Mr. John Mc Kean, and Mr. Graham Toler also exhibit good work in this class.

According to the official list some interiors, by Mr. John Moffat, are also in this class. These are remarkably good presentations of four difficult subjects. One, a drawing room with stained glass windows, is particularly well done. In this every detail of a fully furnished room is beautifully indicated—the draperies, marbles, paintings, the deepest shadows and highest lights are most skilfully treated. It is soft and harmonious, with a remarkable freedom from the spottiness so often seen in this class of work.

X. Y. Z.

IMPRESSIONISM IN PHOTOGRAPHY.*

BY GEORGE DAVISON.

THIS is an age of scientific inquiry in every branch of knowledge. Empiricism, irrational authority, and conventions, have been greatly cast aside, and freedom of thought and scientific investigation have taken their place. Phenomena are closely observed, and a basis of material fact and proof is demanded for every principle that is sought to be established, whether in biology, mental and moral science, or philology. Matter is held to be the storehouse of every possibility, and the observation of its infinite functions the only source of true and useful knowledge and progress.

The supernatural is losing its power to command worship, and a nobler wonder, roused by the laying bare of the natural causes of the phenomena of the universe, reigns in its stead. Poets and philosophers have, equally with scientists, been affected by the freer spirit. Literature has more of the true character of life and nature in it, and the newer light has even written its effect in our later students' text-books. Finally, in art the same influence is discovered in the revolt against conventionalism, and in the scholarly practice of those painters who have been variously called impressionist, naturalistic, and the like.

It would have been indeed strange if, amongst all these changes of principle and action, which we are pleased to call progress, the domain of art had remained untouched and unaffected, for the painter's art has been trammelled by conventions and chained by dogma equally with ethics and science. There have been unnatural conventions in regard to colour, conventions about form and proportions, conventions concerning light and shade, arrangement of lines, and decorative qualities, as well as many other marks and mannerisms imitated in a manner tending to obscure and lead away from the greatest beauty in pictures—namely, their truth to nature.

It has been well said, "It is so much easier to do what one has done before than to do a new thing, that there is a perpetual tendency to a set mode, but Nature abhors mannerism, and has set her heart on breaking up all styles and tricks." Now these "set modes" and conventional treatments in art have been such that the more they have been compared with natural facts—facts of atmosphere, facts of light, facts of colour—the more have their formality and falsity become apparent to unprejudiced observers influenced by the spirit of free and scholarly inquiry. Nothing but a return to nature can break up such "styles and tricks," and free an artist from the tyranny of previous great names and works. It was such a return to nature, such a close observation of natural appearances under the influence of the materialistic tendency of the age, that led to the growth and practice of the body of painters known as impressionists. Abandoning all consideration of the arrangements and mechanism of previous workers, they have consulted only their impressions of natural scenes, and, to those impressions, painted. With one point of sight and one subject of supreme interest, they have aimed to seize, above all else, the action and first impression of that subject. The effect of such work upon the painters of the older conventions, and upon their following amongst the public, was to rouse hot opposition, but the best of the new influences have had very considerable effect upon the more liberal of established painters. De Chesneau, writing of the pictures of M. Monet, says: "In spite of such works as these, the eye of the public—trained to exclusiveness by long intercourse with other and no less legitimate readings of nature, and prevented, in a great measure, by the abuse of facile tricks of painting—refuses as yet to recognise the purpose and merit of this school. But it will come to it."

A more judicious section, those who seek a natural and scientific basis for their practice, has preferred, as far as such tenets permit any crystallizations, to style itself "The Naturalistic School." The painters of this school, seeing the conventional untruths generally practised in pictorial representations in regard

* A paper read last Wednesday night at the Society of Arts; Mr. Francis Cobb occupied the chair.

to light, colour, and atmosphere, have set themselves to the practice of close observation of nature to gain a better knowledge of the infinite mysteries of these phenomena. Truth to nature is the first article of their faith, and the truest that science teaches concerning light and colour, and the manner in which the eye sees, is made a guiding principle. Every naturalistic artist must be a scholar. Happily, a cultured sense arrives at the same preference as that to which, in the main, the scientific inquirer is led. Should any fresh investigation lead to a truer view of physical or mental fact, the naturalistic student, to deserve the name, must readily make a re-adjustment of his principles, and modify his methods in accordance. It is not unnatural that the eccentricities as well as the genuineness of a new development should come to be regarded as distinctive of a school, but it must be remembered that any tenet or practice to be naturalistic must stand the test of scientific investigation. Naturalism, then, instead of signifying indistinctness and eccentricity, as is not uncommonly supposed, purports to be the gospel of common sense, scientific inquiry, and culture in art. It leaves its advocates free to express themselves about what is going on in the world by means of their graphic art, without other trammels than a severe regard to truth, naturalness, and perfect expression. The naturalistic painters find the possibilities of all poetry in nature; it is truthful representation, perfect expression, that constitute their art. They hold that what is seen should be painted, that symbolism and imaginative creations can have but a feeble interest, and that what we have actual contact with in life affords the opportunity for the most powerful expression by graphic art of any abstract quality. It is in the life of to-day, and not in the illustration of other people's ideas, whether past historical subjects or so-called works of imagination and allegory, that the proper province of the painter's art is to be found. To be true, and living, and moving to our sensibilities, the scenes and subjects depicted must be studied directly from nature by the artist.

Should anyone desire to get a better idea of the tenets of the naturalistic school, I would refer him to Mr. Francis Bate's book, "The Naturalistic School of Painting," a fresh, direct, convincing little work which every photographer should read, and, in parts, re-read, and to which I wish to express my own indebtedness.

Under such principles have been produced paintings which have the power of moving a sympathetic, nature loving observer to the keenest of æsthetic pleasure, an ecstacy of enjoyment far beyond any satisfaction derived from the "fitness of symbolism," or decorative arrangement. Some may never have discovered this feeling for subtle representations of natural scenes, but no one is capable of estimating the respective merits of the old and the new, the power of such poetry as is shown in symbolical or decorative work as compared with the poetry of naturalism, who has not felt enraptured by the perfection of naturalness of some of these genuine impressionist paintings. There is a liveliness, an exuberance of joy, a yearning for a sympathetic companion to share the feeling of exultation, when one has happened suddenly upon a subtle fact of natural light, colour, air, or form happily touched off, a curve of the beach, a boat seen from the shore level on a stormy day over the crests of the surf, a broken bit of ground in sunlight, and the like.

It is only in the light of such views, then, that I care to examine or put forward the claims of photography, as, indeed, of any other method, to be admitted as a capable means of artistic expression.

Photography compels to much that is naturalistic. It has proved the keenest critic of conventionalism, and has exerted great influence upon the painter's art; influence, sometimes good or bad, individually, according to the knowledge and power, or the ignorance, of the painter influenced by it, but in the main tending towards greater truth and insight. In regard, however, to its own direct claim to be admitted as a means of artistic expression, it has only happened with the introduction and application to photography of these principles that any serious demand to be recognised in the domain of art has been made. Photographers have previously been rather inclined to accept the slur commonly cast upon their means and results as mechanical, and have exaggerated the limitations which their tools and technique impose upon them. They seem to have been unduly influenced by the patronage of some classes of painters who have despised and contemned photography, partly with justice, seeing the average published results, and partly through ignorance of its possibilities. Photographers have accepted this degradation of their art, and have even joined voice in deprecating any reform or movement which promised better artistic expression as "aping the conventionalities of painting." For example, some of the photographers of the older conventions have latterly objected to any but the most limited use of focussing for expressing the relative interests of a picture, and have even insisted that definition is the distinctive characteristic of photography. They have inveighed against rough surfaced prints as being in imitation of sepia drawing, appearances presumably held to be the sole privilege of the brush workers, and, whilst claiming for decorative, historical, imaginative, and symbolical painting the highest credit in art, they have disclaimed for their own medium any power or province in such work.

Mr. Stillman holds that photography can have no place in art because design is impossible to it, and design he seems to define as "deliberate arrangements" carried out by hand. Mr. Pringle denies the possibility of what he terms "fine art" to photography, or at least to any but combination photography, by the peculiar distinction that he lays down when he says, "Art obtains where a painter simply paints what he has before him. This is not fine art." Mr. Gale finds the greatest happiness in what he alludes to as a transformation of nature and "those ideal representations which are the perfection of art," and in this reference he instances Turner's "Storm." Mr. H. P. Robinson approves and seeks to justify a wilful opposition between art and nature, and he goes with Mr. John Brett in demanding an improvement of nature, an exaltation of natural appearances, and an accentuation of beauties in pictorial representations, a position, perhaps, intended to justify combination printing.

There are other alleged limitations and defects, such as that photography cannot treat the sublime, that the nude is outside its scope, and a variety of cries all more or less included in the general exclamation that photography is merely mechanical.

(To be continued.)

THE PHOTOGRAPHIC CLUB.—On December 24th (Christmas Eve) there will be no meeting; December 31st will be a Lantern evening; subject for January 7th, 1891, "Photo-Micrography."

THE REASON WAS APPARENT.—Lawyer: "On what ground do you seek a divorce?" Female client: "My husband is an amateur photographer, and ——" Lawyer: "That will do. We'll have no trouble about it. My wife has the craze too, and I have been taking my meals at a restaurant for two weeks."—*Norristown Herald.*

LANTERN PLATES.—The Britannia Works Company has sent us some special lantern plates for black tones. After trying several of the specimens, both for printing by contact and in the camera, it was found that they gave good slides, with short exposures, and the images came up rapidly under the action of the quinol developer recommended by the makers. They are rapid, and of a clean working nature. Those tried in the camera were, on account of the dull weather, exposed to the magnesium light softened by ground glass, and yielded good results.

A WAX FINISH.—An exchange says: "An admirable wax finish for furniture woods is made by mixing about three ounces of tallow and three and a quarter pounds of wax with one pint of turpentine, which is constantly stirred while boiling and until cold. The paste is rubbed in, the superfluous wax removed with a wooden scraper, and then gone over with soft woollen cloths until it shines. Some workmen prefer to let the wax dissolve in the turpentine cold, as they fancy the heat diminishes the polishing effect. If a coat of French polish is afterwards applied it deepens the gloss."

ASTRONOMICAL TELESCOPES.*

BY A. A. COMMON, F.R.S., TREASURER TO THE ROYAL ASTRONOMICAL SOCIETY.

AT less than nine inches distance objects become more and more indistinct as they are brought nearer to the eye. From what we have seen of the action of the lens in producing pictures of near and distant objects, we know that some movement of the screen must be made in order to get such pictures sharply focussed, a state of things necessary to perfect vision. We might therefore suppose that the eye did so operate by increasing, when necessary, the distance between the lens and retina, but we know that the same effect is produced in another way; in fact, the only other way. The eye, by a marvellous provision of nature, secures the distinctness of the picture on the retina of all objects beyond a distance of about 9 inches, by slightly but sufficiently varying the curvature of one of the lenses; by an effort of will, we can make the accommodating power of the eye slightly greater, and so see things clearly a little nearer; but at about the distance of 9 inches, the normal eye is unconscious of any effort in thus accommodating itself to different distances. The picture produced by the lens of the eye, whose focal length we will assume to be six-tenths of an inch, falls on the retina, which we will assume further to be formed of a great number of separate sensible points, which, as it were, pick up the picture where it falls on these points, and through the nervous organisation produce the sense of vision. Possibly, when these points are affected by light, there may be some connective action, either produced by some slight spherical aberration of the lens, or otherwise; but I do not wish to go any further in this matter than is necessary to elucidate my subject. What I am concerned with now is the extent to which the sensibility of the retina extends. Experiment tells us that it extends to the perception of two separate points of light, whose angular distance apart is one minute of arc, or, in other words, at the distance we can see best, two points whose distance apart is about 1-400 of an inch. This marvellous power can be better appreciated when we remember that the actual linear distance apart of two such points on the retina is just a little more than 1-6000th of an inch.

In dealing with the shape of small objects, the difference between a circle, square, and triangle can be detected when the linear size of their images on the retina is about 1-2000 of an inch. It may be therefore fairly taken that these separate sensible points of the retina are somewhere about 1-12000 part of an inch apart from each other. Wonderfully minute as must this structure be, we must remember, as we have already shown, that the actual size of the image it deals with is also extremely small. This minuteness becomes apparent when we consider what occurs when we look at some well-known object, such as the full moon. Taking the angular diameter of the moon as thirty minutes of arc, and the focal length of the eye at six-tenths of an inch, we find the linear diameter of the picture of the full moon on the retina is about 1-200 of an inch, and assuming that our number of the points in the retina is correct, it follows that the moon is subject to the scrutiny of 2,800 of these points, each capable of dealing with the portion of the picture that falls upon it. That is to say, the picture, as the retina deals with it, is made up to this number of separate parts, and is incapable of further division, just as if it were a mosaic. I think this is really the case, and as such a supposition permits us to explain not only what occurs when we assist the eye by means of a telescope, but also what occurs when we use the telescope for photographing celestial objects, we will follow it up.

In the case of the eye, we suppose the image of the moon to be made up through the agency of these 2,800 points, each one capable of noting a variation in the light falling upon it. In order to make this rather important point plainer, I have had a diagrammatic drawing made on this plan. Taking a circle to represent the full moon, I have divided it into this number of spaces, and into each space I have put a black dot, large or small, according to the intensity of the light falling on that part of the image, as determined by looking at a photograph of the moon. You will see by the picture of this moon the effect produced. It represents to those who are at a sufficient distance the moon much as it is really seen in the sky.

We can now, with a lens of the same focal length as the eye, obtain a picture of the full moon exactly of the size of the actual picture on the retina, and if we take a proper photographic process, we can get particles of silver approximately of the same sizes as the dots we have used in making our diagram of the moon; the grouping is not exactly the same, but we may take it as precisely so for our purpose. I have not any photographs of the full moon of this size, but I have some here of the moon about five, seven, and eight days old, which give a good idea of what I mean by the arrangements of the particles of silver being like our diagram.

It is now quite apparent that if we can, by any means, increase the size of the picture of the moon on the retina, or make it larger on the photographic plate, we shall be able to employ more of our points in the retina of the eye, or of our particles of silver in the photographic film, and so be able to see more clearly just in proportion as we increase the size of the picture in relation to the size of the separate parts that make it.

Now the telescope enables us to do this for the eye, and a lens of longer focal length will give us a larger photographic picture.

Let us assume that, by means of the telescope, we have increased the power of the eye one hundred times. The picture of the moon on the retina would now be one-half inch in diameter, and instead of employing 2,800 points to determine its shape and the various markings upon it, we should be employing 28,000,000 of these points; and similarly with the photograph, by increasing the size of our lens we shall obtain a picture made up of this enormous number of particles of silver. But we can go further in the magnification of the picture on the retina; we can also use a still longer focus photographic lens.

A power of magnification of one thousand is quite possible under favourable circumstances; this means that the picture of one two-hundredth of an inch would be now of five inches in diameter, so we must deal with only a portion of it. Let us take a circle of one-tenth of this, equalling one-hundredth of our original picture, which in the eye, unaided by the telescope, would have a diameter of one two-thousandth of an inch, or an area of less than one five-millionth of a square inch. This means that, with this magnification, we have increased the power so enormously that we are now employing for the photographic picture two thousand eight hundred million particles of silver, and in the eye the same degree of increase in the number of points of the retina employed in scrutinising

* Continued from page 929.

the picture piece by piece as successive portions are brought into the central part.

Photography enables me to show that the result I have given of the wonderful effect of increasing the optical power is perfectly correct as far as it is concerned. We will deal with a part only of the moon, representing, as I have just said, about one-tenth of its diameter, or one-hundredth of its visible surface. Two such portions of the moon are marked, as you see, on the diagram. I have selected these portions as I am able to show you them just as taken on a large scale by photography, so that you can make the comparison in the most certain manner; but let us first analyse our diagrammatic moon—let us magnify it about ten times, and see what it looks like.

Specifications Published.

18,583. *Nov. 20th*, 1889.—"Optical Lanterns." ALEXANDER HUGHES, 59, Fenchurch Street, London, Optician.

The inventor claims :—

1. The construction and arrangement of biunial, triunial, or other multiplex optical lanterns, in which each optical system is so mounted as to permit of the adjustment of each lantern one to another without distorting the optical axis of the one or the other.

2. A multiplex optical lantern, in which each lantern system is adjustably mounted and pivoted on vertical supports for angular adjustment, and retained in position by telescopic or adjustable supports attached to each lantern.

3. The construction and arrangement of an optical lantern, allowing parts of it to be manufactured of aluminium to reduce the weight, substantially as described.

4. In such an optical lantern, a light box so constructed that the roof or top shall fold down for transport and be capable of being raised by a radial movement around its centre in an angular direction to permit the better ventilation and carrying off of heat.

859. *January 16th*, 1890.—"Aluminium." HELEN WHITE, 2, Church Fields, Cheshunt, Hertford, Widow, Executrix of William White, deceased, late of 2, Church Fields, Cheshunt, aforesaid.

This invention has for its object to effect the manufacture or production of aluminium in a more economical and ready manner than has hitherto been done.

In the manufacture of aluminium cryolite has been used, but it has the serious objection that it is frequently contaminated with iron silica and other impurities. According to this invention, I manufacture the aluminium from aluminium fluoride, which I prefer to prepare artificially, so as to obtain it in a pure or practically pure state, and I utilize the bye products of the manufacture of the aluminium from the aluminium fluoride in the production of fresh quantities of aluminium fluoride as hereinafter described. I may prepare the aluminium fluoride by evaporating to dryness a solution of alumina or aluminium hydrate in hydrofluoric acid.

The aluminium fluoride is heated with sodium or potassium, or a mixture of them, aluminium is liberated, and fluoride of sodium (or of potassium, or of both) is formed. An excess of aluminium fluoride is preferably used, as it helps by combining with the fluoride of sodium (or of potassium, or both) to form a suitable flux for the metal. This flux, when treated with sulphuric acid, gives up its fluorine as hydrofluoric acid, which is used for dissolving alumina or alumina hydrate in preparing fresh supplies of aluminium fluoride.

What I claim is :—

1. The use of the fluoride of aluminium obtained by evaporating to dryness a solution of alumina or aluminium hydrate in hydrofluoric acid.

2. The production of aluminium, substantially in the manner hereinbefore described.

12,921. *August 15th*, 1889.—"The Production and Representation of Instantaneous Photographs." WORDSWORTH DONISTHORPE, 32, Pembridge Villas, Bayswater, Middlesex, Barrister-at-law, and WILLIAM CARR CROFTS, Westminster Chambers, 7, Victoria Street, Westminster, Gentleman.

This invention has for its object improvements in the production and representation of instantaneous photographic pictures.

The pictures are produced upon a sensitive film or surface carried by a long roll of paper or other material.

The roll is continuously unwound from one drum and wound upon another, and in its passage a series of images is successively thrown upon it by a photographic lens. A screen is provided between the lens and the exposed sensitive surface. This screen travels out of the way to permit the image to fall on the sensitive surface, and covers the lens again as soon as the exposure is complete. These operations take place with regularity, and usually great rapidity, so that several pictures are taken in each second during the time that the apparatus remains at work, which will be for many successive seconds, indeed for any length of time which may be desired. The scene selected for photographic presentation will be one of constant movement—for example, a street scene—so that each picture will differ slightly from the preceding and succeeding pictures.

The camera may be arranged in the following manner : In the fore part is the lens, and immediately behind the lens the screen, which regulates the instantaneous exposures. The screen may be an endless band passing around pulleys and travelling at high velocity. In the band there are two perforations or apertures, and twice in each rotation of the band these perforations coincide, and the light is then able to pass from the lens through the perforations on to the sensitive surface. The lens forms the scene upon the sensitive surface. The focus is accurately adjusted before commencing the operation by the aid of a slide on which there is a focussing glass and guide rollers, over which the continuous sensitive paper or material passes.

The screen and the winding apparatus are so geared together that the sensitive surface travels the distance necessary to separate the pictures between one exposure and another. In place of the travelling perforated belt, a disc perforated with a narrow slit, and driven by bevel-wheels, may serve the purpose. After the pictures have been taken, the roll is removed from the camera, and the pictures upon it are developed in the ordinary manner. From this continuous band of negative pictures a similar band of positive pictures is produced, and rendered transparent by the application of vaseline, or vaseline oil, or by any other suitable process.

For the exhibition of the pictures, a lantern similar to the ordinary magic lantern—or, if a non-transparent positive band is used, then a lantern similar to the opaque magic lantern—is employed, in which a brilliant intermittent electric light is provided. The lantern is provided with condensing and focussing lenses, by the aid of which the light, after having passed through the transparent positive picture, is focussed upon a screen. Each picture is thus exhibited only by one flash of the intermittent light, for the band of pictures travels on, and by the time the next flash occurs another picture is in place. Thus several pictures are exhibited upon the screen in each second of time throughout the whole period of exhibition, which will usually be approximately the same as

that occupied in taking the pictures. The change from picture to picture, aud the flashing of the light is so rapid (about seven flashes per second) as not to be discerned by the eye, and the appearance on the screen is that of a picture in which the auimate aud other objects exhibited are in movement. In order that the flash may synchronise accurately with the picture in position, contact pieces are provided upon the travelling band, and by the passage of these the flashes are determined. Or a contiuuous light, electric or other, may be used, and the recurring flashes obtained by a perforated screen travelling at high velocity, as in the camera above-described, the coincidence of the flashes with the centre of each successive picture being insured by increasing or diminishiug the speed of the travelling band of pictures by an arrangement for the insertion or withdrawal of a tapering driving drum, or other appropriate meaus.

Correspondence.

THE PLATINOTYPE COMPANY AND THE REDUCTION OF PLATINUM PRINTS.

SIR,—In the PHOTOGRAPHIC NEWS just to hand, the Platinotype Company say that there must be soue mistake in my reference to their having stated that strong hydrochloric acid would reduce black platinum prints. At the meetiug of the Photographic Society to which they refer, I recited the substance of what I now quote from the report of a meeting of the West London Photographic Society, at page 915 of the NEWS, and also at page 749 of the *British Journal*.

"Mr. Jones (Platinotype Company) gave an account of the platinotype process."

"Mr. Blackmore said that . . . . on putting a very much over-exposed sepia print in the developer it flashed up immediately very dark and dense; then, on transferring it to some strong hydrochloric acid, considerable reduction took place, and the print became quite passable. He would like to know whether the black process was susceptible of reduction in the same way."

"Mr. Jones replied that . . . . the strong acid would reduce a black priut just as it did the sepia one, but would rot the paper."

In answer to my question at the Photographic Society of Great Britain, it appeared that no one present had had such experiences as these. The Platinotype Company now say that they have never experienced the reduction of a black image by hydrochloric acid, and I would ask them whether, to their knowledge, sepia prints are or cau be affected by the strong acid in the manner indicated above. CHAPMAN JONES.

IDEALISTIC PHOTOGRAPHY.

SIR,—In your issue of the 12th iust. you quote a paragraph froui the *Photographic Art Journal* eutitled "Idealistic Photography."

I must poiut out to you that the implication of unfairness coutaiued therein is in itself unfair. The subject was first opened at the London and Provincial Photographic Association by Mr. Phillip Everitt, who read a very able paper on the subject of "Pictorial Definition," in which he showed himself strongly sympathetic with Dr. Emerson's principles. He, unfortunately, declined to allow the paper to be published, but it led to a considerable amount of discussion, the interest taken in the subject generally being very great. That paper was followed after a short time by one by Mr. W. E. Debenham on the "Unnaturalness of Naturalistic Focussing," and another on a following evening by the same gentleman eutitled "Is Blurring Desirable?" Both papers were also received with great interest by the members, and Mr. Debenham was heartily thanked for the exhaustive mauner in which he had dealt with the subject. The papers by Messrs. Newman and Collier also followed on the samo side, condemuing Emersouian ideas, as advocated by Mr. Everitt in his paper.

It is neither within the powers or province of the Association to produce Emersonians, in order to hear *more* on that side of the question, nor to compel those who may exist to find and bring forward more arguments against those in the papers read by the opponents of Dr. Emerson's views.

As the writer of that paragraph was evidently unaware of the exact facts when he wrote, in fairness to those gentlemen who have treated the subject so fully in their papers, I must ask you to publish this explauation, and so repair to some extent the harm which is so often done when statements are made which cannot be supported by facts.

THE HON. SECRETARY, L. and P. P. A.

THE CALCUTTA PHOTOGRAPHIC EXHIBITION.

SIR,—We regret to say that the number of exhibits forwarded to us from abroad is so small that it has been decided to abandon the International Exhibitiou advertised to be held in December, 1890.

The Photographic Society of India beg to tender their best thanks to those who have despatched exhibits, and can only express the hope that on another occasion they will not be deterred from once again assisting us.

All exhibits will be returned, carriage paid, as soon as possible. JOHN S. GLADSTONE,
A. FLEMMING,
Hon. Secs., Photo. Society of India.

Calcutta, November 11th, 1890.

PRINTING FRAMES.

SIR,—Kindly allow a correction to be made as follows: The frame noticed is not Mr. Walter Tyler's, but emanates from me. From notices that have already appeared, many persons seem to think I am "trying to hash up an old dish with new trimmings," and have expressed as much. I beg, however, to state that my frame differs entirely from any previously issued, inasmuch that the back of the frame is designed in such a manner as to firmly grip the print and prevent any chance of the paper moving during the opening or closing of the flap used to examine the prints. From the uotice you give you evidently noticed this particular feature in my frame. By inserting this you will oblige. WILLIAM TYLAR.

Birmingham.

THE YORKSHIRE COLLEGE PHOTOGRAPHIC CLUB SYLLABUS.—January 29th, 1891, Lantern Exhibition; February 26th, "New Priuting Processes," C. H. Bothamley, F.I.C., F.C.S.; March 12th, "Tone and Colour in Lanteru Slides," Prof. Jacob, M.A., M.D.; April 30th, Exhibition of apparatus.

PHYSIOLOGICAL EFFECT OF A BRIGHT LIGHT.—A curious phenomenon was observed at the end of the annual concert given at the Salpétrière Hospital, Paris, by the Lionnet Brothers, assisted by a great number of artists. The concert over, M. Londe, director of the photographic service of the hospital, wished to "take" the audience hall. For this it was necessary to burn a strip of maguesium. The blinding light, although it lasted but ten seconds, threw several of the patients into a cataleptic state. The effect of light, however, ou highly sensitive persons is knowu. It is iu this manuer that, at the Charity Hospital, Dr. Luis acts on his patients by means of the luminous reverberation produced by revolving mirrors.

THE ROYAL INSTITUTION.—The foilowiug is the list of Friday evening lectures at the Royal Institution during the first half of the couiug session:—Friday, Jauuary 23rd, Lord Rayleigh, M.A., D.C.L., LL.D. F.R.S., M.R.I., "Some Applications of Photography"; Friday, January 30th, Sir Edward Fry, Lord Justice, F.R.S., F.S.A., F.L.S., M.R.I., "British Mosses"; Friday, February 6th, Professor J. W. Judd, F.R.S., F.G.S., "The Rejuvenescence of Crystals"; Friday, February 13th, Professor A. Schuster, Ph.D., F.R.S., F.R.A.S., "Some Results of Recent Eclipse Expeditions"; Friday, February 20th, Edward Emanuel Kleiu, M.D., F.R.S., "Infectious Diseases, their Nature, Cause, and Mode of Spread"; Friday, February 27th, Percy Fitzgerald, M.A., F.S.A., "The Art of Acting"; Friday, March 6th, Professor J. A. Fleming, M.A., D.Sc., M.R.I., "Electromagnetic Repulsion"; Friday, March 13th, Felix Semon, M.D., F.R.C.P., "The Culture of the Siuging Voice"; Friday, March 20th, Professor W. E. Ayrton, F.R.S., "Electric Meters, Motors, and Money Matters."

Proceedings of Societies.

The Camera Club.

On Thursday, last week, the last meeting of the Camera Club in its old premises at Bedford Street, Strand, London, was held under the presidency of the Rev. F. C. Lambert, M.A., and Lieutenant Gladstone read a paper on the "Photographing of Interiors."

Mr. Gladstone, in the course of his remarks, said that the images of windows, when photographing interiors, are often visible before development. A stop, giving the focal length of *f*/20 and sometimes a slightly larger focal length, is often convenient to use in such work; an exceedingly small increase in the size of a stop will, where it can be employed, save much time in exposure. Direct sunlight streaming through the windows is usually bad, but in some few cases it is an advantage. When half a window is included in the view, too much light is thrown near it upon the wooden edge of the frame, and causes fog at one of the edges of the plate; the remedy is to bevel and roughen the wooden edge. Wide-angle lenses should always be avoided in interior work if possible; sometimes their use is a necessity, and they give better results to the eye when a wide vertical angle is included on the plate, rather than a wide horizontal angle. He used a tripod head with another head on the top of it, the level of which latter is governed by screws, as in the theodolite; this device is useful when suitable resting places for the feet of the camera cannot readily be found. Circular spirit levels are exceedingly useful. The normal developer employed by any photographer, if diluted with an equal bulk of water, will form a suitable normal developer for interior work. No photographing of interiors should be attempted without backed plates; he used black varnish for the purpose.

Mr. George Davison remarked that the excellent results produced by Mr. Gladstone showed the advantage of taking up one branch of photographic work and sticking to it thoroughly.

Mr. Lyonel Clark spoke of the excellence of the film negatives exhibited by Mr. Gladstone, and wished to know who made the films.

Mr. Gladstone stated that he used Eastman's stripping films.

Mr. Clark thought it best to do without backing; staining the films themselves with eosine would do as well, and some other coal-tar dyes were suitable.

Mr. Corbould said that some eosines were acid, and slowed the plates; some of the others were alkaline, and caused fog.

The Chairman remarked that he, like others, had found that with the long exposures necessary in interiors, the people walking about in the building usually did not spoil the picture, but once a lady walking about with a large white bonnet on her head had spoilt one of his negatives. None of the backings for plates had answered satisfactorily in his hands, but black carbon tissue soaked in equal proportions of glycerine and water had worked best according to his experience.

Mr. A. Maskell thought that direct photographs of monumental brasses would be of more value than rubbings.

Mr. Gladstone thought that the brasses should first have something rubbed over them for a time, to diminish their glare. During long exposures, sometimes parts of the film moved slightly, probably from changes of temperature, so as to present local areas out of focus. An effective size of plate for certain architectural subjects he had found to be 12 by 8 inches. Stripping films gave much better interiors than did any dry plates. Reflections from one or more of the surfaces of the lens would sometimes throw on the plate, where it was not wanted, a secondary image of a window in the field of view.

The Photographic Society of Ireland.

An ordinary meeting of this Society was held at the Rooms, 15, Dawson Street, Dublin, on Friday, 12th inst., Mr. G. Mansfield, president, in the chair. Some queries from the question box having been dealt with, Mr. Greenwood Pim described how he photographed the "Book of Kells" in the library of Trinity College, Dublin, and exhibited some beautiful prints giving a great range of shades representing the varieties of colour in that celebrated work. At the conclusion of Mr. Pim's remarks, a debate on the management of lantern exhibitions was opened by Dr. E. McDowell Cosgrave, and resulted in an animated discussion amongst the members.

The London and Provincial Photographic Association.

December 11th.—Mr. A. Collier in the chair.

Mr. Pemberton asked to what angle a graver should be ground to cut vulcanite.

Mr. A. Haddon said the cutting of vulcanite involved the frequent sharpening of the tool used. A graver such as was used for turning brass work would answer the purpose.

Mr. T. E. Freshwater, referring to the recent explosion of a gas pressure guage at Rochdale, enquired if any member was in possession of more particulars than had been published on the subject.

A Member believed that the gnage was full of oil, and that it was the first time it had been used.

Mr. L. Medland exhibited a "lantern slide exposer;" it was designed to suit hand exposure negatives, which were sometimes a little out in the perpendicular.

The rest of the evening was devoted to the exhibition of lantern slides; a large number was projected on the screen, contributed by Messrs. E. W. Parfitt, Teape, Aldhan, Kellow, Medland, Chang, and Freshwater.

Mr. Teape spoke of a means of remedying over-intensification with the uranium bath by using common washing soda, 10 grains to 1 ounce of water, as a bath, or applied locally with a brush. Reduction could be effected in a few minutes to any depth desired.

The Lantern Society.

At a special general meeting held at 20, Hanover Square, on December 8th, it was resolved that the entrance fee should be abolished, and members joining now are, therefore, only liable for the subscription.

At the ordinary meeting held on the same night, a paper was read by Mr. J. G. Grenfell, F.R.M.S., on "Means of Protection amongst Animals." The paper, which was illustrated by some fifty slides, was of considerable interest, the lecturer describing the various means adopted by animals for their protection in the great struggle for the survival of the fittest. Some of the methods employed were of a most remarkable description, more especially in the cases of mimicry, where the animals reproduce the appearance of natural objects with such marvellous exactitude as to defy detection.

The following are the arrangements for the meetings of the Society up to the end of February:—December 22, Mr. C. E. Gladstone, on "Some Architectural Features of Normandy and Brittany"; January 12, Mr. E. M. Nelson, F.R.M.S., on "The Lantern and its Relation to Photography and the Microscope"; January 26, Mr. C. Harrison, on "The Civilisation of Egypt and Assyria, as illustrated by its Physical Remains and Records"; February 9, Mr. J. Traill Taylor, on "Lenses and Condensers for Lantern Work"; February 23, Exhibition of Lantern Slides for members and their friends.

The Torquay Photographic Association.

A meeting was held on December 9th, when a discussion took place on "Silver Printing and Toning," opened by Mr. A. K. Blunt, M.A. (vice-president).

A series of prints toned by different formulæ was exhibited, also three prints taken by means of the electric arc in the $\frac{1}{10000}$ part of a second, of a jet of water.

Several ladies had joined the Society, which now numbers over fifty members.

The Notts Amateur Photographic Association.

The new Club Rooms were opened for the first time on Monday, December 15th. The Association, which was formed in December, 1884, formerly had rooms over a shop in Market Street. These, however, not being suitable, rooms were selected over Mr. Warwick's in the same street. These are much more comfortable, easy of access, and more suitable in every respect. The walls of the rooms were covered with

interesting photographs, the production of different members of the Association. Mr. S. WELLS presided, and there was a fairly good muster of members and friends. Mr. Henry Cooper was nominated for membership, and Mr. Laucelot Allen was elected a member.

Mr. G. E. SMITH exhibited, by means of his oxyhydrogen lantern, the slides of illustrated Bostou, U.S.A. ; also slides by members, including Mr. R. S. Armitage, Mr. Clements, Mr. Forrester.

Mr. BURROWS' notice of motion that sous of members (uuder eighteeu) be admitted at a reduced subscription was carried unanimously.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

THE ordiuary monthly meeting was held in the Mosley Street Café, Newcastle, on Tuesday, the 9th inst., Mr. J. P. GIBSON in the chair. Five new members were elected.

The new optical lautern, which has been subscribed for by the members, was in operation for the first time, and over 250 slides put through ; the lantern, operated by Messrs. Ridgway and Pratt, gave great satisfaction.

Nominations for officers for the current year were received, and the election will take place at the auuual meeting in Jauuary next.

THE GLASGOW PHOTOGRAPHIC ASSOCIATION.

THE second geueral meeting of the session was held on 4th inst., in the Rooms, 207, Bath Street; Mr. WM. LANG, Junr., F.C.S., was in the chair. Messrs. A. Lindsay Miller and Alexander Munro, Junr., were admitted members, and afterwards Mr. Lang gave his Presideutial Address (see NEWS of last week, and coutinuation in this week's issue).

Mr. GEORGE BELL made a communication regarding the charges of the corporation for water supplied to photographers.

A hand-camera, designed by Mr. Robb for stereoscopic pictures, was shown to members, aud also a series of views taken in Norway with the apparatus.

BRECHIN PHOTOGRAPHIC ASSOCIATION.

THE new rooms of the above Association at 14, St. Mary Street, were opened by the president on the 9th December. They consist of a fair sized reading room, which is also to be used for meetings ; a dark room, in which benches have beeu fitted up and water laid on ; and cloak room.

Mr. ADAMSON, the president, opened with a lecture descriptive of a tour "From Liverpool to the Yosemite Valley by the Straits of Magellau," illustrated with lanteru slides ; and Mr. R. A. McLeau Murray exhibited over fifty slides of the Ruins of Pompeii, with which he intends to illustrate a lecture ou that ill-fated city.

Five honorary and two ordinary members were admitted ; the Rev. H. Campbell, Messrs. J. S. Baxter, D. Hunce, J. Simpson, and Watson as honorary members ; and Messrs. W. Ferguson and Colin Hutcheon as ordinary members.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—At the meeting held on December 10th, Mr. W. Bedford chairmau, four applications for aid were cousidered and granted.

CURIOUS PHOTOGRAPHS.—Remarkable success has been attaiued by Professor Ahu, of Breslau, in applying photography to fix the indications of different diseases of the eye. Another contribution to one of the newest departments of scieuce is Professer Fischer's photographs of cultivatious of luminous bacteria—which were photographed by their own light—the views giving evidence of the constaut movement in which the tiny organisms are unceasingly engaged. One of the greatest anthropologists of the century, in Paris, has been making a collection of the various types of mankind, and he does it by means of the photograph. He iuclines to the opinion that the type or origin of the race to which the person originally belouged is better preserved amoug women than among men.—*Wilson's Photographic Magazine.*

A. J. L., Birmingham.—Your communication has arrived too late.

Answers to Correspondents.

*** TO ADVERTISERS AND OTHERS.—The PHOTOGRAPHIC NEWS will be published on Wednesday next, so that announcements intended for insertion should reach the Publishers on Tuesday afternoon, before five o'clock.

All Communications, except advertisements, intended for publication should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

F. R. A. S.—*Astronomical Photography.* Mr. Maunder's paper is not withdrawn, but only postpoued uutil the next meeting, which will be held at 50, Great Russell Street, Bloomsbury. During the holding of the Winter Exhibition at the Water Colour Society's Gallery, Pall Mall, the regulations do uot permit of our fitting up the oxyhydrogeu lantern which is required for showing the illustratious on a screeu. This can be done at the new premises on the 13th January.

M. P. (Jersey).—"*The Letter.*" The chromotypogravure illustration in the *Graphic* of 22ud ult. is certainly very fiue, but we agree with you iu the poiuts of detail meutioned. There is no *ink* in the pen, and a false lighting in the eyes, which could easily have been rectified.

J. B.—*Blue Developer for Primuline.* Your observatiou is not new. See leading article on the "Diazotype Process" at page 857 of the NEWS. The amidobetanaphthol sulphouic acid there mentioued is equivaleut to a mixture of eikonogen and acetic acid, and the use of it was demonstrated at the lecture.

C. R. PANCOAST.—*Gas for Optical Lantern.* Messrs. Wm. Sugg aud Co. have a double ring fifty-caudle argand, burning fifteen feet of gas per hour, with circular jets fixed level aud concentric, and faced with steatite. This has been tried recently for eulargements, and favourably reported upon, and there is no doubt it would serve well for moderate power optical lanterns. Address : Chariug Cross, W.C.

H. J. C. (Lewishaui).—*Capt. Abney's Reply to Messrs. Hurter and Driffield.* This will be found (page 17) in the curreut number of the *Journal of the Photographic Society*, having been reprinted from the *Journal of the Society of Chemical Industry.* Mr. Chapman Jones's article is also in the same number.

J. G. (West Hampstead).—*Printed Rulings for Half-Tone Zinc Blocks.* Enquire of Mr. J. J. Ayling, 12, Crane Court, Fleet Strcet ; or look at Advertisement on p. cxix. of the YEAR-BOOK.

WILMOT.—*Studies of Hoar-frost.* You ought to have been able to secure some good exposures during the past week. At page 143 of the YEAR-BOOK will be found directions for obtaining official permits, but, so far as our experience goes, iu the North London parks none are required.

LEDBURY.—*Stereoscopic Effect.* By holdiug up a stereoscopic slide at arm's length, and directing the focus of the eyes to au imagiuary point beyond, so as to bring the pictures separately within the range of vision, they will soon coalesce with formation of a ceutral (third) image in true stereoscopic relief. This is done by a species of outward squinting, which is easily acquired by a little practice.

L. E.—*Decimetres and Centimetres.* All through the article the word "decimetre" should have been written "centimetre." This is apparent by the "c.c." being occasionally placed alongside or within brackets. The main calculation is all right, but it must be remembered that *a thousand* cubic centimetres make a litre.

J. R. C. (Whitchurch).—*Lantern Transparencies.* Apply to Mr. Wm. Brooks, Wray Park, Reigate, or to Messrs. York and Son, Laucaster Road, Notting Hill, W.

J. D. (Glasgow).—*Albo-carbon Gas.* Surely there is au ageut in your town ; if not, apply to the Albo-carbon Light Company, Westminster, or to Messrs. Kent and Company, High Holborn.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1686.—*December* 26, 1890.

CONTENTS.

THE YEAR 1890.

THE year now drawing to its close has been of a more eventful character than some of its predecessors in relation to the progress made by photography.

The diazotype processes are but a few months old, yet they are of such a novel character, and give such a power of producing photographs of different colours, that in time they are likely to be extensively utilised for various purposes. At present they are but in the experimental stage, but investigators are at work industriously examining their powers, and in time this research will bear fruit. At present all the pronounced colours of the spectrum can be obtained by the primuline process, but a satisfactory and durable green has as yet not been produced. In this process positive prints are produced from positive transparencies, and not from negatives; the process is likely to be of use for the production of reversed negatives for photo-mechanical processes.

Colonel Waterhouse has discovered, during the year, how to produce direct positives in the camera without long exposures; this is brought about by the use of thiocarbamides in the developer. The results have to be seen before the possible value of the discovery can be realised. Only a few weeks ago we saw some of the results in the shape of strong and brilliant transparencies; they were not imperfect images of no practical pictorial value. The action of sinamine instead of ordinary alkali in the developer might well be tried, but possibly it is not yet obtainable in the market. Thiosinamine, which is much used by Colonel Waterhouse, can be obtained from Germany through Messrs. Burgoyne & Co.; the purchaser would probably have to turn it into sinamine himself, should he desire to try the latter substance. Colonel Waterhouse says that at present there is a lack of certainty in obtaining the best results by his method.

The artistic side of photography is in a lively state. A new "school" of art is attracting attention; its members advocate more softness and less sharpness in photographs, and in the endeavour to obtain pleasing pictorial effects, care little for mere technicalities of any kind. The word "school" is a rather high-sounding term to apply to a few simple matters, still it is nice to begin to learn photography after buying a two-guinea set, then to let the hair grow long, dress in a velveteen coat and slouch hat, take pictures out of focus, and within two months to go about among one's friends as a member of a new school of photographic art, ready to do battle to the death for the new standard.

During the year photographic exhibitions have been increasing in number throughout the land. At the present time a first-rate one is open in Edinburgh, in which city the photographers wisely do not weaken their energies by holding large exhibitions too frequently.

Some new machine cameras have been invented during the year for taking several hundreds of successive pictures per minute, upon an endless band of sensitised paper or other fabric. These are likely to come into use in warfare, also in book illustration; they could be used for newspaper printing if a sufficiently inexpensive sensitive salt could be discovered.

The Camera Club and the Photographic Society are now moving into new premises of their own, the former in Charing Cross Road, and the latter in Great Russell Street, London. The Photographic Society is about to establish a library and a museum.

The larger manufacturing firms in photography are displaying a tendency to combine for mutual aid and protection; so also are the professional photographers; so also are the photographers' assistants. Some of the manufacturers have formed themselves into a section of the London Chamber of Commerce. In photographic, as in all other sections of society, the more highly educated the individuals, the more effective and powerful will be their organisations; and the lower the education of the individuals, the less effective will be their organisations, also the more will they split into sections, and the more will they waste time in squabbling over rules and petty points of detail. Good education and good organisation bear a distinct relation to each other, all other conditions being equal.

Great fluctuations in the price of platinum have taken place during the year. At one time the cost of

its salts rose to double that of a year or two ago, but the recent discovery of platinum in Australia has just brought the price down with a run.

An attempt has been made, and is now in progress, to introduce standard screws and flanges for lens mounts into general use. Photographs are much in need of this improvement, also standard hoods for lenses to take shutters manufactured by different firms.

Among the losses by death during the year, we have to mention the names of the Rev. T. H. Hardwich, Father Perry, Colonel Stuart Wortley, Mr. Baynham Jones, Mr. J. Solomon, Mr. T. J. Collins, and H. B. Berkeley.

PLATE CHANGING.

As the juggler casts a number of balls into the air, and they each rise to the highest point one after the other and then return to his hand, so the photographer has to adopt some means to bring plate after plate under the influence of his lens, so that Father Sol can set his seal upon them. In the old days of wet collodion there was little difficulty about the operation, for a single back—or, rather, rough box—was all that was required; but when dry plates came to the front the case assumed altogether another aspect. No one in his senses would go out armed with a single gelatine plate, so the double back arrangement came into vogue, and as it took up only the same space as the clumsy single back, it was speedily adopted. Excellence of manufacture became a *sine qua non*, for whereas a pinhole or two or a crevice did not excite the rather sluggish susceptibilities of the collodion plate, the dry material was of far too sensitive a description to be thus trifled with. And so it became the custom, by common consent, to supply each camera sold with its regulation complement of three double backs, and this arrangement has held its ground ever since as the most convenient which, on the whole, can be adopted.

But many other plans for bringing the plate under the action of the lens have been suggested and devised, and it is not too much to say that this single question of manipulating glass plates without allowing a trace of light to act upon them has engaged the attention of inventors perhaps more than any other problem connected with photographic apparatus. One of the first outcomes of this endeavour to conquer a difficulty was the production of the changing-box, one of the most successful forms of which was that designed by Hare. In this arrangement, the stock of plates—twelve or fifteen in number—was stored in a grooved box, and, by simple mechanism, each plate in turn could be transferred, by means of a special form of single back, to the camera. This was a capital form of apparatus when the operator knew that he would require to make a number of exposures; but the weight of the box for anything over half-plate size was considerable, and the invention failed to displace the more portable double-back. The same may be said of the multiplex back system, which had also much to recommend it. But, in this case, the weight of the apparatus, when charged with a dozen or more plates, became still more inconvenient, for the box and its load had to be attached to the camera when the picture was being taken. Another disadvantage accruing to this system was that the back of the camera must be rigid, that is, without that play which allows of a back or side swing. In certain cases, therefore, the use of the camera had to be abandoned, or the operator had to be content with a distorted picture.

The introduction of the hand-camera has again aroused attention to this important subject of changing plates with ease and certainty, and we may reasonably hope that, from the vast amount of ingenuity which is being brought to bear upon the matter, some permanent good will result. In some of the newer forms of so-called detective cameras, the plates are made to move from their magazines one by one, to turn from a horizontal to a vertical position, and resume their original place in a most obedient and wonderful manner. In many cases each plate requires to be placed in a special case, or sheath, before it is ready for the magazine. Other cameras, however, dispense with this preliminary operation, and we should, other things being equal, be inclined to choose a form of camera in which the plates can be slipped just as they are taken out of their original boxes; for previous manipulation means chance of stray light, dust, breakage, and other calamities, and it is best dispensed with.

The most perfect method of presenting a sensitive surface to the action of the lens is undoubtedly represented by the old panoramic device—two rollers, which wind out the material in lengths as required; but this naturally requires the use of a flexible web or film. Such films were made in days gone by by Melhuish—who devised the first roll-holder more than thirty years ago—by Woodbury, by Warnerke, and others. It has been reserved for the Eastman Company to produce a film and apparatus for actuating it which are really of a practical nature. But, for many reasons, glass plates will continue to be used by the majority of workers, including all whose daily employment is found under glass. And so the question as to the best means of changing plates remains an important one, and is, perhaps, best answered when the needs of each inquirer are known.

SECURING A "PLEASANT EXPRESSION."—It is an easy thing to laugh where there is something to laugh at; but when nothing funny has happened, laughing to order is a very different matter. The other day a certain German gentleman urged an amateur to photograph his two children when they were laughing. On a certain afternoon the amateur came with his camera, but on hunting up the children it was discovered that, while the little girl was quite willing to smile, the boy was in a very bad humour. In fact, the boy had just been punished by his father, and when he was asked to laugh never felt less humorous in his life. But the camera was there, and the father was set upon having the performance proceeded with. He repeatedly urged the boy, whose mouth did not get beyond a slight twitching at the corners. Then, becoming exasperated, the father shook his finger and exclaimed: "You laugh now, or I vip you again!" And under this awful persuasion the boy made an heroic effort.—ALEXANDER BLACK, in *St. Nicholas* for October.

CHRISTMAS PHOTOGRAPHS.

IT is a remark of the elder Pliny that the nature of man is greedy of novelty. In this respect Christmas is disappointing. Our Christmas—or, to speak more fashionably, Yule-tide—greetings have varied little during a very long time. The familiar stereotyped craving after another's "Merry Christmas," and an alien "Happy New Year," has lost much of its innate diguity and festive warmth. It is now commonly regarded as a forced formula of social politeness, or—so low has it fallen from its original high estate—a disingenuous demand for something to drink. Christmas presents probably owe their prolonged existence to the ingenious tradesman, who labels with this title at the present season everything saleable, from a patent cure for the cramp, to a stuffed crocodile. Christmas stockings are becoming rarer with the rolling years. The stocking of the oldeu time has been long considered, even by the infant understanding, a troublesome absurdity. Christmas trees and Christmas tracts still flourish in ever-green adolescence. Christmas mince pies and Christmas boxes are equally difficult to forget. These, like the poor, we have always with us, and the same may be said of Christmas bills.

It is high time for the photographer to be up and doing. It is for him to vary the weary and stale monotony of Yule-tide by a neat selection of Christmas photographs. These should be, of course, remarkable for congruity, taste, and truth. Absence of colour may, no doubt, be a stumbling-block in their way to popular favour, which, for some unexplored æsthetic reason, looks askance at this season upon monochromatic—and other sobriety. But this defect can, perhaps, be compensated by the elegance of their frames. They might chiefly consist of portraits and scenery. Both should be, except in the large cities, local. The curiosities, the "sights worth seeing," the cynosures of the guide-book, in every town should be put under contribution. In the smallest hamlet, the church, the market, and the hall—or whatever the squire may choose to call his house—would probably meet with some purchasers. Appropriate sentiments, pious or profane, in prose or poetry, must, of course, be deftly displayed on every photograph. The popular phrases of compliment, the well worn "With the compliments of the season," and "Wishing you a merry Christmas," in their multitudinous varieties, must be distiuctly legible. It is, indeed, this legend, or the portraiture of something intimately associated with the so-called festive time—such as a sprig of mistletoe or a mince pie, a piece of holly or a smoking hot plum pudding—which forms the characteristic difference between the Christmas card and the Easter card, the New Year's card, the birthday card, and the valentine. To all these, also, there is no reason why photography should not be applied.

One advantage will be certainly gained. Our Christmas photographs will be representations not of ideal fancy, but of actual fact. In a season of so much sincerity of genuine affection and real benevolence, a needless note of discord has ever seemed to be introduced by the portraiture of much that is altogether inconsistent with truth, or at least with adaptability. Such, for instance, are the pictures of young ladies, with next to nothing on them, playing at skipping-rope, or curiously contemplating a bowl of gold fish. These insufficiently attired females are, it is said, known in the trade as "youthful beauties." In spite of the preposterous unsuitability of their scanty raiment to the frost and snow of winter's reign, they appear to suffer no kind of inconvenience, but disport themselves as though in the sultry sunshine of a midsummer noon. Fair, indeed, they are, but false; incarnations of inconsistency and fraud. False, too, and fair are the presentments of the butterfly, an anomaly in December, and of the heartsease, a darling of June. With these the Christmas photographer will have naught to do. He must also, though this is a matter deeply to be deplored, carefully eschew guardian angels. By so doing he will, indeed, lose fruitful and frequent opportunities of gain, for there is a large section of the public to which these anatomical monsters appeal with peculiar and exclusive force and urgency: but the field of nature is wide, and he will have enough to satisfy him and to spare, without the introduction of a physiological caricature, or of that almost equally objectionable and unprofitable picture of the cock robin everlastingly connected with Christmas, and the cottage buried in snow.

Perhaps the most suitable scenic subjects for Christmas photographs would be representations of nature as she commonly appears in the month of December. Out of the many variations effected by frost and snow, the cunning photographer may make some of his sweetest music. Failing these, he may try his hand at the brooding terrors of the storm, or the winter tempest fermenting in the evening sky.

Next to these subjects in importance is individual portraiture. At a time of general peace and good-will to men, the photograph of a friendly face must surely be a more desirable present than the similitude of a fat turkey; a group of children of a neighbour—children not occupied with the nuisance of snowballs—than a cat, a brandy bottle, a plum pudding, or a goose. People are wont to write their names on the Christmas cards, which they sow broadcast with a liberal hand, partly to remind the donees of their benefactor, and partly from a pleasing reflection that such cards cannot again be sent by these donees to other people. Instances have, indeed, been known of persons who have neglected this salutary precaution receiving, after several transmigrations of their pictorial contributions through fashionable society, and after many days, their own cards back again. The Christmas photograph, on the contrary, would bear on its face the face of him who sent it, or of his family, and would have no meaning if forwarded onwards, like a bad shilling, to a stranger.

There is another advantage which, though chronicled last, is not least in the Christmas photograph. Though the ingenuity of mankind is marvellous in the manufacture of mischief, it is not easy to see how our Christmas photographs could be degraded into expressions of cruelty and insult. That the pretty custom of valentines has considerably suffered in this way, will be tolerably obvious to anyone who will walk through some of the minor and less polite streets of our metropolis towards the middle of February. He will find, to his dismay, that the holy day of the saint who is the patron of actions of charity, benevolence, and love, is now an opportunity greedily seized of anonymous abuse and indecent obloquy. All that the exacerbation of hatred can suggest of ugliness, all that the hand of the uninstructed dauber can execute of deformity, in colours rude as the conceit which presided over its birth, is to be bought for a penny in commemoration of this Christian festival. Christmas cards are becoming subject, alas! to a like degeneration. The picture of a donkey, preceded by the words "From one,"

and followed by "to another," has less of politeness than pungency, though it possesses very little of either. The carefully simulated semblance of a cheque, or of a purse full of gold, is a poor piece of waggery at the best, but must be doubly distressing to the recipient wight who is in sad want of one or both of these rare gifts of fortune; of the reality and not the shadow; and how few of us are not!

Widely different from such pictures as these, and far more really congenial to the spirit of Christmas—not, as it is commonly understood, a season of guzzling and the gratification of the palate, an entertainment so far removed from moral or intellectual happiness that the common consent of mankind has not hesitated to brand it as the lowest of our sensual delights, but a season of sympathy and beneficence—would be a reproduction of some of the works of the master painters who have illustrated this time, or a photograph of living children in the sad livery of poverty and distress—the raw material of our social manufacture—tricked out with no meretricious glow of colour, but a simple symphony of black and white appealing to the ear of the truly Christian heart.

THE HACKNEY PHOTOGRAPHIC SOCIETY, Morley Hall, Hackney, will hold the following meetings:—January 8th, collodio-bromide, Mr. A. Mackie; January 22nd, American lantern slides; February 12th, "Norway," illustrated lantern lecture, Mr. Henry Sturmey; February 26th, lantern evening.

A PHOTO-ASTRONOMICAL OBSERVATORY ON MOUNT ETNA.—*The Corriere di Palermo* sets forth that several years ago a new observatory was built on Etna (at a height of 3,000 metres) through the activity of Professor Tacchini, and the approval and help which the project found in Catania. Professor Tacchini, recognising the necessity that the Observatory at Etna should be joined with another, that it might work with greater regularity, succeeded in inducing the Government to build and organise the observatory connected with the University in the town of Catania. This institution is destined principally for the study of astronomical physics, for celestial photography, for meteorology, and for seismology. Direct astronomical and spectroscopical observations will be made for the most part in the upper story of the Observatory with the great refractor, which has an objective of 35 centimetres in aperture and $5\frac{1}{2}$ metres in focal length. It was made by the celebrated Merz at Munich, and the equatorial mounting was executed by the able mechanician, Caviguato, of Padua, under the direction of the astronomers Lorenzoni and Abbeti, of that town. Other observations will be made with the equatorial of 15 centimetres in aperture, constructed by the renowned American, Clark, to which an apparatus can be added for the photographing of stellar spectra. This instrument will be placed in the garden of the Observatory, liberally given by the Municipality of Catania. In the same place, in a suitable pavilion, will be fixed the photographic telescope, with an objective of 33 centimetres in aperture. This was constructed by Steinheil, and the mounting was made under the direction of Professor Tacchini in the premises of the clever mechanical engineer, Salmsiraghi, at Milan. With this instrument the Observatory at Catania will take part in the great international enterprise of preparing photographic charts of the stars. In the same garden the apparatus of Huggins will be set up, which serves for the photographing of the solar corona. Besides, at the Observatory on Etna, there is an equatorial equal to that of the great refractor; and to this it will be possible to apply the same objective of Merz, and another which, for special observations, astronomical and physical, will be taken to the volcano. Observations in meteorology will be made, some in the upper story of the building, where the apparatus of Mascart for the photographic registration of atmospherical electricity will be worked. Professor Riccò has been appointed regular Professor of Astronomical Physics in the University of Catania, and Director of the two Observatories. He is a member of the International Committee for photographing the stars.

THE CAMERA AND ITS VARIOUS MOTIONS.

BY PROFESSOR W. K. BURTON, C.E.

CHAPTER III.—THE SWING-BACK—THE SLIDING FRONT—THE REVOLVING FRONT.

IN a set of papers on "Optics for Photographers," published in the PHOTOGRAPHIC NEWS, I went so far into detail in connection with the theory of the use of the swing-back that I think a very few words will suffice here.

The vertical swing may be either from the lower edge of the back of the camera, or from the centre. The former is far the commoner arrangement, but the latter has distinct advantages, not in those cases where the swing-back is used merely to secure vertical lines in architectural subjects, but where it is used to bring the foreground into focus as well as the distance.

We generally focus for the middle of the ground glass, or for some part not *very* far from there. Now if we have so done, and then come to the conclusion that it would be of advantage to use the swing-back to bring the foreground into focus, if the back swings from the bottom the effect of swinging it is to put everything out of focus; we have to focus again, and it is only after a somewhat troublesome series of focussing and swinging that we can decide by trial and error that we have swung the back to just the right extent. When the swing is from the centre the thing is quite different. Having once focussed for something not very far from the middle of the plate, we simply swing the back till the foreground comes into as good focus as we can get it, this operation not putting the part first focussed for out of focus, or doing so to only a very slight extent.

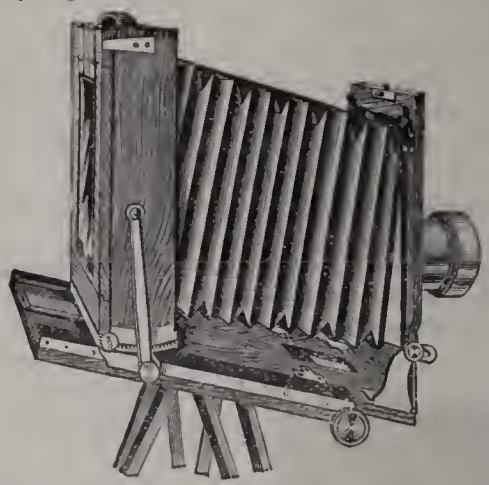

Fig. 7.

The camera of Mr. J. R. Gotz, illustrated here, may be taken as one typical of a camera with back swinging from the centre. The camera is a very ingenious piece of mechanism in many respects.

The fact is, however, that, as regards swinging the back merely to get different parts of the subject into focus at the same time, this should be less practised than it is. It is commonly supposed that, so long as there are no vertical lines in a picture, from houses or the like, any amount of liberty can be taken with the back of the camera. It is quite true that where there are no vertical lines it is often permissible to tip the back of the camera backwards to a certain extent; but if this be done more than a little, the drawing, even of a "pure landscape," may be made perceptibly false. Especially in the case where mountains are included in a landscape should the tipping

of the camera back be avoided, and this is just the case where there is generally the greatest temptation to tip. There is often a wish to tip the whole camera, so as to get in the top of the mountain, and there is sometimes a wish to still farther tip the *back*—or to swing it—so as to get the mountain and the foreground into focus at the same time. There cannot be the smallest doubt that the tendency that there is to the *dwarfing* of mountains so commonly seen in the case of photographs is, at least in a great part, due to the mischievous tendency that there is to the tipping back of the ground glass and the plate, for it must be borne in mind that the effect of such tipping is to diminish the scale of the upper part of the picture *relatively to the lower*. I think it is not too much to say that, in the case of mountain photography, the verticalness of the back of the camera should be as religiously observed as in the case of the photographing of buildings.

A case in which the swing-back is particularly useful is that sometimes met with in which the camera has to be tipped *downwards* to take in a near foreground.

Of the side swing the same may be said as of the vertical swing, so far as the desirability of having the swing from the centre rather than from one side goes; but that, inasmuch as the side swing is comparatively so seldom used, the matter is one of much less importance than in the case of the vertical swing.

The smaller the size of a camera, the less the necessity for a side swing, and indeed for a vertical swing, except for getting vertical lines parallel. I think the side swing may very well be dispensed with in the case of all cameras from half-plate size downwards.

Sliding Fronts.—The power of sliding, and especially of *raising* the front is a very useful one, but really, in its simplest form, needs no explanation. I will here only emphasise what has several times been pointed out by Mr. W. E. Debenham, namely, that if the lens will allow of it, the front should be raised as far as possible, when photographing high buildings, before recourse is had to tipping up the camera and swinging the back. A somewhat more complicated form of sliding front is described in the next paragraph.

The Swing Front and Revolving Front.—Both these adjustments were brought prominently before the public some six or seven years ago, when the camera invented by Mr. S. D. McKellen was first exhibited. This camera displayed so many ingenious novelties that it at once recommended itself to the public, and became one of the most popular cameras that there are. The illustration here given will serve to illustrate the swing front. The motion, it will be seen, is simply a vertical swing. It is useful chiefly to bring the front of the camera parallel with the back, when the camera has been tipped and the back has been swung, and a little consideration will show that, as such, it amounts in reality to an almost unlimited power of raising or lowering the front. In the case of all cameras introduced before the McKellen, the amount of the rise of the front was very limited, and although in the case of most cameras generally sufficient, was not as great as was desirable for some special work. Moreover, in the case of many forms of camera, the bellows is liable to cut off a part of the view if the front be raised as far as possible. This is rendered impossible in the case of the McKellan camera, by the fact that the end of the bellows is *raised with* the front. This will be understood from the above illustration.

Fig. 8.

The introduction of the swing-front (or, more strictly, of the extension of rising power given by it) first made a *revolving front* a useful addition to landscape cameras, and this adjustment was added by McKellen. It is illustrated here, the particular camera shown being that known as the "Thornton-Pickard." The advantage of the revolving front is that, if the lens be fixed *excentrically*,

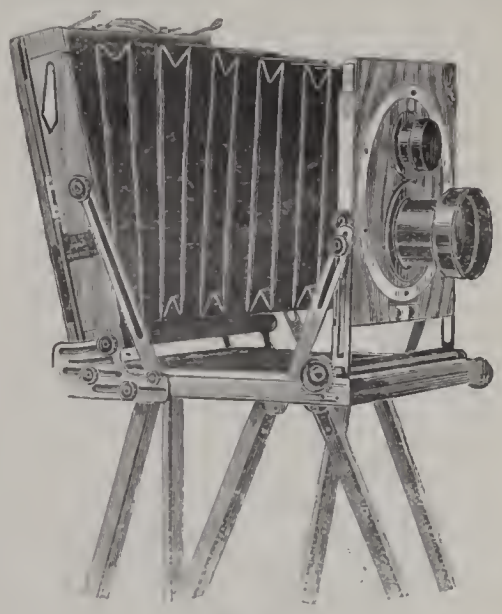

Fig. 9.

a universal motion is added to all others by the combined use of the revolving front and the rising front. The advantage of the revolving front is not great except for large cameras, as, in the case of small ones, the diameter of the flange of any lens likely to be used is nearly as great as that of the front, so that only a slight amount of excentricity is possible. In the case of large cameras, however, it is considerable, and it is even possible, in some cases, to fix two or three flanges for different lenses to the same front, as shown in the illustration. In this case, any one lens can be brought into any desired position by the combined motion of the revolving and rising fronts.

Many of the improvements first introduced by McKellen have been copied by other camera makers in a way that does more credit to their powers of imitation than to their originality.

A NEW INTENSIFYING PROCESS.—Dr. Liesegang thus deseribes in the *Archiv* a curious new process for intensifying weak negatives:—The finished negative is coated with a collodion or varnish in which has been dissolved a portion of some one of the green or red aniline dyes which are sensitive to light. It is then exposed to light for some time, this being allowed to act on the dye *through* the negative. The clear portions are thus bleached out, while under the darker parts of the negative the dye remains unaltered, and hence brings these up to a greater density. Unfortunately, the aniline dyes cannot be made non-sensitive to light, hence the effect vanishes in the course of extended printing from the negative. In place of the aniline, however, a salt of iron may be used, developing afterward as in the "Lichtpaus" process. This last intensification is, of course, permanent.

SOME OF THE TENDENCIES IN PHOTOGRAPHIC ART.*

BY PHILIP H. NEWMAN.

AND now, having lightly touched on a variety of classes of exhibits in this Pall Mall show, it is time for me to direct your attention to that which I conceive to be one of the most important, if not quite the most important, subject for our consideration, and wherein, I think, a decidedly epoch-making departure for good or bad must be admitted—I, of course, allude, as you will have guessed, to the medalled exhibits of Messrs. Davison and Clark. The work of these gentlemen is always brave and conscientious, and worthy of the greatest respect, and in this particular instance their exhibits are highly deserving the awards the Society have given them. But while admitting that the works are in one direction a very great success indeed, I must demur to the success being in the direction that is generally supposed. Messrs. Davison and Clark are artists, artists of the camera if you will, but that is an accident; did their practice lead them to use any other medium as a means of expression they could not help being artists, even if their technical results were not so successful as in the art of photography. Now the general belief is that the works, "Dedham Lock," "Dedham Bridge," and the "Old Farmstead," owe their charms as much to the merits of the printing processes employed, and the accentuation of an out-of-focus motive, as to other characteristics; but it is precisely here that we must distinguish between success and failure. The choice of subjects, composition, and all that technical excellence can give, with one exception, are eminently pleasing and satisfactory, promising artistic and interesting pictues; but this exception in their negatives, emphasised especially in the case of Mr. Davison in his printings, indicated that these gentlemen have thrown away the substance, so to speak, for the shadow, and are satisfied by a result which, because it gives a more or less close resemblance to a second-rate sepia drawing, is deemed artistic.

But I think I hear you say: "Oh! don't you like rough paper, then, and fuzzy prints, and sepia tones?" "Personally, I do like the rough and fuzzy effect. I will allow that my idiosyncrasy is better satisfied when my eye has some artistic work to do, and has to complete for itself a more or less well-defined image. Moderately near-sighted people are favoured in this respect, and perhaps that is one of the reasons the projected enlargement on the screen of a photographic picture gives me far greater enjoyment than any printing process has ever done, mainly, I say, because of this work the eye often has to do in such a case. I shall have occasion to speak further on more particularly of screen enlargements, and will return, for the moment, to fuzziness in prints and rough paper, which, though I have said that I liked, I now desire to make myself clearly understood by adding that, as with every other artistic attribute, I like it in its proper place, without which I emphatically deny its *raison d'etre*. The roughness or smoothness of surface of a work of painting, printing, or photography, is simply a question of scale; argue the matter out as you may, it always comes to that.

Let no one persuade you to the contrary, the use of a rougher paper than the area of your print justifies is an affectation and a sin against good taste. That you may be the more readily convinced that this dictum is neither arbitrary nor empirical, let us look at the subject for a minute or two from a very common-sense standpoint, and I will ask any one with ordinary eyesight how far he places a photograph or other object from his eyes when he is looking at it for ordinary purposes, viz., to be pleased or refreshed by its artistic suggestion, or the memories it may recall. I say its ordinary purposes? I shall be answered, the distance referred to is generally rather less than twice the length of the greatest diameter of the work under inspection. This being so, I will further ask the person inspecting the work at that ordinary distance if he, or she, desires to see the undulations in the texture of the paper or surface before or simultaneously with the subject under view; whether the ribs and marking in the structure of that paper, or surface, contribute in any degree to the enjoyment of the picture? No, I shall be generally answered, not at all, but rather, that the lines and markings militate against that enjoyment, distract the eye, and withdraw in some measure the attention from the picture, or subject, whatever it may be. I may be asked to be more precise as to the proper distance to view a work of art with fairness to the artist and enjoyment to one's self. I can only say—always subject to variable idiosynerasy, of course—that that distance will be approximately given by double the altitude of an equilateral triangle constructed on the greatest height, or width, as the case may be, of the work to be looked at; and I repeat that any paper, or canvas, whose texture asserts itself, and can be distinguished equally with the work printed, or painted, upon it at the distance I have mentioned, is in bad taste, and, indeed, a barbarism and an affront. Who, I ask, but the most ignorant person would think of printing a carte-de-visite on very rough paper? Who but a most affected or ignorant person would pretend to be satisfied with it? When done, should we derive any satisfaction from the works of Teniers, or Gerard Don, had they been painted on brickbats or sandpaper? Would the pictures of Peter de Hooghe, Van der Heyde, or other painters of detail charm us did we see the lines in the canvas falsifying, by their light and shade, the drawing in their work? Of course the reverse of the proposition holds good, and we are none the less displeased with a smooth, hard surface in a large wall painting or fresco. Roughness or granulation here gives life and brilliancy, and, at the same time, a sense of vagueness, which the eye is doubly charmed to correct for itself, and complete our artistic satisfaction. Roughness of surface, then, is, as I have said, a matter of scale in all cases, and a scale which we must naturally apply to the works in the recent photographic exhibition, and I fear very much in their disfavour; for on the application of the test I have mentioned, we shall see the structure of the paper in many instances asserting itself before we have time to enjoy the pictures. I am compelled to dwell particularly on this in a paper addressed to a society of amateurs, and treating on some of the recent tendencies in photographic art, because where professors have been in error, amateurs are most likely to stumble.

Now it is, of course, interesting to see such a very successful work as Mr. Davison's pinhole picture, but it must be remembered that if the rule of scale applies to roughness of paper proportionately with the size of the work, to be consistent, it must equally apply to vagueness of outline from any other cause; indeed, such as the pin-

* Continued from p. 983.

hole gives. The question then arises, does Mr. Davison's pinhole picture justify this vagueness in point of size? I am afraid we are driven to the conclusion that it does not, and quite apart from the considerations of whether, under any circumstances, excepting the necessity of the case where a lens is not obtainable, or for an experimental *tour de force*, a pinhole is desirable at all, or whether, in the nature of things, it is desirable to have photographs excepting of limited dimensions. It is more than questionable whether fuzziness is not entirely out of place, excepting in very large scenic work in landscape, and only tolerable in photography at all in life-sized portraiture. But, because of this very desirability of fuzziness in the life-sized head, it must be the less desirable in the much smaller scale of the landscapes we are speaking of. All praise to Messrs. Davison and Clark for their choice of subject, composition, lighting, skies, and so forth; but we cannot thank them for works on a limited scale affording no point of sharp focus for the eye to rest upon. Assuredly the works of these gentlemen, however successful they may be in one respect, distinctly fail in another, and which I point out as being based on an artistic misconception, and against which every amateur should be warned.

I have gone so far, it will be remembered, as to make use of the phrase, "throwing away the substance for the shadow," and I think it must be allowed advisedly, when we consider that one of the greatest charms of photography, its greatest boast, and, indeed, that in which no other art ever has, or ever will approach it, is in the veracity of its delineation of detail. This charm is surely a substantial one, and it must be asked why photographers should seek by any means to divest their work of it in the shadowy hope of rivalling that of a painter's handling, that individual charm by which genuis, making dexterous use of accidents of stroke and flow of colour, fulfils its bent unfettered, and with the least material interposition between the artist's brain and brush.

That handling we love so much to linger over in the pictures of the old masters—touches that make the dead past live again, touches which wake our souls to sympathy with those whose works shall be immortal, because their touches show for ever their souls within their works. I say that, to try to effect this by means of the camera is to endeavour to lift it from its true position. to give it another *metier*—in short, unworthily to follow in the fatuous footsteps of the fabled frog, and burst in envious emulation. Results such as the camera, or any photographic process can ever give, can in the nature of things never affect us in the same way as those of the pencil, the graver, or the chisel. Photography has its own proper and special fields, and it is a needless prostitution of its legitimate aims to endeavour to make it subserve the imitation of another art.

(To be continued.)

A SUPPLEMENT TO THE PHOTOGRAPHIC NEWS.

Next Friday we shall issue, as a supplement to this journal, a photogravure print of Mr. Lyonel Clark's photograph of Dedham Bridge, which won a prize at the last Exhibition of the Photographic Society. The supplement will be a good work of art; in fact, a companion picture to that of Kingsley's Rectory, which gave so much satisfaction when we issued it some months ago.

THE PROPOSED PHOTOGRAPHIC INSTITUTE.

Recently the under-mentioned members of the Council of the Photographic Society, with Mr. K. B. Murray, Secretary of the London Chamber of Commerce, accepted an invitation from the Lord Mayor to lunch at the Mansion House, and discuss the question of the proposed Photographic Institute:—James Glaisher, F.R.S., Captain W. de W. Abney, R.E., C.B., F.R.S., William England, H. P. Robinson, Dr. Lindsay-Johnson, J. Gale, Sir Henry Trueman Wood, M.A., W. S. Bird.

The Lord Mayor gave courteous consideration to the statements put before him as to the important and constantly extending applications of photographic science and art; as to the recognition of the value of these applications manifested by France, Germany, and other countries in the establishment of schools and institutes of photography maintained by the State; and as to the desirability of steps being taken to found in London an institute for the encouragement of photographic research, and for the perfecting and practical teaching of photographic processes. It was stated that the Photographic Society of Great Britain was desirous of initiating and supporting such a scheme if there were any likelihood of funds being forthcoming. The Lord Mayor was of opinion that a movement in this direction was desirable, and that a well-considered scheme would have his support; that any large amount of money—as, say, £40,000—was, in his opinion, not likely to be subscribed in the City, but a fourth of that sum might be, and kindly promised to call a meeting at the Mansion House, and to preside at it, if proposals were put before him during his tenure of office.

It was decided to refer the question to the following committee:—Sir H. Trueman Wood, J. Gale, K. B. Murray, Dr. Lindsay-Johnson, and W. S. Bird.

The committee has drawn up a report, the text of which is here quoted from the *Journal of the Photographic Society*. It is proposed to take an opportunity of discussing these suggestions at the December meeting of the Society.

The Photographic Institute.

The committee to which was referred the task of formulating a scheme for the proposed Photographic Institute has now the pleasure to submit to the council of the Photographic Society of Great Britain the results of its considerations. It understands that the principal object of the Institute would be to promote the science, art, and industry of photography; and it thinks that the following is the best course to be adopted for the purpose. The heads under which its action would come may be classified as—(1) science; (2) education; (3) art; (4) industry.

1. *Science.*—Its principal duties towards the science of photography would be the encouraging of original research, to be applied both to the investigation of new, and the improvement of existing processes. It might undertake such researches through its own staff, and would offer facilities to others, either in the form of grants of money, or by providing suitable laboratory and other accommodation. Full provision should be made for the systematic examination and testing of photographic apparatus and materials. Possibly by its aid prizes might be offered, and every other means should be adopted to encourage the advance of photography, its application to scientific purposes, and the advance of those sciences which bear upon it.

2. *Education.*—It should provide for theoretical and

practical instruction in all sciences bearing upon photography, in photography itself, and in all the branches of applied photography. For this purpose, lectures would be given, classes held, and regular courses of instruction provided, including laboratory work, and the technical details of all the various photographic applications, especially the photo-mechanical processes. It would hold examinations and grant diplomas and certificates, the course of instruction and the character of the examinations being such that the one would qualify persons to undertake any of the several branches of photographic industry, while the latter would be looked upon as a test of proficiency on the part of employers, and thus secure a preference in employment to successful candidates. Nor should the instruction omit the teaching of art in its bearing on photography. Probably it would be desirable to found travelling and other scholarships. The Institute would be expected to establish a first-class library, and to form a museum both historical and scientific.

3. *Art Exhibitions.*— Its principal duties connected with the art side of photography would probably consist of the holding of exhibitions. These might be both national and international. It might also occasionally be found desirable to hold international congresses.

4. *Industry and Trade.*—As regards the effect of the Institute upon the industrial departments of photography, it would be expected to provide assistance and information for all connected with the business of photography, whether as photographic artists, manufacturers, traders, or others. It would be competent to deal, in the first instance, with such questions as photographic copyright, patents, trade-marks, and merchandise marks. In all cases it should be ready to safeguard the interests and promote the welfare of the many industries resting on photography as a basis.

In order to carry out its duties fully, it would be necessary that a charter of incorporation should be obtained, and suitable premises provided, with all necessary fittings and apparatus. The accommodation which would be required must, of necessity, include the following:—An exhibition gallery, a conference or lecture room, library, museum, class rooms, laboratory, studios, dark rooms, and printing rooms; while among the work rooms would be included some properly fitted for the carrying out of such processes as collotype, Woodburytype, and the different photo-typographical process. In addition to the above, the building would, of course, include the necessary offices. To carry out such a scheme in its entirety would require, no doubt, a sum of from £4,000 to £5,000 a year, together with a capital outlay of some £10,000 or £12,000. The sources of revenue which might be looked for include donations and bequests, subscriptions from members and affiliated societies, fees from students, charges for experimental work, and the rent which might be obtained by hiring out the exhibition gallery and the meeting room. A useful beginning might, however, be made with a much smaller sum, say a total amount of £10,000 guaranteed, if not subscribed. For this, no doubt, suitable premises could be secured, and the maintenance of the Institute provided for a period of seven years. At the end of that time, it might be hoped the public at large would be convinced that the Institute had become a necessity, and would be willing to provide funds for its permanent support.

If the suggestions of the committee recommend themselves to the council of the Society, the committee would further suggest that the project might well be discussed at a meeting of the Society, after which it might be submitted in the form of a circular letter to the different provincial societies; and if the favourable opinion of the photographic public generally were once gained, the committee think that the Society might then well avail itself of the most liberal offer made by the Lord Mayor of London, to summon a public meeting at the Mansion House for the discussion of the proposals. In making this suggestion, the committee hope that if, as is probable, the matter can hardly be brought into a state ripe for public discussion before the termination of Sir Henry Isaac's mayoralty, they may look for the same support from his successor in the chair.

Literary Notices.

Photography for Architects. By F. W. Mills. (*London*, 1890: *Iliffe and Son.*)

This is a book for beginners, for it assumes that the reader knows nothing about photography, and opens by minute descriptions of simple details, such as explaining the use of the different parts of the camera, and informing the student that if he wishes to diminish the image of a building he must plant his camera farther away from it, but if he wishes an enlarged image he must place the camera nearer to the object. The book contains little about architects or architecture, but includes a chapter on the photographing of interiors, also a chapter on the copying of plans and tracings by the ferro-prussiate and other suitable processes.

One of the processes given is Portwin's, which is thus described:—"The paper is first floated on a warm solution of gelatine (1 to 15) to which some suitable pigment has been added. When dry, it is sensitised by immersion in the following simple solution:—

Ferric chloride	... 480 grains
Tartaric acid	... 144 ,,
Water	... 10 ounces

The paper is dried in the dark. The effect of the action of light is to convert the ferric chloride into ferrous chloride in those parts on which the light has acted, thus rendering the gelatine coating soluble in hot water, where it is in contact with the ferrous salt. It will be seen, therefore, that a reversed positive is necessary to yield a positive print. When sufficiently printed, the image is developed by simple immersion in hot water. The insoluble parts remain in the paper and form the image. The great drawback to the process is the necessity for printing from reversed positives; but it is probable that this defect may be remedied."

The author has had some strange experiences with the east wind, or the east wind has had some strange experiences with the author. The latter says:—"When there is an east wind make the exposure half as much again as that advised in the table."

The work is likely to be useful to beginners. Mr. Mills does not trouble his readers with too many formulæ, but seems to have limited himself to a few which have answered in his own hands. He recommends a quinol developer for plates exposed on interiors, and does not trouble his readers by describing any other. He says that he has found ferrocyanide of potassium in the developer to prevent frilling and blisters.

THE PICTURES AT THE EDINBURGH PHOTOGRAPHIC EXHIBITION.—III.

Class III.—Portraits Below Whole-Plate Size in Sets of Twelve Direct Prints.

In this class the "cabinet" reigns supreme, and a truly regal display they make; platinotype is the favourite mode of printing.

With our present knowledge it is difficult to imagine where or how the next step in progress can come in this universally popular size of portraiture. In purity of high-lights, in depth and richness of shadow, in delicacy of half-tone, improvement can scarcely be hoped for. The competition in this class is keen, and it is not an easy matter to single out what may be considered the most worthy of notice, lest unwillingly, or by some oversight, an injustice be done. Perhaps the alphabetical order for the more prominent will be advisable.

Alex. Ayton, jun.—The work of this exhibitor is specially remarkable for its brilliancy combined with softness. The blacks are rich and velvety; the whites are pure and sparkling, without the faintest suggestion of hardness, as each portrait has every grade of tone. The lighting is specially pleasing; the pose most natural; the children are all child-like in pose and expression, being free from all appearance of artificiality. Mr. Ayton's work is of a high order. His large heads are of lovely subjects most sympathetically treated; his children simple, natural, and sweetly beautiful.

John Moffat exhibits a remarkably fine frame of portraits much above the average. His work is, technically, of the highest order, and he secures a piquancy of expression and pose that is very pleasing. There is one of a young lady leaning out of a rustic window that is extremely charming.

Marshall Wane.—The work shown by this exhibitor is of the highest order; brilliant without hardness, soft without flatness, the pose and lighting thoroughly good.

Wane and Allan.—These portraits are by the same firm, and are similar in character to the last, but there is a special softness and delicacy about the exhibits under this name, while the pose of the subjects is markedly natural and free from all strain. They have an ease and grace not too commonly seen.

William Warneuke exhibits a dozen gelatino-chloride prints. They are most exquisitely soft and tender portraits of children charming alike in pose and expression. One especially may be noted. It may be called a procession of three half-length figures, none overlapping, with piquant little faces all in profile: yet there is a perfect unity, brought about by the attention being concentrated on some one object of interest not visible. There is a peculiar charm and originality about this.

W. W. Winter.—This frame of children's portraits (No. 552) is one of exceptional merit. Its distinctive characteristic is the felicitous grouping. In this respect Mr. Winter's work is distinctly prominent, and when to this is added appropriate expression and excellence in *technique*, it makes his contribution one of the most attractive in the rooms.

J. Macmahon sends a fine display of children and adults, delightfully soft in lighting and simple in pose.

J. H. Hogg shows capital work.

R. Slingsby contributes a number of flash-light photographs. Perhaps the highest compliment that can be paid them is that if they were not so labelled, few would be aware they were not taken in ordinary daylight.

J. M. Whitehead, W. J. Kilpatrick, Stanley Hurst, Jamieson & Co., J. M. Whitehead, J. Pettigrew, and E. Y. Poole also send meritorious work in this class.

Class IV.—Portraits, 8½ by 6½ up to 12 by 10 inches, in Sets of Six Direct Prints.

This division has not brought forward so many exhibitors as might have been expected, but the quality of most of the work sent is of a high order.

Ralph W. Robinson sends a set of his "Artists at Home." They have a character all their own, and stand apart from the rest. His work is well-known from previous exhibitions. Among the most prominent of these beautiful studies may be noted the portraits of W. Q. Orchardson, R.A., John Reid, P. H. Calderwood, R.A., and Marcus Stone, R.A.

J. G. Tunny and Co.—No. 699. Three lovely heads, simple and graceful in pose, the lighting very pleasing, and under No. 713 will be found a most charming head of a beautiful child exquisitely treated.

Alex. Ayton, jun., is capitally represented in No. 564. It represents a lovely child naturally posed, the draperies and flesh tenderly delicate, and a rich, broken background of furniture and foliage. Mr. Ayton also sends some large heads with all the qualities of his work noted in Class III.

Marshall Wane.—Of this exhibitor's work, we prefer No. 716, "Provost Brown." This is a particularly fine portrait, rich in colour, and well composed. Portraits of the Earl and Countess of Hopetoun (Nos. 702 and 639, and also No. 319) would have been greatly improved if more space had been allowed above the heads. Nos. 637-8 are free from this defect; they are clear, brilliant portraits full of delicate modelling.

Jamieson and Co.—In No. 206 this firm excels all the other work they have sent. It is a startlingly brilliant full-length of a lady in white satin, near white curtains. The management of the light is remarkably effective, and while intensely brilliant, it is entirely free from hardness. No. 723 is also meritorious.

Messrs. Window and Grove send two frames representing characteristic portraits of well-known actors and actresses. The most effective seem to be those under No. 257, which are printed in silver; they are exceeding rich in colour, and possess fine quality.

John Macmahon sends a series of well-executed portraits of professors and others; also a capital family group (No. 220).

Mrs. Brian Hodgson, S. N. Bhedwar, C. G. Bremner, and R. R. Russel also send interesting portraits.

X. Y. Z.

Another Professional Use of Photography.—A marriage broker is said to be doing an excellent business in Bachmut, Russia. Anybody coming to Bachmut is sure to be met by this man at his hotel with the inquiry, "Sir, do you want to marry?" The marriage broker carries an album full of photographs of people of both sexes who would not mind getting married. On each phototograph may be found details concerning the social and financial standing of the person pictured. On his arrival at Bachmut, the broker visited every house of interest to him in his especial line, and was kindly received everywhere. There are already many happy brides and grooms in the city to whom he points with pride as his customers. Bachmut is especially favourable for operations of this nature, it is said, as it contains many girls of good looks and fair fortunes.—*Photographic Times.*

Notes.

The Camera Club has altered its rules in regard to subscriptions. The annual subscription after the first of January next will be raised for town members to five guineas, country members two guineas, foreign members one guinea, with an exception in favour of the *first* hundred members proposed and elected after the first of January, for whom the town subscription will be only four guineas. For members proposed before the first of January the present subscription will hold, namely, three guineas for town, and one guinea country members.

Of all employers of labour in photography, Mr. John Carbutt, the American dry plate maker, seems to be one of the most popular among his assistants. When he reached his works after his return from his recent visit to Europe, he found, confronting him in his office, a large and handsome floral device, with "J. C." in the centre, and surrounding those letters the following sentence: "The heartfelt expression of the work-people —Welcome home!" The lettering was composed of small red, white, and blue flowers; the whole device was about four feet high, and rested upon a bed of roses. The following week the assistants were surprised at receiving double their usual salary. The work-people thereupon drew up and signed a written testimonial speaking of Mr. Carbutt's many virtues, and expressing the hope that the amicable and harmonious relations existing between him and his work-people may long continue. Mr. Carbutt took back with him several specimens of European cameras, and exhibited them recently at a meeting of the Philadelphia Photographic Society.

A good library tends to increase the prosperity of most scientific organisations, for there are plenty of people who care to possess ready access to a good lending library on class subjects, who do not care to attend public meetings. It is remarkable that several photographic societies have no library, or have some uncatalogued books stored away practically beyond the reach of the members. Even the smaller societies might invest in a box with lock and key, for the storage of books, and start a library by means of photographic books given by its members. It is a wonderful thing that the Photographic Society itself did not long ago take this bold and spirited course; next year, however, it will make a beginning with a library and a museum.

The problem of staining sensitive photographic surfaces to prevent halation now seems to be again attracting attention, and it would be exceedingly convenient if by this method the backing of plates could be avoided. Twenty years or more ago Mr. Carey Lea tried a series of experiments on this subject, and the substance he found to answer best for the purpose was litmus, with the faintest trace of acid to give it a red colour. In the alkaline developer the litmus turned blue, and more or less dissolved out of the film, so nothing was left to interfere with the printing qualities of the negative. The trace of acid in the first instance would probably slow the plate. At the last meeting of the Camera Club the cosines were spoken of as good for the purpose, but one speaker gave a poor account of their action, saying that some slowed and others fogged the plates.

Mr. F. Galton's idea of the comparison of photographs of the same person taken at different periods, from infancy upwards, is slightly indicated by an article with illustrations in the new *Strand Magazine* entitled, "Portraits of Celebrities at different times of their lives." The examples given are, however, only interesting from the point of view of that unscientific person, the "general reader." For instance, the comparison of a photograph of Lord Tennyson at fifty-two with a painting of the poet at the age of twenty-two tells us very little, nor can much be said about three portraits of Professor Blackie, one at the age of five from a painting, another at forty-five from a lithograph, and a third at eighty from a photograph. The series of Mr. Spurgeon's portraits is more complete, as the four examples given —at the age of twenty-one, thirty, thirty-six, and fifty-four—are all from photographs. Miss Terry's and Mr. Irving's portraits are also from photographs, and Mr. Irving's are noticeable because one of his photographs, taken when he was thirty years old, is not the least like him, save as to the hair, which appears to have taken about this time the peculiar wave with which we are all familiar. The concentrated look in the eyes and brows of Sir John Lubbock is repeated in each of the portraits given, and the extraordinary transformation which baldness and a beard have effected in Mr. Algernon Swinburne, who once had luxuriant locks and only a chin tuft, will surprise many.

Experiments in portraiture of this kind, even when conducted on a scientific basis, must be always more or less incomplete and disappointing. When a dozen portraits taken in as many minutes show a face in a different aspect in each, not much dependence can be placed on the trustworthiness of a series taken at intervals of a year or more. Perhaps more accurate knowledge of the changes wrought by time would be obtained by photographing the features separately. A series of photographs of the mouth, for instance, extending over half a century would be extremely curious. The habits, thoughts, and occupation in many cases strongly influence this feature, quite apart from the effects of time. No doubt, as the study of anthropology advances—for it is but in its infancy—something of this sort will be attempted.

Many of the most valuable photographic inventions in the way of apparatus have resulted from the crude efforts of amateurs to overcome special difficulties.

An instance of this is seen in the "handy" camera—an appliance which is largely used in America in connection with microscopic work. The camera was invented by Mr. H. Wangate, of Philadelphia, an ardent microscopist and a specialist, his studies being almost exclusively confined to the minute fungi belonging to the family of *myxogastres*. Though skilful with his pencil, his drawings of these minute organisms being equal to any yet produced, he found that the time demanded was a severe tax, and he determined to call in the assistance of photography.

There was, however, absolutely no camera in the market to meet his requirements. He proceeded to construct one. Procuring a plate-holder of the proper size, he built the camera to suit it, after the plan of the man who carried the bung-hole to a cooper to have a barrel made for it. His materials were some heavy, blackened cardboard and an old piece of a steam-engine fitting some four inches long; his tools, a pocket-knife and a glue-pot, with the brains to use them. With these crude appliances he produced a camera adapted to his microscope, and capable of doing the highest class of work. He uses a Zeiss $\frac{1}{18}$th homogeneous lens constantly, and frequently makes a dozen or more negatives of an evening. Mr. W. H. Walmesley, who recently read a paper on the subject at Detroit, upon seeing the apparatus, was struck with the conviction that, if it could be produced in a form adaptable to any microscope, it would supply an instrument long needed. The result was the "handy" camera.

An improved photographic illusion will shortly be exhibited in a play to be produced at one of Mr. Beerbohm Tree's matinées at the Haymarket. The illusion is the invention of Mr. Van der Weyde, and takes the form of a piece of statuary which has all the appearance of solidity, and yet is nothing but photography. At a recent private view in his studio, he says, two Royal Academicians were so completely deceived that "they literally turned and went away in a rage, so deeply did they resent the artistic illusion." The example already produced and exhibited in America is pronounced by Dr. Talmage to be the first statue he had ever seen which gave the idea of the human hair, and one man made quite a heavy bet that he could put his arms round it; it is needless to say he lost his wager. The production of this photographic curiosity may be looked for with interest.

The instantaneous camera is now an indispensable portion of the traveller's outfit. All who make a tour of the world are bound to bring home photographic mementos of their visits to places of celebrity, or they will not be thought much of by their friends. The Americans, in their business-like way, are the most energetic of tourists. Their usual way of making sure of seeing everything is to prepare a list in their note-books of things and places to be visited, and of ticking off each one as soon as it is inspected. As to lingering over any object of historic interest, it is not to be thought of. The thing is to get the list through, and to make sure that nothing has been omitted. Some indolent tourists have been known to tick off their lists without taking the trouble to look for themselves. Perhaps this is the wisest plan, because it must save the innumerable headaches which the unbroken inspection of churches and galleries is bound to create. But with the instantaneous camera in fashion, the lazy persons run a great risk of being shown up. We should not be surprised to hear that unless the American tourist brings back a series of pictures of things he has seen, he will be looked upon as something of a fraud.

The realistic writer will approve of a gigantic task which an enthusiastic admirer of Flaubert, a certain Count Premuli, has set himself. It is nothing less than an attempt to illustrate that singular book, "Madame Bovary," the forerunner of Zola's materialistic work, by means of instantaneous photographs. One can remember to have met on the street corners the typical personages that have been put into books by the great novelists. Who has not found himself face to face twenty times with Homais, Rodolphi, Emma Bovary? In this case the Count Premuli goes out with his *detective* in his pocket and, bang! he takes a photograph on the sly. Moreover, he does not wait for chance to put these personages in his path, he pursues them—his apparatus levelled upon his unconscious victims. Prevented from taking his subjects into his confidence and asking them simply to pose in certain attitudes, the Count estimates that it will require a dozen years and the aid of a fortune to finish the project. No doubt Count Premuli will derive infinite pleasure from his experience, but from the point of view of the outside world, one is tempted to ask if the game is worth the candle.

The writer in the *Globe* who speaks of the difficulty of finding in the British Museum portraits of contemporary writers who are "looking up," can surely have had no practical experience of this kind of thing. When the portrait of a newly born celebrity, be he a contemporary writer, actor, or artist, is wanted, the last place the editor of a paper, or anybody else who has had a training in this particular direction, would think of going to would be the British Museum. The *Globe* writer says: "Often it is very puzzling to find any picture of a man who is looking up, and the catalogues at the Museum afford no guidance on the point." Of course they do not. Why should they? Unless the catalogues possess the gifts of prophecy and second sight, how on earth are they to tell who is "looking up"? The experienced editor has a very simple method of getting over this seeming difficulty. He finds out the address of the budding celebrity, and asks him for his photograph. It is seldom refused.

NEWSPAPER PICTURES.

THE illustration of newspapers is a new branch of art. Ever since its beginning its apprentices have been trying to find out the simplest and most effective methods for the reproduction of drawings, in order that they might be made with the greatest possible quickness, engraved on metal with the utmost attainable celerity, and printed clearly and well at the rate of twenty thousand copies per hour. To such perfection have the processes for this purpose been brought, that the turning out of pictures all ready for the lightning presses is nowadays a matter of a very short time.

Most interesting of the processes employed in newspaper illustration, from the point of view of simplicity, is what may be termed the "chalk method." Take a thin bed of smooth chalk laid upon a metal surface, and draw upon it with a fine steel point any picture you may desire. The steel point will cut the lines of the picture out of the chalk to the metal, and thus you will have it in the shape of an intaglio. Make a stereotype from this intaglio, and you have your metal plate to print the picture from. Could anything be more simple?

Drawing on a Bed of Chalk.—Such is the idea of the chalk process. In applying it, instead of pure chalk various mixtures are used, such as plaster-of-Paris, with a certain proportion of a white Carolina clay. The stuff, pulverised and stirred up with water, is spread over a rectangular sheet of polished steel, as you would spread a slice of bread with butter, to an even thickness of about one thirty-second of an inch. Now you are ready to begin operations as soon as you have baked the steel plate in an oven for a while, until the layer has been rendered perfectly hard.

It will hardly do for you to attempt to draw your picture directly upon the chalk, lest you make mistakes. The best way is to make your sketch on a piece of paper, and then, laying it down upon the chalk surface, go over the lines with a pencil point, which will indent the paper, and leave marks beneath upon the chalk. Lift the drawing, and you find under it, in the chalk, its reproduction. Now you apply your steel point directly to the chalk, cutting all the lines of the drawing down through the chalk to the surface of the steel plate. When you finish this operation the dark steel of the plate shows through the chalk in all the lines of the sketch; and these lines are perfectly clean and sharp, thanks to the keenness of the knife-like steel point employed. All you have to do for the rest is to pour molten lead over the chalk surface in a mould, and let it get cold. The lines that are cut out of chalk will be reproduced in relief upon the lead, and thus you will have your metal engraving to print the newspaper picture from, mounting it for the purpose on an iron block thick enough to make it level with the type.

Zinc Etching.—Though so advantageous for its simplicity, the chalk method is not so good for fine work in the way of sketches and portraits as the "zinc process," so-called, which *The Washington Star* employs for its pictures. The former, however, by reason of its cheapness, is most useful to provincial newspapers, which cannot afford the comparatively expensive photographic plant required by the latter. In the zinc process, to begin with, an ordinary photograph reduced to the required size is taken with a camera of the pen-and-ink sketch drawn on cardboard by the artist. Next a smooth plate of zinc is "flowed over" with an albumen and bichromate solution, forming a skin on the surface; the glass negative of the picture is laid upon this zinc plate, and the two are put together in the sunlight. What are to be the black lines of the printed drawing are, of course, white and transparent in the negative. The sunlight goes through wherever the negative is transparent, and has the effect of hardening the sensitised skin beneath, so that it clings tightly to the zinc. It requires only one minute to perform this operation. Now the zinc plate is taken and given a coating over the sensitised skin of lithographers' ink, rubbed on with a roller, after which the plate is washed. In all places where the sunlight has not struck the zinc, owing to the opacity of the glass negative, the sensitised skin readily washes off together with the ink that covers it; elsewhere it clings. Thus, after the washing, the perfect drawing in ink remains upon the zinc plate. To make the ink lines harder the plate is brushed with powdered dragon's-blood. Then it is plunged into a bath of acid, which eats away the zinc wherever it is not protected by the ink, so that when it is taken out the lines of the drawing are found all raised above the rest of the surface of the plate, like a map for the blind, and when mounted "type high" on a metal base you have your "cut" ready to print from.

Such is the zinc process, by which the pictures in to-day's *Washington Star* were made. "Processes" have infinitely multiplied within the last few years—so much so, in fact, that the student of engraving is aghast at contemplating their variety. At present, however, the zinc method seems to be the most available for journals of the period. At all events, it is employed by a majority of the big newspapers of the country.

A Third Process, used for newspaper illustration, is photo-engraving, which somewhat resembles the zinc method. A glass plate, however, is used instead of a metal one. This glass plate is covered with a thin layer of sensitised gelatine, which is permitted to dry. Then the photographic glass negative of the drawing, made with the camera, just as in the other case, is laid over the gelatine, and the glass plate and negative, with the gelatine layer between them, are put in the sun for half an hour. The light hardens the gelatine, and makes it cling to the glass plate wherever it strikes through the negative, so that when the glass plate is subsequently put into water all the rest of the gelatine comes off, leaving the drawing on the glass in gelatine lines. Moist plaster-of-Paris is spread over the plate next, and permitted to harden; when it is taken off it is a mould of the drawing. From this mould a plaster "relief" is made, and a reproduction of metal in this relief by stereotyping is the plate to print with.

These are the three methods by which newspapers produce the pictures which go so far to brighten up and help out the interest of the columns of the daily press.—*Washington Star.*

PHOTOGRAPHS ON CELLULOID.—The following method has been invented and patented by Philip H. Mandel, Astoria, N. Y. It is a process of obtaining pictures on celluloid, which consists in treating the surface of the celluloid with acidulated gelatine and chrome alum, then transferring the picture from a tinted and sensitized and exposed photographic paper upon the prepared surface of the celluloid, next passing on the picture and removing the paper, then developing and fixing the picture on the surface of the celluloid, and protecting the picture by a layer of varnish.—*The Picture and Art Trade.*

IMPRESSIONISM IN PHOTOGRAPHY.*

BY GEORGE DAVISON.

In a very able and judicious report of the late Photographic Exhibition, the *Times* reviewer referred to the aim of the newer school of photographers to represent "the impression made on the artist's mind," and he said, "Here there are difficulties. The camera cannot select and discriminate. It cannot omit an ugly object or introduce a beautiful or suitable one. It cannot make those slight adjustments of the landscape which all painters do." Now this seems to suggest that the selection and discrimination is from something not in the particular scene in front of the artist. But the slight adjustments, the introduction of other objects, can be no part of the impression produced on the artist's mind by that particular scene. There is a supposition in this view of an insufficiency in nature, and a necessity for what I have referred to as Mr. Brett's "improvement and exaltation of natural images." Those who adopt this view must look for their beauty and interest in some conventional cleverness of brush work or in the fitness of the parts for telling a story, and not to the subtle truth of the picture. One may readily admit a beauty, an intellectual triumph in a composition, perfect in the fitness of its parts to tell a story or relate some historical incident, but this is a literary quality or it furnishes an antiquarian and didactic interest, and does not constitute the best, if at all the province, of pictorial art. The interest in such work and in symbolism is, as a rule, feeble and superficial for the nature student compared with the absorbing and exquisite pleasure derived from a bit of simple, natural beauty, faithfully and spiritedly painted. For example, what is the interest and pleasure derivable from a mythological or historical subject? According to a man's familiarity with the literature of mythology, according to the extent that his mind has been absorbed by that particular lore, so he appreciates such pictures. Their seeming accuracy may please him. That is classical scholarship being taught and fed by painting; it is not æsthetic pleasure. The same holds with regard to historical painting. The artist may imagine vividly what a suit of armour he has studied would have looked like upon a soldier of the fourteenth century upon a certain battlefield. He may hunt up all the incidents, and study all the customs and costumes of the time and the occasion, and his research may be very creditable, but, after all, what value or subtlety can there be in such work? It is not the province of art to teach or illustrate history, nor is it at its best with any didactic or moral aim. But even in historical pictures, mythological subjects, and the like, there may be something of the natural character, and this may captivate the æsthetic sense. There may be that in such work which, drawn from a study of nature, any and every observer can compare with his own experience. Whether it be figures or inanimate objects, all have gained some sense of their form, proportions, modelling, texture, and general appearance under many circumstances of light and atmosphere, and the chief charm lies in the life-like representation of these known appearances. The common criticism of the public in a gallery—"Oh, that's not natural; nothing like that was ever seen"—when quite unconventional, and not the product of hearsay, is generally the ultimate verdict upon such an imaginative picture, and coincides with the more completely cultivated and scholarly discrimination which discerns where and why the thing is not true. The naturalistic position, then, is that so far as a scene appeals to our experience of nature—harmonious and truthful in its light, atmosphere, relations, incident, and action—so far will it affect most powerfully our æsthetic sensibility, and such harmony and truth are only to be secured by a direct reference to nature.

Mr. Hamerton, in "The Graphic Arts," would make a distinction between truth and delight, but the naturalist, whether painter or observer, finds no opposition between the two, but derives the keenest of æsthetic pleasure from the faithfulness with which his own impressions of nature are expressed for him.

* Continued from page 990.

After all, nature is the best possible painter. Art has performed its highest function when it has enabled us to see "the eternal picture which nature paints in the streets, and has opened our "eyes to the masteries of eternal art." It teaches us to see the meaning, expression, and beauty—the poetry which lies in all natural phenomena, atmosphere and light, forms and actions. Emerson, in his essay on Art, says: "The best pictures can easily tell us their last secret. . . . . There is no statue like this living man, with his infinite advantage over all ideal sculpture, of perpetual variety. . . . . Men do not see nature to be beautiful, and they go to make a statue which shall be. . , . They reject life as prosaic, and create a death which they call poetic. . . . . They eat and drink that they may afterwards execute the ideal. Thus is art vilified; the name conveys to the mind its secondary and bad senses; it stands in the imagination as somewhat contrary to nature, and struck with death from the first."

Turning to the general contention that photography is merely mechanical, this cry may be answered by a reminder that so may brushwork be mechanical; and it is sufficiently answered, I think, by the fact that the work of various photographers is as distinctively individual as obtains in regard to painters. Even leaving figures out of the question, two photographers separately treating the same subject will produce two impressions almost, if not quite, as different in qualities as would two impressionist painters in monochrome. It may be said that the painter is freer to generalise, emphasise, and analyse, as he may please; but if this is said of an actual scene in front of the artist, it must be remembered that the lens, as used by a trained observer, sees very much as the eye sees; and that most of the suppression and selection possible to a painter genuinely consulting his impressions, is also at the command of the photographer. Unnatural emphasis may please a certain school, but it will not bear comparison with nature, and it will in time have its proper value assigned to it. It is also said that one photographer can easily proceed to take exactly the same picture that another has achieved. Well, I do not think it has ever been done yet in respect of any photograph worthy of the name of picture; and supposing it is so, cannot a painter copy the work of a fellow-artist? The mere fact of the means including more mechanism is not a disadvantage if the result be more truthful and life-like.

The *Times* reviewer finds difficulties—I am glad to notice that he does not say impossibilities—in the way of photography giving the impression produced upon the artist's mind. It may be advisable to look more closely into this. What is this selection and discrimination which is impossible to camera craft? What is it which is possible to the painter in monochrome, which is really an essential of good art, that is out of the power of the photographer? Leaving such vague references as "exaltation of natural images," can anything be definitely stated in respect of this rendering of impression; can the finger be placed distinctly upon any quality in handwork from nature—any power of the painter, excluding colour, which is absolutely out of the range of photographic possibility? Our impressions are made up of light and light values in relation to one another—colour, form, binocular vision effect, focus, perspective. The painter may not play with the tone or relative values of his subject and picture. He may not falsify what the eye sees in respect of focus and atmosphere, nor indulge in several points of sight. He cannot do much more than the photographer to express the relative interests of his subject, which must generally depend upon the point of focus of the eye. It will be said, "there is the power of emphasis." But how can the hand-worker, a genuine impressionist, emphasise what the photographer cannot! Does he gain anything by putting a little more gaudiness here, a little extra detail there, in the extreme distance beyond what the scene gives an impression of, as, for instance, in Mr. Brett's own pictures? Does he make his pictures stand out more plainly from their background than in nature, emphasising dark against light, or light against dark, to make the ignorant stare, as in some of the wood engravings in our illustrated journals? This is nothing more nor less than falsity of tone. In criticising Mr. Seymour Haden's famous "Agamemnon" etching, Mr. Ham-

erton asserts that "art is not the slave of nature," and on the ground of some greater purpose he defends what he calls the false tonal values of the plate. What this greater purpose was he does not state, but it is interesting to notice signs of some uncertainty in his opinion, for he almost immediately proceeds to show that, looked at from a certain distance, everything in the etching falls together into fairly truthful relation. If, then, it is admitted that emphasis by falsification of contrast or colour is not permissible, what is this discrimination which is so much insisted on? It would appear to be nothing more nor less than a seizing on those facts which most simply and directly give the spirit and character of a subject. The best of what is felt and thought to be "ideal beauty" is "abridgment and selection." This abridgment and selection is the broad treatment in painting, the effect that the eye sees, and the photographer has the means of seizing or subordinating the same facts by the power of focussing that he possesses over the lens. The *Times* reviewer says the camera "cannot omit an ugly object, or introduce a beautiful one, or make slight adjustments in the landscape." Well, as it is the question of impressions we are discussing, neither can the eye omit, or introduce, or adjust details. But it can go a few yards and find an affinity of delight where there are *no* ugly objects. And if the camera cannot cut out an ugly object the photographer can. Mr. H. P. Robinson does so, and makes *very considerable* adjustments of his landscapes; and Mr. Lake Price has contrived historical subjects not greatly inferior to much that passes in conventional art. Is it a figure that is to be introduced? Surely the photographer may select the best type. Is it a tree he wishes to change, a notice-board, or other incongruous object to remove? These are trifles when he has all nature before him, with infinite scenes and beauties that require no trimming of details. The hand-worker can, if he deems it right, omit and add freely, but the balance is redressed by the consideration that the one labours for a prolonged time at one subject, whilst the other may seek many fresh inspirations in the same time. Too much emphasis is put upon this small limitation, which is really an advantage in photography. It is *the light* that is the first and foremost fact of any scene or picture—the colour, the action, and sentiment of the figures. A severe naturalistic refuses to alter and omit, for, although so doing might introduce only small errors, a principle is involved. He feels that there is no occasion or excuse for it. He might make use of materials drawn from a variety of experiences—a cloud from this day, a figure from that field, a tree from yet another time and place; he might piece sketches together, sketches taken under altogether different circumstances of light and atmosphere, and each sketch might be delightful in itself; but, consisting as they must, of impressions utterly inharmonious, he would have done far better to have studied and expressed the beauty of each subject as it appealed to him complete in nature.

Mr. Brett proposes to exalt all natural appearances by drawing on memory, and foisting a recollection of one scene and object upon quite a different one. Surely he must see that the "choice and exquisite appearances of nature"—his own expression—are too good to be falsified by what is termed idealizing. Again, the perfection that Mr. Gale finds in Turner's "Storm" does not lie in any exaggeration of natural phenomena, nor in any impossible piecing together of the characteristics of one kind of storm with another. It has its effect because, and so far as, the impression made upon us by natural appearances is spiritedly reproduced. There is so much of this rare quality in much of Turner's work that keen pleasure is derived from it, in spite of some exaggerations and inaccuracies. Something less vague than claims for emphasis and the exaltation of natural images must be advanced before justification for painting from anything but nature can be admitted. The artist's work always falls short of his impressions received from nature. He has never given as fully as they impress him the pathos of human life, the radiance of the morning, the glory of the sunset. When he has achieved this, when he has succeeded in seizing for us one tithe of the splendour, the sweetness of nature, one single aspect and expression of the human face perfectly, as we ourselves know nature and life commonly, it will then be time to talk of improvement and exaltation of natural images, and to proceed to invent new combinations, which are to "surpass in delightfulness the real images."

(To be continued.)

TOMBSTONE PHOTOGRAPHY.

Several communications have lately appeared in our British exchanges on the above subject, as to the best means of overcoming the difficulties experienced in this branch of photography, notwithstanding how simple the process appears at first sight, or to those who have never tried it. One of the subjects mentioned in our British contemporary was a yellowish kind of granite, with the letters cut in and gilded. As there was little or no contrast between the stone and the gold, together with the inexperience of the photographer (probably an amateur), the plates resulted in failure, as the lettering did not show distinctly. Notwithstanding that orthochromatic and ordinary plates were tried in strong sunlight as well as dull light, the result was always the same. The advice given to overcome the difficulty was to make common whiting into a stiff paste with water, and then fill the letters in with a small palette knife; when dry, photograph. The result would be an excellent white inscription on a dark ground. Another correspondent, in a subsequent number, states that his plan is to take a small knob of whiting, place it in the palm of the right hand, and pass it over the line of letters to be filled, using considerable pressure—enough, in fact, to crush the whiting as it goes into every crevice of the letters. Then this wiseacre states that you have only to pass a cloth gently over the surface to remove any dust, and take the photograph. He then goes on to say that in case of white tombstones "dark chrome" should be substituted for whiting. So much for experimental theory. It is not necessary for us to state that the resulting negative would not be a photograph of the tombstone as it really is, but it would look like a flat surface the shape of the original, with coarse letters chalked upon it, and certainly not what it was the intention to portray.

The writer, who has probably had as much experience in this line of photography as any other person in this country, acknowledges that the subject is always a more or less difficult one if it is desired to obtain a legible inscription, no matter whether the stone is a fresh white marble, a cold grey granite, or an old crumbling memento of slate or soapstone, with its skull and cross-bones and "memento mori," weather-beaten and overgrown with moss and lichen. The same difficulties seem to exist to bother the amateur. We acknowledge that at first we had some failures in this special line; but we soon learned to set our camera a little to the side, according to the light, and not directly in front of the stone; result, a legible inscription all the time. This is accounted for by the fact that in sunken (V-shaped) letters one side is usually illuminated a little brighter than the other, except when the sun is directly in front or overhead. So we point the lens towards the brightest side of the sunken letters, and achieve our object where it would be almost impossible to get a good inscription if the camera were set up directly in front of these subjects.

In photographing old historic tombstones of discoloured marble, blue slate, grey soapstone, or reddish sandstone, when the inscription is almost illegible, we have frequently resorted to marking a line with our lead-pencil in the middle of the furrow of the sunken letter. Even where the stone was disintegrating and covered with lichens, the single pencil-mark seemed to bring out the whole contour of the letters, and thus save the inscription. This plan has the further advantage that it would be permitted in almost all cases, where such a proceeding as advised in our British exchange would not be tolerated for a moment.—J. F. S., in *The American Journal of Photography.*

A lady who had her photograph taken was showing it to her husband. "Do you think it looks like me?" she asked. "Yes," he said, after a critical examination, "it looks like you, only it seems very quiet."—*American Druggist.*

HOW TO BUILD UP A BUSINESS.*

IN these days nothing excites the average photographer so much as the prospect of obtaining some "'cute idea" or other, some new attraction, by which he may draw a novelty-loving public to his doors. It has been my fortune to have been trained in a studio, and to have had the management of a studio, whose hallways and reception-rooms, hung round with specimens of photographic work, were amongst *the* attractions of the cities wherein they were situated. If country people came to town they did not leave without seeing So-and-so's windows; the few artists of these cities made the study of So-and-so's photographs an incident in their daily walks; and the newspapers thought it their duty to keep their readers informed as to the latest additions to So-and-so's open exhibition of art photographs. And all this apparently concerted excitement was purely spontaneous; the artist-owner of these galleries was courteous to all who met him, but sought favours of none. The people flocked to view his windows because they appreciated the efforts there shown for their edification: his photographs were spoken of in the local art-schools because they were deemed meritorious subjects, full of suggestions to the art students; the press noticed them because it is one of the functions of the press to express public opinion, and in this matter public interest had been aroused, and public opinion was thereupon formed which had to have recognition. Of course, there was money in this idea—if idea it may be called—and not money only, but success and prosperity for the originator, and it was, moreover, something which contributed to the public good. I cannot but think that, if the same means by which success was attained in the case spoken of were followed here and now, the same success, at least in some measure, would follow here also. You shall know all about it in time; the methods employed are not secret; they were not patented, and you need not pay me twenty-five dollars for the process; I will give it to you free. But in giving it thus gratis, I know of a certainty that you will laugh it to scorn. The "pure cussedness" of the ordinary photographer points no other way; but I will give it to you, and you can do with it as you will.

The man of whom I tell you travelled the ordinary road to success. There is no royal or easy road, no short cuts. He who sets out for success with an eternal "Excelsior" in his heart day by day, will surely find it. This photographer realized in the beginning that success must eventually follow earnest, intelligent striving and endeavour. It has been so at all times and in all places. For long years he gave his attention entirely to his art (with him it was an Art, spelt with a big A), spending the days in his work-rooms, mastering one detail after another, and the nights were spent in reading and the cultivation of an artistic mind; and so he became expert in practice, and familiar with the theoretical principles underlying his daily work. In his self-culture optics and chemistry found their place, the study of art, in books and things apart from books, was his recreation, and history, general information, and humorous stories were gathered at odd moments for the amusement and recreation of his patrons, with many other studies. It was his belief that to be an artist in photography was sufficient reward for a life's endeavour, and so for thirty odd years we find him, ever devoted to his life's work, attaining the well-merited success he sought, and enjoying the respect and esteem of his fellow-citizens. He is working quietly there in the old town yet, with an ever-changing stream of young men and women all around him, eager to learn the science from him who has made himself master of it. I can see him yet—now telling a lady sitter of the vicissitudes of the epoch of Venetian art out of which was evolved the original prize of which an accessory near is a reproduction; now explaining to a pupil some law in optics; or giving labour-saving hints to his dark-room assistant; or sitting with all the boys around telling of the difficulties of the early days of the art; always humble and eager to learn, reading his photographic papers as religiously as ever, and discussing some controversy with us to make sure that we did not neglect them. I remember the pleasure people said it gave them to go about his house, and what a privilege we felt it to live and work there, filled as the place was with books, art-treasures, paintings, and restful furnishings. The spirit of the man permeated the house, and as you passed from room to room you felt the hard, matter-of-fact life of the world become more and more distant as your stay became longer. But why do I tell you all this, you ask? Because it has to do with the success he attained, and which we all want to reach in time. That artist opened his mind to receive every good idea or suggestion—he was positively greedy for helpful ideas either in technique or art; at first a farm-hand, then a gardener, he entered photography, beginning with a wooden shanty; and by reading, observation, and work he has elevated himself and his art, and, what may seem to some more important, has secured for himself that temporal prosperity which men look for when age comes on.

At some future time I may tell you other details of this successful career, but I content myself now with an explanation of one reason why the work of this photographer attained such popularity. It was full of endless variation, always progressive, and the best, moreover, he could produce. These characteristics were evident in the work itself. In addition to the careful study of chemistry and the teachings of art, this artist used to buy almost every illustration he could lay hands upon (within moderation, of course). Of illustrated books, magazines, periodicals, papers, drawings, pictures of statuary, collections of photographs, and engravings he possessed a great number, which was always being added to. I have seen him look into every book on a news-stand, and come away with an armful of periodical literature, as though he had struck a "Bonanza;" and afterward it was his delight to criticise the illustrations he had bought, and show us youngsters the suggestions and ideas which could be gathered therein for future help in portrait studies, *genre* pictures, and the arranging of groups. Afterward the most suggestive of these cuts were pasted in large albums for reference, and we found them immensely useful to train the young pupils just beginning studio work. Not that we tolerated imitation, but we used to analyze the pictures and get the detail of their superstructures, and their usefulness is beyond words. Amongst the most useful books were those issued by the Royal Academy and Metropolitan Art Galleries; these, being filled with reproductions of the works of trained artists, were the most valuable helps we could get, excepting always the study of the great masters. In our study of these latter an old edition of Burnet's *Essays* was esteemed greatly, because of the numerous and fine illustrations given therein at every turn.

* From *Wilson's Photographic Magazine*.

Here there is one suggestion for the photographer: You are too conservative—you do not keep pace with the possibilities of your art. Arouse yourselves; the field is still open; there never was more room in photography for earnest, sincere workers than there is now. Photography is not dead—its life has hardly begun, and it has a future before it surpassing any of its sister arts and sciences. A few years' careful work and intelligent striving, and the "Cheap John" question, which now worries you, and all such matters, will be relegated to their proper place—obscurity. The solution of these questions lies with the individual photographer, not with associations. The photographer who will give his mind wholly to his profession, seeking always excellence in work, and the proper catering to his clients, without doubt will receive due appreciation. Public opinion, in the main, is just, and gives to men their due; if your work deserves praise, sooner or later it will be given you. If, by the constant study of good photographic literature, by storing up ideas from all created forms of art, whether set forth by nature or in books, and by the careful observation of the endless variations and forms of human life around, you individualize your ordinary work, and make it interesting and attractive, as well as thoroughly good, there is nothing more absolutely certain than that success—temporal and otherwise—will eventually reach you in a greater measure than you ever dreamed of; but this can only be attained by long-continued, patient, intelligent effort.

PICTURES BY THE NICKEL-IN-THE-SLOT CAMERA.

ONE of the most startling and unique exhibits at the American Institute Fair is the drop-a-nickel-in-the-slot-and-have-your-picture-taken machine. It is surrounded at all hours by a throng, and as many as four hundred pictures, at five cents each, have been taken in a single day by this automatic machine. It promises to be a perfect Bonanza to its inventors. There are only two of these machines in operation at the present time, one in this city and the other in Minneapolis, Minn. This is the way the pictures are taken:—The subject is seated in a revolving metal chair seat, such as is used on a fire-engine, facing a hole in a wooden cabinet. The pretty young girl in charge tells you to look in the hole without winking. She then takes hold of a crank affixed to the machine, and gives it a single twist; it is as if she were trying to hoist a bucket of water from a well. A steel finger, visible from the outside of the machine, reaches forward and ignites a flash-light in what resembles the inside of a soup-bowl. There is a blinding flash, and presto-iseto! Your picture is taken. It requires just four minutes for the picture to be taken by the machine. By some mysterious internal contrivance the picture is developed and thrown out in a little metal case, ready to be displayed on the parlour mantel or in the family album. The results achieved by this remarkable machine are not always entirely satisfactory to the man who has invested his nickel. The pictures are apt to be slightly indistinct, so that, perhaps, it would be as well to provide yourself with a microscope before patronising the machine, in order to see whether it is your picture or not.

JUDGE DUFFY'S DISAPPOINTMENT.

Judge Duffy tried it the other day. The result was anything but satisfactory. The Judge remarked, as he carefully put his picture in his vest pocket, that his mustache looked as if it had been browsed upon by a Harlem goat. He noticed that his eyebrows, too, were missing, and did not know positively whether they had been singed off by the flash-light or burned up by the hot flush of indignation which suffused his face when the young lady operator asked him if he were a married man. It is reported that the Judge was very indignant at the result, and wanted his nickel back. His request, it is said, the young lady could not comply with, because the coin had been dropped in the slot, and had hidden itself somewhere in the internal economy of the machine.

CORONER MESSEMER LOSES HIS WHISKERS.

Coroner E. J. B. Messemer also dropped a nickel in the slot, with a most astonishing result. The picture came out as pallid as the bust of Pallas. His glorious yellow whiskers did not show up with the halo-like beauty with which they appear on the streets. The operator explained that if the Coroner had dyed his whiskers, those golden ornaments would have probably shown up better in the picture. As it was, she said, the machine had an instinctive repugnance to yellow; besides, what could he expect for a nickel? Did he want a cabinet photograph, beautifully coloured, and reposing on a rustic easel, for five cents? The Coroner meekly replied that he only wanted to see himself as others saw him. To this the young lady said that he ought to look in the glass. He then went to hear the automatic piano across the aisle, leaving Congressman Amos J. Cummings to be operated on.

AMOS CUMMINGS BEFORE THE CAMERA.

The Congressman dropped a nickel with a hole in it into the slot. There was a loud clicking of wheels inside the cabinet, as if the machine resented the imposition, and when the flash-light burst on his startled vision the Congressman winked like a toad in a shower. This accounts for the fact that his eyes are closed in the picture. As he held it up to the light Mr. Cummings said the photograph reminded him forcibly of how the Poet Geoghegan looked just after finishing his celebrated poem on "The Moonlight on Melrose Abbey."

ABE HUMMEL'S HIGH FOREHEAD.

Perhaps the happiest effect yet produced by the nickel-in-the-slot picture gallery is that of Abraham Hummel's lofty brow. The brow, it will be observed, extends over the crown of the legal head to the top of the spinal column. As he gazed upon the faint traces of his familiar lineaments Mr. Hummel was heard to remark that he wished there was a nickel-in-the-slot hair restorative machine in the building. He also whispered audibly that if in his dotage he should be weak enough to commit a crime, he fervently hoped that his picture in the Rogues' Gallery might be taken by the nickel-in-the-slot machine, for then not even his mother-in-law would recognize him.—*The Eye, Chicago.*

EUGENE DELACROIX.—In Paris, a magnificent monument has been erected in the Gardens of the Luxembourg to the famous French painter, Eugene Delacroix. Almost with his last breath, the creator of the French School of Romanticism in art dictated a codicil to his will, in which he expressed his desire to be buried on a certain hilly slope in the cemetry of Pere La Chaise, comparatively secluded from the crowd of celebrated sepulchres, and he explicitly gave instruction that no statue of himself was to be raised over his grave. His instructions have been respected, and the tomb in Pere La Chaise is yet unadorned by any effigy in marble or bronze of the great painter.

TIME AND INTENSITY OF LIGHT.—It requires courage to disagree with such a universally received authority on matters photographic as Captain Abney, but we muster enough for the purpose, for once. At a recent meeting of the London Camera Club, he is reported as having said, or "laid down the dictum," that *time and intensity of light were equivalent and interchangeable.* We do not know by what experiments and reasoning he supported his views; but we do know that in certain operations, at least, the theory is opposed by facts. For example, we have proved again and again, and the observation has been made by many independent operators, that if two pieces of bromide paper be exposed under the same negative, the one at, say, a distance of one foot from the source of light, for five seconds, and the other at a distance of two feet for twenty seconds, the longer exposure to the light of weaker intensity will yield a print of a richer and more velvety black than can be produced on the shorter exposure to a higher intensity, notwithstanding the fact that, if Captain Abney's contention were correct, they should be absolutely alike.—*The Beacon.*

ASTRONOMICAL TELESCOPES.*

BY A. A. COMMON, F.R.S., TREASURER TO THE ROYAL ASTRONOMICAL SOCIETY.

I now show you a picture of this part of the diagram, inclosing the portions I wish to speak about, magnified ten times, so that you can see that about twenty-eight of our points, and, by supposition, twenty-eight of our particles of silver on the photographic plate, make up the picture. You will see that these dots vary in size. The difference is due to the amount of light falling within what we may call the sphere of action of each point, and should represent it exactly. The result can hardly be called a picture, as it conveys no impression of continuity of form to the mind. We have got down to the structure or separate parts, and to the limit of the powers of the eye and the photographic plate, of course on the assumption we have made as to the size of the points in the one case, and the particles of silver in the other. I will now show you the same parts of the moon as represented by the circles on our diagram exactly as delineated by photography. You now see a beautiful picture giving mountains, valleys, craters, peaks, and plains, and all that makes up a picture of lunar scenery. We have thus seen how the power of the eye is increased by the enlargement of the picture on the retina by the telescope, and also how, by increasing the size of the photograph, we also get more and more detail in the picture.

We know we cannot alter the number of those separate points on the retina which determine the limit of our powers of vision in one direction, but we may be able to increase enormously the number of particles of silver in our photographic picture by processes that will give finer deposits, and so, in conjunction with more perfect and larger photographic lenses, we may reasonably look for a great improvement in our sense of vision—it may be even beyond that given by the telescope alone; although it always will be something in favour of the telescope that the magnification obtained in the eye is about fifteen times greater than that obtained by photography when the image on the retina is pitted against the photograph of the same size, unless we use a lens to magnify the photograph of the same focal length as the eye, in which case it is equal. But we *may* go much further in our magnification of the photographic image. In other ways there is great promise when we consider the difference in the action of the eye and the chemical action in the sensitive film under the action of light. The eye cannot perceive objects that are not sufficiently illuminated, though this same amount of illumination will, by its cumulative effect, make a photographic picture, so that there are ways in which the photographic method of seeing celestial bodies can be possibly made superior to the direct method of looking with a telescope.

With some celestial objects this has been already done. Stars too faint to be seen have been photographed, and nebulæ that cannot be seen have also been photographed; but much more than this is possible. We may be able to obtain photographs of the surface of the moon similar to those I have shown, but on a very much larger scale, and we may obtain pictures of the planets that will far surpass the pictures we would see by the telescope alone.

I have mentioned that the distance at which the normal eye can best see things is about nine inches, as that gives the greatest angular size to the object, while retaining a sharp picture on the retina; but, as many of us know, eyes differ in this power. Two of the common infirmities of the eyes are long or short-sightedness, due to the pictures being formed behind the retina, in the first case, and in front of it in the other. Towards the end of the thirteenth century, it was found that convex lenses would cure the first infirmity, and, soon afterwards, that concave lenses would cure the second, as can be easily seen from what I have said about the action of these lenses; so that during the fifteenth and sixteenth centuries the materials for the making of a telescope existed; in fact, in the sixteenth century Porta invented the camera obscura, which is, in one sense, a telescope. It seems very strange that the properties of a convex and concave lens, when properly arranged, were not known much earlier than 1608. Most probably, if we may judge from the references made by some earlier writers, this knowledge existed, but was not properly appreciated by them.

Undoubtedly, after the first telescopes were made in Holland in 1608, the value of this unique instrument was fully appreciated, and the news spread rapidly, for we find that in the next year "Galileo had been appointed lecturer at Padua for life, on account of a perspective like the one which was sent from Flanders to Cardinal Borghese." As far as can be ascertained, Galileo heard of the telescope as an instrument by which distant objects appeared nearer and larger, and that he, with this knowledge only, reinvented it. The Galilean telescope is practically, though not theoretically, the simplest form. It is made of a convex lens in combination with a concave lens to intercept the cone of rays before they come to a focus, and render them parallel so that they can be utilised by the eye. It presents objects as they appear, and the picture has less colour in this form than in the other, where a convex eye-glass is used. It is used as one form of opera-glass at the present time. Made of one piece of glass in the shape of a cone, the base of which is ground convex, and the apex slightly truncated and ground concave, it becomes a single lens telescope that can be looked upon just as an enlargement of the outer lens of the eye.

Galileo was undoubtedly the first to make an astronomical discovery with the telescope; his name is, and always will be, associated with the telescope on this account alone.

Very soon after the introduction of the Galilean telescope, the difficulties that arise from the coloured image produced by a single lens turned attention to the possibility of making a telescope by using the reflecting surface of a concave mirror instead of a lens. Newton, who had imperfectly investigated the decomposition of light produced by its refraction through a prism, was of opinion that the reflecting principle gave the greatest possibilities of increase of power. He invented, and was the first to make, a reflecting telescope on the system that is in use to the present day; thus the two forms of telescope—the refracting and reflecting—came into use within about sixty years of each other. It will be perhaps most convenient, in briefly running through the history of the telescope, that I should give what was done in each century.

(To be continued.)

* Continued from page 993.

MR. JULIUS F. SACHSE writes to us that he has seen some good heliochromic pictures by Mr. F. E. Ives, which the latter is about to bring under the notice of the Franklin Institute.

Patent Intelligence.

Specifications Published.

14,304. *September 10th*, 1889.—"New Azo-Colouring Matters." ARTHUR GEORGE GREEN and THOMAS ATKINSON LAWSON, Chemists to the firm of Brooke, Simpson, and Spiller, Ltd., of Atlas Works, Hackney Wick, Middlesex, Aniline Dye Manufacturers.

This invention relates to the preparation of azo-colours of various shades of yellow, orange, and red, most of which have a decided substantive affinity for cotton.

The inventors claim—

1. The preparation of azoxy- and azo-ortho-toluidine, by the alkaline reduction with sodium stannite of nitro-ortho-toluidine, in the manner described in the specification.

2. The preparation of colouring matters by diazotising either of the compounds azoxy- or azo-ortho-toluidine, when obtained as above described, and combining the tetrazo compound so obtained with the sulphonic acids of various phenols and amines, more especially with the para-sulphonic acid of alpha naphthol (corresponding to Piria's naphthionic acid).

3. The colouring matters prepared in the manner as set forth.

18,453. *November 19th*, 1889.—"Holder for Adjusting Lime-light Jets." HENRY STANIFORTH, 62, Fitzwilliam Street, Sheffield, Dentist.

For the raising and lowering, adjusting and centreing lime light jets in optical lanterns and the like, I construct a screw thread with appliances for the clamping of the jet holder on to a brass plate or stage, working horizontally upon guides at each side. Attached to the lower part of the screw thread is fixed a brass wheel with a corresponding screw thread, which is inserted into a slot below, so that, by revolving the wheel, the brass plate or stage holding the jet clamps is raised or lowered.

20,014. *December 12th*, 1889.—"Appliances for Polishing Glass." VICTOR MALEVEZ, of Courcelles, Belginm, Engineer.

My inveution refers to improvements in or connected with glass polishing apparatus, or appliances producing great useful effects while obtaining the same degree of power and care as hitherto.

According to my invention, a ring or frame is carried by a driving shaft, and is provided with a series of small movable polishers receiving motion from or carried by the said ring. These small polishers may be fixed to the said frame, but the important part of my inuvention consists in the mode of adaptation of the said small polishers on the frame in such manner that if desired they may be pivotted, so as to have a double action in addition to the circular movement which is given to them in common by the rotation of the frame, whereby they make a very effective travel by their individual motion about themselves.

These small polishers are applied to the frame by means of spindles passing through brackets, and into the collar of the polishers.

If it is desired to fix the position of the said polishers, a key or cotter is inserted through the collar of the polisher and spindle. It follows that the small polishers can be thus rendered fixed or movable at will.

82. *January 2nd*, 1890.—"Carriers for Supporting Magnesium Flash-Lamps." ROBERT SLINGSBY, 168, High Street, Lincoln, Photographic Artist.

This inveution relates to new or improved carriers for supporting magnesium flash-lamps used for the purpose of securing artistic dispositions of lighting for photographing in halls, theatres, rooms, apartments, or other enclosed spaces.

These new or improved carriers may be arranged horizontally or vertically. When arranged horizontally, the carrier consists of a support stretched across the hall, room, or other enclosed space where the photograph is to be taken, as near the ceiling as possible. To this support is connected, by a special device, a light framework sufficiently large to carry any required number of the usual magnesium flash-lamps, and suspended by pulleys, so that it can be raised or lowered at will to enable the lamps to be charged and lighted.

When the carrier is arranged vertically, it consists of an upright rod provided with a foot to enable it to stand on the floor. One or more arms are adapted to slide on the aforesaid upright rod, each such arm being adapted to carry one or more magnesium flash-lamps, and to be set in various directions in order to spread the area of illumination. These arms can be lowered on the aforesaid upright rod to enable the lamps to be charged and lit, and be then raised thereon to any required height.

The vertical carriers will be found sufficient in photographing ordinary apartments up to, say, 40 feet by 30 feet by 20 feet high: and in photographing groups and interiors of large apartments or spaces, they can be used in conjunction with the horizontally arranged carriers. These carriers may also support suitable reflectors to aid the lamps. They are intended to supply the photographer with facilities for using any number of magnesium flash-lamps he may consider requisite to illuminate any given subject, and for placing the lights so as to secure the best artistic effects.

1,203. *January 23rd*, 1890.—"Photographic Cameras." DAVID CARTER, 15, Gerrard Street, Warwick, Joiner.

This inuvention cannot well be described without the aid of diagrams.

1,388. *January 27th*, 1890.—"An Instrument for Calculating Photographic Exposures." ALFRED WATKINS, The Imperial Flour Mills, Hereford, Miller.

The inventor claims:—

1. An instrument for calculating photographic exposures, consisting of the combination of a set of movable circular slide rules, an actinometer, and a pendulum.

2. The use, in an instrument for calculating photographic exposures, of a set of circular movable slide rules so arranged with stops and pointers as to be mutually dependent upon each other.

3. An instrument for calculating photographic exposures combined and operating as described.

2,263. *February 12th*, 1890.—"Glazing and Roofing Buildings." WILLIAM HENRY HEYWOOD, The Horticultural Works, Colne Road, Huddersfield, Horticultural Engineer.

The object of my invention is to fix asbestos packing in suitable channels, so that the glass bears upon the packing, upon astragal, or iron, or other metallic bars or supports.

The glazing bar with the channels and cap combined are drawn in one piece and bent as required, the cap being preferably in a scroll form, so as to leave a space between the outer edge and the inner part bearing on the glass, this space forming an air chamber, and is designed to prevent capillary attraction.

The use of the packing makes a perfect dust-tight glazing; the glass resting upon a soft cushion prevents breakage and rattle by vibration.

The inner channel is available for conveying away any water which may collect under the cap.

8,160. *May 24th*, 1890.—"Photograph Burnishing Machine." JOHN PITT BAYLY, 18, Fulham Place, Paddington, London, Patent Agent (a communication from abroad by William Entrekin, of 4,384, Main Street, Manayunk, Philadelphia; Pennsylvania, U.S.A., Photographer).

This invention has for its object to provide a photograph burnishing machine having a burnishing tool which is capable of being shifted in a direction transversely to the action of the roll, and thus bring a new burnishing surface into action when required.

The machine comprises a fixed frame in the upper part of which the burnishing tool is secured, preferably in a groove. In the ends of the frame are pivoted midway their length, two side frames, in the upper ends of which is suitably journalled a roller, and the opposite ends of which are provided with locking bolts. These locking bolts engage suitable apertures in the ends of the fixed frame when the pivoted roll carrying frames

are swung over in such manuer as to bring the roll over the burnishing tool.

The bearings in which the roll is mounted are supported upon suitable springs, which tend to keep the roll elevated above the burnishing tool. These bearings have inclined upper faces, corresponding to inclined wedges, joined by a rod, and running in slots, in the ends of the fixed frame. One wedge is provided at its end with a threaded aperture, in which engages the screwed portion of a stem free to turn, but not free to move longitudinally in its fixed bearings. Two of these adjusting screws provided with hand-wheels may be provided if desired, and serve to adjust the pressure upou the photograph between the roll and the burnishing tool. By meaus of suitable set-screws carried by the fixed frame, and acting on the burnishing tool, it may be shifted in a transverse direction for the purpose hereinbefore set forth.

Correspondence.

THE CHRISTMAS HOLIDAYS.

Sir,—I hope you will be able to find room for just a line to notify that I shall close from Wednesday evening over Christmas to the Monday morning, and I hope my customers will not grudge this extra holiday to my assistants, who have had an unusually busy seasou with the moving, and the large increase in business. You may may be interested to know that I have found my electric lights a distinct success and advantage every way during this dull, dark weather. Jonathan Fallowfield.

Charing Cross Road, London, December 20th.

Proceedings of Societies.

The London and Provincial Photographic Association.

December 18th.—Mr. W. E. Debenham in the chair.

A question from the box was read: What qualities are most desirable in a lantern objective?

Mr. T. E. Freshwater said a lens that passed the most light, and gave the flattest field. With an oil lamp a short focus lens should be used, otherwise a large loss of light would result from the distance of the light from the condenser.

Mr. A. Cowan showed a uegative takeu with a flash-light. Four lamps had been used with a charge of one and a-half grains of magnesium powder, the light being diffused by sheets of tissue paper. The negative was quite free from the hard result characteristic of flash-light pictures, having all the appearance of being taken in theordinary way by solar light.

Mr. Pask asked if the intensity of light would be greater on a surface from a uaked light or by interposing a condeuser.

The Chairman said that greater illuminatiou would result by using the optical system of a lantern.

Mr. T. E. Freshwater remarked that a bull's-eye condensed more light than a compound condenser.

The Chairman, by the aid of diagrams on the blackboard, illustrated the amount of light that a good objective should pass.

Mr. J. S. Teape asked if the platiuum from an old developer could be recovered.

Mr. A. Haddon suggested exposing it to light, reducing the ferric salt to the ferrous state, which would reduce the platiuum to the metallic state.

A question from the box: Is $\cdot 008 \times \sqrt{d} =$ the correct diameter of a pinhole for producing best definition when d = distance between ground glass and pinhole?

The question was deferred to the next meeting.

The South London Photographic Society.

At the meetiug held on the 19th iust., Mr. F. W. Edwards in the ehair, three members were elected.

An interesting print of a group of members of the late South London Photographic Society was received from Mr. Atkins, of Bromley. It had been artistically framed by Mr. W. F. Slater,

The West London Photographic Society.

December 12th.—Lantern night.

Mr. W. A. Brown, chairman, referred to the forthcoming exhibition to be held on the 9th and 10th January, and earnestly requested the members to endeavour to make the exhibition a success by sending in pictures for competition. He also stated that the technical meeting, falling on Boxing Day, would be postponed until the 2nd January.

A discussion as to the best means of avoiding smoke from flash-lamps then took place; the employment of a smoke-trap, constructed of hoops of cane, over which calico was strained, was considered the best meaus of overcomiug the difficulty.

Slides by Messrs. Dixon, Varden, Selby, Sims, Wilson, Livingstone, Scanlan, Whiting, Horton, P. J. Martin, Dickins, Dresser, and others were then exhibited.

The Oxford Photographic Society.

At the meeting held ou December 16th, an exhibition was made of the Bostou (U.S.A.) Camera Club slides, "The White Mountains of New Hampshire." The President read the description sent with the slides, and Mr. Stanley Kent provided the lantern. There were one huudred and twenty-eight present. Many of the slides are particularly fiue, but photographs cauot well represent the grandeur of some of the immense scenes.

One member was elected.

The next meetiug will be held ou January 6th, and will be a technical exhibition of members' slides for members only.

The Derby Photographic Society.

The monthly meeting was held on Tuesday at Smith's Restaurant, Victoria Street, with Mr. Bertwin Cooper as chairman.

Mr. W. T. Tucker, of the Loughborough Society, gave a paper entitled "My experience with a Hand-Camera." The lecturer dwelt upon the advantage derived in the use of a hand-camera for obtaiuiug chance pictures, which would otherwise be missed by using large apparatus, and the pleasure gaiued on a tour by dispensing with weighty and larger cameras. He theu described his particular apparatus, and illustrated his remarks by handing round specimens of negatives and prints.

A large collection of Mr. Tucker's slides, appertaining to the lecture, were thrown on the screen by Mr. J. A. Cope.

The Bath Photographic Society.

A meeting was held at the Royal Literary and Scientific Institution on the 17th inst., Mr. W. Pumphrey in the chair.

The subject before the meeting was a demonstration of enlarging with Hume's cantilever apparatus. The Chairman undertook the demonstration, and in the course of his remarks said the tendency was uow towards taking photographs of small size, especially quarter-plate, and then increasing the size afterwards as required. The great advantage offered was that they did not require to carry about an apparatus in the field which need embracc anything larger than the quarter-plate. That size he considered exceedingly convenient, and one which, if an enlarged picture were required, would admit of its being done equally as well as a direct picture. The speaker explained that there were three distinct methods of enlarging. "The first, daylight," he continued, "could not avail to those whose photographic pursuits in the winter were restricted to evening work. When daylight is used for enlarging purposes, we must either suspend our camera in such a way as to obtain direct light from the sky, or fix it horizontally towards a window, and reflect, by means of a mirror or white cardboard fixed at an angle of 45°, rays of light which shall pass through a transparent or partially transparent medium and negative to the lens, and these rays will come to a focus beyond. At that point our screen is placed, upon which the sensitive paper rests. A condition of an enlarging apparatus is that the part supporting the objective and the casel upon which the paper is adjusted be movable, and the adjustment of distances between these two factors determines the degree of alteration in size of the reproductiou. The next method which may be mentioned is one in which the oxy-hydrogen lime-light is used. This is

the next most powerful to daylight. Then in order come the various combinations of hydro-carbons. Here in this apparatus of Hume's we have one of the latter in the form of a duplex paraffin lamp, in which one wick so acts upon the other as to produce a brilliant flame. It is claimed for the apparatus that it is concentric in every part, and theoretically perfect." The gas was then lowered, and an exposure of two minutes given to a negative. Upon development, however, it was found that a longer exposure would have been better. The lecturer then entered into the details of the apparatus, replied to several questions, and promised to treat the subject of enlarging farther at the next meeting on January 27th.

THE GLASGOW AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting of the Glasgow and West of Scotland Amateur Photographic Association was held in the Rooms, 180, West Regent Street, on Monday, December 15th, Mr. ARCHD. WATSON, president, in the chair. A paper on "Intensification" was read by Mr. W. GOODWIN.

Fifteen new members were admitted, making an increase of fifty since October. The office-bearers for 1891 were nominated, and slides by members were shown by means of the lime-light lantern.

THE GLASGOW PHOTOGRAPHIC ASSOCIATION.

THE opening popular meeting of the session of the Glasgow Photographic Association was held on the 11th inst. in the large hall of the Philosophical Society's Rooms, 207, Bath Street, with Mr. WILLIAM LANG, Jun., F.C.S., president, in the chair.

The lecturer for the evening was Mr. PAUL LANGE, President of the Liverpool Amateur Photographic Association, who described a tour in Norway, fully illustrated with views taken by himself and shown by means of the lime-light. Some fine cloud pictures and hoar-frost scenes were also shown on the screen, and were much appreciated by the large audience.

An interesting entertainment was brought to a close with a series of views of the Channel Fleet taken during their recent visit to the Mersey.

ROSA BONHEUR, the famous painter of "The Horse Fair," who is sixty-eight years of age, is said to be in feeble health. She has her studio in the forest of Fontainebleau. As an annex to her vast studio there is a large park enclosed by a forest for Italian buffaloes. She also possesses some lion cubs, and has her ordinary stable for horses and her fold of sheep and goats, besides models of carts, wheelbarrows, and ploughs.

SIZE FOR GOLD LEAF.—A decorator informs us that he uses a size for gold leaf which, if properly made, has no equal, whether the gilding be done on wood, glass, or metal. He claims it to be the "secret size" used by the best artists of London and Paris, and by the justly celebrated Japanese of London, who produce the finest work in gold decoration in their line to be found in the world's market. The formula is as follows:—Take one pound of good pure drying oil; put it in a metal pot with a cover; slowly add to this, after it has come almost to a boiling point, four ounces of pure powdered gum animi (not copal, which is sometimes confounded with it). Take the animi on the point of a palette knife and put it in cautiously little by little, allowing each supply time to dissolve, all the while stirring the mixture. Boil to the consistency of tar, and, while warm, strain through a piece of silk into a heated, wide-mouthed bottle, keep well corked, and, when required, thin with turpentine and mix thoroughly. If a little vermilion is ground with the size, it will show better what is being done in using it.—*The Decorator.*

RECEIVED.—From Ed. Liesegang, Dusseldorf, *Photographischer Almanach und Kalender fur* 1891. This annual maintains its excellent character, and is an enlargement upon its predecessor by forty-four pages. It contains, among other illustrations, a portrait, as frontispiece, of Franz Veress, of whom a biographical sketch is also given.

Answers to Correspondents.

All Communications, except advertisements, intended for publication should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and for the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

LUX.—*The Solar Club Festival.* The portrait sketches accompanying our report on page 964 were rapidly executed by a talented friend of Mr. George Scamell. They represent, first, Mr. Fitzgerald, of the Savage Club, in the act of delivering a humorous recitation on the troubles of a dramatic manager conducting a rehearsal. The gentleman was, unfortunately, carrying his left arm in a sling. The other is Mr. H. C. Triuks, a Danish chemist of saccharine proclivities, member of the Solar Club, and now resident in London.

T. B. LEGH.—*Photo-Mechanical Processes.* We are sending you the address by post; meanwhile begin by reading up Mr. W. T. Wilkinson's book on "Photo-Engraving and Collotype," and also that by Erust Lietze, "Modern Heliographic Processes" (New York; Van Nostrand Company, 1888). The Cantor Lectures of 1878 are still procurable, for two shillings, by making application to the Secretary of the Society of Arts. Lastly, look up the reports of the Camera Club Conference in the NEWS of March last, when the subject came forward for discussion and demonstration as part of their proceedings.

J. EDWARDS (Brighton).—*Matt Varnish.* Messrs. Burton and Pringle give the following formula:—Gum sandarac, 90 grs.; gum mastic, 20 grs.; ether, 2 oz.; pure benzol, ½ to 1½ oz.; according to texture desired; the more benzol added the *finer* the matt surface obtained.

COL. WATERHOUSE.—*Photo-Engravings.* Accept our best thanks for the pair of photo-engravings duly to hand. They are excellent, the view of the bridge over the Hoogly especially so, being soft and delicate with fine atmospheric effect. The Botanic Garden, Calcutta, also makes a capital picture. We reciprocate your good wishes for a happy new year.

ZOSTROW.—*Artificial Leather.* Stamped and coloured vegetable parchment (blotting paper treated with a mixture of two parts of oil of vitriol, and one of water) might, we think, be employed; but we have no actual knowledge of the processes, which are scarcely photographic.

C. S.—*The Place of the Bromide in Developers.* Opinions vary, some authorities putting the bromide into the pyro solution, and others professing to mix it with the ammonia or alkali. The best plan is probably to have it ready in a separate form of concentrated solution, and then supply it from a dropping bottle at the moment of mixing the developer. Only in this way can its proportionate amount be modified according to the requirements of the case, and increased in the event of over-exposure. See Mr. Valentine Blanchard's statement and general recommendation reported on page 893 of the NEWS.

W. Y. D.—*Platinotypes and Sepia Prints.* The discrepancy in evidence as to the effect of hydrochloric acid may arise from two different kinds of prints being called by the same name. Take it for granted that if neither hydrochloric acid nor solution of mercury chloride discharge the photograph, it is a true platinotype. Many of the sepia prints, being only surface toned, will not go through this test.

G. D. (Paris) and T. B. answered by post. Other correspondents in our next.

A. D.—(Leven, Fife) is thanked for sending particulars, which have been passed to the gentlemen on whose behalf the enquiry was made.

RECEIVED.—A copy of Prof. A. H. Church's new work on "The Chemistry of Paints and Painting," Seeley and Company. Also Dr. J. J. Acworth's pamphlet on the "Comparative Absorption and Colour-Sensitiveness of Tinted Gelatino-Bromide Plates."
